Conclusion: Baseline levels of each ACPA isotype and net number of epitopes recognized were comparable across the 3 treatment arms. Concentrations of all ACPA isotypes (IgM, IgA, IgG) were substantially reduced by abatacept + MTX therapy to a greater extent than by either MTX or abatacept alone. Abatacept + MTX also reduced the average number of epitopes recognized over 1 year of treatment more than either monotherapy arms. These results indicate that abatacept impacts the maturation of the ACPA response in patients with early RA, suggesting an alteration in the course of the autoimmune disease process. 1. TNF-Alpha Inhibitors Normalizes Melanocortin Receptor Subtype 2, 3 and 4 Expression in CD8+, CD14+ and CD19+ Leukocyte Subsets in Rheumatoid Arthritis.
Marlene Andersen[1], Michael Kruse Meyer[2], Ivan Nagaev[3], Olga Nagaeva[3], Jarl E.S. Wikberg[4], Lucia Mincheva-Nilsson[3] and Grethe N. Andersen[2]. [1]Aalborg University, Hjørring, Denmark, [2]Hospital of Vendsyssel/Aalborg University, Hjørring, Denmark, [3]University of Umeå, Umeå, Sweden, [4]Department of Pharmaceutical Pharmacology, Uppsala, Sweden.

Background/Purpose: We examined Adalimumab′s effects on melanocortin receptor subtype (MC)1–5 gene expression in important leukocyte subsets in rheumatoid arthritis (RA). The melanocortin system is a neuroimmunomodulatory system with anti-inflammatory and tolerance inducing properties. It consists of MC1–5 and their ligands, the melanocortins: α-, β-, γ- melanocyte stimulating hormones (MSH) and ACTH. Especially CD4+T helper (Th) lymphocytes and $CD14^+$ monocytes express the genes of MC1, 2, 3 and 5. Binding of a melanocortin to its MC inhibits the nuclear translocation of transcription factor NFκB and thereby the synthesis of inflammatory mediators, such as TNFα, adhesionmolecules and NO. While the synthesis of the melanocortins is stimulated by TNFα, the MCs are upregulated by the melanocortins. Thus the melanocortin system is upregulated in inflammation. Adalimumab reduces circulating TNFα, and is therefore supposed to down-regulate melanocortin synthesis and MC expression.

Methods: Blood was drawn at pre-start and at 4 months of Adalimumab 40 mg every other week. Leukocyte subsets were isolated by magnetic beads coated with CD4, CD8, CD14 and CD19 mAB. RNA was extracted and RT-qPCR performed with primers and probes specific to MC1–5, TNFα, TGFβ and IL-10.

Results: 6 females and 1 male with RA according to ACR criteria were examined. Median age 48.0 ±7.2 yrs (SD), disease duration 21 ±71 months. 4 were treated with methotrexate 25 mg/w and 3 with leflunomid 20 mg/d. 3 patients took prednisolon, mean dose 6.67 mg/d. At start and 4 months′ therapy, CRP was 3.0 ±22.1 and 2.9 ±0.6mg/L (median ±SD), respectively, hemoglobin 8.4 ±1.5 and 8.6 ±0.4 mmol/L, DAS28 4.9 ±1.5 and 2.0 ±0.6. At 4 months none took prednisolon. Adalimumab significantly reduced MC2, 3 and 4 mRNA in $CD8^+$, $CD14^+$ and $CD19^+$ leukocyte subsets. In $CD4^+$ Th lymphocytes there was no uniform reaction. IL-10 was lowered in CD4+, and tended as TNFα to be so in CD14+ cells, TGFβ unchanged.

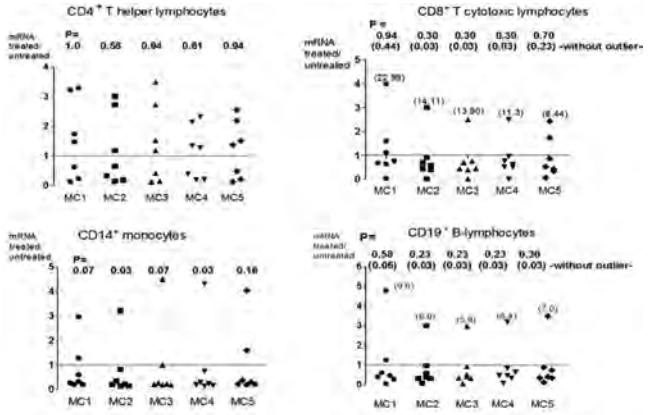

Figure. Quotes between MC1-5 mRNA measured by real-time RT-qPCR adjusted for housekeeping gene 18sRNA and with stimulated peripheral blood monocytes (PBMC) as reference in subtypes of leukocytes from 7 patients with rheumatoid arthritis, before and 4 months after start of adalimumab (Humira®) treatment. *Statistic*: Wilcoxon´s test for paired samples.

Conclusion: Here we show that Adalimumab down-regulates the MC2, 3 and 4 gene expression in the CD14+ monocytes in RA. Thus we have uncovered a new peripheral melanocortin signalling pathway through MC4 in monocytes. Monocytes are known to have an anti-inflammatory autocrin circuit based on the melanocortins, previously thought to operate solely through MC3 as shown in experimental gouty arthritis. Interestingly, our results show, that the MC1–5 gene expression of the $CD4^+$Th lymphocyte does not react uniformly to Adalimumab therapy. The $CD4^+$Th cell has a superior role in the immune reaction, as the central conductor of other cell types. Therefore, it is not surprising, that the powerful melanocortin system in just this very important cell type, seems to be controlled via several redundant mechanisms, interacting to exert fine tuning of the immune reaction.

Analysis of Gene Expression Fluctuation with Abatacept Highlights the Involvement of the Proteasome Pathway As a Mechanism of Action of Abatacept in Rheumatoid Arthritis. C Derambure[1], O Vittecoq[2], G Dzangue Tchoupou[1], Maria-Antonietta d'Agostino[3], P Gaudin[4], C Gaillez[5], M Le Bars[6] and T Lequerré[2]. [1]Inserm 905, Institute for Biomedical Research, University of Rouen, Rouen, France, [2]Rouen University Hospital, Rouen, France, [3]AP-HP Ambroise Paré Hospital, Boulogne-Billancourt, France, [4]University Hospital Grenoble, Grenoble, France, [5]Formerly of Bristol-Myers Squibb, Rueil-Malmaison, France, [6]Bristol-Myers Squibb, Rueil-Malmaison, France.

Background/Purpose: Abatacept (ABA) is a biologic therapy targeting T cells, which play a major role in the pathophysiology of RA. Overall, 57.1% of patients reached LDA (DAS28 [CRP] ≤3.2) after 6 months of treatment with ABA and MTX in the open-label ABA Power Doppler Ultrasonography APPRAISE study, in patients with RA and inadequate MTX response.[1] The objective of this substudy was to explore gene expression fluctuations and to identify the main molecular mechanism modifications that occur in a subset of ABA-treated patients according to their treatment response.

Methods: In this substudy, 19 patients with active RA and inadequate MTX response were treated with approved doses of ABA and MTX. For this analysis, patients were categorized as ABA responders (R; DAS28 ≤3.2 [LDA]) (n=14) or non-responders (NR; DAS28 >3.2) (n=5) following 6 months of treatment. Whole blood was collected in Paxgene tubes for each patient at baseline and 6 months. RNAs were hybridized to a whole human genome 4 × 44K microarray Agilent slide to identify mRNA specifically dysregulated between baseline and 6 months in R and NR patients using GeneSpring GX software and a *t*-test with false discovery rate correction for multiple testing ($p<0.05$). Gene ontology (GO), pathways analysis (curated WikiPathways) and text mining via Natural Language processing were performed to identify the molecular mechanisms regulated by ABA in R and NR. Correlations between gene expression fluctuation and changes in DAS28 were assessed to identify the impact of ABA treatment on disease activity.

Results: After 6 months of treatment with ABA, no genes were significantly differentially expressed in NR patients, whereas 935 genes were significantly differentially expressed in R patients ($p<0.05$). Of these genes, 298 were down-regulated at 6 months and 637 were up-regulated compared with baseline. GO allowed us to identify GO terms enriched only in the list of the 637 up-regulated genes. All of these GO terms were relative to the mRNA process ($p<0.05$). Pathways analysis allowed us to identify 15 curated pathways significantly enriched in the 935 mRNAs dysregulated in R patients ($p<0.05$). The most significant pathways found to be in agreement with the GO analysis were Hs_mRNA_processing_WP411_45374 (p=0.002) and Hs_Proteasome_Degradation_WP183_45274 (p=0.001). Among the 935 genes identified, 7 up-regulated genes were significantly involved in the proteasome degradation pathway, including 65 proteins in humans. Six gene expression fluctuations (among 935) between baseline and 6 months were correlated with variation of DAS28: 3 positive and 3 negative correlations ($p<0.01$).

Conclusion: Comparison of gene expression fluctuations between R and NR to abatacept treatment highlighted 935 genes differentially expressed only in R in our cohort. As the proteasome is required for essential immune functions of activated CD4(+) T cells, and can be defined as a molecular target for suppression of deregulated and unwanted T-cell-mediated immune responses, this study suggests a new mechanism of action for abatacept in patients with LDA. Small sample size may be a limitation. 1. D'Agostino MA, et al. *Arthritis Rheum* 2012;**64**(Suppl):S352.

Disentangling the Effects of Tocilizumab on Neutrophil Survival and Function. Timo Gaber[1], Martin Hahne[2], Cindy Strehl[3], Paula Hoff[4], Yvonne Doerffel[4], Eugen Feist[4], Gerd Burmester[4] and Frank Buttgereit[4]. [1]Berlin-Brandenburg Center of Regenerative Therapies (BCRT), Berlin, Germany, [2]Berlin-Brandenburg School of Regenerative Therapies (BSRT), Berlin, Germany, [3]German Rheumatism Research Center (DRFZ), Berlin, Germany, [4]Charité University Medicine, Berlin, Germany.

Background/Purpose: The synovial tissue in rheumatoid arthritis (RA) represents a hypoxic environment with up-regulated pro-inflammatory cytokines and cellular infiltrates including neutrophils. Tocilizumab, a humanized IgG1 monoclonal antibody directed against the interleukin (IL) 6 receptor, is a potent biologic treatment for RA but the inhibition of the IL6 pathway may also cause unwanted effects such as a decrease in blood neutrophil counts and occasionally high grade neutropenia.

In order to understand both therapeutic and adverse effects of IL6 receptor inhibition, we analysed the effects of tocilizumab on survival, phagocytotic capacity and energy metabolism of neutrophils under normoxic versus hypoxic conditions.

Methods: Human neutrophils were purified, pre-treated with varying doses of tocilizumab and, for comparison, dexamethasone or vehicle and finally stimulated with lipopolysaccharide (LPS) or left unstimulated. Cells

were then incubated under normoxic (18% O_2) or hypoxic (1% O_2) conditions and subsequently analysed.

Results: Both neutrophil survival and energy availability were significantly decreased by tocilizumab in a dose-dependent manner in LPS stimulated cells, but to a greater extent under normoxia as compared to hypoxia. We also found LPS stimulated phagocytotic activity of neutrophils to be significantly higher under hypoxic versus normoxic conditions, but this difference was significantly reduced by tocilizumab.

Conclusion: Tocilizumab is known for both beneficial effects and a higher incidence of neutropenia (>1/100 bis 1/10) when treating RA patients. Our results suggest that both effects can at least in part be explained by a reduction in neutrophil survival and a dose-dependent inhibition of a hypoxia-induced phagocytic activity of infiltrating hypoxic neutrophils, mimicking conditions of the inflamed joint environment.

Implementation of an Acid Dissociation Procedure for Immunogenicity Detection in Patients Treated with ANTI-TNF Drugs. Francisca Llinares-Tello[1], Jose Rosas[2], José M. Senabre-Gallego[1], Gregorio Santos-Soler[1], Carlos Santos-Ramirez[3], Esteban Salas-Heredia[1], Xavier Barber[4], Juan Molina[1], Catalina Cano[1], Ana Pons[1] and Group Aire-MB[1]. [1]Hospital Marina Baixa, Villajoyosa, Spain, [2]Hospital Marina Baixa. Villajoyosa, Villajoyosa, Spain, [3]Hospital Marina Salud, Denia, Spain, [4]CIO, Elche, Spain.

Background/Purpose: To evaluate the application of an acid dissociation procedure in monitoring patients with subtherapeutic serum concentrations of infliximab (IFX), adalimumab (ADL) and etanercept (ETN), using an immunoassay commercialized (Promonitor®-ETN, Progenika Biopharma, S.A., a Grifols Company).

Methods: For 3 years 612 trough samples were analyzed of 247 patients with different rheumatic pathologies treated with IFX (44 patients, 94 samples), ADL (123 patients, 289 samples) and ETN (80 patients, 229 samples). With the standard technology, ADA was detected in 27, 15 and 0% of the patients treated with IFX, ADL and ETN respectively, coinciding always with a level of undetectable drug.

92 samples quantified with detectable but subtherapeutic drug levels at the standard treatment (31 samples of 25 patients with IFX<2 mg/L, 38 samples of 26 patients with ADL<3 mg/L and 23 samples of 18 patients with ETN<2 mg/L), were analyzed for ADA after submitting them to an acid pre-treatment. The protocol of acidification consisted of the incubation of the serum during 15 minutes with acetic acid 300 mM and later neutralization with Tris 1 M fitting to a final dilution 1/10.

Results: With the protocol of acid dissociation anti-ADL antibodies were detected in 46% of the patients with subtherapeutic levels of ADL, which were undetectable with the standard assay (18 samples, 12 patients, middle age: 55 years, 67% women, diagnoses: 8 ankylosing spondylitis (BASDAI: 4,8±1,5), 3 rheumatoid arthritis and 1 psoriasic arthritis (DAS28: 3,5±0,2). In 7 cases ADA's detection after acidificatión was produced already in the first request of monitoring at 6 months of initiated the treatment. In other 3 cases, ADA's positive after dissociation confirmed a previous positive with the standard assay. Initially the treatment was kept with ADL in 5 patients, which ended up by turning out to be positives with the standard technology between 2 and 6 months after the positive with dissociation. Finally, in all the patients a change of treatment was necessary for lack of clinical response, being chosen by another anti-TNF before ADA's evidence. ADL's maximum concentration in the samples with a positive result was of 1,8 mg/L and the title of detected antibodies ranged between 35 and 282 UA/mL. Anti-IFX not anti-ETN antibodies were not detected after the acidificación of the samples by subtherapeutic concentrations of these two drugs.

Conclusion:

1) The acid pre-treatment of the samples increases the sensibility of the test of detection of anti-drug antibodies breaking possible drug-antibody complexes.
2) The monitoring of immunogenicity in patients with subtherapeutic levels of ADL, following a protocol of acid dissociation, has allowed us to detect in a precocious way ADA's presence in these patients contributing to the optimization of the treatment.

This study has received a grant from Spanish Society for Rheumatology.

Gene Expression Analyses of Abatacept- and Adalimumab-Treated Patients from the Ample Trial. S Bandyopadhyay[1], M Maldonado[1], M Schiff[2], ME Weinblatt[3], Roy Fleischmann[4] and SE Connolly[1]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]University of Colorado, Denver, CO, [3]Brigham and Women's Hospital, Boston, MA, [4]University of Texas Southwestern Medical Center, Dallas, TX.

Background/Purpose: The distinct mechanisms of action (MoA) of abatacept (ABA) and adalimumab (ADA) are expected to manifest in different transcriptional profiles in RA patients (pts). This post-hoc analysis assessed peripheral blood gene expression in RA pts from AMPLE treated with ABA or ADA, and the pharmacodynamic (PD) changes between baseline and month (Mth) 3 that correlate with the magnitude of clinical response.

Methods: The AMPLE study has been described elsewhere.[1] Peripheral blood mRNA was isolated from 566 pts at baseline and 3 mths. Whole genome transcriptional profiling used Affymetrix U219 chips, representing 18,567 genes. Differentially expressed genes from baseline to Mth 3 were identified for each treatment (fold-change >/< 0.2, adjusted p-value <0.05) using Bioconductor/LIMMA.[2] PD-response analysis was done by placing pts in non-overlapping groups based on their ACR response at Mth 3. From this, consensus-stabilized k-means clustering was used to reduce the data into the minimal number of PD clusters for ABA- and ADA-treated pts.[3] Genes within these clusters were analyzed by gene-set enrichment analysis (GSEA) to estimate the over-representation of molecular pathways.

Results: Pts treated with ABA had 236 genes significantly up-regulated by Mth 3, while ADA treatment had significant up-regulation of 634 genes (Figure). There was overlap on 221 of the genes up-regulated. Treatment with ABA resulted in the down-regulation of 179 genes, while treatment with ADA resulted in the down-regulation of 513 genes. The therapies overlapped on 172 genes. Across therapies, many genes were significantly regulated in one group but not the other (Figure, black dots). K-means clustering based on ACR response groups at Mth 3 resulted in 6 unique patterns of PD per treatment. GSEA identified 118 pathways enriched across the 6 ABA clusters and 119 pathways enriched in the 6 ADA clusters. Among the pathways showing PD response for both therapies were "NFAT in immune response", "inhibitory PD-1 signaling in T cells" and "T-cell subsets: cell surface markers".

Conclusion: ABA was more selective on modulating gene expression in RA pts, although there was overlap in genes impacted by both therapies. The treatment- and response-dependent clusters might reflect differences related to MoA leading to similar clinical outcomes. Further delineation of the pathways will elucidate how these two agents with unique mechanisms provide comparable efficacy with some differences in safety and tolerability.

1521

Sustained Improvements in Magnetic Resonance Imaging Outcomes with Abatacept Following the Withdrawal of All Treatment in Patients with Early Rheumatoid Arthritis. C Peterfy[1], Gerd Burmester[2], Vivian P. Bykerk[3], B G Combe[4], J C DiCarlo[1], D E Furst[5], T W J Huizinga[6], C S Karyekar[7], D Wong[7], Philip G. Conaghan[8] and P Emery[9]. [1]Spire Sciences, Inc., Boca Raton, FL, [2]Charité – University Medicine Berlin, Berlin, Germany, [3]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [4]Hôpital Lapeyronie, Montpellier, France, [5]University of California at Los Angeles, Los Angeles, CA, [6]Leiden University Medical Center, Leiden, Netherlands, [7]Bristol-Myers Squibb, Princeton, NJ, [8]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [9]University of Leeds, Leeds, United Kingdom.

Background/Purpose: Biologic treatment can lead to improved clinical outcomes in early RA. In the Assessing Very Early Rheumatoid arthritis Treatment (AVERT) study, abatacept (ABA) + MTX achieved significantly higher rates of DAS-defined remission (DAS28 [CRP] <2.6) vs MTX alone at 12 mths of treatment; a small but significantly higher number of patients (pts) on ABA + MTX vs MTX alone sustained remission following the rapid withdrawal of all RA drugs.[1] To assess the progression of structural joint damage in pts with early RA in AVERT, MRI changes were evaluated after 12 mths on treatment and following the withdrawal of all RA medication in pts in DAS-defined remission or LDA.

Methods: Pts with DAS28 (CRP) ≥3.2, onset of symptoms ≤2 yrs, active synovitis in ≥2 joints, who were MTX-naïve and anti-cyclic citrullinated peptide (CCP2) positive were randomized to SC ABA 125 mg/wk + MTX, SC ABA 125 mg/wk monotherapy or MTX alone for 12 mths. All RA treatment was removed after 12 mths (ABA immediately and MTX and steroids tapered over 1 mth) in pts with DAS28 (CRP) >3.2. Gadolinium-enhanced MRI of the clinically worse hand/wrist was performed at baseline and at Mths 6, 12, 18 and 24. Adjusted mean changes from baseline in synovitis, osteitis and erosion were calculated at Mths 12 and 18 for pts with MRI assessments. In a *post hoc* analysis, adjusted mean changes from baseline in synovitis, osteitis and erosion MRI scores were compared in pts who had DAS28 (CRP) <2.6 at both Mths 12 and 18 (after withdrawal).

Results: Pts in the intent-to-treat population had early RA (mean symptom duration 0.56 yrs) with highly inflammatory disease (mean TJC 23.3, SJC 16.5, CRP 17.5 mg/dL), severe disease activity (mean DAS28 [CRP] 5.44 and HAQ-DI 1.42), poor prognostic factors (95.2% RF and anti-CCP2 double positive) and 31.9% were on steroids at baseline (mean dose 7.0 mg/day). Improvements in synovitis and osteitis were greater, and the progression of erosion was less, in the ABA + MTX arm vs MTX, both on treatment (Mth 12) and following all treatment withdrawal (Mth 18); benefits of ABA monotherapy on synovitis at Mths 12 and 18 and osteitis at Mth 12 were intermediate to those of ABA + MTX and MTX alone (Table 1). In pts with DAS28 (CRP) <2.6 at both Mths 12 and 18, MRI benefits were maintained from Mth 12 to Mth 18 (Table 2).

Table 1. Adjusted mean change from baseline in MRI scores (intent-to-treat population)

Adjusted mean change from baseline (95% CI)		ABA + MTX (n=119)	ABA monotherapy (n=116)	MTX (n=116)
Synovitis	Mth 12	−2.35 (232.89, −1.81)* n=91	−1.36 (231.91, −0.80) n=81	−0.68 (−1.24, −0.13) n=84
	Mth 18	−1.34 (232.18, −0.50) n=38	−1.19 (232.01, −0.31) n=35	−0.49 (231.45, 0.46) n=29
Osteitis	Mth 12	−2.58 (233.47, −1.69)* n=91	−1.37 (−2.27, −0.46) n=81	−0.68 (−1.59, 0.24) n=84
	Mth 18	−2.03 (−3.72, −0.34) n=38	0.45 (−1.31, 2.20) n=35	0.34 (−1.55, 2.24) n=29
Erosion	Mth 12	0.19 (−0.46, 0.84)* n=91	1.42 (0.76, 2.07) n=81	1.53 (0.86, 2.19) n=84
	Mth 18	0.13 (−0.74, 1.01)* n=38	1.85 (0.96, 2.74) n=35	2.00 (1.07, 2.93) n=29

*p<0.05 for treatment difference vs MTX (95% CI for the estimate of treatment difference did not cross 0)

Table 2. Adjusted mean change from baseline in MRI scores; *post hoc* analysis in pts with DAS28 (CRP) <2.6 at both Mths 12 and 18

Adjusted mean change from baseline (95% CI)		ABA + MTX (n=18)	ABA monotherapy (n=14)	MTX (n=9)
Synovitis	Mth 12	−1.95 (−2.82, −1.08) n=18	−2.43 (−3.38, −1.48) n=12	−1.25 (−2.62, 0.13) n=6
	Mth 18	−2.14 (−3.14, −1.15) n=16	−2.45 (−3.49, −1.41) n=13	−1.47 (−2.85, −0.10) n=8
Osteitis	Mth 12	−2.39 (−3.15, −1.63) n=18	−2.06 (−2.86, −1.26) n=12	−1.28 (−2.39, −0.16) n=6
	Mth 18	−2.37 (−3.10, −1.63) n=16	−2.23 (−2.98, −1.49) n=13	−1.46 (−2.48, −0.43) n=8
Erosion	Mth 12	0.18 (−0.79, 1.15) n=18	0.42 (−0.57, 1.42) n=12	1.21 (−0.16, 2.58) n=6
	Mth 18	0.09 (−0.93, 1.12) n=16	0.36 (−0.70, 1.41) n=13	1.25 (−0.18, 2.68) n=8

There were no significant treatment differences vs MTX

Conclusion: Abatacept reduced MRI-detected joint inflammation and joint damage in pts with early RA; these benefits may be maintained for at least 6 mths after treatment withdrawal in pts who are in remission or low disease activity, suggesting an alteration in the autoimmune process.

Impact of Sarilumab on Health Related Quality of Life (HRQoL), Fatigue, and Sleep in Rheumatoid Arthritis Patients at Week 24 - Results of a Phase 3, Randomized, Double-Blind, Placebo-Controlled, Multi-Center Study. Vibeke Strand[1], George Joseph[2], Hubert van Hoogstraten[2], Chieh-I Chen[3], Chungpeng Fan[2], Paulo Carita[4], Neil Graham[3], Tanya Momtahen[2] and Mark C Genovese[5]. [1]Biopharmaceutical Consultant, Portola Valley, CA, [2]Sanofi, Bridgewater, NJ, [3]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [4]Sanofi, Chilly-Mazarin, France, [5]Stanford University Medical Center, Palo Alto, CA.

Background/Purpose: Sarilumab, a fully human monoclonal antibody directed against the IL-6 receptor, demonstrated efficacy in the phase 3 part of the RA-MOBILITY study (NCT01061736) in adults with active, moderate-to-severe RA with inadequate responses to methotrexate (MTX).[1] Most common TEAEs included infections and injection site reactions. A higher incidence of serious infections was observed with sarilumab. Lab abnormalities included decreases in neutrophils and increases in transaminases and lipids. This analysis focuses on the impact of sarilumab + MTX on HRQoL, fatigue, and sleep, all of which were pre-defined secondary endpoints at Week 24 among patients who had a patient reported outcome (PRO) measured at that time point. Overall work impairment due to RA was assessed at Week 12.

Methods: The intent-to-treat population included 1,197 patients who were randomized 1:1:1 to receive placebo + MTX, sarilumab 150 mg every two weeks (q2w) + MTX or 200 mg q2w + MTX. The Short Form-36 (SF-36), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), Sleep-Visual Analog Scale (Sleep-VAS) and Work Productivity and Activity Impairment (WPAI) questionnaires were assessed at baseline, Weeks 12 (WPAI only), 24 and 52.

Results: Statistically significant improvements versus placebo + MTX in SF-36 T-Scores for Physical Component Summary (PCS) and Mental Component Summary (MCS), all 8 domains of SF-36, FACIT-F and Sleep-VAS were reported by patients receiving sarilumab 150 mg + MTX and 200 mg + MTX at Week 24, which exceeded the minimum clinically important difference (MCID) in all SF-36 summary and domain scores (PCS and MCS: 2.5; 8 domains: 5.0), FACIT-F (3.0) and Sleep-VAS (4.1) scores in both active treatment groups (Table 1, Bolded). Improvements evident at Week 24 were sustained through Week 52. Statistically significant improvements in WPAI "% overall work impairment due to RA" scores were reported for 150 mg + MTX group at Week 12.

Conclusion: In this Phase 3 trial, patients with active RA receiving either dose of sarilumab q2w + MTX reported clinically meaningful change from baseline in all HRQoL and fatigue scores at Week 24, which were maintained through Week 52. Statistically significant benefit was also reported in sleep and "% overall work impairment due to RA" for sarilumab 150 mg q2w + MTX dose.

Follow-up Data on the Rheumatoid Arthritis Comparison of Active Therapies Trial: Observational Cohort. Robert Lew[1], Denis Rybin[2], Keri Hannagan[1], Hongsheng Wu[3], Edward Keystone[4], Ted R. Mikuls[5] and James O' Dell[5]. [1]VA Boston Heathcare System, Boston, MA, [2]VA Boston Healthcare System, Boston, MA, [3]Wentworth Institute of Technology, Boston, MA, [4]Mount Sinai Hospital, Toronto, ON, [5]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: In this 48-week, double-blinded, non-inferiority trial, 353 methotrexate suboptimal-responders were randomized to two treatment strategies, either the addition of sulfasalazine and hydroxychloroquine (triple therapy [T]) or the addition of etanercept (E). Participants without marked improvement in DAS28 at 24 weeks switched to the alternate treatment, while maintaining the blind. This created 4 treatment subgroups: no switch (T-only, E-only), and switch (T-E, E-T). At 48 weeks treatment blind was broken. Follow-up data on major study outcomes from the observational sub-cohort of participants who consented to long term f/u is presented.

Methods: DAS28 scores, joint assessments, laboratory values, visual analog scale (VAS), HAQ, Health Utilities Index (HUI), EQ5D, and changes in therapy (grouped as either any conventional (DMARDs) or to any biologic were collected every 24 weeks up to week 120 or end of study. The last participants enrolled had minimal potential for follow-up, decreasing overall mean follow-up. We compared two follow-up groups: participants on E at 48 weeks (E-only and T-E) who then changed to a DMARD and participants on T at 48 weeks (T-only and E-T) who then changed to a biologic. Study measure results were compared by simple ANOVA at each follow-up time across the four treatment subgroups. The stability of measures over time within each subgroup was assessed by repeated measures ANOVA.

Results: Of the 353 participants, 289 with 48 week data agreed to extend follow-up. Treatment subgroups consisted of 106 T-only, 103 E-only, 42 T-E, and 38 E-T. Data were available on 213 (74%), 168 (58%), and 162 (56%) at 72, 96, and 120 week, respectively. For week 120, data available within the subgroups ranged from 46% to 59%. With respect to DAS28, the censoring patterns appeared completely at random (at each time the null hypothesis was not rejected). Measures of joint assessment, laboratory values, VAS, HAQ, HUI, and EQ5D were stable over time within subgroups. DAS28 scores and various component scores were slightly higher over time among switchers than non-switchers, but not significantly (NS). Within each subgroup no symptom or disability index rose significantly over time. 218 patients had follow-up data on medication use on or after 48 weeks. In this group at week 48, 90% of 101 patients who ended the study on T continued on DMARDs compared to 48% of the 117 patients who ended the study on E and continued on biologics. Of those who changed treatment at week 48, more changed from E to a DMARD than from T to a biologic (chi-square test $p<0.01$). After week 48 medication change rates remained similar in the two groups.

Conclusion: In this observational cohort, major study outcomes including DAS28 remained stable over time. Those patients who switched therapy at week 24 of the interventional trial had slightly higher DAS28 and component scores. Censoring from the treatment subgroups was similar to the overall cohort indicating that censoring was independent of treatment assignment. Of those with post-study medication data, there was a larger change to DMARDs than to biologics immediately after ending the study. The reasons for this are being explored.

Rituximab Done! What's Next in RA? Ulrich A. Walker[1], Veronika K. Jaeger[1], Katerina Chatzidionysiou[2], Merete Lund Hetland[3], Ellen Margrethe Hauge[4], Karel Pavelka[5], Dan C. Nordström[6], Helena Canhao[7], Matija Tomsic[8], Ronald van Vollenhoven[2] and Cem Gabay[9]. [1]Department of Rheumatology, University Hospital Basel, Basel, Switzerland, Basel, Switzerland, [2]Karolinska University Hospital, Stockholm, Sweden, Stockholm, Sweden, [3]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark, Aarhus, Denmark, [4]DANBIO, Center for Rheumatology and Spine Diseases, Glostrup University Hospital, Glostrup, Denmark, Glostrup, Denmark, [5]Charles University, Prague, Czech Republic, Prague, Czech Republic, [6]ROB-FIN, Helsinki University Central Hospital, Helsinki, Finland, Helsinki, Finland, [7]Rheumatology Research Unit, Instituto de Medicina Molecular, Lisbon, Portugal on behalf of the Rheumatic Diseases Portugal Register, Lisbon, Portugal, [8]University Medical Centre Ljubljana, Ljubljana, Slovenia, Ljubljana, Slovenia, [9]University Hospitals of Geneva/SCQM Registry, Geneva, Switzerland, Geneva, Switzerland.

Background/Purpose: The optimal strategy to use biologics after rituximab (RTX) in RA is unknown. We therefore aimed to evaluate the effectiveness of different biologics after RTX treatment.

Methods: The CERRERA registry, a prospective, longitudinal, multinational database of RA patients (Pts) treated with RTX was analyzed with respect to the effectiveness of tumor necrosis factor alpha inhibitor (TNFi), abatacept (ABA) or tocilizumab (TCZ) as a new biologic after RTX. Pts were included, if they had stopped RTX no longer than 6 months prior to the new biologic, had a baseline (BL) visit within 21 days of commencement of the new biologic, and at least 1 follow up visit. BL characteristics were compared across biological classes and between TCZ mono and TCZ combination therapy (methotrexate (MTX) and/or leflunomide (LEF)).

Results: The inclusion criteria were met by 265 Pts. Demographic and disease characteristics did not differ across treatment groups (Table). Pts on TCZ had a significantly greater decline of DAS28(ESR) and CDAI, than Pts on TNFi or ABA after 6 months of treatment (Figure 1). This effect was also seen after adjusting for prednisone use and the number of previous biologics. DAS28 scores in Pts on TCZ were 1.0 (95% CI 0.2–1.7) and 1.8 (95% CI 1.1–2.6) lower than in Pts on TNFi or ABA, respectively. Similarly, the CDAI was 7.2 (95% CI 0–15) and 7.5 (95% CI 0–15) points lower in Pts on TCZ than on TNFi or ABA. Pts with TCZ more frequently had a good EULAR response than Pts with TNFi or ABA (66% vs 31% & 14%, $p<0.001$). Overall, Pts reported a lower HAQ after 6 months of treatment ($p<0.001$), though the decline did not differ between treatment groups.

When comparing TCZ mono with TCZ combination therapy, ΔDAS28 and ΔCDAI and EULAR response did not differ. The drug retention rates did not differ between all treatments (Figure 2).

Conclusion: In this observational cohort study, TCZ provided a better control of RA activity than ABA or TNFi in Pts who discontinued RTX. There was no difference in effectiveness between TCZ given as mono therapy and TCZ given in combination with non-biologic DMARDs.

Table Baseline characteristics by treatment groups in patients who had stopped RTX. Characteristics between TNFI, ABA and TCZ were compared by X^2, Fisher's exact, ANOVA or Kruskal Wallis tests as appropriate.

		Overall (n = 265)	TNFi (n = 89)	ABA (n = 90)	TCZ (n = 86)	TCZ Mono (n = 27)	TCZ Combination (n = 59)	P value

Cumulative Clinical Response in Rheumatoid Arthritis Patients with Rituximab Repeated Courses after Failure to Tumor Necrosis Factor Inhibitors in Routine Clinical Practice. Catalin Codreanu[1], Ruxandra Ionescu[2], Ioan Ancuta[3], Corina Mogosan[4], Simona Rednic[5], Paulina Ciurea[6], Maria Suta[7], Magda Parvu[8], Andra Balanescu[2], Mihai Bojinca[3], Dan Nemes[9], Codrina Ancuta[10] and Elena Rezus[11]. [1]'Dr. Ion Stoia' Clinical Center of

Rheumatic Diseases, Bucharest, Romania, [2]Sfanta Maria Clinical Hospital, UMF Carol Davila, Bucharest, Romania, [3]Carol Davila University of Medicine and Pharmacy & Cantacuzino Hospital, Bucharest, Romania, [4]'Dr. Ion Stoia' Clinical Center of Rheumatic Diseases, Bucharest, Romania, [5]University of Medicine and Pharmacy, Cluj-Napoca, Romania, [6]Clinical County Hospital,Craiova, Craiova, Romania, [7]Constanta Municipal Hospital, Constanta, Romania, [8]Colentina Clinical Hospital, Bucuresti, Romania, [9]"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, [10]G.T-.Popa Center for Biomedical Research, Iasi, Romania, [11]Recovering Clinical Hospital, Iasi, Romania.

Background/Purpose: The concept of achieving tight control of rheumatoid arthritis (RA) and treating to target has been well established. It focuses on early diagnosis, aggressive treatment and regular monitoring, thus leading to positive outcomes in a significant number of patients with RA who achieve current treatment goals of low levels of disease activity (LDA) or clinical remission (REM).To observe and evaluate the treatment response (REM and LDA) to repeated courses of Rituximab (RTX) in patients with RA treated in current practice in Romania.

Methods: In this open-label, multicenter, prospective observational study (REPEAT), patients were treated with initial (2×1000 mg IV, at 2 weeks apart) and subsequent RTX courses. Clinical assessments, including 28-joint count disease activity score (DAS 28), were performed at baseline (before RTX initiation), and after each retreatment course at 6, 12, 18, 24, 30 and 36 months. Statistical analyses were carried out using STATA SE/11 software: Kruskal-Wallis test for disease activity stages across evaluations, Cuzicks' test for time trend along evaluations.

Results: 1087 patients with active RA and inadequate response to at least one TNF inhibitor, who received an initial RTX treatment were included. Their average age at entry was 56.2 ± 11.2 yrs (mean ± SD) and 86% were women. 929 patients (85.5%) had only one anti-TNF treatment, whereas 158 (14.5%) had more than one. Percentages of remission and LDA are presented below. The Kruskal-Wallis test between evaluations was used, $P<0.0001$, as well as Nptrend for trend across evaluations, $P < 0.0001$.

Time Evaluation after RTX (months)	REM % (pts/n)	LDA % (pts/n)	Treat to Target % (pts/n)
6	9,43 (100/1060)	13,40 (142/1060)	**22,83** (242/1060)
12	19,32 (187/968)	19,42 (188/968)	**38,74** (375/968)

30	44,56 (172/386)	31,87 (123/386)	**76,43** (295/386)
36	51,83 (85/164)	30,49 (50/164)	**82,32** (135/164)

n = patients who completed RTX courses along evaluations

Conclusion: The data show continuous improvement of clinical response after each retreatment course with RTX. Each RTX course led to an increased and cumulative clinical response compared to the previous one, being in line with treat to target principle and EULAR/ACR recommendations.

Sustained Clinical Efficacy after Multiple Courses of Rituximab in Rheumatoid Arthritis Patients with Inadequate Response to Tumor Necrosis Factor Inhibitors: 3-Year Data from Repeat. Catalin Codreanu[1], Ruxandra Ionescu[2], Ioan Ancuta[3], Corina Mogosan[4], Simona Rednic[5], Paulina Ciurea[6], Maria Suta[7], Magda Parvu[8], Andra Balanescu[2], Mihai Bojinca[3], Dan Nemes[9], Codrina Ancuta[10] and Elena Rezus[11]. [1]'Dr. Ion Stoia' Clinical Center of Rheumatic Diseases, Bucharest, Romania, [2]Sfanta Maria Clinical Hospital, UMF Carol Davila, Bucharest, Romania, [3]Carol Davila University of Medicine and Pharmacy & Cantacuzino Hospital, Bucharest, Romania, [4]'Dr. Ion Stoia' Clinical Center of Rheumatic Diseases, Bucharest, Romania, [5]University of Medicine and Pharmacy, Cluj-Napoca, Romania, [6]Clinical County Hospital,Craiova, Craiova, Romania, [7]Constanta Municipal Hospital, Constanta, Romania, [8]Colentina Clinical Hospital, Bucuresti, Romania, [9]"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, [10]G.T.Popa Center for Biomedical Research, Iasi, Romania, [11]Recovering Clinical Hospital, Iasi, Romania.

Background/Purpose: Efficacy and safety of multiple courses of biologics used over extended periods of time in rheumatoid arthritis (RA) is still a medical debate. The purpose: to assess clinical efficacy of subsequent courses with Rituximab (RTX) in patients with active RA despite treatment with a TNF inhibitor in routine clinical practice in Romania.

Methods: Open-label, multicenter, prospective observational study started in 2010,using RTX every 6 months. Clinical efficacy included DAS-28, SDAI and CDAI at baseline and at 6, 12, 18, 24, 30 and 36 months. **Δ** DAS-28, **Δ** SDAI and **Δ** CDAI were calculated based on two consecutive evaluations. Statistical analyses: STATA SE/11.

Results: 1087 patients with active RA and inadequate response to at least one TNF inhibitor who received an initial RTX treatment were included. Their average age at entry was 56.2 ± 11.2 yrs (mean ± SD) and 86% were women. The mean values of disease activity scores steadily decreased after each retreatment indicating significant improvement.

Evaluation	DAS-28 (mean±SD)	SDAI (mean± SD)	CDAI (mean ±SD)
Baseline	5.57 ± 1.48 (n=1071)*	29.5±15.98 (n=1057)**	27.33 ± 15.07 (n=1071)
6 months	4.03 ± 1.13 (n=1060)	13.84 ± 9.33 (n=1041)	12.5 ± 8.82 (n=1060)
12 months	3.42 ± 0.96 (n=968)	9.16 ± 7.48 (n=938)	7.83 ± 6.69 (n=968)
18 months	3.02 ± 0.86 (n=775)	6.58 ± 5.63 (n=761)	5.45 ± 5.12 (n=775)
24 months	2.8 ± 0.76 (n=585)	5.43 ± 5.07 (n=574)	4.21 ± 4.22 (n=585)
30 months	2.69 ± 0.85 (n=386)	5.55 ± 5.49 (n=379)	4.15 ± 4.78 (n=386)
36 months	2.56 ± 0.83 (n=164)	5.27 ± 5.1 (n=159)	3.92 ± 4.2 (n=164)

*Patient's number (n) decreases in time because of the enrolment timeframe and represents the number of patients who reached each evaluation ** SDAI patient's /number is lower as CRP was not determined in all patients. Remission rate progressively increased after each retreatment course: 9.43% (100/1060 pts), 19.32% (187/968 pts), 31.48% (244/775 pts), 41.54% (243/585 pts), 44.56% (172/386 pts) and 51.83% (85/164 pts), whereas initial percentage of patients showing high disease activity (HDA) (66.2%=709/1071 pts) decreased to 18.02% (191/1060 pts), 4.44% (43/968 ps), 1.81% (14/775 pts), 0.68% (4/585 pts), 1.04% (4/386 pts) and 1.22% (2/164 pts) at 6, 12, 18, 24, 30 and 36 months, respectively. Similar trends were observed in SDAI and CDAI scores. All **Δ** DAS-28, **Δ** SDAI and **Δ** CDAI changes, as well as DAS-28 vs. SDAI and DAS-28 vs. CDAI comparisons were statistically significant ($p<0.0001$).

Conclusion: Our study showed a sustained improvement of clinical response after each retreatment course with RTX.

Efficacy of Biologic Treatments in Early Active Rheumatoid Arthritis: An Indirect Comparison. Laura Sawyer[1], Stacey Chang[1], Alex Diamantopoulos[2] and Fred Dejonckheere[3]. [1]Symmetron Limited, London, United Kingdom, [2]Symmetron Limited, Herts, United Kingdom, [3]F. Hoffmann-La Roche, Basel, Switzerland.

Background/Purpose: To date, no head-to-head trials have been conducted comparing the efficacy of biologic treatments for early active rheumatoid arthritis (ERA). Here, we evaluated the effectiveness of tocilizumab (TCZ) compared with other traditional and biologic disease-modifying antirheumatic drugs (tDMARDs and bDMARDs), alone and in combination, in adult patients with moderate to severe ERA who have not been treated with methotrexate (MTX) or bDMARDs.

Methods: A literature review was undertaken to identify randomized controlled trials (RCTs) of tDMARDs and bDMARDs in patients with ERA (duration, <3 years) that reported efficacy outcomes, including the proportions of patients achieving American College of Rheumatology (ACR) scores of 20, 50, 70, and 90 and disease activity score (DAS28)–defined remission (DAS28 <2.6). Study data were pooled using Bayesian network meta-analysis techniques. For ACR response, data were analyzed using a fixed-effects (FE) ordered probit model, which makes efficient use of ordered categorical data and guarantees coherent prediction of multinomial response probabilities. For DAS remission, data were analyzed with an FE binomial logit model. The analysis included only results for treatments in licensed doses. Sensitivity analyses tested the effects of grouping treatments by class and broadening and narrowing inclusion criteria.

Results: We included 16 RCTs of tDMARDs (MTX, sulfasalazine [SSZ], hydroxychloroquine [HCQ]), bDMARDs (abatacept [ABT], adalimumab [ADA], etanercept [ETN], infliximab [IFX], golimumab [GOL], and TCZ), and tofacitinib (Tofa). Results indicate that all bDMARDs + MTX, triple tDMARD therapies, and TCZ and Tofa in monotherapy significantly increased response across all ACR categories versus MTX. (Figure). Probabilities of ACR response to bDMARDs + MTX were broadly similar, with no significant differences between agents. Probabilities of ACR response to

bDMARDs in monotherapy were more varied, with a trend toward higher values for Tofa and TCZ than for ETN or ADA. Only a subset of studies reported DAS remission. Results show that treatment with Tofa or any bDMARD (± MTX) except ADA alone improved the likelihood of DAS remission versus MTX. TCZ (± MTX) generated the highest probability of remission among bDMARD agents and was significantly more effective than all other bDMARDs (± MTX) and Tofa. Results across both outcomes were robust to alternative grouping of interventions and to change in the inclusion criteria.

Conclusion: Based on ACR response, the expected efficacy of bDMARDs + MTX, Tofa and TCZ monotherapy, and triple tDMARD therapy appears comparable in early RA. TCZ and Tofa in monotherapy are more effective than ADA alone and are likely to be more effective than ETN alone. TCZ ± MTX is expected to have the highest probability of generating DAS.

Figure. Median relative treatment effects vs MTX (95% credible interval). PRD, prednisone/prednisolone.

Efficacy and Safety of MK-8457, a Novel SYK Inhibitor for the Treatment of Rheumatoid Arthritis in Two Randomized, Controlled, Phase 2 Studies.

Ronald van Vollenhoven[1], S. B. Cohen[2], Philip Mease[3], Charles G. Peterfy[4], Wolfgang Spieler[5], Judith Boice[6], Sean Curtis[7], Qing Li[7], Ruji Yao[8], Richard Baumgartner[7] and Holly Weng[8]. [1]The Karolinska Institute, Stockholm, Sweden, [2]Metroplex Clinical Research Center, Dallas, TX, [3]University of Washington, Seattle, WA, [4]Spire Sciences LLC, Boca Raton, FL, [5]ZeFOR GmbH Zentrum für Forschung, Zerbst, Germany, [6]Merck Research Laboratories, Whitehouse Station, NJ, [7]Merck & Co., Inc, Whitehouse Station, NJ, [8]Merck & Co., Inc., Whitehouse Station, NJ.

Background/Purpose: Novel, targeted small-molecular medications are needed in the treatment of rheumatoid arthritis (RA). MK-8457 is a novel inhibitor of spleen tyrosine kinase (SYK) and zeta-chain-associated protein kinase 70 (ZAP70) that is being investigated as an RA treatment.

Methods: Two Phase 2, multicenter, double-blind, placebo-controlled trials were conducted in RA subjects (≥ 18 years old). Study 1 was an adaptive study in subjects with active RA despite treatment with methotrexate (MTX) and included MRI; Study 2 included subjects with active RA and an inadequate response or intolerance to anti-TNF-α therapy. Subjects in both studies were randomized to MK-8457 100 mg BID + MTX or placebo + MTX for 24 weeks, this dose has 99% inhibition of basophil CD63 biomarker. The primary endpoints were the American College of Rheumatology 20 (ACR20) response at Week 12 in Study 1 and change from baseline in the Disease Activity Score 28 (DAS28) based on C-reactive protein (CRP) at Week 12 in Study 2. ACR 50 and ACR70 were also evaluated. Subjects were eligible to continue open-label safety extensions for up to 100 weeks upon completion of the initial 24-week treatment period. Safety was monitored by physical examination, vital signs, safety labs, and adverse event (AE) reporting.

Results: Both studies were discontinued early due to serious infections. At the time of study discontinuation, there were 82 subjects (mean age 55 years; 77% female; baseline mean $DAS28^{CRP}$ 5.98) randomized to MK-8457 (n=41) and placebo (n=41) in Study 1. In Study 2, 56 subjects (mean age 59 years; 77% female; baseline mean $DAS28^{CRP}$ 6.12) were randomized to MK-8457 (n=30) and placebo (n=26). Statistically significant efficacy improvement was observed with MK-8457 in Study 1 (MTX-IR), but not in Study 2 (TNF-IR) (Table). Study 1 also showed efficacy on osteitis and synovitis on MRI. At termination, Study 2 only had 31 subjects with Week 12 data; therefore, there was little power to assess efficacy endpoints. There were 27% (MK-8457) vs 10% (placebo) with non-infection gastrointestinal (GI) AEs in Study 1, and; 27% (MK-8457) vs 4% (placebo) with GI AEs in Study 2. In Studies 1 and 2, there were 6 serious respiratory infections (5 pneumonia and 1 bronchitis) and 1 serious case of enterocolitis; 1 subject with presumed opportunistic infection died during the Study 1 extension. The combined serious infection rate per 100 patient-years was 16.3. There were no significant changes in blood pressure in the MK-8547 treated groups.

Conclusion: MK-8457 improved efficacy in subjects with an inadequate response to MTX (Study 1), but not in subjects who failed anti-TNF-α therapy (Study 2), although Study 2 was limited to a small sample size. A high rate of serious infections was observed leading to the termination of both studies suggesting a potential increased infection risk with high degree of SYK and/or ZAP70 inhibition.

Evaluation of the Pharmacokinetics and Safety of the Interactions Between the Anti-Interleukin-6 Monoclonal Antibody Sirukumab and Cytochrome P450 Activities in Patients with Rheumatoid Arthritis. Dick de Vries, Yanli Zhuang, Stanley Marciniak, Zhenhua Xu, Dion Chen, Hugh M. Davis, Honghui Zhou and Francisco Lreon. Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: Interleukin 6 (IL-6) reduces the expression of cytochrome P450 (CYP) enzymes. The goal of the study was to evaluate: 1) the effect of sirukumab on the pharmacokinetics of probe substrates for CYP3A4, CYP2C9, CYP2C19, and CYP1A2 in patients with active rheumatoid arthritis (RA), a disease in which IL-6 is elevated; 2) the safety of a single subcutaneous high dose of sirukumab in RA patients.

Methods: This was an open-label, Phase 1 study in men and women 18–65 years of age, diagnosed with RA and with a screening CRP≥8.0 mg/L. Twelve patients, genotyped to exclude poor metabolizers of CYP2C9 and CYP2C19, were enrolled. Patients received oral "cocktail" administrations of CYP probe substrates (midazolam, warfarin, omeprazole and caffeine) at weeks -1, 1, 3, and 6 weeks relative to a single subcutaneous dose of 300 mg sirukumab. Serum sirukumab concentration and antibodies to sirukumab were analyzed. Safety was monitored through 7 weeks after sirukumab administration. Plasma levels of 4-β-hydroxycholesterol were measured.

Results: AUC_{inf} of each probe substrate before and after sirukumab treatment showed that exposure to midazolam, omeprazole and S-warfarin was reduced modestly (<50%) at 1, 3 and 6 weeks after sirukumab treatment. CRP decreased after sirukumab administration. Mean plasma levels of 4-β-hydroxycholesterol showed an increase of about 25% over time, but the ratio of 4-β-hydroxycholesterol to cholesterol did not change. All 12 patients reported at least one non-serious adverse event, the two most frequent ones being laboratory abnormalities and mild injection site reactions. No new safety findings were observed and no SAEs were reported.

Conclusion: Consistent with its intended suppression of IL-6 effects, treatment with sirukumab may reverse IL-6-mediated suppression of CYP3A4, CYP2C9 and CYP2C19 activities in RA patients. These results suggest the possibility of potential changes in the levels of certain CYP-metabolized medications in RA patients treated with sirukumab. Single high-dose sirukumab and probe cocktail administrations were well tolerated, without new safety findings.

Table 1: Mean (SD) values for AUC_{inf} of each probe substrate before and after sirukumab treatment

	Pre-sirukumab (n=12)	1 week after sirukumab (n=12)		3 weeks after sirukumab (n=12)		6 weeks after sirukumab (n=12)

Autologous Tolerogenic Dendritic Cells for Rheumatoid and Inflammatory Arthritis. Gillian Bell, Amy E. Anderson, Julie Diboll, Rachel Harry, Elaine McColl, Anne Dickinson, Catharien Hilkens and John D Isaracs. NIHR Newcastle Biomedical Research Centre, Newcastle Hospitals Foundation Trust and Newcastle University, Newcastle upon Tyne, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease which results from a breakdown of immune tolerance. Despite their efficacy current RA therapeutics, including biologic and non-biologic DMARDs, generally require chronic administration with the associated risk of adverse effects. The concept of therapeutic tolerance states that it should be possible to reprogram unwanted immune responses, including autoimmunity, and reset the immune system to self-tolerance. Although the concept has been achieved in animal models of autoimmunity and transplantation it has not yet been convincingly demonstrated in humans. We have developed a potentially tolerogenic therapy, autologous tolerogenic dendritic cells (tolDC), and now report the results of a phase 1 safety trial in patients with inflammatory arthritis. The secondary objectives were to assess tolerability and feasibility; exploratory objectives include preliminary evidence of potential efficacy including biomarkers.

Methods: This was an ascending dose, randomised, controlled, unblinded phase I study. Participants had a chronic inflammatory arthritis (75% RA) with an actively inflamed knee joint. Background therapy was maintained throughout the trial. There were three dosing cohorts of 1 million, 3 million and 10 million tolDC; controls received saline washout only. Following screening, participants underwent leukapheresis and leukocytes were transferred to a GMP facility. CD14+ monocytes were positively selected and tolDC differentiated according to our published methods[1]. During differentiation tolDC were loaded with autologous synovial fluid as autoantigen. After 7 days tolDC were administered arthroscopically into the inflamed knee joint following saline washout. Synovial biopsies were taken arthroscopically at baseline and again 14 days later, when intra-articular glucocorticoid was administered for persistent inflammation. The primary endpoint of the study was the proportion of patients experiencing a flare of target knee joint inflammation within 5 days of tolDC administration (knee flare). Secondary endpoints were patient acceptability and the success rate of tolDC preparation.

Results: TolDC were successfully manufactured from 9 patients. The product marginally failed quality control in a tenth case. No knee flares were observed in patients or controls. In most participants there was residual inflammation at day 14 arthroscopy except for two patients in the 10 million tolDC cohort. There was one SAE (flare of RA on day 70, requiring hospital admission and subsequent pneumonia) and several AEs, most of which were deemed unrelated to therapy. Patient acceptability of the intervention was high.

Conclusion: We have peformed a phase 1 study of intra-articular tolDC in patients with inflammatory arthritis. The intervention appeared safe, feasible and acceptable to participants. We are currently planning tracking studies, to study the fate of administered cells, and biomarker analysis. [1]Harry RA, Anderson AE, **Isaacs JD**, Hilkens CM. 1531

CUT-Off LEVEL of Adalimumab and Prevalence of Antibodies ANTI-Adalimumab in Patients with Ankylosing Spondylitis: Results from a LOCAL Registry. Jose Rosas[1], Francisca Llinares-Tello[2], José M. Senabre-Gallego[2], Carlos Santos-Ramirez[3], Esteban Salas-Heredia[2], Xavier Barber[4], Gregorio Santos-Soler[2], Juan Molina[2], Mario García-Carrasco[5], Ana Pons[2], Catalina Cano[2] and Group Aire-MB[2]. [1]Hospital Marina Baixa. Villajoyosa, Villajoyosa, Spain, [2]Hospital Marina Baixa, Villajoyosa, Spain, [3]Hospital Marina Salud, Denia, Spain, [4]CIO, Elche, Spain, [5]Universidad Autónoma de Puebla, Puebla, Mexico.

Background/Purpose: To evaluate the Cut-off level of adalimumab (ADL) and the prevalence of antibodies anti-adalimumab (anti-ADL-ab), in patients with psoriatic arthritis (PsA) and ankylosing spondylitis (AS).

Methods: We included 115 test of serum level of ADL and anti-ADL-Ab from 60 consecutives patients, on treatment with ADL at least 6 months, diagnosed of peripheral arthritis PsA (16 test in 10 patients), or AS (99 test in 50 patients). Clinical characteristics, clinical activity index (DAS28-ESR, SDAI, for peripheral PsA; BASDAI and ASDAS for AS, were recorded.

Serum levels of ADL and anti-ADL-Ab was evaluated by an ELISA kit: Promonitor®-ADL and Promonitor®-anti-ADL-Ab (Progenika Biopharma, S.A., a Grifols Company). Cut-off level for serum level of ADL was >0.004 U/mL and for anti-ADL-Ab was >3.5 U/mL. Serum samples were collected before injection of ADL, and stored frozen -80°C, until analysis.

Receiver operating characteristics (ROC) analysis was used to obtain a cut-off value for ADL trough levels between RA patients with low disease activity (DAS28 ≤ 3.2) versus those with moderate or high activity (DAS28 > 3.2), and for AS patients, between ASDAS ≤2.1 vs >2.1.

Results: We enrolled 60 patients, 56% were women, mean age 48±16 years. In 50 (84%) patients with AS, 99 test (86%) for ADL level and anti-ADL-Ab and in 10 patients (16%), diagnosed of PsA, 16 (14%) test was done.

For the whole patients: the average time of treatment was 9.5±9 years and the average time on treatment with ADL 1.7±1.4 years; in 38 (63%), ADL was the first biological drug administered; the mean BMI was 27 and the prevalence of anti-ADL-Ab was 30% (18 patients: 14 –28%- patients with AS and 4 –40%- of patients with PsA).

In patients with anti-ADL-Ab versus patients without ant-ADL-ab, we obtained significantly higher level of ADL (11.5±5.3 vs 0.12 ± 0.2; p<0.0001), less BASDAI response (2.7±1.8 vs 5.5±2.0; p<0.0001), less ASDAS level (1.8±0.6 vs 3.5±2.6; p=0.008) and less time on treatment with ADL (2.2±1.4 vs 0.8±0.4; p<0.0001). Although the 35% patients without anti-ADL-ab was treated with DMARDs and only 10% of patients with anti-ADL-ab, there was not statistical differences (p=0.2).. The cut-off level of ADL in patients with AS to achieve an ASDAS≤2.1 was 5.4 mg/L, with AUC of 82.9% (sensitivity: 91%; specificity: 75%).

Table 1. Characteristics in responders and non-responders patients in relation with ASDAS results

	Responders (n:42) ASDAS ≤ 2.1	Non-Responders (n:42) ASDAS ≤ 2.1	P
ADL level, mean ± SD	11.0 ± 4.4	1.7 ± 4.1	<0.001
Anti-ADL-ab (%)	2*	71	0.006
BASDAI, mean ± SD	2.5 ± 1.5	5.7 ± 1.8	<0.001
DMARD (%)	40	17	0.4
Time (years) on ADL, mean±SD	1.7±1.2	1.2±1	0,08

(*a patient with a detectable low level of ADL and the anti-ADL-ab was demonstrated using acid dissociation technique).

Conclusion: 1.Cut-off level of ADL in patients with AS to achieve an ASDAS≤2.1 was 5.4 mg/L. 2. Prevalence anti-ADL-Ab in AS was 28%. 3. Anti-ADL-ab is correlated significantly with lower level of ADL, BASDAI and ASDAI results and less time on treatment. 4. Patients responders have occasionally anti-ADL-ab, and significantly higher serum concentrations of ADL than non-responders.

This study has a grant from Spanish Society for Rheumatology.

Efficacy of the Subcutaneous Formulation of Abatacept/Orencia in Rheumatoid Arthritis, a Single-Center Italian Experience. Rossella Reggia[1], Franco Franceschini[1], Angela Tincani[2] and Ilaria Cavazzana[1]. [1]AO Spedali Civili, Rheumatology and Clinical Immunology Unit, Brescia, Italy, [2]Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia, Italy.

Background/Purpose: Abatacept is a selective T cell costimulation modulator indicated for moderately to severely active Rheumatoid Arthritis (RA). Since August 2013 is available in Italy the new subcutaneous (sc) formulation, that consists in a fixed dose of 125 mg of the drug, administered once weekly. Four clinical trials demonstrated an efficacy and a safety profile comparable to those obtained with the intravenous (iv) administration.

Aim of our work was to analyze the clinical response of a series of patients (pts) with RA treated with monthly iv infusion and than converted to the sc formulation.

Methods: We included 48 pts with RA, converted to the sc formulation of Abatacept from October 2013 to April 2014. We divided them into two groups, depending on their need to return to the iv administration for the appearance of a disease flare. The main clinical and serological features of the two groups were compared using the Chi-square, T-test or the Mann-Whitney test when appropriate.

Results: Pts converted to the sc formulation were the 48.5% of all cases receiving Abatacept therapy in our Unit. No pts received the iv "loading dose". Eleven pts (22.9%) returned to the iv administration due to a disease flare (mean DAS 28: 2.35 vs 3.85, p:0.005), after a mean of 7.3 injections (range 4–14). The remaining 38 (77.1%) continued with the sc formulation. The compared parameters between the two groups are summarized in Table 1.

In pts with arthritis flare, disease activity decreased again (mean DAS 28: 2.45 vs 3.85, p:0.009) after returning to the iv administration of the drug (after a mean of 38.2 days).

One patient discontinued the sc formulation for the onset of related side-effects (headache and nausea) not reported with the iv administration.

Conclusion: although the safety profile of the sc formulation of Abatacept seems to confirm the data previously obtained with the iv use of the drug, a high rate of our patients complained a reduced efficacy and needed the return to the traditional way of administration.

We failed to identify clear risk factors that may help toward the selection of pts to which propose the formulation switch. However, if an arthritic flare occurs, the return to the iv administration seems to ensure a good control of the disease again. Therefore, the efficacy of the molecule does not seem to be compromised by an eventual switch failure.

Tab.1 Comparison between the clinical and serological features of patients with and without the need to return to the intravenous administration of Abatacept after the switch to subcutaneous formulation

Analyzed features	Pts who maintained the sc formulation n=38 (77,5%)	Pts who returned to iv formulation n=11 (22,5%)	p:

Study of One Vial (400mg) per Body Infusion of Tocilizumab in Patients with Active Rheumatoid Arthritis. Hiroshi Uda, Koji Shigematsu and Osamu Sariki. Higashiosaka City General Hospital, Higashiosaka, Japan.

Background/Purpose: The treatment of active rheumatoid arthritis (RA) patients are usually started with synthetic disease modifying antirheumatic drugs (DMARDs), but when adequate response are not achieved, biologics DMARDs are introduced. Tocilizumab (TCZ) is one of useful biologics and the infusion dose of TCZ was settled at 8mg/kg. The residues of TCZ fluid were always discarded. The procedure of sucking and discharging of TCZ is troublesome and dispose of TCZ residue is uneconomical. The fixed dose injection become majority of biologics administration, but fixed dose of biologics infusion has not been attempted to date. The present study is carried out to clarify that one vial (400mg) of TCZ infusion per body (body weight >50kg) is effective in the patients with active RA.

Methods: The RA patients who showed inadequate response to synthetic and biologic DMARDs other than TCZ and whose body weight was between 50 to 100kg were enrolled in the present study. The patients discontinued biologics before starting TCZ, and one vial (400mg) per body infusion of tocilizumab every 4 weeks (OBOTO study) was added to synthetic DMARDs. The clinical assessments and blood tests were also carried out every 4 weeks. To the patients who did not achieve clinical remission by one vial (400mg) of TCZ, prednisolone (PSL) and/or methotrexate were added. The patients who achieved clinical remission in 12 months were estimated as responder and others were as non-responders. To the patients who achieved clinical remission, we tapered the dose of PSL and/or DMARDs. We followed up the patients at least for 5 years.

Results: Total of 106 patients was enrolled in the present study. Male and female were 25 and 81 respectively. Seventy-four patients achieved good response, 21 patients achieved moderate response and 11 patients were non-responders. DAS28 remission was achieved in 59 patients. The body weight of the patients enrolled was between 92 to 50 kg and the mean body

weight of responders and non-responders did not differ significantly. After the clinical remission was achieved, PSL and/or DMARDs were decreased. In five years, 12 patients were treated TCZ alone without any synthetic DMARDs or corticosteroids and kept the condition more than 4 years. The rest of responders received either or both PSL (1 to 7.5 mg/day) and MTX (2 to 8mg/week). To the patients who could not achieve clinical remission, dose escalation of TCZ was not attempted in the present study. Serious adverse events including tuberculosis or death were not found. The overall incidence of adverse events of one vial (400mg) of TCZ was less than those of 8mg/kg infusion.

Conclusion: We provide evidence that one vial (400mg) of TCZ infusion is effective in active RA patients whose body weight is over 50 kg. The finding of OBOTO study is quite useful for taking care of active RA patients both financially and technically.

Disease Severity and Treatment of Rheumatoid Arthritis: A Comparative Study Between Sudan and Sweden. Amir Elshafie[1], Abdalla D Elkhalifa[2], Thomas Weitoft[3], Musa Nur[4], Elnour Elagib[4], Mawahib Aledrissy[5], Sahwa Elbagir[6] and Johan Rönnelid[7]. [1]MD, MDpath, PhD, Uppsala, Sweden, [2]MD, Gävle, Sweden, [3]MD, PhD, Gävle, Sweden, [4]MD, FRCP, Khartoum, Sudan, [5]MD, MD internal Medicine, Khartoum, Sudan, [6]M, PhD student, Uppsala, Sweden, [7]Uppsala University, Uppsala, Sweden.

Background/Purpose: To perform a comparative study concerning clinical characteristics and treatment between Sudanese and Swedish RA outpatients.

Methods: A 286 Sudanese and 542 Swedish RA outpatients diagnosed according to 1987 ACR classification criteria were recruited between December 2008 and September 2010 and compared concerning clinical presentation, treatment and laboratory findings including IgM RF.

Results: Age at inclusion, disease duration and median age at disease onset were all significantly lower among the Sudanese patients ($p < 0.0001$). When stratified concerning age of inclusion, Swedish patients between 41–50 years had however a significantly lower age of onset, with a similar trend for all age groups above 30 years. Levels of ESR and number of affected joints were significantly higher among Sudanese RA patients. The proportion of IgM RF positivity was significantly lower among Sudanese RA patients ($p<0.0001$). Higher proportions of Sudanese RA patients were treated with methotrexate and DMARD combinations but none of them on biologics. Sudanese patient used lower doses of methotrexate and sulfasalazine ($p < 0.0001$) and higher doses of prednisolone ($p < 0.0001$) than Swedish patients. The female preponderance was more striking among Sudanese patients ($p < 0.0001$), although smoking was non-existent among the Sudanese female RA patients ($p<0.0001$).

Conclusion: Sudanese RA patients have significantly higher disease activity and are often IgM RF seronegative. Together with reports from Uganda and Cameroon our data indicate a cluster of highly active seronegative RA in central Africa.

Use of Rituximab Compared to Anti-Tnf Agents As Second and Third Line Therapy in Patients with Rheumatoid Arthritis: A Report from the rhumadata® Clinical Database and registry. Denis Choquette[1], Jean-Pierre Raynauld[1], Jean Pierre Pelletier[1], Boulos Haraoui[1], Louis Bessette[2], Edith Villeneuve[1], Marie-Anaïs Rémillard[1], Isabelle Fortin[3], Diane Sauvageau[1] and Louis Coupal[1]. [1]Institut de rhumatologie de Montréal (IRM), Montréal, QC, [2]Centre d'ostéoporose et de rhumatologie de Québec (CORQ), Québec, QC, [3]Centre de rhumatologie de l'est du Québec (CREQ), Rimouski, QC.

Background/Purpose: The order of use of biologic agents after failing a TNF inhibitor is still a question for debate. Phase III trial data in TNF-IR patients show comparable efficacy results across biologic agents and limited head-to-head studies have been published. Prospective registries offer a unique opportunity to observe the effectiveness (combined evaluation of efficacy and safety profile over time) of these agents in a clinical setting. Our objective is to evaluate if patients with rheumatoid arthritis (RA) treated with rituximab (RIT) after failing a first or a second anti-TNF agents (TNF-IR) have a different drug retention rate than patients similarly prescribed anti-TNF agents (pooled adalimumab, etanercept or infliximab) and compare the treatment strategies of using RIT as second or third biologic treatment.

Methods: Data from TNF-IR RA patients prescribed adalimumab (ADA), etanercept (ETA), infliximab (INF) or rituximab (RIT) as second or third biologic agents on or after January 1st 2007 was extracted and subjects taking either ADA, ETA or INF were pooled to form the anti-TNF cohort. Baseline demographics included age, disease duration, HAQ-DI, fatigue and pain visual analog scale evaluations (VAS), TJC, SJC, DAS 28 ESR and SDAI. Five-year drug retention rates were estimated and compared using Kaplan-Meier survival estimates. Statistical analysis was performed using SAS version 9.3. RHUMADATA® is a clinical database and registry used in daily clinical practice at the IRM, CORQ and CREQ.

Results: The data from 226 RA patients were extracted, 153 and 73 having respectively failed a first and a second anti-TNF agent. No clinically significant differences in baseline variables were observed between treatment groups in second and third intention. The 5 year retention rates of second line RIT and anti-TNF use were 74% and 36% respectively (Log-rank $p=0.002$). In patients having failed two anti-TNF, subsequent use of RIT and anti-TNF agents respectively demonstrated 5 year retention rates of 48% and 24% (Log-rank $p=0.004$). Although numerically superior (74% vs 48%) second line use of RIT did not reach statistical difference when compared to third line usage.

Conclusion: As a second line agent, in TNF-IR patients, RIT demonstrates a better 5 year retention rate than anti-TNF agents. As third line therapy, RIT is also statistically superior to anti-TNF agents. Although no statistical difference was demonstrated between second and third line RIT use, it is evident that positioning RIT as second line offers a better long term outcome.

1536

Comparing Abatacept to Adalimumab, Etanercept and Infliximab As First Line Agents in Patients with Rheumatoid Arthritis. Experience from the Rhumadata® Clinical Database and Registry. Denis Choquette[1], Louis Bessette[2], Isabelle Fortin[3], Boulos Haraoui[1], Jean Pierre Pelletier[1], Jean-Pierre Raynauld[1], Marie-Anaïs Rémillard[1], Diane Sauvageau[1], Edith Villeneuve[1] and Louis Coupal[1]. [1]Institut de rhumatologie de Montréal (IRM), Montréal, QC, [2]Centre d'ostéoporose et de rhumatologie de Québec (CORQ), Québec, QC, [3]Centre de rhumatologie de l'est du Québec (CREQ), Rimouski, QC.

Background/Purpose: The order of use of biologic agents is still a question for debate. Phase III trial data in MTX-IR patients show comparable efficacy results across biologic agents and limited head-to-head studies have been published. Registries offer a unique opportunity to prospectively monitor the effectiveness of these agents in a clinical setting. We aim to assess if patients with rheumatoid arthritis (RA) treated with abatacept after failure of a first line agent (MTX-IR) have a different drug survival rate than patients similarly treated with adalimumab, etanercept or infliximab.

Methods: RA patients prescribed a first biologic agent after January 1st2007 were included in the present analysis. We extracted a cohort formed of all patients prescribed abatacept (ABA), adalimumab (ADA), etanercept (ETA) or infliximab (INF) as their first biologic agent. Baseline demographics for this cohort included age, disease duration, HAQ-DI, fatigue and pain visual analog scale evaluation (VAS), TJC, SJC, DAS 28 ESR and SDAI. Person-years of treatment were also compared across biologic agents. Statistical analysis was performed using SAS version 9.3. RHUMADATA® is a clinical database and registry used daily in clinical practice at the IRM, CORQ and CREQ.

Results: A total 340 patients were included in the cohort. No clinically significant differences in baseline characteristics were noted between treatment groups. The 5 year retention rate of ABA, ADA, ETA and INF post MTX failure were 64%, 40%, 49% and 42% without significant statistical differences (Log-Rank $p=0.29$).

Conclusion: Abatacept, adalimumab, etanercept and infliximab after MTX failure have similar 5-years retention rates.

1537

Clinical Characteristics of RA Patients Newly Prescribed Tofacitinib Citrate (tofacitinib) in the United States after Food and Drug Administration Approval: Results from the Corrona US Rheumatoid Arthritis Registry. Arthur Kavanaugh[1], George W. Reed[2], Katherine C. Saunders[2], Andrew S. Koenig[3], Jamie Geier[4], Joel M. Kremer[5], Jeffrey D. Greenberg[6] and Clifton O. Bingham III[7]. [1]University of California San Diego, La Jolla, CA, [2]Corrona, LLC., Southborough, MA, [3]Pfizer, Inc., Collegeville, PA, [4]Pfizer, Inc., New York, NY, [5]Albany Medical College and the Center for Rheumatology, Albany, NY, [6]New York University School of Medicine, New York, NY, [7]Johns Hopkins University, Baltimore, MD.

Background/Purpose: To provide initial characterization of the patients prescribed tofacitinib during the early period after United States (US) Food and Drug Administration (FDA) approval (11/6/2012).

Methods: Rheumatoid Arthritis (RA) patients in the Corrona registry initiating tofacitinib through 3/1/2014 were identified. As a comparator, RA patients with no history of tofacitinib use initiating any biologic agent between 11/6/2012–3/1/2014 were also identified. Patient characteristics at the time of initiation are summarized and compared between groups. Continuous covariates are compared using a rank-sum test; categorical covariates are compared using a chi-square test.

Results: Over the study period, there were 299 RA patients newly prescribed tofacitinib and 2418 newly prescribed biologic disease modifying antirheumatic drugs (bDMARD) in the registry. Clinical characteristics are summarized in the **Table 1.** Tender and swollen joint counts and clinical disease activity index (CDAI) scores were similar for tofacitinib and bDMARD initiators, as were the distribution of CDAI scores (i.e. high/moderate/low disease activity and remission). However, tofacitinib initiators had significantly higher health assessment questionnaire (HAQ) scores. In addition, the mean disease duration was significantly longer for initiators of tofacitinib (13.9 yrs) versus bDMARDs (9.9 years, $p<0.001$). Tofacitinib initiators also had a higher median (IQR) number of prior biologic drugs [tofacitinib 3 (2–4) versus bDMARDs 1 (0–2)]. Use of monotherapy and combination DMARD therapies differed among tofacitinib versus bDMARD users ($p<0.001$), with monotherapy more commonly used for tofacitinib (43%) versus bDMARD (27%) users.

Conclusion: Analysis of this US-based cohort reflects prescriber patient selection decisions. The RA patients with long-standing severe disease and multiple prior biologics have tended to be the patients for whom tofacitinib has been initiated to date compared with those starting a bDMARD during the same time period, although prescribing is not limited to patients with moderate/high disease activity. Monotherapy and combination treatment strategies differed between tofacitinib versus bDMARD treated patients. These factors may impact assessment of the comparative effectiveness and safety of tofacitinib versus other RA therapies during longitudinal followup.

Table 1. Baseline characteristics

Characteristics	Tofacitinib	Biologic DMARDs	p-value*
Mean (SD)	**N = 299**	**N = 2418**

Sustained Clinical Benefit with Multiple Courses of Rituximab in Second Line for All Rheumatoid Arthtritis Patients Irrespective to the Inhibitor of Tumour Necrosis Factor Previously Used. Ioan Ancuta[1], Ruxandra Ionescu[2], Catalin Codreanu[3], Andra Balanescu[2], Elena Rezus[4], Maria Suta[5], Paulina Ciurea[6], Mihaela Milicescu[7], Dan Nemes[8], Codrina Ancuta[9], Mihai Bojinca[1], Magda Parvu[10] and Horatiu Popoviciu[11]. [1]"Dr. I. Cantacuzino" Hospital, Bucharest, Romania, [2]Sfanta Maria Clinical Hospital, UMF Carol Davila, Bucharest, Romania, [3]'Dr. Ion Stoia' Clinical Center of Rheumatic Diseases, Bucharest, Romania, [4]Recovering Clinical Hospital, Iasi, Romania, [5]Constanta Municipal Hospital, Constanta, Romania, [6]Clinical County Hospital,Craiova, Craiova, Romania, [7]"Dr. I. Cantacuzino" Clinical Hospital, Bucharest, Romania, [8]"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, [9]G. T.Popa Center for Biomedical Research, Iasi, Romania, [10]Colentina Clinical Hospital, Bucuresti, Romania, [11]Clinical County Hospital, Tg Mures, Romania.

Background/Purpose: In the last decade, biologic therapy changed dramatically treatment options for rheumatoid arthritis (RA). However, a significant number of patients failed to maintain the initial response to a TNF blocker. More information is needed regarding efficacy and safety of multiple courses of biologics administered over extended periods of time.To assess the clinical benefit of subsequent courses with Rituximab (RTX) in patients with moderate to severe active RA after the failure to different TNF inhibitors used in routine clinical practice in Romania.

Methods: REPEAT is an open-label, multicenter, prospective observational study started in 2010, patients were treated with RTX at each 6 months. Clinical efficacy was assessed at baseline and after each retreatment course at 6, 12, 18, 24, 30 and 36 months. Clinical assessments included disease activity (DAS-28), visual analogue scale (VAS) scores, Δ DAS-28 and Δ VAS. The previous anti-TNF treatments were; adalimumab (ADA), etanercept (ETA) and infliximab (INF). Statistical analyses: STATA SE 11.0 software, Comparison between all treatments and evaluations ANOVA and Kruskal-Wallis and Nptrend for trend across evaluations.

Results: A total of 1087 adult patients with active RA and inadequate response to at least one TNF inhibitor received initial RTX treatment. In our cohort, 929 (85.5%) patients had only one anti-TNF treatment (no switch); 210 (19.3%) patients received ADA, 318(29.3%) received ETA and 401 (36.9%) received INF and the rest of 158 (14.5%) had more than one. As a second TNF inhibitor, 59(5.42%) patients received ADA, 63 (5.79%) received ETA and 36 (3.31%) received INF. Median DAS-28 values for all patients (1087)and each groups ADA, ETA, INF as first TNF inhibitors were: *5.76; 6.05; 5.75; 5.66* at baseline, 3.98; 4.07; 4.11; 3.84 at 6 months, *3,43; 3.43;3.48; 3.33* at 12 months, *2.98; 3.00; 3.11; 2.89* at 18 months, *2.79; 2.72; 2.85; 2.75* at 24 months, *2.67; 2.55;* 2.65; 2.69 at 30 months and *2.57; 2.56; 2.41; 2.6* at 36 months. The median DAS28 values for the group (158) who received a second TNF inhibitor, *5.66; 3.955; 3;56; 2.91; 2.85; 2.71* and *2.57*

followed the same linear decrease across evaluations at baseline, 6;12;18; 24;30 and 36 months. ANOVA test between treatment and evaluations*P < 0.0001*, between previous treatment *P = 0.0014*.DAS-28 score has been improved for all groups of patients, independent from the TNF – inhibitor used as previous treatment. The VAS score was improved in the same manner, independent to previous treatment. ANOVA test between treatment and evaluations P < 0.0001, between evaluations *P < 0.0001*, test between previous treatment *P = 0.0003*.

Conclusion: In our study, Rituximab have demonstrated to be a reliable therapeutic option for all patients regardless the TNF inhibitor used in first line (adalimumab, etanercept or infliximab).

1539

Relation Between Number of Previous Anti TNF Agents and Clinical Response in Rheumatoid Arthritis Patients Treated with Rituximab. Daniela Opris, Diana Mazilu, Violeta Bojinca, Andreea Borangiu, Andra Balanescu, Denisa Predeteanu and Ruxandra Ionerscu. Sfanta Maria Clinical Hospital, UMF Carol Davila, Bucharest, Romania.

Background/Purpose: Debate is still ongoing regarding rituximab (RTX) as a first or second line biologic therapy. The objective of present study is to assess correlations between patient's characteristics, including previous treatments with drug level, clinical response and further evolution.

Methods: A group of 62 consecutive rheumatoid arthritis (RA) patients treated with RTX according to National Guideline (2 iv infusions of 1 g separated by 2 weeks, every 6 months) were followed for 2 years. All patients were previously diagnosed according to ACR 1987 or ACR/EULAR 2010 criteria. Demographic data, clinical (number of tender and swollen joints) and laboratory (ESR-erythrocyte sedimentation rate, CRP- C reactive protein, RF -rheumatoid factor, ACPA - anti cyclic citrullinated peptide) variables were collected at baseline and at each reevaluation. RA activity was evaluated in all patients by using DAS28 4v, Simplified Disease Activity Index (SDAI). All clinical evaluation was performed by two independent assessors. RTX drug level and anti drug antibodies were measured just before a new infusion using Progenika kits (Promonitor®-RTX, Promonitor®-anti-RTX). Patients were excluded if between baseline and next reevaluation had a change in their treatment regimen. The study was approved by local Ethics Committee and all patients gave written informed consent before inclusion. Statistical analysis was performed using SPSS statistical software, version 20.0.

Results: Mean rituximab treatment duration in the cohort was 41,79±27,76 months. All patients had Methotrexate associated. No antidrug atibodies were found. During evaluation period 25 patients (40.32%) had signs of inadequate response to treatment. At baseline, 9 (36%) of this patients had undetectable drug level. At that moment there was no difference between patients with detectable and undetectable drug level regarding DAS28 (3,65±1,12 vs 3,45±1,19, P=0.678) and SDAI (20±15,7 vs 21,7±29,6, P=0.845), nor in their treatment duration (48.8±53.4 vs 27.7±13.7, P=0.294). At follow-up, 6 months from dosing RTX, patients with detectable drug level had significantly lower DAS28 (mean DAS28 2,93±1,2 vs 3,27±1,47, P=0.01) and SDAI (mean 12,33±14,13 vs 14,83±20,51, P=0.033). Significantly higher number of patients with detectable rituximab level had anti citrulinated antibodies (P=0.021) and were rheumatoid factor positive (P=0.049). Number of previous anti TNF agents correlated to rituximab level (r=0.514, P=0.009). 62% of patients with detectable rituximab level were were non-responders to two or more anti TNF agents. All patients with undetectable drug level had only one anti TNF agent as previous biologic treatment.

Conclusion: Significant differences were found in clinical response in patients depending on the rituximab level and number of previous anti TNF agents used. RTX detectable drug level and 2 or more anti TNFs correlated with better clinical response at follow-up. This result support the actual guidelines for RA treatment regarding rituximab as a second line biologic agent.

Treatment Patterns of Biologics Used in Rheumatoid Arthritis and Ankylosing Spondylitis in the US Veterans Population. Brian Sauer[1], Chia-Chen Teng[1], Tao He[1], Jianwei Leng[2], Chao-Chin Lu[1], Neel Shah[3], David J. Harrison[3], Derek Tang[3] and Grant W. Cannon[1]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]Salt Lake City VA and University of Utah, Salt Lake Citty, UT, [3]Amgen Inc., Thousand Oaks, CA.

Background/Purpose: Biologics used for rheumatoid arthritis (RA) and ankylosing spondylitis (AS), including tumor necrosis factor blockers, are a key area of focus for Veterans Affairs (VA) Pharmacy Benefits Programs. This study describes treatment patterns with etanercept (ETN), adalimumab (ADA), and infliximab (IFX) in US veterans with RA or AS during the first year of treatment.

Methods: National VA pharmacy, administrative, and clinical databases were used for this analysis. Eligibility criteria included ≥1 claim for ETN, ADA, or IFX from Jan 1, 2008 to Dec 31, 2011 preceded by at least 180 days of enrollment in the VA. The first drug and date that met this criterion was the index drug and date. Patients had to be ≥ 18 years of age on their index date; have ≥360 days of enrollment following their index date; and have ≥1 claim with an ICD-9-CM diagnosis of RA or AS prior to or within 30-days after their index date. Patients with a diagnosis of psoriatic arthritis, psoriasis, juvenile idiopathic arthritis, Crohn's disease, ulcerative colitis, non-Hodgkin's lymphoma, or chronic lymphocytic lymphoma, prior to or within 30-days of their index date; a claim for their index biologic prior to their index date; who used a biologic prior to its receiving approval for that condition; or who had implausible dosing (≥200% of the maximum labeled dose) were excluded.

Treatment patterns were classified based on whether or not patients were persistent on their index agent for the 360 days after their index date. Non-persistence was defined as a ≥45 day gap in days of supply on their index agent or a claim for a non-index biologic. Non-persistent patients were further categorized based on the first observed event after non-persistence: switching, a claim for a biologic other than their index biologic; restarting, another claim for their index biologic after the ≥45 day gap, or discontinued no subsequent claims for any biologic following the gap.

Results: ETN, ADA, and IFX were the index biologic for 2,109, 2,035, and 263 veterans with RA and 286, 422, and 46 veterans with AS. Approximately half of all patients with RA were persistent on therapy for the entire year; 49.3% of ETN, 51.4% of ADA, and 52.5% of IFX. Persistence in AS was lower (ETN, 42.0% and ADA, 40.0%), but higher with INF, 56.4%. In both RA and AS, switching rates were numerically higher in IFX users (RA: 18.6%; AS: 15.2%) compared with ETN (RA: 11.8%, AS: 10.1%) and ADA (RA: 10.3%, AS: 12.8%). Restarting was more common with ETN and ADA than INF in both RA and AS. Discontinuation rates were similar (11.9–14.0%) across agents in both RA and AS.

Conclusion: Overall, persistence during the first year of therapy for RA and AS was relatively low, 40.0–56.5%. Gaps in therapy occurred in 26.5–34.6% of patients taking self-injected agents, but only 15.5–16.3% of patients taking INF. More work is needed to understand the reasons for non-persistence in this population.

Distinct Regulation of T Helper Cell Differentiation By Biologic DMARD Therapy in Rheumatoid Arthritis. Shingo Nakayamada, Satoshi Kubo, Maiko Yoshikawa, Naoki Yunoue, Yusuke Miyazaki, Kazuyoshi Saito and Yoshiya Tanraka. University of Occupational and Environmental Health, Japan, Kitakyushu, Japan.

Background/Purpose: In the pathogenesis of rheumatoid arthritis (RA), T helper cells can differentiate into functionally distinct subsets, leading to the persistent inflammation and immune abnormality associated with the interactive activation between T cells and B cells. However, little is known about pathological T cell subset targeted by biologic DMARD (bDMARD) therapy such as TNF inhibitor and CTLA4-Ig. We investigated association between the phenotype of $CD4^+$ T helper cells and $CD19^+CD20^+$ B cells and disease activity in patients with RA, and responsiveness to bDMARD treatment.

Methods: Peripheral blood mononuclear cells were obtained from 86 patients with bio-naïve RA and 24 healthy donors (HD). The study included 25 patients treated with TNF inhibitors such infliximab, etanercept and adalimumab, and 15 patients treated with CTLA-4 Ig (abatacept). The blood samples were taken at baseline and week 24 after treatment. The phenotype of T cells and B cells was defined based on comprehensive 8-color flow cytometric analysis for human immune system termed "the Human Immunology Project" by NIH and FOCIS. The results were correlated with the clinical disease activity including the titer of RF and ACPA, CRP, ESR, MMP-3 and simplified disease activity index (SDAI).

Results: The proportion of effector memory T cells was higher in RA compared with HD, whereas the proportions of $CD4^+CXCR3^+$ Th1 cells and $CD4^+CCR6^+$ Th17 cells were not different between RA and HD. The frequency of $CD4^+CXCR5^+ICOS^+$ activated Tfh cells was significantly increased and correlated with RF titer in patients with RA. For B cell subsets, the proportions of $CD19^+CD20^+CD27^-IgD^-$ effector B cells and $CD19^+CD20^-CD38^+$ plasmablasts closely correlated with CRP, ESR and MMP-3. TNF inhibitors and abatacept markedly improved the disease activity scores such as SDAI at 24 weeks post-treatment. Abatacept significantly decreased the proportions of effector memory T cells which consisted of activated Tfh and Th17 cells, and consequently the proportion of naïve T cells increased after abatacept therapy. By contrast, the proportion of naïve T cells has decreased after TNF inhibitors, but those of effector T cells mainly Th17 cell and $CD19^+CD20^+CD27^+IgD^+$ IgM memory B cells has inversely increased. The percentage of $CD4^+CCR4^+CD25^+CD127^{low}$ regulatory T cells significantly decreased after treatment with abatacept and TNF inhibitors.

Conclusion: These results imply that TNF blockade and CD28 costimulation blockade may alter contradictory changes of both T helper cell and B cell differentiation, *i.e.* abatacept decreases activated Tfh cells and Th17 cells whereas TNF inhibitor increases Th17 cells and memory B cells, even though both treatments improve the disease activity in patients with RA. Thus, abnormal regulation of T helper cell differentiation independent of inflammation may underlie in the pathogenesis of RA and needs to be borne in mind in the design of new therapeutic strategies for this disease.

Predicting Successful Long-Term Treatment with Tumour Necrosis Factor-Alpha Inhibitors in Patients with Psoriatic Arthritis. Karen M. Fagerli[1], Kath D. Watson[2], Jonathon Packham[3], Deborah PM Symmons[4], Kimme L. Hyrich[5] and. On behalf of the BSRBR[6]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom, [3]Institute of Science and Technology in Medicine, Keele, United Kingdom, [4]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom, [5]Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom, [6]British Society for Rheumatology, London, United Kingdom.

Background/Purpose: Short-term efficacy of tumour necrosis factor-alpha inhibitor (TNFi) therapy in patients with psoriatic arthritis (PsA) is well documented. In observational studies, effectiveness has mainly been explored in the short term (1–3 years) and predictors of improved short-term drug-survival include male gender, concomitant methotrexate (MTX) use, etanercept (ETN) use and high CRP. The aim of this analysis was to identify predictors of long-term (5 years) persistent treatment with TNFi in patients with PsA.

Methods: We included PsA patients registered with the British Society for Rheumatology Biologics Register starting a TNFi (recruited 2002–2006). Demographics, disease activity (joint counts, patient reported outcomes and inflammatory markers), disability, comorbidities and previous/current treatments were recorded at baseline. Follow-up (biannual for 3 years and then annually) includes changes in treatment, disease activity and adverse events. We identified patients who had continued their initial treatment for 5 years (allowing pauses < 90 days). Univariate logistic regression was used to identify factors associated with 5 years persitent therapy – covariates included age, disease duration, gender, number of previously used non-biologic DMARDs, comorbidity, TNFi-type, co-medication, steroid use, disease activity score (DAS) 28, erythrocyte sedimentation rate (ESR), patient global assessment, tender and swollen joints, current smoking and Health Assessment Questionnaire (HAQ). Age, gender and variables with p-value < 0.25 were included in a multivariate model and a backward section was performed to fit the final model.

Results: We included 666 patients starting TNFi (table). At 5 years, 312 (46.8%) patients were still on their initial treatment. Gender, disease duration, TNFi-type, comorbidity, tender joints, current smoking and HAQ were relevant predictors in univariate analysis ($p<0.25$). Concomitant MTX was not a predictor, neither in the whole cohort or when stratified by TNFi-type, but only 14 patients received infliximab (IFX) as monotherapy. Male gender, absence of baseline comorbidity and use of ETN or adalimumab (ADA) rather than IFX were independently associated with persistent treatment at 5 years (Table). HAQ, disease duration, tender joint count and current smoking were not significant predictors in the multivariate model.

Conclusion: Among this severe cohort of patients with PsA who initiated a TNFi prior to 2007, almost 50 percent were still on their initial treatment at 5 years. The only patient characteristics predicting this were gender and baseline comorbidity status which limits applicability to clinical practice. Concomitant MTX was not a significant predictor of long-term treatment persistence, suggesting an absence of a beneficiary effect across all TNFi therapies, opposed to that seen in rheumatoid arthritis.

Table Baseline variables and logistic regression predicting continued treatment at 5 years

Apremilast, an Oral Phosphodiesterase 4 Inhibitor, Is Associated with Long-Term (52-Week) Improvement in the Signs and Symptoms of Psoriatic Arthritis in DMARD-Naive Patients: Results from a Phase 3, Randomized, Controlled Trial. Alvin Wells[1], Adewale O. Adebajo[2], Jacob A. Aelion[3], Paul Bird[4], Alan Kivitz[5], Frédéric Lioté[6], Piercarlo Sarzi-Puttini[7], ChiaChi Hu[8], Randall M. Stevens[8] and Christopher J. Edwards[9]. [1]Rheumatology & Immunotherapy Center, Franklin, WI, [2]University of Sheffield, Sheffield, United Kingdom, [3]West Tennessee Research Institute, Jackson, TN, [4]Combined Rheumatology Practice, Kogarah, Australia, [5]Altoona Arthritis & Osteoporosis Center, Duncansville, PA, [6]Hôpital Lariboisière & University Paris Diderot, Paris, France, [7]Rheumatology Unit, L. Sacco University Hospital, Milan, Italy, [8]Celgene Corporation, Warren, NJ, [9]University Hospital Southampton, Southampton, United Kingdom.

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor, helps regulate the immune response that causes inflammation and skin disease associated with psoriatic arthritis (PsA). PALACE 4 compared the efficacy and safety of APR with placebo in patients with active PsA who were DMARD-naive.

Methods: Patients were randomized (1:1:1) to placebo, APR 20 mg BID (APR20), or APR 30 mg BID (APR30). Patients whose swollen and tender joint counts (SJC and TJC) had not improved by ≥20% at Week 16 were considered non-responders and were required to be re-randomized (1:1) to APR20 or APR30 if they were initially randomized to placebo, or continued on their initial APR dose. At Week 24, all remaining placebo patients were re-randomized to APR20 or APR30. The analysis comprises data from Weeks 0 to 52.

Results: At baseline, median PsA duration among patients in the full analysis set, overall, was 1.1 years; median SJC was 9.0 and median TJC was 16.0. At Week 16, significantly greater proportions of patients receiving APR achieved modified American College of Rheumatology 20 (ACR20) response (primary endpoint) (placebo: 15.9%; APR20: 28.0% [$P=0.0062$]; APR30: 30.7% [$P=0.0010$]) and modified ACR50 response (placebo: 4.5%; APR20: 11.4% [$P=0.0173$]; and APR30: 11.4% [$P<0.0181$]). ACR70 response was observed in 1.1%, 4.0%, and 4.0% of patients receiving placebo, APR20, and APR30, respectively. Median percent change in SJC at Week 16 was significantly greater with APR compared with placebo (placebo: -16.7%; APR20: -50.0% [$P=0.0001$]; APR30: -42.9% [$P=0.0001$]). Median percent change in TJC at Week 16 was also significantly improved with APR30 compared with placebo (placebo: -8.3%; APR20: -29.5% [$P=0.0007$]; APR30: -33.3% [$P=0.0001$]). At Week 52, modified ACR20/ACR50/ACR70 response was achieved by 53.4%/27.1%/13.7% and 58.7%/31.9%/18.1% of patients continually treated with APR20 or APR30, respectively, from baseline. Among these patients, improvements in SJC/TJC were sustained over 52 weeks; at Week 52 median percent change in SJC/TJC was -89.4%/-67.1% (APR20) and -100.0%/-66.7% (APR30). Consistent results were demonstrated in patients randomized to placebo at baseline and re-randomized to APR20 or APR30 at Week 16 or 24 who completed Week 52 (Table). The most common adverse events (AEs) reported among patients receiving either APR dose during the placebo-controlled period were nausea (12.6%), diarrhea (9.4%), and headache (6.0%). The nature and severity of AEs did not change with long-term exposure through 52 weeks.

Conclusion: Over 52 weeks, APR demonstrated clinically meaningful, sustained improvements in the signs and symptoms of PsA in DMARD-naïve patients. APR demonstrated an acceptable safety profile and was generally well tolerated.

Table 1. Efficacy Outcomes at Week 52 in Patients Receiving APR From Baseline (Data as Observed)

	APR20 n = 132	APR30 n = 141
ACR20, n/m (%)	70/131 (53.4)	81/138 (58.7)
ACR50, n/m (%)	35/129 (27.1)	44/138 (31.9)
ACR70, n/m (%)	18/131 (13.7)	25/138 (18.1)
SJC (0–76)		
Baseline, median	9.0	8.0
Median % change	−89.4	−100.0
TJC (0–78)		
Baseline, median	17.0	15.0
Median % change	−67.1	−66.7

Note: The n reflects the number of patients who completed 52 weeks; actual number of patients available for each endpoint may vary. Baseline values presented were based on the patients who had data at Week 52. n/m = number of responders/number of patients with sufficient data for evaluation.

Economic and Comorbidity Burden Among Moderate-to-Severe Psoriasis Patients Comorbid with Psoriatic Arthritis. Steven R Feldman[1], Yang Zhao[2], Lizheng Shi[3], Jackie Lu[2] and MaryHelen Tran[2]. [1]Wake Forest University School of Medicine, Winston-Salem, NC, [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [3]Tulane University, New Orleans, LA.

Background/Purpose: Psoriasis (PsO) and psoriatic arthritis (PsA) are associated with substantial economic and comorbidity burdens. However, the burden among PsO patients comorbid with PsA has not been evaluated in the biologics era. This study aimed to compare the comorbidity burden, healthcare resource utilization, and costs between moderate-to-severe PsO patients comorbid with PsA and matched controls.

Methods: Adults (18–64 years) with ≥2 distinct PsO diagnoses (ICD-9-CM: 696.1) were identified in the OptumHealth Reporting and Insights claims database (01/2007–03/2012). Moderate-to-severe PsO patients were selected as those receiving ≥1 systemic or phototherapy during the 12-month study period following the index date (randomly selected date after the first PsO diagnosis); PsO patients comorbid with PsA (PsO+PsA cases) were further selected as those with ≥2 distinct PsA diagnoses (ICD-9-CM: 696.0) between 01/2007 and the index date or during the 12-month study period. Controls were free of PsO and PsA in the entire claims history and matched 1: 1 with PsO+PsA cases on age, gender, and geographic region. All patients had at least 12 months of continuous enrollment after the index date. Multivariate regression models were performed to examine the impact of PsO+PsA on comorbidities, medication use, and healthcare utilization and costs between cases and controls, adjusting for demographics, index year, insurance type, non-PsO/PsA related comorbidities. Adjusted cost differences between cases and controls were also estimated.

Results: A total of 1,230 matched pairs of PsO+PsA patients and controls were selected, with mean age 48.5 years and 52.1% of male. During the 12-month period, PsO+PsA patients had significantly higher disease burden in major PsO/PsA related comorbidities assessed than controls, with the top 4 most common being hypertension (35.8% vs. 23.5%), hyperlipidemia (34.6% vs. 28.5%), rheumatoid arthritis (16.6% vs. 0.7%) and diabetes (15.9% vs. 10.0%). Controlling for between-group differences, PsO+PsA patients had more number of prescription medications filled (IRR=2.3), and were more likely to have any inpatient admission (OR=1.6), emergency department (OR=1.3), and outpatient visit (OR=62.7) compared with controls (all $p<0.05$). Additionally, PsO+PsA patients incurred significantly higher total, pharmacy, and medical costs (adjusted annual costs differences: $23,160, $17,696 and $5,077 per patient, respectively, all $p<0.01$) than controls.

Conclusion: Compared with matched controls without PsO and PsA, moderate-to-severe PsO patients comorbid with PsA were more likely to have PsO/PsA-related comorbidities and incurred significantly higher healthcare utilization and costs.

Better Performance of the Leeds and Sparcc Enthesitis Indices Compared to the Mases in Patients with Peripheral Spondyloarthritis during Treatment with Adalimumab. Philip Mease[1], Filip Van den Bosch[2], Joachim Sieper[3], Aileen L. Pangan[4], Nupun A. Varothai[4] and In-Ho Song[5]. [1]Swedish Medical Center and University of Washington, Seattle, WA, [2]Ghent University Hospital, Ghent, Belgium, [3]Charité Universitätsmedizin Berlin, Berlin, Germany, [4]AbbVie Inc., North Chicago, IL, [5]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany.

Background/Purpose: Peripheral spondyloarthritis (pSpA) is characterized by arthritis, enthesitis, and/or dactylitis. Enthesitis is considered a core outcome domain for SpA; however, there is no clear recommendation which of the available enthesitis tools should be used. The objective of this analysis was to evaluate the validity of different enthesitis indices in patients (pts) with non-psoriatic pSpA during treatment with adalimumab (ADA).

Methods: ABILITY-2 is a multicenter phase 3 study. Eligible pts were age ≥18 yrs, fulfilled ASAS pSpA criteria, and had active disease. Pts were randomized to ADA 40 mg every other week (wk) or placebo (PBO) for 12 wks followed by 144 wks of open-label ADA. 29 enthesitis sites based on Leeds (range 0–6) and SPARCC (Spondyloarthritis Research Consortium of Canada, 0–16) enthesitis indices, and the MASES (Maastricht Ankylosing Spondylitis Enthesitis Score, 0–13) were assessed during the study. Discriminatory capacity and sensitivity to change of enthesitis indices at wk 12 were calculated: mean differences from BL to wk 12 in ADA vs PBO-treated pts with corresponding 95% confidence limits, standardized mean differences, and Guyatt's effect sizes. Presence of enthesitis at each anatomical enthesitis site at BL and proportion of sites that show resolution or new onset enthesitis from BL to wk 12, ADA vs PBO, were analyzed.

Results: 165 pts (ADA 84/PBO 81) were randomized. At BL 143 (87%) had ≥1 enthesitis site. The Leeds and SPARCC enthesitis scores showed higher discriminatory ability and sensitivity to change compared to the MASES (Table). Individual enthesitis site analysis suggests that in the overall population the percent change from BL to wk 12 at the following sites may have higher discriminatory capacity to other more axial sites: Achilles tendon (ADA 52.8% vs PBO 13.5%), greater trochanter (42.6% vs 6.8%), lateral epicondyle humerus (63.9% vs 0%), and medial epicondyle humerus (51.2% vs 0%). Among enthesitis sites positive at BL, a greater proportion showed resolution at wk 12 among pts on ADA in the Achilles tendon (ADA 60.4% vs PBO 36.5%, $P=0.019$), medial epicondyle (73.2% vs 48.7%, $P=0.038$), and lateral epicondyle (80.6% vs 52.8%, $P=0.023$). Among sites negative at BL less new onset enthesitis was observed with ADA at the following sites: Achilles tendon (ADA 3.6% vs PBO 10.9%, $P=0.041$), lateral epicondyle (4.7% vs 15.1%, $P=0.006$), greater trochanter (3.4% vs 14.4%, $P=0.005$), quadriceps insertion patella (1.5% vs 7.0%, $P=0.034$), and medial condyle femoral (1.6% vs 9.2%, $P=0.009$).

Table. Enthesitis Index Mean Change (±SD) [95% CL] from Baseline to Week 12, SMD, and Guyatt's Effect Size*

	ADA	PBO	Mean Difference (ADA-PBO)	SMD	Guyatt's Effect Size
Leeds	−1.35 (±1.20) [−1.69, −1.02] n=51	−0.45 (±1.27) [−0.81, −0.09] n=51	−0.90 [−1.39, −0.42]	0.73	−1.07
SPARCC	−2.35 (±2.46) [−2.97, −1.73] n=63	−1.00 (±2.37)[−1.59, −0.41] n=65	−1.35 [−2.19, −0.51]	0.56	−0.99
MASES	−2.02 (±2.78) [−2.76, −1.28] n=57	−1.17 (±2.50) [−1.79, −0.55] n=65	−0.85 [−1.80, 0.10]	0.32	−0.81

*Among patients who had score ≥1 for that index. CL, confidence limit; MASES, Maastricht Ankylosing Spondylitis Enthesitis Score; SD, standard deviation; SMD, standardized mean difference; SPARCC, Spondyloarthritis Research Consortium of Canada.

Conclusion: In ABILITY-2, the LEEDS and SPARCC enthesitis indices showed better discriminatory capacity and sensitivity to change compared to the MASES during treatment with ADA in pSpA patients. Enthesitis sites showing higher discriminatory capacity are peripheral sites predominantly in the Leeds and SPARCC indices which may explain their better performance compared to the MASES, which has fewer peripheral sites.

Risk of Non Melanoma Skin Cancer Among Medicare Psoriasis/Psoriasis Arthritis Patients. Huifeng Yun[1], K. L. Winthrop[2], Lang Chen[3], Wilson Smith[3], Benjamin Chan[2], Fenglong Xie[3], Allison Taylor[3], Ronac Mamtani[4], Frank I Scott[4], James D. Lewis[5] and Jeffrey R. Curtis[3]. [1]University of Alabama at Birmingham School of Public Health, Birmingham, AL, [2]Oregon Health and Science University, Portland, OR, [3]University of Alabama at Birmingham, Birmingham, AL, [4]University of Pennsylvania, Philadelphia, PA, [5]Center for Clinical Epidemiology and Biostatistics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Many systemic treatments for psoriatic arthritis and psoriasis (PsA/PsO) are immune-modulating, which may increase the risk of non-melanoma skin cancer (NMSC). However, the comparative risks of NMSC are unclear. This study aimed to determine if the risks of NMSC associated with biologic and non-biologic treatments for PsA/PsO differ in their NMSC risk.

Methods: Using data from 2006–2011 for 100% of patients with patients with PsA and PsO, we defined separate PsA and PsO cohorts based upon >=1rheumatologist visit for PsA or >= 1 dermatologist visit for PsO, followed by a prescription or administration of etanercept (ETA), adalimumab (ADA), ustekinumab (UST), methotrexate (MTX), cyclosporine (CIC) or ultraviolet light therapy (UV). Patients could be in both cohorts if they meet criteria for each cohort. We identified new treatment episodes, defined specific to each drug as no use of that therapy in the prior 6 month 'baseline' period. Eligible subjects were continuously enrolled in Medicare Parts A, B and D in baseline and throughout follow-up. Patients contributing treatment episodes with history of organ transplantation, infection with human immunodeficiency virus, advanced kidney (hemodialysis-dependent), severe liver disease, or cancer diagnoses were excluded. Follow up started from drug initiation date and ended at the earliest date of: NMSC, a 90 day gap in current exposure, death, loss of Medicare coverage or Dec 31, 2011. We identified NMSC using validated claims-based algorithm with a list of physician diagnosis (ICD9 713.x) and procedure codes and calculated the incidence rate (IR) of NMSC for each treatment. Using pairwise propensity scores (PS), we compared NMSC risks between different treatments during follow-up using Cox regression adjusting for PS quintile.

Results: We identified 10,261 PsA and 31,052 PsO new treatments episodes. For the PsA cohort, 50% of treatment-episode exposure time was in common with the PsO, and 20% of PsO exposure time was in common with PsA exposures. During follow up, patients in the PsA cohort experienced 51 (ADA), 11 (CIC), 31 (ETA), 117 (MTX), <11 (UV) NMSCs, and the PsO cohort experienced 130 (ADA), 106 (CIC), 122 (ETA), 394 (MTX), 273 (UV) NMSCs. The overall IR in PsA was 23.2/1000, ranging from a low of 14.0 (ETA) to a high of 48.9 (CIC). The overall IR in the PsO cohort was 36.3/1000, ranging from 22.4 (ETA) to 53.6 (CIC). After PS quintile adjustment, significant associations with NMSC were observed for ADA compared to ETA (PsA, Hazard ratio (HR): 1.58, 95% confidence interval (CI): 1.01–2.51; PsO, HR: 1.33 95% CI: 1.03–1.71), and ADA compared to MTX (PsA, HR: 1.69, 95% CI: 1.17–2.44; PsO, HR: 1.32, 95% CI: 1.07–1.64).

Conclusion: Among psoriatic arthritis and psoriasis patients enrolled in Medicare, adalimumab had higher rates for NMSC relative to comparator treatments.

Endocrine Co-Morbidities in Patients with Psoriatic Arthritis: A Population-Based Study. Devy Zisman[1], Ron Ilan Ashkenazi[2], Haim Bitterman[3], Guy Shallom[4], Ilan Feldhamer[4], Idit Lavi[5], Sari Greenberg-Dotan[4] and Arnon-Dov Cohen[4]. [1]The Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel, [2]Carmel Medical Center, Haifa, Israel, [3]Chief Physician's Office, Clalit Health Services, Haifa, Israel, [4]Chief Physician's Office, Clalit Health Services, Tel Aviv, Israel, [5]Department of Community Medicine and Epidemiology, Carmel Medical Center, Haifa, Israel.

Background/Purpose: Co-morbidities associated with psoriatic arthritis (PsA) include cardiovascular, ophthalmic and gastrointestinal diseases. The aim of the study was to investigate endocrine co-morbidities in patients with psoriatic arthritis.

Methods: A cross-sectional study was performed in the database of Clalit Health Services, the largest healthcare provider in Israel, between 2000 and 2013. Patients with a diagnosis of PsA were identified (study group). For each of these patients, ten patients matched for age and gender, without a history of psoriasis, rheumatoid arthritis or ankylosing spondylitis were enrolled in the study as a control group. The following morbidities were analyzed: hypo- and hyperthyroidism, hypo- and hyperparathyroidism, hyperprolactinemia, Cushing's disease, Addison's disease, diabetes insipidus, diabetes mellitus (DM), pituitary adenoma, acromegaly and osteoporosis. A t-test was used to compare continuous variables and a chi-square test was used for categorical variables. A univariable model and multivariable logistic regression models were used to assess the association between PsA and endocrine co-morbidities.

Results: The study included 3161 patients with PsA, 1474 males (46.6%) and 1687 (53.4%) females, with a mean age of 58.36 ±15.42 years, and 31610 controls. Comparative analyses demonstrated higher prevalence of hypothyroidism (12.7% vs. 8.6% $p<0.0001$), Cushing's disease (0.3% vs. 0.1% $p<0.0001$), osteoporosis (13.2% vs. 9.1% $p<0.001$) and DM (27.9% vs. 20.7% $p<0.0001$) in the PsA population compared to the control group, respectively. The prevalence of hyperthyroidism, hypo- and hyperparathyroidism, hyperprolactinemia, Addison's disease, diabetes insipidus, pituitary adenoma and acromegaly was not statistically different between the two groups. In multivariate regression analysis models, hypothyroidism after adjustment for age and gender (OR 1.61 95%CI 1.43–1.80), DM after adjustment for age, gender, smoking, obesity and steroids use (OR 1.30 95% CI 1.18–1.42), Cushing's disease after adjustment for age, gender and steroids use (OR=3.79 95% CI 1.64–8.77) and osteoporosis after adjustment for age, gender, steroids use and smoking (OR=1.50 95% CI 1.33–1.70) had a higher prevalence in PsA patients.

Conclusion: A high prevalence of hypothyroidism, osteoporosis, DM and Cushing's disease was found in this cohort of PsA patients. It is recommended that medical practitioners be aware of and look for these co-morbidities while taking care of PsA patients.

1548

Treatment Effect of Ustekinumab on Fatigue in Patients with Psoriatic Arthritis: Results from a Phase 3 Clinical Trial. Christopher T. Ritchlin[1], Proton Rahman[2], Lluís Puig Sanz[3], Alice B. Gottlieb[4], Arthur Kavanaugh[5], Iain B. McInnes[6], Shu Li[7], Yuhua Wang[7], Rita Ganguly[8], Alan M. Mendelsohn[7] and Chenglong Han[8]. [1]University of Rochester Medical Center, Rochester, NY, [2]Memorial University of Newfoundland, St. John's, NF, [3]Universitat Autònoma de Barcelona, Barcelona, Spain, [4]Tufts Medical Center, Boston, MA, [5]University of California San Diego, La Jolla, CA, [6]University of Glasgow, Glasgow, United Kingdom, [7]Janssen Research & Development, LLC., Spring House, PA, [8]Janssen Global Services, LLC., Malvern, PA.

Background/Purpose: To assess the treatment effect of ustekinumab on fatigue using data from PSUMMIT 2.

Methods: Adult patients with active psoriatic arthritis (PsA) despite DMARD (N=132) and/or previous treatment with biologics (N=180) were randomized to receive ustekinumab 45mg, 90mg, or placebo (PBO) at wks 0, 4, and q12wks thereafter through week 40. PBO-treated patients crossed over to receive ustekinumab 45mg at weeks 24, 28 and q12wks through week 40. Fatigue was measured using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-Fatigue, 0–52) and the vitality scales of SF-36 health survey questionnaire (SF-36 VT, 0–100). High scores indicate low severity in fatigue. Clinically meaningful improvement was defined as ≥4 point increase in FACIT-Fatigue or ≥3 point increase in SF-36 VT score from baseline. Disease activity was measured by disease activity score using 28 joints (DAS28), and physical function was measured using Health Assessment Questionnaire (HAQ).

Results: At baseline, patients had a mean FACIT-Fatigue score of 25.8 and had a mean SF-36 VT score of 36.9, which was significantly below the values of the U.S. normal population (50), indicating severe fatigue. Both FACIT-Fatigue and SF-36 VT scores were significantly correlated with DAS28 ($r=0.42$, 0.38, respectively) and HAQ ($r=0.62$, 0.51, respectively) at baseline, and the improvements in FACIT-Fatigue and SF-36 VT scores were significantly correlated with improvement in DAS28 ($r=0.45$, 0.43, respectively) and improvement in HAQ scores ($r=0.43$, 0.41, respectively) at week 24. At week 24, patients who received ustekinumab achieved statistically significantly greater improvement in FACIT-Fatigue score (4.35 vs. 0.86, $p=0.002$) and in SF-36 VT score (3.87 vs. 0.67, $p=0.004$) compared with PBO. Compared to PBO, a greater proportion of ustekinumab-treated patients achieved a clinically meaningful improvement in FACIT-Fatigue (49% vs. 25.5%) or SF-36 VT (45% vs. 29.9%) (all $p<0.01$). No significant differences were observed between the ustekinumab 45 and 90mg groups. The treatment effect on fatigue was consistent across biologically-experienced and DMARD-experienced patients, and maintained through week 52. Patients who were randomized to PBO and switched to active treatment at week 24 achieved comparable improvement at week 52.

Conclusion: Ustekinumab therapy significantly reduces the symptom of fatigue in patients with active PsA. Clinically meaningful improvement in fatigue was observed within 3 doses of ustekinumab therapy.

1549

The Swedish Early Psoriatic Arhtritis (SWEPSA) Registry 5-Yeear Follow-up: Slow Radiographic Progression with Highest Scores in Male Feet and in Patients with Baseline X-Ray Abnormalities. Elke Theander[1], Tomas Husmark[2], Ulla Lindqvist[3], Per T Larsson[4], Annika Teleman[5], Gerd-Marie Alenius[6] and Mats Geijer[7]. [1]Skane University Hospital Malmö, Lund University, Malmö, Sweden, [2]Falu Hospital, Falun, Sweden, [3]Department of Medical Sciences, Rheumatology, University Hospital, Uppsala university, Uppsala, Sweden, [4]Department of Rheumatology, Karolinska University Hospital, Stockholm, Sweden, [5]Spenshult Rheumatological Hospital, Oskarström, Sweden, [6]Department of Public Health and Clinical Medicine, Rheumatology, Umeå University Hospital, Umeå, Sweden, [7]Skåne University Hospital, Lund, Center for Medical Imaging and Physiology, Lund, Sweden.

Background/Purpose: The aim of this study is to describe early X-ray findings in psoriatic arthritis (PsA) patients from the SwePsA registry using the Wassenberg score, evaluate progression of structural damage, analyze correlations to clinical disease parameters and identify predictors of progressive radiographic joint disease.

Methods: Out of 197 SwePsA patients followed for 5 years, 72 (38% of the women and 35% of the men) had radiographs of hands and feet performed

at the 5-year follow-up. According to the SwePsA protocol hand and feet radiographs should be performed in polyarticular disease or when these joints showed signs of inflammation at baseline, and repeated during follow-up. Reading (MG) in chronological order was centralized. Clinical data were collected according to the SwePsA protocol.

Results: Mean (SD) baseline age of the 43 women and 29 men was 48.7 (15.0) and 46.4 (14.5) years respectively. While in the total SwePsA cohort women had higher clinical disease activity (Theander et al, ARD 2014), in this sub-cohort mean baseline DAS28 / DAPSA were similar in women and men (3.94 / 22.27 and 3.73 / 21.63, respectively, ns). However, radiographic abnormalities were more pronounced in men:

Baseline x-rays: Total Wassenberg score was 0 (no abnormalities) in 55% of women and 46% of men. Scores over 10 were unusual and only found in one women and one man. Mean (SD) total scores for women and men at baseline were 1.38 (2.44) vs 3.05 (4.04) respectively, p=0.044, erosion scores 0.30 (0.88) vs 1.17 (2.27), p=0.025, proliferation scores 1.30 (1.99) vs 1.79 (2.41), p=0.35. Feet scores at baseline were 0.30 (0.74) vs 0.93 (1.69), p = 0.039.

5-year follow-up x-rays: Total score was 0 in 42% of women but only in 17% of men (p=0.018). Scores over 10 were now found in 7.2% of women and in 17% of men. Mean (SD) total scores for women and men were 3.37 (4.85) vs 7.79 (12.46), p=0.034, erosion scores 0.86 (1.68) vs 3.41 (8.20), p=0.051, proliferation scores 2.56 (3.49) vs 4.62 (4.92), p=0.041. Feet scores at 5-year follow-up were 0.84 (2.13) vs 2.35 (3.92), in women and men, p=0.028, hand scores 2.58 (3.74) vs 5.55 (8.53), p=0.047.

Baseline and 5-year scores were highly correlated (for total scores: Spearman rho 0.752, p=0.000). Baseline total score correlated with ESR (rho: 0.364, p=0.004) and 5-year score with swollen joint count (rho 0.310, p=0.016), higher BASDAI showed a trend to be associated with lower total score (rho -0.285, p= 0.058).

Male gender and higher total baseline score were the only predictors of radiographic abnormalities after 5 years: OR (male/female): 4.42 (95% CI: 0.35–8.49) p=0.034. Baseline total score: OR: 2.23 (1.80–2.65), p=0.000. Only the baseline Wassenberg score was an independent predictor of radiographic progression.

Disease activity, inflammatory markers, joint counts, delay before inclusion and smoking did not predict 5-year Wassenberg score. None of the 15 patients with the highest scores/progression had received TNF-blockers.

Conclusion: Radiographic progression in early PsA is slow in general, early prevalent in male feet and predicted by baseline radiographic findings. Thus scoring of hand **and** feet X-rays at baseline cannot be substituted by clinical signs, especially not in men.

Prevalence of Enthesitis and Dactylitis, Impact on Disease Severity and Evolution over 12 Months in Psa Patients Treated with Anti-TNF in a Real-World Setting. Proton Rahman[1], Denis Choquette[2], William Bensen[3], Majed Khraishi[4], Saeed Shaikh[3], Regan Arendse[5], Isabelle Fortin[6], Andrew Chow[7], Maqbool Sheriff[8], Eliofotisti Psaradellis[9], John S. Sampalis[9], Susan Otawa[10], Francois Nantel[10], Allen J Lehman[10] and May Shawi[10]. [1]Memorial University of Newfoundland, St. John's, NF, [2]Notre Dame Hospital, Montreal, QC, [3]McMaster University, Hamilton, ON, [4]Nexus Clinical Research, St John's, NF, [5]University of Saskatchewan, Saskatoon, SK, [6]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [7]Credit Valley Rheumatology, Mississauga, ON, [8]Nanaimo Regional General Hospital, Nanaimo, BC, [9]JSS Medical Research, Montreal, QC, [10]Janssen Inc., Toronto, ON.

Background/Purpose: Spondyloarthritis, including psoriatic arthritis (PsA), is characterized by inflammatory arthritis affecting axial and peripheral joints. It is commonly associated with extra-articular and peri-articular manifestations (PAMs) including dactylitis and enthesitis. The aim of this analysis was to evaluate the point prevalence of enthesitis and dactylitis at the time of anti-TNF initiation, their impact on disease severity, and their evolution over time in patients with active PsA treated in a routine clinical practice setting.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis (RA), ankylosing spondylitis (AS), or PsA with infliximab or golimumab as first biologics or after having been treated with a biologic for <6 months. In this analysis, 132 PsA patients enrolled between 2010 and 2013 were included. The time to no PAM (enthesitis/dactylitis) was assessed with the Kaplan-Meier (KM) estimator of the survival function.

Results: At baseline, mean (SD) age and disease duration were 49.1 (10.8) years and 5.8 (7.1) years, respectively. The mean (SD) DAS28 score was 4.0 (1.3). A total of 73 (55.3%) patients had enthesitis and/or dactylitis at baseline; 27 (20.5%) patients had enthesitis, 24 (18.2%) had dactylitis, 22 (16.7%) had both dactylitis and enthesitis, while 59 (44.7%) had none. Significant differences, in disease parameters were observed at baseline based on the presence of a PAM. Specifically, mean (SD) DAS28 was 4.6 (0.8) among patients with enthesitis, 3.9 (1.4) in patients with dactylitis, 4.3 (1.1) in patients with both, and 3.6 (1.4) in patients with none (P=0.023). Similarly, mean (SD) HAQ-DI was 1.5 (0.5), 1.1 (0.8), 1.0 (0.6), and 0.9 (0.6), respectively, in these patient subgroups (P=0.004). A statistical trend was observed for morning stiffness which was 36.7 (34.6), 65.7 (48.1), 54.5 (48.9), and 41.9 (42.3) min in patients with enthesitis, dactylitis, both, and none, respectively (P=0.067).

At 6 and 12 months of treatment, 29.1% and 30.4% of patients with available information, respectively, had enthesitis/dactylitis. Treatment with anti-TNF for 12 months resulted in a significant reduction in the prevalence of PAM (P=0.004). Specifically, among patients with enthesitis and/or dactylitis at baseline who had available data at 12 months, 61.1% did not present any manifestation after 12 months of treatment; while 27.3% of patients without enthesitis/dactylitis at baseline developed a new PAM. Survival analysis showed that, for patients with enthesitis/dactylitis at baseline, the KM-based mean time to no PAM was 9.8 months.

Conclusion: A high prevalence of enthesitis/dactylitis was observed at anti-TNF treatment initiation (55.3%). Patients with enthesitis, dactylitis or both had increased disease activity compared to patients without a PAM. Treatment with infliximab or golimumab for 12 months was associated with a significant reduction in PAMs with low incidence of new cases.

Correlation of Individual HAQ Questions with Disease Activity Measures in Psoriatic Arthritis: Implications for Instrument Reduction. Denis Choquette[1], Carter Thorne[2], Majed Khraishi[3], Isabelle Fortin[4], Regan Arendse[5], Andrew Chow[6], John Kelsall[7], Milton Baker[8], Julie Vaillancourt[9], John S. Sampalis[9], Francois Nantel[10], Allen J Lehman[10], Susan Otawa[10] and May Shawi[10]. [1]Notre Dame Hospital, Montreal, QC, [2]Southlake Regional Health Centre, Newmarket, ON, [3]Nexus Clinical Research, St John's, NF, [4]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [5]University of Saskatchewan, Saskatoon, SK, [6]Credit Valley Rheumatology, Mississauga, ON, [7]The Mary Pack Arthritis Centre, Vancouver, BC, [8]University of Victoria, Victoria, BC, [9]JSS Medical Research, Montreal, QC, [10]Janssen Inc., Toronto, ON.

Background/Purpose: The Health Assessment Questionnaire (HAQ) is commonly used for assessing patient-reported functional status and disease activity in psoriatic arthritis (PsA). However, it has been critiqued for being time-consuming, not easily scored and thus, not contributing to decisions in routine care (1,2). The aim of this analysis was to describe the correlation of individual HAQ questions with patient and physician reported measures used in PsA and to examine whether the instrument could be reduced to better reflect routine clinical practice.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with infliximab or golimumab as first biologics or after <6 months of biologic treatment. Data from PsA patients treated with infliximab or golimumab in 2006–2013 were used. The correlation of each HAQ question with patient and physician (pain, patient global assessment (PtGA), SJC28, TJC28 and physician global assessment (MDGA)) reported measures were described with the Pearson's correlation coefficient. The impact of each HAQ question on the need for help in each HAQ domain was assessed with logistic regression. Factor analysis was used to assess the variability due to each question in HAQ.

Results: A total of 183 PsA patients with 596 HAQ assessments were included. Individual HAQ questions correlated at different extents with each PsA measures (Table 1). All questions showed higher correlations with PtGA and pain compared to MDGA. Regarding patient reported outcomes, Ques-

tion 5A ("Wash / dry your entire body") showed the highest correlation, specifically with pain.

The majority of HAQ questions were significantly associated with the need for help within their corresponding ability category, with the exception of questions Q3B, Q3C, Q4B, Q5C and Q8B.

The results of factor analysis showed that 2 (Q1A and Q3B) out of the 20 HAQ questions accounted for 61.5% of its matrix variance, suggesting that the question on the ability to "dress, tie shoelaces and do buttons", as well as the question on the ability to "lift a full cup or glass" may be the main drivers of HAQ in PsA.

Conclusion: Variability exists in the correlation of individual HAQ questions with patient and physician reported PsA measures. Pain and PtGA are significantly associated with the various domains of HAQ, while clinical outcomes (SJC28 and TJC28) and MDGA are less important. Among PsA patients, the HAQ is driven by components related to dressing and grooming and to eating abilities, suggesting that PsA patients may be facing different challenges than RA patients. This may have implications from an occupational health perspective and in the design of a shorter self-report instrument more suitable for PsA patients.

Sustained Improvements in Workplace and Household Productivity and Social Participation with Certolizumab Pegol over 96 Weeks in Patients with Psoriatic Arthritis.

Arthur Kavanaugh[1], Dafna D. Gladman[2], Désirée van der Heijde[3], Oana Purcaru[4] and Philip Mease[5]. [1]University of California San Diego, La Jolla, CA, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, [3]Leiden University Medical Center, Leiden, Netherlands, [4]UCB Pharma, Brussels, Belgium, [5]Swedish Medical Center and University of Washington, Seattle, WA.

Background/Purpose: Compared to the general population, patients (pts) with psoriatic arthritis (PsA) suffer greater amounts of disability and substantially lower employment rates.[1] The previous results from the RAPID-PsA study indicate significant improvements in work and household productivity and social participation with certolizumab pegol (CZP) vs placebo (PBO) up to Week (Wk) 24, which were maintained to Wk48.[2] The purpose of this report is to examine the long-term effect of CZP on workplace and household productivity in RAPID-PsA up to Wk96.

Methods: The ongoing RAPID-PsA trial (NCT01087788) is double-blind and PBO-controlled to Wk24, dose-blind to Wk48 and open-label to Wk216.[3] Pts had active PsA and had failed ≥1 DMARD. Pts originally randomized to CZP (200mg Q2W or 400mg Q4W, following 400mg loading dose [LD] at Wks 0, 2, 4) continued on their assigned dose in the OLE; PBO pts entering dose-blind phase were re-randomized to CZP LD followed by CZP 200mg Q2W or 400mg Q4W after Wk24 or, for non-responders, Wk16. The validated arthritis-specific Work Productivity Survey (WPS),[4] administered Q4W from baseline (BL), assessed the impact of PsA on workplace and household productivity in the randomized set (RS). WPS responses (LOCF imputation) in pts originally randomized to CZP groups are summarized descriptively over 96 wks.

Results: 409 pts were randomized, of which 273 were assigned to CZP 200mg Q2W or CZP 400mg Q4W. Of the pts randomized to CZP, 91% completed Wk24, 87% Wk48 and 80% Wk96; 60.1% and 61.5% were employed at BL in the CZP 200mg Q2W and CZP 400mg Q4W groups, respectively. At BL, pts randomized to CZP reported on average ~1 wk of paid work, ~2 wks of household duties, and mean 3.7 days of social activities affected over previous month. In employed pts in both CZP groups, decreases in absenteeism and presenteeism reported to Wk24 were continued up to Wk96 (Table). The initial improvements in household productivity and increased participation in social activities reported in both CZP groups over 24 wks were maintained up to Wk96 (Table).

Conclusion: The initial improvements with CZP in workplace and household productivity, and participation in social activities were sustained up to 96 wks, suggesting long-term productivity benefits of CZP treatment in PsA pts.

1553

Disease Activity and Clinical Response Early in the Course of Treatment Predict Long-Term Outcomes in Psoriatic Arthritis Patients Treated with Certolizumab Pegol. Philip Mease[1], Roy Fleischmann[2], Owen Davies[3], Tommi Nurminen[4] and Désirée van der Heijde[5]. [1]Swedish Medical Center and University of Washington, Seattle, WA, [2]Metroplex Clinical Research Center, University of Texas, Dallas, TX, [3]UCB Pharma, Slough, United Kingdom, [4]UCB Pharma, Monheim, Germany, [5]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Early non-response to biologic therapy has been shown to be associated with a low probability of long-term response in rheumatoid arthritis[1] and psoriasis[2]. However, to date there is a shortage of data regarding early identification of non-responders in psoriatic arthritis (PsA). Such analyses may help avoid unnecessary exposure, increase cost-effectiveness and improve the chance of achieving long-term treatment goals. Here we aim to assess the association between disease activity (DA) and clinical response (CR) during the first 12 weeks (wks) of treatment, and attainment/lack of attainment of treatment targets at Wk48 in PsA patients (pts) receiving certolizumab pegol (CZP).

Methods: The relationship between DA state during the first 12 wks of treatment, and Minimal Disease Activity (minDA)3 or DAS28(CRP) <2.6 at Wk48 was assessed post hoc using data from the RAPID-PsA study (NCT01087788).4 DA state was defined using either DAS28(CRP) values: <2.6, 2.6–3.2, 3.2–5.1, >5.1; or PsARC response/non-response. Descriptive analyses are based on all pts randomized to CZP from Wk0. Pts that discontinued treatment during the first 12 wks were excluded from the analysis. For remaining pts, missing data were imputed using LOCF for DAS28 and PsARC, and NRI for minDA.

Results: A relationship between Wk2 DA state and Wk48 minDA was observed, with 68% (17/25) of pts with DAS28(CRP) <2.6 at Wk2 achieving Wk48 minDA, compared with 10% (5/52) of pts with Wk2 DAS28(CRP) >5.1. This trend was maintained at Wk12, by which point more pts had lower DA. 73% (57/78) of pts with Wk12 DAS28(CRP) <2.6 achieved Wk48 minDA, compared to 0% (0/26) of pts with Wk12 DAS28(CRP) >5.1 (Table A). When Wk48 DAS28(CRP) <2.6–a less stringent target that excludes enthesitis and skin manifestations - was used, a similar trend was observed, but more pts in each category achieved the target; however, still only 4% (1/26) of pts with Wk12 DAS28(CRP) >5.1 attained Wk48 DAS28(CRP) <2.6 (Table B). CR at Wk12 was also associated with likelihood of attaining minDA at Wk48: Of 153/256 (60%) CZP pts that achieved Wk12 DAS28(CRP) CR >1.2, 50% (76/153) achieved Wk48 minDA, compared to 32% (17/53) of pts with Wk12 DAS28(CRP) CR 0.6–1.2 and 12% (6/50) of Wk12 non-responders (DAS28[CRP] CR ≤0.6). PsARC response at Wk12 was also associated with Wk48 outcomes: 10.7% (6/56) of Wk12 PsARC non-responders achieved Wk48 minDA, compared to 47.7% (95/199) of Wk12 PsARC responders.

Conclusion: Using DA state and CR level at an early stage of CZP treatment, it was possible to identify PsA pts unlikely to achieve long-term treatment goals. This approach may enable physicians adopting a treat-to-target strategy to determine early on when to change therapy in pts not responding to CZP.

Early and Sustained Modified Psarc Response in Psoriatic Arthritis Patients Treated with Ustekinumab: Results from 2 Phase 3 Studies. Iain B. McInnes[1], Christopher T. Ritchlin[2], Proton Rahman[3], Lluís Puig Sanz[4], Alice B. Gottlieb[5], Shu Li[6], Michael Song[6], Bruce Randazzo[6], Yuhua Wang[6], Alan M. Mendelsohn[6] and Arthur Kavanaugh[7]. [1]University of Glasgow, Glasgow, United Kingdom, [2]University of Rochester Medical Center, Rochester, NY, [3]Memorial University of Newfoundland, St. John's, NF, [4]Universitat Autònoma de Barcelona, Barcelona, Spain, [5]Tufts Medical Center, Boston, MA, [6]Janssen Research & Development, LLC., Spring House, PA, [7]University of California San Diego, La Jolla, CA.

Background/Purpose: We have previously reported the efficacy and safety results of ustekinumab (UST), an IL-12/23 p40 inhibitor, in patients with active psoriatic arthritis (PsA) up to 2yrs of UST treatment from the PSUMMIT 1&II trials. Here, we describe the sustained effects of UST using the modified Psoriatic Arthritis Response Criteria (PsARC) response. Although not validated, the modified PsARC has been widely used in PsA clinical trials and clinical practice.

Methods: Adult PsA patients with active disease (≥5 SJC and ≥5 TJC; CRP≥0.3mg/dL [ULN 1.0 mg/dL]) despite DMARD and/or NSAID therapy (PSUMMIT 1, n=615; PSUMMIT 2, n=312 [of which 180 pts were previously treated with DMARD and/or NSAID, and prior anti-TNFα therapy]) were randomized to UST45mg, 90mg, or PBO at wks 0, 4, and q12wks, thereafter. PBO-treated pts were crossed over to UST45mg at wks24 and 28 followed by q12wk dosing. At wk16, patients with <5% improvement in TJC & SJC entered blinded early escape [EE] (PBO→UST45mg; UST45mg→90mg; 90mg→90mg). No concomitant DMARDs with the exception of MTX (approx 50% of patients in each study) were permitted. Patients were considered a responder using the modified PsARC if improvement was demonstrated in ≥ 2 (including≥1 of the joint criteria) of the following criteria and no deterioration was noted in the other criteria: ≥30% decrease in the swollen joint count, ≥30% decrease in the tender joint count, ≥20% improvement in the patient's overall assessment (VAS), and ≥20% improvement in the physician's overall assessment (VAS). The proportion of patients who were modified PSARC responders and ACR 20 non-responders at wk28 were assessed.

Results: Modified PSARC results are summarized in Table 1. Statistically significantly higher PSARC response rates were observed as early as wk4 for both UST groups vs PBO in the PSUMMIT 1 trial and statistically significantly higher responses were also observed at wks 8, 12 and 24 for both UST dose groups vs PBO in both trials. Responses in both UST dose groups continued to increase after wk24, reached a plateau at wk28 and were maintained through wk52. Patients who were initially randomized to PBO and crossed over to 45mg achieved similar responses to those originally randomized to UST. Higher PSARC responses were consistently observed at wk8–24 for both UST groups vs PBO regardless of baseline MTX status. The early onset of PSARC responses observed was consistent with early onset of ACR20 responses. UST was generally well-tolerated.

Conclusion: Significantly higher PSARC responses were observed as early as wk4–8 for both UST dose groups vs PBO. Improvements observed at wk24 continued to increase at wk28 and were sustained through wk52.

Table 1: Proportion of patients achieving modified PSARC response; randomized patients

	PSUMMIT 1 (TNF naïve)		
	PBO/PBO→45mg†	**UST45mg**	**UST90mg**

1555

An Indirect Comparison and Cost per Responder Analysis of Adalimumab, Methotrexate (MTX) and Apremilast in the Treatment of MTX-naïve Psoriatic Arthritis (PsA) Patients. Vibeke Strand[1], Jenny Griffith[2], Keith Betts[3], Alan Friedman[2], James Signorovitch[3] and Arijit Ganguli[2]. [1]Stanford University, Palo Alto, CA, [2]AbbVie, Inc., North Chicago, IL, [3]Analysis Group, Inc., Boston, MA.

Background/Purpose: Apremilast (APR), a small molecule inhibitor of phospodiesterase 4 (PDE-4), was recently approved for treating PsA patients in the US. To date, there are no studies directly comparing APR to the current standard of care, MTX. This analysis compared the cost per responder for APR versus MTX and adalimumab (ADA) (a TNF inhibitor) from a US perspective.

Methods: A systematic literature review was performed to extract response rates from clinical trials of approved biologics, MTX, and APR. The selected clinical trials were required to be in the MTX-naïve PsA population and have a placebo arm. A subanalysis of the ADEPT trial, a phase 3 trial comparing ADA with placebo, was conducted among patients who did not receive MTX in the 3 month baseline period. Using Bayesian methods, a network meta-analysis was conducted to indirectly compare the efficacy outcomes between approved therapies for PsA at week 16. Based on the response outcomes relative to placebo, the number needed to treat (NNT) was calculated using the inverse of absolute risk reduction. Cost of treatment was defined as the cost of drug (wholesale acquisition cost) required to treat patients for 16 weeks per labelled dose and cost for placebo was assumed to be zero. The incremental cost per responder was calculated by multiplying the cost of treatment and NNT for each of the therapies.

Results: The MIPA[1] trial for MTX, PALACE 4[2] for APR and the ADEPT subpopulation for ADA were the only clinical trials that met inclusion criteria. ACR20 was the common clinical outcome among the trials and was reported at week 16 for both ADA in ADEPT and APR in PALACE4, while week 24 results were reported for MTX in MIPA. In the absence of week 16 efficacy data for MTX, efficacy at week 24 was assumed to be similar at week 16 for this analysis, conservatively. Upon analysis, the NNTs for MTX, APR and ADA were 8.31, 6.69 and 2.63, respectively, and the 16 weeks drug costs were $436, $6,844 and $10,010, respectively. The cost per ACR20 responder was $3,622 for MTX, $45,808 for APR and $26,316 for ADA.

Conclusion: Among MTX-naïve PsA patients, ADA had the lowest NNT compared with MTX and APR at week 16. Compared with MTX and ADA, APR had the highest cost per responder estimates among MTX-naïve PsA patients at week 16.

Integrated Safety of Ustekinumab in Psoriatic Arthritis: 2 Year Follow-up from the Psoriatic Arthritis Clinical Development Program. Arthur Kavanaugh[1], Iain B. McInnes[2], Christopher T. Ritchlin[3], Proton Rahman[4], Lluís Puig Sanz[5], Alice B. Gottlieb[6], Michael Song[7], Bruce Randazzo[7], Shu Li[7], Yin You[7] and Alan M. Mendelsohn[7]. [1]University of California San Diego, La Jolla, CA, [2]University of Glasgow, Glasgow, United Kingdom, [3]University of Rochester Medical Center, Rochester, NY, [4]Memorial University of Newfoundland, St. John's, NF, [5]Universitat Autònoma de Barcelona, Barcelona, Spain, [6]Tufts Medical Center, Boston, MA, [7]Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: To report the safety of ustekinumab(UST) from the psoriatic arthritis (PsA)development program.

Methods: Safety data through up to 2yrs of follow-up were pooled from Ph3 for the analysis of overall safety endpoints. Data were pooled from Ph2(n=146) and Ph3 for AEs of interest**.** In Ph3, adult PsA pts (PSUMMIT I [n=615], PSUMMIT II [n=312]) with active disease (≥5 SJC and ≥5 TJC; CRP≥0.3mg/dL [ULN 1.0 mg/dL]) despite DMARD and/or NSAID or previously treated with DMARD and/or NSAID, and prior anti-TNFα therapy (PSUMMIT II only) were randomized to UST45mg, 90mg, or PBO at wks 0, 4, and q12wks; at wk16, pts with <5% improvement in SJC & TJC entered blinded EE (PBO→UST45mg; UST45mg→90mg; 90mg→90mg). PBO pts crossed over to UST45mg at wks24 and 28 and q12wk dosing. No concomitant DMARDs except MTX (approx 50% in each Ph3 study) were permitted. The PBO-controlled period was 12wks and 16wks for the Ph2 and Ph3 trials, respectively. AEs were reported as the number of events /100 pt-yrs of follow-up (PY). All pts who received ≥1 dose of treatment were included.

Results: 379 and 1018 pts were treated with PBO and UST, resp, for up to 2yrs(duration of follow-up: Ph2 36wks, PSUMMIT1 108wks, and PSUMMIT2 60wks) with 145 PY and 1403 PY overall for the PBO and UST grps, resp. At baseline, 96.8% were white, 52.2% male, mean age 47.6yrs(SD 11.8). Mean BMI was 30.9 kg/m^2(SD 7.1), mean PsA and PsO duration was 7.2 yrs(SD 7.7) and 15.8yrs (SD 12.6), resp. Safety outcomes are detailed in Table 1. Event rates of overall AEs, infections, and SAEs, were comparable among PBO and UST during the PBO-controlled period; rates remained comparable through 2yrs of follow-up. Rates of AEs leading to d/c were higher in PBO. Overall AE rates were not impacted by baseline MTX or prior anti-TNF usage. 1 squamous cell carcinoma (90mg), 1 serious infection (PBO) and 1 MI (PBO) were reported during PBO-controlled period. With up to 2yrs of follow-up, rate of infections was similar in 90mg vs 45mg grps; serious infections were numerically greater in the 90mg vs 45 mg grp(2.1/100PY [95% CI:1.1,3.5] vs 0.5/100PY [95% CI: 0.1,1.3], resp), and included 2 pts in the 90mg grp with multiple events(most were single events without apparent trend). 4 non-melanoma skin cancers (NMSC)(0.64/100PY) occurred in the 90mg grp and no NMSCs occurred in the 45mg grp. 3 malignancies(0.4/100PY), other than NMSC, occurred in 45mg grp and none in 90mg grp. Major adverse cardiovascular event(MACE) rates were low and

no dose effects were observed(1.15 vs 0.24 for 45mg and 90mg, resp). No cases of active TB or serious opportunistic infections, RPLS, demyelination, anaphylaxis or serum sickness-like reactions were reported.

Conclusion: Pooled safety data show that UST was well tolerated at both doses with up to 2yrs of follow-up without new safety signals. The safety profile of UST in the PsA clinical development program was generally comparable to that observed in the psoriasis population.

Clinical Response in Subjects with Psoriatic Arthritis Following One Year of Treatment with Brodalumab, an Anti-Interleukin-17 Receptor Antibody. Mark C Genovese[1], Philip Mease[2], Maria W. Greenwald[3], Christopher T. Ritchlin[4], A Beaulieu[5], Atul A. Deodhar[6], Richard Newmark[7], JingYuan Feng[8], Ngozi Erondu[9] and Ajay Nirula[7]. [1]Stanford University Medical Center, Palo Alto, CA, [2]Swedish Medical Center and University of Washington, Seattle, WA, [3]Desert Medical Advances, Palm Desert, CA, [4]University of Rochester Medical Center, Rochester, NY, [5]Centre de Rhumatologie, St-Louis, QC, [6]Oregon Health and Sciences University, Portland, OR, [7]Amgen, Thousand Oaks, CA, [8]Amgen Inc, Thousand Oaks, CA, [9]Amgen, Inc., Thousand Oaks, CA.

Background/Purpose: Interleukin-17 (IL-17) plays a role in the pathogenesis of psoriatic disease of both skin and joint. We sought to assess long-term efficacy and safety of brodalumab, a human anti-IL-17 receptor A monoclonal antibody, in patients with psoriatic arthritis (PsA) in an open-label extension (OLE) of a Phase 2 study (NCT01516957).

Methods: Adults with active PsA (Classification Criteria for Psoriatic Arthritis and ≥3 tender and ≥3 swollen joints) for ≥6 months were randomized to brodalumab (140 or 280 mg Q2W) or placebo. At week 12, subjects could enroll in an OLE; all subjects received 280 mg brodalumab. Outcomes based on available data up to week 52 from the ongoing study included American College of Rheumatology 20% response (ACR20), ACR50, changes in DAS 28, CDAI, and ACR response components. Safety was assessed by monitoring adverse events (AEs).

Results: The majority of enrolled subjects (113 brodalumab and 55 placebo) were female (64%), white (94%), and rheumatoid factor negative (92%). Mean age, weight, and duration of PsA at baseline were 52 years, 91 kg, and 9 years, respectively. 156 subjects entered the OLE (52 prior placebo, 53 prior 140 mg, 51 prior 280 mg).

ACR20 and ACR50 response rates (observed), which were higher in brodalumab arms than in placebo at week 12, continued to improve and were sustained through week 52 across all groups (Figure 1). Improvements in DAS 28, CDAI, and several ACR components, observed from baseline to week 12, continued through week 52.

During the OLE (through week 52), 142 subjects reported AEs; most frequently reported (≥5% of subjects in any treatment group) were nasopharyngitis, arthralgia, psoriatic arthropathy, upper respiratory tract infection, bronchitis, nausea, sinusitis, and oropharyngeal pain. Ten subjects reported serious adverse events during the OLE through week 52: including 1 case each of acute myocardial infarction, invasive ductal breast carcinoma, metastatic lung cancer, melanoma, pyelonephritis, and streptococcal septic arthritis. Exposure adjusted AE rates (per 100 subject years) were 706 (all brodalumab) and 757 (placebo). Exposure adjusted SAE rates were 11 (brodalumab) and 8 (placebo). No deaths, clinically significant neutropenia (≥ Grade 2), or mycobacterial/fungal/opportunistic infections were reported.

Conclusion: Brodalumab treatment was associated with significant clinical response with continued improvement from weeks 12 to 52.

Evaluation of Extreme Enthesitis and/or Patient-Related Outcome Score As Potential Surrogates for Fibromyalgia and As Potential Confounding Factors of Anti-TNF Response. M Dougados[1], H Jones[2], A Szumski[2], I Logeart[3] and J Coindreau[4]. [1]Université Paris René Descartes and Hôpital Cochin, Paris, France, [2]Pfizer Inc., Collegeville, PA, [3]Pfizer, Paris, France, [4]Pfizer Inc., New York, NY.

Background/Purpose: Differentiating between pain related to spondyloarthritis (in particular polyenthesitis) and pain related to fibromyalgia can be challenging, both in daily practice and in clinical trials. Some rheumatologists believe an "extreme" enthesitis score and/or pain/Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score may reflect a "fibromyalgia" disease. Additionally, depression is frequently observed in fibromyalgia patients; thus, an "extreme" enthesitis and/or pain/BASDAI score may correlate with an elevated depression score. The purpose of this post-hoc analysis was to evaluate patients with spondyloarthritis in order to: 1) estimate the percentage of patients with such "extreme" scores; 2) evaluate the relationship between "extreme" scores and depression; 3) evaluate the effect

of baseline "extreme" scores on treatment outcome for etanercept and placebo.

Methods: Patients with non-radiographic axial spondyloarthritis participated in a randomized clinical trial and received double-blind etanercept 50 mg or placebo weekly. For this analysis, patients were divided into those who did vs. those who did not have extreme scores at baseline. Extreme baseline scores were defined as the highest quintile for enthesitis score (≥6), and/or scores ≥8 on 3 of 5 BASDAI items (morning stiffness duration was excluded). Depression was evaluated using the Hospital Anxiety and Depression Scale, depression subscale (HADS-D). Treatment outcome was the Assessment of SpondyloArthritis (ASAS) 40 response rate at week 12.

Results: Of the 213 patients at baseline, 35 (16%) met only enthesitis criteria, 31 (15%) met only BASDAI criteria, 12 (6%) met both criteria, and 135 (63%) met neither criteria. Patients with extreme enthesitis and/or BASDAI scores vs. those without were more likely to have moderate to severe depression at baseline: 20/68 (29%) vs. 10/118 (9%) of patients had HADS-D score >11 ($P<0.001$). For patients with vs. without extreme scores, no significant difference existed in week 12 ASAS40: etanercept 13/41 (32%) vs. 21/60 (35%); placebo 5/36 (14%) vs. 12/68 (18%).

Conclusion: Extreme enthesitis and/or BASDAI scores correlated with depression at baseline, but did not have an effect on week 12 ASAS40 in either the etanercept or placebo treatment group.

1559

Long Term Improvements in Physical Function Are Associated with Improvements in Dactylitis, Enthesitis, Tender and Swollen Joint Counts, and Psoriasis Skin Involvement: Results from a Phase 3 Study of Ustekinumab in Psoriatic Arthritis Patients. Arthur Kavanaugh[1], Lluís Puig Sanz[2], Alice B. Gottlieb[3], Christopher T. Ritchlin[4], Shu Li[5], Yin You[5], Alan M. Mendelsohn[5], Michael Song[5], Proton Rahman[6] and Iain B. McInnes[7]. [1]University of California San Diego, La Jolla, CA, [2]Universitat Autònoma de Barcelona, Barcelona, Spain, [3]Tufts Medical Center, Boston, MA, [4]University of Rochester Medical Center, Rochester, NY, [5]Janssen Research & Development, LLC., Spring House, PA, [6]Memorial University of Newfoundland, St. John's, NF, [7]University of Glasgow, Glasgow, United Kingdom.

Background/Purpose: To evaluate the association of improvements in tender and swollen joint counts (TJC, SJC), psoriasis skin involvement, and dactylitis/enthesitis (in patients affected at baseline) with improvement in physical function using data from the ustekinumab (UST) PSUMMIT 1 trial in psoriatic arthritis (PsA) pts.

Methods: Adult PsA pts (n=615) with active disease (≥5 SJC and ≥5 TJC;CRP≥0.3mg/dL) despite DMARD and/or NSAIDs were randomized to UST45mg, 90mg, or PBO at wks 0, 4, and q12wks. Pts treated with prior anti-TNF agents were excluded. Stable concomitant MTX was permitted but not mandated. At wk16, pts with <5% improvement in TJC and SJC entered blinded early escape (PBO→UST45mg; UST45mg→90mg; 90mg→90mg). PBO-treated patients subsequently crossed over to UST45mg at wk24. Pts received q12wks dosing to wk88, with final efficacy evaluation at wk100 and safety assessment at wk108. The percent change from baseline in enthesitis score, dactylitis score, TJC and SJC by HAQ responder status (response defined as achieving≥0.3 point improvement from baseline) was assessed at wks 52 and 100.The correlation between change from baseline in HAQ and percent change from baseline in TJC, SJC, enthesitis and dactylitis were also determined at wks 52 and 100.

Results: At baseline; mean(median) TJC and SJC values were 23.5(20.0) and 13.5(10.0), respectively. 441(71.7%) and 296(48.1%) patients had enthesitis or dactylits at baseline, respectively; 440(71.7%) patients had >3% BSA psoriasis skin involvement. Improvements in TJC, SJC, dactylitis and enthesitis, and PASI scores were generally greater in HAQ responders compared with HAQ non-responders at both wk52 and wk100(Table). Significant correlations were demonstrated between the HAQ change from baseline with percent change in outcomes parameters for all outcomes(Table) at wk52 and wk100. In addition, associations were observed at earlier time points at wk24/wk28 [TJC -0.39/-0.36; SJC -0.27/-0.20; enthesitis 0.30/0.28(all p<0.0001); dactylitis 0.19/0.18 (p=0.001/p=0.002); PASI -0.24/-0.10(p<0.0001/p=0.0397)].

Conclusion: Based on this post-hoc analysis of the PSUMMIT 1 population, improvements in physical function as measured by HAQ were associated with improvements in TJC, SJC, dactylitis and enthesitis, and these correlations were observed as early as week 24 and continued through week100. Improvement in skin disease was also associated with improvements in HAQ.

Table: Summary of percent change from baseline at wk52 and wk100 in HAQ responders; randomized patients at baseline [mean(median)]

Rheumatoid Factor Status Is a Predictor of Osteoporosis in Patients with Psoriatic Arthritis. Frank Behrens[1], Michaela Koehm[2], Eva C. Scharbatke[3], Bianca Wittig[4], Marc Schmalzing[3], Holger Gnann[5], H M Lorenz[6], Diamant Thaci[7] and Harald Burkhardt[1]. [1]Goethe-University Frankfurt, Frankfurt, Germany, [2]Fraunhofer Institute for Molecular Biology and Applied Ecology IME, Project Group Translational Medicine & Pharmacology TMP, Frankfurt/Main, Germany, [3]University of Würzburg, Würzburg, Germany, [4]Abbvie Deutschland GmbH & Co. KG, Wiesbaden, Germany, [5]Abteilung Biostatistik, GKM Gesellschaft für Therapieforschung mbH, München, Germany, [6]University Hospital Heidelberg, Heidelberg, Germany, [7]University Hospital Schleswig Holstein Campus Luebeck, Lübeck, Germany.

Background/Purpose: Osteoporosis is an important comorbidity in patients with rheumatic diseases, but risk factors for osteoporosis in Psoriatic Arthritis (PsA) patients have not been explored.

Methods: We evaluated baseline characteristics of active PsA patients enrolled in a German observational multicenter study with Adalimumab (ADA). Multiple logistic regression analyses were utilized to identify risk factors for osteoporosis. Risk factors were confirmed in a validation cohort.

Results: At baseline, 6.0% (N=88) of patients in the initial PsA cohort (N=1467) had osteoporosis as indicated by medical history. Logistic regression analyses (1194 patients with adequate data for modeling) found that age, systemic glucocorticoid use and rheumatoid factor (RF) seropositivity were significantly associated with osteoporosis. As the association between RF status and osteoporosis has not been previously described in PsA, we evaluated a second cohort of PsA patients (validation cohort; N = 1762) to determine whether this association could be verified. As in the initial cohort, positive RF status was associated with a >2-fold increase in the risk of osteoporosis in patients with PsA in the same range as use of glucocorticoids. The rate of osteoporosis was 5.4% (168/3102) in the total cohort and 12.1%

(35/290) in RF-positive patients. Analysis of typical PsA-features like confirmed nail involvement, enthesitis and dactylitis and active psoriasis suggests that it is unlikely that the RF-positive PsA patients were misdiagnosed RA-cases. The full set of predictors of osteoporosis of the full cohort (2956 patients with adequate data) is shown in Table 1. Negative predictors were male gender and higher functional (FFbH) scores.

Conclusion: RF seropositivity is an independent risk factor for osteoporosis in active PsA patients. Other variables that increase the risk of osteoporosis are steroid use, older age, longer disease duration, recent hospitalization, female gender, and worse functional status.

Variable	Range	Odds ratio*	95% CI	*P* value
Positive predictors				
Systemic glucocorticoid use	1 = yes, 0 = no	2.783	1.938–3.995	<0.0001

Apremilast, an Oral Phosphodiesterase 4 Inhibitor, and the Impact of Baseline Weight and BMI on ACR20 and HAQ-DI Response: Pooled Results from 3 Phase 3, Randomized, Controlled Trials. Georg A. Schett[1], Philip Mease[2], Dafna D. Gladman[3], Arthur Kavanaugh[4], Adewale O. Adebajo[5], Juan J. Gomez-Reino[6], Jurgen Wollenhaupt[7], Maurizio Cutolo[8], Eric Lespessailles[9], ChiaChi Hu[10], Randall M. Stevens[10], Christopher J. Edwards[11] and Charles A. Birbara[12]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Swedish Medical Center and University of Washington, Seattle, WA, [3]University of Toronto, Toronto Western Hospital, Toronto, ON, [4]University of California San Diego, La Jolla, CA, [5]University of Sheffield, Sheffield, United Kingdom, [6]Hospital Clinico Universitario, Santiago, Spain, [7]Schoen-Klinik Hamburg-Eilbek Teaching Hospital of the University of Hamburg, Hamburg, Germany, [8]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, [9]University of Orléans, Orléans, France, [10]Celgene Corporation, Warren, NJ, [11]University Hospital Southampton, Southampton, United Kingdom, [12]University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Apremilast (APR) is a phosphodiesterase 4 inhibitor that helps to regulate the immune response that causes inflammation and skin disease associated with psoriatic arthritis (PsA). PALACE 1, 2, and 3 compared the efficacy and safety of APR with placebo in patients with active PsA despite prior disease-modifying antirheumatic drugs (DMARDs) and/or biologics, including biologic failures. We assessed the impact of baseline weight and body mass index (BMI) on clinical response to APR over 24 weeks in a pooled analysis.

Methods: Patients were randomized (1:1:1) to receive placebo, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by baseline DMARD use (yes/no). Patients whose swollen and tender joint counts had not improved by ≥20% at Week 16 were considered non-responders and were required to be re-randomized (1:1) to APR20 or APR30 if they were initially randomized to placebo, or continued on their initial apremilast dose. At Week 24, all remaining placebo patients were re-randomized to APR20 or APR30.

Results: 1,493 patients were randomized, received ≥1 dose of study medication (placebo: n=496; APR20: n=500; APR30: n=497), and were comparable across treatment groups for demographics, disease characteristics, and prior/concurrent therapy. At baseline, mean (SD) weight was 85.7 (20.6) kg and mean (SD) BMI was 29.9 (6.5) kg/m^2. At Week 16, a significantly greater proportion of patients receiving APR20 or APR30 achieved a modified ACR20 response vs placebo (primary endpoint) in all 3 PALACE trials. APR30 was associated with significant improvements in Health Assessment Questionnaire-Disability Index (HAQ-DI) score vs placebo at Week 16 (key secondary endpoint) across all 3 trials. At Week 16, similar ACR20 response rates and improvements in HAQ-DI scores were observed across all weight and BMI ranges (Table). A favorable treatment effect for both APR treatment groups vs placebo was observed, irrespective of baseline body weight or BMI. Overall, the treatment effect was dose-dependent, with greater effects generally observed in APR30 patients over APR20 patients. These treatment effects were generally maintained at Week 24.

Conclusion: APR demonstrated a favorable treatment effect in patients with active PsA. Comparable improvements in the signs and symptoms of PsA and physical function were observed across a broad range of baseline weight and BMI values. Results suggest that no dose adjustment is required to account for baseline body weight or BMI.

Psoriasis Longitudinal Assessment and Registry: Global Update upon Full Enrollment. Bruce Strober[1], Alan Menter[2], Craig Leonardi[3], Lyn Guenther[4], Kavitha Goyal[5], Wayne Langholff[6], Steve Calabro[5] and Steve Fakharzadeh[7]. [1]University of Connecticut Heatlh Center, Farmington, CT, [2]Baylor Research Institute, Dallas, TX, [3]Central Dermatology, St. Louis, MO, [4]The Guenther Dermatology Research Centre, London, ON, [5]Janssen Services, LLC, Horsham, PA, [6]Janssen Research and Development, LLC, Spring House, PA, [7]Janssen Services, LLC, Spring House, PA.

Background/Purpose: To report the baseline demographics and clinical characteristics of participants enrolled in the Psoriasis Longtitudinal Assessment and Registry (PSOLAR) study.

Methods: PSOLAR is a multicenter, prospective, longitudinal, observational study initiated by the FDA designed to follow psoriasis patients for 8 years in academic and community settings. Eligible patients are aged ≥18 years, have a diagnosis of psoriasis and are currently receiving or are candidates to receive systemic therapies for psoriasis. Demographics and medical/family history are collected at enrollment, including self-reported diagnosis of psoriatic arthritis. Evaluations at 6 month intervals include: adverse events, disease activity, quality of life, economic status, healthcare utilization and interval therapies.

Results: PSOLAR is fully enrolled, with sites in North America, Latin America, and Europe having recruited 12 095 patients as of 23 August 2013. Baseline characteristics at enrollment were as follows: mean age 48.6 years; median age 49.0 years; 13% were ≥65 years of age; 54.9% male; 82.9% white; mean body mass index (BMI) 30.9 (SD 7.2); and mean psoriasis duration 17.5 years (SD 13.5 years). Psoriatic arthritis was self-reported in 35.7% of patients and 96.9% of patients had plaque-type psoriasis. Mean and median historical peak psoriasis activity as measured by PGA were 3.11 and 3.0 respectively, and by BSA, 29.7% and 20.0% respectively.

Co-morbidities included cardiovascular disease in 38.3%, pulmonary disorders in 14.4%, psychiatric disorders in 20.7%, and endocrine disorders in 18.8%; 6.2% had a previous skin cancer. Infections requiring treatment in the 3 years preceding enrollment occurred in 24.5% of patients; 21.5% were bacterial. The mean body surface area (BSA) coverage was 12.1% (SD 17.5%) and mean physicians' global assessment (PGA) score 2 (SD 1.2).

Psoriasis medications (current and historical) included topicals (96.9%), phototherapy (54.5%), systemic steroids (23.4%), systemic agents [e.g. MTX, cyclosporine] (47.9%), and biologic agents (etanercept 40.3%, adalimumab 29.4%, ustekinumab 18.8%, infliximab 16.0%, and efalizumab 11.1%).

Conclusion: PSOLAR is fully enrolled with 12 095 patients with an accrual of 31 818 patient- years of followup as of August 23, 2013. Participation is global with the majority of patient representation from North America. Clinical features are as expected for a moderate to severe psoriasis population, including a 35.7% prevalence of self-reported psoriatic arthritis. Serious adverse events and adverse events of interest have been presented for the overall registry and future analyses will provide similar data with respect to various treatment groups represented in PSOLAR.

Malignancies in the Psoriasis Longitudinal Assessment and Registry Study: Cumulative Experience. David Fiorentino[1], Mark Lebwohl[2], Vincent Ho[3], Richard Langley[4], Kavitha Goyal[5], Steve Fakharzadeh[6], Steve Calabro[5] and Wayne Langholff[7]. [1]Stanford University School of Medicine, Redwood City, CA, [2]Mount Sinai Medical Center, New York, NY, [3]University of British Columbia, Vancouver, BC, [4]Dalhousie University, Halifax, NS, [5]Janssen Services, LLC, Horsham, PA, [6]Janssen Services, LLC, Spring House, PA, [7]Janssen Research and Development, LLC, Spring House, PA.

Background/Purpose: To report the cumulative incidence of malignancies excluding non-melanoma skin cancers (NMSC) in the PSOLAR study.

Methods: PSOLAR is a multicenter, longitudinal, observational study evaluating long-term safety and clinical outcomes for patients eligible to receive treatment with biologics and/or conventional systemic agents for psoriasis (includes patients with self-reported psoriatic arthritis. The incidence of malignancies excluding NMSC (ie, basal/squamous cell carcinomas) in PSOLAR overall and by treatment groups is reported. Rates of malignancy are assessed using a definition of exposure based on whether patients had ever been exposed to a given therapy at any time prior to the event. In cases of exposure to >1 therapy, the rule for attribution of malignancy to a treatment group is ustekinumab first, infliximab/golimumab second, other biologics third (nearly all adalimumab or etanercept), or non-biologic therapy fourth, which is consistent with the pre-specified analytic plan.

Results: PSOLAR is fully enrolled and as of the August 23, 2013 data cut has 31, 818 cumulative patient-years of follow up with 12, 095 patients; 36% of those patients had self-reported psoriatic arthritis. Unadjusted cumulative rates of malignancy (excluding NMSC) overall and across treatment groups: overall 0.68 events per 100 patient years of observation (PYO) [95% CI: 0.59, 0.77; 215/31818], ustekinumab 0.51 per 100 PYO [95% CI: 0.37, 0.68; 45/8870 PYO], infliximab/golimumab (almost exclusively infliximab) 0.64 per 100 PYO [95% CI: 0.42, 0.93; 27/4205, other biologics (almost exclusively etanercept/adalimumab) 0.74 per 100 PYO [95% CI: 0.60, 0.91; 98/13167], and non-biologic therapy 0.81 per 100 PYO [95% CI: 0.59, 1.08; 45/5576]. The cumulative rates per 100 PY for the overall registry population for the most frequent specific malignancies were: breast cancer 0.13 [40], prostate cancer 0.09 [30], lung cancer 0.08 [26], and melanoma 0.07 [22]. Limitations: Rates have not been adjusted for demographic and clinical differences among treatment groups and are subject to attribution rules.

Conclusion: In the current evaluation, reflecting a median duration of 2.5 years of follow-up, cumulative unadjusted rates of malignancies in PSOLAR are comparable across treatment groups. The most frequently reported malignancies in the registry are comparable with the most frequently reported malignancies in the general population. Additional evaluation of malignancies with accruing longitudinal exposure will be informative.

Long-Term (104-Week) Safety Profile of Apremilast, an Oral Phosphodiesterase 4 Inhibitor, in Patients with Psoriatic Arthritis: Results from a Phase 3, Randomized, Controlled Trial and Open-Label Extension. Philip Mease[1], Adewale O. Adebajo[2], Dafna D. Gladman[3], Juan J. Gomez-Reino[4], Stephan Hall[5], Arthur Kavanaugh[6], Eric Lespessailles[7], Georg A. Schett[8], Kamal Shah[9], Randall M. Stevens[9], Lichen Teng[9] and Jürgen Wollenhaupt[10]. [1]Swedish Medical Center and University of Washington, Seattle, WA, [2]University of Sheffield, Sheffield, United Kingdom, [3]University of Toronto, Toronto Western Hospital, Toronto, ON, [4]Hospital Clinico Universitario, Santiago, Spain, [5]Cabrini Health and Monash University, Melbourne, Australia, [6]University of California San Diego, La Jolla, CA, [7]University of Orléans, Orléans, France, [8]University of Erlangen-Nuremberg, Erlangen, Germany, [9]Celgene Corporation, Warren, NJ, [10]Schön Klinik Hamburg Eilbek, Hamburg, Germany.

Background/Purpose: Apremilast (APR), a phosphodiesterase 4 inhibitor, helps regulate the immune response that causes inflammation and skin disease associated with psoriatic arthritis (PsA). PALACE 1, a phase 3 randomized trial with an open-label extension, compared the efficacy/safety of APR with placebo (PBO) in pts with active PsA despite prior conventional DMARDs and/or biologics.

Methods: Pts were randomized (1:1:1) to receive PBO, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by baseline DMARD use (yes/no). Pts whose swollen/tender joint counts had not improved ≥20% at Wk 16 were considered non-responders and were re-randomized (1:1) to APR20 or APR30 (PBO pts) or continued on their initial dose (APR pts). At Wk 24, all remaining PBO pts were re-randomized to APR20 or APR30. Double-blind APR treatment continued to Wk 52; pts could continue to receive APR during an open-label, long-term treatment phase. The analysis reports safety findings from the APR-exposure period (Wks 0 to ≤104).

Results: 504 pts were randomized and received ≥1 dose of study medication (PBO: n=168; APR20: n=168; APR30: n=168). A total of 490

(410.3 pt-years) and 344 (306.2 pt-years) pts received APR in the Wk 0 to ≤52 and Wk >52 to ≤104 APR-exposure periods, respectively. During the Wk >52 to ≤104 period, AEs occurring in ≥5% of APR-exposed pts were nasopharyngitis and URTI (Table). Most AEs were mild/moderate in severity between Wks >52 to ≤104 and in general, no increase was seen in the incidence or severity of AEs with longer term exposure. During the Wk >52 to ≤104 exposure period, diarrhea and nausea occurred at lower rates (1.7% and 1.2%, respectively) than in the Wk 0 to ≤52 period (15.3% and 12.4%, respectively). Serious AEs occurred in 6.4% (APR20) and 4.7% (APR30) over the Wk >52 to ≤104 APR-exposure period.Through Wk 104, serious infections were reported by 5 pts receiving APR during Wks 0 to ≤52 and 3 pts receiving APR during Wks >52 to ≤104; none were opportunistic infections. No cases of tuberculosis (new or reactivation) were reported with either APR dose. Discontinuations due to AEs occurred at a lower rate in the combined APR-exposure pts during the Wk >52 to ≤104 (1.5%) APR-exposure period than in Wks 0 to ≤52 (8.2%). Discontinuation rates due to diarrhea and nausea also decreased over the Wk >52 to ≤104 APR-exposure period. Marked laboratory abnormalities were generally infrequent and returned to baseline with continued treatment or were associated with a concurrent medical condition.

Conclusion: APR demonstrated an acceptable safety profile and was generally well tolerated for up to 104 wks, with no new safety concerns identified with long-term exposure. These data continue to support that specific laboratory monitoring is not needed with APR.

Apremilast, an Oral Phosphodiesterase 4 Inhibitor, Is Associated with Improvement of Pain, Fatigue, and Disability in Patients with Psoriatic Arthritis: Results from 3 Phase 3, Randomized, Controlled Trials.

Dafna D. Gladman[1], Vibeke Strand[2], Arthur Kavanaugh[3], Philip Mease[4], Christopher J. Edwards[5], Maurizio Cutolo[6], Frédéric Lioté[7], Paul Bird[8], Randall M. Stevens[9], Lichen Teng[9], Marla Hochfeld[9] and Georg A. Schett[10]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]Stanford University, Portola Valley, CA, [3]University of California San Diego, La Jolla, CA, [4]Swedish Medical Center and University of Washington, Seattle, WA, [5]University Hospital Southampton, Southampton, United Kingdom, [6]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, [7]University Paris Diderot, Paris, France, [8]Combined Rheumatology Practice, Kogarah, Australia, [9]Celgene Corporation, Warren, NJ, [10]University of Erlangen-Nuremberg, Erlangen, Germany.

Background/Purpose: Apremilast (APR) is an oral phosphodiesterase 4 inhibitor that helps regulate the immune response that causes inflammation and skin disease associated with psoriatic arthritis (PsA). The PALACE 1, 2, and 3 trials compared the efficacy and safety of APR with placebo in patients with active PsA despite prior conventional disease-modifying antirheumatic drugs (DMARDs) and/or biologics, including biologic failures.

Methods: Patients were randomized (1:1:1) to receive placebo, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by baseline DMARD use (yes/no). Patients whose swollen and tender joint counts had not improved by ≥20% at Week 16 were considered non-responders and were required to be re-randomized (1:1) to APR20 or APR30 if they were initially randomized to placebo, or continued on their initial apremilast dose. At Week 24, all remaining placebo patients were re-randomized to APR20 or APR30. This analysis reports data over 52 weeks.

Results: In the pooled PALACE 1–3 population, a significantly greater proportion of patients receiving APR20 and APR30 achieved a modified ACR20 response vs placebo at Week 16 (placebo: 18.8%; APR20: 32.0% [$P<0.0001$]; APR30: 37.0% [$P<0.0001$]) (primary endpoint). At Week 16, significant improvements were observed with APR20 and APR30 (PALACE 1–3, pooled) for multiple patient-reported outcomes compared with placebo (placebo; APR20; and APR30, respectively): least-squares (LS) mean changes in Health Assessment Questionnaire-Disability Index (HAQ-DI) (−0.07; −0.16 [$P=0.0009$]; and −0.21 [$P<0.0001$]), pain visual analog scale (VAS) (−5.8; −10.7 [$P=0.0009$]; and −12.7 [$P<0.0001$]), 36-item Short-Form Health Survey version 2 (SF-36v2) physical component summary (PCS) (1.9; 3.3 [$P=0.0016$]; and 3.9 [$P<0.0001$]), and SF-36v2 Physical Functioning (PF) domain (1.3; 2.7 [$P=0.0057$]; and 3.6 [$P<0.0001$]) scores. APR30 also significantly improved the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) score at Week 16 (1.1; 1.5 [$P=NS$]; and 3.5 [$P<0.0001$]). In patients initially randomized to APR who completed Week 52, improvements were sustained at Week 52 across the individual studies (Table). The most common adverse events reported for up to 24 weeks of APR treatment were diarrhea (12.2%), nausea (10.1%), and headache (8.0%) (PALACE 1–3; pooled). The safety profile of APR through 52 weeks was similar to that observed with APR for up to 24 weeks of treatment.

Conclusion: Among patients continuously treated with APR, sustained clinically meaningful improvements in patient-reported outcome measures of pain, physical function, and fatigue were observed through Week 52. APR demonstrated an acceptable safety profile and was generally well tolerated through 52 weeks.

Impact of APR on Parameters of Pain, Disability, and Fatigue at Week 52 (Data as Observed)

	PALACE 1		PALACE 2		PALACE 3	
Mean Change From Baseline	**APR20 n=124**	**APR30 n=130**	**APR20 n=125**	**APR30 n=114**	**APR20 n=120**	**APR30 n=126**
HAQ-DI (0–3)*	−0.37	−0.32	−0.19	−0.33	−0.33	−0.35
Pain VAS (0–100 mm)*	−17.8	−20.3	−13.5	−12.9	−14.9	−18.7
SF-36v2 PCS (0–100 mm)$^{\mu}$	7.8	6.5	5.1	6.4	6.3	5.9
SF-36v2 PF (0–00 mm)$^{\mu}$	7.0	5.7	4.1	5.0	5.7	5.9

1566

The Efficacy and Safety of Biological Disease Modifying Anti-Rheumatic Drugs and Apremilast in the Treatment of Psoriatic Arthritis: A Systematic Review and Meta-Analysis. Arthur N. Lau[1], Michael Zoratti[2], Alfred Cividino[1], William Bensen[1], Jonathan D. Adachi[1] and Christopher Edwards[3]. [1]Division of Rheumatology, McMaster University, Hamilton, ON, [2]Department of Clinical Epidemiology & Biostatistics, McMaster University, Hamilton, ON, [3]NIHR Wellcome Trust Clinical Research Facility, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom.

Background/Purpose: Currently, there are a number of effective therapies for psoriatic arthritis (PsA). The objective of this systematic review was to assess the efficacy (PSARC, ACR 20/50/70 and PASI75 response) and adverse event profile (AEs) (any AEs, serious AEs, and infection rate) of using TNF inhibitors or new therapies including Ustekinumab and Apremilast to treat active PsA.

Methods: This review included all published/unpublished RCTs comparing biologics or Apremilast to placebo in PsA patients. Multiple mechanisms of action (MOA) were included: TNF inhibitor (Adalimumab, Certolizumab, Etanercept, Infliximab and Golimumab), IL12/23 inhibitor(Ustekinumab) and PDE4 inhibitor(Apremilast). The databases MEDLINE(n=245), EMBASE(n=1551) and CENTRAL(n=223) were searched. Conference abstracts from the ACR and American Academy of Dermatology (2009–13) were hand searched. Two reviewers independently screened titles/abstracts/full text for eligibility. Data extraction and risk of bias assessment were performed in duplicate using Cochrane's Risk of Bias Assessment.

Results: 18 studies (5433 participants) were included. Kappa for full text and risk of bias was 0.8545 and 0.9217 respectively. When the MOAs were pooled, the risk ratio (RR) for achieving PSARC, ACR20,50,70, and PASI75 at 12–16 and 24 weeks(wk) were all statistically significant. The likelihood of achieving the primary outcome ACR20 (12–16wk) had RR=2.74(95%CI=2.27–3.32) with significant heterogeneity (I^2= 65%) which was explained by *a priori* subgroup analysis (by MOA). When comparing the ACR20 (12–16wk) response by MOA, the RR was 3.99 (95%CI: 2.91–5.46), 2.03 (95%CI: 1.70–2.42) and 2.08 (95%CI: 1.66–2.59) respectively for the TNF, PDE4 and IL12/23 inhibitors. RR of achieving ACR20 response (24wk) by MOA is shown in figure1. Low heterogeneity (I^2<40%) was seen for the outcomes ACR50,70 at 12–16/24wk respectively, suggesting there may be comparable efficacy of each MOA class for these outcomes. There was no significant increase in risk for any AEs or severe AEs, except a mild increase in risk of infections at 24wk (RR=1.15, 95%CI= 1.00–1.32).

Conclusion: TNF inhibitors, Ustekinumab & Apremilast all appear to produce significant benefits on joint and skin disease for individuals with PsA. The safety profile, aside from a slight increased risk of infections, appears acceptable. When comparing the three MOAs, the TNF inhibitors appeared most effective in achieving an ACR20 response at 12–16wk. However, by 24wk there was no significant difference between TNF inhibition and Apremilast while a significant difference remained between TNF inhibition and Ustekinumab. Whilst head to head trials are needed to definitively draw such conclusions, incorporating additional RCTs in future analyses will provide greater power to characterize this relationship.

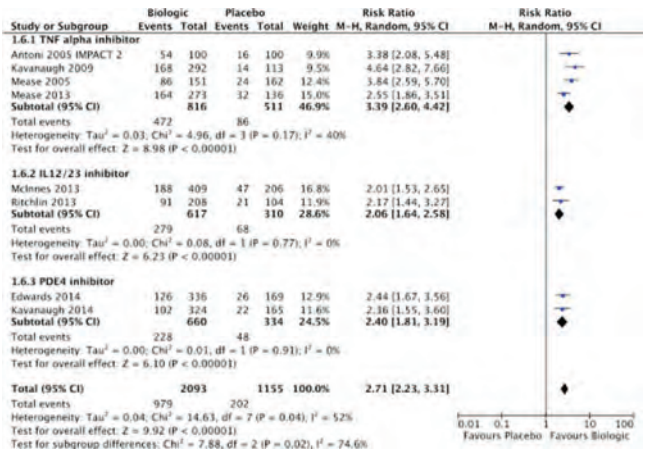

Fig1: RR for achieving ACR20 response (24wk) vs placebo by MOA

The Spectrum of Autoimmune Ophthalmic Manifestations in Psoriatic Disease. Sergio Schwartzman[1], Anton Kolomeyer[2] and David Chu[3]. [1]Hospital for Special Surgery, New York, NY, [2]University of Pittsburgh, Pittsburgh, PA, [3]Rutgers, Newark, NJ.

Background/Purpose: Psoriatic disease is characterized by the presence of psoriasis with or without an association of extra-dermal manifestations. Inflammatory forms of arthritis are the most common concomitant findings in this continuum but not infrequently other organ systems manifest involvement. There is a dearth of primary literature on autoimmune ocular manifestations in patients with Psoriasis (Ps) and Psoriatic arthritis (PsA) although the prevalence of uveitis in PsA has been documented to be as high as 25.1%. [1]

The purpose of this study is to describe the pattern of ocular inflammation in patients with psoriatic disease.

Methods: Retrospective chart review of ocular manifestations in patients with Ps and PsA from two tertiary care centers in the United States specializing in autoimmune ophthalmic disease. Data was collected on age, gender, ethnicity, associated autoimmune disease, ocular manifestations, HLA Typing, systemic immunomodulating agents and ocular therapy

Results: 20 patients were identified with the following characteristics:

Age in years at Diagnosis of Ophthalmic Disease mean +/− SD	45.9 SD +/− 14.4
Male/Female	5/15
Race	1 Hispanic, 2 African Americans. 17 Caucasians
Psoriatic Disease	6 Ps, 14 PsA
Additional Systemic Illnesses	3 Sarcoid, 2 RA
Pattern of PsA	8 Oligoarticular, 2 Axial, 1 Polyarticular (not available in 3 pts)
Ophthalmic Illness	6 Anterior Uveitis, 3 Panuveitis 2 Scleritis, 1 Episcleritis, 3 Sclerouveitis, 2 PUK, 1 Vasculitis, 1 Multifocal Choroiditis
Systemic Therapy	Systemic and Local Steroids, Sulfasalzine, Methotrexate, Mycophenolate, Cyclosporin, Adalimumab, Infliximab, Certolizumab, Etanercept, Cytoxan, Rituximab
Number of Patients Requiring More than One Immunomodulatory Medication	11

Conclusion: The breadth and severity of ocular manifestations in patients with Ps and PsA is diverse. This is the largest cohort of patients with autoimmune ophthalmic manifestations and psoriatic disease described to date. There are several unique features of this cohort:

1. 30% of patients had only skin disease.
2. Although it appears that anterior uveitis is the most common autoimmune ocular manifestation of this group of diseases in this cohort of patients it tends to be chronic, differentiating this ocular manifestation from the pattern in Ankylosing Spondylitis.
3. 33% of patients had an overlap of two underlying systemic autoimmune diseases.
4. When ocular manifestations do occur in patients with psoriatic disease, they tend to be more severe and require more than one immunomodulatory therapy.
5. The most common pattern of PsA in patients with autoimmune ophthalmic disease is the oligoarticular form.

Joint Damage Is Not Associated with Smoking Status in Patients with Psoriatic Arthritis. Hernán Maldonado-Ficco, Arane Thavaneswaran, Vinod Chandran and Dafna D. Gladrman. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: The association between smoking and radiographic progression has been established in axial spondyloarthritides and rheumatoid arthritis (RA) but this association has not been established in psoriatic arthritis (PsA). The **aim** of this study was to determine the effects of cigarette smoking on clinical joint damage in patients with psoriatic arthritis.

Methods: From 1306 PsA patients followed prospectively between 1978 and 2014 as part of an observational cohort, a total of 1107 that started treatment after the first visit was included in the current study. We defined clinical damage as limitation of movement of more than 20% of the range that is not related to a joint effusion, the presence of flexion contractures, fused or flail joints, or evidence of surgery in a particular joint. We used clinical damage as it is assessed at each protocol visit and we have previously demonstrated that clinical joint damage in linked to radiological joint damage. We evaluated the smoking status at the baseline visit up until the first development of clinical joint damage. Smoking status was defined as 'non-smoker', 'past smoker' and 'current smoker'. Time to development of joint damage was assessed using a Cox Regression Analysis to determine the factors predictive of clinical damage, including age, sex, dactylitis and smoking status, joint counts, treatment and HLA B*27 status.

Results: Among the 1107 patients, 55.6% were males, with a mean age of 46 years, duration of psoriasis 17.4 years and the duration of PsA 8.4 years at baseline. 55.6% of the patients were non-smokers, 24.4% were past-smokers and 12.4% were current smokers. 7.9% of the patient had clinical joint damage and 26% had dactylitis at baseline. Males, HLA-B*27 positivity, higher age at diagnosis of PsA, clinical damage at baseline, dactylitis and swollen joints were associated with a higher probability of developing clinically damaged joints whereas current and past-smokers at baseline were associated with a lower probability of developing clinically damaged joints compared to non-smokers.

Conclusion: Unlike what occurs in RA and ankylosing spondylitis, the clinical damage in PsA was not associated with smoking status but was associated with disease-specific features.

Disclosure: H. Maldonado-Ficco, None; **A. Thavaneswaran**, None; **V. Chandran**, None; **D. D. Gladman**, None.

Persistence of Biologic Therapy in Psoriatic Disease: Results from the Psoriasis Longitudinal Assessment and Registry. Alan Menter[1], Kim Papp[2], Gerald G. Krueger[3], Matthias Augustin[4], Francisco Kerdel[5], Melinda Gooderham[6], Kavitha Goyal[7], Steve Fakharzadeh[8], Wayne Langholff[9], Jan Sermon[10], Steve Calabro[7] and David Pariser[11]. [1]Baylor Research Institute, Dallas, TX, [2]Probity Medical Research, Waterloo, ON, [3]University of Utah, Salt Lake City, UT, [4]University Clinics of Hamburg, Hamburg, Germany, [5]University of Miami, Miami, FL, [6]SKiN Centre for Dermatology, Peterborough, ON, [7]Janssen Services, LLC, Horsham, PA, [8]Janssen Services, LLC, Spring House, PA, [9]Janssen Research and Development, LLC, Spring House, PA, [10]Janssen-Cilag, Beerse, Belgium, [11]Eastern Virginia Medical School and Virginia Clinical Research, Inc, Norfolk, VA.

Background/Purpose: We evaluated persistency (treatment longevity) of biologics in patients (pts) with psoriasis (PsO), as well as with psoriatic arthritis (PsA) in the context of a large disease-based registry.

Methods: PSOLAR evaluates safety and clinical outcomes for PsO pts eligible to receive treatment with systemic agents. The study includes 36% pts (n=4317) with self-reported PsA. Duration of therapy was defined as time (in days) between first dose of biologic and the first of: 1) discontinuation 2) switch 3) registry withdrawal or 4) last database cutoff (August 23, 2013). Separate analyses were performed for: 1st line (bio-naïve; i.e. first biologic started on registry), 2nd line (second biologic started while on registry) and 3rdline usage (third biologic started while on registry) to reduce confounding associated with prior exposures for overall population and for subset with PsA. Baseline demographics and reasons for stop/switch were summarized. Persistence was assessed by Kaplan-Meier (KM) analysis for time to therapy stop/switch separately for ustekinumab (UST), infliximab (IFX), adalimumab (ADA), and etanercept (ETN). Cox proportional hazard regression was used to compare time to stop/switch of UST with time to stop/switch of other biologics for each cohort.

Results: The highest starts were attributed to UST (1833 pts) and ADA (1303) with lower starts for ETN (537) and IFX (327). Among UST starts, the proportions of 1st, 2nd and 3rd line usage were 20%, 31%, and 30%; ADA starts 31%, 48%, and 15%; ETN starts 54%, 29% and 13%; IFX starts 19%, 28% and 32%, respectively. Baseline clinical characteristics were generally comparable across biologics and cohorts, with some variability: prevalence of severe PsO was greater for UST and IFX vs ADA and ETN (higher BSA and higher proportions of pts with PGA score of 4 and 5). Fewer pts discontinued UST than IFX, ETN, and ADA in all 3 lines. Overall, median duration of therapy was generally longer for UST vs the 3 anti-TNF therapies. For first line starts, a better persistence was observed for UST based on statistically significant differences in time to stop/switch for each biologic vs UST (IFX vs UST: HR3.04; CI:1.66–5.57; p=0.0003; ADA vs UST: HR4.99; CI:3.39–7.35; p<0.0001; ETN vs UST: HR5.59; CI:3.77–8.29; p<0.0001). Similar results were observed for analysis of 2nd and 3rd line starts. In the subgroup with self-reported PsA, for first line starts, better persistence was observed with UST vs ETN (HR 2.53; CI 1.39–4.62; p=0.0024) but there were no significant differences vs IFX and ADA. UST had better persistence than all 3 anti-TNFs in the analyses of 2nd and 3rdline starts. Reasons for stop/switch were similar across biologics and cohorts (most frequent reason-lack of efficacy). Data were not adjusted for expected variability such as socioeconomic factors (eg, access to medication), setting of administration (self vs HCP office, e.g, UST was likely often administered in a HCP office which may affect persistency), and geographic region.

Conclusion: Persistence of UST therapy in psoriatic disease was significantly better than anti-TNF therapies in biologic- naïve and experienced PsO pts, with lower rates of stopping/switching and higher median days on therapy.

Relationship Between Psoriatic Arthritis Severity, Duration, and Comorbidities. Stacy Tanner[1], Molly McFadden[2], Daniel Clegg[3] and Jessica Walsh[1]. [1]University of Utah, Salt Lake City, UT, [2]University of Utah, SLC, UT, [3]University of Utah Medical Ctr, Salt Lake City, UT.

Background/Purpose: People with psoriatic arthritis (PsA) have an increased risk for several comorbidities that negatively impact quality of life and survival. Defining the relationships between comorbidities and PsA characteristics may help identify subsets of PsA patients at high risk for comorbidities. The objective of this study was to determine if PsA severity or duration associated with the number of comorbidities.

Methods: This was a cross-sectional study of PsA participants in the Utah Psoriasis Initiative Arthritis Registry. Data were collected with questionnaires, interviews, and examinations between 1/22/2010 and 4/21/2014. Disease severity measures included a functional assessment [BASFI], a quality of life instrument [Psoriatic Arthritis Quality of Life (PsAQOL)], and disease activity measures, [68 tender joint count (TJC), 66 swollen joint count (SJC), BASDAI, Physician Global, Patient Global, and a cutaneous physician global assessment multiplied by the body surface area (PGAxBSA)]. To analyze PsA duration, a proportional odds logistic regression model was used to test for an association between PsA duration (<5 years, 5–15 years, and >15 years) and number of comorbidities (0, 1–2, or ≥3 comorbidities), after adjustment for age, gender, race, body mass index (BMI), TJC, and SJC. For severity assessments, a general linear model was used to test for differences in the mean score for each instrument after adjusting for age, gender, race, BMI, and PsA duration.

Results: PsA was diagnosed and phenotyped by a rheumatologist in 190 participants (Table 1). Compared to participants with PsA duration 15 years had higher mean numbers of comorbidities, but the difference was statistically significant only in the group with duration of 5–15 years (Table 2). The number of comorbidities was associated with BASFI (Table 3), but not with measures of quality of life or disease activity (data not shown).

Conclusion: Higher numbers of comorbidities may be associated with longer PsA duration and functional limitations as measured by BASFI. Anticipated analysis of a larger number of participants in a multi-center comorbidity project will provide a better understanding of the relationships between comorbidities, PsA duration, and PsA severity.

Musculoskeletal Complaints and Psoriatic Arthritis in Primary Care Patients with Psoriasis. M.C. Karreman[1], A.E.a.M. Weel[1], M. van der Ven[1], M. Vis[1], I. Tchetverikov[2], T.E.C. Nijsten[1], J.M.W. Hazes[1] and J.J. Luime[1]. [1]Erasmus University Medical Center, Rotterdam, Netherlands, [2]Albert Schweitzer Hospital, Dordrecht, Netherlands.

Background/Purpose: Musculoskeletal complaints(MSC) account for about 10% of the General Practitioner (GP) consultations[1], in a small percentage the underlying disease is psoriatic arthritis (PsA). Evidence suggests that when a psoriasis patient visits the GP with MSCs, GP's don't always link the existing psoriasis with the MSC limiting early referral of PsA. This may be explained by the limited knowledge about the frequency of MSC and PsA in psoriasis patients in primary care.[2,3]

Our objective was to estimate the prevalence of MSC and PsA in primary care patients with psoriasis.

Methods: We conducted a cross-sectional study in adult primary care patients with psoriasis. Patients were identified from GP records by ICPC code S91 for psoriasis. Responding patients reporting pain in joints, entheses or the lower back were checked on eligibility by a telephone interview and invited for clinical evaluation. Ultrasonoghraphy (US) of the enthesis was performed if a patient had at least one tender enthesis (LEI/MASES) by an independent trained examiner. Patients were referred to a rheumatologist if clinical evaluation suggested the presence of arthritis or axial disease or ultrasonography of the enthesis showed positive Power Doppler(PD) signal. A PsA case was defined by opinion of the rheumatologist or fulfilling the CASPAR criteria with PD signal in an enthesis on US.

Results: 649 psoriasis (PsO) patients from 97 GPs were invited (Table 1). Of the 1722 responders (65.0 %), 890(51.7%) were willing to participate of which 672 (75.5%) reported MSC at the telephone interview (TI) and 527 were clinically evaluated. 145 out of the 672 patients dropped out between TI and the visit, mostly without giving any reason. The 832 patients that did not want to participate reported MSC in 19.7% (n=164) on the reply slip.

Among the 527 patients we found 54 new cases of PsA(10.2%): inflammatory arthritis (n=11), axial disease (n=3), enthesitis (n=37; confirmed by US) and a combination of symptoms(n=3). Another 62 existing PsA patients were identified. This led to a prevalence of 6.7% among PsO patients that responded (n=1722) and 4.4% among all invited PsO patients (n=2649) assuming no additional cases in the non-responders (Table 2).

Conclusion: Among psoriasis patients with musculoskeletal complaints in primary care (n=836) the prevalence of PsA is estimated to be 13.8% (95%CI 11.6%-16.2%), which would decrease to 4.4% (95% CI 3.7%-5.2%) among all PsO patients if no additional cases would be observed in the non-responders. Besides 54 of the 116 cases (46.6%) hadn't been diagnosed before our study, this indicates underdiagnosis of PsA in primary care.

Table 2. Prevalence of PsA

	Prevalence (n = 116)	**Prevalence new cases (n = 54)**
Overall (n = 2649)	4.4 (3.7–5.2)	2.0 (1.6–2.7)
Responders (n = 1722)	6.7 (5.6–8.0)	3.1 (2.4–4.1)
Psoriasis patients with MSC (n = 836)	13.8 (11.6–16.2)	6.5 (5.0–8.3)

Numbers presented in % (95%CI)

Apremilast, an Oral Phosphodiesterase 4 Inhibitor, Is Associated with Long-Term (52-Week) Improvements in Enthesitis and Dactylitis in Patients with Psoriatic Arthritis: Results from a Phase 3, Randomized, Controlled Trial. Christopher J. Edwards[1], Jacob A. Aelion[2], Adewale O. Adebajo[3], Alan Kivitz[4], Paul Bird[5], ChiaChi Hu[6], Randall M. Stevens[6] and Alvin Wells[7]. [1]University Hospital Southampton, Southampton, United Kingdom, [2]West Tennessee Research Institute, Jackson, TN, [3]University of Sheffield, Sheffield, United Kingdom, [4]Altoona Arthritis & Osteoporosis Center, Duncansville, PA, [5]Combined Rheumatology Practice, Kogarah, Australia, [6]Celgene Corporation, Warren, NJ, [7]Rheumatology & Immunotherapy Center, Franklin, WI.

Background/Purpose: Apremilast (APR) is a phosphodiesterase 4 inhibitor that helps regulate the immune response that causes inflammation and skin disease associated with psoriatic arthritis (PsA). PALACE 4 compared

the efficacy and safety of APR with placebo (PBO) in patients with active PsA who were DMARD-naïve. We evaluated the impact of APR treatment over 52 weeks on enthesitis and dactylitis among PALACE 4 patients.

Methods: Patients were randomized (1:1:1) to PBO, APR 20 mg BID (APR20), or APR 30 mg BID (APR30). Patients whose swollen and tender joint counts had not improved by ≥20% at Week 16 were considered non-responders and were required to be re-randomized (1:1) to APR20 or APR30 if initially randomized to placebo, or continued on their initial apremilast dose. At Week 24, all remaining PBO patients were re-randomized to APR20 or APR30. The analysis comprises data from Weeks 0 to 52. Enthesitis was evaluated based on MASES (range 0–13), which indicates the number of painful entheses out of 13 entheses sites. The dactylitis count (range 0–20) is the number of digits (hands and feet) with dactylitis present; each digit is rated as 0 (no dactylitis) or 1 (dactylitis present).

Results: At Week 16, a significantly greater proportion of patients receiving APR20 or APR30 achieved the modified ACR20 response vs PBO (primary endpoint). In patients initially randomized to APR and with enthesitis (n=228) or dactylitis (n=173) at baseline, APR was associated with improvements in enthesitis and dactylitis over 52 weeks, as evidenced by reductions in MASES and dactylitis count. At Week 16, median percent changes in MASES were 0.0% (PBO), −20.0% (APR20; P=0.2948), and −50.0% (APR30; P=0.0008). In patients initially randomized to APR and completing 52 weeks, median percent changes in MASES were −66.7% (APR20) and −75% (APR30) (Table); 39.6% (APR20) and 45.9% (APR30) of patients achieved a score of 0, indicating no pain at any of the entheses assessed. Median percent changes in dactylitis count at Week 16 were −50.0% (PBO), −70.8% (APR20; P=0.0691), and −69.2% (APR30; P=0.1494). In patients initially randomized to APR and completing 52 weeks, both doses resulted in a median 100% decrease in the dactylitis count; a dactylitis count of 0 was achieved in 68.6% (APR20) and 68.8% (APR30) of patients. The most common adverse events reported during the PBO-controlled period were nausea (12.6%), diarrhea (9.4%), and headache (6.0%). The safety profile of APR for up to 52 weeks was similar to that observed with APR for up to 24 weeks of treatment (PBO-controlled period).

Conclusion: Among patients continuously treated with APR through 52 weeks, sustained improvements in both enthesitis and dactylitis were observed in patients with active PsA, who had enthesitis or dactylitis at baseline. APR demonstrated an acceptable safety profile and was generally well tolerated for up to 52 weeks.

Enthesitis and Dactylitis at Week 52 in Patients Receiving APR From Baseline

MASES*	APR20 n=91	APR30 n=85
Baseline, median	3.0	2.0
Median % change from baseline	−66.7	−75.0
Patients achieving score of 0, %	39.6	45.9
Dactylitis count$^{\mu}$	**n=70**	**n=64**
Baseline, median	2.0	2.5
Median % change from baseline	−100	−100
Patients achieving score of 0, %	68.6	68.8

The n represents the number of patients with a baseline value >0 and a value at Week 52. *MASES ranges from 0 to 13, with 0 indicating no pain at any assessed entheses and 13 indicating pain at all assessed entheses. $^{\mu}$Dactylitis count is the sum of all scores for each of the 20 digits, with each digit scored as 0=absence or 1=presence of dactylitis.

1573

Norwegian Psoriatic Arthritis Patients Are More Obese Than Rheumatoid Arthritis and Axial Spondyloarthropathy Patients. Brigitte Michelsen[1], Andreas P. Diamantopoulos[1], Arthur Kavanaugh[2] and Glenn Haugeberg[3]. [1]Hospital of Southern Norway Trust, Kristiansand, Norway, [2]University of California San Diego, La Jolla, CA, [3]University of Agder, Kristiansand, Norway.

Background/Purpose: Higher rates of obesity in psoriatic arthritis (PsA) compared to rheumatoid arthritis (RA) have been described. Obesity, C-reactive protein (CRP) and inflammatory arthritides itself are known risk factors for cardiovascular disease. Obesity is also shown to affect response to therapy in patients with inflammatory arthritis. This study aimed to compare BMI in RA, PsA and ax-SpA and additionally to examine for possible correlation between BMI and CRP in these diseases.

Methods: All the RA, PsA and ax-SpA patients that visited the out-patient clinic during the year 2013 were included. The RA patients had a diagnosis verified by the treating rheumatologist, the PsA patients all fulfilled the ClASsifcation for Psoriatic ARthritis (CASPAR) criteria and the ax-SpA patients all fulfilled the ASAS classification criteria for ax-SpA. BMI was calculated as the patient's weight in kilograms divided by height in meters, squared. CRP was assessed by turbidimetry (mg/L). The unadjusted analyses of BMI and CRP were performed using analyses of variance (ANOVA) with post hoc tests (Tuckey HSD; homogeneity of variance). The adjusted analyses were performed by use of a General Linear Model with adjustments for age, sex, smoking, years of education, disease duration and multiple comparisons (Bonferroni). Correlation analysis of BMI and CRP was performed by use of Spearman's rho.

Results: A total of 1045 RA, 351 PsA and 314 ax-SpA patients were included. Respectively, mean (SD) age was 62.9 (13.9), 55.2 (12.3), 48.2 (12.8) years, mean disease duration 12.5 (10.6), 9.9 (8.0), 13.2 (11.7) years, mean years of education 11.5 (3.6), 12.4 (3.6), 12.9 (3.5) years, percentages currently smoking 20.7, 18.6, 23.6 % and percentage females 68.0, 49.0 and 34.1%. In both unadjusted and adjusted analyses the PsA patients had significantly higher mean BMI compared to the RA and ax-SpA patients. The male PsA patients had significantly higher BMI than the RA and the ax-SpA patients in the unadjusted analyses, but this difference was only significant for the PsA patients compared to the RA patients in the adjusted analyses. For females the PsA patients had significantly higher BMI than the RA and the ax-SpA patients both in the unadjusted and in the adjusted analyses. There was only a significant correlation between BMI and CRP for females (rho=0.18, p<0.001).

	RA (n=1045)		PsA (n=351)		Ax-SpA (n=314)		p	
Unadjusted analyses BMI (SE) (kg/m^2)	25.9 (0.2)		27.7 (0.2)		26.4 (0.3)		**<0.001^a** 0.259^b **0.002^c**	
	Males (n=334)	**Females (n=711)**	**Males (n=179)**	**Females (n=172)**	**Males (n=207)**	**Females (n=107)**	**Males**	**Females**
	26.8 (0.4)	25.5 (0.2)	28.1 (0.3)	27.2 (0.4)	26.8 (0.3)	25.7 (0.5)	**0.023^a** 0.992^b **0.034^c**	**<0.001^a** 0.885^b **0.018^c**
	RA (n=1045)		**PsA (n=351)**		**Ax-SpA (n=314)**		**p**	
Adjusted analyses BMI (SE) (kg/m^2)	25.9 (0.2)		27.4 (0.3)		26.1 (0.3)		**<0.001^a** 1.000^b **0.002^c**	
	Males (n=334)	**Females (n=711)**	**Males (n=179)**	**Females (n=172)**	**Males (n=207)**	**Females (n=107)**	**Males**	**Females**
	26.7 (0.3)	25.5 (0.2)	28.1 (0.4)	27.1 (0.4)	27.1 (0.4)	25.6 (0.5)	**0.037^a** 1.000^b 0.194^c	**<0.001^a** 1.000^b **0.031^c**

a: RA - PsA, **b:** RA – ax-SpA, **c:** PsA - ax-SpA.

Conclusion: In our population of patients with inflammatory arthritides, PsA patients were significantly more obese than RA and ax-SpA patients. These differences were more pronounced for female patients. A weak correlation between CRP and BMI was found, but only for females. Both CRP and obesity are independent cardiovascular risk factors. Given the increased risk of cardiovascular events in inflammatory arthritides, obesity represents a potentially important modifiable risk factor.

University Students with Psoriatic Nail Changes Have a Greater Number of Tender Enthesial Points Than Those with Normal Nails. A Eftal Yucel, Melih Pamukcu, Elif Durukan, Busra Tosun, Berk Batman, Omer Ozkan and Anil Korcak. Baskent University Faculty of Medicine, Ankara, Turkey.

Background/Purpose: Nail pitting is present in about 10% of healthy adults, and more than 50% of patients with psoriatic arthritis. We believe that the prevalence of spondyloarthritis, especially psoriatic arthritis is higher than published in literature. Most of those patients are undiagnosed or diagnosed with different diseases. Enthesitis is the primary pathology of spondyloarthritis particularly psoriatic arthritis. It was suggested that enthesitis was an autoinflammatory lesion linking nail and joint involvement in psoriatic disease. Additionally, subclinical enthesopathy was detected more frequently

in patients with psoriatic arthritis than those with psoriasis. We hypothesized that individuals with psoriatic nail changes would have a larger magnitude of enthesitis than those with normal nails. To support this hypothesis, we aimed to determine the association between psoriatic nail changes and enthesitis as well as the frequencies of both.

Methods: We examined the hand nails of university students for psoriatic nail changes, including pitting, leukonychia, longitudinal and horizontal ridging, pitting, subungal hyperkeratosis, onycholysis, splinter hemorrhages, red spot and oil drop. All students underwent manual palpation of 14 enthesial sites (quadriceps to patella, patella to tibia, Achilles, plantar fascia, medial epicondyle, lateral epicondyle, supraspinatus) that were described in the Spondyloarthritis Research Consortium of Canada (SPARCC) Enthesitis Index. Additionally, tenderness of spinous processes of thoracic vertebrae and sacroiliac joints were recorded.

Results: Three hundred seventy-seven university students (240 female, 137 male) who are attending to the faculties of medicine (229 students) and of dentistry (148 students) were included in this study. Two hundred thirty two (61.6%) of 377 students had at least one psoriatic nail change. Less specific nail changes for psoriasis such as leukonychia, horizontal and longitudinal ridging were very common among the university students (Table 1). Pitting was observed in 52 (13.8%) students. Eighty-eight (23.3%) of 377 participants had at least one tender enthesial point. The most frequently affected enthesial site was supraspinatus insertion (Table 2). Students with pitting or any other psoriatic nail changes had a greater number of tender enthesial points than those with normal nails ($p=0.002$ and $p=0.006$, respectively).

Conclusion: Pitting was detected more frequently than published in the literature among university students and pitting or any other psoriatic nail changes correlated with tender enthesial points.

Table 1. Psoriatic nail changes in university students

Nail change	N (%)
Leukonychia	136 (36.1)
Horizontal ridging	62 (16.4)
Longitudinal ridging	58 (15.4)
Pitting	52 (13.8)
Subungal hyperkeratosis	19 (5.0)
Onycholysis	18 (4.8)
Splinter hemorrhages	6 (1.6)
Red spot	1 (0.3)
Oil drop	0 (0)

Table 2. Frequency of affected enthesial points in university students

Enthesial points	N (%)
Supraspinatus	55 (14.6)
Thoracic vertebrae	27 (7.2)
Sacroiliac joints	20 (5.3)
Lateral epicondyle	20 (5.3)
Medial epicondyle	18 (4.8)
Achilles	12 (3.2)
Quadriceps to patella	10 (2.7)
Patella to tibia	9 (2.4)
Plantar fascia	8 (2.1)

The Association Between Obesity and Disease Phenotype in Psoriatic Arthritis. Lihi Eder[1], Cheryl Rosen[2], Vinod Chandran[1] and Dafna D. Gladman[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Toronto, Toronto western Hospital, Toronto, ON.

Background/Purpose: Obesity is associated with an increased risk of developing psoriatic arthritis (PsA) in patients with psoriasis. This study aimed to assess whether obesity is associated with a distinct phenotype of PsA.

Methods: A cross-sectional analysis was performed among patients with early PsA (≤2 years from the diagnosis) from a large PsA clinic and compared them to patients with psoriasis alone (PsC). Patients with PsA met the CASPAR criteria. Patients with PsC were examined by a rheumatologist to exclude the presence of arthritis. The participants were assessed according to a standardized protocol. Demographic, clinical and radiographic information was retrieved from the clinic database. The primary predictor was Body Mass Index (BMI) at the first visit to the clinic that was classified to normal (BMI30). The association between BMI and clinical and radiographic outcomes was assessed using Cochran-Armitage and linear trend tests.

Results: A total of 305 early PsA and 498 PsC patients were analyzed. Higher BMI was associated with older age (years) at onset of PsA (Normal: 38 ± 14, Overweight: 44 ± 14, Obese: 47 ± 11, $p^{trend}<0.0001$) and psoriasis (Normal: 27 ± 17 years, Overweight: 29 ± 15, Obese: 33 ± 15, $p^{trend}=0.009$). A similar trend was observed in patients with psoriasis alone, higher BMI was associated with older age (years) at onset of psoriasis (Normal: 28 ± 16, Overweight: 39 ± 16, Obese: 32 ± 16, $p^{trend}=0.01$). In addition, a longer delay (years) from the onset of symptoms to the time of the diagnosis was found in overweight and obese patients (Normal: 2.8 ± 5.8, Overweight: 3.9 ± 10, Obese: 6 ± 9.4, $p=0.02$). No difference was observed in the pattern and severity of the skin, nail or joint manifestations across the three BMI groups. Patients with higher BMI were more likely to have new bone formation at the pelvic and heel entheses (each <0.001) however no difference was observed in the extent of radiographic erosive damage. The frequency of overweight and obesity was higher in PsA compared to psoriasis alone only among participants who were older than 40 years of age (Table 1) while no difference in BMI was observed among younger individuals.

Conclusion: Obesity may mark a distinct phenotype of PsA. Higher BMI is associated with older onset of PsA and psoriasis. This finding may suggest that obesity predisposes to late-onset psoriatic disease but has little role in the development of early onset disease.

The association between BMI and PsA vs. Psoriasis by age group

		BMI Category			
		Normal BMI<25	Overweight 25≥BMI>30	Obese BMI≥30	P value
Age ≤40	PsA(N=120)	45 (37.5%)	47 (39.2%)	28 (23.3%)	0.21
	PsC(N=184)	84 (45.7%)	63 (34.2%)	37 (20.1%)	
Age >40	PsA (n=185)	35 (18.9%)	64 (34.6%)	86 (46.5%)	0.0002
	PsC(N=314)	91 (29%)	129 (41.1%)	94 (29.9%)

Reversal of Damage in Psoriatic Arthritis. Amir Haddad[1], Ker-Ai Lee[2], Arane Thavaneswaran[1], Vinod Chandran[1], Richard J. Cook[2] and Dafna D. Gladman[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Waterloo, Waterloo, ON.

Background/Purpose: Psoriatic arthritis could lead to severe damage and disability. However, cases of improvement in joint damage over time have been reported in the literature. We aimed to determine the prevalence of damage reversal in a large cohort of patients with psoriatic arthritis and to identify predictors of this unique feature.

Methods: In a cohort of PsA patients established in 1978, radiographic assessments are made every two years with readings by at least 2 investigators. A consensus rating according the modified Steinbrocker scoring (mSS) method classifies each of 42 hand and foot joints on a 0–4 scale where grade 0=normal, 1= juxtaarticular osteopenia or soft tissue swelling, 2= erosion, 3= erosion and joint space narrowing and 4=total destruction. Reversal of damage was defined as a decrease in the total mSS confirmed on second reading. Disease characteristics of the study population were presented using descriptive statistics. A transitional multistate model was applied to investigate ratios of transition intensities in the Steinbrocker staging of each joint, with a working independence assumption used for joints within the same patient. A reversible Markov model was applied to investigate predictors for damage reversal and progression including age, sex, disease duration, the number of actively inflamed joints at baseline and treatment with MTX and biologics in the course of follow up.

Results: Of 537 PsA patients with baseline and at least 1 follow-up radiographs with all available data 56.2% were males, had a mean (SD) age of 43.7 (12.7) and disease duration of 7.0 (8.3) years. 32.4% and 66.9% were treated with DMARDs and biologics, respectively. 373 patients developed at least 1 damaged joint. 117/537 patients (21.8%) had evidence of reversal in damage in at least one joint. Of the20,307 assessed joints in 537 patients, 339 joints had improvement in damage, of whom the majority 213 out of 348 transitions were from mSS 2 to 1 and had an intensity score of 0.025 (0.022, 0.029) as apposed to the highest estimated progression rate of 0.061 (0.055, 0.067). 164 joint improvement occurred before treatment with biologics in 63

patients, of whom the majority 104/168 transitions were also from mSS 2 to 1. When analyzing the data on the 89,965 patient-joint assessments, treatment with biologics was a predictor for transition to a state of joint improvement (RR=2.25 (1.79,2.83) P 0.0001) and less for joint progression (RR=0.67 (0.61,0.74) P 0.0001).

Conclusion: A number of patients have reversal in damage (21.8%), which occurred in 1.7% of the assessed joints. Treatment with biologics is a predictor for joint improvement and less progression of damage. Transitions of joint improvement were observed also in patients not treated with biologics.

Disclosure: A. Haddad, None; **K. A. Lee**, None; **A. Thavaneswaran**, None; **V. Chandran**, None; **R. J. Cook**, None; **D. D. Gladman**, None.

1577

Value and Prediction of Minimal Disease Activity in Patients with Psoriatic Arthritis. Arthur Kavanaugh[1], Philip Mease[2], Laura C. Coates[3], Iain B. McInnes[4], Maja Hojnik[5], Alex Dorr[6], Ying Zhang[6], Benoit Guerette[6], Alan Friedman[6] and Dafna D. Gladman[7]. [1]University of California San Diego, La Jolla, CA, [2]Swedish Medical Center and University of Washington, Seattle, WA, [3]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [4]University of Glasgow, Glasgow, United Kingdom, [5]AbbVie, Ljubljana, Slovenia, [6]AbbVie, Inc., North Chicago, IL, [7]University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: The prediction of treatment outcomes based on early response could be useful in guiding decisions to adjust therapy. The objective was to determine if week (wk) 12 SJC and TJC, DAS28, CDAI and RAPID3 scores are predictive of achievement of a minimal disease activity (MDA) target at wk 24 in patients (pts) with Psoriatic Arthritis (PsA) and to evaluate patient-reported outcomes (PROs) associated with achieving MDA.

Methods: This post hoc analysis used pt data from ADEPT, a double blind randomized trial of adalimumab (ADA) versus placebo (PBO) in pts with moderate to severely active PsA and an inadequate response to NSAIDs. Pts who achieved MDA at wk 24 were termed as "achievers", while those who did not, were termed "non-achievers" (NAs). PROs studied in association with MDA were: quality of life by DLQI and SF-36 scores (total, physical and mental component summary scores (P/MCS)), and fatigue by FACIT scores. The following criteria at wk 12 were considered as possible predictors of achieving MDA at wk 24: tender joint count (TJC) of 28 and 78 joints and swollen joint count (SJC) of 28 and 76 joints, DAS28, CDAI and RAPID3. The likelihood of predicting achievement of wk 24 MDA was assessed by ROC-AUC analysis, negative and positive predictive values (N/PPV).

Results: At wk 24, 24/62 pts (38.7%) on ADA treatment, and 4/60 pts (6.7%) on PBO treatment achieved MDA. While radiographic progression was low, overall, in the ADEPT trial, achievers had no progression compared to mild progression in NAs, although this difference was not statistically significant (-0.31 ± 1.88 vs. 1.26 ± 5.93, $p= 0.201$). Achievers also had higher total SF-36 scores (81.6 ± 16.8 vs. 52.1 ± 21.2, $p<0.001$), SF-36 PCS (51.0 ± 7.2 vs. 35.0 ± 10.8, $p<0.001$) and FACIT scores (43.5 ± 10.6 vs. 30.5 ± 12.2, $p<0.05$). There was no difference in the SF-36 MCS and DLQI scores of achievers compared to that of NAs. MDA achievers had lower mean SJC 76, TJC 78, DAS28(CRP), RAPID3 and CDAI scores at wk 12 than NAs, and greater improvement from BL to wk 12 in mean SJC 76 and TJC 78 scores. Wk 12 DAS28, CDAI and RAPID3 all predicted wk 24 MDA with an AUC 0.94–0.96 (table); Wk 12 TJC was a slightly better predictor than wk 12 SJC, with 28 joint-counts having similar accuracy to 78 joint-counts. All of the criteria cut points, as determined by ROC analysis, had high NPV for wk 24 MDA (table).

Wk 12 criterion	Area under the Curve (CL)	ROC Threshold	PPV	NPV
TJC28	0.89 (0.83, 0.94)	1.00	0.60	0.95
TJC78	0.91 (0.86, 0.97)	3.00	0.61	0.96
SJC28	0.80 (0.72, 0.89)	3.00	0.46	0.98
SJC76	0.84 (0.76, 0.91)	4.00	0.46	0.94
DAS28 (CRP)	0.96 (0.92, 0.99)	2.84	0.75	0.97
CDAI	0.97 (0.94, 1.00)	10.00	0.80	0.97
RAPID3	0.95 (0.90, 1.00)	1.30	0.75	0.97

Conclusion: In pts with PsA, the achievement of MDA was associated with improvements in HRQoL, physical function and fatigue. Wk 12 composite scores such as CDAI or RAPID3 remission and DAS28(CRP) LDA, as well as SJC and TJC had good ability to predict the likelihood of achieving MDA at wk 24, with 28 joint counts being as informative as 78 joint counts in this analysis. These quick and convenient tools can be used to guide treatment decisions at an early timepoint.

Abatacept Improves Synovitis As Assessed By Magnetic Resonance Imaging (MRI) in Psoriatic Arthritis - Preliminary Analysis from a Single Centre, Placebo-Controlled, Crossover Study. Agnes Szentpetery[1], Eric J. Heffernan[1], Muhammad Haroon[2], Phil Gallagher[1], Anne-Marie Baker[1], Martina Cooney[1] and Oliver FitzGerald[1]. [1]St. Vincent's University Hospital, Dublin, Ireland, [2]Cork University Hospital, Cork, Ireland.

Background/Purpose: Abatacept is a soluble, fully human fusion protein which selectively inhibits T-cell activation via the CD80/CD86:CD28 co-stimulation pathway and decreases serum levels of inflammatory cytokines and proteins implicated in the pathogenesis of psoriatic arthritis (PsA). Improvement in skin psoriasis has been shown with abatacept treatment previously with greatest reduction in PASI using 3 mg/kg dose. It has been proposed that 10 mg/kg of abatacept, the approved dose for rheumatoid arthritis may be an effective treatment choice for PsA.

The objectives of the study were (1) to study both skin and joint-related clinical outcomes prior to and 6 months after introducing abatacept treatment in PsA; (2) to investigate MRI changes of an inflamed knee joint over time in PsA patients on abatacept.

Methods: Biological treatment-naïve PsA patients fulfilling the CASPAR criteria with active disease for >3 months (>3 swollen and >3 tender joints) with clinical synovitis of a knee and the presence of a psoriatic skin lesion were enrolled to the study. Patients were randomised to receive abatacept 3mg/kg or placebo infusion on day 1, 15 and 29; thereafter abatacept 10mg/kg was administered every 28 days for 5 months. A stable dose of methotrexate (7.5–25 mgs/week) for >3 months prior to randomization was the only concomitant DMARD permitted in the study. Ga-enhanced MRI of the same involved knee was performed at baseline, 2 and 6 months and scored using the PsAMRIS method by one consultant radiologist. For the semi-quantitative method each knee was divided into 4 anatomical regions; medial (MED) and lateral (LAT) parapateller recesses, intercondylar notch (ICN) and suprapatellar pouch (SPP). A synovitis score ranging from 0 to 3 was assigned to each region and then added for a total synovitis score (MRS) ranging from 0 to 12 per knee.

Results: 15 patients (8 female/ 7 male) with mean age of 44.6 (±14.6) years were randomized by June 2014. Four (27%) patients were on methotrexate, the remainder did not receive any DMARDs during the study.

At baseline, mean DAS28-ESR was 4.9 ± 1 and DAS28-CRP was 4.7 ± 0.9. Median PASI, HAQ, PsAQol and DLQI were 3.8 (0–16.2), 1 (0–2.125), 10 (1–17) and 3 (0–27) respectively. Mean synovitis scores at MED, LAT, ICN and SPP regions were 2.07 (±0.9), 2.21 (±0.9), 1.4 (±0.8) and 1.85(±1) respectively at baseline, mean MRS was 7.6 (±3.4).

As per EULAR criteria 87.5 % of patients responded to the treatment at 6 months and 75% were good responders. Patients' TJC68, SJC68, duration of morning stiffness, global health score, DAS28-ESR, DAS28-CRP, HAQ and PsAQol reduced significantly at 6 months compared to baseline. Median MRS decreased over the study period and was significantly lower at 6 months compared to baseline ($p=0.016$).

Conclusion: Six months of abatacept treatment reduced synovitis scores as assessed by MRI. The results of our study suggest that 10 mg/kg of abatacept is a potent treatment option in PsA.

Change in Weight from Baseline with Apremilast, an Oral Phosphodiesterase 4 Inhibitor: Pooled Results from 3 Phase 3, Randomized, Controlled Trials. Philip Mease[1], Dafna D. Gladman[2], Arthur Kavanaugh[3], Adewale O. Adebajo[4], Juan Gomez-Reino[5], Jurgen Wollenhaupt[6], Georg A. Schett[7], Kamal Shah[8], ChiaChi Hu[8], Randall M. Stevens[8], Christopher Edwards[9] and Charles A. Birbara[10]. [1]Swedish Medical Center, Seattle, WA, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, [3]University of California San Diego, La Jolla, CA, [4]University of Sheffield, Sheffield, United Kingdom, [5]Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain, [6]Schön-Klinik, Hamburg, Germany, [7]University of Erlangen-Nuremberg, Erlangen, Germany, [8]Celgene Corporation, Warren, NJ, [9]NIHR Wellcome Trust Clinical Research Facility, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, [10]University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Apremilast (APR) is a PDE4 inhibitor that helps regulate the immune response. PALACE 1, 2, and 3 assessed the efficacy and safety of APR in pts with active psoriatic arthritis (PsA) despite prior DMARDs and/or biologics. We evaluated weight change from BL in PALACE 1, 2, and 3.

Methods: Pts were randomized (1:1:1) to PBO, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by baseline DMARD use (yes/no). Patients whose swollen and tender joint counts had not improved by ≥20% at Wk 16 were considered non-responders and were required to be re-randomized (1:1) to APR20 or APR30 if initially randomized to placebo, or continued on their initial apremilast dose. At Wk 24, all remaining PBO patients were re-randomized to APR20 or APR30. The pooled analysis comprises data for the PBO-controlled period (Wks 0 to 24) and the APR-exposure period (Wks 0 to ≥52) up to cutoff date, 3/1/2013.

Results: During the PBO-controlled period, 495 pts received PBO, 501 received APR20, and 497 received APR30. At cutoff, 720 pts had received APR20 and 721 had received APR30. At BL, mean/median weight was 86.4/84.0 (PBO), 86.1/84.0 (APR20), and 84.5/83.0 (APR30) kg. Weight decrease was spontaneously reported as an AE in a small proportion of pts during both the PBO-controlled (PBO: 0.4%; APR20: 1.0%; APR30: 1.4%) and APR exposure (APR20: 1.4%; APR30: 1.8%) periods. No pts in the PBO-controlled and 2/1,441 pts (APR20: 1; APR30: 1) in the APR-exposure period discontinued due to weight decrease. An additional analysis using observed weight measurements collected at selected visits assessed changes from BL weight. In the PBO-controlled period, most pts remained within 5% of their BL weight (PBO: 92.1%; APR20: 83.5%; APR30: 86.4%). A larger proportion of APR-treated pts experienced any weight loss (APR20: 57.9%; APR30: 56.8%) vs PBO (40.1%). Weight loss >5% was experienced by 3.9% (PBO), 12.7% (APR20), and 11.0% (APR30) (Table). At the end of the PBO-controlled period, mean/median weight change from BL was 0.09/0.0 (PBO), -1.16/-0.60 (APR20), and -0.96/-0.60 (APR30) kg. In the APR-exposure period (Wks 0 to ≥52), most pts remained within 5% of BL weight (APR20: 77.0%; APR30: 75.8%); 57.3% (APR20) and 57.1% (APR30) experienced weight loss. Weight loss did not lead to any overt medical sequelae or manifestations through the APR-exposure period. In an analysis to determine the relationship between weight loss and GI AEs, weight loss was not associated with diarrhea or nausea/vomiting.

Conclusion: APR was associated with a small rate of weight decrease reported as an AE. The incidence of observed weight loss was higher with APR vs PBO, although most pts remained within 5% of their BL weight. Observed weight loss did not appear to be dose-dependent and did not lead to overt clinical sequelae. No association between weight loss and incidence of other AEs, including GI AEs, was apparent.

% Change From BL to End of Period, n (%)	PBO-Controlled Period* Wks 0 to 24			APR-Exposure Period§ Wks 0 to ≥52	
	PBO n = 491 Pt-yrs = 168.1	APR20 n = 496 Pt-yrs = 211.6	APR30 n = 491 Pt-yrs = 209.5	APR20 n = 708 Pt-yrs = 677.7	APR30 n = 711 Pt-yrs = 687.2
<−5%	19 (3.9)	63 (12.7)	54 (11.0)	116 (16.4)	126 (17.7)
≥−5% to <0%	178 (36.3)	224 (45.2)	225 (45.8)	290 (41.0)	280 (39.4)
0%	67 (13.6)	45 (9.1)	57 (11.6)	51 (7.2)	53 (7.5)
>0% to ≤5%	207 (42.2)	145 (29.2)	142 (28.9)	204 (28.8)	206 (29.0)
>5%	20 (4.1)	19 (3.8)	13 (2.6)	47 (6.6)	46 (6.5)

*PBO-controlled period includes all data through Wk 16 for pts initially assigned to PBO who escaped, and data through Wk 24 for all other pts.
§Includes all pts who received ≥1 dose of APR, regardless of when APR was initiated, with all available data up to the cutoff of 3/1/2013.

Gender Differences in Disease Activity Accounting for Inflammatory Biomarkers in a Psoriatic Arthritis Routine Care Cohort. Soumya M. Reddy[1], Jose U. Scher[1], Christopher Swearingen[2] and Yusuf Yazici[1]. [1]New York University School of Medicine, New York, NY, [2]University of Arkansas, Little Rock, AR.

Background/Purpose: Routine care cohorts can provide data about patient phenotypes, treatment choices and responses in the 'real world'. Studying the true impact of psoriatic arthritis (PsA) and the role of available treatment options for patients seen in routine clinical environment may help physicians care for these patients more effectively. The purpose of this study is to evaluate patient characteristics, disease activity, treatment choices and responses in a routine care psoriatic arthritis cohort in a university setting.

Methods: New York University PsA Cohort, established in 2005, as part of the Arthritis Registry Monitoring Database and has been following patients with PsA prospectively as part of routine care. Clinical data is collected through MDHAQ (for function, pain, patient global assessment, fatigue, patient self report joint counts, physician global assessment), and 28 tender and swollen joint counts. In addition, medication history, demographic data and selected laboratory tests are collected. We analyzed patient characteristics and medication use along with disease activity in our cohort.

Results: 497 patients were seen to date (48.5% female, mean age 49.6 yr, disease duration 11.9yr, years of education 16.4, White 64%, Black 1.6%, Hispanic 6.8%, Other 27.6%). No differences were noted between males and females. However, female patients with PsA had significantly worse function (2.0 vs 1.6, p=0.005), pain (4.9 vs 4.2, p=0.006), pt global (4.6 vs 3.7, p=0.001), RAPID 3 scores (11.6 vs 9.4, p=0.001), fatigue (4.6 vs 3.2, p<0.001), and pt reported joint counts by RADAI (9.9 vs 7.9, p=0.017) compared to males with the disease. After adjusting for age and education; pain, patient global scores, RAPID3 scores, and fatigue remained significant. No differences in ESR and duration of morning stiffness were noted. Although CRP levels were overall lower in females, the values were not statistically significant (4.6 vs 9.9, p=0.060). Differences in RAPID3 scores between females and males remained significant after adjusting for CRP and disease duration. (Table 1) No differences were noted in the proportion of patients treated with prednisone, DMARDs, biologics, or combination DMARD/Biologics among females and males.

Table 1: Differences in RAPID3 in Females and Males Adjusting for Disease Duration and CRP

	Female	Male	
RAPID3 adjusting for Duration	12.0 (0.6)	10.0 (0.5)	**0.011**
RAPID3 adjusting for CRP	11.8 (0.7)	9.9 (0.6)	**0.021**

Conclusion: In this routine care cohort of almost 500 PsA patients, females had worse disease activity compared to males, despite receiving the same type of medication. The differences persisted even after adjusting for disease duration and CRP levels. The reasons for this seemingly undertreatment among females needs further study.

Inflammatory Back Pain in Psoriasis and Psoriatic Arthritis Is Suggestive of Undiagnosed Spondyloarthropathies. Majed Khraishi[1], Heather Jones[2] and Annette Szumski[2]. [1]Memorial University of Newfoundland, St. John's, NF, [2]Pfizer Inc., Collegeville, PA.

Background/Purpose: Patients with psoriasis (Ps) and/or psoriatic arthritis (PsA) may have clinical features suggestive of axial skeletal abnormalities and should be assessed for the presence of spondyloarthropathies (SpA). The purpose of this post-hoc analysis from 2 clinical trials is to assess the prevalence, demographic and disease characteristics of Ps patients with and without PsA with MRI evidence of sacroiliitis (SI) abnormalities or axial involvement. We also investigated how common screening questionnaires perform in detecting inflammatory back pain (IBP) that may be suggestive of other SpAs.

Methods: From the PRESTA trial, the medical history of patients with Ps and PsA were analyzed for axial involvement. From the PREPARE trial, patients with Ps who had baseline MRIs were analyzed and characteristics assessed between those with and without MRI evidence of SI abnormalities (SI +/–). Results of the PASQi and TOPAS questionnaires in the PREPARE trial were assessed for patient-reported IBP and compared with their respective patients' SI findings to determine possible trends in each IBP +/– and SI +/– group.

Results: In the PRESTA trial, 747 patients with Ps/PsA were evaluated and 41% (304/747) had axial involvement. Those with axial involvement had a longer duration of PsA, greater Ps-affected BSA, and higher PASI, DAS28, TJC, SJC, HAQ, EQ-5D scores than those without (Table 1). A total of 186 Ps patients with MRIs were analyzed in the PREPARE trial; 47% were SI+ who tended to be older with a lower Ps-affected BSA than those who were SI– (Table 1). Only 43% (38/88) of Ps patients who were SI+ were also diagnosed with PsA. IBP was evaluated in 128 patients from the PREPARE trial with the PASQi and ToPAS questionnaires of which 45% (57/128) were IBP+ and 33% (19/57) of those were also SI+. These patients tended to be older, have a higher Ps-affected BSA, and higher PASI compared to 38 patients who were IBP+/SI– (Table 2). 58% (41/71) of patients who were IBP– were SI+ and have the fewest number of females versus the 2 IBP+ groups. 47% (9/19) of Ps patients who were IBP+/SI+ did not have PsA.

Conclusion: Patients with spinal involvement tended to be older with longer disease duration. Patients with Ps, with or without a PsA diagnosis, may exhibit clinical features of SpAs. These findings suggest that patients should be evaluated carefully for the presence of entities such as non-radiographic axial SpA and radiologic evidence of SI regardless of PsA diagnosis or reported IBP. The PASQi and TOPAS questionnaires detected 1/3 of Ps/PsA patients who reported IBP were SI+ which may be useful in detecting the possibility of SpAs.

Table 1: Baseline characteristics for patients with and without SI and axial involvement in the PRESTA and PREPARE and clinical trials

Cumulative Inflammatory Burden Is Independently Associated with Increased Arterial Stiffness in Patients with Psoriatic Arthritis. Jiayun Shen[1], Qing Shang[1], Ying Ying Leung[2], Edmund Li[1], Tracy Y. Zhu[1] and Lai-Shan Tam[1]. [1]Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore.

Background/Purpose: Patients with psoriatic arthritis (PsA) are at increased risk of cardiovascular (CV) morbidity compared with the general population, probably as a result of chronic inflammation interacting with traditional CV risk factors. Two cross-sectional studies (n<30) had reported increased arterial stiffness in patients with PsA. However, these studies were unable to assess the effect of inflammation over time. In this study, we examined whether the cumulative inflammatory burden over time is associated with an increase in arterial stiffness in a prospective cohort of PsA patients.

Methods: 72 PsA patients were followed up for 6.6±0.17 years. Clinical and cardiovascular risk factors were assessed at baseline and last visit. Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were measured at each clinic visit. Cumulative inflammatory burden was represented by the cumulative averages of repeated measures of ESR and CRP, which were calculated from the area under the curve divided by the follow up time. Arterial stiffness was measured at the last visit as brachial-ankle pulse wave velocity (PWV) by a dedicated tonometry system (Non-Invasive Vascular Profile Device VP-2000; Omron Healthcare, Bannockburn, Illinois, USA). The correlation among PWV and cumulative averages of ESR (ca-ESR) and CRP (ca-CRP), as well as baseline and last follow up clinical parameters and CV risk factors were explored.

Results: The median PWV at last follow up was 1463 (interquartile range: 1331–1676) cm/s. There was a significant correlation between PWV and ca-ESR (Spearman's rho: 0.390, p =0.001). PsA patients were divided into 2 groups based on whether their PWV value is ≥ (High PWV group) or st hr, p =0.005], There was also a trend suggestive of an increased ca-CRP in the High PWV group (p =0.087). The High PWV group were older, had a longer disease duration and a higher prevalence of having Framingham 10-year CV risk score (FRS) of 10% at baseline. The High PWV group also had a lower body mass index (BMI), higher systolic blood pressure (SBP) and damage joint count at PWV assessment. In the regression analysis, high ca-ESR (defined as ≥75th percentile: 37 mm/1st hr) was associated with a higher likelihood of being in the High PWV group [OR: 5.969 (95% confidence interval: 1.361–26.176), p =0.018, adjusted for baseline clinical parameters and CV risk factors; and 5.140 (1.162–22.734), p=0.031, adjusted for last visit parameters, respectively].

Conclusion: Cumulative inflammatory burden was associated with increased arterial stiffness in patients with PsA even after adjustment for CV risk factors, emphasizing the important role of chronic inflammation in accelerating the development of CV risks in PsA patients.

Table 1. Clinical features at baseline and last follow up in patients with high and low PWV group

	Baseline			Last follow up		
	Low PWV	High PWV	*p* value	Low PWV	High PWV	*p* value

Screening for Psa in Primary Care Psoriasis Patients with Musculoskeletal Complaints with PEST, PASE & Earp. M.C. Karreman[1], A.E.a.M. Weel[1], M. van der Ven[1], M. Vis[1], I. Tchetverikov[2], M. Wakkee[1], T.E.C. Nijsten[1], J.M.W. Hazes[1] and J.J. Luime[1]. [1]Erasmus University Medical Center, Rotterdam, Netherlands, [2]Albert Schweitzer Hospital, Dordrecht, Netherlands.

Background/Purpose: Psoriatic Arthritis (PsA) is a progressive inflammatory joint disease that can lead to severe joint damage. New treatment strategies can be very effective in early stages of the disease. This requires early recognition of the symptoms to be PsA. Several screening tools have been developed to enhance early recognition. However, most were developed in secondary care, while early recognition should ideally take place in primary care.

Our objective was to evaluate the screening performance of the PEST, PASE and EARP to identify psoriatic arthritis among primary care psoriasis patients with recurrent spells musculoskeletal complaints (MSC).

Methods: We conducted a cross-sectional study in adult primary care patients with psoriasis who reported recurrent spells MSC. Patients were selected by ICPC code S91 for psoriasis and the presence of recurrent spells of MSC (joints, enthesis or low back pain) was determined by telephone interview. Patients completed the PEST, PASE & EARP questionnaires before clinical evaluation by a trained research nurse. Assessments included PASI, LEI/MASES, 66/68-joint count and the presence of nail-psoriasis. If clinical evaluation suggested the presence of arthritis or axial disease, or ultrasound (US) evaluation showed Power Doppler signal in an enthesis, patients were referred to the rheumatologist.

A PsA case was defined by fulfilling the CASPAR criteria. Sensitivity and specificity were determined for the PEST and EARP cut off ≥3 and PASE cut off ≥44 as well as ≥47.

Results: 480 psoriasis patients participated with a mean±SD age of 55.9±13.9 years and 50.8% being male (Table 1). We found 54 new cases of PsA (10.2%). Among the cases the skin was slightly more affected and more tender joints were reported, while nails were affected evenly compared to the non-cases. The PEST had a true positive rate of 63.0% and a false positive rate of 30.0%, for the EARP this was 87.0% and 67.1%. The PASE had a true positive rate of 62.9% and a false positive rate of 45.6% at the cut off of ≥44 and 55.6% and 36.4% at the cut off of≥47 (Table 2).

Conclusion: Modest sensitivity was observed for the PEST and PASE with an acceptable false positive rate for the PEST, while the EARP had high true and false positive rate, which is undesirable for screening. The performance of all screening tools was lower than previously reported in secondary care settings.

Table 1 Characteristics of the study population (n=480)

	Non-Cases (n=426)	Cases (n=54)

Evaluation of the Patient Acceptable Symptom State in Patients with Psoriatic Arthritis. Pinar Cetin[1], Dilek Solmaz[2], Murat Keser[1], Ismail Sari[1], Merih Birlik[1], Nurullah Akkoc[1] and Fatos Onen[1]. [1]Dokuz Eylul University School of Medicine, Izmir, Turkey, [2]Namik Kemal University School of Medicine, Tekirdag, Turkey.

Background/Purpose: The Patient Acceptable Symptom State (PASS), a single-question outcome, has been defined as an absolute level of patient well-being, which was used in the evaluation of treatment efficacy in several rheumatologic diseases. We aimed to evaluate the acceptability, reliability and discriminant capacity of the PASS in patients with psoriatic arthritis (PsA).

Methods: This study included PsA patients who fulfilled the CASPAR criteria. Disease activity was assessed in the patients by using "Composite Psoriatic Disease Activity Index (CPDAI)", "Bath Ankylosing Spondylitis Disease Activity Index (BASDAI)", "Patient Global" and "Disease Activity Score (DAS) 28". "Psoriasis Area Severity Index (PASI)" was used for the measurement of severity of *psoriasis* and high-sensitive C-reactive protein (hs-CRP) level was measured as laboratory parameter of disease activity. Other follow-up parameters such as "Bath Ankylosing Spondylitis Functional Index (BASFI)","Health Assessment Questionnaire (HAQ)" and "Ankylosing Spondylitis Quality of Life (ASQoL)" were also included in the study. PASS (+) and PASS (–) groups were compared for demographic features and disease severity parameters using Mann-Whitney U test. Stepwise logistic regression was used to assess contributors to PASS. PASS thresholds were estimated with receiver operating characteristic (ROC) curve analysis. Cut off levels targeting the 75th percentile of the cumulative distribution were also determined.

Results: There were 101 PsA patients (34 male, 67 female; mean age: 46.8 ± 11.5). Eighteen (17.8%) patients had predominantly axial disease, 52 (51.5%) had predominantly peripheral disease and 31 (30.7%) had mixed symptoms. Thirty-four (33.6%) of 101 patients were in PASS. The patients with an acceptable status had significantly lower mean CPDAI, BASDAI, DAS28-CRP, ASQoL and patient global scores than the others (Table 1). The significant contributor to PASS was BASDAI (r:−0,343 Exp(B): 0.71; p<0.001). PASS (+) 75th percentile thresholds were 4.3 for BASDAI (sensivity:70.6%, specificity: 64%) and 4.0 for CPDAI (sensivity:76.5%, specificity: 54%).

Conclusion: PASS can be considered as a method in determination of PSA disease activity in the future.

Table 1. Clinical and demographic feautures of the PASS (+) and PASS (–) PSA patients

Presence of Swollen and Tender Joints in Patients Fulfilling Minimal Disease Activity Criteria. Josefina Marin[1], Maria L. Acosta Felquer[2], Leandro Ferreyra-Garrot[1], Santiago Ruta[3], Javier Rosa[1] and Enrique R. Soriano[4]. [1]Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Rheumatology Section, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [3]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [4]Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Argentina.

Background/Purpose: Minimal disease activity (MDA) is a composite measure created for patients with psoriatic arthritis (PsA) that encompasses many clinically important aspects of PsA: arthritis, psoriasis, enthesitis, pain, patient-assessed global disease activity, and physical function. A patient is considered to be in MDA if fulfills 5/7 criteria. In theory, a patient could be in MDA, but still have several tender and/or swollen joints.Objectives:1) To evaluate the number of patients fulfilling MDA criteria that still have several tender/swollen joints, and 2) To analyze the components of MDA that contribute most to prevent patients achieving MDA.

Methods: Consecutive patients with PsA (CASPAR criteria) were included, and all components of MDA score were assessed by a single experienced Rheumatologist. Patients were classified as in MDA if they fulfilled 5/7 criteria (tender joint count (TJC; 0–68) $\leq$ 1; swollen joint count (SJC; 0–66) $\leq$ 1; PASI $\leq$ 1 or BSA $\leq$ 3%; patient pain score on a visual analog scale (VAS; 0–100) $\leq$ 15; patient global assessment of disease activity (PaGA; VAS; 0–100) $\leq$ 20 mm; Health Assessment Questionnaire (HAQ; 0–3) $\leq$ 0.5; and tender entheseal points (0–13) $\leq$ 1). Percentage of patients with >= 2 tender and/or swollen joints within patients in MDA was calculated. We also calculated the percentage of patients not fulfilling each one of the criteria for those patients with 4 out of 7 MDA criteria.

Results: 83 patients were included. Patient's characteristics according to MDA status are shown in the table. Among the 41 patients fulfilling MDA criteria, only one patient (2.4 %) showed more than 2 tender joints (3 tender joints), and two other patients showed >=2 swollen joints (one patient two and one patient three swollen joints). Altogether 7.4 % of patients, fulfilling MDA criteria presented a clinically significant number of tender/swollen joints.Among patients fulfilling MDA criteria, only 24 % fulfilled all 7 criteria, and 32 % and 43% fulfilled 6 and 5 criteria respectively. Of those patients not in MDA status, 17 (40.5 %) fulfilled 4/7 criteria. Among those patients, the criteria more often not fulfilled were: patient pain score VAS $\leq$ 15= 100 %; PaGA VAS $\leq$ 20 mm =76.5 %; and PASI $\leq$ 1 = 65 %. Only 29 %, 18 %, 6% and 6 % did not fulfilled tender joint count, HAQ, swollen joint count and entheseal tenderness criteria, respectively.

Characteristics	MDA (n=41)	No MDA (n=42)	P value
Male sex (%)	23 (56)	21 (50)	0.578
Mean age yrs (SD)	55.6 (13.6)	51.2(14.3)	0.1528
Median months disease duration (IQR)	36 (12–96)	31.5 (10–48)	0.3460
Mean pain VAS mm (SD)	17.5(20.1)	52.7 (20.1)	<0.0001
Mean Patient Global Activity VAS mm (SD)	14 (18.2)	47.2 (21.2)	<0.0001
Mean swollen joint count (SD)	0.3 (0.6)	2.7 (2.6)	<0.0001
Mean tender joint count (SD)	0.3 (0.6)	1.8 (2.6)	0.0003

Mean tender entheseal points (SD)	0.12 (0.33)	0.49 (0.87)	0.0121
Mean PASI (SD)	1.5 (2.2)	3.8 (4.8)	0.0074
Mean DAS28 (SD)	2.3 (0.71)	3.7 (1.1)	<0.0001
Mean CPDAI (SD)	2.1 (1)	4 (1.9)	<0.0001
Mean ESR (SD)	19.8 (14.2)	24.8 (19.5)	0.1737
Number with >=2 tender joint count (%)	1 (2.4)	27 (64.3)	<0.0001
Number with >=2 swollen joint count (%)	2 (4.9)	18 (43)	0.002

Conclusion: Although possible in theory, only a minority of patients fulfilling MDA criteria present a clinically significant number of tender and/or swollen joints. In patients that were close to fulfill MDA criteria patient's VAS scores (pain and disease activity) and PASI were the most frequent reasons to fall short to MDA status.

Quantitative Proteomic Analysis of Synovial Fluid and Skin Identifies Putative Psoriatic Arthritis Biomarkers. Daniela Cretu[1], Kun Liang[2], Dafna D. Gladman[3], Eleftherios Diamandis[4] and Vinod Chandran[3]. [1]University of Toronto, Mount Sinai Hospital, Ontario, Canada, Toronto, ON, [2]University of Waterloo, Waterloo, ON, [3]University of Toronto, Toronto Western Hospital, Toronto, ON, [4]University of Toronto, Toronto, ON.

Background/Purpose: Psoriatic arthritis (PsA) is a unique form of arthritis occurring in 30% of psoriasis patients. There is a high prevalence of undiagnosed PsA in psoriasis patients; therefore identifying soluble biomarkers for PsA will help in screening psoriasis patients for appropriate referral to a rheumatologist. Potential PsA biomarkers likely originate in sites of inflammation, such as inflamed joints and skin, and subsequently enter systemic circulation. We hypothesize that quantitative proteomic analysis of synovial fluid (SF) and skin obtained from PsA patients, willgenerate a comprehensive list of proteins specific to PsA, facilitating the identification of potential PsA screening biomarkers.

Methods: SF was obtained from swollen knee joints of 10 PsA patients, and age/sex matched early osteoarthritis (OA) controls. Likewise, skin biopsies were obtained from involved and uninvolved skin of 10 PsA, and 10 age/sex matched psoriasis patients. Using strong cation exchange chromatography, followed by tandem mass spectrometry, we characterized the proteomes of pooled SF and pooled skin samples. Extracted ion current (XIC) intensities were used to calculate protein abundance ratios, and utilized to classify upregulated proteins. Selected reaction monitoring (SRM) assays were developed to quantify these potential PsA markers in individual patient samples. Identified markers were subsequently measured in serum samples from 33 PsA and 15 PsC patients, using commercially available or in-house developed enzyme-linked immunosorbent assays (ELISA).

Results: We quantified a total of 443 and 1922 proteins in SF and skin extracts, respectively, but only 17 proteins represented upregulated proteins in PsA SF, while 47 proteins were specifically elevated in PsA-derived skin. SRM validation confirmed that 12 and 8 proteins were indeed elevated in an independent set of PsA SF and involved PsA skin, respectively. Based on the fold change between PsA and controls, the associated P-values, and the cellular localization, we ranked the proteins, and selected the following putative markers for validation in the serum - S100A9, M2BP, CD5L, MMP3, CRP, EPO, POSTN, and ITGB5. Only ITGB5, (1.2$\pm$0.5 compared to 0.8$\pm$0.6; P=0.007), M2BP (553.0$\pm$150.9 compared to 453.0$\pm$115.0; P=0.027), EPO (19.6$\pm$12.3 compared to 13.7$\pm$12.2;P=0.035), and MMP3 (3.4$\pm$3.4 compared to 1.8$\pm$1.1; P=0.046) were significantly elevated in PsA serum compared to PsC.

Conclusion: Proteomic analysis of PsA SF and skin has identified 20 candidate biomarkers, and 4 of these have been confirmed in serum following a small-scale validation. In the future, these markers must be validated in a larger and independent sample cohort, in order to identify their clinical utility in PsA patients. Additionally, these proteins may also uncover aspects of PsA pathobiology that are currently unknown.

The Economic Impact of Psoriatic Arthritis in Toronto, Ontario. Dafna D. Gladman, Melissa Yu, Michal Bohdanowicz, Arane Thavaneswaran and Vinod Chandran. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: This study aimed to quantify the direct and indirect costs of psoriatic arthritis (PsA) at a single center in Toronto, Ontario and to assess whether these costs varied with respect to socioeconomic status.

Methods: Participants were identified from the Psoriatic Arthritis Clinic at Toronto Western Hospital in Toronto, Ontario. To be included in the study, patients fulfilled the Classification criteria for Psoriatic Arthritis (CASPAR) and attended the clinic for $\geq$ 1 year. Participants were excluded if they were <18 years old or if they were non-English speakers.

Consented participants completed a questionnaire that included healthcare utilization, out-of-pocket expenses, and productivity losses in the preceding 12 months. **Results** from this survey were supplemented with a chart review of participant's prescription medication in the past year, demographic information, socioeconomic characteristics, and disease severity measures.

Direct costs were estimated according to the Ontario Drug Benefit Formulary, Ontario Health Insurance Plan, or industry averages. Indirect costs were estimated from productivity losses due to sick days or early

retirement. Age, sex, education, marital status, employment status and household income were used as indicators of socioeconomic status. The relationship between cost of PsA and socioeconomic status was assessed using the Kruskal-Wallis test, with significance of $p < 0.05$.

Results: Of the 188 patients included in the study, the mean annual direct cost of PsA was $15,802 per patient, of which $5,499 and $10,219 accounted for non-pharmacologic and pharmacologic costs, respectively. Women, unemployed, and lower income patients had significantly higher non-pharmacologic costs, whereas patients under the age of 65 had significantly higher pharmacologic costs compared to their counterparts. Thirteen % of patients were unemployed due to psoriatic arthritis, with an average 3.3 years of lost employment.

Conclusion: This study showed that PsA generates a substantial economic burden for patients in Toronto, Ontario. This burden is composed of healthcare resource consumption as well as productivity loss due to early retirement. Furthermore, age, sex, employment status, and income are all significantly associated with the direct cost of PsA. Information from this study will help to estimate the cost-effectiveness of new PsA medications and to allocate healthcare resources more effectively to certain socioeconomic groups in need.

Resistance Training in Patients with Psoriatic Arthritis Improves Function, Disease Activity and Quality of Life. Diego Roger Silva[1], Fabio Jennings[1], Emilia Moreira[1] and Jamil Natour[2]. [1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [2]Escola Paulista de Medicina/ Universidade Federal de São Paulo, São Paulo, Brazil.

Background/Purpose: Psoriatic arthritis (PSA) is a chronic inflammatory arthritis, defined as the association of inflammatory arthropathy and skin psoriasis. The literature is still very scarce with regard to non-pharmacological treatments for patients with PSA, specially physical exercise.

Objective: The aim of this study was to assess the effectiveness of resistance training in improving functional capacity, muscle strength, quality of life and disease activity in patients with PSA.

Methods: Forty-one patients aged between 18 and 65 years with diagnosis of psoriatic arthritis were selected to this study.,The patients were randomized into two groups: intervention group and control group. The intervention group (IG) underwent resistance exercise twice a week, for twelve weeks. The control group remained on the waiting list with the conventional drug therapy. The outcome measurements were: BASFI and HAQ-S for functional capacity, one maximum-repetition test (! RM) for strength (1RM), SF-36 questionnaire for general quality of life; and BASDAI and DAS-28 for disease activity. The evaluations were done by a blinded evaluator at baseline (T0), 6 weeks (T6) and 12 weeks (T12) after the beginning of the study.

Results: At baseline the groups were homogeneous regarding clinical and demographic characteristics. The IG significantly improved functional capacity measured by HAQ-S and disease activity measured by BASDAI, compared to CG, at week 12. Regarding quality of life, the IG improved the domains "pain" and "general health status" compared to CG. ($p < 0.05$). There was improvement in muscular strength in almost all exercises in IG, except in the exercise for biceps. In the CG, the improvement in strength was observed only on "crucifix" (bilateral) and "leg extension" (bilateral) exercises. However, there was statistical differences between groups only on exercise "leg extension" (right side) in favor of IG.

Conclusion: Resistance training is effective in improving physical capacity, disease activity and quality of life of patients with psoriatic arthritis. The clinical improvements were not coupled to significant changes in muscular strength.

Risk of Opportunistic Infection and Herpes Zoster Infection in a Psoriasis/Psoriatic Arthritis Cohort. Kevin L. Winthrop[1], Lang Chen[2], John Baddley[2], Allison Taylor[2], Benjamin Chan[3], Huifeng Yun[4], Sarah Siegel[1] and Jeffrey R. Curtis[5]. [1]Oregon Health & Science University, Portland, OR, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Oregon Health and Science University, Portland, OR, [4]University of Alabama at Birmingham School of Public Health, Birmingham, AL, [5]The University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Psoriasis/Psoriatic arthritis (PsO/PsA) often requires treatment with systemic agents. Some of these agents are associated with infectious adverse events. Few studies have described the background incidence of opportunistic infections (OIs) or Herpes zoster (HZ) infections, in a cohort of PsO/PsA patients.

Methods: We used the US Medicare dataset from 2006–2011 to identify a large cohort of PsA and PsO patients. We defined PsA and PsO as those with >1 rheumatologist-diagnosis code for psoriatic arthritis (ICD 9 696.0) or >1 dermatologist-diagnosis code for psoriasis (ICD 9 696.1) respectively, followed by a prescription for etanercept (ETA), cyclosporine (CIC), ustekinumab (UST), adalimumab (ADA), methotrexate (MTX) or ultraviolet light (UV) therapy. Patients had at least 6 months of continuous Medicare enrollment prior to the first date of exposure to these therapies. We excluded patients with organ transplantation, human immunodeficiency virus infection, advanced kidney and liver disease, or cancer with a 183-day period prior to cohort inception. Pairwise propensity scores (PS) were calculated and used to control for potential differences between comparator treatments. We used validated-claims based algorithms to identify OIs and HZ events among exposure groups. Patient exposures were censored at time of serious infection, death, end of study, loss of coverage, or 90 days following end of treatment exposure whichever came first. For OIs and for HZ, we calculated crude incidence rates in all exposure groups, and used Cox-proportional hazard regression models to calculate hazard ratios for these outcomes between exposure groups while adjusting for PS quintile.

Results: We identified 10,261 PsA individuals and 31,052 PsO individuals. Of the PsA cohort, there were fewer than 11 OI infections yielding an overall incidence rate of 1.5 (95% CI: 0.7–3.0) per 1,000 py, while the PsO cohort also had fewer than 11 OI infections with an overall incidence rate of 1.5 (95% CI: 0.6–3.0) per 1,000 py. For HZ, there were 82 HZ infections in the PsA cohort yielding an overall incidence rate of 16.1 (95% CI: 12.8–20.0) per 1,000 py, with the incidence rate ranging from 13.5 (95% CI: 4.3, 41.7) per 1,000 py for the UV therapy group to 20.0 (95% CI: 13.3–30.2) per 1,000 py for the ETA group. Of the PsO cohort, there were fewer than 391 HF infections with an overall incidence rate of 13.0 (95% CI: 11.8, 14.4) per 1,000 py. The incidence rate ranged from 11.1 (95% CI: 7.4–16.7) per 1,000 py for the CIC group to 14.3 (95% CI: 2.2–16.7) per 1,000 py for the MTX group. Rates of HZ infection were similar by exposure groups, but were higher than rates found in rheumatoid arthritis patients of the same age. For both the PsA and PsO cohorts, there were no significant associations by treatment type for either OI or the HZ infection, even when compared to the UV therapy group.

Conclusion: Among Medicare enrollees with PsA or PsO, biologic treatments were not associated with an increased risk of either OIs or HZ compared to non-biologic treatment (e.g. UV light).

Apremilast, an Oral Phosphodiesterase 4 Inhibitor, Is Associated with Long-Term (104-Week) Improvements in Patients with Psoriatic Arthritis: Results from a Phase 3, Randomized, Controlled Trial. Arthur Kavanaugh[1], Adewale O. Adebajo[2], Dafna D. Gladman[3], Juan J. Gomez-Reino[4], Stephan Hall[5], Eric Lespessailles[6], Philip Mease[7], Georg A. Schett[8], ChiaChi Hu[9], Randall M. Stevens[9] and Jürgen Wollenhaupt[10]. [1]University of California San Diego, La Jolla, CA, [2]University of Sheffield, Sheffield, United Kingdom, [3]University of Toronto, Toronto Western Hospital, Toronto, ON, [4]Hospital Clinico Universitario, Santiago, Spain, [5]Cabrini Health and Monash University, Melbourne, Australia, [6]University of Orléans, Orléans, France, [7]Swedish Medical Center and University of Washington, Seattle, WA, [8]University of Erlangen-Nuremberg, Erlangen, Germany, [9]Celgene Corporation, Warren, NJ, [10]Schön Klinik Hamburg Eilbek, Hamburg, Germany.

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor that may modify the immune response, has been shown effective in psoriatic arthritis (PsA). PALACE 1 compared the efficacy and safety of APR with placebo in patients with active PsA despite prior conventional DMARDs and/or biologics, including biologic failures.

Methods: Patients were randomized (1:1:1) to receive placebo, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by baseline

DMARD use (yes/no). Patients whose swollen and tender joint counts (SJC and TJC) had not improved by ≥20% at Week 16 were considered non-responders and were required to be re-randomized (1:1) to APR20 or APR30 if they were initially randomized to placebo, or continued on their initial apremilast dose. At Week 24, all remaining placebo patients were re-randomized to APR20 or APR30. Double-blind APR treatment continued to Week 52; patients could continue to receive apremilast during an active treatment, long-term phase of up to 4 years, for a total follow-up of up to 5 years. Efficacy in patients randomized to apremilast at baseline and with evaluable data at Week 52 and Week 104 is described herein (analysis: as observed).

Results: 504 patients were randomized and received ≥1 dose of study medication (placebo: n=168; APR20: n=168; APR30: n=168). At Week 52, modified ACR20 response was achieved by 63.0% and 54.6% of patients continually treated with APR20 or APR30 from baseline, respectively. Among patients who were randomized to APR at baseline, 97 APR20 and 101 APR30 patients remained in the study and completed evaluations at Week 104. Approximately 80% of patients who completed year 1 were maintained on therapy at year 2. In patients receiving APR from baseline, improvements were sustained over 104 weeks for multiple endpoints (Table), including (1) modified ACR20/ACR50/ACR70 of 61.3%/29.8%/16.0% (APR20) and 66.3%/35.6%/19.8%, respectively (APR30); (2) median percent change in SJC/TJC of −88.9%/−80.5% (APR20) and −87.5%/−76.7% (APR30); (3) mean change in Health Assessment Questionnaire-Disability Index (HAQ-DI) of −0.33 (APR20) and −0.43 (APR30), and greater than 50% achieving minimal important differences ≥0.30; (4) mean change in 28-joint count Disease Activity Score (DAS-28) of −1.61 (APR20) and −1.83 (APR30); and (5) achievement of DAS <2.6 in 35.1% (APR20) and 38.6% (APR30) of patients. Consistent results were demonstrated in patients randomized to placebo at baseline and re-randomized to APR20 or APR30 at Week 16 or 24 who completed Week 104. No new safety signals were observed with treatment through 104 weeks.

Conclusion: Over 104 weeks, APR demonstrated sustained clinically meaningful improvements in the signs and symptoms of PsA, physical function, and associated skin symptoms. ACR 20 response at Week 104 was 66% for APR 30. APR continued to demonstrate an acceptable safety profile and was generally well tolerated.

Outcomes at Week 52 and Week 104 (Data as Observed)

	Week 52		Week 104	
	APR20 n = 120*	APR30 n= 132*	APR20 n= 97*	APR30 n= 101*
ACR20, n/m (%)	75/119 (63.0)	71/130 (54.6)	57/93 (61.3)	67/101 (66.3)
ACR50, n/m (%)	29/117 (24.8)	32/130 (24.6)	28/94 (29.8)	36/101 (35.6)
ACR70, n/m (%)	18/117 (15.4)	18/130 (13.8)	15/94 (16.0)	20/101 (19.8)
SJC, median % change	−78.8	−77.8	−88.9	−87.5
TJC, median % change	−69.2	−62.5	−80.5	−76.7
HAQ-DI (0–3), mean change	−0.37	−0.32	−0.33	−0.43
HAQ-DI MCID, ≥0.30§, n/m (%)	55/120 (45.8)	59/132 (44.7)	50/97 (51.5)	55/101 (54.5)
DAS-28 (CRP), mean change	−1.40	−1.31	−1.61	−1.83
DAS-28 (CRP), <2.6, n/m (%)	39/120 (32.5)	30/129 (23.3)	34/97 (35.1)	39/101 (38.6)
PASI-50, n/m (%)	28/53 (52.8)	41/68 (60.3)	22/41 (53.7)	29/53 (54.7)
PASI-75, n/m (%)	13/53 (24.5)	25/68 (36.8)	15/41 (36.6)	16/53 (30.2)

n/m = number of responders/number of patients with sufficient data for evaluation.
*The n reflects the number of patients who were randomized to APR 20 BID (APR 20) and APR 30 mg BID (APR30) at baseline and had data available at the specific time point; actual number of patients available for each endpoint may vary.
§Pre-specified MCID threshold, based on the literature (Mease PJ, et al. *Ann Rheum Dis.* 2004;63[Suppl 1]:391) at the time of protocol and analysis.

1591

Exploring the Association of Serum Paraoxonase and Arylesterase Activities with Cardiovascular Risk in Psoriasis and Psoriatic Arthritis.
M. Elaine Husni[1], Danielle Brennan[1], WH Wilson Tang[2] and Stanley Hazen[2]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]CCF, Cleveland, OH.

Background/Purpose: Psoriatic diseases are systemic inflammatory joint and skin disorders associated with increased cardiovascular (CV) morbidity. Paraoxonase (PON) and Arylesterase (ARYL) are antioxidant enzymatic proteins associated with High Density Lipoproteins (HDL). These levels have been associated with providing systemic protection against HDL and LDL lipid peroxidation and promoting the atheroprotective properties. Previously reports show PON/ARYL levels are significantly reduced in RA and SLE. While it is known that the risk for CV disease is elevated in patients with psoriatic disease relative to the general population, we believe this is the first report between serum PON/Aryl levels and risk of coronary heart disease (CHD) using Framingham risk score (FRS) in Psoriasis (PsO) and Psoriatic Arthritis (PsA) patients. We sought to compare the prevalence of FRS and the levels of related biomarkers in patients with PsO and PsA.

Methods: We performed a cross sectional study of 289 patients (age 49(+/−13.2), 51% males) with PsO and PsA from our Cardiometabolic Outcome Measures in Psoriatic Arthritis Study (COMPASS), a longitudinal cohort with a focus on cardiovascular health from 2011–2014. Baseline serum PON/ARYL levels were obtained from our cohort (N = 238, PsA 57%, PsO, 43%). The disease cohorts were each further subdivided into 3 groups based on their FRS; FRS <10% (low risk, PsA/PsO n=111/76), 10–20% (intermediate risk, PsA/PsO n=17/23) and FRS ≥ 20% (high risk group, PsA/PsO n=8/3), respectively. Analysis of variance (ANOVA) was used to compare mean serum levels across FRS categories (Kruskal-Wallis for comparison of medians). Odds ratios (OR) and 95% confidence interval from logistic regression were computed to show the association of PON/Aryl levels to increased CV risk (FRS ≥ 20%). P values < 0.05 are considered statistically significant.

Results: A statistically significant inverse relationship between the mean levels of serum Aryl activity (126.8 ± 29.0, 117.9 ± 37.3, 86.6 ± 19.4 μmol/min/mL, p = 0.001) and the levels of increasing CHD risk were found in PsA patients. A similarly strong inverse relationship between serum PON activity (median: 667.0, 544.0, 268.0 nmol/min/mL, P = 0.051) and increasing levels of CHD risk also existed in the PsA population. There was no significant relationship between both PON (p=0.45) and Aryl (p=0.19) compared to FRS in the PsO population.

Baseline PON and Aryl were significantly associated with FRS≥20% (natural-log transformed PON OR: 0.19 (0.05, 0.69), p=0.01; Aryl OR: 0.95 (0.92, 0.98), p=0.002). No significant associations with PON/Aryl and increased CV risk were found within the PsO population.

Conclusion: Exposure of increased burden of inflammation (PsA>PsO>controls) is associated with more severe CV risk in patients with PsA. This association may be mediated by novel biomarkers for dysfunctional HDL. The stronger relationship between FRS and PON/Aryl activity levels in the PsA patients is hypothesized to be due to the greater level of systemic inflammatory disease and oxidative stress. Given the early onset of PsA (before the age of 40), this test can potentially provide an incremental benefit to assess CV risk.

1592

Ability of Clinical Variables to Predict Radiographic Damage in Psoriatic Arthritis.
Vinod Chandran[1], Arane Thavaneswaran[1], Richard J. Cook[2] and Dafna D. Gladman[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Waterloo, Waterloo, ON.

Background/Purpose: Psoriatic Arthritis (PsA) is an inflammatory arthritis associated with psoriasis that leads to progressive joint damage. Biomarkers in addition to clinical features may help stratify patients with PsA at high risk of joint damage so that they may be aggressively treated. Our

purpose was to determine the predictive value of clinical features to predict joint damage in PsA.

Methods: The study was conducted in a large prospective cohort of patients with PsA who are assessed according to a standard protocol that includes detailed clinical evaluation every 6 months and radiographic evaluation every 2 years. Patients who had at least 2 radiographs were included in this study. Radiographic joint damage progression was defined as increase in the count of radiographically damaged joints between 1st and 2nd radiographic assessment in any of the following joints- wrists, MCP, PIP, DIP, MTPs and 1st IP of toes (total 42 joints). The following clinical variables at the time of first radiographic assessment were evaluated as predictors- age, sex, age at diagnosis of psoriasis and PsA, duration of psoriasis and PsA, PASI, active, swollen, clinically damaged and radiographically damaged joint count, dactylitis, presence of axial disease, ESR, SF-36, HAQ, NSAID, DMARD and biologic use at baseline, HLA-B*27 and HLA-C*6. Univariate followed by multivariate models were developed to determine association of clinical variables with radiographic damage progression. ROC curves were constructed using variables found to be significantly associated with radiographic progression.

Results: 656 (380 males) with a mean age of 43 years, age at onset of psoriasis 28 years and of PsA 37 years were included. At the time of the first radiograph these patients had 11active, 5 swollen, 9 clinically damage, 4 radiographically damaged joints. The ESR was 24 mm/hr and PASI score 5. 33% had dactylitis and 45% had evidence of axial disease. 17% were HLA-B*27 and 32% HLA-C*06 positive. Their SF-36 PCS was 36.5 and HAQ 0.8. In univariate analyses older age, age at diagnosis of psoriasis, duration of psoriasis and PsA, active, swollen, clinically damaged and radiographically damaged joint counts, dactylitis, axial arthritis, ESR, HAQ and treatment with DMARDs were associated with radiographic progression ($p<0.05$). The predictors independently associated with radiographic progression in a multivariate reduced model are shown in Table 1. The area under the curve of the ROC curves was 0.71.

Table 1: Predictors of radiographic damage progression in a multivariate reduced model

Predictors	OR (95% CI)	P value
Age (1 year increase)	1.01 (1.004, 1.02)	0.001
Active joint count	1.01 (1.001, 1.02)	0.04
Clinically damaged joint count	0.98 (0.97, 0.998)	0.03
Radiographically damage joint count	1.16 (1.14, 1.19)	<0.0001
Axial arthritis	1.19 (1.001, 1.42)	0.05
Dactylitis	1.49 (1.25, 1.78)	<0.0001

Conclusion: Clinical features have only a fair ability to discriminate patients who have radiographic joint damage progression in PsA. Therefore, identifying biomarkers that predict joint damage is an important research question.

Neutrophil-Lymphocyte Ratio As a Marker of Disease Activity in Psoriatic Arthritis. Vinod Chandran, Arane Thavaneswaran and Dafna D. Gladman. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory arthritis associated with psoriasis. There are few biomarkers for disease activity in PsA. Traditional acute phase reactants are elevated only in about 50% of patients with active PsA. Neutrophil-Lymphocyte Ratio (NLR) has been recently shown to be a marker of inflammation with prognostic value in inflammatory, cardiovascular and malignant diseases. We therefore evaluated NLR as a marker of disease activity in patients with PsA.

Methods: The study was conducted in a large PsA cohort were patients are seen accordingly to a standard protocol that includes clinical and laboratory assessment. Swollen joint count (SJC) and PASI score were used as measures of disease activity in PsA at baseline. NLR was calculated from the neutrophil and lymphocyte count obtained from a complete blood count done at the time of clinic assessment. Pearson correlation between NLR and disease activity markers (SJC, PASI) and traditional acute phase reactants [ESR, haemoglobin (Hb), platelet count] were investigated. The association between ESR, Hb, platelet count and NLR with SJC and PASI score was determined using univariate and multivariate linear regression. Since the NLR was not normally distributed, lognormal transformation was done.

Results: 1130 (631 males) with a mean age of 45 years, age at onset of psoriasis 29 years and of PsA 38 years were included. At the time of the first assessment these patients had 11 active, 5 swollen and 8 clinically damaged joints and the PASI score was 5.3. The mean ESR was 23 mm/hr, Hb 139 g/dL, platelet count 286,000/microL and NLR 3.2. The NLR significantly correlated with SJC ($r=0.12$, $p<0.0001$), PASI ($r=0.15$, $p<0.0001$), ESR ($r=0.24$, $p<0.0001$), Hb ($r=-0.18$, $p<0.0001$) and platelet count ($r=0.15$, $p<0.0001$). Multivariate linear regression analysis showed that NLR (β 0.16, $p = 0.04$) and ESR (β 0.11, $p = 0.003$) were independently associated with SJC. Similarly, multivariate linear regression analysis showed that NLR (β 0.41, $p = <0.0001$) and ESR (β 0.11, $p = 0.007$) were independently associated with PASI score.

Conclusion: NLR has a potential as a marker of disease activity in PsA independent of traditional acute phase reactants. Further evaluation to determine threshold of abnormal values in the context of psoriatic disease, as well as prognostic value in predicting joint damage and cardiovascular disease is required.

Persistence of Low Disease Activity after Tumor Necrosis Factor Inhibitor Withdrawal in Patients with Psoriatic Arthritis. Doquyen H. Huynh[1], Carol J. Etzel[2], Vanessa Cox[3], Philip Mease[4] and Arthur Kavanaugh[5]. [1]UC San Diego School of Medicine, San Diego, CA, [2]Corrona, LLC., Southborough, MA, [3]CORRONA, Inc, Southborough, MA, [4]CORRONA, Seattle, WA, [5]UCSD School of Medicine, La Jolla, CA.

Background/Purpose: The increased use of tumor necrosis factor inhibitors (TNFi) has improved clinical outcomes for psoriatic arthritis (PsA) patients and made low disease activity (LDA) and remission viable treatment goals. Due to factors such as pharmacoeconomic considerations, concern for long term side effects, and patient preferences, there has been increasing interest in the possibility that TNFi may be discontinued by patients achieving remission or LDA, with maintenance of clinical benefit. The purpose of this study is to determine the duration of clinical benefit among PsA patients discontinuing TNFi while in LDA, and to identify patient characteristics and disease related factors that may be associated with prolonged clinical benefit.

Methods: An observational cohort study of PsA patients in the CORRONA registry who discontinued TNFi use after achieving LDA. LDA was defined as CDAI $\leq$ 10 and skin psoriasis physician global assessment $\leq$ 20/100. Patients were considered to have lost clinical benefit if: 1) increase in CDAI to $>$ 10; 2) increase in skin assessment to $>$20; or 3) increase in concomitant DMARD or prednisone doses or start of DMARD, prednisone, or biologic agents. Clinical data were collected at baseline (the time of TNFi discontinuation) and at loss of clinical benefit or the last clinic visit. Kaplan Meier analyses were used to estimate duration of clinical benefit. Both univariable and multivariable Cox proportional hazard analyses were used to evaluate characteristics associated with duration of benefit.

Results: Of 5945 PsA patients in CORRONA, 325 discontinued TNFi while in LDA and had follow up data available. Mean age was 52.6 years, mean BMI 30.1, mean duration of PsA 9.8 years, and 51.9% were female. 52.6% of patients discontinued their 1st TNFi, and 31.1% discontinued their 2nd TNFi. Mean duration of TNFi use was 1.5 years. 53.5% used TNFi as monotherapy, 42.2% used concomitant MTX; 29% took low dose prednisone. 146 patients lost clinical benefit, due to: increased CDAI (31.5%), initiation or increase in DMARD (32.2%), TNFi restart (6.8%), initiation or increase in prednisone (9.6%) or worsening skin disease (15.8%). The median time to loss of benefit was 29.2 months. 179 patients still had persistent benefit at their last clinic visit. Patients with higher disease activity at TNFi discontinuation had increased risk of losing clinical benefit (hazard ratios [HR] for: CDAI $>$ 3.2 vs $<$3.2 - HR 1.43 ($p = 0.032$), patient global assessment $>$ 5 vs $<$ 5/10 - HR 1.7 ($p= 0.007$), moderate vs low DAS - HR 1.65 ($p = 0.017$). Interestingly smokers had significantly higher risk for loss of benefit (HR vs non-smokers 1.76; $p= 0.027$) in both univariable and multivariable analysis. Number of TNFi used and overweight or obese status did not significantly affect loss of benefit.

Conclusion: PsA patients who achieve LDA on treatment may maintain clinical benefit after discontinuation of TNFi. Patients with higher disease activity at the time of discontinuation and smokers may have less success at stopping therapy.

Economic Evaluation of Sequencing Strategies in the Treatment of Psoriatic Arthritis in the United States. Thomas Tencer[1], Zoe Clancy[1], Helene Cawston[2], Sandrine Cure[3] and Frank Zhang[1]. [1]Celgene Corporation, Warren, NJ, [2]OptumInsight, Nanterre, France, [3]OptumInsight, Uxbridge, United Kingdom.

Background/Purpose: In the treatment of psoriatic arthritis (PsA), switching between alternative biologic treatments is common. A cost-effectiveness model was developed to assess the impact of placing apremilast, a new oral treatment, before biologics in PsA patients who had failed conventional disease-modifying antirheumatic drug therapy, from a U.S. payer perspective.

Methods: A lifetime Markov state transition cohort model was developed to compare 2 treatment sequences in the base-case: apremilast followed by adalimumab followed by etanercept vs. adalimumab followed by etanercept. Patients who failed etanercept were assumed to receive best supportive care (BSC) as the last line of treatment. Response to therapy was assessed using the Psoriatic Arthritis Response Criteria (PsARC) at the end of the clinical trial periods, ranging from 12 to 16 weeks depending on drug. Non-responders moved to the next line of therapy. A 16.5% annual dropout rate was assumed for each drug. Treatment efficacy inputs were obtained from a meta-analysis and trial results. Drug costs were sourced from 2013 Wholesale Acquisition Costs prices, and a 3% annual discount rate was applied to costs and quality-adjusted life-years (QALYs). Apremilast was assumed to be priced at a discount to biologics. Utilities were estimated from the Health Assessment Questionnaire and Psoriasis Area and Severity Index response using a previously published regression equation.

Results: The apremilast arm provided an additional 2.53 years with a PsARC response and an additional 0.78 QALYs. Total time spent on the biologics was reduced by 0.34 years and time spent in BSC was reduced by 2.85 years. Under base-case assumptions, placing apremilast before biologics was found to be the dominant strategy (costs reduced by $28,794). Sensitivity analyses indicated that several parameters (e.g., cost of BSC and baseline utility) influence the incremental cost-effectiveness ratio. Similar results were obtained with different biologic drugs in the sequence.

Conclusion: Placing apremilast before biologics is a cost-saving strategy in the treatment of PsA.

Clinical Characteristics and Outcome of Golimumab Treatment Differs Between Bio-naïve and Patients Previously Exposed to Biologicals. Nationwide Results on Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA), Ankylosing Spondylitis (AS) and Other Spondylarthritidies (SpA). Saedis Saevarsdottir[1], Michele Santacatterina[2], Carl Turesson[3], Helena Forsblad[4], Lennart Jacobsson[4] and Staffan Lindblad[2]. [1]Rheumatology Unit, Department of Medicine, Karolinska institutet and Karolinska University Hospital, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]Section of Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, [4]The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.

Background/Purpose: Golimumab is a TNF inhibiting biological drug that was approved in Sweden in 2010 for the treatment of RA, PsA and AS. Our previous analyses have demonstrated similar drug adherence as for other TNF-inhibitors and better adherence in bio-naïve patients (Saevarsdottir S et al, ACR 2013). Given that, the aim of the current study in an updated dataset with longer follow-up time, was to investigate the differences in clinical characteristics and drug survival probability between golimumab treated patients that were bio-naïve compared to those previously exposed to biologicals, separately for patients with RA, PsA, AS as well as other SpA.

Methods: Data were retrieved for all patients initiating golimumab treatment in 2010–2013 from the nationwide SRQ register. A survival analysis (Kaplan Meier) was performed over 24 months with right censoring and log-rank test of equality across strata.

Results: Of 2106 patients initiating golimumab treatment during the study period, 849 (40%) had RA, 454 (22%) PsA, 303 (14%) AS, 242 (12%) SpA and 258 (12%) had other diagnoses. The proportions of women in RA/PsA/AS/SpA patient groups were 78%/50%/29%/55%, respectively; and their median age at baseline was 54/48/42/40 years. In patients with RA/PsA/AS/SpA, the proportions receiving golimumab as the first biological treatment were 48%/46%/42%/40%; and the proportions receiving concurrent disease-modifying anti-rheumatic drugs (DMARDs) were 76%/64%/32%/47%.

Several baseline characteristics differed between bio-naïve patients (0) and those previously exposed to biological treatment (1–2 or 3+ biologic drugs, see Table 1, parameters showing significant difference in each disease are mentioned below). Bio-naïve patients were less likely to have concurrent treatment with DMARDs (PsA, AS), prednisolone (all) and NSAID (all); and they reported lower HAQ (RA, PsA, SpA), DAS28 (RA, PsA), inflammatory markers (CRP/ESR: RA, SpA), VAS-global health (RA, PsA, SpA) and VAS-pain (RA) at baseline. Furthermore, bio-naïve were more likely to be male (RA, PsA), older (RA, PsA, AS) and with short disease duration (RA, AS, SpA).

The drug survival probability over 24 months was also higher in bio-naïve patients (RA, AS, trend for PsA but less so for SpA).

Conclusion: In this real-life nationwide cohort, patients starting golimumab as their first biologic were treated with co-medication to a lesser extent, but had more favorable prognostic factors, and better drug survival over two years compared to those previously treated with other biologics. Patterns were similar for the various rheumatologic diseases treated with golimumab. It is of major importance to take previous biologic exposure into account when evaluating new biologics in observational studies.

Work Productivity Improvement Associated with Apremilast, an Oral Phosphodiesterase 4 Inhibitor, in Patients with Psoriatic Arthritis: Results of a Phase 3, Randomized, Controlled Trial. Frank Zhang[1], Thomas Tencer[1], Stan Li[1] and Vibeke Strand[2]. [1]Celgene Corporation, Warren, NJ, [2]Biopharmaceutical Consultant, Portola Valley, CA.

Background/Purpose: Apremilast (APR) is an oral phosphodiesterase 4 inhibitor that helps regulate the aberrant immune response that causes the joint symptoms, systemic inflammation, and skin disease associated with psoriatic arthritis (PsA). The Work Limitations Questionnaire (WLQ) measures the degree to which employed individuals are experiencing limitations on the job due to their health problems, as well as health-related productivity loss. The PALACE 1

study compared the efficacy and safety of APR with placebo in patients with active PsA despite prior or concurrent conventional disease-modifying anti-rheumatic drugs (DMARDs) and/or prior biologics. The objective of the current analysis was to assess the effect of APR on work productivity and work limitations of employed patients in the PALACE 1 study.

Methods: Patients were randomized (1:1:1) to receive placebo, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by baseline DMARD use (yes/no). Treatment efficacy was assessed at Week 16 based on the intent-to-treat population. Employed patients completed the WLQ, a 25-item questionnaire that assesses the impact of chronic health conditions on work performance and productivity, at baseline and Week 16. Work limitations were categorized into 4 domains, which were then used to calculate the WLQ index: physical demands (PDS), mental demands (MDS), time management demands (TMS), output demands (ODS). Improvement in the WLQ index, and its 4 domains, is represented by a negative change from baseline. Improvement in work productivity is represented by a positive improvement in percentage of productivity loss.

Results: 504 patients were randomized (mean age: 50.4 years; 49.4%: male). Of these 261 who were both employed and completed at least 1 component of the WLQ were analyzed. At Week 16, APR20 and APR30, vs. placebo, were associated with a greater mean change from baseline in PDS (−5.58 and −6.24 vs. −2.14), MDS (−2.22 and −5.18 vs. 1.15), TMS (−4.03 and −8.76 vs. −4.25), and ODS (−5.92 and −10.3 vs. −1.34), resulting in a greater mean improvement in the WLQ index (−0.01 and −0.03 vs. 0.00), which corresponds to a higher median percent improvement of productivity loss (18.9% and 24.7% vs. −3.7%). Higher productivity improvements were also observed among APR20 and APR30 ACR20 responders at Week 16—PDS (−11.8 and −7.61), MDS (−8.56 and −11.0), TMS (−7.88 and −15.8), and ODS (−10.6 and −20.1), respectively—resulting in a higher mean improvement in the WLQ index (−0.03 and −0.05, respectively), which corresponds to a higher median percent improvement in work productivity (57.9% and 46.8%), respectively.

Conclusion: APR20 and APR30 increased work productivity and improved work limitations among patients active PsA who were not adequately controlled with prior or concurrent conventional DMARDs and/or prior biologics.

Serum Fetuin-a, Intercellular Adhesion Molecule -1 and Interleukin -18 Levels in Ankylosing Spondylitis and Psoriatic Arthritis. Hanna Przepiera-Bedzak[1], Katarzyna Fischer[2] and Marek Brzosko[1]. [1]Department of Rheumatology and Internal Diseases Pomeranian Medical University in Szczecin, Szczecin, Poland, [2]Independent Laboratory of Rheumatic Diagnostics, Pomeranian Medical University in Szczecin, Szczecin, Poland.

Background/Purpose: In recent years, increased incidences of metabolic disorders have been observed in patients with systemic inflammatory rheumatic diseases. Fetuin-A, Intercellular Adhesion Molecule -1(ICAM-1) and interleukin 18 (IL-18) have been implicated in the endothelial function and atherosclerosis. The aim of the study was to investigate serum levels of fetuin-A, ICAM-1and IL-18 in ankylosing spondylitis (AS) and psoriatic arthritis (PsA).

Methods: We studied 123 patients and 20 controls. We recorded: age, sex, disease duration, treatment type, history of metabolic disorders, VAS, BASDAI, PASI, BMI, waist-hip ratio. Blood was collected for analysis of fetuin-A, ICAM-1, IL-18, IL-6, IL-23, VEGF and EGF by ELISA method. We assessed lipid profile, CRP and ESR. This work was supported by a grant from the National Science Centre in Poland (UMO-2011/03/B/NZ5/04192).

Results: A total of 59 AS (43,5 ± 12,5; 12F/47M) and 64 PsA (49,7 ± 12,9 years; 36 F/28 M) patients were studied. Serum fetuin-A, ICAM-1and IL-18, levels were significantly higher in patients compared to controls ($p<0,05$).

No differences were found in serum fetuin-A, ICAM-1 and IL-18 levels in AS and PsA patients.

Serum fetuin-A positively correlated with triglycerides (r=0,3; p=0,02) and VEGF (r=0,3; p=0,02) in AS and with IL-23 (r=0,2; p=0,05) and VEGF (r=0,3; p=0,04) in PsA patients.

Serum ICAM-1 positively correlated with IL-6 (r=0,3; p=0,007) and ESR (r=0,3; p=0,007) in AS and with IL-6 (r=0,2; p=0,05) in PsA patients.

Serum Il-18 positively correlated with CRP (r=0,25; p=0,05), cholesterol (r=0,4; p=0,01), triglycerides (r=0,4; p=0,04) and BASFI (r=0,3; p=0,02) in AS and with IL-6 (r=0,3; p=0,03) and VEGF (r=0,3; p=0,04) in PsA patients.

No differences were found in comparison of subjects to treatment type regarding to serum fetuin-A, ICAM-1 and IL-18 levels in AS and PsA patients.

Conclusion: Serum fetuin-A, ICAM-1, IL-18, levels were increased and correlated with disease activity in AS and PsA patients. Serum fetuin-A and IL-18 correlated with triglycerides in AS patients.

Comparison of Rheumatoid Arthritis, Ankylosing Spondylitis, and Psoriatic Arthritis Pregnancies: Disease Activity, Treatment, and Outcomes. Megan E. B. Clowse. Duke University Medical Center, Durham, NC.

Background/Purpose: While it has long been reported that rheumatoid arthritis (RA) improves with pregnancy, there is very limited information about ankylosing spondylitis (AS) or psoriatic arthritis (PsA). We sought to explore similarities and differences between disease activity and treatment in pregnancy.delivery, and the postpartum experience for women with RA, AS, and PsA.

Methods: The pregnancies in women with RA, juvenile inflammatory arthritis (JIA), AS, other spondyloarthropathies (Spondy), and PsA were collected through a prospective pregnancy registry collected at a single center. For analysis, pregnancies were divided into 3 groups by diagnosis: RA & JIA, AS & Spondy, and PsA. Medications, disease activity, and pregnancy complications were collected throughout pregnancy to a post-partum visit. The physician's global assessment (PGA) was used to compare disease activity between the diseases. Non-parametric statistical testing was used due to small sample sizes. A generalized estimating equation controlled for multiple pregnancies in some women.

Results: 62 pregnancies in 50 women were completed between January 2008 and May 2014. Of these, 37 were in women with RA (including 10 with JIA), 17 with AS/Spondy (including 11 with AS and 6 with other forms), and 8 with PsA (see table). Disease Activity: While the large majority of women with RA (96.5%) or AS/Spondy (80%) had either improved or stable disease activity over the course of pregnancy, 40% of women with PsA had increasing disease activity (p=0.02). Medications: Overall, 32.2% took no medications for arthritis in pregnancy, 8% took only prednisone, 21% took SSZ, HCQ, and/or a TNF inhibitor and prednisone, and 38.7% took SSZ, HCQ, and/or a TNF inhibitor without prednisone. About a third (35.5%) of all pregnancies received TNF-inhibitors. Medication use was similar across the diagnoses (see table)

Pregnancy Outcomes: Half of the pregnancies in women with PsA were complicated by preeclampsia and/or preterm birth, compared to 18.9% with RA and 5.9% with AS (p=0.046). Overall, prednisone exposure was associated with preterm birth and/or preeclampsia (38.9%) compared to those without prednisone exposure (11.4%, p=0.029).

Postpartum: Women with PsA continued to have more active disease than other women; AS/spondy patients improved following delivery. Breastfeeding: Far fewer women with PsA (14.3%) were breastfeeding at follow-up, compared to women with RA (76.9%) or AS/Spondy (80%, p=0.006).

Conclusion: It appears that the experience in pregnancy may be different for women with PsA compared to women with RA or AS/Spondy, with higher levels of disease activity as pregnancy progresses and following delivery, a higher rate of preterm birth and preeclampsia, and greater difficulties with breastfeeding. This small cohort demonstrates an urgency to study PsA in pregnancy.

Is There a Role for Inflammasome Activation in PsA Pathogenesis and Its Comorbidities? Rodolfo Perez Alamino[1], Raquel Cuchacovich[2], Arnold Zea[3] and Luis R. Espinoza[2]. [1]LSUHSC, New Orleans, LA, [2]LSU Medical Center, New Orleans, LA, [3]Stanley Scott Cancer Center, New Orleans, LA.

Background/Purpose: New data has emerged about the role of the inflammasome in psoriasis and psoriatic arthritis (PsA). The assembly of the inflammasome components in innate immune cells (monocytes) results in the rapid activation of Caspase-1, which cleaves pro-IL-1β and pro-IL-18 to generate active forms of these cytokines. We *hypothesized* that: "inflammasome activation occurs in monocytes, as a key element on the initiation and amplification of the innate immune response in PsA pathogenesis". Therefore, it was decided: 1) To determine whether inflammasome activation occurs in monocytes of PsA patients and, 2) To determine the relationship between inflammasome activation with disease activity and metabolic syndrome in these patients.

Methods: After informed consent, 13 PsA patients (CASPAR criteria) and 16 age-matched healthy individuals attending to the outpatient Rheumatology clinic were enrolled. Demographic, laboratory and clinical data was recorded. Disease activity was determined by DAS-28 score. Blood pressure, diabetes history, lipid profile and waist circumference data were included. Metabolic syndrome (MS) was defined following the International Diabetes Federation (IDF) criteria. Purified monocytes were plated and stimulated for 18 h with LPS (100ng/ml) in presence or absence of Caspase-1 inhibitor. CD14 and Caspase-1 expression was analyzed by flow cytometry. Cell lysates and supernatants were collected for determination of Caspase-1 and NLRP3 protein by Western blot and cytokine levels by ELISA, respectively. Student's *t*test and Mann-Whitney tests were used for statistical analysis.

Results: Sixty two percent (62%) of patients were females, mostly (77%) Caucasians. The mean age was 45.15 (SD 9.7) years and mean disease duration was 6.7 (SD 5.5) years. Ten patients presented with active disease, mean DAS28 3.25 (SD 1.2). Metabolic syndrome was present in 77% of patients.

The percentage of $CD14^+$/$Caspase1^+$was numerically higher in PBMC-monocytes from PsA patients compared to normal controls (33.5 $\pm$ 13 vs. 22.5 $\pm$ 11.3, respectively), although difference did not reach statistical significance ($p<0.1$). Caspase-1 expression was confirmed by Western blot. No differences were found regarding cytokine levels. Purified monocytes from PsA patients displayed a robust inflammatory response after LPS stimulation where Caspase-1, NLRP3, IL-1β and IL-18 were highly expressed. Neither Caspase-1 nor cytokine expression were associated with disease activity. In a subset of PsA patients with MS, there was a trend to higher IL-1β levels (19.4 $\pm$ 24.8 vs. 4.1 $\pm$ 6.6) ($p=0.08$).

Conclusion: In this pilot study, PsA patients showed an enhanced expression of inflammasome activation, although difference did not reach statistical significance. Further studies including a larger number of patients are needed to truly establish a role of inflammasome activation in PsA pathogenesis and associated comorbidities**.**

Are There Gender Specific Differences in Patient Characteristics at Initiation of Biologic Treatment in Ankylosing Spondylitis and Psoriatic Arthritis? John Kelsall[1], William Bensen[2], Wojciech Olszynski[3], Niall Jones[4], Isabelle Fortin[5], Andrew Chow[6], Milton Baker[7], Saeed Shaikh[8], Denis Choquette[9], Emmanouil Rampakakis[10], John S. Sampalis[10], May Shawi[11], Francois Nantel[11], Susan Otawa[11] and Allen J Lehman[11]. [1]The Mary Pack Arthritis Centre, Vancouver, BC, [2]St Josephs Hospital and McMaster University, Hamilton, ON, [3]University of Saskatchewan, Saskatoon, SK, [4]University of Alberta, Edmonton, AB, [5]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [6]McMaster University, Hamilton and Credit Valley Hospital, Mississauga, ON, [7]University of Victoria, Victoria, BC, [8]McMaster University, Hamilton, ON, [9]Institut de rhumatologie de Montréal (IRM), Montréal, QC, [10]JSS Medical Research, Montreal, QC, [11]Janssen Inc., Toronto, ON.

Background/Purpose: The prevalence of ankylosing spondylitis (AS) is 2–3 times higher in men compared to women whereas psoriatic arthritis (PsA) is generally considered a disease affecting both genders equally. Recent studies have suggested that clinical differences exist between men and women with the latter experiencing a higher burden of disease (1–4). This analysis examined gender-specific differences with respect to patient and disease parameters at initiation of the first anti-TNF agent (infliximab; IFX) for the treatment of AS and PsA in a Canadian routine clinical practice setting.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis (RA), ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with IFX or golimumab as first biologics or after having been treated with a biologic for <6 months. Patients with AS and PsA treated with IFX who were enrolled between 2005 and 2012 were included in this analysis.

Results: Among the 303 AS patients and 91 PsA patients, 189 (62.4%) and 49 (53.3%) were male, respectively. Mean age and disease duration at initiation of IFX treatment were comparable between genders (Table 1). Overall, disease parameters in AS patients were similar between genders with the exception of CRP which was significantly lower in female patients and HAQ-DI which was significantly higher (Table 1). Among PsA patients, females reported a significantly greater functional disability and showed a higher DAS28 compared to men.

Table 1: Patient Characteristics at Baseline by Gender

Parameter Mean (SD)/%	Male	Female	P-Value
AS	**n=189**	**n=114**	
Age: years	44.8 (12.2)	46.9 (10.8)	0.142
Disease duration: years	9.9 (10.3)	8.8 (9.4)	0.360
C-Reactive Protein (CRP): mg/L	20.9 (27.4)	14.3 (19.9)	*0.044*
Patient Global (PtGA): VAS mm	61.4 (26.8)	64.7 (23.4)	0.751
Physician Global (MDGA): NRS 0–10	6.5 (1.9)	6.7 (1.8)	0.635
Morning stiffness: min	73.5 (42.3)	75.2 (38.9)	0.736
HAQ-DI	1.16 (0.56)	1.32 (0.62)	*0.018*
ASDAS	3.8 (1.0)	3.7 (1.0)	0.238
BASDAI	6.3 (2.0)	6.7 (2.0)	0.101
BASFI	6.1 (2.4)	6.3 (2.3)	0.529
Prior biologic (<6 months)	7.4%	13.2%	0.099
Concomitant DMARD	28.6%	37.7%	0.098
Concomitant NSAID	78.4%	86.0%	0.098
PsA	**n=49**	**n=42**	
Age: years	48.6 (10.8)	48.9 (8.9)	0.862
Disease duration: years	6.9 (7.4)	6.8 (10.8)	0.980
C-Reactive Protein: mg/L	11.1 (14.4)	15.7 (23.8)	0.342
Patient Global: VAS mm	46.6 (27.0)	55.0 (28.9)	0.168
Physician Global: NRS 0–10	5.6 (2.0)	6.0 (2.3)	0.369
Pain: VAS mm	43.9 (25.6)	49.1 (26.1)	0.355
Morning stiffness: min	61.4 (48.1)	55.2 (42.2)	0.527
HAQ-DI	0.92 (0.58)	1.43 (0.66)	*<0.001*
TJC28	5.0 (5.0)	6.8 (5.4)	0.105
SJC28	3.9 (4.0)	4.0 (3.6)	0.939
PASI	4.2 (5.6)	2.4 (5.7)	0.188
DAS28	3.8 (1.6)	4.6 (1.5)	*0.036*
Prior biologic (<6 months)	23.8%	14.3%	0.245
Concomitant DMARD	71.4%	78.6%	0.434
Concomitant corticosteroid	11.9%	4.1%	0.163

Conclusion: Overall, some significant differences in disease parameters were observed between genders in AS and PsA at anti-TNF initiation. Female AS patients experience greater functional impairment compared to men. Female PsA patients, in addition to higher HAQ, also show greater disease activity as measured by DAS28. These results suggest that female patients appear to be receiving their first biologics at a higher level of disease activity. Whether this represents a gender bias in prescribing, or a gender based difference in the acceptance of biologic treatment, requires additional research.

Th9 Cells in Inflammatory Cascades of Autoimmune Arthritis. Siba Raychaudhuri[1], Anupam Mitra[2], Ananya Datta Mitra[2], Christine Abria[2] and Smriti K. Raychaudhuri[2]. [1]Univ California Davis/VA Sac, Davis, CA, [2]VA Sacramento Medical Center, Mather, CA.

Background/Purpose: Interleukin (IL)-9, a member of IL-2 cytokine family was recently attributed to a novel CD4 T cell subset termed Th9 cells in the murine system. It is secreted by naïve CD4+ T cells in response to TGF-β and IL-4. IL-9 can also be secreted by Th17 cells and itself induces Th17 cells to differentiate and regulate autoimmune and inflammatory diseases by enhancing their secretion of IL-17. These observations provoked us to elucidate the pathogenic role of IL-9 in autoimmune arthritis.

Methods: From peripheral blood and synovial fluid (SF) of psoriatic arthritis (PsA) (n = 8), rheumatoid arthritis (RA) (n = 10) and osteoarthritis (OA, n = 10) patients, mononuclear cells were obtained and magnetically sorted for CD3+ T cells. IL-9 levels in SF and serum were measured by enzyme linked immunosorbent assay (ELISA). Proliferative effect of human recombinant IL-9 (rIL-9) on CD3+ T cells of peripheral blood and SF was assessed by MTT (3-(4, 5-Dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide, a yellow tetrazole) and CFSE dilution (Carboxyfluorescein succinimidyl ester) assays. The CD3+ cells from peripheral blood were activated with anti-CD3/CD28 cocktail.

Results: IL-9 levels were significantly elevated in SF and serum of PsA patient and RA patients as compared to SF and serum of OA (Figure 1). Further we demonstrated that activated synovial T cells of PsA and RA patients produced significantly more IL-9 than those of OA patients. In MTT and CFSE dilution assays, rIL-9 (MTT, OD: 0.642 ± 0.02) induced significant proliferation of CD3+ T cells of peripheral blood (Figure 2) and SF (Figure 3) derived from RA and PsA patients compared to media. Further, initial observations suggest that IL-9 receptor ab inhibits IL-9 induced proliferation of the activated SF derived T cells in inflammatory arthritis.

Conclusion: Our data showed that serum and SF of PsA and RA patients have higher concentration of IL-9 than matched OA controls. Moreover, rIL-9 induced marked proliferation of RA and PsA derived activated CD3+ T cells of SF from RA and PsA patients. Thus, IL-9 is likely to play a critical role in the inflammatory cascades of autoimmune arthritis. More importantly IL-9 provides a unique target to develop therapy for PsA patients where we do not have many options like in RA.

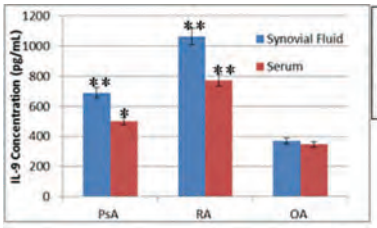

Figure 1: IL-9 in SF and serum of PsA and RA were elevated compared to OA patients (*=p<0.01, **=p<0.001, ANOVA, as compared to OA)

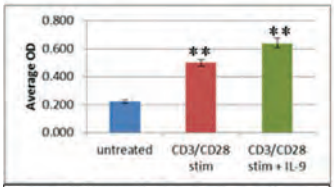

Figure 2: Human rIL-9 (10ng/ml) induced marked proliferation of activated CD3+ cells in serum of RA patients. (*=p<0.01, **=p<0.001, unpaired t-Test, as compared to untreated cells)

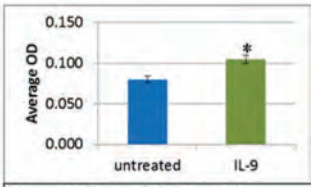

Figure 3: Human rIL-9 (10ng/ml) induced marked proliferation of CD3+ cells in SF of RA patients. (*=p<0.01, unpaired t-Test, as compared to untreated cells)

1603

Effect of Methotrexate on the Immunogenicity of TNF Inhibitors in Spondyloarthritis Patients. Alejandro Villalba[1], Chamaida Plasencia-Rodriguez[1], Diana Peiteado[1], Laura Nuño[2], Gema Bonilla[3], Alejandro Balsa[4], Emilio Martín-Mola[4] and Dora Pascual-Salcedo[5]. [1]Hospital La Paz - IdiPaz, Madrid, Spain, [2]Hospital La Paz-IdiPaz, Madrid, Spain, [3]Hospital La Paz, Madrid, Spain, [4]Hospital Universitario La Paz, Madrid, Spain, [5]La Paz University Hospital, Madrid, Spain.

Background/Purpose: The spondyloarthritis (SpA) patients treated under TNF inhibitors (TNFi) with detectable antidrug antibodies (ADA) often develop loss of efficacy. Concomitant therapy with methotrexate (MTX) appears to reduce the the immunogenicity of biological drugs. Our aim was to analyze if the use of combined therapy with MTX and TNFi can reduce the incidence of ADA and whether its effect is MTX dose dependent in SpA patients.

Methods: In this retrospective observational study, 162 SpA patients (including ankylosing spondylitis, Psoriatic SpA, SpA associated with *inflammatory bowel disease* and undifferentiated SpA) were included. The patients are treated with infliximab (Ifx) or adalimumab (Ada). The presence of ADA were measured at baseline and before each administration by ELISA to complete a follow up of 3 years. The patients were divided in two groups [MTX-15 (dose <15 mg/week) and MTX+15 (≥15 mg/week)] to study the influence of baseline MTX dose on immunogenicity. The statistical analysis was performed using SPSS 11.0.

Results: Eighty nine out of 162 (54,9%) patients were male. Eighty five out of 162 (52,5%) patients received Ifx and 77 out of 162 (47,5%) Ada. The mean duration of treatment was 13.38±9.19 years to Ifx and 12.71±10.46 years for Ada. Forty five patients received MTX weekly at baseline [25/85 (29.4%)in Ifx and 20/77 (26%)in Ada]. The mean dose of MTX was 15,9±4.76 mg/week. Twenty nine out of 162 (17,9%) patients developed ADA, and ADA presence was significantly higher in SpA patients on Ifx therapy [21/85(24.7%) in Ifx vs 8/77 (10.4%) in Ada, p=0.018)]. The presence of ADA was less frequent in SpA patients taking MTX [3/45 (6.7%) with MTX vs 26/117 (22,2%) without MTX, p=0.022]. No statistically differences were observed in the influence of baseline MTX dose on the ADA appearance (in Ifx: 2/18 (11,1%) in MTX+15 vs 1/9 (11,1%)in MTX-15, p=1,0; in Ada: 1/14 (7,4%) in MTX+15 vs 0/4 (0,0%)in MTX-15, p=1,0).

Conclusion: In this cohort of SpA patients treated with Ifx and Ada, the use of MTX has a preventive effect on the ADA development. However, the baseline MTX dose is not a determinant factor to get this effect. Further prospective studies are needed to confirm these data.

ACR/ARHP Poster Session B
Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Autoimmune Disease Transition, Disease Subsets and Prediction of Flares, Cytokines and Autoantibodies
Monday, November 17, 2014, 8:30 AM–4:00 PM

1604

IFN-γ (Th_1), IL4 (Th_2), and IL5 (Th_2) Are Elevated in Pre-Clinical SLE and Predict Transition to Classified Disease Prior to Appearance of Autoantibodies or Clinical Criteria. Rufei Lu[1], Melissa E. Munroe[2], Joel M. Guthridge[2], Krista M. Bean[2], Dustin Fife[2], John B. Harley[3], Judith A. James[2] and Michael P. Keith[4]. [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Cincinnati Children's Hospital Medical Center; US Department of Veterans Affairs Medical Center, Cincinnati, OH, [4]Walter Reed National Military Medical Center, Bethesda, MD.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a clinically diverse autoimmune disease that often begins with a pre-disease period of autoantibody production and symptom accrual. Identifying reliable and biologically relevant predictors for future SLE onset could contribute to understanding disease pathogenesis, discovering disease-specific targetable pathways and facilitating prevention of this debilitating disorder.

Methods: To assess potential mechanistic pathways dysregulated early in lupus autoimmunity and to identify serum biomarkers that can accurately

forecast SLE development, we measured 13 autoantibodies and 34 circulating soluble mediators including cytokines, chemokines, and soluble receptors in serially collected serum samples from time points before and after meeting ACR classification in 55 individuals who subsequently developed SLE and 60 matched healthy controls.

Results: Elevated IL-4 (median, 13.9 vs 2.67 pg/mL), IL-5 (median, 51.14 vs 11.18 pg/mL), and IFN-γ levels (median, 9.12 vs 0.81 pg/mL) are present in subsequent SLE patient sera long before the disease classification (≥3.4 years) [compared to the healthy controls, $p<0.05$]. Path analysis shows that the elevation of IL-4 and IL-5 likely precede development of the majority of lupus specific autospecificities. Random forest modeling during the *preclinical period* identified IFN-γ (Th_1), IL-4 (Th_2), and IL-5 (Th_2) as reliable predictors of future SLE onset of SLE with only a 3.27% out of bag (OOB) prediction error. The best set of predictive biomarkers *at/after disease classification* includes IFN-γ, IL-4, IL-5 MCP-3, and TGF-β (3.68% OOB classification error).

Conclusion: These results suggest that dysfunctional Th_2 related pathways likely potentiate autoantibody production during the pre-clinical period and abnormal elevations in Th_1 cytokine levels exacerbate immune dysregulation. This longitudinal case-control retrospective study has not only provided a panel of SLE predictors to help develop prevention strategies, but strengthened the hypothesis that dysregulated Th_1 and Th_2 pathways are involved in early SLE pathogenesis.

1605

Elevated Regulatory Mediators and Interferon Gamma Associated Responses, but Not Interferon Alpha, BLyS or IP-10, Accompany High-Titer Anti-Ro Autoantibodies in Asymptomatic Mothers of Children with Neonatal Lupus.

Peter M. Izmirly[1], Robert M. Clancy[1], Melissa Munroe[2], Sara Rasmussen[1], Amit Saxena[1], Jose U. Scher[1], Aikaterini Thanou[2], Stan Kamp[2], Joan T. Merrill[2], Jill P. Buyon[1] and Judith James[2]. [1]New York University School of Medicine, New York, NY, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: Mothers of children with neonatal lupus offer a unique opportunity to study the drivers and consequences of autoantibody production in the absence of ongoing maternal inflammation/damage or concurrent immunotherapeutics since many of these women are clinically asymptomatic with high titer anti-Ro antibodies identified solely by disease in the child. This study was initiated to assess the contribution of soluble mediators in the innate, adaptive and effector arms of the immune system to the production of anti-Ro responses independent of other autoantibodies or established systemic lupus erythematosus (SLE), Sjogren's syndrome (SS) or rheumatoid arthritis (RA).

Methods: Soluble mediators (N= 32) were examined including cytokines, chemokines, and soluble receptors using validated multiplex bead-based (xMAP) or enzyme-linked immunosorbent assays in serum from 44 anti-Ro positive women within 5 years of a pregnancy complicated by either heart block (N=36) or skin rash (N=8). Autoantibodies were measured by Bio-Rad Bioplex ANA2200 and recombinant and native Ro60/52 proteins by ELISA. Antibodies to dsDNA, Sm, and RNP were all negative. Based on questionnaire, phone interview, and review of medical records, 18 mothers were completely asymptomatic, 8 had either photosensitivity or Raynauds, and 18 had a combination of mild complaints, including articular and cutaneous symptoms and did not fulfill SLE (ACR or SLICC), SS or RA criteria. Comparisons were made with sera obtained from 156 healthy controls and 94 SLE patients (30 = anti-Ro positive).

Results: Compared to healthy controls, asymptomatic/undifferentiated anti-Ro positive mothers had significant ($p<0.0001$) alterations in 21 of 32 tested mediators. These mothers had higher levels of IFN g and associated molecules (MIG, MIP-1a) ($p<0.0001$) than ANA negative healthy controls at levels that were comparable with SLE patients. However, levels of IFNa and associated molecules important in SLE (BLyS, IP-10) were much lower in anti-Ro positive mothers than SLE patients, and similar to healthy controls ($p<0.0001$). These anti-Ro positive mothers also had higher levels of Th17 (IL-17A, IL-21, IL-6), Th1 (IL-2, TNFa), Th2 (IL-4, IL-6), shed TNF receptors (TNFRI, TNFRII, sCD40L) and regulatory responses (IL-1RA) compared to healthy controls ($p<0.0001$). In addition, these anti-Ro positive mothers had dramatically higher levels of IL-1RA and TGFb compared to SLE patients including those with anti-Ro ($p<0.0001$). No significant differences in soluble mediator levels were noted between anti-Ro positive mothers who were completely asymptomatic and those with mild rheumatic symptoms.

Conclusion: High titer anti-Ro positive asymptomatic neonatal lupus mothers have dysregulated levels of soluble mediators across several inflammatory and immune pathways; however, BlyS and IP10, which appear temporally important in transition to clinical SLE, are not elevated. This cohort provides a unique opportunity to dissect critical pathways resulting in autoimmunity absent overt disease, thus guiding the development of targeted therapeutics for decreasing anti-Ro antibodies and risk of neonatal lupus, as well as providing insights into lupus pathogenesis.

1606

Profiling a Broad Range of Autoantibodies in Healthy and Systemic Lupus Erythematosis Revealed Autoantibody Patterns Associated with Autoantibody Transition and Disease Activity.

Quan-Zhen Li Li[1], Edward Wakeland[1], Prithvi Raj[2], Honglin Zhu[1], Xiaoxia Zuo[3], Mei Yan[1] and Indu Raman[1]. [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]University of Texas Southwestern Medical Center, dallas, TX, [3]Xiangya Hospital of Hunan Medical Univ, Changsha, China.

Background/Purpose: Autoantibodies targeting to nuclear antigens are serological hallmarks of SLE, however, the processing of autoantibody production during the transition from normal to autoimmunity and the pathogenicity of the autoantibodies related with the disease activities are still unclear.

Methods: In this study, we first measured the serum anti-nuclear antibody (ANA) in 2,353 healthy controls (HC) and 500 SLE patients by ELISA. We then screened the levels of IgG and IgM autoantibodies (autoAbs) targeting to a broad range of nuclear and non-nuclear antigens using proteomic microarrays bearing 95 autoantigens, in a cohort of 121 well defined SLE patients and the same number of matched HCs. For a subset of samples, we also measured the IgA subtype of AutoAbs using autoantigen arrays.

Results: ANA testing showed a positivity of 92.5% in SLE, in which 78% with high ANA titers (>40 AU) and 14.5% with moderate to low ANA (20–40 AU). About 25% of HCs also exhibited positive ANA among which 9% with high titer (>40 AU). Autoantigen array analysis revealed high prevalence of IgG autoAbs in SLE patients, the average number of positive IgG autoAbs in SLE were 28.5 and over 95% of SLE harbor more than 5 autoAbs, comparing with average of 3 IgG autoAbs with only 25% have more than 5 autoAbs in HCs ($p<0.05$). A group of 19 IgG autoAbs targeting to various nuclear antigens (dsDNA, chromatin, nucleosome, histone, Sm/RNP, PCNA, CENP-B, etc.) were identified to be significantly enriched in SLE patients by clustering analysis. The presence of IgG autoantibodies against DNA antigens (dsDNA, ssDNA, chromatin, nucleosome, histone) were most significantly associated with disease activity (SLEDAI) and lupus nephritis ($r=0.56$, $p<0.001$) in SLE. Among the normal populations, the young females (age 20–45) with high ANA (>20) tend to carry more IgG autoAbs than other groups, however, majority of the IgG autoAbs identified in HCs were those targeting to non-nuclear antigens, such as cell matrix (collagens, alpha-actinin, heparin sulfate, etc) and phospholipid proteins (cardiolipin). The ANA negative NCs showed low positivity for both IgG and IgM autoAbs, however, the ANA positive NC exhibited higher IgM specificities targeting to 33 non-nuclear and nuclear antigens whereas in SLE the IgM autoAb reaction were relatively lower. Interestingly we noticed a subgroup of SLE patients who have active disease (SLIDAI>10) with lupus nephritis exhibited strong positivity for both IgG and IgM autoantibodies again DNA-associated antigens (dsDNA, ssDNA, chromatin, nucleosome, histone). IgA autoabs were detected in 17 (out of 30) SLEs, preferentially targeting to RNA-associated antigens (Ro, La, Sm/RNP and Ribo phophoproteins).

Interestingly, 3 of the ANA- SLE who have no IgG autoAbs showed positive IgA autoantibodies.

Conclusion: Breach in immune tolerance in normal population was usually accompanied by production of autoantibodies against non-nuclear antigens and the transition from IgM to IgG autoAbs was an indication of increased pathogenicity of the autoantibodies. IgG autoantibodies against nuclear antigens especially DNA associated antigens were closely related with the disease activitity and renal damage in SLE.

B Cell and Neutrophil-Related Transcripts Predict and Characterize a Lupus Flare. Mikhail Olferiev[1], Kyriakos A. Kirou[2] and Mary K. Crow[2]. [1]HSS, New York, NY, [2]Hospital for Special Surgery, New York, NY.

Background/Purpose: Lupus flare reflects an increase of disease activity that is associated with significant morbidity and accumulation of tissue damage. Prediction and prevention of lupus flare is an important goal of lupus research and, ultimately, clinical management. Our aim was to identify perturbations in molecular and cellular mechanisms that precede and coincide with lupus flare.

Methods: PBMC samples, clinical and laboratory data were collected longitudinally from 19 patients meeting ACR criteria for SLE. From 2 to 8 visits/patient (total 90 data points) were analyzed. All patients experienced at least one SELENA-SLEDAI flare. Patients did not receive biologic agents during flare visits, but therapy was otherwise uncontrolled. Transcriptional profiles were obtained for each visit using Affymetrix HG U133Plus 2.0 GeneChips (by Novo Nordisk). SELENA-SLEDAI, BILAG and physician global assessments were compared to identify a point of maximum disease activity (flare). The flare point was set as day 0 for each patient over a 2 year interval. The remaining visits were arranged by time before or after flare. An mRNA profile for each transcript was established using the smoothing-splines mixed effect model (Berk M., 2012). All fitted models were classified by hierarchical clustering, and obtained clusters were studied using the gene-enrichment profiler database (Xavier lab; Benita Y. et al., 2010) and the DAVID v6.7 database to link functionally-related transcripts. The selected cell-specific or function-related genes were refitted and dynamic changes over one year intervals preceding and following flare were characterized.

Results: From 22190 transcripts, the models were successfully fit for 3189 transcripts. Clustering identified 9 major patterns over the observed time course. Most striking was the rise of B cell-related transcripts, including IRF4, SPIB, CD19, CD22, and CD79b, as early as 180 days before lupus flare. Subsequently, transcripts expressed in the myeloid lineage [mannose receptor (MRC1/CD206), CLEC10A/CD301, GPR137B] and those linked to lysosomal function [N-acetylgalactosaminidase (NAGA), acid phosphatase 2 (ACP2), scavenger receptor class B (SCARB2), and endolyn (CD164)] were decreased. B cell-related transcripts rapidly declined immediately prior to flare, while a distinct transcript cluster, including SIGLEC5/CD170, FPR1, IL1R2, SLC11A1, CR1, C1RL, emerged and coincided with flare. A tissue enrichment profiler identified those transcripts as highly expressed in blood neutrophils. The mean level of neutrophil-related transcripts correlated with SLEDAI and BILAG scores at time of flare ($R=0.49$ and $R=0.44$, respectively; $p<0.001$ for both).

Conclusion: Despite the clinical heterogeneity that characterizes flare in individual patients, a common sequence of molecular events was observed preceding and during lupus flares. Strikingly, changes in the B cell population were observed as early as 6 months before flare. Similarly, perturbations in myeloid lineage transcripts occurred prior to flare. An increase in neutrophil-related transcripts is an indicator of lupus flare and correlates with disease activity at time of flare.

Erythrocyte C4d and Antibodies to Anti-C1q Are Associated with Proteinuria in Lupus Nephritis. Jill P. Buyon[1], R. Ramsey-Goldman[2], Richard Furie[3], Chaim Putterman[4], Kenneth Kalunian[5], John Conklin[6], Tyler O'Malley[6], Derren Barken[6] and Thierry Dervieux[6]. [1]New York University School of Medicine, New York, NY, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]North Shore-LIJ Health System, Great Neck, NY, [4]Albert Einstein College of Medicine, Bronx, NY, [5]UCSD School of Medicine, La Jolla, CA, [6]Exagen Diagnostics, Inc., Vista, CA.

Background/Purpose: Biomarkers of renal response in patients with systemic lupus erythematosus (SLE) may provide clues to pathogenesis and drive translation to treatment. This study was initiated to evaluate the association between renal activity and the changes in erythrocyte bound complement C4d product (EC4d), anti-C1q, anti-dsDNA antibodies and low complement.

Methods: The study enrolled 289 SLE patients (mean age 40 years, 92% females) meeting the 1982 ACR classification criteria. All patients were evaluated at one time point as part of a cross-sectional study and a subset of 34 patients (mean age 34 years, 94% female) were followed monthly for an average of 9 months. Among patients enrolled in the cross sectional study, the presence of proteinuria was defined by the renal domain on the SELENA-SLEDAI (increase >0.5 g thus implies active and not chronic proteinuria). For the longitudinal study, proteinuria was defined using the random protein to creatinine ratio (expressed as g/g). Complement protein levels (C3 and C4) were determined using immunoturbidimetry, antibodies to anti-C1q and anti-dsDNA were determined by ELISA and EC4d was determined using flow cytometry (expressed as mean fluorescence intensity [MFI]). Statistical analyses consisted of non-parametric tests, and Chi-square tests. Longitudinal changes in urine protein as a function of the change in the biomarkers were evaluated using generalized linear mixed models effects using random intercept and fixed slopes.

Results: Among 289 SLE, 12% presented with proteinuria at the time of the clinical assessment. Higher EC4d levels were observed in the SLE patients who presented with proteinuria compared to those who did not (median 21 MFI [Interquartile range, IQR: 15–29] vs 12 MFI [IQR: 7–22], $p<0.01$). Abnormal EC4d levels (>20 MFI) were found in 62% of patients with proteinuria compared to 27% of patients without ($p<0.001$). In contrast, the presence of the low complement component of the SELENA-SLEDAI domain was not significantly different between the groups (53% versus 36% $p=0.08$). Neither Anti-C1q nor anti-dsDNA antibodies differentiated between the two groups at baseline. Among the 34 SLE patients followed monthly, a decrease in EC4d levels to lower than 20 MFI was associated with a concomitant decrease of 0.7 g/g urine protein to creatinine ratio ($p=0.0018$) (**Table**). Similarly, the decrease in anti-C1q levels to lower than 80 units was accompanied by decreased proteinuria ($p=0.0015$). Normalization of low complement or loss of anti-dsDNA was non-significantly associated with proteinuria ($p>0.19$). In multivariate analysis both EC4d and anti-C1q were independently associated with proteinuria ($p<0.01$).

Conclusion: These data suggest that longitudinal changes in EC4d and anti-C1q levels track with changes in proteinuria. EC4d correlates more strongly with proteinuria than traditional measures of complement.

Table: Mixed model effect estimates

	Estimate (SEM) g/g	P value
EC4d≤20 MFI	−0.70±0.22	0.0018
Anti-C1q≤80 units	−1.12±0.35	0.0015
Normal Complement (C3/C4)	−0.33±0.24	0.19
Loss of Anti-dsDNA	+0.07±0.29	0.81

Dissection of the Type I Interferon Response in Systemic Lupus Erythematosus : Serum IFNα Is Elevated in Lupus Nephritis and Correlates with IFN Score; IFNβ Is Elevated in Mucocutaneous Disease. Julie Ducreux[1], Fabien Colaone[2], Séverine Nieuwland[1], Patrick Blanco[3], Thierry Defrance[4], Pierre Vandepapeliere[2], Géraldine Grouard-Vogel[2], Frédéric A. Houssiau[1] and Bernard R. Lauwerys[1]. [1]Université catholique de Louvain, Brussels, Belgium, [2]NEOVACS SA, Paris, France, [3]CHU Bordeaux, Bordeaux, France, [4]INSERM, Lyon, France.

Background/Purpose: Type I interferons play a role in the pathogenesis of systemic lupus erythematosus (SLE), but their mechanisms of action are still not fully understood. In this study, we measured serum concentrations of IFNα, IFNβ and IFNω in a cross-sectional cohort of SLE patients followed at a single center, and investigated whether they correlate with clinical or biological indices of disease activity. The link between serum IFNα and IFN

signature in SLE whole blood cells was further evaluated in a prospective set of samples from patients included in the IFNα kinoid study.

Methods: Sera from 178 patients with SLE were harvested during a visit at the Lupus Clinic, and stored at −80°. Serum IFNα, IFNβ and IFNω were measured by ELISA. BILAG scores, serum C3 and double-stranded DNA antibody titers were retrieved from the medical records. Active mucocutaneous disease was defined based on the presence of a mucocutaneous BILAG A, B or C. Because persistent hematuria results in a renal BILAG B score, only renal BILAG A was considered for the definition of active renal disease. Whole blood transcriptome (GeneChip HGU133Plus 2.0 chips) and serum IFNα concentrations were determined at day 0, 112 and 168 in an additional cohort of 28 patients (SLEDAI between 4 and 10) included in the IFNα kinoid trial. Statistical analyses (Mann-Whitney tests and Spearman correlations) were performed using Prism 5.0 software.

Results: 14 out of 178 patients had active renal disease, and 33 had active mucocutaneous disease. Ouf of them, 7 displayed both renal and mucocutaneous disease activity.

Serum IFNα and IFNβ, but not IFNω, were significantly higher in the presence of a renal BILAG A. However, when patients with simultaneous renal and mucocutaneous involvement were discarded, only serum IFNα remained significantly higher in the presence of active renal disease (median concentration 4.53 *versus* 0 pg/ml, $p < 0.0001$).

Similarly, serum IFNβ and IFNα, but not IFNω, were significantly higher in the presence of a mucocutaneous BILAG A, B and C. However, when patients with simultaneous mucocutaneous and renal involvement were discarded, only serum IFNβ remained significantly higher in the presence of active mucocutaneous disease.

There was a low, albeit significant correlation between serum IFNα and serum dsDNA titers or C3 concentrations. In the set of patients included in the IFNα kinoid trial, the IFN signature score displayed a strong and significant correlation with serum IFNα concentrations (Spearman $r = 0.54$, $p < 0.0001$).

Conclusion: Our data indicate for the first time that the type I interferon response in SLE is different according to the affected system. The IFN signature score observed in SLE whole blood cells is driven by IFNα. Increased IFNα in systemic and renal disease and IFNβ in mucocutaneous disease indicate that distinct pathogenic mechanisms are involved in these different manifestations of the disease.

1610

New Autoantigens Associated with Lupus Nephritis. Sachiko Onishi[1], Yuki Tanaka[2], Tatsuhiko Miyazaki[3], Jun Ishizaki[1], Takuya Matsumoto[1], Endy Adnan[1], Hitoshi Yamasaki[1], Koichiro Suemori[1], Takafumi Okura[1], Masaki Yasukawa[1] and Hitoshi Hasegawa[1]. [1]Ehime University Graduate School of Medicine, Toon, Japan, [2]Ehime University, Toon, Japan, [3]Gifu University Hospital, Gifu, Japan.

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by the production of a variety of autoantibodies and is considered a prototype immune complex disease. Anti-dsDNA antibodies contribute to the pathogenesis of lupus nephritis (LN). However, since anti-dsDNA antibodies are not sufficient for the diagnosis, prognosis or evaluation of disease activity, other autoantibodies associated with LN need to be identified. Using an N-terminal biotinylated protein library (BPL) we screened for autoantigens reacting with LN patient sera and then further characterize these autoantigens.

Methods: We screened for autoantigens using the AlphaScreen method with the sera from 3 SLE patients with different disease complications; thrombocytopenia, nephritis or serositis. Antigens used for screening were created using the 2296 cDNA library from a wheat cell-free protein production system in the Ehime University Cell-Free Sciences and Technology Research Center. The proteins characteristic of nephritis were selected, and immunoprecipitation was performed using serum from patients with LN. Immunohistochemical staining of renal tissues was carried out with antibodies against proteins positive in the immunoprecipitation. The specificity of the identified autoantigens was analyzed by an enzyme-linked immunosorbent assay (ELISA) with serum from approximately 250 patients with various autoimmune diseases such as polymiositis/dermatomyositis, systemic sclerosis, and rheumatoid arthritis.

Results: We screened 66 proteins which reacted with LN patient sera at a high levels. Of these, ten proteins showed strong reaction specifically to SLE sera with immunoprecipitation. Immune complex deposition of these ten proteins was confirmed by immunohistochemical staining of renal biopsy tissue and autopsy renal tissue of LN. Clear deposition of 2 proteins, ribosomal RNA processing 8 (RRP8) and transition protein 1 (TNP1), was seen in some renal tissues. ELISA analysis showed that RRP8 and TNP1 reacted to the sera from some SLE patients but have little or no reaction with those from other autoimmune diseases. In addition, anti-RRP8 and anti-TNP1 antibodies were detected in 5 and 7 out of 11 LN patients, respectively.

Conclusion: The AlphaScreen method using BPL created by wheat germ cell-free protein synthesis proved to be useful for autoantibody screening. We have identified RRP8 and TNP1 as new LN autoantigens. RRP8 and TNP1 may play an important role in the pathogenesis of LN.

Modular Transcriptional Neutrophil Signature As Predictive of Nephritis and of Its Severity in SLE Patients. Noémie Jourde-Chiche Sr.[1], Stéphane Burtey[2], Nathalie Bardin[3], Elizabeth Whalen[4], Bertrand Gondouin[2], Scott Presnell[5], Bertrand Dussol[6], Gilles Kaplanski[7], Jean-Robert Harle[2], Yvon Berland[2], Virginia Pascual[8], Damien Chaussabel[4] and Laurent Chiche[9]. [1]Aix-Marseille Université - APHM, Marseille, France, [2]APHM, Marseille, France, [3]Hopital de la Conception, Marseille, France, [4]BRI, seattle, WA, [5]bri, seattle, WA, [6]AP Marseille, Marseille, France, [7]INSERM U608, Marseille, France, [8]Baylor University, Dallas, TX, [9]CHU Marseille, Marseille, France.

Background/Purpose: Lupus nephritis (LN) is a serious complication of SLE. Reliable biomarkers to assess and/or predict renal involvement in SLE patients are needed. The aim of this study was to better assess the link between blood transcriptional signatures and LN.

Methods: Consecutive SLE patients (ACR criteria) were followed-up prospectively. Blood samples were split in: group 1, samples collected at the time of a biopsy-proven LN with active lesions, either proliferative (class III or IV) or not (class II or V); group 2, patients sampled at the time of an extra-renal flare; group 3, patients sampled at their first clinically quiescent visit (no flare or treatment modification in the past 60 days and SLEDAI $\leq$4). Microarray data were generated using Illumina beadchips and analyzed using modular repertoire analyses. Modules with ^{3} 20% transcripts differentially expressed compared to matched healthy controls were considered active.

Results: In addition to the IFN-related modules (M1.2, M3.4 and M5.12), modular repertoire analysis in SLE patients revealed a strong upregulation of M5.15, a module of 24 transcripts annotated "neutrophil". There was no significant correlation between IFN modules and M5.15 activity. At the individual level, spearman correlations between modules and SLEDAI were significant for M5.12 ($r=0.25$, $p=0.03$), but not for M5.15 ($r=0.21$, $p=0.09$). M5.15, however, was the only module strongly associated with LN (Wilcox t-test $p=0.009$), although there was a trend for M5.12 ($p=0.099$). M5.15 was not associated with cutaneous, articular or hematological flares.

Group 1 comprised 24 patients, with proliferative ($n=14$) or non-proliferative ($n=10$) LN. Group 2 comprised 11 patients with an extra-renal flare. Group 3 comprised 34 patients, among whom 22 had a past history of LN. A neutrophil modular signature (M5.15 $\geq$ 20%) was observed in 16/24 (67%), 2/11 (18%) and 16/34 (47%) of patients respectively from group 1, 2 and 3 (Fisher's exact test $p=0.027$). In group 2, 1 patient with a neutrophil signature had a history of LN, the other subsequently had a LN flare (class III at M24). In group 3, 9/16 had a previous LN and 4/16 subsequently developed a LN flare (class IV at M18, M21 and M36; class V at M13).

M5.15 activity was neither correlated to age, gender or ethnicity, nor with the titer of anti-dsDNA ($p=0.7$). There was a strong correlation between daily corticosteroid dose and M5.15 ($r=0.45$, $p<0.0001$). M5.15 was not significantly correlated with 24h proteinuria or serum creatinine but was correlated with acute renal failure ($p=0.03$) and serum albumin ($r=-0.30$, $p=0.01$). In group 1, the median value of M5.15 in patients was significantly higher in patients with proliferative than non proliferative LN (66.7 vs 18.8 %, $p=0.04$). After initiation of treatment in patients with proliferative LN and $\geq$3 consecutive evaluation ($n=10$), a trend was observed between the decrease of M5.15 activity and remission at M6 ($p=0.13$).

Conclusion: Modular repertoire analysis demonstrates that neutrophil signature in SLE patients is correlated with the occurrence and severity of lupus nephritis and may help in the design of disease prognostic and/or activity biomarkers.

1612

Deficient Repair of DNA Double-Strand Breaks and Increased Apoptosis in Patients with Lupus Nephritis. Vassilis Souliotis[1] and Petros P. Sfikakis[2]. [1]Institute of Biology, Medicinal Chemistry and Biotechnology, National Hellenic Research Foundation, Athens, Greece, Athens, Greece, [2]First Department of Propedeutic Internal Medicine, Laikon Hospital, Athens University Medical School, Athens, Greece.

Background/Purpose: Accumulation of apoptotic cells leads to excessive autoantigen presentation and autoantibody formation in autoimmunity, whereas mandatory to avoid apoptosis is the efficient repair of DNA double-strand breaks (DSBs). Herein, we tested the hypothesis that in patients with lupus nephritis, a severe complication of the prototypic systemic autoimmune disease, the DSBs repair is deficient and linked with increased apoptosis in peripheral blood mononuclear cells.

Methods: The intrinsic DNA damage and the DNA repair capacity using γH2Ax foci measurement by confocal microscopy and comet assay, as well as the induction of apoptosis following *ex vivo* treatment with genotoxic drugs (cisplatin, melphalan) were evaluated in peripheral blood mononuclear cells from lupus nephritis patients (n=6). Healthy individuals (n=10), age- and gender-matched to patients were served as controls.

Results: We found that the intrinsic DNA damage was significantly higher in lupus patients than in healthy volunteers ($p<0.01$). Particularly, using comet assay, lupus patients showed Olive Tail Moment values of 15.8+2.3 arbitrary units, while healthy controls only 3.0+1.4 units. Also, using confocal microscopy, the percentage of the γH2AX positive cells was 13.6+1.8 in lupus patients and 4.6+0.9 in healthy controls. Moreover, the genotoxic agent-induced apoptosis rates were significantly higher in lupus than in control cells ($p<0.01$). That is, melphalan dose as low as 9.9+4.8μg/ml was sufficient to induce detectable levels of apoptosis in lupus patients, while healthy controls required doses of 32.3+7.7μg/ml. The corresponding values for cisplatin treatment were 29.8+8.3μg/ml and 67.7+5.5μg/ml, respectively. Finally, following *ex vivo* treatment of mononuclear cells with a genotoxic agent, DSBs repair efficiency was inversely correlated with the apoptosis rates of these cells, being significantly lower in lupus than in control cells ($p<0.01$). That is, melphalan-induced DNA damage was removed with $t_{1/2}$=9.1+2.4h in healthy controls and 51.3+7.6h in lupus patients, with the corresponding values for cisplatin-induced damage being 4.2+1.5h and 25.4+5.9h, respectively. Results in lupus cells were not associated with individual disease activity level or treatment modalities at the time of study.

Conclusion: We demonstrated that circulating mononuclear cells from lupus nephritis patients are characterized by higher intrinsic DNA damage and profoundly reduced DSBs repair capacity. Since failure to repair DNA lesions such as DSBs leads to mutations, genomic instability and induction of apoptosis, these results suggest a novel mechanism by which deficient repair of DSBs may contribute to the induction of systemic autoimmunity.

Circulating microRNAs As Candidate Biomarkers of Diagnosis in Systemic Lupus Erythematosus. Juyang Jung[1], Ja-Young Jeon[2], Bong-Sik Kim[2], Hyoun-Ah Kim[2] and Chang-Hee Suh[3]. [1]Ajou university of medical school, Suwon, South Korea, [2]Ajou University School of Medicine, Suwon, South Korea, [3]Ajou University School of Med, Suwon, South Korea.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by polyclonal B-cell activation and elevated production of pathogenic autoantibodies. MicroRNAs (miRNAs) are short, noncoding RNAs that regulate gene expression on the posttranslational level, which can be measured in the circulation, and are emerging as novel biomarkers in various diseases. However, a systematic analysis of circulating miRNAs in SLE patients has been rarely addressed. We attempted to identify circulating miRNAs associated with the susceptibility to SLE in Korean populations, and to elucidate their significance in clinical phenotypes of SLE.

Methods: Blood samples were collected from Korean SLE patients (n = 70) and normal controls (NC, n = 40) at the rheumatology clinic, Ajou University Hospital. The microRNA PCR arrays identified miRNAs differentially expressed in SLE patients and NC. For the microRNA PCR arrays, we isolated total RNA from plasma samples of 10 SLE patients and 10 NC. The RNAs were pooled in each sample group (n = 10) with an equal amount of RNAs. A miRNA expression profiling analysis was performed and compared between SLE patients and NC. To verify the microRNA PCR arrays results, we performed the quantitative real-time PCR in samples from SLE patients (n = 70) and NC (n = 40).

Results: Nine miRNAs were differentially expressed in plasma between SLE patients and NC by miRNA PCR array. The plasma expression level of hsa-miR-17-5p, hsa-miR-19a-3p, hsa-miR-21-5p, hsa-miR-25-3p, hsa-miR-92a-3p, hsa-miR-223-3p, and hsa-miR-30e-5p were up-regulated in the SLE patients compared to the NC. The plasma expression level of hsa-miR-26b-5p and hsa-miR-150-5p were down-regulated in the SLE patients compared to the NC. The hsa-miR-30e-5p, hsa-miR-92a-3p, and hsa-miR-223-3p were significantly up-regulated in plasma from patients with SLE by quantitative real-time PCR. Especially, the hsa-miR-223-3p was significantly associated with oral ulcer ($p<0.001$) and lupus anticoagulant ($p=0.031$).

Conclusion: Our data suggest that plasma hsa-miR-30e-5p, hsa-miR-92a-3p and hsa-miR-223-3p may be novel important promising biomarkers in the diagnosis of SLE. These novel and promising markers warrant validation in larger prospective studies.

Functional Analysis of Interferon Responsiveness in PBMC from SLE Donors Identifies Subgroups with Higher and Lower Disease Activity. Rachael Hawtin[1], Wouter Korver[2], Erik Evensen[2], Diane Longo[2], Drew Hotson[2], Nikil Wale[2], Andy Conroy[2], Alessandra Cesano[2], Barbara Mittleman[2], Tsung Lin[3], Vikram R. Rao[4], Elena Peeva[3], Stephen Benoit[3], Martin Hodge[3], James D. Clark[3], Aaron R. Winkler[3] and Jean-Baptiste Telliez[3]. [1]Nodality Inc., South San Francisco, CA, [2]Nodality, Inc., South San Francisco, CA, [3]Pfizer Biotherapeutics Research and Development, Cambridge, MA, [4]Pfizer, Cambridge, MA.

Background/Purpose: Interferons (IFN) reportedly are central to SLE pathogenesis and increased expression of IFN regulated genes (the 'IFN signature') is associated with active disease. Clinical utility of the IFN signature is unclear, and refinement to define further patient subgroups may improve disease management. Toll-like receptor (TLR) activation leads to IFNα induction. To increase understanding of the role of IFNs in SLE pathobiology, and connectivity between IFN and TLR signaling, functional profiling of immune signaling downstream of IFNα, IFNγ and TLR modulators in peripheral blood mononuclear cells (PBMC) of SLE donors was performed and compared with signaling in healthy donors (HD).

Methods: Single Cell Network Profiling (SCNP) is a multiparametric flow cytometry based technology that enables simultaneous analysis of signaling networks in multiple immune cell subsets. PBMC from 60 SLE patients (meeting ACR criteria (2007), SELENA SLEDAI ≥6) and 59 HD were profiled by SCNP, interrogating IFN modulated JAK-STAT signaling and TLR modulated signaling relevant to SLE. CD4+/− CD45RA+/− T cells, CD20+ B cells, CD14+ monocytes and CD11b+ myeloid dendritic cells were profiled (see Table 1).

Table 1. Overview of nodes and cell subsets interrogated

Modulator	Intracellular Reads	Cell Subsets Analyzed
IFNα	p-STAT1, p-STAT3, p-STAT5	B cells, Monocytes, T cell subsets
IFNγ	p-STAT1, p-STAT3, p-STAT5	B cells, Monocytes, T cell subsets
Pam3CSK4 (TLR1/2)	p-ERK, p-p38, Ikb, p-c-Jun, p-CREB	Monocytes
LPS (TLR4)	p-ERK, p-p38, Ikb, p-c-Jun, p-CREB	Monocytes
R848 (TLR7/8)	p-ERK, p-p38, Ikb, p-c-Jun, p-CREB	B cells, Monocytes, mDCs
CpG-C (TLR9)	p-AKT, p-ERK, p-S6, IkB, p-STAT3	B cells

Results: IFNα and IFNγ modulated p-STAT1, -3 and -5 signaling was more heterogeneous in SLE vs HD. An SLE subgroup demonstrated low IFNα/high IFNγ signaling in lymphocytes and monocytes. Based on low IFNα->p-STAT5 /high IFNγ->p-STAT1 modulated signaling in B cells, the SLE-IFN subgroup was defined as outside the 95 percentile (z-score>+/−1.96) of HD, comprising 20 of 60 SLE samples.

The SLE-IFN subgroup was 9.4-fold more likely to be positive for anti-dsDNA antibodies (Fisher's exact test p-val<0.001), consistent with published data on the IFN signature and its link to disease activity, and

supporting the clinical relevance of this observation. Significant associations with ANA Ab positivity (p=0.04), report of a new rash (p=0.03) and age (p=0.04) were also identified. No significant associations with other clinical or demographic parameters were identified.

Strikingly, the members of the SLE-IFN subgroup displayed higher TLR7/8 modulated signaling in B cells (Wilcoxon test p=0.003–0.03, depending on the intracellular readout), and dendritic cells (p=0.03), but not in monocytes. Moreover, TLR9 signaling was lower in B cells (p=0.02), and TLR1/2 and TLR4 modulated signaling was lower in monocytes (p=0.003–0.01).

Conclusion: These data identify potential connectivity in immune signaling across cell subsets and signaling pathways that underlie disease pathobiology and further define SLE donor subgroups. Refinement of the IFN signature in SLE through SCNP may facilitate the clinical applicability of the signature to better inform patient stratification for treatment options.

MiR-127-3p As a Novel Regulator of Type I Interferon Signaling Pathway in SLE. Bo Qu, Xiao Han and Nan Shen. Institute of Health Sciences, Shanghai Institutes for Biological Sciences (SIBS), Chinese Academy of Sciences (CAS) & Shanghai Jiao Tong University School of Medicine (SJTUSM), Shanghai, China, Shanghai, China.

Background/Purpose: Type I interferon(IFN) is a critical pathogenic factor in Systemic Lupus Erythematosus(SLE) and its associated nephritis, as elevated IFN inducible genes have been found in the kidney tissues and deficiency of IFN receptor protects lupus mouse model from developing nephritis. Reduced miR-146a is in part the reason for uncontrolled IFN response in peripheral blood cells of SLE. However, we are not clear if there are abnormally expressed kidney miRNAs that are responsible for the overactivated IFN response in the renal tissue of SLE. Our previous miRNA profiling data showed that miR-127-3p was one of the most reduced miRNAs in renal biopsies of lupus nephritis patients, raising the question whether miR-127-3p plays a role in IFN signaling. In this study, we explored the regulatory function of miR-127-3p in IFN signaling and its therapeutic effects on SLE.

Methods: miR-127-3p was quantified by RT-qPCR. Interferon-stimulated response element(ISRE)-luciferase reporter assay and western blotting were used to investigate the function of miR-127-3p. Genes affected by miR-127-3p were identified by microarray. Antagomir(chemical modified miRNA inhibitors) was used to inhibit the function of miR-127-3p to validate its function. We administrated agomir(chemical modified miRNA mimics) into pristane induced lupus mouse model to investigate the in vivo function of miR-127-3p.

Results: To test its function in IFN signaling, we transfected miR-127-3p together with ISRE-luciferase reporter plasmids into Hela cells and then stimulated the cells with IFN. We found that miR-127-3p inhibited IFN mediated expression of the reporter gene. Consistently, miR-127-3p inhibited IFN induced phosphorylation of STAT1 and STAT2, which are two major upstream molecules that activate ISRE mediated gene expression. We further revealed that most of the IFN inducible genes were inhibited by miR-127-3p in Hela cells. In addition, in human primary renal mesangial cells, loss of function of miR-127-3p augmented IFN signaling including enhanced ISRE mediated reporter gene expression, stronger phosphorylation of STAT2 and elevated expression of IFN inducible genes. By Ribonucleoprotein Immuno-Precipitation assay, we identified JAK1, the upstream tyrosine kinase of STAT1 and STAT2, as the target of miR-127-3p. To elucidate the mechanism of reduced miR-127-3p, we screened several inflammatory factors and found that IFN inhibited miR-127-3p in renal cells. What's more, we injected IFN into the mice and found that IFN inhibited the expression of miR-127-3p in their kidneys. To test its therapeutic effects, we examined a short-term phenomenon, pulmonary hemorrhage(PH), in pristane induced lupus mouse model and found that administrating miR-127-3p alleviated PH and inhibited IFN inducible gene Mx1 in peripheral blood cells.

Conclusion: Our study shows renal miR-127-3p can inhibit IFN signaling, indicating a new mechanism of overactivated IFN response in the kidney of SLE. Preliminary in vivo data suggest miR-127-3p has therapeutic potential in SLE. Ongoing mouse model studies about the effects of miR-127-3p on lupus nephritis will give us more insights into its therapeutic value.

Functional Profiling of PBMC from SLE Patients Versus Healthy Controls Identifies Subgroups with Disease-Associated Dysfunctional Signaling. Rachael Hawtin[1], Wouter Korver[2], Erik Evensen[2], Diane Longo[2], Drew Hotson[2], Nikil Wale[2], Andy Conroy[2], Alessandra Cesano[2], Barbara Mittleman[2], Shirley Tu[2], Matt Westfall[2], Tsung Lin[3], Vik Rao[3], Elena Peeva[3], Stephen Benoit[3], Martin Hodge[3], James D. Clark[3], Jean-Baptiste Telliez[3] and Aaron R. Winkler[3]. [1]Nodality Inc., South San Francisco, CA, [2]Nodality, Inc., South San Francisco, CA, [3]Pfizer Biotherapeutics Research and Development, Cambridge, MA.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a multisystem rheumatic disease with widely differing clinical manifestations and outcomes. Treatment is generally immunosuppressive, with no available biomarkers to inform therapeutic selection for a given patient or disease manifestation. Profiling the immune signaling pathways in PBMCs from patients with active SLE and healthy donors (HD) enables improved understanding of pathobiology and provides a basis for rational treatment decisions.

Methods: Single Cell Network Profiling (SCNP) is a multiparametric flow cytometry based technology that enables simultaneous quantitative analysis of signaling networks in multiple immune cell subsets. PBMC from 60 SLE patients meeting ACR (2007) criteria with SELENA-SLEDAI scores ≥6 were profiled by SCNP and compared to PBMC from 59 age, gender and race matched HD in the presence and absence of modulators of immune function (11 cytokines; 5 toll-like receptor (TLR) modulators and IL-1β; B cell-specific modulators CD40L and Anti-IgD, and PMA), across B (defined by IgD and CD27) and T (CD4/CD45RA) cell subsets, monocytes, and dendritic (HLA-DR, CD11b, CD123) cells, and evaluated through induced p-STATs, MAPK, PI3K and NFkB pathway readouts.

Results: SLE vs HD: SLE PBMC overall had a broader signaling range than HD, with median modulated signaling in B and T cells lower in SLE. Exceptions include IFNγ->p-STAT1 in B cells and CD45RA+CD4+ T cells, IL-2->p-STAT5 in CD45RA+CD4+ T cells, IL-4->p-STAT6 in T cell subsets, and IL-10->p-STAT1, −3 in T cell subsets. Modulation of p-STAT1 by IFNγ, IL-10 and IL-27, and IL-6->p-STAT3 was increased in SLE monocytes. TLR->p-ERK, but not NFkB signaling was increased in monocytes. SLE mDCs showed elevated TLR7/8 induced IkB degradation. Unmodulated levels of intracellular readouts and PMA induced signaling were similar between SLE and HD, suggesting that 1. Signaling differences are not the result of elevated unmodulated levels of signaling and 2. Overall signaling capacity is not compromised in SLE.

SLE donor subgroups: Distinct signaling profiles were identified based upon multivariate analysis of signaling within the SLE population. Not only was signaling quantitatively more broadly distributed in SLE vs HD, distinct subgroups were also observed (Table 1). Associations of dysfunctional signaling with donor demographics, including belimumab treatment will be presented.

Table 1. Subgroups of SLE patients based on modulated signaling outside the range for HD.

Modulator	Intracellular Readout	Cell Subset	SLE subgroup identified with higher/lower signaling compared to HD
IFNα	p-STAT1, -3, -5	B cells, monocytes, T cell subsets	Lower
IFNγ	p-STAT1, -3, -5	B cells, monocytes, T cell subsets	Higher
IL-4	p-STAT5	B cell subsets	Lower
IL-6	p-STAT5	T cell subsets	Lower
IL-7	p-STAT5	B cells	Higher
IL-10	p-STAT1	Monocytes	Higher
IL-10	p-STAT5	Monocytes	Lower
IL-21	p-STAT3	B cell subsets	Lower
CD40L	IkB, p-AKT, p-ERK, p-S6	B cells	Lower

Anti-IgD	p-AKT, p-S6	B cells	Lower
TLR7/8, TLR9	IkB, p-ERK	B cells	Lower
TLR1/2, TLR4, TLR7/8	IkB	Monocytes	Lower
TLR1/2, TLR4, TLR7/8	p-ERK	Monocytes	Higher
IL-1b	p-CREB, p-ERK, p-c-Jun	Monocytes	Higher
TLR7/8	IkB	mDCs	Higher

Conclusion: These SCNP data identify both modulator-specific, disease-associated dysfunctional signaling and SLE donor subgroups based upon cell subset specific immune signaling capacity. Ongoing analyses will inform on the clinical relevance of these observations to enable functional refinement of the spectrum of SLE and identification of novel targets for therapeutic intervention.

Single Cell Interferon Signatures in Lupus Patient Monocytes Reveal a Differential Impact of Interferon Signaling Between Monocyte Subtypes. Zhongbo Jin[1], Mark A. Jensen[1], Jessica M. Dorschner[1], Danielle Vsetecka[1], Shreyasee Amin[1], Ashima Makol[1], Floranne C. Ernste[2], Thomas Osborn[3], Kevin G. Moder[1], Vaidehi Chowdhary[1] and Timothy B. Niewold[1]. [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester, MN, [3]Mayo Clinc, Rochester, MN.

Background/Purpose: Type I interferon (IFN) is a primary pathogenic factor in human systemic lupus erythematosus (SLE). IFN gene expression signatures have been observed in whole blood and mixed peripheral blood mononuclear cell populations in SLE, but the significance of this IFN signaling in immune cell subsets is still incompletely understood. We examined gene expression in individual SLE patient monocytes to explore the impact of increased IFN-induced transcription in single cells.

Methods: CD14++CD16- classical monocytes and CD14dimCD16+ non classical monocytes from SLE patients were purified by magnetic separation. The Fluidigm C1 System was used for single cell capture and target gene pre-amplification, and equal numbers of classical and non-classical monocytes were studied. rtPCR was used to quantify expression of 87 monocyte-related genes, 17 of which were IFN-induced genes. An individual cell IFN score was generated based upon the expression of the 17 IFN-induced genes.

Results: Monocytes from the same SLE patient blood sample demonstrated varying levels of IFN-induced gene expression. In classical monocytes, high IFN score correlated with CD32a, IL1B, and IL8 expression. In non-classical monocytes, high IFN score was correlated with a larger number of inflammatory mediators, including cytokines such as IL12, IL23, and IL15; the immune receptors CD36, CD32a, CD80, and TLR7; and inflammatory signaling genes such as RELA, STAT2, IRAK1, IRAK4, and MyD88. CD16 transcripts were detected in a small group of classical monocytes, despite a lack of surface CD16 expression, suggesting that these cells may be transitioning from classical to non-classical subgroup. In these cells, CD16 expression was positively correlated with IFN score ($p=0.019$).

Conclusion: This study revealed striking diversity in the IFN responses of individual monocytes, and supports the idea that IFN signaling has distinct effects upon classical and non-classical monocytes, as the IFN signature correlated with a diverse panel of inflammatory mediators in the non-classical subset. IFN may contribute to the transition from classical to non-classical subtype in SLE. Single cell studies can reveal effects of IFN on single immune cells and uncommon populations such as non-classical monocytes, which may be masked in whole blood or mixed cell populations.

Suppression of IFN-α Production from Systemic Lupus Erythematosus Immune Complexes Via C1 Complex Enzymatic Properties. Jing Yao Leong[1], Joo Guan Yeo[1], Thaschawee Arkachaisri[1] and Jinhua Lu[2]. [1]KK Women's and Children's Hospital, Singapore, Singapore, [2]National University of Singapore, Singapore, Singapore.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease associated with the development of auto-antibodies particularly against nuclear antigens. Previous studies have revealed the possible role of type I interferon, IFN-α, in disease pathogenesis. Notably the formation of immune complexes (auto-antibodies with auto-antigens) can result in the production of IFN-α via Fc receptor signaling. Hereditary homozygous deficiency in the complement protein, C1q has shown a high penetrance of 88–93% in afflicted individuals resulting in disease development. Remarkably it was shown in recent years that C1q has the capacity to suppress immune complex mediated IFN-α production. Considering that in vivo C1q functions as the sensory adaptor in the C1 complex, we compared C1 with C1q in modulating immune complex-mediated IFN-α production from peripheral blood mononuclear cells (PBMCs).

Methods: Serum samples were obtained from 15 SLE patients and assayed for the presence of auto-antibodies (anti-nucleosome) via ELISA. The monocytic U937 cell line was UV-irradiated and the apoptotic supernatant was harvested after 24 hours. The apoptotic supernatant was incubated with SLE sera to form immune complexes. The immune complexes were pre-treated with C1 complex or, as controls, C1q or PBS. Human PBMCs, isolated from healthy donors by Ficoll- Hypaque density centrifugation were treated with the immune complexes for 24 hours and IFN-α production was measured by ELISA.

Results: After screening 15 SLE patients for anti-nucleosome autoantibodies, 4 patients with disease activity (SLEDAI-2K $\geq$ 4) and high titer of anti-nucleosome (>60 R units/ml, where clinical cutoff $\geq$20 R units/ml) were selected. SLE sera were incubated with UV-irradiated U937 apoptotic supernatant to form SLE immune complexes. Human PBMCs were stimulated with SLE immune complexes and assayed for IFN-α production. Healthy control serum elicited 86.7 $\pm$ 8.0 R units/ml IFN-α (media control was 85.7 $\pm$ 3.5 R units/ml), whereas SLE patient A elicited 674.7 $\pm$ 244.3 R units/ml IFN-α, SLE patient B elicited 243.8 $\pm$ 37.0 R units/ml IFN-α ($p < 0.05$), SLE patient C elicited 1115.8$\pm$ 166.5 R units/ml IFN-α ($p < 0.05$), and SLE patient D elicited 142.6 $\pm$ 7.4 R units/ml IFN-α ($p < 0.05$). SLE patient C immune complexes were treated with C1, C1q or PBS and C1 and C1q showed a dose-dependent inhibition in IFN-α induction (853.2 $\pm$ 16.3, 701.1 $\pm$ 1.0, 508.4 $\pm$ 18.6 and 192.1 $\pm$ 16.4 R units/ml respectively) as compared to PBS-treated SLE immune complex (1362.3 $\pm$80.5 R units/ml). Furthermore, it was noted that, at equal molar concentration of C1 and C1q, C1-treated SLE immune complex suppressed immune complex-induced IFN-α production more effectively than C1q-treated immune complex.

Conclusion: C1 is the natural complex encompassing C1q and C1-treated SLE immune complexes exhibit suppressed IFN-α induction from human PBMCs. C1 appeared to be more potent than C1q in inhibiting immune complex-induced IFN-a production showing corporation among the complement classical pathway in providing enhanced protection against SLE pathogenesis as compared with C1q alone.

Interferon Dysregulation in an Academic SLE Cohort Is Associated with Distinct Signaling Differences in Blood Neutrophils Versus PBMCs. David Drubin[1], Xiang Guo[2], Linglin Yang[2], Rong Zeng[2], Yuling Wu[2], Mustimbo EliPollard Roberts[2], Reynald Lescarbeau[1], Aaron Van Hooser[1], Michael Macoritto[1], Michelle A. Petri[3] and Wendy White[4]. [1]Selventa, Cambridge, MA, [2]MedImmune LLC, Gaithersburg, MD, [3]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [4]MedImmune, Gaithersburg, MD.

Background/Purpose: Interferons (IFNs) have long been implicated in the pathogenesis of systemic lupus erythematosus (SLE). However, the specific consequences of the IFN activity have not been defined. In this study, the biology associated with an IFN activity signature was assessed in SLE blood neutrophil and PBMC fractions.

Methods: RNA was collected from isolated blood PBMC and neutrophil fractions from a cohort of 46 SLE patients and 23 healthy

donors. The patients fulfilled both ACR and SLICC criteria for SLE and represented a clinical population with a SLEDAI range of 0–12 (median 2), with 63% treated with prednisone, a cytotoxic immunosuppressant, or both. Patients were grouped by positive or negative IFN activity by assessing 21 IFN-inducible genes in whole blood, and gene expression changes were determined by RNA sequencing. Gene expression differences were analyzed further to determine the most likely upstream mechanistic explanations for the data in each comparison. The significance of these mechanisms is based on the evaluation of two metrics: supporting gene change enrichment using a hypergeometric distribution, and directional consistency as assessed by a binomial distribution. Differential mechanisms between positive and negative IFN groups were examined in the context of those with inferred activity significantly different in SLE compared to healthy donors.

Results: This analysis identified mechanisms inferred to be distinctly active in positive vs. negative IFN neutrophils. Table 1 indicates the gene expression support for representative mechanisms where enrichment and directional consistency are both significant ($p<0.05$ vs healthy, $p<0.1$ Negative vs Positive) for the indicated comparisons. Positive IFN neutrophils exhibited distinctly active biology, including IFNG, mTOR and CCL5 consistent signaling. Additionally, mechanisms preferentially associated with IFN positive neutrophils including TLR signaling and IFNA, as well as many mechanisms in common and at similar levels with IFN negative neutrophils, were also active. TGFB1 and MAPK1 activation were distinct in negative IFN neutrophils. Mechanisms activated in PBMCs were very similar between the IFN groups, with most activated to similar extents.

Conclusion: Our analysis supports that in a patient population with low SLEDAI scores, the IFN activity signature in blood correlates with biological differences that predominate in neutrophils. The work permits better understanding of the impact of IFN signaling in SLE, by demonstrating different effects in neutrophil vs PBMC fractions in an academic cohort.

Table 1. Representative mechanism association with IFN activity in neutrophil and PBMC fractions

		Mechanism Direction and Gene Expression Change Evidence			
	Mechanism	IFN Pos vs Healthy N-2432 Gene changes P-939 Gene changes	IFN Neg vs Healthy N-325 Gene changes P-989 Gene changes	IFN Pos vs IFN Neg N-569 Gene changes P-61 Gene changes	Activation Behavior in IFN-Pos vs IFN-Neg

Antibody to Malondialdehyde-Acetaldehyde Adducts (MAA) As a Potential Biomarker of Inflammation in Systemic Lupus Erythrematosus (SLE).

Andy Hollins[1], Michael Duryee[1], Michelene Hearth-Holmes[1], Ted R. Mikuls[1], Zhixin Zhang[1], Kaihong Su[1] and Geoffrey M. Thiele[2]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: Studies have shown that malondialdehyde-acetaldehyde (MAA) is formed as a result of lipid peroxidation of cellular membranes and is capable of binding or adducting to various macromolecules. MAA-adducted macromolecules are cytotoxic, proinflammatory and result in a robust specific adaptive immune response to the MAA structure. Previous studies have shown serum anti-MAA antibodies present in inflammatory diseases including; atherosclerosis, aortic aneurysm, alcoholic liver disease, and recently rheumatoid arthritis. The purpose of this study was to examine the potential utility of anti-MAA antibody isotypes as biomarkers in systemic lupus erythematosus (SLE). We also explored whether anti-MAA antibody isotypes were associated with two novel biomarkers that we have recently demonstrated to be increased in SLE, neutrophil extracellular traps (NETs) and NOD27/NLRC5.

Methods: Eighty-eight SLE patients, all satisfying ACR classification criteria, and 92 controls were examined. Serum antibody levels were measured by enzyme-linked immunosorbent assay (ELISA) for levels of IgG, IgA, and IgM specific to the MAA epitope. Spearman correlation coefficients were used to examine associations of MAA isotypes with NETs and NOD27/NLRC5.

Results: MAA IgG concentration was significantly higher ($p=0.004$) in SLE patients ($M=488.7$ mg/L) compared to controls ($M=331.7$ mg/L) Figure 1. There was a strong trend ($p=0.064$) observed in MAA IgM concentrations between SLE samples ($M=769.7$ mg/L) and controls ($M=586.7$ mg/L). There was no difference observed between control and SLE groups for MAA IgA concentrations. Levels of MAA IgG demonstrated modest but statistically significant correlations with levels of NOD27/NLRC5 ($r=.256$, $p=0.0508$) and NB4 NET ($r=.213$, $p=0.048$) within the SLE group.

Conclusion: These data show that patients with SLE have significantly higher levels of MAA IgG and IgM compared to controls. In addition, MAA IgG concentrations were positively correlated with circulating levels of NB4 NETs and NOD27, consistent with the increased inflammatory burden that characterizes SLE. MAA has been shown to contribute to protein modifications eliciting strong immune responses and recruitment of proinflammatory cytokines. Whether MAA adduct formation and resulting immune responses mediate tolerance loss in SLE, as has been shown in other conditions, or other complications of SLE such as premature atherosclerosis warrants further investigation.

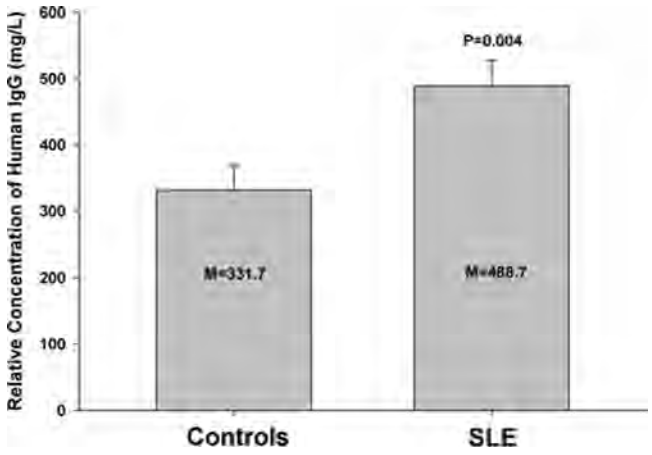

Figure 1. Serum samples were assayed by ELISA for the presence of IgG anti-MAA antibodies.

1621

A Shift Towards Trans-Signalling Explains Relatively Low CRP Despite an Active Interleukin-6 (IL-6)/IL-6-Receptor (IL-6R) System in SLE.
Martyna Skwarek, Babett Heschel, Julia Fantana and Martin Aringer. University Medical Center and Faculty of Medicine at the TU Dresden, Dresden, Germany.

Background/Purpose: IL-6 has been found increased in SLE, while CRP, which is directly stimulated by IL-6, usually remains low. We therefore analyzed the IL-6/ IL-6 R system in SLE.

Methods: Peripheral blood mononuclear cells (PBMC) of 41 SLE patients and 71 healthy individuals (HC) were prepared. CRP and disease activity (by ECLAM) were recorded. Serum IL-6 and sIL-6R were measured by ELISA. For determining the percentages of CD126 and CD130 positive cells, PBMC were directly stained with PE-labelled or control antibodies. For analyzing IL-6 induced Stat3 phosphorylation, PBMC were stimulated with rhIL-6 (250 ng/ml) for 15 min, fixed with formaldehyde (2%), permeabilized with methanol (80%), and stained with PE-labelled antibodies to phosphorylated Stat3 (pStat3) or control antibodies. For in vitro experiments on the influence on receptor expression, healthy PBMC were incubated for 24 hours with or without the addition of IL-6, IL-10, tumor necrosis factor (TNF), interferon-α (IFNα), or combinations of these cytokines. Stained cells were immediately analyzed on a Becton Dickinson FACSCalibur fluorocytometer, gating for lymphocytes. As a semiquantitative measure of pStat3 contents mean fluorescence intensity (mfi) was used.

Results: SLE serum IL-6 levels (median (range)) (3.6 (0.69–69.3) pg/ml) were significantly ($p<0.0001$) higher than those of HC (0.9 (0.12–10.5) pg/ml) and correlated with disease activity (Spearman $r= 0.41$, $p= 0.01$). CRP was slightly increased in SLE (1.8 (1.0–40.8) pg/ml vs 0.8 (0.3–4.8) pg/ml for HC, $p<0.0001$). The percentage of CD126+ lymphocytes (mean±SD) was decreased in SLE (48±16 % vs. 61±11% for HC $p<0.0001$). In line with reduced receptor expression, the IL-6 induced increase in pStat3 was significantly reduced in SLE (Δmfi 14.2 (−19.91–37.15) vs. HC (Δmfi 18.8 (−2.2–50.06), $p=0.004$). In a mirror image to the membrane receptor, soluble IL6 receptor (sIL-6R) serum levels were increased in SLE (42.1 (24.1–109.6) ng/ml as compared to (38.6 (16.4–80.5) ng/ml in HC, $p=0.05$). Moreover, sIL-6R was negatively correlated with the percentage of CD126+ lymphocytes (Spearman $r=-0.35$, $p=0.03$). In vitro stimulation assays showed that the reduction in CD126+ cells could be mimicked by combinations of IL-6 with either IFNα (−39± 13%) or TNF (−16± 6%).

Conclusion: In SLE, combinations of IFNα or TNF with IL-6, all of which are increased in response to immune complexes, apparently lead to shedding of the cellular IL-6 receptor CD126 and thus increase sIL-6R. This shifts the IL-6 system towards trans-signalling, directing the effects of the increased IL-6 away from conventional signalling, as responsible for increased CRP, and towards effects on cells carrying gp130 only.

1622

Th1 and Th2 Cytokines Are Associated with Cerebral Atrophy in Systemic Lupus Erythematosus.
Mariana Postal[1], Aline T. Lapa[1], Karina de Oliveira Peliçari[1], Nailu A. Sinicato[1], Fernando Augusto Peres[1], Wesley Geraldo Ferreira[1], Roberto Marini[1], Lilian Costallat[2], Fernando Cendes[1] and Simone Appenzeller[3]. [1]State University of Campinas, Campinas, Brazil, [2]State University of Campinas, Campinas, United Kingdom, [3]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: Cerebral atrophy has been described to occur in systemic lupus erythematosus (SLE) with variable frequency. The pathophysiology of central nervous system (CNS) involvement in SLE remains unclear. The proposed mechanisms that are likely due to the assault of several autoimmune system changes include circulating immune complexes, corticosteroid use, autoantibodies, and cytokine release. The aim of this study was to determine the prevalence of cerebral atrophy and to elucidate the possible role of sera Th1 (IL-12, IFN-γ,TNF-α) and Th2 (IL-4, 5,6 and 10) cytokines levels in SLE.

Methods: Consecutive SLE patients followed at the rheumatology unit of the State University of Campinas were enrolled in this study. The control group was consisted by age and sex matched healthy individuals. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Neurological manifestations were analyzed according to the ACR classification criteria. Mood and anxiety disorders were determined through Becks Depression and Becks Anxiety Inventory. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current drug exposures. Magnetic resonance imaging (MRI) scans were performed in a 3T Phillips® scanner using a standardized protocol. Sagittal T1 weighted images were used for semiautomatic volumetric measurements. Volumes smaller 2 standard deviation from the means of controls were considered abnormal. Total dose of corticosteroids and other immunosuppressant medications used since the onset of disease were calculated by data obtained by careful review of the medical charts. Sera samples were obtained from all participants in the absence of infections. Th1 (IL-12, IFN-γ,TNF-α) and Th2 (IL-4, 5,6 and 10) cytokines sera levels were measuredby ELISA using commercial kits. Data were compared by non-parametric tests.

Results: We included 146 SLE patients (138 women; mean age of 26.60±13.42 years; range 9–67) and 91 (86women; mean age of 27.82± 15.23 years; range 5–80) age and sex matched healthy controls. The median and range of cerebral volume in SLE patients was 1064.16cm^3(range 831.1–1449.24) cm^3, compared to healthy volunteers 1134.46 (range 880.01–1417.59) cm^3($p<0.001$). Cerebral atrophy was identified in 20 (13.69%) SLE patients and in none of controls ($p<0.001$). Significantly increased Th1 [IL-12 ($p<0.001$), IFN-γ ($p<0.001$), TNF-α ($p<0.001$)] and Th2 [IL-4 ($p=0.002$), IL-5 ($p<0.001$), IL-6 ($p=0.001$) and IL-10 ($p<0.001$)] levels were observed in SLE patients compared to controls. We observed an association between cerebral atrophy and IL-12 ($p=0.044$), IFN-γ ($p=0.017$) and IL-10 ($p=0.003$). We did not observe association between cerebral volume and corticosteroidsor any other clinical or laboratory manifestations.

Conclusion: IL-12, IFN-γ and IL-10 were associated with cerebral atrophy in SLE, suggesting immunological basis for global atrophy in SLE. Cytokines have been highlighted as potential contributory factors to cerebral atrophy in SLE.

Increased CD95 (Fas) Expression on Naive B Cells Is Associated with a Switch to Double Negative and Plasma Cells in the Peripheral Blood, and Correlates with Disease Activity in Systemic Lupus Erythematosus.
Julie Ducreux, Séverine Nieuwland, Frédéric A. Houssiau and Bernard R. Lauwerys. Université catholique de Louvain, Brussels, Belgium.

Background/Purpose: systemic lupus erythematosus (SLE) is characterized by a break of tolerance to autoantigens, and polyclonal activation of B cells. We performed multicolor flow cytometry analyses of B cell subsets in SLE patients and controls, in order to increase our understanding of the B cell activation steps characteristic of the disease.

Methods: PBMC from 16 SLE patients and 5 controls were analyzed using the following flow cytometry markers : CD5, IgD, CD27, CD20, CD19, CD38, CD95 and intracellular survivin, and their control isotypes. The data were acquired using a BD FacsCantoII and analyzed using FlowJo software. Serum C3 concentrations were retrieved from the medical records of the patients.

Results: SLE patients had significantly less CD19+CD20+IgD+CD27- naive B cells compared to controls (40.5 ± 30.7 versus 70.4 ± 8.5 % of total B cells, $p = 0.048$). By contrast, proportions of CD19+CD20+IgD-CD27- double negative (11.6 ± 8.8 versus 4.2 ± 1.6 %, $p = 0.029$) and CD19+CD20-CD38+ plasma cells (11.5 ± 18,4 versus 1.5 ± 1.0 %, $p = 0.015$) were significantly higher in SLE patients compared to controls. Proportions of CD19+CD20+IgD-CD27+ conventional memory B cells were also higher in SLE patients, but the difference was not significant (24.5 ± 18.7 versus 11.9 ± 4.4 %, $p = 0.15$).

Percentage of CD95 (Fas) positive cells was significantly higher in SLE naive (24.5 ± 17,4 versus 2.4 ± 1.3 %, $p = 0.001$), but also in double negative B cells compared to controls. Almost all SLE and control plasma cells expressed CD95. Strikingly, expression of CD95 on naive B cells correlated negatively with the proportion of naive B cells themselves ($r = -0.50$, $p = 0.022$), and positively with the proportions of double negative ($r = 0.46$, $p = 0.034$) and plasma cells ($r = 0.57$, $p = 0.007$).

In all B cell subsets, expression of CD95 displayed a significant positive correlation with intracellular expression of survivin ($r = 0.63$, $p = 0.002$), a

cell proliferation and anti-apoptotic marker. Finally, we observed a significant negative correlation between both CD95 ($r = -0.53$, $p = 0.036$) or survivin ($r = -0.50$, $p = 0.048$) expression in naive B cells and serum C3.

Conclusion: CD95 expression on naive B cells is associated with a switch to double negative and plasma cells in the peripheral blood of SLE patients. The positive correlation between CD95 and survivin expression in SLE B cell subsets confirms that CD95 is a marker of B cell activation in SLE. Activation (CD95 and survivin expression) of naive B cells correlates with disease activity. Further studies on additional cross-sectional and longitudinal samples are ongoing.

The Role of B Lymphocyte Stimulator in Monocyte Subpopulation Differentiation in SLE. Eoghan M. McCarthy[1], Joan Ní Gabhann[2], Siobhán Smith[2], Michele Doran[3], Gaye Cunnane[4], S. Donnelly[5], Donough Howard[1], Paul G. O'Connell[1], Caroline Jefferies[2] and Grainne M. Kearns[1]. [1]Beaumont Hospital, Dublin, Ireland, [2]Royal College of Surgeons in Ireland, Dublin, Ireland, [3]St. James's Hospital, Dublin, Ireland, [4]St James's Hospital and Trinity College Dublin, Dublin, Ireland, [5]Mater Misericordiae University Hospital, Dublin 7, Ireland.

Background/Purpose: Monocytes are increasingly recognised to play a key role in the pathogenesis of SLE. Different subpopulations of monocytes contribute to the disease through dysregulated pro and anti-inflammatory responses. B Lymphocyte Stimulator(BLyS) has been shown to promote disease activity in SLE however its effect on monocyte subpopulation differentiation has not previously been reported. This study sought to investigate the effect of BLyS on monocyte subpopulations in healthy controls and SLE patients.

Methods: 25 Patients with matched controls were recruited. CD 14+ monocyte subpopulations were analysed by Flow Cytometry using the following markers: M1 CD86+ HLA-DR+; M2a CD163+ CD206+; M2b CD86+ HLA-DR+ CD163+. qPCR was utilised to investigate gene expression for the subsets markers as follows: M1 CXCL10; M2a CCL17; M2b CCL1. Serum levels of cytokines were measured by ELISA. Differences between groups were examined using the Mann Whitney.

Results: Following stimulation with BLyS a significant increase in the pro-inflammatory M1 and anti-inflammatory M2a monocyte subpopulations was observed in healthy controls and SLE patients with a corresponding decrease in M2b levels.

Interestingly SLE patients demonstrated a trend toward increased M1 levels in both the resting state and following BLyS stimulation in comparison to controls. In keeping with this SLE patient M1 monocytes exhibited significantly enhanced HLA-DR MFI expression in the resting state and following stimulation compared to controls. Furthermore a significant increase in CD86 MFI was observed following BLyS stimulation in patients, a result not replicated in controls. No differences were observed between patients and controls with regard to the M2b subpopulation.

In keeping with the literature SLE patients exhibited significantly reduced basal M2a levels. Surprisingly however, following BLyS stimulation an increased percentage of M2a monocytes was observed in patients compared to healthy controls(12.7% v 8.3%) such that the fold change from baseline in M2a monocytes between patients and controls following BLyS stimulation was significantly different (3.6 v 1.4,p= 0.0096).

In support of this qPCR confirmed a significant increase in the M2a-associated gene CCL 17 in SLE patients following stimulation, a result not replicated in controls. No absolute differences were observed in expression for the M1-associated gene(CXCL10) and M2b-associated gene(CCL1).

Strikingly BLyS stimulation significantly increased the M1 subpopulation in SLE patients with evidence of immunological activity(dsDNA+ve), an observation not replicated in dsDNA –ve patients.

Finally determination of M1 and M2 subset associated cytokines by ELISA confirmed significantly enhanced levels of both CXCL10(M1) and CCL17(M2a) in the serum of SLE patients with a strong correlation seen between CXCL10 and both dsDNA levels and disease activity. CCL17 demonstrated modest correlation with disease activity.

Conclusion: Our study highlights a heterogenous response to BLyS stimulation in both healthy control and SLE patient monocytes. SLE patient monocytes appear to have enhanced pro and anti-inflammatory responses to BLyS a finding which warrants further investigation.

Interferon Stimulates Transglutaminase Activity on Human Monocytes and Their Microparticles. Kimberly Carroll[1], Elizabeth Mitton-Fitzgerald[1], Brittany Bettendorf[2], Claudia Gohr[1], Mary E. Cronin[1] and Ann K. Rosenthal[1]. [1]Medical College of Wisconsin, Milwaukee, WI, [2]Medical College of Wisconsin, Wauwatosa, WI.

Background/Purpose: Microparticles (MPs) are circulating membrane-bound vesicles derived from blood and endothelial cells via a highly regulated process. They are immunomodulatory and have been implicated in autoimmunity and Systemic Lupus Erythematosus (SLE). We recently showed that MPs derived from SLE patients contain higher protein and activity levels of type II transglutaminase (Tgase). Tgases are protein crosslinking enzymes whose activity increases antigenicity of certain proteins. This enzyme family has been implicated in SLE pathogenesis, perhaps by stimulating autoantibody formation against such proteins as C3, which are major Tgase substrates. The cell source of MPs responsible for increased Tgase activity on SLE MPs is unknown. We explored the hypothesis that interferon, a key cytokine in SLE, could promote Tgase activity on human monocytes and their MPs.

Methods: MPs were isolated from non-adherent human monocyte THP-1 cells by differential centrifugation of conditioned media in cultures treated with or without 1000 U/ml interferon gamma or 10–1000 U/ml interferon alpha for 24– 72 hours. Tgase activity was measured on the MP sample and THP-1 cell layer using a standard radiometric assay. Tgase protein levels for type II Tgase and factor XIIIA were measured in cells and on MPs with Western blotting. Similar experiments were carried out with human umbilical vein endothelial cells (HUVECs) and Jurkat cells (human T lymphocytes).

Results: An increase in type II Tgase protein as evidenced by Western blotting was noted on the cell layer of interferon gamma treated THP-1 cells. This corresponded to a slight, 1.56 fold increase in Tgase specific activity after interferon gamma exposure at 72 hours ($p=0.18$). Interestingly, a dramatic increase in Tgase activity was observed on MPs from interferon gamma treated cells with specific activity increasing 5.61 fold ($p=0.02$) over control MPs (figure 1). There were no differences in protein levels of factor XIIIA nor were there increases in Tgase activity with thrombin treatment, which activates latent Factor XIIIA. HUVECs and Jurkat cells did not respond similarly. Interferon alpha did not increase Tgase activity on any of the cell types tested.

Conclusion: Interferon gamma specifically increases Tgase activity and type II Tgase protein levels on human monocytes and has marked stimulatory effects on Tgase activity on monocyte-derived MPs. Increased Tgase activity may contribute to autoantibody formation through post-translational modification of proteins, such as C3, and their location on MPs may be important. Tgase inhibitors ameliorate SLE in animal models. Our data lend additional support for Tgase inhibitors as potential therapies for SLE.

Autoantibodies Against High Mobility Group Box 1 (HMGB1) in Patients with SLE. Fleur Schaper, Gerda Horst, Daan van Beijeren Bergen en Henegouwen, Johan Bijzet, Karina de Leeuw, Alja Stel, Pieter C Limburg, Peter Heeringa and Johanna Westra. University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: High mobility group box 1 (HMGB1) is a damage-associated molecular pattern and can be divided in three separate domains: the A Box, B Box and the acidic tail. Box A by itself serves as a competitive antagonist for HMGB1 and inhibits HMGB1 activity. In an earlier study we showed that anti-HMGB1 antibodies are present in Systemic Lupus Erythematosus (SLE) patients and may play a role in the pathogenesis of the disease, but are not present in patients with systemic vasculitis. In this study we investigate the relation between anti-HMGB1 antibodies and disease activity, renal involvement, anti-dsDNA antibodies and medication use. We performed cross-sectional and longitudinal analyses.

Methods: Seventy-one SLE patients, 25 age and sex matched healthy controls (HC), and 15 disease control patients with incomplete lupus (fulfilled less than 4 of the ACR criteria), were included in this study. All 71 SLE patients were measured during quiescent or mild (SLEDAI ≤ 4) disease, and 28 were also measured during an exacerbation (SLEDAI ≥ 5). Furthermore, in a subgroup of patients (n=11) longitudinal levels of HMGB1 were determined over a period of three years. Serum levels of anti-HMGB1 IgG and IgM were measured using an in house ELISA. Epitope recognition was measured by ELISA against Box A and B IgG. Data are presented as arbitrary units (AU).

Results: Quiescent as well as active SLE patients showed a significant increase in anti-HMGB1 IgG compared to HC (median 236 vs 339 vs 46 AU respectively). Incomplete lupus patients also had an increased anti-HMGB1 level compared to HC ($p=0.03$), but lower compared to SLE patients (ns). Patients recognized both Box A and Box B epitopes of the molecule. Anti-HMGB1 IgM levels were not different in patients versus controls. We did find an association with disease activity, as there was a significant decrease in Box A recognition after exacerbation ($p=0.028$). No differences were found comparing active patients with renal involvement to patients without for anti-HMGB1 IgG, IgM, Box A and Box B. There was also no effect of immunosuppressive medication, including hydroxychloroquine, on anti-HMGB1 levels. Finally, longitudinal values of anti-HMGB1 IgG showed similar patterns compared to anti-dsDNA and might even increase shortly before an increase in anti-ds DNA levels are seen.

Conclusion: Anti-HMGB1 antibodies seem specific for SLE, as they were significantly increased compared to HC. Interestingly, also incomplete lupus patients showed already a minor increase of anti-HMGB1 antibodies. Antibodies directed to Box A decreased after an exacerbation, indicating a correlation with disease activity. Furthermore, longitudinally levels of anti-HMGB1 seemed to increase before an increase in anti-dsDNA levels occurred, which might indicate an interesting new biomarker in the follow-up of SLE patients.

The Global Antiphospholipid Syndrome Score (GAPSS) Differentiates Between Transient Ischemic Attack and Stroke in Patients with Antiphospholipid Antibodies. Savino Sciascia[1], Giovanni Sanna[2], Veronica Murru[3], Dario Roccatello[4], Munther A. Khamashta[5] and Maria Laura Bertolaccini[3]. [1]Rayne Institute, St. Thomas Hospital, London, United Kingdom, [2]St. Thomas' Hospital, London, United Kingdom, [3]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [4]UNIVERSITY OF TURIN (ITALY), TURIN, Italy, [5]Lupus Research Unit, The Rayne Institute, St Thomas Hospital, Kings College London School of Medicine, London, United Kingdom.

Background/Purpose: Arterial event are frequent in the antiphospholipid syndrome (APS) and stroke is a major clinical manifestation of syndrome. Recently, we conducted a study in a large cohort of Systemic Lupus Erythematosus (SLE) patients applying a risk score for APS clinical manifestations (Global APS Score or GAPSS), demonstrating that risk profile for APS can be successfully assessed. In this study, we aimed to evaluate the clinical usefulness of the GAPSS in differentiating between transient ischemic attack (TIA) and stroke in a cohort of patients tested positive for aPL who sufferedcerebrovascular events.

Methods: We included 40 consecutive SLE patients attending the Louise Coote Lupus Unit at St Thomas Hospital, London, all with a history of cerebravoscular events. Demographic, clinical and laboratory characteristics were collected. aPL profile included anticardiolipin antibodies (aCL), lupus anticoagulant (LA), anti β2 glycoprotein I antibody (anti-β2GPI), and antibodies to phosphatidylserine-prothrombin complex (aPS/PT). Cardiovascular risk factors were assessed following NICE guidelines (1). The GAPSS system was calculated for each patient (2,3).

Results: Nineteen patients (47.5%) had stroke, 16 (40%) a transient ischemic attack (TIA), defined as neurologic symptoms or signs lasting less than 24 hours by a neurologist. Five patients (12.5%) experienced both. Thirty patients (75%) fulfilled the current APS classification criteria. Higher values of GAPSS were seen in patients who experienced stroke (alone or in association with TIA) when compared to those with TIA alone (10.13 ± 3.3 [range 5–16] vs. 6.3 ± 4.6 [range 3–13], $p=0.033$). This observation was confirmed when compared patients who had a history of stroke alone with patients with TIA alone (9.95 ± 3.29 [range 5–16] vs. 6.3 ± 4.6 [range 3–13], $p=0.029$). Patients who experienced both stroke and TIA showed the highest GAPSS but the difference was only statistically significant when compared to those with TIA alone (10.8 ± 3.63 [range 7–16] vs. 6.3 ± 4.6 [range 3–13], $p=0.03$).

Conclusion: The GAPSS is a valid tool for risk stratification for ischemic manifestation in the setting of cerebrovascular events. This tool may help identifying a more "at risk" population in whom a tailored prophylaxis therapy might be beneficial.

1628

Upregulation of Myxovirus Resistance Protein 1 in Patients with Neuropsychiatric Systemic Lupus Erythematosus. Yuka Shimizu, Shinsuke Yasuda, Takashi Kurita, Sanae Shimamura, Ikuma Nakagawa, Atsushi Noguchi, Haruki Shida, Toshiyuki Watanabe, Michihito Kono, Kenji Oku, Toshiyuki Bohgaki, Olga Amengual, Tetsuya Horita and Tatsuya Atsumi. Hokkaido University Graduate School of Medicine, Sapporo, Japan.

Background/Purpose: Nervous system disease is one of the most common manifestations in patients with systemic lupus erythematosus (SLE) that significantly affects morbidity and mortality. Due to the complexity of clinical presentation of neuropsychiatric lupus (NPSLE), there are no specific markers for the diagnosis or for the evaluation of disease activity. A link between type I interferon (IFN) and SLE has been established by a series of studies. Recent studies have shown up-regulated IFN-inducible genes in the peripheral blood of lupus patients, which is correlated with disease activity[1)]. We previously reported that gene expression levels of Mx1 (myxovirus resistance protein 1), one of the IFN-inducible genes, was increased in lupus peripheral T cells compared with healthy controls[2)]. But it has not been revealed how the overexpression of Mx1 affects specific organs in lupus patients. Based on the report detecting Mx protein in active lesions of brain tissues from patients with multiple sclerosis (MS)[3)], we hypothesized that Mx1 is one of the factors related to the pathogenesis or the biomarker of NPSLE.

Methods: This study comprised 20 patients with NPSLE, 9 patients with SLE who were not considered NPSLE (non-NPSLE), and 20 patients with other non-inflammatory neuropsychiatric diseases as a disease control group. We evaluated the level of Mx1 in serum and cerebrospinal fluid (CSF) by enzyme-linked immuno-sorbent assay (ELISA). There was no significant

difference in disease activity (SLEDAI) between those with NPSLE or without.

Results: The levels of Mx1 in serum and CSF were correlated in patients with SLE (R=0.36). The levels of Mx1 in CSF were higher than that of serum in both patients with NPSLE ($p<0.05$) and non-NPSLE ($p<0.05$). The levels of serum Mx1 were significantly higher in patients with NPSLE than in those with non-NPSLE and other non-inflammatory neuropsychiatric diseases ($p<0.01$, $p<0.001$, respectively, Figure). The levels of Mx1 in CSF were significantly higher in patients with NPSLE than in those with other non-inflammatory neuropsychiatric diseases ($p<0.001$).

Conclusion: The upregulation of Mx1 was significantly correlated with NPSLE, suggesting that serum Mx1 is one of the candidates of biomarker for NPSLE.

1629

Added Value of the Determination of Anti-Ribosomal and Anti-Ku Antibodies for Diagnosis of Systemic Lupus Erythematosus. Johannes Schulte-Pelkum[1], Diana Carmona-Fernandes[2], Maria Jose Santos[2], Roger Albesa[1] and Michael Mahler[1]. [1]INOVA Diagnostics, San Diego, CA, [2]Faculty of Medicine, University of Lisbon, Lisbon, Portugal.

Background/Purpose: Anti-dsDNA antibodies (aab) are known as important serological marker to aid in the diagnosis of systemic lupus erythematosus (SLE) and are part of the ACR classification criteria. In addition, anti-ribosomal P (Rib-P) AAB are a specific diagnostic marker for SLE. Lately, anti-Ku AAB were also described to be present with a high prevalence in SLE patients. Here we describe the evaluation of new chemiluminescent immunoassays (CIA, QUANTA Flash®) for the detection of anti-Rib-P and anti-Ku AAB, and show that testing for these AAB might add value to the diagnosis of SLE.

Methods: Sera (125) from patients suffering from SLE and 280 control sera including rheumatoid arthritis (RA), juvenile idiopathic arthritis (JIA), psoriatic arthritis (PsA) ancylosing spondylitis (AS) and healthy controls (HC) were tested using QUANTA Flash Ribosomal P, QUANTA Flash dsDNA, and QUANTA Flash Ku (prototype).

Results: 58/125 of the SLE Patients and 13/280 controls tested positive for antibodies against dsDNA corresponding to a sensitivity of 46.6% (95% CI of 37.4–55.5%) and a specificity of 95.4% (95% CI of 92.2–97.5%). 37/125 of the SLE patients and 14/280 controls tested positive for anti-Rib-P AAB corresponding to a sensitivity of 29.6% (95% CI: 21.8–38.4%) and a specificity of 95.0% (95% CI: 91.8–97.2%). In addition, 20/125 of the SLE patients and 5/280 controls sera tested positive for anti-Ku AAB corresponding to a sensitivity of 16.0% (95% CI: 10.1–23.6%) and a specificity of 98.2% (95% CI: 95.9–99.4 %). The reactivities against Rib-P and Ku show minimal overlap. Therefore, when combining the two markers, the sensitivity and specificity for SLE were 41.6% (95% CI: 32.9–50.8%) and 93.2% (95% CI: 89.6–95.9%), respectively. Table 1 part A shows a summary.

In the group of dsDNA negative samples anti-Ku (OR=8.1) and anti-Rib-P(OR=2.3) results could be used to discriminate SLE patients from controls. 16 /67 sera from SLE patients and 18/267 control sera had a positive test result for either anti-Rib-P or anti-Ku, thus discriminating SLE from controls with a specificity of 93.3% (95% CI 89.6–96.0%). Table 1 part B shows the individual and combined sensitivities, specificities and Odd ratios.

Table 1 Sensitivities, specificities and Odd ratios summarized (Part A: complete cohort, Part B: dsDNA negative sub cohort)

QUANTA Flash®	Sensitivity	95% CI	Specificity	95% CI	OR	95% CI
Part A: complete cohort (n=405)						
dsDNA	46.6%	37.4–55.5%	95.4%	92.2–97.5%	17.8	9.2–34.3
Rib-P	29.6%	21.8–38.4%	95.0%	91.8–97.2%	8.0	4.1–15.5
KU	16.0%	10.1–23.6%	98.2%	95.9–99.4%	10.5	3.8–28.6
either Rib-P or Ku	41.6%	32.9–50.8%	93.2%	89.6–95.9%	9.8	5.4–17.6
Part B: dsDNA negative sub cohort (n=334)						
Ku	13.4%	6.3–24.0%	98.1%	95.7–99.4%	8.1	2.6–25.2
Rib-P	10.4%	4.3–20.3%	95.1%	91.8–97.4%	2.3	0.9–6.0
either Rib-P or Ku	23.9%	14.3–35.9%	93.3%	89.6–96.0%	4.3	2.1–9.1

Conclusion: Our data confirm that anti-Rib-P and anti-Ku AAB represent potentially useful biomarkers to aid in the diagnosis of SLE. Interestingly, the reactivity against these two antigens shows only minimal overlap and thus, the combination of both markers showed high sensitivity and specificity for SLE. In addition, a significant portion of anti-dsDNA negative SLE patients were positive for anti-Rib-P or anti-Ku AAB. More studies will be needed to confirm this observation.

A Novel NMR Biomarker of Inflammation (GlycA) Is Elevated in Systemic Lupus Erythematosus. Cecilia P. Chung[1], Michelle J. Ormseth[1], Annette M. Oeser[1], Joseph F. Solus[1], Margery A. Connelly[2], James D. Otvos[3] and C. Michael Stein[1]. [1]Vanderbilt University, Nashville, TN, [2]LipoScience, Inc., Raleigh, NC, [3]LipoScience Inc., Raleigh, NC.

Background/Purpose: Nuclear magnetic resonance (NMR) spectra from samples analyzed for lipoproteins also contain a peak (termed GlycA) resulting from glycosylated proteins. GlycA is not only a novel marker of inflammation but was also associated with coronary heart disease in the MESA study. Little is known about GlycA in patients with systemic lupus erythematosus (SLE). Therefore, we tested the hypothesis that GlycA concentrations were elevated in patients with SLE and associated with other markers of inflammation.

Methods: We compared concentrations of GlycA in 116 patients with SLE and 83 control subjects, frequency-matched for age, sex, and race. GlycA was detected by NMR, as a signal from methyl group protons on the carbohydrate portions of glycosylated proteins. SLE disease activity index (SLEDAI) and the SLE Collaborating Clinics damage index (SLICC) were calculated. Acute phase reactants [erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)] were measured using standard methods by the hospital clinical laboratory and interleukin-6 (IL-6) using a Lincoplex ELISA assays.

Results: Patients with SLE had higher concentrations of GlycA [398 (350–445) μmol/L] than control subjects [338 (298–393) μmol/L, $p<0.001$]. In patients with SLE, concentrations of GlycA were significantly associated with ESR, CRP, IL-6, systolic and diastolic blood pressure. (Table)

Table: Association of GlycA with disease characteristics

	Rho	P
ESR	0.43	<0.001
CRP	0.59	<0.001
IL-6	0.27	0.003
Systolic blood pressure	0.23	0.01
Diastolic blood pressure	0.21	0.02
SLEDAI	0.15	0.11
SLICC Damage Index	0.02	0.83

Conclusion: Concentrations of GlycA are higher in patients with SLE than control subjects and are associated with markers of inflammation and blood pressure, but not with SLE disease activity/chronicity scores.

Cell Bound Complement Activation Products and Their Relationship to Disease Activity and Quality of Life Measures in Systemic Lupus Erythematosus. Richard Furie[1], Jill P. Buyon[2], R. Ramsey-Goldman[3], Chaim Putterman[4], Kenneth Kalunian[5], Tyler O'Malley[6], John Conklin[6], Derren Barken[6] and Thierry Dervieux[6]. [1]North Shore-LIJ Health System, Great Neck, NY, [2]New York University School of Medicine, New York, NY, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, [4]Albert Einstein College of Medicine, Bronx, NY, [5]UCSD School of Medicine, La Jolla, CA, [6]Exagen Diagnostics, Inc., Vista, CA.

Background/Purpose: To assess the association between cell bound complement activation products (CBCAPS) and measures of disease activity and quality of life in systemic lupus erythematosus (SLE).

Methods: SLE patients (1997 ACR classification criteria) with active disease as defined by an SLE disease activity 2000 index (SLEDAI 2K) ≥ 6 points or the presence of a 2004 British Isles Lupus Assessment Group (BILAG) index A or B score were eligible for enrollment. However, only those screened patients with elevated CBCAPS (e.g. erythrocyte C4d levels [EC4d] above 15 units) were permitted entry into the study. Clinical activity measures, consisting of a modified SLEDAI 2K (mSLEDAI 2K excludes complement and anti-dsDNA components) and a BILAG index score, and quality of life assessments (short-form 36 [SF-36]) were performed monthly for one year. Patients were also evaluated monthly for EC4d and erythrocyte C3d (EC3d), serum complement levels (C3/C4) and anti-dsDNA antibody concentrations at each visit. EC4d and EC3d levels were determined by flow cytometry, and the mean net fluorescence intensity (MFI) was log transformed for the analysis. Statistical analysis consisted of generalized linear mixed models with random intercept and fixed slopes.

Results: 33 patients (mean age 35 years; 94% female) were evaluated monthly for a total of 303 study visits (median 10 visits per patient, range 3–13). Anti-dsDNA positivity was observed in 61% and low complement levels in 70% of the cohort. The average (SEM) baseline EC4d and EC3d levels were 54.0±21.6 and 15.6±10.0 Net MFI, respectively, and decreased to 28.8±4.4 and 4.2±0.8 net MFI at the last visit. Similarly, the average mSLEDAI 2K and composite BILAG score (A=12, B=8, C=1 point) were 6.8±0.8 and 15.7±1.8 points at baseline, respectively, and decreased to 2.8±0.8 and 8.5±1.3 points, at the last visit. Mean SF-36 scores ranged from 42 (general health) to 68 (role emotional) at baseline. Generalized linear mixed models showed that the number of monthly follow up visits was significantly associated with clinical improvement (decreased mSLEDAI 2K and BILAG scores; increased SF36 scores). As presented in the Table, decreases in EC3d levels and increases in C4 levels were associated with reductions in mSLEDAI 2K and BILAG index scores, whereas increases in C3 levels were associated with reductions in mSLEDAI 2K only. The analysis also revealed that decreasing EC4d and EC3d levels were associated with improving quality of life ($p<0.05$) in 6/8 domains of the SF-36. Changes in C4 were not significantly associated with changes in quality of life measures. Increased C3 was associated with lower quality of life in 2/8 domains of the SF-36 (physical function and role physical).

Conclusion: Our data reveal that EC4d and EC3d levels are associated with changes in disease activity and quality of life measures in SLE.

Is Liopxin A4 a Biomarker for Systemic Lupus Erythematosus? Manal Sedky Abdou[1], Dina Effat[2], Lamiaa Mansour[1], Mona mohsen Abdul Salam[1] and Noha abd El Baky[1]. [1]faculty of medicin, cairo university, cairo, Egypt, [2]faculty of medicin, cairo university, giza, Egypt.

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by autoantibody production and immune complex deposition which trigger both a local and systemic inflammatory response. The continuation of inflammation could be due to failure of the healing process resulting from insufficiency of the pro-resolution lipid mediators such as lipoxin A4 (LXA4) which might lead to progression and flares of lupus. Thus, we assessed the levels of serum and urinary LXA4 in SLE patients and in healthy controls, and correlated them with various clinical and laboratory data as well as renal biopsy and disease activity indices.

Methods: Forty female SLE patients, diagnosed according to the ACR revised criteria for SLE, were included in this study as well as forty healthy age & sex matched subjects who served as the control group. All patients were subjected to full history taking, clinical examination, assessment of disease activity (SLEDAI and renal SLEDAI), laboratory investigations including serum LXA4 and urinary LXA4/creatinine ratio using Enzyme Linked Immunosorbent Assay (ELISA) and renal biopsy. The SLE patients were divided into 2 groups: Group I: 20 patients without nephritis and Group II: 20 patients with nephritis. Statistical analysis was done using SPSS computer software package, version 15.0, 2006.

Results: Urinary LXA4/creatinine ratio levels were significantly higher in all SLE patients when compared to healthy controls ($p=0.037$). The median level of urinary LXA4/ creatinine ratio was lower in SLE patients with nephritis than those without nephritis (0.1, 0.3 ng/ml respectively), but this difference was not statistically significant ($p=0.11$). The urinary LXA4/ creatinine ratio levels were significantly lower in SLE patients with cardiovascular manifestations, as well as those with neuropsychiatric manifestations ($p=0.009$, 0.04 respectively).There was no significant statistical correlation between serum LXA4 and urinary LXA4/creatinine ratio ($r=0.065$, $p=0.7$). There was a positive significant correlation only between urinary LXA4 /creatinine ratio and ESR ($p=0.008$), but no significant correlation between serum LXA4 and urinary LXA4/creatinine ratio and other laboratory parameters including anti-ds DNA, C3 and C4. There was no significant statistical correlation between the level of serum LXA4 and urinary LXA4/creatinine ratio and activity scores (SLEDAI and renal SLEDAI) in all SLE patients. Also, there was no significant difference between WHO classes of Lupus nephritis in SLE patients as regards serum LXA4 and urinary LXA4/ creatinine ratio.

Conclusion: This is a novel study that showed that the urinary LXA4/ creatinine ratio levels were significantly lower in SLE patients with cardio-

vascular and those with neuropsychiatric manifestations, however, it was non significantly lower in patients with nephritis. This may suggest that insufficiency of LXA4 may be responsible for some of the systemic manifestations of SLE, making the disease progressive and more serious. Accordingly, LXA4 could be an inflammatory biomarker for systemic manifestations in SLE patients.

Galectin-3-Binding Protein Is Associated with Disease Activity, but Not with Atherosclerosis in SLE Patients. Susan Kay[1], Niels Heegaard[2] and Anne Voss[3]. [1]Rheumatology, Odense, Denmark, [2]Cinical Biochemistry and Pharmacology, Odense, Denmark, [3]Reumatology, Odense, Denmark.

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have an increased risk of cardiovascular disease (CVD), which may be due to an increased prevalence of atherosclerosis. Atherosclerosis is recognized as being associated with chronic inflammation. SLE is characterized by activation of the innate immune system and an increased expression of type I interferon (IFN) leading to chronic inflammation. Galectin-3 binding protein(G3BP) is a putative marker of IFN activation and has recently been shown to be increased in plasma of SLE patients. The objective of this study was to quantify plasma G3BP and determine the association of G3BP and atherosclerosis in SLE.

Methods: In a population-based predominantly Caucasian cohort we recruited 80 SLE patients. Atherosclerotic burden was assessed by cardiac CT scan for coronary calcium score (CAC) and carotid duplex for carotid intima-media thickness (IMT) and plaque using the ARIC study plaque definition. The presence of atherosclerosis was defined by a CAC >0 and/or carotid plaque. A total of 38 patients were found to be negative for atherosclerosis and 42 patients were found to be positive. The concentration of galectin-3 binding protein (G3BP, 90k/Mac-2 BP) was determined in plasma samples by a commercially available sandwich-type enzyme-linked immunosorbent assay (eBioscience). Samples were diluted 1:100 and concentrations were determined by extrapolation to standard curves obtained with known concentrations of G3BP.

Results: Mean plasma galectin-3-binding protein in the entire study population was 59.54 ng/ml. Plasma galectin-3-binding protein did not significantly differ between SLE patients with atherosclerosis and without atherosclerosis. G3BP levels were significantly correlated with disease activity as expressed by SLEDAI ($P=0.02$).

Conclusion: The inflammatory marker galectin-3-binding protein is not significantly associated with atherosclerosis, but we confirm its association with disease activity in SLE patients.

Thrombophilia Associated with DFS70 Antibodies. Julien Marlet[1], Jean-Luc Charuel[1], Isabelle Martin-Toutain[1], Pascale Ghillani-Dalbin[1], Zahir Amoura[1], Annick Ankri[2] and Makoto Miyara[1]. [1]Pitié-Salpêtrière Hospital (AP-HP), Paris, France, [2]Groupe Hospitalier Pitié Salpétrière, service d'hématologie biologique, Paris, France.

Background/Purpose: The search for antinuclear antibodies (ANA) by indirect immunofluorescence (IIF) on Hep-2 cells is routinely performed as the first step for the biological diagnosis of systemic autoimmune diseases. Anti-DFS70 antibodies are a type of ANA defined by a nuclear dense fine speckled (DFS) IIF pattern, first described in 1994. It has also been reported that anti-DFS70 antibodies were the most frequent type of ANA found in healthy individuals. We therefore conducted a retrospective study on a large number of patients tested positive for anti-DFS70 antibodies.

Methods/Patients: The first group of patients, the anti-DFS+ group, included patients selected among those undergoing routine antinuclear antibodies testing (ANAs) at the Pitié-Salpêtrière hospital (Paris, France). Patient inclusion started on the 1st of July 2011 and ended on the 31st of July 2013. The criterion of inclusion was an ANA testing positive with a DFS pattern at titer higher or equal to 1:80. Anti-DFS70 antibodies were confirmed with QUANTA Flash DFS70 immunoassay (Inova diagnostics). 441 patients were included.

The second group of patients, the thrombosis group, included patients consulting in hematology at the Pitié-Salpêtrière hospital (Paris, France) who were screened for the first time for a factor V Leiden mutation, a test performed only in patients with a history of thrombosis. Patient inclusion started on the 1st of January 2013 and ended on the 31st of December 2013.

Clinical history of all patients was retrospectively analyzed by clinical chart review of medical records.

Results: The anti-DFS+ group included 441 patients. The prevalence of SARD among anti-DFS+ patients was low (18%, n=81) consistent with previous reports and the majority of them were followed up in internal medicine departments (82 %). Among them, 51 patients had SLE (11.6 %), 9 RA (2 %), 15 primary Sjogren syndrome (3.4 %) 3 inflammatory myositis (0.7 %) and 2 with mixed connective tissue diseases. Among the other patients, 17 patients had multiple sclerosis (3.9 %) and 16 thyroiditis (3.6 %).

Moreover, we observed an unexpectedly high prevalence of thrombotic events in the anti-DFS+ group (12 %, 54 patients).

We thus constituted a control thrombosis group with patients followed in a single tertiary center for thrombosis. All patients referred (n=67) for the first time to the center for thrombotic events were included. Interestingly, 10.4% of patients in the thrombosis group were positive for anti-DFS antibodies.

Prevalence of arterial thrombosis and venous thrombosis in the whole DFS+ population were respectively of 2.9 %, 6.1 % and prevalence of obstetric syndrome (fetal loss, HELLP or pre-eclampsia) in anti-DFS+ women was 6.3 %. One patient had both arterial and venous thrombosis, another had both arterial thrombosis and obstetric syndrome and four patients had both venous thrombosis and obstetric syndrome.

Conclusion: Presence of DFS70 antibodies on ANA testing may be associated with thrombophilia.

Disclosure: J. Marlet, None; **J. L. Charuel**, None; **I. Martin-Toutain**, None; **P. Ghillani-Dalbin**, None; **Z. Amoura**, None; **A. Ankri**, None; **M. Miyara**, None.

Association Between Carrying at Least One Apolipoprotein1 Variant Allele and Hypertension in Lupus Patients with Normal Renal Function. Ashira Blazer[1], H. Michael Belmont[1], Robert Clancy[2], Peter M. Izmirly[3] and Jill P. Buyon[3]. [1]NYU School of Medicine, New York, NY, [2]NYU Medical Center, New York, NY, [3]New York University School of Medicine, New York, NY.

Background/Purpose: The apolipoprotein1 (APOL1) gene encodes a 3 domain protein found both in serum and intracellularly in endothelial cells among other cell types. Variant APOL1 has undergone positive selection as the serum protein offers heterozygous advantage by promoting lysis of Trypanosoma Brucei conferring resistance to African Trypanosomiasis. Populations native to endemic regions carry this variant at high frequencies with 30% of African Americans (AA) heterozygous for the gene and 12% homozygous. The intracellular form of APOL1 is a cytokine mediated apoptosis factor. Recently homozygous status for APOL1 risk allele (RA) has been associated with non-diabetic end stage renal disease by multiple causes including Lupus Nephritis (LN). While the mechanism of disease progression has not yet been described, we postulate that aberrant apoptosis in the renal vasculature may lead to arterial dysfunction and renal injury.This study was undertaken to establish a relationship between carrying at least one APOL1 RA and known clinical indicators of renal vascular dysfunction in a sample of 34 AA lupus patients with average eGFR above 60 (calculated by the CKD Epi formula).

Methods: APOL1 G1 and G2 risk alleles were genotyped by PCR/DNA sequencing. All patients satisfied ACR criteria for SLE. The patients were distributed into 2 groups: those carrying 2 wild type (WT) alleles (WT/WT) and those with at least 1 RA (G1/WT, G2/WT, G1/G1, G2/G2, G1/G2). Charts were reviewed to assess clinical parameters including demographics, medical comorbidities, medications, vital signs, and laboratory values.

Results: There were 18 patients in the WT group and 16 in the risk variant (RV) group (G1/WT= 10pt; G2/WT=3pt; G2/G2= 1 pt; G1/G2= 2pt; G1/G1= 0pt). Subjects were AA (100%) and predominantly female (WT: 100%; RV: 81%). Hypertension was defined as diagnosis of HTN on chart review, taking at least 1 antihypertensive drug, or having BP over 140 systolic and/or 90 diastolic on at least 2 clinic visits. The APOL1 RA was strongly associated with HTN with 69% of the RV group meeting criteria for HTN compared to 22% of the WT group (odds ratio: 7.7; p value: 0.009). Subgroup analysis of 15 patients with biopsy proven LN showed a higher effect size (odds: ratio of 16; p value: 0.04). There was no significant difference in age, disease duration, disease activity, eGFR, proteinuria, or history of LN between the groups. Next the relationship between inflammation and APOL1 regulation was assessed. As a surrogate of mononuclear cells residing at

patient blood vessels and renal tissue and to evaluate the capacity of macrophages to serve as a source of APOL1, THP1 macrophages were stimulated with hY3 ssRNA and we found that APOL1 was a strongly upregulated transcript.

Conclusion: AA SLE patients carrying at least 1 APOL1 RA have an increased risk of HTN before onset of clinically significant renal disease potentially suggesting vascular dysfunction associated with this gene. Increased APOL1 transcription in the setting of inflammation may increase the gene effect in heterozygous carriers.

Disease Phenotype Is Associated with TH1, TH2 and TH17 Cytokines in Childhood-Onset Systemic Lupus Erythematosus. Karina Oliveira Peliçari[1], Mariana Postal[1], Renata Brabosa[2], Nailu A. Sinicato[1], Fernando Augusto Peres[1], Roberto Marini[1] and Simone Appenzeller[3]. [1]State University of Campinas, Campinas, Brazil, [2]Faculdade de Ciencias Medicas, Universidade Estadual de Campinas, Campinas, Germany, [3]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: Childhood-onset Systemic lupus erythematosus (cLES) is an autoimmune disease characterized by periods of activity and remission. There is a wide spectrum of manifestations, such as hematologic and immunologic, which are commonly found. The cytokine profile assists in the diagnosis, determination of disease activity and may predict future damage caused by the disease. To determine the serum levels of Th1 (IL-12 and TNF-α), Th2 (IL-6 and IL-10) and Th17 (IL-17) cytokines in cSLE and to evaluate their role in different disease phenotypes.

Methods: We included 53 consecutive cSLE patients [median age 21 years (range 13–28)] and 51 age and sex-matched healthy controls [median age 20 years (8–33)]. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Neurological manifestations were analyzed according to the ACR classification criteria. Mood and anxiety disorders were determined through Becks Depression and Becks Anxiety Inventory in all subjects. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/ American College of Rheumatology Damage Index (SDI)] and current drug exposures. Th1 (IL-12 and TNF-α), Th2 (IL-6 and IL-10) and Th17 (IL-17) cytokines levels were measured by ELISA using commercial kits. Data were compared by non-parametric tests.

Results: Serum IL-6 ($p=0.002$), IL-10 ($p=0.028$), IL-17 ($p=0.009$) and TNF-α ($p=0.04$) levels were increased in cSLE patients when compared to healthy controls. TNF-α levels were significantly increased in patients with active disease (SLEDAI$\geq$3) ($p=0.004$). IL-6 ($p=0.006$) and TNF-α ($p=0.024$) levels were significantly increased in patients with nephritis and IL-10 levels were increased in patients with elevated ESR ($p=0.013$). We observed that IL-17 was associated with migraine ($p=0.040$) and IL-6 with thrombocytopenia ($p=0.022$) and low complement ($p=0.014$). IL-12 ($p=0.008$) and IL-17 ($p=0.005$) were associate with anxiety. No association between cytokine levels and SDI scores or medication was observed.

Conclusion: Cytokines play a central role in cSLE and may be responsible for different disease phenotype. TNF-α is associated with SLEDAI and may be a biomarker of disease activity, Th1 and Th2 responses may play a role in lupus nephritis and Th1 and Th17 may play a role in neuropsychiatric symptoms in cSLE. Longitudinal studies are needed to determine if these cytokines may be used as biomarkers in cSLE.

LACK of Association of ANTI CCP and Arthritis in SLE. Adrian Pablo Salas[1], Mariana Alejandra Pera[2], Pierina Sansinanea[2], Mercedes Argentina García[2], Valeria Arturi[2], Ana Carolina Costi[2], Claudia Elizabeth Pena[2], Adriana Testi[3], Josefina Marcos[4] and Ariel Vulcano[1]. [1]HIGA San Martin, La Plata, Argentina, [2]HIGA San Martín La Plata, La Plata, Argentina, [3]HIGA San Martin, La Plata - Buenos Ai, Argentina, [4]HIGA San Martín, La Plata, Argentina.

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by multiplicity of auto antibodies, many of them play an unknown role in disease pathogenesis. Anti cyclic citrulinated antibodies (aCCP Ab) predict the progression to rheumatoid arthritis in patients with recent onset arthritis, and are associated with erosive disease. Its utility in SLE has not been determined yet, but their positivity has been linked to arthritis, and presence of erosions in small retrospective studies. The aim of this study was to evaluate the prevalence of aCCP Ab in a cohort of patients with SLE and the possible association with clinical manifestations of disease.

Methods: the presence of third generation aCCP 3 Ab (ELISA) was evaluated in 100 consecutive, ambulatory patients with diagnosis of SLE 1997 ACR from January 2011 to June 2011, and medical records were reviewed retrospectively. The cumulative presence of photosensitivity, malar rash, alopecia, discoid lesions, Raynaud's phenomenon, arthritis, myositis, nephropathy, hemolytic anemia, lymphopenia, neutropenia, thrombocytopenia, serositis, myocarditis, pulmonary intersticiopathy, panniculitis, neuropsyquiatric lupus and antiphospholipid syndrome (APS) was evaluated. Categorical variables were compared by Fisher or Chi2 test 2 t.

Results: data of 83 patients was analyzed. aCCP Ab were positive in 15/83 cases (18%). Not significant association was found between a CCP Ab and any clinical manifestations, including the presence of arthritis: 13/15 (86.6%) in aCCP Ab positive group vs. 56/67 (83.6%) in the negative aCCP group. 28/83 (34%) patients developed lupus nephritis, none of them presented positive aCCP (OR: 0.00, p:0. 005, CI: 0.00–0.45).

Conclusion: The aCCP Ab was positive in only 18% of patients studied. No association was detected between the ACCP Ab and any clinical manifestation of SLE.Further prospective studies are needed to establish the role of this antibodies in SLE.

Anti-Dense Fine Speckled 70 Antibodies: Long-Term Followup Study of Clinical Associations in a US Laboratory Patient Population. Mark H. Wener[1] and Kathleen Hutchinson[2]. [1]University of Washington, Seattle, WA, [2]University of Washington, SEATTLE, WA.

Background/Purpose: The recently recognized nuclear dense fine speckled immunofluorescence (IF) ANA pattern is associated with antibodies to the dense fine speckled 70 (DFS70) antigen. Presence of antiDFS70 may identify populations with a low prevalence of autoimmune rheumatic disease. Long-term followup evaluation of the associations of antiDFS70 is limited.

Methods: Serum samples sent for ANA tests to our clinical laboratory were tested for ANA by a multiplex bead assay and HEp2 IF in 2011. Specimens with a positive IF ANA but negative for tested ANA subsets were identified. Randomly selected samples from that population were tested using a commercial anti-DFS70 ELISA and chart reviews were done on positive samples. Long-term followup based on chart review was performed in 2014.

Results: Long-term followup (at least 6 months, range 6 to 36 months) was available for 32 patients. No definitive autoimmune rheumatic disease was diagnosed in any patient. One patient was treated with hydroxychloroquine for possible undifferentiated connective tissue disease, in part because of the persistent positive ANA, arthralgias, and hearing problems felt most likely to be due to otosclerosis. One patient was diagnosed with celiac disease, one patient had idiopathic glomerulosclerosis with other features of autoimmune disease, and one patient had idiopathic pulmonary fibrosis requiring lung transplant. Two patients developed multiple sclerosis. Common clinical symptoms were arthralgias and/or myalgias (7/32) including 4 diagnosed with fibromyalgiaAsthma was found in 3 patients, irritable bowel syndrome in 3 patients, and headaches (including migraines) in 5. Two patients were diagnosed with depression. No chronic atopic dermatitis, cystitis or malignancy (diagnoses previously reported with antiDFS70) were found.

Conclusion: None of our subjects had an identified autoimmune rheumatic disease on long-term followup. From this U.S. population, although small, we provide additional support for the proposal that sera with only DFS70 antibodies may help identify patients who do not have a rheumatologic disease despite a positive ANA IF test.

Serum Anti-Müllerian Hormone Levels in SLE Patients. the Disease Severity and Cyclophosphamide Reduce the Ovarian Reserve. Gerardo Marino[1], Laura Messuti[1], Maria Rita Gigante[1], Angela Barini[2], Silvia Canestri[1], Antonella Barini[2], Barbara Tolusso[1], Elisa Gremese[1] and Gianfranco Ferraccioli[1]. [1]Division of Rheumatology, Institute of Rheumatology and Affine Sciences, Catholic University of the Sacred Heart, Rome, Italy, [2]Department of Laboratory Medicine, Institute of Biochemistry and Clinical Biochemistry, Catholic University of The Sacred Heart, Rome, Italy.

Background/Purpose: Systemic lupus erythematosus (SLE) predominantly affects women of childbearing age, can lead to severe organ involvement and may require prolonged immunosuppressive therapy. Anti-Müllerian Hormone is produced by the granulosa ovary cells and serum levels of Anti-Müllerian Hormone are used as a measure of ovarian reserve, reflecting the number of primary follicles. The aim of the study was to compare serum levels of AMH in a cohort of patients with SLE and healthy controls to assess whether the presence of the disease, the treatments used and/or other clinical parameters may affect the ovarian reserve.

Methods: 75 women with SLE of childbearing age, aged between 18 and 42 years and with regular menses, and 30 healthy controls age-matched (p=0.3) were evaluated. Anti-Müllerian Hormone levels were measured in peripheral blood samples (kit AMH Gen II ELISA, Beckman Coulter). Clinical and demographic characteristics, disease duration, pattern of organ involvement and previous and current therapies were collected at the time of sampling. 14 patients (18.7%) had been treated with cyclophosphamide (cumulative dose 8.3 ± 5.4 g), and of the remaining, 36 (48.0%) with other DMARDs (methotrexate, azathioprine, mycophenolate mofetil, cyclosporine) and 25 (33.3%) with anti-malarials only.

Results: Patients with SLE had a mean age of 30.2±6.3 years, a disease duration of 8.4±5.1 and 25 patients (33.3%) had a severe organ involvement (mainly renal and neurological, 14 were treated with cyclophosphamide, 11 with other DMARDs). Serum levels of AMH were comparable between patients and controls (4.3±3.3 vs 5.2±3.2 ng/ml, respectively, p=0.15). Considering patients on the basis of organ involvement, patients with major organ involvement had AMH levels (3.4±2.7 ng/ml) significantly lower than control subjects (p = 0.04); no difference was found between patients with minor organ involvement (AMH 4.7±3.4 ng/ml) and control subjects (p=0.45). Considering the treatments used, patients with major organ involvement treated with cyclophosphamide showed serum AMH levels lower than controls (3.3±4.0 ng/ml, p=0.04) and tendentially lower than patients not treated with cyclophosphamide (3.3±4.0 vs 4.5±3.0, p=0.09). There were no associations between the use of other DMARDs than cyclophosphamide and lower AMH levels in SLE patients compared to controls.

Conclusion: In the whole cohort of SLE patients, the ovarian reserve was overall comparable to that of healthy controls, whereas a reduction of the ovarian reserve was associated with the use of cyclophosphamide and the severity of the disease.

Cyclophosphamide Diminishes Plasmablasts and Transitional B Cells and Suppresses Autocrine Production of B Cell Activating Factor of Tumor Necrosis Factor Family (BAFF) in These Cells in Patients with Systemic Lupus Erythematosus. Yuko Okamoto[1], Yasuhiro Katsumata[1], Yasushi Kawaguchi[1], Manabu Kawamoto[1], Takahisa Gono[1], Masanori Hanaoka[1], Tomoaki Higuchi[1], Hidenaga Kawasumi[1] and Hisashi Yamanaka[2]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: B cell activating factor of tumor necrosis factor family (BAFF) is a positive regulator of B cell function and expressed in dendritic cells, monocytes/macrophages, and T cells. Clinical studies have demonstrated that BAFF is overexpressed in many patients with systemic lupus erythematosus (SLE). Furthermore, autocrine BAFF expression in B cells from SLE patients with high disease activity was reported. Although cyclophosphamide (CY) has remained the treatment of choice for major organ involvement in SLE, its precise therapeutic mechanism in SLE remains to be elucidated. At the 2010 ACR meeting, we reported CY predominantly and immediately suppresses activation and viability of plasmablasts *in vivo* and *in vitro*. In this study, we aimed to further clarify the precise effect of CY on human B cell subsets and BAFF expression on B cells in SLE.

Methods: We studied 10 consecutive patients with recent onset or flare of SLE in whom monthly intravenous CY and oral prednisolone were initiated, and 10 normal healthy controls (NHCs). Peripheral blood mononuclear cells (PBMCs) were isolated from heparinized whole blood of these subjects by density gradient centrifugation before and after CY initiation. Immunofluorescence staining of PBMCs for flow cytometric analyses was performed using anti–CD19, anti–CD27, anti–CD38, anti–IgD, anti–IgM, and anti–BAFF antibodies, which specifically recognizes membrane–bound BAFF and does not bind to shed soluble BAFF. Serum BAFF levels were measured by enzyme–linked immunosorbent assay (ELISA).

Results: The frequencies of plasmablasts ($CD19^+/CD27^{high}/CD38^{high}$), transitional B cells ($CD19^+/CD27^-/CD38^{high}$), and double negative memory B cells ($CD19^+/CD27^-/IgD^-$) were significantly higher in SLE patients than in NHCs, whereas the frequencies of memory B cells ($CD19^+/CD27^+$) were significantly lower in NHCs ($p < 0.01$ in all comparisons). $CD27^+$ memory B cells were further classified into $CD27^+IgD^+$ pre–switched memory B cells and $CD27^+IgD^-$ switched memory B cells. The frequencies of pre–switched and switched memory B cells were significantly lower in SLE patients than in NHCs ($p = 0.0003$ and 0.03, respectively). Two weeks after the initiation of CY, the frequencies of plasmablasts and transitional B cells in SLE patients significantly decreased ($p < 0.01$ in both comparisons), while the frequencies of pre–switched and switched memory B cells in SLE patients significantly increased ($p = 0.02$ and 0.002, respectively). The mean fluorescence intensity (MFI) of the membrane bound–BAFF on plasmablasts, memory B cells ($CD19^+/CD27^+$) and transitional B cells were significantly higher in SLE patients than in NHCs ($p = 0.002$, 0.02, and 0.007, respectively), and decreased significantly two weeks after the initiation of CY ($p = 0.004$, 0.01, and 0.01, respectively). Serum BAFF levels in SLE patients also significantly decreased with clinical amelioration following treatment ($p = 0.002$).

Conclusion: This study shows that administration of CY predominantly and immediately diminishes plasmablasts and transitional B cells, and the BAFF overexpression in these cells. These findings indicate that therapeutic effect of CY on SLE is at least partly exerted through this mechanism.

Baseline Factors That Predict High BLyS Levels in Patients with Systemic Lupus Erythematosus (SLE) and High Disease Activity. David Roth[1], April Thompson[2], Tom Tang[2], Anne Hammer[2] and Charles T. Molta[1]. [1]GlaxoSmithKline, Philadelphia, PA, [2]GlaxoSmithKline, Research Triangle Park, NC.

Background/Purpose: Post hoc analyses from the BLISS trials demonstrated that patients with high baseline B-lymphocyte stimulator (BLyS) levels (≥2 ng/ml) had an increased risk of a clinically meaningful flare over 1 year.

Objectives: BLyS levels are not routinely collected in clinical practice; analyses were conducted to identify clinical variables that may predict high BLyS levels in patients with SLE high disease activity.

Methods: Data from BLISS-52 (NCT00424476) and BLISS-76 (NCT00410384) were pooled (GSK200619). High disease activity was defined as anti-dsDNA positive and low complement (low C3 and/or low C4). Those subjects with high disease activity and elevated BLyS levels (≥2 ng/ml) were examined. Univariate and stepwise logistic regression were employed to identify a subset of baseline factors (e.g. demographic, disease activity, laboratory, biomarker and SLE medication usage) predictive of high baseline BLyS levels. Only baseline factors at the 0.05 significance level entered the final logistic regression as covariates.

Results: A total of 243 out of 1664 (15%) subjects had high disease activity and high baseline BLyS levels (≥2 ng/ml). Most subjects were female (n=221, 91%); mean age was 34 (10.2 SD) years, and mean SELENA-SLEDAI score was 11.5 (4.39 SD). Significant baseline predictors of high baseline BLyS levels included positive anti-Smith (≥15 U/ml; $\chi2 = 10.96$, p<0.01), low C3 ($\chi2 = 7.85$, p<0.01), anti-dsDNA (>200 IU/ml; $\chi2 = 7.28$, p<0.01) and anti-dsDNA (80–200 IU/ml; $\chi2 = 3.57$, p=0.058), use of immunosuppressant medication ($\chi2 = 11.74$, p<0.01), proteinuria (≥0.5 g/24 h; $\chi2 = 10.48$, p<0.01) and elevated C-reactive protein (>3 mg/L; $\chi2 = 40.69$, p<0.01).

Conclusion: Positive anti-Smith, low C3, positive anti-dsDNA, immunosuppressant usage, proteinuria, and elevated C-reactive protein were predictors of high BLyS and may be useful clinical parameters in identifying SLE patients with high disease activity at risk of flare.

A Prospective Study of Vitamin D Effects on T Cells Phenotype in Patients with Systemic Lupus Erythematosus Treated with Different Regimens of Supplementation for Two Years. Silvia Piantoni, Laura Andreoli, Alessandra Zanola, Francesca Dall'Ara, Mirko Scarsi and Angela Tincani. Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia, Italy.

Background/Purpose: Vitamin D (VD) receptor is constitutively expressed on the membrane of multiple cells, including lymphocytes. Recent studies highlight that VD may have an action on T cells, inhibiting Th1 and Th17 response and enhancing Th2 and T regulatory (Treg) function.

After repeated antigenic presentation, T cells undergo different functional and phenotypical modifications, leading to the differentiation into highly experienced memory T cells (CD45RA+CCR7-). Similarly, the down-modulation of CD28 may lead to the expansion of the CD28- T cells, a subpopulation with peculiar effector activities (high γ-IFN production and cytotoxic function).

As the best of our knowledge, little is known about the effect of VD on CD28- T cell population and in the differentiation of memory T cells.

The aim of this study is to verify the effect of VD on the circulating levels of T cells in a cohort of SLE patients (pts).

Methods: 34 SLE pts were followed-up for 24 months. In the first year, 16 pts (group 1) were supplemented with an intensive regimen of colecalciferol (300.000UI for the first month and 50.000UI/monthly as maintenance), whereas 18 (group 2) were supplemented with a standard regimen (25.000UI monthly).

During the second year, patients switched to the other regimen.

Phenotypic analysis of peripheral T lymphocyte and the quantification of the intracytoplasmatic production of IL-4 and γ-IFN from peripheral blood mononuclear cells (PBMC) was evaluated by flow-cytometry.

Wilcoxon-signed rank test and Mann-Whitney test were used for the comparisons.

Results: At baseline, no significant difference emerged in VD levels and among main T cell subtypes in SLE pts, with the exception of CD8+CD28- T cells which were expanded in group 1 (group 1 vs. 2, 74.5 vs. 26.6 % of CD8+ T cells; $p<0.01$). These pts had a greater serological disease activity (group 1 vs. 2, antidsDNA= 16.6 vs. 4.1 UI/ml; $p=0.02$).

After 24 months, an increase of the absolute number of Treg cells (CD4+CD25highCD127low) was observed, independently from the regimen of supplementation. Over two years of treatment, a progressive increase in peripheral induced (CCR7-) Treg cells and in the total amount of CD4+CD45RA+CCR7- T cells was seen in both groups, whereas a gradual significant reduction of the CD8+CD28- T cells was observed only in group 2 (table 1–2).

In the group 1, PBMCs of 8 pts were evaluated for cytokines production at baseline and after 12 months of treatment: a reduction of γ-IFN/IL-4 (from 12.1 to 3.2; $p=0.01$) among CD8+ T cells was detected.

Conclusion: VD may promote the enhancement of peripheral induced Treg cells and the production of Th2 cytokines. Further studies will be necessary to understand the role of highly experienced memory T cells and of CD28- T cells. In our cohort, the expansion of CD8+CD28- T cells may reflect a greater serological activity in SLE pts.

Role of Inflammasome Activation in Systemic Lupus Erthematosus: Are Innate Immune Cells Activated? Rodolfo Perez Alamino[1], Raquel Cuchacovich[2], Arnold Zea[3] and Luis R. Espinoza[2]. [1]LSUHSC, New Orleans, LA, [2]LSU Medical Center, New Orleans, LA, [3]Stanley Scott Cancer Center, New Orleans, LA.

Background/Purpose: Systemic lupus erythematosus (SLE) presents with a wide spectrum of clinical and immunologic abnormalities. On the other hand, exciting data is emerging about the role of the inflammasome in autoimmune disorders. The assembly of the inflammasome components in innate immune cells (monocytes) results in the rapid activation of Caspase-1, which cleaves pro-IL-1β and pro-IL-18 to generate active forms of these cytokines. Because the precise etiology and the aberrant immune dysfunction in SLE are not completely understood, we hypothesized that: "inflammasome activation occurs in monocytes as a key element on the initiation and amplification of the innate immune response in SLE pathogenesis‹. Therefore, the aims of the present study were: 1) To determine whether inflammasome activation occurs in monocytes of SLE patients, and 2) To determine the relationship between inflammasome-related cytokines and disease activity in these patients.

Methods: After informed consent, 13 SLE patients and 13 age-matched healthy individuals attending the outpatient arthritis clinic were enrolled. Demographic, laboratory and clinical data were recorded. A score ≥ 6 (SELENA-SLEDAI) was defined as active disease. Purified monocytes were plated and stimulated for 18 h with LPS (100ng/ml) in the presence or absence of Caspase-1 inhibitor. CD14 and Caspase-1 expression was analyzed by flow cytometry. Cell lysates and supernatants were collected for determination of Caspase-1 and NRLP3 protein by Western blot and cytokine levels by ELISA, respectively. Student's t test and Mann-Whitney tests were used for statistical analysis. The study was approved by the LSU IRB committee.

Results: Ninety two percent (92%) of patients were females and 67% African-Americans. Mean age was 33.2 years and mean disease duration was 10 years. Six patients presented with active disease. Lupus nephritis was diagnosed in 3 patients. The percentage of CD14+/Caspase-1 was significantly higher ($p<0.01$) in PBMC-monocytes from SLE patients compared to normal controls (70.7 ± 11.1 vs 33.5 ± 13.0, respectively). These findings directly correlated with higher plasma levels of IL-1β (0.4 ± 0.28 vs 0.15 ± 0.24 pg/ml, $p<0.05$) and IL-18 (725.2 ± 215.4 vs 479.2 ± 125.2 pg/ml, 0.01). Caspase-1 expression was confirmed by Western blot. Purified monocytes from SLE patients displayed a robust inflammatory response after LPS stimulation where Caspase-1, NLRP3, IL-1β and IL-18 were highly expressed. The production of IL-18 was reduced by 3 fold when Caspase-1 inhibitor was added to the cultures. Plasma levels of IL-18 were significantly higher in SLE clinical patients with active disease ($p<0.05$). Neither Caspase-1 or IL-1β expression was associated with SLE clinical features and disease activity.

Conclusion: Innate immune cells in SLE patients exhibited enhanced inflammasome activation, characterized by high expression of Caspase-1, NLRP3, IL-1β and IL-18, and in-vitro suppression of IL-18 production by Caspase-1 inhibitor. These findings provide novel insights into the pathogenesis of SLE and potential new avenues to explore the development of newer therapeutic strategies in the management of the disease.

Mycophenolic Acid and Ribavirin Induces Cytoplasmic Autoimmunogenic Rods and Rings Structures in Vivo. Gerson D Keppeke Sr.[1], Eunice Nunes[2], Maria Lucia Ferraz[3], Sandro F. Perazzio[1], Mônica Prado[1], Edward K.L. Chan[4] and Luis Eduardo C. Andrade[1]. [1]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo, Sao Paulo, Brazil, [3]Universidade Federal de São Paulo, São Paulo, Brazil, [4]University of Florida, Gainesville, FL.

Background/Purpose: Autoantibodies to IMPDH2 occur in Hepatitis C patients receiving ribavirin (RBV) & interferon-α (IFN-α). Anti-IMPDH2 antibodies recognize "rods and rings" (RR) cytoplasmic structures in indirect immunofluorescence on HEp-2 cells (IIF-HEp-2). In vitro inhibition of

IMPDH2 by RBV or mycophenolic acid (MPA) induces RR formation. We investigate the in vivo formation of RR structures in patients and mice treated with RBV or MPA.

Methods: Sequentially retrieved RBV/IFN-α-treated HCV (n=108) and MPA-treated Systemic Lupus Erythematosus (SLE) patients (n=78) were tested for anti-RR autoantibodies. Peripheral blood mononuclear cells (PBMC) from 18 MPA-treated SLE and 17 RBV/IFN-α-treated HCV patients were analyzed for RR+ PBMC by double-labeling IIF with human anti-RR serum and rabbit anti-IMPDH2 IgG. Cryosections from 3 untreated and 3 RBV-treated (0.4 mg/day; 3 months) BALB/c mice were screened for RR.

Results: Forty-one (38%) HCV and none of the SLE patients presented anti-RR autoantibody ($p<0.0001$). In vivo RR formation in PBMC occurred in all RBV/IFN-α-treated HCV (28.2±15.2% RR+ cells) and MPA-treated SLE (22.3±15.1% RR+ cells) patients ($p=0.13$). The frequency of RR+ PBMC in HCV correlated with the duration of treatment ($r=0.55$; $p=0.01$). In SLE there was no correlation with duration of treatment ($r=-0.01$; $p=0.95$), time interval from last dose ingested prior to sample collection ($r=0.04$; $p=0.86$) and daily dose ($r=0.30$; $p=0.21$). RBV-treated mice showed widespread RR structures, with variable proportion of RR+ cells in the several tissues: spleen (21.5%), stomach (57.8%), liver (70.7%), kidney (38.8%), heart (13.3%), brain (56.2%), muscle (23.7%), skin (37.1%). Untreated mice showed RR only in spleen (16.3%) and pancreas (14.9%).

Conclusion: Ribavirin and MPA generate in vivo formation of IMPDH2-rich RR structures in PBMC from HCV and SLE patients, respectively. In addition, RBV-treated mice show widespread formation of RR with variable proportion of RR-positive cell across the several tissues. These findings support further studies for the investigation of the consequences of widespread RR formation in patients receiving chronic treatment with RBV or MPA, as well as the understanding of the role of in vivo RR structures on the generation of anti-IMPDH2 autoantibodies.

Interferon Gene Signature Expression and Serological Differences in Japanese and Non-Japanese SLE Patients. Hitoshi Kohsaka[1], Kosuke Kotani[2], Tomonori Ishii[3], Tomoya Miyamura[4], Masato Okada[5], Toshihiko Aranishi[2], R. Maciuca[6], William P. Kennedy[6] and Junko Ohata[2]. [1]Tokyo Medical and Dental University (TMDU), Tokyo, Japan, [2]Chugai Pharmaceutical co., ltd, Tokyo, Japan, [3]Tohoku University, Sendai, Japan, [4]Department of Internal Medicine and Rheumatology, Clinical Research Institute, National Hospital Organization Kyushu Medical Center, Fukuoka, Japan, [5]St. Luke's International Hospital, Tokyo, Japan, [6]Genentech, Inc, South San Francisco, CA.

Background/Purpose: Elevated expression of interferon(IFN)-regulated genes in peripheral blood cells has been reported in systemic lupus erythematosus (SLE) patients and is known as the IFN signature. The IFN signature in SLE has been reported to be correlated with disease-related autoantibodies such as anti-dsDNA and anti-RNP and with disease activity. Differential expression of the IFN signature among SLE patients has been reported and may indicate that the patient subgroups categorized with IFN signature expression levels have distinct biological differences. We determined the IFN signature using a 3-gene surrogate for the expression of the IFN-regulated genes[1)] and serological biomarkers described below in Japanese SLE patients. We compared these results to reported values for non-Japanese SLE populations[2)].

Methods: Peripheral blood samples from healthy volunteers (HVs) and SLE patients were analyzed in Japanese and American/European[1)]populations. SLE patients with SELENA-SLEDAI (SS) score >6 and without active renal nephritis, CNS or hematological disease were eligible. Three IFN-regulated genes (EPSTI1, HERC5 and TYK1) were chosen to represent the overall IFN signature of IFN-regulated genes, and the standardized average values of PCR quanitified expression of the three genes are reported as the IFN signature metric (ISM) score. The titers of autoantibodies and serological markers (C3, C4, anti-dsDNA, anti-RNP, ANA, ENA and serum BAFF) were measured from the same patients.

Results: The mean of ISM scores in HVs were lower than in the SLE patients. The ISM score distribution range of HVs was higher in Japanese (n=20) than in non-Japanese (n=60); the ISM score at the 95 percentile of distribution was 1.7 and 1.0, respectively. The mean of ISM score of Japanese SLE patients (n=60, SS score 8.9±2.3) was 2.9±1.1, which is higher than in non-Japanese SLE patients (2.0±1.5) with similar disease activity(n=238, White n=76, Black n=34, Hispanic n=114, other n=14, SS score 9.8±3.3). ISM scores in non-Japanese patients showed correlations with anti-dsDNA titer, positive ENA, serum BAFF levels, hypocomplementemia and SS score. In contrast, ISM scores in Japanese patients were generally high as a whole population, and did not correlate with these findings. Although the frequency of anti-dsDNA antibody positive patients was comparable between the two populations, the median (IQR) titer was lower in Japanese [34 IU/mL (28–76)] than non-Japanese patients [53 IU/mL (14–193)[1)]]. Serum BAFF correlated with ISM scores in non-Japanese SLE patients but not in Japanese patients. The profiles in ISM and serological abnormality (SA) in two ethnic populations demonstrated a contrast; high ISM/ high SA or low ISM/ low SA in non-Japanese versus high ISM/ low SA in Japanese patients.

Conclusion: The differences in ISM and SA profiles between Japanese and non-Japanese SLE patients suggests that there are demographic differences in molecular pathophysiology of SLE. These differences may have implications for therapeutic interventions that target the innate and/or adaptive immune system.

Molecular, Cellular and Histopathologic Assessment of Baseline Characteristics of Sixteen Subjects with Discoid Lupus Erythematosus Prior to Treatment with AMG 811 (anti-IFNγ). Barbara Sullivan[1], Roberto Guzman[1], Christopher B. Russell[2], Greg Arnold[1], Michael Boedigheimer[1], Connie Ma[1], James Chung[1], Victoria P. Werth[3] and David A. Martin[2]. [1]Amgen, Thousand Oaks, CA, [2]Amgen, Seattle, WA, [3]Veteran Affairs Medical Center, Philadelphia, PA.

Background/Purpose: Discoid Lupus Erythematosus (DLE), the most common chronic cutaneous form seen in LE, includes inflammation leading to scarring, telangiectasias, atrophy, and/or dyspigmentation. Elevated levels of IFN-γ mRNA have been described in DLE skin biopsy specimens, and patients with DLE have an IFN transcriptional signature in both blood and skin. AMG 811 is a human monoclonal antibody that selectively targets and neutralizes human IFN-γ, and results from a randomized, placebo-controlled, crossover study in DLE subjects have been previously reported (NCT01164917; Werth et al, 2013). The primary results demonstrated acceptable safety and PK profiles without apparent clinical benefit. Evidence of a pharmacodynamic effect in the blood (e.g. inhibition of IFN-γ) was apparent; however, heterogeneity in skin samples prevented definitive conclusions about the effects of AMG 811 in diseased skin.

Methods: This multi-center clinical study included 16 subjects with DLE enrolled in a randomized, single-dose crossover study. DLE subjects required a history of skin biopsy consistent with the diagnosis of DLE (Gilliam and Sontheimer classification); a diagnosis of SLE (ACR criteria) was not required, however 14 of 16 subjects had both DLE and SLE. Microscopic histopathology was performed on punch biopsies obtained from discoid lesional and non-lesional areas, and the abundance of CD3+, CD4+, CD8+, CD68+ and Ki67+ cells were quantitated by laser scanning cytometry. Whole blood and skin RNA and serum proteins were analyzed by microarray and ELISA, respectively.

Results: The baseline CLASI activity and damage scores ranged from 10 to 34 and 6 to 35, respectively (maximum 70), reflecting heterogeneity in the anatomic location and severity of the DLE skin involvement in this cohort. A range of microscopic pathology findings was observed including acanthosis, keratinocyte apoptosis, inflammatory cell infiltrates and dermal mucinosis. As with psoriasis, there was a wide range of elevated numbers of CD3+, CD4+, CD8+ T cells, CD68+ macrophages and as well as Ki67+ proliferating cells in the lesional skin compared to non-lesional skin. The AMG 811 PD score, a microarray signature described previously, was significantly higher

in DLE lesional skin compared with non-lesional skin. Histopathology and RNA transcript analysis revealed substantial intra- and inter-subject heterogeneity between skin biopsies from DLE subjects as compared to published results from subjects with psoriasis. Pathway analysis of the transcriptome suggested differential activation of both the interferon and IL-17 pathways.

Conclusion: Discoid subjects in this small clinical study demonstrated a high level of clinical, histologic and molecular heterogeneity at baseline, creating hurdles for measuring response to therapy. Analysis of clinical and/or skin biomarkers may improve understanding of the heterogeneity within DLE, and may better enable subgroup selection for assessment of response to therapeutic treatments.

Relationship Between Apom/S1P Levels and Atherosclerosis in Women with Systemic Lupus Erythematosus. Sonali Narain[1], Sylvain Galvani[2], Christina Christoffersen[3], Peiying Yang[4], Maureen A. McMahon[5], Timothy Hla[2] and Jane E. Salmon[1]. [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell College of Medicine, New York, NY, [3]University of Copenhagen, Copenhagen, Denmark, [4]University of Texas MD Anderson Cancer Center, Houston, TX, [5]UCLA David Geffen School of Medicine, Los Angeles, CA.

Background/Purpose: SLE patients are at risk for atherosclerotic cardiovascular disease (ASCVD). In some SLE patients, high density lipoprotein (HDL) has impaired vasoprotective effects, and this "proinflammatory" HDL (piHDL) is more prevalent in those with ASCVD. The protective effect of HDL in atherosclerosis is attributable, in part, to its ability to deliver to S1P to receptors on endothelial cells. Apolipoprotein M (ApoM) is a component of some HDLs and serves as a chaperone of sphingosine 1-phosphate (S1P), a critical mediator of vascular homeostasis. S1P interacts with its receptors on endothelial cells to prevent vascular injury and inflammation. We hypothesized that the ApoM/S1P axis is deregulated in SLE.

Methods: We performed a cross-sectional study to measure ApoM and S1P levels in SLE patients. Plasma samples were obtained from 52 SLE patients who were part of a University of California Los Angeles cohort followed for ASCVD and met at least four of eleven 1982 ACR SLE Classification Criteria (Table 1). Patients on statins or with renal failure (Cr $>$ 2.0) were excluded. Plasma lipid levels were measured using standard methods. Measurement of pro-inflammatory HDL was performed using a cell free LDL oxidation assay. ApoM was measured using a standardized ELISA and S1P levels by mass spectrometry. Statistics were performed using GraphPad Prism 6.0 and SPSS using appropriate non-parametric tests.

Results: Total plasma ApoM and S1P levels were significantly lower in the SLE patients compared to previously published levels in healthy controls (HC). Mean ApoM level was 0.75 $\pm$ 0.28 mmol/L in lupus patients versus 0.92 $\pm$ 0.32 mmol/L in HC ($p<0.0001$) and mean S1P level was 47.08 $\pm$ 17.08 ng/ml in lupus patients versus 221.7 $\pm$ 84.25 ng/ml in HC ($p=0.004$). There was a positive correlation between levels of ApoM and S1P ($r = 0.34$, $p=0.013$). ApoM levels negatively correlated with body mass index (BMI) ($r = -0.54$, $p<0.0001$) and SLE disease duration ($r = -0.33$, $p=0.017$). Level of S1P was negatively correlated with BMI ($r = -0.45$, $p=0.002$) and hs-CRP ($r = -0.46$, $p=0.008$). There was no statistically significant association of ApoM or S1P levels with piHDL status, plaque status, intimal medial thickness (IMT), smoking, age, hypertension, lipid levels, ethnicity or lifetime prednisone use. In a multivariate regression combining these variables, only BMI and disease duration was significantly associated with ApoM levels.

Conclusion: Although total plasma levels of ApoM and S1P in circulation appeared to be significantly lower in SLE patients, they were neither associated with cardiovascular risk factors nor established plaque or piHDL. Studies comparing ApoM/S1P levels in SLE patients with age and sex matched healthy controls and ApoM/S1P levels in lipid sub-fractions of SLE patients are ongoing. We postulate that levels of ApoM and S1P may be influenced by inflammation status of SLE patients as this has been previously reported in patients with sepsis.

Patient Demographics

Gender (F:M)	52:0
Age (yrs $\pm$ SD)	44.98 + 13.2
Carotid Plaque n, (%)	15 (28.9)
SLE Disease duration (yrs $\pm$ SD)	12.92 + 9.1
Total Cholesterol (mg/dl)	186.2 + 37.1
HDL (mg/dl)	60.23 + 19
BMI (baseline) kg/m^2 $\pm$ SD	26.98 + 5.8
Smoking n, (%)	12 (24.5)
Diabetes mellitus n, (%)	0 (0)
Hypertension n, (%)	15 (22.9)

Urinary T Cells and Macrophages Strongly Reflect the Disease Activity, Kidney Function, and the Histopathologic Classification in Patients with Lupus Nephritis. Yoko Wada[1], Minoru Sakatsume[1], Masaaki Nakano[2] and Ichiei Narita[1]. [1]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [2]School of Health Sciences, Faculty of Medicine, Niigata University, Niigata, Japan.

Background/Purpose: Lupus nephritis (LN) is one of the common manifestations of systemic lupus erythematosus (SLE), and the occurrence of LN is considered to be a very important factor influencing the course of the disease. Although kidney biopsy is the gold standard for defining the histopathologic class of LN, it is invasive and sometimes associated with a risk of bleeding; furthermore, repeated biopsies are not always applicable in clinical practice. For this reason, some form of novel non-invasive examination would be useful for detecting renal flare-up in LN patients. We have already reported that, in patients with glomerulonephritis, T cells and macrophages appear in the urine when there are accompanying signs of active cellular infiltration such as cellular crescent formation and diffuse interstitial cell infiltration, but not when active inflammatory lesions are absent. In the present study, we assessed the utility of urinary immune cell analysis in patients with SLE by examining the correlation between the numbers of urinary inflammatory cells and disease activity, kidney function, and histopathological classification of lupus nephritis.

Methods: Sixty-four samples from 56 patients with SLE, who had been referred to Niigata University Hospital between 2004 and 2013, were recruited for this study. Flow-cytometric analysis of urinary inflammatory cells was performed for each sample. Numbers of urinary T cells or macrophages were determined by multiplying the number of viable cells in the gated mononuclear cell region in each sample by the percentage of urinary CD3-positive or CD14-positive cells in the population, respectively. The numbers of urinary CD3-positive cells (T cells) and CD14-positive cells (macrophages), laboratory markers, kidney function, and SLE disease activity index (SLEDAI) were examined in each subject and compared with reference to their urinalysis data. The data were also analyzed by Spearman's rank correlation coefficient and stepwise multiple regression analysis to determine the relationship with urinary T cells and macrophages. In 15 patients who underwent kidney biopsy simultaneously, the relationship between histopathologic classification and the number of urinary inflammatory cells was examined.

Results: The number of urinary CD3-positive cells was significantly elevated in patients with both proteinuria and abnormal urinary sedimentation, relative to patients with proteinuria alone or normal urinalysis data. The number of CD3-positive cells was positively correlated with serum Cr, abnormal urinary sedimentation, and SLEDAI, and negatively correlated with serum CH50, while the number of urinary CD14-positive cells was positively correlated with serum Cr, abnormal urinary sedimentation, 24-hour urinary protein excretion, and SLEDAI. Among the 15 patients who underwent kidney biopsy, 8 showing a significant increase in the total number of CD3-positive cells and CD14-positive cells ($\geq$120/ml urine) were diagnosed as ISN/RPS class III or IV, while the remaining 7 were diagnosed as ISN/RPS class V.

Conclusion: These results indicate the usefulness of urinary immune cell analysis for assessment of patients with SLE.

High Specificity of Skin Immunoglobulin Deposits for diagnosing SLE in Patients with Lupus Nephritis. Marco Ulises Martinez-Martinez[1], Maria Daniela De Avila[2], Mario Perales[2], Lourdes Baranda[2], Susana Román Acosta[2], Jaime Antonio Borjas García[2] and Carlos Abud-Mendoza[1]. [1]Hospital Central & Facultad de Medicina, Universidad Autónoma de San Luis Potosí, San Luis Potosí, Mexico, [2]Hospital Central y Facultad de Medicina, Universidad Autónoma de San Luis Potosí, San Luis Potosí, Mexico.

Background/Purpose: Deposit of different classes of immunoglobulins is the main feature of lupus nephritis;[1] because of its high specificity, a patient is classified as having systemic lupus erythematosus (SLE) if he or she has antinuclear or anti-dsDNA antibodies and biopsy-proven nephritis.[2] Granular deposition of immunoglobulins at the dermoepidermal junction [lupus band (LB)] is distinctive of SLE, but its utility for SLE diagnosis is indefinite. The main objective was to evaluate concordance of immunoglobulin deposits between kidney and skin in patients with SLE. The secondary objective was to evaluate the accuracy of the LB as a diagnostic test for SLE in patients with lupus nephritis and controls with other non-SLE nephropathies.

Methods: All patients who required kidney biopsy in the last 10 months were invited to participate in the study. From all patients who signed informed consent, kidney and non-exposed-skin biopsies were taken at the same moment and were evaluated for immunoglobulins (IgG, IgM, IgA) and complement proteins (C1q and C3) deposits. A different evaluator assessed kidney and skin biopsies; nevertheless, to assess the technique's reliability, we obtained a weighted kappa of 0.89 (CI: 0.78–0.99) when they evaluated the same set of 20 images. Intensity of fluorescence for each biopsy specimen was graded from 0 to 4 + (negative=0, and positive= 1–4+).

Results: We included 25 patients with lupus nephritis and 28 controls (other nephropathies). In the 25 patients with lupus nephritis, IgG was positive in 23 (92%) in kidney and 13 (52%) of skin biopsies; IgA in 20 (80%) of kidney and 4 (16%) of skin biopsies; IgM 23 (92%) of kidney and 9 (36%) of skin biopsies; C3 in 24 (96%) of kidney and 3 (12%) of skin; C1q in 24 (96%) and 11 (44%) of skin biopsies. The table 1 shows the high sensitivity and specificity of kidney immunoglobulin deposits for diagnosing SLE and highlights the good specificity of C1q, IgA, and IgM deposits in the skin.

Table 1. Accuracy of immunoglobulin deposits in skin or kidney for diagnosing SLE

	Sensitivity	Specificity	PPV	NPV	LR (+)	LR (-)
IgG skin	0.52 (0.20–0.46)	0.86 (0.67–0.96)	0.76 (0.50–0.93)	0.67 (0.49–0.81)	3.64 (1.36–9.72)	0.56 (0.36–0.87)
IgG kidney	0.92 (0–74–0.99)	0.79 (0.59–0.92)	0.79 (0.60–0.92)	0.92 (0.73–0.99)	4.29 (2.09–8.81)	0.10 (0.03–0.39)
IgA skin	0.47 (0.33–0.61)	1 (0.82–1.0)	1 (0.28–1.0)	0.57 (0.42–0.71)	∞	0.84 (0.71–1.0)
IgA kidney	0.80 (0.59–0.93)	0.79 (0.59–0.92)	0.77 (0.56–0.91)	0.81 (0.62–0.94)	3.73 (1.79–7.79)	0.25 (0.11–0.57)
IgM skin	0.36 (0.18–0.57)	0.93 (0.76–0.99)	0.82 (0.48–0.98)	0.62 (0.46–0.76)	5.04 (1.20–21.15)	0.69 (0.50–0.94)
IgM kidney	0.92 (0–74–0.99)	0.54 (0.34–0.72)	0.64 (0.46–0.79)	0.88 (0.64–0.99)	1.98 (1.31–3.0)	0.15 (0.04–0.59)
C3 skin	0.12 (0.03–0.31)	0.93 (0.76–0.99)	0.60 (0.15–0.95)	0.54 (0.39–0.69)	1.68 (0.31–9.25)	0.95 (0.79–1.13)
C3 kidney	0.96 (0.80–1.0)	0.68 (0.48–0.84)	0.73 (0.54–0.87)	0.95 (0.75–1.0)	2.99 (1.73–5.15)	0.06 (0.01–0.41)
C1q skin	0.44 (0.24–0.65)	1 (0.82–1.0)	1 (0.62–1.0)	0.67 (0.50–0.80)	∞	0.56 (0.40–0.79)
C1q kidney	0.96 (0.80–1.0)	0.79 (0.59–0.92)	0.80 (0.61–0.92)	0.96 (0.78–1.0)	4.48 (2.19–9.15)	0.05 (0.01–0.35)

PPV: positive predictive value, NPV: negative predictive value, LR: likelihood ratio, (+): positive, (−): negative.

Conclusion: Deposits of immunoglobulins are more common in kidney than skin. High specificity of LB justifies its use as a diagnostic tool for SLE; the high specificity of LB suggests its utility for SLE diagnosis.

Prevalence and Prognostic Implications of IgG4 in Membranous Lupus Nephritis. David Herrera Van Oostdam, Marco Ulises Martinez-Martinez, Cuauhtémoc Oros-Ovalle, David Martínez-Galla, Gerardo Tonatiu Jaimes-Piñón, Natalia Alemán-Sánchez and Carlos Abud-Mendoza. Hospital Central & Facultad de Medicina, Universidad Autónoma de San Luis Potosí, San Luis Potosí, Mexico.

Background/Purpose: Patients with membranous lupus nephritis (MLN) have increased risk of thrombosis and different prognosis than other classes of lupus nephritis (LN). Previous studies demonstrated an association of idiopathic membranous nephropathy with IgG4+ against A2-phospholipase receptor. Scarce studies evaluate this fact in LN. To determine the prevalence of IgG4 deposits in renal biopsies of patients MLN (pure or combinations with proliferative LN). A secondary objective was to establish the prognosis of patients with IgG4 deposits.

Methods: Cross-sectional study. We included patients with LN class V or combination (classes V+III or V+IV) according to the 2004 ISN/RPS criteria. All patients with a kidney biopsy from January 1st 2008 to January 30th 2013 were included; all samples were stained with IgG4 using antibody anti-IgG4 (MRQ44, Cell Marque).

Results: We included 65 renal biopsies: 24 class IV+V, 23 class V, and 18 class III+V; 6/65 were IgG4 +. Patients with IgG4+ had a median age of 36 years (IQR 26yr), median of SLEDAI 8 (IQR 4) vs 12 in IgG4- (IQR 8; p 0.7). Patients with IgG4+ had median blood eosinophil count of 70 (IQR 171) vs IgG- 0 (IQR 30; p 0.03). IgG4 deposits were associated with plasmatic cell infiltration in renal biopsy (OR 42, IC 95% 2.4–228; p 0.03). All patients with IgG4+ had renal involvement as the first manifestation of SLE. Treatment: 28% of IgG4+ and 41% of IgG4- of patients received methylprednisolone pulses before renal biopsy, since their first manifestation was a rapidly progressive glomerulonephritis. Renal failure (GFR <60 ml/min) was similar in both groups (43% in IgG4+ and 42% in IgG4-). Fifty percent of patients with IgG4+ who required dialysis at baseline still continued this therapy at 12 months vs 8% of IgG4- patients.

Conclusion: The prevalence of IgG4 deposits in MLN was 10%. All patients who had MLN as their first SLE manifestation were IgG4 +. Patients with IgG4 +LN showed worse prognosis.

Association of Glomerular Macrophage Phenotypes and Urine Soluble CD163 with Disease Activity in Human Lupus Nephritis. Naotake Tsuboi, Nobuhide Endo, Seiichi Matsuo and Shoichi Maruyama. Nagoya University Graduate School of Medicine, Nagoya, Japan.

Background/Purpose: In addition to the effector roles of classically activated macrophages for tissue injury, recent studies have shown that alternatively activated (M2) macrophages are involved in resolution of inflammation in animal models of kidney disease. But, clinical relevance of M2 macrophage in human disease is largely unknown. The current study aimed to evaluate renal accumulation of macrophage phenotypes in human lupus nephritis (LN) and significance of soluble form of CD163 (sCD163), a representative marker for M2 cells, for LN disease activity.

Methods: Plasma, urine and kidney biopsy samples were obtained from 74 patients with LN. Histological features were classified according to the ISN/RPS LN criteria. Immunohistochemical analyses using anti-human CD68, CD163 or CD204 antibodies were performed for identification of macrophage phenotypes. Concentrations sCD163 and MCP-1 in plasma and urine were measured by ELISA.

Results: Immunohistological analysis in LN glomeluli revealed more than 70% of $CD68^+$ macrophages was merged with $CD163^+$ cells and more than 90% of $CD163^+$ cells was merged with $CD68^+$ cells. However, $CD163^+$ cells appeared to be more than $CD68^+$ cells in interstitum, indicating the different origin of glomerular and interstitial $CD163^+$ macophages. The cell counts of glomerular $CD68^+$, $CD163^+$ or $CD204^+$ macrophages were increased in association with severity of biopsy active index (BAI) score in LN. Interstitial $CD68^+$, $CD163^+$ or $CD204^+$macrophage infiltration correlated with eGFR. Urine sCD163 level showed stronger correlation with the number of glomerular CD163 positive cell counts (r=0.501) and BAI score (r=0.644) than plasma sCD163 levels with both of the above (r=0.289 and r=0.295, respectively). Correlation of urine sCD163 with BAI was comparable to that of urine MCP-1 levels (r=0.592) and was much better than NGAL (r=0.174) in LN.

Conclusion: These results suggest that $CD163^+$ or $CD204^+$ macrophage is the dominant phenotype in kidneys of LN patients, and urine sCD163 level has a potential significance for estimation of disease activity in human LN.

Biomarkers of Lupus Nephritis and Ethnic Disparities in Systemic Lupus Erythematosus. Adnan Kiani[1], Laurence S. Magder[2] and Michelle Petri[3]. [1]Johns Hopkins University, Baltimore, MD, [2]University of Maryland, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: Lupus nephritis eventually occurs in 50% of Caucasian SLE patients and 75% of African-Americans. African Americans have a more severe presentation of SLE and more often progress to end stage renal disease (ESRD). We have found a number of serum and urine biomarkers that have been associated with lupus nephritis. Therefore, we compared Caucasians and African-Americans with respect to levels of these biomarkers.

Methods: Urinary tumor necrosis factor-like weak inducer of apoptosis (TWEAK), vascular cell adhesion molecule 1 (VCAM-1), monocyte chemoattractant protein 1 (MCP-1) and osteoprotegrin (OPG) were measured in a longitudinal cohort of SLE patients by ELISA (R&D). We analyzed the relationship between these potential urine biomarkers and Caucasian or African-American ethnicity.

Results: Urinary TWEAK levels were higher among Caucasians than African-Americans (p=.033). Urinary VCAM-1, MCP-1 and OPG levels were higher among African-Americans than Caucasians, but the results were not statistically significant (Table 1).

Table 1: Mean (SD) of Each Biomarker by Ethnicity

	TWEAK (p=.033)		VCAM-1(p=0.62)		MCP-1 (p=0.16)		OPG (p=0.21)	
	N	Mean log-Tweak (SD)	N	Mean log OPG (SD)	N	Mean (SD)	N	Mean (SD)
Caucasian	175	0.12 (0.10)	32	2.59 (0.96)	37	3.40 (2.00)	37	3.35 (2.44)
African-American	96	0.09 (0.09)	40	2.80 (0.85)	43	4.19 (1.77)	43	4.17 (1.94)

Conclusion: Systemic lupus erythematosus and lupus nephritis disproportionately affect racial/ethnic minorities. Renal outcome has not improved in African-Americans or in the South in United States. Our results show that not all urine biomarkers are worse in African-Americans. Surprisingly, urinary TWEAK was higher in Caucasians. The others, however, were higher in African-Americans. The identification of ethnicity-specific biomarkers of renal activity would allow ethnicity-specific regimens. Further larger studies are needed to corroborate our findings.

Serum Cystatin C As a Biomarker for Clinical Practice in Patients with Lupus Nephritis. Hua Zhou, Di Lu, Hairong Tang and Lining Wang. The First Hospital of China Medical University, Shenyang, China.

Background/Purpose: Cystatin C has been developed as a novel biomarker of renal function in last decade and thought as more sensitive than serum creatinine (sCr). However, the clinical significance of serum cystatinC (sCysC) in lupus nephritis (LN) has been rarely reported. We aim to compare serum CysC with traditional indices of renal function and SLEDI in LN patients.

Methods: 75 patients with renal biopsy approved LN based on the ISN/ACR 2003 classification criteria were from The First Hospital of China Medical University since 2009 to 2014. sCysC (mg/L), sCr (umol/L), blood urea nitrogen (BUN, mmol/L), glomerular filtration rate (GFR, ml/min) measured by MDRD and EPI equation, serum albumin (sAlb, mg/L) and urinalysis including 24hr total protein (uTP, g/day), albumin (uAlb, g/L), and Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) were measured before and 6 months after glucosteroid and cyclophosphamide(CTX) treatment. The correlation between sCysC and each traditional indicator were analyzed by Person and the difference of these indices before and after-treatment was analyzed by student ttest.

Results: sCysC showed closer correlation with traditional indices of renal impairment and SLE activity (Table1). sCysC also displayed a better statistical p value in the response to the treatment of glucosteroid and CTX than sCr and BUN (Table2).

Conclusion: The significance of sCysC should be more emphasized in clinical practice in LN patients. Prospective study needs to be contacted on the effect of early treatment giving based on the increase of sCysC but before sCr rise in large cohort of patients with lupus nephritis.

Table 1. Comparison of sCysC with SCr and BUN in correlation efficiency with disease activity of lupus nephritis

	eGFR(MDRD) r (p value)	eGFR(EPI) r (p value)	sAlb r (p value)	uTP/day r (p value)	uAlb r (p value)	SLEDAI r (p value)

Thrombotic Microangiopathy and Poor Renal Outcome in Lupus Patients Is Not Associated with Antiphospholipid Syndrome and/or Other Lupus Conventional Features. Gabriela Hernandez-Molina, Paola García-Trejo, Norma Uribe and Antonio R. Cabral. Instituto Nacional de Ciencias Medicas y Nutricion, Mexico City, Mexico.

Background/Purpose: To assess acute thrombotic microangiopathy (aTMA) and chronic vascular lesions (cTMA) in lupus nephropathy and to evaluate their association with extrarrenal lupus features, antiphospholipid (APS) clinical and/or serological criteria, low complement and renal survival.

Methods: We studied consecutive lupus patients (2008–2012) according to the following inclusion criteria: renal biopsy, at least two determinations of aCL (IgG-IgM), anti-b_2GP-I (IgG-IgM), lupus anticoagulant and ≥1 year of post-biopsy follow-up. We excluded patients with overlap syndromes, diabetes mellitus, uremic hemolytic syndrome, thrombotic thrombocytopenic purpura and malignant hypertension. A blinded nephropathologist evaluated all biopsies. aTMA was defined as a fibrin thombi in arterioles and glomeruli and cTMA as arterial fibrous intimal hyperplasia and/or organized thrombi and/or fibrous occlusion and/or subcapsular ischemic cortical atrophy. We retrospectively collected demographic and clinical data (lupus and APS features, immunosuppressors and anticoagulant use), hypocomplementenemia as well as renal survival assessed as chronic dialysis. We used X^2, t-student and U-Mann Whitney test, plotted survival curves and Cox regression analysis.

Results: We studied 90 lupus kidney biopsies from patients with disease duration at the time of the biopsy of 5.9 years and a median post-biopsy follow-up 2.4 of years (range 1–6.5). Eleven patients (12.2%) had cTMA and 3 (3%) aTMA. There were no differences in age, lupus duration, hypertension, immunosuppressors use, extra-renal lupus features (arthritis, vasculitis, serositis, hematologic, neurologic, Raynaud, cutaneous) and APS prevalence between patients with cTMA or without cTMA. We did not find any difference in the presence of low C3 (63% vs. 62%), low C4 (72% vs. 73%) nor in the frequency of aCL IgG (27% vs 30%), anti-β_2GP1 IgG (36% vs 46%), anti-β_2GP1 IgM (22% vs 40%) and AL (20% vs13%) among patients with and without cTMA, respectively. Patients with cTMA had less frequently aCL-IgM (27% vs 66%, p=0.02), a higher prevalence of chronic dyalisis (54.5% vs 24% p=0.06), a higher frequency of class IV nephropathy (100% vs 40%, p=0.01) also with a higher activity index (7.5 vs 2, p=0.03). At four years of follow-up, 28% of cTMA patients and 62% non-cTMA patients were free of dialysis (log Rank p=0.03). At the Cox analysis, cTMA was associated with chronic dialysis (RR 2.9, CI 95% 1.1–8.1, p=0.03).

Conclusion: cTMA confered a poor renal outcome. Unlike published studies, cTMA was not associated with lupus or antiphospholipid clinical or serological features. Other factors hitherto not studied are involved in the pathogenesis of this histopathological feature.

Lupus Nephritis: Clinicopathological Correlation in 126 Biopsies. Milagros Ricse[1], Javier Narváez[2], Gloria Albert[1], Paula Estrada[1], Helena Borrell[1], Eugenia de Lama[1], Xavier Fulladosa[1], Manel Rubio Rivas[1], Olga Capdevila[1], Francesca Mitjavila[1], Xavier Juanola[3] and Joan Miquel Nolla[1]. [1]Hospital Universitario de Bellvitge, Barcelona, Spain, [2]Hospital Universitario de Bellvitge. Barcelona. Spain, Barcelona, Spain, [3]University Hospital Bellvitge, Barcelona, Spain.

Background/Purpose: To analyze the correlation between clinical and laboratory data and type of histological injury in a cohort of patients with lupus nephritis (LN).

Methods: The sample comprised 243 patients with SLE treated between 1980 and 2013 at a tertiary university hospital that does not attend pediatric populations. Patients were registered in a specific database. Patients diagnosed with LN classes 2–5 according to the WHO classification or the ISN/RPS classification (in use since 2004) were selected for analysis. In each case, the presence of arterial hypertension, renal insufficiency (RI), nephrotic syndrome (NS), hematuria, and cylindruria was assessed at the time of the biopsy; 24-h urine protein value was also recorded.

The specificity, sensitivity, PPV, NPV, LR +, LR-, and accuracy for each of the clinical and laboratory data in order to diagnose the different histological types of LN.

Results: The diagnoses were: **a)** *Class II Mesangial proliferative lupus nephritis*, 45 cases (35%); **b)** *Class III Focal lupus nephritis*, 16 (13%); **c)** *Class IV Diffuse lupus nephritis* 49 (39%), and d) *Class V Membranous lupus nephritis*, 16 (13%).

The mean levels of proteinuria were: a) class II; 1.62 g/24 h; b) class III: 1.53 g/24 h; c) class IV; 2.12 g/24 d) class V; 5.15 g/24 h. The only significant differences observed were between LN class V and the other histological types of LN. Five patients had proteinuria below 0.5 g/24 h (3 class II and 2 class IV) and 12 had proteinuria 0.5–1 g/24 (3 class II, 3 III, 4 IV and 2 class V).

The discriminative values of other clinical and laboratory data for the diagnosis of the different types of LN are shown in Table 1.

	Sensitivity	Specificity	PPV	NPV	LR+	LR−	Accuracy
CLASS II	–	–	–	–	–	–	–
Renal insufficiency	4%	83%	13%	61%	0.26	1.16	0.547
Arterial Hypertension	4%	78%	10%	59%	0.20	1.23	0.515
Nephrotic syndrome	18%	54%	18%	54%	0.39	1.51	0.412
Hematuria	69%	40%	39%	70%	1.14	0.79	0.500
Cylindruria	4%	81%	12%	61%	0.24	1.17	0.539
CLASS III	–	–	–	–	–	–	–
Renal insufficiency	6%	86%	6%	86%	0.46	1.09	0.761
Arterial Hypertension	6%	83%	5%	86%	0.36	1.13	0.730
Nephrotic syndrome	6%	60%	2%	81%	0.16	1.56	0.531
Hematuria	56%	35%	11%	85%	0.87	1.23	0.380
Cylindruria	13%	87%	13%	87%	0.98	1.00	0.777
CLASS IV	–	–	–	–	–	–	–
Renal insufficiency	20%	94%	67%	65%	3.14	0.85	0.650
Arterial Hypertension	35%	96%	85%	70%	8.90	0.68	0.722
Nephrotic syndrome	53%	75%	58%	72%	2.15	0.62	0.666
Hematuria	61%	35%	38%	59%	0.94	1.11	0.452
Cylindruria	22%	94%	69%	65%	3.46	0.83	0.658
CLASSV	–	–	–	–	–	–	–
Renal insufficiency	19%	88%	19%	88%	1.59	0.92	0.793
Arterial Hypertension	0%	82%	0%	85%	0.00	1.22	0.714
Nephrotic syndrome	63%	68%	22%	93%	1.96	0.55	0.674
Hematuria	63%	36%	13%	87%	0.98	1.03	0.396
Cylindruria	13%	87%	13%	87%	0.98	1.00	0.777

Parameters with a high LR + (greater than 3) and an acceptable diagnostic accuracy were the presence of RI, arterial hypertension and cylindruria in LN class IV. The presence of NS in classes IV and V also had a relatively high LR +. However, at the time of diagnosis or during follow-up, eight patients with LN class II had NS (excluding those patients with nephrotic-range proteinuria undergoing class transformation). Although uncommon, the presence of cylindruria was also observed in LN class II (one patient), class III (2) and type V (2).

In LN class II, none of the clinical and laboratory data had a LR- high enough (<0.5 to 0.3) to be a useful parameter to discard it.

Conclusion: In LN, only class IV and to a lesser extent class V present a good correlation between the clinical/ laboratory and histological data. In general, clinical/laboratory data cannot predict the type of histological lesion. In our experience, more than half of patients with mild proteinuria (below 1 g/24 h) presented advanced forms of LN (classes III, IV or V).

1656

Rate of Histological Transformation to Higher Grade Nephritis in Class II Mesangial Proliferative Lupus Glomerulonephritis. Andrea Zacarias[1], Javier Narváez[2], Gloria Albert[1], Milagros Ricse[1], Paula Estrada[1], Melany Pestaña[1], Chema Mora[1], Jesus Rodriguez Moreno[1], Xavier Fulladosa[1], Manel Rubio Rivas[1] and Joan Miquel Nolla[1]. [1]Hospital Universitario de Bellvitge, Barcelona, Spain, [2]Hospital Universitario de Bellvitge. Barcelona. Spain, Barcelona, Spain.

Background/Purpose: Class II mesangial proliferative lupus nephritis has generally been considered a mild form of the condition, with a good response to glucocorticoid treatment. However, some recent studies have questioned this assumption after observing high rates of recurrence and histological transformation to more serious classes. Our aim was to analyse the baseline clinical features and clinical response at one year after treatment in patients with mesangial proliferative lupus nephritis (MPLN) identified at their first renal biopsy.

Methods: The sample comprised 243 patients with SLE treated between 1980 and 2013 at a tertiary university hospital that does not attend pediatric populations. Patients were registered in a specific database (ACHILLES Project). Patients with renal biopsy-confirmed MPLN according to the WHO classification (created in 1982 and modified in 1995, in use until 2004) or the ISN/RPS classification (in use since 2004) were selected for analysis. Data were collected ambispectively. Patients who presented remission (partial or complete) after completing induction therapy were considered "responders". "Non-responders" were those who presented "no response" (complete or partial absence of response of renal disease after completing induction therapy), class transformation or death due to lupus nephritis.

Results: Forty-five patients (36 women) were identified with a mean age (SD) at the time of diagnosis of nephritis of 39.5 (12.3) years. The median time between diagnosis of SLE and the development of nephritis was 33 months. Proteinuria above 0.5 g/24h was found in 42 (93%) patients, hematuria in 31 (69%), cylindruria in one (2%), mild renal insufficiency in two (4%), and hypocomplementemia in 22 (49%). Mean proteinuria was 1.62 (1.03) g/24 h.

Eight patients had nephrotic syndrome (17%) at the time of diagnosis or during follow-up, excluding patients with nephrotic range proteinuria undergoing class transformation. In the diagnostic biopsy, the mean activity index was 2.09 (1.6) and the chronicity index 0.5 (1.8).

All patients were treated with prednisone (dose 0.5 to 1 mg/kg/day). Thirty-three patients (73%) also received treatment with hydroxychloroquine.

At one year after biopsy, 30 (67%) patients achieved complete remission, seven (16%) partial remission and eight (17%) were non-responders. In six of the eight non-responders a second renal biopsy showed transformation to a higher grade of nephritis (class IV in three cases and class V in the other three), resulting in poor renal and poor overall outcome (one of these patients died at six months of follow-up due to SLE lupus activity in the context of transformation to class IV).

Conclusion: In our cohort of patients with MPLN, the rate of non-responders at one year following treatment reached 17%, and was associated with a high rate of transformation to higher grade nephritis. Our data highlight that renal biopsy should be repeated early in patients who fail to respond to glucocorticoid treatment in order to identify those who may require intense immunosuppressive therapy.

1657

Does Advanced Age Influence the Type of Renal Injury and the Prognosis of Lupus Nephritis? Eulalia Armengol[1], Javier Narváez[2], Helena Borrell[1], Sergi Heredia[1], Milagros Ricse[1], Eva Benavent[1], Alex Roset[1], Carmen Gomez Vaquero[1], Joan Torras[1], Francesca Mitjavila[1] and Joan Miquel Nolla[1]. [1]Hospital Universitario de Bellvitge, Barcelona, Spain, [2]Hospital Universitario de Bellvitge. Barcelona. Spain, Barcelona, Spain.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease that usually affects young people. Several reviews have shown that age may have an effect on the clinical expression of the disease and have suggested that in terms of its presentation and clinical course late-onset SLE is generally less severe. Although there is no unanimous agreement, most authors take late onset SLE to refer to disease occurring after

age 50. Our objetive was to examine whether advanced age influences the type of histological lesions and prognosis of lupus nephritis.

Methods: The sample comprised 243 patients with SLE treated between 1980 and 2013 at a tertiary university hospital that does not attend pediatric populations. Patients were registered in a specific database. Patients with lupus nephritis confirmed by renal biopsy and follow-up time of at least two years (n = 79) were selected for analysis. Patients were divided into two groups according to age: over 50 (n = 30) and under 50 (n = 49). "Responders" were defined as patients who presented remission (partial or complete) after completing induction therapy, and "non-responders" were patients in whom no improvement was observed in the analytical parameters, those with histological transformation, and those who died of causes related to nephritis.The Student t test was used to compare continuous variables between groups, or the Mann-Whitney test when variables were not normally distributed. To compare qualitative variables the chi-square or Fisher's exact test was used when the expected frequency was less than 5. The level of significance was set at $p < 0.05$.

Results: In the 79 patients (64 women), mean age at the time of diagnosis of nephritis was 45 years ± 14 (range 17–80) and mean time since onset of SLE was 15.9 months (range 0 – 456). In 81% (64/79) of cases, renal disease was present at the time of diagnosis or during the first year of follow-up. The mean SLEDAI score was 15 ± 7.6. The main results of the comparative study between age groups are shown in the following table:

	Age ≤ 50 years (N = 49)	Age > 50 years (N = 30)	*p*
Sex (male/female)	11/38	4/26	*0.268*
Evolution course of SLE in months (median)	2 (0–230)	1 (0–456)	*0.504*
Lupus nephritis Class II	7 *(14%)*	7 *(23%)*	*0.363*
Lupus nephritis Class III	10 *(20%)*	4 *(13%)*	*0.367*
Lupus nephritis Class IV-S	12 *(24.5%)*	5 *(17%)*	*0.349*
Lupus nephritis Class IV-G	13 *(26.5%)*	9 *(30%)*	*0.850*
Lupus nephritis Class V	7 *(14%)*	5 *(17%)*	*0.852*
Activity Index (mean ± SD)	7.8 ± 4.5	6 ± 4	*0.151*
Chronicity Index(mean ± SD)	1.5 ± 1.5	1.3 ± 1.9	*0.467*
Responders/No responders	40 *(82%)*/9 *(18%)*	24 *(80%)*/6 *(20%)*	*0.121*
Development of renal insufficiency	7 *(14.3%)*	3 *(10%)*	*0.114*

No significant differences were observed between age groups in either the type of renal injury or prognosis.

With regard to treatment, no differences were observed in the percentage of patients who were given hydroxychloroquine, corticosteroids or immunosuppressants, but the use of statins ($p = 0.038$) and ACE inhibitors ($p = 0.033$) was higher in the over 50s group.

Conclusion: Advanced age does not determine the type of histological lesion, nor does it appear to be a poor prognostic factor in lupus nephritis.

Renal Thrombotic Microangiopathy in Systemic Lupus Erythematosus: Novel Risk Factors and Clinical Outcomes. Ana Barrera-Vargas[1], Rodrigo Rosado-Canto[2], Javier Merayo-Chalico[1], Jorge Alcocer-Varela[1] and Diana Gómez-Martín[1]. [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición, Mexico City, Mexico.

Background/Purpose: Thrombotic microangiopathy (TMA) is characterized by microvascular occlusion, systemic or intrarenal platelet aggregation and mechanical injury to erythrocytes. It is a pathological endpoint that results from a disruption of the normal platelet–endothelial interface. TMA is one of the renal vascular lesions which can be found in systemic lupus erythematosus (SLE). The prevalence of renal TMA in SLE varies broadly between studies (8.1–24.3%), and there has been controversy regarding its prognostic value, as well as its association with antiphospholipid (APL) antibodies. The aim of this study was to evaluate risk factors and clinical outcomes for renal TMA in SLE patients.

Methods: A retrospective, single-center study was performed. Renal biopsies from 245 SLE patients between 2008 and January 2014 were studied. We included patients with renal TMA, as well as controls adjusted by glomerulonephritis class, glomerular filtration rate (GFR), activity and chronicity indexes, and follow-up time. The variables that were measured included: autoantibody profile; hypertension, disease activity, SLEDAI, C3 and C4 levels, leukocyte and lymphocyte count, treatment and GFR at the time of the biopsy; GFR, SLEDAI and treatment during follow-up. Differences between groups were analyzed by Student t test or Mann-Whitney U test. Association between variables was assessed by OR (95% CI). Multivariate analysis was performed by binary logistic regression model.

Results: Twenty-three patients with renal TMA and 21 controls were included. TMA prevalence was 9.38%. 90.9% of subjects were female; mean age was 26.04 years in the TMA group and 27.9 years in controls. Mean follow-up was 25.56±14.39 months. At the time of the biopsy, GFR (ml/min/1.73m^2) was 33.6±8.33 in the TMA group and 37.91±7.5 in controls; 56% of patients in the first group and 42.8% in the second required dialysis at that time. Two patients in the TMA group were diagnosed with thrombotic thrombocytopenic purpura (TTP); none of the others had clinical features suggestive of systemic TMA. Lymphopenia, platelet count, higher mean arterial pressure (MAP) and anti-Ro/SSA antibodies were associated with TMA. There was no association with APL syndrome or antibody positivity. There were no differences in SLEDAI score, GFR, end-stage renal disease (ESRD) or mortality between both groups throughout the follow-up period. At the end of follow-up, ESRD rates were 43.4% in the TMA group, and 42.8% in controls. After multivariate analysis, variables that remained significantly associated with renal TMA were: lymphopenia < 1000 cells/uL (OR 10.75, 95% CI 1.34–85.86, p=0.025), anti-Ro/SSA antibodies (OR 9.007, 1.49–54.11 95% CI, p=0.016), and MAP (OR 0.97, 95% CI 0.959–0.994, p=0.009).

Conclusion: Lymphopenia and anti-Ro/SSA positivity were independent risk factors for renal TMA in SLE patients. This association could be related to their potential role in endothelial dysfunction and damage. Outcomes were similar for patients with the same GFR and biopsy characteristics, regardless of the presence of TMA.

The Clinical Relevance of a Repeat Biopsy in Lupus Nephritis (LN) Flares. Milagros Ricse[1], Javier Narváez[2], Gloria Albert[1], Paula Estrada[1], Sergi Heredia[1], Andrea Zacarias[1], Helena Borrell[1], Eulalia Armengol[1], Xavier Fulladosa[1], Joan Torras[1], Olga Capdevila[1], Francesca Mitjavila[1] and Joan Miquel Nolla[1]. [1]Hospital Universitario de Bellvitge, Barcelona, Spain, [2]Hospital Universitario de Bellvitge. Barcelona. Spain, Barcelona, Spain.

Background/Purpose: Renal biopsy is the gold standard for assessing renal activity and hence guiding treatment. Whether a repeat renal biopsy is helpful during flares of LN remains unclear. In the present study, we retrospectively reviewed LN patients who had more than one renal biopsy, in the hope of finding the clinical advantage of repeat biopsy

Methods: The sample comprised 243 patients with systemic lupus erythematosus (SLE) treated between 1980 and 2013 at a tertiary university hospital that does not treat pediatric populations. The patients were registered in a specific database. From a total of 126 patients with LN, we selected those who underwent 2 renal biopsies for analysis. Renal biopsies were evaluated according to the WHO classification or the ISN/RPS classification (in use since 2004).

Results: We identified 28 SLE patients with LN for whom it was possible to compare reference and repeat biopsies. In total, 56 renal biopsies were considered. Overall, in 14 patients (50%), paired biopsies showed changes in the pathological pattern. Table 1 shows the pathological classification on repeat biopsy:

Reference biopsy	Repeat biopsy
Class II Mesangial LN N=9	**1 switched to Class I**
	2 no shift in pathological class
	6 switched to higher grade nephritis (Class IV: 3 cases, Class V: 3 cases)
Class III Focal LN N=4	**2 no shift in pathological class**
	2 switched to higher grade nephritis (Class IV: 1 case, Class V: 1 case)
Class IV Diffuse LN N= 13	**1 switched to Class II and 3 to Class III**
	9 no shift in pathological class
Class V Membranous LN N=2	**1 switched to Class IV**
	1 no shift in pathological class

In the subgroup of patients with Class II mesangial LN, the repeat biopsy showed a transformation to a higher grade of nephritis (Class IV or V) in 67% of the cases.

In contrast, in most patients (65%) with proliferative classes (III and IV), there was no shift in histological class on repeat biopsy. Of the 2 patients with Class V membranous LN, only 1 changed to a proliferative class. Clinically significant class switches during LN flares were more frequent in patients with non-proliferative lesions (Classes II and V) than those with proliferative lesions (classes III and IV) in their reference biopsy ($p<0.05$).

The mean renal activity index on first biopsy was 8.85 (SD: 4.43) and on repeat biopsy it was 7.26 (SD: 3.84) ($p = 0.315$). The mean chronicity index for the first biopsy was 1.95 (SD: 2.53) and for the repeat biopsy it was 2.52 (SD: 2.39) ($p<0.001$).

The pathological transition could not be predicted by any clinical characteristics. After the repeat biopsy, 10 (36%) of patients had a change of treatment regimen: 8 received an increase in immunosuppression; while in 2 cases immunosuppressive therapy was decreased or stopped.

Conclusion: Pathological conversion was highly prevalent (50%) in patients with LN. Overall, 66% of cases with class II mesangial LN in a reference biopsy showed transformation to a higher grade of nephritis (class IV or V) on repeat biopsy, so early repeat biopsy is advisable for this subgroup of patients. In contrast, in most patients (65%) with proliferative Classes (III and IV) in a reference biopsy, there was no shift in histological class on repeat biopsy.

Repeat biopsy might be helpful in guiding treatment, both to identify those patients for whom it is necessary to intensify immunosuppression therapy, and to avoid unnecessary increased immunosuppression therapy in others.

A Systematic Review and Network Meta-Analysis of Cyclophosphamide and Mycophenolate Mofetil in Lupus Nephritis. Jasvinder Singh[1], Ahmed Kotb[2], Alomgir Hossain[2] and George A. Wells[3]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Ottawa, Ottawa, ON, [3]Univ of Ottawa Faculty of Med, Ottawa, ON.

Background/Purpose: Patients consider common side effects of medications prominently in treatment decision-making. To our knowledge, with the exception of a Cochrane review that analyzed data up to April 2012, limited or no information exists on comparisons of common, non-fatal side effects of immunosuppressive medications used for the treatment of lupus nephritis. Our objective was to perform an up to date systematic review and network meta-analysis (NMA) to compare harms/safety of cyclophosphamide (CYC) and mycophenolate mofetil (MMF) for the treatment of lupus nephritis.

Methods: Cochrane and ACR librarians performed an updated search for immunosuppressive medications for lupus nephritis up to September 2013 updating the data from the systematic review that formed the basis of the 2012 ACR lupus nephritis treatment recommendations and the published Cochrane Review. We abstracted safety data related to the following harms/adverse events (AEs): alopecia, nausea, ovarian failure, endocrine AEs, cytopenia and leucopenia. Bayesian network meta-analyses (NMA) were conducted. A binomial likelihood model, which allows for the use of multi-arm trials was used. Informed priors were assigned for basic parameters and odds ratios, as well as risk ratios and risk differences, and 95% credible intervals were modeled using Markov chain Monte Carlo methods. Brooks-Gelman-Rubin plots were used to assess model convergence. Model fit was examined using the deviance information criterion (DIC) and the residual deviance. The degree of inconsistency was assessed by comparing statistics for the deviance and deviance information criterion in fitted consistency and inconsistency models. In further sensitivity analyses, fixed effects models and models using vague priors were also conducted.

Results: Compared to MMF, CYC was associated with higher risk of alopecia by almost 4-fold, leucopenia by 3-fold and ovarian failure by 6-fold (**Table 1**). The higher risk of cytopenia with CYC almost reached statistical significance (**Table 1**). The risk of nausea and endocrine side effects did not differ significantly between CYC and MMF. Risk differences between CYC and MMF are provided in **Table 1**.

Conclusion: Our systematic review and meta-analysis identified several important differences between the harms of CYC and MMF in patients with lupus nephritis. These findings provide clinicians and patients with the magnitude of differences in these common side effects and can help patients with treatment decision-making.

Table 1: Comparison of cyclophosphamide (CYC) vs. mycophenolate mofetil (MMF)

Comparison	RR (95% CI)	Risk Difference (95% CI)
Alopecia, CYC vs. MMF	**3.69 (1.77, 6.86)**	**17.16 (4.79, 34.94)**
Nausea, MMF vs. CYC	0.37 (0.14, 1.10)	−2.32 (−10.86,0.27)
Endocrine AEs*, CYC vs. MMF	1.52 (0.70, 3.42)	2.04 (−1.72, 8.58)
Cytopenia, CYC vs. MMF	1.62 (0.99, 2.76)	8.58 (−0.13, 19.77)
Leucopenia, CYC vs. MMF	**2.82 (1.63, 4.64)**	**9.24 (3.48, 17.13)**
	Peto's odds ratio (95% CI)	
Ovarian failure, CYC vs. MMF	6.36 (2.59, 15.63)	–

*Diabetes and hyperglycemia; **significant odds ratios are in bold**

Are Repeat Renal Biopsies Important in Managing Lupus Nephritis Flares? Angela Pakozdi, Ravindra Rajakariar, Michael Sheaff and Dev Pyne. Barts Health NHS Trust, London, United Kingdom.

Background/Purpose: Lupus nephritis (LN) is the major cause of morbidity and mortality in patients with systemic lupus erythematosus. The role of repeat kidney biopsies (RB) to guide treatment or to predict outcome and prognosis has been controversial. In this retrospective study we focused on histological characteristics of RBs and aimed to identify any clinical variables useful to predict histological changes.

Methods: In a large single-centre cohort of 257 patients from 1988–2014 with biopsy proven LN, 58 (23%) had two or more biopsies (a total of 68 RBs). LN classes based on glomerular pathology were defined according to the ISN/RPS classification. Clinical and laboratory data were obtained from electronic records of patients.

Results: The median time between initial and RB was 33 months [IQR, 15–84]. Caucasians (n=8) had a lower RB rate of 16% compared to blacks (n=37, 33%; p=0.010). Indication for RB was worsening proteinuria (n=38, 71%; of which 23 had associated rising creatinine, 61%), rise in serum creatinine alone (n=6, 11%) and lack of treatment response (n=9, 17%) defined as <50% reduction in proteinuria. At time of RB, 25 (78%) had raised dsDNA, 33 (73%) had low complements. LN class transition occurred in 31 (48%), most commonly from class II or V to III or IV (n=11, 36%). 6 RB (6.8%) showed inactive lesions either due to FSGS or advanced sclerosing LN. 42 (65%) had a change in their treatment regime. Immunosuppression was more likely to be escalated in case of a class switch (87% vs. 38%, p=0.002). The histological transition could not be predicted by any serological or biochemical variables.

Conclusion: Over a 1/3 of our LN patients showed histological transition to a more aggressive class, based on which the majority (87%) had treatment escalation. Histological transition could not be predicted by clinical values. Hence, we conclude that RB remains an important tool to guide management of selected patients with LN, in particular those with initial class II or V who flare.

Lupus Nephritis Patients Who Stopped Maintenance Immunosuppressive Therapy without Relapse. Robert S. Katz[1] and Lauren Kwan[2]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL.

Background/Purpose: The current guidelines from both the American College of Rheumatology and the American Society of Nephrology suggest initiating induction therapy for Class III and Class IV lupus nephritis with cyclophosphamide or mycophenolate mofetil and then starting maintenance therapy, generally mycophenolate mofetil or azathioprine. However, the duration of maintenance therapy is not specified in the guidelines. Many patients with lupus nephritis take these maintenance medications indefinitely.

Methods: We reviewed the charts of lupus nephritis patients in a rheumatology office practice whose biopsies showed Class III or Class IV lupus nephritis. All had been treated with mycophenolate mofetil or cyclo-

phosphamide and then switched to maintenance therapy. We describe the course of 6 patients who stopped their immunosuppressive maintenance therapy and 2 patients who never began maintenance immunosuppressive treatment.

Results: 6 patients stopped their maintenance immunosuppressive therapy for Class III or Class IV lupus nephritis. One patient with class III and one patient with class IV lupus nephritis never started it. All are still doing well without a renal or systemic disease flare up. The reasons these patients stopped the maintenance therapy included fertility and pregnancy concerns, doubt that continuing maintenance medicine was necessary, and lack of compliance.

Table 1.

Gender	Age	Renal Class	Maintenance Drug	Length on Maintenance Medication	Current time off Maintenance Medication	Current Outcome of Nephritis
F	58	III	Mycophenolate Mofetil	16 Months	2 1/2 years	Remission
F	45	III	Mycophenolate Mofetil	4 Months	4 months	Remission
F	31	III	Mycophenolate Mofetil	18 Months	3 years	Remission
F	27	III	No Maintenance	0	2 years	Mildly active
F	57	IV	No Maintenance	0	6 months	Remission
F	60	III	Azathioprine	1 year		Remission
F	47	III	Mycophenolate Mofetil	2 years	1 year	Remission
F	31	IV	Azathioprine	1 1/2 years	6 months	Remission

Conclusion: Previous studies have shown that patients with class III and IV lupus nephritis, who go into remission with induction therapy, with normalization of creatinine and a significant reduction of proteinuria, are likely to stay in remission. It is unknown whether they need indefinite maintenance therapy. The lupus patients described here were able to discontinue maintenance immunosuppressive therapy, or never began it, and are doing well without relapse of their nephritis. We did not find any Class III or IV lupus nephritis patients who flared after discontinuing immunosuppressive treatment in this small sample.

This study suggests that the duration of treatment with maintenance immunosuppressive therapy should be evaluated and guidelines amended to address the duration of maintenance medication based on patient responses to induction treatment.

1663

Influence of Ethnicity on Efficacy of Current Immunosuppressive Protocols in Proliferative Lupus Nephritis. Angela Pakozdi, Ravindra Rajakariar, Michael Sheaff and Dev Pyne. Barts Health NHS Trust, London, United Kingdom.

Background/Purpose: Lupus nephritis (LN) is a major complication of systemic lupus erythematous (SLE) and prevalence is estimated to be 50–60%. Recently, variable responses to induction regimes have been observed in different ethnic groups with Hispanics and Blacks tending to respond better to Mycophenolate Mofetil (MMF) than intravenous cyclophosphamide (CYC) (1). Limited data is available for Asians from the Indian Subcontinent. Our aim was to examine retrospectively the influence of ethnicity on LN outcome in our large single centre cohort of SLE patients.

Methods: We identified 119 SLE patients with biopsy proven LN diagnosed 1992–2013 from our electronic database. LN classes based on glomerular pathology were defined according to the ISN/RPS classification. Complete remission (CR) was defined as 24-hour proteinuria <0.5g. Clinical and laboratory data were obtained from patient records.

Results: Of 119 LN patients, 80 (67%) had proliferative LN (class III or IV, of which 21% had concomitant membranous, class V lesions). Among those, 16 were male (20%) and 64 female (80%). 35 were African black or Afro-Caribbean (44%), 28 were Asians from the Indian Subcontinent (35%), and 17 were Caucasians (21%). The median age was 27 years (IQR, 20–38) at SLE diagnosis and 31 years (IQR, 24–40) at LN diagnosis. There was no difference in baseline characteristics among ethnic groups, apart from increased frequencies of ENA antibodies in Blacks compared to Caucasians, specifically RNP (n=18, 54.5% vs. n=2, 11.8%; p=0.000) and Sm antibodies (n=13, 39% vs. n=1, 6%; p=0.002). The main induction regimes were CYC given either intravenously or orally (n=49, 61%; with a median 6-month cumulative dose of 6.3g, IQR, 3–9), or MMF (n=25, 31%; with target dose 3g/day). All patients had a tapering course of high dose corticosteroids. At 6 months, CR was achieved in 13 patients (46%) in the Asian subgroup, in 10 (31%) in the Black subgroup and in 8 (47%) in Caucasians. At 24 months, 16 Asians (67%), 14 Blacks (61%) and 10 Caucasians (83%) reached CR. At 6 months, MMF achieved a higher rate of CR in Blacks than CYC (n=7, 70% vs. n=3, 23%, respectively; p=0.024) and showed a trend in Asians (n=6, 75% vs. n=7, 41%, respectively; p=0.114). In contrast, in Caucasians, CR rate was similar in both treatment arms at 6 months (n=5, 56% in CYC vs. n=3, 50% in MMF, p=0.833). At month 24, there was a non-statistical trend for greater response to MMF than CYC in Asians and Blacks, but not in Caucasians. Up to date, 20 patients (25%) have developed end-stage kidney disease with the highest rate in Blacks (n=13, 37%). Severe infections tended to be more common in patients treated with CYC than MMF (n=7, 15% vs. n=2, 8%; p=0.642). CYC caused gonadal toxicity in 6 patients (14%).

Conclusion: Current ACR guidelines (2) recommend using MMF rather than CYC for LN class III/IV induction therapy in African Americans and Hispanics. Our retrospective study provides supportive evidence that MMF tends to achieve higher remission rates in Blacks, and is at least as effective as CYC in Caucasians and Asians from the Indian Subcontinent, with fewer adverse events.

1664

Novel Risk Factors for Systemic Lupus Erythematosus (SLE) Flares in Patients with End-Stage Renal Disease: Is SLE in Patients with End-Stage Renal Disease a "sleeping beauty"? Jorge Alcocer-Varela[1], Mariana Quintanar[2], Javier Merayo-Chalico[1], Ana Barrera-Vargas[1] and Diana Gómez-Martín[1]. [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Mexico City, Mexico.

Background/Purpose: Renal involvement in systemic lupus erythematosus (SLE) is frequent, and a high percentage of patients (~15%) develop end-stage renal disease (ESRD) even with optimal treatment. It is widely supposed that ESRD in these patients leads to an indefinite remission period. Currently, information about SLE activity in patients with renal replacement therapy is quite scant. The aim of this study was to identify risk factors for SLE flares in patients with ESRD.

Methods: A retrospective, case-control study was performed in a tertiary care center in Mexico City from 1993 to 2014. Cases (n=50) were patients with SLE diagnosis (at least 4 American College of Rheumatology criteria) who had any extra-renal flare (any increase in systemic lupus erythematosus activity index –SLEDAI- score that required the modification of immunosuppressive treatment) after at least three months of renal replacement therapy (RRT). Controls (n=50) were patients with SLE and ESRD but without any flares, studied during the same period of time as cases (±3 months). Association between variables was calculated by X^2 test and OR (95% CI). Multivariate analysis was performed by logistic regression. p values less than 0.05 were considered statistically significant.

Results: There was a higher percentage of men in the case group (24 vs 8%, p=0.029). At the time of the SLE flare, patients had required dialysis for a mean period of 23.1±3.6 months. There was no difference in the time period between SLE diagnosis and the beginning of dialysis in both groups (p=0.06). Variables previous to the exacerbation which had significant differences in the univariate analysis are showed in Table 1. Variables that remained significant after multivariate analysis were: history of fever secondary to SLE [OR 3.20 95%CI 1.02–10.04, p=0.046], history of hematologic activity [OR 4.02 95%CI 1.02–15.79, p=0.046], low C4 levels prior to the flare [OR 19.62 95%CI 3.72–103.3,p<0.001], anticardiolipin IgM positivity [OR 4.32 95% CI 1.07–17.43, p=0.040], presence of lupus anticoagulant [OR 9.38 95% CI 1.26–69.79, p=0.029], age at the beginning of renal replacement therapy [OR 0.92 95%CI 0.88–0.96, p<0.001], and adjusted SLEDAI score (excluding renal items) three months prior to exacerbation [OR 0.57 95%CI 0.37–0.87, p=0.010].

Conclusion: Our findings suggest that immunologic parameters, such as low C4 levels and antiphospholipid antibodies might play a key role in predisposing to flares in patients with SLE and ESRD. Moreover, patients who initiate RRT at older age and who have had persistent disease activity are at a higher risk for extrarenal flares during follow-up.

Table 1. Variables associated with development of (univariate analysis)

Prior to exacerbation	OR	95% CI	p value
History of different types of activity			
Hematologic	10.2	2.20–47.90	0.001
Hemolytic anemia	6.76	1.41–32.36	0.007
Persistent thrombocytopenia (<150,000/uL)	3.16	1.03–9.68	0.037
Persistent leukopenia (<3,000/uL)	10.28	2.20–47.90	0.001
Persistent lymphopenia (<1,000/uL)	2.97	1.30–9.68	0.009
Serositis	2.57	1.12–5.89	0.024

1665

Efficacy Versus Safety of Prednisone in Lupus Nephritis Since 1988. Tanmayee Bichile[1], Laurence S Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland School of Medicine, Baltimore, MD.

Background/Purpose: Morbidity and damage due to prednisone use in the treatment of SLE is recognized, but prednisone has been a requisite of lupus nephritis induction regimens. We examined, by calendar years, the prednisone exposure and urine protein in lupus nephritis patients in a large single-center cohort.

Methods: We identified 76 SLE patients who had: 1) biopsy-proven Class III or IV lupus nephritis 2) cohort visit prior to their biopsy with elevated urine protein (dip stick of 2+ to 4+) and at least 4 cohort visits in the year following their biopsy. For each patient, the average daily prednisone dose, urine dipstick, serum cholesterol, and systolic blood pressure in the year following the biopsy were calculated.

Results: The average daily dose of prednisone was lower in more recent years, but the average urine protein was better.

Table 1. Mean prednisone dose and urine dipstick scores in the year following renal biopsy, by calendar year and stratified by urine protein level prior to biopsy

Urine dipstick measure in the visit prior to biopsy	Year	Number of Patients	Average Daily Prednisone Dose in year following biopsy[1]	Average score on urine dipstick over the year following biopsy[2]
2	1988–1999	5	10.2	2.1
	2000–2005	10	20.9	1.6
	2006–2012	15	7.6	1.3
3–4	1988–1999	11	19.2	2.7
	2000–2005	24	17.1	2.2
	2006–2012	11	15.2	1.8

[1]P-value for differences between years with respect to mean daily dose of prednisone, adjusting for baseline dipstick equals 0.063.
[2]P-value for difference in mean urine dipstick score by year, adjusting for baseline dipstick score equals 0.047.

Prednisone use above 20mg daily (mean) had a major effect on total cholesterol, but not on systolic blood pressure (mean).

Table 2. Mean change (from pre-biopsy) in cholesterol and systolic blood pressure by average daily dose of prednisone in the year following biopsy

Average Daily Prednisone Dose	Sample Size	Mean change in Cholesterol	Mean change in systolic BP
0–9 mg/d	27	−2.3	−2.5
10–19 mg/d	28	−12.3	−5.7
20+	21	25.2	−0.4

Conclusion: Prednisone dose in Class III-IV lupus nephritis has been reduced in recent years, with no deleterious effect on urine protein (in fact there has been improved control of urine dipstick protein). The effect of prednisone on traditional risk factors was surprising. Patients receiving more than 20 mg/day of prednisone had a major increase in serum cholesterol. However, in those receiving 10–19 mg/d prednisone, there was a surprising decrease in both cholesterol and systolic blood pressure.

1666

The Relevance of Urinary Podocyte Number and Urinary Podocalyxin Level with Response to Treatment and 1 Year Renal Prognosis in Systemic Lupus Erythematosus. Hiroshi Kajiyama[1], Keiju Hiromura[2], Daisuke Ikuma[1], Hidekazu Ikeuchi[2], Hiroyuki Kurosawa[3], Yoshiaki Hirayama[3], Fumio Gondaira[3], Masanori Hara[4], Yoshihisa Nojima[2] and Toshihide Mimura[1]. [1]Saitama Medical University, Saitama, Japan, [2]Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan, [3]Denka Seiken Co. Ltd., Niigata, Japan, [4]Yoshida Hospital, Niigata, Japan.

Background/Purpose: Podocytes are glomerular visceral epithelial cells, whose number decrease due to death and/or detachment from capillary wall leads to severe proteinuria and end stage kidney disease. Podocalyxin (PCX) is one of the podocyte markers, and we reported in ACR meeting last year that two different urine PCX-related biomarkers, urine numbers of PCX-positive cells (podocytes, U-Pod) and urine levels of PCX (U-PCX) were higher in systemic lupus erythematosus (SLE) patients with kidney disease (KD) than those without KD. Purpose of this longitudinal study is to clarify the relevance of U-Pod and U-PCX with the response to treatment and renal prognosis.

Methods: U-Pod were determined by counting PCX-positive cells in sediments from urine samples. U-PCX were measured by sandwich ELISA, normalized to urine creatinine levels. Patients with proteinuria (defined as more than 0.2 urine protein/creatinine ratio, U-PCR) and/or renal failure (defined as estimated glomerular filtration rate, eGFR, less than 60 mL/min/1.73m^2) were defined as KD(+), and other patients were defined as KD(−). Patients were recruited between October 2010 and March 2013, 18 SLE-KD(+) patients (ISN/RPS Classification, IV: 5 patients, IV+V: 2 patients, V: 2 patients, biopsy was not performed in 9 patients), and 11 SLE-KD(−) patients. U-Pod, U-PCX, U-PCR and eGFR were obtained around the treatment start, and at 1, 3, 6 and 12 months (mo) after treatment. Correlation of cumulative U-Pods generated by the summations of U-Pods in first 6 months with one year change of eGFR was determined. Statistical analysis was done with Wilcoxon signed-rank test and Spearman correlation. $p<0.05$ was defined as statistical significance. Each value was described as median and interquartile range.

Results: In KD(−), U-Pod, U-PCX, and U-PCR were not significantly changed all through the year. In KD(+), U-PCR was significantly improved from 6 mo after treatment (before treatment 2.86 (0.91, 5.16), vs 1 mo 1.15 (0.42, 3.99) p=0.2366, vs 3 mo 0.41 (0.21, 3.80) p=0.0894, vs 6 mo 0.31 (0.11, 0.95) p=0.0004, vs 12 mo 0.22 (0.08, 0.72) p=0.0061). U-Pod significantly improved at 1 mo after treatment (before treatment 1.65 (0, 6.07), vs 1 mo 0.30 (0, 1.48) p=0.0084, vs 3 mo 0.30 (0, 0.60) p=0.0046, vs 6 mo 0 (0, 0.45) p=0.0037, vs 12 mo 0 (0, 0.25) cells/mL p=0.0039). Interestingly, U-PCX improvement delayed significantly, and was observed from 6 mo (before treatment 360.0 (160.0, 586.8), vs 1 mo 363.5 (185.5, 540.8) p=0.4204, vs 3 mo 294.0 (114.0, 422.5) p=0.072, vs 6 mo 154.9 (65.5, 251.5) p=0.0039, vs 12 mo 66.6 (41.5, 178.3) μg/gCr p=0.0008). One year changes of eGFR (subtracting 12 mo eGFR from pre-treatment eGFR) were −2.067 (−10.59, 16.00) mL/min./1.73m^2 in KD(+) and −20.61 (−35.75, 1.002) mL/min./1.73m^{2}in KD(−). There was no significant correlation of cumulative U-Pods with one year change of eGFR both in KD(+) and KD(−) (p=0.7228, and p=0.3831).

Conclusion: U-Pod significantly improves one month after treatment much faster than U-PCR and U-PCX, suggesting that U-Pod reflects acute inflammation, and that U-PCX is more relevant to filter dysfunction of podocyte. Cumulative podocyte loss may not affect decline of eGFR in one year in SLE.

1667

'probability of 3 and 6 Month Complete Response in Lupus Nephritis'. Homa Timlin[1], Michelle Petri[1] and Laurence S Magder[2]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland School of Medicine, Baltimore, MD.

Background/Purpose: Lupus nephritis is a major cause of morbidity and mortality. The complete response rate is the most sensitive in detecting differences among therapeutic regimens. Mycophenolate mofetil has become the primary induction and maintenance therapy for lupus nephritis.

The purpose of this study was to assess the effect of MMF on the complete response after starting mycophenolate mofetil as initial therapy for

class III, IV or V in immunosuppressant naïve patients with lupus nephritis by using 5 criteria including BMS, ACR, LUNAR, ALMS, and ACCESS.

Methods: This is a retrospective study on 21 SLE patients who had begun mycophenolate mofetil shortly after a biopsy-confirmed diagnosis of lupus nephritis. They consisted of 18 females, 3 males, 9 African Americans, 8 Caucasians, and 4 other ethnicities. Ages ranged from 18 to 70 with a mean age of 37 (SD=15). There were 5 patients with class III, 9 with class IV, 4 with class III-V, 1 with class IV-V and 2 with class V lupus nephritis. At baseline, 76% had positive anti-dsDNA, 67% had low C3, 57% had low C4 and 71% had albumin below 3.5. The initial dose of mycophenolate mofetil was 1000mg twice daily. If no improvement, it was increased to 1500 mg twice daily after one month. The baseline urine protein to creatinine ratio ranged between 0.635 to 11.91grams, with only 1 patient being below 1 gram at baseline. Patients were on a renal sparing regimen (52%) and hydroxychloroquine (86%). Depending on the response index, complete response was defined, as reaching a urine protein to creatinine ratio of $<$ 0.2–0.5 grams, improvement in creatinine or estimated glomerular filtration rate of 10–25%, normalization of urinalysis and tapering dose of steroids.

Results: 52% of SLE patients reached 0.5 grams of proteinuria within 51 days of starting mycophenolate mofetil (95% confidence interval 29%–74%). 77% reached 0.5 grams or less within 260 days (95% confidence interval 57%–97%). The probability of response at 90 and 180 days is shown in the table for each response index.

Response Definition	Probability of response within 90 days	Probability of response within 180 days
BMS	14%	38%
ACR	23%	58%
LUNAR/ALMS/ACCESS	24%	31%

Conclusion: This study demonstrates that the majority of previously naive immunosuppressant patients can reach a complete response within 6 months after initiation of mycophenolate mofetil. Furthermore, the estimate of long term response was highest in the ACR criteria.

Identifying Patient Perceptions of Medication Decision Making Barriers in Minorities with Lupus Nephritis. Jasvinder A Singh[1], Haiyan Qu[2], Jinoos Yazdany[3], W. Winn Chatham[2], Maria Dall'era[3] and Ricahrd Shewchuk[4]. [1]University of Alabama and VA Medical Center, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of California, San Francisco, San Francisco, CA, [4]University fo Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Studies suggest that adherence to medications for lupus nephritis is low. However, there are limited data available on the barriers that patients with lupus nephritis, encounter in their decisional processes involving immunosuppressive medications. Our objective was to identify a comprehensive array of patient-reported barriers (issues) and the relative difficulty these presented for racial/ethnic minority patients with lupus nephritis in their medication adherence decision-making process.

Methods: Barriers involved in the medication decision-making process were queried and then prioritized using a voting procedure during 8 Nominal Group Technique (NGT) meetings that were convened with participants who received treatment for lupus nephritis clinics at University of Alabama at Birmingham (UAB) and University of California at San Francisco (UCSF). The participants were asked "What sorts of things make it hard for people to decide to take the medicines that doctors prescribe for treating their lupus kidney disease?" We aggregated the prioritized responses from each NGT meeting by combining the same or very similar responses from different groups. The voting totals for the same or very similar responses were summed across groups.

Results: 51 patients with lupus nephritis participated in 8 NGT meetings: 26 African Americans (4 nominal groups), 13 Hispanic (2 nominal groups) and 12 Caucasian (2 nominal groups). Patients had a mean age of 40.6 years (SD=13.3), disease duration was 11.8 years (SD=8.3), 35.3% had education level of college and beyond. 55.8% needed help with reading health materials from a family member, indicating low health literacy. The participants generated 248 responses (range=19–37 responses/meeting). Across the 8 groups, about 41% of responses were endorsed by patients as relatively more important barriers than others in their decision making process (range=32–54% of endorsed/total). More agreement about the importance of barriers was observed among Caucasian and Hispanic patients (range=32–38% endorsed) than among African American patients (41–53% endorsed). Across the 8 groups, 33 barriers were endorsed as relatively more important than others in decision-making. Overall, participants allocated about 53% of the available votes from all groups as an endorsement of importance to just 7 barriers: potential for side effects, cost, doubts about efficacy, weight gain worries, fear of damage to other organs, potential for causing other conditions, and concerns about long-term risks.

Conclusion: We found general consistency of perceived barriers to medication use in lupus nephritis patients across all groups. NGT and its robustness as a patient-centered approach helped us generate objective, semi-quantitative information regarding factors that influence the decision making process in patients with lupus nephritis. An improved understanding of patient-perceived barriers to medication use will help us design interventions and educational materials for patients with lupus nephritis (e.g., decision aid).

Validation of a Machine Learning Lupus Nephritis Decision Support Tool to Predict Complete Response to Therapy. Bethany Wolf[1], John Christian Spainhour[1], John Arthur[1], Michael Janech[1], Michelle Petri[2], Adnan Kiani[3] and Jim Oates[1]. [1]Medical University of South Carolina, Charleston, SC, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD.

Background/Purpose: The American College of Rheumatology treatment guidelines for lupus nephritis (LN) recommend that induction therapy be changed when response to therapy has not occurred within six months. Response is not defined, and renal fibrosis can occur while waiting for this endpoint. Therefore, an early treatment decision support tool is needed. The goal of this project was to create and validate such a tool.

Methods: 140 patients with active LN were recruited within 12 months of renal biopsy and prospectively evaluated for one year after start of induction therapy. Patients came from two prospective cohorts (the Hopkins cohort and the Medical University of SC) and two randomized controlled trials (the Lupus Nephritis Assessment of Rituximab (LUNAR) and the abatacept lupus nephritis trial). Renal biopsy International Society of Pathology/Renal Pathology Society (ISN/RPS) class, demographics, serum complement, anti-double stranded DNA antibody (dsDNA), and creatinine values, and urine protein/creatinine (traditional biomarkers, per Dall'Era and Wofsy Arthritis Care & Research 2011;63(3):351–357) and novel biomarker values were determined at 0 & 3 months. Seventeen novel biomarkers measured (see table) were based on those in an initial discovery set of 52 candidate biomarkers that were significantly different between groups or that showed promise in the literature. Patients were randomly assigned to training (n=99) and external validation (n=41) sets, stratifying for ISN/RPS class. Baseline and three-month traditional and novel biomarker, ISN/RPS class, treatment regimen, age, sex, and race were used to train random forest models predictive of one-year complete response (CR) to therapy. External validation sets were used to determine the performance of the trained one-year CR model. The process of randomization into training and validation sets and model training/validation was repeated 1000 times, and the median model results were reported.

Results: Several individual biomarkers were different between the two groups ($P<0.001$). The resulting test of the LN Decision Support Tool (LNDST) demonstrated the clinically meaningful performance reported in Table I for both models, but the novel biomarker panel had superior specificity for cutpoints giving equal sensitivity.

Validation of performance for random forest models of complete response to therapy. Reported as median model from 1000 different training and validation sets

	Accuracy	ROC AUC	sensitivity	specificity	PPV	NPV
Traditional variables	0.72	0.70	0.95	0.30	0.50	0.76
Novel and traditional variables	0.76	0.76	0.95	0.50	0.62	0.82

Novel biomarkers studied: Cystatin C, N-acetyl-beta-D-glucosaminidase, neutrophil gelatinase associated lipocalin, osteoprotegerin, TNF-like weak inducer of apoptosis, eotaxin, granulocyte monocyte colony stimulation factor, interferon alpha2, interferon gamma, interleukin 1, 6, and 8, interleukin 2 receptor alpha, Interferon gamma-induced protein 10, macrophage inflammatory protein 1beta, monocyte chemotactic protein 1, and platelet derived growth factor

Conclusion: This study demonstrates the ability of the LNDST to predict CR. Implementation of LNDST may assist clinicians in following the ACR guidelines for treatment of LN.

Background/Purpose: To describe the profile of patients included in RELESSER with histologically confirmed lupus nephritis (LN).

Methods: RELESSER is a multicentre cross-sectional study, with information retrospectively collected from the charts of patients with SLE followed up at participant rheumatology units. Globally, 359 variables including demographic and clinical data, activity, severity, comorbidities, treatments and mortality were recorded. The following renal data were included: WHO LN histological type, proteinuria, haematuria, leukocyturia, cellular casts and creatinine clearance, treatment response, recurrence, development of ESRD and/or the need for dialysis or renal transplantation. We performed a descriptive analysis by calculating means ± SD for numerical variables and frequencies for qualitative variables. Chi-square or t-Student tests were applied to analyse their relationship with LN. Odds ratio and confidence intervals were calculated by using simple logistic regression. Statistical significance was $p<0.05$.

Results: LN was confirmed in 1092 patients (31%). Most patients were female (86%), Caucasian (90%), and the mean age at disease onset was 33±14 years. Most patients developed LN in the first year after SLE diagnosis. Most had LN proliferative forms (70%), and there were only 16 cases of thrombotic microangiopathy (TMA). The risk of LN development was significantly lower among women ($p<0.001$), and higher as lower was the age of the disease onset and among hispanic ethnicity ($p<0.001$). Complete response to treatment was achieved in 68.3% of patients, whereas 17.9% remained with renal activity. A higher risk for persistence of renal activity was found with higher levels of baseline serum creatinine (1 vs 0.91, $p=0.004$) and proteinuria (2.76 vs 2.4, $p=0.006$). ESRD was clinically associated with positive a-dsDNA, low complement, pleuropericarditis, seizures (all $p<0.001$), and haemolytic anemia ($p=0.015$).TMA was a risk factor for ESRD, and the necessity of dialysis or renal transplantation (all $p<0.05$).ESRD was an independent mortality risk factor ($p<0.001$).326 recurrences were recorded, with a mean time to first recurrence of 47 months (0–28),regardless of histology.The lower was the serum creatinine and older was the age at LN onset, the lower was the recurrence risk.TMA was a risk factor for recurrence ($p=0.016$). Recurrences were related with persistent lupus activity and ESRD (both, $p<0.001$). During the follow up, the LN development associations are described in Table 1. LN was a poor prognostic factor associated with increased mortality risk OR 2.4 (1.81–3.22), $p<0.001$.

Table 1.

	OR (CI)
Malar rash	1.54 (1.33–1.78)**
Pleurisy	1.95 (1.66–2.29)**
Pericarditis	2.07 (1.73–2.50)**
Alveolar and interstitial lung disease:	1.73 (1.23–2.44)*
Alveolar hemorrhage	3.56 (1.77–7.19)**
Seizures	2.40 (1.84–3.13)**
Psychosis	1.88 (1.20–2.94)*
Haemolytic anemia	2.39 (1.89–3.03)**
Leukolymphopenia	1.38 (1.19–1.61)**
Thrombocytopenia	1.49 (1.26–1.76)**
a-dsDNA	4.77 (3.82–5.95)**
a-Sm	1.73 (1.45–2.05)**
Antiphospholipid syndrome:	1.57 (1.29–1.92)**
lupus anticoagulant	1.28 (1.06–1.55)*
arterial/venous thrombosis	1.84 (1.35–2.51)**/1.60 (1.27–2.01)**
Low complement levels	4.48 (3.53–5.68)**

*: $p<0.05$; **: $p<0.001$

Conclusion: LN, mainly proliferative forms, affects almost one third of patients with SLE, and is often associated with the occurrence of other severe lupus manifestations, being a poor prognostic factor. TMA and relapses are associated with worse outcome in renal function.

Renal Relapses Are Common in Lupus Nephritis. Angela Pakozdi, Ravindra Rajakariar, Michael Sheaff and Dev Pyne. Barts Health NHS Trust, London, United Kingdom.

Background/Purpose: Renal relapses are part of the natural history of lupus nephritis (LN) and represent a significant challenge not only because they are associated with an increased risk of decline in renal function, but also there is a cumulative toxicity of immunosuppressive treatments. In this retrospective study, we aimed to review renal flare frequency and management in a large single centre cohort of adult LN patients.

Methods: Patients with biopsy proven LN were identified from our electronic database. LN classes based on glomerular pathology were defined according to the ISN/RPS classification. Clinical and laboratory data were obtained from electronic records of patients. Complete remission (CR) was

defined as proteinuria <0.5g/day, whilst partial remission (PR) was defined as >50% reduction in baseline proteinuria achieving <2g/day. We defined proteinuric flares as proteinuria >1g/day in patients with CR, and doubling of proteinuria in cases of PR.

Results: 104 (87%) of 119 SLE patients with biopsy proven LN achieved either CR (n=84, 81%) or PR (n=20, 19%). 34 (33%) had at least one flare (27 had preceding CR and 7 had PR); among those 8 had >2 flares (19%). 21 patients (64%) had class 3 or 4 LN, 7 (21%) class 5 LN, 4 (12%) class 2 LN and 1 (3%) focal segmental glomerulosclerosis. The median time between remission and relapse was 29 months (IQR, 16–66) in CR, and 13 months (IQR, 3–32) in PR (p=0.089). The maintenance immunosuppressive drug at time of flare was Mycophenolate Mofetil (MMF, n=13, 42%) or Azathioprine (AZA, n=10, 32%). 15 (48%) had Angiotensin blockers (ATB), and 22 (71%) were on low dose Corticosteroids (CS) (<10mg/day). Non-adherence to treatment at time of relapse was documented in 7 cases (22%). At the time of flare, the median proteinuria was 1.7g (IQR, 1.3–3.2) in CR, and 2.5g (IQR, 1.4–3.8) in PR. 14 (41%) had raised Creatinine, 14 had raised dsDNA (47%), 18 had low complements (56%) at flare. To treat relapse, 13 patients (45%) started a new immunosuppressive drug (Cyclophosphamide n=6, MMF n=5, Rituximab n=1 or AZA n=1), 3 (10%) had immunosuppressive drug dose escalation, 4 (14%) were treated with CS alone, and 6 (21%) were treated with ATB. After treatment, proteinuric outcome was available for 24 patients: 16 patients (67%) achieved CR, 6 (25%) reached PR, whilst 2 (8%) did not go into remission. 5 patients (15%) reached stage 5 chronic kidney disease after the flare.

Conclusion: LN renal flares are common. Our study shows that a third of LN patients develop at least one relapse after reaching remission, usually within 3 years. The length of time to flare tends to be shorter in cases of preceding PR than in CR. Lack of adherence to long term immunosuppression was identified as a significant factor in LN flare (22% cohort). Patients with LN in remission require close follow-up.

Facilitating the Medication Decision-Making process—What Do Patients with Lupus Nephritis Say? Ricahrd Shewchuk[1], Haiyan Qu[2], W. Winn Chatham[2], Jinoos Yazdany[3], Maria Dall'era[3] and Jasvinder A Singh[4]. [1]University fo Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of California, San Francisco, CA, [4]University of Alabama and VA Medical Center, Birmingham, AL.

Background/Purpose: Low medication adherence in lupus nephritis puts patients at risk for poor outcomes, but to our knowledge, relatively little is known about what patients perceive as facilitative factors in medication decisional processes. Our objective was to comprehensively identify factors that racial/ethnic minority patients with lupus perceive as facilitating decisions to take their lupus medications as prescribed.

Methods: We conducted 8 Nominal Group Technique (NGT) meetings with patients with lupus nephritis who received treatment from lupus clinics at University of Alabama at Birmingham (UAB) and University of California at San Francisco (UCSF). Patient perceptions of facilitators influencing the medication decision-making outcome were generated by asking the following question: "What sorts of things make it easier for people to decide to take the medications that doctors prescribe for treating their lupus kidney disease?" Patients in each NGT meeting prioritized a subset of facilitative factors in terms of importance using a voting procedure. To obtain an aggregated result, responses with the same or very similar wording generated by different groups were combined and the voting totals for all prioritized responses were summed across groups.

Results: 52 patients with lupus nephritis participated in 8 NGT meetings: 27 African Americans (4 nominal groups), 13 Hispanic (2 nominal groups) and 12 Caucasian (2 nominal groups). Mean age was 40.6 years (SD=13.3), disease duration was 11.8 years (SD=8.3), 34.6% had education level of college or greater, 55.8% needed help with reading health materials, indicating low health literacy. The participants generated 281 responses (range=26–42 responses/meeting). 36% of all responses were endorsed across all groups by patients as relatively more important than others in facilitating decisions to take prescribed medications (range=31–52% of endorsed facilitators/total). More variation in the level of agreement about the importance of specific facilitators was observed with African American patients (range 31–52%) than with Caucasian (32–37%) and Hispanic patients (31–34%). Overall, participants allocated about 57% of the available votes from all groups as an endorsement of perceived importance to 8 facilitators that can be briefly summarized as: demonstrated efficacy, longevity expectations, symptom relief, expectations for living a more normal life, family, cost and affordability, awareness of potential risks and benefits, and minimal side effects.

Conclusion: A general consistency of factors perceived to facilitate medication decision making by lupus nephritis patients was noted across ethnic/racial groups. Patient-identified facilitators of lupus medication adherence can inform the design of effective educational materials for patients with lupus nephritis.

Background/Purpose: Little is known about patient reported outcomes (PRO) in lupus nephritis (LN), and no studies using a disease targeted PRO tool have been undertaken thus far. Herein, we describe quality of life (QOL) among patients with LN using a valid and reliable disease targeted PRO measure (LupusPRO).

Methods: Cross sectional data obtained from patients with systemic lupus erythematosus (SLE) during psychometric evaluation studies of LupusPRO from various countries were compared between those: 1) with and without LN and 2) with active and inactive-LN." Data compared included demographics, disease characteristics, and LupusPRO constructs. Presence of LN was present if listed among the ACR classification criteria (ACR-LN), while presence of active LN was based on presence of urinary casts, hematuria, proteinuria or pyuria in the disease activity assessment (SELENA-SLEDAI) performed at the time of the study visit. LupusPRO has Health related QOL (HRQOL) and non-HRQOL constructs. HRQOL domains include lupus symptoms, cognition, medication, procreation, physical health, emotional health, pain-vitality and body image. Non-HRQOL domains include desires-goals, social support, coping and satisfaction with care. Non-parametric tests were used to make comparisons, and p values $\leq$ 0.05 were considered significant.

Results: There were 1,259 SLE patients; ninety-four percent were women and their mean (SD) age was 41.7 (13.5) yrs. Five-hundred and thirty-nine had ACR-LN. These patients were younger, had greater disease activity (PGA, Total SELENA-SLEDAI) and damage (SLICC/ACR) than those without LN. Summary HRQOL and non-HRQOL scores were similar in both groups; however, those with ACR-LN had significantly worse scores on medications and procreation domains, while those without ACR-LN had worse scores on Pain-Vitality domains (Table 1).

129/540 ACR-LN patients had active LN. Patients with active LN were younger, had significantly greater disease activity (PGA, Total SELENA-SLEDAI), worse HRQOL and non-HRQOL than patients with inactive LN.

Specific domains scores adversely affected among active LN patients were lupus symptoms, medications, procreation, emotional health, body image and desires-goals (Table 1). Satisfaction with care was significantly higher among patients with active LN as compared to inactive LN patients.

Conclusion: LN adversely affects several specific QOL domains and physicians need to be aware of these concerns.

ACR/ARHP Poster Session B

Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics: Systemic Sclerosis, Diagnostic and Therapeutic Aspects

Monday, November 17, 2014, 8:30 AM–4:00 PM

1674

Long-Term Efficacy of Rituximab in Systemic Sclerosis. Javier Narváez[1], Juan Jose Alegre Sancho[2], Ivan Castellvi[3], Susana Herrera[2], Maria Molina Molina[4], Diego Castillo[3], Isabel de la Morena Barrio[2], Montserrat Robustillo Villarino[2], Angels Martínez Ferrer[2], Desamparados Ybañez García[2], Elia Valls Pascual[2], Josep Maria LLobet[3], Francisca Gil Latorre[2] and Joan Miquel Nolla[4]. [1]Hospital Universitario de Bellvitge. Barcelona. Spain, Barcelona, Spain, [2]Hospital Universitario Dr Peset, Valencia, Spain, [3]Hospital de Sant Pau, Barcelona, Spain, [4]Hospital Universitario de Bellvitge, Barcelona, Spain.

Background/Purpose: It has been proved in several studies with a small number of patients that Rituximab (RTX) can prevent worsening of interstitial lung disease (ILD) and improve skin fibrosis in patients with Systemic Sclerosis (SSc). Recently, a multicentre case-control study of the EUSTAR cohort has confirmed these favorable results *(Jordan S, et al. Ann Rheum Dis 2014 Jan 17 [Epub ahead of print]).* Moreover, RTX may be effective on calcinosis. However, little is known about its long-term effect. Our objective was to assess the efficacy of RTX on skin involvement, ILD and calcinosis in series of patients with refractory SSc.

Methods: Patients with refractory SSc treated with RTX *(off label use)* were recruited from 3 hospitals. At baseline, the following data were collected: gender, age, type and duration of the SSc, clinical features, modified Rodnan skin score (mRSS), HRCT, pulmonary function tests (PFTs), walking test, sPAP (measured by echo), previous and present treatments, and indication and dosage of RTX. Throughout the follow up, clinical changes, as well as changes in HRCT and PFTs, were registered. We also recorded the changes in the dosage of corticosteroids, number of RTX cycles, duration of treatment, and withdrawals. The package SPSS 17.0 was used for descriptive statistics, and quantitative variables were compared using the t-test for paired samples.

Results: Thirty SSc patients treated with RTX were included in the analysis. The majority were women (86.7%), with a mean age of 54 years, and a mean of 9.4 years of evolution of the disease. Subtypes: DSSc 50%, LSSc 37%, and Overlap syndromes 13.3%. The baseline mean mRSS was 15. Clinical features: ILD 80% (NSIP 67%), calcinosis 37%, pulmonary hypertension 10%, joint disease 49%. The baseline mean FVC, DLCO and TLC values were 70%, 47% and 73%, respectively.

The indication for RTX was: ILD (73.4%), arthritis (36.6%), calcinosis (33.3%) and severe skin involvement (19.7%). The most used previous treatments were cyclophosphamide(50%) and mycophenolate (46.6%). RTX was always used in a RA dosage, mainly in monotherapy (46.7%), or in association with mycophenolate (40%). When data were collected, patients had received a mean of 1.7 cycles (1–5) of RTX, with a dosing interval which ranged from 6 to 15 months, and a mean of 12.8 months (1–43) of treatment. The mean mRSS was significantly reduced at follow-up (17.2 ± 10.9 vs. 14 ± 9.8; $p=0.012$), without significant changes of the HRCT (76.9%) and/or PFTs in patients with ILD. The 40% of patients with calcinosis reported improvement. There was also a good response, in terms of TJC and SJC, in patients with arthritis ($p=0.024$ and 0.019, respectively). The dose of corticosteroids was significantly reduced (10.1 ± 8.8 vs. 5.3 ± 2.9 mg, $p=0.003$). Two patients with severe ILD died despite RTX, and there were 3 withdrawals for various reasons.

Conclusion: RTX is an effective long-term therapy in refractory SSc which can improve skin fibrosis, arthritis and calcinosis, and also prevent deterioration of ILD (stabilization of lung function).

Regional Implantation of Adipose Tissue-Derived Cells Induces a Prompt Healing of Long-Lasting Indolent Digital Ulcers in Patients with Systemic Sclerosis. Nicoletta Del Papa[1], Gabriele Di Luca[2], Domenico Sambataro[1], Eleonora Zaccara[2], Wanda Maglione[2], Armando Gabrielli[3], Paolo Fraticelli[3], Gianluca Moroncini[3], Lorenzo Beretta[4], Alessandro Santaniello[5] and Claudio Vitali[6]. [1]Istituto G.Pini, Milan, Italy, [2]Osp. G. Pini, Milano, Italy, [3]Università Politecnica delle Marche, Ancona, Italy, [4]Referral Center for Systemic Autoimmune Diseases, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy, [5]Referral Center for Systemic Autoimmune Diseases, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy, [6]Istituto San Giuseppe, Lecco, Italy.

Background/Purpose: Fingertip digital ulcers (DUs) are a rather frequent and invalidating complication in the course of systemic sclerosis (SSc), often showing a very slow or null tendency to heal, and causing intense local pain. Furthermore, most of the commonly used systemic and local therapeutic procedures have demonstrated to be scarcely or totally inadequate to induce a rapid healing in the SSc-related DUs. Recently stem cell therapy has emerged as a new approach to accelerate wound healing, and some case reports have been published where local or regional transfer of bone marrow stem cells (BMSCs) was effective in improving or healing SSc-related ischemic lesions. Adipose-derived stem cells (ASCs) are considered another source of multipotent stem cells potentially able to induce angiogenesis and tissue repair.In the present study we have tentatively treated long lasting and poorly responsive to traditional therapy SSc-related DUs by the implantation of autologous adipose-tissue derived cells (ATDCs) fraction, that it know to contains both the ASCs and the stromal/vascular cell (SV) component.

Methods: Fifteen patients with SSc having a long lasting DU in only one fingertip, unresponsive to intensive systemic and local treatment, were enrolled into the study. The grafting procedure consisted in the injection, at the basis of the corresponding finger, of 0.5–1 ml of ATDCs fraction, separated by centrifugation of adipose tissue collected through liposuction from subcutaneous abdominal fat. Time to healing after the procedure was the primary end point of the study, while reduction of pain intensity (measured by visual analogue scale), and of analgesic consumption represented secondary end point. Furthermore, the after therapy variation of the number of capillaries, observed in the nailfold video-capillaroscopy (NVC) exam, and of the resistivity in the digit arteries, measured by high resolution echo-color doppler were also taken into account.

Results: A rather speed healing of the DUs was reached in all of the enrolled patients (mean time to healing 4.23 weeks; range 3–8 weeks). A significant reduction of pain intensity was observed after few weeks ($p<0.001$), while the number of capillaries was significantly increased at second (3 months) and third (6 months) NVC assessment ($p<0.0001$ in both cases, with respect to the basal examination). Finally, a significant after treatment reduction of digit artery resistivity was also recorded ($p<0.0001$).

Conclusion: Even with the limitations related to the small number of patients included, and to the open-label design of the study, the strongly favourable outcome we observed suggests that the local grafting with ATDC, containing both ASCs and SV fraction, could represent a promising option for the treatment of SSc-related DUs unresponsive to more consolidated therapies.

Physical Therapy for Systemic Sclerosis: Systematic Review and Meta-Analysis. Madhavi Peddi[1], Maria A. Lopez-Olivo[2], Prashanth Peddi[1], Gisela Espinosa Cuervo[3] and Maria E. Suarez-Almazor[2]. [1]The University of Tyler Texas, Tyler, TX, [2]The University of Texas, MD Anderson Cancer Center, Houston, TX, [3]Instituto Mexicano del Seguro Social, Mexico City, Mexico.

Background/Purpose: Physical therapy and rehabilitation are often recommended to improve function in patients with systemic sclerosis (SSc), but a systematic review of the evidence supporting these interventions has not

been performed. We conducted a systematic review to evaluate the efficacy of physical therapy alone or in combination with exercise in patients with SSC.

Methods: We searched electronic databases (MEDLINE, EMBASE, the Cochrane Collaboration library, and Web of Science) up to April, 2013. The reference lists from reviews were also searched. Two independent reviewers selected controlled trials (randomized or not) evaluating the efficacy of any physical therapy modality either alone or in combination with exercise in patients with SSc. Data was appraised and collected independently by two reviewers. Outcomes of interest were functional status, health-related quality of life, and hand mobility (measured by Health Assessment Questionnaire, Short Form-36 items, and Hand Mobility in Scleroderma, respectively). Meta-analysis was performed when data was available for 2 or more studies with the same outcome.

Results: Six studies with 221 patients were included. Five were randomized controlled trials and one was a controlled clinical trial. None of the studies were blinded; therefore, the risk of performance bias was judged to be high. All studies were conducted at single center in an outpatient setting. The weighted mean age of patients assigned to the treatment group was 57.6 years and 55.9 years for the control group. Disease duration was 9.0 years and 8.7 years, respectively. There were substantial variations in the interventions and duration of physical therapy across trials. Therapy modalities included connective tissue massage, Manual Lymphatic drainage, and Mc Mennell joint manipulation, among others. Patients treated with any modality of physical therapy had higher scores in functional status (mean difference, MD, −0.33; 95% CI −0.46, −0.19), physical component of health-related quality of life (MD 3.3; 95% CI 1.1, 5.5) and hand mobility (MD −0.22; 95% CI −0.37, −0.06) at 2 to12 weeks compared with standard of care. However, this improvement was not sustained for hand mobility, 12 weeks after stopping treatment (at 24 weeks) (MD −2.6; 95% CI −6.3, 1.0). No differences were observed by type of therapy modality.

Conclusion: Rehabilitation in patients with SSc improves functional status, ability to perform physical activities, and hand mobility 2 to12 weeks after therapy. However, loss of improvement in had mobility at 24 weeks suggests continuation of therapy is important to preserve the benefits of physical therapy.

Association of Gastrointestinal Symptoms with Immunosuppressant Use in the Prospective Registry of Early Systemic Sclerosis Cohort. Tracy M. Frech[1], Maureen Murtaugh[2], Ami A. Shah[3], Jessica K. Gordon[4], Victoria K. Shanmugam[5], Robyn T. Domsic[6], Monique Hinchcliff[7], Faye N. Hant[8], Shervin Assassi[9], Virginia D. Steen[10] and Dinesh Khanna[11]. [1]Salt Lake City VAMC, Salt Lake, UT, [2]University of Utah School of Medicine, SLC, UT, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]Hospital for Special Surgery, New York, NY, [5]The George Washington University, Washington, DC, [6]University of Pittsburgh, Pittsburgh, PA, [7]Northwestern University Feinberg School of Medicine, Chicago, IL, [8]Medical Univ of South Carolina, Charleston, SC, [9]University of Texas Health Science Center at Houston, Houston, TX, [10]Georgetown University Medical Center, Washington, DC, [11]University of Michigan Health System, Ann Arbor, MI.

Background/Purpose: The Prospective Registry of Early Systemic Sclerosis (PRESS) is a multicenter incident cohort study of patients with early diffuse cutaneous systemic sclerosis (dcSSc; < 2 years duration). Gastrointestinal tract (GIT) symptoms are common in this patient population. The goal of this study was to analyze whether immunosuppressant choice differentially impacts GIT symptoms in early dcSSc.

Methods: There are currently 71 patients enrolled in the PRESS study at various centers in the United States. Data is collected longitudinally using REDCap, an NIH funded database including demographics, disease characteristics, physical exam data, and patient reported outcomes. PRESS patients who had both a complete gastrointestinal tract questionnaire (SCTC UCLA GIT 2.0) and immunosuppressant regimen recorded were included in this analysis. Statistical analysis was performed using SAS version 9.4. Fisher's exact was to examine associations between two categorical variables and unpaired t-test or Wilcoxin ranked sum was used for continuous variables. Significance was assigned at $p < 0.05$.

Results: A total of 37 PRESS patients had the presence or absence of an immunosuppressant at the baseline visit/ and a complete GIT 2.0 recorded. In this subgroup of PRESS patients, the most common immunosuppressant used was mycophenolate mofetil (n=17) followed by methotrexate (n=5) and cyclophosphamide (n=3). The mean age of this patient population was 52 years (12.8) and 24 were women. The average BMI was 25.2 (17.8–40.5). Fifteen patients reported > 5 kg of weight loss over the past year; 5 of those patients had > 20 kg of weight loss. In these 15 patients with weight loss there were significantly worse scores for total GIT 2.0 (p=0.03), soilage (p=0.01), social function (p=0.05) and emotional well-being (p=0.04).

There were no significant differences in the GIT 2.0 total and component scores between different immunosuppressive regimens (Table 1). No PRESS patients reported a complete absence of gastrointestinal tract symptoms.

Conclusion: Gastrointestinal symptoms captured by the GIT 2.0 are common in early dcSSc. In patients with weight loss, scores for soilage, social, and emotional well-being are significant aspects of GIT involvement. In the PRESS cohort specific immunosuppressant exposure was not a strong driver of GIT symptoms, however, further longitudinal study in this patient population is planned.

Initial Therapy with an Endothelin Receptor Antagonist Is Associated with Worse Outcomes in Patients with Systemic Sclerosis and Pulmonary Arterial Hypertension: Observations from the Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma (PHAROS) Cohort. Matthew R. Lammi[1], Lesley Ann Saketkoo[1], Stephen C. Mathai[2], Robyn T. Domsic[3], Christine M. Bojanowski[4], Virginia D. Steen[5], Daniel E. Furst[6] and Pharos Investigators[5]. [1]LSU Scleroderma and Sarcoidosis Patient Care and Research Center, New Orleans, LA, [2]Johns Hopkins University, Baltimore, MD, [3]University of Pittsburgh, Pittsburgh, PA, [4]LSU Health Sciences Center, New Orleans, LA, [5]Georgetown University Medical Center, Washington, DC, [6]University of California, Los Angeles, Department of Medicine, Los Angeles, CA.

Background/Purpose: Pulmonary arterial hypertension (PAH) is a leading cause of mortality in systemic sclerosis (SSc). Although medications have improved their prognosis, optimal therapy remains undefined. The goal of this study was to compare time to clinical worsening (TTCW) and survival based on initial oral PAH therapy.

Methods: Using data from the PHAROS registry (a multicenter prospective observational study enrolling SSc patients with incident pulmonary hypertension), patients with group I PAH, 6 months of initial therapy with either an endothelin-receptor antagonist (ERA), phosphodiesterase-5 inhibitor (PDE5), or a combination of ERA/PDE5 were included. Patients treated initially with prostacyclins were excluded. The starting point for all analyses was the date of therapy initiation. Outcomes were survival and TTCW, defined as the first occurrence of death, PAH-related hospitalization, lung transplant, initiation of parenteral prostacyclin, or worsening symptoms.

Results: Ninety-eight patients (initial ERA=24, initial PDE5=59, initial ERA/PDE5=15) were included; no significant differences in baseline variables existed. TTCW was significantly worse in patients initially started on ERA compared to PDE5 or ERA/PDE5 (p=0.0001, Fig 1). Baseline factors

independently associated with shorter TTCW were initial ERA (HR 0.38, p=0.009), lower DLCO (HR 0.69 per 10% change, p=0.04), and higher PVR (HR 1.10 per Wood unit change, p=0.007). Three year survival was significantly worse in the initial ERA group (52.9%) compared to the PDE5 (91.5%) or ERA/PDE5 group (92.9%, p=0.004, Fig 2). The only baseline factor independently associated with risk for death in this cohort was initial ERA therapy (HR 0.22, p=0.004).

Conclusion: Compared to PDE5 or combination ERA/PDE5, initial therapy with an ERA in SSc-PAH patients was associated with a significantly worse TTCW and survival, even after adjustment for commonly accepted prognostic factors. Although these findings may be the result of unmeasured imbalances between groups, it is plausible that known ERA side effects such as fluid retention may have led to clinical worsening. Further study into the optimal initial oral therapy in patients with SSc-PAH is needed.

A Double Blind Randomized Control Trial of Oral Tadalafil in Interstitial Lung Disease of Scleroderma. Jyoti Parida, Alok Nath, Zafar Neyaz and Vikas Agarwal. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background/Purpose: We conducted a single center double-blind, randomized, placebo-controlled trial to determine the effects of oral Tadalafil on lung function and health-related symptoms in patients with scleroderma-related interstitial lung disease (ILD).

Methods: We enrolled 39 patients with scleroderma- related ILD patients who received oral Tadalafil 20 mg or matching placebo every alternate day for 6 months. The primary outcome measure was change in forced vital capacity (FVC, expressed as % of the predicted value) from baseline values and secondary outcome measures were change in Diffusion Lung Capacity for Carbon Monoxide (DLCO), Total Lung Capacity (TLC), Health Assessment Questionnaire (S HAQ), Medical Outcomes Study 36-item Short-Form General Health Survey (SF-36) and 6 min walk distance at the end of 6 months of treatment with Tadalafil in comparison to placebo group.

Results: Of 39 patients, 30 completed 6 months of treatment and were included in the analysis. At 6 month, although there was no statistically significant difference in change in FVC (% predicted) from baseline between the 2 groups, patients receiving Tadalafil had shown an improvement in mean (+SE) FVC of 1.82±2.08 whereas patients in placebo group had no change in mean FVC. Out of secondary outcome measures, the only significant difference between the 2 groups was found in patient global assessment scores which was significantly improved in Tadalafil group ($p<0.05$). There was a trend for improvement in TLC, breathing score in visual analogue scale (VAS) and physician global assessment score favoring Tadalafil although the difference between the 2 groups were not significant ($P>0.05$). There was no significant difference in adverse events between both groups.

Conclusion: Treatment with 6 month oral Tadalafil (20 mg alternate days) in patients with scleroderma-related ILD resulted in improvement in patient global assessment score. There was a trend for improvement for lung function, physician global assessment and VAS breathing scores. A larger multicentric study with sufficient power and high dose of Tadalafil may determine the efficacy of Tadalafil in ILD.

Table: Change in outcome measures from Baseline to 6 month in Tadalafil vs placebo group

Characteristics	Baseline	Value at 6 month	Difference
Tadalafil Group (n 17)

An Indirect Comparisons Analysis of Medications Used for Treatment of Raynaud's Phenomenon. Sampath Manickam[1], Elie Donath[2], Sandeep Dayanand[3] and Jonathan Greer[4]. [1]University of Miami Palm Beach Internal Medicine, West Palm Beach, FL, [2]University of Miami Miller School of Medicine Palm Beach Regional Campus, Atlantis, FL, [3]University of Miami Palm Beach Internal medicine, West palm beach, FL, [4]Arthritis & Rheumatology Associates, Boynton Beach, FL.

Background/Purpose: There are several pharmacological treatments used for treatment of Raynaud's phenomenon: calcium channel blockers, endothelin receptor antagonists, phosphodiesterase-5 enzyme inhibitors. The treatments have shown varying efficacy for relieving the symptoms of raynaud's phenomenon. One of the main determinants of the medications used for treatment of Raynaud's phenomenon is cost. The objective of this research is to perform a comparison of several pharmacological treatments for

raynaud's phenomenon. The medications that were analyzed were: Bosentan, Vardenafil, Tadalifil, Sildenafil, Udenafil, MQX-503 (a topical nitro formulation), Amlodipine. The main outcomes that were analyzed were Raynaud phenomenon attack frequency (number of attacks per day) and Raynaud condition score (a scale of 1 to 10, with higher scores indicating more severe symptoms).

Methods: Studies were extracted from a computerized literature search of PubMed, MEDLINE and EMBASE of all relevant RCT's. 8 RCT's, including 491 patients, were identified. There were two outcomes of interest: Raynaud phenomenon attack frequency (number of attacks per day) and Raynaud condition score. There were several outcomes of interest for safety: headache, nausea, vomiting, dizziness. Studies were included if they provided data at 10 weeks. For each outcome, a fixed-effects meta-analysis was employed to compare each drug to placebo. A mixed-treatment comparisons analysis was then utilized to compare each of these drugs to one another indirectly. Calculation of the probability that each treatment is best was implemented using the Bayesian Markov chain Monte Carlo method.

Results: In terms of Raynaud phenomenon attack frequency at 10 weeks, patients taking Vardenafil only had a 0.01 reduced attack frequency when compared to Amlodipine. In terms of Raynaud phenomenon attack frequency at 10 weeks, patients taking MQX-503 only had a 0.44 reduced attack frequency both were compared to Amlodipine. In terms of Raynaud condition score at 10 weeks, patients taking Vardenafil had a reduced 0.13 reduced Raynaud condition score when compared to Amlodipine (95% CI −2.55 to 2.77). In terms of rank probability, Tadalifil had a 44% chance of being the option most likely to be associated with the lowest Raynaud condition score at 10 weeks. The degree of incoherence (measuring how closely the network fits together) was low for all outcomes.

Conclusion: There are many parameters that determine the selection of a medication in the treatment of Raynaud's phenomenon such as cost, side effects and tolerability. Our analysis attempts to compare various medications for Raynaud's phenomenon in a network meta-analysis. The goal was to compare Raynaud phenomenon attack frequency and Raynaud Condition score. Based on the above statistical analysis, Vardenafil and Tadalifil may be considered to be superior options to other medications for reducing Raynaud phenomenon attack frequency and Raynaud condition score at 10 weeks.

Heart Transplantation in 6 Patients with Systemic Sclerosis and a Primary Cardiac Involvement. Alena Ikic[1], Emmanuel Chatelus[2], Eric Epailly[1], Hélène Kremer[1], Jean Sibilia[2], Jacques Gottenberg[1], Sabine Pattier[3], Erwan Flecher[4], Céline Goeminne[5] and Thierry Martin[1]. [1]Strasbourg University Hospital, Strasbourg, France, [2]University Hospital of Strasbourg, Strasbourg, France, [3]Nantes University Hospital, Nantes, France, [4]Rennes University Hospital, Rennes, France, [5]Lille University Hospital, Lille, France.

Background/Purpose: There is no specific treatment for primary cardiac involvement in SSc. Even if heart transplantation is an option, only 1 case have been reported[1]. The aim of the study was to collect data of patients with SSc and a primary cardiac involvement requiring a heart transplantation in order to establish the clinical course and expectable outcomes for this procedure.

Methods: Retrospective chart review of patients with SSc and a primary cardiac involvement requiring a heart graft in one of the major transplantation centers in France.

Results: A national survey allowed us to identify 6 patients fulfilling ACR/EULAR 2013 classification criteria for SSc. They had a history of primary cardiac involvement with an unequivocal indication for heart transplantation. 4/6 patients were women, 50% had lcSSc and 1 patient had an overlap with RA (Table 1). The median age at SSc diagnosis was 28 years and time to cardiac dysfunction diagnosis was 2.5 years. All patients had at least another systemic involvement, mostly gastrointestinal and/or musculoskeletal. Immunosuppressive treatment excluding corticosteroids has been prescribed to 3 patients.

In the year before transplantation, all patients were classified NYHA functional capacity III or IV and 5 of them required at least 1 hospitalisation. Median time from cardiac dysfunction diagnosis to transplantation was 4 years. The leading indication was heart failure requiring intravenous vasopressors except for 1 patient who was transplanted for recurrent ventricular arrhythmia. Cardiac pre-transplantation structural, functional and hemodynamic data are presented in Table 2.

The histopathology specimen of the explanted heart revealed myocardial fibrosis compatible with SSc primary cardiac involvement in all patients. Infectious complications occurred in 4 patients, 2 patients had ischemic lesions and 1 patient died from an unexplained graft failure. Median intensive care unit stay after the surgery was 22 days. During a median follow-up of 2.8 years, 4 patients had at least one acute cellular rejection, mainly of mild grade. Mild heart allograft vasculopathy occurred after a median of 2 years in 3 of 4 patients in whom coronary arteries were explored.

Conclusion: Symptomatic cardiac involvement in SSc has a bad prognosis. Heart transplantation is a relatively safe life-saving procedure in carefully chosen SSc patients with primary cardiac involvement manifesting with progressive dysfunction and/or arrhythmic complications.

Mycophenolate Mofetil Versus Azathioprine in Scleroderma-Associated Interstitial Lung Disease: Results from the Australian Scleroderma Cohort Study. Claire Owen[1], Gene Ngian[1], Kathleen Elford[1], Owen Moore[2], Mandy Nikpour[2], Wendy Stevens[2], Susanna Proudman[3], Janet Roddy[4], Jane Zochling[5], Catherine Hill[6], Peter Nash[7], Allan Sturgess[8] and Joanne Sahhar[1]. [1]Monash Health, Melbourne, Australia, [2]St Vincent's Hospital, Melbourne, Australia, [3]Royal Adelaide Hospital, Adelaide, Australia, [4]Royal Perth Hospital, Perth, Australia, [5]Menzies Research Institute Tasmania, Hobart, TAS, Australia, [6]Queen Elizabeth Hospital, Adelaide, Australia, [7]Sunshine Coast Rheumatology, Maroochydore, Australia, [8]The St George Hospital, Sydney, Australia.

Background/Purpose: Systemic sclerosis-associated interstitial lung disease (SSc-ILD) is common and when progressive, associated with significant morbidity and mortality. Cyclophosphamide is frequently used as first line therapy but evidence is lacking for sustained benefit and toxicity remains a concern. Consequently, patients are often switched to azathioprine (AZA) for maintenance therapy.

We report the efficacy and tolerability of mycophenolate mofetil (MMF) in the management of SSc-ILD and compare this with AZA.

Methods: Patients in the Australian Scleroderma Cohort Study treated with at least 3 months of MMF or AZA for SSc-ILD confirmed on high resolution computed tomography were identified. Pulmonary function tests (absolute and percent predicted values) at 6-monthly intervals were retrieved. Stability was defined as $<10\%$ change in absolute forced vital capacity (FVC), whilst $\geq 10\%$ increase or decrease defined improvement or decline respectively.

The Wilcoxon sign-rank test was used to compare lung function at 12 months prior to commencement (T-1), baseline (T0), 12 months (T1) and 24 months (T2).

Results: 17 and 49 patients were treated with MMF or AZA for a mean of 3.7±1.4 and 3.8±3.1 years, respectively, with 66% of both groups previously treated with cyclophosphamide. Patients were treated with an average MMF dose of 1.57g/day and AZA of 100mg/day.

Mean age at commencement was 54.6±9.3 years for MMF and 52.9±12.9 years for AZA (p=0.23). Patients in both groups were predominantly female and Caucasian with long-standing disease (10.9±3.7 years for MMF vs. 12.7±7.3 years for AZA, p=0.28). Disease was diffuse in 65% of patients on MMF and 51% on AZA.

Median absolute FVC at T-1 for MMF treatment was 2.5L, declining to 2.3L at T0 (p=0.02). At T1 and T2, FVC was stable at 2.1L (p=0.63) and 2.1L (p=0.93). Median absolute diffusion capacity (DLCO) also demonstrated decline prior to treatment (12.2 to 9.8, p=0.03), with stability at T1 (10.4, p=0.83) and T2 (11.9, p=0.04). Stability or improvement was seen at T1 in 12/15 and T2 in 9/11 cases. Comparable efficacy was achieved with AZA (16/19 cases were stable or improved at T1 and 14/19 at T2).

Adverse events leading to discontinuation were less common in the MMF group (2/17 vs. 13/49). Gastrointestinal complications were the main cause for discontinuation in both groups.

Conclusion: In patients with SSc-ILD with declining pulmonary function, MMF treatment was associated with stability in FVC and DLCO comparable to AZA and was better tolerated, suggesting a potentially superior role as maintenance therapy.

Botulinum Toxin-a for the Treatment of Severe Raynaud Phenomenon. Lucía Ruiz Gutiérrez[1], Ana Pérez Gómez[1], Nuria Valdeolivas Casillas[2], Henry Moruno Cruz[1], Eduardo Cuende Quintana[1], Ana Sánchez Atrio[1], Ana Turrión Nieves[1], Atusa Movasat[1], Cristina Bohórquez Heras[1], Fernando Albarrán Hernández[1], Maria Liz Romero Bogado[1], Susana Medina Montalvo[2] and Melchor Álvarez de Mon[1]. [1]Hospital Príncipe de Asturias, Immune System Diseases/Rheumatology department, Alcalá de Henares, Madrid, Spain, [2]Hospital Príncipe de Asturias, Dermatology department, Alcalá de Henares, Madrid, Spain.

Background/Purpose: Raynaud's phenomenon (RP) is characterized by transient episodes of vasoconstriction of the arteries and arterioles of the extremities in response to cold or emotional stimuli. Depending on the severity of the vascular insult, it can cause superficial ulceration or deep-tissue necrosis. Pharmacological treatments aim to enhance blood flow but their efficacy is not uniform.

Methods: We present a series of 7 patients with Raynaud's phenomenon with bad response to conventional pharmacological therapy that have been treated with local botulinum neurotoxin-A. Patients' characteristics are summarized in table 1. Exclusion criteria included botulinum toxin allergy, active infection at the site of injection, previous digital sympathectomy and pregnancy.

A cumulative total dose of 30–60 units of botulinum toxin was injected into the palmar aspect of the hand. Prior to infiltration, obstructive pathology was ruled out by Doppler ultrasound; also, a nailfold capillaroscopy test was performed before and after the infiltration. Variables such as the number of episodes per day, pain during the episodes, recuperation time, finger color and presence of digital ulceration or necrosis have been studied baseline, 30 minutes, one week and one month after the infiltration.

Results: 30 minutes after infiltration, three patients felt no improvement, two assessed slight improvement and two very important improvement. At the patients' one-week and thirty-days follow-up visits two patients did not perceive any change and four experienced great amelioration. Patients that did not register any change where those with fewer subjective clinical complaints and normal Doppler ultrasound and capillaroscopy tests.

The variable with the most remarkable response was pain, with important pain decrease in all of the cases. Three patients presented digit ulcers at baseline visit; ulceration healing was noted in all of them, two of them one week after the injection and the other one, one month after.

Three patients reported mild "weakness" after being injected and one reported slight thenar-eminence pain that lasted a few days. None of the patients suffered any systemic complications related to the toxin.

Conclusion: Botulinum toxin-A is a safe and effective therapeutic option for patients with severe Raynaud's phenomenon that have failed to conventional treatment.

Table 1

PATIENT	SEX	AGE	ASSOCIATED DIAGNOSIS	PREVIOUS MANAGEMENT
1	Female	52	CREST	- Calcium channel blockers - Prostacyclin Analogs
2	Female	51	CREST	- Calcium channel blockers
3	Female	41	CREST	- Calcium channel blockers
4	Female	35	CREST	- Calcium channel blockers - Prostacyclin Analogs - Pentoxifylline - Endothelin receptor antagonists
5	Female	41	MCTD	- Calcium channel blockers
6	Female	48	Reynolds syndrome	- Calcium channel blockers
7	Female	37	Primary RP	- Calcium channel blockers

CREST: Calcinosis, Raynaud phenomenon, Esophageal dysmotility, Sclerodactyly, Telangiectasia
MCTD: mixed connective tissue disease

Treatment of Scleroderma Associated Lung Disease with Mycophenolate Mofetil: A Community-Based Study. Audrey Bearden[1], Kent Kwasind Huston[2] and Judy Foxworth[3]. [1]University of Missouri-Kansas City, Kansas City, MO, [2]The Center for Rheumatic Disease, Kansas City, MO, [3]The University of Missouri-Kansas City, Kansas City, MO.

Background/Purpose: Interstitial lung disease occurs in over 80% of patients with scleroderma. Cyclophosphamide is the only treatment proven to benefit scleroderma lung disease in a large randomized placebo-controlled trial. However, the clinical benefit is modest and potential adverse effects are a major concern. Mycophenolate mofetil (MMF) has been reported to stabilize scleroderma lung disease in case series from academic institutions. However, patient characteristics may vary from the academic to community setting and the relevance of these reports to the broader rheumatology community is uncertain. Our purpose is to analyze the effect of MMF in scleroderma lung disease from a community-based rheumatology clinic.

Methods: Patients who fulfilled the 2013 ACR/EULAR classification criteria for scleroderma were identified in a community-based rheumatology practice. All patients included had evidence of scleroderma lung disease and treatment with MMF. Exclusion criteria were patients treated for < 4months, >14 months between baseline data and initiation of MMF, or >24 months after initiation of MMF for follow-up data. Lung functions, CT scans, and clinical symptoms were analyzed at baseline and post treatment. A total of thirteen patients were identified who met the above criteria. A paired student t-test was performed to assess pre and post MMF treatment change in forced vital capacity (FVC) and diffusion capacity for carbon monoxide (DLCO).

Results: A total of 22 patients met inclusion criteria. Of these 22 patients, 1 was deceased from pulmonary arterial hypertension, 2 stopped treatment before follow-up due to severe diarrhea, and 6 did not have timely baseline or follow-up data. This left 13 patients for analysis who were treated an average of 10 months with MMF. There was no significant difference between baseline and post treatment values for FVC or DLCO (p=0.89, p =0.76, respectively). The mean % predicted FVC pre and post MMF was 72 and 72 respectively. The mean % predicted DLCO pre and post MMF was 66 and 67 respectively. There were only two individuals who experienced a significant decline in FVC from baseline to follow up as defined by national criteria (absolute change in FVC of 10%).Baseline and post treatment CT scans were also evaluated. Of the 13 patients, 9 had stable CT findings, 2 worsened, and 2 improved. Clinical symptoms of cough and dyspnea were all stable or improved on MMF therapy.

Conclusion: MMF appears effective in preventing progression of scleroderma lung disease in a community-based setting. Compared to historical controls, we would have expected worsening lung function in the absence of treatment as seen in the placebo arm of the Scleroderma Lung Study. Limitations to our study include the lack of a standard protocol for individual rheumatologists to record symptoms, clinical findings, or standard intervals for pulmonary function tests and CT scans. Also, pre and post treatment CT scans were not universally interpreted by the same radiologist. These limitations were expected given the nature of rheumatology practice outside of academic centers. Our study supports the use of MMF for scleroderma lung disease in the community-based setting.

Effects of Mycophenolate Mofetil on Pulmonary Lung Function in Interstitial Lung Disease of Systemic Sclerosis. Michael Pham and W Leroy Griffing. Mayo Clinic Arizona, Scottsdale, AZ.

Background/Purpose: Interstitial lung disease remains a primary driver of morbidity and mortality in patients suffering from systemic sclerosis. Cyclophosphamide currently is the treatment with the most data and experience; however, toxicity and poor tolerance often limit its clinically modest usefulness. Mycophenolate mofetil (MMF) has received growing interest as an alternative agent. In this study, effects of MMF on pulmonary lung function in systemic sclerosis-associated interstitial lung disease were examined.

Methods: Twenty patient cases were retrospectively reviewed having met the American College of Rheumatology's criteria for systemic sclerosis. Interstitial lung disease was defined and characterized by high-resolution chest tomography. Cases were included if treatment was greater than 1 gram per day dosing of MMF for at least 6 months. Pulmonary function test results were collected prior to and following treatment initiation at 6 month intervals for a total 30-month monitoring time span.

Results: Six-to-twelve months prior to MMF initiation, mean predicted forced vital capacity (%FVC) was 74% ± 15.9% (mean ± SD) and declined to 71.3% ± 16.8% at treatment baseline. Following MMF initiation, the mean %FVC remained stable at 70.7% ± 12.9% and 71.2% ± 14.2% at the 6-to-12 and 12-to-18 month follow-up interval period, respectively. Mean rate of change in %FVC or *%FVC velocity* was −0.25% ± 0.93% per month prior to MMF treatment. Following MMF treatment, rates of decline reversed and %FVC velocity was +0.18% ± 0.62% per month at the 6-to-12 month follow-up interval – a statistically significant improvement (p=0.005). Mean predicted diffusion capacity of carbon monoxide (%DLCO) was 54.3% ± 14.4% prior to treatment. After MMF treatment, %DLCO improved to 56.1% ± 15.2% by the 6-to-12 month follow-up interval and to 57.4% ± 19.0% by the 12-to-18 month follow-up interval. These results are summarized in Figure 1 below.

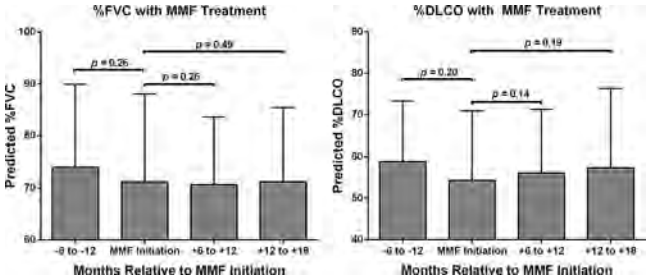

Figure 1

Conclusion: We report trends of stability with %FVC and trends of improvement with %DLCO over an 18-month period following MMF treatment. Our findings suggest mycophenolate mofetil is a promising alternative treatment for interstitial lung disease of systemic sclerosis. However, these observations were not statistically significant and further emphasize the need for a higher powered randomized clinical trial.

DUAL Energy Computed Tomography for the Evaluation of Calcinosis in Systemic Sclerosis. Vivien Hsu[1], Mark Bramwit[2] and Naomi Schlesinger[3]. [1]RWJ Med Schl Scleroderma Prog, New Brunswick, NJ, [2]Robert Wood Johnson University Hospital, New Brunswick, NJ, [3]Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ.

Background/Purpose: To better characterize the soft tissue details of systemic sclerosis–related (SSc) calcinosis of the hands using dual-energy computer tomography (DECT). DECT is an imaging modality used similarly to study monosodium urate (MSU) deposition in gout (1).

Methods: Fourteen patients with symptomatic hand SSc-calcinosis had DECT imaging and their clinical characteristics reviewed.

Results: Eight of 14 patients had diffuse SSc and 6 also had rheumatoid arthritis (RA). Herein are 3 DECT images: *Image 1:* a caucasian male with lifelong calcinosis due to diffuse scleroderma, whose painful deposits drain intermittently. *Image 2:* a caucasian female with limited SSc and RA for 15 years, whose calcinosis was found by imaging. *Image 3:* an African-American female with diffuse scleroderma and RA for 10 years. Her calcinosis caused painful wrist swelling, but despite surgery, continues to accumulate.

On DECT imaging, calcinosis was most commonly found in the subcutaneous (SQ) fat pads of the fingertips and along tendon sheaths and muscle groups. Acro-osteolysis was present in most (93%) patients, 7 (50%) with calcinosis nearby. No MSU was identified. Our cohort also had pulmonary fibrosis (79%), ischemic digital ulcers (71%) and bowel (43%) complications.

Conclusion: SSc-calcinosis affects diffuse and limited SSc. We found DECT imaging better defined the soft tissue details and was useful in the evaluation of SSc-calcinosis.

References:

1. Choi K: Ann Rheum Dis 2009; 68 (10):1609.

Image 1: 3D image shows acro-osteolysis of the 2nd and 3rd digits, extensive calcification in the SQ fat (volar) of the second digit (arrow), punctate deposits in the fat pad of thumb, lateral to the scaphoid bone, and between several MCP joints.

Image 2: Acro-osteolysis with associated calcinosis in the fat pads of all fingertips (small arrows); extensive calcification seen around the 1st and 2nd MCP and ulna (adjacent to the carpal tunnel) (medium arrow). The distal 5th phalanx is completely eroded (large arrow). The wrist deposits appear separate from the tendons.

Image 3: Soft tissue calcifications seen throughout the fingers and wrist with marked destruction at the radio-carpal joint. The scaphoid may be partially collapsed. There is severe penciling with nearly complete bone resorption (large arrow) of mid portion of 2nd phalanx.

Key Role of Cardiac Biomarkers in the Assessment of Systemic Sclerosis: Contribution of High Sensitivity Cardiac Troponin. Jerome Avouac[1], Christophe Meune[2], Camille Gobeaux[3], Didier Borderie[3], Guillaume Lefevre[4], Andre Kahan[5] and Yannick Allanore[1]. [1]Paris Descartes University, Rheumatology A Department and INSERM U1016, Cochin Hospital, Paris, France, [2]Paris 13 University, University Hospital of Paris-Seine-Saint-Denis, Cardiology Department, Bobigny, France, [3]Paris Descartes University, Biochemistry A department, Cochin Hospital, Paris, France, [4]Clinical Chemistry and Hormonology Department, Tenon Hospital, paris, France, [5]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France.

Background/Purpose: Microangiopathy is a cardinal feature of systemic sclerosis (SSc), which plays a critical role in the development of primary myocardial involvement and pulmonary hypertension, two major causes of death in SSc. Our aim was to measure plasma concentrations of two cardiac biomarkers, high sensitive Cardiac troponin T (HS-cTnT), a marker of myocyte necrosis and/or ischemia, and N-terminal fragment of pro-BNP (NT-proBNP), a marker of cardiac strain, in two large cohorts of SSc patients and controls.

Methods: 161 SSc patients (135 women, 84%) with a mean ± SD age of 57±17 years were included and were compared to 213 healthy controls (170 women, 80%, mean ± SD age of 55±11 years).

Results: Among the SSc cohort, mean disease duration was 9±8 years, 65 patients (40%) had the diffuse cutaneous subset. HS-cTnT and NT-proBNP plasma levels were significantly increased in SSc patients versus controls ($p=0.0001$ and $p<0.0001$ respectively). SSc patients were more likely to have above the cut-off value concentrations of HS-cTnT (>14 ng/L) and NT-proBNP than controls (30/161 patients (19%) with HS-cTnT >14 ng/l vs. 4/213 controls (2%), $p<0.0001$; 17/161 patients (11%) with increased NT-proBNP levels vs. 8/213 controls (4%), $p=0.02$). Similar results were observed in the subgroup of patients free of any cardiovascular risk factors. Multivariate logistic regression analysis confirmed diabetes mellitus ($p=0.006$), high blood pressure ($p=0.02$), precapillary pulmonary hypertension (PH) ($p=0.04$), ESR >28 mm/H1 ($p=0.007$) and the diffuse cutaneous subset ($p=0.004$) as factors independently associated with HS-cTnT >14 ng/L. Increased NT-proBNP concentrations were only associated with the presence of precapillary PH ($p=0.0001$). The combination of increased HS-cTNT and NT-proBNP levels had the highest positive predictive value for the diagnosis of precapillary PH (67%) compared to HS-cTnT (20%) or NT-proBNP (35%) alone.

Conclusion: Plasma levels of HS-cTnT and NT-proBNP are increased in SSc patients. Associated factors with increased HS-cTnT include the diffuse cutaneous subset and precapillary PH, which reflect the severity of the disease. In addition, the combination of increased HS-cTnT and NT-proBNP plasma concentrations display higher positive predictive value for the diagnosis of precapillary PH than each marker alone. Given the prognostic significance of these biomarkers, they might be helpful to select the patients that justify further examinations in case of suspicion of cardiac complication.

1688

Early Detection of Left Ventricular Morphological, Functional Abnormalities and Myocardial Characteristics in Systemic Sclerosis without Cardiac Symptoms Using Cardiac Magnetic Resonance Imaging: A Preliminary Report. Kaita Sugiyama[1], Hitomi Kobayashi[1], Yasuyuki Kobayashi[2], Yosuke Nagasawa[1], Natsumi Ikumi[1], Takamasa Nozaki[1], Hirotake Inomata[1], Hidetaka Shiraiwa[1], Hiromi Karasawa[1], Noboru Kitamura[1], Mitsuhiro Iwata[1], Yoshihiro Matsukawa[1] and Masami Takei[1]. [1]Nihon University School of Medicine, Tokyo, Japan, [2]St.Marianna University School of Medicine, Kawasaki, Japan.

Background/Purpose: Systemic sclerosis (SSc) is associated with an increased prevalence of cardiac involvement despite often being clinically silent. Cardiac involvement is a major factor in decreasing SSc survival rates because it is associated with a 70% 5-year mortality rate. Cardiac magnetic resonance imaging (CMR) is useful in SSc since it focuses on late gadolinium enhancement (LGE) abnormalities, ventricular morphology, and function. Our study aimed to comprehensively analyze CMR and investigate the association between CMR findings and brain natriuretic peptide (BNP) in SSc patients (pts) without cardiac symptoms.

Methods: Consecutive female pts with SSc without cardiac symptoms as well as healthy female controls were enrolled. SSc pts and control subjects with no history or clinical findings of systemic and pulmonary hypertension determined by echocardiography, coronary artery disease, valvular heart disease, atrial fibrillation, diabetes mellitus, and dyslipidemia underwent non-contrast or contrast CMR on a 1.5T scanner. Left ventricular (LV) function was measured using LV ejection fraction (EF), end-systolic volume (ESV), end-diastolic volume (EDV), stroke volume (SV), and cardiac output (CO). LV hypertrophy was measured by absolute LV mass (LVM) and LVM index (LVMI) determined by the LVM/body surface area. LGE was obtained to assess myocardial fibrosis. Myocardial inflammation was assessed with black blood T2-WI. Serum BNP concentrations were measured simultaneously in all participants.

Results: We compared 35 SSc pts (mean age, 55.9±7.1 years)—19 with diffuse type and 16 with limited type—with 20 healthy controls (mean age, 56.9±3.1 years). There were no significant differences in characteristics such as age, gender, and cardiovascular risk factors, between SSc and control group. Compared with the control group, the SSc group had a significant higher EDV with tendency toward a high LVMI. There was no difference in EF between the control and SSc groups. SSc with LGE was detected in 16 of 35 pts (46%). The main finding observed in 9 of these 16 (56%) pts was a linear pattern without coronary distribution. A patchy nodular enhancement pattern was observed in 7 pts (44%). LVMI and mass/EDV were significant higher in the LGE (+) group than in the LGE (−) group ($P>0.001$, $P=0.003$, respectively). T2-WI imaging showed myocardial inflammation in 6 of 35 pts (17%). The mean BNP level of the SSc group was significantly higher than that of the control group ($P=0.04$). The mean BNP level of the SSc with LGE group was significantly higher than that of the SSc without LGE group ($P=0.023$). BNP level was significantly correlated with LVMI and EF in the SSc group ($P=0.04$, $P=0.05$, respectively).

After adjustment for age, disease duration, and BNP, the SSc with LEG group did not have a modified association with LVMI.

Conclusion: SSc patients without cardiac symptoms have a high prevalence of cardiac abnormalities. SSc patients with LGE had abnormal morphology associated with LVMI and serum BNP even with a normal EF. Further studies are needed to determine whether CMR abnormalities affect prognosis or treatment strategy.

Microhaemorrages and Giant Capillaries in Nailfold Videocapillariscopies Are Able to Accurately Predict Disease Activity Level in Systemic Sclerosis. Domenico Sambataro[1], Nicoletta Del Papa[1], Gianluca Sambataro[2], Wanda Maglione[2], Eleonora Zaccara[2] and Claudio Vitali[3]. [1]Istituto G.Pini, Milan, Italy, [2]Osp. G. Pini, Milano, Italy, [3]Istituto San Giuseppe, Lecco, Italy.

Background/Purpose: Systemic Sclerosis (SSc) is a connective tissue disease characterized by Raynaud's phenomenon, skin fibrosis and involvement of internal organs such as lung, heart, bowel, and kidney. The microvascular involvement is considered an hallmark of disease. Nailfold Videocapillaroscopy (NVC) is a simple method able to identify the disease-related microvascular alterations in an easily accessible capillary bed and is commonly used for diagnosis and patients' sub-setting.

Aim of this study is to evaluate whether the number of micro-haemorrhages (MHE), micro-thrombosis (MT), giant capillaries (GC), and normal or dilated capillaries (Cs) in NVC could predict disease activity (DA) in SSc.

Methods: One hundred and seven patients (57 with limited cutaneous and 50 with diffuse cutaneous SSc, 10 males) meeting the 2013 ACR/EULAR classification criteria, were selected for this study. The European Scleroderma Study Group (ESSG) index was taken as gold standard for DA assessment. Score ≥ 3.5 and $=3$ were considered as indicative of highly and moderate DA, respectively. NVC was performed on 8 fingers (second to fifth of both hand) in the middle of nailfold taking 4 consecutive fields of 1 millimeter with a 200× magnification lens. The following NVC features were considered: total number of MHE/MT aligned in the same row on the cuticle (here called NEMO score); total number of GC (GC score); mean number of Cs observed in all NCV fields (Cs score).

Non-parametric tests were used to compare the NVC scores with the variables here taken into account. Receiver operating characteristic (ROC) curves were constructed by plotting sensitivity and specificity values of NVC scores in correctly classifying patient having or not an active disease phase. Logistic regression model was also tested to assess the contribution of the NVC scores in predicting the presence of DA.

Results: NEMO and GC scores were positively correlated with ESSG index ($R=0.65$, $p<0.0001$, and $R=0.47$, $p<0.0001$, respectively), whilst Cs score showed a negative correlation with that DA index ($R=-0.30$, $p<0.001$).

The area under the curve (AUC) of receiver operating characteristic (ROC) plots, obtained by NEMO score sensitivity and specificity values in classifying patients with ESSG index ≥ 3.5, was significantly higher than the corresponding AUC derived from either GC or Cs scores ($p<0.001$ and $p<0.0001$, respectively). A modified score, defined by the presence of given number of MHE/MT and GC, had a good performance in classifying active patients (ESSG index ≥ 3, sensitivity 95.1%, specificity 84.8%, accuracy 88.7%).

Conclusion: This newly proposed NCV scoring system, here named mNEMO score, seems to be a valid tool to predict DA level in SSc. In addition, it appears also feasible since it can be derived simply during an outpatient visit and in a rather short time.

It is, of course, evident that a patient with a positive mNEMO score should be addressed to a more careful clinical, instrumental, and serological evaluation to confirm the suspicion and define a more precise clinical profile.

Background/Purpose: Ischemic digital ulcers (DU) represent a major complication of systemic sclerosis (SSc) leading to hand disability. We investigated the impact of controlling the ulcerative disease on hand disability and quality of life in SSc patients following one year of bosentan treatment.

Methods: ECLIPSE is a 2-year prospective, observational study. Patients with SSc who experienced at least one DU in previous year and received bosentan to prevent occurrence of new DU were included between October 2009 and March 2011.Demographical and clinical data were collected at inclusion and at 1 year, as well as disability scores (Cochin hand function scale (CHFS), health assessment questionnaire disability index (HAQ-DI)), pain score (Visual Analog Scale), and quality of life (SF-36). A controlled ulcerative disease was defined by healing of all DU present at inclusion and the absence of new ulcer between inclusion and one-year follow-up. Data are presented as means ± standard deviations.

Results: Follow-up data were available at one year for 120 patients out of the 190 included patients. Patients' characteristics were similar to those of the overall cohort. Mean age at inclusion and at SSc diagnosis were 54 ± 15 and 44 ± 15 years, respectively. SSc was diffuse in 42% of the cases. At inclusion, patients had been receiving bosentan for 15.6 ± 22.1 months. During the one-year follow-up, 46 (38%) patients experienced an episode of new DU and the incidence of the event was 0.6 event/patient-year [95% confidence interval: 0.44–0.81]. Nevertheless, the proportion of patients with at least one DU decreased from 61% to 22% and the number of DU per patient decreased from 1.4 ± 1.8 to 0.6 ± 1.6 ($p < 0.0001$). In parallel disability scores decreased from 29.4 ± 20.1 to 25.0 ± 20.2 ($p=0.005$) on the CHFS and from 0.96 ± 0.68 to 0.88 ± 0.73($p=0.04$) for the HAQ-DI; the pain score decreased from 4.3 ± 3.1 to 2.9 ± 2.8 ($p<0.0001$). Improvements in the physical and mental components of the SF-36 were non-significant except for bodily pain ($p=0.04$) and mental health ($p = 0.01$).

Patients with a controlled ulcerative disease ($n=58$) significantly improved CHFS ($p = 0.04$), HAQ-DI ($p = 0.04$), and physical component of the SF-36 ($p = 0.05$) compared with patients with an uncontrolled disease ($n=62$).

During the one-year follow-up, 21 (17%) patients discontinued bosentan for an adverse event including 5 patients presenting elevated aminotransferases

Conclusion: In patients with SSc receiving bosentan, a controlled ulcerative disease is associated with a significant attenuation of disability.

Systemic Sclerosis Patients with Pulmonary Hypertension Have a Lower Change in End Tidal Carbon Dioxide Following Three Minutes of Step Exercise Than Systemic Sclerosis Patients without Pulmonary Hypertension: A Cross-Sectional Study. Elana J. Bernstein[1], Jessica K. Gordon[2], Robert F. Spiera[2], Wei-Ti Huang[2], Evelyn M. Horn[3] and Lisa A. Mandl[2]. [1]Columbia University College of Physicians & Surgeons, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]New York Presbyterian Hospital/Weill Cornell Medical College, New York, NY.

Background/Purpose: Pulmonary hypertension (PH) is a leading cause of death in patients with systemic sclerosis (SSc). Transthoracic echocardiogram and pulmonary function testing are standard noninvasive screening methods for PH. However, both are limited in their ability to distinguish between SSc patients with and without PH. The gold standard diagnostic test for PH is right heart catheterization (RHC), which although accurate, is expensive, invasive, and has associated risks. Finding an accurate, noninvasive technique to screen for PH in the SSc population is an important unmet need.

The submaximal heart and pulmonary evaluation (step test) is a standardized, noninvasive, submaximal stress test that consists of a 5.5 inch high step that patients step up and down on for 3 minutes. During the test, end tidal carbon dioxide, which is positively correlated with cardiac output and pulmonary blood flow and inversely correlated with the minute ventilation to carbon dioxide production ratio (V_E/V_{CO2}) and reflects the severity of PH, is monitored. Our primary aim was to determine whether SSc patients with PH would have a lower change in end tidal carbon dioxide (ΔP_{ETCO2}) from rest to end-exercise on the step test than SSc patients without PH. Our secondary aim was to determine whether SSc patients with PH would have a higher V_E/V_{CO2} than those without PH. We also examined differences in validated self-report questionnaires and biomarkers between SSc patients with and without PH. We hypothesized that SSc patients with PH would have a lower ΔP_{ETCO2} and higher V_E/V_{CO2} than SSc patients without PH.

Methods: This is a cross-sectional study of 27 patients with limited or diffuse cutaneous SSc who underwent an RHC within 24 months of study entry. All patients were administered the step test between May 2012 and August 2013. ΔP_{ETCO2} and V_E/V_{CO2} were compared between patients with and without PH, defined as a mean pulmonary artery pressure $\geq$ 25 mmHg on RHC. Differences in self-report data and biomarkers were also compared between groups. Statistical analysis was performed using Kruskal-Wallis, chi square, and Fisher exact tests, as appropriate.

Results: See Table 1 for patient characteristics. SSc patients with PH had a statistically significantly lower median ΔP_{ETCO2} than SSc patients without PH (−2.1 [−5.1 – +0.7] vs. 1.2 [−0.7 - +5.4], p=0.035) and a statistically significantly higher median V_E/V_{CO2} (53.4 [39–64.1] vs. 36.4 [31.9–41.1], p=0.035) than SSc patients without PH. There were no statistically significant differences in self-report data or biomarkers between groups (Table 1).

Conclusion: ΔP_{ETCO2} and V_E/V_{CO2} as measured by the step test are statistically significantly different between SSc patients with and without PH. Neither traditional self-report outcome measures nor biomarkers differed between groups. Further prospective studies are needed to evaluate the step test as a screening tool for PH in the SSc population.

The Additive Value of Nailfold Videocapillaroscopy Patterns to Disease-Specific Autoantibodies in Discrimination of Patients with Systemic Sclerosis at Risk for Severe Organ Involvement. I.M. Markusse, J. Meijs, B. de Boer, A. a. Schouffoer, N. Ajmone Marsan, L. J. M. Kroft, M. K. Ninaber, T. W. J. Huizinga and J.K. de Vries-Bouwstra. Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Severe nailfold videocapillaroscopy (NVC) patterns in patients with systemic sclerosis (SSc) are associated with a high risk of organ involvement. SSc-specific autoantibodies seem to be associated with different NVC scleroderma patterns. Whether the combination of autoantibodies and NVC pattern contributes to better discrimination of patients at risk for organ involvement remains unclear. The aim of this study is to explore the association between clinical phenotype and the combination of autoantibodies and NVC pattern, in order to compose individualized screening programs for organ involvement.

Methods: Data on NVC patterns and anti-centromere (ACA), anti-topoisomerase (anti-Scl70) and anti-ribonucleoprotein (anti-RNP) autoantibodies was investigated in 167 patients of the Leiden Systemic Sclerosis Cohort. The prevalence of autoantibodies and NVC scleroderma patterns (early, active, late) was described. Clinical phenotypes were evaluated for different combinations of autoantibodies and NVC pattern.

Results: 148/167 patients (89%) had a NVC scleroderma pattern: early in 16 patients (11%), active in 77 patients (52%), late in 55 patients (37%). Of these 148 patients, 82 (55%) were ACA+, 52 (35%) were anti-Scl-70+ and 17 (11%) were anti-RNP+. In 19 patients with a non-scleroderma NVC pattern, 11 (58%) were ACA+, 6 (32%) were anti-Scl-70+ and 2 (11%) were anti-RNP+.

Similar distributions of NVC patterns were found in ACA+ and ACA− patients (p=0.185), as also in anti-Scl-70+ and anti-Scl-70− patients (p=0.293). None of 17 anti-RNP+ patients had an early pattern, compared to 16/131 anti-RNP− patients (12%) (p=0.127). Overall, and probably due to small numbers, no significant difference in distribution of NVC patterns between anti-RNP+ and anti-RNP− patients was shown (p=0.178).

ACA+ patients with an early pattern tend to have less organ involvement than patients with an active or late pattern: less skin involvement, higher gas transfer for CO (DLCO), less vascular lesions (table). Early patterns in anti-Scl-70+ (n=3) and anti-RNP+ patients (n=0) were too rare to evaluate. In anti-Scl-70+ patients with a late pattern, more interstitial lung disease, lower DLCO, less vascular lesions and a higher NT-proBNP were seen, compared to an active pattern (table). Similar trends were seen in anti-RNP+ patients (table). ACA+, anti-Scl-70+ and anti-RNP+ patients with a late NVC pattern, seem to have more often a DLCO <70% of predicted and a higher NT-proBNP.

Conclusion: Early NVC patterns in ACA+ SSc patients seem to correlate with less severe organ involvement, while a late pattern in ACA+, anti-Scl-70+ or anti-RNP+ patients seems to correlate with more severe organ involvement. These data indicate that the combination of NVC pattern and antibodies can contribute to discrimination of SSc patients that need extensive organ screening.

Table: Clinical phenotypes stratified for systemic sclerosis specific autoantibodies and nailfold capillaroscopy pattern (anti-Scl-70+ patients and anti-RNP+ patients with an early pattern were left out because of low numbers, n=3 and n=0, respectively).

Progressive Disease in Systemic Sclerosis after One Year of Follow-up; Results of a Standardized Multidisciplinary Health Care Program. Jessica Meijs, Anne Schouffoer, Nina Ajmone Marsan, Lucia Kroft, Maarten K. Ninaber, T.W.J. Huizinga and Jeska K. De Vries-Bouwstra. Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: The aim of this study is to evaluate disease course of systemic sclerosis (SSc) patients participating in a single centre multidisciplinary health-care program over one year of follow-up, and to evaluate which baseline variables discriminate patients with progressive disease.

Methods: Baseline characteristics and one year follow-up results from patients with diffuse cutaneous SSc (DcSSc), or limited (cutaneous) SSc (L(c)SSc) referred to the multidisciplinary health-care program were evaluated. Progressive disease was defined as: SSc-related decease, decrease of ≥10% of forced vital capacity (FVC), decrease of ≥15% of diffusing capacity for carbon monoxide (DLCO), decrease of ≥10% of body weight, decrease of ≥ 30% of estimated glomerular filtration rate, increase of ≥30% modified Rodnan Skin Score (mRSS) (with Δ ≥3) or ≥0.25 increase of Scleroderma Health Assessment Questionnaire. The number of patients with progressive disease was determined. Logistic regression analysis was used to determine the association between baseline characteristics and presence of progressive disease. Discriminative ability of the multivariable model was expressed as the area under the receiver operating characteristic (AUC) curve.

Results: Between April 2009 and January 2014 303 SSc patients were referred to the health-care program, of which 164 underwent re-evaluation after one year (mean 13.5, range 10–23 months). Sixty-six patients (38% of 172) had progressive disease, including 8 patients who died ≤18 months after first evaluation. Progressive disease was found in 27 (33%) patients with DcSSc, 32 (50%) with LcSSc, and seven (26%) with LSSc (Table 1). Type of skin involvement, mRSS and disease duration could not independently discriminate progressive patients. Multivariable analysis showed that friction rubs and proximal muscular weakness were most significantly associated with progressive disease, additional to type of SSc, age, gender, disease duration, autoantibody profile and use of immunosuppressive therapy. The multivariable model showed fair discrimination (AUC 0.718 [95% CI 0.636–0.800]).

Conclusion: Thirty-eight percent of SSc patients showed progressive disease after one year follow-up, with highest frequency of progression among patients with LcSSc. The strongest predictors of progressive disease were friction rubs and proximal muscular weakness; pattern of skin involvement and disease duration were not independently discriminative. These observations underline the relevance of strict follow-up in all SSc patients as well as the need for more effective treatment strategies.

Table 1. Progressive disease in SSc according to subtype of SSc

Progression, N (%)	Total	DcSSc	LcSSc	LSSc

1694

a Feasibility Study of Subjective and Objective Assessment of Sublingual Abnormalities in Systemic Sclerosis. Tracy M. Frech[1], John Pauling[2], Maureen Murtaugh[3], Lee S. Shapiro[4], Bernard Choi[5], Ryan Farraro[5] and Robyn T. Domsic[6]. [1]Salt Lake City VAMC, Salt Lake, UT, [2]Royal National Hospital for Rheumatic Disease, Bath, United Kingdom, [3]University of Utah School of Medicine, SLC, UT, [4]The Center for Rheumatology, Albany, NY, [5]University of Irvine, Irvine, CA, [6]University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Sublingual frenulum abnormalities are reported in systemic sclerosis (SSc), but the exact nature and clinical relevance of such abnormalities is unknown. Laser speckle contrast imaging (LSCI) is an emerging method for assessing tissue perfusion but has not been applied to the gastrointestinal tract (GIT) in SSc. We report a feasibility study evaluating clinical associations and inter-rater agreement using a novel scoring chart to assess sublingual abnormalities in SSc patients and healthy controls (HC). We also report preliminary findings and associations following objective assessment of sublingual perfusion using LSCI in SSc.

Methods: Ten patients fulfilling 2013 ACR/EULAR classification criteria for SSc and 8 HC were recruited from two different SSc clinics. SSc patients completed the GIT 2.0 questionnaire and baseline demographics were documented. A 0–2 Likert scale was used to assess sublingual frenulum thickness, frenulum length, mucosa pallor and the presence of sublingual and labial telangiectases. A composite index of scores for each domain was calculated for each subject. Photographs of the sublingual frenulum were obtained under standardised conditions to allow blinded assessment by 2 separate assessors of sublingual abnormalities without knowledge of GIT symptoms. Baseline perfusion (in arbitrary flux units [fu]) of the frenulum was assessed using LSCI in subjects with SSc.

Results: Each of the frenulum measures differed between HC and SSc (Mann-Whitney U, $p = 0.0003$). No HC had a composite score of greater than 2. Positive associations were identified between clinical frenulum assessment (rater 1), domains of GIT 2.0, disease duration and LSCI perfusion in SSc. Inter-rater agreement for individual domains of frenulum scoring chart and composite index revealed moderate agreement for assessment of frenulum (Table 1) with a weighted kappa for the total score is 0.53 (moderate agreement). When LSCI was applied to the frenulum, the perfusion index was 2308 fu (1810–3203). The perfusion index correlated negatively with disease duration, -0.64 ($p < 0.05$) and with social component of the GIT 2.0, -0.67 ($p = 0.05$).

Conclusion: This feasibility study confirms the presence of clinical sublingual abnormalities in SSc, which can be categorised using a simple scoring chart with moderate inter-rater agreement. Perfusion of the sublingual frenulum can be assessed by LSCI and may correlate with disease duration and GIT 2.0 self-report. Efforts to refine image capture and scoring shall be undertaken to improve blinded inter-rater agreement before embarking on a larger study exploring the significance of clinical and LSCI perfusion sublingual abnormalities in SSc.

Table 1: Frenulum Assessment

Validation of Vesmeter As a Diagnostic Tool of Scleroderma. Yoshihiro Hishitani[1], Yoshihito Shima[2], Toshio Tanaka[2] and Atsushi Kumanogoh[2]. [1]Kinki Central Hospital, Itami, Japan, [2]Osaka University Graduate School of Medicine, Suita, Japan.

Background/Purpose: Objective method to evaluate the skin involvement in the patients with scleroderma has not been definitely established. We have developed Vesmeter, a computer-linked device to simultaneously quantify the skin characteristics such as viscosity, elasticity and softness, and have reported its usefulness to evaluate the skin characteristics of patients with scleroderma. Here, we validated Vesmeter as a diagnostic tool of scleroderma.

Methods: Using Vesmeter, we evaluated the skin characteristics of patients with scleroderma and healthy volunteers. 17 points of the body were evaluated, like modified Rodnan's skin score. First, we compared the skin characteristics of scleroderma patients with that of healthy volunteers matched by age and sex. Second, we conducted bivariate Receiver Operating Characteristic (ROC) analyses to examine which points and parameters are useful to diagnose scleroderma. Third, using whole data of healthy volunteers, we conducted logistic regression and ROC analysis to validate Vesmeter as a diagnostic tool of scleroderma.

Results: 39 patients with scleroderma and 413 healthy volunteers were included. Among the healthy volunteers, 78 people were selected at random, matching age and sex with patients as the control group for the first and second analyses. Regarding the background of the 2 groups, body weight of patients was lighter than controls. As the result of the comparison of skin characteristics, patients' skin were statistically harder and showed higher elasticity than control on both fingers, left hand, both forearms (Figure 1), both lower legs, and both feet. Viscosity of patients' skin were also statistically higher than control on both fingers, both hands, both forearms, face, chest, right femur, and right foot. As the result of bivariate ROC analyses, moderate accuracy to distinguish patients from control was recognized by softness of both fingers and both forearms, elasticity of right finger and both forearm, and viscosity of left finger, right hand, both forearms, and face. Based on this result, age, body weight, softness of both fingers and right forearm, elasticity of left forearm, and viscosity of face, left finger, right hand, and both forearms were selected variables for the next logistic regression and ROC analysis using whole data of 413 healthy volunteers. (One of softness and elasticity was used because of the multi-collinearity). This ROC analysis resulted in high accuracy (AUC = 0.92514, Sensitivity = 0.7949, Specificity = 0.9562) to diagnose scleroderma (Figure 2).

Conclusion: Vesmeter showed high accuracy to diagnose scleroderma.

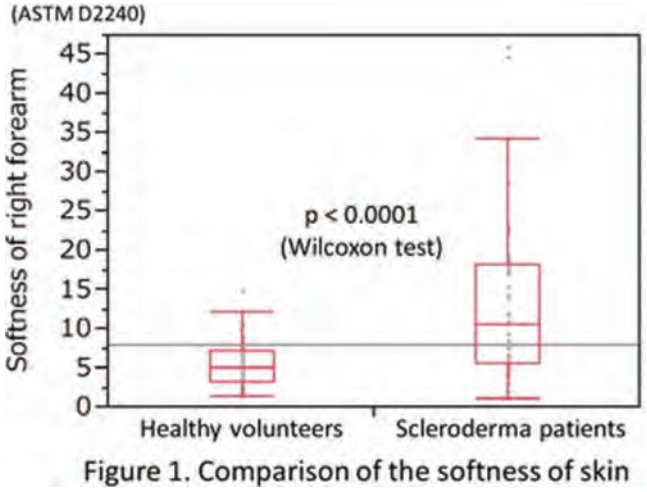

Figure 1. Comparison of the softness of skin

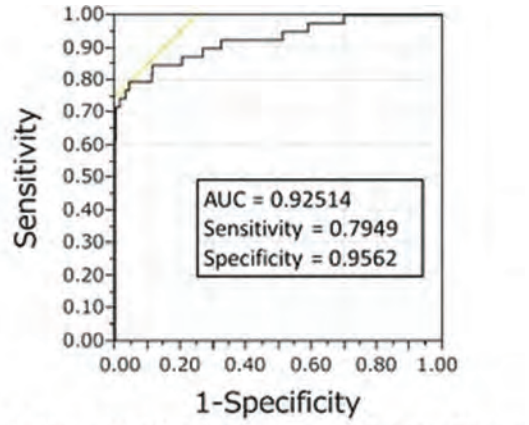

Figure 2. Vesmeter for the diagnosis of scleroderma

Left Atrial Area Measurement Is Useful for Evaluating Left Ventricular Diastolic Dysfunction Coexisting with Pulmonary Arterial Hypertension Associated with Systemic Sclerosis. Sumiaki Tanaka, Nobuhiro Sho, Tatsuo Nagai, Yoshiyuki Arinuma and Shunsei Hirohata. Kitasato University School of Medicine, Sagamihara, Japan.

Background/Purpose: Pulmonary arterial hypertension (PAH) is a crucial organ involvement affecting survival of patients with connective tissue disease (CTDs), such as systemic sclerosis (SSc), systemic lupus erythematosus (SLE), and mixed connective tissue disease (MCTD). Although some powerful PAH-specific drugs improve the survival of patients with idiopathic PAH, the prognosis of patients with PAH associated with SSc remains still poor. To explore the characteristics relevant to the poor survival of patients with PAH associated with SSc under treatment with PAH-specific drugs, we performed exploratory data analysis using echocardiogram (ECHO) in patients with PAH associated with CTDs.

Methods: We analyzed 1002 ECHO reports from 54 patients with PAH associated with CTDs, including 22 patients with SSc, and 33 patients with CTDs other than SSc (SLE:12, MCTD:16 and other CTDs: 5), who had been diagnosed as PAH based on right heart catheterization test and treated with PAH-specific drugs between April 2005 and March 2013 in our hospital. We selected systolic pulmonary arterial pressure (PAP), cardiac output (CO), and right atrial (RA) and left atrial (LA) areas which were traced at end-diastolic time on 4 chamber view as parameters. Comparison of these parameters between patients with PAH associated with SSc (PAH-SSc(+)) and patients with PAH associated with other CTDs (PAH-SSc(−)) was carried out using mixed effects model in which we set presence or absence of SSc, WHO-functional class (WHO-FC), and age at ECHO performed as fixed effects, and patient as a random effect. We also compared the serum levels of brain natriuretic peptide (BNP) between patients with PAH-SSc(+) and patients with PAH-SSc(−) with the same strategy. Representative value estimated by our model was displayed as mean (95% confidence interval) value adjusted for WHO-FC and age.

Results: PAH-specific drugs used for treatment of the patients, including bosentan, ambrisentan, sildenafil, tadalafil, epoprostenol, and beraprost (an oral prostacyclin analog that is only available in Japan). Mean of age and WHO-FC, which were substituted into our model to estimate the adjusted values, were 52.2 and 2, respectively. As shown in Table, systolic PAP was higher and RA area size was smaller in patients with PAH-SSc than in patients with PAH-SSc(−). By contrast, LA area size was significantly greater in patients with PAH-SSc(+) than in patients with PAH-SSc(−). Finally, serum level of BNP was higher in patients with PAH-SSc(+) than in patients with PAH-SSc(−) (log[BNP]: 1.906 (1.880 – 1.931), 1.839 (1.817 – 1.861),respectively, p=0.0002, n=2781).

Conclusion: The results demonstrate that greater LA area size and higher levels of BNP, indicating left ventricular diastolic dysfunction, coexists with PAH associated with SSc. Thus, the data emphasize the usefulness LA area size as well as RA area size for the appropriate management of patients with PAH-SSc using PAH-specific drugs.

Table 1. Parameters of ECHO in Patients with PAH-CTDs

values	PAH-SSc(+)	PAH-SSc(−)	p	n
systolic PAH (mmHg)	51.1 (49.2–52.8)	61.4 (60.0–63.0)	<0.0001	1002
CO (L/min)	5.13 (4.93–5.31)	4.90 (4.74–5.05)	0.0853	681
RA area size (cm2)	17.7 (16.4–19.0)	21.0 (20.0–21.9)	0.0002	381
LA area size (cm2)	19.6 (18.7–20.6)	18.2 (17.4–18.9)	0.0181	381

Means (95%CI) were estimated with mixed effects models (fixed effect: SSc, age, and WHO-FC(4), random effect: patient) and adjusted for age (52.2yo), and WHO-FC(2). p value was calculated for presence or absence of SSc.

High Frequency Skin Ultrasound Detects Subclinical Diffuse Dermal Involvement in Patients with Limited Cutaneous Systemic Sclerosis. Alberto Sulli, Barbara Ruaro, Carmen Pizzorni, Giorgia Ferrari, Elena Bernero, Sabrina Paolino and Maurizio Cutolo. Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy.

Background/Purpose: The modified Rodnan's skin score (mRSS) is the validated method to detect both severity and extension of skin involvement, and high frequency skin ultrasound (US) is a valid and reproducible technique to measure dermal thickness (DT) in patients with systemic sclerosis (SSc) (1–4). Skin involvement is critical for sub-classification of the disease into different subsets (5). The aim of the study was to detect by US possible subclinical skin involvement in limited cutaneous SSc (lcSSc) patients, in those skin areas apparently not affected on the basis of a normal mRSS.

Methods: Fifty lcSSc patients (ACR 2013 or LeRoy 2001 criteria) (mean disease duration 5±5 years) and fifty age-matched healthy subjects were analysed during clinical follow-up and after informed consent. Both mRSS and US were used to evaluate DT in the usual seventeen areas of the skin (cheeks, fingers, dorsum of hands, forearms, arms, chest, abdomen, thighs, legs, feet) of SSc patients. US was also performed in the same seventeen skin areas of healthy subjects, looking for DT differences in comparison with lcSSc patients. Nailfold videocapillaroscopy (NVC) was performed in lcSSc patients to identify the proper pattern of microangiopathy (Early, Active or Late) and calculate the microangiopathy evolution score (MES) (6–7).

Results: US detected significantly higher DT in lcSSc patients than in healthy subjects in all skin areas with exclusion of thighs ($p<0.0001$ for all). In particular, DT was significantly higher in lcSSc patients than in healthy subjects in four out of six skin areas where the mRSS was normal (=0) (arms, chest, and abdomen) in agreement with the diagnosis of lcSSc. At the level of the thighs DT was higher in lcSSc patients than in healthy subjects, but this was not statistical significant ($p=0.16$). As assessed by US, a positive correlation was found between DT and both progressive NVC patterns ($p<0.001$) and MES ($p=0.0015$).

Conclusion: This study strongly suggests that subclinical diffuse dermal involvement may be detectable by high frequency skin ultrasound already in lcSSc patients in almost 70% of skin areas where the mRSS was normal. This observation should be of relevance for future classification of SSc disease subsets, since patients with either lcSSc or diffuse cutaneous SSc often display similar organ/laboratory markers of involvement.

Peripheral Blood Eosinophil Counts Increase in Patients with Systemic Sclerosis and Associated with Its Disease Severity. Tamao Nakashita[1], Shinji Motojima[1], Katsutoshi Ando[2] and Akira Dibatake[3]. [1]Kameda Medical Center, Kamogawa City, Japan, [2]Juntendo university, tokyo, Japan, [3]Kameda Medical Center, Kamogawa city, Japan.

Background/Purpose: Increased levels of serum pro-fibrotic cytokines such as IL-4 and IL-13 and plasma CXCL4 have been previously reported in patients with systemic sclerosis (SSc). These pro-fibrotic cytokines also play an important role for differentiation and migration of eosinophils and eosinophils themselves release pro-fbrotic cytokines such as IL-11 and TGF-beta. Accordingly, we hypothesized that eosinophils might contribute, at least partly, to fibrotic process of SSc.

Methods: We retrospectively reviewed the peripheral blood eosinophil counts (PB-EOS) in 70 untreated patients with SSc (diffuse 14, limited 56) and compared with those in other major connective tissue diseases including 126 patients with RA, 10 with PM/DM, 19 with primary Sjögren's syndrome (SjS), 20 with SLE and 8 with mixed connective tissue disease (MCTD). The diagnosis was made according to the criteria of ACR, except that criteria used for MCTD was that by Japan Ministry of Health, Labor and Welfare. All the patients were not on treatment by glucocorticoid and/or immunosuppressant. We also evaluated the association with disease severity of SSc, that is, the grade of interstitial lung disease (ILD) and skin sclerosis. The severity of ILD was graded into 4, grades 0 to grade 3, according to the extent of ILD on chest CT by the method of Gochuico et al. (Arch Intern Med 2008). Chest CT images were graded by 2 independent respirologists. The skin sclerosis was evaluated by modified Rodnan's skin score (mRodnan SS).

Results: The mean of coefficient of variance of PB-EOS in 8 patients was 0.32, suggesting that PB-EOS are considerably stable. The order of mean PB-EOS was as follows; diffuse-SSc (mean 312/mcL) > limited-SSc (210) > PM/DM (164) = RA (154) > pSJS (128) > MCTD (73) = SLE (57) (> indicates significantly different). ILD was observed in 39 % (27/70) of SSc patients, and the numbers of SSc patients with grade 0/1/2/3 were 43/15/9/3, respectively. PB-EOS positively correlated with ILD grade in SSc ($rs = 0.26$, $p < 0.02$), but not in RA ($rs = 0.02$) and other diseases. M-Rodnan SS also correlated with PB-EOS ($rs = 0.35$, $p = 0.003$) and ILD severity ($rs = 0.57$, $p < 0.0001$).

Conclusion: It was suggested that eosinophils contribute, at least in part, to fibrotic process in SSc and anti-eosinophil strategy might become a treatment option when such drugs become available. It is also suggested that the mechanism of ILD is somewhat different between SSc and RA. Authors have no COI.

Endothelial and Platelet Microparticles As Potential Novel Biomarkers of Peripheral Microvascular Dysfunction in Systemic Sclerosis and Primary Raynaud's Phenomenon. John D. Pauling[1], Daniel Moreno-Martinez[2], Fiona Wilkinson[2], Ben Parker[3], Jacqueline A. Shipley[4], Darren Hart[4], Neil J McHugh[1] and Yvonne Alexander[2]. [1]Department of Pharmacy and Pharmacology, University of Bath, Bath, United Kingdom, [2]Manchester Metropolitan University, Manchester, United Kingdom, [3]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester Academic Health Sciences Centre, Manchester, United Kingdom, [4]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom.

Background/Purpose: Microparticles (MPs) are membrane-bound vesicles derived from vascular and intravascular cells such as endothelial cells (EMPs) and platelets (PMPs). MPs form during cell activation or apoptosis and may directly contribute to disease pathogenesis. Circulating MPs have been found to be higher in systemic sclerosis (SSc) compared with healthy controls, however their precise functional role remains to be elucidated. The present study was undertaken to establish whether plasma MP levels differ between primary Raynaud's phenomenon (RP) and SSc and whether EMP and PMP levels correlate with dynamic assessment of digital microvascular function assessed using laser speckle contrast imaging (LSCI).

Methods: Patients with SSc (n=24, 22 with limited cutaneous SSc) and primary RP (n=16) not taking anti-platelet agents, NSAIDs or steroids were recruited to the study. Platelet-free plasma was obtained using citrated blood following a 2-step centrifugation regime. Digital perfusion at the volar aspect of the distal left middle finger was assessed using LSCI during a standardised local cold challenge (15°C for 60s). Digital perfusion was assessed at baseline, immediately following cold challenge (t0) and at 5 minute intervals during re-perfusion (t5, t10 and t15 respectively). Plasma levels of EMPs (AnnexinV+/CD31+/CD42b-) and PMPs (AnnexinV+/CD31+/CD42b+ or AnnexinV+/CD31-/CD42b+) were quantified using flow cytometry.

Results: Plasma levels of EMPs (161271/ml vs. 171318/ml) and PMPs (186348/ml vs. 246758/ml) did not differ between SSc and primary RP. Higher EMP levels were found in patients with SSc and a history of digital ulceration (DU) or digital pitting (DP) (median 198643/ml vs. 144840/ml, $p=0.03$). No additional associations between MP levels and disease characteristics were identified. Consistent positive correlations between MP levels and digital perfusion following cold challenge (but not at baseline) were

identified in SSc (Table). In contrast, there were consistent negative correlations between PMP (but not EMP) levels and digital perfusion at both baseline and following cold challenge in primary RP (Table).

Conclusion: This is the first study to explore the relationship between circulating MP levels and peripheral microvascular dysfunction in primary RP and SSc. Higher EMPs were associated with a history of DU/DP in SSc. Higher EMP and PMP levels, however, were associated with higher digital perfusion following local cold challenge in SSc. In contrast, higher PMP levels were associated with lower digital perfusion in primary RP. There was no association between EMP levels and digital perfusion in primary RP. Additional work is needed to explore factors leading to MP generation and their contribution to peripheral microvascular dysfunction in primary RP and SSc. MPs may have the potential to act as biomarkers of peripheral microvascular dysfunction/damage in primary RP and SSc.

Table

			Baseline	t0	t5	t10	t15
SSc	EMPs	Spearman's rho	0.05	0.42	0.42	0.46	0.46
		p value	0.821	0.044	0.043	0.026	0.025
	PMPs	Spearman's rho	0.377	0.047	0.009	0.006	0.001
		p value	0.19	0.42	0.52	0.54	0.64
Primary RP	EMPs	Spearman's rho	−0.34	−0.33	−0.13	−0.39	0.09
		p value	0.149	0.20	0.648	0.131	0.753

Laser Speckle Contrast Analysis in the Follow-up of Digital Ulcers in Systemic Sclerosis Patients. Barbara Ruaro, Alberto Sulli, Teresa Cannavale, Marco Amedeo Cimmino, Carmen Pizzorni, Sabrina Paolino and Maurizio Cutolo. Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy.

Background/Purpose: Typical clinical aspects of systemic sclerosis (SSc) include microvascular damage and reduction of peripheral blood perfusion, resulting in increased incidence of digital ulcers (DUs) (1–2). Several studies report different methods to assess the severity of DUs but, to the best of our knowledge, ulcer blood perfusion was not assessed (3–5). This study investigates blood perfusion (BP) of DUs by laser speckle contrast analysis (LASCA), a non-contact technique, during treatment for ten days with local medications (6).

Methods: During their regular planned follow-up and systemic treatment, twenty SSc patients with DUs of recent onset (mean age 63±12 years, mean disease duration 7±6 years) were enrolled after informed consent. Local BP was studied in all patients by LASCA before starting local treatment (T0), both at the level of the dorsal and palmar aspect of the hands (6). Subsequently, regions of interest (ROIs) were created at the level of the fingertips, periungual, ulcer and periulcer areas and the perfusion values were reported as perfusion units (PU) (6). Hydrocolloid dressing was daily applied on ulcer area (7). After 10 days of treatment (T1) LASCA was repeated. Visual analogic scale for DU pain (VAS-pain) (score 0–10) was administered to patients before and after the treatment. The patients marked on the line from 0 ("no pain") to 10 ("worst imaginable pain") the intensity of DU pain that they felt (8). Statistical analysis was performed by non parametric tests.

Results: A statistically significant increase of BP was observed from T0 to T1 in the ROIs created at the level of the ulcer area (due to granulation tissue) (median 37 vs 57 PU, $p<0.0001$), as well as a significant decrease of BP was observed in the periulcer area (due to decreased inflammatory reaction) (median 108 vs 90 PU, $p<0.0001$). A positive correlation was observed between fingertip BP and periungual BP at both T0 ($r=0.66$, $p=0.02$) and T1 ($r=0.44$, $p=0.05$). There was a statistically significant decrease of VAS-pain scale during the ten days of treatment (median 9 vs 8; $p=0.001$).

Conclusion: LASCA seems to offer a quantifiable and safe method to evaluate local blood perfusion changes of the DU area during local treatment, and it most likely represents a reliable technique to monitor DU evolution in SSc patients.

Short-Term Effects of Iloprost on Micro-Vessels Hemodynamics in Systemic Sclerosis Patients Evaluated By Laser Doppler Flowmetry. Florenzo Iannone, Cinzia Rotondo, Mariangela Nivuori, Emanuela Praino, Laura Coladonato, Michele Covelli and Giovanni Lapadula. Rheumatology Unit, Bari, Italy.

Background/Purpose: Iloprost is a milestone in the treatment of Raynaud's Phenomenon (RP). However, it has transient hemodynamic effects due to a very short half-time, thereby a treatment protocol has been never validated and the interval time between infusions is empirical. We aimed at evaluating the short and medium term effects of Iloprost on blood flux, assessed by Laser Doppler (LD), in patients with RP associated to Systemic Sclerosis (SSc).

Methods: 19 SSc patients, aged 55.9±16 (mean ±SD) years with disease duration of 9.3±6 years, have undergone Iloprost infusions (50 ng at 1.5 ng/Kg/min) for 3 consecutive days. The LD flowmetry (Periflux System 5000, Perimed) was performed at baseline and after heating test (heat stimulus of 44 degree centigrade), and ischemic/occlusive test (200 mm/Hg pressure applied by air-bracelet on brachial artery for 3 min) before Iloprost (T0), at the end of 3 consecutive days of treatment (T1), at 24h (T2) and at 7 days (T3) after last administration of Iloprost. During occlusive test, LD evaluated the micro-vessels flux at rest (RF), flux at pick (PF), the percentage variation between RF and PF (RF/PF %), and recovering and hyperemic times before and after occlusion. During heating test, LD evaluated percentage variation between perfusion units before and after heating test (pre-postPUvar%). Comparisons between times were assessed by repeated measures ANOVA. The results are expressed as average of 4 fingers at each time. Statistic significance was set at $p<0.05$. During the study no variation of the baseline therapy was allowed.

Results: We observed a prompt improvement, even though transient, of LD parameters following Iloprost infusion. A statistically significant difference ($p<0.05$) (Tab.1) was found for RF/PF%, showing a time decreasing improvement. In particular the percentage difference comparing to T0 was: −10,26% at T1, −7,4% at T2, −7,8% at T3. For percentage variation between perfusion units before and after-heating test (pre-postPUvar%) a decreasing trend were observed, in particular the variation among times comparing to baseline is: +0.54 % at T1, −18.71% at T2, −19.37 % at T3).

TEST	LD Parameters	Baseline (T0)	End of infusion (T1)	24h after infusion (T2)	7 days after infusion (T3)	p value
OCCLUSION	Resting flux (RF)	86.7 ± 37,1	77.7 ± 45.5	80.2 ± 87	79.9 ± 39.46	0.821
	Flux at Peak (FP)	132.3 ± 51.1	118.8 ± 46.8	122.4 ± 45.9	121.9 ± 55.9	0.742
	% variation RF/PF	86.6 ± 37	77.7 ± 45	80.2 ± 35	79.8 ± 39	0.000
	Half hyperemic time	16.3 ± 23.9	14.5 ± 32.9	16.05 ± 19.7	15.1 ± 21.6	0.982
	Time at peak	162.1 ± 194.8	147.6 ± 246.1	147.9 ± 144.4	121.8 ± 139.6	0.795
HEATING	% variation pre and post	48.1 ± 28	48.36 ± 32	39.1 ± 21	38.7 ± 24	0.021

Conclusion: Microcirculation hemodynamic changes induced by Iloprost seem to run out within 24h after the last infusion, particularly when assessed by the occlusive test. Although the Iloprost treatment is an important tool in SSc associated RF, is yet necessary to define the suitable timing to obtain long-lasting benefit.

1702

Antiphospholipid Antibodies in Systemic Sclerosis: Prevalence and Clinical Significance? Anjali Shetty[1], Suncica Volkov[1], Claudia Vergara[2] and William Swedler[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]University of Illinois Chicago, Chicago, IL.

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune disease characterized by collagen deposition and vascular changes of the skin

and internal organs, leading ultimately to fibrosis. Antiphospholipid (aPL) antibodies are immunoglobulins directed against negatively charged phospholipid-binding proteins mostly involved in blood coagulation. It has been suggested that aPL antibodies including anticardiolipin (aCL) and anti-beta-2-glycoprotein I (aβ2GPI) antibodies may play a role in the pathogenesis of SSc related vascular impairment. This study investigates the prevalence of antiphospholipid antibodies including aCL and aβ2GPI antibodies in patients with systemic sclerosis. We also evaluated a possible relationship between clinical findings in SSc including Raynaud's phenomenon, digital ulcers, and interstitial lung disease, and the presence of aCL/aβ2GPI antibodies.

Methods: A hundred patients who met the American College of Rheumatology classification criteria for systemic sclerosis were included in the study. There were ten men and ninety women with a median age of 58 years. Thirty-five percent had diffuse cutaneous SSc and 65 percent had limited cutaneous SSc. Assessment of organ involvement to detect systemic complications of SSc included presence of Rayanud's phenomenon, digital ulcers or pitting scars, and interstitial lung disease. Interstitial lung disease was characterized by pulmonary fibrosis seen on high-resolution computed tomography or chest radiography, or occurrence of "velcro" crackles on auscultation, not due to another cause such as congestive heart failure. Anticardiolipin IgG, IgM, and IgA and anti-beta-2-glycoprotein I IgG, IgM, and IgA antibodies were measured by enzyme-linked immunosorbent assay. Clinical associations were measured using conditional and simple logistic regression models.

Results: Twenty-seven percent of patients with systemic sclerosis were positive for either anticardiolipin or anti-beta-2-glycoprotein I (aβ2GPI) antibodies. A positive association was found between the presence of anticardiolipin antibody and interstitial lung disease (p=0.038). This association was maintained after adjusting for age, sex, and race (OR 2.765, 95% CI 1.038–7.368, p=0.0412). Anticardiolipin testing was not sensitive for predicting lung involvement with a sensitivity of 0.419, however, it had a high specificity at 0.789 for predicting lung involvement. There was no predictive value found for testing aCL and aβ2GPI antibodies with regards to Raynaud's phenomenon or digital ulcers.

Conclusion: Our study showed a positive association with aCL antibodies and interstitial lung disease in patients with systemic sclerosis. The use of aCL antibodies as a biomarker of pulmonary disease in SSc should be further explored.

Table 1. Association of positive anticardiolipin and anti-beta-2-glycoprotein I antibody testing with clinical features in SSc patients

	Raynauds phenomenon Odds ratios (95% confidence intervals)	*Digital Ulcers* Odds ratios (95% confidence intervals)	*Interstitial Lung Disease* Odds ratios (95% confidence intervals)
Anticardiolipin antibody	OR1.844 (0.175–19.427)	OR1.387 (0.522–3.688)	OR2.765 (1.038–7.368)
Anti-beta2-glycoprotein I antibody	OR0.629 (0.033–12.012)	OR3.427 (0.382–30.8)	OR0.845 (0.076–9.398)

3 Department of Clinical Immunology, Royal Free Hospital, London (UK)

4 Centre for Rheumatology and Connective Tissue Diseases, UCL Medical School, Royal Free Campus, London (UK)

Background/Purpose: Anti-PM/Scl antibodies are heterogeneous autoantibodies in scleroderma (SSc) directed mainly against 75kDa and 100kDa human exosome components, associated with overlap syndromes. Published data suggest that up to 12.5% of SSc patients carry this seropositivity with associations with myositis, mild skin involvement, pulmonary fibrosis, articular involvement and calcinosis and a lower prevalence of pulmonary arterial hypertension and gastrointestinal involvement. In this study, we characterised the clinical and detailed serological phenotype of anti-PM/Scl positive SSc patients from a single centre cohort of 2200 patients and identified a cohort within this group with increased risk of malignancy.

Methods: Anti-PM/Scl positive SSc patients identified by indirect immunofluorescence pattern and confirmed on counter-immunoelectrophoresis were enrolled in the study. Demographics and clinical data on skin, internal organ involvement and history of malignancy were recorded.

Results: 70 anti-PmScl positive patients were identified (3.1% of cohort), with frequent lung, gastrointestinal and muscle involvement as described previously (table 1). 48 patients (68.6%) had antibodies targeting both PM/Scl 75 and 100; 6 (8.6%) PM/Scl 75 only and 16 (22.8%) PM/Scl 100 antibody only. There was a significant association between positivity for anti-PM/Scl 100 alone and malignancy (p=0.037) when compared to presence of both reactivities or reactivity to PM/Scl75 alone. 13 patients (18.6%) had developed a malignancy, 4 of these had onset within 36 months from SSc diagnosis and all were positive for anti-PM/Scl 100, combined with anti-PM/Scl75 in 7/13 (53.8%). The study population standardized incidence ratio (SIR) for cancer was 2.14 (CI 95%: 1.55–2.74), with higher values showed for male gender (SIR 3.10, CI 95%: 1.55–4.65) than female gender (SIR 1.95, CI 95%: 1.31–2.61). 7/13 were adenocarcinoma, mainly breast, 4/13 squamous cell and the remainder haematological malignancy.

Conclusion: The association of malignancy with PM/Scl reactivity in SSc is of interest in the context of recent studies describing a potential pathogenic role of anti-RNA polymerase III antibodies with malignant disease in SSc. This cohort is otherwise representative of others in terms of demographics and clinical characteristics and underlines the importance of close surveillance for concurrent malignancy in all SSc disease subphenotypes.

Table 1. Prevalence of clinical, instrumental and laboratory features in the study population

	Total PM-Scl population (n=70, 100%)		PM-Scl Patients with Cancer (n=13, 18.6%)		Cancer VS non cancer population – p value
Median Age	58.4 ± 14.0		60.9 ± 10,3		0.566
Female Sex	56	80.0%	9	69.2%	0.277
Median Age at SSc onset	44.1 ± 14.5		46.5 ± 9.9		0.365
Age at Cancer onset ± SD			55,2 ± 11.7		N.A.
Smoking history	32	45.7%	7	53.8%	0.486
LcSSc	47	67.1%	10	76.9%	0.740

CXCL4 Promotes Fibrosis By Increasing Expression of Extracellular Matrix Modifying Factors and By Facilitating Epithelial/Endothelial Mesenchymal Transition. W. Marut, A.J. Affandi, A. Limpers and T.R.D.J. Radstake. University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Systemic sclerosis (SSc) is a degenerative disorder, characterized by vascular abnormalities and immunological disturbances followed by excessive fibrosis in multiple organ systems. In a recent proteomic study we identified the chemokine - CXCL4 as a novel predictive biomarker for SSc[#]. Here we aim to elucidate the pathologic role of CXCL4 in SSc on fibroblasts and epithelial/endothelial cells.

Methods: The effect of CXCL4 was evaluated *ex vivo* on primary dermal fibroblasts, epithelial cells, and endothelial cells. Gene expression analysis

was performed using qPCR. Analysis of $CD44^{+}CD24^{-/low}$ expression in epithelial cells was measured using flow cytometry. The production of superoxide by mitochondria in fibroblasts was visualized by flow cytometry using the MitoSOX™ Red reagent. Hydrogen peroxide production by fibroblasts was measured by AmplexRed.

Results: After CXCL4 treatment, both, endothelial and epithelial cells acquired fibroblast-like, mesenchymal appearances, and showed upregulation of mesenchymal markers (such as N-cadherin, vimentin, and αSMA). Moreover, epithelial cells exposure to CXCL4 resulted in the acquisition of the $CD44^{high}/CD24^{low}$ antigen phenotype, which is associated with induction of an EMT (epithelial-mesenchymal transition). In human dermal fibroblasts, CXCL4 increased expression of collagen type I, and suppressed transcription factor Fli-1. Additionally, the levels of reactive oxygen species (ROS), such as superoxide anion and hydrogen peroxide, were increased upon stimulation with CXCL4.

Conclusion: Our results suggest that CXCL4 can directly promote the fibrotic process, by transition of fully differentiated epithelial and endothelial cells into activated myofibroblasts, a process called epithelial/endothelial mesenchymal transition (EMT/EndoMT). Moreover CXCL4 might indirectly drive fibrosis by inhibition of Fli-1 and induction of collagen type I expression in fibroblasts. Further, CXCL4 increases ROS production in fibroblasts, which additionally stimulate synthesis and deposition of extracellular matrix (ECM) and promote fibrosis. In accordance with high level of CXCL4 in the circulation and skin of SSc patients[#], we demonstrate novel mechanisms in which CXCL4 could contribute to SSc phenotype.

The Lectin Pathway of Complement – a Potential Role in the Pathogenesis and Disease Manifestations of Systemic Sclerosis. Michael Osthoff[1], Gene-Siew Ngian[2], Melinda Dean[3], Mandana Nikpour[4], Wendy Stevens[5], Susanna Proudman[6], Damon Eisen[2] and Joanne Sahhar[7]. [1]The University of Melbourne, Melbourne, Australia, [2]Royal Melbourne Hospital, Parkville, Australia, [3]Australian Red Cross Blood Service, Brisbane, Australia, [4]University of Melbourne, Fitzroy, Australia, [5]St. Vincent's Hospital, Fitzroy, Australia, [6]Royal Adelaide Hospital, Adelaide, Australia, [7]Monash Health, Melbourne, Australia.

Background/Purpose: Repetitive episodes of ischemia and reperfusion (I/R) are a cardinal feature of the pathogenesis of systemic sclerosis (SSc), which precedes tissue fibrosis. The complement system is a key mediator of tissue damage after I/R, primarily by activation of the lectin pathway. This study investigated whether serum levels and polymorphisms of mannose-binding lectin (MBL) and ficolin-2 (FCN2), two pattern recognition receptors of the lectin pathway, are associated with the predisposition to, and clinical features of SSc.

Methods: A case-control study was undertaken involving 90 patients with SSc according to the American College of Rheumatology (73/90) or the LeRoy and Medsger criteria (17/90) from a single SSc outpatient clinic and 90 age- and sex-matched blood donors. MBL and FCN2 levels and polymorphisms were measured in both groups, and in cases correlated with clinical data.

Results: MBL levels and genotypes were equally distributed in cases and controls while there were some significant differences in *FCN2* polymorphisms. Median MBL levels were higher in SSc cases with diffuse disease compared to controls (2.6 vs. 1.0 μg/ml, $p<0.001$).

In cases, higher MBL levels were associated with the presence of clinical findings associated with vascular dysfunction and local tissue damage (digital ulcers, calcinosis and pitting). Moreover, MBL levels were associated with fibrotic disease manifestations as evidenced by the presence of diffuse disease (median 2.6 vs. 0.8 μg/ml, $p=0.002$), the modified Rodnan skin score ($r=0.39$, $p<0.001$), and interstitial lung disease as measured by forced vital capacity ($r=-0.33$, $p=0.001$). Importantly, MBL levels also correlated with the SSc Health Assessment Questionnaire scores ($r=0.33$, $p=0.002$). Results for FCN2 levels were less striking. Phenotypic MBL results were largely confirmed by analysis of MBL polymorphisms. MBL levels were not associated with the presence of autoantibodies or hypocomplementemia.

Conclusion: Overall, predisposition to SSc was not influenced by the lectin pathway of complement in our matched case-control study. However, our preliminary data suggest that MBL, and to a lesser extent FCN2 may modulate disease manifestations of SSc, particularly in diffuse cutaneous disease.

Acknowledgments: Kathleen Elford, Scleroderma Nurse for her assistance in collection of data and samples. SSc patients were recruited from Monash Health as part of the Australian Scleroderma Cohort Study (ASCS), a longitudinal, prospective study of SSc patients.

Figure 1: Serum mannose-binding lectin levels in SSc cases and healthy controls. MBL levels were analysed in SSc cases overall and stratified according to skin involvement (limited cutaneous vs. diffuse cutaneous). Horizontal bars indicate median and 25-75 percentiles. Abbreviations: MBL, mannose-binding lectin. Lc SSc, limited cutaneous systemic sclerosis; Dc SSc, diffuse cutaneous systemic sclerosis.

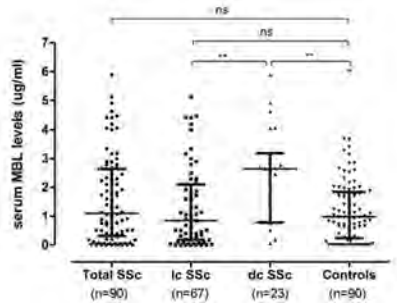

Figure 2. Correlation of serum MBL levels with activity and extent of disease in SSc cases. A. Correlation with extent of skin involvement as assessed by the modified Rodnan skin score (mRSS). B. Correlation with extent of functional disability as assessed by the Scleroderma Health Assessment Questionaire (SSc HAQ). C. Correlation with extent of pulmonary involvement as assessed by forced vital capacity (FVC, % predicted).

Prevention of SU5416-Induced Pulmonary Hypertension in a TGFβ Dependent Genetic Mouse Model of Scleroderma Using the Endothelin Receptor Antagonist Macitentan. Emma C. Derrett-Smith[1], Vincent Sobanski[2], Sarah Trinder[2], Adrian J Gilbane[2], Marc Iglarz[3], David J. Abraham[2], Alan M. Holmes[4] and Christopher P Denton[1]. [1]UCL Medical School Royal Free Campus, London, United Kingdom, [2]UCL Medical School, London, United Kingdom, [3]Actelion Pharmaceuticals Ltd., Allschwil, Switzerland, [4]UCL, London, United Kingdom.

Background/Purpose: Pulmonary arterial hypertension (PAH) is an important complication of systemic sclerosis (SSc) that occurs in around 10% of cases. We have previously shown that a TGFbeta dependent transgenic mouse strain (TβRIIΔk-fib) is susceptible to organ based pathology relevant to SSc and that pulmonary endothelial injury is associated with development of PH with perturbed VEGF, BMP and endothelin signalling. In this study, we have prevented the development of PH in this mouse strain using macitentan, a potent endothelin receptor antagonist recently licensed to treat PAH in connective tissue disease based upon a significant effect on morbidity and mortality in PAH.

Methods: SU5416, a VEGF receptor inhibitor, was administered to all TβRIIΔk-fib transgenic (TG) mice and littermate wildtype (WT) animals to induce endothelial injury with subsequent endoluminal proliferation and PH in

transgenic mice only. Mice were treated with either 50mg/kg macitentan daily by oral gavage or vehicle alone (n=8 each group). The development of PH in each group was assessed by histology and immunohistochemistry of vessel architecture, *in vivo* haemodynamic studies and RV mass index measurements.

Results: Compared with WT littermates, after SU5416, all TG mice developed a prominent perivascular chronic inflammatory infiltrate and smooth muscle layer hypertrophy, as previously described. RV mass index was elevated in TG animals receiving vehicle compared to other groups (TG vehicle 0.29±0.007, TG macitentan 0.24±0.007, $p<0.05$). The increase in RV systolic pressure in TG animals treated with SU5416 was also abrogated by macitentan (figure 1) without any significant change in systemic arterial blood pressure in any group. Explanted TG lung fibroblasts showed an increase in proliferation and migration with upregulation of VEGF and TGFbeta signalling and downregulation of endothelin receptor A compared with WT littermates. There was obliterative pulmonary arteriolar occlusion in 21% of vessels in TG mice treated with vehicle. In contrast, no vessels in WT mice or TG mice treated with macitentan developed this histological change.

Conclusion: Macitentan prevents the development of histological and haemodynamic PH in this mouse model of SSc. These findings support a pivotal role for perturbed endothelin activity in a model that is induced by altered TGFbeta signalling and triggered by experimental VEGF inhibition. It underpins the value of this model as a platform for experimental therapeutic studies as well as providing insight into pathogenic mechanisms of disease.

High Oxidative Stress in Fibrotic and Non-Fibrotic Skin of Patients with Systemic Sclerosis. Khalil I. Bourji[1], Alain Meyer[2], Emmanuel Chatelus[2], Erika Pigatto[1], François Singh[2], Bernard Geny[2], Leonardo Punzi[1], Jacques-Eric Gottenberg[2], Franco Cozzi[1] and Jean Sibilia[2]. [1]University Hospital of Padova, Padova, Italy, [2]University Hospital of Strasbourg, Strasbourg, France.

Background/Purpose: Systemic Sclerosis (SSc) is a chronic multisystemic connective tissue disease characterized by progressive fibrosis affecting skin and internal organs. Despite serious efforts to unveil pathogenic mechanisms of SSc, they are still unclear. High levels of Reactive Oxygen Species (ROS) in affected skin have been shown, but the role of oxidative stress remains controversial (1, 2, 3). In this study we assess ROS levels in non-fibrotic (NS) and fibrotic (FS) skin of patients with SSc and we compare them with those obtained from healthy controls (CS).

Patients and Methods: We enrolled 9 SSc patients fulfilling the EULAR/ACR classification criteria (4) and 7 healthy controls. Patients were 4 men and 5 women with mean age of 46±10 yrs. Controls were matched by sex and age. All patients were affected by diffuse cutaneous form of SSc and the ANA pattern anti-Scl70. Mean disease duration was 7.5±5 yrs. Skin involvement was evaluated by modified Rodnan Skin Score (mRSS). Skin samples (4mm punch biopsy) were taken from fibrotic skin (FS) and non-fibrotic skin (NS) of patients and from healthy controls (CS) as well. To detect ROS, specimens were analyzed immediately after sampling by electron paramagnetic resonance spectroscopy (5).

Results: ROS levels (expressed as median and range, unit of measurement was AU/mg) were 118.6×10^3 (52.4×10^3– 225.7×10^3) in FS, 89.6×10^3 (34.8×10^3– 163.1×10^3) in NS and 36.8×10^3 (17×10^3–65.1×10^3) in CS. ROS levels in Fibrotic (FS) and Non-fibrotic (NS) skin of SSc patients were significantly higher than in Healthy Control (CS) ($p=0.002$ and $p=0.009$, respectively). Although ROS levels in FS were raised in comparison to NS, this difference was not statistically significant ($p=0.24$). ROS levels of FS were correlated with DLCO ($r=-0.59$, $p=0.09$), VC ($r=-0.75$, $p=0.02$) and ESR ($r=0.70$, $p=0.03$). All other clinical and lab parameters showed no significant correlation.

Conclusion: Our results confirm the presence of high oxidative stress either in non-fibrotic skin (NS) or in fibrotic skin (FS) of SSc patients, but with higher tendency in the latter. Raised ROS levels in non-fibrotic skin (NS) of SSc patients might be a hint of early involvement in skin fibrogenesis. However, a longitudinal prospective study is necessary for such proof.

The Pathogenic Role of Immune Complexes Containing Scleroderma-Specific Autoantibodies in the Inductor Phase of the Disease. Cecilia B. Chighizola[1], Elena Raschi[2], Laura Cesana[2], Silvana Zeni[3], Maria Orietta Borghi[4] and Pier Luigi Meroni[5]. [1]Istituto Auxologico Italiano, University of Milan, Cusano Milanino, Italy, [2]Istituto Auxologico Italiano, Milan, Italy, [3]Division of Rheumatology, Istituto G. Pini, Milano, Italy, [4]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy, [5]Division of Rheumatology, Istituto G. Pini, Milan, Italy.

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune condition characterized by excessive tissue fibrosis, microvascular alterations and immune dysfunction with the production of peculiar autoantibodies. These autoantibodies are highly specific for SSc diagnosis, and provide the most reliable tool to predict disease subset and the pattern of internal organ involvement. Despite such diagnostic and prognostic role, no evidence supporting the pathogenic potential of these autoantibodies has to date been raised.

Therefore the aim of this study is to evaluate for the first time the pathogenicity of immune complexes (IC) from scleroderma patients in the inductor phase of the disease, using skin fibroblasts from healthy controls as cellular in vitro model.

Methods: Fibroblasts have been isolated from skin biopsies obtained from healthy controls and then cultured in adequate conditions. IC have been purified from sera of scleroderma patients bearing different autoantibody specificities (antibodies against centromeric proteins [ACA], DNA topoisomerase I [ATA], RNA polymerase [ARA] and Th/To [anti-Th/To]) or of healthy controls using polyethylen glycol precipitation. Cell cultures have been incubated with pathologic and control IC and with cell activating agonists as TLR3 [Poly(I:C)] and TLR4 (LPS) ligands. Several parameters of fibroblast activation have been assessed in the different experimental conditions. In particular, mRNA levels of type I interferons (IFN-alpha and IFN-beta) have been investigated by real-Time PCR; ICAM-1 expression has been evaluated by cell-ELISA and the secretion of IL-6 and IL-8 in culture supernatants has been measured by commercial ELISA kits. Furthermore, the involvement of intracellular signaling pathways culminating with the activation of p38 MAPK, NFkB and JNK has been assessed by Western Blotting.

Results: Stimulation of normal skin fibroblasts with pathologic IC induced a significant increase in the gene expression levels of both IFN-alpha and IFN-beta; similar results have been observed in the presence of TLR agonists but not of control IC. In addition, the expression of ICAM-1 and the secretion of IL-6 and IL-8 were up-regulated by Poly(I:C), LPS and IC from scleroderma patients but not from healthy controls. Further, pathologic IC induced the activation of p38 MAPK, NFkB and JNK.

Conclusion: Our data provide the first demonstration of the pathogenic role of IC isolated from scleroderma patients with different autoantibody specificities in the inductor phase of SSc. Indeed, pathologic IC can interact with normal skin fibroblasts, inducing a pro-inflammatory phenotype mediated by p38 MAPK, NFkB and JNK. These evidences fit well with the diagnostic and prognostic role of scleroderma-specific autoantibodies, providing novel insights into SSc etiopathogenesis and potentially leading to new treatment strategies.

1709

Demonstration of Enhanced Hemodynamics with Topical Alprostadil Cream (RayVa®) Utilizing Laser Doppler Imaging in Primates. Susan Meier-Davis and Salma Debar. Apricus Biosciences, San Diego, CA.

Background/Purpose: Currently, there are no approved treatments in the United States for Raynaud's Phenomenon (RP). Prostanoids, i.e., prostacyclin (PGI2) and Alprostadil (PGE1); may be used to treat severe cases but have limited applicability for outpatient use due to intravenous administration. RayVa®or Alprostadil topical cream is being developed to treat the symptoms associated with Raynaud's Phenomenon (RP) secondary to scleroderma. In an ongoing Phase 2a study, topical administration of RayVa® to affected individuals is being assessed for changes in blood flow and temperature relative to treatment.

The active pharmaceutical ingredient in RayVa® is Alprostadil or the synthetic analog of the endogenous Prostaglandin E1 (PGE1). Owing to the proprietary penetration enhancer, dodecyl-2-N,N-dimethylaminopropionate hydrochloride (DDAIP-HCl), RayVa®is administered topically for a local delivery of alprostadil to the site of action without the need for systemic exposure.

This nonclinical study was conducted to demonstrate hemodynamics after local delivery utilizing Laser Doppler Imaging (LDI) and assessing varying dose levels of the alprostadil cream relative to placebo in non-human primates (NHP).

Methods: NHP were anesthetized and baseline blood flow recorded with LDI. Following baseline measurements, the animal's hands were placed in an ice-water bath for 2 minutes followed by application of placebo cream on one hand and one dose level of the alprostadil topical cream on the other hand. Both hands were imaged every 15 minutes from the end of the application until baseline blood flow was reached for a maximum of two hours.

The topical alprostadil cream consisted of 0.42% alprostadil and 2.5% DDAIP/HCl, administered at two alprostadil dose levels; 300 and 1000 micrograms. The placebo cream contained no alprostadil and 2.5% DDAIP-HCl.

Results: Alprostadil topical cream did not elicit clinical abnormalities in the majority of animals over the study duration. After cold-challenge, administration of the topical alprostadil cream induced a dose-responsive, statistically significant increase ($p<0.05$) in hemodynamic parameters relative to the placebo cream over the assessment period. The time-to-peak response was reached within 15 minutes after application and post-cold-challenge. The statistically significant increase in the hemodynamic response to the alprostadil cream was at least one hour in duration.

Conclusion: Topical alprostadil cream (RayVa®) induced a dose-responsive increase in hemodynamics relative to placebo utilizing LDI in NHP. Local application of the vasodilator may be a beneficial treatment for patients with restricted blood flow to distal extremities, as seen in Raynaud's Phenomenon. The observed hemodynamic changes support the RayVa® dose levels selected for an ongoing Phase 2a clinical trial assessing both blood flow and temperature changes in affected hands from individuals diagnosed with Raynaud's phenomenon secondary to scleroderma.

Endothelin-1 Is a Downstream Mediator of Profibrotic Effects by Transforming Growth Factor-β1 in Systemic Sclerosis Skin Fibroblasts. Tomoaki Higuchi[1], Yasushi Kawaguchi[1], Akiko Tochimoto[1], Yuko Ota[1], Yasuhiro Katsumata[1], Takahisa Gono[1], Masanori Hanaoka[1], Yuko Okamoto[1], Hidenaga Kawasumi[1] and Hisashi Yamanaka[2]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune connective tissue disorder characterized by excess collagen deposition, vascular changes and production of autoantibodies that affects multiple organs. Transforming growth factorβ1 (TGF-β1), that promotes collagen synthesis, extracellular matrix (ECM) remodeling and myofibroblast differentiation, is thought to play a key role in the pathogenesis of SSc. The vasoconstrictive peptide endothelin-1 (ET-1) is also known as potent fibrotic factors. ET-1 binds to two distinct subtype of G protein coupled receptors, ET receptor A (ETRA) and ET receptor B (ETRB). The fibrotic functions of each ET receptor remain unclear partly because the distribution and expression of ET receptors differs according to the disease situations, the respective organs or the cell types. The aim of our study was to examine the effects of TGF-β1 on the fibrogenic phenotype of SSc skin fibroblasts through ET-1 production and to clarify how the signal transduction through TGF-β1 is associated with upregulation of ET-1.

Methods: Human SSc skin fibroblasts (SSc fibroblasts) were obtained from 5 SSc patients. Recombinant TGF-β1, recombinant ET-1, SIS3 as an inhibitor of Smad3 phosphorylation, SP600125 as an inhibitor of c-JUN N-terminal kinase (JNK), BQ123 as a selective ETRA antagonist, BQ788 as a selective ETRB antagonist and bosentan as a dual ETRA/ETRB receptor antagonist were used in this study. SSc fibroblasts were incubated with TGF-β1 in the presence of SIS3 or SP600125. In addition, the effects of BQ123, BQ788 or bosentan were explored. The expression of ET-1, CTGF and type I collagen was evaluated using ELISA and real time RT-PCR. ETRA and ETRB expressions were assessed by immunohistochemistry and fluorescence activated cell sorting (FACS) analysis.

Results: Both ETRA and ETRB were expressed in SSc fibroblasts as detected by immunohistochemistry. TGF-β1 increased ET-1 in the levels of mRNA and protein and this increase in ET-1 was suppressed by either SIS3 or SP600125. Upregulation of *COL1A1* and *CTGF* by TGF-β1 were reduced by either ETRA or ETRB antagonist, and the effects were enhanced by dual ETRA/ETRB antagonist.

Conclusion: We herein revealed that TGF-β1 produced ET-1 through both Smad and JNK cascade and dual ETRA/ETRB antagonist contributed to diminishing COL1A1 and CTGF mRNA in fibroblasts. These findings suggest that the fibrogenic effects by TGF-b1 may in part be explained by the autocrine stimulation of ET-1. The dual ETRA/ETRB might be a novel therapeutic strategy for the SSc skin fibrosis.

The Relationship Between Vascular Biomarkers and Disease Characteristics in Systemic Sclerosis: Elevated MCP-1 Is Associated with Predominantly Fibrotic Manifestations. Yasemin Yalcinkaya[1], Suzan Cinar[1], Sevil Kamali[1], Lale Ocal[1], Gunnur Deniz[1] and Murat Inanc[2]. [1]Istanbul University, Istanbul, Turkey, [2]Division of Rheumatology, Department of Medicine, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey.

Background/Purpose: To determine the relationship between vascular biomarkers reflecting the vascular injury and organ involvement in systemic sclerosis (SSc).

Methods: Seventy-two SSc patients (66 female) fulfilling 2013 ACR/EULAR Criteria were evaluated. Serum samples of patients were collected for flow-cytometric analysis of CD40L, tPA, MCP-1, sE-selectin, IL-8, IL-6, VEGF, sP-selectin, TGF-β1 and VCAM levels (Bender MedSystems) in SSc patients and 20 healthy controls. **Results** were compared with Pearson chi-square / Fischer's and Mann Withney tests.

Results: The mean age of the patients was 44.9 and disease duration from the appearance of first non-Raynaud symptom was 3.2 ± 2.4 years. Of the patients 23 (32%) had diffuse and 49 (68%) limited cutaneous involvement, 15 (21%) were anti-centromere (+) and 34 (47%) were anti-Scl70 (+). In SSc patients, levels of tPA ($p=0.02$), MCP-1 ($p=0.001$), sE-selectin ($p=0.008$), TGF-β1 ($p=0.001$) were significantly higher, sP-selectin ($p=0.011$) and IL-8 ($p=0.001$) were lower than healthy controls (table-1).

Table-1: Vascular Biomarkers in Healthy Controls and Systemic Sclerosis

Biomarker Levels (mean ± SD)	Healthy Controls (n=20)	Systemic Sclerosis (n=72)
sCD40L (pg/ml)	24620 ± 13051	27847 ± 33315
tPA (pg/ml)	2415 ± 1279	4036 ± 6961*
MCP-1 (pg/ml)	907 ± 300	1302 ± 550**
sE-selectin (ng/ml)	205 ± 78	269 ± 106**
IL-8 (pg/ml)	49 ± 73**	22 ± 80
IL-6 (pg/ml)	0	0.6 ± 2.8
VEGF (pg/ml)	704 ± 363	776 ± 591
sP-selectin (ng/ml)	364 ± 137*	287 ± 86
TGF-β1 (pg/ml)	2421 ± 4785	8277 ± 8592**
VCAM (pg/ml)	3231 ± 1435	3945 ± 1754

*$p<0.05$, **$p<0.01$ When groups were compared with Mann-Whitney test*
MCP-1 and sE-selectin levels were correlated with disease activity (r=0.243, p=0.040 and r=0.303, p=0.010) (Valentini et al.)

Conclusion: MCP-1, t-PA, TGF-β1, sE-Selectin, sP-Selectin and IL-8 were differently regulated in SSc patients. MCP-1 was the prominently biomarker correlated with manifesatations related to fibrosis and may be a surrogate marker for fibrotic disease activity. Treatment and smoking may have an effect on cytokine profile. Vascular biomarkers can be used to predict the characteristics and severity of SSc warranting prospective studies.

Monocytic Angiotensin and Endothelin Receptor Imbalance Determines Secretion of the Profibrotic Chemokine Ligand CCL18. Judith Rademacher[1], Jeannine Guenther[2], Angela Kill[3], Elise Siegert[4] and Gabriela Riemekasten[5]. [1]Charité University Hospital and German Rheumatism Research Centre, a Leibniz Institute, Berlin, Germany, 10117 Berlin, Germany, [2]Charité University Hospital and German Rheumatism Research Centre, a Leibniz Institute, Berlin, Germany, Berlin, Germany, [3]Charité University Hospital, German Rheumatology Research Center, a Leibniz Institute, Berlin, Germany, [4]Charité – University Hospital, Berlin, Germany, [5]Charité University Hospital and German Rheumatism Research Centre, a Leibniz Institute, Berlin, Germany.

Background/Purpose: Circulating monocytes are progrenitor of extracellular matrix producing cells involved in fibrosis and show highest expression of angiotensin II (ATR) and endothelin receptors (ETR) compared to other peripheral blood mononuclear cell (PBMC) subsets(1, 2). Stimulating autoantibodies (aab) against AT_1R and ET_AR are elevated in patients with Systemic Sclerosis (SSc) and associated with mortality and the development of disease complications such as PAH, lung fibrosis and digital ulcers(3). SSc-IgG positive for Anti-AT_1R and Anti-ET_AR-aabs induces through the respective receptors the production of the profibrotic chemokine CCL18 in PBMCs(2).

We analysed whether effects of autoantibodies (aab) against angiotensinII receptor type 1 (AT_1R) and endothelin receptor type A (ET_AR) in patients with Systemic Sclerosis (SSc) might be influenced by expression of respective receptors and their functional counterparts AT_2R and ET_BR.

(2) Gunther J, et al. Arthritis research & therapy. 2014 Mar 11;16(2):R65. PubMed PMID: 24612997.
(3) Riemekasten G, et al. Annals of the rheumatic diseases. 2011 Mar;70(3):530–6. PubMed PMID: 21081526.

Methods: AT_1R, AT_2R, ET_AR and ET_BR expression was measured on CD14+ monocytes of 29 SSc patients and 18 healthy donors by flow cytometry. PBMCs of 11 healthy donors were analyzed for receptor expression as well and in vitro stimulated with affinity purified IgG of SSc patients and normal controls. Afterwards, CCL18 concentration was measured in the supernatants by ELISA.

Results: Monocytes of SSc-patients presented higher expression of all 4 receptors compared to NC and an increased AT_1R/AT_2R ratio. ET_AR/ET_BR ratio was significantly reduced in patients with lung fibrosis and correlated negatively with the modified Rodnan Skin Score (Spearman rank correlation's coefficient $r=-0.49$, $p<0.01$).

PBMCs stimulated with SSc-IgG showed higher CCL18 concentration in supernatants than PBMCs stimulated with NC-IgG ($p<0.0001$). CCL18 induction by NC-IgG and SSc-IgG correlated with AT_1/AT_2 ratio (SSc-IgG: $r=0.72$, $p=0.03$, NC-IgG: $r=0.98$; $p<0.0001$) and negatively with ET_A/ET_B ratio (SSc-IgG: $r=-0.82$, $p=0.03$, NC-IgG: $r=-0.93$; $p=0.007$) of receptor positive monocytes.

Conclusion: Receptor expression might reflect systemic activation of the angiotensin and endothelin system in SSc. Since patients with lung fibrosis and high mRSS showed a reduced ET_AR/ET_BR ratio, imbalance of ATR and ETR may influence effects of aab in SSc and could serve as a marker for disease complications. High AT_1R/AT_2R but low ET_AR/ET_BR ratios on monocytes correspond to higher secretion of CCL18 suggesting a link between receptor expression and monocytic function.

1713

Increased Number of $CD206^+$cells in Peripheral Blood and Skin of Systemic Sclerosis Patients. Stefano Soldano[1], Paola Contini[2], Renata Brizzolara[1], Paola Montagna[1], Barbara Villaggio[3], Alberto Sulli[4], Carmen Pizzorni[4], Sabrina Paolino[1], Bruno Seriolo[4] and Maurizio Cutolo[4]. [1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy, [2]Division of Clinical Immunology, Department of Internal Medicine, University of Genova, Genova, Italy, [3]Research Laboratory of Nephrology, Department of Internal Medicine, University of Genova, Genova, Italy, [4]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy.

Background/Purpose: Systemic sclerosis (SSc) is characterised by microvascular damage, immune cell activation and fibrosis of the skin and internal organs. In SSc, the immune-inflammatory infiltrate is primarily made of macrophages and T cells (1). The alternatively activated macrophages (M2) are characterized by an increased expression of specific markers, primarily CD206 (macrophage mannose receptor-1) and macrophage scavenger receptors, and participate in the fibrotic process through the production of pro-fibrotic molecules (i.e. fibronectin, TGFβ) (2). The study investigated the presence of $CD206^+$cells in the peripheral blood and skin of SSc patients. The capability of SSc serum to induce the expression of CD206 in peripheral blood mononuclear cells (PBMCs) of healthy subjects was also investigated.

Methods: Eight SSc patients (mean age 65±7 years) who fulfilled the new criteria of EULAR/ACR (3) and five age matched healthy subjects (HS) were enrolled into the study, after signing of Informed Consent and local Ethical Committee approval. Peripheral blood from SSc patients and HS was analysed by flow cytometry (FC) to detect the presence of cells positive for CD206 and CD14 (a marker of monocyte/macrophage lineage). Skin biopsies were obtained from four of the enrolled SSc patients who were characterized by a "limited" cutaneous involvement (lSSc) and the five HS. The PBMCs obtained from the HS enrolled were plated into FlexPerm chamber slides (2×10^6cells/spot) and maintained for 12 hours in growth medium at 10% of fetal bovine serum in order to isolate the monocyte/macrophage cells. These monocyte/macrophage cells were stimulated for 48 hours with serum from SSc patients and the HS themselves. The expression of CD206 and CD68 (a macrophage marker) was evaluated by immunohistochemistry (IHC) on skin biopsies and by immunocytochemistry (ICC) on cultured human monocyte/macrophages derived from PBMCs.

Results: In the peripheral blood of SSc patients, the percentage of $CD206^+$cells was significantly higher than that of the HS ($p<0.01$). The FC confirmed that the $CD206^+$cells belong to the monocyte/macrophage lineage given the co-expression of CD14. In the skin of SSc patients, the $CD206^+$cells were detected in the immune-inflammatory infiltrate which is characterized by the presence of macrophages ($CD68^+$cells). Conversely, in the skin of HS no $CD206^+$cells were observed. ICC showed that SSc serum stimulated PBMCs-derived monocyte/macrophage cells to express CD206 and also induced these cells to express CD68 thus indicating their activation into macrophages. Conversely, serum from HS was unable to stimulate the expression of CD206 in these cells.

Conclusion: These preliminary results show the presence of $CD206^+$cells in both peripheral blood and skin of SSc patients. Moreover, the ability of SSc serum to induce the expression of this M2 macrophage marker in PBMCs-derived macrophages might support a possible involvement of this cell subset in the pathogenesis of SSc.

IL-6 Trans-Signalling Activates M2 Macrophage Polarisation and Mediates Fibrotic Response in Scleroderma. Rebecca Alade, Shiwen Xu, Korsa Khan, Angela Tam, Christopher P. Denton and Voon H. Ong. UCL Medical School Royal Free Campus, London, United Kingdom.

Background/Purpose: IL6 is a key mediator in activation of extracellular matrix (ECM) in scleroderma (SSc) fibroblasts and via its interplay with chemokines may modulate mononuclear cell recruitment and fibrosis. We have explored the role of IL6 in macrophage differentiation in SSc and its regulation of fibrotic response.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from patients with early stage diffuse cutaneous SSc (dcSSc) (n=12) and healthy controls (n=6) via Ficoll gradient centrifugation. Dermal fibroblasts were cultured from skin biopsies from healthy controls (n=4) and dcSSc (n=4). Flow cytometry was used to quantify M2 macrophages in PBMCs defined by $CD68^+CD163^+$ cells. A magnetic-activated cell sorting (MACS) based protocol was used to select $CD14^+$ cells. $CD14^+$Cells were stimulated for 7 days with M-CSF before further stimulation with M-CSF alone or IL6/sIL6R. Flow cytometry was then used to determine the effect of IL6 trans-signalling on macrophage polarisation. Control and dcSSc fibroblasts were stimulated with conditioned media(CM) from cultured M2 macrophages. Western blot analysis for Collagen type-1 (Col-1) and alpha smooth muscle actin (αSMA) were used to assess ECM protein levels induced by CM and the effect of CM on fibroblast contractile response was evaluated with collagen gel contraction assays.

Results: PMBCs were isolated from healthy controls (n=6) mean age (37 ± 13.8 months), and dcSSc patients (n=12), mean age (42.2 ±15.6 years) and disease duration (34.2 ±15.6 months). Flow cytometry of PBMCs demonstrated significantly higher proportion of circulating M2 macrophages (mean ± SEM %) in dcSSc patients compared to healthy controls (9.3±0.3% vs 1.4±1.2%, $p=0.0087$) respectively. There is no significant difference in the total number of $CD68^+$macrophages between the two groups. Stimulation of isolated macrophages with IL6/sIL6R polarised the M2 macrophage population by (4-fold, $p<0.02$) and (1.6-fold, $p<0.04$) in control and SSc macrophages respectively. Cultured fibroblasts treated with CM generated from SSc M2 macrophages led to increased synthesis of ECM proteins αSMA (3-fold, $p<0.04$) and Col-I (3.2-fold, $p<0.04$) compared with control macrophages in the presence of control fibroblasts. CM from SSc M2 macrophages induced contraction of control fibroblasts leading to (4mm±0.3,$p<0.05$) reduction in collagen gel diameter compared to control CM.

Conclusion: Our data indicate that M2 macrophage phenotype in early stage scleroderma may partly be polarised by IL-6 trans-signalling. This supports the critical role of distinct macrophage subpopulation in regulation of key fibrotic markers, myofibroblastic differentiation and contractile response in SSc. Elucidating these pathways may lead to better understanding of macrophage biology in disease pathogenesis and the potential for targeted specific subpopulation as emerging therapeutics in SSc.

Serum Levels of CD163/Tweak Predict Risk of Digital Ulcers in Patients with Systemic Sclerosis. Otylia M. Kowal-Bielecka[1], Marek Bielecki[2], Beata Trzcinska-Butkiewicz[3], Malgorzata Michalska-Jakubus[4], Marek Brzosko[3], Dorota Krasowska[4] and Krzysztof Kowal[5]. [1]Department of Rheumatology and Internal Medicine, Medical University in Bialystok, Bialystok, Poland, [2]Department of Orthopedics and Traumatology, Medical University of Bialystok, Bialystok, Poland, [3]Pomeranian Medical University, Szczecin, Poland, [4]Medical University of Lublin, Lublin, Poland, [5]Department of Allergology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland.

Background/Purpose: TNF-like weak inducer of apoptosis (TWEAK) regulates inflammation, angiogenesis and tissue remodeling. CD163 molecule, a scavenger receptor and marker of alternatively activated macrophages, modulates TWEAK activity through binding and internalization of TWEAK molecule. It has previously been shown that, in a crossectional study, high serum concentrations of soluble CD163 (sCD163) and high CD163/TWEAK ratio were associated with lack of digital ulcers (DU) in patients with systemic sclerosis (SSc) [1].

The aim of the present study was to investigate whether serum levels of soluble CD163 (sCD163), soluble TWEAK (sTWEAK), or sCD163/sTWEAK ratio can predict clinical course of DU in patients with (SSc).

Methods: 50 patients fulfilling the ACR/EULAR classification criteria of SSc who were followed for at least 1 year were included. Serum levels of sCD163 and sTWEAK were measured using commercially available ELISA kits. Digital ulcers were defined as painful area of loss of tissue on the volar surface of fingertips or around the nail distal to the proximal interphalangeal digital crease, present at the time of assessment. In addition, evaluation of SSc patients included assessment of disease subset (diffuse/limited SSc), modified Rodnan skin score, the presence of interstitial lung disease, pulmonary hypertension, results of pulmonary function tests, echo-Doppler, autoantibody testing (anticentromere antibodies, anti-Scl-70 antibodies) and erythrocyte sedimentation rate.

Results: At baseline DU were present in 18 patients. During follow-up DU healed in 12 SSc patients and persisted in the remaining 6. In addition, 5 patients without DU at baseline developed new DU during follow-up. Because of relatively low numbers, patients with recurrent/persistent DU and those with new DU were analyzed together (n=11). In the remaining 27 patients DU were not found at any visit.

There were no significant differences in baseline sCD163 levels between SSc patients in whom DU healed, those with persisted/new DU or those without DU at any visit. In contrast, baseline serum levels of sTWEAK were significantly higher in SSc patients who subsequently experienced healing of DU compared with SSc patients with DU at follow-up and with SSc patients who never had DU ($p<0.05$ for both comparisons). Accordingly, baseline sCD163/sTWEAK ratio was significantly lower in SSc patients with healed DU as compared with those with persisted/new DU at follow-up and with those who never had DU ($p<0.05$ for both comparisons).

In univariate analysis baseline DU, anticentromere antibodies (ACA) and sCD163/sTWEAK ratio were significantly associated with outcome of DU. In multivariate analysis including baseline DU, ACA and sCD163/sTWEAK ratio, baseline DUs were the strongest independent predictor of risk of DU at follow-up.

Conclusion: Our results suggest that CD163-TWEAK interactions might play a role in the development/healing of DU in SSc and indicate that sCD163/sTWEAK serum ratio is a potential biomarker of peripheral vascular disease in SSc.

1716

MHC Class I and Class II Genes Influence Systemic Sclerosis Susceptibility, Clinical Presentation and Autoantibody Profile in a Mexican Admixed Population. Tatiana Sofia Rodriguez-Reyna[1], Joaquin Zuniga[2], Julio Granados[3], Pamela Mercado Velazquez[4], Carlos Nunez Alvarez[4], Neng Yu[5], Sharon Alosco[5], Alfredo Cruz Lagunas[6] and Edmond Yunis[7]. [1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico, [2]Instituo Nacional de Enfermedades Respiratorias Ismael Cosio Villegas, Mexico, Mexico, [3]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubira, Mexico, Mexico, [4]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico, [5]American Red Cross Blood Services - Northeast Division, Dedham, MA, [6]Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico, [7]Dana Farber Cancer Institue, Boston, MA.

Background/Purpose: Systemic Sclerosis (SSc) exhibits great clinical and serologic variability in different populations. Herein we determined MHC class I and II alleles and extended haplotypes in a cohort of Mexican SSc patients to evaluate the contribution of these loci to SSc susceptibility, clinical and autoantibody profile, and to determine the prevalence of Amerindian, Caucasian and African haplotypes.

Methods: We included 159 SSc patients (ACR or LeRoy-Medsger criteria), with homogeneous ancestry (at least 3 generations). Patients were

classified in diffuse cutaneous (dcSSc) and limited cutaneous systemic sclerosis (lcSSc) based on the extent of their skin involvement. They were evaluated to determine presence and severity of organ involvement (Medsger's severity scale). Peripheral venous blood was obtained to test for ANA, SSc-associated antibodies and sequence based MHC class I and II typing. We included 234 healthy, ethnically matched individuals as controls. Admixture estimations and principal component analysis (PCA) were performed. IRB approval was obtained for this study, which was performed according to the Helsinki Declaration contents; informed consent was obtained for every participant. Differences were evaluated using Student's t test, X^2, Fisher exact test and Bonferroni when appropriate, p values <0.05 were considered significant.

Results: We found female predominance (98% vs 84%; p=0.004) and longer disease duration in lcSSc patients (13 vs 8 years; p=0.001); higher proportion of interstitial lung disease (44 vs 24%, p=0.01) and gastrointestinal involvement (73 vs 57%, p=0.03) in dcSSc patients. Anti-Topoisomerase I antibody predominated in dcSSc patients (p=0.0009), and anticentromere (ACA) in lcSSc patients (p=0.005). HLA allele analysis showed increased frequency of HLA-B*08:01 in SSc (gene frequency (gf) 4%) and in dcSSc (gf=4%) patients when compared to controls (gf=0.6%; p=0.01, OR 7.1, 95%CI 2–31; and p=0.004, OR 7.5, 95%CI 1.6–47, respectively); increased frequency of HLA-DRB1*11:04 in dcSSc patients (gf=7.8%) when compared to controls (gf=1.7%, p=0.01, OR 4.8, 95%CI 1.6-14-5); decreased frequency of HLA-DQB1*03:01 in SSc (gf=14.5%) and in lcSSc patients (gf=12.7%) when compared to controls (gf=24.7%, p=0.008, OR 0.5, 95%CI 0.3–0.7; and p=0.009, OR 0.4, 95%CI 0.2–0.7, respectively). Antibody analysis revealed association of HLA-DRB1*08:02 and HLA-DQB1*0402 alleles with anti-Topoisomerase I antibody (p=0.03, OR 2.2, 95%CI 1.2–4; and p=0.00001, OR 5.3, 95%CI 2.8–10, respectively), and HLA-DQB1*0302 was negatively associated to the presence of this autoantibody (p=0.04, OR 0.34, 95%CI 0.15–0.71). Admixture estimations using HLA-B showed significant increase in the percentage of Caucasian genes (33% in lcSSc vs 23% in dcSSc) and reduced percentage of African genes in lcSSc patients (13% vs 24% in dcSSc).

Conclusion: MHC Class I and II genes contribute to Systemic Sclerosis susceptibility, influence clinical presentation and autoantibody profile. Genetic admixture shows different components in dcSSc and lcSSc subsets and in controls.

Endothelial to Mesenchymal Transition Contributes to the Development of Pulmonary Vasculopathy in Systemic Sclerosis PAH. Robert Good[1], Adrian Gilbane[2], Sarah Trinder[2], David Abraham[3], Christopher Denton[3] and Alan M. Holmes[2]. [1]UCL, LONDON, United Kingdom, [2]UCL, London, United Kingdom, [3]UCL Medical School, London, United Kingdom.

Background/Purpose: Vascular complications in Scleroderma (SSc) patients are associated with high mortality, particularly in patients who develop pulmonary arterial hypertension (SSc-PAH). Vascular complications, thought to arise from initial activation and dysfunction of the endothelium can lead to: elevated vascular leak, inflammation, mesenchymal hypertrophy by activation of resident smooth muscle cells and fibroblasts, and neointima formation. Recent studies suggest that as well as resident mesenchymal cells, endothelial cells can undergo endothelial-mesenchymal transition (EndoMT), and acquire a mesenchymal phenotype which may contribute to the expansion of the mesenchymal cell population. Here we sought to determine the prevalence of EndoMT in SSc-PAH patients and pre-clinical models of PAH, and assess the cellular effects on pulmonary artery endothelial cells (PAECs) functions.

Methods: Using lung tissue from SSc-PAH patients (n=3), healthy control (HC) donors (n=3), and from the hypoxia/SU5416 pre-clinical murine model of PAH (n=5), EndoMT was determined by immunofluorescence based on co-expression of vWF and αSMA. EndoMT was induced in human PAECs (n=3) *in vitro* by TNFα [5ng/ml], IL-1β [0.1ng/m;] and TGFβ [5ng/ml] in combination. Morphological changes were assessed by light microscopy and phalloidin staining. Western blotting and immunofluorescence was used to quantify: CD31, vWF, occludin, VE-cadherin, αSMA, calponin and collagen type 1 expression. Conditioned media was collected from PAECs, PAECs following treatment to initiate EndoMT and SSc-PAH and HC fibroblasts; levels of inflammatory secretion was quantified by MSD arrays. The capacity of homogenous EndoMT monolayers (n=6) and mixed cultures of 1:10 EndoMT:PAECs (n=6) cells to form exclusion barriers was assessed using trans-well permeability FITC-albumin assays.

Results: Co-localisation of vWF and αSMA was observed in ≤5% of pulmonary arteries from SSc-PAH patients and hypoxia/SU5416 mice. PAECs treated with TNFα, IL-1β and TGFβ exhibited significant changes in morphology, loss of endothelial markers and elevated expression of mesenchymal markers by day 6. There was a significant ($P<0.05$) increase in secretion of pro-inflammatory chemokines by EndoMT cells compared to PAECs including IL-6 [474±95 vs.12±6.6 pg/ml] and IL-8 [620±71 vs.28±6.5 pg/ml]. EndoMT cells alone or in mixed 1:10 ratio cultures with PAECs, exhibited a significant ($P>0.01$) 5-fold increase in permeability compared to PAECs alone. Consistent with this, EndoMT cells co-cultured with PAECs in a ratio of 1:10 led to 2.5-fold significant ($P>0.05$) increase in permeability.

Conclusion: The co-localisation of vWF and αSMA present in the pulmonary arteries of SSc-PAH patients and pre-clinical models of PAH, is indicative of EndoMT. We demonstrate EndoMT leads to a loss of normal PAEC morphology and an enhanced secretion of pro-inflammatory chemokines. Furthermore EndoMT cells failed to form integral biological barriers and contributed to enhanced permeability of PAEC barriers. Collectively our data suggests that EndoMT may contribute to the loss of normal endothelium function and the development of SSc-PAH.

Background/Purpose: Systemic sclerosis (SSc) is a multi-organ fibrotic disease associated with auto-immune abnormalities. Several clinical and experimental observations suggest that B cells are involved in the inflammatory and fibrotic processes responsible for the disease; but their exact role has yet to be precisely explored. In this work, we assessed the B cell homeostasis modifications in a murine model of SSc (HOCl mouse), both at a phenotypic and functional level, during the course of the disease.

Methods: Overall, 48 Balb/c mice underwent daily subcutaneous injection of hypochlorous acid (HOCl) or PBS, and were then sacrificed at day 21 (early, inflammatory stage) or day 42 (late, fibrotic stage) from the beginning of the protocol (n=12 in each of the 4 groups). Mouse spleens were retrieved and immediately dissected. The distribution of the splenic leucocyte populations (B cells, T CD4 and CD8 cells, macrophages) and B cell subsets (transitionnal, follicular, marginal zone, B1 and regulatory B cells) was analyzed by flow cytometry. The functional properties of B cells were evaluated by MACS- or FACS-sorting the different subsets, and measuring the secretion levels of 20 cytokines in culture supernatants, after stimulation by LPS and CD40L for 48h.

Results: The phenotypic analysis showed a B cell expansion in the HOCl mice at both stages of the disease. This expansion concerns mainly the transitional and B1a cells at the early stage; and mostly the mature forms (follicular and marginal zone) and B1b cells at the later stage. The regulatory $CD5^+$ $CD1d^{hi}$ B cells were also shown to expand at both times of the disease, but more importantly during the inflammatory stage.

At a functional level, the large screening of B cell secretion capacities identified 2 cytokines that were differently produced within the 4 groups: IL-6 and MIP-1α. Those 2 cytokines, that display pro-inflammatory and pro-fibrotic properties, were produced in more important levels in the supernatant of B cells culture from HOCl mice, at both stages of the disease. Within the B cell compartment, IL-6 was mainly secreted by the marginal zone (MZ) subset. Due to its potential regulatory effects, a special focus was also given

on IL-10 secretion. Levels of IL-10 in the supernatant of B cells appeared similar in the 4 groups.

Conclusion: To our knowledge, this study is the first to find evidence of B cell homeostasis alterations in murine model of SSc. It further implies a potential implication of B cells in the pathogenesis of this disease, either by secretion of cytokines (like IL-6 and MIP-1α) or by expansion of pathogenic subsets (such as marginal zone B cells). The exact role of the regulatory B cell subset, that may exert beneficial properties, needs further studying, as the expansion of the $CD5^+$ $CD1d^{hi}$ B cells in HOCl mice seems inconsistent with the similar secretion of IL-10 in the 4 groups. Nevertheless, in light of those results, the B cell appears to be a relevant target for therapy in SSc.

Periostin May Promote Productin of Extracellular Matrix By Modulating TGF-β Signaling in Human Skin Fibroblasts. Yukie Yamaguchi[1], Noriko Koumitsu[1], Kazuhiko Arima[2], Kenji Izuhara[2] and Michiko Aihara[1]. [1]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Saga Medical School, Saga, Japan.

Background/Purpose: Systemic sclerosis (SSc) results in significant morbidity and mortality due to organ fibrosis characterized by increased deposition of extracellular matrix (ECM). Periostin is one of the matricellular proteins, a class of ECM-related molecules defined by their ability to modulate cell–matrix interactions. Recent studies revealed that periostin serves as a critical regulator of wound healing, epithelial mesenchymal transition, and fibrosis. We previously reported elevated serum periostin levels in SSc patients which correlated with severity of skin sclerosis. However, the pathogenic role of periostin in fibrosis has not been well elucidated. In this study, we further examined the role of periostin on transforming growth factor-β (TGF-β) signaling mediating fibrosis.

Methods: Periostin levels in skin and lung primary fibroblasts obtained from SSc patients were first determined. To enhance the function of periostin, we overexpressed periostin in human skin fibroblasts and examined protein levels of ECM proteins, α-smooth muscle actin (α-SMA), matrix metalloproteinases (MMPs) in the presence or absence of TGF-β by immunoblotting. Interaction of periostin with TGF-β receptors (TGF-βRI, TGF-βRII) was assessed by immunoprecipitation assay. Furthermore, effects of periostin to Smad proteins following TGF-β stimulation were also evaluated.

Results: Periostin was strongly expressed in skin and lung primary fibroblasts obtained from SSc patients compared with healthy subjects. Although single stimulation of recombinant periostin (rP) did not increase ECM protein levels, rP-treated fibroblasts and periostin overexpressed fibroblasts produced significant ECM proteins in the presence of TGF-β compared to respective control fibroblasts stimulated with TGF-β alone. Overexpression of periostin enhanced the induction of α-SMA in the presence of TGF-β and increased expression of MMP-1, which is reported to associate TGF-β activation. In addition, phosphorylation of Smad 2/3 by TGF-β was not affected by periostin, but a level of Smad 7, a TGF-β-inducible inhibitor of TGF-β signaling, was reduced in periostin expressed fibroblasts stimulated with TGF-β.

Conclusion: Periostin may contribute to fibrosis by enhancing TGF-β signaling via TGF-β activation and Smad 7 inhibition, which leads to further ECM deposition and periostin generation. Periostin may be a therapeutical target molecule mediating fibrosis.

GATA6 Deficiency Activates UPR Pathways in Endothelial Cells during the Development of Pulmonary Arterial Hypertension. Rong Han[1], Rosanne Van Deuren[2], Stefania Lenna[1], Izabela Chrobak[1], Timothy Radstake[3], Carol Feghali-Bostwick[4] and Maria Trojanowska[1]. [1]Boston University, Boston, MA, [2]University Medical Center Nijmegen, Nijmegen, Netherlands, [3]University Medical Center Utrecht, Utrecht, Netherlands, [4]Medical University of South Carolina, Charleston, SC.

Background/Purpose: Pulmonary arterial hypertension (PAH) is a severe lung complication of systemic sclerosis (SSc), and accounts for a large proportion of SSc-related deaths. As a manifestation of the SSc vasculopathy in pulmonary arteries, PAH is characterized by endothelial dysfunction, inflammation, and vascular wall remodeling. The transcription factor GATA6 is produced at high level in the normal pulmonary vasculature, including endothelial cells and smooth muscle cells, but its level is markedly reduced in both SSc-PAH and idiopathic PAH (IPAH) lungs. Furthermore, genetically modified mice that lack Gata6 in endothelial cells develop PAH spontaneously, suggesting that downregulation of GATA6 is an early and key event that leads to endothelial dysfunction and the development of PAH (*Ghatnekar et al, 2013*). Given that various stimuli induce endothelial dysfunction through the unfolded protein response (UPR) and autophagy pathways, we aim to test the hypothesis that GATA6 deficiency induces ER stress and autophagy in endothelial cells during the process of PAH development.

Methods: Sections of lung specimens from SSc-PAH patients were stained for BiP and CHOP, two major players of UPR pathways, by immunohistochemistry. The level of these two proteins were similarly tested in the lungs of two mouse models of PAH: chronic hypoxia-induced, and endothelial conditional knockout of GATA6 (GATA6 CKO). Expression of UPR and autophagy pathway genes in the lungs of these mouse models was measured by quantitative RT-PCR. GATA6 expression was blocked by siRNA in human pulmonary endothelial cells (HPAECs) cultured *in vitro* and the expression of UPR pathway genes was measured by quantitative RT-PCR. BiP and CHOP protein levels were also determined by western.

Results: BiP and CHOP levels were low in lung sections from healthy human subjects, but increased dramatically in the lungs of patients with SSc-PAH. Similarly, these two proteins were more abundant in the lungs from the two mouse models of PAH than in the lungs of wild-type mice. Specifically, BiP and CHOP were found in endothelial cells and macrophages in both human and mouse PAH lungs. In addition to BiP and CHOP, other UPR pathway genes such as PERK, ATF6, and XBP1, and autophagy markers LC3B, ATG3, ATG5, and ATG12 were also upregulated in murine lung by chronic hypoxia or loss of GATA6 from endothelial cells, but hypoxia treatment of GATA6 CKO mice did not have any additive effect on the expression of these genes. Consistent with the above *in vivo* data, deleting GATA6 in HPAECs with siRNA increased ATF4 mRNA level and BiP and CHOP protein levels *in vitro*.

Conclusion: GATA6 deficiency disrupts endothelial homeostasis and triggers a stress response, including the activation of UPR and autophagy pathways. Chronic activation of these pathways in endothelial cells contributes to the development of PAH.

Investigating the SCF/c-Kit Pathway in Scleroderma Fibrosis. Bahja Ahmed Abdi, Oseme Etomi, Xu Shiwen, David Abraham, Christopher Denton and Richard J. Stratton. UCL Medical School, London, United Kingdom.

Background/Purpose: Stem cell factor (SCF) is a potential driving factor in the development of systemic sclerosis (SSc) and a possible therapeutic target. SCF is a cytokine which acts via c-Kit, a tyrosine kinase receptor, present on the surface of progenitor cells, mast cells and melanocytes. This relationship with mast cells potentially drives pruritus, an under-reported but significant problem in SSc, which can suggest disease activity. The greatly altered pigmentation seen in SSc may also reflect altered SCF/c-Kit signalling affecting melanocytes. Previous work from our laboratory has demonstrated increased levels of SCF and c-kit in SSc fibroblasts compared to healthy controls Our aim was to measure the activity of SCF/c-Kit pathway in Systemic sclerosis.

Methods: Blister fluid, tissue and plasma samples were harvested from healthy controls (HC) and SSc patients. The SCF and c-Kit protein levels in SSc and HC lung fibroblasts were determined by western blotting. SCF (soluble and membrane bound) and c-kit gene expression was measured using quantitative PCR (qPCR) from control and SSc lung fibroblasts and epidermal sheet. The levels of SCF and c-Kit in SSc and HC were assessed by ELISA. The expression of CD117 positive lung fibroblasts was analysed by FACS.

Results: The soluble SCF mRNA expression was enhanced in SSc lung fibroblast samples by qPCR compared to healthy controls (soluble transcript: 23 versus 10 copy number respectively $p=0.008$ and membrane bound: 1.1 versus 0.7 $p=$NS). C-kit was expressed at low levels in both SSc and HC

fibroblasts (0.31 versus 0.28 copy number, p=NS). Western blotting showed increased SCF protein levels in SSc lung fibroblasts compared to controls with relative density scan of 2.25 and 0.76 respectively (p=0.009) while the level of c-Kit protein expression was low in both SSc and control fibroblasts (0.16 vs 0.25) p=NS. Furthermore, measuring the epidermal sheet for SCF gene expression in SSc and HC showed that the soluble SCF isoform had 537 and 366 copy number respectively, while the membrane bound isoform showed gene copy numbers of 106 for SSc and 134 for HC. Using ELISA, SCF plasma levels were found to be lower in SSc patients (1272pg/ml) than the HC group (1425pg/ml) p=0.04, as were the plasma c-Kit levels (13ng/ml versus 16ng/ml respectively) p=0.028. Levels of SCF in conditioned media of cultured lung fibroblasts were higher in SSc (150ng/ml) vs HC (130ng/ml) p=0.002 but lower in blister fluid 1223pg/ml vs 1414 pg/ml respectively. C-Kit was undetectable in conditioned media and blister fluid. A subpopulation of CD117 positive cells was found in both SSc and HC lung fibroblasts (1.26% SSc cells, 2.3% HC).

Conclusion: We demonstrated that the full length soluble SCF mRNA is found at higher levels in the epidermis and in the lung fibroblasts of SSc subject and that SCF appears at slightly higher levels in SSc fibroblast conditioned media. However, when measured in plasma or blister fluid SCF was lower or unaltered in SSc when compared to controls. Cultured fibroblasts were heterogeneous and only a minority were positive for c-Kit. If SCF is important in SSc pathogenesis then it might be acting locally on a small subpopulation of c-Kit positive cells.

TLR4 and TLR7 Are Required for Gadolinium Based Contrast Agent Induction of Dermal and Pulmonary Fibrosis in an Adenine-Induced Model of Chronic Renal Failure. Peter J. Wermuth and Sergio A. Jimenez. Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center, Thomas Jefferson University, Philadelphia, PA.

Background/Purpose: Nephrogenic Systemic Fibrosis (NSF) is a generalized progressive fibrotic disorder that occurs in some patients with renal insufficiency exposed to various gadolinium based contrast agents (GdBCA). TLR4 and TLR7 signaling has been reported to be necessary for the *in vitro* establishment of a profibrotic phenotype by the GdBCA Omniscan in normal human macrophages. In this study, we examined the role of TLR4 and TLR7 in the development of NSF-like lesions *in vivo* in mice with renal failure induced by a high adenine diet following exposure to GdBCA by intratracheal instillation.

Methods: Chronic renal failure was induced in normal mice and in TLR4 and TLR7 knockout (TLR4 KO) and (TLR7 KO) mice by *ad libitum* feeding of a standard rodent diet supplemented with 3% adenine for 30 days. Two weekly doses of either the GdBCA Omniscan (100 μL of a 0.5 M solution, corresponding to a 0.05 mmol/kg dose) or an equal volume of normal saline were administered by intratracheal instillation to mice with either normal renal function or with adenine diet-induced chronic renal failure. Mice were sacrificed 56 days after the final instillation and tissues were isolated for analysis of the severity of tissue fibrosis by histological examination (hematoxyllin/eosin and Masson's trichrome stains) and by assays of collagen content employing a standard hydroxyproline assay of hydrolyzed tissue samples.

Results: Histopathology studies showed mononuclear cell infiltration and severe peribronchial fibrosis and moderate diffuse interstitial fibrosis in lungs isolated from adenine-fed control (C57BL6/J) mice instilled with Omniscan. In contrast, lungs from adenine-fed TLR4 KO or TLR7 KO mice maintained normal lung histology. Mice of all three strains with normal renal function instilled with Omniscan and mice with either normal or ablated renal function instilled with saline also demonstrated no fibrosis. Hydroxyproline content was increased ~3 fold in the lungs of Omniscan-instilled wild type mice with adenine diet-induced renal failure. In contrast, the lungs of Omniscan-instilled TLR4 KO and TLR7 KO mice with or without renal failure had normal hydroxyproline levels.

Conclusion: The present study demonstrates for the first time *in vivo* that the ability to induce significant tissue fibrosis and increased collagen deposition in mice with adenine induced renal failure exposed to the gadolinium contrast agent Omniscan requires signaling through TLR4 and TLR7. These results indicate that targeting of TLR signaling could be a valuable strategy to prevent or treat NSF and other TLR-mediated chemically-induced fibrotic disorders.

Identification of the Microbiome As a Potential Trigger of Systemic Sclerosis By Metagenomic RNA-Sequencing of Skin Biopsies. Michael Johnson[1], Zhenghui Li[1], Michelle Dimon[2], Tammara A. Wood[1], Robert Lafyatis[3], Sarah Arron[2] and Michael Whitfield[1]. [1]Geisel School of Medicine at Dartmouth, Hanover, NH, [2]University of California, San Francisco, San Francisco, CA, [3]Boston University, Boston, MA.

Background/Purpose: Systemic sclerosis (SSc) is a rare and poorly understood systemic autoimmune disease that results in skin fibrosis and severe internal organ involvement. There is a limited understanding of its pathophysiology and there are little data to indicate what may trigger the disease. Previous studies have suggested a variety of bacterial and viral pathogens as a trigger of systemic sclerosis (SSc), though neither a definitive pathogen nor a mechanism of pathogenesis has been established. Here we used RNA-seq to identify differences in the skin microbiome associated with SSc to test the hypothesis that an environmental microbiome component may be more strongly associated with SSc skin.

Methods: RNA-seq was performed on eight patients with early diffuse SSc and four controls, to a depth of 200 million reads per patient. All patients were diagnosed with diffuse systemic sclerosis (dSSc) and were not on immunosuppressive therapy at the time of biopsy. Each patient was assigned to their respective intrinsic gene expression subset: five patients mapped to the inflammatory subset, and three patients in the fibroproliferative subset; one patient classified in the inflammatory subset exhibited both inflammatory and fibroproliferative gene expression signatures. RNA-seq data were analyzed using Integrated Metagenomic Sequence Analysis (IMSA) to quantify non-human sequence reads in each sample, and compared to the NCBI taxonomic database to identify significantly enriched pathogens between groups. Differences in immunoreactivity of SSc and healthy controls were confirmed by Western blot and mass spectrometry using fungal lysates probed with human sera.

Results: Little difference in viral and bacterial read counts were found between SSc patients and healthy controls. However, a significant difference in the fungal mycobiomes of SSc and controls was evident for the read counts of *Rhodotorula glutinis*. Within SSc, the highest read counts were consistently found in patients classified in the inflammatory intrinsic subset ($p = 0.02$ vs. controls). Lower *R. glutinis* read counts were found in three fibroproliferative patients ($p = 0.15$ vs. controls); virtually no *R. glutinis* or other *Rhodotorula* sequence reads were present in controls. We were able to assemble the D1–D2 hypervariable region of the 28S ribosomal RNA (rRNA) of *R. glutinis* from each of the SSc samples. We observe differences in immunoreactivity to *R. glutinis* between SSc and healthy controls as determine by Western blot and mass spectrometry to autoantibody-bound proteins. Validation and expansion of these results are being performed by fungal Internal Transcribed Spacer (ITS) sequencing from SSc and control biopsies.

Conclusion: These results suggest the microbiome, and *R. glutinis* specifically, may be a trigger or potential modifier of the inflammatory response in SSc. We found *R. glutinis* to be most significantly associated with the inflammatory subset of SSc, extending our prior work. Anatomical and temporal differences in the abundance of this pathogen in the context of host genetics may be associated with differences in clinical presentation and molecular phenotypes.

Loss of IRF5 Ameliorates Tissue Fibrosis in a Murine Model of Systemic Sclerosis. Ryosuke Saigusa[1], Yoshihide Asano[1], Takashi Taniguchi[1], Yohei Ichimura[1], Takehiro Takahashi[1], Tetsuo Toyama[1], Ayumi Yoshizaki[1], Tadatsugu Taniguchi[2] and Shinichi Sato[1]. [1]University of Tokyo Graduate School of Medicine, Tokyo, Japan, [2]Institute of Industrial Science, University of Tokyo, Tokyo, Japan.

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disorder with clinical manifestations that result from fibrosis development, immune activation and vascular injuries. A genome-wide association study showed the involvement of genetic variants in the development of SSc. In particular, a single nucleotide polymorphism within the promoter region of interferon regulatory factor 5 (IRF5) was associated with an increase in SSc. This polymorphism results in a decrease in steady-state IRF5 transcript levels,

accompanied with longer survival and milder interstitial lung disease. In this study, we explore the function of IRF5 in the development of SSc utilizing a bleomycin (BLM)-induced SSc mouse model in mice deficient in IRF5 (*Irf5*$^{-/-}$mice).

Methods: Wild type (WT) and *Irf5*$^{-/-}$mice were induced to develop SSc following BLM treatment. Dermal thickness and fibrosis were measured by histological analyses. The quantity of the collagen-specific amino acid hydroxyproline was also measured. Immunohistochemistry and quantitative reverse transcription-PCR were conducted to evaluate the degree of inflammation and the expression of cytokines, growth factors, chemokines, and cell adhesion molecules.

Results: Dermal and pulmonary fibrosis in BLM-treated *Irf5*$^{-/-}$ mice was attenuated as compared to WT mice. Consistent with this, inflammatory cell infiltration induced by BLM treatment was suppressed in the mutant mice. Further, IRF5 deficiency modulated the expression of cell adhesion molecules toward the induction of Th1-skewed inflammation by BLM treatment, as represented by the lower expression of intercellular adhesion molecule-1 and glycosylation-dependent cell adhesion molecule-1 in the lesion skin and lung of *Irf5*$^{-/-}$ mice than in those of wild type mice. Finally, matrix metalloproteinase 13 mRNA and protein expression was higher in the skin and lung of the BLM-treated *Irf5*$^{-/-}$ mice.

Conclusion: With BLM treatment, *Irf5*$^{-/-}$ mice exhibited attenuated tissue fibrosis due to the alterations to fibroblasts, immune cells and cell adhesion molecules, indicating a pivotal contribution of IRF5 to pathological tissue fibrosis. As such, our results experimentally lend support to the notion that reduced IRF5 transcripts as a result of a nucleotide polymorphism in the IRF5 promoter region accounts for the attenuation of SSc manifestations.

The SYK Inhibitor Fostamatinib Limits Tissue Damage and Fibrosis in a Bleomycin-Induced Scleroderma MOUSE MODEL. Omer Nuri Pamuk[1], Guray Can[1], Suleyman Ayvaz[1], Turan Karaca[1], Gulsum Pamuk[1], Selim Demirtas[1] and George C. Tsokos[2]. [1]Trakya University Medical Faculty, Edirne, Turkey, [2]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA.

Background/Purpose: The possible antifibrotic effects of various kinase inhibitors has been studied before in SSc. Spleen tyrosine kinase (Syk) is a protein tyrosine kinase which activates intracellular signal transduction pathways and has been claimed to be involved in the pathogenesis of systemic autoimmune diseases. We investigated the ability of a small drug Syk inhibitor, fostamatinib, to protect mice from bleomycin-induced SSc.

Methods: Four study groups of Balb/c mice were included in this study: control, bleomycin (administered subcutaneously to BALB/c mice for 21 days), bleomycin and fostamatinib (mice fed with chow containing a Syk inhibitor for 21 days) and fostamatinib alone groups. Skin and lung tissue specimens were obtained and evaluated histologically.

Results: Mice treated with bleomycin alone had significantly more skin thickness (416.1±6.1) compared to control (260.1±10.1) and fostamatinib (254.3±7.9) treated mice ($p<0.001$). Mice subjected to bleomycin and fed with fostamatinib-containing chow generated more (312.3±4.4) dermal thickness than control and fostamatinib-treated mice (p values <0.001) but, significantly less when compared to mice treated with bleomycin alone ($p<0.001$).Alveolar hemorrhage, edema, damage and leukocyte scores in the lungs of mice treated with bleomycin were significantly higher v compared to control or fostamatinib alone-treated mice (p values <0.001). At the end of the 21-day bleomycin administration, there was apparent prominent fibrosis which was reduced significantly in the group of mice which received in parallel fostamatinib. Following fostamatinib treatment, Syk, phospho-Syk, and TGF-β expression decreased in both skin and lung tissues

Conclusion: The Syk inhibitor fostamatinib prevented bleomycin-induced fibrosis and inflammation in the skin and the lung. The anti-fibrotic effect of fostamatinib is linked to reduced Syk phosphorylation and TGF-β expression. The Syk pathway appears as a potential molecular target for therapeutic intervention in SSc.

Therapeutic Efficacy of Mesenchymal Stem Cells in Diffuse Murine Hypochlorite-Induced Systemic Sclerosis. Alexandre Maria[1], Claire Bony[1], Karine Toupet[1], Christian Jorgensen[2], Philippe Guilpain[3] and Daniele Noel[4]. [1]Inserm, Montpellier, France, [2]Clinical Immunology and Osteoarticular Diseases Therapeutic Unit, CHU Lapeyronie., Montpellier, France, [3]Department of Internal Medicine, Montpellier, France, [4]UM1, Montpellier, France.

Background/Purpose: Systemic sclerosis (SSc) is a rare intractable disease with unmet medical need and fibrosis-related mortality. Absence of efficient treatments has prompted to develop novel therapeutic strategies among which mesenchymal stem cells (MSCs) appear one of the most attractive options. Herein we provide the first preclinical study using MSCs in the relevant hypochlorite (HOCl)-induced murine model of diffuse SSc, recapitulating the main features of the disease: multivisceral fibrosis, vasculopathy, and autoimmunity.

Methods: Balb/c mice underwent six weeks of daily intradermal injections of HOCl leading to SSc-HOCl phenotype. Different doses of syngenic bone marrow-derived MSCs (2.5×10^5; 5×10^5 or 10^6cells) were infused in the tail vein of the mice, either the day before disease induction, or at day 21. Skin thickness was measured weekly, and samples of skin and lung were taken at euthanasia (d42) to assess by RT-qPCR the expression of collagens I and III, TGF-β1, alpha-smooth actin muscle (α-SMA), MMP-1 and -9, Tissue Inhibitor of MMP (TIMP1), Hepatocyte Growth Factor (HGF), VEGFA, IL-1β, TNF-α, IL-6, IL-10, Superoxide Dismutase (SOD2), and Heme Oxygenase (HMOX1). Anti-scl70 antibodies levels were measured in sera by ELISA.

Results: We first compared the effects of different doses of MSCs (2.5×10^5; 5×10^5 and 10^6) infused the day before disease induction, on clinical and biological parameters. When considering skin thickness in time, we observed a slower progression in MSC-treated mice, with the best results obtained with the lowest dose of 2.5×10^5 MSCs. At euthanasia, a lower expression of fibrotic markers (collagens I and III, TGF-β1, α-SMA) was observed in both skin and lung of treated mice, consistent with histological improvement and inversely proportional to the injected dose. Importantly, sera from treated mice exhibited lower levels of anti-scl70 autoantibodies and enhanced antioxidant capacity, confirming the systemic effect of MSCs. Of interest, MSC administration was also efficient when infused at d21 while disease is known to be established. We further provide evidence at a molecular level that in skin and lung tissues, MSCs exerted an anti-fibrotic role by normalizing extracellular matrix remodeling parameters (MMP-1 and -9, TIMP-1, HGF, VEGFA), as well as reducing pro-inflammatory cytokines (IL1β, TNF-α, IL-6, IL-10) and increasing antioxidant defenses (SOD2, HMOX1).

Conclusion: In conclusion, this preclinical study is the first to demonstrate the therapeutic efficacy of MSCs in SSc, acting through the modulation of inflammation, tissue remodeling and antioxidant defenses. The benefits observed in a curative approach are particularly promising in sight of clinical perspectives.

1727

Poly(ADP-ribose) Polymerase-1 (PARP-1) Suppresses the Profibrotic Effects of Transforming Growth Factor â in Systemic Sclerosis. Yun Zhang. University Hospital Of Erlangen, Erlangen, Germany.

Background/Purpose: The enzyme poly(ADP-ribose) polymerase-1 (PARP-1) transfers negatively charged ADP-ribose units from the donor β-NAD onto various substrate proteins either as mono- or oligomeric moieties or as linear or branched poly (ADP-ribose) (PAR) chains. Those modifications can have pronounced regulatory effects on the half-life or the enzymatic activity of target proteins. Recent studies demonstrated that PARP-1 can poly(ADP-ribosyl)ates (PARylates) members of the Smad family of transcription factors. However, the role of PARP1 in the pathogenesis of SSc has not been investigated.

Methods: The expression of PARP1 in human skin and in experimental fibrosis was determined by qPCR and immunohistochemistry. TGFβ signalling was analysed by Smad reporter assays and target gene analysis after 1mM selective PARP1 inhibitor 3-Aminobenzamide (3AB). Bleomycin-induced skin fibrosis and Tsk-1 mice were used to

evaluate the effect of PARP deficiency and PARP inhibition (10mg/kg/d 3AB) *in vivo*.

Results: Decreased expression of PARP1 was detected by immunohistochemistry in skin sections of SSc patients.particularly in fibroblasts. Inhibition of PARylation by 3AB augmented the stimulatory effects of TGFβ on fibroblasts *in vitro*. PARP1 inhibition increased Smad dependent transcription in reporter assays and promoted the transcription of TGFβ/Smad target genes. Treatment with 3AB also stimulated the collagen release and fostered the expression of contractile proteins with increased expression of α-smooth muscle actin (α-SMA) and enhanced formation of stress fiber formation compared to fibroblasts stimulated with TGFβ alone. Inhibition of PARylation also exacerbated experimental fibrosis *in vivo*. Treatment with 3AB induced a more severe fibrotic response to bleomycin with increased dermal thickening by up to 103% ($p<0.0001$), hydroxyproline contents and myofibroblast counts compared to control mice ($p<0.0001$ and $p=0.0059$). Inhibition of PARylation also strongly exacerbated fibrosis in Tsk-1 mice. Meanwhile, after bleomycin injection, dermal thickening, hydroxyproline contents and myofibroblast counts of PARP1 knockout mice were increased by 85% ($p=0.0046$), 67% ($p=0.0098$) and 56% ($p=0.0043$) compared to wild-type mice.

Conclusion: We demonstrate that PARP1 negative regulates canonical TGFβ signalling. The down-regulation of PARP1 in SSc fibroblasts may thus directly contribute to hyperactive TGFβ signalling and to persistent fibroblast activation in SSc.

Disclosure: Y. Zhang, None.

Bromodomain Inhibitor JQ1 Modulates Collagen Processing and Ameliorates Bleomycin Induced Dermal Fibrosis in Mice. Sarah Trinder[1], Mary Tarriela[2], Adrian Gilbane[1], Robert Good[3], Xu Shi-Wen[3], David Abraham[4] and Alan M. Holmes[1]. [1]UCL, London, United Kingdom, [2]Centre for Rheumatology and Connective Tissue Diseases, London, United Kingdom, [3]UCL, LONDON, United Kingdom, [4]UCL Medical School, London, United Kingdom.

Background/Purpose: Systemic sclerosis (SSc) is a complex pro-inflammatory scarring disease, characterised by elevated deposition of extracellular matrix (ECM) proteins, in particular collagen type I. The disease is heterogeneous affecting both the skin and visceral organs including kidney, lung and heart. The SSc fibroblast is a key cell which promotes a pro-inflammatory and fibrotic microenvironment that can lead to the loss of normal tissue architecture and organ function. The mechanisms that contribute to the formation and persistence of the SSc dermal fibroblast remain unclear. We have previously shown the epigenetic bromodomain and extra-terminal domain-containing proteins (Brd) which bind to acetylated histone residues, play a significant role in pulmonary fibrosis. Here we seek to explore the contribution of Brd proteins in the development of dermal fibrosis using a specific inhibitor of Brd proteins (Brd 2, 3, 4 and T), JQ1.

Methods: We investigated the dose-response of JQ1 on SSc and healthy control (HC) donor ($n\geq3$) dermal fibroblasts. We assessed the effects on collagen deposition and processing using the Scar-in-a-Jar *in vitro* fibrosis assay, by western blot and immuno-florescence microscopy for collagen type I ($n=4$). To determine the effect of JQ1 in a pre-clinical model of skin fibrosis, female C57BL/6 mice were given three weekly subcutaneous injections of 100μl sterile saline ($n\geq6$) or 0.1U/ml bleomycin ($n\geq6$) for 14 days and treated with 12mg/kg/day JQ1 ($n\geq6$) or vehicle ($n\geq6$). After 14 days histological analysis for fibrogenic proteins and ECM was performed on skin, and pro-inflammatory chemokines in sera assessed by ELISA.

Results: IL-6 and MCP-1 secretion by SSc and HC donor fibroblasts was significantly ($P<0.05$) inhibited in a dose dependent manner by JQ1. Consistent with this JQ1 attenuated SSc collagen deposition and processing ($P<0.05$). Assessment of JQ1 in a pre-clinical model of dermal fibrosis demonstrated a markedly attenuation of dermal thickening *in vivo*($P<0.05$). Consistent with this we observed significant reduction in fibrogenic markers including αSMA, and collagen expression in the skin ($P<0.05$). Furthermore secretion of the inflammatory marker, IL-6 was significantly attenuated ($P<0.05$).

Conclusion: We have assessed the functional effects of the Brd inhibitor, JQ1, on SSc dermal fibroblasts and the development of dermal fibrosis in a pre-clinical model of dermal fibrosis. We demonstrate that JQ1 markedly attenuated the excessive deposition and processing of collagen type I by SSc fibroblasts. In keeping with Brd proteins playing a pivotal role in the development and progression of dermal fibrosis, JQ1 significantly inhibited ECM deposition *in vivo*. Our data suggests a key role for Brd proteins in the persistence of the SSc dermal fibroblast phenotype.

Adenosine A2A Receptor (A2AR) Promotes Collagen Type 3 Expression Via β-Catenin Activation. Miguel Perez-Aso[1] and Bruce N. Cronstein[2]. [1]New York University, New York City, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: A2AR stimulation promotes collagen 1 and 3 (Col1 and Col3) synthesis, principal mediators of fibrosis and scarring. We have recently demonstrated that the A2AR is a fine-tune modulator of collagen balance that signals via PKA/EPAC2/AKT but is independent of Smad2/3 signaling. Wnt signaling is an important player in the progression of fibrosis, and other recent studies have suggested that cAMP and Wnt pathways converge. Since A2AR is Gs-linked and increases cAMP, we determined whether A2AR and Wnt signaling interact.

Methods: Primary human dermal fibroblasts (<5 passages) were stimulated by the A2AR-selective agent CGS21680 (1μM) and β-catenin, dephosphorylated β-catenin and β-catenin phospho-Ser552 levels were determined in cytosolic and nuclear fractions by Western Blot. Nuclear translocation of β-catenin was determined by confocal microscopy. β-catenin was knocked down by transfection with specific-siRNA or scrambled-siRNA and protein levels determined by Western Blot.

Results: Stimulation of A2AR rapidly (15 min) increases cellular β-catenin levels to 196±13% of control ($N=3$, $P<0.01$). Similarly CGS21680 stimulates de-phosphorylation of β-catenin (188±27% of control; $N=5$, $P<0.05$) and promotes β-catenin phosphorylation at Ser 552 (239±15% of control; $N=5$, $P<0.001$), the site of β-catenin activation by AKT. Furthermore, CGS21680 stimulates translocation of β-catenin to the nucleus, as confirmed by confocal microscopy and Western Blot. We next knocked down β-catenin (54±5% decrease in β-catenin siRNA *vs* scramble siRNA; $N=10$, $P<0.001$) and determined the effect of A2AR stimulation on collagen production. A2AR-stimulated increases in Col1 scramble-siRNA transfected cells (63±22% increase, $N=7$) which were unaffected by β-catenin knockdown (53±17% increase, $N=7$). In contrast, β-catenin knockdown abrogates A2AR-stimulated increments in Col3 synthesis by 73% (scramble-siRNA 66±14% increase of Col3 *vs* β-catenin-siRNA 18±16% increase of Col3; $P<0.05$, $N=8$).

Conclusion: Our results strongly indicate that A2AR stimulation activates both canonical and non-canonical Wnt pathways for increased Col3 synthesis, leading to dermal fibrosis and excessive scarring.

Identification of Novel Scleroderma –associated Antigens and Development of an Autoantibody Assay Panel Enabling Their Subsequent Validation. Hans-Dieter Zucht[1], Petra Budde[1], Peter Schulz-Knappe[1], Nicolas Hunzelmann[2], Karsten Conrad[3] and Prof. Dr. Matthias Schneider[4]. [1]Protagen AG, Dortmund, Germany, [2]University of Cologne, Cologne, Germany, [3]Technische Universität Dresden, Dresden, Germany, [4]Univ. Duesseldorf, Duesseldorf, Germany.

Background/Purpose: Scleroderma (systemic sclerosis or SSc) has a highly variable clinical presentation and course resulting in difficulties for disease management. When SSc is suspected, autoantibodies (AAB) are tested. The most frequently observed AABs, anti-topoisomerase I (anti-Scl70), anti-centromere (ACA) and anti-RNA polymerase III (ARA) are associated with different subtypes of SSc and with specific organ involvements and disease severity. Those biomarkers have recently been included in the new SSc classification criteria, but are only present in about 60–70% of SSc patients. Our aim is to identify additional highly frequent SSc-associated autoantigens using a high-throughput Luminex bead-based profiling platform as well as the development of a complementary ELISA-based autoantibody assay kit for enabling validation of the novel panel of SSc antigens to illustrate their clinical utility.

Methods: A systematic and undirected approach was undertaken to screen for autoantibodies in human serum samples of 100 individuals with SSc and related overlap syndromes using 7000 recombinant protein targets. Active and passive control groups comprised healthy controls and serum samples of other systemic autoimmune diseases including systemic lupus erythematosus (SLE), and early rheumatoid arthritis (RA). The frequency of autoantibodies for a particular antigen was determined by applying the mean value of the signal intensity of the healthy control cohort plus 2 standard deviations (SD) as a cut-off. Then, the frequency of 116 candidate antigens in 1100 healthy controls and 90 SSc samples was assessed using a connective tissue disease array. Afterwards, ELISAs were developed for 7 antigens with high frequency in SSc or higher frequency in SSc subtypes. The performance of ELISAs was analyzed in comparison with the Luminex multiplex system in additional 150 SSc samples.

Results: Sera of 100 SSc patients with limited or diffuse SSc or overlap syndromes were tested for established and novel autoantigens. 30% of SSc patients were previously tested negative for ACA and anti-Scl70. The frequency of established and novel autoantibodies in the test cohort ranged from 40% to 10% in descending order: CENPB: 40%, Scl70: 36%, TRIM21 (Ro52): 27%, antigen 1: 28%, antigen 2: 27%, antigen 3: 17%, antigen 4: 15%, antigen 5: 13%, antigen 6: 11% and antigen 7: 4%. While autoantibodies to antigens 1–4 were more frequently observed in limited SSc, autoantibodies to antigens 5–7 were more abundant in diffuse SSc. Autoantibody reactivity above the cut-off level was identified in 50% of the previously negative-tested SSc patients. ELISA and Luminex showed good qualitative agreement. The genes encoding for these proteins were found being enriched in pathways of histone modifications and chromatin remodeling suggesting their involvement in epigenetic processes.

Conclusion: Using a combination of Luminex bead-arrays for high-throughput autoantibody profiling and complementary ELISA development provides an alternative route to discover and verify novel SSc-associated autoantibodies. By measuring 7 antigens the number of autoantibody positive SSc patients increased from 68% to 84%.

Translocation of IGFBP-5 to the Nucleus and Its Interaction with Nucleolin Do Not Dictate Its Fibrotic Effects. Yunyun Su and Carol Feghali-Bostwick. Medical University of South Carolina, Charleston, SC.

Background/Purpose: Insulin-like growth factor binding protein (IGFBP)-5 is one of six IGFBPs. IGFBP-5 is the most conserved member of the family. IGFBP-5 levels are increased in systemic sclerosis (SSc) skin and lung tissues. We previously reported that IGFBP-5 is a pro-fibrotic factor that induces extracellular matrix (ECM) production and deposition. IGFBP-5 promoted a fibrotic phenotype *in vitro* in primary human fibroblasts, *in vivo* in mouse lung and skin, and *ex vivo* in human skin. Since IGFBP-5 contains a nuclear localization signal (NLS) that facilitates its nuclear translocation, we sought to examine the role of nuclear translocation on the fibrotic activity of IGFBP-5 and identify IGFBP-5 binding partners relevant for its nuclear compartmentalization.

Methods: We generated functional wild type IGFBP-5 and IGFBP-5 with a mutated NLS. Abrogation of nuclear translocation in the NLS mutant was confirmed using immunofluorescence and immunoblotting of nuclear and cytoplasmic cellular extracts. The fibrotic activity of wild type and NLS-mutant IGFBP-5 was examined *in vitro* in primary human fibroblasts and *ex vivo* in human skin. We identified IGFBP-5 binding partners using immunoprecipitation and Mass Spectrometry. Binding of IGFBP-5 to its partner was validated using co-immunoprecipitation and immunoblotting. We examined the effect of the partner on IGFBP-5 localization and function via sequence-specific silencing in primary human fibroblasts.

Results: Our results show that IGFBP-5-induced ECM production *in vitro* in primary human fibroblasts is independent of its nuclear translocation as the NLS-mutant IGFBP-5 retained fibrotic activity. The NLS-mutant IGFBP-5 also induced fibrosis *ex vivo* in human skin maintained in organ culture, thus confirming and extending the *in vitro* findings. Nucleolin, a nucleolar protein that can serve as a nuclear receptor, was identified as an IGFBP-5 binding partner. Silencing nucleolin in primary human fibroblasts reduced IGFBP-5 translocation to the nucleus but did not block the ability of IGFBP-5 to induce ECM production and a fibrotic phenotype.

Conclusion: IGFBP-5 transport to nucleus requires an intact NLS and nucleolin. However, nuclear translocation is not necessary for IGFBP-5 fibrotic activity. Our data provide further insights into the mechanism mediating the fibrotic activity of IGFBP-5 and the role of nuclear compartmentalization in IGFBP-5-induced fibrosis.

Attenuation of Sclerodermatous Graft Versus Host Disease (sclGVHD) in IL4RA Receptor-Deficient Mice. Katia Urso[1], Kelly Tsang[2], Robert Lafyatis[3] and Antonios O. Aliprantis[2]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]Boston University School of Medicine, Boston, MA.

Background/Purpose: Scleroderma is a rare autoimmune disease characterized by the accumulation of fibrotic tissue in multiple organs including the skin, gut and lungs. To date, the cause of this disease has not been identified and specific treatments are unavailable. SclGVHD in mice recapitulates many scleroderma manifestations and can be used to determine potential therapeutic pathways. Previously, we identified activation of the Interleukin-13 (IL-13) cytokine pathway in the skin of both murine sclGVHD and a subset of scleroderma patients characterized by an "inflammatory" gene expression signature. We also showed that host mice lacking IL4RA, a functional subunit of IL-13 and IL-4 receptors, are protected from the cutaneous manifestations of sclGVHD. The purpose of this study is to define the mechanism that protects IL4RA-deficient mice from sclGVHD.

Methods: Splenocytes from B10.D2 mice were transferred into either BALB/c *Rag2*$^{-/-}$ or BALB/c *Rag2*$^{-/-}$*Il4ra*$^{-/-}$ hosts to induce sclGVHD. Seven days after cell transfer the skin was processed for histopathology and scored blindly for inflammation. Subcutaneous lymph-nodes (sLN) were isolated, collagenase digested and analyzed by flow cytometry. sLN cells were also stimulated in vitro for 5h with LPS, PMA and ionomycin to analyze IL-10 production by intracellular cytokine staining. mRNA was extracted from skin and sLN and subjected to qRT-PCR. Student's t-tests, with n=10–13 per group, were used to determine statistical significance.

Results: One week after cell transfer IL4RA-deficient mice lost significantly less weight than control sclGVHD mice (8.44% ± 4.25 of baseline body weight vs. 16.28% ± 3.68, $p<0.0001$) and displayed less skin inflammation as assessed by histopathologic score (1.50 ± 0.53 for BALB/c *Rag2*$^{-/-}$ and 0.80 ± 0.42 for BALB/c *Rag2*$^{-/-}$*Il4ra*$^{-/-}$, $p=0.0042$). Despite reduced skin inflammation, the sLNs of BALB/c *Rag2*$^{-/-}$*Il4ra*$^{-/-}$ mice showed significantly higher cellularity ($8.7 \pm 2.33 \times 10^6$ vs. $3.09 \pm 1.23 \times 10^6$, $p<0.0001$), with elevated numbers of T cells, B cells and myeloid CD11b$^+$Ly6C$^+$ cells compared to BALB/c *Rag2*$^{-/-}$ controls. Cells from these three populations also produced more IL10 than those isolated from control mice when stimulated ex vivo. In addition, among the CD4$^+$ T-cells, Il4RA-deficient hosts had a significantly higher frequency of Foxp3$^+$ regulatory T-cells (13.92% ± 1.95 vs. 6.82% ±1.40, $p<0.0001$). qRT-PCR analysis also revealed elevated *Il10* transcripts in the sLNs of BALB/c *Rag2*$^{-/-}$*Il4ra*$^{-/-}$ hosts ($p=0.0008$). In contrast, no differences were observed in transcript levels of chemokines important for the homing of immune cells to sLNs, including *ccl19* and *cxcl13*.

Conclusion: IL4RA promotes sclGVHD early in the disease course by promoting infiltration of immune cells into the skin and suppressing the expansion of regulatory T-cells and IL-10 expression. Surprisingly, the sLNs of mutant mice contained more adaptive and innate immune cells. Additional data are needed to understand if this accumulation of cells in sLN of IL4RA-deficient mice is due to a defect in the pathways that control apoptosis, proliferation or the migration of activated cells from the sLN to the skin.

Immunomodulatory Effects of Dietary Non-Digestible Oligosaccharides in T Cell-Mediated Autoimmune Arthritis. Rebecca Rogier[1], Tom Ederveen[1], Anita Hartog[2], Birgitte Walgreen[1], Liduine van den Bersselaar[1], Monique M. Helsen[1], Paul Vos[2], Johan Garssen[3], Linette Willemsen[3], Wim B. van den Berg[1], Marije I. Koenders[1] and Shahla Abdollahi-Roodsaz[1]. [1]Radboud university medical center, Nijmegen, Netherlands, [2]Danone Nutricia Research, Utrecht, Netherlands, [3]Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands.

Background/Purpose: Accumulating evidence indicates the relevance of intestinal microbiota in shaping the immune response and supports its contribution to the development of autoimmune diseases. Prebiotic non-digestible oligosaccharides are known to selectively support growth of commensal Bifidobacteria and Lactobacilli and adjust the microbiota composition. The aim of this study was to assess the efficacy of microbiota modulation using non-digestible oligosaccharides as a therapeutic approach for T cell-dependent autoimmune arthritis.

Methods: IL-1 receptor antagonist (IL-1Ra) deficient mice spontaneously developing an autoimmune T cell- and interleukin (IL)-17- dependent arthritis were used for this study. We previously showed that spontaneous arthritis in IL-1Ra−/− mice depends on the presence of commensal microbiota, since germ-free mice develop less severe disease. To examine the feasibility of microbiota modulation as a therapeutic approach during established disease, IL-1Ra$^{-/-}$ mice which had already developed arthritis under conventional microbial status were orally fed a prebiotic diet containing 2.5% or 5% short-chain galacto- and long-chain fructooligosaccharides (scGos:lcFos, 9:1). Disease progression was monitored and intestinal and systemic T cell differentiation was studied.

Results: Oral treatment of arthritic IL-1Ra$^{-/-}$ mice with scGoslcFos significantly suppressed the progression of arthritis. Furthermore, dual-energy X-ray absorptiometry scanning revealed that a prebiotic diet containing scGoslcFos significantly improved bone mineral density and tended to increase bone mineral content in arthritic IL-1Ra$^{-/-}$mice.

Gene expression of T-bet and RORγt, the Th1 and Th17-related transcription factors, in lymph nodes draining the arthritic joints was significantly reduced in the group receiving the scGoslcFos diet. Flow cytometry analysis of the lymph nodes showed no effect on the percentages of Th1, Th17 and regulatory T cells (Tregs). However, the percentage of CD3$^+$CD4$^+$ IL-4 producing cells tended to be increased in the scGoslcFos treated group.

Interestingly, small intestine lamina propria of mice receiving scGoslcFos diet contained increased percentages of CD3$^+$CD4$^+$ FoxP3$^+$regulatory T cells. In addition, intestinal gene expression of the Treg-related transcription factor FoxP3 as well as anti-inflammatory cytokine IL-10 were increased with scGoslcFos. Accordingly, small intestine lamina propria lymphocytes of mice receiving the 5% scGoslcFos diet produced significant higher levels of IL-10 upon ex vivo stimulation with PMA and ionomycin. Production of IL-4 and IFNγ also tended to be increased, while production of TNFα, IL-6 and IL-17 was not affected by the prebiotic diet.

Conclusion: Our data suggest that scGoslcFos suppresses arthritis progression, potentially through induction of anti-inflammatory cytokines such as IL-10 and IL-4. Suppression of disease progression using dietary intervention with prebiotic scGoslcFos may be applicable as a therapeutic approach to suppress autoimmune arthritis.

IL-22 Plays a Significant Role in the Initiation and Augmentation of Th17-Dependent Experimental Arthritis. Debbie M. Roeleveld[1], Renoud Marijnissen[2], Rebecca Rogier[1], Birgitte Walgreen[1], Monique M. Helsen[1], Liduine van den Bersselaar[1], Shahla Abdollahi-Roodsaz[1], Wim B. van den Berg[1] and Marije I. Koenders[1]. [1]Radboud university medical center, Nijmegen, Netherlands, [2]Radboud University Medical Center, Nijmegen, Netherlands.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, inflammatory autoimmune disease that leads to progressive destruction of cartilage and bone. IL-22 and IL-22-producing T helper cells are elevated in RA patients, suggesting a role for this cytokine in the pathogenesis of this disease. Interestingly, IL-22 is a dual cytokine with both proinflammatory and anti-inflammatory properties, and therefore its exact role in RA pathology requires further investigation.

The aim of this study was to elucidate the role of IL-22 in the initiation and severity of a spontaneous model of experimental arthritis by using gene knockout mice and neutralizing antibodies for IL-22.

Methods: IL-1Ra-deficient mice develop spontaneous arthritis due to excess IL-1 signaling, and we previously demonstrated the importance of IL-17 and Th17 cells in this model (Koenders, Arthritis Rheum 2008). To investigate the role of IL-22 in this Th17-dependent arthritis model, we compared IL-1Ra$^{-/-}$ − IL-22$^{+/+}$ mice to mice lacking both IL-1Ra and IL-22. Paw joint swelling was scored weekly, and mice were sacrificed at the age of fifteen weeks. In addition, IL-1Ra-deficient mice were treated for 4 weeks with anti-IL-22 neutralizing antibodies administered after onset of arthritis to inhibit disease progression.

Results: Mice deficient for IL-1Ra and IL-22 showed reduced arthritis development, reaching a disease incidence of only 54% compared to an incidence of 93% in IL-1Ra$^{-/-}$ − IL-22$^{+/+}$ mice. In addition, macroscopically scored joint swelling (scale 0 to 4) of mice that did develop arthritis was significantly reduced from 1,83 for the IL-22$^{+/+}$ mice, to 1,27 for the IL-22-deficient mice. The reduction of inflammation was confirmed by histological analysis, that also showed protection against cartilage damage. Furthermore, significantly reduced bone damage was observed in IL-22 deficient mice as determined by X-ray analysis. Finally, IL-1Ra-deficient mice treated with anti-IL-22 antibodies after the clinical onset of arthritis showed reduced progression on inflammation and significant inhibition on bone erosion. This indicates that not only the onset but also the progression of arthritis in this Th17-driven arthritis model is dependent on IL-22.

Conclusion: These findings suggest that the Th17 cytokine IL-22 plays an important role both in the initiation and augmentation of Th17-dependent experimental arthritis, and might therefore be an interesting new target in RA treatment.

T–cell Tolerance Induction By the Glycosylated Type II Collagen Peptide-Based Vaccination in Murine Arthritis. Vilma Urbonaviciute[1], Changrong Ge[1], Bingze Xu[1], Susanne van den Berg[1], Balik Dzhambazov[2], Johan Bäcklund[1] and Rikard Holmdahl[1]. [1]Karolinska Institute, Stockholm, Sweden, [2]Plovdiv University, Plovdiv, Bulgaria.

Background/Purpose: Type II collagen (CII) has been suggested as a possible autoantigen in RA, since autoimmunity to CII is commonly detected in patients with RA. Also a RA-like disease, collagen-induced arthritis (CIA) can be induced in rodents expressing H-2Aq and H-2Ar MHC class II haplotypes after immunization with heterologous CII. Autoreactive T cells in both RA and CIA recognize the same immunodominant CII epitope 259–273, which binds both CIA-associated mouse H-2Aq and human RA-associated HLA-DRB1 MHC class II molecules. CII-reactive T cells from RA patients predominantly recognize the immunodominant CII 259–273 epitope when it is glycosylated at positions 264 and 270. Glycosylation of the lysine side chain at position 264 is of particular importance for CIA development as well as for tolerance induction to CII. It has been previously shown in our laboratory that administration of soluble MHC class II molecules in complex with the glycosylated CII peptide 259–273 (GalOK264/Aq) can prevent CIA development and ameliorate chronic relapsing disease, which can be relevant for patients with RA. However, the exact mechanism of tolerance induction by GalOK264/Aq complexes remains to be elucidated.

Methods: We established Vb12-transgenic mouse model, which have galactosylated CII epitope specific T cells and the corresponding clonotypic antibody to track them unambiguously. By immune-phenotyping of galactosylated CII epitope specific T cells we investigated the role of CII-reactive T cells in tolerance induced by vaccination with GalOK264/Aq complexes.

Vb12-tg mice were immunized with rat CII emulsified in CFA. 100 mg of GalOK264/Aq complexes or PBS were injected intravenously day 3 post-immunization. Day 10 post-immunization T cells from draining (inguinal) lymph nodes were either directly analyzed by FACS or restimulated in vitro with galactosylated CII peptide and the numbers of cytokine-expressing T cells were determined by FACS or ELISPOT and cytokine concentrations in cell culture supernatants were evaluated by ELISA.

Results: Injection of Vβ12 transgenic mice with GalOK264/Aq complexes leads to reduction in number of the galactosylated CII-specific T cells. Also the proportion of T cells expressing CD69, an early activation marker, within galactosylated CII specific T cell population, was reduced in vaccinated mice compared to PBS controls. Further phenotypic analysis of galactosylated CII-specific T cells revealed that vaccination with GalOK264/Aq of Vβ12 transgenic mice leads to an increased expression of the co-inhibitory molecules such as PD-1 and LAG3.

Furthermore, administration of Aq/gal-K264 complexes significantly attenuates Th1 and Th17 responses in galactosylated CII specific T cells both in and Vβ12-transgenic- and B6NQ mice.

Conclusion: Thus, vaccination with GalOK264/Aq complexes skews the CII specific T cell responses from activation and differentiation into effector cells toward antigen specific immune tolerance phenotype.

Immune Related Adverse Events Associated with Anti-CTLA-4 Antibodies: Systematic Review and Meta-Analysis. Anne Bertrand, Marie Kostine, Thomas Barnetche and Thierry Schaeverbeke. Bordeaux University Hospital, Bordeaux, France.

Background/Purpose: CTLA-4 is a costimulatory molecule that downregulates T-cell activation and promotes an immunotolerance, well known by rheumatologist since the use of Abatacept. Targeting CTLA-4 is a recent strategic approach in cancer control: blocking CTLA-4 enhances an antitumor immunity by promoting T-cell activation and cytotoxic T-lymphocytes proliferation. This induction of a tolerance break against the tumor may be responsible for immune related adverse events (irAEs) in most responder patients, some of which concerning rheumatologists.

Objective

To assess the incidence and nature of irAEs in oncologic treatment with anti-CTLA-4 antibodies (Ipilimumab and Tremelimumab).

Methods: A systematic search of literature up to February 2014 was performed in MEDLINE, EMBASE and Cochrane databases to identify relevant articles. Reading and data extraction were performed independently by two readers. Pooled incidence was calculated using R software with the package meta. Heterogeneity was quantified using I^2.

Results: The literature search identified 491 articles and a manual search retrieved 4 other articles. Finally, 121 articles were full-text reviewed and 80 finally included in the study. 1265 patients from clinical trials were included for meta-analysis.

Anti-CTLA-4 antibodies were mainly given for melanoma, and in few studies for renal cell carcinoma, mesothelioma and pancreatic, gastric, oesophagal, colorectal, prostatic and bladder cancer.

Described irAEs consisted of skin lesions such as rash, pruritus and vitiligo, colitis, and less frequently inflammatory hepatitis, hypophysitis, thyroiditis and some rare events such as sarcoidosis, uveitis, Guillain-Barré syndrome, immune-mediated thrombocytopenia, auto immune inflammatory myopathy and polyarthritis.

The overall incidence of all-grade irAEs was 72% (CI95%: 61%–83%). The overall incidence of high-grade irAEs was 24% (CI95%: 18%–30%).

The risk of developing irAEs was dependent of dosage with incidence of all-grade irAEs being evaluated to 61% (CI95%: 56%–66%) for Ipilimumab 3mg/kg and 78,5% (CI95%: 65%–72%) for Ipilimumab 10 mg/kg.

Death due to irAEs occurred in less than 1% of patients (colic bowel perforation).

The median time of onset of irAEs was about nine weeks (IQR: 6–12) after the onset of treatment, corresponding with the first three cycles but varies according to the organ system involved.

Such immune activation could also be indicative for tumor-specific T-cell activation, and irAEs occurrence was associated with clinical response to CTLA-4 blocking: 61% of the patients presenting with irAEs experience a clinical remission (partial or complete), or at least a stabilisation of the cancer.

Conclusion: The price of potential long-term survival to metastatic tumors (such as melanoma) is atypical immune toxicity, reflecting the immune mechanism of action of anti-CTLA-4 antibodies. Rheumatologists will be involved in care of some irAEs such as arthralgia or polymyalgia rheumatica/giant cell arteritis, as recently published. A better knowledge of these irAEs and its management in a multidisciplinary approach will help to reduce morbidity and therapy interruptions.

Disclosure: A. Bertrand, None; **M. Kostine**, None; **T. Barnetche**, None; **T. Schaeverbeke**, None.

1737

Altered Phenotype and Function of Senescent Regulatory T Cells in Rheumatoid Arthritis. Johannes Fessler, Chrsitine Schwarz, Anja C. Ficjan, Rusmir Husic, Evelyne Höller, Angelika Lackner, Winfried B. Graninger and Christian Dejaco. Medical University Graz, Graz, Austria.

Background/Purpose: Immunosenescence accompanied by accumulation of senescent T cells is a hallmark feature in the pathogenesis of rheumatoid arthritis (RA). Here we characterize a novel senescent regulatory T cell (Tregs, $CD4^+CD28^-FoxP3^+$) subset in RA patients.

Methods: Prospective, cross-sectional study on 35 patients with RA [mean age 58 ($\pm$SD 9.5), 71.4% female, SDAI 8.15 ($\pm$1.2)] and 25 healthy controls [HC, mean age 56.4 ($\pm$6.7), 60% female]. We used flow cytometry to determine the prevalence of senescent $CD4^+CD28^-FoxP3^+$ T cells and to characterize their phenotype, proliferation, cytokine production and apoptosis. T cell receptor diversity was determined by RT-PCR. *In vitro* generation of senescent Tregs was performed in cell culture experiments using magnetic bead isolated $CD4^+CD25^+CD127^{low}$Tregs and stimulation with anti-CD3/CD28 beads, interleukin (IL) -2 with or without TNF-α (100ng/ml) for 14 days.

Results: Two percent [$\pm$2.8] of $CD4^+$ T cells were $CD28^-FoxP3^+$ in RA patients whereas this subset was almost absent in HC [0.6 ($\pm$0.8), p=0.077]. The number of $CD4^+CD28^+FoxP3^+$ Tregs was comparable in both groups [28.6 ($\pm$18.5) vs. 32.7 ($\pm$18), p=0.480]. *In vitro* assays showed that exposure of $CD4^+CD28^+$ Tregs to TNF-α led to a downregulation of CD28 and thus to the $CD28^-FoxP3^+$ phenotype.

Surface receptor expression analysis of $CD28^-FoxP3^+$ and $CD28^+FoxP3^+$ Tregs demonstrated that $CD28^-FoxP3^+$ cells expressed higher levels of the regulatory protein PD-1 [17.45% (0–36.4) vs. 5.45% (1.8–13.5), p=0.034], whereas CTLA-4 expression was similar in both subsets. Production of various cytokines including IL-2, IL-4, IL-10, IL-17, TNF-α and IFN-γ was increased in $CD28^-FoxP3^+$ compared to $CD28^+FoxP3^+$ Tregs [all p<0.05] whereas proliferation rate was lower than in the $CD28^+$ counterparts [50% (0–93.6) non proliferating cells vs. 4.6% (0–30.6), p=0.001]. In contrast, apoptosis induction was higher in $CD28^-FoxP3^+$ than in $CD28^-FoxP3^+$ Tregs [22.1% (0–30.8) vs. 4.4% (0–7.8), p<0.001]. TCR diversity was also reduced in $CD28^-FoxP3^+$ Tregs compared to their $CD28^+$ counterparts [median TCR diversity score: 84 (36–104) vs. 115 (109–125), p=0.037].

Conclusion: We discovered a novel T cell subset which combines both senescent as well as regulatory properties. This subset favors the proinflammatory milieu and shows altered phenotype and function compared to normal (non-senescent) Tregs.

Prominent Role of CCR6+ T Helper Cells in the Pathogenesis of ACPA+ Patients with Early RA. Sandra M.J. Paulissen[1], Jan Piet van Hamburg[2], Nadine Davelaar[2], Heleen Vroman[2], Johanna MW Hazes[3], P.H.P. de Jong[4] and Erik Lubberts[2]. [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Erasmus MC, University Medical Center, Rotterdam, Netherlands, [3]Erasmus MC University Medical Center Rotterdam, Rotterdam, Netherlands, [4]Erasmus University Medical Center, Rotterdam, Netherlands.

Background/Purpose: Presence of serum anti-citrullinated protein antibodies (ACPAs) in patients with rheumatoid arthritis (RA) predicts worse disease course and a more erosive disease. In the pathogenesis of RA, inflammatory T cells play a central role. In this context, we recently found increased proportions of pathogenic peripheral CCR6+ memory T helper cells in patients with early RA compared to healthy individuals. However, it is unclear how T cell proportions are distributed between ACPA+ and ACPA- patients. Therefore alterations in peripheral T cell populations and their pathogenic potential were examined in ACPA+ and ACPA- patient groups.

Methods: A nested matched case control study was performed including n=27 ACPA+ and n=27 ACPA- patients with early RA. T cell profiles (Treg, Th1, Th2, Th17, Th22 and various less well classified populations) from these ACPA+ and ACPA- patients were generated based on chemokine receptor, cytokine and transcription factor expression. Differentially present T cell populations were isolated from peripheral blood and analyzed for their pathologic potential in a co-culture system with RA derived synovial fibroblasts (RASF).

Results: In comparison to ACPA- patients, ACPA+ patients have higher proportions of regulatory T cells (Treg) and CD4+ memory CCR6+ T cells. Since the CCR6+ T cell population is still a heterogeneous population, four

CCR6+ T cell subpopulations were distinguished by differential expression of CXCR3 and CCR4. All four CCR6+ subpopulations shared Th17 cell characteristics such as Rorγt and CCL20 expression, but IL-17A, IL-17F, IL-22 and IFN-γ expression differed greatly between these subpopulations. However, even the population with lowest expression of these cytokines showed high pathological potential as shown by stimulating IL-1β, IL-6, IL-8, COX-2 and MMP-3 expression upon co-culture with RASF. Indeed, despite dissimilar Th17 and Th1 characteristics between the CCR6+ subpopulations, all four showed highly increased pathological potential in co-culture compared to naive and T-helper-1 cells.

Conclusion: ACPA+ and ACPA- patients can be distinguished by the distribution of Treg and CCR6+ T helper cell subpopulations. These CCR6+ subpopulations exhibit dissimilar T-helper-17 and T-helper-1 characteristics, but all possess high pathological potential, including the population that has low IL-17A/F and IL-22 expression. These findings indicate a prominent role of CCR6+ T helper cells in the pathogenesis of ACPA+ patients with early RA and may contribute to the worse disease outcome in ACPA+ patients.

Immunomodulatory Properties of CD271+ and CD271- Synovial Mesenchymal Cells. Alicia Usategui[1], Manuel J. Del Rey[1], Regina Faré[1], Gabriel Criado[1], Vanessa Miranda[1], Juan D. Cañete[2] and Jose L. Pablos[1]. [1]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain, [2]Hospital Clínic of Barcelona, Barcelona, Spain.

Background/Purpose: Mesenchymal stem cells (MSC) have been isolated from synovium and represent a fraction of synovial fibroblast (SF) cultures. CD271+ is considered a MSC surface marker that is also present in a small fraction of primary cultures of SF. Bone marrow or synovial derived CD271+ cells have shown increased chondrogenic potential but their immunosuppressive properties have not been analyzed. We have analyzed the immunosuppressive potential of CD271+ compared to CD271- primary SF cultures from human osteoarthritic synovial tissues.

Methods: Osteoarthritic synovial membranes were obtained at knee joint replacement surgery (n=9). CD271+/− separation was carried out by magnetic sorting of passage 0 SF cultures and confirmed by flow cytometry. Multipotent differentiation capability of SF to adipocytes, chondroblasts and osteoclasts was studied using standard *in vitro* tissue culture-differentiating conditions and staining with oil red, alcian blue or alizarin red, respectively. Immunomodulatory properties of CD271+/− sorted cells were analyzed in co-cultures with T lymphocytes obtained from healthy donors (ratio 1:10), stimulated with anti-CD3/CD28 beads. T-cell proliferation was measured by CellVue dye dilution as detected by flow cytometry. T-cell cytokine production (IL-2, IL-10, IL-17 and IFN-γ) in supernatants was quantified by ELISA. Quantitative data were analyzed by Mann Whitney or one-sample t-test.

Results: Primary passage 0 OA SF cultures contained (11.27±7.25%) CD271+ cells. After sorting, both CD271+ and CD271- SF cultures contained multipotential MSC capacity to differentiate to adipocytes, chondroblasts and osteoclasts in specific differentiation media. Both types of cells significantly inhibited the proliferation of anti-CD3/CD28 stimulated T cells and there were no quantitative differences between CD271+ and CD271- cells (70.46±6.56% and 73.53±13.15% respectively compared to single T-cell parallel cultures where proliferation was set to 100%). Co-culture of SF and T lymphocytes induced a significant increase in IL-2, IL-10, IL-17 and IFN-γ production by T cells that was similar in CD271+ and CD271- cells.

Conclusion: These data confirm that SF cultures contain a CD271+ cell fraction. Both CD271+ and CD271- SF cultures showed multipotential and immunomodulatory properties previously described as characteristic of MSC. T-cell anti-proliferative effect and non-specific up-regulation of T-cell cytokine production were similar in CD271+ and CD271- SF.

Predicting the Evolution of Inflammatory Arthritis in ACPA-Positive Individuals: Can T-Cell Subsets Model Help? Laura Hunt[1], Agata Burska[2], Elizabeth M.A. Hensor[1], Jackie L. Nam[1], Frederique Ponchel[1] and Paul Emery[1]. [1]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [2]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds., Leeds, United Kingdom.

Background/Purpose: ACPA+ individuals with non-specific musculoskeletal symptoms are at high risk of developing rheumatoid arthritis (RA). We previously demonstrated dys-regulation of T-cell subsets with loss of naïve and regulatory T-cells (Treg) in early RA. The aim of the current study is to demonstrate the predictive value of T-cell subset analysis for progression towards inflammatory arthritis (IA) onset in ACPA+ individuals.

Methods: 82 ACPA+ individuals without clinical synovitis at recruitment were followed. 120 healthy controls provided a reference group. T-cell subset analyses were performed using 6-colour flowcytometry for naïve T-cells (CD4+CD45RB+CD45RA+CD62L+), Treg (CD4+CD25^{high}Foxp3+CD127^{low}) and inflammation related cells (IRC: CD4+CD45RB+CD45RA+CD62L-). We calculated one-sided 95% reference ranges for each subset (age-related for naïve and Treg) and classified values as normal or abnormal accordingly. Using Cox proportional hazards regression we created a risk score; each subset's coefficient rounded to nearest 0.5, multiplied by 2, then a total score for each person was calculated. Risk categories were then derived based on the proportions of patients progressing at each score level.

Results: In this cohort 40/82 (49%) developed IA within a median follow-up of 6.4 months (range 1–52 months). Cox regression analysis (Table 1) allowed categorisation into moderate and high risk. Within the high risk group 78% (18/23) progressed to IA in a median of 8 months compared to 37% (22/59) within the moderate group (Table 2; Figure 1).

Conclusion: T-cell dys-regulation in ACPA+ individuals with non-specific musculoskeletal pain may be useful in predicting progression to IA. Further modelling will be needed to quantify the added clinical utility of T-cell subsets in predicting progression to IA.

Table 1: Sensitivity and specificity of T-cell subset frequencies for progression to IA; results of multivariable Cox regression and risk scores for each subset

	Cut-off	Sensitivity	Specificity	HR (95% CI)	Coefficient: score
Naïve	<LLN for age	30.0 (18.1, 45.4)	83.3 (69.4, 91.7)	1.6 (0.8, 3.3)	0.5:1
IRC	>4.56	32.5 (20.1, 48.0)	90.5 (77.9, 96.2)	2.4 (1.2, 4.6)	0.9:2
Treg	< LLN for age	45.0 (30.7, 60.2)	73.8 (58.9, 84.7)	1.6 (0.8, 2.9)	0.4:1

LLN=lower limit of normal (one-sided age-related 95% reference range)

Table 2: Proportions of people progressing to IA according to T-cell risk score; risk categories derived

T-cell risk score	% progressed to IA (n/N)	Risk category	Median (95% CI) months to IA
0	31% (10/32)	Moderate	50 (41, 58)
1	44% (12/27)		
2	73% (11/15)	High	8 (1, 16)
3	86% (6/7)		
4	100% (1/1)		

Figure 1: Kaplan-Meier survival plot showing cumulative survival for people at moderate or high risk of progression to IA

Anti-TNFα Treatment Increases IL-17A+ and IL-22+ T Cells in Spondyloarthritis Regardless of Concomittant Gut Inflammation. Thomas Andersen[1], René Østgård[2], Bent Deleuran[2], Malene Hvid[1] and Henning Glerup[3]. [1]Aarhus University, Aarhus, Denmark, [2]Aarhus University Hospital, Aarhus, Denmark, [3]Regional Hospital of Silkeborg, Silkeborg, Denmark.

Background/Purpose: The pro-inflammatory Th17 associated cytokines IL-17A and IL-22 have been proposed as important mediators of the inflammation seen in spondyloarthritis (SpA) and inflammatory bowel disease (IBD). A strong link between the development of SpA and IBD has been established, with Th17 cells as presumed pivotal players in the co-development of these inflammatory diseases. The aim of this study was to investigate differences in Th17 expression between SpA patients with subclinical gut inflammation, and SpA patients without gut inflammation. Further, changes in Th17 levels with anti-TNFα-therapy was investigated.

Methods: Thirty SpA patients with high (>100 mg/kg, n=15) and with normal (<50 mg/kg, n=15) fCal, and 14 healthy controls (HC) were included in this study. Patients with known psoriasis or IBD at the time of enrollment were excluded. All patients were eligible for anti-TNFα treatment, which was initiated at the day of enrolment in the study continuing for 52 weeks. During treatment mean BASDAI changed from 60 + 66 at baseline to 15 + 21 at 52 weeks. At baseline patients were clinically examined and all had a capsular endoscopy done and fCal was measured. Peripheral blood mononuclear cells (PBMCs) were isolated at baseline and at week 12, 20 and 52. Multicolour flow cytometry was performed in order to evaluate percentage of IL-17A, IL-22 and IL-23R expressing CD45RO T cells. Further, PBMCs were analysed for the expression of the Th17 defining chemokine receptor 6 (CCR6) and the gut-homing integrin complex alfa4-beta7.

Results: Similar percentages of IL-17A, IL-22 and CCR6 expressing CD45RO T cells between SpA patients with high or low faecal calprotectin were observed. No difference in the gut homing potential of the IL-17A and IL-22 expressing T cells in either of the SpA groups evaluated as CD3+CD4+CD45RO+ lymphocytes double positive for alfa4 and beta7, was observed.

Since no differences in the two groups were observed, they were merged and further evaluated as one. Percentages of IL-17A+ 2.0% (1.4% - 2.4%), IL-22+ 2.9% (2.0% - 4.2%) and CCR6+ 20% (14.4% - 24.3%) CD45RO T cells at baseline was elevated compared to HCs IL-17A 1.16% (0.8%- 1.5%), IL-22 1.7% (1.0% - 2.3%) CCR6 9.5% (7.7% - 15.7%), respectively.

Despite major clinical improvement in the treatment period, the percentage of IL-17A+ CD45RO T cells increased to 3.1% (2.0% - 4.8%), IL-22+ CD45RO T cells increased to 3.8% (2.5%- 5.3%) and CCR6+ CD45RO T cells increased to 24.1% (18.7% - 27.1%) after 52 weeks of anti-TNFα therapy. No change in the percentage of alfa4/beta7+ or IL-23R+ CD45RO T cells was observed at any time-point.

Conclusion: Anti-TNFα therapy improved clinical disease activity of the SpA patients substantially. Surprisingly, underlying inflammatory activity, in the form of Th17/22 cells persisted, even 1 year after initiation of anti-TNFα therapy. The persistently elevated levels of Th17 cells could be involved in the on-going disease progression seen in SpA patients even with clinically low, and well-controlled disease activity.

Depletion of Reactive Oxygen Species Biases T Cells to Proinflammatory Cytokine Production in Rheumatoid Arthritis. Zhen Yang[1], Eric L. Matteson[2], Jorg J. Goronzy[1] and Cornelia M. Weyand[1]. [1]Stanford University School of Medicine, Stanford, CA, [2]Mayo Clinic, Rochester, MN.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease, genetically associated with polymorphisms in HLA class II molecules. CD4 cells produce proinflammatory cytokines and orchestrate multiple disease-relevant functions in the inflamed joint. How threshold settings in intracellular signaling cascades in such CD4 T cells affect arthritogenic functions is insufficiently understood.

Reactive oxygen species (ROS) are classically considered harmful as they can cause oxidative stress. However, they also have critical cytoprotective functions by modulating cellular signal transduction. Intracellular ROS derive from mitochondria as a byproduct of metabolic activity. Cells possess a complex machinery for ROS removal, with the principal cellular reductant NADPH deriving from the pentose phosphate pathway (PPP), where glucose-6-phosphate dehydrogenase (G6PD) functions as the rate-limiting enzyme.

Methods: Naive CD4 T cells from patients with seropositive RA and age-matched controls were isolated and their T cell receptors were cross-linked. The following parameters were measured in resting and poststimulation T cells: ROS production, cell cycle progression and apoptotic susceptibility; commitment to the Th1, Th17, Th2 and Treg lineage. Expression of G6PD transcripts was quantified by RT-PCR. To attenuate intracellular ROS levels, cells were treated with the SOD mimetic Tempol. Synovial membrane biopsies were typed for HLA-DRB1*04 by RT-PCR. Mitochondrial mass was quantified by measuring copy numbers of mitochondrial DNA.

Results: Intracellular ROS in RA T cells were consistently decreased below 70% of those in controls ($p=0.01$). The ROS loss in RA T cells was associated with faster cell cycle progression ($p<0.001$), increased apoptotic susceptibility ($p=0.01$) and premature conversion of the naïve to memory phenotype ($p=0.05$). Treating T cells with the ROS scavenger Tempol could mimic this differentiation defect. RA T cells were prone to differentiate into IFN-γ and IL-17-producing cells, whereas the frequencies of IL-4-producing and FoxP3-expressing cells were indistinguishable in RA and control cells. RA T cells had a reduced mitochondrial mass and their intracellular NADPH concentrations were increased ($p=0.04$). Further evidence for a more active PPP in RA T cells came from increased expression levels of G6PD ($p=0.03$). The reduction of mitochondrial mass was reproduced in synovial tissue biopsies, where HLA-DRB1*04+ patients expressed significantly reduced mitochondrial DNA ($p=0.05$).

Conclusion: Intracellular ROS levels in RA T cells are reduced, imposing reductive stress. ROS loss may result from reduced mitochondrial mass, but also from enhanced production of the reductant NADPH. ROS depletion fundamentally shifts the functional behavior of human T cells, enhancing their cell cycle progression and swaying their differentiation towards proinflammatory Th1 and Th17 cells. The data delineate a mechanistic connection between intracellular redox imbalance and athritogenic T cell functions, with the prospective of therapeutically influencing such T cell defects via restoration of ROS production.

Antigen-Specificity Regulates Peripheral Homeostasis of Regulatory T Cells. Laura Su[1] and Mark Davis[2]. [1]University of Pennsylvania, Philadelphia, PA, [2]Stanford, Stanford, CA.

Background/Purpose: One key mechanism of peripheral tolerance involves regulatory T cells (Tregs). Tregs are best known for the expression of the transcription factor Foxp3 that drives many Treg-specific gene expressions. Defects in Foxp3 expression result in severe autoimmunity, but an increased numbers of Tregs can also be pathologic and contributes to the evasion of tumor surveillance. Thus, the appropriate balance between regulatory and effector T cells is essential to maintain self-tolerance while preserving effective immunity. How antigen-recognition impacts Treg homeostasis is not known. The goal of this study is to characterize the peripheral Treg repertoire in healthy people in order to establish the foundation for evaluating Treg homeostatic dysregulation in rheumatoid arthritis and other autoimmune diseases.

Methods: Antigen-specific T cells were identified directly *ex vivo* using peptide-MHC (pMHC) tetramers. We selected self-peptides from gp100, citrullinated fibrinogen (cit-Fib), or preproinsulin (PPins) for their relevance in vitiligo, rheumatoid arthritis, and type I diabetes. Three foreign antigens from the influenza virus (HA, PB1, and PA) were selected for comparison. Tetramer staining was performed using blood from de-identified healthy blood donors, followed by staining for CD25, CD45RO, Foxp3, and Ki67 expression. Tetramer tagged cells were magnetically enriched and analyzed by flow cytometry. We also compared the frequency of antigen-specific Foxp3+ cells in adult blood versus the cord blood.

Results: We show vastly different Foxp3 expression between self antigen-specific T cells versus flu-reactive T cells. On average, 10% of autoantigen-specific T cells express Foxp3, whereas less than 1% of flu-reactive T cells specific for HA are Foxp3+. This difference is likely due to antigen exposure, because many more HA-specific T cells express Foxp3 in cells from the cord blood. Moreover, the robustness of the T cell response also determines Foxp3 expression. We examined

three distinct flu-reactive T cell populations and found that the frequency of Foxp3+ cells is highest in the least abundant PA-specific T cells, followed by PB1-specific T cells, and lowest in the most highly expanded and memory dominant HA-specific T cells. In contrast, antigen exposure increases Treg frequency in self-reactive T cell populations, and this correlates with an increase in cellular proliferation.

Conclusion: These data demonstrate that peripheral homeostasis between Tregs and conventional T cells are regulated by antigen-specificity. Contextual differences in ligand exposures alter this balance and this has significant implications for autoimmunity.

CD4+ T Cell Subpopulations in Blood and Synovial Fluid Defined By Differential Expression of Integrins. Deepak A. Rao[1], Adam Chicoine[2], Peter A. Nigrovic[3], Soumya Raychaudhuri[4], Michael B. Brenner[5] and ACR Authors 2014. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital/Harvard University, Cambridge, MA, [4]Manchester Academic Health Sciences Centre, Manchester, United Kingdom, [5]Brigham & Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: CD4+ T cells are important mediators of inflammation in rheumatoid arthritis; however, the specific CD4+ T cell populations most important in driving disease pathology remain unclear. CD4+ T cells are often divided into subsets based on effector functions (e.g. Th1, Th2, Th17). Here we describe an alternative strategy of defining T cell subpopulations in blood and synovial fluid based on differential expression of integrins and other migratory receptors that help cells localize to specific target tissues. Blockade of integrin-dependent migration is already employed clinically; therefore, understanding patterns of migratory receptor expression that allow infiltration into the joint and other target organs is of significant interest.

Methods: We developed multiparametric flow cytometry panels to characterize expression of integrins and other migratory receptors on blood and synovial fluid CD4+ T cells. Dimensional reduction was performed using Spanning tree Progression of Density normalized Events (SPADE) to identify CD4+ T cell subpopulations that express specific combinations of migratory receptors.

Results: More than half of circulating memory CD4+ T cells coordinately express α3, α5, and α6 integrins. α4 integrin is expressed on ~25–50% of circulating memory CD4+ T cells, but in a distinct pattern such that memory CD4+ T cells can be divided into 3 groups based on the differential expression of α4 and α6 integrin (α4+α6-, α4-α6+, α4+α6+). Both central memory and effector memory CD4+ T cell subsets contain these populations, while naïve T cells lack significant expression of either α chain. Interestingly, both CD4+CD25+CD127- regulatory T cells and CD4+ CLA+ 'skin-homing' cells fall predominantly within the α4-α6+ population. Both α4-α6+ and α4+α6+ cells co-express β1, while α4+α6- cells co-express β7 rather than β1. α4β7+ cells constitute ~10–20% of circulating memory CD4+ T cells; however, these cells are rare in inflammatory synovial fluid, in which almost all CD4+ T cells express β1. Small populations of circulating memory CD4+ cells also express α1, α2, αV, and αE integrins and CD146, with certain subsets substantially enriched in synovial fluid. SPADE analyses allowed for visual demonstration of cell subpopulations defined by migratory receptor expression.

Conclusion: Differential integrin expression identifies CD4+ T subpopulations in a manner non-redundant with traditional methods of classifying T cells. Specific integrin-defined memory CD4+ subpopulations are enriched in synovial fluid compared to blood, suggesting that certain integrins, in particular β1 integrins, may promote CD4+ T localization to the joint. Further characterization of integrin-defined T cell subpopulations that can infiltrate the joint may lend new insights into mechanisms of synovial inflammation.

1745

Memory Stem T Cells Are Selectively Enriched in Patients with Rheumatoid Arthritis, Contract upon Anti-TNF Treatment, and May Provide a Long-Term Reservoir of Arthritogenic Lymphocytes. Nicoletta Cieri[1], Giacomo Oliveira[1], Raffaella Greco[2], Mattia Baldini[3], Elena Baldissera[3], Fabio Ciceri[2] and Chiara Bonini[1]. [1]Experimental Hematology Unit, San Raffaele Scientific Institute, Milan, Italy, [2]Hematology and Bone Marrow Transplantation Unit, San Raffaele Scientific Institute, Milan, Italy, [3]Clinical immunopathology and advanced medical therapeutics, San Raffaele Scientific Institute, Milan, Italy.

Background/Purpose: The T-cell memory compartment is multi-faceted and encompasses multiple subsets with divergent properties. In addition to central memory (T_{CM}) and effector memory (T_{EM}) cells, the spectrum of immunological memory has been recently extended with the identification of memory stem T cells (T_{SCM}). Gene expression profiling, corroborated by *in vitro* and *in vivo* experimental results, posits T_{SCM} upstream T_{CM} and T_{EM} in T-cell ontology (Gattinoni, Nat Med 2011; Cieri, Blood 2013). While self-renewing T_{SCM} would be highly desirable if bearing protective specificities, this very same cell subpopulation may also represent a foe when considering T-cell mediated pathologies. We hypothesized that, in these clinically relevant contexts, T_{SCM} may represent a reservoir of long-lived T cells with undesired and detrimental specificities responsible for disease perpetuation.

Methods: we characterized T_{SCM} dynamics in 15 patients with active rheumatoid arthritis (RA) and upon treatment with etanercept (median time from anti-TNF treatment onset: 3 months). T-cell subset composition and function was evaluated by 11-colors multiparametric flow cytometry.

Results: we found that T_{SCM} cells, defined as $CD45RA^+$-$CD62L^+CD95^+$, are significantly more represented in terms of frequencies and absolute counts in patients with active RA as compared to age- and sex-matched healthy controls. Of notice, the extent of T_{SCM} expansion correlated with disease severity (quantified by DAS28 score), suggesting an active role of T_{SCM} in disease pathophysiology. Functionally, expanded $CD4^+$ T_{SCM} displayed a preferential T_H17 polarization, known to have a fundamental pathogenic role in rheumatic synovitis, and thus further corroborating T_{SCM} lymphocytes as a potential novel player in RA pathogenesis and perpetuation. Importantly, TNF-a neutralization, upon etanercept administration, efficiently reduced the frequency and number of circulating T_{SCM} and restored T-cell homeostasis in responder patients. Prior to etanercept treatment, T_{SCM} lymphocytes expressed TNFR2 to significantly higher levels compared to the other T-cell subsets both in $CD4^+$ and $CD8^+$ compartments, suggesting that TNF-a might act as a costimulatory signal for T_{SCM} lymphocytes in the context of RA. Finally, ongoing experiments will elucidate whether T_{SCM} accumulation is due to the selective expansion of arthritogenic clones through the characterization of the TCR repertoire and antigen-specificities of T_{SCM} cells from RA patients.

Conclusion: Understanding the dynamic and quantitative aspects of T_{SCM} lymphocyte behavior in RA will have profound implications for devising strategies to counteract T-cell dysfunction in RA patients.

Involvement of IL-17-Producing MAIT Cells in the Pathogenesis of Rheumatoid Arthritis. Eri Hayashi, Asako Chiba, Mie Kitagaichi, Kurisu Tada, Ken Yamaji, Naoto Tamura, Yoshinari Takasaki and Sachiko Miyake. Juntendo University School of Medicine, Tokyo, Japan.

Background/Purpose: Mucosal-associated invariant T (MAIT) cells are a subset of innate-like lymphocytes which are restricted by the MHC-related molecule-1 (MR1) and express a semi-invariant TCRα chain: Vα7.2-Jα33 in humans and Vα19-Jα33 in mice. Previously, our group has reported that murine MAIT cells produced high levels of IL-17 and exacerbated arthritis by enhancing inflammatory responses by using animal models of arthritis. Recent studies have revealed that MAIT cells are abundant in humans. MAIT cells constitute about 5–10% of abT cells in peripheral blood and intestine, suggesting that MAIT cells may play important roles in human autoimmune diseases. In this study, we aimed to investigate whether MAIT cells are involved in the pathogenesis of rheumatoid arthritis (RA).

Methods: Peripheral blood mononuclear cells(PBMC) of RA patients and

age- and sex- matched healthy subjects were separated by Lymphoprep. PBMC were stained with anti-human monoclonal antibodies against CD3, γδTCR, Vα7.2TCR, and CD161, and MAIT cells were identified as $CD3^+\gamma\delta TCR^-V\alpha7.2TCR^+CD161^{high}$ cells by FACS. The expression of HLA-DR and CCR9 on MAIT cells and other T cell subsets were also assessed. PBMC (2×10^6 cells per well in 96-well culture plates) were stimulated with phorbol-myristate-acetate (50ng/ml) and ionomycin (500ng/ml) for 3 hours. Breferdin A was added in the last 2 hours of culture. After surface staining, cells were permeabilized by using BD Cytofix/Cytoperm Fixation/Permeabilization Solution Kit and intracellular cytokine staining for IL-17A, IFNγ, TNFα and IL-6 was performed. Cells were analyzed on FACS LSR Fortessa with Flowjo softwere.

Results: The percentages of MAIT cells were decreased in RA patients compared with healthy controls. The reduction in MAIT cell frequency was more enhanced in RA patients with active disease. There was a tendency of increased HLA-DR expression on MAIT cells from patients with lower MAIT cell frequencies. MAIT cells produced IL-17A, IFNγ, TNFα and IL-6 upon stimulation, and the frequency of IL-17A-producing MAIT cells was inversely correlated with that of MAIT cells in RA. However, there was no correlation with the frequencies of IFNγ-, TNFα- or IL-6- producing cells and that of MAIT cells. We also found the negative correlations in the frequency of a gut-homing chemokine receptor CCR9-positive MAIT cells with that of MAIT cells in RA.

Conclusion: We demonstrated that the frequency of MAIT cells was reduced in RA. The elevated expression of HLA-DR and IL-17 production by MAIT cells indicated the activated state of remaining MAIT cells in RA. The increase of CCR9-positive MAIT cells indicates the recruitment of gut MAIT cells to the peripheral blood in RA.

$CCR6^+CD4^+$ Cells Are Counterparts of Follicular T-Cells Supporting Autoantibody Production in Rheumatoid Arthritis. Karin ME Andersson[1], Dan Hu[2], Ron Cialic[2], Nicola Cavallini[3], Vijay K. Kuchroo[4], Malin Erlandsson[1], Howard Lee Weiner[2] and Maria Bokarewa[5]. [1]University of Gothenburg, Gothenburg, Sweden, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]University of Göteborg, Göteborg, Sweden, [4]Brigham and Women's Hospital, Boston, MA, [5]University of Goteborg, Goteborg, Sweden.

Background/Purpose: CCR6 has been associated with rheumatoid arthritis (RA) in genome-wide association studies. CCR6 expression characterises Th17 cells recruited to inflamed joints of RA patients. The purpose of this study was to characterize gene transcription in the peripheral lymphocytes in RA patients.

Methods: $CCR6^+CD4^+$ cells were isolated from peripheral blood leukocytes of 14 RA patients and 6 healthy controls by magnetic beads. The isolated cells consisted of 85% $CCR6^+CXCR3^-$cells and had a viability of 94%. Cells were stimulated with PMA/ionomycine for 4h, supernatants were collected for cytokine analysis and cell pellets were used for gene expression analysis using nCounter Analysis System (NanoString Technologies).

Results: Transcription analysis showed that 140 genes had significant ($p<0.05$) ≥1.5-folds difference between $CCR6^+CD4^+$ cells of RA patients and healthy controls. As expected, RA patients $CCR6^+CD4^+$ cells were also $CCR5^-CXCR3^-$. Despite the intense immunosuppression with methotrexate and TNF-inhibitors, RA lymphocytes had had higher transcription of Th17 cytokines (IL17F, IL17A, IL22). Also Th17 (Rorc) and Th1 (Tbx21 and Egr-2) differentiation genes were enhanced, while other genes regulating IL-22 production (Ahr and NFAT1) were repressed. Genes controlling the formation of Th17(Beta) and Th17(23) subtypes were increased, and inhibitors of this formation were repressed. Transcription of IL23 receptor complex genes (IL23R, Jak2, *e.g.*) was up-regulated and production of IL23A and CCL20 was increased.

RA lymphocytes had a significant increase in the follicular T helper cell profile, characterized by the surface markers CXCR5 and ICOS, and the master transcription regulator Bcl-6. CXCR5 expression was combined with higher CCR6 and lower CXCR3. The enrichment of $CXCR5^+CCR6^+CXCR3^-$ phenotype was supported by expression of cytokine IL21. The cytokines activating the gp130-receptor family (IL31, IL35 and Lif), were increased. Interestingly, gp130-associated signalling in the CCR6+CD4+ cells was dampened by low IL27R, low STAT signal (reduced STAT1, STAT3, STAT4) and low transcriptional regulator AhR, suggesting that the gp130 activation occurs on a cell populations different from the studied, *e.g.* B-cells.

Conclusion: This study demonstrates that $CCR6^+CD4^+$ T cells of RA patients have features of proliferative, proinflammatory and IL17 producing cells controlled through TGFb and IL23 mediated signalling. $CCR6^+CD4^+$ T cells are a source of $CXCR5^+$ Tfh cells efficient producers of IL21 cytokine presumably stimulating autoantibody production in RA patients.

Molecular Mechanisms Underlying $1,25(OH)_2D_3$-Mediated Suppression of Th17 Cell Activity. Wendy Dankers[1], Jan Piet van Hamburg[1], Wida Razawy[1], Nadine Davelaar[1], Anne-Marie Mus[1], Patrick Asmawidjaja[1], Johannes van Leeuwen[1], Edgar Colin[2] and Erik Lubberts[1]. [1]Erasmus MC, University Medical Center, Rotterdam, Netherlands, [2]ZGT, Almelo, Netherlands.

Background/Purpose: Vitamin D has suppressive effects on autoimmune diseases, such as rheumatoid arthritis (RA). Within these diseases, Th17 cells play a crucial role in the processes underlying chronic inflammation. Currently, Th17 cells are of high interest in the development of novel therapeutics, such as the development of antibodies against IL-17A or specific small molecule inhibitors of RORγt, the Th17 cell associated transcription factor.

Previously we have shown that the active vitamin D metabolite $1,25(OH)_2D_3$is capable of directly inhibiting the polarization and pathogenic activity of Th17 cells. However the molecular mechanisms underlying this modulation of Th17 cell activity by vitamin D are currently unclear.

Methods: Therefore $CD4^+CD45RO^+$ (memory) and $CCR6^+$ memory T-helper cells were sorted from peripheral blood of patients with early RA and healthy volunteers. They were cultured under in the presence or absence of $1,25(OH)_2D_3$. The expression of cytokines and transcription factors of interest was analyzed using microarray based gene expression profiling, flow cytometry, ELISA and/or RT-PCR.

Results: In the presence of $1,25(OH)_2D_3$ the pro-inflammatory cytokines IL-17A, IL-17F and IL-22 were inhibited. Also the expression of Th17 signature genes like RORγt and IL-23R was reduced. On the other hand we find an increase in IL-4 and IL-10 expression.

Interestingly neutralization of IL-4 partly reversed the effect of $1,25(OH)_2D_3$ on the inhibition of IL-17A, IL22 and RORγt expression. In addition, the inhibition of IL-17F by $1,25(OH)_2D_3$ was almost completely absent when IL-4 was blocked.

In contrast to IL-4, IL-10 neutralization had limited effects in these cultures.

Because the effect of $1,25(OH)_2D_3$ is only partially dependent on IL-4, we examined factors that could play a role independent of IL-4. Gene expression profiling revealed that two transcription factors that are known to play a role in Th17 differentiation, EOMES and IRF8, are up regulated by $1,25(OH)_2D_3$. EOMES and IRF8 are direct regulators of RORγt expression. Blocking IL-4 does not affect this up regulation, indicating that EOMES and IRF8 might be important in the IL-4 independent regulating of Th17 polarization by $1,25(OH)_2D_3$.

Conclusion: From these findings, we conclude that $1,25(OH)_2D_3$ is a direct modulator of Th17 cell activity. This modulation is partly dependent on up regulation of IL-4. IL-4 independent mechanisms may include the down-regulation of RORγt expression via up regulation of IRF8 and EOMES.

The Effect of a Pro-Inflammatory Milieu on Tregalizumab (BT-061)-Induced Regulatory T-Cell Activity. Jan Kubach[1], Faiza Rharbaoui[2], Martin Koenig[2], Jörg Schüttrumpf[2], Silke Aigner[2], Benjamin Dälken[2] and Helmut Jonuleit[1]. [1]University of Mainz Medical Center, Mainz, Germany, [2]Biotest AG, Dreieich, Germany.

Background/Purpose: Regulatory T cells (Tregs) are essential for maintaining normal immune homeostasis. We have previously reported that tregalizumab is a humanized, non-depleting, CD4 agonistic antibody that selectively activates Tregs. The specific functionality of tregalizumab may originate from the recognition of a unique epitope on domain 2 of CD4 that is not recognized by other anti-CD4 monoclonal antibodies. Tregalizumab is in clinical development for the treatment of rheumatoid arthritis (RA). Currently, a Phase IIb trial -*TREAT 2b*- is in progress to further evaluate the efficacy and safety of tregalizumab and define the optimal dose in combination with methotrexate (MTX) in adults with RA and an inadequate response to MTX.

Recent data have shown that pro-inflammatory cytokines may have a profound negative effect on the suppressive properties of Tregs or on the responsiveness of effector cells to suppression. Serum cytokine levels for RA patients have been reported in the range of: IL 1β: 0–0.269 ng/mL; IL-6: 0–1.078 ng/mL; TNFα: 0.001–2.952 ng/mL (Meyer et al., 2010). Therefore, we performed *in vitro* studies to investigate the effects of pro-inflammatory cytokines on the ability of tregalizumab to activate Treg suppressive activity.

Methods: Allogenic effector T cells (Teffs) isolated from healthy volunteers were co-cultured with freshly isolated Tregs and APCs from a different blood donor (mixed lymphocyte reaction, MLR) in the presence of different concentrations of cytokines as previously described by Trinschek *et al.*(2013). Cell proliferation was measured by incorporation of radioactive thymidine. Suppression was derived by the ratio of the radioactive count obtained in the co-culture in presence of Treg versus no Treg. At least 3 independent experiments were performed at different days using cells isolated from different blood donors.

Results: In the absence of cytokine, activation of Tregs with tregalizumab resulted in strong suppression of Teff proliferation, on average at least 50% reduction of cell proliferation was measured with tregalizumab at 1 μg/mL. In presence of pro-inflammatory cytokines, little effects were observed. At the concentrations tested, corresponding to levels rarely measured in plasma from RA patients (up to 2000 ng/mL of IL-1β and 500 ng/mL of IL-6), neither IL-1β nor IL-6 inhibited tregalizumab-induced suppression of Teff proliferation. In case of TNFα, only the highest concentrations tested (50 and 100 ng/mL) had a marginal effect on tregalizumab-induced suppression.

Conclusion: In this *in vitro* study, activation of Tregs by tregalizumab and the suppression of Teffs was not notably inhibited by pro-inflammatory cytokines, only moderately by TNFα at very high concentration. This result gives further insights into the potential of tregalizumab to activate Tregs in the presence of systemic levels of pro-inflammatory cytokines that are elevated in autoimmune diseases such as RA. Further *in vitro* investigations are in progress to determine if the observed moderate effect of TNFα is the result of a reduction of Treg suppressive activity or an increased Teff-resistance to Treg suppression. In similar experimental conditions, effects of MTX or prednisolone will also be assessed.

CD4 Aptamer-RORγt shRNA Chimera Inhibits IL-17 Synthesis By Human CD4$^+$ T cells. Cong-Qiu Chu[1], Pingfang Song[2], Yuan K. Chou[2], Xiaowei Zhang[2], Roberto Meza-Romero[2], Kentaro Yomogida[2] and Gil Benedek[2]. [1]Oregon Health & Science Univ, Portland, OR, [2]Oregon Health & Science University, Portland, OR.

Background/Purpose: RNA interfering (RNAi)-mediated gene silencing holds great promise for manipulating T cells to study basic T cell biology and for developing potential T cell targeted therapeutics. However, efficient delivery of small interfering RNA (siRNA) specifically into primary T cells represents a major hurdle to the widely use of RNAi technology. We explored the use of single-stranded oligonucleotide aptamers as vehicle to deliver small hairpin RNA (shRNA) to target Th17 cells.

Methods: An RNA aptamer specifically binds to CD4 was previously selected and sequenced. siRNA to retinoic acid related orphan receptor (ROR)-γt was previously designed and tested. A cDNA encoding the CD4 aptamer and RORγt shRNA was constructed and the CD4 aptamer-RORγt shRNA (CD4-AshR-RORγt) chimera was generated using *in vitro* T7 RNA transcription. 2′-F-dCTP and 2′-F-dUTP were incorporated into CD4-AshR-RORγt for RNase resistance. CD4$^+$ human T lymphoma cells, Karpas 299 constitutively expressing RORγt were tested for CD4-AshR-RORγt internalization. Human CD4$^+$ T cells were polarized to Th17 cells for analysis of CD4-AshR-RORγt delivery efficiency and suppression of RORγt expression and IL-17 production.

Results: The CD4 aptamer and RORγt shRNA was transcribed to form a stable single chimeric aptamer-shRNA molecule, CD4-AshR-RORγt. CD4-AshR-RORγt was labeled with flurochrome Cy3 via Cy3-CTP incorporation during RNA transcription. CD4-AshR-RORγt was specifically uptaken by CD4$^+$ Karpas 299 cells and primary human CD4$^+$ T cells as visualized by confocal microscopy and flow cytometry. The RORγt shRNA moiety of CD4-AshR-RORγt chimera was cleaved and released by endoribonuclease Dicer. CD4-AshR-RORγt suppressed RORγt gene expression in Karpas 299 cells and CD4$^+$ T cells in a dose dependent manner, but did not affect Tbox21 gene expression. Furthermore, 50–70% IL-17A production by CD4$^+$ T cells was inhibited by CD4-AshR-RORγt, but not by mock-CD4-AshR-RORγt or CD4-AshR-scrambled sequence.

Conclusion: The present data in our study revealed that CD4 aptamer can serve as a delivery vehicle for shRNA that targets a specific gene in CD4$^+$ human T cells. CD4-AshR-RORγt specifically silenced the targeted RORγt gene expression and led to a marked decrease of Th17 differentiation and IL-17 production. CD4-AshR-RORγt can be evaluated for the development of a therapeutic agent in treatment of Th17 mediated inflammatory disorders.

1752

CD30 As a Target of Aptamers and Delivery Portal for Aptamer-shRNA to Block Th17 Cells. Cong-Qiu Chu[1], Pingfang Song[2], Yuan K. Chou[2] and Shao Tao[2]. [1]Oregon Health & Science Univ, Portland, OR, [2]Oregon Health & Science University, Portland, OR.

Background/Purpose: Aptamers are single-stranded 20 –100 nucleotides (RNA or DNA) that bind to molecular targets with high affinity and specificity due to their stable three dimensional shapes and were referred as "chemical antibodies". Aptamers are being investigated and developed as therapeutic agents and carriers for cell type specific delivery of drugs including small interfering RNA (siRNA). CD30 is expressed by activated Th17 cells a plays a critical role in Th17 cell differentiation.

Methods: Single stranded DNA (ssDNA) or RNA CD30 aptamers were synthesized. A chimera of RNA CD30 aptamer-small hairpin RNA (shRNA) against retinoic acid related orphan receptor (ROR)-γt (CD30-AshR-RORγt) was generated *in vitro* from a cDNA template by *in vitro* T7 RNA transcription. Human PBMC were stimulated with anti-CD3 and CD28 and polarized towards Th17 differentiation. CD30 aptamers or CD30-AshR-RORγt was incubated with the stimulated PBMC. ELISA and intracellular cytokine staining were used to quantify IL-17A production and Th17 cells.

Results: An ssDNA aptamer against CD30 was able to inhibit IL-17A production by anti-CD3/CD28 stimulated PBMCs in a dose dependent manner. The inhibitory effect of ssDNA CD30 aptamer was comparable to that by anti-CD30 antibody. CD30 RNA aptamer alone had a lesser inhibitory effect on IL-17A production but could enhance the effect of ssDNA CD30 aptamer. CD30-AshR-RORγt chimera was internalized by activated but not resting CD4$^+$ T cells. Compared with a CD30-AshR-scramble sequence, CD30-AshR-RORγt inhibited 60–70% of IL-17A production and IL-17A producing CD4$^+$ T cells.

Conclusion: CD30 Aptamers showed significant inhibitory effects on IL-17A production by human PBMCs. In addition being a target by CD30 aptamers, CD30 expressed by activated CD4$^+$ T cells can serve as a portal for aptamer mediated delivery of RNAi to target T cell genes. CD30 aptamers and CD30-AshR-RORγt chimera have the potential to be developed as a novel class of therapeutic agents to treat Th17 mediated inflammatory diseases.

Human T-Cells Express RANKL in Response to Combination of ZAP-70, Calcineurin and Voltage-Gated K+-Channel Signaling Following Co-Ligation of the Adhesion Molecule CD2 and the T-Cell Receptor Complex. Bohdan P. Harvey and Zehra Kaymakcalan. AbbVie Bioresearch Center, Worcester, MA.

Background/Purpose: Human T lymphocytes promote osteolysis in rheumatic diseases through the production of the osteoclastogenic cytokine RANKL. We have previously demonstrated that RANKL secretion is

mediated by the simultaneous engagement of the lymphocyte function-associated antigen 2 (CD2) and T-cell receptor (TCR/CD3). However, the cell signaling events involved in its expression and release from T-cells are poorly understood. By using a variety of signaling mutants of Jurkat as well as chemical inhibitors to cell signaling factors, we sought to elucidate the role of the TCR signaling complex and that of ion channel-mediated signaling cascades in the induction of RANKL by CD2.

Methods: The human T-cell line Jurkat and several signaling mutant derivatives were exposed to various combinations of bead bound anti-CD3, CD2 and CD28 antibodies. Total soluble RANKL was determined by osteoprotegrin capture sandwich ELISA. A Jurkat clone with a stably integrated NFAT-luciferase reporter (NFAT-Luc) was used to assess the signaling events leading to NFAT activation, a known regulator of RANKL expression, in response to cross-linking of CD3, CD2 and CD28 for 4 hrs. Prior to being exposed to the bead-bound antibodies, these cells were treated with a panel of chemical inhibitors to a variety of signaling factors including kinases (PI3K, CaMKII, AKT and PKC), phosphatase (calcineurin), calmodulin (CaM), calcium (TRPC3) and potassium ion channels (Kv1.1, 1.2 and 1.5) at broad concentration ranges. Cytotoxicity was evaluated by CellTiter-Fluor®.

Results: Similar to primary human T lymphocytes, Jurkat cells secreted RANKL only in response to cross-linking of both CD2 and CD3. This process was dependent on ZAP70 signaling but was independent of the following components associated with TCR signaling: beta-chain of the TCR, CD45, and PLCgamma. Cross-linking of CD3 and CD28 failed to induce RANKL secretion in wild-type cells even though high levels of IL-2 were generated. A 2-fold higher level of NFAT-Luc activation was observed with CD2/CD3 co-ligation as compared to CD28/CD3 and from the panel of inhibitors, chlorpromazine HCl, an inhibitor of both calmodulin and K+-channel signaling, was more effective at blocking NFAT-Luc activation by CD2/CD3 co-ligation than that of CD28/CD3, suggesting that these signaling cascades contribute to RANKL expression regulated by NFAT in response to CD2. Additional inhibitors to either calcium or potassium signaling cascades (FK 506, a calcineurin inhibitor, and 4-aminopyridine, a Kv1.1 & 1.2 inhibitor, respectively) also blocked CD2/CD3-induced activation of the NFAT reporter without cytotoxicity; however, inhibition was not restricted to CD2 since CD28/CD3-induced signaling was also affected.

Conclusion: Our results demonstrate that T-cells secrete RANKL in a ZAP70-dependent manner and only require the co-ligation of CD3 and CD2 in the absence of the co-stimulatory receptor CD28. Furthermore, calcineurin and voltage-gated K+-channel signaling cascades were shown to induce the activation of NFAT in response to CD2/CD3 co-ligation, suggesting that these pathways may contribute to the expression RANKL in the inflamed RA synovium by T-cells.

Peripheral CD5$^+$ b-Cells in ANCA-Associated Vasculitis. Sebastian Unizony[1], Noha Lim[2], Vincent Carey[3], Deborah J. Phippard[2], Nadia Tchao[2], Eli M. Miloslavsky[1], Peter A. Merkel[4], Paul Monach[5], William St. Clair[6], Robert F. Spiera[7], Adam Asare[2], Philip Seo[8], Carol A. Langford[9], Gary S. Hoffman[10], Cees Kallenberg[11], Ulrich Specks[12] and John H. Stone[1]. [1]Massachusetts General Hospital, Boston, MA, [2]Immune Tolerance Network, Bethesda, MD, [3]Brigham and Women's Hospital, Boston, MA, [4]Vasculitis Center, Division of Rheumatology, University of Pennsylvania, Philadelphia, PA, [5]Boston University, Boston, MA, [6]Duke University, Durham, NC, [7]Hospital for Special Surgery, New York, NY, [8]Johns Hopkins Vasculitis Center, Johns Hopkins University, Baltimore, MD, [9]Center for Vasculitis Care and Research, Cleveland Clinic, Cleveland, OH, [10]Cleveland Clinic Foundation, Cleveland, OH, [11]University of Groningen, Groningen, Netherlands, [12]Mayo Clinic, Rochester, MN.

Background/Purpose: We explored the utility of peripheral CD19$^+$ CD5$^+$ B-cells (CD5$^+$ B-cells) as biomarkers in ANCA-associated vasculitis (AAV).

Methods: CD5$^+$ B-cells were measured longitudinally by flow cytometry in patients randomized to rituximab (RTX, n = 99) or CYC followed by AZA (CYC/AZA, n = 98) for the treatment of AAV (RAVE trial). Number of CD5$^+$ B cells/mL and %CD5$^+$ B-cells within the total population of CD19$^+$ B-cells were determined. Outcomes assessed were disease activity, induction treatment failure, disease severity, relapse, and in the RTX arm, relapse-free survival according to %CD5$^+$ B-cells at B-cell *redetection* (10–68 CD19$^+$ B-cells/mL) and *reconstitution* (≥ 69 CD19$^+$ B-cells/mL) using %CD5$^+$ B-cells as dichotomous (>30% and ≤30% [1]) and categorical predictor. Repeated measure ANOVA, Wilcoxon, Fisher's, logrank and Cox PH tests were used.

Results: Median CD5$^+$ B-cell numbers and %CD5$^+$ B-cells were comparable between groups at baseline. After an initial decline, CD5$^+$ B-cell numbers increased in the RTX arm, but remained low in the CYC/AZA cohort. In both groups, %CD5$^+$ B-cells increased during remission induction and declined thereafter (**Fig 1**). %CD5$^+$ B-cells correlated inversely with disease activity in RTX-treated patients (baseline 12%, remission 28% and relapse 23%; $p < 0.05$), but not in CYC/AZA-treated patients (**Fig 2**). No significant association was observed between CD5$^+$ B-cells and induction failure or disease severity. Disease relapses were not preceded consistently by declines in %CD5$^+$ B-cells. Once B-cells returned in the RTX arm, %CD5$^+$ B-cells did not predict time to flare (**Fig 3**). The hazard ratio (HR) for relapse in patients with >30% CD5$^+$ B-cells (versus ≤30%) at B-cell *redetection* was 1.14 (95% CI 0.49–2.64; P = 0.75). The HR for relapse in patients with >30% CD5$^+$ B-cells (versus ≤30%) at B-cell *reconstitution*, was 0.9 (95% CI 0.31–2.55; P = 0.84). Division of patients by quartiles of %CD5$^+$ B-cells upon B-cell repopulation failed to show any trend in time to relapse following the order of the strata.

Conclusion: In patients with AAV treated with CYC or RTX CD5$^+$ B-cells do not predict treatment response, relapse or disease severity.

Proteomic Analysis of ANCA Vasculitis Serum Reveals Broad Neutrophil Activation, Angiogenesis, and Selective Inflammatory Pathway Activation. Melissa Parker, David Gold, Koustubh Ranade and Ethan Grant. MedImmune, LLC, Gaithersburg, MD.

Background/Purpose: ANCA vasculitis is characterized by the presence of autoantibodies directed against MPO, PR3 and other neutrophil proteins. Binding of these autoantibodies to activated neutrophils is thought to be an important driver of the pathology underlying this disease. To date, investigation of serum biomarkers in this patient population have been limited. A more comprehensive approach to defining the biomarker profile would aid in our understanding of the mechanisms underlying the disease, may point to novel therapeutic targets, and would aid in the definition of biomarkers to monitor disease activity and therapeutic response.

Methods: ANCA vasculitis (n=46) and healthy control (n=30) donor serum samples were obtained from commercial sources. Vasculitis samples were derived from patients with positive c-ANCA or p-ANCA patterns by immunofluorescence analysis. Anti-PR3 and anti-MPO autoantibody levels were measured by ELISA to assess autoantibody status of the vasculitis samples. Proteomic profiling was performed using SOMAscan™ and multiplexed analysis on the Luminex® platform.

Results: Measurement of anti-MPO and anti-PR3 antibodies in the ANCA vasculitis sera indicated that approximately one-third of the samples had detectable levels of one or the other of these most common autoantibodies. Multiplexed proteomic analysis of control and vasculitis serum samples revealed elevated TNFα, GM-CSF, IL-7, eotaxin, MCP-1, CXCL1, sCD40L, IL-21, growth factors such as VEGF, EGF, and FGF-2 (see Table). Increased levels for these analytes were observed with both conventional Luminex® multiplex assay and with the SOMAscan™ analysis that measures levels of more than 1,200 protein analytes. No clear difference in levels of these biomarkers was apparent in patient samples with or without detectable antibodies against MPO or PR3. Further analysis of the SOMAscan™ data indicated a pattern of increased levels of proteins in several classes. Across vasculitis serum samples, we observed an elevation in levels of biomarkers associated with angiogenesis, select inflammatory mediators, platelet activation and markers of tissue remodeling/repair. Interestingly we also observed clear increases in the levels of several autoantigens associated with this disease – MPO, PR3, lactoferrin and moesin. This finding is consistent with heightened neutrophil activation, and in patients with autoantibodies against these proteins, may drive immune complex-mediated inflammation.

Table 1. Serum concentrations of select analytes measured by multiplex analysis (mean ± SD in pg/ml)

	Healthy control	ANCA vasculitis	*P*

Conclusion: A deep analysis of the biomarker profile of ANCA vasculitis serum revealed upregulation of pathways related to angiogenesis, neutrophil and platelet activation, and tissue repair. These data provide a view more comprehensive than previously reported of the altered serum profile in ANCA vasculitis patients and highlight candidate biomarkers to track disease activity and therapeutic responses.

Molecular Diagnosis Reveals a Surprising Prevalence of Limited Gpa Among Patients with Orbital Inflammatory Diseases. James T. Rosenbaum[1], Dongseok Choi[2], Christine Harrington[3], Patrick Stauffer[3], David Wilson[3], Seema Gupta[3], Roger Dailey[3], John Ng[3], Eric Steele[3], Patrick Yeatts[4], Peter Dolman[5], Valerie White[5], Gerald Harris[6], Craig Czyz[7], Jill Foster[7], Deepak Edward[8], Hind Alkatan[8], Bobby Korn[9],Don Kikkawa[9], Dinesh Selva[10], Sander Dubovy[11], Chris Alabiad[11], David Tse[11], Michael Kazim[12], Payal Patel[12] and Stephen R. Planck[3]. [1]OHSU, Portland, OR, [2]Oregon Health and Science University, Portland, OR, [3]Oregon Health & Science University, Portland, OR, [4]Wake Forest University, Winston-Salem, NC, [5]University of British Columbia, Vancouver, BC, [6]Medical College of Wisconsin, Milwaukee, WI, [7]Ohio State Univeristy, Columbus, OH, [8]King Khaled Eye Hospital, Riyadh, Saudi Arabia, [9]University of California, San Diego, San Diego, CA, [10]Royal Adelaide Hospital, Adelaide, Australia, [11]University of Miami, Miami, FL, [12]Columbia University, New York City, NY.

Background/Purpose: Gene expression profiling provides diagnostic and therapeutic information in several malignancies, but its role in evaluating inflammatory disease is relatively untested. We hypothesized that gene expression profiling could provide diagnostic information for orbital inflammatory diseases which include thyroid eye disease (TED or T in Figure 1), sarcoidosis (S in figure), granulomatosis with polyangiitis (GPA or G in figure), or nonspecific orbital inflammation (NSOI (N in figure), previously known as pseudotumor).

Methods: Formalin-fixed orbital biopsies, 20 from healthy controls (C in Figure 1), 25 from subjects with NSOI, 25 from subjects with TED, 6 from subjects with GPA, and 7 from subjects with sarcoidosis were obtained by an international consortium, divided into discovery and validation sets, and analyzed with regard to histopathology and gene expression using microarray.

Results: Principal coordinate analysis (Figure 1), heat maps (Figure 2), and Venn diagrams showed distinct gene expression profiles for healthy controls and subjects with TED, GPA, or sarcoidosis. A statistical method called random forest based on 39 probe sets identified controls, GPA, or TED with an average accuracy of 76% ($p=0.02$ compared to random) while two expert pathologists had accuracies of 49% and 58% respectively (neither significant compared to random). Random forest analysis indicated that 52% of tissues from patients with nonspecific inflammation were consistent with a diagnosis of GPA.

Conclusion: Molecular diagnosis by gene expression profiling is more accurate than histopathology in differentiating forms of orbital inflammatory disease. Although NSOI is a heterogeneous collection of diseases, many patients with NSOI have a gene expression profile resembling GPA. A limited form of GPA affecting the orbit is far more common than previously realized. Molecular diagnosis should be tested for its ability to identify GPA affecting sinuses and nasal or subglottic mucosa.

1757

An Analysis of the Incidence and Characteristics of ANCA Positive Vasculitis before and after the Christchurch Earthquake. Ben McGettigan[1], John L. O'Donnell[1], Peter T. Chapman[2], Christopher Frampton[3] and Lisa K. Stamp[3]. [1]Canterbury Health Laboratories, Christchurch, New Zealand, [2]Christchurch Hospital, Christchurch, New Zealand, [3]University of Otago, Christchurch, Christchurch, New Zealand.

Background/Purpose: At 1251 on 22 February 2011 a magnitude 6.4 earthquake struck Christchurch killing up to 185 people and causing widespread damage to buildings in the city centre and surrounds. Multiple building collapses during the busy lunchtime period in Christchurch when the earthquake occurred will have resulted in significant environmental exposures. Prominent involvement of the upper and lower respiratory tracts suggests that inhaled antigens may have a role in pathogenesis of ANCA associated vasculitis. An increased incidence and severity of MPO positive vasculitis was observed after the Kobe earthquake in 1995. The aim of this study was to describe the incidence and characteristics of ANCA positive vasculitis before and after the 2011 Christchurch earthquake.

Methods: All ANCA tests reported by Christchurch pathology centres over a 2 year period prior to February 21 2010 (period 1) and the 2 year period after February 22 2011 (period 2) were extracted from laboratory information systems. Clinical notes from patients with positive MPO or PR3 antibodies were reviewed to confirm newly diagnosed vasculitis cases who resided within the Christchurch area. Demographic information and organ involvement was confirmed on all newly diagnosed cases and compared between periods using Fisher's exact and independent t-tests. Total Canterbury population was obtained from Statistics New Zealand.

Results: In period 1, 2592 total ANCA requests were processed; of these 37 (1.4%) were MPO positive and 100 (3.9%) were PR3 positive. 13/37 (35%) patients were subsequently confirmed to have newly diagnosed MPO positive vasculitis and 9/100 (9%) patients were confirmed to have PR3 positive vasculitis. In period 2, 2416 total ANCA requests were processed; of these 32 (1.3%) were MPO positive and 118 (4.9%) were PR3 positive. 7/32 (21.9%) patients were confirmed to have newly diagnosed MPO positive vasculitis and 11/118 (9.3%) newly diagnosed PR3 positive vasculitis. The rate of MPO vasculitis per 100,000 population was 3.45 in period 1 and 1.93 in period 2 (RR 1.8 95%CI 0.66–5.29). The rate of PR3 vasculitis per 100,000 population was 2.39 in period 1 and 3.03 in period 2 (RR 0.79 95%CI 0.29–2.09). In the post-earthquake period those with a new diagnosis of MPO

vasculitis were significantly younger than those diagnosed in the pre-earthquake period (Table1).

Conclusion: In contrast to a previous study we have shown no statistically significant difference in rate of newly diagnosed MPO or PR3 positive vasculitis after a major earthquake. A longer study period post-earthquake may be required. The earlier age of onset of MPO vasculitis post-earthquake is of interest and may relate to younger people being in the areas of greatest building collapse in the city center. Further information of location at the time of the earthquake will be required.

Table 1: Demographic and clinical characteristics pre (period 1) and post (period 2) the 2011 Christchurch earthquake

PR3 vasculitis	Period 1 (n=9)	Period 2 (n=11)	p value
Age years; mean (SEM)	63.0 (5.2)	68.7 (4.4)	0.41
% male	100%	63.6%	0.09
PR3 mean (SEM)	1224 (550)	934.8 (360.5)	0.66
Renal involvement	5 (55.6%)	4 (36.4%)	0.65
Respiratory involvement	8 (88.9%)	8 (72.7%)	0.59
MPO vasculitis	**Period 1 (n=13)**	**Period 2 (n=7)**	**p value**
Age years; mean (SEM)	71.3 (2.9)	58.4 (5.3)	0.03
% male	10/13 (77%)	5/7 (71.4%)	1
MPO mean (SEM)	623.7 (199.4)	462.3 (154.6)	0.59
Renal involvement	11/13 (84.6%)	5/7 (71.4%)	0.59
Respiratory involvement	6/13 (46.2%)	2/7 (28.6%)	0.64

1758

Environmental Risk Factors for Granulomatous Polyangiitis (GPA): Southern Hemisphere Similar to Northern Hemisphere. Lisa K. Stamp[1], Peter T. Chapman[2], Richard A. Watts[3], Christopher Frampton[1] and John L. O'Donnell[4]. [1]University of Otago, Christchurch, Christchurch, New Zealand, [2]Christchurch Hospital, Christchurch, New Zealand, [3]Rheumatology Department Ipswich Hospital and University of East Anglia, Ipswich, United Kingdom, [4]Canterbury Health Laboratories, Christchurch, New Zealand.

Background/Purpose: GPA is a rare condition of unknown etiology. Prominent involvement of the upper and lower respiratory tracts suggests that inhaled antigens may trigger systemic immunopathogenic responses. Although no definite inhaled environmental factor has been identified farming and solvent exposure have been reported to be associated with GPA in Northern hemisphere studies. A latitudinal gradient has been observed in both Northern and Southern hemispheres with higher rates of disease in those areas closest to the North and South Poles. The aim of this study was to determine any environmental risk factors for GPA in Canterbury New Zealand (latitude 43°–44°S), with a particular focus on inhaled antigens.

Methods: A case-controlled study was undertaken. All GPA cases fulfilled ACR or CHCC criteria. Each case was age ± 10yrs and gender matched with four controls (2 osteoarthritis or fracture and 2 asthma or emphysema). A structured questionnaire to assess potential environmental agents was administered. Data was analyzed using conditional logistic regression to allow for the individual matching of cases and controls.

Results: 49 cases and 196 controls were recruited. 53% were male and 97.5% were New Zealand European. The mean ± SD age of the cases was 64.9 ± 12.4yrs and controls 59.5 ± 14.6yrs. In the 2 years prior to the first symptoms attributable to GPA 14.3% of cases and 18.6% of controls lived in a rural environment ($p=0.48$). Place of birth within New Zealand (whether North Island or South Island) had no influence on risk ($p=0.7$).

Any reported exposure to dust (specifically silicon and grain dust) increased the risk of GPA, OR 3.6 (1.5 – 8.3, $p=0.003$). GPA was associated with a higher intensity of exposure to silica ($p<0.001$), metals ($p=0.003$) and solvents ($p<0.001$).

Occupation as a farm worker was associated with GPA OR 3.43 (1.5 –7.5, $p=0.002$). In the year prior to the first symptoms attributable to GPA cases were significantly more likely to have lived on, worked on or visited a farm than controls OR 2.7 (1.3–5.9; $p=0.009$). There was no significant relationship between exposure to crops (OR 1.7; 0.8–3.6; $p=0.16$). However exposure to livestock was associated with an increase risk (OR 2.3; 1.1–5.0; $p=0.02$), specifically exposure to sheep (OR3.6; 1.6–7.7; $p=0.001$). GPA was also associated with more time spent in the garden (Cases 22.7 ± 4.1 hrs/month vs. controls 13.2 ± 2.0 hrs/month $p=0.04$). Specific gardening activities were associated with increased risk including digging (OR 3.2; 1.4–7.0; $p=0.003$), mowing (OR 2.7; 1.3–5.8; $p=0.008$) and planting (OR 2.6; 1.2–5.5; $p=0.013$).

Conclusion: Previous studies have identified a latitudinal gradient and a peak in GPA disease onset in the winter months. We have shown activities associated with exposure to inhaled antigens, in particular those related to farming or gardening activities may increase the risk of GPA. We have replicated findings from northern hemisphere studies identifying dust and solvent exposure as well as farm exposure as risk factors for the development of GPA.

Analysis of Employment, Work Disability and Quality of Life of Patients with ANCA-Associated Vasculitis. Lucas Benarous[1], Benjamin Terrier[1], Alice Berezne[2], Bertrand Dunogué[3], Hervé Laborde-Casterot[1], Pascal Cohen[4], Xavier Puéchal[4], Nathalie Costedoat-Chalumeau[4], Claire Le Jeunne[4], Dominique Choudat[1], Luc Mouthon[4] and Loïc Guillevin for the French Vasculitis Study Group[4]. [1]Cochin Hospital, Paris, France, [2]Paris Descartes University, Internal Medicine department, Cochin Hospital, Paris, France, [3]Hôpital Cochin, Paris, France, [4]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France.

Background/Purpose: Improved therapeutic strategies for ANCA-associated vasculitis (AAV) have transformed acute and life-threatening diseases into chronic ones responsible for marked morbidity that could impact employment, work disability and quality of life (QoL). The French EXPO-VAS inquiry aimed to analyze work, handicaps and QoL of AAV patients and identify their determinants.

Methods: Patients with AAV seen in our department were included in a cross-sectional study assessing employment, work disability and QoL. Specific and non-specific questionnaires, including SF-36, were sent to 531 AAV patients. QoL was compared to that of the general population, patients with end-stage renal disease (ESRD), and previously reported AAV patients from the EUVAS cohort. Clinical-biological data that could affect QoL were recorded, and their determinants analyzed.

Results: Questionnaires were completed by 198 patients (109 women (55%), mean age 59±14 years). Diagnoses were granulomatosis with polyangiitis for 132 (67%), eosinophilic granulomatosis with polyangiitis (EGPA) for 42 (21%) and microscopic polyangiitis for 24 (12%). Among 94 working-age (<60 years) patients, 57% had jobs, consistent with their qualifications for 81%; 77% were stably employed, with 67% working full-time. Concerning the impact of AAV, 23% of workers felt that their disease qualitatively limited the nature of their work, while 43% felt it limited the quantity of work they could do; 77% of patients did not benefit from any workstation adaptation; 50% thought their disease had hindered their careers and 43% that it had led to a salary reduction. 33% were not employed and not looking for work; and 9% were looking for a job. These results were comparable for the different vasculitides. QoL was significantly impaired for AAV patients compared to the general population ($P<0.0001$). In contrast, QoL of AAV patients was significantly better than that of ESRD patients. Finally, our AAV population's QoL was similar to that of the EUVAS cohort, except for our patients' physical functioning, which was better ($P<0.001$), and their mental health, which was more impaired ($P<0.001$). Physical health determinants for our population were an EGPA diagnosis, long disease duration and its neurological involvement, whereas mental health determinants were ear, nose & throat signs and cardiovascular involvement.

Conclusion: Our findings showed that AAV patients' QoL was impaired compared to the general population, mainly for patients with EGPA and long-standing disease. In contrast, normal employment seemed to be preserved.

1760

United Kingdom & Ireland Vasculitis Registry – Cross-Sectional Data on the First 1085 Patients. Jan Sznajd[1], Alan D. Salama[2], David Jayne[3], Afzal Chaudhry[3], Michael Robson[4], Joe Rosa[1], Neil Basu[5], Sarah Moran[6], Michael Venning[7], Peter Lanyon[8], Asheesh Sharma[9], Mark A. Little[10], Richard Watts[11] and Raashid Luqmani[12]. [1]Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [2]University College London, London, United Kingdom, [3]Addenbrookes Hospital University of Cambridge, Cambridge, United Kingdom, [4]King's College London, London, United Kingdom, [5]University of Aberdeen, Aberdeen, United Kingdom, [6]Cork University Hospital, Cork, United Kingdom, [7]Manchester Royal Infirmary, Manchester, United Kingdom, [8]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom, [9]University Hospital Aintree Liverpool, Liverpool, United Kingdom, [10]Trinity College Dublin, Dublin, Ireland, [11]Ipswich Hospital NHS Trust, Ipswich, United Kingdom, [12]Oxford NIHR Musculoskeletal Biomedical Research Unit, Oxford, United Kingdom.

Background/Purpose: Clinical care and research into systemic vasculitis is hampered by its rarity and its presentation to a wide array of medical specialties. We aimed to establish a UK and Ireland registry of patients with different forms of vasculitis (UKIVAS) in order to amalgamate our clinical experience and provide comparative outcome data on a large cohort of patients from multiple centres. This will inform research (trials, immunogenetics, epidemiology), service planning and commissioning (particularly of expensive biologic agents).

Methods: We are recruiting patients with systemic vasculitis under regular care of a variety of specialists across the UK and Ireland. We developed web-based software to enable prospective collection and central storage of anonymised clinical data with local storage of patient identifiable information. The application was designed for use by each centre as the local clinical database and audit tool.

Results: To date, we have recruited 1085 patients from 18 centres. The median age at diagnosis was 55.8 years (IQR 40.9–66.0) with similar gender distribution; almost 90% were white Caucasians; 87% were prevalent cases at the time of recruitment. The majority had one of the anti-neutrophil cytoplasm antibody (ANCA) associated vasculitides: granulomatosis with polyangiitis (GPA) (42%), microscopic polyangiitis (MPA) (25%), or eosinophilic granulomatosis with polyangiitis (EGPA) (9%); the remainder were defined as giant cell arteritis (GCA) (5.6%), unclassified ANCA associated vasculitis (3.8%), anti-glomerular basement membrane disease (2.3%), Behcet's (2.3%), IgA vasculitis (2.3%), Takayasu's (1.2%), polyarteritis nodosa (1%) and other types of vasculitis (<1% each). Biopsies were performed in 755 (69.6%) patients; results were positive in 466/555 (84%) GPA and MPA (Vs. 54% EGPA and 52% GCA). The majority (82.1%) received oral corticosteroids and cyclophosphamide (56% overall, 68% in GPA/MPA) for induction. The most common maintenance treatment with corticosteroids was azathioprine (39.5%). The detailed characteristics of the whole cohort and the 3 largest groups are shown in Table 1.

Conclusion: We have established a web-based registry for systemic vasculitis which can be used for gathering data at a national level and potentially linked with other international databases. The clinical features and treatment regimens reflect the predominance of ANCA vasculitis with renal involvement, with relative under-representation of other types of vasculitis. The introduction of new non-renal centres, the opportunity to biobank samples and longitudinal observation of this cohort will support further development of this project and research in vasculitis. The UKIVAS registry will be a useful way of identifying patients who may wish to take part in future clinical trials.

Table 1. Selected characteristics of all vasculitis patients and the 3 largest groups recruited in UK and Ireland vasculitis (UKIVAS) registry.

		Total	GPA	MPA	EGPA
Demographics	Number of patients (% of total)	1085 (100)	453 (42)	269 (25)	99 (9)
	Female/male ratio	1.14	1.00	1.01	1.11
	Median age at diagnosis in years (IQR)	55.2 (40.0–65.7)	59.4 (47.0–67.4)	67.9 (53.9–76.6)	55,8 (48,2–65,2)
	Median duration of the disease in years (IQR)	4.0 (0.9–8.9)	5.5 (1.9–11.5)	2.2 (0.1–0.7)	4,9 (1,5–10,2)
Organ involvement	Kidney	56%	55%	86%	25%
	ENT	44%	74%	12%	67%
	Respiratory	42%	54%	32%	80%

Standardisation of Disease Assesment in Systemic Vasculitis: Use of a Novel Web-Based Software Training Application. Jan Sznajd[1], Joe Rosa[1], David Gray[1], Jennifer O'Donoghue[1], Joanna Robson[1], Surjeet Singh[1], Richard Philipson[2], Judith Brown[2], Thor Ostenfeld[2] and Raashid Luqmani[3]. [1]Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [2]GlaxoSmithKline R&D, Brentford, United Kingdom, [3]Oxford NIHR Musculoskeletal Biomedical Research Unit, Oxford, United Kingdom.

Background/Purpose: The Birmingham Vasculitis Activity Score (BVAS) and Vasculitis Damage Index (VDI) are validated clinical assessment tools for the systemic vasculitides. However use of BVAS and VDI is limited, partly due to lack of training but also lack of perceived need. The increasing use of biological agents in vasculitis means that BVAS and VDI can provide quantifiable evaluation prior to treatment and be used to monitor response and outcome. We aimed to develop and test an online training tool for clinicians managing vasculitis patients and allow certification of clinical assessment in vasculitis. We present pilot data on the performance of this training package.

Methods: The training package (which consists of an introductory lecture, a manual plus 20 simple and 40 advanced vasculitis case scenarios selected from a large pool of cases) has been extensively used for clinical trials. Historically we have used paper cases; most recently 51 participants scored 3060 cases manually. We built an online customized interactive web-based application and tested it amongst a group of international physicians and research nurses specialized in vasculitis during 3 clinical trial investigators' meetings, and one educational meeting for UK rheumatology fellows. The overall pass mark for each set of cases was set at 85% and 75% agreement with gold standard for BVAS and VDI respectively (and at least 50% for each individual case). In case of failure to achieve the required mark, cases could be reset allowing reattempts. The application provided immediate formal evaluation on completion and detailed feedback on performance of each evaluated case. We analyzed the percentage agreement, number of attempts per case and time needed to complete the training by each observer, as well as their own feedback.

Results: Over the course of 4 events 3980 cases were scored online by 78 participants; 33.3% passed the advanced section on their first attempt. The number of reattempts per BVAS case decreased from 1.08 (1 in 14 cases

retaken) in the introductory set to 1.05 (1 in 21 cases retaken) in the advanced set, showing intra-training improvement. Median time to complete a case was 4.18 (IQR 2.50–6.67) minutes and there was a trend showing a decrease in time taken per case as the participants progressed through the cases. The average mark at completion was 92.3% (range 86.6–96.4) for BVAS and 92% (range 88.9–95.0) for VDI. Overall 100% completed the training and were awarded certification. 59.2% of participants agreed that the training should be mandatory for all doctors who treat vasculitis patients.

Conclusion: We have developed a web-based training package to enhance clinicians' ability to evaluate patients with systemic vasculitis, based on assessment of BVAS and VDI. This package is easy to use, feasible and acceptable to participants to facilitate their ability to manage patients with vasculitis, although its effectiveness needs to be validated in clinical setting. Currently we are expanding the number of cases based on clinical data from observational studies to allow for randomized case selection and retakes using different clinical scenarios.

The Muscle Biopsy Is a Useful and Noninvasive Procedure in Diagnosing Systemic Vasculitis Affecting Small-to-Medium-Sized Vessels: A Prospective Evaluation. Takahiro Nunokawa, Takayasu Kise, Naoto Yokogawa, Kota Shimada and Shoji Sugii. Tokyo Metropolitan Tama Medical Center, Tokyo, Japan.

Background/Purpose: Histopathological confirmation is required for the diagnosis of systemic vasculitis. However, patients suspected of vasculitis often only have lesions with a low diagnostic yield for biopsies, such as ENT and lungs. In addition, the biopsy of an involved organ, especially the nerve and kidney, is an invasive procedure carrying the risk of significant complications. In contrast, a muscle biopsy is simple and minimally invasive. However, while the muscle biopsy combined with the nerve biopsy is effective for demonstrating vasculitic neuropathy, the utility of the muscle biopsy alone is uncertain. Herein we assess the accuracy and utility of the muscle biopsy in detecting small-vessel vasculitis (SVV), or medium-vessel vasculitis (MVV) in clinical practice.

Methods: Consecutive patients with suspected SVV or MVV seen at our hospital between 2012 and 2014 were prospectively studied. Patients for whom a skin or renal biopsy were indicated were excluded from this study because the skin biopsy is less invasive than the muscle biopsy while the renal biopsy can provide useful information about the severity and prognosis of the disease in addition to its diagnostic value. Muscle biopsies were performed in the bilateral vastus lateralis of the quadriceps femoris because of its hypervascularity unless the patient presented myalgia in the other muscles. Imaging studies of muscles were not routinely performed. The definition of a positive muscle biopsy was the presence of inflammatory infiltrates with fibrinoid necrosis in the vessels.

Results: Forty-seven patients underwent muscle biopsies. Diagnosis of SVV or MVV was made in 34 patients in the follow-up period lasting more than six months. An unrelated condition was diagnosed in ten patients while nothing could be diagnosed in three patients. Of the 34 patients in whom SVV or MVV was diagnosed, a positive muscle biopsy was obtained in 20 patients (15 with MPA, 3 with PN, and 2 with EGPA) while other findings led to the same diagnosis in 14 (7 with MPA, 3 with GPA, 3 with PN, 1 with rheumatoid vasculitis). The sensitivity of the muscle biopsy was 59%. Of the 12 patients presenting vasculitic neuropathy, muscle biopsies demonstrated vasculitis in nine patients, with 75% sensitivity. Myalgia was seen in ten (50%) vasculitis patients with positive biopsies and in two (14.3%) patients with negative biopsies ($p = 0.031$). There were no complications in the procedure except for delayed wound healing in one patient.

Conclusion: The muscle biopsy is a safe method which offers a high diagnostic yield in diagnosing SVV or MVV in the absence of indications for a skin or renal biopsy. Further, the muscle biopsy can be used in place of the nerve biopsy for diagnosing vasculitis in patients with vasculitic neuropathy.

Tobacco Differentially Affects the Clinical-Biological Phenotype of ANCA-Associated Vasculitides at Diagnosis. Lucas Benarous[1], Benjamin Terrier[1], Bertrand Dunogué[2], Pascal Cohen[3], Xavier Puéchal[3], Claire Le Jeunne[3], Luc Mouthon[3] and Loïc Guillevin for the French Vasculitis Study Group[3]. [1]Cochin Hospital, Paris, France, [2]Hôpital Cochin, Paris, France, [3]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France.

Background/Purpose: Occupational and non-occupational exposures may play a role in the occurrence of ANCA-associated vasculitides (AAV) and affect their initial clinical-biological phenotype. Among these potential exposures, tobacco use could represent a factor that could influence AAV characteristics at diagnosis. However, these effects could differ according to the type of AAV, since granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) involve different pathophysiological mechanisms.

Methods: AAV patients entered in the FVSG database with available information on previous and current smoking habits were analyzed. The clinical-biological phenotype at diagnosis was compared according to current tobacco use (current smokers) or not (including previous and never smokers).

Results: This analysis concerned 1165 patients (545 men and 620 women; mean age of 52.8±16.1 years). AAV diagnoses were: GPA for 583 (50%), MPA for 256 (22%) and EGPA for 326 (28%). Among them, 973 patients (84%) were never smokers, 116 (10%) were previous smokers and 76 (6%) were current smokers. Among GPA patients, current smokers (n=55), compared to non-current smokers (n=528) respectively, were younger (44.5±13.5 vs. 52.0±16.3, P=0.0001), more frequently men (64 vs. 48%, P=0.016) and had more frequent cutaneous involvement (50 vs. 32%, P=0.025), and tended to have more frequent arthralgias (67 vs. 54%, P=0.11) and less frequent constitutional symptoms (33 vs. 47%, P=0.08) and ear, nose & throat (ENT) involvement (73 vs. 83%, P=0.13). BVAS, PR3-ANCA–positivity and inflammatory parameters were similar for the 2 groups. Among EGPA patients, current smokers (n=15), compared to non-current smokers (n=311) respectively, were also younger (41.1±15.8 vs. 50.3±15.2, P=0.028) and had less frequent constitutional symptoms (29 vs. 62%, P=0.02), arthralgias (7 vs. 35%, P=0.04), renal involvement (0 vs. 26%, P=0.025) and MPO-ANCA–positivity (0 vs 30%, P=0.02). BVAS and inflammatory parameters were comparable for the 2 groups. Finally, analysis of MPA patients was impossible because only 6 (2%) were current smokers.

Conclusion: These results suggest that tobacco use could differentially affect GPA and EGPA clinical-biological phenotypes, while no conclusion can be drawn for MPA. Moreover, they support the role of environmental exposures in AAV development and its phenotype.

1764

Clinical and Other Differences Observed Between Cocaine Induced and Non-Cocaine Induced Anti-Neutrophil Cytoplasmic Antibody Positive Vasculitis. Santhi Penmetsa[1], N. Suzanne Emil[2], Joshua Duchesne[1], Wilmer Sibbitt Jr.[3], Arthur Bankhurst[4] and Roderick Fields[5]. [1]University of New Mexico Health sciences center, Albuquerque, NM, [2]Presbyterian Medical Group, Rio Rancho, NM, [3]University of New mexico health sciences center, Albuquerque, NM, [4]University of NM Med Ctr, Albuquerque, NM, [5]University of New Mexico health Sciences center, Albuquerque, NM.

Background/Purpose: Objective: To compare various factors including clinical manifestations, laboratory data and mortality in between two groups of patients with anti-neutrophil cytoplasmic antibody (ANCA) positive vasculitis: with cocaine use and without cocaine use. The goal of this study is to evaluate clinical differences and similarities between these two groups as there are no previous studies per literature review. This also may help clinicians to better understand these two disease processes and to further aid in diagnostic and management approaches.

Methods: Adult patients with a diagnosis of ANCA positive vasculitis between 2000 and 2012 were selected and a total 46 patients were included in this study of which 22 Patients were cocaine users (age range 26–61) and 24 patients (age range 17–80) with no history of cocaine use. Clinical manifestations, laboratory data, pertinent serology, skin biopsy and other diagnostic data were gathered and were analyzed in each category. Each of

these factors was compared between the Cocaine use and non-cocaine use group.

Results: Cocaine-associated ANCA positive vasculitis group had higher proportion of the patients with abnormal perinuclear ANCA (pANCA) (86% vs 66.7%, P=0.084), myeloperoxidase (MPO), (100% vs 66%), abnormal both MPO and proteinase 3 (PR3) antibodies (32% vs 4.2%, P=0.015) compared with non-cocaine use group. This group also has higher concentrations of anti- phospholipid antibodies (50% vs 4%) compared to non-cocaine use group. Skin lesions were significantly more frequent in cocaine use group (81.8% vs 33.3%, P=0.0009) with female sex preponderance for facial lesions. Pulmonary renal involvement and complications as well as mortality (12.5% vs none) were higher in non-cocaine use group compared to cocaine associated vasculitis group.

Conclusion: ANCA positive vasculitis, the cocaine-associated and non-cocaine associated have their own distinctive clinical, laboratory and other diagnostic characteristics as well as complications. It is important for clinicians to be aware of these differences in order to recognize cocaine-associated ANCA positive vasculitis in high-risk populations since management and long term prognosis differ. More studies are needed to evaluate the significance of the presence of the related antibodies in pathogenesis, follow up and management of ANCA positive vasculitis with immunosuppressive therapy in long term.

1765

Comparison of Clinical Characteristics of Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis By the Serotype Specificity to Myeloperoxidase and Proteinase-3. Takamasa Murosaki, Takeo Sato, Yoichiro Akiyama, Katsuya Nagatani and Seiji Minota. Jichi Medical University, Tochigi, Japan.

Background/Purpose: To correlate the clinical characteristics of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) with myeloperoxidase (MPO)-ANCA and proteinase-3 (PR3)-ANCA, and to detect clinical characteristics of AAV in Japanese patients.

Methods: The clinical data of AAV patients from 2005 to 2014 were retrieved retrospectively. AAV patients were divided into three subgroups: MPO single positive-AAV (MPO-AAV), PR3 single positive-AAV (PR3-AAV), and double positive AAV. The clinical diagnosis was based on the European Medicines Agency Algorithm along with pathological findings. The clinical characteristics of AAV such as age, sex, organ involvement, treatment, and prognosis were evaluated and compared between MPO and PR3-ANCA.

Results: Among 165 patients positive for ANCA, 77 patients were diagnosed with MPO-AAV, 13 with PR3-AAV, 4 with double positive AAV, and 71 with non-AAV. The clinical diagnosis of MPO-AAV included microscopic polyangiitis (MPA) in 55, granulomatosis with polyangiitis (GPA) in 15, and eosinophilic granulomatosis with polyangiitis (EPGA) in 8. PR3-AAV included 10 GPA, 2 MPA, and 1 EGPA. All patients with double positive AAV were diagnosed with MPA. Patients PR3-AAV were younger than those with MPO-AAV (median age 70 vs. 55 years old, P=0.006). Involvement in the eyes (46.2% vs. 6.5%, P < 0.001), nose (53.8% vs.19.4%, P = 0.013), and ears (61.5% vs. 23.4%, P = 0.009) was higher in PR3-AAV. There was no difference in gender ratio or involvement in other organs between MPO and PR3-AAV. In both MPO and PR3-AAV, the respiratory system was most frequently involved (83.1% vs. 76.9%). The respiratory involvement in MPO and PR3-AAV included interstitial pneumonia (49.4% vs. 7.7%, P=0.004), nodular shadow (7.8% vs. 53.8%, P<0.001), alveolar hemorrhage (3.9% vs. 7.7%, P=0.47), and bronchitis (12.9% vs. 0%, P=0.191). All AAV patients except one with MPO-AAV were treated with glucocorticoid, and immunosuppressant was added as initial remission induction therapy in 20.8% and 46.2% of the patients with MPO- and PR3-AAV, respectively. In 58.4% and 23.0% of the patients with MPO- and PR3-AAV, respectively, glucocorticoid alone was sufficient for disease-activity suppression, however, in 20.8% and 30.8% of the patients with MPO- and PR3-AAV, respectively, additional immunosuppressant was required during the course. During 2 years, the relapse rate in the patients with PR3- was higher than that in those with MPO-AAV (log-rank test, P=0.046), and COX hazard analysis revealed that PR3-ANCA showed a higher relapse rate (hazard ratio 2.54, 95% CI 0.974–6.605, P=0.057). There was no difference in the survival between patients with MPO- and PR3-AAV (log-rank test, P=0.931).

Conclusion: Unlike AAV patients in Western countries, MPO-AAV was predominant in Japan. The clinical characteristics were different between MPO and PR3-AAV. The involvement of the respiratory system was most frequent in both AAVs. In contrast to Western countries, alveolar hemorrhage was rare in Japanese, and in half of MPO-AAV patients, glucocorticoid alone was sufficient. Higher relapse rate in PR3-AAV than in MPO-AAV was similar to reports from Western countries.

Comparison of Clinicopathologically- and Serologically-Based Classification Systems for ANCA-Associated Vasculitis. Sebastian Unizony[1], Eli M. Miloslavsky[1], Miguel Villarreal[2], Peter A. Merkel[3], Paul Monach[4], E. William St. Claire[5], Cees Kallenberg[6], David Ikle[2], Robert F. Spiera[7], Nadia Tchao[8], Deborah J. Phippard[8], Linna Ding[9], Carol A. Langford[10], Philip Seo[11], Gary S. Hoffman[12], John H. Stone[1] and Ulrich Specks[13]. [1]Massachusetts General Hospital, Boston, MA, [2]Rho, Chapel Hill, NC, [3]Vasculitis Center, University of Pennsylvania, Philadelphia, PA, [4]Boston University, Boston, MA, [5]Duke University School of Medicine, Durham, NC, [6]University of Groningen, Groningen, Netherlands, [7]Hospital for Special Surgery, New York, NY, [8]Immune Tolerance Network, Bethesda, MD, [9]NIAID, Bethesda, MD, [10]Center for Vasculitis Care and Research, Cleveland Clinic, Cleveland, OH, [11]Johns Hopkins Vasculitis Center, Johns Hopkins University, Baltimore, MD, [12]Center for Vasculitis Care and Research, Cleveland Clinic Foundation, Cleveland, OH, [13]Mayo Clinic, Rochester, MN.

Background/Purpose: Genome-wide association studies suggest that PR3-ANCA-positive ANCA-associated vasculitis (AAV) is genetically distinct from MPO-ANCA AAV. We evaluated patients enrolled in the RAVE trial according to ANCA type (PR3- versus MPO-ANCA) as opposed to disease type (granulomatosis with polyangiitis [GPA] versus microscopic polyangiitis [MPA]) to explore whether either classification predicts clinical course and response to treatment.

Methods: The RAVE trial randomized 197 patients to receive rituximab (RTX) or CYC followed by AZA (CYC/AZA) for remission induction. Demographics, clinical features, response to induction treatment, and disease flares were analyzed according to ANCA type and AAV diagnosis. Chi square, Fisher and Mann-Whitney tests were used for univariate analyses. Logistic regression was used for multivariate analyses.

Results: ***Demographic characteristics and baseline organ system involvement:*** Considerable overlap existed between ANCA type and AAV diagnosis with regard to patient demographics and clinical phenotype (Table 1). Patients with GPA and PR3 were younger, more often male, and had more constitutional, ocular and ENT manifestations compared to those with MPA and MPO. Renal disease was more common among patients with MPA and MPO..

Response to treatment: PR3-positive patients achieved complete remission (CR) at 6 months more frequently when treated with RTX (65%) than CYC/AZA (48%) (p = 0.04) (Table 2). Findings were consistent after adjustments for age, sex and new versus relapsing disease. No significant association between CR at 6 months and treatment allocation was seen for MPO patients. When stratified by AAV diagnosis, the proportion of patients in CR at 6 months was not significantly different between treatment arms. The difference in response to treatment was no longer seen at 12 and 18 months, by which time the effects of RTX had waned.

Disease relapse: A higher percentage of PR3 and GPA patients had experienced flares at 12 and 18 months than did their MPO and MPA counterparts. There were no differences in time to first flare.

Conclusion: PR3-positive patients were more likely to achieve CR at 6 months if treated with RTX than with CYC/AZA. This observation requires confirmation in future studies but supports the concept that classifying patients according to ANCA type rather than AAV diagnosis may be highly relevant to the choice of remission induction therapy. Patient demographics, clinical features, and disease relapse were similar when patients were stratified by either AAV diagnosis or ANCA type.

Table 1. Baseline characteristics

	ANCA type			AAV type		
	MPO (n = 66)	PR3 (n = 131)	p-value	MPA (n = 48)	GPA (n = 147)	p-value

1767

Granulomatosis with Polyangiitis (Wegener's) According to Geographic Origin and Ethnicity: Clinical-Biological Presentation and Outcome. Benjamin Terrier[1], Christophe Deligny[2], Xavier Puéchal[3], Pascal Godmer[4], Pierre Charles[5], Gilles Hayem[6], Bertrand Dunogué[7], Pascal Cohen[3], Serge Arfi[8], Luc Mouthon[3] and Loïc Guillevin for the French Vasculitis Study Group[3]. [1]Cochin Hospital, Paris, France, [2]CHU Fort de France, Fort de France, France, [3]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France, [4]Department of Internal Medicine, Centre Hospitalier Bretagne Atlantique de Vannes, Vannes, France, [5]Institut Mutualiste Montsouris, Paris, France, [6]Hopital Bichat, Paris Cedex 18, France, [7]Hôpital Cochin, Paris, France, [8]Centre hospitalier Universitaire de Fort de France, Fort de France, Martinique.

Background/Purpose: Granulomatosis with polyangiitis (Wegener's) (GPA) is an ANCA-associated vasculitis (AAV) predominantly affecting small-sized vessels, involving mainly the upper and lower respiratory tracts and kidneys. Cytoplasmic labeling by ANCA directed against proteinase-3 (PR3) is associated with >80% of the systemic GPA forms. GPA mainly affects white Europeans (Caucasians/Hispanic), with mean age at diagnosis of 52 years. Recent data revealed an AAV genetic component in European patients. Rarely, GPA may also affect non-Europeans. This study aimed to describe GPA clinical-biological presentation and outcome in black sub-Saharan Africans and Afro-Caribbeans.

Methods: Among 915 GPA patients included in the FVSG database, geographic origin and ethnicity were known for 761. Clinical-biological presentations and outcomes of white Europeans vs black sub-Saharans and Afro-Caribbeans were analyzed.

Results: Among the 761 patients with available geographic origin and ethnicity, 690 (91%) were white Europeans and 22 (2.9%) were sub-Saharans (n=8) or Afro-Caribbeans (French West Indies, n=14). While sex ratios were similar for the 2 populations, sub-Saharans and Afro-Caribbeans, compared to white Europeans, were younger at GPA diagnosis (41.7±14.7 vs 52.1±16.0; P<0.001), had more frequent chondritis (19 vs 6%; P<0.05), central nervous system involvement (18 vs 4.3%; P<0.05), severe granulomatous manifestations [eg retroorbital tumor (9.1 vs 0.9%; P<0.05), subglottic stenosis (19 vs 2.2; P<0.01) and pachymeningitis (13.6 vs 1.6%; P<0.01)]. In contrast, sub-Saharans and Afro-Caribbeans had less frequent fever (20 vs 51%; P<0.05), weight loss (25 vs 51%; P<0.05), kidney involvement (38 vs 59%; P=0.07), cardiovascular involvement (0 vs 15%; P=0.06) and peripheral neuropathy (4.5 vs 22%; P=0.06), and their serum creatinine levels (70 vs. 175 μmol/L; P<0.01) and BVAS (12.3±7.2 vs 19.6±9.1; P<0.01) were significantly lower. Finally, relapse-free survival tended to be shorter for sub-Saharans and Afro-Caribbeans (median survival 44.8 vs 59.8 months), without reaching the significance [HR 1.75 (0.92–4.80); P=0.08]. Overall survival was similar for the 2 populations.

Conclusion: Our findings indicated different GPA clinical presentations in white Europeans vs sub-Saharans and Afro-Caribbeans, with blacks having more frequent severe granulomatous manifestations and less frequent constitutional symptoms, renal involvement and peripheral neuropathy. Prognoses did not differ according to geographic origin.

1768

Cardiac Involvement in Granulomatosis with Polyangiitis: A Magnetic Resonance Imaging Study of 31 Consecutive Patients. Grégory Pugnet[1], Xavier Puéchal[1], Benjamin Terrier[1], Hervé Gouya[2], Andre Kahan[3], Paul Legmann[2], Loïc Guillevin[1] and Olivier Vignaux[4]. [1]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France, [2]AP-HP Cochin Hospital, Department of Radiology B, Paris, France, [3]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [4]Cochin University Hospital, Paris, France.

Background/Purpose: Cardiac manifestations in granulomatosis with polyangiitis (GPA) patients are usually considered to be rare but may be life-threatening. However specific cardiac involvement in GPA is probably underestimated during life because many of these cardiac disturbances are subclinical. Contrast-enhanced cardiac magnetic resonance imaging (CMRI) may be a sensitive tool to detect and analyze cardiac involvement in ANCA associated vasculitis. The objective of our study was to assess the prevalence and patterns of cardiac abnormalities detected by cardiac magnetic resonance imaging in patients with GPA.

Methods: Thirty-one consecutive patients with either new or relapsing GPA underwent CMRI to determine morphological, functional, perfusion at rest and delayed enhancement abnormalities.

Results: At least one abnormality on CMRI was observed in 19/31 patients (61.3%). Four patients (14.8%) had an impaired left ventricle (LV) ejection fraction with evidence of clinically cardiac failure in two of them. LV kinetic abnormalities were found in 11 patients (36.7%). Myocardial delayed contrast enhancement (DCE) was detected in 9/31 patients (29%), 6 of whom with cardiac manifestations. DCE was mainly nodular (n = 7/9). Myocardial early contrast enhancement was detected in 5 of the 31 patients (16.1%) and was always associated with DCE in the same territory. CMRI detected pericarditis in 7 patients (22.6%). GPA of less than 18 months duration as compared with GPA of longer duration had greater LV ejection fraction (P=0.008) and less CMRI abnormalities (P=0.04), DCE (P=0.19) or LV hypokinesia (P=0.04). Patients who presented with new-onset GPA had less CMRI abnormalities than patients who experienced a relapse (P= 0.02).

Conclusion: CMRI is an accurate technique for diagnosing heart involvement in GPA and for analyzing precisely its mechanisms including inflammatory, microvascular and fibrotic components. This unique noninvasive information may have important clinical implications in early and accurate assessment of cardiac lesions in GPA patients but also to detect cumulative non reversible damage. Moreover, it may have prognostic implications.

1769

Abdominal Visceral Adipose Tissue Measured By DXA As a Novel Surrogate Marker of Cardiovascular Risk in Primary Necrotizing Vasculitides. Bertrand Dunogué[1], Karine Briot[2], Sami Kolta[3], Alexis Regent[4], Pascal Cohen[5], Alice Berezne[6], Xavier Puéchal[5], Claire Le Jeunne[5], Luc Mouthon[5], Christian Roux[7], Loïc Guillevin for the French Vasculitis Study Group[5] and Benjamin Terrier[8]. [1]Hôpital Cochin, Paris, France, [2]Paris Descartes University, Paris, France, [3]Paris Descartes University, Cochin

hospital, Paris, France, [4]Institut Cochin, INSERM U1016, CNRS UMR 8104, Université Paris Descartes, Paris, France, Paris, France, [5]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France, [6]Paris Descartes University, Internal Medicine department, Cochin Hospital, Paris, France, [7]Paris Descartes University, Cochin Hospital, Paris, France, [8]Cochin Hospital, Paris, France.

Background/Purpose: Studies have shown a strong prevalence of cardiovascular events among patients with primary necrotizing vasculitides. Recent studies indicate that visceral adipose tissue (VAT) is highly associated with insulin resistance and cardiovascular events. Dual energy X-ray absorptiometry (DXA) is a validated technique able to accurately determine cross-sectionally the mass of discreet fat deposits.

Objective. To assess the relevance of abdominal adipose tissue measurement as potential surrogate markers for cardiovascular risk in patients with primary necrotizing vasculitides.

Methods: Patients with ANCA-associated vasculitides (AAN) and polyarteritis nodosa (PAN) seen in our department were prospectively included in an ongoing cross-sectional study assessing cardio-vascular complications and other sequelae (OSTEOVAS cohort). Alongside the evaluation of usual clinical and extra-clinical features associated with increased cardiovascular risk, DXA was performed to evaluate body composition and abdominal adipose tissue (subcutaneous adipose tissue (SAT) and visceral adipose tissue (VAT).

Results: Sixty-five patients were analyzed (38 females, mean age 50±18 years, mean disease duration of 85±79 months). Diagnoses were granulomatosis with polyangiitis (GPA) in 33 patients, microscopic polyangiitis in 6, eosinophilic GPA in 18, and PAN in 8. Five (7.7%) patients had developed cardiovascular complications. The median daily dose of corticosteroid was 5 mg/day (0–80). High cardiovascular risk defined by the NCEP-ATPIII was found in 11 (16.9%) patients. Using univariate analysis, cumulated dose of corticosteroids ($p=0.038$), Vascular Damage Index (VDI) ($p=0.008$), and VAT/SAT ratio ($p=0.009$) were significantly associated with high cardiovascular risk. Using multivariate analysis, VAT/SAT ratio remained independently associated with high-risk status [OR 1.07 (1.03–1.12), $p=0.004$]. VAT/SAT ratio was also independently correlated with an increased Framingham cardiovascular risk score ($p<0.01$).

Among factors correlated with a higher VAT/SAT ratio, we identified male gender ($p<0.0001$), age ($r=+0.31$, $p=0.014$), cumulated corticosteroid dose ($r=+0.26$, $p=0.048$), VDI score ($r=+0.26$, $p=0.04$), Body Mass Index ($r=+0.35$, $p=0.006$), waist circumference ($r=+0.56$, $p<0.0001$), and elevated troponin levels at time of assessment ($r=+0.36$, $p=0.007$).

Conclusion: This is the first study showing a significant association between a high VAT/SAT ratio assessed by DXA and cardiovascular risk in patients with primary necrotizing vasculitides. Abdominal adipose tissue seems to be an accurate and independent surrogate marker of cardiovascular risk in these patients.

Increased Risk of Chronic Obstructive Pulmonary Disease in Granulomatosis with Polyangiitis: A General Population-Based Study. Neda Amiri[1], Mohsen Sadatsafavi[1], Eric C. Sayre[2], John M. Esdaile[3] and J. Antonio Avina-Zubieta[2]. [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada, Richmond, BC, [3]University of British Columbia, Department of Medicine, Division of Rheumatology, Vancouver, BC.

Background/Purpose: Chronic obstructive pulmonary disease (COPD) is increasingly recognized as an inflammatory condition. We aimed to identify the risk of newly recorded COPD among patients with incident GPA cases compared to the control population using a combination of physician billing codes and hospitalization data covering the entire province of British Columbia, Canada.

Methods: Our data includes all health professionals and hospital visits covered by the comprehensive provincial medical services plan (1990–2010) and all dispensed medication (1996–2010), for all BC residents.

We conducted a retrospective matched cohort study among new cases with GPA meeting a pre-defined criteria as follows: **a)** diagnosis of GPA (ICD-9-CM 446.4) in adults on at least two visits within a two-year period between 1996 and 2010 by a non-rheumatologist physician; **b)** diagnosis of GPA on at least one visit by a rheumatologist or from hospitalization; **c)** absence of a prior GPA diagnosis between January 1990 and December 1995 (to ensure incident GPA cases). Ten controls matched by birth year, sex and calendar year of follow-up were selected from the general population. Incident COPD cases were identified using a validated algorithm (first ICD-9-CM: 491, 492, 496, 493.2, or ICD-10-CM J43 or J44) from hospitals or death certificates. We estimated incidence rate ratios (IRRs) by comparing GPA cases with age-, sex- and entry-time-matched comparison cohorts. Multivariable Cox-regression models adjusting for confounders were also used. Sensitivity analyses were conducted to assess for unmeasured confounders (e.g. smoking).

Results: Among 512 patients with incident GPA, (mean age 57.7, 54% female) 34 developed COPD. This translated to a 20.25 incident rate (IR) per 1000 person-years in the GPA cohort compared to 4.10 IR / 1000 person-years in the control population. The age-, sex- and entry-time matched RR was significantly increased in the GPA cohort (**See table**). The risk of developing COPD was the highest in the first year following diagnosis of GPA (17 fold). The results also remained statistically significant after adjusting for the potential impact of unmeasured confounders (adjusted RRs ranging between 5.03 and 5.58 in all sensitivity analyses).

Conclusion: To our knowledge, this is the first general population-based study that shows a six-fold increase in risk of COPD in patients with GPA. The highest incidence of COPD in the first year following diagnosis supports the role of immune mediated inflammation in the pathogenesis of COPD.

Table: Risk of Incident COPD according to GPA Status

	GPA n = 512	**Non-GPA** n = 5,798
COPD cases, N	34	100
Incidence Rate/1000 Person-Years	20.25	4.10
Age-, sex-, and entry time-matched IRRs (95% CI)	**4.94 (3.24–7.36)**	**1.0**
< 1 year of disease duration	16.93 (8.05–36.49)	1.0
< 2 years of disease duration	11.21 (5.93–21.03)	1.0
< 3 years of disease duration	7.72 (4.40–13.26)	1.0
< 4 years of disease duration	6.77 (4.00–11.17)	1.0
< 5 years of disease duration	5.64 (3.42–9.06)	1.0
> 5 years of disease duration	3.95 (1.59–8.60)	1.0
Multivariable RR (95% CI)	**5.59 (3.31–9.43)**	1.0
Male	5.20 (2.48–10.9)	1.0
Female	6.22 (2.90–13.33)	1.0

Arterial Thrombotic Events in Systemic Vasculitis. Alexander Tsoukas[1], Sasha Bernatsky[1], Lawrence Joseph[2], David Buckeridge[2], Patrick Belisle[3] and Christian A. Pineau[1]. [1]McGill University Health Centre, Montreal, QC, [2]McGill University, Montreal, QC, [3]Research Institute of the McGill University Health Centre, Montreal, QC.

Background/Purpose: To estimate the incidence rate of clinically apparent arterial thrombotic events and associated comorbidities in patients with primary systemic vasculitis.

Methods: Using large-cohort administrative data from Quebec, Canada, we identified all patients with vasculitis, including those with polyarteritis nodosa and granulomatosis with polyangiitis. Incident myocardial infarctions and cerebrovascular events after the diagnosis of vasculitis were ascertained longitudinally via billing and hospitalization data and compared to rates of a general population comparator group. The incidences of comorbidities (DMII, dyslipidemia, and hypertension) were also collected.

Results: Among the 836 patients identified with vasculitis, the myocardial infarction event rate was substantially higher in younger patients, with rates up to 268.1 events per 10,000 pt years [95% CI 67.1–1070.2] in males aged 18–45 with polyarteritis nodosa, approximately 30 times that seen in the age- and sex-matched control group. The cerebrovascular event rate was also substantially higher, particularly in adults aged 45–65 regardless of vasculitis type. All patient groups with vasculitis had elevated incidences of diabetes, dyslipidemia and hypertension compared to the general population.

Conclusion: Atherothrombotic event rates were elevated in patients identified as having primary systemic vasculitis. While incident rates of cardiovascular comorbidities were also increased, the substantial elevation in

myocardial infarctions seen in young adults suggests a disease-specific component which requires further investigation.

Venous Thromboembolic Events in Eosinophilic Granulomatosis with Polyangiitis (EGPA). Chiara Baldini[1], Francesco Ferro[1], Nicoletta Luciano[1], Antonio Tavoni[2], Francesca Sernissi[1], Daniela Martini[1], Sara L'Abbate[1], Marta Mosca[3] and Stefano Bombardieri[3]. [1]Rheumatology Unit, Pisa, Italy, [2]Immunoallergology Unit, Pisa, Italy, [3]Rheumatology Unit, University of Pisa, Pisa, Italy.

Background/Purpose: Previous studies have documented an increased risk of venous thromboembolic events in patients with antineutrophil cytoplasmic antibodies (ANCA) associated vasculitides (AAV) as compared to healthy subjects. However, only a limited number of studies have analyzed the prevalence of thrombosis in eosinophilic granulomatosis with polyangiitis (EGPA).Aim of the study was to determine the frequency of venous thromboembolic events (VTE) in a single center cohort of patients with EGPA and to describe its relation with disease clinical manifestations and activity.

Methods: Patients diagnosed with EGPA (1990 ACR classification criteria) from 1994 to 2014 were included in the study. Data were retrospectively retrieved from patients' charts, including gender, demographic data, cumulative clinical features, ANCA status and BVAS at the baseline. In patients with VTE (i.e deep venous thrombosis and/or pulmonary embolism), EGPA characteristics and disease activity at the time of VTE occurrence were also collected. Categorical variables were compared using Fisher's exact test; continuous variables were compared using Student's t-test. A 2-tailed value of $p < 0.05$ was taken to indicate statistical significance.

Results: The systematic search of our database identified 89 patients, among whom 51 were included in the study. Median (IQR) age at the EGPA diagnosis was 59 (41–62.2) years and their M:F sex ratio was 1.04. During a median (IQR) follow-up of 72.2 (14.8–135.2) months, 6/51 (11.8%) EGPA patients presented at least one VTE. One patient presented 4 recurrent thromboses despite anticoagulant therapy; overall, then, 9 VTE were recorded. Lower-limb deep venous thromboses (DVTs) were the most common VTE manifestations, representing the 89% (8/9) of all the VTE in our series. One patients developed also a pulmonary embolism, while another presented a cardiac intra-ventricular thrombus. Six (67%) VTE occurred within 6 months before the EGPA diagnosis. The patient with recurrent thromboses presented 2 DVTs before the EGPA diagnosis and 2 further DVTs within 15 months after the EGPA diagnosis. The patient with the pulmonary embolism, developed the VTE 13 years after EGPA diagnosis concomitantly with a femoral neck fracture. According to our analysis, factors associated with the occurrence of VTE were renal involvement ($p=0.01$), nephrotic range proteinuria >3 g/24 h ($p = 0.03$) and a FFS>1 ($p=0.03$). No differences were observed regarding theANCA status and the BVAS score at the diagnosis between the groups.

Conclusion: The results of this study confirm a higher risk of VTE in patients with EGPA. The pathogenesis of thrombosis in EGPA calls for further studies.

Otolaryngologic Lesions Are Not Rare and Closely Related with Pachymeningitis and Cranial Neuropathy in MPO-ANCA Associated Vasculitis. Takahiro Nunokawa, Naoto Yokogawa, Kota Shimada and Shoji Sugii. Tokyo Metropolitan Tama Medical Center, Tokyo, Japan.

Background/Purpose: Recently several case reports of serous otitis media (SOM), hypertrophic pachymeningitis (HP) and cranial neuropathy (CN) have been reported in connection with MPO-ANCA associated vasculitis (MPO-AAV). However, there are few clinical studies on the lesions. Herein, we address the frequency and the characteristics of these manifestations in patients with MPO-AAV.

Methods: This retrospective study focused on consecutive patients in whom MPO-AAV was diagnosed between 2003 and 2014 at Tokyo Metropolitan Tama Medical Center. We investigated their clinical and radiological profile by reviewing the medical records.

Results: A total of 111 patients with MPO-AAV were seen at the hospital in this period. There were 19 patients (17%) with at least one of the manifestations: SOM, HP, or CN. SOM was observed in 16 cases (14%), and constituted the first manifestation of the disease in 11 cases. HP and CN were seen in eight (7%) and seven (6%) patients, respectively. Of the patients presenting with SOM, seven patients had HP and/or CN (4 with HP and CN, 2 with CN, 1 with HP). Of three HP patients unassociated with SOM, CN was detected in one. There were no patients with isolated CN. Of the 11 patients examined by MRI, six patients demonstrated intense inflammation in the epipharynx. There was a significant difference in the rate of glomerulonephritis between the patients with the manifestations and those without them (32% vs. 73%; $P = 0.0006$). Furthermore, none of the patients with HP exhibited glomerulonephritis.

Conclusion: SOM is not a rare manifestation in MPO-AAV and often precedes other manifestations. There is a close relationship among SOM, HP and CN. Inflammation in the epipharynx might play a role as a pre-condition for the development of SOM and HP.

Granulomatosis with Polyangiitis (Wegener's): Endoscopic Management of Tracheobronchial Stenosis - Results from a Multicenter Experience in 47 Patients. Benjamin Terrier[1], Agnes Dechartres[2], Charlotte Girard[3], Stéphane Jouneau[4], Jean-Emmanuel Kahn[5], Robin Dhote[6], Jean Cabane[7], Estibaliz Lazaro[8], Thomas Papo[9], Nicolas Schleinitz[10], Guillaume Le Guenno[11], Luc Mouthon[12] and Loïc Guillevin for the French Vasculitis Study Group[12]. [1]Cochin Hospital, Paris, France, [2]Hotel Dieu, Paris, France, [3]CHU, Lyon, France, [4]CHU, Rennes, France, [5]Internal Medicine, Foch Hospital, Suresnes, France, [6]Avicenne University Hospital, Bobigny, France, [7]Saint-Antoine, Paris, France, [8]CHU, Pessac, France, [9]Bichat Hospital, Paris, Paris, France, [10]APHM, marseille, France, [11]Internal Medicine department, Clermont-Ferrand, France, [12]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France.

Background/Purpose: Tracheobronchial stenosis (TBS) is noted in 12 to 23% in patients with granulomatosis with polyangiitis (GPA), and includes subglottic stenosis (SGS) and bronchial stenosis. The optimal systemic treatments and endoscopic interventions providing the best efficacy, and the best timing for such interventions, remain unclear, explaining why, in the 2010s, TBS remains a therapeutic challenge in the management of GPA patients.

Methods: To analyze the endoscopic management of TBS in GPA and to identify factors associated with the efficacy of endoscopic interventions, we conducted a French nationwide retrospective study that included 47 patients with GPA-related TBS. We also compared characteristics of GPA patients with TBS with GPA patients without TBS included in the French Vasculitis Study Group.

Results: Compared to patients without TBS, those with TBS were younger, more frequently female, and had less frequent kidney, ocular and gastrointestinal involvement and mononeuritis multiplex.

173 procedures were performed in 47 patients. Endoscopic procedures included 137 tracheal and 50 bronchial interventions, mainly endoscopic dilatation, local steroid injection and conservative laser surgery, and less frequently stenting. Per-endoscopic events were noted in only 5/173 cases (2.9%). After the first endoscopic procedure, cumulative incidence of endoscopic treatment failure was 49% at 1 year, 70% at 2 years and 80% at 5 years.

Factors significantly associated with a higher cumulative incidence of treatment failure were a shorter time from GPA diagnosis to endoscopic procedure [HR 1.08 (1.01–1.14); P=0.01] and a bronchial stenosis [HR 1.96 (1.28–3.00); P=0.002]. A prednisone dose ≥30 mg/day at the time of the procedure was associated with a lower cumulative incidence of treatment failure [HR 0.53 (0.31–0.89); P=0.02]. No difference was observed according to the immunosuppressive agents used.

Finally, 13 patients (28%) experienced recurrent bacterial bronchopulmonary infections as late complications of tracheobronchial involvement, fatal in 2 cases (4%).

Conclusion: TBS represent severe and refractory manifestations with high rate of restenosis. High-dose systemic corticosteroids at the time of the procedure and increased time from GPA diagnosis to bronchoscopic inter-

vention are associated with a better event-free survival. In contrast, bronchial stenoses are associated with a higher rate of restenosis than SGS.

Predicting Relapse in Patients with Granulomatosis with Polyangiitis - the Potential Use of Monitoring *in Vitro* ANCA Production. Judith Land, Wayel H. Abdulahad, Coen A. Stegeman, Peter Heeringa and Abraham Rutgers. University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: Patients with granulomatosis with polyangiitis (GPA) suffer from frequent disease relapses, with up to 50% of patients relapsing within 5 years. Several risk factors for relapse have been described, such as persistent ANCA titers and *Staphylococcus aureus* nasal carriage. However, no method to predict a relapse in individual patients is currently known. Changes in measures that reflect the pathogenic process in the patient may be useful to improve relapse prediction in these patients.

Methods: Forty-nine patients with GPA were monitored for a period of 8–16 months, with 3–7 sampling moments for each patient. At each time point peripheral blood mononuclear cells were cultured in presence of CpG-oligodeoxynucleotides, B-cell activating factor and interleukin-21 for 12 days. Subsequently supernatants were analysed for PR3-ANCA by Phadia EliA, results being expressed in response units (RU), and production of total IgG was assessed by ELISA. Moreover, ANCA titers were determined by immunefluorescence. B cell phenotypes were analysed by using flow cytometry on whole blood stained for CD19, CD24, CD27 and CD38. With these markers percentages and total numbers of B cells were determined, and naive, transitional, memory and regulatory B cells were distinguished. Median values from the last measured time point before relapse were compared to non-relapsing patients. For non-relapsing patients the average value of all time points measured was used. All patients were also scored based on their inclusion sample and subsequently analyzed for differences in disease-free survival.

Results: During follow-up 12 patients relapsed. Patients that relapsed showed higher median values of *in vitro* PR3-ANCA (9.1 RU vs 2.2 RU) as well as higher ANCA titers compared to the non-relapsing patients. The higher levels of PR3-ANCA IgG were not a reflection of higher total IgG production, levels of IgG were in fact decreased in patients before relapse. Three patients relapsed directly after the inclusion sample, two of which showed >15 RU of *in vitro* PR3-ANCA. Of the remaining nine patients, six were positive for PR3-ANCA, and also showed an increase in this measure prior to relapse. Patients that had >2 RU of *in vitro* PR3-ANCA at inclusion showed lower disease-free survival, while no such difference was observed for ANCA titer or total IgG. The median percentages of memory and regulatory B cells, both CD24hiCD38hi and CD24hiCD27+, were lower in patients prior to relapse. However, no differences in disease-free survival were observed when patients were divided based on percentage at inclusion. When analyzing the absolute numbers of B cell subsets patients with low numbers of CD27+ memory B cells at inclusion were shown to be more prone to relapse.

Conclusion: This study shows a few promising factors to assist in the prediction of relapse in GPA patients, most notably *in vitro* ANCA production. Finding a better predictive factor for relapse in GPA would allow for timely intervention and possibly prevention of relapse in patients. Currently 80 PR3-ANCA positive GPA patients are being monitored with this method to strengthen these data.

Factors Predictive of ANCA-Associated Vasculitis Relapse in Patients Given Rituximab-Maintenance Therapy. Benjamin Terrier[1], Christian Pagnoux[2], Guillaume Geri[1], Alexandre Karras[3], Chahéra Khouatra[4], Olivier Aumaitre[5], Pascal Cohen[6], Francois Maurier[7], Olivier Decaux[8], Hélène Desmurs-Clavel[9], Pierre Gobert[10], Thomas Quemeneur[11], Claire Blanchard-Delaunay[12], Pascal Godmer[13], Xavier Puéchal[6], Luc Mouthon[6] and Loïc Guillevin for the French Vasculitis Study Group[6]. [1]Cochin Hospital, Paris, France, [2]University of Toronto, Toronto, ON, [3]Hôpital Européen Georges Pompidou, APHP, Paris, France, [4]CHU Louis Pradel, Lyon, Lyon, France, [5]CHU, Clermont-Ferrand, France, [6]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France, [7]Department of Internal Medicine, Metz, France, [8]Rennes University Hospital, Rennes, France, [9]University of Lyon, LYON, France, [10]Centre Hospitalier d'Avignon, Avignon, France, [11]CH, Valenciennes, France, [12]Hôpital de Niort, Niort, France, [13]Department of Internal Medicine, Centre Hospitalier Bretagne Atlantique de Vannes, Vannes, France.

Background/Purpose: Rituximab (RTX) was shown to be as effective as cyclophosphamide to induce remission in patients with ANCA-associated vasculitis (AAV). The prospective MAINRITSAN trial compared RTX to azathioprine (AZA) to maintain AAV remission after a corticosteroid-and-cyclophosphamide induction regimen. Patients were randomly assigned to receive 500-mg RTX infusions on D1, D15 and 5.5 months later, then every 6 months until 18 months, or AZA for 22 months (initial dose: 2 mg/kg/d). Trial results demonstrated that RTX was superior to AZA at maintaining AAV remission during the planned 28 months of observation. Extended follow-up showed that late relapses could occur in RTX-treated patients. In this follow-up study, we analyzed these relapses occurring after RTX-maintenance therapy, aiming to identify factors predictive of them.

Methods: For the 57 patients randomized to the RTX arm, data on their relapses were recorded during the 28-month trial and extended follow-up, and factors predictive of relapse were identified with univariate and multivariate analyses.

Results: Fifty-six patients (men 64%; mean age 54±13 years) were analyzed, with median follow-up at 50 months. Fifteen (26%) patients experienced at least 1 major relapse after a median of 40 (range 8–52) months. Three relapses occurred during the 28-month trial, while 12 relapses occurred during extended follow-up. According to univariate analysis, relapse-associated factors were: granulomatosis and polyangiitis (Wegener's) diagnosis [HR 5.39 (0.70–41.5), P=0.11], proteinase-3 (PR3)-ANCA at AAV diagnosis [HR 6.29 (0.82–48.2), P=0.08], glomerular filtration rate <60 mL/min [HR 0.43 (0.14–1.36), P=0.15], and persistent ANCA-positivity 6 months [HR 2.21 (0.80–6.12), P=0.13] and 12 months [HR 4.45 (1.60–12.4), P<0.01] after starting maintenance therapy. Multivariate analysis retained the following factors as being significantly associated with relapse: PR3-ANCA–positivity [HR 12.5 (1.47–106), P=0.02] and persistent ANCA-positivity at 12 months [HR 7.79 (2.51–24.2), P<0.01]. The 50-month cumulative relapse rates were 82.5, 23.4 and 0%, respectively, for patients with PR3-ANCA and ANCA positivity at 12 months, patients with PR3-ANCA and negative ANCA at 12 months, and those with myeloperoxidase-ANCA.

Conclusion: A quarter of AAV patients who received RTX-maintenance therapy experienced late relapses during extended follow-up. Factors predictive of relapse for these patients were PR3-ANCA–positivity and persistent ANCA positivity 12 months after starting maintenance therapy. Our findings suggest that pursuing RTX-maintenance therapy in these patients could be beneficial to prevent relapses.

***Staphylococcus Aureus* Nasal Carriage and Relapses, Bvas, ANCA-Positivity and Cotrimoxazole Use in ANCA-Associated Vasculitis.** Boun Kim Tan[1], Yoann Crabol[1], Jason Tasse[2], Frederic Laurent[2], Xavier Puechal[3], Christine Vinter[4] and Loïc Guillevin[1]. [1]Hôpital Cochin, University Paris V Descartes, Paris, France, [2]International Centre for Research in Infectious Diseases, Lyon, France, [3]French Vasculitis Study Group (FVSG), Paris, France, [4]Hôpital Cochin, Paris, France.

Background/Purpose: *Staphylococcus aureus* (SA) nasal carriage has been reported to be more frequent and associated with persistent ANCA-positivity and relapse in patients with granulomatosis with polyangiitis (GPA). Antibiotics, including cotrimoxazole (CTX), usually active against SA, have been shown to prevent relapses in some GPA patients. Nasal

carriage of SA and its small colony variants (SCV; intracellular SA with altered virulence phenotypes involved in chronic recurrent infection models) is unknown, respectively, during other ANCA-associated vasculitides (AAV), and those AAV and GPA.

Methods: All consecutive patients (09/2012–05/2013) with GPA, eosinophilic granulomatosis with polyangiitis (EGPA) or microscopic polyangiitis (MPA), followed at the French National Vasculitis Referral Center, and hospitalized patients, without vasculitis or specific risk factors for SA carriage (controls), were enrolled. All had bilateral anterior nasal swab cultures and SA-carriage frequencies were determined for each group. The French National Reference Center for Staphylococci identified the strains. Associations between SA nasal carriage and clinical manifestations, Birmingham Vasculitis Score (BVAS)-assessed disease activity, ANCA or C-reactive protein (CRP) level, and CTX impact on SA nasal carriage and BVAS were analyzed.

Results: A total of 119 AAV (GPA, n=80; EGPA, n=28; MPA, n=11) patients and 28 controls were enrolled. SA nasal carriage among the 3 AAV groups did not differ: 24 (30%) GPA, 8 (28.6%) EGPA and 3 (27.3%) MPA (P=0.971). Controls had non-significantly less frequent SA carriage (13.8%; P=0.39). SA-SCV phenotypes were identified in samples from 5/24 (20.8%) GPA, 1/8 (12.5%) EGPA and 2/3 (66.7%) MPA patients. SA nasal carriage was not significantly associated with number of prior relapse (P=0.866), BVAS (P=0.724), ANCA-positivity (P=0.657) or CRP level (P=0.340) for AAV, or GPA prior relapses (P=0.971) or BVAS (P=0.485). However, CTX use (usually as prophylaxis) was associated with a lower BVAS (P=0.029) and tended to be associated with a lower SA nasal carriage rate [9/43 (20.9%) patients on CTX vs 25/71 (35.2%) not on CTX; P=0.09].

Conclusion: Based on our results, SA nasal carriage did not differ among the AAV considered but seemed more frequent than in controls. Notably, CTX use, but not SA carriage, was associated with a lower BVAS and might reflect its intrinsic antiinflammatory rather than antimicrobial activity. Further bacterial analyses are needed to determine SA-strain susceptibility to CTX and identify known epidemic SA clones among those isolated from AAV carriers.

Background/Purpose: A key goal in the management of ANCA-Associated Vasculitis (AAV) is to improve and preserve health-related quality of life (HRQOL). Several studies have found that patients with AAV have reduced HRQOL. We conducted a non-blinded, randomized–controlled, remission-maintenance trial (MAINRITSAN) to investigate the effects of rituximab versus azathioprine for AAV maintenance therapy on health-related quality of life.

Methods: In the phase III MAINRITSAN study, once complete remission was obtained for eligible patients (18–75 years old) with a combined glucocorticoid and pulse cyclophosphamide, 115 patients with newly diagnosed (2/3 of the enrolments) or relapsing (1/3) AAV, who fulfilled the American College of Rheumatology classification criteria(5) and/or the Chapel Hill Consensus Conference definition classification for AAV (6), were enrolled and randomly assigned, at a 1:1 ratio, to receive a 500-mg rituximab (RTX) infusion on D1, D15, 5.5 months later, then every 6 months for a total of 5 infusions over 18 months, or azathioprine (AZA) maintenance therapy for 22 months at the initial dose of 2 mg/kg/d. Mean changes every 3 months in SF-36 and HAQ from baseline to month 24 were analyzed. ClinicalTrials.gov, http://clinicaltrials.gov/, NCT00748644.

Results: Mean improvements in HAQ, from baseline to month 24 were statistically significantly greater in the rituximab group (−0.16 points) than in the control group (P = 0.038). As demonstrated by SF-36, baseline HRQOL in study patients was significantly impaired compared with age- and gender-matched US norms. At month 24, mean changes from baseline in SF-36 PCS scores trended to be greater in rituximab group (−3.95 points, P = 0.067) but surprisingly mean changes from baseline in SF-36 MCS were statistically significantly greater in azathioprine group (−4.23 points, P = 0.041).

Conclusion: Rituximab treatment to maintain AAV remission in the MAINRITSAN trial resulted in statistically significant but maybe not clinically meaningful improvement in physical functions.

Plasmapheresis Therapy in ANCA-Associated Vasculitides: A Single-Center Retrospective Analysis of Renal Outcome and Mortality. David Solar-Cafaggi, Yemil Atisha-Fregoso and Andrea Hinojosa-Azaola. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.

Background/Purpose: ANCA-associated vasculitides (AAV) are rare, potentially fatal diseases with multiorgan involvement. Evidence for the use of plasmapheresis (PLEX) in patients with severe forms of AAV is limited and its long-term benefits on mortality and renal outcome are still unclear. The aim of our study was to evaluate renal outcome and mortality in clinical ground of AAV patients undergoing PLEX.

Methods: Retrospective study of patients with Granulomatosis with Polyangiitis (GPA) and Microscopic Polyangiitis (MPA) and positivity for MPO or PR3-ANCA antibodies attended at our center from 2000 to 2012. In 25 patients, PLEX was added to conventional therapy (high-dose steroids plus one or more immunosuppressants); they were compared with 25 patients treated only with conventional therapy without PLEX, matched for age (± 7 years), activity of disease (BVAS/GW, range ± 6) and glomerular filtration rate (GFR) (MDRD range ± 16 ml/min) at the time of intervention. Demographic data, comorbidities, clinical and laboratory characteristics were recorded. Outcome variables were mortality, dialysis dependence and GFR at 12 months. Statistics: Descriptive statistics, Student T-test, Mann-Whitney U-test, Chi-square, Fisher exact test, McNemar's test and Kaplan-Meier survival analysis, log-rank test, $p<0.05$.

Results: Patients were mainly female (56%) and GPA (78%), mean age 47 years and BVAS/GW of 13. The only basal differences between patients with and without PLEX were more positivity for anti-PR3 (p=0.02), more frequency of methylprednisolone pulses ever (p=002) and lower accrued doses of CYP (p=0.01) in patients with PLEX. Main indication for PLEX was glomerulonephritis (96%).

At the time of intervention more patients in the PLEX group were on dialysis (p=0.02) and received concomitant methylprednisolone pulses (p=0.02) compared to patients without PLEX. At 12 months, both groups showed improvement in GFR before and after intervention (18.3±13.7 and 43.2±37.4 ml/min, p=0.001 in PLEX group; 23.5±14.5 and 39.6±25.1 ml/min, p=0.001 in conventional therapy group), but no difference was found between groups (p=0.85). No

differences were found in dialysis dependence between groups at 12 months (p=0.49), but more patients that completed one year of follow-up and were on dialysis at the time of intervention were free of dialysis at 12 months in the PLEX group (68% vs 32%, p=0.01) compared to patients without PLEX (20% vs 20%, p=1.0). Patients in the PLEX group presented more frequency of severe infections during the first 3 months (p=0.04). Survival at 12 months was 80% in the PLEX group and 96% in the conventional therapy group, with no differences in survival at outcome between groups (p=0.13, log-rank). Infection was the main cause of death in both groups.

Conclusion: In our population with AAV, both PLEX and conventional therapy improved renal function after the intervention, but no differences were found in dialysis dependence between groups at 12 months. Survival was similar in patients with and without PLEX, and infections were the main cause of death.

Outcomes of Triple Therapy (Plasma Exchange, Cyclophosphamide and Systemic Corticosteroid) for Anti-Neutrophil Cytoplasm Antibody (ANCA)-Associated Vasculitis. Joanna Ueng[1], Katerina Pavenski[2] and Laurence Rubin[3]. [1]University of Toronto, Toronto, ON, [2]St. Michael's Hospital, Toronto, ON, [3]St. Michael Hospital, Toronto, ON.

Background/Purpose: Microscopic polyangiitis (MPA), granulomatosis with polyangiitis (GPA), and Churg-Strauss Syndrome (CSS) are syndromes known as ANCA-associated vasculitis (AAV). In addition to immunosuppressive therapy, plasma exchange (PLEX) may be indicated in patients with pulmonary hemorrhage and/or severe renal insufficiency. However, PLEX may be associated with serious adverse effects such as infection. The objective of this study was to characterize and examine outcomes in patients with AAV treated with PLEX, in addition to corticosteroid and cytotoxic agents, at a major referral centre for PLEX.

Methods: A retrospective chart review was performed on all patients with AAV treated with PLEX at a major referral centre for PLEX between January 1, 2002 to May 31, 2012. Patients with GPA, MPA, CSS, systemic p-ANCA vasculitis, and systemic c-ANCA vasculitis were included while those with incomplete 3 and 12 month follow-up were excluded. Demographic, clinical, laboratory, and radiographic data from electronic and paper medical records were collected. Acute kidney injury (AKI) was defined as an increase in serum creatinine by ≥26.5 umol/L within 48 hours, or a ≥1.5 times increase above baseline serum creatinine within 7 days. Disease activity was assessed by the Birmingham Vasculitis Activity Score (BVAS) (v.3). Primary outcomes were survival at 1 year, dialysis dependence at 1 year, and dialysis dependence at 3 months from initiation of PLEX. The study was approved by the institution's Research Ethics Board.

Results: Forty-nine patients with AAV were treated with PLEX during the study period. Outcomes are reported for 43 patients, which excludes 4 patients lost to follow up and 2 patients with 3 and 12 month follow up that occurred outside the study period. 58% were male, and the median age was 59 years (range 25–83). This was the first presentation of AAV for 60%. GPA, MPA, CSS, systemic p-ANCA vasculitis, and systemic c-ANCA vasculitis was the primary diagnosis in 39%, 28%, 0%, 5%, and 28% of patients. Both pulmonary hemorrhage and AKI were present in 66%. The mean BVAS (v.3) score at presentation was 17.9. Triple therapy with systemic corticosteroid, cyclophosphamide, and PLEX occurred in 90%. Survival at 1 year, dialysis dependence at 1 year, and dialysis dependence at 3 months was 88%, 28%, and 37%, respectively. Renal recovery amongst those who were dialysis-dependent at presentation was 37% and 47% at 3 months and 1 year, respectively. Infection, bleeding (non-pulmonary hemorrhage), symptomatic hypotension, and catheter-related thrombosis occurred in 44%, 20%, 5%, and 2% of patients.

Conclusion: With triple therapy, 88% of patients with AAV survived at least 1 year. Almost 50% of patients who were dialysis-dependent on presentation experienced renal recovery after 1 year. An international randomized controlled trial is currently underway to investigate the specific role of PLEX in the treatment of AAV.

Long-Term Outcomes Among Patients with Renal Disease Secondary to ANCA-Associated Vasculitis: Temporal Trends over 25 Years. Rennie L. Rhee[1], Susan L Hogan[2], Caroline J. Poulton[2], Julie Anne G. McGregor[2], J. Richard Landis[1], Ronald Falk[2] and Peter A. Merkel[3]. [1]University of Pennsylvania, Philadelphia, PA, [2]UNC Kidney Center, Chapel Hill, NC, [3]Vasculitis Center, University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Significant advances have been made in the diagnosis and treatment of patients with ANCA-associated vasculitis (AAV). However, little is known about how these advances have changed long-term outcomes especially among patients with renal involvement. The objective of this study was to examine temporal changes of long-term outcomes, including the impact of early diagnosis and duration of cyclophosphamide use in AAV.

Methods: An inception cohort of patients with AAV from the Glomerular Disease Collaborative Network diagnosed from 1985 and 2009 was evaluated. All patients had a positive test for ANCA and a renal biopsy consistent with AAV. Patients were categorized into 5-year time periods based on year of diagnosis. The primary outcome was occurrence of end-stage renal disease (ESRD) or death in 5 years; secondary outcome was occurrence of relapse in 5 years. Kaplan-Meier estimates, Cox proportional hazard models, and linear contrasts were used for analysis. Models were adjusted for age, sex, race, diagnosis (granulomatosis with polyangiitis, microscopic polyangiitis, or renal-limited vasculitis), ANCA type (C/PR3 or P/MPO), site (tertiary care or community practice), duration of disease before biopsy, extra-renal organ involvement, and serum creatinine (SCr) at time of diagnosis. In a subgroup of patients with no event by 12 months, duration on cyclophosphamide (CYCdur, months) up to 12 months was also included.

Results: Data was available on 568 patients who met the inclusion criteria. Across the 5 time periods, there were no significant differences in baseline characteristics or duration of follow-up; however, over time increasing proportions of patients were managed in a tertiary care center and baseline SCr decreased (**Table**). There was a decreasing 5-year risk of ESRD or death across the time periods and an increasing 5-year risk of relapse, p for trend $<$ 0.001 (**Figure**). After adjustment for baseline characteristics, the risk of relapse was similar between the time periods (p for trend = 0.698) but the risk of ESRD or death continued to decrease over time (p for trend = 0.008). SCr was the only significant predictor of decreasing risk of ESRD or death (HR 1.14, 95% CI 1.08–1.21, P<0.001) while CYCdur was not associated with risk of ESRD or death.

Conclusion: In patients with AAV, over 25 years, the risk of ESRD or death decreased and the risk of relapse has not changed. A lower SCr at diagnosis, a potential marker of earlier disease detection, is the strongest predictor of improvement in risk of ESRD or death.

Table: Patient characteristics at diagnosis

Characteristic	All	Time Period 85–89	90–94	95–99	00–04	05–09	*p*-value for trend

Long-Term Follow-up of Non-HBV Polyarteritis Nodosa and Microscopic Polyangiitis with Poor-Prognosis Factors. Maxime Samson[1], Xavier Puéchal[2], Hervé Devilliers[3], Pascal Cohen[2], Boris Bienvenu[4], Kim Heang Ly[5], Alain Bruet[6], Brigitte Gilson[7], Marc Ruivard[8], Edouard Pertuiset[9], Mohamed Hamidou[10], Benjamin Terrier[2], Christian Pagnoux[11], Luc Mouthon[2], Loic Guillevin[12] and The French Vasculitis Study Group (FVSG)[12]. [1]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France; Internal Medicine and Clinical Immunology, Dijon University Hospital, Dijon, France, [2]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France, [3]Department of internal medicine and systemic diseases, Dijon, France, [4]CHU Côte de Nacre, CAEN, France, [5]CHU Dupuytren, Limoges, Limoges, France, [6]Department of Nephrology and Internal Medicine, CH de Poissy Saint-Germain-en-Laye, Poissy, France, [7]Department of Nephrology and Internal Medicine, CH de Verdun, Verdun, France, [8]CHU Estaing, Clermont–Ferrand, Clermont–Ferrand, France, [9]René Dubos Hospital, Pontoise, France, [10]CHU Hôtel Dieu, Nantes, Nantes, France, [11]University of Toronto, Toronto, ON, [12]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France.

Background/Purpose: To study the long-term outcomes of 65 patients with non-HBV polyarteritis nodosa (PAN) or microscopic polyangiitis (MPA) enrolled in a prospective, randomized, open-label trial,[1] with Five-Factor Score (FFS)-defined poor-prognosis factors, focusing on survival, relapses, clinical and laboratory findings, therapeutic responses and sequelae.

Methods: Patients' data were updated in 2014. The new Chapel Hill criteria were applied to classify PAN and MPA. The following definitions were used: relapses: recurrence and/or new appearance of ≥1 vasculitis manifestation(s) after remission lasting ≥3 months; failure: no clinical remission with the assigned treatment. Times to relapse and/or death were calculated from treatment onset. For survival analyses, data were censored after 90 months of follow-up.

Results: Mean±SD overall follow-up was 65.6±47.5 months, comparable for PAN and MPA patients. For the 65 patients (41 MPA and 24 PAN), mean age at diagnosis was 55.3±17.0 years, mean Birmingham Vasculitis Activity Score 2003 23.7±8.8; FFS=1, 2 or ≥3 for 27, 30 or 8 patients, respectively; ANCA-positivity: 2 (8.3%) PAN (1 $cANCA^+$ and 1 $pANCA^+$, anti-myeloperoxidase [MPO]– and proteinase–3–negative) and 34 (82.9%) MPA ($pANCA^+$, 90.6% MPO-specific). Patients received 3 methylprednisolone pulses and corticosteroids (CS) and were randomized to receive 6 or 12 intravenous cyclophosphamide (CYC) pulses. After treatment, 53/65 (81.5%, 32 MPA and 21 PAN) entered remission. Treatment was intensified for the 12 nonresponders: 4 achieved remission and 8 died before remission. After remission, 25/57 (43.9%, 18 MPA, 7 PAN) patients relapsed 29.4±27.4 months after starting treatment. The respective 3-, 5- and 7-year overall survival rates were 79.5%, 72.3% and 64.4%, with no significant difference between PAN and MPA patients (p=0.241). Overall survival tended to be shorter for patients given 6 versus 12 CYC pulses (p=0.157). The respective 1-, 3- and 5-year relapse-free–survival rates were 84%, 68.4% and 52.4%, comparable for PAN and MPA patients. The relapse-free–survival difference between patients that received 6 versus 12 CYC pulses tended to decline during follow-up and was no longer significant at 90 months (p=0.07). At the last follow-up visit, 38/65 (58.5%) patients were still alive, 12/38 (31.6%) were still taking CS and 8/38 (21.1%) an immunosuppressant (IS). The mean vasculitis damage index score for the 57 patients with ≥1 remission(s) was 2.3±1.5, with the most frequent sequelae being hypertension (50%), chronic renal failure (creatininemia >150 μmol/L) (44.6%) and neuropathy (23.2%). Notably, 7 patients, all with MPA, progressed to end-stage renal failure and required chronic dialysis; 2 of them received kidney transplants.

Conclusion: For non-HBV PAN or MPA patients with FFS≥1 at diagnosis, overall survival at 7 years reached 64%. Relapses were frequent during long-term follow-up, even for patients who had received 12 CYC pulses at diagnosis, thereby confirming that PAN and MPA patients with FFS≥1 at diagnosis require post-remission maintenance therapy with an IS or biotherapy.

The Importance of Histopathological Classification of ANCA-Associated Glomerulonephritis in Renal Function and Renal Survival. Valeria Scaglioni[1], Marina Scolnik[1], Luis J. Catoggio[1], Carlos Federico Varela[2], Gustavo Greloni[2], Silvia Christiansen[3] and Enrique R. Soriano[1]. [1]Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Argentina, [2]Nephrology Service. Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [3]Pathology Service. Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.

Background/Purpose: Histological changes in renal biopsy are the gold standard for establishing the diagnosis of antineutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis (GN). In 2010 a new histopatological classification for ANCA-associated GN (ANCA GN) was developed by an international working group of renal pathologist. The scheme divides ANCA GN into 4 categories: focal (≥50% normal glomeruli), crescentic (≥50% glomeruli with cellular crescents), mixed (<50% normal, <50% crescentic, <50% globally sclerotic glomeruli) and sclerotic (≥50% globally sclerotic glomeruli). It has been demonstrated that these categories at baseline correlate

strongly and independently with renal function at 1 and 5-years follow up.

Objective: The aim of this study was to determine whether the new histopathologic classification scheme is associated to changes in renal function and renal survival in a cohort of patients with ANCA associated vasculitis (AAV) who underwent kidney biopsy in a single center.

Methods: We included retrospectively all patients with diagnosis of ANCA GN between January 2002 and May 2013 and had at least 1 year of follow-up. Baseline date was defined as the date of the biopsy. Renal biopsies were reviewed and classified according to the new classification. Serum creatinine, estimated glomerular filtration rate (eGFR) at time of the biopsy, death, requirement of dialysis, use of immune suppression and plasmapheresis at follow up were recorded.

Results: Forty-four patients (77.2% females) were included (table 1). The mean age was 63.7 (SD:17.5). 25 (56.8%) patients were pANCA positive, 14 (31.8%) cANCA positive, and 5 (11.3%) were ANCA negative. Four patients died during first year of follow up (1 within each biopsy category). Among surviving patients, overall mean improvement in eGFR at 1 year was 13.2-ml/min/1.73 m^2. Age and sex were not significantly associated with the 1-year eGFR change. There was a significant difference in the mean change in eGFR at 1 year based on the histopathologic class (table 2). Focal biopsies were associated with the highest eGFR at presentation, whereas crescentic, mixed and sclerotic were associated with lower eGFRs. Crescentic class was associated with the greatest 1-year improvement in eGFR while sclerotic class did not show significant improvement.

Conclusion: Our study shows association between crescentic class and improvement in eGFR and association between sclerotic class and reduction in eGFR at 1-year. These results support the use of the histopathologic classification in determining renal prognosis of patients with ANCA GN.

Prognostic Factors for Interstitial Lung Disease with Microscopic Polyangiitis. Takeshi Shoda, Tohru Takeuchi, Takaaki Ishida, Hideyuki Shiba, Youhei Fujiki, Daisuke Wakura, Shuzo Yoshida, Takuya Kotani, Shigeki Makino and Toshiaki Hanafusa. Osaka medical college, Osaka, Japan.

Background/Purpose: Many patients with interstitial lung disease (ILD) complicated by microscopic polyangiitis (MPA) show a UIP pattern on chest CT. The prognosis is poorer than that of ILD-free MPA(1). However, the details remain to be clarified.

To investigate the prognosis of pulmonary fibrosis with microscopic polyangiitis (MPA-ILD) and prognostic factors.

Methods: Of patients with MPA who were admitted to our hospital between 2001 and 2013 based on the EMEA classification in 2007, the subjects were MPO-ANCA-positive patients with ILD on HRCT. Using the clinical data and fibrosis score on HRCT(2), we examined prognostic factors.

Results: There were 42 patients with MPA-ILD, consisting of 20 males and 22 females, with a median age (interquartile range) of 73 years (range: 69–76 years). The MPO-ANCA, KL-6, Aa-DO2, %FVC, %DLco/VA, and RV/TLC values at the start of treatment were 189 (52–459) EU, 446 (261–615) U/mL, 25.7 (12–34), 81.3 (69–95)%, 61.4 (45–71)%, and 41.1 (33–50)%, respectively. Concerning HRCT images, 30 patients showed a UIP pattern, and 12 showed a non-UIP pattern. PSL was administered to 41 patients. In 37, it was combined with immunosuppressive drugs (CY was used in 16). In 8, apheresis was performed. In 37 patients, the MPO-ANCA level was maintained below the detection limit.

With respect to the prognosis, 8 patients died (exacerbation of interstitial pneumonia: 2, infection and alveolar hemorrhage: 2, pulmonary hypertension: 1, sudden death: 2, and renal failure: 1). The 5- and 10-year survival rates after the start of treatment were 81.6 and 68.0%, respectively.

Univariate analysis using Cox's proportional hazard model showed that prognostic factors for lung disease-associated death included the HRCT score ($p<0.001$), CPFE ($p=0.025$), and administration of CY ($p=0.041$). However, on multivariate analysis of these factors, the HRCT score was significantly correlated ($p=0.006$).

Conclusion: Treatment for MPA-ILD was continued, and the prognosis was more favorable than previously reported. Marked fibrosis and CPFE at the start of treatment were considered to be prognostic factors for lung disease-associated death. Immunosuppressive therapy early after onset may improve the prognosis of MPA-ILD.

Survival of Microscopic Polyangiitis (MPA) Patients with and without Pulmonary Fibrosis (PF). Lina María Saldarriaga Rivera, Natllely Ruiz and Luis F. Flores-Suarez. Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico.

Background/Purpose: Pulmonary fibrosis (PF) occurs in up to 30% of patients with microscopic polyangiitis (MPA). Data suggest PF implies a higher mortality. We examined the survival of our MPA patients according to the presence or absence of PF.

Methods: Retrospective analysis of all MPA patients present in a single respiratory referral centre from 2003-present. All patients were defined according to the CHCC 2012 Nomenclature. Univariate analysis was used to establish proportions with means ± SD and medians calculated; bivariate analysis was used to compare groups, Student's t test for continuous variables and X^2 test with Yates correction for categorical variables. Kaplan-Meier analysis was done for survival. Significance was established when $p<0.05$.

Results: From 37 MPA patients (35 MPO-ANCA positive, 2 PR3-ANCA positive), the majority were females (67.5%); 15/37 (40.5%) had PF with equal gender distribution. Women were predominant in those without PF (77.2%, $p<0.05$). PF antedated other disease manifestations for more than a year in 14/15 PF patients. One developed it concurrently. The median survival of the group was 37 months (2–156). Myalgias were more frequent in those with PF (53.3% vs 18.2%), while hematuria (33.3 vs 56.5%), acute respira-

tory failure (6.7% vs. 36.7%) and lymphopenia (0 vs. 22.7%) were less frequent (all significant). Lung hemorrhage was more frequent in those without PF (68.2% vs 33.3%, p=0.08). No other significant differences in clinical or paraclinical variables were seen, being similar at disease onset in both groups. There were 6 deaths, 5 with and 1 without PF; 1 lost to follow-up patient without PF was censored as death for survival analysis. By 41 months, there is a trend for a better cumulative survival in patients without PF (88 vs 70%) (graph), irrespective of PF being present at onset or during disease evolution.

Conclusion: While we acknowledge the limitations of this study (sample size, need of longer follow-up), it suggests that patients with MPA and PF have a worst outcome than those without PF, even when patients without PF presented with more severe manifestations (respiratory failure, lung hemorrhage, renal symptoms). Interestingly the majority of these patients had PF antedating other MPA manifestations, probably due to referral bias. The influence of this mode of presentation and other factors in outcome is subject to further evaluation.

Vasculitis As Underlying Cause of Death in the United States: 1999 – 2010. Alicia Rodriguez-Pla[1], Paul A. Monach[2] and Jose Rossello-Urgell[3]. [1]Boston University, Boston, MA, [2]Vasculitis Center, Boston University School of Medicine, Boston, MA, [3]Baylor Institute for Immunology Research, Dallas, TX.

Background/Purpose: Current data on mortality rates of primary vasculitis, which were tradionally associated with a dreadful prognosis, are limited. Therefore, we aimed to estimate the mortality rates of the main primary vasculitis disorders using the most current publicly available mortality data in the USA.

Methods: To obtain mortality rates of vasculitis as the underlying cause of death, we used the CDC Wonder Underlying Cause of Death database and its query system, which contains data from 1999 to 2010. We used the following ICD-10 codes for the queries: D69.0 (Allergic purpura) for Henoch-Schonlein purpura, D89.1 (Cryoglobulinaemia), M30.0 (Polyarteritis nodosa), M30.1 (Polyarteritis with lung involvement [Churg-Strauss]) for eosinophilic granulomatosis with polyangiitis, M30.3 (Mucocutaneous lymph node syndrome [Kawasaki]), M31.0 (Hypersensitivity angiitis) for Goodpasture's syndrome, M31.3 (Wegener's granulomatosis) for granulomatosis with polyangiitis (GPA), M31.4 (Aortic arch syndrome [Takayasu]), M31.5 (Giant cell arteritis [GCA] with polymyalgia rheumatica [PMR]) and M31.6 (Other giant cell arteritis) for GCA, M31.7 (Microscopic polyangiitis), and M35.2 (Behcet's disease). Results were obtained by year, gender, and race. To obtain age-adjusted mortality rates we used year 2000 U.S. standard population. Mortality rates are given as number of deaths per million. Mantel-Haenszel chi-square was used to analyze trends.

Results: During the twelve-year period, vasculitis was the underlying cause of death of 7,888 patients. Age-adjusted mortality rate was 2.22 per million (95% CI: 2.17–2.27). There were more deaths in females (4,412) than in males (3,476), but the age-adjusted mortality rate was higher in males than in females (2.28 vs 2.16 per million). Age-adjusted mortality rate was clearly higher in Whites (2.34, 2.28–2.39) than in Black/African American population (1.19, 1.08–1.31). Regarding disease-specific mortality, GPA accounted for 51.2% of all vasculitis deaths. Interestingly, there were no deaths for GCA with PMR. Year 2000 showed the highest mortality (2.58, 2.40–2.77), whereas the lowest level was seen in 2008 (1.79, 1.64–1.94). Since 1999, there has been a significant trend to the decrease ($p<0.0001$).

Conclusion: The most current public data indicates that mortality by vasculitis remains very low, which is clearly related to the low incidence of these disorders. Age-adjusted mortality rate was higher in males and in White, which can be explained by the fact that GPA, which is more frequent in males and White, is responsible for half of the overall number of deaths. There is a clear trend to a progressive decrease of the mortality rates by primary vasculitis over the 12-year period of the study. Recent introduction of biological treatments, less toxic therapeutic regimens, such as shortening cyclophosphamide treatment, earlier diagnosis as a result of higher awareness and improved diagnostic tools may have presumably contributed to this decrease in mortality rates. Our findings should be taken with caution until quality studies to determine the reliability of the data about these rare diseases available in national databases are performed.

IIS La Princesa, Madrid, Spain, [7]Hospital Universitario Lucus Augusti, Rheumatology Division, Lugo, Spain, [8]Immunology department, Hospital Universitario Virgen del Rocío, Sevilla, Spain, [9]Rheumatology Department. Basurto University Hospital, Bilbao, Spain, [10]Instituto de Parasitología y Biomedicina López-Neyra, IPBLN-CSIC, Armilla (Granada), Spain, [11]Hospital Marques de Valdecilla, Santander, Spain.

Background/Purpose: Henoch-Schönlein purpura (HSP) is essentially a childhood disease, being the most common type of vasculitis in children and an infrequent condition in adults. An increased familial occurrence supports a genetic predisposition for this vasculitis. In this context, the role of the HLA (human leukocyte antigen) region in the HSP pathogenesis has previously been studied. However, data reported so far on the potential association of HSP with HLA-DRB1 alleles are scarce and they were generally the result of small series of HSP patients with often contradictory results. To further investigate whether *HLA-DRB1* alleles are implicated in the susceptibility and severity of HSP, we performed a study that encompassed the largest series of HSP patients ever assessed for genetic studies in Caucasian individuals.

Methods: Our study population included 279 Spanish patients diagnosed with HSP and 335 sex and ethnically matched controls. HSP patients fulfilling the American College of Rheumatology (Arthritis Rheum 1990; 33: 1114–21) and the Michel et al (J Rheumatol 1992; 19: 721–8) classification criteria were recruited from Hospital Universitario Lucus Augusti (Lugo), Hospital Universitario Marqués de Valdecilla (Santander), Hospital Universitario La Princesa (Madrid), Hospital Universitario San Cecilio (Granada) and Hospital

Universitario de Basurto (Bilbao). HLA-DRB1 phenotypes were determined using PCR-SSOP Luminex.

Results: After adjusting the results for multiple testing corrections, we disclosed a statistically significant increased frequency of *HLA-DRB1*01* in HSP patients compared to controls ($p<0.001$, OR=3.98 [95% CI: 2.68–5.95]). In contrast, a significantly decreased frequency of *HLA-DRB1*03* was observed in HSP patients compared to controls ($p<0.001$, OR=0.18 [95% CI: 0.085–0.37]). When patients were stratified according to the presence of nephritis or gastrointestinal manifestations, we disclosed that although no specific HLA-DRB1 association with nephritis was observed, *HLA-DRB1*07* was significantly reduced in the group of HSP patients who experienced gastrointestinal manifestations ($p=0.0011$, OR=0.36 [95% CI: 0.19–0.71]) even after adjusting the results for multiple testing correction ($p=0.012$).

Conclusion: Our study supports an association of HSP with *HLA-DRB1*01*. In contrast, a protective effect against the development of HSP was observed in individuals carrying the *HLA-DRB1*03* allele. *HLA-DRB1*07* exerts a protective effect against the development of gastrointestinal manifestations in patients with HSP.

IIS La Princesa, Madrid, Spain, [7]Hospital Universitario Lucus Augusti, Rheumatology Division, Lugo, Spain, [8]Immunology department, Hospital Universitario Virgen del Rocío, Sevilla, Spain, [9]Rheumatology Department. Basurto University Hospital, Bilbao, Spain, [10]Instituto de Parasitología y Biomedicina López-Neyra, IPBLN-CSIC, Armilla (Granada), Spain, [11]Hospital Marques de Valdecilla, Santander, Spain.

Background/Purpose: Henoch-Schönlein purpura (HSP), the most common type of primary small-sized blood vessel leukocytoclastic vasculitis, is characterized by infiltration of the small blood vessels with polymorphonuclear leukocytes and presence of leukocytoclasia. Skin, joint, gastrointestinal tract and kidney involvement may be affected in patients with HSP. Although the etiology of HSP remains unknown, environmental factors and a susceptible genetic background have been associated with HSP. In this regard, the role of the HLA (human leukocyte antigen) region in the HSP pathogenesis has previously been studied in small series of HSP patients, but contradictory results were obtained. To further establish whether HLA-B alleles are implicated in the susceptibility and severity of HSP, we performed a study that encompassed the largest series of HSP patients ever assessed for genetic studies in Caucasian individuals.

Methods: Our study population included 279 Spanish patients diagnosed with HSP and 335 sex and ethnically matched controls. HSP patients fulfilling the American College of Rheumatology (Arthritis Rheum 1990; 33: 1114–21) and the Michel et al (J Rheumatol 1992; 19: 721–8) classification criteria were recruited from Hospital Universitario Lucus Augusti (Lugo), Hospital Universitario Marqués de Valdecilla (Santander), Hospital Universitario La Princesa (Madrid), Hospital Universitario San Cecilio (Granada) and Hospital Universitario de Basurto (Bilbao). HLA-B phenotypes were determined using PCR-SSOP Luminex.

Results: *HLA-B*41* was significantly increased in patients with HSP compared to controls ($p=0.0001$, OR=3.68 [95% CI: 1.75–8.27]) even after adjusting the results for multiple testing correction ($p=0.0018$). Since previous studies suggest a potential association between *HLA-DRB1*01* and HSP susceptibility, we also evaluated the implication of *HLA-B*41* independently of *HLA-DRB1*01* status in HSP patients and healthy controls. For this purpose we excluded from the analysis patients and controls carrying HLA-DRB1*01 alleles. Interestingly, the association remained statistically significant ($p=0.01$, OR=2.93 [95% CI: 1.20–7.14]).

Conclusion: Our study indicates that *HLA-B*41* is associated with the susceptibility to HSP in Spanish individuals, irrespective of *HLA-DRB1* status.

Are EULAR/Printo/PRES Classification Criteria Appropriate for Classification of IgA Vasculitis in Adults? Alojzija Hočevar[1], Ziga Rotar[2], Vesna Jurcic[3], Joze Pizem[3], Sasa Cucnik[2], Alenka Vizjak[3] and Matija Tomsic[4]. [1]University Medical Centre Ljubljana, 1000 Ljubljana, Slovenia, [2]University Medical Centre Ljubljana, Ljubljana, Slovenia, [3]University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia, [4]BioRx.si, University Medical Centre Ljubjana, Ljubljana, Slovenia.

Background/Purpose: In 2010 EULAR/PRINTO/PRES proposed new classification criteria for pediatric IgA vasculitis (IgAV). In pediatric population these criteria have a higher diagnostic sensitivity than the 1990 American College of Rheumatology (ACR) criteria, while they have thus far not been evaluated in adults. Our main objective was to compare the diagnostic sensitivity of the EULAR/PRINTO/PRES and ACR classification criteria in adult IgAV.

Methods: Adult IgAV cases fulfilling the 2012 revised International Chapel Hill Consensus Conference (CHCC) Nomenclature of Vasculitides definition of IgAV at a secondary/tertiary rheumatology referral center were critically reviewed in partially retrospective (from January 1, 2010 to December 31, 2012) and partially prospective (from January 1, 2013 to April 30, 2014) manner and we assessed whether these patients also fulfilled either the ACR or EULAR/PRINTO/PRES criteria. Biopsy samples were retrieved from the archive and were reevaluated by two pathologists.

Results: Between January 1, 2010 and April 30, 2014 (52 months observation period) 100 consecutive new adult IgAV cases fulfilling the CHCC Nomenclature of Vasculitides definition of IgAV were identified. There were 60 males and 40 females. Median age was 63.2 years (range 18–92, interquartile range (IQR) 40.1–77.2). 4/100 patients were $\leq$ 20 years old at disease presentation. The mean symptom duration was 14 days (range 1–150). Purpura was present in all cases, necrotic in 46/100 and bullous in 11/100 cases. Joints (arthralgia or arthritis) were involved in 46/100, gastrointestinal tract in 38/100, and kidneys in 58/100 patients. General symptoms were present in 18/100 cases. In all patients IgA deposition in vessel walls was documented on direct immunofluorescence staining. Leucocytoclastic vasculitis was observed in 97/100 cases. Granulocytes in vessel wall were found in 85/100 cases. The diagnostic sensitivity of the EULAR/PRINTO/PRES classification criteria was 100 %, and 90 % for the ACR classification criteria (Figure 1).

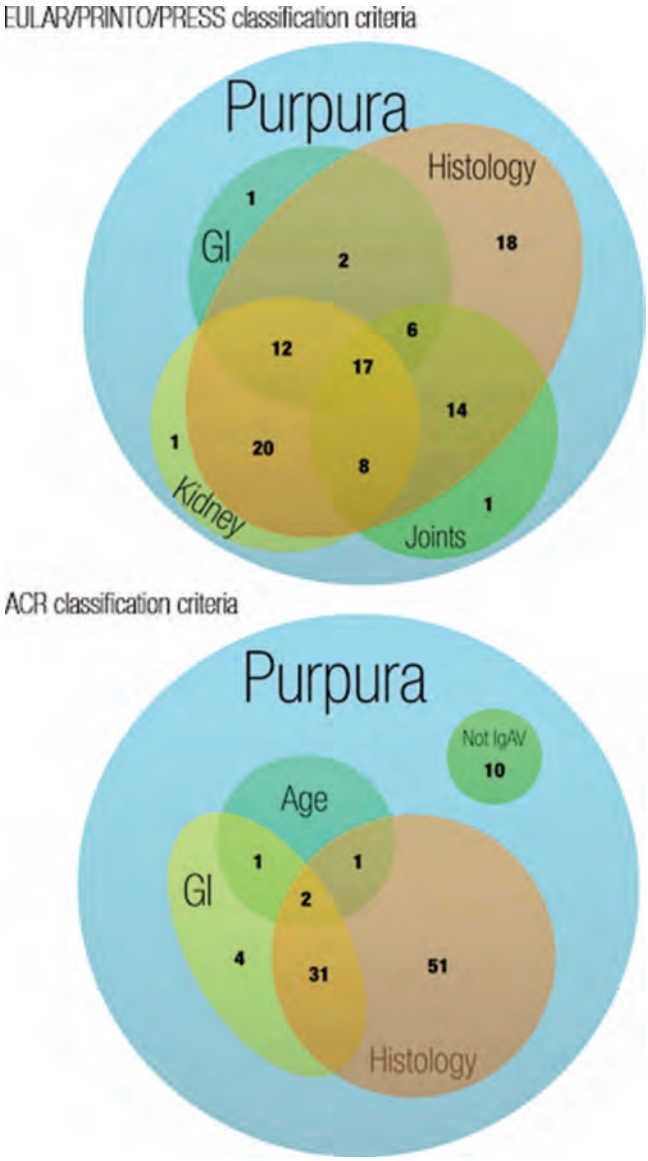

Figure 1. Venn diagram of fulfilled classification criteria items.

Conclusion: Our study supports the use of the 2010 EULAR/PRINTO/PRES criteria not only in children but also in the adult population and show that they are more sensitive than the 1990 American College of Rheumatology IgA vasculitis criteria.

1790

Follow up of an Unselected IgA Vasculitis (Henoch-Schönlein Purpura) Population at Single Rheumatology Center. Alojzija Hočevar[1], Ziga Rotar[2], Jaka Ostrovrsnik[2] and Matija Tomsic[3]. [1]University Medical Centre Ljubljana, 1000 Ljubljana, Slovenia, [2]University Medical Centre Ljubljana, Ljubljana, Slovenia, [3]BioRx.si, University Medical Centre Ljubljana, Ljubljana, Slovenia.

Background/Purpose: In our population IgA vasculitis (IgAV) has an annual incidence rate of 5.1 cases per 10^5 adults increasing with patients' age which makes it by no means uncommon contrary to common belief. Little data is available in the literature about the clinical picture and prognosis of adult IgAV. Available data is most often limited to adult IgAV cases with kidney disease. Our aim was to determine short-term outcomes in an unselected adult IgAV population diagnosed at a single secondary/tertiary rheumatology center.

Methods: We performed an electronic and paper chart review of all adult IgAV cases, diagnosed in our center between January 1, 2010 and December 31, 2013. Appropriate descriptive statistical methods and post hoc tests were used describe our cohort (e.g. Mann-Whitney test, Fisher exact test).

Results: During the observation period 96 new adult IgAV cases were identified. Clinical characteristics at presentation are shown in Table 1. Disease severity was higher in males (median BVAS3 13 vs. 9, p=0.027), and in patients with generalized purpura in contrast to purpura limited to lower limbs (median BVAS3 14 vs. 9, p=0.014). Treatment of IgAV consisted of systemic glucocorticoids (oral 67/96; additional i.v. metil prednisolone pulses 13/96), intravenous cyclophosphamide (9/96), hyperimmune gammglobulins (4/96), plasma exchange (2/96) and mycophenolate mofetil (1/96). During acute phase of the disease 3/96 patients died. Two deaths were attributed to vasculitis (intractable GI hemorrhage in the first; and alveolar hemorrhage in the second patient), while one succumbed following generalized CMV infection and heart failure attributable to immunosuppressive treatment. 18/93 (19.4%) survivors were lost to follow up. The remaining 75/93 (80.6%) patients were followed for a median of 8.4 (IQR 4.8–19.2) months. IgAV relapsed in 13/75 cases (one, two and three times in 8/75, 4/75 and 1/75 cases, respectively). 8/13 (76.9%) patients had a single organ, and 5/13 a multi-organ relapse. Skin was involved in 11, joints in 3, GI tract in 2, and kidney in 2 cases. At last visit urinary abnormalities were present in 13/68 patients. 13/68 had microhameturia (1+, 2+ and 3+ in 6, 3 and 4 cases, respectively); 4/68 had mild proteinuria and 1 patient had proteinuria >1 g per day. Renal function remained stable in 67/68, and worsened in 1/68 case. 7/75 (9.3%) patients died during follow up (cause of death: infection 2; cardiovascular disease 4; unknown 1). In 2/68 survivors malignancy was diagnosed (1 hematologic; 1 teratoma).

Table 1. Clinical characteristic of IgAV patients at presentation and at last follow up

Clinical characteristic of IgAV	at presentation N=96	at last follow-up visit N=68
% male	60	60
Age (median; IQR)	63.4 (40.8-77.3)	/
Purpura # (%)	96 (100)	6 (8.8)
necrotic # (%)	43 (44.8)	0
Joint involvement # (%)	44 (45.8%)	0
arthralgia # (%)	21 (42.7)	0
arthritis # (%)	41 (21.9)	0
GI tract involvement # (%)	35 (36.4)	2 (2.9)
Kidney involvement # (%)	56 (58.3)	13 (19.1)
nephritic or nephrotic syndrome # (%)	10 (10.4)	1 (1.5)
BVAS3 (median; IQR)	12 (6-17)	3 (1-3)*

**patients in remission not included
Legend: GI gastrointestinal tract

Conclusion: Our findings suggest that even in short-term IgAV might not be as benign as perceived thus far. From our data it is impossible to conclude whether this is due to the nature of the IgAV or due to the fact that IgAV seems to be more common in older adults, who also have more comorbidities.

González-López[1], Ricardo Blanco[1], Javier Loricera[1], Vanesa Calvo-Río[1], Trinitario Pina Murcia[2], Carmen Gonzalez-Vela[1], Marina Lacalle[1], Javier Rueda-Gotor[1], Lino Álvarez[1], Leyre Riancho-Zarrabeitia[1] and Miguel A. González-Gay[1]. [1]Hospital Universitario Marqués de Valdecilla. IDIVAL. Santander. Spain, Santander, Spain, [2]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IDIVAL, Santander, Spain.

Background/Purpose: The European League Against Rheumatism (EULAR) proposed in 2006 a new classification criteria for Henoch-Schönlein Purpura (HSP). We aimed to establish the applicability of these criteria in patients with primary cutaneous vasculitis (CV). We also compared these criteria with previously established classification criteria for HSP.

Methods: A series of 766 (346 women/420 men; mean age 34 years) consecutive unselected patients with CV was assessed. Of them, 124 with secondary CV or with CV associated to other well defined entities were excluded from the analysis. The 2006 EULAR criteria for HSP were tested in the remaining 642 patients with primary CV. Two sets of criteria for HSP were also used for comparisons: **a)** the 1990 American College of Rheumatology (Arthritis Rheum 1990; 33: 1114–21), and **b**) the ACR-modified criteria proposed by Michel et al. in 1992 (J Rheumatol 1992; 19: 721–8).

Results: 451 (70.2%) of 642 patients were classified as having HSP according to the EULAR-2006 criteria, 405 (63.1%) using the ACR-1990 criteria, and 392 (61.1%) by the Michel-1992 criteria. However, only 336 patients (52.3%) met at the same time the EULAR-2006 and the ACR-1990 criteria, and only 229 patients (35.7%) fulfilled both the EULAR-2006 and Michel et al criteria. Noteworthy, only 276 (43%) patients met the three set of criteria. Children fulfilled all the sets of criteria more commonly than adults (215 [66.6%] of 323 versus 61 [19%] of 319 respectively; $p<0.0001$).

Conclusion: According to our results, the EULAR-2006 criteria show a poor concordance with previous sets of classification criteria for HSP.

Clinical-Biological and Pathological Spectrum and Outcome of IgA Vasculitis in Adults. Alexandra Audemard[1], Evangeline Pillebout[2], Patrice Cacoub[3], Noémie Jourde-Chiche[4], Zahir Amoura[5], Noemie Le Gouellec[6], Francois Maurier[7], Boris Bienvenu[8], Geoffrey Urbanski[9], Sébastien Sanges[10], Aurélie Hummel[11], Alban Deroux[12], Loic Raffray[13], Luc Mouthon[14], Loïc Guillevin for the French Vasculitis Study Group[14], Eric Thervet[15] and Benjamin Terrier[16]. [1]Centre Hospitalier Universitaire de Caen, Caen, France, [2]Saint Louis, Paris, France, [3]Groupe Hospitalier Pitié Salpétrière, Service de Médecine Interne, DHU i2B, Paris, France, [4]CHU, Marseille, France, [5]Pitié-Salpêtrière Hospital (AP-HP), Paris, France, [6]Internal Medicine, Lille, France, [7]Department of Internal Medicine, Metz, France, [8]CHU Côte de Nacre, CAEN, France, [9]CHRU, Lille, France, [10]Service de médecine interne, Centre National de Référence de la Sclérodermie Systémique, Hôpital Claude Huriez, CHRU Lille, Lille, France, [11]Necker Hospital, Paris, France, [12]CHU Grenoble, Grenoble, France, [13]INTERNAL MEDICINE, bordeaux, France, [14]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France, [15]Hopital Européen Georges Pompidou, APHP, PARIS, France, [16]Cochin Hospital, Paris, France.

Background/Purpose: IgA vasculitis is an immune-complex small-vessel vasculitis that mainly affects children and, more rarely, adults, in whom it seems to be more severe, because of gastrointestinal and renal involvements. Data on therapeutic management are lacking. The IGAVAS study was designed to describe IgA-vasculitis presentation and evaluate treatment efficacies. Here, we characterize its presentation and outcome.

Methods: French centers in university and general hospitals retrospectively included 235 patients with IgA vasculitis. We collected information on clinical-biological presentation and outcomes, particularly renal involvement, and analyzed the features associated with renal involvement from diagnosis through the last follow-up visit, and renal insufficiency, defined as estimated glomerular filtration rate (eGFR) using MDRD <60 ml/min/1.73 m^2.

Results: 235 patients (143 men and 92 women, mean age 50 ± 19 years) were enrolled. At disease onset, the most common manifestations were: purpura in all patients with skin necrosis (28%), glomerular nephropathy (64%), arthralgias/arthritis (63%) and gastrointestinal involvement (53%), mainly abdominal pain and intestinal bleeding; 34% had constitutional symptoms. Mean serum IgA level was 3.9 ± 1.8 g/L, with only 37% exceeding the upper the limit of normal (>3.5 g/L). Among the 150 patients with renal involvement, mean eGFR was 80 ± 34 ml/min/1.73 m^2, including 19% with eGFR <60 mL/min/1.73 m^2. Mean proteinuria was 2.56 g/24 h and 85% had microscopic hematuria. IgA vasculitis was always histologically confirmed, mainly in skin and kidney biopsies. The most frequent histological findings in the skin were leukocytoclastic vasculitis (92%), IgA deposits (81%) and fibrinoid necrosis (28%). In the kidney, IgA deposits were seen in 98%, and endocapillary and extracapillary glomerulonephritis in 51% and 42%, respectively. Among the 76% of the patients treated, 82% received corticosteroids alone, with immunosuppressants combined for 18%. After median follow-up of 31 months, 98% achieved initial renal remission but 23% relapsed. Six patients died, 3 of vasculitis flares. Among patients with renal involvement, mean eGFR at last follow-up was 81 ± 31 ml/min/1.73 m^2, including 27% with eGFR <60 mL/min/1.73 m^2. Three patients required dialysis and 1 had kidney transplantation. Older age, tubulointerstitial lesions on kidney biopsy and baseline eGFR were associated with a poor renal prognosis.

Conclusion: This large population enabled description of the clinical-biological presentation and outcome of IgA vasculitis in adults, and showed high frequencies of renal and gastrointestinal involvements and relapse rates. The analysis of the different therapeutic strategies is ongoing.

1793

Efficacy and Safety of IFN-Alpha in Induction and Maintenance of Remission in Patients with Eosinophilic Granulomatosis with Polyangiitis (EGPA). Single Center Observational Study. Benjamin Seeliger[1], Martin Foerster[1], Anne Moeser[1], Janett Happe[1], Claus Kroegel[1] and Thomas Neumann[2]. [1]Jena University Hospital, Internal Medicine I, Jena, Germany, [2]Jena University Hospital, Internal Medicine III, Jena, Germany.

Background/Purpose: To evaluate the efficiency and safety of IFN-alpha in induction and maintenance of remission in patients with EGPA and to describe its effects on lung function tests and corticosteroid (CS) tapering.

Methods: Retrospective, single-center cohort study in patients with EGPA (according to ACR criteria), who were insufficiently controlled with CS and other immunosuppressant therapies (AZA, MTX, MMF). Patients were treated with Peg-IFN-alpha (135μg per week) or IFN-alpha2b (3×9 million units per week) for induction and maintenance of remission. Remission was defined as a Birmingham Vasculitis Activity Score (BVAS) of 0. After achieving remission, time to first relapse and total occurrence of relapses were recorded. Patients received lung-functioning tests before treatment and at time of remission. Adverse events were recorded.

Results: 25 patients, age of 50 (±9.5) years were evaluated for induction of remission and in 21 patients IFN was continued for maintenance of remission. Five-factor-score (FFS) at initiation of treatment was 0 in 18 (72%) and ≥1 in 7 (28%) in patients. Mean BVAS at initiation of treatment was 8.3 (2–21). Previous therapies were CYC (N=4), AZA (N=3), Omalizumab (N=3), MTX (N=1), MMF (N=1), Rituximab (N=1).

Treatment was discontinued in 18 of 25 (72%) patients and 7 (28%) were still on IFN after a mean time of treatment of 31 (2–131) months. Of 25 patients, 21 (84%) achieved remission and mean time to remission was 5 (3–12) months. CS were tapered from 18.75 (5–50) mg per day to 5 (0–30) mg per day at time of remission ($p<0.001$).

FEV1 increased from 74.8 (25–102) % to 89.1 (50–133) % at time of remission ($p=0.001$).

Four patients discontinued therapy before remission was achieved due to side effects (N=3) and treatment failure (N=1). Of 21 patients treated for maintenance of remission, 8 (38%) were still in remission after a median time of 21 (4–57) months without relapsing. 13 (62%) suffered a total of 15 relapses (4 major and 11 minor) after a median of 12 (4–42) months. Most relapses were associated with rapid CS-withdrawal.

Adverse events were frequent and forced discontinuation of treatment in 11 of 18 patients: depression (N=4), polyneuropathy (N=3), autoimmune hepatitis, toxic liver damage, anemia, alopecia and chronic nausea (each N=1). Other adverse events occurred as flu-like-symptoms (76%), leucopenia (44%) and thrombopenia (36%) but were transient and did not require a change in treatment regime. 4 of 18 patients IFN discontinued treatment due to lack of efficacy in remission induction (N=1) or prevention of relapse (N=3).

Conclusion: IFN is effective in both induction of remission and maintenance of remission while depression is the main side effect that limits therapy. As IFN showed good effect on CS-tapering and on asthma in particular, it can be considered as an alternate treatment in EGPA patients without life- or organ-threatening manifestations.

The Sting Pathway Regulates Bone Remodeling in a Model of Autoimmune Disease. Rebecca Baum[1], Jason M. Organ[2], David B. Burr[3], Ann Marshak-Rothstein[1], Katherine A. Fitzgerald[1] and Ellen M. Gravallese[4]. [1]University of Massachusetts Medical School, Worcester, MA, [2]Indiana University School of Medicine, Indianapolis, IN, [3]Indiana University School of Medicine, Indianapolis, Indiana, [4]UMass Memorial Medical Center, Worcester, MA.

Background/Purpose: Cytosolic DNA sensors detect viral and bacterial DNA, inducing inflammatory cytokines and type I IFNs via the adaptor stimulator of interferon genes (STING) to clear infection. The STING pathway also responds to endogenous DNA from dying cells and contributes to autoimmune disease. We have identified a potentially important role for cytosolic DNA sensor pathways in bone by studying a mouse that develops inflammatory polyarthritis and articular erosions in the setting of DNA accrual. In this model, DNA accumulates in macrophages due to deletion of the lysosomal endonuclease DNaseII and is detected by cytosolic sensors that signal through STING. Type I IFNs in DNaseII−/− mice lead to anemia-related embryonic lethality; thus co-deletion of the type I IFN receptor is required (DNaseII/IFN-IR double deficient, (DKO) mouse). We investigated the impact of DNA and of the STING pathway in bone in this model of autoimmune disease.

Methods: STING−/− mice were intercrossed with DKO mice to generate STING/DNaseII/IFN-IR triple knock out (TKO) mice. uCT was performed on TKO, DKO, and control femurs from 6–16 month-old mice. Mesenchymal colony forming unit (CFU) assays were used to determine the number of osteoblast precursor cells in bone. uCT was performed on femurs from 6 month-old STING−/− and littermate controls. Finally, RNA from wild type (WT) osteoblasts was analyzed for the expression of cytosolic DNA sensors. To determine the potential for osteoblasts to respond directly to DNA, MC3T3 osteoblast-lineage cells were transfected with poly(dA:dT) and RNA was analyzed by qPCR.

Results: Inflammatory cytokines in the DKO model would be expected to induce bone loss in the axial skeleton, as well as articular erosions. Paradoxically, we found that bone accumulates in long bones, with significant replacement of the marrow cavity by 16 months. CFU assays demonstrate increased osteoblast precursor numbers, and osteoid is also significantly increased in DKO compared to controls (13,881 vs. 424 μm^2, p=0.02). Surprisingly, ectopic bone forms in DKO spleens, a site of DNA accrual in macrophages. We thus sought to define the contribution of cytosolic DNA sensor pathways to bone accrual. STING deficiency almost completely abrogates both arthritis and bone accrual in the spleen and long bones of DKO mice (BV/TV: Het = 0.44%, DKO = 11.47%, TKO = 1.99%, p<0.02 compared to DKO). STING also contributes to bone homeostasis, independent of DNaseII deficiency, as revealed by uCT performed on femurs from STING−/− and littermate controls (BV/TV: STING−/− = 1.39%, WT = 0.62%, p=0.011). Furthermore, cytosolic DNA sensors are expressed in osteoblasts and expression of several sensors is increased in osteoblasts upon transfection with a DNA ligand.

Conclusion: The STING pathway plays a role in bone remodeling in situations of DNA accrual as well as in bone homeostasis. Cytosolic DNA sensors are expressed in differentiating osteoblasts and expression is upregulated by DNA. These findings have relevance to SLE and other autoimmune diseases in which DNA plays a pathogenic role. Discovery of new pathways linking bone and the immune system may identify new targets for the treatment of bone loss in inflammatory autoimmune diseases.

Denosumab Restores Cortical Bone Loss at the Distal Radius Associated with Aging and Reduces Wrist Fracture Risk. Analyses from the Cross-over Group in the Extension of Denosumab Pivotal Fracture Trial. JP Bilezikian[1], CL Benhamou[2], CJF Lin[3], JP Brown[4], NS Daizadeh[3], PR Ebeling[5], A Fahrleitner-Pammer[6], E Franek[7], N Gilchrist[8], PD Miller[9], JA Simon[10], I Valter[11], CAF Zerbini[12] and C Libanati[3]. [1]College of Physicians and Surgeons, Columbia University, New York, NY, [2]CHR d'Orléans, Orléans, France, [3]Amgen Inc., Thousand Oaks, CA, [4]CHU de Québec Research Centre and Laval University, Quebec City, QC, [5]Monash University, Clayton, Australia, [6]Medical University, Graz, Austria, [7]Medical Research Center, Polish Academy of Sciences, Warsaw, Poland, [8]The Princess Margaret Hospital, Christchurch, New Zealand, [9]Colorado Center for Bone Research, Lakewood, CO, [10]George Washington University, Washington, DC, [11]Center for Clinical and Basic Research, Tallinn, Estonia, [12]Centro Paulista de Investigação Clinica, São Paulo, Brazil.

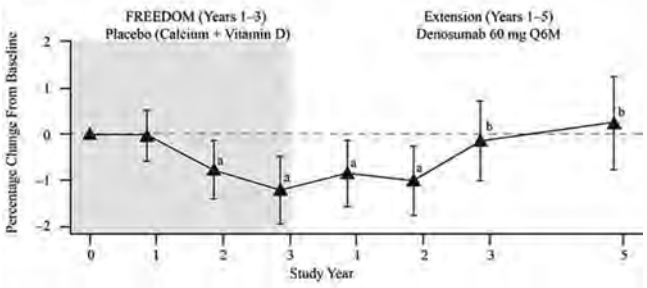
Background/Purpose: Cortical bone loss is a major determinant of increased fracture risk. Denosumab (DMAb) has been shown to increase BMD at sites of cortical bone, including the radius, a skeletal site not responsive to most osteoporosis treatments. Here, we evaluated changes over time in radius BMD and wrist fracture incidence during 3 years of placebo (Pbo) and up to 5 subsequent years of DMAb therapy in FREEDOM and its Extension (EXT).

Methods: We evaluated 2207 women who received Pbo during FREEDOM (3 years) and enrolled in the EXT to receive DMAb 60 mg Q6M (cross-over group); all women received daily calcium and vitamin D. A subset of these women (n=115) participated in a distal radius DXA substudy and were evaluated at baseline and during FREEDOM and EXT. Analysis of mean percentage changes in BMD over time from FREEDOM and EXT baselines consisted of a repeated measure model. Wrist fracture rates (per 100 subject-years), rate ratios, and 95% CI were computed.

Results: At FREEDOM baseline, the mean (SD) 1/3 radius T-score was –2.53 (1.18). During FREEDOM, daily calcium and vitamin D alone was associated with a progressive and significant loss of BMD at the 1/3 radius (–1.2%); however, during EXT, DMAb halted and reversed bone loss (Figure). With 5 years of DMAb treatment, a significant gain in BMD (1.5% at EXT Year 5) was observed, compared with EXT baseline. The wrist fracture rate during the Pbo period in FREEDOM was 1.02 (0.80–1.29) per 100 subject-years. During the first 3 years of EXT, BMD recovered to the original baseline levels in response to DMAb and the wrist fracture rate remained comparable to the FREEDOM Pbo rate (Table); with 2 additional years of DMAb treatment, BMD increased further and the wrist fracture rate declined to levels significantly lower than the FREEDOM Pbo rate (rate ratio=0.57, 95% CI=0.34–0.95; p=0.03).

Conclusion: In untreated women with postmenopausal osteoporosis, cortical bone density at the radius declined significantly. DMAb treatment for 3 years fully reversed this bone loss, and 2 additional years of treatment resulted in further BMD gains that translated to significantly lower wrist fracture rates, highlighting the clinical importance of reversing cortical bone loss.

Figure. Distal Radius BMD Percentage Change From FREEDOM Baseline Through Extension Year 5



BMD percentage change from FREEDOM baseline; data are least squares means (95% CI). [a]$p < 0.05$ compared with FREEDOM baseline; [b]$p < 0.05$ compared with Extension baseline. Q6M = every 6 months.

Table 1. Wrist Fracture Rates During FREEDOM and Through Extension Year 5 (N = 2207 Cross-over subjects)

	FREEDOM (Years 1–3) Placebo (Calcium + Vitamin D)	Extension (Years 1–5) Denosumab 60 mg Q6M			
Denosumab exposure	NA	Year 1	Year 2	Year 3	Year 4 Year 5
Wrist fractures, n	67	58			19

1796

Autotaxin Is Highly Expressed in Systemic Sclerosis (SSc) Skin, Mediates Dermal Fibrosis Via IL-6, and Is a Target for SSc Therapy. Flavia V. Castelino[1], Leaya M. George[1], Gretchen Bain[2], Lance Goulet[2], Robert Lafyatis[3] and Andrew M. Tager[1]. [1]Massachusetts General Hospital, Boston, MA, [2]PharmAkea Pharmaceuticals, San Diego, CA, [3]Boston University School of Medicine, Boston, MA.

Background/Purpose: Autotaxin (ATX) is an enzyme present in biological fluids that is responsible for the production of the lipid mediator, lysophosphatidic acid (LPA). We previously implicated LPA and its receptor, LPA_1 in SSc pathogenesis.[1] Here we studied the role of ATX in SSc dermal fibrosis using the bleomycin (BLM) mouse model and skin biopsy samples from SSc patients and healthy controls. We evaluated the role of IL-6, a cytokine implicated in SSc, in mediating ATX-induced fibrosis. Additionally, we investigated the therapeutic potential of targeting ATX, by using a novel ATX inhibitor, PAT-048 in this model.

Methods: BLM or saline (PBS) was administered subcutaneously to C57Bl/6 mice daily for 3, 7, 14 and 28 days. 6mm dermal punch biopsies were obtained and ATX levels were measured by qPCR and ELISA. ATX inhibition with PAT-048 (20mg/kg oral gavage daily) was assessed in the model. PAT-048 was administered concurrently with BLM or PBS for 28 days, or initiated at 7 or 14 days after BLM. Dermal thickness was measured using H&E-stained sections. Collagen was visualized by Masson's trichrome stain, and quantified by hydroxyproline measurement. Skin IL-6 expression was evaluated by immunohistochemistry (IHC). The effect of LPA-induced ATX expression was tested on human dermal fibroblasts transfected with IL-6 siRNA. Additionally, healthy and SSc dermal fibroblasts were stimulated with LPA and IL-6 *in vitro*, and IL-6 and ATX induction were evaluated by ELISA, respectively. Skin ATX expression was measured in SSc patients and healthy controls by qPCR, and IL-6 expression by IHC.

Results: ATX expression at both the mRNA and protein level was increased at Day 3 after BLM injection (3-fold increase, $p=0.05$) suggesting a role for ATX early in fibrosis. Treatment with PAT-048 attenuated BLM-induced dermal fibrosis in all treatment groups (50% reduction, Day 28, $p=0.01$), and reduced IL-6 expression in the dermis. *In vitro* studies of human dermal fibroblasts showed that LPA-induced ATX expression was attenuated with siRNA knockdown of IL-6 (65% reduction, $p<0.05$). SSc fibroblasts demonstrated increased LPA-induced IL-6 expression, and increased IL-6-induced ATX expression, compared to healthy fibroblasts. Furthermore, ATX expression was increased in SSc skin (n=7) compared to healthy controls (n=5; 3-fold increase, $p=0.006$) and IL-6 expression by IHC was increased in SSc skin compared to healthy controls (n=3 per group).

Conclusion: We demonstrate that ATX has an important role in SSc fibrosis. Pharmacologic inhibition of ATX with a novel inhibitor, PAT-048, attenuated dermal fibrosis and IL-6 expression. Knock-down of IL-6 in fibroblasts *in vitro* abrogated LPA-induced ATX expression, suggesting an autocrine loop for ATX/LPA/IL-6 signaling. Both ATX and IL-6 are increased in SSc skin compared to healthy controls, and LPA-induced IL-6 and IL-6-induced ATX expression are increased in SSc fibroblasts, further supporting an ATX/LPA/IL-6 autocrine loop in SSc. Targeting ATX may thus be an effective new therapeutic strategy for SSc fibrosis.

1797

One-Year Survival of Adults with Systemic Sclerosis Following Lung Transplantation: A Nationwide Cohort Study. Elana J. Bernstein, Eric R. Peterson, Joan M. Bathon and David J. Lederer. Columbia University College of Physicians & Surgeons, New York, NY.

Background/Purpose: Lung transplantation is a potentially life-saving treatment for patients with systemic sclerosis (SSc) who have developed end-stage lung disease due to interstitial lung disease and/or pulmonary hypertension. However, many transplant programs are hesitant to offer lung transplantation (LTx) to those with SSc due to concerns about extrapulmonary involvement that might affect short- and long-term survival. However, survival data for lung transplantation in SSc are sparse. The primary aim of this study was to determine whether adults with SSc have higher 1-year mortality rates after LTx compared to those with interstitial lung disease (ILD) or pulmonary arterial hypertension (PAH) not due to SSc. We hypothesized that adults with SSc would have higher 1-year mortality rates after LTx than those with ILD or PAH not due to SSc.

Methods: We performed a retrospective cohort study of adults who underwent double or single LTx in the United States between May 4, 2005 (the date of implementation of the lung allocation score) and September 14, 2012. Data were provided by the United Network for Organ Sharing, a non-profit organization that records data on all solid organ transplants performed in the US. Subjects were included if they were at least 18 years of age at the time of LTx; had a diagnosis of SSc, ILD, or PAH; and were transplanted at a center that has performed at least 1 LTx for SSc. Subjects were excluded if they had received a heart-lung transplant; if they received a LTx from a living donor; or if they had missing data on survival time. We modeled diagnosis (SSc) as the independent binary variable of interest in stratified Cox regression models where survival time was the dependent variable, adjusting for recipient, donor, and procedural factors (Table 1). We used multiple imputation to account for missing covariate data.

Results: A total of 3763 adults were transplanted during the study period and met inclusion criteria: 229 with SSc, 201 with PAH, and 3333 with ILD (Table 1). The 1-year unadjusted mortality rate following LTx per 100 person-years was 21.4 among adults with SSc, 19.0 among adults with PAH, and 17.8 among adults with ILD. A diagnosis of SSc was associated with a multivariable-adjusted 48% relative increase in the 1-year mortality rate compared to a diagnosis of ILD (HR 1.48, 95% CI 1.01–2.17). However, a diagnosis of SSc was not associated with a relative increase in the 1-year mortality rate compared to a diagnosis of PAH (HR 0.85, 95% CI 0.50–1.44).

Conclusion: Adults with SSc had a 48% increased risk of death at 1 year following LTx compared to adults with ILD, but no increase in risk of death at 1 year compared to adults with PAH. Rather than denying SSc patients LTx because of their SSc diagnosis, variables need to be identified that will enable risk stratification of these patients prior to LTx, with particular attention to modifiable risk factors.

Interaction Between Innate Immunity and Anti-Ro52 Antibodies is Critical for the Induction of Sjogren's Syndrome-like Disease in Mice.
Paulina Kaplonek[1], Barbara Szczerba[2], Nina Wolska[1], Paulina Rybakowska[1], Arkadiusz Klopocki[1], Paromita Dey[2], Astrid Rasmussen[1], Kimberly Hefner[3], Stephen Young[4], Donald U. Stone[4], David M. Lewis[4], Lida Radfar[4], R. Hal Scofield[1], Kathy Moser Sivils[1], Harini Bagavant[1] and Umesh Deshmukh[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University of Virginia, Charlottesville, VA, [3]Hefner Eye Care and Optical Center, Oklahoma City, OK, [4]University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background/Purpose: Autoantibodies reactive with Ro52 are present in almost 70% of Sjögren's syndrome (SS) patients. This study was undertaken to investigate the role of Ro52 induced immune responses in the pathogenesis of SS in an experimental mouse model system.

Methods: New Zealand Mixed (NZM) 2758 mice were immunized with mouse Ro52, adsorbed on to alum adjuvant. Control mice were injected either with Maltose binding protein (MBP) or only with alum. Mice were monitored for anti-Ro52 antibody production, sialoadenitis, serum cytokine levels, and pilocarpine induced salivation. Antibody binding to salivary gland cells was analyzed *in vivo* and *in vitro* by immunofluorescence. Sera from immunized mice were passively transferred into untreated or alum injected NZM2758 mice. Internalization of antibodies by live cells was investigated by using the salivary gland cell line SCA9–15. Clinical data from the Oklahoma pSS patient cohort that met the AECG classification criteria for SS was analyzed for anti-Ro reactivity, minor labial salivary gland biopsy focus scores, and xerostomia.

Results: By day 30 post-immunization, Ro52 immunized mice generated immunoprecipitating anti-Ro52 antibodies and they had the maximum drop in saliva production. The glandular dysfunction in these mice was significantly associated with the level of anti-Ro52 antibody. Both Ro52 immunized and control mice showed evidence for very mild sialoadenitis. However, only Ro52 immunized mice had antibody deposition in their salivary glands. Passive transfer of Ro52 immune sera induced salivary gland dysfunction in the recipient mice, only if the recipients were pre primed with alum. The levels of IL-1α and CXCL1 were significantly upregulated in alum injected mice, indicative of the inflammasome pathway activation. *In vitro*, antibodies from Ro52 immune sera were internalized by SCA9–15 cells and the antibodies recognized cytoplasmic Ro52. The antibody internalization was inhibited by Cytochalasin D treatment, indicating it to be an active uptake process. Amongst the 298 pSS patients in Oklahoma cohort, 28 patients (9.3%) were anti-Ro positive and had a focus score of 0; and 37 anti-Ro positive patients (12%) had a focus score of >0 but <1. Several of these patients have dry mouth and dry eyes.

Conclusion: Our data show for the first time that antibodies induced by Ro52 are capable of inducing salivary gland dysfunction and this phenomenon is dependent on the activation of innate immunity. The mouse model presented in this study mimics a subset (22%) of pSS patients in our cohort, who are biopsy negative (or have low focus scores) and are anti-Ro antibody positive. In this group of patients, in the absence of sialoadenitis, it is possible that salivary gland dysfunction is caused by autoantibodies. Our data also suggests that antibody deposition within the salivary glands might be an important step for the induction of glandular dysfunction. Overall this study suggests that down modulation of autoantibody responses should constitute a major therapeutic strategy for the treatment of SS.

Elevated Indoleamine-2,3-Dioxygenase (IDO) Activity and Kynurinene-3-Monooxygenase (KMO) Expression in Interferon Positive Primary Sjogrens Syndrome Patients Is Associated with Increased $CD25^{hi}FoxP3^{+}$ regulatory Tcells: A Skew Towards Neurotoxicity or an Attempt to Rescue?
Naomi I Maria[1], Cornelia G. van Helden-Meeuwsen[1], Zana Brkic[1], Sandra M.J. Paulissen[2], Virgil A. Dalm[1], Paul L. van Daele[1], P. Martin van Hagen[1], Sinead M. Gibney[3], Andrew Harkin[3], Hemmo A. Drexhage[1], Erik Lubberts[2] and Marjan A. Versnel[1]. [1]Erasmus Medical Center, Immunology, Rotterdam, Netherlands, [2]Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands, [3]Trinity College Institute of Neuroscience, Neuropsychopharmacology, Dublin, Ireland.

Background/Purpose: A role for indoleamine-2,3-dioxygenase (IDO) in suppression of effector T-cell function and promotion of regulatory T-cell (Treg) differentiation has been described. IDO - the rate-limiting enzyme in tryptophan (TRP) catabolism - is driven in part by type I and type II IFNs. Systemic overactivation of IFN-signaling is evident in Primary Sjögrens syndrome (pSS), and could shift the delicate regulatory balance towards a more auto-reactive state in these patients. Interestingly aberrant systemic TRP catabolism, resulting in a shift from neuroprotective towards neurotoxic downstream metabolites, has been associated with mood disturbances as well as neurophsychiatric consequences, and possibly contributes to symptoms of fatigue and depression in pSS. Here we investigate the role of IDO and downstream TRP catabolism in pSS and hypothesize an increase in Tregs, in concordance with increased IDO-activity in IFNpositive pSS patients.

Methods: In a Cohort of 20 Healthy controls (HC), 18 IFNnegative and 21 IFNpositive pSS patients, diagnosed according to the 2002 American-European criteria, $CD4^{+}CD45RO^{+}$ T helper (Th) memory cell populations defined by chemokine receptor expression: $CD25^{hi}FoxP3^{+}$ Tregs, $CCR6^{+}CCR4^{+}CXCR3^{-}CCR10^{-}$ Th17, $CCR6^{+}CCR4^{+}CXCR3$-$CCR10^{+}$ Th22, CCR6-CXCR3+CCR4- Th1 and $CCR6^{-}CXCR3^{-}CCR4^{+}$ Th2-cells were analyzed by flow cytometry in peripheral blood mononuclear cells (PBMCs). Analysis of TRP and Kynurenine (KYN) were performed simultaneously in serum using HPLC. $CD14^{+}$ monocyte mRNA-expression of $IDO_1$and downstream enzymes was assessed using real-time quantitative PCR, to investigate the direction of downstream TRP catabolism in pSS.

Results: Activity of IDO ($p=0.0054$) – as determined by measuring levels of the KYN/TRP-ratio in sera – and $CD25^{hi}FoxP3^{+}$ Tregs ($p=0.039$) were significantly increased in IFNpositive pSS patients. In addition, $CD25^{hi}FoxP3^{+}$ Tregs significantly correlated with the KYN/TRP-ratio ($p=0.002$;$r=0.509$) as well as the IFNscore ($p=0.011$;$r=0.375$). Peripheral monocytes showed an upregulation of IDO-expression ($p<0.0001$) in IFN-positive pSS, also highly correlating with the IFNscore ($p<0.0001$;$r=0.816$). Interestingly the neuroprotective downstream enzymes KAT1 ($p=0.0003$), KAT3 ($p=0.016$) and KAT4 ($p=0.04$) were downregulated, whereas the neurotoxic enzymes KMO ($p=0.0057$) and KYNU ($p=0.0001$) – which convert KYN into the neutoxic metabolite Quinolinic acid – were upregulated in these patients, suggesting a skew towards neurotoxicity.

Conclusion: Here we find enhanced IDO activity in coherence with increased $CD25^{hi}FoxP3^{+}$ Tregs, and evidence for a shift towards production of more neurotoxic metabolites – previously associated with "sickness behavior" – in IFNpositive pSS. This imbalance towards neurodegenerative effects might contribute to increased fatigue and depressive symptoms in these patients. However, whether this shift in Tregs reflects an immune rescue-mechanism or increases "tolerance to self" remains unknown. Intervening in these IFN and IDO-induced imbalances offers new possibilities for therapeutic interventions.

Objectively Measured Sedentary Behavior Is a Distinct Risk Factor from Low Moderate-to-Vigorous Activity in Predicting Subsequent Frailty: Evidence from Osteoarthritis Initiative. Jing Song[1], Lee A. Lindquist[1], Rowland W. Chang[1], Pamela A. Semanik[2], Linda S. Ehrlich-Jones[3], Jungwha Lee[1], Min-Woong Sohn[1] and Dorothy D. Dunlop[1]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Rush University Medical Center, Chicago, IL, [3]Rehabilitation Institute of Chicago, Chicago, IL.

Background/Purpose: Physical frailty represents a state of high vulnerability for adverse health outcomes including disability and mortality. Physical activity interventions to improve health have largely focused on increasing moderate activities and paid limited attention to sedentary behavior. While being physically active is related to less frailty, it is not clear if time spent in sedentary behavior is a separate risk factor from low activity for frailty onset. If a distinct risk factor, the effectiveness of public health initiatives to reduce physical frailty and its sequelae may be improved by incorporating strategies to reduce sedentary behavior.

Methods: We prospectively examined the relationship between accelerometer measured sedentary time with incident physical frailty. We studied 1570 Osteoarthritis Initiative participants aged 49 years or older at elevated risk for developing physical frailty due to knee osteoarthritis (KOA) or KOA risk factors. Physical frailty ascertainment employed a validated definition based on objective assessments: low gait speed (<0.6 meters/second) or/and inability to perform one single chair stand without using arms. Hazard ratios for developing frailty during 2 years of follow-up were estimated from discrete survival methods controlled for time spent in moderate activities, socioeconomic (age, sex, race/ethnicity, marital status, income, education) and health factors (body mass index, chronic conditions, high depressive symptoms, radiographic knee OA, chronic knee symptoms, hip OA, chronic hip symptoms, general pain, smoking, alcohol), and waking hours.

Results: The incidence of frailty in this high risk group was 18.5 per 1,000 person-years. Greater sedentary time during waking hours was significantly related to subsequent frailty onset (unadjusted hazard ratio [HR] = 1.29 per sedentary hour, 95% confidence interval [CI]: 1.08, 1.54). Figure 1 demonstrates the strong relationship between sedentary time and incident frailty adjusting for age, gender, and BMI. Importantly, this relationship held (HR= 1.36 per sedentary hour, 95% CI: 1.04, 1.78) after controlling for moderate activity and other covariates.

Conclusion: These prospective data demonstrated a significant increased risk for the development of frailty per hour of sedentary time among adults with or at risk for knee OA. Importantly, sedentary time was significantly related to frailty onset, independent of time spent in moderate activities. These findings support sedentary behavior as a separate risk factor for frailty, distinct from insufficient moderate activity. Interventions which promote reducing sedentary behaviors in addition to increasing physical activity may help to diminish frailty onset.

Figure. Adjusted physical frailty incident rate.

The Association of Knee Shape with Sex: The Osteoarthritis Initiative. Barton L. Wise[1], Lisa Kritikos[1], Felix Liu[2], Neeta Parimi[2], John A. Lynch[2], Yuqing Zhang[3] and Nancy E. Lane[1]. [1]Center for Musculoskeletal Health, UC Davis School of Medicine, Sacramento, CA, [2]University of California at San Francisco, San Francisco, CA, [3]Boston University School of Medicine, Boston, MA.

Background/Purpose: Incidence of knee osteoarthritis (OA) is much higher in women than in men. Previous studies have shown that bone shape is a risk factor for knee OA. However, few studies have examined whether knee bone shape differs between men and women. The purpose of the present study was to determine whether there are differences between men and women in the shape of the bones that form the knee joint.

Methods: We used information from the NIH-funded Osteoarthritis Initiative (OAI), a cohort of persons aged 45–79 at baseline who either had symptomatic knee OA or were at high risk of it. Among participants aged between 45 and 60 years, we randomly sampled 339 knees without radiographic OA (i.e., Kellgren/Lawrence grade of 0 in central readings on baseline radiograph). We characterized distal femur and proximal tibia shape of these selected radiographs using Active Shape Modeling (ASM). ASM generates independent modes that together explain the variance in the shape of a bone across a population. We performed linear regression analysis to examine the association between sex and proximal tibia and distal femur shape, adjusting for age, race, body mass index (BMI) and clinic site. Beta coefficients and 95% confidence intervals were estimated to represent the difference in bone shape between women and men.

Results: The mean age was 52.7 years (±4.3 SD) for both men and women. There were 192 female and 147 male knees for the distal femur analysis. Thirteen modes were derived for femoral shape, accounting for 95.5% of the total variance. Distal femur Mode 1 had the greatest effect size for association with sex ($p<0.0001$); Modes 3, 5, 6, 8 and 12 were also significantly associated. For tibial shape, 191 female knees and 149 male knees were used for the analysis. Ten modes explained 95.5% of shape variance. Of the significantly associated modes in the femur, Mode 2 had the greatest effect size for the association with sex ($p=0.009$); Modes 3 and 4 were also significantly associated. See tables for effect sizes and descriptions of all modes significantly associated with sex.

Conclusion: The shapes of the distal femur and proximal tibia that form the knee joint differ by sex. Additional analyses are warranted to assess whether the difference in risk of OA between the sexes arises from bone shape differences.

Distal Femur Shape with Sex (Significant Modes)

Mode	Variance Explained (%)	Mode Description – primary alteration of shape with increasing value of mode	Standard deviation differences by mode between men and women (95%CI)	P-value for difference
1	43.1	Increased shaft width relative to epicondylar width, and deepening of intercondylar fossa.	1.044 (0.85 to 1.23)	<0.0001
3	11.5	Decreased inferior projection of medial and lateral condylar heads with respect to the patellar groove.	0.23 (0.03 to 0.43)	0.024
5	4.9	Increased excursion of the medial epicondyle, narrowing of the shaft, deepening of the groove between the lateral epicondyle and condyle.	−0.258 (−0.47 to −0.05)	0.017
6	3.1	Increased depth and acuity of the intercondylar fossa.	−0.306 (−0.52 to −0.09)	0.005
8	2.0	Decreased extension of the lateral epicondyle.	−0.487 (−0.7 to −0.27)	<0.0001
12	1.0	Decreased extension of lateral epicondyle with increased extension of medial epidondyle.	0.317 (0.1 to 0.54)	0.005

Proximal Tibial Shape with Sex (Significant Modes)

Mode	Variance Explained (%)	Mode Description – primary alteration of shape with increasing value of mode	Standard deviation differences by mode between men and women (95%CI)	P-value for difference
2	11.9	Tibial head shifted laterally in relation to the shaft, and head width increased. The lateral tibial plateau is more concave.	−0.30 (−0.51 to −0.08)	0.009
3	9.7	Slightly increased tibial width, depression of medial plateau and elevation of lateral plateau.	−0.22 (−0.43 to −0.01)	0.038
4	5.5	Lateral plateau extended laterally and elevated, with medial plateau depressed.	−0.25 (−0.46 to −0.04)	0.021

Are Outcomes after Total Knee Arthroplasty Worsening over Time? a Time-Trends Study of Activity Limitation and Pain Outcomes. Jasvinder A Singh[1] and David Lewallen[2]. [1]University of Alabama and VA Medical Center, Birmingham, AL, [2]Mayo Clinic college of medicine, Rochester, MN.

Background/Purpose: To examine whether function and pain outcomes of patients undergoing primary total knee arthroplasty (TKA) are changing over time.

Methods: The Mayo Clinic Total Joint Registry provided data for time-trends in preoperative and 2-year post-operative activity limitation and pain in primary TKA patients from 1993–2005. We used chi-square test and analysis for variance, as appropriate. Multivariable-adjusted analyses were done using logistic regression.

Results: In a cohort of 7,229 patients who underwent primary TKA during 1993–2005, mean age was 68.4 years (standard deviation (SD), 9.8), mean BMI was 31.1 (SD, 6.0) and 55% were women. Crude estimates showed that preoperative moderate-severe overall limitation were seen in 7.3% fewer patients and preoperative moderate-severe pain in 2.7% more patients in 2002–05, compared to 1992–95 ($p<0.001$ for both). At 2-years, crude estimates indicated that compared to 1992–95, moderate-severe post-TKA overall limitation was seen in 4.7% more patients and moderate-severe post-TKA pain in 3.6% more patients in 2002–05, both statistically significant **(**$p^2$0.018) and clinically meaningful. In multivariable-adjusted analyses that adjusted for age, sex, anxiety, depression, Deyo-Charlson index, body mass index and preoperative pain/limitation, patients had worse outcomes 2-year post-TKA in 2002–2005 compared to 1993–95 with an odds ratio (95% confidence interval (CI); p-value) of 1.34 (95% CI: 1.02, 1.76, $p=0.037$) for moderate-severe activity limitation and 1.79 (95% CI: 1.17, 2.75, $p=0.007$) for moderate-severe pain.

Conclusion: Patient-reported function and pain outcomes after primary TKA have worsened over the study period 1993–95 to 2002–05. This time-trend is independent of changes in preoperative pain/limitation and patient characteristics.

Knee Osteoarthritis and All-Cause Mortality: The Wuchuan Osteoarthritis Study. Qiang Liu[1], Xu Tang Sr.[2], Jingbo Niu[3], Xu Wu[2], Yan Ke[4], Jian Huang[5], Rujun Li[4], Hu Li[4], Xin Zhi[4], Kai Wang[4], Zhengming Cao[1] and Jianhao Lin[2]. [1]Arthritis Institute, People's Hospital, Peking University, Beijing, China, [2]Peking University Health Science Center, Beijing, China, [3]Boston University, Boston, MA, [4]Peking University People's Hospital, Beijing, China, [5]The Second Affiliated Hospital of Inner Mongolia Medical University, Hohhot, China.

Background/Purpose: Several studies published recently found that knee osteoarthritis (OA) is associated with an increased mortality in Caucasians. While prevalence of knee OA is higher in Chinese than Caucasians, no study has examined whether knee OA increases mortality in Chinese population.

Methods: Between 8/2005-10/2005 1025 residents aged ≥ 50 years were recruited using door-to-door enumeration in randomly selected rural communities in Wuchuan, China. Subjects completed a home interview and had a hospital examination including weight-bearing posteroanterior semiflexed view of radiographs at TF joints and skyline view of radiographs at PF joints. We defined a knee as having whole ROA if either K/L score at TF joint ≥ 2 or presence of PFOA based on OARSI criteria. Symptomatic knee OA (SxOA) was recorded if both pain (i.e., knee pain occurred on most days in past month) and whole ROA were present at the same knee. Subjects were followed until November 31, 2013. Follow-up time for each subject was computed as the amount of time from the date of knee radiograph was obtained to the date of the first of the following events: death; the last date of contact; or the end of follow-up. All-cause mortality was calculated by dividing the number of deaths by the number of person-years of follow-up. We used a Cox-proportional hazard models to examine the relation of whole knee ROA and knee SxOA, respectively, to the all-cause mortality adjusting for age, sex, body mass index (BMI), education, income level, level of daily physical activity, and comorbidities.

Results: Among 1025 participants (men: 49.3%, mean age: 55.5 years, mean BMI: 22.4 kg/m^2) prevalence of whole knee ROA and SxOA at baseline was 17.7% and 6.2, respectively. For K/L grading, the weighted kappa for inter-rater reliability was 0.80 (95% confidence interval (CI): 0.72–0.88) and the intra-rater reliability was 0.92 (95% CI: 0.86–0.99). Over the follow-up period 99 subjects died. The mortality rate was higher among subjects with knee SxOA (32.6/1000 person-years) than those without SxOA (10.9/1000 person-years). After adjustment for age, sex and other potential confounders, subjects with knee SxOA had 90% higher mortality rate than those without SxOA (hazard ratio=1.9, 95% confidence interval(CI): 1.0–3.5). While mortality among subjects with whole knee ROA (20.1/1000 person years) was higher than those without it (10.5/1000 person-years), after adjusting for age, sex and other potential confounders the association was not statistically significantly (hazard ratio=1.2, 95% CI: 0.7–1.9) (Table).

Conclusion: Knee SxOA was associated with an increased risk of all-cause mortality among the residents in the rural areas of China. Future studies to understand the mechanisms underlying this association are needed.

Increased Mortality in Ankylosing Spondylitis - Results from a National Population Based Study. Sofia Exarchou[1], Elisabeth Lie[2], Johan Askling[3], Helena Forsblad-d'Elia[4], Carl Turesson[1], Lars Erik Kristensen[5] and Lennart T. Jacobsson[2]. [1]Section of Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden, [2]Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, [3]Clinical Epidemiology Unit, Rheumatology Unit, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden, [4]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, [5]Lund University, Malmö, Sweden.

Background/Purpose: Ankylosing spondylitis (AS) is characterized both by inflammation of the axial skeleton and systemic inflammation, and may also involve joints, entheses and other organs. For other rheumatic chronic inflammatory diseases, such as rheumatoid arthritis, an increase in mortality compared to the background population has consistently been shown, whereas for AS, information on survival is scarce. The aims of the present study were to: 1) determine mortality in AS vs the general population, overall and by gender, and 2) to investigate factors associated with death in the AS cohort.

Methods: From the National Patient Register (NPR) we identified a nationwide cohort of patients who were diagnosed with AS at a rheumatology or internal medicine department at least once between Jan 2001 and Dec 2009. A general population comparator, matched on year of birth, gender at the first registered diagnosis year of the AS patient, was identified from the census register, with 5 matched controls per index-patient. Socioeconomic variables and comorbidities (prior to the start of follow up) were identified from Statistics Sweden, NPR and the national Drug Prescription Register. The period of risk began on Jan 1st 2006 or at the first date of registered diagnosis thereafter in those with previously undiagnosed AS and extended until death, emigration, or Dec 31st 2012 (end of observation). Incidence Rate Ratios (IRR) were calculated when comparing mortality in AS and control cohorts and Cox regression models were used to determine predictors for death in the AS cohort.

Results: Among the 8 600 AS patients and the 40 460 controls, there were 496 and 1533 deaths, respectively (34% vs 31% due to cardiovascular disease – CVD). Mortality was increased in AS with an overall IRR of 1.71 (95% CI: 1.55 – 1.90), as well as for men (IRR = 1.65, 95% CI: 1.47 – 1.86) and women (IRR = 1.89, 95% CI: 1.55 – 2.29) in separate analyses. Male gender and higher age predicted death in the AS cohort. In addition, lower level of education and several comorbidities, both general (CVD, diabetes, pulmonary

and malignant diseases) and AS-related (previous small or large joint surgery) were associated with increased risk of death in age/-sex adjusted analyses.

Conclusion: Mortality in this national, population-based AS cohort was increased both in men and women compared to matched controls from the general population. Both general and AS-related comorbidities predicted death suggesting that both traditional and AS-specific risk factors may affect survival.

Table: Predictors of Mortality in AS (age- and sex-adjusted analysis)

	Baseline frequencies (%)	Hazard Ratio	95% CI
Higher education *(12 yrs vs. ≤ 12 yrs)*	2648 (30.8)	0.67	0.52–0.85
Longer duration *(Diagnosis made before Jan 2006 vs after 2006)*	5846 (68.0)	1.49	1.19–1.86
General comorbidities registered before start of follow up:			
Cardiovascular disease or medication (CVD)	2954 (34.4)	2.04	1.62–2.55
Diabetes	418 (4.9)	1.94	1.52–2.47
Chronic lung disease	164 (1.9)	3.04	2.28–4.06
Malignancy	427 (5.0)	1.75	1.39–2.22
AS-related comorbidities registered before start of follow up:			
Joint surgery (small or large joints)	645 (7.5)	1.44	1.15–1.81
Aortic valve insufficiency	79 (0.9)	1.24	0.71–2.15
Inflammatory bowel disease	644 (7.5)	1.29	0.97–1.73
Anterior uveitis	1731 (20.1)	0.90	0.70–1.15

Prevalence and Associating Factors with Atypical Femoral Fractures: An Asian Single Center Based Case-Control Study. Dam Kim[1], Yoon-Kyoung Sung[1], Soo-Kyung Cho[1], Minkyung Han[1] and Yee-Suk Kim[2]. [1]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [2]Hanyang University Hospital, Seoul, South Korea.

Background/Purpose: Although the use of bisphosphonates has been shown to reduce vertebral and proximal femur fracture risk in patients with osteoporosis, current evidence suggests that there is an association between bisphosphonate use and atypical femoral fractures (AFFs). However, the extent of this risk remains unclear, especially in Asian population. In this study, we aimed to estimate the proportion of AFFs among total patients with femoral fractures and to compare the characteristics of patients with AFFs with that of patients with classic femoral fractures (CFFs).

Methods: Between 2003 and 2013, a total of 578 female patients with low-energy femoral fractures who had been hospitalized at an Asian single university hospital were retrospectively enrolled. Radiographs and medical records were reviewed by medical doctors. Patients were classified into two groups according to the site of fracture: AFF group for patients with subtrochanteric or diaphyseal femoral fractures and CFF group for patients with intertrochateric or neck fractures. After estimating the prevalence of AFF among patients with low-energy femoral fractures, we assessed the association of bisphosphonate use and AFFs with using multivariate logistic regression analysis.

Results: Twenty-seven patients (4.7%) with AFFs and 551 patients (95.3%) with CFFs were identified. Of the patients with AFFs, 11 (40.7%) had been treated with bisphosphonates compared with 40 (7.3%) in the CFF group. Patients with AFFs were younger than CFFs group (71.2 $\pm$ 9.5 vs. 76.9 $\pm$ 8.7, $p<0.01$). Without correction for age, patients with AFFs appeared to have a higher cortical thickness index (1.1 $\pm$ 0.4 vs. 0.98 $\pm$ 0.4, $p<0.05$) compared to patients with CFFs. With adjusting the age, body mass index, types of injury (slip or fall), and history of rheumatoid arthritis, bisphosphonate was the only predictor for atypical fractures (OR 9.8, CI 3.7–26.4). Among the patients with using bisphosphonate when they fractured (n=44), the proportion of AFFs was nearly 21% (n=9). The proportions of AFFs among femoral fractures were increased according to the duration of bisphosphonate; 15.4% (6 among 39 patients) in patients with less than 5 years and 60% (3 among 5 patients) in patients over 5 years, respectively.

Conclusion: The proportion of AFFs was around 5% among the patients with femoral fractures and AFF were associated with bisphosphonate use in Asian ethnicity. Longer duration of treatment resulted in augmented risk, though any period in bisphosphonate use could cause atypical femur fracture.

Problems with Fee for Service Payments for Academic Rheumatology Practices: A Need for Payment Reform:. Allen P. Anandarajah[1] and Christopher T. Ritchlin[2]. [1]Univ of Rochester Medical Ctr, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY.

Background/Purpose: The current fee-for-service model rewards providers for the volume of services. The model is designed to deliver higher compensation for care of more complex cases. Rheumatologists in tertiary care institutions, who provide care for a larger proportion of complex cases, however, are under increasing pressure to care for a higher volume of patients in shorter time intervals.

Purpose is to examine if care for more complex rheumatology cases provides higher financial compensation compared to less complex cases, in an outpatient, academic rheumatology practice.

Methods: We conducted a financial analysis of different faculty outpatient rheumatology clinics at the University of Rochester of Medical Center from July 2012 to June 2013. One clinic session was defined as a 4 hour block. We compared three clinics: one dedicated to care of patients with systemic lupus erythematosus (SLE) comprised of patients with complex medical problems, one comprised of rheumatoid arthritis (RA)patients, with conditions of moderate complexity and a general rheumatology (GR) clinic comprised of patients with less complex problems. The following independent variables were collected: total patient numbers, coding levels and procedures including joint injections and ultrasound. The outcome variable, average revenues for an average clinic, were analyzed.

Results: On average, a total of 7.5 patients, (0.6 new, 6.9 established patients) were seen in the SLE clinic. This compared with a total of 8.9 patients in the RA clinic (0.9 new, 8.0 established) and 6.5 patients in the GR clinic (1.2 new, 5.4 established). The SLE and RA clinics performed on average 0.7 and 1.9 joint injections respectively while the GR clinic had 4.3 joint injections and 1.2 ultrasounds per clinic. The coding patterns for the different clinics are shown in Table 1. The average revenues received for each level of visit, ultrasound and procedures was used to calculate the total revenue for each individual clinic. The average revenues and RVUs for the SLE clinic were calculated to be $1,034.58 and 13.3 respectively. The RA clinic generated 6.2% more in revenue ($1,098.66) and 19.3% more in RVUs (15.8) while the GR clinic collected 24.5% more in revenues ($1,287.81) and 65.9% more in RVUs (22.0) than the SLE clinic. The difference in payments for a year (based on 8 clinics a week for 46 weeks) was calculated to be $23,578.85 more for the RA and $93,186.36 for the GR clinics compared with the SLE clinic.

Conclusion: The current pay structure provides greater financial and RVU compensation for the care of less complex rheumatology cases than the care of complex multisystem diseases. Procedures may be a major contributor to the difference in revenues. Payment reforms are therefore needed to adeqaute compensation for the care of patients with complex rheumatologic problems.

Table 1: coding patterns in percentages for the different outpatient clinics

	FU 2	FU 3	FU 4	FU 5	NEW 3	NEW 4	NEW 5
SLE	0.2%	16%	39.5%	44.3%	3.5%	46.3%	50.2%
RA	0.2%	35.2%	65.2%	0.4%	0%	40.6%	59.4%
GR	0.6%	41.25	55.9%	2.3%	1.4%	27.2%	71.4%

FU= established patients; NEW= new patients

Role of HLA-B*5801 Genetic Testing and a Safety Programme When Initiating Allopurinol Therapy for Chronic Gout Management: A Cost-Effectiveness Analysis. Di Dong[1], Wei Chuen Tan-Koi[2], Gim Gee Teng[3], Eric Finkelstein[4] and Cynthia Sung[4]. [1]Duke-NUS Graduate Medical School, Singapore, Singapore, [2]Saw Swee Hock School of Public Health, National

University of Singapore, Singapore, Singapore, [3]Division of Rheumatology, University Medicine Cluster, National University Health System, Singapore, Singapore, [4]Duke-NUS Graduate Medical School, Singapore., Singapore, Singapore.

Background/Purpose: To conduct a cost-effectiveness analysis from a health system perspective of various strategies in managing chronic gout to mitigate risk of allopurinol-induced Stevens-Johnson Syndrome and Toxic Epidermal Necrolysis, including three that utilize results of HLA-B*5801 genetic testing.

Methods: A decision tree model was developed to estimate costs and quality-adjusted life years (QALYs) over 20-year horizon for patients with chronic gout who fulfil the criteria for initiating ULT with either allopurinol or probenecid. Strategies modelled were: (a) Standard ULT with allopurinol as first-line drug (ULT); (b) Standard ULT with allopurinol as 1st line drug coupled to a safety programme (ULT+SP) that monitors for signs of SJS/TEN; (c) HLA-B*5801 genetic testing-guided ULT treatment (G->ULT) in which choice of 1st line ULT is based on test results (probenecid for test positive, allopurinol for test negative) and avoidance of allopurinol in HLA-B*5801 positive patients; (d) genetic testing to enrol test positive patients in a safety programme when initiating allopurinol (G->SP); test negative patients would receive allopurinol without SP; (e) HLA-B*5801 genetic guided ULT with the safety programme (G->ULT->SP) in which test positive patients are initially given probenecid, but non-responders are subsequently switched to allopurinol in the presence of the safety programme; (f) No ULT and treatment of acute flares only (no ULT). Although inputs are based on the Singapore context, the model is a general template that can be readily adapted to other populations and countries.

Results: No ULT and treating acute flares only has the lowest QALYs and highest costs. Compared with standard ULT, G->ULT increases cost by US$910 but reduces QALYs, despite the reduction in SJS/TEN risk. ULT+SP has an incremental cost-effectiveness ratio (ICER) of US$102,030/QALY compared to ULT alone. G->SP achieves the same QALYs as ULT+SP but at higher cost. G->ULT->SP results in an ICER of $93,030/QALY compared to standard ULT. (***Figure 1 and 2***)

Conclusion: Standard care with allopurinol as first line treatment for chronic gout without genetic testing remains the optimal strategy from a cost-effectiveness perspective based on a threshold of US$50,000/QALY. A safety programme for all patients is not cost-effective, but may become so if implementation costs decrease. If genetic testing costs decrease, testing may become cost-effective if results are used to guide the selection of 1st line ULT, with allopurinol as 2nd line ULT for HLA-B*5801 positive patients in the presence of a safety programme.

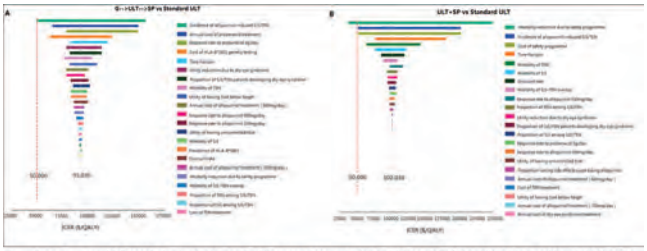

Figure 1. One-way sensitivity analysis. (Panel A) G->ULT->SP compared to standard ULT, yields an ICER of $93,030/QALY. Using $50,000/QALY as the threshold for cost-effectiveness, G->ULT->SP is not cost-effective unless when the incidence of allopurinol-induced SJS/TEN is higher than 0.4% in the population. Other inputs are not influential on the cost-effectiveness results when varies within the sensitivity range. (Panel B) ULT+SP compared to standard ULT, yields an ICER of $102,030/QALY. Using $50,000/QALY as the threshold for cost-effectiveness, ULT+SP is not cost-effective unless the safety programme can reduce SJS/TEN mortality by 60%, when the cost of safety programme is below $30, or when the incidence of allopurinol-induced SJS/TEN is higher than 0.4% in the population. Other inputs are not influential on the cost-effectiveness results when varies within the sensitivity range.

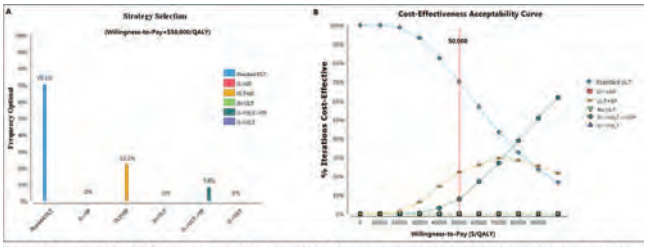

Figure 2. Probabilistic Sensitivity Analysis . (Panel A) In a simulation of 10,000 runs where all input variables are randomly drawn from the assigned distributions during each run, standard ULT was the optimal strategy in 70.1% of iterations. ULT+SP and G->ULT->SP are optimal in 22.1% and 7.8% of interations, respectively. G->SP, no ULT, and G->ULT are dominated strategies that are not preferred. (Panel B) Based on a willingness-to-pay of $50,000/QALY, Standard ULT is the optimal strategy. When the willingness-to-pay is higher than $80,000/QALY, G->ULT->SP becomes the optimal strategy.

Is Team Care Better? a Comparison of Rheumatoid Arthritis Disease Activity Among Patients Cared for in Practices with Nurse Practitioners and Physicians Assistants Versus Rheumatologist Only.

DH Solomon[1], Liana Fraenkel[2], Bing Lu[1], Erika Brown[1], Peter Hsun Tsao[3], Elena Losina[1], Jeffrey N. Katz[1] and Asaf Bitton[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: The Affordable Care Act proposes more widespread use of mid-level providers (MLPs), such as nurse practitioners and physician assistants, but little is known about the process and outcomes of the care they provide. This is of particular interest in rheumatology, where there is a predicted workforce shortage by the year 2025. We set out to compare the outcomes of care provided by MLPs for rheumatoid arthritis (RA) in rheumatology practices with that provided by rheumatologists alone.

Methods: This study was conducted in 7 rheumatology practices in the US – 4 with MLPs and 3 without. The primary outcome was RA disease activity, categorized as remission, low, moderate, or high, using standardized measures (e.g., DAS28, RAPID3, CDAI). We abstracted the following information from medical records for patients with RA from the most recent 2 years: RA treatments, serologic status, disease duration, and disease activity measures. We compared patient characteristics and disease activity for visits across the MLP and rheumatologist only practices. We performed a repeated measures analysis to compare disease activity for visits with MLPs versus those with rheumatologists. These contrasts were made with ordinal logistic regression and expressed as proportional odds ratios. Sensitivity analyses also examined 1) the area under the curve (AUC) for disease activity over the 2-year study period (linear regression) and 2) the change in disease activity between visits (ordinal logistic regression).

Results: Records from 301 patients, including 1982 visits were reviewed: 1168 visits with MLPs and 814 with rheumatologists. Overall, patients had a mean age of 61 years and 77% were female. 69% of patients seen by MLPs and 70% of those seen by rheumatologists were seropositive. In the primary adjusted analysis, patients seen in MLP practices were more likely to have better disease activity (OR 0.32, p = 0.004, reduced probability for higher disease activity) than those seen in practices with only rheumatologists (see Table). Similar trends were observed in the AUC analysis. However, there were no differences in the change in disease activity comparing patients seen in practices with MLPs versus rheumatologist only.

Conclusion: While non-randomized trials are subject to confounding by indication, patients seen in practices with MLPs for RA had reduced disease activity over a 2-year observation period compared with those seen in rheumatology only practices; although no differences were observed in the change in disease activity between visits. Two competing possibilities emerge that further research can help clarify: patients seeing MLPs are less sick to begin with or their care is associated with better disease control when MLPs are part of the team.

Table: Categorical disease activity measures compared across patients seen in practices with mid-level providers versus those without, based on adjusted regression models*

Variable	Primary analysis (OR, 95% CI) †	Secondary analysis, change between visits (OR, 95% CI) †	Secondary analysis, area under the curve (b coefficient)**
Mid level provider (vs not)	0.32 (0.17-0.60)	0.98 (0.94-1.03)	−6.35 (p = 0.0055)
Disease activity category at baseline	. . .	. . .	9.85 (p < 0.001)
Age, per year	0.99 (0.98-1.02)	1.00 (0.99-1.00)	−0.005 (p = 0.95)
Female gender	2.24 (1.09-4.61)	0.98 (0.93-1.02)	0.34 (p = 0.89)
Duration of RA, per year	1.18 (0.87-1.61)	1.01 (0.99-1.03)	0.92 (p = 0.59)
Seropositive	1.26 (0.69-2.30)	1.02 (0.98-1.06)	1.08 (p = 0.59)
DMARD use, any	0.64 (0.43-0.95)	0.99 (0.94-1.03)	−2.85 (p = 0.20)

* The Disease activity category at baseline was not entered into all analyses since it was part of the outcome. Abbreviations: RA, rheumatoid arthritis; DMARD, disease-modifying anti-rheumatic drug. † Odds ratio denotes the probability of a one level increase in disease activity, with odds ratios less than one denoting a reduced probability. They were calculated using a proportional odds model that accounted for the hierarchical clustering. ** The b coefficients denote the area under the disease activity curve for the 24 months, with scores of 0-3 interpolated for each month. They were calculated in generalized linear models.

Improper Use of Antinuclear Antibody (ANA) Test Can Result in Misdiagnosis, Increased Patient Anxiety, and Wasted Health Care Resources. Sahar Eivaz Mohammadi[1], Imam H Shaik[1], Parag Chevli[1], Fernando Gonzalez-Ibarra[1], Sohini Sarkar[1], Saurav Acharya[1], Prerna Dogra[1], Hesam Hekmatjou[2], Maushmi Savjani[2], Waheed Abdul[2] and Valentin Marian[1]. [1]Jersey City Medical Center-Barnabas Health, Jersey City, NJ, [2]St. George's University SOM, St. George's, Grenada.

Background/Purpose: Results of serologic tests for autoantibodies, including tests for Antinuclear antibodies (ANAs) and antibodies to specific nuclear antigens such as double-stranded DNA (dsDNA), play an important role in the diagnosis of connective tissue disorders (CTDs) such as systemic lupus erythematosus (SLE). ANAs are often detected in many healthy individuals without CTDs (~13%). Although a negative ANA test makes SLE highly unlikely, the positive results without significant clinical and laboratory features will lead to inappropriate tests and misdiagnoses.

Methods: This is a retrospective chart review of patients on whom ANA test has been performed at a 330-bed community hospital in U.S. over a period of one year. All relevant details like demographics, locations, physician service, clinical features, history of CTDs, prior ANA results, additional tests and their results were noted. The justification for ordering the ANA test was compared against clinical and laboratory parameters included in the 2012 SLICC classification criteria for SLE.

Subsequently, true and false positive incidence was calculated. For all the negative or positive ANA tests, special attention was given to the indications of testing based on chart analysis. The 2012 SLICC clinical classification criteria were applied retrospectively to all cases regardless the ANA results; more than two positive parameters by SLICC criteria were proposed as a justification to order ANA test. The results are compared using 2×2 chi-square test.

Results: During one year period, ANA was ordered for a total of 465 patients (Male=151, Female=314). Among them, 12.47% (n=58) had prior history of CTDs and 0.98% (n=4) had prior ANA positivity. In the remaining 403 patients, ANA was found positive (titers ≥1:80) in 6.94% (n=28) and negative in 93.05% (n=375). By applying 2×2 chi-square test, was shown that ANA positivity or diagnosis of CTD is very unlikely if less than 2 SLICC parameters are present with a p value <0.05 (Table 1)

Out of all 465 cases, only one new case of Anti phospholipid antibody syndrome was identified. A total of $39,297 was spent on ANA, and $87,165 on additional tests ordered in conjunction or following a positive ANA. It was noted that a large number of cases where ANA sub-serologies are ordered without knowing the ANA. This ordering pattern is against recommendation by "Choosing Wisely" campaign endorsed by ABIM and ACR.

Conclusion: Testing for ANA and related serology had cost approximately $126,000/yr for a medium size hospital and lead to no new SLE cases. ANA sub-serologies had cost the hospital $87,165 and according to "Choosing Wisely" campaign, were not indicated in more than 93% of cases, as these were negative ANA by IIF. In our hospital the lab was instructed to cancel the additional sub-serologies unless the ANA turns positive.

Table 1.

	ANA negative	**ANA positive**	Marginal row totals
SLICC score 2 or above	**302** (297.77) [0.06]	**18** (22.23) [0.81]	320
SLICC score < 2	**73** (77.23) [0.23]	**10** (5.77) [3.11]	83
Marginal column totals	375	28	403 (Grand Total)

The Chi-Score statistic is 4.2058. The *P* value is 0.040287. The result is significant at p<0.05.

1811

The Burden of Depression on Healthcare Utilization in a Population-Based Cohort of Patients with Systemic Lupus Erythematosus. Alfredo Aguirre[1], Gaobin Bao[1], S. Sam Lim[2] and Cristina Drenkard[1]. [1]Emory University, Atlanta, GA, [2]Emory University School of Medicine, Division of Rheumatology, Atlanta, GA.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic disease that disproportionately strikes black women. Depression is a potentially debilitating co-morbidity that affects 15–75% of SLE patients and is more severe and unrecognized among blacks compared to whites. Data from a mostly white SLE cohort suggests an association between depression and high emergency department (ED) use. However, no study has assessed the impact of depression on healthcare utilization among patients representative of the SLE population in the Southeastern United States (US). We examined the relationship between depression and healthcare utilization in a predominantly black SLE cohort, expecting depression to be associated with increased ED and inpatient usage.

Methods: Georgians Organized Against Lupus (GOAL) is a longitudinal cohort of validated SLE patients largely drawn from a population-based lupus registry established in Atlanta, Georgia. Annual patient-reported surveys furnish data on demographics, disease outcomes and healthcare utilization from GOAL participants, of whom 78% are black, 35% live under the Federal Poverty Level and 11% are uninsured. All cases fulfilled at least 4 of the American College of Rheumatology (ACR) Classification Criteria for SLE, or 3 ACR criteria with a final diagnosis of SLE by the attending rheumatologist. We used data from the 2013–14 annual survey to examine the relationship between depression, as assessed by the 9-item Patient Health Questionnaire (PHQ-9), and utilization of inpatient and ED resources in the past year.

Results: 566 participants were included in this analysis. Nearly half (46%) of the GOAL participants had visited the ED, while 27% had been admitted to the hospital. Among those with depression (PHQ-9 score =/>10), 58% had visited the ED, as compared to 41% of those with a score <10 (p=0.0001). Patients with and without depression had a mean of 1.7 ED visits and 1.1 ED visits annually, respectively (p<0.0001).

Conclusion: A greater proportion of depressed SLE patients had accessed ED resources for care. In addition, increasing depression severity was associated with higher frequency of ED visits. We did not find an association between depression and hospitalization as was hypothesized, suggesting that depressed patients who visited the ED did not meet inpatient admission criteria. Our data gesture toward deficiencies in the routine care of depressed SLE patients that may contribute to avoidable ED utilization, and suggest the potential utility of depression screening modalities in the assessment of SLE patients who resort to the ED for care. Further research is needed to determine whether demographic factors have an effect on the association between depression and ED visits and whether increased ED utilization may be due to subpar quality, coordination or type of care for those with depressive symptoms.

Investigation of the Sting/Interferon Pathway Activation in a Novel Vasculopathy and Pulmonary Syndrome. Yin Liu[1], Adriana Almeida de Jesus[2], Bernadette Marrero[1], Dan Yang[3], Gina A. Montealegre Sanchez[2], Steve Brooks[1], Zuoming Deng[2], Amy Paller[4], Manfred Boehm[3] and Raphaela Goldbach-Mansky[2]. [1]NIAMS/NIH, Bethesda, MD, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD, [3]National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD, [4]Northwestern University Feinberg School of Medicine, Chicago, IL.

Background/Purpose: We have recently studied a group of patients with a prominent interferon (IFN) signature in the blood, distinct from IL-1 mediated autoinflammatory diseases. Six patients with *de novo*

gain of function mutations in *TMEM173*, which encodes *ST*imulator of *I*nterferon *G*enes (STING), presented with early onset systemic inflammation, vasculopathy/vasculitis, and pulmonary inflammation. STING is an adaptor molecule for cytosolic DNA sensing pathway, which leads to IFNb production. The identification of an IFN activating mutation allows us to examine the cellular origin of the IFN and the IFN response signature in patients' cells.

Methods: Patients alive (n=4) were evaluated clinically and immunologically. STING ligand cGAMP was used to assess its function in stimulation assays in patients' and controls' Peripheral Blood Mononuclear Cells (PBMCs), fibroblasts and endothelial cells. Transfection studies of STING wildtype or mutant constructs in HEK293T cells were performed and IFNb transcription in patient peripheral blood cell subsets, fibroblasts, and healthy control endothelial cells were assessed.

Results: Whole blood transcriptional profiling by RNA_seq showed significant upregulation of IFN regulated genes compared with healthy controls. Constitutively increased transcription of IFNβ and other downstream targets of STING in patient PBMCs indicate constitutive STING/IFN pathway activation. qRTPCR analysis of RNA extracted from flow cytometer sorted cells indicates that monocytes produce by far the highest level IFNb. Transcriptional analysis by RNA_seq suggests that the STING/IFN pathway was also constitutively activated in patient fibroblasts. When stimulated with STING ligand cGAMP, patients' fibroblasts are more sensitive and have exaggerated transcription of IFNβ but not IL-1, IL-6 and TNF. STING is expressed in endothelial cells (EC) and *in vitro* STING pathway stimulation leads to EC activation and damage.

Conclusion: *S*TING-*A*ssociated *V*asculopathy with onset in *I*nfancy (SAVI) is a novel autoinflammatory disease caused by *de novo* gain of function mutations in *TMEM173*, which leads to constitutive STING activation and elevated IFNβ secretion. The identification of a mutation in the IFN pathway suggests the use of therapeutic agents blocking this pathway and allows us to study the cellular origin and the organ manifestations of the inflammation.

DNA Sensors Regulate Inflammation in a Model of Autoimmune Arthritis. Rebecca Baum[1], Shruti Sharma[1], Sudesh Pawaria[1], Susan Carpenter[2], Katherine A. Fitzgerald[1], Ann Marshak-Rothstein[1] and Ellen M. Gravallese[3]. [1]University of Massachusetts Medical School, Worcester, MA, [2]University of California, San Francisco, San Francisco, CA, [3]UMass Memorial Medical Center, Worcester, MA.

Background/Purpose: Innate immune sensors such as cytosolic DNA sensors and toll-like receptors (TLRs) detect viral or bacterial DNA, resulting in production of proinflammatory cytokines and type I IFNs to clear infection. Pathways involved in detecting this foreign DNA include: 1) cytosolic DNA sensors that signal through stimulator of interferon genes (STING); 2) the cytosolic sensor absent in melanoma 2 (AIM2); and 3) endosomal TLRs that traffic via Unc93. DNA derived from endogenous retroelements or dying cells have also been shown to activate these pathways, contributing to autoimmune disease. We examined the role of DNA sensor pathways in a mouse model of inflammatory arthritis in which the lysosomal endonuclease DNaseII is deficient. In this model, DNA accrual results in production of proinflammatory cytokines and type I IFNs. Since type I IFNs lead to anemia-related embryonic lethality, co-deletion of the type I IFN receptor is required (DNaseII/IFN-IR double deficient (DKO) mouse).

Methods: To investigate the contribution of DNA sensor pathways to inflammatory polyarthritis, genes involved in DNA sensor signaling were deleted on the DKO background, yielding three triple knock out (TKO) strains: STING TKO, AIM2 TKO and Unc93 TKO mice. Inflammation was assessed by clinical scoring (scale of 1–12) and by scoring of histologic inflammation in ankle joints (scale of 1–4). Anti-nuclear antibody (ANA) staining was evaluated as another marker of disease. To determine whether STING contributes to inflammation in immune-complex mediated arthritis, serum transfer arthritis (STA) was induced in STING$-/-$ and littermate control mice.

Results: DKO mice develop significant distal polyarthritis. Clinical joint inflammation was completely absent in STING TKO mice, confirming a prior report (Ahn et al., PNAS 109:19386, 2013). However, STING deficiency did not diminish inflammation in the STA model, demonstrating that STING contributes to arthritis in the setting of DNA accrual. Clinical inflammation was significantly reduced in both AIM2 TKO and Unc93 TKO mice compared to DKO mice, demonstrating a role for the inflammasome and TLRs. Average clinical scores: DKO = 5, Het control mice = 0, STING TKO = 0, Unc93 TKO = 4, AIM2 TKO= 3.5 ($p<0.05$ for all strains compared to DKO). Histologic inflammation scores showed a similar pattern (DKO = 3.5, Het = 0, STING TKO = 0.5, AIM2 TKO = 2, Unc93 TKO = 3 ($p<0.05$ for all strains compared to DKO). The bright ANA staining pattern generated from sera of DKO mice was completely abrogated in the Unc93 TKO, but was unchanged in the STING TKO and AIM2 TKO strains.

Conclusion: These data indicate that stimulation of several innate immune sensor pathways by endogenous DNA can contribute to inflammatory polyarthritis. Although deletion of STING had the greatest impact in abrogating arthritis, the AIM2 and Unc93 pathways also contributed to joint inflammation. The TLR/Unc93 pathway, but not the STING or AIM2 pathways, mediated ANA production. These data are directly relevant to clarifying the mechanisms by which polyarthritis occurs in SLE and suggest new targets for treatment. In addition, these data demonstrate that distinct DNA sensing pathways play unique roles in disease mechanisms.

RNA-Containing Immune Complexes Shift Human Neutrophils from Phagocytosing Cells to Efficient Releasers of Oxidized DNA in a Process Requiring Crosstalk Between Toll-like Receptors and Fc Gamma Receptor IIa. Christian Lood[1], Xizhang Sun[1], Lena Tanaka[1], Andrew Oberst[2], Jeffrey Ledbetter[3] and Keith B. Elkon[1]. [1]University of Washington, Seattle, WA, [2]Department of Immunology, University of Washington, Seattle, WA, [3]Division of Rheumatology, University of Washington, Seattle, WA.

Background/Purpose: Neutrophil extracellular traps (NETs), the extrusion of chromatin to capture microbes, has recently emerged as a possible mechanism that may increase the autoantigenic burden as well as promote the prominent type I interferon (IFN) signature seen in most patients with systemic lupus erythematosus (SLE). Apparent spontaneous NETosis is observed *ex vivo* in low-density granulocytes, a cell population markedly increased in SLE. *In vitro* SLE RNA-containing immune complexes (RNA ICs) are reported to induce NETs from neutrophils obtained from SLE, but not healthy individuals. Since the precise requirements for RNA ICs and neutrophils in the induction of NETs have not been defined, we investigated the requirements for IC-induced NETosis in normal neutrophils, analyzed the crosstalk between FcgRs and TLRs, and characterized the released DNA material with regard to its source and oxidation.

Methods: Neutrophils, isolated from healthy individuals, were stimulated with RNA ICs, and DNA release and 8-OHdG content, analyzed by fluorescence microscopy and ELISA. The origin of the released DNA was assessed by analyzing 16S (mitochondria) and 18S (chromosomal) expression by qPCR. Phagocytosis was measured by flow cytometry.

Results: Immobilized IgG mimicking tissue-deposited ICs readily induced NETosis in neutrophils in a NADPH oxidase- and PAD4-dependent, but TLR-independent manner. In contrast, soluble endotoxin-free aggregated IgG (HAGG) did not induce NETosis whereas soluble RNA ICs were potent inducers of NETs. This process was dependent on TLR activation since addition of RNases efficiently degraded the RNA contained within the IC, and completely abrogated the ability of soluble RNA ICs to induce NETosis. Despite the fact that degradation of RNA inhibited NETosis, removal of the TLR ligand by RNase markedly increased the phagocytosis of RNA ICs by neutrophils suggesting that TLR activation suppressed phagocytosis. Consistent with this hypothesis, addition of a TLR agonist (R848) inhibited phagocytosis of ICs, but not beads, in neutrophils. Flow cytometric analysis revealed that the underlying mechanism involved rapid down-regulation of FcgRIIA on the neutrophil cell surface upon TLR activation, which reduced its phagocytic capacity and promoted progression into NETosis. The released DNA from RNA IC-activated neutrophils had high 8-OHdG content and was mainly of chromosomal origin, although some mitochondrial DNA was present as well. The chromosomal DNA was enriched for MPO, whereas the mitochondrial DNA was enriched for 8-OHdG oxidation.

Conclusion: i) Extensive aggregation of FcgR on neutrophils, as may occur in tissue deposits, appears sufficient to induce NETosis; ii) In the fluid phase, both FcgR aggregation and TLR ligation are necessary to stimulate

NETosis; iii) TLR-ligand activation in neutrophils downregulates FcgRIIA expression thereby inhibiting further phagocytosis of ICs but enabling NETosis; iv) ICs induce release of oxidized DNA of chromosomal and mitochondrial origin. Deciphering the underlying signaling pathways regulating the crosstalk between FcgRs and TLRs in induction of NETosis may provide novel therapeutic targets.

STAT3-Mediated Regulation of Mitochondrial Membrane Potential Is Critical for NLRP3 Inflammasome Activation. Jehad H. Edwan[1], Raphaela Goldbach-Mansky[2] and Robert A. Colbert[3]. [1]NIAMS NIH, Bethesda, MD, [2]NIH Building 10 Room 6D47B, Bethesda, MD, [3]NIAMS/NIH, Bethesda, MD.

Background/Purpose: Self-activating mutations in NLRP3 cause a spectrum of autoinflammatory diseases known as cryopyrin-associated periodic syndromes (CAPS). NLRP3 is a key component of a multiprotein complex known as the inflammasome that mediates the maturation of the proinflammatory cytokine IL-1beta, and can induce rapid cell death in a process known as pyronecrosis. Although several models for inflammasome activation have been proposed the precise molecular mechanism, as well as the role of NRLP3 mutations, remains to be elucidated. Emerging evidence suggests that mitochondria are involved in inflammasome activation. STAT3 associates with the mitochondrial inner membrane in a GRIM-19 dependent manner and has been implicated in regulating cellular respiration. Here we asked whether regulation of mitochondrial membrane potential plays a role in NLRP3 inflammasome activation.

Methods: We used whole blood cells from NOMID patients and healthy controls, THP-1 cells with STAT3, NLRP3, GRIM-19, or OSCP expression knocked down, and monocytes derived from NLRP3-deficient mice. Cells were stimulated with LPS in the presence of inhibitors of STAT3, followed by ATP. Cell supernatants were collected and incubated with IL-1beta-capturing beads. Cells were fixed and permeabilized. Then beads were added back to cells, and the mixture of cells with beads was stained with anti-IL-1beta, CD14, and CD16 antibodies and then evaluated by flow cytometry. LPS stimulated cells were also evaluated using immunofluorescence and western blot analysis.

Results: By flow analysis we provide evidence that inhibition of STAT3 function in NOMID and healthy control monocytes, as well as knockdown of STAT3 in THP-1 cells, results in a significant decrease in inflammasome activation. Using confocal microscopy to visualize pyronecrosis, we provide evidence that this process is NLRP3 dependent. Knockdown of GRIM-19 in THP-1 cells also inhibited NLRP3 activation, suggesting a requirement for mitochondrial STAT3. Enhancement of the mitochondrial membrane potential in STAT3 knockdown cells bypassed the effect of STAT3 knockdown, and reconstituted inflammasome activation, whereas knockdown of OSCP significantly reduced inflammasome activation.

Conclusion: These data suggest a previously unrecognized role for STAT3 in regulating mitochondrial membrane potential, which can regulate NLRP3 inflammasome activation. These results point toward mitochondrial STAT3 as a novel therapeutic target for NOMID and other NLRP3-mediated inflammatory diseases.

Toll-like Receptor 4-Induced Interleukin-1 Defines the Intestinal Microbiome and Mucosal Immune Response in Arthritis-Prone IL-1 Receptor Antagonist Deficient Mice. Tom Ederveen[1], Rebecca Rogier[1], Jos Boekhorst[1], Harm Wopereis[2], Johan Garssen[2], Sacha van Hijum[1], Fons A.J. van de Loo[1], Marije I. Koenders[1], Wim B. van den Berg[1] and Shahla Abdollahi-Roodsaz[1]. [1]Radboud university medical center, Nijmegen, Netherlands, [2]Danone Research, Wageningen, Netherlands.

Background/Purpose: Interleukin-1 (IL-1) plays a pivotal role in inflammation and autoimmunity. Mice deficient in the IL-1 receptor antagonist ($IL\text{-}1Ra^{-/-}$) spontaneously develop a T cell-driven autoimmune arthritis, which we previously showed to depend on the presence of commensal microbiota. Recent findings suggest alteration of intestinal microbiome in new-onset rheumatoid arthritis (RA). The aim of this study was to investigate the role of IL-1 receptor signaling and the involvement of Toll-like receptor (TLR) 2 and TLR4 in defining the intestinal microbiota and the associated mucosal and systemic immune response.

Methods: Multiplex 454 pyrosequencing of V5 and V6 hyper-variable regions of fecal bacterial 16S rRNA was used to define intestinal microbial communities in BALB/c wild type (WT), $IL\text{-}1Ra^{-/-}$ and IL-1Ra/TLR double knock-out (DKO) mice. For gene sequencing analysis, a customized workflow based on Quantitative Insights Into Microbial Ecology (QIIME version 1.2) was adopted. Intestinal T cell differentiation was studied in lamina propria lymphocytes using flow cytometry and gene expression was assessed by qPCR.

Results: Excessive IL-1R signaling strongly affected the composition of intestinal microbiota and resulted in a significant reduction in species diversity compared to WT mice. Both alpha diversity (number of unique taxonomic entities) and phylogenetic diversity (PD) whole tree (based on taxonomic distance) were significantly diminished in $IL\text{-}1Ra^{-/-}$mice compared to WT. Interestingly, the loss of species diversity was absent in IL-1Ra/TLR4 DKO, but not IL-1Ra/TLR2 DKO mice, suggesting that IL-1R-driven skewing of bacterial diversity depends on TLR4.

$IL\text{-}1Ra^{-/-}$ mice exhibited significantly increased abundance of the genus *Helicobacter* and reduced *Prevotella* ($p = 0.008$ and $p = 0.004$, respectively). Importantly, significant alterations in the genera *Xylanibacter*, *Prevotella*, *Streptococcus*, and *Ruminococcus* were markedly normalized in TLR4, but not TLR2, deficient mice, identifying a role for TLR4 in IL-1 mediated shifts in microbial community.

In line with the relevance of intestinal microbiota in mucosal helper T cell polarization, $IL\text{-}1Ra^{-/-}$ mice had greatly increased Th1 and Th17 in small intestine lamina propria, while Treg proportions were unaffected. Also, small intestine lamina propria lymphocytes produced increased levels of IL-17 when stimulated with PMA and ionomycin *ex vivo*. Although expression of IL-1 itself remained unaltered, intestinal IL-23p19 mRNA expression was increased in $IL\text{-}1Ra^{-/-}$ mice. Interestingly, mucosal expression of both IL-1β and IL-23 was significantly diminished in IL-1Ra/TLR4 DKO mice. Moreover, splenic expression of IL-6 and RORγt was increased in $IL\text{-}1Ra^{-/-}$, and suppressed in IL-1Ra/TLR4 DKO mice.

Conclusion: These data indicate a clear role for the IL-1 pathway in defining the intestinal microbiota and mucosal immune response in autoimmune prone mice, potentially driven by TLR4.Understanding the molecular and cellular mechanisms linking the intestinal T cell response with extra-intestinal disease may help identify novel therapeutic targets in autoimmune diseases including RA.

Connecting Two Pathways through Ca^{2+} Signaling: NLRP3 Inflammasome Activation Induced By a Hypermorphic *PLCG2* Mutation. Jae Jin Chae[1], Yong Hwan Park[1], Chung Park[2], Il-Young Hwang[2], Patrycja Hoffmann[1], John Kehrl[2], Ivona Aksentijevich[1] and Daniel L. Kastner[1]. [1]National Human Genome Research Institute, Bethesda, MD, [2]National Institute of Allergy and Infectious Diseases, Bethesda, MD.

Background/Purpose: Previously, we reported that a novel variant, p.Ser707Tyr, in phospholipase Cγ2 (PLCγ2) is the cause of a dominantly inherited autoinflammatory disease, APLAID (autoinflammation and PLCγ2-associated antibody deficiency and immune dysregulation). The APLAID patients suffered from early onset recurrent blistering skin lesions, pulmonary disease, arthralgia, inflammatory eye and bowel disease, and mild immunodeficiency. The hypermorphic mutation enhances the PLCγ2 activity and causes an increase in intracellular Ca^{2+} release from ER stores. As increased intracellular Ca^{2+}signaling has been associated with NLRP3 inflammasome activation, we studied the role of the NLRP3 inflammasome in the pathogenesis of this disease.

Methods: Human peripheral blood mononuclear cells (PBMCs) were isolated from healthy controls and two affected patients. Inflammasome activation was analyzed by Western blotting of secreted interleukin-1β (IL-1β). Intracellular Ca^{2+}levels were measured with the FLIPR Calcium 4 assay kit.

Results: First, we confirmed that PLC-inositol trisphosphate ($InsP_3$)-mediated Ca^{2+} release can trigger the activation of the NLRP3 inflammasome in human PBMCs in much the same way as was previously shown in the mouse. Since the S707Y APLAID mutation disrupts the autoinhibition of PLCg2, which leads enhanced PLCγ2 activity, patients' leukocytes had elevated basal levels of intracellular Ca^{2+}. Upon stimulation with extracel-

lular $CaCl_2$, an activator of the NLRP3 inflammasome, patients' cells release significantly higher amounts of Ca^{2+} into the cytosol than the cells of healthy controls. Consistent with that the increase of cytoplasmic Ca^{2+} mediates the activation of the NLRP3 inflammasome, in the absence of inflammasome activators, PBMCs from patients with APLAID secreted IL-1β whereas control PBMCs secreted IL-1β only following the stimulation with $CaCl_2$. The IL-1β secretion from LPS-primed patients' PBMCs was attenuated by use of a PLC inhibitor and intracellular Ca^{2+}blockers. Finally, we found that the constitutive IL-1β secretion from patients PBMCs was substantially reduced by the treatment with NKH477, the water-soluble analog of forskolin, which is a potent activator of adenylyl cyclase. These results suggest cAMP as a potential target for therapy of APLAID and other NLRP3 mediated diseases.

Conclusion: Our findings suggest that the inflammation in patients with APLAID is partially driven by the activation of the NLRP3 inflammasome. These data link two seemingly distinct molecular pathways and provide new insights in the pathogenesis of APLAID and autoinflammation.

Subchondral Bone Mineral Density Improves Prediction of Knee Osteoarthritis Progression Compared with Clinical Factors Alone: Data from the Osteoarthritis Initiative. Michael P. Lavalley[1], Grace H. Lo[2], Lori Lyn Price[3], Jeffrey Driban[3], Charles Eaton[4] and Timothy E. McAlindon[3]. [1]Boston University, Boston, MA, [2]Michael E. DeBakey VA Medical Center, Baylor College of Medicine, Houston, TX, [3]Tufts Medical Center, Boston, MA, [4]Center for Primary Care and Prevention, Memorial Hospital of Rhode Island, Providence, RI.

Background/Purpose: A prediction rule for knee osteoarthritis (OA) progression would have great clinical utility in identifying at-risk patients for intervention. Rules using clinically available measurements have so far demonstrated modest predictive ability. Dual energy X-ray absorptiometry is widely available and provides rapidly evaluable quantitative data on tibial subchondral bone mineral density (BMD) that is associated with OA severity.

Our goal was to create a prediction rule for medial joint space loss (a proxy for OA progression) based on clinical factors; and to quantify the benefit of adding the ratio of the periarticular medial to lateral bone mineral density (M:L paBMD) to the rule.

Methods: Subjects were from the Osteoarthritis Initiative (OAI) progression subcohort, with X-ray readings at both 24- and 48-month visits, medial joint space score < 3 at 24 months, and a valid 30- or 36-month BMD value. Weight-bearing PA fixed flexion knee X-rays were assessed for medial tibio-femoral joint space using the OARSI atlas. Knees were imaged with GE Lunar Prodigy Advance scanners, providing M:L paBMD values. Loss of medial joint space, including within OARSI grade worsening, between 24 and 48 months was used as the outcome in logistic regression for the prediction models. Clinical factors chosen for their predictive ability from 24 months were considered for the base model. M:L paBMD was added to the base model to determine if it materially improved prediction, with cross-validation used in this evaluation. Discriminative ability was based on the area under the ROC curve (AUC) and calibration by the Hosmer & Lemeshow test (H&L). The benefit of adding M:L paBMD was evaluated by 1) change in AUC, 2) net reclassification improvement (NRI) based on the percent of subjects with improved prediction, and 3) integrated discrimination improvement (IDI) based on the mean improvement in predicted probabilities.

Results: 496 subjects were included; 68 (14%) experienced medial joint space loss; 48% were female; 15%, 16%, 36%, 30%, and 3% respectively had Kellgren & Lawrence scores 0 – 4; 2% had recent knee injury; 35% had hand OA (> 3 nodes) on physical exam at OAI entry. The mean (SD) for age was 64.4 (9.2) years; BMI 29.5 (4.9) kg/m^2; VAS knee-specific pain 3.4 (2.9) on a 0–10 scale; femoral neck BMD. 96 (.15) g/cm^2; and M:L paBMD 1.1 (.14). The base model included age, BMI, gender, recent injury, knee pain, hand OA, and femoral neck BMD as predictors. The change in AUC, NRI and IDI were statistically significantly improved in the model with M:L paBMD (Table). The H&L test did not find poor calibration in either model.

Conclusion: The M:L BMD ratio provided a meaningful improvement in predictive ability for 2-year medial joint space loss compared to using only clinical predictors. An instrument combining clinical characteristics with M:L paBMD may be useful as a predictive tool for structural progression in patients with knee OA.

Table 1. Cross-Validated Measures of Model Prediction of Medial Joint Space Loss with addition of the Ratio of Periarticular Medial to Lateral Bone Mineral Density (M:L paBMD)

	Base Model*	Base Model* + M:L paBMD	Comparison (95% Confidence Interval), p-value
ROC Area Under the Curve (AUC)	0.645	0.745	0.102 (0.051, 0.154) 0.001
Hosmer & Lemeshow Calibration Test (H&L) p-value	0.330	0.102	
Net Reclassification Improvement (NRI)			0.681 (0.434, 0.923) 0.001
Subjects with medial joint space loss			
Net % Improved		32%	
Subjects with no medial joint space loss			
Net % Improved		36%	
Integrated Discrimination Improvement (IDI)			0.072 (0.043, 0.101) 0.001
Subjects with medial joint space loss			
Average Predicted Probability	0.176	0.239	
Subjects with no medial joint space loss			
Average Predicted Probability	0.140	0.125	

* Base model has the predictors: age, BMI, gender, recent injury, knee pain, hand OA (> 3 hand nodes), and femoral neck BMD; outcome in both models is medial joint space loss.

Discordance of Hip Pain with Radiographic Hip Osteoarthritis: The Osteoarthritis Initiative. Chan Kim[1], Michael C. Nevitt[2], Pia M. Jungmann[3], Irina Tolstykh[4], Nancy E. Lane[5], Thomas M. Link[4] and David T. Felson[6]. [1]Boston University, Boston, MA, [2]UCSF (University of California, San Francisco), San Francisco, CA, [3]Technische Universitaet Muenchen, Munich, Germany, [4]University of California, San Francisco, San Francisco, CA, [5]Center for Musculoskeletal Health, UC Davis School of Medicine, Sacramento, CA, [6]University of Manchester, Manchester, United Kingdom.

Background/Purpose: It is assumed that persons with hip pain from osteoarthritis (OA) are likely to have radiographic OA, making it possible to readily diagnose disease, but there is little data addressing the agreement of hip pain with x-ray OA. We previously reported poor agreement between hip pain and RHOA (radiographic hip osteoarthritis) in the Framingham population. However, the Framingham study used long limb x-rays that may have yielded imperfect RHOA estimates. We examined concordance of hip pain and RHOA in the Osteoarthritis Initiative (OAI) where subjects obtained pelvis x-rays and were asked a more comprehensive set of questions about hip pain.

Methods: OAI is a multicenter longitudinal cohort study of OA that included 4796 individuals aged 45–79. AP pelvis x-rays were obtained, and definite RHOA was defined using UCSF criteria: 1) definite osteophytes plus definite JSN (both score ≥ 2) OR 2) definite osteophytes or definite JSN plus sclerosis, cysts or femoral head flattening OR 3) definite femoral osteophytes regardless of other features OR 4) definite moderate-severe JSN (superolateral JSN $>=2$ or superomedial JSN $>=3$) regardless of other features. Using a card with visual homunculus, subjects were asked whether they had hip pain on most days in a month. Those who said 'yes' were defined as having frequent hip pain and were asked another question for location of pain: groin, front of the leg (anterior), outside the leg (lateral), lower back, buttocks, or 'don't know'. The pain evaluation was done for both hips. We examined sensitivity (Sn), specificity (Sp) and positive and negative predictive values (PPV, NPV) for location specific pain with RHOA. Sn was defined as % of hips with RHOA that had hip pain. PPV was % of hips with pain that have RHOA. To ensure that we included hips that may have OA and to increase our sensitivity, we did another analysis for possible RHOA.

Results: X-rays from 8732 hips were evaluated. The prevalence of definite RHOA was 6.3%, and possible RHOA was 12.3%. For definite RHOA, the Sn of frequent hip pain was only 23.8%, and the Sp was 84.1% and the PPV for hip pain was only 9.1% (table 1). However, for analysis restricted to hip pain localized to the groin, the PPV rose to 16.5%. Of those

with RHOA, only 7.1% had pain localized to the groin. Anterior hip pain resulted similarly to groin pain, but performance for other sites was diagnostically poorer. For possible RHOA (data not shown), the diagnostic test performance did not differ greatly from definite RHOA.

Conclusion: We found poor agreement between hip pain on most days and RHOA in the ipsilateral hip. Hip pain questions with the highest PPV were hip pain with groin or anterior pain, but most persons with this pain had negative radiographs for hip OA suggesting that x-rays are insensitive to the presence of disease. Many middle aged and older persons with chronic hip joint area pain may have OA even though x-rays are negative.

Table 1.

	Hip pain and definitive RHOA			
Pain definition* (prevalence) N = 8,732)	**Sensitivity: % of RHOA hips that have pain N = 550 (18.6%)**	**Specificity: % of No RHOA hips that have pain N = 8182 (81.4%)**	**PPV: % of painful hips that have RHOA**	**NPV: % of nonpainful hips that have RHOA**
Frequent hip pain in past year (16.4%)	23.8% (131/550)	84.1% (6880/8182)	9.1% (131/1433)	94.3% (6880/7299)

The Co-Occurrence Patterns of MRI Lesions and Incident Knee Osteoarthritis: The MOST Study. Jingbo Niu[1], David T. Felson[2], Tuhina Neogi[2], Michael C. Nevitt[3], Cora E. Lewis[4], James Torner[5], Ali Guermazi[2], Frank Roemer[6] and Yuqing Zhang[2]. [1]Boston University, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]UCSF (University of California, San Francisco), San Francisco, CA, [4]University of Alabama, Birmingham, Birmingham, AL, [5]University of Iowa, Iowa City, IA, [6]Klinikum Augsburg, Augsburg, Germany.

Background/Purpose: MRI imaging provides insights of tissue-specific lesions of osteoarthritis (OA) and has the advantage of identifying earlier pathological changes that are not evident on radiographs. While MRI lesions often co-occur, the co-occurrence patterns and their relation to the risk of incident OA have not been well evaluated. We identified distinct subgroups of knees using a latent class model according to patterns of pathological changes on MRI and examined their relation to incident radiographic knee OA (incROA).

Methods: The MOST Study recruited 3,026 subjects with or at risk for knee OA. We obtained baseline knee MRI and knee radiographs at each visit. MRIs were scored using the Whole Organ Magnetic Resonance Score (WORMS). Tibiofemoral (TF) incROA was defined by a new occurrence of KL≥2 on PA view radiograph by Month 84, and patellofemoral (PF) incROA was defined by a new occurrence of PF OA on lateral view. For specific lesions on MRI in the *TF* joint, i.e., cartilage morphology, meniscal tear, meniscal extrusion, bone marrow lesion, synovitis, and effusion, we used the worst WORMS score among all sub-regions to represent the severity of that lesion in the knee. We performed latent class modeling (SAS: Proc LCA) to identify subgroups of knees by patterns of MRI lesions. Each knee was assigned to a specific subgroup according to its highest membership probability. We then examined the relation of subgroups of MRI lesions to the risk of *TF* incROA after adjusting for age, sex, race, clinic site, history of knee injury and surgery using logistic regression model. We took the same approach to identify subgroups of MRI lesions in the *PF* joint and assess their relation to *PF* incROA.

Results: Among 579 knees without *TF* OA (mean age: 60.1 years, BMI 29.2 kg/m^2, 59% women), we identified 4 subgroups based on baseline MRI lesions with average posterior probability 0.82: mostly normal (Group 1, 48.0%); predominantly cartilage lesion (Group 2, 24.9%); predominantly meniscal lesions (Group 3, 13.8%); and combined cartilage and meniscal lesions (Group 4, 13.3%) **(Table)**. In Group 3, meniscal tear was more prevalent than meniscal extrusion. Bone marrow lesion, synovitis, and effusion were common in Groups 2 and 4. The risk of *TF* incROA was 12.2%, 22.9%, 31.3% and 44.2%, for Group 1, 2, 3 and 4, respectively. The corresponding odds ratios (ORs) of TF incROA and 95% CI were 1.0, 2.5 (1.4, 4.4), 5.4 (2.8, 10.5), and 8.2 (4.3, 15.7). Similarly, 4 subgroups of MRI lesions were identified in *PF* joints among 660 knees without *PF* OA. The ORs of *PF* incROA for each subgroup were 1.0, 4.3, 8.9, and 17.0, respectively.

Conclusion: The latent class analysis allowed insights of the patterns of MRI lesions. Among the four subgroups of MRI lesions we identified, the co-occurrence of cartilage and meniscal lesion markedly increased the risk of incident ROA, and the meniscal lesion subgroup posed a higher risk than the cartilage lesion subgroup.

Table Baseline MRI lesions in the subgroups identified by latent class analysis

		Group1	**Group 2**	**Group 3**	**Group 4**

Increasing Synovitis and Bone Marrow Lesions Are Associated with Incident Joint Tenderness in Hand Osteoarthritis. Ida K. Haugen[1], Barbara Slatkowsky-Christensen[1], Pernille Boyesen[1], Sølve Sesseng[1], Désirée van der Heijde[1] and Tore K. Kvien[2]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]PsAID taskforce, EULAR, Zurich, Switzerland.

Background/Purpose: As hand osteoarthritis (OA) studies with repeated MRI are lacking, longitudinal associations between synovitis and bone marrow lesions (BMLs) and pain are unknown. Our aim was to explore whether changes of synovitis and BMLs are related to changes in joint tenderness in a longitudinal hand OA study.

Methods: We included 70 patients (63 women, mean (SD) age 67.9 (5.5) years) from the Oslo hand OA cohort with 1.0T MRI and clinical joint examination at baseline and 5-year follow-up. All patients had longitudinal Short Tau Inversion Recovery (STIR) images of the interphalangeal joints of dominant hand, n=69 had longitudinal T1w fat-suppressed (fs) pre-Gadolinium (Gd) images, and n=48 had longitudinal T1w fs post-Gd images. The paired MRIs were scored according to the OMERACT hand OA MRI score for synovitis and BMLs on 0–3 scales. We allowed 0.5 increments for smaller changes. The same rheumatologist examined the finger joints for presence of joint tenderness at baseline and follow-up. Among joints without tenderness at baseline, we explored whether increase of synovitis and BMLs (no change/decreasing synovitis and BMLs as reference) were associated with incident tenderness in the same joint using Generalized Estimating Equations. Among joints with tenderness at baseline, we explored whether decrease or

loss of synovitis and BMLs (no change/increasing synovitis and BMLs as reference) were associated with loss of joint tenderness. Separate models were performed for synovitis and BMLs, respectively. The analyses were adjusted for age, sex, BMI and follow-up time.

Results: At baseline, synovitis was present in 204/379 (53.8%) joints (n=5 missing), of which the majority was grade 1 (n=139) and grade 2 (n=54). BMLs were present in 108/552 (19.6%) joints, of which the majority (n=80) was grade 1. Joint tenderness was found in 280/664 (40.2%) joints.

The mean (SD) follow-up time was 4.7 (0.4) years. Increase/incident synovitis and BMLs were seen in 96/373 (25.7%) and 88/551 (16.0%), respectively. Decrease of synovitis and BMLs occurred in 63/373 (16.9%) and 47/551 (8.5%) joints, and 39 (10.5%) and 30 (5.4%) joints had complete loss of synovitis and BMLs, respectively. Increasing/incident synovitis and BMLs were significantly associated with incident tenderness in the same joint (Table). The associations were independent of each other (data not shown). No associations were found between decreasing synovitis and BMLs and loss of joint tenderness during follow-up (Table). However, there was a non-significant trend that loss of synovitis was associated with loss of joint tenderness (OR 1.78, 95% CI 0.83, 3.77).

Conclusion: The Oslo hand OA cohort is the first hand OA study with longitudinal MR images of the hands. Increasing synovitis and BMLs were significantly associated with incident joint tenderness. Loss of synovitis was associated with loss of tenderness, but the association was statistically non-significant.

The association with incident joint tenderness (in joints without tenderness at baseline)

	N (%) joints with incident tenderness	Crude analysis OR (95% CI)	Adjusted analysis OR (95% CI)
Synovitis			
- No change/decrease	46/175 (26.3%)	1.0 (ref.)	1.0 (ref.)
- Increase	23/45 (51.1%)	2.53 (1.39, 4.61)	2.62 (1.35, 5.06)
Bone marrow lesions			
- No change/decrease	88/265 (33.2%)	1.0 (ref.)	1.0 (ref.)
- Increase	29/47 (61.7%)	2.73 (1.33, 5.59)	2.84 (1.22, 6.60)

Inflammation Is Associated with Erosive Progression in Patients with Hand Osteoarthritis: A Prospective Ultrasonography Study. Marion C. Kortekaas[1], Wing Yee Kwok[2], Monique Reijnierse[2], Theo Stijnen[2] and Margreet Kloppenburg[2]. [1]Flevoziekenhuis, Almere-Stad, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Erosive hand osteoarthritis (OA) is a subset that shows inflammatory features with ultrasound or MRI much more frequent than non-erosive hand OA, and can progress relatively fast. Whether inflammatory features are associated with erosive progression is unknown. Therefore, we investigated relationships between inflammatory ultrasound features and erosive progression over 2.3 years follow-up in hand OA patients.

Methods: In 56 consecutive hand OA patients (mean age 61 years, 86% female), recruited from the rheumatology outpatient clinic and all fulfilling ACR criteria, effusion, synovial thickening and Power Doppler signal (PDS) were assessed in all interphalangeal joints (IPJs) with ultrasound using standardized methods at baseline and after 2.3 years. Radiographs were scored at both time-points for osteophytes and joint space narrowing using the OARSI method and for erosive disease, defined as E(rosive)- and R(emodelled)-phase, using the Verbruggen-Veys method. Progression was defined as a non-erosive joint becoming erosive, or E-phase becoming R-phase. R-phases at baseline were excluded. Associations were analysed using GEE logistic regression, adjusting for age, gender, BMI and baseline structural abnormalities.

Results: At baseline 51 IPJs (18 patients) and at follow-up 100 IPJs (26 patients) were erosive, hence 49 IPJs showed erosive progression. Moderate/severe synovial thickening and PDS at baseline were associated with erosive progression: adjusted odds ratio (95% confidence interval) 6.3 (2.3–17.5) and 6.9 (2.0–23.3), respectively. Effusion showed a trend: 2.7 (0.94–7.7). Persistent inflammation, defined as inflammation present both at baseline and follow-up, showed stronger associations with erosive progression compared to inflammation present either at baseline or follow-up.

Conclusion: Inflammatory ultrasound features, especially when persistent, are associated with erosive progression in hand OA, implicating that inflammation plays a role in its pathogenesis and could be a therapeutic target.

ACR Concurrent Abstract Session
Pediatric Rheumatology - Clinical and Therapeutic Aspects: Pediatric Systemic Lupus Erythematosus
Monday, November 17, 2014, 2:30 PM–4:00 PM

1824

A Randomized Double-Blind Placebo-Controlled Trial of Vitamin D Supplementation in Juvenile-Onset Systemic Lupus Erythematosus: Improvement in Disease Activity and Fatigue Scores. Glauce Lima, Juliane Paupitz, Liliam Takayama, Eloisa Bonfa and Rosa M R Pereira. Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: Vitamin D has an important immunomodulatory effect but there are no clinical trials that directly addressed the benefit from boosting the serum level of 25-hydroxyvitamin D in Juvenile-onset Systemic Lupus Erythematosus (JoSLE). The aim of this study is, therefore, to evaluate the vitamin D supplementation in disease activity scores and fatigue in JoSLE patients.

Methods: This study was a randomized double-blind placebo-controlled 24-week trial. Forty female JoSLE patients were randomized (1:1) to receive either oral cholecalciferol 50,000 IU/week (JoSLE-Vit D) or placebo (JoSLE-PL). Mean glucocorticoid dose and immunosuppressive medications remained stable throughout the study. Serum levels of 25 hydroxyvitamin D (25OHD) were measured using a radioimmunoassay technique (DiaSorin, Stillwater, Minnesota, USA). Disease activity was assessed by the SLE Disease Activity Index (SLEDAI) and by European Consensus Lupus Activity Measurement (ECLAM). Fatigue was assessed using Kids Fatigue Severity Scale (K-FSS), scores with an adapted range from 1 to 5 with low levels indicating higher fatigue. Longitudinal regression models were used to estimate the association between levels of 25OHD, disease activity and fatigue. T-test or Mann-Whitney test were performed to see differences between groups.

Results: Groups were similar regarding age (p=0.61), body mass index (p=0.28), frequency of organ involvements (p>0.05), mean glucocorticoid dose (11.90 ± 9.5 vs. 15.30 ± 14.82 mg/day, p=0.38) and frequency of immunosuppressive drugs (84 vs. 75%, p=0.490), SLEDAI (3.57 ± 2.87 vs. 4.35 ± 4.22, p=0.51), ECLAM (2.31 ± 1.74 vs. 2.35 ± 2.09, p=0.95), and fatigue scores at baseline (3.21 ± 0.90 vs. 2.90 ± 0.88, p=0.29). There was also no difference in the serum levels of 25OHD at the baseline between JoSLE-Vitamin D and JoSLE-PL (19.1 ± 6.6 vs. 19.5 ± 4.5 ng/mL, p=0.81). After 24 weeks of supplementation, the mean level of 25OHD was higher in JoSLE-Vit. D group compared to JoSLE-PL group (31.15 ± 8.89 vs. 16.56 ± 5.88 ng/mL, p<0.001). At the end of intervention, a decrease in SLEDAI score was observed in JoSLE-Vit. D compared to JoSLE-PL [Δ(final – baseline) SLEDAI: −0.58 ± 3.11 vs. 1.2 ± 3.67, p=0.01)] and a tendency of decrease in ECLAM score: (ΔECLAM: −0.63 ± 1.11 vs. 0.3 ± 0.20, p=0.083). Regarding fatigue evaluation, an improvement of fatigue related to social life score was found in JoSLE-VD compared to JoSLE-PL group (ΔFatigue: 0.47 ± 1.07 vs. −0.2 ± 0.95 vs. p=0.024). Cholecalciferol (50,000IU/week) intervention was well tolerated with no serious adverse events.

Conclusion: This study suggests that cholecalciferol supplementation 50,000IU/week for 6 months is effective to decrease disease activity and improve fatigue in JoSLE patients. (NCT01892748).

Cognitive Performance Scores for the Pediatric Automated Neuropsychological Assessment Metrics in Childhood-Onset Systemic Lupus Erythematosus. Patricia Vega-Fernandez[1], Shana Vanderburgh[2], Deborah M. Levy[3], Frank A. Zelko[4], Eyal Muscal[5], Natasha M. Ruth[6], Adam M. Huber[7], Marisa S. Klein-Gitelman[8], Kasha Wiley[9], Wenjie Zheng[9], Lori B. Tucker[10], Tresa Roebuck-Spencer[11], Jun Ying[2] and Hermine Brunner[12]. [1]Cincinnati Children's Hospital, Cincinnati, OH, [2]University of Cincinnati, Cincinnati, OH, [3]The Hospital for Sick Children and University of Toronto, Toronto, ON, [4]Northwestern University Feinberg School of Medicine, Chicago, IL, [5]Texas Children's Hospital, Houston, TX, [6]Medical University of South Carolina, Charleston, SC, [7]IWK Health Centre, Halifax, NS, [8]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [9]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [10]BC Children's Hospital and University of British Columbia, Vancouver, BC, [11]University of Oklahoma, Norman, OK, [12]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background/Purpose: Patients with childhood-onset SLE (cSLE) may experience neuropsychiatric SLE (NPSLE) manifested as neurocognitive dysfunction (NCD). Formal neurocognitive testing (FNCT) is the most accepted method for diagnosing NCD. However, access is limited and it is costly and time-consuming. The Pediatric Automated Neuropsychological Assessment Metrics (PedANAM) is a computerized test battery that assesses multiple domains of cognitive performance. However, it is unclear how PedANAM-generated variables can be interpreted in a clinical setting as measures of NCD.

Our purpose was to explore and initially test approaches to the calculation of a summary score (PedANAM Cognitive Performance Score (PedANAM-CPS)) to screen NCD in cSLE with high sensitivity.

Methods: Two cohorts were analyzed. The development cohort included cSLE patients (pts) and controls that completed the PedANAM and FNCT at two research study visits 18 months apart. The validation cohort consisted of cSLE pts and controls recruited in a clinical setting who completed the PedANAM and Pediatric Perceived Cognitive Function-43 questionnaire (PCF-43). Candidate PedANAM-CPSs were generated based upon the development cohort's first visit using 3 statistical methods: 1) *Simple-summary score:* Mean accuracy score of all PedANAM's subtests; 2) *Logit-based score* developed by logistic regression modeling; 3) *PCA-based score* derived from Principal Component Analysis (PCA). The latter 2 methods assigned in a different way a statistical weight to each subtest accuracy score. Receiver operating characteristic curve analysis was used to assess the accuracy of candidate scores as predictors of NCD in the study cohorts.

Results: A total of 166 pts were studied, including 108 cSLE pts (Table 1). As shown in Table 2 the candidate PedANAM-CPSs significantly differentiated between NCD and non-NCD groups. The Logit-based and PCA-based scores performed well and were able to detect NCD on the second visit of the development and validation cohorts. The usefulness of the 3 PedANAM-CPS scores and their cut-off scores to define NCD was confirmed when using visit 2 data of the development cohort and the validation cohort.

Conclusion: Candidate PedANAM-CPS showed good construct and criterion validity, with a Logit-based score performing somewhat better for discriminating cSLE pts based on the presence or absence of NCD. The PedANAM-CPS may be a useful tool to summarize cognitive performance in assessing for NCD in cSLE. Confirmation studies are required to confirm its overall accuracy and clinical usefulness in cSLE.

Table 1 Demographics of Development and Validation Dataset at Enrollment *

Variable	Category	Development Dataset			Validation Dataset

A Renal Activity Index May Predict Histological Activity in Lupus Nephritis in Children. Khalid Abulaban[1], Michael Bennett[1], Marisa Klein-Gitelman[2], Stacy P. Ardoin[3], Kelly A. Rouster-Stevens[4], Lori B. Tucker[5], Kasha Wiley[6], Shannen Nelson[7], Karen Onel[8], Nora G. Singer[9], Kathleen M. O'Neil[10], Elizabeth Brooks[11], B Anne Eberhard[12], Lawrence K. Jung[13], Lisa F. Imundo[14], Tracey Wright[15], David Witte[16], Jun Ying[17], Prasad Devarajan[1] and Hermine I. Brunner[7]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Anne & Robert H Lurie Childrens Hospital of Chicago, Chicago, IL, [3]Ohio State University College of Medicine, Columbus, OH, [4]Emory University School of Medicine, Atlanta, GA, [5]BC Children's Hospital and University of British Columbia, Vancouver, BC, [6]Cincinnati Children's Hospital Medical Center, c, OH, [7]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [8]University of Chicago Hospitals, Chicago, IL, [9]Division of Rheumatology, MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH, [10]Riley Hospital for Children, Indianapolis, IN, [11]Univ Hospitals of Cleveland, Cleveland, OH, [12]Cohen Children's Medical Center, Lake Success, NY, [13]Children's National Medical Center, Washington, DC, [14]Pediatric and Adult Rheumatology Columbia University Medical Center, New York, NY, [15]UT Southwestern Medical Center, Dallas, TX, [16]Cincinnati Children's Hospital, Cincinnati, OH, [17]University of Cincinnati, Cincinnati, OH.

Background/Purpose: Lupus Nephritis (LN) occurs in up to 80% of childhood-onset Systemic Lupus Erythematosus (cSLE) and it has a worse prognosis than adults. The current gold standard for diagnosing LN and assessing its activity is a kidney biopsy interpreted using the International Societies for Nephrology & Renal Pathology (ISN/RPS) classification. Kidney biopsies are invasive and too costly to assess the course of LN. The objective of this study is to develop and initially validate for Children a Renal Activity Index (C-RAI) to non-invasively monitor LN activity, considering both traditional measures of LN (LN-TM) and recently discovered renal biomarkers (RBM).

Methods: In this ongoing prospective study, 83 children with LN were studied at the time of the kidney biopsy; LN-TM [GFR, complements, anti-dsDNA antibodies, urinary protein/creatinine ratio], clinical indices [Systemic Lupus International Collaborating Clinics Renal Activity Score (SLICC-RAS), renal domain score of BILAG (BILAG-R) and SLEDAI (SLEDAI-R)] were all obtained, and the RBM (Table 1) were measured. Histological findings were rated by a single nephropathologist who provided ISN/RPS class, NIH Glomerular Activity Index (GLAI; range 0–24) and Tubulointerstitial Activity Index (TIAI; range = 0–21) scores (Criterion Standards). Prior to statistical analysis, RBM levels were normalized by urine creatinine and logarithmically transformed. LN-TM, RBM and clinical indices that showed significance in univariate analysis at a p-value<0.10 were considered in stepwise multivariate logistical regression models as C-RAI candidate predictors, using the GLAI and TIAI as dependent variable (outcome). The accuracy of the C-RAI of predicting and discriminating LN activity was assessed by receiver-operating characteristic curve (ROC) analysis.

Results: Means and percentages of the values of LN-TM, clinical indices and RBM levels are summarized inTable1. Based on multivariate logistical

regression modeling, histological activity measurement does not necessitate consideration of clinical indices but rather select LN-TM and RBM. Levels of C3, NGAL, CP, MCP1 and TF were found to be candidate C-RAI's for predicting high LN activity (GLAI>10) with outstanding accuracy [area under the ROC curve (AUC) = 0.9]. NGAL and HPX were excellent predictors of high interstitial inflammation with active LN (TIAI > 5; AUC = 0.88) (Figure1).

Conclusion: C3 level, NGAL, CP, MCP1, TF, and HPX are good potential components for C-RAI to measure histological LN activity in the glomeruli and interstitium. Confirmation in a larger data set is required.

Anti-Ro and Anti-La Antibodies in the General Pregnant Population. Evelyn V. Rozenblyum[1], Sharon Sukhdeo[1], Edgar Jaeggi[2], Lisa Hornberger[3], Philip Wyatt[4], Carl A. Laskin[5] and Earl D. Silverman[6]. [1]University of Toronto, Toronto, ON, [2]The Hospital for Sick Children, University of Toronto, Toronto, ON, [3]Stollery Children's Hospital, Edmonton, ON, [4]North York General Hospital, Toronto, ON, [5]University of Toronto and LifeQuest Centre for Reproductive Medicine, Toronto, ON, [6]The Hospital for Sick Children, Toronto, ON.

Background/Purpose: Neonatal lupus erythematosus (NLE) is a passively transferred autoimmune disease that occurs in babies born to pregnant women with anti-Ro and anti-La antibodies. The most serious complication of NLE is congenital heart block (CHB). In pregnancies of women with a known autoimmune condition and positive anti-Ro antibodies, the incidence of CHB is approximately 1–2% of live births. We have previously shown that only pregnant women with moderate-high titre of antibodies were at risk to deliver a child with CHB. However, the rate of anti-Ro antibody positive pregnant women in an otherwise healthy population is unknown as is their risk for delivering a child with CHB.

Objectives: 1) Determine the rate of anti-Ro/La antibodies in the general pregnant population.

2) Determine if the incidence of CHB is increased in healthy pregnant women with positive Ro/La antibodies compared to pregnant women with known autoimmune disease and positive anti-Ro/La antibodies.

Methods: Antibody testing was performed on 15198 pregnant women who were having concurrent Maternal Serum Screening in the Metropolitan Toronto area. Maternal self-reported outcomes of prenatal, pregnancy, and post-natal medical conditions were reported, along with fetal outcomes of pre and post-natal illnesses. Autoantibody titres were stratified into negative, low, moderate, and high positive.

Results: 1152/151598 (7.6%) of the pregnant women had anti-Ro antibodies and 179/15198 (1.2%) had moderate-high titres (at risk to deliver a child with CHB). 779 (5.1%) had anti-La antibodies, with the majority being low titre. During the course of the study there were 13 cases of CHB that were unrelated to our maternal sample population- 10 to well women and 2 to women with an autoimmune disease. All of these women had moderate-high titre anti-Ro antibodies, while only 31% had moderate-high titre anti-La antibodies. During the course of the study 39 pregnant women with a known autoimmune disease and anti-Ro antibodies (at risk to deliver a child with CHB) were prospectively followed. 2/39 delivered a child with CHB. Both of these women had moderate-high titre anti-Ro antibodies while 15/37 pregnant women who delivered a child without CHB had moderate-high titre anti-Ro antibodies. Therefore 2/17 (11.8%) women with moderate-high titre anti-Ro antibodies and an autoimmune disease delivered a child with CHB.

Conclusion: The incidence of CHB is reported to be between 1:10–15,000 pregnancies. Therefore, based on our data showing 1.2% of otherwise well pregnant woman had moderate-high titre anti-Ro antibodies (at risk to deliver a child with CHB), for each child with CHB we predict that 120–180 children without CHB will be delivered to otherwise healthy women, and incidence of 0.5–0.8%. In contrast, in women with a known autoimmune disease and moderate-high anti-Ro antibody titre, we found a 11.8% incidence of CHB. Therefore the risk for a woman with a known autoimmune disease and moderate-high titre anti-Ro antibodies was approximately 10× that of otherwise healthy pregnant women. These data therefore suggest that the anti-Ro antibody repertoire differs between these 2 groups of pregnant women.

Adverse Pregnancy Outcomes in Adolescents and Young Women with Systemic Lupus Erythematosus: A National Estimate. Nicole Ling, Isabel E. Allen, Erica F. Lawson and Emily von Scheven. University of California, San Francisco, San Francisco, CA.

Background/Purpose: Pregnant women with SLE have increased risk of adverse outcomes including lupus flare, spontaneous abortion, preeclampsia/eclampsia, premature birth and maternal death, but pregnancy outcomes among adolescents and young women with SLE have not been well-explored. Our goal was to compare pregnancy outcomes among adolescents and young women with and without SLE, and to identify associated risk factors.

Methods: We studied the 2000–2011 Nationwide Inpatient Sample (NIS), Healthcare Cost and Utilization Project (HCUP), Agency for Healthcare Research and Quality. The NIS contains annual discharge data from all-payer hospital stays from about 1,000 nationwide hospitals, to approximate a 20% stratified sample of U.S. community hospitals. Hospitalizations of individuals age 21 or less with ICD-9 discharge diagnoses associated with pregnancy were included (delivery, liveborn, abortion, ectopic pregnancy, or intrauterine death). SLE hospitalizations were identified by a 710.0 ICD-9 code. After applying sampling weights, unadjusted odds ratios to estimate the risk of adverse pregnancy outcomes among individuals with and without SLE were calculated. Multi-variate logistic regression was performed to examine the independent effect of age, race, and socio-economic status on pre-eclampsia/eclampsia.

Results: 9,125,224 estimated hospitalizations were included in the analysis, of which 4,142 had SLE. Hospitalized women with SLE were slightly older (mean age 19.4 with range 14–21 vs.19 with range 8–21), more likely to be black (34% v. 21%), more likely to carry a discharge diagnosis of nephritis (11% v. 0.02%) or aPL (2.7% v. 0.1%), and more likely to undergo hemodialysis (0.35% v. 0.0%), all $p<0.0001$. Socioeconomic status repre-

sented by median household income quartiles for patient zip codes were not different across groups.

Table 1: Unadjusted weighted estimates of outcomes of unique pregnancies by hospital discharge data in those with and without SLE

Outcome	SLE N = 4,142	Non-SLE N = 9,121,082	P*	OR (95%CI) +
	N (%) unless noted			
Maternal Outcomes				
Pre-eclampsia and Eclampsia	657 (16)	417,676 (4.6)	<0.0001	3.9 (3.3 4.7)
Death during hospitalization	15 (0.37)	490 (0.005)	<0.0001	69.7 (22.6 214.6)
Fetal Outcomes				
Preterm	843 (20)	736,665 (8.1)	<0.0001	2.9 (2.5 3.4)
Low birth weight or fetal growth retardation	0 (0)	20 (0)	0.97	1 (0.0004 0.0005)
Spontaneous abortion or Intrauterine death	179 (4.3)	99,426 (1.1)	<0.0001	4.1 (2.9 5.8)
Induced abortion	90 (2.2)	11,749 (0.13)	<0.0001	17.2 (10.4 28.3)
Ectopic pregnancy	$^{2}10$ ($^{2}0.24$)^	30,293 (0.3)	0.61	0.7 (0.17 2.78)
Congenital Anomalies	58 (1.4)	29,185 (0.32)	<0.0001	4.4 (2.5 7.8)

* CHI^2 Analysis
\+ Unadjusted logistic regression
^**Unable to report cell sizes less than or equal to 10, per HCUP data use regulations.**

Conclusion: This large national dataset demonstrated increased risk of pre-eclampsia/eclampsia, maternal death, preterm labor, spontaneous and induced abortion, and congenital anomalies in pregnant adolescents and young women with SLE compared to those without SLE. This is similar to previous findings in the literature regarding adult women with SLE. Disease duration and activity, medication exposure and age of SLE onset for the study population are not known. Additional analyses are planned to further explore outcomes with multivariate modeling and to characterize risk factors associated with poor pregnancy outcomes among adolescents and young women with SLE.

Role of Fluorinated Steroids in Preventing the Progression of Anti-SSA/Ro Associated Isolated Congenital Heart Block to Disease Beyond the Conduction System. Ummara Shah[1], Amit Saxena[1], Sara Sahl[1], Deborah Friedman[2], Jill P. Buyon[1] and Peter M. Izmirly[1]. [1]New York University School of Medicine, New York, NY, [2]New York Medical College, Valhalla, NY.

Background/Purpose: The cardiac manifestations of neonatal lupus (cardiac NL) characteristically present as conduction disease. A major concern is the extension of injury beyond the AV node, which can include endocardial fibroelastosis (EFE), dilated cardiomyopathy (DCM), and hydrops fetalis. Predictably, the overall case fatality for this more extensive disease is high, approaching 50%. Treatment of isolated block with fluorinated steroids (FS) to prevent disease progression has been considered but clear benefit has yet to be established. Moreover, this approach carries the potential for maternal and fetal toxicity. This study was initiated to determine whether FS given for the management of isolated advanced block prevents the development of disease beyond the AV node and whether in those cases FS has a survival benefit at 6 months.

Methods: Medical records from the Research Registry for Neonatal Lupus were reviewed. Inclusion was restricted to anti-Ro60 exposed cases presenting as isolated advanced block in utero and grouped according to whether FS were initiated within one week of detection or no treatment was given. Excluded were cases involving cardiac NL diagnosed after birth, inability to determine timing of FS initiation, FS initiation after one week of detection, and inability to determine timing of extranodal disease defined as EFE, DCM and/or hydrops fetalis.

Results: One hundred and seventy-four cases of cardiac NL met the study inclusion criteria. In the FS treated group (N=78), 12 (15.4%) fetuses developed extranodal disease compared to 12 (13.54%) in the untreated group (N=96), P=0.83. There were no significant differences in maternal age, race/ethnicity, diagnosis of Sjogren's syndrome and/or Systemic Lupus Erythematosus, or concomitant presence of anti-Ro52 or anti-SSB/La, between the FS and untreated groups. Although there was a significant difference between time of detection of advanced block between the groups (mean 22.4 weeks for FS vs. 24.5 weeks for untreated, P=0.004), the ventricular rate at detection was higher in the FS treated group (68.7 bpm) compared to the untreated group (63.1 bpm), P=0.052. There was no difference between the ventricular nadir between the two groups (53.5 bpm for FS vs. 52.9 bpm for untreated). The time from detection of advanced block to onset of extranodal disease tended to be longer in those receiving FS (5.78 weeks) compared to those untreated (1.9 weeks), P=0.28. For fetuses exposed to dexamethasone, there was no significant difference in cumulative dose between those that developed cardiomyopathy and those that did not (mean 318 mg vs. 251 mg, P=0.25). The case fatality rates at 6 months of post partum life were similar between the groups (7/78, 9% for FS vs. 8/96, 8.3% for untreated, P=1.0).

Conclusion: These data provide evidence for decision making regarding the use of dexamethasone in the management of isolated congenital heart block. The development of more advanced disease approaches 15% and institution of dexamethasone should not be routinely instituted solely for prevention of this complication.

ACR Concurrent Abstract Session
Quality Measures and Quality of Care
Monday, November 17, 2014, 2:30 PM–4:00 PM

1830

A Novel Population Care Model in Rheumatoid Arthritis – Significant Improvement in Quality and Reduction in Cost of Care. Eric D. Newman[1], William T. Ayoub[2], David M. Pugliese[3], Chelsea Cedeno[1], Jason Brown[1], Thomas M. Harrington[1], Thomas P. Olenginski[1], Androniki Bili[1], Alfred E. Denio[1], Lisa L. Schroeder[1], Dennis Torretti[1], Tarun Sharma[1], Lyudmila Kirillova[1], Susan Mathew[1], Jonida Cote[1], Brian Oppermann[2], Cynthia Sullivan[2], Shantanu Bishwal[4], Brian DelVecchio[3] and Howard Aylward[2]. [1]Geisinger Health System, Danville, PA, [2]Geisinger Health System, State College, PA, [3]Geisinger Health System, Wilkes-Barre, PA, [4]Geisinger Health System, Wilkes Barre, PA.

Background/Purpose: Rheumatoid arthritis (RA) is a common chronic disease with significant morbidity, mortality, and cost. To optimize care for RA patients, we developed a novel value-based population care model - AIM FARTHER (**A**ttribution, **I**ntegration, **M**easurement, **F**inances, **A**nd **R**eporting of **THER**apies). AIM FARTHER was designed to improve quality and reduce cost of RA care.

Methods: The AIM FARTHER model was designed and implemented for all RA patients cared for by the 17 rheumatologists within our health system (n=~2,300 patients). Components included 1) registry development; 2) defining roles and attribution; 3) integration of primary and specialty care; 4) strategic approach to RA care; 5) RA quality measure bundle development; 6) task management and performance reporting; and 7) a new financial/incentive model. The RA quality bundle included 8 measures – RA on DMARD (Disease Modifying Anti-Rheumatic Drug), Active RA on DMARD, RA with CDAI (Clinical Disease Activity Index), RA at low disease activity, TB testing if on biologic, Influenza vaccination, Pneumococcal vaccination, and LDL (low density lipoprotein) checked. These measures were collected electronically, providing the analytics for a patient scorecard (Figure 1). The scorecard was used to close care gaps, rolled up into provider and department performance reports, and shared transparently. Analysis of AIM FARTHER included quality (individual measures and "all or none" bundle score) and cost (biologic de-escalation savings).

Results: AIM FARTHER was implemented August 2012 (2,150 RA patients) with 22 month follow-up (2,378 RA patients). Significant improvement was noted in all quality measures except active RA on DMARD (92% to 93%)(Figure 2). Final values were RA on DMARD 90%, RA with CDAI 84%, RA at low disease activity 53%, TB testing on biologic 93%, Influenza vaccine 75%, Pneumococcal vaccine 72%, and LDL checked 95%. The all or none bundle improved from 22% to 40% (40% of the 2,378 RA patients had achieved 100% of their applicable quality measures). Cost savings from biologic de-escalation were $720,000 for 2013 with projected savings estimate of $1.2 million for 2014.

Conclusion: AIM FARTHER is a novel care model employing provider engagement, process redesign, measurement, and information technology to provide optimal care for patients with RA. AIM FARTHER showed significant improvement in quality measures and reduction in cost of care for a population of over 2,300 RA patients. Additionally, it supports the pivotal role that rheumatology can play in the systematic care of patients with RA.

Figure 1. Patient Quality Measure Scorecard

Disease Activity Measures		
RA on DMARD	ON DMARD	NON BIOLOGIC
Active RA on DMARD	ACTIVE RA ON DMARD	14.00
RA at Low Disease Activity	CDAI < 10	CDAI Date: 12/4/2013
CDAI Completed	CDAI COMPLETED	
Drug Safety Measures		
PPD if on Biologic	PPD N/A	
Flu Vaccine (Yearly)	FLUVAX NOT DONE	
Pneumococcal Vaccine	PNEUMOVAX DONE	
Comorbidity Measures		
LDL Checked	LDL COMPLETED	Most Recent LDL: 142

Monitoring Patients with Rheumatoid Arthritis in Routine Care – Experiences from a Treat-to-Target Strategy Using the Danbio Registry. Merete Lund Hetland[1], Dorte Vendelbo Jensen[2] and Niels Steen Krogh[3]. [1]DANBIO, Glostrup Hospital, Glostrup, Denmark, [2]DANBIO, Glostrup, Denmark, [3]ZiteLab ApS, Copenhagen, Denmark.

Background/Purpose: Monitoring patients with rheumatoid arthritis (RA) in clinical practice with regular assessment of disease activity (e.g. DAS28) is recommended as a part of a treat-to-target strategy, but little is known about its feasibility. In Denmark, prospective, nationwide collection of data on patients with RA in routine care has been conducted in the DANBIO database since year 2006 (1). We present the development over time in patient inclusion and disease control.

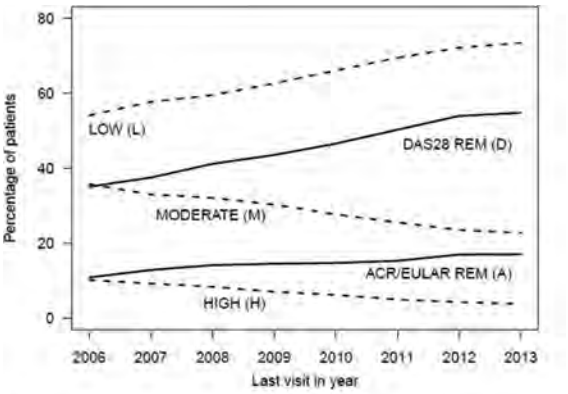
Methods: DANBIO serves as an electronic patient file in routine care. Disease activity score (DAS28) is presented in colour, encouraging a treat-to-target strategy. Patients are followed twice yearly.

Results: From Jan 1st 2006 to Dec 31st, 2013, the number of RA patients increased from 2,395 to 14,249 (age at time of inclusion: 60(50–59) (median(IQR)) years, 73% women, 87.2% IgM-RF positive, 54% erosive, disease duration 4 (0–11) years, HAQ 0.75(0.25–1.375), DAS28 3.9(2.7–5.1)).

By 2013, 9,054 patients were bDMARD naïve (MTX: 76%; other csDMARD: 21%), 4,254 pts received bDMARD (etanercept(28%) and adalimumab (21%) most prevalent; 66% in combination with MTX), and 941 pts had formerly received bDMARD.

In 2006, 54% of the 2,395 patients had low disease activity (DAS28<3.2) (figure). In 2013 it was 73% of 14,249 patients. For high disease activity it was 10% and 4%, respectively. The fraction of patients in DAS28 remission (DAS28<2.6) was 35% in 2006 and 55% in 2013. For ACR/EULAR remission it was 11% and 17%, respectively.

The prevalence of patients with RA in Denmark (which has ≈5.6 mill inhabitants) has in a medical technology review in 2002 been estimated to be ≈18,000 for patients who attend rheumatology clinics and departments, and ≈35,000 for patients with self-reported disease (2). By 2013, DANBIO's coverage may thus be estimated to be 40%–79%. For the subgroup receiving bDMARD, coverage is 94% (3).



Patients with data	2006	2007	2008	2009	2010	2011	2012	2013
L	1296	2632	3084	4511	6202	7662	9149	10471
M	856	1506	1664	2182	2595	2818	2984	3239
H	243	421	434	506	582	547	543	539
T	2395	4559	5182	7199	9379	11027	12676	14249
D	840	1711	2134	3135	4370	5545	6842	7808
A	260	586	733	1046	1381	1687	2151	2431

Figure. Number of RA patients in DANBIO by end of each year.
Patient distribution according to disease activity (L, M, H) and remission status (R, A)

Conclusion: By using an electronic platform, Danish rheumatologists included 40–79% of all RA patients into the DANBIO database during an 8 year period for prospective registration, thereby creating a data repository for quality improvement and research purposes with high external validity.

The demographic characteristics of the "real-life" cohort are typical for RA, and it covers all disease states regarding treatment, disability and disease activity. By 2013, 17% and 55% of patients were in ACR/EULAR remission and DAS28 remission, respectively, and 73% had low disease activity.

Thus, systematic monitoring of real-life RA patients with a treat-to-target strategy with real-time feedback to the physician is feasible, whereas the aim of treat-to-target is not achieved in a substantial proportion of patients in routine care.

National Quality Forum Measure Achievement and Costs in Rheumatoid Arthritis Patients in a Large Managed Care Population. Roxanne Meyer[1], Susan C. Bolge[2], Joseph Tkacz[3], Brenna Brady[3] and Charles Ruetsch[4]. [1]Janssen Scientific Affairs, Horsham, PA, [2]Janssen Scientific Affairs, LLC, Horsham, PA, [3]Health Analytics, LLC, Columbia, MD, [4]Health Analytics LLC, Columbia, MD.

Background/Purpose: The American College of Rheumatology and National Quality Forum (NQF) recommend monitoring quality measures among rheumatoid arthritis (RA) patients. Previously we described the proportion of RA patients within a large managed care population meeting the criteria of RA specific NQF quality measures[1–2]. This study examines the relationship between NQF measure attainment and healthcare expenditure.

Methods: Using the Optum™ Clinformatics™ database of insured individuals, 8 NQF RA quality measures (0054, 0589, 0590, 0592, 0597–0599, and 0601) were assessed among a sample of RA patients during calendar year 2011. NQF definitions may be found at http://www.qualityforum.org/QPS/. Mean specific healthcare costs, in addition to total healthcare costs, were calculated for all members eligible for analyses. The standard cost field, which is an estimate of the allowed payment for all provider services, was selected as the primary outcome of interest. **Results:** The majority of individuals were female and in their mid-fifties (mean age of 52.8). Measure achievement ranged from 55.9% (measure 0592) to 80.8% (measure 0054). The mean cost of care for individuals meeting the measure was $18,642, range 12,488-$21,300. Those patients who did not meet the measures had an average cost of care of $14,923, range $13,013 - $19,293. The primary drivers of cost were pharmacy and office expenses, accounting for 42.3% and 28.6% of total costs, respectively.

Table 1: Total HealthCare Costs (means) USD ($)

NQF Measure	Meeting the Measure	Not Meeting the Measure
NQF 0054 - DMARD Therapy	$21,314	$19,356
NQF 0589 - New DMARD Baseline Serum Creatinine	$15,182	$13,388
NQF 0590 - New DMARD Liver Function Test	$15,292	$13,314
NQF 0592 - Annual ESR or CRP	$17,945	$12,329
NQF 0601 - New RA patient ESR or CRP	$12,910	$13,624
NQF 0597 - Methotrexate Use Liver Function Test	$19,243	$17,787
NQF 0598 - Methotrexate User CBC Test	$19,173	$17,991
NQF 0599 - Methotrexate User Serum Creatinine	$19,526	$17,181

Conclusion: In general, meeting quality measures was associated with an increased cost of care. Pharmacy costs were similar between patients who did and did not meet the measures. Individuals who met the measures had higher office costs while those individuals who did not meet the measure trended towards higher inpatient costs and had significantly higher outpatient costs. These findings suggest that increased quality in healthcare may lead to lower inpatient and outpatient hospital costs, but that the overall cost of care for RA patients is likely to remain high due to intensive pharmacotherapy regimens.

Quality of Primary Care Management of Patients with and without Rheumatoid Arthritis (RA). Jessica Widdifield[1], Claire Bombardier[2], Jacqueline Young[1], Noah Ivers[2], R. Liisa Jaakkimainen[3], Sasha Bernatsky[4], J. Michael Paterson[1], J. Carter Thorne[5], Pooneh S.Akhavan[6], Debra Butt[1], Vandana Ahluwalia[7] and Karen Tu[1]. [1]Institute for Clinical Evaluative Sciences, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]Sunnybrook Health Sciences Centre, Toronto, ON, [4]McGill University Health Centre, Montreal, QC, [5]Southlake Regional Health Centre, Newmarket, Newmarket, ON, [6]Mount Sinai Hospital, Toronto, ON, [7]William Osler Health Center, Brampton, ON.

Background/Purpose: Little is known about the quality of care received by patients with multiple chronic conditions in primary care and whether quality care is different for those with RA. Our aims were to evaluate the burden of specific types of co-morbidity and compare quality of care by primary care physicians for patients with and without RA.

Methods: We used the **E**lectronic **M**edical **R**ecord **A**dministrative data **L**inked **D**atabase (EMRALD), comprised of 163,039 adult patients from 271 primary care physicians in Ontario, Canada. We used a validated EMR-based algorithm with a 74.4% sensitivity, 99.9% specificity, 90.0% PPV, and 99.7% NPV for identifying patients with RA. All patients not identified by the algorithm were classified as non-RA patients. Validated disease-specific EMR-based algorithms were also used to identify patients with hypertension (HTN), diabetes mellitus (DM), and ischemic heart disease (IHD). Quality measures were adapted from published guidelines and expert opinion for each specific comorbidity. They include preventative (eg. vaccinations), screening (eg. cardiovascular risk control) and comorbidity management and treatment measures. Stratified analyses were performed among patients with vs without RA to identify the frequency of comorbidity and to assess performance of key process and outcome measures. Process measures indicating whether tests or assessments have been performed (eg. patients with DM whose HbA1c level were performed) were determined. Outcome measures reflect the results of the assessments (eg. patients with DM and HbA1c $< 7.0\%$). Logistic regression was used to adjust for age and sex for comparison between RA and non-RA patients.

Results: We identified 1,427 RA patients (prevalence 0.9%) and 74% were female. The average age of the RA and non-RA patient groups were 62 years and 51 years, respectively. Unadjusted for age and sex, RA patients had a higher documentation of influenza vaccinations and bone mineral density (BMD) tests than non-RA patients (table). RA patients also had significantly higher prevalence of HTN (39% vs 25%), DM (14% vs 10%), and IHD (10% vs 5%). Process measures in terms of the numbers of patients who were routinely monitored and treated for the management of these chronic conditions were similar in patients with and without RA. After adjusting for age and sex, no differences were observed between the groups on all measures except that RA patients were more likely to receive pneumococcal vaccinations and undergo BMD tests.

Conclusion: Ontario primary care physicians provide similar quality of care for patients with and without RA. Pneumococcal vaccination and BMD tests were more frequent among RA patients, likely due to corticosteroid/immunosuppressant use. Further research is required to evaluate how 'shared care' between primary care physicians and rheumatologists can optimize prevention and screening measures to help decrease the development of comorbidity in RA.

	Indicators	RA patients n=1,427	Non-RA patients n=161,612
Process	Influenza Vaccination in the past 18 months	718 (50.3%)	51,532 (31.9%)
Process	Pneumococcal vaccination ever	505 (35.4%)	27,832 (16.9%)
Process	> 65 years AND BMD test recorded ever	394 (62.7%)	18,061 (47.2%)
	Patients with HTN	**552 (38.7%)**	**39,424 (24.5%)**
Process	Patients with HTN AND BP tested in the past 15 mo.	509 (92.2%)	35,918 (91.1%)
Outcome	Patients with HTN and BP test < 160/100mmHg	398 (72.1%)	26,166 (66.4%)
	Patients with Diabetes	**204 (14.3%)**	**16,575 (10.3%)**
Process	Diabetics with HbA1c tested in the past 6 mo.	126 (61.8%)	11,372 (68.6%)
Outcome	Diabetics with HbA1c < 7.0% in the past 12 mo.	102 (50%)	7,388 (44.6%)
	Patients with IHD	**138 (9.7%)**	**8,223 (5.1%)**
Process	Patients with IHD AND on a statin in the past 15 mo.	110 (79.7%)	6,993 (85.0%)
Outcome	Patients with IHD AND LDL< 2.0mmol/L in the past 15 mo.	60 (43.5%)	3,675 (44.7%)

Uptake of the American College of Rheumatology's (ACR) Rheumatology Clinical Registry (RCR): Quality Measure Summary Data. Natalie Fisk[1], Melissa Francisco[1], Jinoos Yazdany[2] and Salahuddin Kazi[3]. [1]American College of Rheumatology, Atlanta, GA, [2]University of California, San Francisco, San Francisco, CA, [3]UT Southwestern Medical Center, Dallas, TX.

Background/Purpose: The RCR is designed to provide ACR members with an infrastructure for quality reporting related to rheumatoid arthritis, gout, osteoarthritis, osteoporosis, and drug safety. Currently in its fifth year of operation, the RCR contains data on over 38,000 patient encounters.

Here we report the uptake of the RCR by U.S. rheumatologists and performance on quality measures regarding functional status, disease modifying anti-rheumatic drug (DMARD) use, tuberculosis screening, prognosis, and disease activity assessment for RA patients in 2011, 2012, and 2013.

Methods: Data derive from retrospective medical records abstractions performed by providers and/or designated practice staff for a sample of patients seen by rheumatologists. Reporters submit data on quality measures via a secure, web-based registry system. Patients included in the denominator of all quality measures are >= 18 years of age with a diagnosis of RA who are receiving treatment by the reporting rheumatology provider. Additional details of each measure are listed in Table 1. We report the mean performance on each quality measure, defined as percentage of eligible patients receiving recommended care.

Results: Table 1 summarizes performance on RA measures reported through the RCR. The table includes data from the current reporting period (CY2013) as well as comparative data from CY2012 and CY2011. For the current reporting period, 215 rheumatology providers from 123 practices submitted data on 6,963 encounters with RA patients. During CY2012, 197 rheumatology providers in 115 practices submitted data on 9,154 encounters with RA patients. In CY2011, 224 rheumatology providers in 129 practices submitted data on 8,096 encounters with RA patients. Reporting providers practice in sites ranging from solo offices to large academic medical centers.

Table 1. Performance on RA Measures Assessed through the RCR

	CY2011		CY2012		CY2013	
	Patient Encounters (N)	QM Performance Rate	Patient Encounters (N)	QM Performance Rate	Patient Encounters (N)	QM Performance Rate
Disease activity assessed at least once within 12 months, using a standardized descriptive or numeric scale or composite index, and classified as low, moderate or high	8075	43.3%	6485	54.4%	5702	81.0%
Functional status assessment performed at least once within 12 months, and documented using a standardized descriptive or numeric scale, standardized questionnaire, or notation of assessment of the impact of RA on patient activities of daily living	8077	70.5%	6485	86.6%	6068	87.1%
Patient prescribed, dispensed, or administered at least one ambulatory prescription for a DMARD within 12 months	7808	97.9%	6485	86.6%	6748	96.8%

Documentation of TB screening performed and results interpreted within 6 months prior to receiving first course DMARD	1650	73.6%	1048	92.9%	909	90.5%
Assessment and classification of disease prognosis at least once within 12 months	7771	49.5%	6441	73.4%	5398	77.5%

Conclusion: Performance rates increased on four out of five measures from CY2011 to CY2012. Based on preliminary results, it appears that use of the RCR to track quality measures increases performance.

Anti-Osteoporosis Medication Use after Hip or Vertebral Fracture. Robert A. Overman[1] and Chad L. Deal[2]. [1]University of North Carolina, Chapel Hill, NC, [2]Cleveland Clinic, Cleveland, OH.

Background/Purpose: Current National Osteoporosis Guidelines recommend treatment with an approved osteoporosis medication after hip and vertebral fracture. Only 20% of patients receive osteoporosis therapy after hip fracture. We examined the rates of treatment within 365 days of an osteoporosis medication after hip and vertebrae fracture in a large health care system.

Methods: We evaluated use of anti-osteoporosis medications after fracture by identifying all patients over age 40 who had a hip fracture that was surgically repaired and all vertebral fracture patients undergoing augmentation (kyphoplasty or vertebroplasty) based on administrative billing Common Procedure Terminology (CPT) codes between 2010 and September 2013. These patients were then linked to their electronic medical record (EMR) data. We define the index date as the date of the surgical procedure with patients followed until death, AOM use, or 365 days. AOMs in this analysis are bisphosphonates, denosumab, teriparatide, estrogen, or raloxifene. Dates of medication use are based on start and stop dates in the EMR. Basic demographic variables including age, race, gender, prior AOM use, and site of fracture, were collected from the patients EMR and are presented as mean (standard deviation [SD]) or n (%).We evaluated initiation or continuation of AOM at 90, 180, and 365 days post-index and factors associated with their initiation. Hazard ratios (HR) (95% confidence interval [CI]) were created with cox proportional hazards model and are adjusted for gender, race, age by decade, and site of fracture.

Results: There were 1,352 hip fractures and 296 vertebral fractures undergoing augmentation between January 2010 and December 2012. Mean age was 80.9 (SD 12.7) for hip and 75.0 (SD 12.5) for vertebral fractures. Women were the majority population for both hip (73.1%) and vertebral fractures (72.6%). Caucasians made up the majority of both populations (hip 89.6%; vertebral 92.2%). First event was AOM use for 16.1% (hip: 11.1%, vertebral: 39.2%) and death for 11.3% (hip: 12.5%, vertebral 5.7%) of the population. Prior to index date 24.2% of hip and 40.5% of vertebral fracture patients were prescribed an AOM. AOMs were used at fracture or within 90 days for 12.0%, 13.2%, and 14.6% for hip fracture and 34.5%, 37.8% and 45.3% for vertebral fractures at 90,180 and 365 days respectively. Vertebral fractures were associated with an increased likelihood of AOM treatment by 365 days (HR 3.1; 95% CI 2.4, 4.0), women (79.2% of population) were no more likely to be treated (HR 1.3 95% CI 0.9, 1.8) compared to men, and AOM use prior to fracture was associated with treatment by 365 days (HR 3.6; 95% CI 2.8, 4.7).

Conclusion: Treatment gaps continue to persist for hip fracture patients with 14.6% of patients receiving treatment by 365 days after fracture, and while only 45.3%% of vertebral fracture patients having augmentation receiving therapy by 365 days. Patients with a vertebral fracture and those who were treated before fracture were more often placed on AOM. Treatment after fracture helps has been demonstrated to reduce the likelihood of additional fractures and interventions are needed to increase treatment rates in these at risk populations.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Clinical Aspects III: Malignancies, Vaccinations, Pregnancy and Surgery
Monday, November 17, 2014, 2:30 PM–4:00 PM

1836

Safety of Zoster Vaccination Administration in Rheumatic Patients on Current Biologic Therapy. Stephen Lindsey[1], Brandi Oufnac[2] and Holly Walker[2]. [1]Ochsner Clinic Baton Rouge, Baton Rouge, LA, [2]Ochsner Health Systems, Baton Rouge, LA.

Background/Purpose: Herpes Zoster (HZ) occurs in 1 in 3 people in the U.S. during their lifetime. The greatest risk factor is age. Immune suppression from illness or medications is also a strong risk factor. RA increases zoster rates 1.5 – 2 times normal as does > 10mg prednisone per day. Studies are mixed on the role of Mtx and antiTNF's on HZ. Zoster vaccine has been shown to lower risk and is approved for all patients over 50 by the FDA and recommended for patients over 60 by the Advisory Committee on Immunization Practices (ACIP). Guidelines from the ACIP and ACR do not recommend HZ vaccine in patients on biologic therapies. However, recent large data-base studies have not found an increase in zoster complications in patients inadvertently given the vaccine while on biologics. These data encouraged our group to evaluate the safety of this vaccine in current biologic users.

Methods: Since July 2012, all 160 patients with RA, PSA & AS receiving IV biologics in our infusion center have been prospectively assessed for HZ vaccine as well as 142 patients on subq biologics for the same indications. RA accounts for 93% of infusion and 66% of subq patients. All biologics were represented. Remicade was the most common infusion followed by Orencia. Enbrel was the most common subq followed by Humira.

Inclusion/exclusion criteria for vaccination included: age > 50, no hx anaphylaxis to neomycin or gelatin, no episodes of HZ in last 4 years, pregnancy, patient consent, and disease activity stable - moderate or less on consecutive visits. No patients had an active infection or malignancy.

If patient meets criteria, vaccine given at next interval scheduled dose of biologic, which is **held**. Example - hold Enbrel 1 week, Humira 2 weeks, Orencia 4 weeks, Remicade 8 weeks. Mtx was held week of vaccine and restarted 1 week post vaccine. Biologic restarted 2 weeks after vaccine. In 17 Rituxan patients vaccine was given 2–4 weeks pre Rituxan or > than 6 months post Rituxan. No other vaccines were given the week of the HZ vaccine.

Results: Of 160 infusion patients 110 (68%) have been vaccinated; over 60% had been on biologic > 5 years, 5% < 1 year. No patient developed disseminated HZ. One patient had significant swelling and tenderness at the injection site. Most common reasons not to vaccinate: 11 with recent HZ, 14 < age 50, and 17 with disease activity issues. Of 142 subq patients, 42 (32%) have been vaccinated; over 50% had been on biologic > 5 years, 10% < 1 year. No patients developed disseminated HZ or had a significant local reaction. Most common reasons not to vaccinate: 74 patients < 50, 12 with disease activity issues, 5 with HZ vaccine concerns and 5 with recent HZ. No patients in either group developed HZ within the six weeks post vaccination. Two patients vaccinated since 2012 in our infusion cohort have developed HZ at 16 and 20 months and none in the subq patients. Prior to 2012, only 7 and 8 % of the cohorts had received HZ vaccine.

Conclusion: HZ vaccination in chronic RA, PSA or AS patients on current IV or subq biologic therapies appears safe using this protocol. No occurrence of disseminated HZ occurred. There was no increased incidence of HZ in the early post vaccination period.

[1]The University of Manchester, Manchester, United Kingdom, [2]Université Paris-Sud, Le Kremlin Bicêtre, France, [3]Uppsala University, Uppsala, Sweden, [4]Karolinska Institutet, Stockholm, Sweden, [5]Copenhagen University Hospital at Gentofte, Gentofte, Denmark, [6]DANBIO, Glostrup Hospital, Glostrup, Denmark, [7]The Danish Cancer Society, Copenhagen, Denmark, [8]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom, [9]German Rheumatism Research Center, Berlin, Germany, [10]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany, [11]Instituto de Medicina Molecular, Universidade de Lisboa, Lisbon, Portugal, [12]Instituto de Medicina, Universidade de Lisboa, Lisbon, Portugal, [13]BIOBADASER Registry, Madrid, Spain, [14]Universite Paris Diderot, Paris, France, [15]Department of rheumatology CHU, Strasbourg, France, [16]Universite′ Montpellier, Montpellier, France, [17]Charles University, Prague, Czech Republic, [18]Radboud University Medical Centre, Nijmegen, Netherlands, [19]University of Geneva, Geneva, Switzerland, [20]Reumatologia Universita e Policlinico di Bari, Bari, Italy.

Background/Purpose: Rheumatoid arthritis (RA) is associated with a 2–3 fold increased risk of both Hodgkin and non-Hodgkin lymphoma (HL; NHL). The risk of lymphoma, in particular diffuse large B-cell lymphoma (DLBCL) is greatest in patients with persistently active RA: those patients that are also most likely to receive biologics. There has been a concern that TNF inhibitors (TNFi) could increase the risk of lymphoma via reduced immunosurveillance. Conversely, TNFi may, by improved disease control, decrease lymphoma risk, especially risk of DLBCL. This abstract describes a EULAR initiative to describe the spectrum of lymphomas occurring in biologic-naïve patients with RA and those treated with biologics.

Methods: Patients with RA were included from 11 European biologics registers in 8 countries and followed prospectively for the occurrence of first ever lymphoma, confirmed with histology. Patients were considered to be exposed to a biologic agent after receiving the first dose and lymphomas were attributed to the most recently received biologic drug. For the TNFi cohort, prior exposure to biologic drugs was not permitted. Prior exposure to TNFi was allowed for other biologic drugs. Frequency of lymphoma subtypes was recorded for each drug class.

Results: Data for 130462 patients were available for the analysis (Sweden: n=61527, Denmark: n=21454, UK: n=17907, Germany: n=12581, Portugal: n=5031, Spain: n=4590, France: n=4512, Czech Republic: n=2860): mean age 59, 74% female. In total 520 lymphomas with subtype information were included in the table. Patient years were available for 493 lymphomas, corresponding to an overall crude incidence rate (IR) of 8.3 (95% CI 7.6, 9.1).

DLBCL was the most frequent subtype (37% of all lymphomas; Table). 9% of lymphomas were HL and 6% T-cell, with no cases of hepatosplenic T-cell lymphoma. Importantly, the distribution of subtypes was similar across treatment groups.

Conclusion: This large collaborative analysis of European registries has successfully collated subtype information on more than 500 lymphomas. There was no evidence of modification of the distribution of lymphoma subtypes reported in patients following exposure to biologics. This collaboration facilitates more detailed analyses, accounting for age, sex, country and specific TNFi, as well as RA-related factors.

Table. Subtypes of lymphoma reported in biologic-naïve and –exposed cohorts of patients with rheumatoid arthritis

	All N= 130462	sDMARD N=71866	TNFi N= 41078	RTX N=9880	TOC N= 4800	ABA N=2838

Background/Purpose: Swedish and Danish national biologics registers (*) have reported a possible increase in melanoma risk with TNF inhibitors. Since melanomas are uncommon, the association is difficult to evaluate in other individual registers. We therefore planned a EULAR collaborative project.

Methods: Patients with RA from 11 European biologics registers in 9 countries were included. Patients were followed prospectively from start of a new biologic treatment until the occurrence of first invasive histology-confirmed cutaneous melanoma, using an ever-exposed approach. For the TNFi cohort, prior exposure to biologic drugs was not permitted. Prior exposure to TNFi was allowed for other biologic drugs. For each register, incidence rates and standardized incidence ratios (SIR) of melanoma were calculated by using age- sex- and calendar year-specific rates from the general population of the corresponding country as reference. Poisson regression models were used to summarize the register-specific SIRs to overall SIR estimates. Rates of melanoma in biologic exposed patients were compared to those in biologic-naïve patients enrolled in participating registers by calculating incidence rate ratios (IRR). Overall SIRs and IRRs were calculated, taking the size of the registers into account.

Results: Overall, 114,291 patients were available for analysis: mean age 58 years; 74% female. 287 developed a first invasive melanoma. Background population rates varied due to differences in the incidence by country, calendar years and differences in the age and sex distribution of the corresponding RA cohorts (Table). The SIRs for biologic naïve patients were similar across the registers whereas there was variation in SIRs between TNFi cohorts (table). The overall IRRs did not show a significantly increased melanoma risk for any of the biologic therapies compared to biologic-naïve patients. Similar results were found with other drug exposure models (data not shown).

Conclusion: This large European collaborative project of 11 registers from 9 countries did not confirm an increased risk of melanoma following exposure to TNFi, although an association cannot be completely ruled out with these data.

Table. Number of melanomas, standardized incidence ratios and incidence rate ratios in different treatment groups of RA

Risk of Recurrent Non-Melanoma Skin Cancer with Methotrexate and Anti-TNF Use in Rheumatoid Arthritis. Frank I Scott[1], Ronac Mamtani[1], Colleen Brensinger[1], Kevin Haynes[2], Zelma ChiesaFuxench[1], Huifeng Yun[3], Jie Zhang[4], Lang Chen[5], Fenglong Xie[5], David Margolis[1], James D. Lewis[2] and Jeffrey R. Curtis[6]. [1]University of Pennsylvania, Philadelphia, PA, [2]Center for Clinical Epidemiology and Biostatistics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [3]University of Alabama at Birmingham School of Public Health, Birmingham, AL, [4]Univ. of Alabama at Birmingham, Birmingham, AL, [5]University of Alabama at Birmingham, Birmingham, AL, [6]The University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Methotrexate (MTX) and anti-TNF drugs have been hypothesized to increase the risk of a first non-melanoma skin cancer (NMSC). Among patients with prior NMSC, it is unknown what impact use of these medications has on a second NSMC.

Methods: We performed a cohort study using Medicare data from 2006–2011. We identified Caucasian patients with rheumatoid arthritis (RA) and a first recorded NMSC on the basis of a diagnostic code for NMSC and related surgical procedure within 60 days according to a validated algorithm. We assessed for MTX, anti-TNF, abatacept, and rituximab use before and after the initial NMSC diagnosis. Hydroxychloroquine and sulfasalazine (HCQ/SSA) were assessed as comparator therapies. We excluded individuals with HIV, organ transplant, xeroderma pigmentosa, albinism, and psoriasis. Follow-up began at the latest of either ≥1 year after the first NMSC surgery or a 6-month period without an NMSC diagnosis after surgery. The primary outcome was a second NMSC. Drug exposure was categorized as never, current, or recently discontinued after the start of follow-up. We adjusted for exposure to these drugs prior to incident NMSC. Cox regression was used to compute hazard ratios (HR) and 95% confidence intervals, adjusted for age, sex, latitude, urban or nursing home residence, and covariates assessed at baseline including comorbidities, glucocorticoids, actinic keratosis, and number of dermatology visits.

Results: 5994 individuals with RA had a first NMSC; 847 developed a second NMSC. Baseline actinic keratoses were more common in those with a second NMSC (65.2% vs 53.2%). Other baseline characteristics were similar. Current exposure to MTX was associated with a significantly increased risk of a second NMSC (Table 1). When stratified by concomitant exposure to anti-TNFs, SSA, or HCQ as background therapies, MTX use was consistently associated with a numerically but not statistically significant increased risk of a second NMSC. Risk of a second NMSC increased with longer duration of MTX exposure relative to no MTX exposure. Use of an anti-TNF, abatacept, or rituximab were not associated with an increased risk of second NMSC compared to those not using each agent, with the exception of short-term anti-TNF use (HR 1.46, 95%CI 1.01–2.10).

Conclusion: Current MTX use increased the risk of a second NMSC among those with a prior NMSC. This association was not observed with anti-TNF drugs, rituximab, or abatacept.

Table 1: Impact of Current MTX on recurrent NMSC

Combination of interest	Adjusted HR (95% CI)*

Pregnancy Outcomes Following Exposure to Abatacept during Pregnancy. M Kumar[1], L Ray[1], S Vemuri[2] and T Simon[1]. [1]Bristol-Myers Squibb, Hopewell, NJ, [2]Bristol-Myers Squibb, Plainsboro, NJ.

Background/Purpose: Limited data are currently available in the medical literature to guide counseling of patients regarding pregnancy outcomes when treated with abatacept, a selective T-cell co-stimulation modulator approved for the treatment of RA. We characterized pregnancy outcomes following maternal and paternal exposure to abatacept.

Methods: Pregnancy data were obtained on abatacept-exposed patients from clinical studies and the company post-marketing safety database. This dataset includes all medically confirmed cases of pregnancy with outcome data reported to the manufacturer, beginning with Phase I studies of abatacept (1995) until April 1, 2014. Pregnancies with maternal or paternal exposure to abatacept were captured. Congenital anomalies were identified using the Center for Disease Control's birth defects surveillance system, Metropolitan Atlanta Congenital Defects Program (MACDP; version 08/07).

Results: A total of 140 pregnancies with known outcomes were identified: 132 cases were maternal and 8 cases were of paternal exposure. Eighty cases (72 maternal; 8 paternal) were from clinical studies and 60 (all maternal) were from post-marketing reports. More than 50% of cases were from the United States, Canada, Argentina, and Mexico. The median maternal age was 32 years (15–44 years). Outcomes from pregnancies with maternal exposure to abatacept are reported in Table 1. Among the pregnancies with maternal exposure to abatacept, there were 7 MACDP-identified congenital anomalies out of 76 live births. Of the 8 pregnancies with paternal exposure to abatacept, there were 7 live births and 1 induced abortion, with no congenital anomalies identified. There did not appear to be any pattern of congenital anomalies for abatacept exposure. When data were available regarding concomitant medications, MTX was the most common relevant reported agent (see Table).

Table. Reported outcomes of pregnancies with maternal abatacept exposure

Outcomes	Count, n (%) n=132	Exposure to concomitant medications,** n (%) MTX	LFM	MMF/MMS	AZA
Births					
Total live births	76 (57.8)	28 (21.2)	6 (4.5)	4 (3.0)	3 (2.3)
Live births with congenital anomalies	7 (5.3)				
Cleft lip/cleft palate	1 (0.8)	–	–	–	–
Down syndrome*	1 (0.8)	–	–	–	–
Congenital aortic anomaly	1 (0.8)	–	–	–	–
Meningocele	1 (0.8)	–	–	1 (0.8)	–
Pyloric stenosis	1 (0.8)	–	–	–	–
Skull malformation	1 (0.8)	–	–	–	–
Ventricular septal defect; congenital arterial malformation	1 (0.8)	–	1 (0.8)	–	–
Abortion					
Spontaneous	33 (25.0)	15 (11.4)	1 (0.8)	2 (1.5)	1 (0.8)
Induced†	19 (14.4)	11 (8.3)	2 (1.5)	1 (0.8)	–
Late	1 (0.8)	–	–	–	–

Missed	1 (0.8)	–	–	–	–
Fetal death‡	2 (1.5)	2 (1.5)	–	–	–

*Resulted in fetal death.
†One case due to intrauterine fetal death.
‡Fetal death was defined as intrauterine death of a fetus >20 weeks.
**Only concomitant medications that are Pregnancy Category D or higher in the United States are listed.
AZA, azathioprine; LFM, leflunomide; MMF, mycophenolate mofetil; MMS, mycophenolate sodium.

Conclusion: As shown, the available data for abatacept do not indicate any pattern of congenital anomalies. Abatacept should be used during pregnancy only if the potential benefit to the mother justifies the potential risk to the fetus. The company continues to monitor and collect information on the outcomes of abatacept-exposed pregnancies, and an ongoing registry study with the Organization of Teratology Information Specialists (OTIS) continues to collect data that will be reported separately.

Eventual Joint Failure and Surgery Rates in Rheumatoid Arthritis Remain High in Patients with Moderate Disease Activity in the First 5 Years of Disease. Elena Nikiphorou[1], Lewis Carpenter[1], Sam Norton[2], Josh Dixey[3], Patrick Kiely[4], David Walsh[5] and Adam Young[6]. [1]University of Hertfordshire, Hatfield, United Kingdom, [2]King's College London, London, United Kingdom, [3]New Cross Hospital, Wolverhampton, United Kingdom, [4]St. Georges Healthcare NHS Trust, London, United Kingdom, [5]University of Nottingham, Nottingham, United Kingdom, [6]ERAS, St Albans City Hospital, St Albans, United Kingdom.

Background/Purpose: It is well-established that sustained high disease activity in RA results in worse outcomes. In reality many patients remain in low/moderate disease activity states, yet their outcomes, especially in the long term, are less well studied.

Methods: The study was based on the Early RA Study (ERAS, n=1465, 1986–1999) and the Early RA Network (ERAN, n=1236, 2002–2012). Standard clinical, radiological and laboratory measures were performed yearly for a maximum (median) 25(10) and 10(3) years respectively. Clinical databases were validated with national sources: the National Joint Registry (2003–2011), Hospital Episode Statistics (1997–2011) & National Death Register (1986–2011). Treatment regimens followed guidelines of the era, mainly conventional DMARDs +/− steroids, and latterly biologics. Joint interventions were categorized into major (large joint replacements), intermediate (mainly synovectomies and arthroplasties of wrist/hand, hind/forefoot) or minor (mainly soft tissue). Mean DAS was calculated for each patient from year 1 to 5 and categorized into either sustained low [m5DAS(low)] moderate disease [m5DAS(mod)] or high [mDAS(high)] disease activity if DAS28 was persistently lower than 3.2, between 3.2–5.1 or greater than 5.1 respectively.

Results: Of 2321 (86%) with complete 5year DAS data, 854 (37%) had m5DAS(low), 1066 (46%) m5DAS(mod) and 401 (17%) m5DAS(high). 770 (29%) patients had undergone a total of 1602 procedures over the 25 years of study; cumulative incidence rate of major interventions was 21.7% (19.4–24.0%) and of intermediate 21.5% (17.8–25.5%). In multivariate Cox regression models controlling for age at disease onset, gender, recruitment year, symptom duration, rheumatoid factor, BMI, HAQ, Haemoglobin, ESR and baseline erosions, patients with m5DAS(low) were 44% and 46% less likely to have intermediate and major joint surgery respectively compared to patients with moderate disease activity over the first 5 years ($P<0.05$). Patients with m5DAS(high) were 49% more likely to have intermediate surgery than those with m5DAS(mod) over the first 5 years ($P<0.05$) (Figure 1). A similar trend was observed for major surgery, but statistical significance was not reached.

Conclusion: Patients with sustained moderate disease activity in the first 5 years of disease, despite conventional DMARD therapy, still remain at high risk of joint failure and surgery. This poses important management challenges in health systems where restrictions exist in the use of biologic DMARDs, which are based on DAS28 levels and exclude moderate RA. The results demonstrate that any therapy that keeps patients in low disease activity or remission states is beneficial in terms of long-term outcomes.

High Rates of Failure after Biological DMARD Discontinuation While in Remission in a Japanese Multi-Center Registry. Kazuki Yoshida[1], Mitsumasa Kishimoto[2], Helga Radner[1], Kazuo Matsui[3], Masato Okada[2], Yukihiko Saeki[4], Daniel H. Solomon[1] and Shigeto Tohma[5]. [1]Brigham and Women's Hospital, Boston, MA, [2]St. Luke's International Hospital, Tokyo, Japan, [3]Kameda Medical Center, Kamogawa, Japan, [4]Osaka-Minami Medical Center, Osaka, Japan, [5]Sagamihara Hospital, National Hospital Organization, Sagamihara, Japan.

Background/Purpose: Since the introduction of biological disease-modifying antirheumatic drugs (bDMARDs) and tight control strategies, remission has become a more feasible treatment target for an increasing number of patients. As a result, there is an increased interest in appropriate treatment strategies after achieving disease control, such as bDMARD discontinuation while in remission. However, the outcome of such discontinuation in typical clinical practice has not been widely studied. We conducted a multi-center longitudinal observational study of bDMARD discontinuation while patients were in remission to describe the proportions of RA patients who remain in remission and how treatment or disease activity changes occur after discontinuation.

Methods: We utilized data from the National Database of Rheumatic Diseases by iR-Net in Japan (NinJa) multi-center registry. Patients who used bDMARDs on at least two consecutive visits and had visits in remission defined by the Clinical Disease Activity Index (CDAI) ≤ 2.8 followed by discontinuation of their bDMARDs while in remission were examined. The baseline variables were defined at the first visit off bDMARDs. The outcomes were defined as the rate of all-mode failure as well as the non-mutually exclusive individual modes of failure: reuse of bDMARDs, loss of CDAI remission, intensification of non-biological DMARDs or of oral glucocorticoids.

Results: Among 744 patients who initially achieved remission on bDMARDs, 31 patients discontinued their bDMARDs while remaining in remission and had additional follow up visits. In this 31-patient study cohort, 93.5% were female, the median disease duration was 6.0 [interquartile range 5.0, 9.0], 83.9% discontinued tumor necrosis factor inhibitors, 90.3% discontinued their first bDMARD, 72.4% had reported radiographical erosions. At the baseline, treatments were as follows: methotrexate use 54.8%, non-steroidal antiinflammatory drugs (NSAIDs) use 35.5%, oral glucocorticoid use 45.2% The probability of being free of all-mode failure was 29.0% at 1 year and 24.0% at 2 years. When dissected into individual modes of failure, loss of CDAI remission and reuse bDMARD were approximately 40% at 2 years, whereas non-biological treatment intensification was approximately 10–20%. Regarding changes in the non-biological treatment as non-failures,

35.5% remained in remission without bDMARDs at 1 year, and 29.6% at 2 years.

Conclusion: We found a high rate of failure by the all-mode failure, indicating difficulty of maintaining disease control after discontinuing bDMARDs even in patients who were in CDAI remission. Modification of non-biological treatment was observed in some of the patients who remained in remission. Considering the cost of bDMARDs, such coping strategy to maintain disease control after bDMARD discontinuation may need further investingation.

Randomised Controlled Non-Inferiority Study of Dose Reduction and Withdrawal of Adalimumab and Etanercept in Rheumatoid Arthritis.

Noortje van Herwaarden[1], Aatke van der Maas[1], Michiel Minten[1], Frank H.J. van den Hoogen[2], Ronald F. van Vollenhoven[3], Johannes W.J. Bijlsma[4], Bart van den Bemt[1] and Alfons A. den Broeder[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]Rheumatology Centre Sint Maartenskliniek and Radboud university medical center, Ubbergen (Nijmegen), Netherlands, [3]Unit for clinical therapy research (ClinTrid), Karolinska Institute, Stockholm, Sweden, [4]University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: TNF inhibitors (TNFi) have proven to be effective in the treatment of rheumatoid arthritis (RA). They are however associated with side effects and high costs, making dose reduction or discontinuation an attractive option. The primary aim of this study (DRESS) was to assess non-inferiority with regard to persistent disease worsening (flare) between a TNFi dose reduction strategy and usual care in daily clinical practice.

Methods: Patients with RA and low disease activity using adalimumab or etanercept were randomised (2:1) to a dose reduction strategy or usual care, both in tight control setting. The TNFi dose reduction strategy consisted of stepwise increasing the interval between injections every 3 months until flare or discontinuation.[1] In case of flare, the TNFi was restarted or escalated. A flare was defined as DAS28-CRP increase >1.2 or DAS28-CRP increase >0.6 and current DAS28-CRP ≥3.2, compared to baseline DAS28-CRP.[2] A persistent flare was defined as a flare duration ≥ 12 weeks. During 18 months follow up, data were collected on DAS28-CRP, HAQDI, EQ-5D, RA medication use, and costs. The primary outcome was the difference in proportions of patients with persistent flare between the two groups compared against a non-inferiority (NI) margin of 20%.

Results: 180 patients were included (table 1). Cumulative incidence of persistent DAS28-CRP flare was not significantly higher in the dose reduction group compared to the usual care group, 10% versus 12% of patients respectively (difference 2%, 95% CI −10 to 12), the upper limit of the 95% CI being clearly below the NI margin. Mean DAS28-CRP remained low, with only at 9 months follow up a significant, but small, difference between groups (figure 1A). HAQ scores remained stable in both groups (figure 1B) as did quality of life (figure 1C). In the dose reduction group, the TNFi could successfully be stopped at 18 months in 20% (95% CI 13 to 28) of patients, the interval successfully increased in 43% (95% CI 34 to 53) and in 37% (95% CI 28 to 46) of patients no dose reduction was possible. Incidence and nature of serious adverse events were similar between groups. Costs were significantly lower in the dose reduction group (mean difference per patient €9k).

Conclusion: A simple tight control TNFi dose reduction strategy has been shown to be non-inferior to usual care in maintaining disease control, function and quality of life, while reducing exposition to TNFi and costs.

Identification of a Patient Phenotype Which Impacts Response to Therapy in Rheumatoid Arthritis Clinical Trials: Certolizumab Pegol Phase 4 Trial Data. Jeffrey R. Curtis[1], Melvin Churchill[2], Alan Kivitz[3], Laura Gauer[4], Christopher Herrem[4], David Carter[5], Jeffrey Melin[4] and Yusuf Yazici[6]. [1]The University of Alabama at Birmingham, Birmingham, AL, [2]Arthritis Center of Nebraska, Lincoln, NE, [3]Altoona Arthritis & Osteoporosis Center, Duncansville, PA, [4]UCB Pharma, Smyrna, GA, [5]UCB Pharma, Brussels, Belgium, [6]New York University Hospital for Joint Diseases, New York, NY.

Background/Purpose: The PREDICT trial (NCT01255761) examined predictability of certolizumab pegol (CZP) treatment success at Week (Wk) 52 based on response at Wk12 assessed by RAPID3 and CDAI in RA patients (pts).[1] The objective of this post-hoc analysis was to evaluate whether a defined somatic comorbidity phenotype (SCP) influenced treatment response.

Methods: Pts were randomized to RAPID3 or CDAI for treatment response assessment and received CZP standard dosing regimen for 52 wks. Response at Wk12 was assessed (RAPID3 Responder, ≤6 or 20% improvement from Baseline [BL]; CDAI Responder, ≤10 or 20% improvement from BL), and pts with no improvement (<1 point CDAI improvement/no RAPID3 improvement) were to be withdrawn. The SCP, hypothesized to have suboptimal treatment response, was defined *a priori* as a diagnosis of depression, chronic pain, fibromyalgia or myalgias, and use of medications indicated for the treatment of depression, anxiety or neuropathic pain; insomnia diagnosis and narcotics were not included. The full analysis set (FAS; N=733), of which 313 pts had SCP at BL and ongoing during trial, is presented.

Results: At BL, 43% (313/733) of pts met the SCP classification: 23% due to medical diagnoses only (predominantly depression), 29% due to concomitant medications only (predominantly SSRIs, analgesics/antipyretics and other centrally acting agents), and the remaining 48% were due to both (predominantly depression and SSRI use). The proportion of pts with SCP was similar in the RAPID3 and CDAI arms; a similar proportion, with and without SCP, were withdrawn due to lack of efficacy by Wk12.

Among all pts randomized to CDAI (n=365), 79% without vs 73% with SCP were classified as Responders at Wk12 (Table); Wk12 Responders without SCP were approximately twice as likely to achieve LDA at Wk52 compared to those with the phenotype (41% vs 21%, respectively; Table). In addition, overall, pts without SCP were twice as likely to achieve LDA at Wk52 compared to those with the phenotype (32% vs 16%, respectively; Table).

In contrast, this phenotype was less differentiating among pts randomized to RAPID3 in the 3 outcomes examined (Table). Comparing CDAI to RAPID3, the likelihood of being classified as a Wk12 Responder was incrementally greater for those without (79% vs 63%) than those with the SCP (73% vs 68%) (Table).

Conclusion: In this large RA clinical trial population we have identified a potentially important phenotype that includes depression and chronic pain syndromes. Pts with this phenotype appear less likely to achieve LDA or be classified as a Responder when using CDAI as the outcome measure; however response rates were similar regardless of SCP when RAPID3 was used. Depending on the outcome measure used, enrolling large numbers of pts with this phenotype into an RA trial may affect the proportion able to achieve LDA/remission making it advisable to consider identifying such pts at screening.

Tocilizumab Combination Therapy or Monotherapy or Methotrexate Monotherapy in Methotrexate-Naive Patients with Early Rheumatoid Arthritis: 2-Year Clinical and Radiographic Results from a Randomized, Placebo-Controlled Trial. Gerd Burmester[1], William Rigby[2], Ronald F. van Vollenhoven[3], Jonathan Kay[4], Andrea Rubbert-Roth[5], Ricardo Blanco[6], Ariella Kelman[7], Sophie Dimonaco[8] and Nina Mitchell[8]. [1]Charité-Universitätsmedizin Berlin, Free University and Humboldt University of Berlin, Berlin, Germany, [2]Geisel School of Medicine at Dartmouth, Lebanon, NH, [3]Karolinska Institute, Stockholm, Sweden, [4]UMass Memorial Medical Center, Worcester, MA, [5]University of Cologne, Cologne, Germany, [6]Hospital Marques de Valdecilla, Santander, Spain, [7]Genentech, South San Francisco, CA, [8]Roche Products Ltd., Welwyn Garden City, United Kingdom.

Background/Purpose: Treatment with tocilizumab (TCZ) in combination with MTX or as monotherapy (Mono) in MTX-naive patients (pts) with early RA resulted in improved signs and symptoms and inhibition of joint damage at wk 52 of the 104-wk, double-blind, placebo-controlled trial FUNCTION.[1] Results to wk 104 are presented.

Methods: Pts were randomized 1:1:1:1 to TCZ 8 mg/kg (TCZ8) + MTX, TCZ8 Mono, TCZ 4 mg/kg (TCZ4) + MTX, or MTX for 104 wks. Pts received IV TCZ q4w, with MTX escalated from 7.5 mg qw to 20 mg qw by wk 8. Inclusion criteria have been described.[1] At wk 52, TCZ4 + MTX and MTX pts who had not achieved low disease activity (DAS28 ≤3.2) switched to blinded escape therapy with TCZ8 + MTX. Efficacy end points (DAS28, ACR responses, and van der Heijde–modified Total Sharp Score) were assessed in the intent-to-treat (ITT) population, and a subgroup analysis was performed for postescape data. Adverse events (AEs) were evaluated under the treatment group in which the AE occurred. Wk 104 analyses were exploratory; no statistical testing was performed.

Results: At wk 52, 95/290 (33%) TCZ4 + MTX pts and 142/289 (49%) MTX pts switched to TCZ8 + MTX escape therapy. Baseline characteristics of escape pts were consistent with those of the full ITT population.[1] Clinical efficacy was maintained through wk 104 in the TCZ8 groups, with similar proportions at wks 52 and 104 achieving ACR20/50/70 responses and DAS28, ACR/EULAR Boolean/Index, and Clinical Disease Activity Index criteria remission. Inhibition/slowing of radiographic progression was also maintained. In TCZ4 + MTX and MTX pts who switched to escape with TCZ8 + MTX at wk 52, further improvement in efficacy from the point of escape was generally seen at wk 104. Despite the inhibition of structural joint damage after escape, joint damage was numerically greater than in pts who received TCZ8 Mono or TCZ8 + MTX throughout (Table). TCZ serum levels were similar with both Mono and combination TCZ treatment. AE rates were similar across groups, with serious AE and serious infection rates numerically higher in the TCZ groups (Table). There were 14 deaths (9 reported earlier[1]); 5 occurred in year 2. Underlying causes varied and included 4 due to infection (2 MTX; 2 TCZ4 + MTX), 3 due to malignancy (1 TCZ8 + MTX; 2 TCZ8 Mono), and 2 due to cardiovascular disease (1 TCZ4 + MTX; 1 TCZ8 Mono).

Conclusion: Pts with early RA who received TCZ8 + MTX or TCZ8 Mono for the duration of the study had sustained improvement in disease activity and maintained joint damage inhibition over 104 wks. Efficacy improved further in pts receiving MTX or TCZ4 + MTX who switched to escape with TCZ8 + MTX at wk 52; the overall degree of joint damage (though generally minor) was greater than that in pts who received TCZ8 for the entire study, highlighting the importance of early initiation of optimal therapy. Safety was consistent with the known safety profile of TCZ.

The Association Between Hydroxychloroquine Treatment and Cardiovascular Morbidity Among Rheumatoid Arthritis Patients. Michael Shapiro[1] and Yair Levy[2]. [1]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [2]Meir Medical Center, Kfar Saba, Israel.

Background/Purpose: Accelerated atherosclerosis and cardiovascular disease are the main causes of mortality in Rheumatoid Arthritis (RA). The anti-malarial drug Hydroxychloroquine (HCQ) has long been used in the treatment of RA due to its anti-inflammatory properties. Recent studies have demonstrated that HCQ has additional beneficial effects on cardiovascular risk factors by lowering LDL levels, reducing the risk for diabetes and improving elasticity of atherosclerotic arteries. Our aim was to examine the independent effect of HCQ treatment on cardiovascular morbidity among RA patients.

Methods: We conducted a retrospective cohort study in the Meir Medical Center. Participants were diagnosed with RA, were 18 or older at the time of diagnosis and had been treated in the medical center between 2003 and 2013. Patients were divided into two groups, those who had been treated with HCQ during the course of their disease and those who had never received the drug. The two groups were compared in regard to possible confounding factors, including parameters of disease severity, common cardiovascular risk factors and additional medications. The endpoints of our study were arterial and venous events, including: Myocardial Infarction (MI), stroke, Transient Ischemic Attack (TIA), mesenteric event, Pulmonary Embolism (PE) and peripheral venous thrombosis. The two groups were compared using a multivariate logistic regression.

Results: We identified 514 RA patients that adhered to our inclusion criteria, 241 patients had been treated with HCQ for an average duration of 5 years and 273 patients had never been treated with the drug. We found that 13.3% of the treated patients suffered from cardiovascular events compared to 38.1% in the non-treated group. HCQ treatment had a significant protective effect for all cardiovascular events examined (OR=0.271, 95%CI 0.159 to 0.462). When comparing for specific endpoints we found a difference regarding the dosage of HCQ. A dose of 400mg per day of HCQ had a statistically significant protective effect for MI (OR= 0.405, 95%CI 0.181 to 0.908), for stroke and TIA (OR= 0.352, 95%CI 0.130 to 0.955) and for venous events (OR= 0.159, 95%CI 0.045 to 0.562). The lower dose of 200 mg per day demonstrated a protective effect for MI (OR=0.194, 95%CI 0.055 to 0.686), and no significant effect on other endpoints.

Conclusion: The use of HCQ is independently associated with decreased risk for cardiovascular morbidity among RA patients, particularly when using the higher dose of 400 mg per day. This newly demonstrated effect of HCQ should be considered in the overall management of RA.

Effect of Disease Duration on Clinical Outcomes in Moderate Rheumatoid Arthritis Patients Treated with Etanercept Plus Methotrexate in the Preserve Study. Josef S. Smolen[1], David Collier[2], Annette Szumski[3], Heather Jones[3] and Lisa Marshall[3]. [1]PsAID taskforce, EULAR, Zurich, Switzerland, [2]Amgen, Inc., Thousand Oaks, CA, [3]Pfizer Inc., Collegeville, PA.

Background/Purpose: Previous studies evaluating various treatment strategies indicate that disease duration is a key determinant of outcomes in rheumatoid arthritis (RA). While data suggest that RA patients with longer established disease do not respond as well to treatment compared with patients with early disease, this evidence is limited. The objective of this sub-analysis was to determine the effect of disease duration on treatment response in patients with moderately active RA receiving induction therapy with etanercept (ETN) plus methotrexate (MTX) for 36 weeks in the PRESERVE study.

Methods: In the induction phase of the PRESERVE study, patients with moderately active RA (DAS28 >3.2 and ≤5.1) despite stable doses of oral MTX received open-label ETN 50 mg QW plus MTX (titrated to ≤25 mg/week as needed through week 28) for 36 weeks. Patients were stratified by disease duration at baseline: 0–≤6 mo, >6mo–≤2 yr, >2yr–≤5 yr, >5yr–≤10 yr and >10 yr. Baseline demographic and disease characteristics and treatment response (DAS28, CDAI, HAQ) were compared across disease duration categories. Analyses using observed cases (OC) were conducted in all patients who received ≥1 ETN/MTX dose (mITT population).

Results: A total of 833 patients receiving ETN50/MTX (baseline disease duration: 0–≤6 mo, n=41; >6mo–≤2 yr, n=198; >2yr–≤5 yr, n=204; >5yr–≤10 yr, n=172; >10 yr, n=218) were included. At baseline, more established disease was significantly associated with higher age and a higher swollen joint count (Table). In addition, a significantly greater proportion of patients with longer disease duration were rheumatoid factor and CCP3 antibody positive. HAQ score at baseline significantly correlated with greater duration of disease while baseline DAS28 and CDAI were similar across disease duration subgroups. Significant changes from baseline in DAS28, CDAI and HAQ were observed at Week 4 and at all time-points up to Week 36 in all disease duration categories (all P<0.0001). These observed improvements in clinical measures of disease activity and quality of life were similar among disease duration subgroups (Table).

	Disease Duration

Baseline, Mean (SD) (unless stated)						
Age	47.7 (12.1)	46.3 (12.2)	46.3 (12.0)	48.7 (12.1)	52.0 (10.6)	<0.001*
RF Positive, n (%)	32 (78.0)	117 (59.7)	146 (71.9)	134 (77.9)	173 (80.1)	<0.001†
CCP3 Ab Positive, n (%)	34 (82.9)	126 (64.3)	157 (77.7)	143 (83.1)	181 (84.2)	<0.001†
Swollen Joint Count	3.2 (1.9)	3.5 (2.4)	3.6 (2.2)	3.9 (2.9)	4.4 (2.9)	0.001*
DAS28	4.4 (0.5)	4.3 (0.5)	4.4 (0.4)	4.4 (0.4)	4.4 (0.4)	0.401*
CDAI	17.2 (3.4)	17.8 (4.9)	17.4 (4.7)	17.7 (5.2)	18.5 (5.3)	0.180*
HAQ	1.1 (0.6)	1.1 (0.6)	1.1 (0.6)	1.2 (0.6)	1.3 (0.6)	0.003*
Week 36, Adjusted mean change (SE)						
DAS28	−2.0 (0.2)	−2.0 (0.1)	−2.1 (0.1)	−2.0 (0.1)	−1.9 (0.1)	NS‡
CDAI	−12.1 (1.0)	−12.2 (0.4)	−12.2 (0.4)	−12.0 (0.5)	−11.3 (0.4)	NS‡

HAQ	−0.52 (0.08)	−0.55 (0.04)	−0.59 (0.03)	−0.57 (0.04)	−0.58 (0.03)	NS‡

*1-way ANOVA; †Chi-square; ‡Not significant for all pair-wise comparisons

Conclusion: In the PRESERVE trial, improvements in clinical outcomes in response to open-label therapy with ETN plus MTX in patients with moderately active RA was largely unaffected by differences in disease duration before treatment initiation. The use of induction with ETN plus MTX in moderate RA may prevent the poorer outcomes often associated with longer disease duration.

Risk of Cancer in Patients with Severe Psoriatic Arthritis Requiring Tumour-Necrosis Factor Alpha Inhibition. Karen M. Fagerli[1], Louise K. Mercer[2], Kath D. Watson[2], Jonathon Packham[3], Deborah PM Symmons[4], Kimme L. Hyrich[5] and. On behalf of the BSRBR[6]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom, [3]Institute of Science and Technology in Medicine, Keele, United Kingdom, [4]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom, [5]Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom, [6]British Society for Rheumatology, London, United Kingdom.

Background/Purpose: Few studies have explored risk of cancer in psoriatic arthritis (PsA). There are concerns that the risk may be raised, not only by the primary disease, but also by the treatments given including conventional disease modifying treatments (especially ciclosporin), tumour necrosis factor inhibitors (TNFi) and phototherapy. Skin psoriasis itself is associated with an increased risk of non-melanoma skin cancer (NMSC). Our objective was to compare the incidence of cancer among a cohort of patients with severe PsA patients receiving tumour TNFi to that in the general population.

Methods: All patients with PsA starting a TNFi in the British Society for Rheumatology Biologics Register (BSRBR, recruited 2002–2006) were included. Cancers were identified by flagging patients with the national cancer register which reported using the International Classification of Diseases version 10 (ICD 10). All patients were followed from registration (start of TNFi) until death or 2011/12/31, whichever came first. Standardised incidence ratios (SIR) with 95% confidence intervals (CI) were calculated using age and gender specific cancer rates for the general English population for (1) overall cancer risk (ICD 10: C1-C9) and (2) NMSC (C44) for the whole cohort and separately for men and women.

Results: 709 patients contributed 5286 patient years of follow-up; mean (SD) age was 45.7 (11.2), median disease duration (IQR) was 11 (6–17) years. Mean (SD) DAS28 was 6.0 (1.2). 11 (1.6%) patients had a cancer registered prior to baseline, none of which had a further cancer. Nearly all (98%) had previous or current exposure to methotrexate at baseline and 45.6% had previous or current exposure to ciclosporin. Information on baseline PUVA exposure was only available for 163 (23%) patients and 11 (6.7%) had been exposed. 27 cancers in 26 patients were observed, including 14 skin cancers (12 NMSC and 2 melanomas). Overall, there was no increased risk of malignancy observed in this cohort (SIR 0.87, 95% CI 0.58–1.27) compared to the general population. There was a significantly increased incidence for NMSC although the precision of the estimate was low (SIR 1.97, 95% CI 1.02–3.45) likely reflecting low number of events.

Table: Overall and non-melanoma skin cancer standardised incidence ratios

	Overall n=709		Male n=331		Female n=378	
Total follow-up (person-years)	5286		2437		2849	
	O/E	SIR (95% CI)	O/E	SIR (95% CI)	O/E	SIR (95% CI)
All malignancies	27/30.9	0.87 (0.58–1.27)	13/12.8	1.02 (0.54–1.74)	14/18.1	0.77 (0.42–1.29)
NMSC	12/6.1	1.97 (1.02–3.45)	4/2.9	1.40 (0.38–3.58)	8/3.2	2.49 (1.07–4.91)

O = Observed, E = Expected

Conclusion: In this population of severely active PsA patients recruited early in the TNFi-era, the overall incidence of malignancy was reassuringly similar to that of the general population. Incidence of NMSC was increased, which may be related to PsA itself, skin psoriasis, phototherapy and/or immune-modulatory treatment.

1849

Risk of Malignancy Among Medicare Psoriasis/Psoriasis Arthritis Patients. Huifeng Yun[1], Kevin L. Winthrop[2], Lang Chen[3], Wilson Smith[3], Benjamin Chan[4], Fenglong Xie[3], Allison Taylor[3] and Jeffrey R. Curtis[3]. [1]University of Alabama at Birmingham School of Public Health, Birmingham, AL, [2]Oregon Health & Science University, Portland, OR, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Oregon Health and Science University, Portland, OR.

Background/Purpose: The introduction of biologics has greatly changed the treatment of psoriatic arthritis (PsA) and psoriasis (PsO). However, there are concerns regarding the risk of malignancy associated biologic medications. This analysis evaluated the association between malignancy and biologics among US patients with PsA or PsO enrolled in the Medicare program

Methods: Using data from 2006–2011 for 100% of patients with patients with PsA and PsO, we defined separate PsA and PsO cohorts based upon >= 1 rheumatologist visit for PsA or >= 1 dermatologist visit for PsO, followed by a prescription or administration of etanercept (ETA), adalimumab (ADA), ustekinumab (UST), methotrexate (MTX), cyclosporine (CIC) or ultraviolet light therapy (UV). Patients could be in both cohorts if they meet criteria for each cohort. We identified new treatment episodes, defined specific to each drug as no use of that therapy in the prior 6 month 'baseline' period. Patients contributing treatment episodes with history of organ transplantation, infection with human immunodeficiency virus, advanced kidney (hemodialysis-dependent), severe liver disease, or cancer diagnoses were excluded. Eligible subjects were continuously enrolled in Medicare Parts A, B and D in baseline and throughout follow-up. We excluded treatment episodes of UV if patients were on biologics or DMARDS at baseline, and episodes of non-biologic therapy if patients were on biologics during the baseline. Follow up started from the drug initiation date and ended at the earliest date of: malignancy (exclude non-melanoma skin cancer), a 90 day gap in current exposure, death, loss of coverage or Dec 31, 2011. We identified malignancy using validated claims-based algorithm using physician diagnoses (ICD9 140–208, except 173.x), cancer-related procedures and chemotherapy. We calculated the incidence rate (IR) of malignancy for each exposure. Using pairwise propensity scores (PS) to balance multiple confounders, we compared malignancy risk using Cox regression, adjusting for PS quintile.

Results: We identified 10,261 PsA and 31,052 PsO new treatments episodes. For the PsA cohort, 50% of treatment-episode exposure time was in common with the PsO, and 20% of PsO exposure time was in common with PsA exposures. During follow up, patients in the PsA cohort experienced 13 (ADA), <11 (CIC), 10 (ETA), 50 (MTX), <11 (UV) malignancies, the PsO cohort experienced 29 (ADA), 26 (CIC), 28 (ETA), 123 (MTX), 64 (UV) malignancies. The overall IR in PsA was 8.1/1000, ranging from a low of 4.2 (UV) to a high of 11.3 (MTX). None of the hazard ratios for comparisons between biologic and non-biologic exposure groups reached statistical significance. The overall IR in the PsO cohort was 9.2/1000 ranging from 5.0(ETA) to 12.9 (CIC). After multivariable adjustment, there was a significantly lower risk for ETA compared to non-biologic therapies: ETA versus CIC (HR: 0.50 95% CI: 0.27–0.93), ETA versus MTX (HR: 0.56 95% CI: 0.35–0.87), ETA versus UV (HR: 0.49 95% CI: 0.29–0.83).

Conclusion: Among older patients with psoriasis and psoriatic arthritis, there was no evidence of an increased risk of malignancy for patients treated with biologics compared to non-biologic therapies, and some possibility of a reduced risk.

The Incidence and Risk Factors for Psa in Patients with Psoriasis – a Prospective Cohort Study. Lihi Eder[1], Amir Haddad[1], Hua Shen[2], Cheryl Rosen[1], Vinod Chandran[1], Richard J. Cook[2] and Dafna D. Gladman[3]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Waterloo, Waterloo, ON, [3]Toronto Western Research Institute, Toronto Western Hospital, Toronto, ON.

Background/Purpose: There are limited data regarding the incidence of PsA in patients with psoriasis. We aimed to estimate the incidence of PsA in a prospective cohort of psoriasis patients and to identify risk factors for the development of PsA in these patients.

Methods: The setting is a prospective longitudinal cohort study of psoriasis patients without arthritis at baseline. Patient with a diagnosis of psoriasis confirmed by a dermatologist were enrolled. All patients were evaluated by a rheumatologist at baseline. Exclusion criteria included the presence of inflammatory arthritis or spondylitis in the past or at the time of assessment. All study participants were then reassessed annually by a rheumatologist for signs and symptoms of arthritis. Information was collected about their lifestyle habits, co-morbidities, skin activity and medications. Patients who developed inflammatory arthritis or spondylitis were classified as PsA if they fulfilled the CASPAR criteria. Patients who failed to come to the yearly assessment were requested to fill out the Toronto Psoriatic Arthritis Screen (ToPAS II) questionnaire, a screening questionnaire designed to detect PsA among patients with psoriasis. Subjects scoring ≥8 points on the ToPAS II were classified as suspected PsA. We summarize the results of 7 years of follow up and report the annual incidence of PsA from the onset of psoriasis that was estimated using an event per person-years analysis. Cox proportional hazard model, with time-dependent explanatory variables and date of enrollment as the time of origin, was used to compute the multivariate relative risk (RR) for incident PsA adjusting for sex and age.

Results: The results of the 579 patients who were recruited from January 2006 and followed until December 2013 are summarized. The mean duration of follow up was 3.5±1.9 years per person. A total of 46 patients developed PsA since enrollment and 9 additional patients were considered suspected cases of PsA according to their scoring in ToPAS II. The annual incidence rate of confirmed cases was 3.1 (95% confidence interval (CI) 2.2, 4.0) PsA cases per 100 psoriasis patients. When suspected cases were included in the analysis, the annual incidence rate increased to 3.7 (95% CI 2.7, 4.7) PsA cases per 100 psoriasis patients. The distribution of the time to development of PsA was fit with an exponential model, suggesting a constant hazard rate. The following variables predicted the development of PsA: flexural psoriasis (RR 4.9 p=0.03), nail pitting (RR 2.3 p=0.006), higher modified Nail Psoriasis Severity Index score (RR 2.8 p=0.008) and lower level of education (high school incomplete vs. University RR 3.33, p=0.04). Obesity vs. normal weight predicted the development of PsA when suspected cases of PsA were included in the analysis (RR 2.3 p=0.03)

Conclusion: The incidence of PsA in patients with psoriasis is higher than previously reported. Flexural psoriasis, psoriatic nail lesions, lower level of education and obesity predict the development of PsA in patients with psoriasis.

1851

Serious Infection Events in the Psoriasis Longitudinal Assessment and Registry Study: Cumulative Experience. Robert Kalb[1], David Fiorentino[2], Mark Lebwohl[3], Craig Leonardi[4], John Toole[5], Kavitha Goyal[6], Steve Calabro[6], Wayne Langholff[7] and Steve Fakharzadeh[8]. [1]SUNY at Buffalo, School of Medicine and Biological Sciences, Buffalo, NY, [2]Stanford University, Redwood City, CA, [3]Mount Sinai Medical Center, New York, NY, [4]Central Dermatology, St. Louis, MO, [5]University of Manitoba, Dermadvances Research, Winnipeg, MB, [6]Janssen Services, LLC, Horsham, PA, [7]Janssen Research and Development, LLC, Spring House, PA, [8]Janssen Services, LLC, Spring House, PA.

Background/Purpose: To report the cumulative rates of serious infections in the Psoriasis Longitudinal Assessment and Registry (PSOLAR) study.

Methods: PSOLAR is a multicenter, longitudinal, observational study evaluating long-term safety and clinical outcomes for patients eligible to receive treatment with biologics and/or conventional systemic agents for psoriasis (includes patients with self-reported psoriatic arthritis. Serious infections are defined as serious events (e.g. requiring hospitalization) classified into the MedDRA system organ class of Infections and infestations. The rates of serious infections in PSOLAR overall and by treatment groups are reported through the most recent data cut-off date (Aug 23, 2013) using exposure within 91 days preceding the event. In cases of exposure to >1 therapy, the rule for attribution of serious infections to a treatment group is ustekinumab first, infliximab/golimumab second, other biologics third (nearly all adalimumab or etanercept), or non-biologic therapy fourth, which is consistent with the pre-specified analytic plan.

Results: PSOLAR is fully enrolled with 12 095 patients reflecting 31 818 cumulative patient-years of follow up. 36% of the 12 095 patients had a self-reported diagnosis of psoriatic arthritis. The median duration of follow-up is 2.5 years. Unadjusted rates of serious infection, based on exposure within 91 days preceding the event were: ustekinumab 0.95 events per 100 patient years of observation (PY)[95% CI: 0.71, 1.24; 52/5497 PY, infliximab 2.77 per 100PY[95% CI: 2.15, 3.51; 68/2457 PY], etanercept 1.67 events per 100 PY [95% CI: 1.32, 2.09; 78/4666 PY], adalimumab 1.88 per PY [95% CI: 1.54, 2.27; 106/5645 PY], non-biologics 1.26 per 100 PY[95% CI: 1.08, 1.46; 169/13421 PY], and overall 1.50[95% CI: 1.37, 1.64; 478/31817]. Limitations: Rates have not been adjusted for demographic and clinical differences among treatment groups and are subject to attribution rules.

Conclusion: With nearly 32 000 patient years of follow-up, the overall rate of unadjusted cumulative rate of serious infections in the PSOLAR registry population is 1.50 per 100 PY. The rates of serious infection for ustekinumab and the no biologic treatment groups are lower than rates for infliximab, adalimumab and etanercept. Future analyses may characterize infections further and adjust for differences among treatment groups.

Increased Cardiovascular Risk in Patients Recently Diagnosed with Psoriatic Arthritis: A Population-Based, Cohort Study. Katelynn Wilton[1], Floranne C. Ernste[1], Cynthia S. Crowson[2], Eric L. Matteson[2], Hilal Maradit Kremers[2] and Marta Sánchez-Menéndez[3]. [1]Mayo Clinic Rochester, Rochester, MN, [2]Mayo Clinic, Rochester, MN, [3]Centro Medico de Asturias, Oviedo, Spain.

Background/Purpose: Patients diagnosed with rheumatoid arthritis and psoriatic arthritis (PsA) have an increased risk of multiple comorbidities that predispose them to cardiovascular disease (CVD). Although it has been documented that the Framingham Risk Score (FRS) underestimates the 10-year risk of CVD in patients with rheumatoid arthritis, the predictive accuracy of the FRS has not been evaluated in PsA.

Methods: The study population comprised a population-based inception cohort of patients with PsA who fulfilled the ClASsification of Psoriatic ARthritis (CASPAR) criteria between 1989 and 2008. Data on CVD risk factors and all CVD events (myocardial infarction, CV death, angina, revascularization procedures, heart failure, stroke and intermittent claudication) were collected via medical record review. For each patient, the 10 year FRS (Circulation 2008;117;743–753) was calculated at time of PsA diagnosis. Poisson regression models were used to obtain the standardized incidence ratio (SIR), which is the ratio of observed CVD in PsA to predicted CVD obtained from the FRS.

Results: Among 150 incident PsA patients without a history of CVD, 32 patients experienced a CVD event during a mean follow-up of 11.6 years corresponding to an absolute risk of 17.4 per 1000 person years. Of 126 patients who were ≥30 years of age and without a history of CVD at time of PsA diagnosis, the mean FRS was 9.7%. Accounting for length of follow-up, this translated to 10 predicted events. However, 18 patients experienced a CVD event in the first 10 years, corresponding to a 10 year cumulative incidence of 17% (95 % confidence interval [CI]: 10–24%). This was almost twice as high as predicted by the FRS (SIR: 1.80; 95% CI: 1.14–2.86; p=0.012). This two-fold increased CVD risk was consistent across age groups.

Conclusion: We observed a higher than expected incidence of CVD events within our inception cohort of patients with PsA, with an actual risk of about twice that predicted by the FRS. This increased risk underscores the need for close cardiovascular follow-up in this population.

Persistence and Predictors of Biologic TNFi Therapy Among Biologic naïve Psoriatic Arthritis Patients in a US Registry. Philip Mease[1], David Collier[2], Chitra Karki[3], Guo Li[4], Bojena Bitman[5] and Jeffrey D. Greenberg[6]. [1]Swedish Medical Center, Seattle, WA, [2]Amgen, Inc., Thousand Oaks, CA, [3]Corrona, LLC., Southborough, MA, [4]Axio Research LLC, Seattle, WA, [5]Amgen, Inc., San Francisco, CA, [6]New York University School of Medicine, New York, NY.

Background/Purpose: Registry data regarding biologic DMARD therapy as a mono or combo (combined with a traditional oral DMARD) in subjects with Psoriatic Arthritis (PsA) are limited. Our aim was to characterize biologic naïve PsA patients who initiated TNFi as mono or combo therapy, estimate length of time on initial TNFi and identify characteristics associated with longevity of initial TNFi use.

Methods: Data from the US Corrona registry was used. Patients (pts) with a diagnosis of PsA ≥ 18 yrs of age, bio-naïve and initiated TNFi on Jan 1st 2005 or later with at least 3m of follow-up were included. Survival analyses were performed using Kaplan-Meier curves estimating time on initial therapy since TNFi initiation, either as mono/combo therapy. Proportional hazard models were used to identify factors associated with risk of therapy change since initiation. A propensity score (PS) for mono vs combo was estimated and comparisons made using inverse probability weighting based on propensity probabilities. Median time to therapy change was calculated.

Results: 519 biologic naïve PsA pts met the inclusion criteria, with 61% vs. 39% initiating a TNFi as combo or mono therapy, respectively. 51% of pts initiating a TNFi were female, mean age was 51.6 yrs and mean disease duration of 6.3 yrs. The combination therapy group had significantly higher proportion of women (57.1% vs 42.3%), higher clinical disease activity index (CDAI) (mean (SD): 12.5 (11.1) vs 9.6 (9.9)), higher body mass index (mean(SD) 31.9 (7.4) vs 30.7 (6.5), higher proportion of history of diabetes (11.3% vs 6.5%) and higher history of methotrexate use (89.9% vs 68.2%) compared to monotherapy initiators.

Median time on combo and mono therapy since TNFi initiation in the PS matched pts was 32.8 months and 30.8 months respectively [Figure 1]. Significant factors associated with change in initial therapy were disability index measured by mHAQ (HR (95% CI): 2.6 (1.7–3.9)) and CDAI (HR (95% CI): 1.03 (1.01–1.04)). The models were adjusted for age, gender, body mass index, alcohol use, smoking history, mHAQ, and whether the patient was on mono/combo therapy. Persistency for mono vs combo therapy differed by individual TNFi. For example, pts on ETN mono therapy had higher persistency than combo therapy (47.3m on mono vs 19.1m in combo) with a HR of 1.93 (95% CI, 1.15–3.25). Among the pts on IFX, combo therapy was more persistent with a HR of 0.46 (95% CI, 0.24–0.88).

Conclusion: Over a third of PsA pts in the Corrona registry initiated TNFi as monotherapy. Even when adjusting for channeling bias with PS, overall survival on TNFi therapy was similar between mono and combo-treated pts. Greater degree of disability and disease activity use were associated with shorter duration of mono therapy. Some differences in survival on drug were noted between TNFi medicines, potentially related to background disease severity, immunogenicity, and/or other factors.

Figure 1: Kaplan-Meier Survival Curves of Time to Therapy Change, by Initial TNFi Therapy

1854

Systemic Lupus Erythematosus Patients Have Increased Risk of Short Term Adverse Events after Total Hip Arthroplasty. Jordan Roberts[1], Lisa A. Mandl[2], Edwin Su[2], David J. Mayman[2], Mark P. Figgie[2], Arielle Fein[2], Yuo-Yu Lee[2], Ummara Shah[3] and Susan M. Goodman[2]. [1]Weill Cornell Medical College, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]New York University School of Medicine, NYC, NY.

Background/Purpose: Total Hip Arthroplasty (THA) is the most frequent orthopedic procedure performed in lupus (SLE) patients. Whether SLE patients have higher rates of complications after THA than osteoarthritis (OA) patients is unknown. This study compares 6 month adverse event (AE) rates in SLE to matched OA controls.

Methods: Patients enrolled in our institution's THA registry from 2007–2011 were eligible. SLE was identified by ICD-9 code 710.0, and the diagnosis confirmed by chart review. AEs were identified by chart review and self-report questionnaire. SLE patients were matched 2:1 with OA controls by age, gender, year of surgery and hip resurfacing vs. THA. Fractures and other autoimmune diseases were excluded. Baseline characteristics of SLE and OA patients were compared and regression analysis performed to identify independent predictors of AEs.

Results: 58 SLE THA were matched to 116 OA controls. Mean age was 52 years (SLE) vs. 50 years (OA) (p-value=0.57), 90.5% were female. Pre-operative corticosteroid use and perioperative "stress dose" steroids were more common in SLE than OA (44.8% vs. 0.9%; p-value<0.0001 and 53.7% vs. 1.7%, %; p-value<0.0001, respectively). 47.4% of SLE had Charlson-Deyo co-morbidity scores (excluding SLE) ≥1 vs. 13.1% of OA (p-value<0.0001). Spinal/epidural was more common in OA (98.3% OA vs. 82.5% SLE; p-value<0.0001); more SLE received spinal alone (14% SLE vs. 0.9% OA; p-value<0.0001). There was no difference in operative time (86.9 minutes SLE vs. 84.4 OA; p-value=0.65). Length of stay was longer in SLE (6.0 days vs. 4.7; p-value=0.0008). Within 6 months after surgery, SLE had more falls (10.3% vs. 1.7%; p-value=0.02), DVTs (5.2% vs. 0%; p-value=0.036), acute renal disease (8.6% vs. 0%; p-value=0.004), superficial wound infections (6.9% vs. 0.9%, p-value=0.043) and revision surgeries (5.2% vs. 0%; p-value=0.036). Overall, 50% of SLE had any AE vs. 19.8% OA (p-value<0.0001) and 34.5% of SLE had a major AE vs. 10.3% OA (p-value=0.0001). In a multiple logistic regression analysis controlling for comorbidities and anesthesia type, SLE had an increased risk of AEs compared to OA (OR 3.77; 95% CI 1.74–8.16). Interestingly, co-morbidity scores were not significantly associated with risk of AE (Table 1). Among SLE there were no significant differences in AE rates between those taking pre-operative corticosteroids vs. none or those receiving perioperative stress-dose steroids vs. none.

Conclusion: SLE is an independent risk factor for AE after THA. SLE patients had higher rates of fall, acute renal disease, DVT, infection, revision surgery, and longer lengths of stay than matched OA controls. AE rates within SLE were not significantly associated with steroid use. Further research is needed to better understand the causes of increased AE risk in SLE patients.

Table 1: Multivariate Logistic regression*

A) Any Adverse Event	Odds Ratio	95% Confidence Limits	P-value
SLE vs. OA	3.77	1.74–8.16	0.0008
Charlson-Deyo Comorbidity Index** >=1 vs. 0	1.69	0.76–3.76	0.20
Epidural Block vs. no	1.29	0.35–4.73	0.71

B) Any Major Adverse Event: (Major AE= DVT, PE, fall, fracture, additional surgery, acute renal disease, cardiac event– MI, cardiac event–dysrhythmia, deep surgical site infection, bleeding event requiring transfusion, pneumonia, neuropathy, death)

	Odds Ratio	95% Confidence Limits	P-value
SLE vs. OA	3.70	1.52–8.89	0.004
Charlson-Deyo Comorbidity Index** >=1 vs. 0	1.82	0.75–4.41	0.19
Epidural Block vs. no	0.87	0.22–3.35	0.84

C) Any Minor Adverse Event: (Minor Adverse Event= superficial infection, ecchymosis, erythema, incision site drainage, spinal headache, poor wound healing)

	Odds Ratio	95% Confidence Limits	P-value
SLE vs. OA	3.54	1.41–8.91	0.007
Charlson-Deyo Comorbidity Index** >=1 vs. 0	1.19	0.46–3.12	0.72
Epidural Block vs. no	1.91	0.37–9.86	0.44

* All models control for disease (SLE vs. OA), comorbidities and type of anesthesia
** Charlson-Deyo comorbidity index was calculated by excluding SLE

1855

Not Keeping up with the Times: High Mortality and Early Death Due to Disease in North American Natives with Systemic Lupus Erythematosus (SLE). Ripneet Puar[1], Carol A. Hitchon[1], David B. Robinson[1], Hani El-Gabalawy[1], Navjot Dhindsa[1] and Christine A. Peschken[2]. [1]University of Manitoba, Winnipeg, MB, [2]University of Manitoba, Canada, Winnipeg, MB.

Background/Purpose: Reports in recent decades show drastic improvements in survival of SLE patients, with 10–15 year survival rates of >90%. However, little is known about North American Natives (NAN) with SLE. We compared mortality in NAN SLE patients to Caucasian (CA) SLE patients.

Methods: Patients from a single academic center were followed from 1990–2013 using a custom database. Variables included date of birth, diagnosis, age at disease onset, ethnicity, clinic visits dates, and vital status if known. Records of all patients with a diagnosis of SLE (≥4 American College of Rheumatology criteria) were abstracted. For patients who had not been seen in the last 2 years, updated vital status was obtained from the hospital medical records department. Ethnicity was by self-report, and categorized into NAN, CA and other. Age at diagnosis, disease duration and age at last follow up or age at death was calculated and compared between ethnic groups. Survival time was compared between NAN and CA using Kaplan Meier and Cox proportional hazard models, and person years of life lost (PYLL) was calculated for the 2 groups.

Results: A total of 861 patients with SLE were identified: 217 (25%) NAN, 534 (62%) CA, and the remaining 110 (13%) were of other ethnic backgrounds and were excluded from subsequent analyses. NAN patients were younger at diagnosis (NAN = 32±15 years vs. CA = 37±15 years; p=0.001), and had a shorter disease duration at last follow-up compared to CA (NAN = 11±8 years vs. CA = 16±10 years; p=0.001), but more NAN compared to CA were deceased by the end of the follow-up period (25% vs. 17%, p = 0.013.) Proportion of females, damage scores (SDI) and mean number of ACR criteria met (ACRc) did not differ, but NAN had more frequent nephritis (48% vs. 29%, p < 0.001) and arthritis (90% vs. 67%, p < 0.001). Mean age at death was younger in NAN (NAN = 50±16 years vs. CA = 63±16 yrs p=0.001). Survival rates were significantly worse in NAN compared to CA: 5 year survival was 92% vs. 97%; 10 year survival 85% vs. 92%; 15 year survival 78% vs. 88% respectively (p<0.001) (Figure 1).

After adjustment for ACRc, SDI, gender, age at diagnosis, disease duration, and onset decade (to account for survival bias and changes in treatment over time) NAN were more than twice as likely to die (hazard ratio 2.4; 95%CI: 1.6–3.6) compared to CA. PYLL for NAN (123/1000) was strikingly high compared to CA (39/1000). CA were more likely to die of atherosclerosis or malignancy (54% vs 18%), while NAN were more likely to die of lupus or lupus complications (27% vs. 16%); p= 0.005.

Conclusion: While survival in our CA patients was comparable to recent standards, we have found a twofold higher risk of mortality and threefold increase in PYLL in NAN SLE compared to CA SLE patients. Reasons for this remain unclear and highlight an urgent need for improved care delivery for NAN with SLE to decrease the significant morbidity and mortality burden from this disease.

1856

National Hospitalization Trends in Lupus Reveal Rising Rates of Herpes Zoster and Declines in Pneumocystis Infections. Sara G. Murray, Gabriela Schmajuk, Laura Trupin, Lianne S. Gensler and Jinoos Yazdany. University of California, San Francisco, San Francisco, CA.

Background/Purpose: Infection is a major cause of morbidity and mortality in systemic lupus erythematosus (SLE). With changing therapeutic practices over the past 15 years, it is unknown whether infectious complications of SLE have also evolved. In this study, we used the Healthcare Cost and Utilization Project National Inpatient Sample (NIS) to evaluate trends in hospitalizations for severe infections in SLE patients.

Methods: Using data from the 2000 to 2011 NIS, a nationally representative 20% sample of all US hospitalizations, we compared hospitalizations among individuals ≥ age 18 who met a validated administrative definition of SLE to hospitalizations of non-SLE patients. Primary outcomes were a discharge diagnosis of a severe infection (bacteremia, pneumonia, opportunistic fungal infection, herpes zoster (VZV), cytomegalovirus, or pneumocystis jirovecii pneumonia (PCP)). Direct standardization was used to generate annual rates of infection in SLE hospitalizations adjusted for age, gender, and a modified Charlson Comorbidity Index in comparison to non-SLE hospitalizations. Adjusted logistic regression models with an effect modification term for SLE and year were used to investigate differences in rates of infections over time among SLE vs. non-SLE hospital discharges.

Results: We identified 361,484 hospitalizations for SLE between 2000 and 2011. Compared to non-SLE hospitalized patients, SLE patients were younger (51 vs. 62 years) and predominantly female (89% vs. 54%), but had a similar comorbidity index (1.2 for both groups). In adjusted logistic regression analyses, a diagnosis of SLE was significantly associated with discharge diagnoses for bacteremia (OR 1.5, 95% CI 1.5–1.6), pneumonia (OR 1.3, 95% CI 1.2–1.3), fungal infections (OR 3.0, 95% CI 2.8–3.2), VZV (OR 2.0, 95% CI 1.9–2.2), cytomegalovirus (OR 5.0, 95% CI 4.2–6.1), and PCP (OR 3.7, 95% CI 2.7–5.1). Between 2000 and 2011, hospitalizations for VZV in patients with SLE increased more rapidly than rates in the non-SLE population, from 52 to 100 cases per 10,000 SLE admissions compared to 24 to 27 cases per 10,000 non-SLE admissions, even after adjustment (p for effect modification 0.036, Figure 1). Conversely, hospitalizations for PCP in SLE decreased over time, from an adjusted rate of 5 to 2 per 10,000 admissions, but remained stable at 1 per 10,000 in the non-SLE population (p for effect modification 0.021).

Conclusion: Among patients with SLE, hospitalizations for VZV are rising at a rate disproportionate to the non-SLE population, while hospitalizations for PCP in SLE are declining. These trends likely reflect changing immunosuppressive treatments and practice patterns in SLE, although further research is needed to determine which therapies significantly affect risk.

Figure 1. Adjusted rates of SLE hospitalizations for Herpes Zoster (VZV) and Pneumocystis (PCP) in comparison to non-SLE hospitalizations between 2000 and 2011 (95% confidence intervals).

Determinants of Annual Healthcare Utilization and Overall Cost of Care in Individuals with Systemic Lupus Erythematosus in a Large Insurance Claims Database: Glucocorticoid Use.

Shih-Yin Chen[1], Chan-Bum Choi[2], Qian Li[3], Wei-Shi Yeh[1], Yuan-Chi Lee[4], Amy H Kao[1] and Matthew H. Liang[5]. [1]Biogen Idec, Cambridge, MA, [2]VA Healthcare System, Boston, MA, [3]Evidera, Lexington, MA, [4]Formerly of Evidera, Lexington, MA, [5]Harvard Medical School, Boston, MA.

Background/Purpose: Newer therapeutic agents in systemic lupus erythematosus (SLE) may increase cost of care but their effect on limiting the duration and the dosage of glucocorticoids (GC) use ("steroid sparing") may reduce costs and improve other outcomes. This study investigated the determinants of healthcare utilization and costs with the use of GC among adult SLE patients (18–64 years old) in the US using a large administrative database.

Methods: This cross-sectional study analyzed insurance claims in 2007–2011 from established SLE patients identified by their ICD-9-CM diagnosis codes. Five patient groups defined by their oral GC use during the one-year study period were studied: non-GC users, <60 day of GC-use, ≥60 days of GC in low-dose (≤7.5mg), medium-dose (>7.5 to ≤15mg), or higher-dose (>15mg). Annual healthcare utilization and costs were compared across these groups and dose-response was examined among users with ≥60 days of GC. Incremental costs of GC groups, calculated as the difference in total healthcare costs compared with non-GC group, were estimated from multivariable regressions adjusting for demographic and clinical characteristics and stratified by immunosuppressant use. Immunosuppressant use as a surrogate for SLE disease severity was stratified to evaluate the potential cost-saving associated with GC-sparing therapies.

Results: A total of 50,230 patients with SLE were identified, including 52% non-GC users, 20% with <60 days of GC use, and 10% low-dose, 10% medium-dose, and 8% higher-dose with ≥60 days of GC use. GC users had higher healthcare utilization and costs (Figure 1). Incremental costs were significant (all $p<0.01$) for medium-dose ($5,319–$6,913) and higher-dose ($12,517–$15,019) GC groups, regardless of other immunosuppressant use (Figure 2). The incremental costs for low-dose GC group with concomitant immunosuppressants ($1,285; $p=0.04$) were smaller than the incremental costs for low-dose GC group without concomitant immunosuppressants ($2,514; $p<0.01$).

Conclusion: In this large national sample, any GC use especially at higher dose was associated with higher healthcare utilization and costs in patients with SLE. Therapies with GC-sparing effect that can allow patients to maintain on low GC dose may potentially reduce the healthcare economic burden in the treatment of SLE.

Standardized Mortality Ratios for Cause-Specific Deaths in Lupus Patients Followed Prospectively at a Single Centre Lupus Clinic. Barry J. Sheane, Dominique Ibanez, Dafna D. Gladman and Murray B. Urowitz. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Despite the significant improvement in survival rates of patients with systemic lupus erythematosus (SLE) over the last four decades, mortality rates have remained at least 3 times that of the general population. We have recently reported from our longitudinal cohort study that infection is responsible for almost half of all deaths in lupus within the first 5 years of disease, and for over a third of deaths overall.

The aim of this study was to examine the standardized mortality ratios (SMR) for all-cause and cause-specific deaths in SLE patients followed prospectively at a large lupus clinic between 1970 and 2012.

Methods: Primary causes of death were recorded and acquired from autopsy reports, discharge summaries, hospital notes, and death certificates and divided into 5 categories: active lupus, atherosclerosis-related, infection, malignancy and 'other', all as determined by the certifying clinician. For determination of the SMRs, cause-of-death data for the general population (by age, sex and year) were extracted from official records of the relevant provincial registry. SMRs were calculated as the ratio of observed deaths in the SLE cohort to the age, sex and year-match in the general population for all-cause and causes due to infection, atherosclerosis and malignancy.

SMRs were modelled using Poisson regression with the log of the expected number of events as an offset, and adjusted for age, sex, disease duration and decade of death.

Results: Of 259 patients known to have died, causes of death were established in 198 cases. Mean disease duration to time of death was 15.0 ± 11.3 years. Sixty-eight deaths were attributable to infection, 44 to atherosclerosis, 23 to malignancy and 39 due to active lupus.

For deaths due to all causes, the SMR falls significantly for the succeeding decade, from 12.02 (CI 7.67 – 18.82) for a female with < 5 years of SLE in the 1970s to 5.08 (CI 2.18 – 11.87) in the 2000s ($p < 0.0001$), with a similar decrease in those with SLE > 5 years.

For infection, there is a significant decade-on-decade reduction in the SMR, from 188 (CI 86 – 409) in the 1970s, to 117 (CI 42 – 324) in the 1980s, 73 (CI 21 – 256) in the 1990s and 46 (CI 10 – 203) in the 2000s ($p < 0.0001$), regardless of disease duration.

The SMRs for atherosclerosis and malignancy have also decreased over the 4 decades, from 14.09 (CI 9.99 – 16.86) and 1.79 (CI 1.12 – 2.87) in the 1970s, respectively, to 6.43 (CI 1.63 – 13.16) and 1.3 (CI 0.2 – 8.57) ($p > 0.05$).

Conclusion: Infection is the dominant cause of death in SLE, despite significant decreases in SMR over the last 40 years. Its prevalence as a cause-of-death is 40 times that of the general population. While primary prevention of cardiovascular disease should continue to be targeted in SLE, improvement in strategies to prevent and adequately treat infection in SLE require prioritisation.

1859

Age-Specific Predictors of Mortality in SLE. Dominique Ibanez, Dafna D. Gladman and Murray B. Urowitz. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Mortality is 3 to 5 times greater in SLE patients then it is in the general population – especially among younger patients where it can be over 10 times greater.

Aim: The aim of this study is to determine the age-specific predictors of mortality in Lupus patients.

Methods: All patients followed in a longitudinal cohort of lupus patients since 1970 were studied. Potential predictors for mortality were sex, coronary artery disease(CAD) ever (MI or Angina), Adjusted Mean SLEDAI-2K (AMS), SLICC/ACR Damage Index (SDI), current use of steroids, antimalarials, immunosuppressives, and infection. Each of the variables was evaluated at every clinic visit and used to predict mortality. Prediction models were evaluated using all of the deaths and for all visits with age < 40, for ages between 40 & 60 and for ages ≥ 60 separately. In the models with separate ages, AMS was evaluated only for the visits included in the period of analysis.

Statistical Analysis: Risk factors for death were evaluated using time-dependent covariate survival analysis.

Results: 1439 patients are included in the analysis. Depending on duration of followup, patients could be included in one or more age interval. 967 were seen at ages < 40, 730 were seen at ages between 40 & 60 and 262 were seen at ages ≥ 60. In total, there are 1264 (87.8%) female, 958 (67%) caucasian, 178 (12%) black, 140 (10%) Asian and 163 (11%) other. Age at SLE diagnosis was 30.3 ± 13.6.

A total of 211 patients died. 51 (24.2%) deaths occurred in patients aged < 40, 80 (37.9%) deaths in patients between the ages of 40 & 60 and 80 (37.9%) deaths occurred in patients over 60 years old.

Table 1 shows the hazard ratio for each of the potential predictors for mortality for age-specific intervals. The proportion of patients who died at each age interval increases from 5.3% for ages < 40, 11.0% for ages between 40 & 60, 30.5% for ages ≥ 60.

Disease duration is a predictor when all age groups are combined but not in age-specific analysis. Sex differences are only seen in older age with male at an increased hazard. AMS in the age specific intervals, SDI and steroids increases the hazard for death in all age intervals (with borderline significance in younger patients for steroids). Presence of infection increases the risk of death in patients aged < 60 while previous CAD ever increases the chance of mortality only in patients between the ages of 40 & 60. Antimalarials have a protective effect for patients under the age of 60. Immunosuppressives have a negligible effect in all age groups.

Conclusion: Predictors for mortality change with age intervals. Disease activity, damage and steroids are predictors of mortality in all age intervals. In older patients is male gender is a predictor and in younger patients infection and CAD ever are predictors for mortality. The use of antimalarials is protective for individuals younger than 60.

Serum Calprotectin and Disease Relapse in ANCA-Associated Vasculitis. Juliana B Draibe[1], Ruth J. Pepper[1], Peter A. Merkel[2], Alan D. Salama[1] and for The RAVE-ITN Investigators[3]. [1]University College London, London, United Kingdom, [2]Vasculitis Center, University of Pennsylvania, Philadelphia, PA, [3]Immune Tolerance Network, San Francisco, CA.

Background/Purpose: In ANCA-associated vasculitis (AAV) disease relapses remain common but there are no reliable means to predict them. We previously demonstrated that serum calprotectin levels were elevated during active AAV and that patients in the NORAM trial who relapsed had higher levels during initial presentation with active AAV than non relapsers. The objectives of this study were to validate calprotectin as a biomarker of relapse using samples from the Rituximab in ANCA-associated Vasculitis (RAVE) trial.

Methods: Serum samples were obtained from 182 subjects enrolled in the RAVE trial at baseline (B), 1 month (m1), and 2 months (m2) following enrollment and initiation of treatment. Serum levels of calprotectin were evaluated by ELISA. Absolute calprotectin levels and changes in levels from B to m1 or m2 and between m1 and m2 were calculated for subjects and stratified according to subsequent disease relapse by 18 months of follow-up.

Results: Serum levels of calprotectin were similar between relapsers and non-relapsers (NR) at B and m1, but at m2, levels were significantly higher in relapsers (relapsers median 4750 ng/ml, range 1364–26071 vs non-relapsers 3769 ng/ml, 1020–9964; $p=0.04$). There was no correlation between calprotectin and ANCA titer or CRP, and only weak correlation with white cell count ($r=0.27$, 0.3,

0.38, at B, m1, and m2 respectively, all p<0.0003). The percentage reduction in levels between m1 and m2 were significantly lower in relapsing patients compared to non-relapsing patients (relapsers +9.7% vs non-relapsers −9.8; p=0.035) confirming that relapsing patients failed to suppress calprotectin to the same extent as non-relapsers. Time to relapse was significantly faster in those patients with an increase in calprotectin between B and m2 or between m1 and m2, when compared to those in whom levels showed no change or reduction (p=0.0004 and p=0.04 respectively) [Figure].

Conclusion: Failure to suppress calprotectin following induction AAV treatment is associated with greater and faster rates of disease relapse. These findings have now been confirmed in two independent cohorts. Calprotectin may be a biomarker predictive of relapse in AAV and should be investigated for use in clinical trials and clinical practice.

The Role of Macrophage Migration Inhibitory Factor (MIF) and *MIF* Gene Polymorphisms in the Pathogenesis of Granulomatosis with Polyangiitis. Antoine G. Sreih[1], Rana Ezzeddine[2], Juan Fan[3], Lin Leng[3], Simon Carette[4], David Cuthbertson[5], Gary S. Hoffman[6], Nader A. Khalidi[7], Carol A. Langford[8], Carol McAlear[9], Paul Monach[10], Philip Seo[11], Ulrich Specks[12], Steven R. Ytterberg[12], Peter A. Merkel[13] and Richard Bucala[14]. [1]The University of Pennsylvania, Philadelphia, PA, [2]Bristol-Myers Squibb, Wallingford, CT, [3]Yale University, New Haven, CT, [4]University of Toronto, Toronto, ON, [5]University of South Florida, Tampa, FL, [6]Center for Vasculitis Care and Research, Cleveland Clinic Foundation, Cleveland, OH, [7]St. Joseph's Hospital, McMaster University, Hamilton, ON, [8]Center for Vasculitis Care and Research, Cleveland Clinic, Cleveland, OH, [9]Vasculitis Center, University of Pennsylvania, Philadelphia, PA, [10]Boston University, Boston, MA, [11]Johns Hopkins Vasculitis Center, Johns Hopkins University, Baltimore, MD, [12]Mayo Clinic, Rochester, MN, [13]Vasculitis Center, Division of Rheumatology, University of Pennsylvania, Philadelphia, PA, [14]Yale University School of Med, New Haven, CT.

Background/Purpose: Macrophage Migration Inhibitory Factor (MIF) is an immunoregulatory cytokine that may play a central role in the pathogenesis of granulomatous diseases. Two functional polymorphisms have been identified in the *MIF* gene promoter that correlate with MIF production *in vivo:* a -794 CATT repeat (*rs5844572*) and a −173 G/C SNP (*rs755622*). This project aimed to study the association of *MIF* polymorphisms and MIF cytokine in granulomatosis with polyangiitis (Wegener's, GPA) and to examine the role of MIF in a murine model of granulomatous vasculitis induced by *Candida albicans* water-soluble fraction (CAWS).

Methods: The human study involved 488 Caucasian patients with GPA and 551 healthy age- and sex-matched controls. Genotyping for the CATT site was performed by PCR plus capillary electrophoresis; SNP analysis was performed by real-time PCR. The frequencies of high expression *MIF* genotypes (>5 CATT repeats and -173 C SNP) were compared between patients and controls. MIF plasma levels were measured by ELISA in 78 patients and 45 controls. Wild type C57BL/6 mice and MIF lung-transgenic mice, some treated with anti-MIF, were injected with CAWS and analyzed for survival and for pulmonary pathology.

Results: The percentage of individuals carrying more than 5 CATT repeats (high *MIF* expression) was 60.9% in patients with GPA and 53.7% in controls (p=0.02). There was no difference in the −173 G/C SNP polymorphisms between these groups. Patients with GPA had higher mean plasma MIF levels than controls (15.9 +- 10.4 ng/dl vs. 6.7 +- 5 ng/dl, p<0.0001). A significantly higher percentage of MIF transgenic mice died when injected with CAWS as compared to wild type (Figure 1A). Injection of anti-MIF mAb protected transgenic mice from dying (Figure 1B). MIF lung-transgenic mice also exhibited more pulmonary granulomas than wild type mice (Mean number = 11.5 ± 0.8 /mm^2 in transgenic vs. 7.9 ± 1.4 /mm^2 in controls, p=0.1) (Figure 2A and 2B).

Conclusion: Compared to controls, patients with GPA have an increased frequency of high-expression *MIF* CATT, and higher plasma MIF levels. In a murine model of granulomatous vasculitis, higher MIF expression increased mortality and pulmonary granulomas while injection of anti-MIF mAb protected mice from dying. MIF seems to play a critical role in the pathogenesis of GPA. Pharmacologic MIF inhibition may offer a promising therapy for GPA.

1862

The Association of Low-Density Granulocytes with Disease Activity and Response to Treatment in ANCA-Associated Vasculitis. Peter C. Grayson[1], Carmelo Carmona-Rivera[1], Lijing Xu[2], Noha Lim[2], Adam Asare[2], Deborah J. Phippard[2], Mariana J. Kaplan[1], Peter A. Merkel[3] and Paul A. Monach[4]. [1]National Institutes of Health, Bethesda, MD, [2]Immune Tolerance Network, Bethesda, MD, [3]Vasculitis Center, University of Pennsylvania, Philadelphia, PA, [4]Vasculitis Center, Boston University School of Medicine, Boston, MA.

Background/Purpose: To discover new pathways involved in the pathophysiology of ANCA-associated vasculitis (AAV) and identify potential clinical biomarkers through use of whole-genome gene expression profiling. Given the recent discovery of a pathogenic link between AAV and neutrophil extracellular trap (NET) formation, the study also sought to determine if patients with AAV have low-density granulocytes (LDGs) in peripheral blood. LDGs are a distinct subset of neutrophils described in systemic lupus erythematosus (SLE) that separate with PBMC in density gradient preparations and are prone to form NETs.

Methods: The source of clinical data and link biospecimens was a randomized controlled treatment trial in AAV. RNA-sequencing of whole blood from 112 subjects with AAV was performed during active disease at the baseline study visit (BL) and during remission 6 months later (6M). Gene expression in subjects who met the primary trial outcome of clinical remission at 6M was compared to patients who did not enter remission at 6M (responders vs. nonresponders) using the generalized linear model likelihood ratio test. A multi-gene composite score was created by calculating z-scores on a per gene per sample basis. Enrichment of relevant gene set signatures was tested using Gene Set Enrichment Analysis (GSEA). Measurement of neutrophil-related gene expression in PBMC collected concomitantly to whole blood samples was performed by qPCR and compared by ANOVA. LDGs were directly isolated from PBMC fraction by negative selection in 5 additional patients with AAV not enrolled within the clinical trial.

Results: There were no baseline differences in disease activity, clinical features, treatment status, and neutrophil counts between responders (n=77) and nonresponders (n=35). After filtering transcripts expressed in <50% of subjects, there were 44,532 total aligned reads. Differential expression between responders and nonresponders was seen in 2,346 transcripts at BL visit ($p<0.05$). Unsupervised hierarchical clustering demonstrated a distinct cluster of granulocyte-related genes that included genes coding for myeloperoxidase (MPO) and proteinase 3 (PR3), the major autoantigens in AAV. A granulocyte gene signature composite score was 10-fold higher in nonresponders versus responders ($p<0.001$) and 4-fold higher in subjects during active disease (BL) than remission (6M) ($p<0.001$). The signature in AAV strongly overlapped an LDG signature seen in lupus ($FDR_{GSEA}<0.001$). Increased transcription of PR3, but not MPO, measured in PBMC collected in a subset of subjects was associated with active disease ($p<0.01$) and failure to meet the primary trial outcome of remission at 6M ($p<0.001$), validating the findings from whole-blood profiling and localizing the source of granulocyte gene expression to LDGs. In isolation studies, LDGs were found in every patient with AAV and, similar to SLE, were noted to readily form NETs in the absence of stimulation.

Conclusion: In patients with AAV increased expression of a granulocyte gene signature is associated with disease activity and response to treatment. The source of this signature is likely LDGs, which may be a key pathogenic cell in AAV.

CCX168, an Orally Administered C5aR Inhibitor for Treatment of Patients with Antineutrophil Cytoplasmic Antibody-Associated Vasculitis. Pirow Bekker[1], David Jayne[2], Annette Bruchfeld[3], Matthias Schaier[4], Kazimierz Ciechanowski[5], Lorraine Harper[6], Michel Jadoul[7], Mårten Segelmark[8], Daina Selga[9], Istvan Szombati[10], Michael Venning[11], Christian Hugo[12], Paul L. van Daele[13], Ondrej Viklicky[14], Antonia Potarca[15] and Thomas J. Schall[15]. [1]Chemocentryx, Inc., Mountain View, CA, [2]Addenbrookes Hospital University of Cambridge, Cambridge, United Kingdom, [3]Karolinska Institute, Stockholm, Sweden, [4]University of Heidelberg, Heidelberg, Germany, [5]Pomeranian Medical University, Szczecin, Poland, [6]University of Birmingham, Birmingham, United Kingdom, [7]Cliniques Saint-Luc, Brussels, Belgium, [8]Linkoping University, Linkoping, Sweden, [9]Lund University, Lund, Sweden, [10]Budaclinic, Budapest, Hungary, [11]Manchester University, Manchester, United Kingdom, [12]Dresden University, Dresden, Germany, [13]Erasmus Medical Center, Immunology, Rotterdam, Netherlands, [14]Instit of Clin and Exp Med, Prague, Czech Republic, [15]ChemoCentryx, Inc., Mountain View, CA.

Background/Purpose: CCX168 is a potent, specific C5aR inhibitor in clinical development for ANCA-associated vasculitis. The initial focus of this randomized, double-blind, placebo-controlled clinical trial was on renal disease activity, since CCX168 showed profound efficacy in a mouse model of MPO ANCA-induced glomerulonephritis. CCX168 indeed showed renal disease efficacy of oral 30 mg CCX168 given twice daily for 12 weeks based on eGFR (up to 6.8 mL/min/1.73 m^2 increase over 12 weeks), urinary ACR (mean decrease up to 63% over 12 weeks), and MCP-1:creatinine (up to 72% decrease over 12 weeks).

Methods: The purpose of this investigation was whether CCX168 treatment also has any effect on non-renal disease activity. The Birmingham Vasculitis Activity Index (BVAS) is a global disease activity index. Efficacy based on BVAS was evaluated to assess the potential non-renal disease activity of CCX168. 25 patients completed this clinical trial; 9 received placebo+cyclophosphamide (CYC)+full dose prednisone (60 mg/day), 8 received CCX168+CYC+low dose prednisone (20 mg/day), and 8 received CCX168+CYC+no prednisone.

Results: Baseline characteristics and Week 12 results on renal and non-renal disease activity are shown in the table.

		CCX168+CYC+Low-Dose Steroids (N=8)	CCX168+CYC+ No Steroids (N=8)	SOC: CYC+High-Dose Steroids (N=9)
Baseline Characteristics				
Age, years	mean (SD)	55.3 (16.3)	54.9 (15.0)	57.7 (14.0)
Gender, M/F	%	70/30	50/50	50/50
Duration of ANCA disease, months	median (range)	0.5 (0–162)	0 (0–53)	0 (0–32)
ANCA disease status, new/relapsed	%	70/30	75/25	88/12
Anti-MPO/Anti-PR3 positive	%	40/60	63/37	63/37
BVAS	median (range)	11 (5–30)	11 (5–28)	9 (3–15)
eGFR, ml/min/1.73 m^2	mean (SD)	56.8 (14.6)	52.4 (17.7)	56.9 (25.2)
U-Albumin:creatinine ratio, mg/g	mean (SD)	386 (346)	341 (287)	417 (416)
Efficacy Results				
Steroids rescue events	n (%)	0 (0%)	1 (13%)	1 (11%)
eGFR change at Wk 12, ml/min/ 1.73 m^2	mean (SEM)	6.8 (2.1)	0.6 (3.6)	2.2 (3.3)
U-ACR % change at Wk 12	mean	−63%	−59%	−9%
U-MCP-1:creatinine % change at Wk 12	mean	−72%	−52%	−37%
BVAS Total				
Response* at Wk 12	% of pts	86%	88%	44%
Remission** at Wk 12	% of pts	29%	25%	33%
BVAS Renal				
Response at Wk 12	% of pts	71%	50%	38%
Remission at Wk 12	% of pts	29%	25%	25%
BVAS Non-Renal				
Response at Wk 12	% of pts	83%	88%	57%
Remission at Wk 12	% of pts	67%	50%	43%
BVAS Total %Change at Wk12	mean ± SEM	−71 ± 9%	−65 ± 11%	−26 ± 25%
BVAS Renal %Change at Wk12	mean ± SEM	−64 ± 10%	−50 ± 15%	−16 ± 26%
BVAS Non-Renal %Change at Wk12	mean ± SEM	−81 ± 33%	−83 ± 29%	−15 ± 6%

* Response: BVAS decrease ≥50% plus no worsening in any body system; ** Remission: BVAS of 0 plus prednisone dose ≤10 mg/day.

Conclusion: In addition to an effect on renal disease activity, CCX168 treatment of patients with ANCA-associated vasculitis also resulted in a salutory effect on non-renal disease activity based on the non-renal component of the BVAS.

Granulomatosis with Polyangiitis or Microscopic Polyangiitis: Long-Term Outcomes of the Prospective Wegent Trial Comparing Azathioprine Vs Methotrexate for Remission-Maintenance in 126 Patients. Xavier Puéchal[1], Christian Pagnoux[2], Elodie Perrodeau[3], Mohamed Hamidou[4], Jean-Jacques Boffa[5], Xavier Kyndt[6], François Lifermann[7], Thomas Papo[8], Dominique Merrien[9], Amar Smail[10], Philippe Delaval[11], Catherine Hanrotel-Saliou[12], Bernard Imbert[13], Chahéra Khouatra[14], Marc Lambert[15], Charles Leské[16], Kim Heang Ly[17], Edouard Pertuiset[18], Pascal Roblot[19], Marc Ruivard[20], Jean-François Subra[21], Jean-Francois Viallard[22], Benjamin Terrier[1], Pascal Cohen[1], Luc Mouthon[1], Philippe Ravaud[3] and Loïc Guillevin for the French Vasculitis Study Group[1]. [1]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France, [2]University of Toronto, Toronto, ON, [3]Epidemiology, Université Paris-Descartes, Paris, Paris, France, [4]CHU Hôtel Dieu, Nantes, Nantes, France, [5]Hôpital Tenon, Paris, Paris, France, [6]CH, Valenciennes, Valenciennes, France, [7]CH Côte d'Argent, Dax, Dax, France, [8]Bichat Hospital, Paris, Paris, France, [9]CH Compiègne-Noyon, Compiègne, France, [10]CHU Amiens Nord, Amiens, France, [11]CHU Rennes Sud, Rennes, France, [12]CHU Cavale Blanche, Brest, Brest, France, [13]CHU, Grenoble, Grenoble, France, [14]CHU Louis Pradel, Lyon, Lyon, France, [15]Internal Medicine University Lille Hospital, Lille, Lille, France, [16]CH, Cholet, Cholet, France, [17]CHU Dupuytren, Limoges, Limoges, France, [18]René Dubos Hospital, Pontoise, France, [19]CHU, Poitiers, Poitiers, France, [20]CHU Estaing, Clermont–Ferrand, Clermont–Ferrand, France, [21]CHU, Angers, Angers, France, [22]Hôpital Haut-Lévêque, Bordeaux, CHU Bordeaux, France.

Background/Purpose: Results of the previously reported randomized–controlled WEGENT trial demonstrated that, at 28 months, methotrexate (MTX) is as effective as azathioprine (AZA) for maintaining remission of granulomatosis with polyangiitis (GPA, Wegener's) or severe microscopic polyangiitis (MPA) (NEJM 2008;359:2790–803). The long-term outcomes of patients included in the WEGENT trial were analyzed in this study.

Methods: Long-term outcomes were ascertained for 126 patients enrolled in the WEGENT trial between 1999 and 2004. Data on survival, relapse, immunosuppressant use, cancer, infection and cardiovascular morbidity were collected. All patients were analyzed according to their randomization group. Demographic, clinical and laboratory parameters at trial entry were evaluated as potential prognostic factors for death or relapse in multivariate models.

Results: Median follow-up was 11.8 years. The 10-year overall survival rate was 74.8% [95% CI 64.5–86.9] for the AZA arm and 79.9% [95% CI 70.3–90.7] for the MTX arm, with no between-arm survival difference (HR MTX vs AZA = 0.79 [95% CI 0.37–1.70]; P=0.55). No long-term between-arm differences were observed for adverse events, severe adverse events, infections, cancer, relapses and severe relapses. The 10-year survival rate without relapse was 26.3% [95% CI 17.3–40.1] in the AZA arm and 35.1% [95% CI 24.9–49.4] in the MTX arm, with no significant between-arm difference (HR MTX vs AZA = 0.78 [95% CI 0.51–1.20]; P=0.26). The 10-year survival rate without severe side effects was also comparable for the two groups (HR MTX vs AZA = 1.02 [95% CI 0.64–1.63]; P=0.93), as was survival without relapse and severe side effects (HR MTX vs AZA = 1.04 [95% CI 0.66–1.63]; P=0.87). Taking into account only the 97 GPA patients, no between-arm differences were observed for these survival parameters. Survival without relapse was shorter for GPA than MPA patients (HR 2.16 [95% CI 1.22–3.83]; P=0.009). Multivariate analyses retained the glucocorticoid dose at the end of the scheduled 12-month maintenance-drug regimen (HR 1.18 [95% CI 1.09–1.29]; P<0.001), glucocorticoid duration (HR 1.01 [95%CI 1.00–1.02]; P<0.04), and PR3-ANCA–positivity (HR 3.68 [95% CI 2.07–6.55]; P<0.001) as being significantly prognostic of long-term relapses. Each additional month or mg of glucocorticoid at the end of the maintenance regimen increased the probability of relapse or death by 1% or 15%, respectively.

Conclusion: This long-term analysis confirmed that AZA and MTX are comparable options for maintaining GPA or MPA remission. It showed that the overall survival is good, even though relapses and adverse events remain matters of concern. Further studies are needed to reduce the long-term relapse rate of ANCA-associated vasculitides.

Increased Risk of Myocardial Infarction and Cerebrovascular Accidents after Diagnosis of Granulomatosis with Polyangiitis: A General Population-Based Cohort Study. Neda Amiri[1], Natasha Dehghan[1], Eric C. Sayre[2], Kamran Shojania[1] and J. Antonio Avina-Zubieta[2]. [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada, Richmond, BC.

Background/Purpose: Limited literature is available on the incidence of myocardial infarction (MI) and cerebrovascular accidents (CVA) in patients with Granulomatosis with Polyangiitis (GPA). We assessed the risk of MI and CVA in cases with GPA compared to controls from the general population using hospitalization databases and physician billings that encompasses the entire province of British Columbia, Canada. We further determined the time trend risks of MI and CVA since diagnosis of GPA.

Methods: Our data included all visits to health professionals and all hospital admissions from 1990 to 2010 as well as all dispensed medication from 1996 to 2010 for all individuals.

We conducted a retrospective matched cohort study among new cases with GPA meeting a pre-defined criteria as follows: **a)** diagnosis of GPA (ICD-9-CM 446.4) in adults on at least two visits within a two-year period between 1996 and 2010 by a non-rheumatologist physician; **b)** diagnosis of GPA on at least one visit by a rheumatologist or from hospitalization; **c)** absence of a prior GPA diagnosis between January 1990 and December 1995 (to ensure incident GPA cases). Ten controls matched by birth year, sex and calendar year of follow-up were selected from the general population. **Incident MI and CVA** events based on hospitalization or death certificate were recorded as an outcome. We estimated relative risks (RRs) comparing GPA with age-, sex- and entry time-matched comparison cohorts, adjusting for potential cardiovascular risk factors. Sensitivity analyses were conducted to assess for unmeasured confounders (e.g. smoking).

Results: Among 640 incident cases of GPA (54.2% female, mean age 58.6), 28 developed a first time MI and 25 CVA events with an incident rate (IR) of 13.9 and 12.3 per 1000 person-years, respectively. Compared with the age, sex, and entry-matched controls, the incidence rate ratio (IRR) were 3.3 (95% CI 2.1–5.0) and 3.2 (95% CI 2.0–5.1) for MI and CVA respectively. The risk of developing MI and CVA was highest within the first year following diagnosis of GPA, decreasing over time and persisting after 5 years (**see table**). After adjusting for covariates, the results remained significant for both MI and CVA. The results also remained statistically significant after adjusting for the potential impact of unmeasured confounders (adjusted RRs ranging between 2.57 and 3.84 in all sensitivity analyses).

Conclusion: This large general population-based study found an increased an increased risk of MI and CVA in patients with GPA. Furthermore, the risk is highest in the first year of disease and decreases subsequently persisting at 5 years of follow up. Our results support increased monitoring for cardiovascular disease in patients with GPA, including management of traditional risk factors to reduce this risk.

Table: Risk of Incident MI and CVA according to GPA Status

	GPA N = 608	**Non-GPA N = 6,169**
Cases of MI, n	28	108
Incidence Rate/1000 PY	13.9	4.2
Age-, sex-, and entry time-matched RRs (95% CI)	3.3 (2.1–5.0)	1.0
1 year of disease duration	6.0 (2.7–12.7)	1.0
2 years	3.9 (1.9–7.4)	1.0
3 years	3.1 (1.6–5.6)	1.0
4 years	3.5 (2.0–5.9)	1.0
5 years	3.4 (2.0–5.6)	1.0
Multivariable RR (95% CI)	**3.9 (2.2–6.7)**	**1**
	GPA N = 623	**Non-GPAN = 6,307**
Cases of CVA, n	25	99
Incidence Rate/1000 PY	12.3	3.8
Age-, sex-, and entry time-matched RRs (95% CI)	3.2 (2.0–5.1)	1.0
1 year of disease duration	7.1 (3.3–14.5)	1.0
2 years	5.1 (2.7–9.2)	1.0
3 years	4.5 (2.5–7.8)	1.0
4 years	4.0 (2.3–6.8)	1.0
5 years	4.1 (2.4–6.7)	1.0

Birth Outcomes in Women with a History of Juvenile Idiopathic Arthritis. Debbie Ehrmann Feldman[1], Evelyne Vinet[2], Sasha Bernatsky[3], Ciaran Duffy[4], Elizabeth Hazel[5], Marie-Pierre Sylvestre[1], Garbis Meshefedjian[6] and Anick Bérard[1]. [1]Université de Montréal, Montréal, QC, [2]McGill University Health Center, Montreal, QC, [3]McGill University, Montreal, QC, [4]Children's Hospital of Eastern Ontario, Ottawa, ON, [5]McGill University Heatlh Center, Montreal, QC, [6]Public Health Department of Montreal, Montreal, QC.

Background/Purpose: Although there is a higher frequency of adverse birth outcomes in women with rheumatoid arthritis, little is known on the subject regarding women who had juvenile idiopathic arthritis (JIA) as children or adolescents. The objective of our study was to determine whether children born to women who had JIA in childhood and adolescence had more adverse birth outcomes than children born to mothers who never had JIA.

Methods: We designed a retrospective cohort study using administrative data that covered the entire population of the province of Québec, Canada. We identified 1756 females with a diagnosis of JIA who had given birth (first birth: stillbirth or live birth) between 01/01/1983 and 12/31/2010 from the

Quebec physician reimbursement and hospitalization databases. We also assembled a cohort of women from the population database who did not have a diagnosis of JIA, matched 4:1 for date of first birth (± 3 months), age (± 5 years) and region of residence (using the postal code) to serve as a control group (n=7024). We compared birth outcomes (stillbirth, prematurity, small for gestational age, and the presence of major congenital anomalies diagnosed within the first year post birth) in those who had JIA and those who did not. We used logistic regression, adjusting for maternal age, sex of the infant, maternal education, hypertension during pregnancy and gestational diabetes.

Results: For the entire cohort, the mean age at delivery was 24.9 years (standard deviation 4.4; range 16 to 46 years). There were more adverse birth outcomes in the JIA group, except for stillbirths. Women who had had JIA were at higher risk for having a premature baby (adjusted relative risk (95% confidence interval) 1.18 (1.00,1.4)), a small for gestational age baby (adjusted relative risk (95% confidence interval) 1.19 (1.04–1.36)), and a child with a major congenital anomaly (adjusted relative risk (95% confidence interval) 6.49 (4.88–8.10)). The prevalence of neural tube defects was especially high in the JIA group (1.7% vs 0.04% in the non JIA group) as were congenital heart and circulatory defects (1.2% in the JIA group vs 0.6% in the non JIA group).

Conclusion: Women who had JIA are at higher risk for adverse birth outcomes. The implications are that women with a history of JIA who are pregnant must be monitored closely. Further research is needed to understand possible pathophysiologic mechanisms in JIA and pregnancy as well as pharmaco-epidemiologic studies to explore the effects of medications during childhood and youth (including during the peri-pubescent period) on future birth outcomes.

1867

Mandibular Movement in Healthy Individuals from 4–17 Years of Age. Peter Stoustrup[1], Kasper Dahl Kristensen[2], Annelise Küseler[3], Thomas Klit Pedersen[4] and Troels Herlin[4]. [1]University of Aarhus, Aarhus C, Denmark, [2]Specialist Oral Health Center for Western Norway, Rogaland Stavanger, Norway, [3]Aarhus University, Aarhus, Denmark, [4]Aarhus University Hospital, Aarhus, Denmark.

Background/Purpose: Assessment of mandibular movement capacity is an important part of the clinical orofacial examination of patients with juvenile idiopathic arthritis (JIA). The aim of the present study was twofold: 1) To establish age-related normative values for maximal mouth opening capacity and mandibular laterotrusion in healthy individuals. 2) To establish a universal cut-off value for "normal" range of motion in children and adolescent patients to be used in future clinical orofacial examinations of patients with JIA.

Methods: A total of 1114 healthy Danish individuals between the ages of 4–17 years were included in this cross-sectional population-based study. During a routine dental examination the maximal mouth opening capacity and laterotrusion capacity (the sideway excursion of the mandible) were assessed in each individual according to a standardized measurement protocol with calibrated metallic rulers. The measurements were adjusted for overbite and midline deviations. Exclusion criteria: diagnosis with temporomandibular dysfunction, previous orofacial complaints, jaw fractures or hypermobility.

Results: The mean maximal mouth opening gradually increased from 38 mm (SD 6.1 mm) at age four to 54.5 mm (SD 6.8 mm) at age 17. A linear increase in the opening capacity was observed between the age of four to 11; Beyond the age of 11 only minor changes of 4 millimeters were observed. No inter-gender difference in maximal mouth opening capacity was observed ($p>0.15$).

The mean total laterotrusion capacity (right excursion + left excursion) gradually increased from 15.4 mm (SD 3.1 mm) at age four to 20.1 mm (SD 3.7 mm) at age 17. A statistical significant inter-gender difference of 0.8 mm (SD 0.4 mm) was observed in relation to the total laterotrusion capacity; however, the clinical relevance of this significant difference is questionable.

Conclusion: Normative values of maximal mouth opening capacity and laterotrusion capacity in individuals between four and 17 years of age were established. Our findings oppose the use of a single universal cut-off value for "normal" range of motion in children and adolescent patients. Instead we recommend including the age-related normative values of mandibular range of motion in the orofacial examination of patients with JIA.

Can DAS 28 at 3 Months after the 1st Biologic Therapy Predict Subsequent Sustainable Clinical Remission in Polyarticular Juvenile Idiopathic Arthritis Patients? Tomohiro Kubota[1], Syuji Takei[2], Tsuyoshi Yamatou[3], Tomokazu Nagakura[4], Hiroyuki Imanaka[3], Yukiko Nonaka[3], Tomoko Takezaki[3], Harumi Akaike[3] and Mio Matsuura[5]. [1]Kagoshima University Hospital, Kagoshima City, Japan, [2]Kagoshima University, Kagoshima, Japan, [3]Kagoshima University Hospital, Kagoshima, Japan, [4]House of Meguminoseibo, Usuki, Japan, [5]Kagoshima University, Kagoshima-Shi, Japan.

Background/Purpose: To avoid the progression of joint damage, early decision making is important in JIA patients who failed to achieve sustainable clinical remission by the 1st biologic agents. Therefore, we examined whether the scores of DAS 28 at 3 months after initiating the 1st biologic therapy can predict subsequent sustainable remission with the 1st biologic agents in the polyarticular JIA (pJIA) patients.

Methods: pJIA patients who had started the 1st biologic agents at the Kagoshima University Hospital were involved in this study. The patients were divided into two groups according to the subsequent efficacy of the 1st biologic agents; patients who successfully maintained clinical remission with the 1st biologic agents (remission group) and the patients who were eventually obliged to switch to the 2nd biologic agents due to the lack of efficacy (switching group).

Results: Scores of DAS28 of 14 pJIA patients involved in this study gradually improved after starting the 1st biologic agents. However, 6 of 14 patients (43%) failed to maintain their clinical remission and eventually switched to the 2nd biologic agents at 9 months (median, range 6–18 months) after initiating the 1st biologic agents (switching group). The rest of 8 patients (57%) achieved sustainable clinical remission with the 1st biologic agents (remission group).

There were no significant differences between the two patients' groups as to sex ratio, age at onset, disease duration at initiating biologics. However, Das28 score at 3 months of the 1st biologic therapy was significantly higher in switching group (1.75 ± 1.0) than that of remission group (3.8 ± 0.87)($p=0.001$) (Figure 1). The receiver operating characteristic (ROC) analysis revealed that the cut-off point of DAS28 to discriminate the two patients' group was 2.37 (sensitivity 100%, specificity 88.9%).

Conclusion: Evaluating DAS28 at 3 month after initiating biologic therapy was useful in predicting subsequent sustainable clinical remission. Patients with DAS28 >2.37 at 3 month after initiating the 1st biologic agents should be considered to switch to the 2nd biologic agents in the treatment of pJIA.

1869

Child Pain, Function, and Psychological Outcomes in an Intensive Interdisciplinary Pediatric Pain Rehabilitation Program. Cara Hoffart, Rawni Anderson, Amy Chapman, Brandi Dorton, Danielle Feltrop, Misty Wilson and Dustin Wallace. Children's Mercy Hospital, Kansas City, MO.

Background/Purpose: We examined the functional, psychological, and pain-related outcomes among children with chronic pain completing an intensive interdisciplinary pediatric pain rehabilitation program. We hypothesized that baseline psychological measures (i.e. anxiety, depression) will predict longer treatment course while baseline pain severity would not correlate with program duration in an interdisciplinary pain rehabilitation program.

Methods: This outpatient program provides 5–6 hours of daily intensive physical and occupational therapy in addition to yoga, self-regulation training, and behavioral health intervention. All pain medications are discontinued, and no invasive therapeutic procedures are utilized. 31 patients (27 female) age 11–18 with chronic musculoskeletal pain completed Functional Disability Inventory, 100 mm Visual Analog Scale, PROMIS Anxiety, Depression, and Mobility, PRCQ-catastrophizing, and the Pain Acceptance Questionnaire for Adolescents at baseline, the end of each week, and 28 have completed a one-month follow-up and 14 have completed a six-month follow-up. Paired samples *t*-tests and correlations were conducted with SPSS (V.20) and supplemented with hierarchical linear modeling (HLM7) for time-series analyses of pain, functioning, and psychological factors.

Results: The mean program duration was 3.7 (± 0.9) weeks, determined by achievement of functional goals. Using paired samples t-tests, current pain (VAS 0–100) significantly decreased from 59.1 to 36.7 ($P<0.001$) and 26.9 ($P=.004$) at 1- and 6-month follow-up, respectively. FDI improved from 27.3 to 13.8 between baseline and program end ($P<0.001$), and continues to improve at 1- and 6-month follow-up to 7.7 ($P<0.001$) and 4.4 ($P=.006$) respectively, reflecting increased physical ability. Patient reported anxiety and depression decline significantly ($P<0.001$), while pain acceptance increases significantly during treatment ($P<.001$). Treatment program duration correlated with greater baseline disability (FDI $r=.462$; $P=.009$), and presence of conversion symptoms ($r=.548$; $P=.004$). Patients with greater pain acceptance (CPAQ-A; $r=-.433$; $P=.015$) at baseline required shorter treatment intervention.

Conclusion: Children with chronic musculoskeletal pain successfully restore function and improve pain without pharmacotherapy. Baseline functional disability and psychological factors correlate with treatment program duration. Prospective studies are warranted to determine long-term efficacy and effectiveness of this interdisciplinary program.

Children and Parent Satisfaction in the Pediatric Rheumatology Clinic: Patient Orientated Quality Service Measures. Jenny Tekano[1], Lori B. Tucker[2] and Audrea Chen[3]. [1]BC Children's Hospital, Vancouver, BC, [2]BC Children's Hospital and University of British Columbia, Vancouver, BC, [3]research student, Vancouver, BC.

Background/Purpose: Patient satisfaction is a multidimensional concept, and is a component of quality care. Inclusion of patient experience with care is highly relevant in improving service delivery. There have been few attempts to measure satisfaction in the pediatric tertiary care setting, inclusive of child as well as parent assessment. We aimed to assess child and parent perspectives on their care in a multidisciplinary pediatric rheumatology outpatient service.

Methods: Parents and children (≥9 yrs) attending the Pediatric Rheumatology clinics over a 4 month period in 2013 at BC Children's Hospital, Vancouver, BC, were asked to complete a anonymous questionnaire to assess satisfaction with clinical care. The questionnaire items were addressing 3 general areas: 1) information 2) clinical care and services, 3) global impact of disease on children's quality of life. Separate parent and child questionnaires were given. Respondents were asked to rate agreement or disagreement with item statements on a 5 point Likert scale. There were 4 open ended questions asking most difficult issue in coping with disease, top likes and dislikes about the clinic services, and changes they would suggest in the clinic.

Results: 376 parents and 284 children completed the questionnaire, with patient diagnoses of juvenile idiopathic arthritis (146), systemic lupus, dermatomyositis or vasculitis (45), or other rheumatic disease (91). The majority of parents (92%) and children (85%) reported general satisfaction with care received, and most also felt their questions were answered in the clinic (parents 95%; children 87%). Although parents find written material provided in clinic helpful (80%), 40% of children do not find this information helpful. Only 22% of parents report they feel to be the best judge of whether their child requires treatment or a medication. Positive qualities of the staff (helpful, caring, friendly) were mentioned by a large number of parents (60%) and children (68%) in open ended questions about the clinic. Structural issues of clinic attendance (wait time, parking, travel) were issues reported by many parents and children. One quarter of parents and children report having a lot of pain due to their disease. 37% of children report being unable to fully participate in activities, and 29% report difficulty in school due to their illness. Physical restrictions, pain, and need for medications and procedures were the most frequent difficulties reported in open questions by children; parents reported feeling helpless and concern about unknown future as major difficulties for them in coping.

Conclusion: Children with rheumatic disease and their parents receiving care through a multidisciplinary pediatric rheumatology team expressed global satisfaction with care provided, particularly interpersonal aspects. Families and patients had difficulties with process quality measures. Results indicated gaps in understanding and engagement amongst children and teens, pointing towards a need to implement changes in this area. A critical analysis of patient and family experience is a valuable tool in ensuring that the services provided are tailored to the needs of patients and families.

Puberty and Disease Activity in JIA. Philomine A. van Pelt[1], Aike.a. Kruize[2], Anita C.S. Hokken-Koelega[3], Radboud JEM Dolhain[4], Johannes WJ Bijlsma[5] and Nico M. Wulffraat[5]. [1]Erasmus MC, Rotterdam, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands, [3]Erasmus Medical Center- Sophia Children's Hospital, Rotterdam, Netherlands, [4]Erasmus MC University Medical Center Rotterdam, Rotterdam, Netherlands, [5]University Medical Centre Utrecht, Utrecht, Netherlands.

Background/Purpose: Delayed puberty and decreased final length has been reported in chronic diseases like Crohn's disease and JIA with a disease onset at prepubertal age. This may be due to systemic effects of inflammation, undernutrition or medication, for example glucocorticoids or MTX. Treatment with anti TNF has shown to restore delayed growth in JIA.

Nowadays patients are treated intensively with disease modifying drugs including biologicals to reach remission. Our objectives are to describe growth, onset and progression of puberty in established JIA patients who are treated intensively.

Methods: All consecutive JIA patients aged 10 –24 years were asked to participate in this observational follow-up study. Demographic and disease related items were obtained yearly as well as Tanner puberty stages: Pubic Hair Girls (PHG), Breast stage (Bre), Menarche (Men), Pubic Hair Boys (PHB), Genital Stage (Gen). Reference Values were obtained from the Dutch National Growth Study. Median age at reaching each pubertal stage was estimated by Kaplan Meier survival estimates based on data from patients of Caucasian origin and younger than 21 years. The progression of puberty is defined as the difference in median age between the tanner stage 2 3&4 and 4&5. Parametric tests are used to determine differences between patients and healthy controls, non parametric tests are used to determine differences between patient groups.

Results: 138 patients were included; 91 girls (66%) and 47 boys (34%). Ten percent have systemic onset type of JIA, 24% oligo- persistent, 55% oligo-extended and polyarticular course, 11% other subtypes of JIA.

Median disease duration is 7,8 years (IQR 6,7). Median JADAS27 is 3,7 (IQR 6,7), median active joint count is 0,0 (2,0), median DAS 28 is 2,16 (1,30). MTX is used in 79% of the patients, anti TNF in 14% and systemic corticosteroids in 23%. Median SDS length is −0,29 (IQR 1,38), SDS weight −0,27 (1,46), SDS BMI −0,08 (1,71). PHG, Bre, PHB and Gen are delayed in all stages 2–5, more pronounced in stage 5. Median delay compared to healthy controls in PHG stage 5 is 3,4 years, in Bre stage 5 3,4 years, in Menarche 3,5 years, in PHB stage 5 1,6 years and in Gen stage 5 1,7 years. The progression of puberty was delayed between all stages in both girls and boys, most markedly delay was seen between stage 4&5 of PHG and Bre. No significant differences are seen between users and non-users of systemic corticosteroids, MTX or biologicals. Subtype of JIA, disease activity and age at onset did not significantly influence results.

Conclusion: Due to intensive treatment, disease activity in JIA patients is low and growth is comparable to healthy age related persons. However, puberty is still remarkably delayed. Further investigation into clinical relevance and cause of delayed puberty is needed.

This study was funded by Dutch Arthritis Foundation

ACR Concurrent Abstract Session
Epidemiology and Public Health III: Gout and Systemic Lupus Erythematosus

Monday, November 17, 2014, 4:30 PM–6:00 PM

1872

Gout in Older Adult. Mara McAdams-DeMarco[1], Anna Kottgen[2], Bridget Burke[3], Andrew Law[4], Josef Coresh[1] and Alan N. Baer[5]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]University Hospital Freiburg, Freiburg, Germany, [3]Johns Hopkins University, Baltimore, MD, [4]Johns Hopkins, Baltimore, MD, [5]Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: To evaluate whether traditional and genetic risk factors in middle-aged members of a longitudinal population-based cohort predict the onset of gout in older age.

Methods: We studied the incidence and prevalence of gout in white older adults using the Atherosclerosis Risk in Communities Study, a prospective US population-based cohort study of middle-aged adults enrolled between 1987–1989 with ongoing follow-up. A genetic urate score (GUS) was formed from common urate-associated single nucleotide polymorphisms for eight genes. The adjusted hazard ratio (HR) and 95% confidence intervals (CI) of incident gout by traditional and genetic risk factors in middle age were estimated using a Cox Proportional Hazards model.

Results: Of the 9,526 participants, 46.2% were male and the mean (SD) age at cohort enrollment was 54.0 (5.7). The overall prevalence of gout was 8.9%; 31.9% of those with a history of gout reported a physician diagnosis of this inflammatory arthritis at age 65 or older. By age 65 the prevalence of gout was 9.0% for men and 3.3% for women, conditioned on survival to age 65. The cumulative incidence from middle age to age 65 was 8.6% in men and 2.5% in women as well as 8.0% for those in the 4th quartile of GUS, 5.0% for those in the 3rd quartile, 3.8% for those in the 2nd quartile and 3.3% for those in the 1st quartile, conditioned on survival to age 65 (Figure). In middle age, increased adiposity, beer intake, protein intake, smoking status, hypertension, diuretic use, and kidney function (but not sex) were associated with an increased risk of gout in older age. In addition, high genetic risk (100 μmol/L increase in GUS) was associated with a 3.29-fold (95% CI: 1.63, 6.63) increased risk of gout in older age.

Conclusion: In this US population-based cohort, traditional risk factors that were present in middle-age were associated with the development of gout in older age.

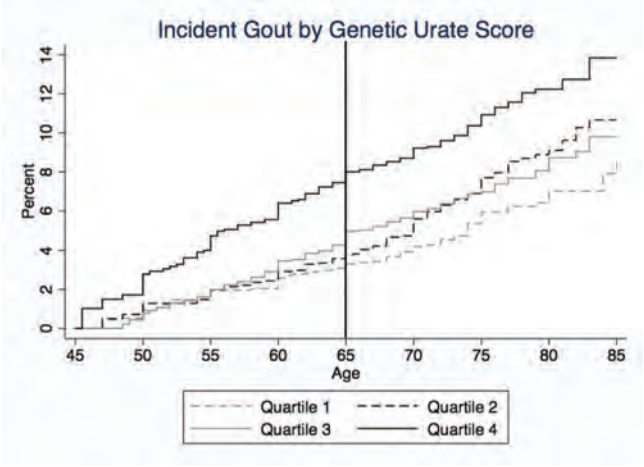

Figure: Cumulative incidence of gout by quartile of genetic urate score. The incidence of gout for participants of ARIC was estimated using a Kaplan-Meier approach. All cumulative incidences (%) should be interpreted as the percentage of participants with gout, conditioned on survival to that age. The genetic urate score is measured in μmol/L. Quartile 1 of the genetic urate score ranges from −59.1 to −13.1; quartile 2 from −13.2 to 0.3; quartile 3 from -.4 to 12.0 and quartile 4 from 12.1 to 60.8.

Food Sources of Protein and Risk of Incident Gout in the Singapore Chinese Health Study. Gim Gee Teng[1], An Pan[2], Jian-Min Yuan[3] and Woon-Puay Koh[4]. [1]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, [2]Saw Swee Hock School of Public Health, National University of Singapore, Singapore, Singapore, [3]Division of Cancer Control and Population Sciences, University of Pittsburgh Cancer Institute, and Department of Epidemiology, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, [4]Duke-NUS Graduate Medical School Singapore, Singapore, Singapore.

Background/Purpose: The Health Professional Follow up Study in Caucasian men showed that intakes of meat and seafood increased risk of gout, while dairy products, especially low-fat dairy products, reduced the risk (1). Purine rich vegetable intake had no association with incident gout (1). Studies evaluating diet on gout risk in Asian populations are lacking. Most of these studies focused on alcohol intake and evaluated on hyperuricemia rather than gout as the dependent variable. We examined the relation of dietary protein and protein sources with incident gout among Chinese men and women.

Methods: We used data from the Singapore Chinese Health Study, a prospective cohort study with 63,257 Chinese adults aged 45–74 years at recruitment from 1993 to 1998. Dietary information was collected via a validated food frequency question, and physician-diagnosed gout was self-reported during the two follow-up visits of 1999–2004 and 2006–2010. We conducted analysis among 51,114 participants without gout at baseline and who responded to the follow-up questionnaires. Cox proportional hazards models were used to calculate the relative risk (RR) and 95% confidence interval (CI) with adjustment for potential confounding factors, including age, sex, alcohol intake, body mass index and hypertension. All multivariate models were further adjusted for protein sources.

Results: Among 51,114 subjects interviewed at either or both interviews, after a mean follow-up of 11.1 (SD 3.7) years, there were 2,167 incident gout cases with mean age of onset at 61.3 (SD 8.1) years. Participants with gout were more likely to be men, more highly educated, ever smokers, weekly or daily alcohol drinkers and to have higher BMI then those without gout. 36.8% of gout subjects had hypertension compared with 21.4% among those without gout. Compared to the lowest quartile intake, the multivariate-adjusted RRs (95% CI) of incident gout in the highest quartile were 1.27 (1.12–1.44) for total protein (P_{trend}=0.001); 1.28 (1.12–1.47) for poultry (P_{trend}=0.001); and 1.16 (1.02–1.32) for fish and shellfish (P_{trend}=0.014). Conversely, intakes of soy and other legumes were associated with reduced risk, the RR (95% CI) in the highest quartile intake being 0.87 (0.77–1.00) for soy foods (P_{trend}=0.01) and 0.85 (0.74–0.97) for legumes (P_{trend}=0.02). There was no association between intake of red meat (including pork), eggs, dairy products, grain products, nuts and seeds, and risk of gout. There was no significant interaction between sex, BMI, history of hypertension, smoking and alcohol consumption status, and intake of foods on risk of gout.

Conclusion: Total protein intake, mainly contributed by poultry, fish and shellfish, was associated with increased risk of gout in this population. Conversely, soy and legume foods may be related to reduced risk of gout. The general advice of replacing red meat with "white meat" such as poultry may

not be advisable. Myths of deleterious effect of soy and legume intake on gout may be debunked. Other health benefits of soy plus a possible protective effect on gout makes it a plausible vegetable-based meat substitute.

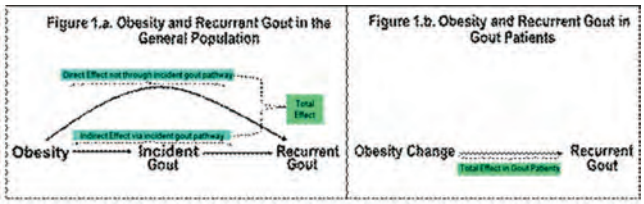
Obesity Paradox in Recurrent Gout – a Metrological Clarification and Remedy. Uyen Sa D.T. Nguyen[1], Qiong Louie-Gao[1], Yuqing Zhang[1], David T. Felson[1], Michael P. Lavalley[2] and Hyon Choi[3]. [1]Boston University School of Medicine, Boston, MA, [2]Boston University, Boston, MA, [3]Harvard Medical School, Boston, MA.

Background/Purpose: Obesity is a strong risk factor of incident gout, but previous research showed no such association with recurrent gout among gout patients. These paradoxical findings occur because the causal net effect (**i.e.,** *total effect*) of obesity on recurrent gout in gout patients cannot be validly estimated using conventional methods. We demonstrate that the paradox can be clarified using an appropriate mediation analysis, and illustrate a design to estimate the total effect of BMI on recurrent gout in incident gout patients.

Methods: We used data from the Multiple Risk Factor Intervention Trial (MRFIT), prospectively collected at baseline and annually over 7 years. BMI at baseline was categorized as: >30 kg/m^2(obese), 25–29.9 (overweight), and <25 (normal) and self-report of physician-diagnosis of gout was our outcome. We followed subjects without gout at baseline to determine the first occurrence of gout and their recurrent gouts by the 84-month visit. We assessed the effect of BMI on recurrent gout with the conventional method of restricting on incident gout patients and using logistic regression. We then clarified the paradox using marginal structural modeling (MSM) for mediation analysis. We estimated the total effect of BMI on recurrent gout by decomposing the *total effect* into its components **(Figure):** the *indirect effect* of BMI via its effect on incident gout, and the *direct effect* of BMI on recurrent gout not through its effect on incident gout. Finally, we determined the association of change in BMI categories **before and after** incident gout on risk of recurrent gout among incident gout patients. All analyses were adjusted for known confounders.

Results: Of 11,655 subjects without gout at baseline (mean age 46 years; 21% normal, 56% overweight, 23% obesity), 408 people developed incident gout, and 131 had recurrent gout. Conventional method showed that the adjusted odds ratio (OR) for recurrent gout was 1.10 (95%CI: 0.52,2.30) for obese compared with normal BMI (**Table**). Using MSM, the *indirect effect* of obesity compared with normal-weight on risk of recurrent gout (via its effect on incident gout) was 2.62 (95%CI:2.01,3.40); the *direct effect* not through incident gout was 1.13 (95%CI:0.82,1.56); and the *total effect* was 2.94 (95%CI:1.59,5.41) (**Table**). Among incident gout patients, the adjusted total effect of increasing BMI after incident gout on risk of recurrent gout was 1.84 (95%CI:1.02,3.32) (**Table**).

Conclusion: We showed that the effect of obesity at baseline on risk of recurrent gout is almost entirely through its effect on incident gout. Conditioning on incident gout and estimating the effect of baseline obesity on the risk of recurrent gout would provide only an estimate of its direct effect, as the indirect effect is blocked. In order to examine the total effect of obesity on recurrent gout in those with incident gout, BMI change must be assessed before and after incident gout.



Obesity and Recurrent Gout in the General Population*							Conventional Method*	Obesity and Recurrent Gout in Gout Patients*

Can Allopurinol Survival Impact Reverse Depending on Patients' Characteristics? a Propensity-Score-Based Subgroup Analysis. Na Lu[1], Hyon Choi[2], Maureen Dubreuil[3], Qiong Louie-Gao[1] and Yuqing Zhang[1]. [1]Boston University School of Medicine, Boston, MA, [2]Harvard Medical School, Boston, MA, [3]Boston University Medical Center, Boston, MA.

Background/Purpose: Several studies have reported that allopurinol use is associated with a decreased risk of death or cardiovascular outcomes. While these studies reported the overall average effect of allopurinol, the impact may vary depending on the patients' characteristics. This line of research could help identify patients who will get the greatest benefit from allopurinol use, as well as those who may face a hazardous impact (thus conferring a patient-oriented, personalized medicine approach). To address these issues, we assessed whether the survival impact of allopurinol varies across the distribution of propensity scores (PS) in a general population-based cohort study.

Methods: We conducted an incident user cohort study with PS matching using a UK general population database. Eligible subjects were aged ≥40 years and had a record of hyperuricemia (serum urate >357 μmol/L for women and >416 μmol/L for men) between January 2000 and May 2010. For each 6-month period during the study follow-up, each allopurinol initiator was matched to a non-initiator by PS using the greedy-matching method. Subjects were followed until death, loss to follow-up, or the study period ended, whichever came first. We calculated the all-cause mortality rate and examined the association of allopurinol initiation with the risk of mortality using a Cox proportional hazard model. We then examined whether the effect of allopurinol varied across PS level categories (Table).

Results: Our study included 6,947 allopurinol initiators and 6,947 non-initiators. All measured potential confounders were evenly distributed between the two groups. The mortality rate was 39/1000 person-years in allopurinol initiators and 46/1000 person-years in non- initiators, resulting in an overall HR of 0.86 (95% CI: 0.78–0.96). Our subgroup analysis by PS showed a reversal of HR from hazardous in the lowest PS groups (HR of the lowest PS group, 1.67) to increasingly protective with higher PS groups (HR of the highest PS group, 0.65) (**Table**). The most obvious difference in patient characteristics between the top and bottom 20th percentile PS groups was the presence of gout (>98% vs. 38%), suggesting that treatment of gout patients is life-saving (compared to the hazardous impact of treating asymptomatic hyperuricemia).

Conclusion: Our findings suggest that the association of allopurinol with the risk of all-cause mortality may vary widely from conferring a protective versus hazardous impact, according to patients' characteristics (reflected in PS). However, a potential alternative explanation may be extreme levels of residual confounding. Nevertheless, if confirmed, these potentially opposite subgroup effects would help to identify individuals who will receive the maximum benefit from allopurinol, thus helping to achieve a germane patient-oriented, personalized medicine approach in this common practice context.

Table 1. Risk of Mortality Associated with Initiation of Allopurinol According to Propensity Score Categories

Propensity score percentile	Mean propensity score*	Allopurinol Initiator				Allopurinol Non-Initiator				
		No.	Death	Person-Year	IR	Death	Person-Year	IR	IRR	HR

Influence of Alcohol Consumption on the Risk of SLE Among Women in the Nurses' Health Studies. Medha Barbhaiya, Bing Lu, Shun-Chiao Chang, Jeffrey A. Sparks, Elizabeth W. Karlson and Karen H. Costenbader. Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Prior case-control studies have reported an inverse association between moderate alcohol consumption and the development of SLE. However, case-control studies may be prone to recall bias and reverse causation. A prior prospective study did not demonstrate an association between alcohol intake and SLE development, although this study was limited by small sample size (34 confirmed cases, Formica MK et al, *J Rheum*, 2003). We assessed the association between alcohol consumption and risk of SLE among women followed in the Nurses' Health Study (NHS) and NHSII. We hypothesized that alcohol consumption, possibly through anti-inflammatory effects, would be associated with lower risk for SLE compared to no alcohol consumption.

Methods: The NHS enrolled 121,701 U.S. female registered nurses in 1976. NHS II began in 1989, enrolling 116,430 female nurses. Lifestyle and environmental exposures were collected through biennial questionnaires. Alcohol consumption was assessed with a semi-quantitative food frequency questionnaire completed every 4 years. Participants in NHS and NHSII who provided alcohol data at baseline (1980 in NHS and 1989 in NHSII) were included. Cumulative average alcohol consumption until 2–4 years prior to SLE diagnosis date (for cases) across repeated measures was used instead of one-time measure to best represent long-term alcohol consumption. The incident SLE cases were identified using the connective tissue disease screening questionnaire (CSQ), followed by medical record review. Cox proportional hazards models were used to assess associations, after controlling for time-varying covariates. HRs from the two cohorts were meta-analyzed using DerSimonian and Laird random effects models.

Results: 118 incident SLE cases developed in NHS from 1980–2008, and 92 incident SLE cases developed in NHSII, 1991–2009. Mean age at diagnosis was 53.6 (± 8.2) years in NHS and 43.4 (± 5.7) in NHSII. Most SLE cases (97% in NHS, 100% in NHSII) were ANA positive, while 33% of NHS SLE cases and 53% of those in NHSII had a positive anti-dsDNA antibody test at diagnosis. In both NHS and NHSII, there was a suggestion of a protective effect of alcohol intake on risk of SLE, although it was not statistically significant (**Table**). Meta-analysis of the multivariable-adjusted results from both cohorts demonstrated a suggested protective effect of alcohol consumption in women who consume >0 to 10 gms/day (HR 0.75, 95%CI 0.54, 1.04) and >10 gms/day (HR 0.61,95% CI 0.37, 1.01).

Conclusion: In these large prospective cohorts of women followed for many years before the diagnosis of SLE, we found a potential protective association between long-term alcohol consumption and reduced risk of developing SLE. Further studies are needed to confirm these findings.

1877

Pregnancy Outcomes in SLE: Before and after. Elizabeth V. Arkema[1], Kristin Palmsten[2], Christopher Sjöwall[3], Elisabet Svenungsson[4], Jane E. Salmon[5] and Julia F Simard[6]. [1]Karolinska Institutet, Stockholm, Sweden, [2]University of California, San Diego, La Jolla, CA, [3]Linköping University, Linköping, Sweden, [4]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [5]Hospital for Special Surgery, New York, NY, [6]Stanford School of Medicine, Stanford, CA.

Background/Purpose: Numerous investigators have demonstrated that the risks of pre-eclampsia, preterm delivery, and fetal death are increased in lupus pregnancies. Adverse events during pregnancy, delivery, and the post-natal period occur for many reasons, and it is often unclear whether they are SLE-related. Furthermore, it is well established that before the clinical diagnosis of SLE, pathogenic autoantibodies are present in individuals who eventually develop lupus, and they may drive inflammation.

Given the challenges in identifying and accessing a proper comparator group, most published work has focused on clinical cohorts and case series. A few studies that used national or population-based data to answer such questions face different methodological limitations - particularly SLE misclassification due to use of a single ICD code to define cases. This work compares pregnancies and outcomes in women with SLE using a stricter classification and considers outcomes in women whose SLE is believed to onset after pregnancy.

Methods: Data from a matched cohort of individuals with SLE and the general population using national Swedish registers were linked to the Medical Birth Register (MBR) to identify all pregnancies between 1973 and 2011. SLE was defined as ≥2 SLE ICD codes in the Patient Register (PR) with ≥1 SLE code from a specialist. We restricted to first pregnancy and excluded multiple gestations. Using the first observed SLE interaction with the health care system as a proxy for diagnosis, we categorized SLE as prevalent at birth (n=604), incident within 0–2 (n=72) and 2–5 years (n=135) after birth, and none (n=18229). Maternal health and delivery characteristics were obtained from the MBR, PR, and Death Register. Outcomes included pregnancy morbidity such as pre-eclampsia, maternal death, size for gestational age, APGAR scores, and stillbirth. We compared frequency of outcomes by SLE exposure at pregnancy/birth (prevalent, in 0–2y, in 2–5y, and none). Modified Poisson regression with robust error variance estimated risk ratios and 95% CI with SLE as exposure for maternal and fetal outcomes adjusted for maternal age and other a priori determined confounders.

Results: Patients with SLE were more likely to have poorer pregnancy outcomes including small for gestational age (SGA), preterm deliveries, pre-eclampsia, stillbirths, and lower one minute APGAR compared to the general population. For many outcomes we saw a trend where the closer to pregnancy the diagnosis of SLE was made (with prevalent SLE being most proximal) the higher the risk of poor outcomes (**Figure**).

Conclusion: Maternal SLE is associated with adverse outcomes to mothers and their newborn. Mothers whose SLE presented shortly after pregnancy also had higher risk of these outcomes compared to pregnancies and births from the general population.

ACR Concurrent Abstract Session
Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes II: Clinical Perspectives
Monday, November 17, 2014, 4:30 PM–6:00 PM

1878

A Combination of Celecoxib and Famciclovir Is Efficacious in the Treatment of Fibromyalgia: Results of a Phase IIa Randomized, Double-Blind, Placebo-Controlled Study. William Pridgen[1], Carol Duffy[2], Judith Gendreau[3] and R Michael Gendreau[3]. [1]Innovative Med Concepts, Tuscaloosa, AL, [2]University of Alabama, Tuscaloosa, AL, [3]Gendreau Consulting, LLC, Poway, CA.

Background/Purpose: Fibromyalgia (FM) is a common chronic pain syndrome with symptoms that include widespread pain, fatigue, sleep disruption and cognitive impairment. It is known that infections and other types of stressors are capable of triggering the development of FM. We hypothesize that these stressors could be responsible for triggering a reactivation of latent herpesviruses, and that this reactivation could in turn lead to the central nervous system dysregulation seen in this condition. The present study was designed to evaluate an anti-viral drug combination selected for activity against herpes class viruses.

Methods: A total of 143 patients selected using the ACR 2010 FM criteria were enrolled at 12 sites in a 16-week, double-blind, placebo-controlled trial. Patients were randomized (1:1) to receive a proprietary combination of celecoxib + famciclovir or placebo. Outcome measures included a 24-hour recall pain numeric rating scale (NRS), Fibromyalgia Impact Questionnaire (FIQ-R), Patient Global Impression of Change (PGIC), and the PROMIS fatigue short form at baseline, and after 6, 12 and 16 weeks of study participation.

Results: The primary efficacy endpoint was change in pain from baseline. Pain reduction was evaluated using the pain NRS and the 7-day recall pain item from the FIQ-R. Change from baseline was determined using an MMRM approach with LOCF/ BOCF imputation for missing data. A significant decrease in pain was observed for patients on treatment vs. placebo at 16 weeks by both measures. The absolute change on the NRS was −1.9 units vs −1.1, comparing active to placebo (p=0.031). On the FIQ-R item, the change was -2.2 vs −0.92 (p=0.001). Key secondary endpoints included analysis of the PGIC, where a value of "1" or "2" was considered a clinical responder. Significantly improved PGIC response rates were noted at endpoint: 33.3% for active vs 19.2% in placebo patients (p=0.031). Total FIQR score change at the endpoint visit was −17.54 vs −7.87 (p=0.002), while changes in the 3 domains were 14.29 vs −5.44 (p=0.004) for Function, −4.29 vs −1.89 (p=0.003) for Overall Impact, and −16.77 vs −7.90 (p=0.004) for Symptoms. In addition, improvements in fatigue were seen at endpoint on the PROMIS fatigue (−7.62 units vs −4.15; p=0.020).

The safety profile was especially encouraging. Despite the celecoxib component, gastrointestinal and nervous system treatment emergent adverse events were reported significantly more often in the placebo treatment group (GI: 29.0% vs 42.5%; nervous system: 17.4% vs 23.3%; active to placebo), and study completion rates favored active treatment over placebo (82.6% vs. 60.8%) (largely driven by higher placebo discontinuation rates due to adverse events and lack of efficacy).

Conclusion: A proprietary combination of famciclovir, which we postulate is inhibiting herpesvirus replication, and celecoxib, known to inhibit both herpesvirus replication and reactivation, was efficacious in treating multiple symptoms of FM. Given the simultaneous improvement in many domains and the surprising tolerability of this combination of drugs, we believe this combination warrants further study as a potential new therapy for fibromyalgia patients.

1879

The Efficacy of Pregabalin for Treating Fibromyalgia Patients with Moderate or Severe Baseline Widespread Pain. Andrew Clair and Birol Emir. Pfizer Inc, New York, NY.

Background/Purpose: Pregabalin has demonstrated efficacy for the treatment of fibromyalgia (FM), but insufficient evidence exists on how the efficacy of pregabalin may differ by baseline pain severity. The objective of these analyses was to assess the efficacy of 12 weeks of pregabalin treatment to provide symptomatic pain relief in FM patients with moderate or severe baseline pain scores.

Methods: These analyses used data from 5 Phase III clinical trials ranging between 8–15 weeks of pregabalin versus placebo (study numbers 1008105, A0081056, A0081077, A0081100, A0081208) to evaluate the efficacy of pregabalin at doses of 300 mg/day, 450 mg/day, or flexible dosing (300–450 mg/day BID) for the treatment of FM. FM was defined by ACR 1990 criteria at screening of widespread pain ≥3 months and pain in ≥11 of 18 specific tender point sites. Patients were adult (aged ≥18 years), with mean baseline pain scores that were classified as moderate (≥4–<7) or severe (≥7–10) and a score ≥40 mm on the Visual Analog Scale of Short-form McGill Pain Questionnaire. A mixed effects model repeated measures analysis was used to estimate change in pain at 12 weeks after treatment initiation by baseline severity (moderate or severe) and treatment.

Results: Overall, 679 (300 mg/d pregabalin), 670 (450 mg/d pregabalin), 250 (flexible dosing pregabalin), and 927 (placebo) patients were evaluated. The results of change in pain score at 12 weeks are displayed in the figure.

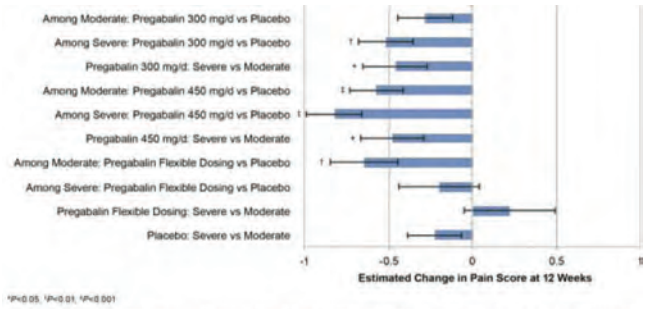

Figure. Estimated mean (SE) differences in change in pain score at 12 weeks in FM patients with moderate or severe baseline pain treated with pregabalin or placebo.

Among patients who had moderate baseline pain, significantly larger mean ± SE reductions in pain score were observed with pregabalin versus placebo at doses of 450 mg/d (−0.572 ± 0.161, $P<0.001$) and flexible dosing (−0.647 ± 0.203, $P=0.002$) with a non-significant reduction at the 300 mg/d dose (−0.282 ± 0.165). Patients with severe baseline pain showed significant improvements over placebo with pregabalin doses of 300 mg/d (−0.516 ± 0.164, $P=0.002$) and 450 mg/d (−0.822 ± 0.165, $P<0.001$), but not with flexible dosing (−0.200 ± 0.242). When patients were grouped by pregabalin dose assignment, patients with severe baseline pain exhibited greater improvements in pain score than patients with moderate baseline pain with 300 mg/day (−0.461 ± 0.191, $P=0.016$) and 450 mg/day doses (−0.476 ± 0.189, $P=0.012$), but not with flexible dosing (+0.220 ± 0.272).

Conclusion: Pregabalin is efficacious at 12 weeks of treatment in reducing pain in FM patients with baseline moderate pain and severe pain severity, with reductions that appear larger in patients with severe pain. The trend of larger changes following flexible dosing in patients with moderate versus severe baseline pain scores comes from a study of Japanese patients and additional research would be required to determine if this may be accounted for by differences in the average daily dose.

1880

Moderate Alcohol Consumption Is Associated with Lower Risk (and severity) of Chronic Widespread Pain: Results from a Population-Based Study. Gary J. Macfarlane and Marcus Beasley. University of Aberdeen, Aberdeen, United Kingdom.

Background/Purpose: Amongst patients with fibromyalgia, alcohol consumption has been reported in a single clinical study to be associated with lower severity of symptoms. This study aimed to a) determine whether alcohol consumption is associated with the reporting of chronic widespread pain (CWP) in an unselected population sample, and whether a dose-risk relationship is evident; b) amongst persons with CWP confirm whether the level of reported alcohol consumption is associated with symptom severity.

Methods: The MUSICIAN study sampled patients, aged over 25 years, registered at general practices in two areas of Great Britain. Information, collected by postal questionnaire, included current pain and usual alcohol consumption. Respondents were classified according to whether they satisfied the definition of chronic widespread pain (CWP) in the ACR 1990 criteria for fibromyalgia. Pain intensity and disability was measured by the Chronic Pain Grade and disabling pain defined as grade III or IV. Respondents reported whether they had ever drunk alcohol regularly and if so how much they currently drank per week (in units). Potential confounders of the relationship collected were: age, body mass index, employment status and amount smoked. Analysis was by logistic regression with those who had never regularly consumed alcohol as the referent group compared with 0–5, 6–10, 11–12, 21–35, 35+ units/week.

Results: 13587 persons participated (mean age 55 yrs, 57% female) of which 2060 reported CWP and answered the questions on Chronic Pain Grade. There was a significant relationship between level of alcohol consumption and risk of reporting CWP. Risk decreased with increasing consumption with the lowest risk amongst those consuming 21–35 units/week (OR 0.61; 95% CI 0.50–0.75) while those consuming higher amounts did not have a reduced risk. This protective effect persisted after adjustment with only minor attenuation of effect (21–35 units/week 0.63; 0.51, 0.78). The effect was evident in both males and females. Amongst persons with CWP there was a strong and significant relationship between increasing alcohol consumption and lower likelihood of disability (table) which was not explained by measured confounders.

Number of units per week	CPG I/II	CPG III/IV	OR	Adjusted OR
Never drunk regularly	353 (52.9%)	314 (47.1%)	1.00	1.00
0 to 5	396 (67.1%)	194 (32.9%)	0.55 (0.44–0.69)	0.63 (0.49–0.82)
6 to 10	283 (75.5%)	92 (24.5%)	0.37 (0.28–0.48)	0.46 (0.34–0.63)
11 to 20	216 (82.1%)	47 (17.9%)	0.24 (0.17–0.35)	0.33 (0.22–0.49)
21 to 35	96 (81.4%)	22 (18.6%)	0.26 (0.16–0.42)	0.30 (0.17–0.52)
More than 35	23 (48.9%)	24 (51.1%)	1.17 (0.65–2.12)	0.67 (0.32–1.40)

Conclusion: Moderate alcohol consumption was associated with a lower prevalence of CWP and associated with markedly lower levels of disability in those with CWP. One possible mechanism is through alcohol's agonist effects on the neurotransmitter γ-aminobutyric acid (GABA) and disruptions to GABA pain inhibitory pathways have been suggested in persons with fibromyalgia. Another is through the psychological benefits of alcohol including stress relief and mood enhancement. However alcohol consumption as a marker for other lifestyle factors, or that people avoided alcohol because of their pain and disability, cannot be excluded.

Patients Who Fail Biologics Are More Likely to Have Concomitant Fibromyalgia. Robert S. Katz[1] and Jessica L. Polyak[2]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL.

Background/Purpose: One area not assessed by studies to evaluate the efficacy of new medications in patients with inflammatory arthritis is whether the patient may have concomitant fibromyalgia. This may well impact response to treatment. We evaluated whether patients who have inflammatory arthritis and failed various biologic therapies were more likely to also have fibromyalgia.

Methods: Patients taking biologics were evaluated in a rheumatology office practice. We determined patients whether they responded or failed various biologic therapies. Diagnoses included rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, and lupus.

Results: 219 patients in a rheumatology office practice taking biologic response modifiers were divided into those with inflammatory arthritis (RA/PsA/AS/SLE) who were thought to have concomitant fibromyalgia (36pts, 16.4%) and those with only inflammatory arthritis but without fibromyalgia (183pts, 83.5%).

Of the patients with inflammatory arthritis or lupus with concomitant fibromyalgia, those who failed 2 or more biologics was 15, (41.7%). Patients with inflammatory arthritis or lupus but without concomitant fibromyalgia who failed 2 or more biologics was 41 pts (22.4%).

Conclusion: Patients who failed biological therapies often had concomitant fibromyalgia. This may be a significant factor in the lack of efficacy of these drugs. Whereas they may control the symptoms of inflammatory disease and patients get partial satisfaction, the fact that they want to try other biologic therapy may be due, in part, to the presence of concomitant fibromyalgia. This should be assessed in future studies to evaluate new medications for patients with inflammatory joint disease.

Disclosure: R. S. Katz, None; **J. L. Polyak**, None.

Examination of Patients Newly Diagnosed with Fibromyalgia: Use of Guideline-Recommended Therapies and Opioids in Clinical Practice. Sonali N. Shah[1], Rachel Halpern[2], Joseph C. Cappelleri[3], Elizabeth T. Masters[4], Andrew G. Clair[1], Cori Blauer-Peterson[2] and Damon Van Voorhis[5]. [1]Pfizer, Inc., New York, NY, [2]Optum, Eden Prairie, MN, [3]Pfizer, Inc., Groton, CT, [4]Pfizer Inc, New York, NY, [5]Optum Life Sciences, Eden Prairie, MN.

Background/Purpose: Fibromyalgia (FM) affects 2–5% of adults in the United States. Pregabalin (antiepileptic drug [AED]), and duloxetine and milnacipran (serotonin and norepinephrine reuptake inhibitors), are approved to treat FM. FM treatment guidelines also include gabapentin (AED), amitriptyline (tricyclic antidepressant), selective serotonin reuptake inhibitors (SSRIs), and tramadol; in general, opioids, particularly strong opioids, are not recommended. This study evaluated treatment patterns of recommended and non-recommended medications among patients newly diagnosed with FM.

Methods: This retrospective study used medical and pharmacy claims data and enrollment information for adult commercial health plan members of a large US health plan. Patients had ≥2 medical claims with a diagnosis (dx) of FM from January 2008-February 2009; the date of the first FM dx was the *index date*. Patients also had: 6 months of pre-index and 12 months of post-index continuous enrollment; no pre-index FM dx; and ≥1 pharmacy claim for an FM guideline medication (pregabalin, gabapentin, duloxetine, milnacipran, amitriptyline, or SSRI) or for an opioid on or within 6 months after the index date. The date of the first medication (Rx) was the *treatment date*. The principal outcomes were indicators identifying patients with ≥1 fill of an FM guideline Rx or opioid during each 3-month interval (quarter) of the 12-month post-index period. Descriptive analysis was conducted.

Results: The study sample was 96,175 patients with mean age 47.3 years and 72.5% female. Fifty-six percent of patients were prescribed opioids on their treatment dates and 44% received an FM guideline Rx; 17% of opioid recipients were prescribed tramadol. The figure shows that 55% of patients were prescribed opioids only or opioids as well as FM guideline Rx in the first quarter after FM dx. The percentage of patients with FM guideline Rx (with or without opioids) was consistent through the post-index period. The percentage of patients who received opioids only decreased over time. However, >20% of patients were treated only with opioids in each quarter and an additional 18% received opioids in addition to FM guideline Rx.

Conclusion: In the 12-month post-index, a substantial proportion of patients were prescribed opioids and more than half did not receive FM guideline Rx. These real-world utilization results indicate that an opportunity may exist for improved FM management using recommended therapies in clinical practice.

Differential DNA Methylation Associated with Rheumatoid Arthritis in Disease Discordant Monozygotic Twins. Amy Webster[1], Flore Zufferey[2], Darren Plant[3], Anne Barton[4], Frances Williams[2] and Jane Worthington[5]. [1]Arthritis Research UK Centre for Genetics and Genomics, The University of Manchester, Manchester, United Kingdom, [2]Dept Twin Research and Genetic Epidemiology, Kings College London, London, United Kingdom, [3]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academy of Health Sciences, Manchester, United Kingdom, [4]Arthritis Research UK Centre for Genetics and Genomics, University of Manchester, Manchester, United Kingdom, [5]The University of Manchester, Manchester, United Kingdom.

Background/Purpose: Previous epigenetic studies of rheumatoid arthritis (RA) using prevalent cases and unrelated controls have indicated that DNA methylation is altered in patients with RA. However case control studies of unrelated individuals do not allow matching for important confounders such as the underlying genetic variability and environmental exposures, which may influence disease development and the epigenome. By investigating DNA methylation differences in disease discordant monozygotic (MZ) twins, such confounding effects may be mitigated, increasing the power to detect alterations to the methylome which might be associated with RA.

Objectives: To identify a DNA methylation signature in RA using disease discordant monozygotic twins.

Methods: Twin subjects were recruited from the Rheumatoid Arthritis Twin Study (Manchester) and TwinsUK (London). Each twin pair included one twin classified as having RA according to established classification criteria (n=63) while the other was classified as not having RA (n=63) at the time samples were collected. Whole blood DNA was bisulfite converted and an epigenome-wide association study was performed using the HumanMethylation450 BeadChip (Illumina). A detection threshold was applied and probes with a detection-p value >0.01 were removed. Differentially methylated positions (DMPs) were identified using linear regression following quantile normalisation.

Results: 30 CpG sites were differentially methylated at a false discovery rate of 10%. One of the most significant DMPs, cg07693617 ($p=1.05\times10^{-6}$) lies in the *PRKCZ* gene which contains 22 differentially methylated CpG sites in the gene body and 5' UTR. Interestingly this gene was found to be hypermethylated in RA fibroblast-like synoviocytes in a previous epigenome-wide association study.

Conclusion: This is the largest study to date of DNA methylation in RA discordant MZ twin pairs. We have identified 30 CpG sites with a potential role in RA development and added to the evidence for an association at PRKCZ. While further validation and replication studies are required, these preliminary data support the hypothesis that DNA methylation is altered in patients with RA and provides a plausible biological mechanism to account for the observed twin discordance in RA.

Integrative Omics Profiling Reveals Dysregulated Novel Pathways Mediated By microRNAs and DNA Methylation in Osteoarthritis. Kathleen M. Fisch[1], Ryuichiro Akagi[2], Oscar Alvarez-Garcia[1], Takeshi Teramura[1], Yuta Muramatsu[1], Masahiko Saito[3], Stuart Duffy[1], Shawn Grogan[1], Takahisa Sasho[4], Darryl D'Lima[1], Andrew I. Su[1] and Martin K. Lotz[1]. [1]The Scripps Research Institute, La Jolla, CA, [2]The Scripps Research Institute, San Diego, CA, [3]Toho University Sakura Medical Center, Sakura, Japan, [4]Chiba University School of Medicine, Chiba, Japan.

Background/Purpose: Osteoarthritis (OA) is a prevalent joint disease, with several identified clinical risk factors. However, the search for genetic risk factors by candidate gene and genome-wide association studies of human OA populations has identified only a small number of candidate genes and pathways potentially involved in the disease. Thus, we aim to build a genome-wide molecular profile of OA to elucidate regulatory mechanisms of OA pathogenesis and to identify possible therapeutic targets.

Methods: We extracted total RNA from full-thickness articular cartilage from 18 human donors (8 normal and 10 OA) and performed mRNA and microRNA sequencing on an Illumina HiSeq 2000 (single-end, 100bp reads). DNA was extracted from full-thickness articular cartilage from 23 different human donors (11 normal and 12 OA) and we performed a DNA methylation assay on the Illumina Infinium HumanMethylation450 BeadChip. The RNA sequencing data were analyzed using the Tuxedo package to align raw reads to the human genome, quantify gene expression and perform differential expression analysis. We used the Bioconductor package ChAMP to perform differential methylation analysis. We employed downstream functional enrichment analyses for transcription factors and microRNAs using Fisher's Exact Test, pathway analyses using the Bioconductor package SPIA, and network analyses using Cytoscape. Finally, we created an interaction network using the Human Integrated Protein-Protein Interaction Reference using enriched and additional OA related transcription factors. This network was annotated with differentially expressed mRNAs, microRNAs with validated targets in this network and their methylation status.

Results: Several genes, microRNAs and transcription factors are differentially expressed and reveal unique molecular signatures of OA (Figure 1). Many of these genes and microRNAs possess differentially methylated promoters. In addition, they are key regulators of a novel OA regulatory network (e.g., miR-21, miR-155, CEBPB, FOXO3) (Figure 2). We validated the microRNA targets in this network and the hypomethylation of the miR-21 promoter. We discovered that miR-21 targets the transcription factors HIF1A and CEBPB, providing a regulatory mechanism for the downregulation of these transcription factors and their targets.

Conclusion: Our findings reveal a complex regulatory interaction network of OA pathogenesis controlled by microRNAs, transcription factors and DNA methylation and suggest therapeutic targets to treat or delay disease progression.

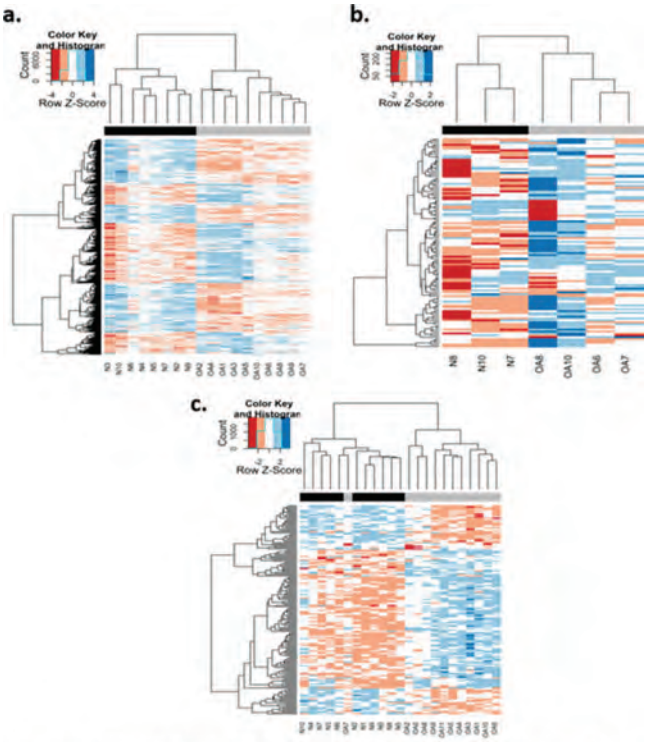

Figure 1. Hierarchical clustering of significantly dysregulated (a.) genes, (b.) microRNAs, (c.) CpG sites in articular cartilage from normal and OA donors reveals a distinct molecular signature of OA.

Figure 2. Novel OA pathway reveals that transcription factors enriched in the differentially expressed gene set are themselves differentially expressed. Several of these transcription factors are targets of differentially expressed miRNAs. In addition, several of these genes and microRNAs are differentially methylated. Pink: Upregulated; Green: Downregulated; Circle: Gene; Square: microRNA; Blue outline: Hypomethylated; Yellow outline: Hypermethylated; Red lines: validated microRNA targets.

1886

A Novel Monocyte-Specific Transcript Underlies the Chromosome 21q22 Intergenic Genetic Association in Ankylosing Spondylitis. Katelin Haynes, Tony Kenna, Evgeny Glazov, Matthew A. Brown and Gethin Thomas. University of Queensland Diamantina Institute, Brisbane, Australia.

Background/Purpose: A major finding of the GWAS era of common disease gene-mapping has been that observed associations more often involve intergenic locations than protein-coding regions. Whilst there has been substantial interest in the potential role of ncRNA in heritable diseases, as yet to our knowledge in no common disease has a polymorphism in a ncRNA been demonstrated to cause disease, and very few examples exist in monogenic diseases. Of the 43 independent genetic associations that have been reported for ankylosing spondylitis, most occur in intergenic, intronic or other untranslated regions of the genome. Two in particular, at chromosomes 2p15 and 21q22, occur in intergenic regions with no annotated transcription.

Methods: We have used a new technique known as CaptureSeq, which utilises RNAseq on samples enriched for transcripts from a genomic region of interest allowing the detection of transcripts expressed at too low levels for detection by conventional RNAseq. Using this technique, we undertook ultra-deep transcriptional profiling in peripheral blood mononuclear cells from 5 cases carrying the protective allele and 5 carrying the susceptibility allele at the 21q22 locus.

Results: We identified two completely novel divergently transcribed long non-coding RNAs (lncRNA) expressed from this region, which were upregulated in AS cases compared with healthy controls, as well as those subjects carrying the susceptibility allele. This overexpression in PBMCs was confirmed in two independent data sets, using both RNAseq and qPCR.

To further elucidate the potential function of this novel transcript we mined the FANTOM5 Atlas of human gene expression which showed expression of the 21q22 transcripts almost exclusively in CD14+ monocytes. We confirmed this in purified CD14+ cells from our PBMC samples with no expression seen in any other cell type. Expression was also significantly enhanced by stimulation of the monocytes with microbial components.

Conclusion: This is the first example of a role for a lncRNA in AS, and one of the first in any human disease where a polymorphism influences disease by effects on an ncRNA. Our findings strongly support a role for monocytes in AS aetiology possibly through responses to microbes. Monocyte antigen presentation has previously been implicated in AS and is strengthened by the identification of the *HLA-B27-ERAP1* genetic interaction. Aberrant microbial-induced CD14+ monocyte expression of the 21q22 transcript presents a novel potential mechanism by which AS might be influenced by microbes.

Genome-Wide DNA Methylation Analysis of Twin Pairs Discordant for Systemic Sclerosis Reveals Distinct Signatures in Blood and Dermal Fibroblasts. Paula S. Ramos[1], Rick Jordan[2], James Lyons-Weiler[2], Thomas A. Medsger Jr. [2] and Carol A. Feghali-Bostwick[1].[1]Medical University of South Carolina, Charleston, SC, [2]University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Systemic sclerosis (SSc) is a chronic, multisystem, autoimmune inflammatory disease with genetic and non-genetic contributions to risk. The etiology of SSc, including the reasons underlying the wide variation in disease heterogeneity and severity remain unknown. The low concordance rate (4.2%) between monozygotic twins suggests an important role for acquired genetic changes such as epigenetic factors in SSc susceptibility. In order to characterize the genome-wide DNA methylation profile of blood and dermal fibroblasts in SSc, we performed an epigenome-wide analysis of DNA methylation on twin pairs discordant for SSc.

Methods: DNA methylation profiling was performed using the Illumina Infinium HumanMethylation450 BeadChip, which allows the annotation of approximately 480,000 CpG sites. Genome-wide methylation was assessed in genomic DNA isolated from: (1) blood from 34 discordant twin pairs, and (2) skin fibroblasts cultured from dermal punch biopsies of 12 twin pairs discordant for SSc. An efficiency analysis was performed with caGEDA to determine best normalization and feature selection methods and identify differentially methylated probes between unaffected and affected twins. Ingenuity Pathway Analysis (IPA) was used for pathway analysis.

Results: We identified 68 CpGs in blood and 103 CpGs in dermal fibroblasts with significant changes in DNA methylation levels between the SSc-affected and healthy twins. These CpGs locate to 55 genes in the blood and 73 in the fibroblasts. While 45 (66%) CpGs were hypomethylated in the blood of the affected twin, 63 (58%) were hypomethylated in the dermal fibroblasts. Pathway analysis of the genes differentially methylated in the blood revealed an enrichment of genes in the antigen-presentation pathway (P=2.47E-06) and genes involved in dermatological, immunological and hematological diseases (P=1.98E-05). These enrichments were mostly driven by multiple probes in genes in the HLA region that consistently showed either hyper- or hypomethylation in the affected twins. In skin fibroblasts, pathway analysis revealed an enrichment of genes involved in gene expression (P=8.5E-06) and organismal development (P=1.90E-05). Prominent members of the differentially methylated genes included HOX and T-box transcription factor genes that showed multiple probes with consistent hyper- or hypomethylation in the affected twins.

Conclusion: These data support a role for DNA methylation differences in mediating susceptibility to SSc and identify gene sets with differential methylation that may be involved in the pathogenesis of the disease. The distinct methylation profiles observed between blood and dermal fibroblasts suggest that tissue-specific epigenetic signatures may be responsible for the clinical heterogeneity of the disease.

1888

PU.1, Mitf, and Their Novel Co-Partner, Eomes, Set up a Transcription Factor Network That Is Critical for Osteoclast Differentiation. Heather Carey[1], Sankha Ghosh[1], Eason Hildreth III[1], Jennifer Cabrera[1], Dias Kurmashev[1], Wael N. Jarjour[2], Ramiro Toribio[1], Sudarshana Sharma[1] and Michael Ostrowski[1]. [1]The Ohio State University, Columbus, OH, [2]The Ohio State University Wexner Medical Center, Columbus, OH.

Background/Purpose: Osteoclasts are bone resorbing cells which differentiate from myeloid precursors. The crosstalk between osteoblasts and osteoclasts tightly regulates the dynamic and continuous process of bone remodeling. Deregulation of this delicate balance is implicated in osteoporosis pathology. A variety of transcription factors including PU.1, MITF, NFATc1, and cFOS are essential for osteoclast differentiation. However, the interplay between these factors is not fully defined. We have previously shown that the transcription factors MITF and PU.1 act as a complex to regulate multiple genes required for osteoclast function. This study was designed to understand the global transcriptional regulatory processes involved in osteoclast differentiation.

Methods: We examined transcriptional regulation of target genes by MITF and PU.1 in myeloid precursors and osteoclasts using ChIP-Seq to map the genome-wide binding of these factors. In parallel, microarray analysis was performed to monitor target gene expression changes over the course of differentiation. We also queried the sequences jointly bound by PU.1 and MITF to search for conserved binding sequences potentially indicating novel co-partners in osteoclasts. We used micro-computed tomography and histological analysis to examine the effects of myeloid lineage-specific and osteoclast-specific deletion of PU.1 and its copartners *in vivo* and *in vitro.*

Results: ChIP-Seq and microarray profiling revealed that MITF and PU.1 jointly regulate the transcription of over 1000 genes in developing osteoclasts. Most of the MITF/ PU.1 co-bound regions were found in distal enhancer-like elements at the same sites in both myeloid precursors and osteoclasts. Overlap of our ChIP-Seq and microarray data sets utilizing Gene Set Enrichment Analysis (GSEA) revealed that transcription factor genes were the only subset significantly enriched in genes with PU.1/ MITF co-bound regions. These transcription factors include NFATc1, c-FOS, and NFKB, which are already known to be essential for osteoclast differentiation. Additionally, 38% of genomic regions jointly bound by PU.1 and MITF in developing osteoclasts contained the binding motif of the T-box transcription factor EOMES. Conventional ChIP assays validated binding of EOMES to MITF/PU.1 bound regions. Micro-computed topography analysis of murine bone has demonstrated that the loss of PU.1 or EOMES in osteoclasts and

their myeloid precursors leads to a severe osteopetrotic phenotype in neonatal mice due to highly deficient osteoclast differentiation and function.

Conclusion: Our results demonstrate that MITF and PU.1 set up a transcription factor regulatory network in myeloid precursors which triggers osteoclast differentiation in response to cues from the bone microenvironment. Ablation of PU.1 or its novel copartner EOMES results in disruption of this transcription factor network and therefore halts the differentiation program.

Rheumatoid Arthritis (RA)-Associated Risk Allele *LBH* Alters the Function of a Differentially Methylated *LBH* Enhancer. Deepa Hammaker[1], Gary S. Firestein[2], Wei Wang[3], John W. Whitaker[4] and Anna-Karin Ekwall[5]. [1]University of California San Diego, La Jolla, CA, [2]University of California at San Diego School of Medicine, La Jolla, CA, [3]UCSD, La Jolla, CA, [4]UCSD, San Diego, CA, [5]UC San Diego, La Jolla, CA.

Background/Purpose: Recent data suggest that epigenetics, including DNA methylation, contributes to imprinting RA fibroblast-like synoviocytes (FLS) and alters their behavior. To understand how RA-associated risk alleles and differential methylation affect cis-regulatory regions, we compared differentially methylated loci (DML) in RA FLS with fibroblast DNase I hypersensitive sites. The differentially methylated enhancers (DMEs) were then integrated with RA-associated SNPs to identify key regulatory sites. In this study, we found and characterized an RA-associated SNP that colocalized with a DME in a key cancer-related gene that regulates cell growth and differentiation, namely limb-bud and heart development (*LBH*).

Methods: 15,220 RA-associated DMLs identified using Illumina 450k chips from 11 RA and 11 OA FLS were integrated with DNase I hypersensitive sites in the ENCODE database for 125 cell-types/conditions, including lung fibroblasts. These DMEs were then compared with GWAS data. Genomic DNA was isolated and the 1.4kb region with the WT allele (G) or RA SNP (T) of *lbh* was cloned into minimal promoter pGL4.23-luciferase construct. For methylation studies, plasmids were methylated with the CpG-methyltransferase M.SssI and S-adenosyl methionine. Methylation of all CpGs was verified by bisulfite modification and pyrosequencing. The WT, RA SNP or control plasmids (1ug) were transfected into cultured RA FLS by nucleofection with Renilla construct. Firefly luciferase activity was normalized to renilla.

Results: A DNase I hypersensitive site that is hypomethylated in RA FLS was identified in a 1400 bp region upstream of the *LBH* gene transcription start site. An RA and SLE-associated SNP (rs906868, G/T) was identified in the same region. We first determined the transcription differences between the WT and RA SNP in transfected RA FLS. Surprisingly, luciferase activity was significantly decreased in the WT group compared with the RA SNP ($19\pm7\%$, $p=0.02$, $n=9$ lines), suggesting that the regulatory region decreases gene expression in WT cells. The RA SNP had no effect on luciferase expression compared with control. We then evaluated whether CpG methylation of the plasmids altered function of the enhancer region. Methylation of the RA SNP plasmid significantly decreased the luciferase activity by $46\pm4\%$ compared with the unmethylated ($p=0.0005$, $n=5$ lines). In contrast, methylation increased the luciferase activity in the WT group ($42\pm17\%$, $p=0.049$, $n=5$ lines) but not in the control group.

Conclusion: We identified a novel candidate regulatory region by integrating ENCODE with RA GWAS and RA DNA methylation databases. The RA-associated allele in *lbh* eliminated its regulatory function. This is the first demonstration that an RA risk allele in a regulatory region has functional effects. By altering enhancer function of a gene that is intimately involved with cell proliferation (*LBH*), the risk allele could contribute to the aggressive behavior of RA FLS. Furthermore, the functional effects of methylation are distinctly different between RA-associated alleles and WT. These data provide evidence that combinations of epigenetic and risk allele data can provide new clues to the pathogenesis of RA.

Consistent Inhibition of Bone Destruction By Denosumab in Important Subgroups of Japanese Patients with Rheumatoid Arthritis. Naoki Ishiguro[1], Yoshiya Tanaka[2], Hisashi Yamanaka[3], Toshiyuki Yoneda[4], Takeshi Ohira[5], Naoki Okubo[6], Harry K. Genant[7], Desiree van der Heijde[8] and Tsutomu Takeuchi[9]. [1]Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [3]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [4]Indiana University School of Medicine, Indianapolis, IN, [5]Daiich Sankyo Co. Ltd, Tokyo, Japan, [6]Daiichi Sankyo Co. Ltd, Tokyo, Japan, [7]University of California, San Francisco, CCBR-Synarc, Newark, Tiburon, CA, [8]Leiden University Medical Center, Leiden, Netherlands, [9]Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Denosumab is a fully human monoclonal antibody (IgG_2 subclass) that binds specifically to RANKL, inhibits osteoclast-induced bone resorption by preventing the binding of RANKL to RANK, and has been examined in the DRIVE Study to determine its efficacy and safety in Japanese patients with rheumatoid arthritis (RA). The primary endpoint was the change in the bone erosion from baseline to 12 months. Subgroup analyses were undertaken to understand whether denosumab was broadly effective upon progression of the bone erosion in RA patients.

Methods: The DRIVE Study was a 12-month, phase II, randomized, double-blind trial in RA patients receiving methotrexate (MTX) treatment. Patients were randomized to one of four treatment groups which were denosumab (60 mg every 6 months (Q6M), 60 mg every 3 months (Q3M) or 60 mg every 2 months (Q2M)) or placebo. Randomization was stratified by glucocorticoid use and rheumatoid factor (RF) status at screening. All patients basically continued the MTX treatment and a supplement of calcium and vitamin D throughout the study. The bone erosion score was assessed by the modified Sharp-van der Heijde method. Subgroup analyses were conducted according to the risk factors for radiographic damage: RA disease duration, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), RF status, anti-cyclic citrullinated peptide (anti-CCP) antibody, swollen joints (SWJ), and glucocorticoid use.

Results: The analysis was performed in 340 patients (88 in placebo, 85 in Q6M, 82 in Q3M and 85 in Q2M). Denosumab significantly inhibited the progression of bone erosion from baseline to 12 months compared to placebo. Changes from baseline in modified Sharp erosion score at 12 months (Mean $\pm$ SD) were 0.99 ± 2.69 in placebo, 0.27 ± 0.98 in Q6M (compared to placebo, $p=0.0082$), 0.14 ± 0.53 in Q3M ($p=0.0036$), and 0.09 ± 1.52 in Q2M ($p<0.0001$). The subgroups with risk factors for radiographic damage tended to show consistent results for the primary endpoint in total group.

Change of modified Sharp bone erosion score from baseline to 12 months in subgroups

		Placebo N = 88	Denosumab 60 mg Q6M N = 85	Q3M N = 82	Q2M N = 85

	Absence	0.72±1.51	0.22±0.74	0.07±0.50	0.20±1.92

N = Number of patients who received ≥ 1 dose of investigational product and had a baseline and at least 1 post-baseline measurement of the radiograph score.
Data are mean ± SD.
RA=rheumatoid arthritis, CRP=C-reactive protein, ESR=erythrocyte sedimentation rate, RF=rheumatoid factor, Anti-CCP=anti-cyclic citrullinated peptide, SWJ=swollen joints

Conclusion: Denosumab significantly inhibited the progression of the bone erosion at 12 months in Japanese patients with RA. While some subgroups were small, denosumab also consistently inhibited the progression of the bone erosion in important subgroups. These results indicate that

denosumab could inhibit the progression of bone destruction in RA patients with risk factors for radiographic damage.

Early MRI Endpoints Provide a Valid Measure of Structural Damage While Reducing Study Duration and Participant Numbers in Rheumatoid Arthritis Clinical Trials. Joshua Baker[1], Philip G. Conaghan[2], Paul Emery[3], Daniel Baker[4] and Mikkel Østergaard[5]. [1]Philadelphia VA Medical Center, Philadelphia, PA, [2]University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [3]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [4]Janseen R&D, Spring House, PA, [5]Copenhagen Center for Arthritis Research, Copenhagen University Hospital at Glostrup, Glostrup, Denmark.

Background/Purpose: We used data from a large randomized controlled clinical trial of an effective biologic (golimumab, GO-BEFORE study) to compare the associations of disease activity and disease severity with two imaging techniques to measure joint erosion: 1) early progression in rheumatoid arthritis magnetic resonance imaging scores (RAMRIS) and 2) radiographic progression. We subsequently assessed the potential impact of incorporating these MRI scores in clinical trial design.

Methods: MRI of the dominant hand was performed and RAMRIS scores were determined at baseline, week 12 and week 24. van der Heijde-Sharp (vdHS) scores were determined for x-rays at baseline and week 52. Progression in vdHS and RAMRIS erosion scores were defined as a change of >0.5. Associations between X-ray and MRI outcomes with clinical features associated with severe disease and structural damage were evaluated to assess convergent validity. Iterative Wilcoxon ranksum tests assessed the sample size requirements to detect a significant difference in the change in structural damage score between combination therapy (methotrexate+golimumab) and methotrexate monotherapy. Sample size calculations were also performed based on dichotomous progression outcomes.

Results: MRI progression at 12 and 24 weeks was associated with greater DAS28(CRP), CRP, and vdHS at baseline, and greater HAQ scores at 2-years (**Table 1**). These associations were similar in magnitude to those seen with X-ray progression at 1-year. Ranksum testing for differences in the change in structural damage between treatment and controls arms achieved significance ($p<0.05$) with fewer total study subjects when MRI erosion score was the outcome assessed (175 for MRI at 12/24 weeks v. 300 subjects for ΔvdHS at 52 weeks) (**Figure 1**). When the study sample was enriched with subjects with a synovitis score >5 (a level previously associated with MRI progression) at baseline, the study sample further decreased to 125. Sample size calculations demonstrated that a study enriched with 117 subjects with synovitis scores >5 would have 80% power to detect a difference in the proportion of subjects progressing on MRI at 12 weeks. A sample size calculation based on an unenriched population and using 1-year x-ray progression as the outcome estimated a study size of 470 subjects.

Conclusion: Early MRI erosion score outcomes have convergent validity comparable to that of 52-week x-ray progression. Use of MRI in clinical trials would decrease sample sizes and reduce length of follow-up for studies assessing differences in structural damage progression between groups.

Table 1: Clinical characteristics of MRI/x-ray progressors and non-progressors within the MRI sub-study (convergent validity).

	MRI 24 Weeks (N=238)			X-ray 52 Weeks (N=238)		
	Progression (N=52)	No Progression (N=186)	P Value	Progression (N=62)	No Progression (N=176)	P Value
Baseline DAS28(CRP)	5.81 (1.13)	5.53 (1.06)	0.1	5.79 (1.10)	5.52 (1.06)	0.09
Baseline CRP	1.8 (0.95, 3.4)	1 (0.4, 2.5)	0.002	2 (0.8, 4.2)	1 (0.4, 2.4)	0.001
Baseline vdHS	15 (3.25, 29.8)	4.5 (2, 13)	0.002	9 (2.9, 26)	4.5 (2, 15)	0.01
ΔHAQ Score (2-years)*	0.036 (0.78)	−0.14 (0.59)	0.08	−0.054 (0.74)	−0.12 (0.61)	0.5

In Vivo Visualization of Cortical Microchannels in Metacarpal Bones in Patients with Cutaneous Psoriasis By High Resolution Peripheral Computed tomography - Detecting Cortical Pathologies before the Clinical Onset of Psoriatic-Arthritis. David Simon, Francesca Faustini, Arnd Kleyer, Judith Haschka, David Werner, Axel J. Hueber, Michael Sticherling, Georg Schett and Juergen Rech. University of Erlangen-Nuremberg, Erlangen, Germany.

Background/Purpose: Normal bones present cortical micro-channels (CMC), which carry micro-vessels and ensure communication between the bone marrow and the synovial compartment. Only recently these structures have been visualized in vivo in rheumatoid arthritis patients through high resolution peripheral computed tomography (HR-pQCT). We hypothesized that it is possible to detect and characterize these channels in healthy subjects (HS) and subjects with cutaneous psoriasis (PSO), assuming that PSO patients could present changes in bone microstructure previous to the onset of joint involvement.

Methods: HR-pQCT (XtremeCT, Scanco Medical, Switzerland) scanning of the dominant hand was carried out on PSO patients without history of synovitis, dactylitis or enthesitis and HS. Image resolution was set at 82 μm voxel size. Images of the 2nd metacarpal head (MCH2) were downsized to the minimum of one slice with the 3D evaluation program provided by the manufacturer. Transversal, sagittal and coronal images were obtained using the subdim feature of the 3D evaluation program. Transversal slices (Fig.1) were projected at the level of the insertion of the joint capsule. Sagittal and coronal planes were set exactly into the middle of the MCH2. Demographic and clinical data were collected for the two groups of subjects. The study was

conducted upon approval by the local ethic committee and the National Radiation Safety Agency (BfS). Patients participated after signing informed consent.

Results: PSO patients (N=56,M/F: 36/20, mean age 47.0±13.8 y) were compared to HS (N=24, M/F: 10/14, mean age 43.8±11.9 y). The subjects were comparable per age and sex. PSO patients exhibited moderately severe disease (PASI 7.9±8.9) and disease duration of 12.7±14.3 y, the most frequent phenotype being psoriasis vulgaris (78.6%), 60.7% presented scalp lesions, 48.2% had nail lesions. Imaging analysis was blindly performed by two readers. Inter- and intra-reader reliability was high (r=0.96 and r=0.98). In PSO patients 607 CMC were found vs. 97 in HS in the MCH2. Expressed as mean number of CMC this accounts for 10.8±9.1 vs. 4.1±3.7 ($p<0.001$). No correlation was found for the CMC number in the PSO patients and the severity of the cutaneous disease and its duration nor for the age of the subjects.

Conclusion: Visualization of cortical pathologies as small as 81 microns can be obtained by this technique. These images resemble rather histopathologic slices in vitro (Fig. 1). In our study cutaneous psoriatic patients with no clinical history of arthritis showed a significant higher number of these cortical channels compared to healthy subjects, suggesting an increased communication between bone marrow and joint in this phase of disease previous to the onset of joint involvement.

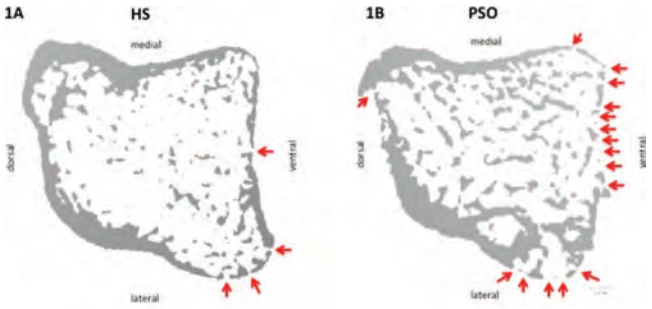

Figure 1 Transversal HR-pQCT slices of MCP joint 2
Panel A shows CMC in a healthy subject (arrows); panel B shows CMC in a PSO patient.
Arrows indicate cortical micro channels with a size smaller than 81 microns.

1893

Substantial Structural Lesions on MRI in the Sacroiliac Joints of Patients with Non-Radiographic Axial Spondyloarthritis Even in the Absence of MRI Inflammation. WP Maksymowych[1], S Wichuk[1], H Jones[2], A Szumski[2], L Marshall[2], J Bukowski[2] and RG Lambert[1]. [1]University of Alberta, Edmonton, AB, [2]Pfizer Inc., Collegeville, PA.

Background/Purpose: Treatment of axial SpA is increasingly aimed at intervention early in the disease course before radiographic sacroiliitis has appeared and when response to treatment is greatest. If radiographs do not indicate sacroiliitis, the Assessment of SpondyloArthritis (ASAS) classification criteria indicate that bone marrow edema (BME)/osteitis on MRI is a requirement, but this may also occur non-specifically, and some patients lack MRI inflammation. The purpose of this analysis was to assess the relative importance of structural lesions on MRI in the sacroiliac joints (SIJ) of patients with non-radiographic axial SpA (nr-axSpA).

Methods: Patients had axial SpA per the ASAS classification criteria, but did not meet modified NY radiographic criteria. Patients had symptoms for >3 months and <5 years, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) ≥4, and failed ≥2 NSAIDs. Patients were randomly assigned to etanercept 50 mg/week or placebo, then after 12 weeks, all patients received open-label etanercept 50 mg/week. Clinical and health outcomes were assessed throughout the study, and MRI of the SIJ and spine was performed by two central readers at baseline, weeks 12 and 48 to assess BME using the Spondyloarthritis Research Consortium of Canada (SPARCC) score. Additionally, a post-hoc analysis was conducted to score structural lesions using the SPARCC SIJ structural method, which assesses fat metaplasia, erosion, backfill, and ankylosis on T1-weighted spin echo (T1WSE) MRI. Two independent readers scored baseline and 48 week T1WSE MRI scans from 187 cases blinded to patients and short tau inversion recovery (STIR) MRI scans. Mean scores of the readers were used. SPARCC SIJ BME score ≥2 was used as the operational definition of positive MRI evidence of inflammation. For these analyses, all patients were combined, independent of randomization.

Results: Mean (SD) age was 32 (7.8) years, 60.5% were male, and mean (SD) duration of disease symptoms was 2.5 (1.8) years. A total of 73% of patients were human leukocyte antigen B27 (HLA-B27) positive and 81% met the ASAS MRI imaging criteria at baseline. Additionally, 61% had a structural lesion on MRI at baseline comprised of erosion (58%), backfill (23%), fat metaplasia (18%), and ankylosis (7%). Of the patients who were ASAS MRI positive, 65% had a structural lesion on MRI, compared to 43% who were ASAS MRI negative. Of the patients with SPARCC SIJ BME score ≥2 at baseline, 79% had a structural lesion on MRI compared to 35% with SPARCC SIJ BME score <2. Relative frequencies of MRI structural lesions in patients with SPARCC SIJ BME ≥2 vs <2 were: erosions (78% vs 30%), backfill (36% vs 5%), fat (22% vs 13%), and ankylosis (7% vs 7%).

Conclusion: Structural lesions on MRI occur frequently in nr-axSpA despite the absence of radiographic sacroiliitis and even in the absence of MRI inflammation. This finding strongly reinforces the concept of nr-axSpA as an early stage of axial SpA.

1894

Is It Worth to Include MRI of the Spine in the ASAS Classification Criteria for Axial Spondyloarthritis? Manouk de Hooge[1], Jean-Baptiste Pialat[2], Antoine Feydy[3], Monique Reijnierse[1], Pascal Claudepierre[4], Alain Saraux[5], Maxime Dougados[3] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Hôpital Edouard Herriot, Lyon, France, [3]Descartes University, Cochin Hospital, Paris, France, [4]Henri Mondor Teaching Hospital, Creteil, France, [5]CHU de la Cavale Blanche, Brest Cedex, France.

Background/Purpose: Spinal MRI lesions suggestive of axial Spondyloarthritis (axSpA) are not included in the ASAS definition of a positive MRI, but do occur in the absence of affected sacroiliac joints (SIJ). It is unknown how often this happens and if it is useful to perform a MRI of the spine in patients (pts) with negative MRI-SIJ. The objective of this study was to investigate the prevalence of a positive MRI-spine in pts with short symptom duration and a negative MRI-SIJ.

Methods: Pts aged 18–50 with inflammatory back pain (IBP) (≥3 months, ≤3 years) from 25 participating centers in France were included in the DESIR-cohort (n=708). All available baseline MRIs of the spine were independently scored by 2 well-calibrated central readers who were blind to any other data. MRIs-SI were scored according to the ASAS definition[1] (lesions highly suggestive of sacroiliitis plus ≥1 lesion on ≥2 consecutive slices or >1 lesion on 1 slice). Inflammatory lesions on MRI-spine suggestive of spondylitis were scored when visible on ≥2 consecutive slices and according to the ASAS consensus definition[2] (≥3 lesions). In case of disagreement, an experienced radiologist served as adjudicator. MRI was considered positive if 2/3 readers agreed.

Results: All pts with MRI-spine and MRI-SIJ (n=650) were included in the analyses. There were 231 pts (35,5%) with a positive MRI-SIJ and 102 pts (15.7%) with a positive MRI-spine; 67 pts (10.3%) were positive for both MRI-SIJ and MRI-spine, 384 (59.1%) were negative for both; and 35 pts (5.4%) had a positive MRI-spine but a negative MRI-SI. Thirty of these were <45 years at symptom onset (entry criterion for ASAS axSpA criteria); 8 of these 30 pts fulfilled the modified New York criteria, 16 of these 30 pts fulfilled the clinical arm of the ASAS axSpA criteria and 6 pts did not fulfil the criteria. All these 6 pts were HLA-B27 negative. Therefore, if the MRI-spine would be considered to count for imaging for the ASAS criteria, 6 additional pts would have been classified and 16 pts would have fulfiled both the imaging and clinical arm; Two of the 5 pts with age >45 years at symptom onset fulfilled the mNY criteria.

Overall, only 25 pts (3.8%) had a pos MRI-spine without sacroiliitis on MRI or radiographs.

Conclusion: In 3.8% of IBP pts aged 18–50 ≥3 spinal inflammatory lesions suggestive of axSpA are found in absence of sacroiliitis on MRI or radiograph. Therefore the yield of including MRI-spine as additional imaging criterion in the ASAS axSpA classification criteria is considered unacceptably low.

Sacroiliitis at Diagnosis in Children with Juvenile Spondyloarthritis. Pamela Weiss[1], Rui Xiao[2] and Nancy Chauvin[1]. [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA.

Background/Purpose: The prevalence of sacroiliitis in children with juvenile spondyloarthritis (JSpA) at diagnosis is unknown. We aimed to evaluate: 1) the prevalence of sacroiliitis at diagnosis using radiographs and MRI; and 2) the association of physical examination and a history of back pain with acute sacroiliitis, using MRI as the reference standard.

Methods: We performed a single center prospective cross-sectional study of 39 children with newly diagnosed JSpA. Children were eligible for inclusion if they were diagnosed with enthesitis-related arthritis (ERA) or psoriatic arthritis (PsA) according to the International League of Associations for Rheumatology criteria in the prior 6 months. On the same day subjects had a musculoskeletal examination and imaging, which included a single AP pelvic radiograph and a non-contrast pelvic MRI with STIR. Radiographs were scored using the modified New York criteria. Acute sacroiliitis on MRI was defined as bone marrow edema within the sacrum or adjacent ilium with or without accompanying capsulitis, enthesitis, or effusion. Univariate logistic regression was used to test the association of clinical factors with acute sacroiliitis.

Results: Mean age of the JSpA subjects was 14.0 ± 2.7 years. 49% were male and 44% were HLA-B27$^+$. 35 and 4 children met criteria for ERA and psoriatic arthritis, respectively. Nine (23%) children had acute sacroiliitis; in 5 subjects it was bilateral. Of the 9 children with acute sacroiliitis on MRI, 7 (78%) had erosions or sclerosis on MRI and 5 (56%) had changes on conventional radiography. 2 subjects met radiologic criteria for ankylosing spondylitis. Of the subjects with acute sacroiliitis only 4 (44%) reported a history of back pain or tenderness on palpation of the sacroiliac joints. 3 (33%) and 14 (47%) of children with JSpA with and without sacroiliitis met the ASAS inflammatory back pain criteria. Male sex, hip arthritis, alternating buttock pain, higher c-reactive protein, HLA-B27 positivity, and decreased lateral flexion were associated with a higher odds of acute sacroiliitis, albeit statistically insignificant (Table).

Conclusion: This is the first study reporting the prevalence of acute sacroiliitis at diagnosis in children with JSpA. Sacroiliitis is common at diagnosis and may be asymptomatic. Nearly half the cases of sacroiliitis would have been missed if radiographs were the only imaging modality.

Table. Clinical features in MRI+ and MRI- subjects (N=39)

Clinical Feature	MRI+ N=9 N (%)	MRI− N=30 N (%)	p-value$^+$	OR of acute sacroiliitis (95% CI)
Psoriatic arthritis	1 (25)	3 (75)	0.92	–

Validation of a Novel IFN-Regulated Gene Score As Biomarker in Chronic Atypical Neutrophilic Dermatosis with Lipdoystrophy and Elevated Temperature (CANDLE) Patients on Baricitinib, a Janus Kinase 1/2 Inhibitor, a Proof of Concept. Hanna Kim[1], Steve Brooks[2], Yin Liu[1], Adriana Almeida de Jesus[1], Gina A. Montealegre Sanchez[1], Dawn C. Chapelle[1], Nicole Plass[1], Yan Huang[1] and Raphaela Goldbach-Mansky[1]. [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD, [2]NIAMS/NIH, Bethesda, MD.

Background/Purpose: CANDLE syndrome is a novel autoinflammatory disease with strong IFN response signature. We hypothesize that IFN dysregulation may drive clinical manifestations in CANDLE and treatment with baricitinib, a JAK 1/2 inhibitor, will reduce the IFN-regulated genes (IRG) signature (Liu, 2012). Clinical improvement has been seen in CANDLE patients on baricitinib with significantly decreased steroid requirement and symptom scores (Montealetre, 2013). We assess IRG expression in CANDLE patients on increasing doses of bariticinib and validate an IRG score as a potential biomarker.

Methods: 12 CANDLE patients (1.8–24.7yo, 9 male) enrolled in a NIH compassionate use protocol for baricitinib were assessed at baseline and on increasing doses (2–11mg/day). Initial IRG list included all genes at least 2× upregulated in a chronic hepatitis patient and healthy peripheral blood mononuclear cells (PBMCs) exposed to IFN alpha was selected for IFN pathway genes in Ingenuity Pathway Analysis (IPA, Ingenuity® Systems). IFN alpha, beta, and gamma and IFN receptor genes were added. IRGs with lowest Z-scores and little variability from initial studies on 10 CANDLE patients were cut to reduce list to 31 IRGs. These and 4 housekeeping genes, were analyzed through RNA extracted from PAX gene tubes by the NanoString nCounter gene expression system (Seattle, WA). 3 healthy pediatric and 1 healthy adult were used as controls (HCs). IRG scores were calculated by a) summing Z-score IRGs (summary score) and b) summing normalized value for IRGs on 0–1 scale (normalized score) for the a) 31 genes selected above and b) 6 most highly expressed IRGs at baseline in 9 CANDLE patients from previous RNAseq data. The 6 and 31 gene IRG scores were assessed for correlation. Mean of 6 gene IRG scores from all baselines were compared to mean IRG scores on treatment via t-test. Paired t-test of 6 gene IRG scores in patients on the lowest and highest dose of treatment was also done excluding flaring patients.

Results: IRGs scores at 31 genes versus 6 genes highly correlate (linear model R^2: 0.95–0.99). Summary scores versus normalized scores strongly correlate (linear model R^2: 0.72–0.76). Normalized 6 gene IRG score significantly decreased (p=0.003) on treatment (mean 0.9, 5mg/day, 0.22mg/kg/day) from baseline (mean 1.9). With mean summary score (4828 vs. 2124), p value was 0.02. Paired analysis of 8 CANDLE patients showed significant decrease in normalized 6 gene IRG score (p=0.03, mean score 1.01 vs. 0.38) at higher dose versus lower dose (0.25 vs. 0.12 mg/kg/day) but summary score was not significant (mean score 1915 vs. 946).

Conclusion: 6 and 31 gene IRG score highly correlate. 6 gene normalized and summary IRG score significantly decrease in CANDLE patients on barcitinib treatment versus baseline with dose-dependent decrease with 6 gene normalized IRG. Preliminary analysis indicates normalized score may be a better biomarker than summary score. The IRG score may be useful as a biomarker in CANDLE syndrome and other autoinflammatory conditions with IFN-driven pathology, particularly for JAK inhibitor treatment. Further pharmacodynamics studies to correlate pharmacokinetics, IRG score, and clinical status are needed.

Circulating T-Helper Cell-Associated Cytokines and Chemokines in Localized Scleroderma. Kathryn S. Torok[1], Katherine Kurzinski[2], Christina Kelsey[3], Kelsey Magee[4], Jonathan Yabes[4], Abbe N. Vallejo[4], Thomas A. Medsger Jr.[4] and Carol A. Feghali-Bostwick[5]. [1]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [3]University of Pittsburgh/UPMC, Pittsburgh, PA, [4]University of Pittsburgh, Pittsburgh, PA, [5]Medical University of South Carolina, Charleston, SC.

Background/Purpose: Localized scleroderma (LS) is an autoimmune disease of the skin and underlying tissues which results in disfigurement and orthopedic complications, especially when the onset is in childhood. LS has both inflammatory and fibrotic components, making it similar to systemic sclerosis (SSc), its 'companion' disease. Identifying potential biomarkers involved with disease propagation may lead to future therapeutic targets. T-helper (Th) cell subsets and their associated cytokines are thought to contribute to the pathogenesis of systemic sclerosis (SSc). Traditionally, a Th2 predominant response has been supported, but more recent data also implicate Th1, Th17 and various chemokine involvement. This concept in LS has only been partially investigated, with studies evaluating only a handful of cytokines associated with Th cell lineages, and not examined in reference to disease activity. This study was designed to extensively evaluate the Th-cell associated plasma cytokine and chemokine profiles of patients with pediatric LS.

Methods: Plasma samples were obtained from 69 pediatric LS patients and 71 healthy pediatric controls. Twenty-nine cytokines and chemokines were analyzed using a Th1, Th2, and Th17 Millipore luminex panel comparing LS to healthy controls, with additional analyses predetermined to be dedicated to disease activity parameter. The modified Localized Scleroderma Severity Index (mLoSSI) and the Physician Global Assessment of Disease Activity (PGA-A) were the main parameters compared to the cytokine/chemokine levels. Mann-Whitney U test was employed to compare cytokine levels between LS and healthy groups and Spearman rank correlation was used to determine relationships between individual analytes and clinical parameters ($p < 0.05$). Type I error due to multiple testing was controlled for using the Benjamini-Hochberg method.

Results: The levels of the following cytokines were significantly elevated in LS patients compared with healthy controls: IP-10, MCP-1, IL-17A, IL-12p70, GM-CSF, IFN-γ, IFN-α2 and PDGF-bb. When LS patients were further divided into active (n=30) and inactive states (n=39), IP-10 was significantly elevated in the active group compared to inactive (median: 2087.3 vs. 880.5 pg/ml, respectively). IP-10 levels were also significantly correlated with the Physician Global Assessment of Disease Activity (PGA-A) score ($r_s = 0.450$, $p = 0.005$) and with the modified Localized Scleroderma Severity index (mLoSSI) score ($r_s = 0.343$, $p = 0.004$).

Conclusion: SSc and LS share a similar histopathology with infiltration of lymphocytes and their associated effector cytokines in skin specimens. In the current study we demonstrated a serological presence of IP-10, MCP-1, IL-17A, IL-12p70, GM-CSF, IFN-γ and IFN-α2 in localized scleroderma, with IP-10 being highly correlated with active disease. Prior SSc studies have also found similar cytokine and chemokine profiles in the circulation, with recent literature supporting a potential role of IP-10 in SSc disease severity. These findings suggest a potential immunological link between these two clinically different diseases.

Identification of "autoinflammatory interferonopathies"? a New Class of Autoinflammatory Conditions? Adriana Almeida de Jesus[1], Zuoming Deng[1], Stephen Brooks[2], Yin Liu[1], Hanna Kim[1], Gina A. Montealegre Sanchez[1], Dawn C. Chapelle[1], Yan Huang[1], Philip Hashkes[3], Gulnara Nasrullayeva[4], Maria Teresa Terreri[5], Bita Arabshahi[6], Marilynn G. Punaro[7], Lakshmi N. Moorthy[8], Adam Reinhardt[9], Clovis A. Silva[10], Emilia I. Sato[11], Vibke Lilleby[12], Thomas Fleisher[13] and Raphaela Goldbach-Mansky[1]. [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD, [2]NIAMS/NIH, Bethesda, MD, [3]Shaare Zedek Medical Center, Jerusalem, Israel, [4]Azerbaijan Medical University, Baku, Azerbaijan, [5]University of Federal De Sao Paulo, Sao Paulo, Brazil, [6]Inova Fairfax Hospital for Children, Fairfax, VA, [7]University of Texas Southwestern Medical Center, Dallas, TX, [8]Robert Wood Johnson Medical School-Rutgers University, New Brunswick, NJ, [9]Children's Specialty Physicians, Omaha, NE, [10]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [11]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil, [12]Department of Rheumatology, Oslo University Hospital, Rikshospitalet, Oslo, Norway, [13]National Institutes of Health, Bethesda, MD.

Background/Purpose: The role of IL-1 in the pathogenesis of many of the monogenic autoinflammatory diseases is clinically validated by the response to IL-1 blocking therapies. However, patients who are unresponsive to IL-1 blocking therapy have more recently been identified. We have identified mutations in proteasome components as the cause of CANDLE syndrome and a mutation affecting IFN beta secretion as the cause for a severe vasculopathy and lung disease, SAVI. CANDLE and SAVI patients do not respond to IL-1 inhibition and consistently demonstrate marked up-regulation of IFN-inducible genes. These data suggest that autoinflammatory phenotypes can also be caused by IFN signaling dysregulation.

Methods: Total RNA was extracted from total blood collected in PaxGene tubes and RNA sequencing was performed using HiSeq 2000 Illumina® platform (Illumina). Blood DNA was extracted and whole exome sequencing was performed using human exome capture by Agilent V4 (51Mbp) exome enrichment kit, followed by next generation sequencing using Illumina HiSeq2000.

Results: Using RNA sequencing we have identified a group of 11 patients with markedly differentially expression of IFN inducible genes. WES was performed in 8 patients and parents (trios) and in 3 individual patients in order to identify genetic defects affecting the IFN signaling pathway. Seven probands were female and 4 were male; 4 probands were Hispanic, 2 were Asian and 1 proband was Caucasian, Israeli, Azerbaijani, Iranian and Norwegian, respectively. All patients presented with immunodysregulatory phenotypes with clinical similarities to the previously described interferonopathies, including skin vasculitis/vasculopathy, panniculitis, myositis and basal ganglion calcifications, but did not have a genetic diagnosis identified prior to evaluation at the NIH. The bioinformatics variant annotation, analysis and filtering workflow has allowed us to successfully identify *de novo* mutations in IFN-regulating genes in 2 of the 8 trios. In one patient, we found a disease causing *de novo* and somatic mutation in *TREX1*. This patient also presented with an in-frame deletion in *DHX9* inherited from her mother and a missense mutation in *MAVS* inherited from her father. In one patient, we identified a *de novo* mutation in *DHX9* and this patient was also a compound heterozygous for mutations in *IFIH1/MDA5*. In a third patient, we found a missense mutation in *TREX1* inherited from the mother and a heterozygous variant in *MB21D1* (gene encoding cGAS) was detected in one patient. For this last patient, parental samples are not available yet for evaluation of inheritance. All mutations described were confirmed by Sanger sequencing.

Conclusion: RNA sequencing and genetic analysis can be an important tool for the identification of patients with an IFN signature and guide the search for disease causing variants in IFN-regulating genes by WES. These preliminary findings need to be validated in larger groups of patients. The validation of the pathogenic role for interferon dysregulation in patients with autoinflammatory phenotypes may lead to the identification of a clinical subset with poor IL-1 responses that may respond to targeted therapies that block the IFN signaling pathways.

Blockade of Interleukin-33 Signaling Prevents Death in a Mouse Model of Familial Hemophagocytic Lymphohistiocytosis. Julia Rood[1], Portia Kreiger[2], Erietta Stelekati[1], E. John Wherry[1] and Edward M. Behrens[3]. [1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [2]Alfred I. duPont Hospital for Children, Wilmington, DE, [3]The Children's Hospital of Philadelphia, Philadelphia, PA.

Background/Purpose: Cytokine storm syndromes, such as macrophage activation syndrome and familial hemophagocytic lymphohistiocytosis (FHL), represent important causes of mortality in pediatric rheumatology. Studies of a mouse model of FHL, in which lymphocytic choriomeningitis virus (LCMV) infection of perforin knockout (PKO) mice triggers the disease, have demonstrated that FHL is driven by an excess of LCMV-specific $CD8^+$T cells and their overproduction of interferon-γ (IFNγ). This over-exuberant T cell response is thought to arise from excess antigen stimulation through the T cell receptor (TCR). However, data from our lab and others suggest that other receptors may play an additional role, as mice deficient in both perforin and MyD88, a critical adaptor protein in non-TCR signaling, are protected from FHL.

Interleukin-33 receptor (IL-33R) is one of the receptors upstream of MyD88 and generates pro-inflammatory signals in response to the tissue damage-associated cytokine IL-33. Recent work has suggested that IL-33 signaling is necessary for mounting an effective anti-viral $CD8^+$ T cell response to LCMV in wildtype mice. However, the role of IL-33 signaling in

FHL has not been investigated. In this study, we sought to determine whether blockade of IL-33 signaling in the LCMV/PKO model of FHL would sufficiently limit the $CD8^+$T cell response to prevent the development of disease.

Methods: PKO mice were infected i.p. with 2×10^5 PFU LCMV-Armstrong and received 150 μg i.p. of either IL-33R-blocking antibody or isotype control every 2 days, beginning on day 3 post-infection. Mice were monitored for weight loss, survival, complete blood count, serum cytokines, spleen and liver histology, LCMV titers, frequency of antigen-specific $CD8^+$T cells, and T cell cytokine production.

Results: LCMV-infected PKO mice receiving IL-33R blocking antibody (IL-33RB) showed reduced weight loss (P=0.0170) and highly reduced mortality (HR =11.79, P=0.0021). IL-33R blockade reduced levels of serum IFNγ 16-fold (P=0.0005) and lowered frequencies of IFNγ-producing $CD8^+$ T cells (P=0.0003). Additionally, IL-33RB mice had reduced hepatic parenchymal damage, although leukopenia, anemia, and thrombocytopenia were not improved. Despite the reduced inflammation in IL-33RB mice, they maintained similar frequencies of LCMV-specific $CD8^+$T cells compared to isotype-treated controls and showed equivalent titers of LCMV in the spleen.

Conclusion: IL-33R blockade improves morbidity and mortality in a mouse model of FHL without exacerbating viral infection. Our results identify signaling via the tissue damage-associated cytokine IL-33 as an additional pathway contributing to disease and suggest blockade of this pathway as a viable treatment strategy for FHL.

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is a severe inflammatory disease of unknown etiology. We utilized a genomic approach to interrogate the molecular pathogenesis of this disorder.

Methods: Single nucleotide polymorphism (SNP) genotypes from Illumina arrays were obtained in 988 children with sJIA and 431 healthy subjects and combined with *in silico* SNP data from 7579 healthy subjects. The collection was divided into 9 strata by country of origin, and after stringent quality control, we performed genome-wide SNP imputation and association testing in each stratum, followed by meta-analysis. A second round of imputation using a more densely genotyped reference panel was performed in regions with $p < 1E\text{-}7$. To investigate the role of specific major histocompatibility complex (MHC) proteins, we imputed classical HLA alleles and their subordinate amino acid positions. To assess whether sJIA-associated noncoding MHC variation conferred risk through regulatory mechanisms, we used RegulomeDB to analyze MHC SNPs with $p < 1E\text{-}5$. RegulomeDB integrates and queries regulatory information from over 100 tissues and cell lines, including DNAse hypersensitivity, transcription factor (TF) ChIP-seq and histone ChIP-seq data from ENCODE, plus expression quantitative trait loci (eQTL) data.

Results: Meta-analyses of >1.3M SNPs identified significant associations ($p < 1.5E\text{-}8$) between sJIA and 6 SNPs between *BTNL2* and *HLA-DQA1*, as well as a susceptibility locus in a noncoding region of chromosome 1 nearest to the long intergenic noncoding RNA, *LOC284661*. Conditional analysis of the phase 2 imputation data identified *HLA-DRB1* (p_{peak} = 1.6E-10) and *HLA-DQA2* ($p_{regression}$ = 4.6E-7) as independent susceptibility loci. It also revealed a 10kb sJIA-associated region on chromosome 1 that contained 8 sJIA-associated SNPs ($p < 1.5E\text{-}8$). Conditional analyses of imputed HLA alleles identified *HLA-DRB1*1101* (p_{peak} = 3.1E-9) and *HLA-DPB1*03* ($p_{regression}$ = 3.2E-4) as independent risk factors, while position 58 of HLA-DRB1, which defines the -DRB1*11 alleles, was also significantly associated with sJIA ($p = 1.4E\text{-}7$). Using RegulomeDB to examine 886 MHC SNPs with $p < 1E\text{-}5$, we found 13 sJIA-associated SNPs with strong evidence that they influenced transcription factor binding and were also linked to expression of a gene target (RegulomeDB scores 1a - 1f). These SNPs were located nearest to *HLA-DQA1*, *HLA-DRB1*, *HLA-DRA*, *TNXB*, *NOTCH4* and *C2*. 12 of 13 SNPs were *cis* eQTLs for 1 or more MHC class II (MHCII) genes in lymphoblastoid cell lines (LCLs) and/or monocytes, 8 of which were eQTLs for *HLA-DRB5*. 3 of 13 SNPs resided within TF ChIP-seq peaks in GM12878 LCLs. 7 of 13 SNPs resided in H3K27ac ChIP-seq peaks (marks of active enhancers) in GM12878 LCLs and/or monocytes, 6 of which were cell-type specific. In all, 9 of 13 SNPs were located within histone modification signatures that were specific to GM12878 LCLs.

Conclusion: This study implicates the MHCII locus and a region of chromosome 1 upstream of *LOC284661* in sJIA susceptibility. The data suggest that the MHCII locus influences sJIA susceptibility through both protein coding variation and noncoding variation that alters gene expression.

Interferon-γ (IFNγ) in Macrophage Activation Syndrome (MAS) Associated with Systemic Juvenile Idiopathic Arthritis (sJIA). High Levels in Patients and a Role in a Murine MAS Model. Claudia Bracaglia[1], Ivan Caiello[1], Kathy De Graaf[2], Giovanni D'Ario[2], Florence Guilhot[2], Walter Ferlin[2], Lidia Meli[1], Giusi Prencipe[1], Sergio Davi[3], Grant Schulert[4], Angelo Ravelli[5], Alexei Grom[4], Cristina De Min[2] and Fabrizio De Benedetti Sr.[1]. [1]Division of Rheumatology, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy, [2]Novimmmune S.A., Plan-Les-Ouates, Geneva, Switzerland, [3]Istituto Giannina Gaslini, Genova, Italy, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Istituto Giannina Gaslini and University of Genova, Genova, Italy.

Background/Purpose: IFNγ is the pivotal mediator in murine models of primary HLH. Given the similarities between primary and secondary (sHLH), including MAS, we analyzed IFNγ levels in patients with sJIA and MAS and evaluated the pathogenic role of IFNγ in a murine MAS model.

Methods: We measured levels of IFNγ, IFNγ-related chemokines (CXCL9, CXCL10, CXCL11), and IL-6 in patients with sHLH (n=14), and in patients with sJIA (n=54) of whom 20 had MAS at sampling using the Luminex multiplexing assay and evaluated their relation to disease activity. The effect of the anti-IFNγ antibody XMG1.2 was assessed in IL-6 transgenic (IL6TG) mice in which a MAS-like syndrome leading to death is triggered by TLR ligands (Strippoli, Arthritis Rheum 2012). An LPS LD50 (5 μg/gr body weight) was used, as a trigger for MAS, followed 10 hours later by administration of 100 μg/gr of XMG1.2.

Results: Levels of IFNγ and of IFNγ-related chemokines [median pg/ml(IQR)] were markedly elevated in active MAS and active sHLH, with no significant differences between active sHLH [IFNγ 34.7(23.9–170.1); CXCL9 33598(3083–127687); CXCL10 4420(799.7–8226); CXCL11 1327(189–2000)] and active MAS [IFNγ 15.4(5.1–52.6); CXCL9 13392(2163–35452); CXCL10 1612(424.8–4309); CXCL11 564.8(197.5–1007)]. Levels in active sJIA without MAS at sampling [IFNγ 4.88(3.2–8.7); CXCL9 836.5(470.9–2505); CXCL10 307.3(198.9–693.7); CXCL11 121.7(62–197.1)] were lower (all p-values <0.01) than in active sHLH or active MAS. IL-6 was not different between the three groups. In active MAS, platelet count was inversely related to IFNγ (r=−0.53; p=0.02), CXCL9 (r=−0.51; p=0.03) and CXCL10 (r=−0.58; p=0.009). In the murine MAS model, treatment with the anti-IFNγ antibody XMG1.2 resulted in increased survival (XMG1.2-treated 10 survivors/10 treated; control-treated 5/10; p=0.033).

Conclusion: IFNγ, and IFNγ-related chemokine levels were increased in patients with MAS compared to patients with active sJIA without MAS, and associated with low platelet count. Neutralization of IFNγ increased survival in murine MAS.

Utility of Glyca, a Novel Inflammatory Marker, for Assessment of Rheumatoid Arthritis Disease Activity. Michelle Ormseth[1], Cecilia P. Chung[1], Joseph F. Solus[1], Annette M. Oeser[1], Margery A. Connelly[2], Jim Otvos[2] and C Michael Stein[1]. [1]Vanderbilt University, Nashville, TN, [2]LipoScience, Inc., Raleigh, NC.

Background/Purpose: GlycA is a novel inflammatory biomarker measured from the nuclear magnetic resonance (NMR) spectra obtained for lipoprotein particle analysis. It represents a distinct peak composed primarily of glycosylated acute phase proteins. Glyc A is associated with inflammatory markers, and development of cardiovascular disease. We hypothesized that GlycA is a biomarker of disease activity and systemic inflammation in rheumatoid arthritis (RA).

Methods: We conducted a cross-sectional study including 166 patients with RA and 90 control subjects. GlycA was measured using a previously validated algorithm from the NMR lipoprotein particle profile which quantifies the NMR signal originating from N-acetylglucosamine and N-acetylgalactosamine residues on carbohydrate side chains of circulating glycoproteins. Disease activity of RA was quantified by DAS28 score and functional capacity by the modified health assessment questionnaire. Markers of inflammation including erythrocyte sedimentation rate (ESR), high sensitivity C-reactive protein (CRP), interleukin 6 (IL-6) and tumor necrosis factor alpha (TNF-α) were measured. GlycA concentrations were compared between patients with RA and control subjects and correlated with disease activity and markers of inflammation in RA.

Results: Patients with RA had higher GlycA concentration (median [interquartile range]: 398 μmol/l [348, 473 μmol/L]) compared to control subjects (344 μmol/l [314, 403 μmol/l], P<0.001). Among patients with RA GlycA was strongly correlated with DAS28 and its components including tender and swollen joint count, global health visual analog scale score and acute phase reactants CRP and ESR (P < 0.001, Table). Similarly, GlycA was strongly associated with proinflammatory cytokines, IL-6 and TNF-α, and RA functional capacity (P ≤ 0.002, Table).

Table: Association between GlycA and RA disease activity and inflammation

	Spearman Rho	P value
DAS28	0.576	<0.001
Tender joints	0.283	<0.001
Swollen joints	0.288	<0.001
Global health	0.304	<0.001
CRP	0.614	<0.001
ESR	0.643	<0.001
IL-6	0.388	<0.001
TNF-α	0.245	0.002
mHAQ	0.235	0.002

Conclusion: GlycA is a novel inflammatory marker that is useful for assessment of disease activity and systemic inflammation in patients with RA.

Disclosure: M. Ormseth, None; **C. P. Chung**, None; **J. F. Solus**, None; **A. M. Oeser**, None; **M. A. Connelly**, LipoScience, Inc., 3; **J. Otvos**, LipoScience, Inc., 3; **C. M. Stein**, None.

1903

Change in 14-3-3η Expression in Early RA Patients Treated with Dmards Corresponds with Change in DAS28 and Good EULAR *Responses*. Dirkjan van Schaardenburg[1], Mairead Murphy[2], Yuan Gui[2], Samina Turk[1], Walter P. Maksymowych[3] and Anthony Marotta[2]. [1]Reade, Amsterdam, Netherlands, [2]Augurex Life Sciences Corp., North Vancouver, BC, [3]University of Alberta, Edmonton, AB.

Background/Purpose: 14-3-3η is a mechanistic marker that up-regulates inflammatory and joint damage factors that are implicated in the RA pathophysiological process[1]. It is a potent inducer of TNF-α and IL-6 and we have previously described that low 14-3-3η levels prior to the initiation of anti-TNF and tocilizumab therapy marks good EULAR response and DAS remission. There is an unmet need for mechanistic biomarkers that enhance prediction of response to therapy. We also recently described that lower baseline plasma 14-3-3η levels mark good EULAR response in an RA cohort treated with DMARDs. In this study we tested plasma levels in the same cohort at year 1 to determine whether a change in 14-3-3η expression from baseline informs the change in DAS28 and response to therapy.

Methods: Three hundred and 80 (380) patients from the Reade early RA cohort were assessed for 14-3-3η titres at baseline and at year 1 follow up. All patients were DMARD naïve at baseline, mean age was 54 years, 73% were female and median duration of symptoms was 4 months (IQR 2–7). Fisher's Exact test was performed to assess the relationship between baseline to year 1 change in 14-3-3η and a Good EULAR response and DAS remssion (<2.6) at year 2 follow up. Spearman rank correlations were used to identify associations between change in 14-3-3η and change in DAS28. A nominal logistic regression, controlling for baseline DAS, was used to investigate if change in 14-3-3η is a predictor of Good EULAR response.

Results: Mean (SD) year 1 plasma 14-3-3η levels [3.3 ng/ml (6.0)] were significantly lower than baseline levels [4.4 ng/ml (6.9)], p=0.0004 reflecting the modifiability of 14-3-3η plasma concentrations over this period. The change in 14-3-3η titres significantly correlated with the change in DAS from baseline to year 2 (r=0.12, p=0.02) across the whole cohort. The Fisher Exact test revealed that a decrease in 14-3-3η from baseline to year 1 was significantly associated with a Good EULAR response [LR = 4.4, OR(95%CI)=1.6 (1.1–2.4), p=0.023] and remission [LR = 4.5, OR(95%CI)=1.3 (1.0–1.7), p=0.022] at year 2. In a bivariate model controlling for baseline DAS28, a decrease in 14-3-3η, was an independent predictor of a Good EULAR response yielding an LR of 4.2, p = 0.04. Both baseline DAS28 (LR=15.6, p<0.0001) and the change in 14-3-3η (LR=5.1 p=0.024) were independent predictors of remission at year 2.

Conclusion: 14-3-3η plasma levels decrease with DMARD therapy and their change correlates with the change in DAS28 and predict both a good EULAR response and DAS remission. These clinical findings align with the mechanistic understanding of 14-3-3η as a potent upregulator of inflammatory and joint damage factors and how a decrease in its expression corresponds with a reduced burden of disease.

Rheumatoid Factor Isotype Testing to Identify Individuals in the Preclinical Period of Rheumatoid Arthritis. M. Kristen Demoruelle[1], Anthony Kahr[1], Mark C. Parish[1], Marie L. Feser[1], Ryan W. Gan[2], Jason R. Kolfenbach[1], William R. Gilliland[3], Jess D. Edison[3], Michael H. Weisman[4], James R. O'Dell[5], Ted R. Mikuls[6], Richard M. Keating[7], Peter K. Gregersen[8], Jane H. Buckner[9], Jill M. Norris[2], V. Michael Holers[1] and Kevin D. Deane[1]. [1]University of Colorado School of Medicine, Aurora, CO, [2]Colorado School of Public Health, Aurora, CO, [3]Walter Reed National Military Medical Center, Bethesda, MD, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]Veteran Affairs Nebraska Western Iowa Health Care System and University of Nebraska Medical Center, Omaha, NE, [6]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [7]Scripps Clinic, La Jolla, CA, [8]Feinstein Institute for Medical Research, Manhasset, NY, [9]Benaroya Research Institute at Virginia Mason, Seattle, WA.

Background/Purpose: Rheumatoid arthritis (RA)-related autoantibody (Ab) testing for Abs to cyclic citrullinated peptide (CCP) and rheumatoid factor (RF) are used in the clinical diagnosis of RA. In addition, RA-related Ab elevations in asymptomatic individuals indicate an increased risk of future RA and define a preclinical period of RA development. These at-risk subjects could be considered for prevention strategies in RA, but a challenge in effective identification of individuals at-risk for RA is the varied methods of Ab testing. For example, RF can be tested by nephelometry (RFneph) as is commonly used in clinical labs or by ELISA for RF isotypes (IgM/A/G). Studies demonstrate RFIgM and/or RFIgA is highly sensitive in classifiable RA, but the utility of RF isotype testing in addition to RFneph is not well known in preclinical RA.

Methods: We evaluated subjects with classifiable RA (1987 ACR criteria) from the Studies of the Etiology of RA (SERA) project (N=566) and the Department of Defense Serum Repository (DoDSR; N=83; all with pre-diagnosis and 47/83 with post-diagnosis samples). Controls were 200 random blood donors for SERA RA cases and 83 DoDSR matched controls for DoDSR RA cases. All subjects were tested for RFneph and RF isotypes (IgM/A/G by ELISA). Cut-off levels for all RF assays were determined as <5% positive in a separate set of 491 blood donors. CCP3.1 (IgG/IgA INOVA) testing was performed in all subjects using manufacturers cut-off levels.

Results: The diagnostic accuracy of Ab testing is listed in Table 1. All RFs and CCP3.1 had high specificity for classifiable RA including SERA RA and DoDSR post-diagnosis. In DoDSR pre-diagnosis testing, sensitivity for future RA was 41% for RFneph and 63% for CCP3.1. Sensitivity increased to 69% when positivity for the following Abs was considered: RFneph, CCP3.1, RFIgA or RFIgM. In DoDSR RA cases who were negative for RFneph and CCP3.1 in pre-diagnosis testing (N=29), adding RFIgA or RFIgM (but not IgG) testing identified an additional 10% of subjects who developed classifiable RA (Table 2).

Conclusion: Herein RFneph and CCP3.1 had fair diagnostic accuracy for future RA; however, RFIgA and IgM (but not IgG) testing allowed for identification of 10% more individuals who would develop future RA, while maintaining high specificity (93% for RFIgA or IgM pre-diagnosis). These findings suggest that RFneph misses some RF positivity that is detectable by isotype testing. As such, in addition to CCP3.1 and RFneph, RFIgM and RFIgA testing may be clinically meaningful in identifying subjects at-risk for future RA, especially if interventions become available to prevent progression from preclinical to classifiable RA.

Table. Sensitivity and Specificity of Rheumatoid Factor Isotypes in Classifiable and Preclinical RA

	RFIgA	RFIgM	RFIgG	≥1 RF isotype	RFIgA or RFIgM	RFneph	CCP3.1	RFneph or CCP3.1	RFIgA, RFIgM, RFneph or CCP3.1
SERA RA cases (N=566)†*									
Sensitivity	41.3	59.0	44.3	64.8	62.6	61.5	67.8	77.6	80.6
Specificity	98.0	94.5	94.5	91.0	94.0	95.0	94.0	89.0	85.5
DoDSR RA cases, post-diagnosis (N=47)‡									
Sensitivity	61.7	68.1	31.9	80.9	80.9	66.0	75.6	85.1	87.2
Specificity	91.7	93.6	100	87.2	87.2	95.7	89.4	85.1	78.7
DoDSR RA cases, pre-diagnosis (N=83)μ*									
Sensitivity	44.6	43.4	24.1	53.0	53.0	41.0	62.7	65.1	68.7
Specificity	94.0	98.8	98.8	92.8	92.8	97.6	92.8	90.3	87.5

†Sensitivity and specificity analyzed in comparison with 200 random blood donor controls
‡ 47 post-diagnosis samples were available for 83 DoDSR RA cases. Median time post-diagnosis = 2.2 years. Cases were compared to 47 matched controls
μ243 pre-diagnosis samples were available for 83 DoDSR RA cases. Calculated using 1 sample per case, and if ≥1 sample available, the sample closest to the time of diagnosis was used for analysis; median 1.4 years prior to RA diagnosis. Cases were compared to matched controls.
*SERA RA cases were older than DoDSR RA cases (median age 58 v. 40 years) and had a higher proportion of women subjects (77% v. 41%).

Table 2. RF Isotype Positivity in DoDSR RA Cases Negative for RF by Nephelometry and CCP3.1 in Pre-diagnosis Testing*

	Prevalence of positivity (%)		
	RFneph(−) (N=49)	CCP3.1(−) (N=31)	CCP3.1(−) and RFneph(−) (N=29)
RFIgM	14.3	12.9	6.9
RFIgA	14.3	6.5	3.4
RFIgG†	2.0†	3.2†	0†
≥1 RF isotypes	24.5	16.1	10.3
RFIgA or RFIgM‡	24.5	16.1	10.3

*From the 83 DoDSR RA cases, these results include testing of cases who were negative for RFneph and/or CCP3.1 in their pre-diagnosis sample that was closest to the time of their diagnosis; median 1.4 years prior to RA diagnosis.
†RFIgG testing did not identify any subjects pre-diagnosis of RA that were not identified as seropositive by CCP3.1 or RFneph testing.
‡RFIgA or RFIgM positivity was present in only 6 of 83 (7.2%) of DoDSR matched controls, and this high specificity (93.8%) adds further value to the identification of 4 of 29 (10.3%) preclinical RA subjects who will go on to develop classifiable RA.

Within-Day Variation and Influence of Physical Exercise on Circulating Galectin-3 in Patients with Rheumatoid Arthritis and Healthy Individuals. Saida Farah Issa[1], Anne Friesgaard Christensen[2], Tine Lottenburger[2], Kirsten Junker[3], Hanne M. Lindegaard[1], Kim Hoerslev-Petersen[4] and Peter Junker[1]. [1]Department of Rheumatology, Odense University Hospital, Odense, Denmark, [2]Department of Rheumatology, Vejle Hospital, Vejle, Denmark, [3]Institute of Molecular Medicine, Cardiovascular & Renal Research, University of Southern Denmark, Odense, Denmark, [4]Research Unit at King Christian X Hospital for Rheumatic Diseases, Graasten, Graasten, Denmark.

Background/Purpose: Galectin-3 has been suggested as a pro-inflammatory mediator in Rheumatoid Arthritis(1). Thus, Galectin-3 is over-expressed in RA-synovitis and bone erosions were significantly decreased in GAL-3 −/− mice compared with wild type animals (2,3). Furthermore, in long-standing RA, Galectin-3 was increased in synovial fluid and serum compared with osteoarthritis and controls (2). These findings indicate that Galectin-3 may serve as biomarker for synovitis pathology in RA.

The objectives of this study were to investigate whether serum Galectin-3 exhibits circadian variation and/or is influenced by physical exercise in patients with RA at different stages and controls.

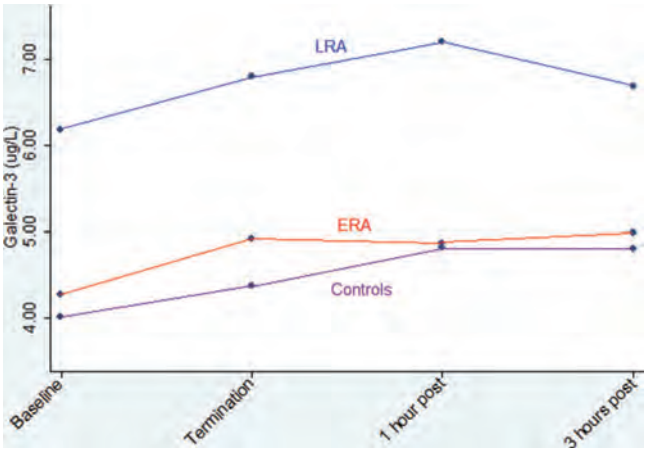
Methods: The study on circadian patterns comprised eleven patients with newly diagnosed RA, disease duration less than 6 months (ERA), 10 patients with long-standing RA (5–15 years (LRA)) and 16 self-reportedly healthy control subjects. During 24 hours 7 blood samples were drawn at 3-hour intervals starting at 10 a.m. through 10 p.m. and at 7 and 10 a.m. on the following day. The study on the effect of physical activity included 10 patients with ERA, 10 with LRA and 14 controls. The participants underwent a standardized exercise program and four blood samples were drawn before, during and after exercise. Serum Galectin-3 was quantified by ELISA (R&D systems). An age and sex adjusted mixed model analysis was applied in both substudies.

Results: Circadian variation substudy: Galectin-3 was borderline increased at baseline in ERA and LRA, 6.03 ug/l (*95% CI 4.44;7.61*) and 5.95 ug/l (*4.44;7.47*) vs. 4.51 ug/l (*3.48;5.53*) in control subjects (p = 0.08). There was no association between time of blood sampling and Galectin-3 in serum (p = 0.85).

Physical exercise substudy: Baseline mean Galectin-3 in both subsets was also elevated, however without reaching statistical significance in the ERA group; LRA 6.18 ug/l (*95% CI 4.46;7.89;* p = 0.01), ERA 4.27 ug/l (*3.23;5.30;* p = 0.68) vs controls 4.01 ug/l (*3.10;4.91*). A submaximal physical challenge elicited comparable Gal-3 increments at 10–15% above

baseline with peak values 1–3 hours post exercise in RA patients and controls (p-value < 0.001), fig. 1.

Figure 1. Galectin-3 increments in healthy controls, and in patients with early (ERA) and longstanding rheumatoid arthritis (LRA) before and after termination of exercise.



Conclusion: Circulating Galectin-3 was increased in early and longstanding RA. Galectin-3 did not exhibit circadian variation. Galectin-3 increased comparably in RA patients and healthy controls following submaximal exercise, which should be avoided before bloodsampling for Galectin-3 determination.

IL-6 Blockade Reduces Circulating N-Terminal Pro-Brain Natriuretic Peptide Levels in Patients with Active Rheumatoid Arthritis. Atsuma Nishiwaki[1], Hitomi Kobayashi[1], Yasuyuki Kobayashi[2], Isamu Yokoe[1], Noboru Kitamura[1], Hidetake Shiraiwa[1], Takamasa Nozaki[1], Hirotake Inomata[1], Natsumi Ikumi[1], Kaita Sugiyama[1], Yousuke Nagasawa[1] and Masami Takei[3]. [1]Nihon University School of Medicine, Tokyo, Japan, [2]St.Marianna University School of Medicine, Kawasaki, Japan, [3]Nihon University School of Medicine, Itabashi Tokyo, Japan.

Background/Purpose: Patients with rheumatoid arthritis (RA) have a 1.5–2.0 fold higher risk of developing congestive heart failure (CHF) than the general population. Small increases in N-terminal pro-brain natriuretic peptide (NT-proBNP) levels predict left ventricular (LV) dysfunction and cardiac stress. NT-pro BNP is also associated with pro-inflammatory cytokines such as interleukin 6 (IL-6). Data relating to the effects of IL-6 blocking agents (tocilizumab, TCZ) on circulating NT-proBNP levels in patients with active RA are lacking but may be informative. We therefore investigated the effects of TCZ therapy on the NT-proBNP levels in RA patients without cardiac symptoms before and after 24 weeks of treatment.

Methods: RA patients with active disease with an inadequate clinical response to non biologic DMARDs and non-RA healthy control were enrolled. Exclusion criteria were diabetes, previous cardiovascular events, cardiopathy, hypertension and renal disease. The RA patients received TCZ once a month for 24 weeks. Serum NT-pro BNP levels were measured at baseline and week 24. Clinical and biological monitoring was performed at baseline and 24 weeks after the start of TCZ treatment. We explored the associations between NT-pro BNP and the RA disease activity score for Simple Disease Activity Index (SDAI) scores. The anti-citrullinated protein antibody (ACPA) titre was divided into high and low levels using a cut-off of 30 units/mL. Fisher test and multivariable linear regression analyses were performed to identify the correlations.

Results: 90 patients (mean age, 56.4 ± 10.4 years; 85% female) and a matched 30-patient control group (mean age 55.6±3.4 years; 86% female) were enrolled. The SDAI at baseline was 22.5 ± 12.7. The 24-week SDAI scores were significantly lower than those at baseline ($p = 0.03$). The NT-proBNP levels at baseline were significantly higher than control group ($p=0.04$). The median (interquartile range) levels of the NT-proBNP significantly decreased from baseline (121.78 [52.81–230.24] pg/mL) to 24 weeks (57.13 [29.50–128.67] pg/mL, $p = 0.004$) following TCZ treatment. NT-proBNP levels in the high ACPA group tended to be higher than the low ACPA group ($p = 0.07$). The change in NT-proBNP levels was significantly correlated with the change in the SDAI score ($r = 0.455$, $p = 0.003$). After adjustment for age, gender, erythrocyte sedimentation rate (ESR), and RA duration, the association between the change in NT-proBNP levels and the change in SDAI remained significant ($p = 0.023$).

Conclusion: This is the first study to report the effect of IL-6 blocking agent on circulating NT-proBNP levels in patients with active RA. Our results suggest that blocking IL-6 in patients with RA without cardiac symptoms does not increase but rather decreases circulating NT-proBNP levels by around 52%, which was also related to a reduction in disease activity. Our data also suggest that RA-specific autoimmunity against citrullinated proteins might relate to subclinical cardiac stress. TCZ treatment may influence the presence of subclinical left ventricular dysfunction or cardiac stress which may progress to overt CHF.

Clinical Evaluation of Anti-Aminoacyl tRNA Synthase Antibodies in Rheumatoid Arthritis Patients. Masakazu Matsushita, Ken Yamaji, Naoto Tamura and Yoshinari Takasaki. Juntendo University School of Medicine, Tokyo, Japan.

Background/Purpose: Anti-Jo-1 is an autoantibody that is specifically detected in the blood sera of patients with polymyositis/dermatomyositis (PM/DM). The corresponding antigen is known to be histidyl-tRNA synthase, an aminoacyl-tRNA synthase (ARS) localized to the cytoplasm. Recently, autoantibodies to other ARSs have been identified and patients with these antibodies have distinguishing clinical symptoms such as lesions of the lung or skin, a condition known as anti-ARS antibody syndrome. We measured anti-ARS antibodies in rheumatoid arthritis (RA) patients and evaluated its clinical characteristics.

Methods: At our hospital, 228 ambulatory RA patients were selected for the study. We evaluated the positive rate of anti-ARS antibodies in the blood sera of these patients. Anti-ARS antibodies were measured using the EUROLINE Myositis Profile 3 test system (EUROIMMUN Inc., Lubeck, Germany). Five anti-ARS antibodies can be measured using this kit: anti-OJ, anti-EJ, anti-PL-12, anti-PL-7, and anti-Jo-1 antibodies. For blood serum testing positive for any one of these antibodies, we performed an indirect immunofluorescence assay by using HEp-2 cells to determine whether a reaction occurred in the cytoplasm. We grouped the participants into anti-ARS antibody-positive and -negative groups, and evaluated age, gender, male-to-female ratio, anti-CCP antibodies, rheumatoid factor levels, presence of interstitial pneumonia (IP), and frequency of usage of methotrexate or biologics.

Results: Anti-ARS antibodies were detected in 6.1% (14 patients) of all RA patients. Specifically, anti-PL-7 antibodies were detected in 6 patients (2.6%), anti-EJ antibodies in 4 patients (1.8%), anti-PL-12 antibodies in 2 patients (0.9%), anti-OJ antibodies in 1 patient (0.4%), and anti-Jo-1 antibodies in 1 patient (0.4%). When the blood sera of these patients were allowed to react with HEp-2 cells by using the indirect immunofluorescence method, we detected staining in the cytoplasm of all patients. When we compared the anti-ARS antibody-positive and -negative groups, differences in age or gender were not observed. However, the frequency of interstitial pneumonia in the anti-ARS antibody-positive group was significantly higher ($P < 0.05$). A detailed investigation of the antibodies revealed that anti-PL-7 and anti-PL-12 antibodies were detected at a significantly higher level in patients with IP. Biologics were administered in 3 patients in the anti-ARS antibody-positive group; however, concomitant myositis or exacerbation of IP was not observed. No significant difference was observed between the positive and negative groups in terms of anti-CCP antibody values or rheumatoid factor levels.

Conclusion: Anti-ARS is an autoantibody that is detected specifically in PM/DM patients; however, we demonstrated that it is also detected in RA

patients. In particular, anti-PL-7 and anti-PL-12 antibodies were detected efficiently in RA patients with IP, suggesting that these autoantibodies are associated with IP. Our investigation showed that biologics could be administered safely to RA patients with anti-ARS antibodies.

Pregnancy Outcomes in the Tofacitinib RA Safety Database through April 2014. A. Marren[1], Y. Chen[1], D. Frazier[2] and J. Geier[3]. [1]Pfizer Inc, Collegeville, PA, [2]Pfizer Inc, Groton, CT, [3]Pfizer Inc, New York, NY.

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Its effect in pregnant women is of interest, as tofacitinib has been shown to be fetocidal and teratogenic in rats and rabbits at exposures 146 times and 13 times (respectively) the maximum recommended human dose. There are no adequate, well-controlled tofacitinib studies in pregnant women; per the RA clinical development program protocols, all studies exclude pregnant subjects and require use of highly effective contraception by females with child-bearing potential, and study treatment discontinuation if a subject becomes pregnant. To understand potential effects of tofacitinib, pregnancies in the RA clinical development program were reviewed.

Methods: Cases were identified from Pfizer's internal safety database through April 30, 2014, from interventional (one clinical study is ongoing; database not locked) and non-interventional studies, plus cases from post-marketing reporting. Cases were limited to females administered tofacitinib/placebo/blinded therapy at time of conception and/or fetal subjects exposed to tofacitinib/placebo/blinded therapy through maternal exposure. Potential duplicate cases were eliminated; remaining cases were reviewed for any pregnancy-related outcome and abnormalities, which were categorized as healthy newborns, spontaneous abortion, medical termination, still-birth, pending, or lost to follow-up.

Results: A total of 35 cases were identified. In the tofacitinib RA clinical studies of ~6,000 subjects with nearly 17,000 patient-years of follow-up, there were 32 cases of maternal tofacitinib exposure. Subject age ranged from 22 to 40 years. Of the 32 cases, 31 received tofacitinib; 13 had 5 mg BID, 1 had 5 mg QD, 12 had 10 mg BID, 2 had 20 mg QD, 1 had 15 mg BID, and 2 whose therapy at conception is still blinded. One subject received placebo/methotrexate (MTX). Ten of the 32 cases were also taking MTX. The pregnancy outcomes with tofacitinib were: 14 healthy newborns (including 1 low birth weight and 1 pre-term birth), 6 spontaneous abortions, 4 medical terminations, 1 still-birth (at approximately 17 weeks gestation), 1 congenital malformation of pulmonary valvar stenosis reported in a 32-year-old subject with diabetes and hypertension, 2 pending outcome, and 3 lost to follow-up; the placebo-treated subject experienced a spontaneous abortion. The remaining 3 cases receiving tofacitinib were reported from other data sources including 2 cases from 2 non-interventional clinical studies and 1 from post-marketing reporting. Fetal subjects had maternal exposure to tofacitinib. Of the 3 cases, 1 had a spontaneous abortion; outcomes were still pending for the other 2 cases.

Conclusion: Most cases with reported outcomes had healthy newborns. Adverse outcomes including spontaneous abortions and congenital malformation were observed in RA subjects who became pregnant during tofacitinib therapy. Pregnancy outcomes in subjects receiving tofacitinib will continue to be monitored through routine pharmacovigilance and via a post-approval safety study within the Organization of Teratology Information Specialists (OTIS) registry.

Incidence of Congestive Heart Failure in Subjects with Rheumatoid Arthritis Receiving Anti-Tumour Necrosis Factor Drugs: Results from the British Society for Rheumatology Biologics Register for Rheumatoid Arthritis. Alper van Sijl[1], Mamas Mamas[2], Mark Lunt[3],. BSRBR Control Centre Consortium[4], Kath Watson[5], Deborah P. Symmons[4] and Kimme L. Hyrich[6]. [1]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom, [2]Manchester Heart Centre, Manchester Royal Infirmary, Oxford Road, Manchester, UK; Institute of Cardiovascular Sciences, University of Manchester, Manchester, United Kingdom, [3]University of Manchester, Manchester, United Kingdom, [4]Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom, [5]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [6]Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom.

Background/Purpose: Subjects with rheumatoid arthritis (RA) are at a higher risk of developing cardiovascular (CV) disease compared to the general population, with an increased incidence of congestive heart failure (CHF) possibly mediated by chronic inflammation. Anti-tumour necrosis factor (TNFi) drugs might reduce the incidence of new CHF by supressing inflammation. However, TNFi are associated with a worsening of existing CHF. The aim of this analysis was to compare the incidence of CHF in subjects with RA treated with TNFi to that in those receiving non-biologic drugs (nbDMARDs).

Methods: Patients with a physician diagnosis of RA enrolled in the British Society for Rheumatology Biologics Register, a national prospective cohort study established in 2001 to monitor the long-term safety of TNFi. Potential CHF events were verified according to Framingham criteria by a cardiologist from death certificates and from clinical follow-up forms of consultants. New CHF which occurred within 6 months after another cardiac event (eg. myocardial infarction) was excluded. Risk of CHF was compared between the two cohorts using a Cox regression model, propensity scores adjusted. Subjects were censored at first episode of CHF, death, first missed dose of TNFi + 180 days, last returned clinician follow-up or 31/01/2014, whichever came first.

Results: A total of 87 validated first CHFs were analysed: 48 in 3,662 nbDMARD subjects and 39 in 12,397 TNFi-exposed subjects. After adjustment for differences in baseline characteristics, the hazard ratio (95%-confidence interval) of CHF in patients on TNFi compared to nbDMARD was: 0.31 (0.18–0.52). Similar results were found for analysis limited to first TNFi only and in patients without prior history of ischaemic heart disease.

Conclusion: No increased risk of CHF was observed in those patients selected for TNFi therapy compared to those receiving nbDMARD therapy. A reduced risk of CHF was noted in patients treated with TNFi.

Table. Association between exposure to TNFi and development of first CHF

	nbDMARD (n=3662)	TNFi (n=12397)
Years of follow-up per subject, median (IQR)	5.0 (2.5–7.7)	5.1 (1.9–8.0)
Person-years of exposure, pyrs	18 698	62 244
Number of verified CHFs, n (%)	48 (1.31)	39 (0.31)
Crude incidence rate of verified CHFs per 10 000 person-years (95%-confidence interval)	25.67 (19.53–34.40)	6.27 (4.58–8.58)
Risk of CHF between nbDMARD and TNFi		
- Unadjusted HR (95%-CI)	Referent	0.24 (0.16–0.37)
- Age- and gender adjusted HR (95%-CI)	Referent	0.47 (0.30–0.72)
- PD-adjusted HR (95%-CI)	Referent	0.25 (0.14–0.44)

Fully adjusted model by propensity score (PD) consisting of age, gender, DAS28, disease duration, HAQ, steroid use, NSAIDs, COXIBs, hypertension, diabetes mellitus, angina pectoris, myocardial infarction, smoking history and use of statins, antiplatelets, ACE-inhibitors, warfarin and digoxin.

Risk of Hypersensitiviy Among Medicare Patients with Rheumatoid Arthritis Who Were Taking Biologics. Huifeng Yun[1], Fenglong Xie[2], Lang Chen[2], James Lewis[3] and Jeffrey R. Curtis[2]. [1]University of Alabama at Birmingham School of Public Health, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Healthcare providers have been alerted to the potential drug hypersensitivity reactions (HSRs, an adverse drug reaction that are uncommon but may be severe and can result in mortality) in patients (pts) with RA, especially those receiving intravenously (IV) administered biologics. One case of a fatal HSR has been reported and associated with tocilizumab (TCZ). The risks of HSRs in population-based RA cohorts are unclear, as is understanding whether risks differ by specific agent. We compared drug-specific risks for HSR among RA pts enrolled in the US Medicare.

Methods: Using Medicare data from 2006–2011 for 100% of pts with RA, we identified new users of infliximab (INF), abatacept (ABA), rituximab (RIT), TCZ and injected biologics (e.g. anti-TNF therapy).For each biologic administration (Adm), follow up started on the date of drug infusion/injection and ended at the earliest date of: HSR, subsequent biologic Adm, death, coverage loss, 30-day follow-up period, or Dec 31, 2011. We identified HSR using validated claims-based algorithms in three settings: A) Inpatient (IP) or emergency departments (ER) for anaphylactic shock, B) Outpatient (OTP) for anaphylactic shock plus a diagnosis of bronchospasm, stridor, hypotension, epinephrine, injection of diphenhydramine and CPR (Disease and symptom list); C) IP or ER for unspecified allergy plus a diagnosis from the above disease and symptom list. We calculated the incidence rate (IR) of HSR for each biologic within 0–1, 2–14 and 15–30 days of Adm. Robust Poisson regression was used to compare the HSR risks across biologics adjusting for age, gender, Charlson comorbidity score, concomitant steroid (GCs) and methotrexate (MTX) use. Sensitivity analysis was conducted using a nested case-crossover design to reduce within-person confounding.

Results: We identified 429,565 biologic Adms or prescription fills among 54,902 new biologic users. Of these, 29.9% were for ABA, 4.5% RIT, 2.2% TCZ, 23.2% INF, 43.8% injected biologics. Of 137 HSR cases we identified during follow-up, 77% occurred in an IP setting, 17.5% ED and 5.5% OTP. Among 64 cases occurring within 1 day of biologic Adm, 33%, 13.2%, 59.4% were identified by criterion A, B, and C respectively. The IRs for HSR ranged from 3.0 to 337.2 per 1,000,000 person years across different biologics and timing of exposure. After adjustment, and using abatacept 15–30 days as the referent, ABA, INF, RIT and TOC infusions were associated a significant higher risk of HSR (Table). Concomitant GCs had significant positive association with HSR whereas MTX had a significant inverse association with HSR. Sensitivity analysis yielded similar results. There were no additional deaths occurring within 30 days aside associated with HSRs.

Conclusion: Among RA pts taking biologics, rituximab and tocilizumab were most strongly associated with HSRs within one day of administration. The absolute IR of HSR events for all biologic exposures were low.

Table. Events, absolute incidence rate and adjusted risk ratio of hypersensitivity reaction, by biologic exposures and timing of exposure

Biologic and Timing of Exposure	Events	Incidence rate per 1,000,000 person days	Adjusted Risk Ratio* (95% CI)
0–1 days			
Abatacept	<11	31.1	5.30 (2.05–13.7)
Infliximab	36	180.3	35.7 (17.2–74.3)
Rituximab	13	337.2	44.1 (18.9–103.5)
Tocilizumab	<11	316.2	47.2 (16.8–132.6)
2–14 days			
Abatacept	<11	3.0	0.52 (0.17–1.55)
Infliximab	14	11.0	2.17 (0.94–5.02)
Rituximab	<11	12.6	1.66 (0.45–6.14)
Tocilizumab	<11	8.3	1.23 (0.16–9.73)
15–30 days			
Abatacept	<11	5.8	1.00 (Ref)
Infliximab	12	8.7	1.76 (0.74–4.17)
Rituximab	<11	0.5	0.74 (0.09–5.84)
Tocilizumab	<11	1.2	1.18 (0.15–9.36)
0–30 days, any injectable anti-TNF	27	0.5	0.84 (0.40–1.80)

* Adjusting for age, gender, Charlson comorbidity score, concomitant steroid and methotrexate use

1911

Disease Modifying Anti-Rheumatic Drug Use and the Risk of Incident Hyperlipidemia in Patients with Early Rheumatoid Arthritis: A Retrospective Cohort Study. Rishi Desai, Wesley Eddings, KP Liao, DH Solomon and Seoyoung C. Kim. Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Rheumatoid arthritis (RA) increases patients' risk of developing cardiovascular diseases (CVD). Hyperlipidemia is an important CVD risk factor in the general population. The objective of this study was to compare the risk of incident hyperlipidemia in early RA patients after initiation of disease modifying anti-rheumatic drugs (DMARDs).

Methods: We conducted a cohort study in patients receiving their first RA diagnosis after at least 12 months without evidence of RA or DMARD prescription, using insurance claims data (2001–2012). Four mutually exclusive groups were defined based on DMARD initiation, TNF-α inhibitors $\pm$ non-biologic (nb) DMARDs, methotrexate $\pm$ non-hydroxycholorquine nbDMARDs, hydroxychloroquine $\pm$ non-methotrexate nbDMARDs, and other nbDMARDs only. The primary outcome was incident hyperlipidemia as defined by a diagnosis and a prescription for a lipid-lowering agent. For the subgroup of patients with laboratory results available, we analyzed change in lipid levels as the secondary outcome. Multivariable Cox proportional hazard models estimated the relationship between DMARD use and incident hyperlipidemia. Propensity scores (PS) were calculated to improve confounding control. PS decile-stratified analyses were performed for each pairwise comparison after asymmetrically trimming at 2.5th and 97.5th percentile of the PS distribution to address confounding by indication.

Results: Of the 17,145 RA patients included in the study, 364 developed hyperlipidemia. The incidence rates (95% confidence interval (CI)) for hyperlipidemia per 1,000 person-years were 30.7 (21.9–41.8) for TNF-α inhibitors, 28.9 (24.9–33.4) for methotrexate, 20.1 (16.3–24.6) for hydroxychloroquine, and 36.4 (26.5–48.7) for other nbDMARDs. The adjusted hazard ratios(HR) (95% CI) for hyperlipidemia were 1.41 (0.99–2.00) for TNF-α inhibitors, 0.81 (0.63–1.04) for hydroxychloroquine, and 1.33 (0.95–1.84) for other nbDMARDs compared with methotrexate in the full cohort, while 1.18 (0.80–1.73), 0.75 (0.58–0.98) and 1.41 (1.01–1.98), respectively in the PS trimmed cohort. In the subgroup analysis, hydroxychloroquine use showed significant reduction in low density lipoprotein (−8.9 mg/dl, 95% CI −15.8, −2.0), total cholesterol (−12.3 mg/dl, 95% CI −19.8, −4.8) and triglyceride (−19.5 mg/dl, 95% CI −38.7, −0.3) from baseline compared with methotrexate.

Conclusion: Based on both a reduced adjusted HR for incident hyperlipidemia and a reduction in lipid levels, use of hydroxychloroquine may be associated with a lower risk of hyperlipidemia among early RA patients. A possible increase in the risk of hyperlipidemia in TNF-α inhibitor initiators was noted in our primary analysis, but not in the PS stratified analysis. These findings suggest a complex relationship between DMARDs, inflammation and lipids.

Table. Relative risk of hyperlipidemia in patients with early rheumatoid arthritis based on DMARD use

Exposure	Unadjusted HR (95% CI)	Multivariate adjusted* HR (95% CI)	Propensity score adjusted** HR (95% CI)
Methotrexate	Reference	Reference	Reference
TNF-α inhibitors	1.08 (0.76–1.52)	1.41 (0.99–2.00)	1.18 (0.80–1.73)
Hydroxychloroquine	0.70 (0.54–0.89)	0.81 (0.63–1.04)	0.75 (0.58–0.98)
Other nbDMARDs	1.25 (0.90–1.74)	1.33 (0.95–1.84)	1.41 (1.01–1.98)

*Adjusted for age, gender, cardiovascular risk factors and comorbidities, cardiovascular drug use, pain medications and healthcare use in the prior year in a cox proportional hazard regression model.
** Propensity score decile stratification was used to derive hazard ratios after asymmetrically trimming at 2.5th and 97.5th percentile of the PS distribution.

1912

Tocilizumab Therapy for Rheumatoid Arthritis Patients with Chronic Renal Insufficiency. Shunsuke Mori, NHO Kumamoto Saishunsou National Hospital, Kumamoto, Japan.

Background/Purpose: Renal involvement is relatively common in rheumatoid arthritis (RA) patients. Recent randomized controlled trials of anti-tumor necrosis factor-α (anti-TNFα) showed that the concomitant administration of methotrexate (MTX) is superior to monotherapy. However, the dose of MTX must be reduced in RA patients with chronic renal insufficiency (CRI) because MTX elimination is delayed in these patients. In contrast, the ACT-RAY trials indicated that the efficacy of tocilizumab (TCZ) monotherapy is comparable with combination therapy with MTX. The present study was intended to evaluate the efficacy and safety of TCZ therapy in RA patients with CRI.

Methods: The subjects were all patients with RA who had started TCZ therapy at our hospital from April 2008 to December 2013. Pretreatment characteristics were compared between patients with and without CRI. Clinical disease activity index (CDAI) levels and hemoglobin values as well as adverse events were recorded during the follow-up period of the first 24 weeks. CRI was defined as an estimated glomerular filtration rate (eGFR) $<$ 60 ml/min for 3 months.

Results: A total of 105 patients were included in this study and among these.37 patients (35.2%) were diagnoses with CRI. Mean eGFR levels in the CRI group and in non-CRI group were 43.7 ml/min and 80.9 ml/min, respectively. Sixty percent of CRI patients and 70% of non-CRI patients were refractory to anti-TNFα agents. CRI patients were significantly older (75.3 years versus 62.0 years, $p < 0.0005$) and had longer RA duration (9.8 years versus 5.4 years, $p = 0.005$). There was no significant difference in the other RA-related markers between both groups. Approximately 85% of patients in each group showed high or median disease activity. Biopsy-proven amyloidosis was observed in one patient in the CRI group. Hypertension was observed at a significantly higher rate in the CRI group (81% versus 36.8%, $p < 0.0005$). Of note, serum levels of hemoglobin were significantly lower in CRI patients compared with non-CRI patients (11.2 g/dl versus 12.5 g/dl, $p < 0.0005$). Eighty-one percent of CRI patients received TCZ monotherapy, while 49% of non-CRI patients used MTX concomitantly with TCZ. Mean changes of CDAI at week 24 from baseline were 17.1 (26.7 to 9.6) in the CRI group and 17.5 (25.8 to 8.3) in the group without CRI. Rates of patients with low disease activity or remission at week 24 were 62.2 % of CRI patients and 55.9% of non-CRI patients. Mean hemoglobin levels were significantly increased over time during TCZ therapy. At week 24, mean increases of 1.2 g/dl (11.2 to 12.4, $p < 0.0005$) and 0.8 g/dl (12.5 to 13.3, $p = 0.005$) were observed in the CRI group and in the non-CRI group, respectively. Adverse events occurred in two patients without CRI (diverticulitis and acute cholecystitis). Neither serious adverse event nor aggravation of renal function was reported in the CRI group.

Conclusion: TCZ therapy was effective in reduction of disease activity and improvement of hemoglobin levels in RA patients with CRI. In addition, TCZ showed stable safety and tolerability profiles even in CRI patients.

Rosuvastatin Induced Carotid Plaque Regression in Patients with Inflammatory Joint Diseases: The RORA-As Study. Silvia Rollefstad[1], Eirik Ikdahl[1], Jonny Hisdal[2], Inge C. Olsen[1], Ingar Holme[3], Hilde Berner Hammer[1], Knut T. Smerud[4], G Kitas[5], Terje R. Pedersen[6], Tore K. Kvien[7] and Anne Grete Semb[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Uslo University Hospital-Aker, Oslo, Norway, [3]Oslo University Hospital, Oslo, Norway, [4]Smerud Medical Research International AS, Oslo, Norway, [5]The Dudley Group of Hospitals NHS Foundation Trust, Dudley, United Kingdom, [6]University of Oslo, Oslo, Norway, [7]PsAID taskforce, EULAR, Zurich, Switzerland.

Background/Purpose: Patients with rheumatoid arthritis (RA) and carotid artery plaques (CP) have increased risk of acute coronary syndromes. Statin treatment with low density lipoprotein cholesterol (LDL-c) goal $\leq$ 1.8 mmol/L is recommended for patients with CP in the general population. In the **RO**suvastatin in **R**heumatoid **A**rthritis, **A**nkylosing **S**pondylitis and other inflammatory joint diseases (**RORA-AS)** study, the aim was to evaluate the effect of 18 months intensive rosuvastatin treatment on change in CP height.

Methods: Eighty-six patients (60.5% female) with CP and IJD [RA (n=55), ankylosing spondylitis (n=21) and psoriatic arthritis (n=10)] were treated with rosuvastatin to obtain LDL-c goal. CP height was evaluated by B–mode ultrasound.

Results: Age was 60.8±8.5 years (mean±SD). At baseline, median number and height of CP was 1.0 (range 1–6) and 1.80 mm (IQR 1.60, 2.10), respectively. Change in CP height after 18 months rosuvastatin treatment was −0.19±0.35 mm (p<0.001). Baseline and change in LDL-c was 4.0±0.9 mmol/L and −2.3±0.8 mmol/L (p<0.001). Mean LDL-c level during 18 months rosuvastatin treatment was 1.7±0.4 mmol/L (area under the curve). The degree of CP height reduction was independent of the LDL-c level exposure during the study period (p=0.36) (adjusted for age/gender/blood pressure)(Fig. 1a). Attainment of LDL-c ≤ 1.8 mmol/L or the change in LDL-c did not influence the degree of CP height reduction (p=0.44 and p=0.46, respectively) (Figure 1b). The higher the CP at baseline - the larger height reduction after 18 months with rosuvastatin treatment (p< 0.001) (Fig. 2). Disease activity during the study period measured by DAS28 (area under the curve) was inversely associated with change in CP height (p=0.02), so that patients with the highest disease activity had the smallest change in CP height and vice versa.

Conclusion: This is the first clinical study showing that intensive lipid lowering with statin induced regression of atherosclerosis in patients with IJD. Our results indicate that disease activity may influence the effect of anti-atherosclerotic treatment.

IL-17A Deficiency Promotes Periosteal Bone Formation in a Model of Inflammatory Arthritis. Anita T. Shaw[1], Yukiko Maeda[1], Catherine Manning[1] and Ellen M. Gravallese[2]. [1]University of Massachusetts Medical School, Worcester, MA, [2]UMass Memorial Medical Center, Worcester, MA.

Background/Purpose: Enthesial and periosteal bone formation in spondyloarthropathies (SpAs) are important sequelae of disease that contribute to patient morbidity. Anti-TNF therapies do not significantly alter progression of this debilitating process; therefore, new agents that inhibit both inflammation and bone formation are being sought. IL-17A contributes to inflammation in many diseases, including SpAs, and is a potential therapeutic target. IL-17A promotes osteoclastogenesis through induction of RANKL in synovial fibroblasts and by inducing expression of the proinflammatory cytokines TNF, IL-1 and IL-6. However, the effects of IL-17A on bone-forming osteoblasts (OB) have not been fully elucidated and data are conflicting as to whether it promotes or protects from bone formation. We investigated the impact of IL-17A on OB differentiation *in vitro* and determined its role on bone formation in an *in vivo* murine model of arthritis.

Methods: The effect of IL-17A on the Wingless (Wnt) signaling pathway, a critical pathway for OB differentiation, was determined using calvarial OBs from TOPGAL mice containing a reporter construct for Wnt signaling. Cells were cultured in the presence of IL-17A throughout differentiation and Wnt activity was determined. Calvarial OBs were also treated with IL-17A at early, mid and late stages of differentiation and qPCR analysis of Wnt signaling antagonist expression was performed. Periosteal bone formation is a prominent feature in the K/BxN serum transfer arthritis (STA) model. To determine the effects of IL-17A on OB function *in vivo*, STA was induced in IL-17A null and wild type mice. Periosteal bone formation was quantitated and ankle joints were also analyzed for erosion severity.

Results: Long-term culture of TOPGAL calvarial OBs with IL-17A suppressed Wnt signaling, as reflected by a reduction in Wnt reporter activity. In addition, preliminary staining with von Kossa demonstrated inhibition of matrix mineralization in these cells cultured with IL-17A. Expression of the Wnt antagonists dickkopf (DKK)1, DKK2, DKK3, secreted frizzled related protein (sFRP)2 and sFRP4 mRNA expression in calvarial OBs was reduced to one-fifth of baseline levels by treatment with IL-17A at an early stage of differentiation (day 7). However, inhibition was reversed by day 21 of differentiation. IL-17A null and wild type mice displayed similar clinical and histologic inflammation scores, as well as similar articular bone erosion scores. Importantly however, IL-17A null mice formed significantly more periosteal bone than wild type mice ($p < 0.05$).

Conclusion: IL-17A may promote OB differentiation in early stages by suppressing expression of antagonists of Wnt signaling. However, the net effect of long-term treatment of OBs with IL-17A is inhibition of differentiation. These *in vitro* findings are borne out *in vivo*, as mice lacking IL-17A develop a significantly greater amount of periosteal bone than wild type mice. However, deficiency of IL-17A did not affect inflammation or the degree of bone erosion in this model. These findings have potential clinical significance, as blocking IL-17A in patients with SpAs may further exacerbate the extent of periosteal bone formation.

IL-17 Gene Transfer induces Myeloid Precursor Cells That Initiate Epidermal Hyperplasia Independently of IL-23R$^+$/CD4$^+$ and $\gamma\delta$ T Cells. Erika Suzuki, Ritu Sarin, Emanual Maverakis and Iannis E. Adamopoulos. University of California at Davis, Sacramento, CA.

Background/Purpose: IL-17 is elevated in both the lesional skin and arthritic joints of psoriatic arthritis (PsA) patients. Although the IL-23/IL-17 axis has been linked with PsA pathology the direct effect of IL-17 on myeloid cells in PsA is elusive.

Methods: We performed gene transfer of IL-17 and GFP control by hydrodynamic delivery of minicircle (MC) DNA in control (C57BL/6) mice and mice treated with topical imiquimod. The psoriatic features were analyzed and scored for disease progression histologically. Further phenotypic analysis of cell populations was performed by flow cytometry, RT-qPCR, and *in vivo* imaging using nanoprobes. Characterization of molecular pathways was also performed in *Il23r*$^{-/-}$*Rag*$^{-/-}$ and *Tcrd*$^{-/-}$ transgenic mice.

Results: We have identified a unique IL-17R^{hi}CD11b$^+$Gr-1^{hi} cell subset induced by IL-17 that is associated with epidermal hyperplasia. Specifically 4 days post-IL-17 gene transfer we observed evidence of exacerbated epidermal hyperplasia, acanthosis, parakeratosis and Munro microabscess formation that were absent in GFP control mice. Gene expression of keratinocyte proliferation and inflammation biomarkers such as *Keratin 16 (K16), S100a7, S100a8, Cxcl1, Cxcr2* and *Ltb4r1* were consistently elevated post-IL-17 gene transfer and this correlated with an increase of Cxcl1 (a neutrophil chemoattractant) in the serum. Utilizing *Il23r*$^{-/-}$*Rag*$^{-/-}$ and *Tcrd*$^{-/-}$ mice, we demonstrated that genetic ablation of *IL-23r*, or the complete absence of T, B and $\gamma\delta$ T cells did not affect the pathologic features induced by IL-17. On the contrary, depletion of CD11b$^+$Gr-1^{hi} cells resulted in a complete rescue of skin pathology as evidenced by histology and gene expression.

Conclusion: Herein we demonstrate that IL-17 induces the expansion of an IL-17R^{hi}CD11b$^+$Gr-1^{hi} pathogenic cell subset, which is directly responsible for inducing a constellation of features that resemble human psoriatic disease. Collectively our data underscore the importance of innate immune cells in the pathogenesis of PsA and paves the way for the design of novel therapeutics to combat this disabling condition.

Stromal Overexpression of Transmembrane TNF Induces Spa-like Arthritis and Spondylitis in Mice. Leonie M. van Duivenvoorde[1], Melissa N. van Tok[1] and Dominique L. Baeten[2]. [1]Department of Clinical Immunology and Rheumatology and Department of Experimental Immunology, Academic Medical Centre/University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center / University of Amsterdam, Amsterdam, Netherlands.

Background/Purpose: The immunopathology of spondyloarthritis (SpA) is determined by inflammation and structural damage, in particular osteoproliferation, of axial and peripheral joints. The failure of TNF blockers to prevent ongoing osteoproliferation raised the concept that inflammation and osteoproliferation are uncoupled processes in SpA. However, inflammation and osteoproliferation are linked in HLA-B27 tg rats, high CRP is associated with radiographic progression in axial SpA, and NSAID treatment can retard osteoproliferation. Here, we propose that inflammatory mediators distinct from soluble TNF can drive pathologic osteoproliferation in SpA. Based on our observations on soluble versus transmembrane TNF (tmTNF) expression in SpA synovitis, we explored if and how tmTNF drives experimental spondyloarthritis.

Methods: tmTNF mice (TgA86)[1], provided by Dr Kollias (Athens), were studied clinically over time for arthritis and spondylitis development. At 3, 6 and 8 months joints were collected and analyzed for inflammation and osteoproliferation. To assess the contribution of stromal versus hematopoietic tmTNF expression, tmTNF tg mice and WT mice were lethally irradiated and rescued by bone marrow of either WT or tmTNF tg mice. Mice were evaluated for 16 weeks until sacrifice for histologic analysis.

Results: tmTNF mice (100%; n>50) spontaneously developed arthritis, visualized by deformed joints and loss of grip strength, and spondylitis as evidenced by crinkled tails and hunchback formation, starting at 4 weeks of age and progressing over time. Analysis of 3 months old mice revealed that arthritis was characterized by inflammation of synovium and enthesis. Hypertrophic chondrocytes, as marker for osteoproliferation, were observed outside the bone in the connective tissue next to the inflammation. In spondylitis, inflammation was found in connective tissue located at the junction of the annulus fibrosus with the vertebral bone. Hypertrophic chondrocytes were observed at the edge of the vertebral body, in conjunction with the ongoing inflammation. X-ray images from 8 months old mice also revealed bridging of the tail vertebra. These typical SpA-like features were not observed in any of the non-transgenic littermates.

In the functional experiments, irradiated tmTNF tg mice receiving tmTNF tg BM developed arthritis and spondylitis with 100% incidence 3 weeks after BMT, albeit the arthritis was less severe than in non-irradiated tmTNF tg mice. Interestingly, tmTNF tg mice receiving WT BM also developed both arthritis and spondylitis with the same incidence, onset and severity as the control group. In sharp contrast, WT mice that received tmTNF tg BM did not develop any arthritis, and spondylitis occurred less frequently (66%) and later (10 weeks after BMT) than in the control group.

Conclusion: tmTNF overexpression induces experimental arthritis and spondylitis with radiographic and histologic proven new bone formation,

indicating that inflammatory mediators can indeed drive osteoproliferation. The data indicate the relevance of the transmembrane form of TNF and the role of the stromal compartment in the pathophysiology of SpA.

IL-23 Expression and Activation of Autophagy in Synovium and PBMCs of HLA-B27 Positive Patients with Ankylosing Spondylitis. Barbara Neerinckx, Shea Carter and Rik Lories. KU Leuven, Leuven, Belgium.

Background/Purpose: IL-23 may play a key role in the pathogenesis of ankylosing spondylitis (AS). Some studies describe indeed increased serum levels of IL-23 in AS patients compared to healthy controls [1–3]. Recent evidence also shows enhanced IL-23 production in the gut of AS patients. This upregulation of IL-23 expression in the gut seems to be the result of activation of autophagy rather than of an activated unfolded protein response [4]. We investigated IL-23 expression and the role of autophagy *ex vivo* in the synovium and peripheral blood mononuclear cells (PBMCs) of HLA-B27 positive AS patients.

Methods: Synovial tissues were obtained by needle arthroscopy from actively inflamed knees from patients with AS (HLA-B27 positive; n=11), other forms of spondyloarthritis (SpA) (HLA-B27 positive; n=9 or HLA-B27 negative; n=10), rheumatoid arthritis (RA) (HLA-B27 positive or negative; n=10) or other inflammatory joint diseases ('non SpA/RA inflammatory joint disease') (HLA-B27 positive or negative; n=10)) and from multiple organ donors as non-inflammatory controls (HLA-B27 negative; n=10). PBMCs were isolated from whole blood samples taken from patients with AS (HLA-B27 positive; n=17), RA (HLA-B27 negative; n=19) and healthy controls (HLA-B27 negative; n=12). None of the patients was treated with TNF inhibitors. Expression of IL-23 and autophagy genes in all samples was analyzed using quantitative RT-PCR (SYBR green) with primers for *IL23p19* and autophagy genes (*ATG16L1, IRGM, MAP1LC3A, ATG5, HSPA8* and *HSP90AA1).*

Results: In the synovial tissues, *IL-23p19* expression was consistently increased in the inflammatory samples compared to the non-inflammatory samples. There was no difference in *IL-23p19* expression in AS patients as compared to non-AS SpA and other inflammatory diseases. In PBMCs, surprisingly, the expression of *IL-23p19* was significantly lower in AS patients than in healthy controls with expression levels in RA patients extending over the whole range between AS patients and controls. No difference in expression of autophagy associated genes was found in the synovial tissues between the groups. In the PBMCs, there was a lower expression of *ATG16L1*, *IRGM* and *HSP90AA1* in AS patients compared to healthy controls. The expression of *MAP1LC3A*, *ATG5* and *HSPA8* was not statistically different between the three groups.

Conclusion: Notwithstanding the recent evidence in gut samples of AS patients, our data do not support evidence for higher IL-23 expression and activation of autophagy in synovium or PBMCs of HLA-B27 positive AS patients. The production of IL-23, possibly driven by autophagy, in AS patients seems to be a tissue specific phenomenon with an important role reserved for the gut.

IL23 Overexpression Demonstrates Gut-Joint Inflammation Link and Increased Expression of Spondyloarthopathy Associated Genes *In Vivo*. Donald Souza II, Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT.

Background/Purpose: It has been well established that a close relationship exists between gut inflammation and spondyloarthropathies. Polymorphisms in the receptor for IL23 are associated not only with ankylosing spondylitis (AS) but also with inflammatory bowel disease (IBD). AS and IBD are both associated with elevated concentrations of serum IL23. Moreover.IL23 is active at mucosal surfaces and is produced by the gut, suggesting that the intestinal mucosa could be a key site of IL23 production in spondyloarthropathy. Minicircles are small circular DNA vectors which can be used in vivo to provide for long-term transient expression of transgenes without the risk of immunogenic responses that can be caused by the bacterial backbone in standard plasmids. Recently, Sherlock et al. demonstrated that overexpression of IL23 using minicircle DNA technology in the hepatocytes of mice was sufficient to lead to severe entheseal inflammation with infiltration by macrophages and neutrophils, and expansion of periosteal osteoblasts. Disease features included sacroiliitis, axial enthesitis, psoriasis, and aortic root inflammation. However, no gut phenotype was reported.

Methods: IL23 minicircle DNA vector or empty vector was administered via hydrodynamic injection to adult B10RIII female mice obtained from Jackson Labs (Bar Harbor, ME). A volume equivalent of 10% body mass (~2mL) was injected IV to the lateral tail vein in 6–8 seconds to facilitate cellular uptake of material. Mice were monitored daily for signs of arthritis and skin lesions. Arthritis severity was graded using a 0–4 score per paw for a maximum score of 16. Upon sacrifice (14 and 28 days), serum was collected for cytokine analysis, paw and gut tissue for histologic assessment (Bolder Biopath, Boulder, CO), skin, entheses and gut tissues for mRNA analysis via RT-PCR.

Results: IL-23 overexpression using minicircle DNA transfection resulted in a similar rapid and pronounced rheumatic and skin phenotype as previously reported (e.g. development of synovitis, enthesitis, and psoriatic-like skin lesions). In addition, sustained and elevated serum concentration of IL23 is associated with intestinal inflammation. Significant and region specific gut expression of IL23 pathway associated genes IL17A, IL17F & IL22 induced by IL23 overexpression was demonstrated, with maximal expression seen in proximal ileum and lesser expression seen in colon. Furthermore, ileum expression of disease associated genes S100A8 and REG3g were increased with IL23 overexpression versus empty vector control. Histologic analysis also demonstrated region specific gut pathology, with colons displaying none to minimal inflammation and ileums displaying minimal to moderate inflammation with crypt abscesses, mild hyperplasia and inflammatory infiltrates in the lamina propria, characteristic of features seen in IBD.

Conclusion: These studies demonstrate that minicircle DNA transfection offers a powerful tool for interrogating molecular and tissue specific mechanisms in vivo and provides opportunities to dissect the influence of the IL-23 pathway on the inflammatory gut-joint link seen in spondyloarthropathies.

HLA-B27 Expression Shapes the Intestinal Microbiota. Mark Asquith[1], Phoebe Lin[1], Tejpal Gill[2], Justine Debelius[3], Patrick Stauffer[1], Sean Davin[1], Gail Ackermann[3], Robert A. Colbert[2], Rob Knight[3] and James Rosenbaum[4]. [1]Oregon Health and Science University, Portland, OR, [2]NIAMS/NIH, Bethesda, MD, [3]University of Colorado Boulder, Boulder, CO, [4]Legacy Hospital, Portland, OR.

Background/Purpose: The intestinal microbiota plays a central role in both health and disease. Beyond shaping local immune responses in the gut, it is increasingly clear that the microbiota also influences immune responses in the periphery. With respect to spondyloarthopathies (SpAs), the development of reactive arthritis following enteric infection and the resistance of germ-free animals to disease supports its contribution to pathogenesis. In this study we used the HLA-B27 transgenic rat model to test the hypothesis that expression of HLA-B27, a key SpA risk allele, shapes the intestinal microbiome and may contribute to B27-associated spondyloarthropathy.

Methods: We used both 16s sequencing and quantitative real-time PCR to analyze the microbiota community structure of WT and B27+ rats. Samples were collected from ileum, cecum and colon of rats during the post-weaning period (3–6 wks), at disease onset (8–12 wks) and after the establishment of disease (15+ weeks). Samples were collected from multiple rat lines expressing the HLA-B27 transgene, including those on the Fischer, Lewis and DA backgrounds.

Results: We identified a number of B27-dependent changes to the intestinal microbiome, including eight operational taxonomic units (OTUs) that were more abundant in the microbiota of B27 animals relative to controls on all three backgrounds examined. These included *Bacteroides, Clostridia* and *Lactobacilli spp.* Notably, segmented filamentous bacteria (SFB) were a dominant member of the ileal microbiota of disease-susceptible Lewis and Fischer rats but largely absent in disease-resistant DA rats. Mucus-degrading bacterium *Akkermansia muciniphila* was upregulated ~300 fold in B27 vs WT animals in disease-susceptible rats on the Fischer background. Many of these changes were not evident during the post-weaning period.

Conclusion: HLA-B27 expression strongly modulates the intestinal microbiota and B27-dependent changes were observed in all tissue sites examined. This provides compelling rationale to functionally examine the

contribution of defined bacteria to B27-mediated SpA and to identify their association with disease in humans. The strong age-dependent effects on the microbiota indicate this is a critical consideration for such studies.

1920

Predicting SLE Disease Activity in the Next Year Based on Measures of Four Gene Transcripts and Two Proteins. Laurence S Magder[1], Eric Zollars[2], Jadwiga Bienkowska[3], Chris Stebbins[4], Carrie Wager[4], Linda Burkly[4], Nicolas Wisniacki[5], Ann Ranger[4] and Michelle Petri[2]. [1]University of Maryland School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Biogen Idec Inc., Cambridge, MA, [4]Biogen Idec, Cambridge, MA, [5]Formerly with Biogen Idec, Cambridge, MA.

Background/Purpose: Multiple gene transcripts and proteins in blood or urine have been observed to correlate with disease activity in SLE. However some observed associations might be spurious, due to confounding by correlation with other biomarkers or patient characteristics. In this study, we explored the relationship between six proposed biomarkers and SLE activity over a 1 year period while controlling for potential confounding variables.

Methods: At an initial visit, two proteins and four gene transcripts or signatures were measured in 280 SLE patients. Levels of the BAFF gene transcript, plasma cell (PC) gene signature, IFN gene signature, and an LDG-associated Neutrophil gene signature were assessed in PAXgene-preserved peripheral blood by global microarray and qPCR. For proteins, BAFF was measured in serum and TWEAK in urine (both by ELISA). Disease activity during the next year was quantified by SELENA-SLEDAI modified to exclude complement and dsDNA. Repeated measures linear regression models were fit to determine which markers were predictive of disease activity over a one year period, controlling for age, race, sex, and other markers. Non-linear relationships between biomarker levels and disease activity were also explored.

Results: In univariate analyses, all markers analyzed except BAFF protein were significantly associated with future disease activity. After controlling for race, the PC signature was no longer significantly associated. After controlling for BAFF mRNA levels, the IFN signature was no longer significantly associated. Controlling for sex, race, and other biomarkers we found that: 1) a 1 standard deviation (SD) increase in BAFF was associated with a mean SLEDAI increase of 0.26 in the follow-up ($p=0.0034$), 2) those patients within the top 15% of the Neutrophil gene signature expression had a 0.66 higher mean SLEDAI during follow-up ($p=0.0056$), and 3) the relationship between the SLEDAI score and urinary TWEAK protein was constant until the 85th percentile of TWEAK after which a 1 SD increase in TWEAK was associated with a 0.58 increase in mean SLEDAI ($p=0.0006$). In a similar analysis focusing on renal disease activity, a 1 SD increase in the IFN signature was associated with a mean renal SLEDAI increase of 0.11 ($p=0.04$). The Neutrophil signature remained significant at a similar level as for overall disease activity, and the relationship between renal SLEDAI score and urinary TWEAK was linear with a 1 SD increase in TWEAK being associated with a 0.25 increase in mean renal SLEDAI ($p<0.0001$).

Conclusion: BAFF gene transcript, LDG-associated neutrophil gene signature, and high levels of urinary TWEAK appear to be independently and additively associated with disease activity. Our results suggest that the association between IFN and overall disease activity is due to the association between IFN and BAFF. Our results also suggest that an observed association between PC and disease activity is due to confounding by race. Thus, given that biomarkers are correlated with each other and other risk factors for disease, it is important to adjust for confounding when assessing biomarker/disease relationships.

The Deposition of Complement C4d Split Product on Platelets and Erythrocytes Correlate with Disease Activity and Improvement in Systemic Lupus Erythematosus. Joan T. Merrill[1], Aikaterini Thanou[1], Stan Kamp[1], John Conklin[2], Derren Barken[2] and Thierry Dervieux[2]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Exagen Diagnostics, Inc., Vista, CA.

Background/Purpose: We sought to evaluate the usefulness of cell bound complement activation products (C4d deposition on erythrocytes [EC4d] and platelets [PC4d]) in the monitoring of disease improvement in systemic lupus erythematosus (SLE).

Methods: 58 patients with SLE from the Oklahoma Lupus Cohort were evaluated at two visits (baseline and follow-up) with the stipulation that there must be at least mild/moderate disease activity, in the clinician's opinion, at the first visit. Standard of care treatments were given. Clinical assessments included the Systemic Lupus Erythematosus Disease Activity Index without the complement and anti-dsDNA descriptors (non serologic SLEDAI or ns-SLEDAI) and the British Isles Lupus Assessment Group (BILAG 2004) index. Serum C3 and C4 levels were measured with nephelometry. EC4d and PC4d were determined using flow cytometry (expressed as mean fluorescence intensity [MFI], and natural log transformed). Statistical analysis included linear regression, and multivariate linear mixed effect models using a random intercept and fixed slope.

Results: At baseline, mean ns-SLEDAI score was 6.4 ± 0.4 while the cumulative BILAG multiorgan score was 10.3 ± 0.9. At baseline, C3 and C4 levels were negatively associated with disease activity using the ns-SLEDAI score ($p<0.04$) but less consistently with the BILAG index score ($p>0.06$). Baseline natural log transformed EC4d and PC4d levels were both positively and significantly associated with the SLEDAI and BILAG scores ($p<0.05$). At the time of the follow-up visit (median 1.5 month, range 1–9 months from the baseline visit), there was a significant decrease in the SLEDAI (average decrease -2.4 ± 0.4) and BILAG (average decrease -3.1 ± 0.9) compared to baseline with linear mixed effects models indicating greater clinical improvement associated with the time to follow-up visit (Table). After adjusting for the time to follow-up, linear mixed effects model analysis revealed that the change in C3 or C4 levels correlated with the change in BILAG index scores ($p<0.05$) but less well with the ns-SLEDAI score ($p>0.10$). In contrast, the change in EC4d and BC4d correlated with the clinical change on both instruments ($p<0.03$). Finally, multivariate analysis of the change in the BILAG index score with PC4d, serum C3 and C4 as predictors (after adjusting for the time to follow-up) revealed that PC4d was associated with change in disease activity (slope estimate$=1.80\pm0.76$; $p=0.02$) while C3 and C4 were not ($p>0.7$).

Conclusion: These pilot findings suggest that cell bound complement measures could provide a sensitive marker for SLE disease improvement which might be useful for early optimization of treatment dosing.

Table. Linear Mixed Effects Model Estimates

	Non serologic SLEDAI score	BILAG Index score
Months since baseline	0.66 ± 0.18 $p<0.01$	1.12 ± 0.36 $p<0.01$
Complement C3 (mg/dL)	-0.02 ± 0.01 $p=0.12$	-0.05 ± 0.02 $p=0.02$
Complement C4 (mg/dL)	-0.06 ± 0.03 $p=0.11$	-0.13 ± 0.06 $p=0.04$
EC4d (Log_e net MFI)	$+0.88 \pm 0.41$ $p=0.04$	1.8 ± 0.8 $p=0.03$
PC4d (Log_e net MFI)	$+0.83 \pm 0.32$ $p=0.01$	2.1 ± 0.6 $p<0.01$

Hydroxylchloroquine Use Is Associated with Decreased Soluble TNF Receptor Levels in SLE Patient Samples. Rufei Lu[1], Adam Przebinda[1], Melissa E. Munroe[2], Joel M. Guthridge[2], Joan T. Merrill[2] and Judith A. James[2]. [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex systemic autoimmune disorder with a waxing and waning clinical course. Hydroxychloroquine (HCQ) is a well-tolerated and effective antimalarial medication which decreases disease flares and delays damage accrual in SLE. Additionally, a pre-disease study has shown that HCQ can potentially be a useful preventative therapy for delaying the onset of SLE. The exact mechanism by which HCQ might delay disease onset or flares is not well understood. One major obstacle of HCQ mechanistic studies is the confounding effects from other major immune modulating therapies used by SLE

patients. Our goal is to elucidate the effects of HCQ on cellular changes and circulating soluble mediator concentration without the confounding effects of other major immunosuppressants (IS) in human lupus patients *in vivo*.

Methods: As part of the Biomarkers of Lupus Disease (BOLD) study, 103 patients donated baseline blood samples of whom 41 had transient IM steroid therapy, then all IS and some hydroxychloroquine treatments stopped. Patients were followed until flare. Eligibility criteria included (> 4 ACR SLE classification criteria and SLEDAI > 6 or BILAG ≥ 2 B or 1 A scores. Cellular immunophenotyping and soluble mediators, including 52 cytokines, chemokines, and soluble receptors, were measured over time using xMAP multiplex technology and sandwich ELISA. Significant differences were determined using non-parametric tests. A longitudinal analysis was performed using mixed generalized linear models.

Results: At baseline, SLE patients taking HCQ (n=27) had significantly lower levels of soluble TNFR I [median, 112.67 pg/mL; interquartile range (IQR), 103.5 –144.6 pg/mL] and TNFR II (median, 318.6 pg/mL; IQR, 266.8 – 374.8 pg/mL) compared to SLE patients not taking HCQ (n=10) (TNFR I, median, 186.63; IQR, 120.09–301.44; TNFR II, median 519.6; IQR, 332.16–641.00; p-value <0.05). In addition to the soluble TNFRs, SLE patients taking HCQ had significantly lower frequency of CD194hi Naïve B cells population (median, 1.54%; IQR, 0.15% - 5.48%) compared to SLE patients not taking HCQ (median, 5.57%; IQR, 2.03% - 13.19%; p-value < 0.05). SLE patients that stayed on HCQ during the six month study (n=17) retained their low levels of TNFR II. Patients who had never taken HCQ or were taken off of HCQ (n=20) showed a significant reduction in their TNFR II levels at the time of the next flare (p-value <0.05). TNFR II levels did remain higher than those observed in individuals that remained on HCQ.

Conclusion: HCQ may contribute to disease suppression via an effective reduction in soluble TNF and other chemokine receptor levels. These findings suggest a likely focus for further pathophysiologic studies of SLE.

Vitamin D Restores Lupus Myeloid Angiogenic Cell Function Via Down-Regulation of IP-10/CXCL-10. John A. Reynolds[1], David W. Ray[2], Yvonne Alexander[3] and Ian N. Bruce[4]. [1]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Institute of Inflammation and repair, Manchester Academic Health Science Centre, The University of Manchester, United Kingdom, Manchester, United Kingdom, [2]Institute of Human Development, The University of Manchester, Manchester, United Kingdom, [3]Manchester Metropolitan University, Manchester, United Kingdom, [4]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Institute of Inflammation and repair, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom.

Background/Purpose: Endothelial repair is important for the maintenance of vascular integrity and is impaired in patients with SLE. Myeloid angiogenic cells (MACs) contribute to endothelial repair via paracrine secretion of pro-angiogenic factors. These cells express vitamin D receptors (VDR) and so may be modulated by vitamin D status. Given the prevalence of vitamin D deficiency in SLE we aimed to determine whether vitamin D could restore MAC function in lupus.

Methods: SLE patients were screened for vitamin D deficiency (25(OH)D<20ng/ml) using LC-MS and deficient patients were treated with high-dose cholecalciferol for 3 months. Myeloid angiogenic cells (MACs) were cultured from PBMCs of vitamin D deficient lupus patients (or healthy controls, HC) for 7 days. $1,25(OH)_2D_3$ (calcitriol) 10nM or vehicle was added at day 1 and replaced when the media was changed. Myeloid marker expression was measured using RT-qPCR. MAC migration towards SDF-1 was assessed using Transwell assays. Conditioned media from MACs was added to human aortic endothelial cells (HAoECs) on Matrigel for 14 hours and the resulting network analysed. Anti-IP-10 antibody was used to block the effects of IP-10 on network formation. Image analysis of network density (number of closed loops) was performed offline using ImageJ software. IP-10 was measured in the conditioned media by ELISA.

Results: Vitamin D deficient SLE patients had an increased number of MACs compared to controls (p=0.04). Despite this, these cells had impaired migratory capacity (p=0.006) and a trend toward reduced angiogenic capacity (p=0.13). Culture with vitamin D had no effect on lupus MAC migration.

Vitamin D significantly increased the number of MACs *in vitro*, and *in vivo* after the patients were treated (p=0.04 and p=0.03 respectively). MACs expressed surface markers consistent with M2 macrophages. The expression CD206 and CD68 was significantly increased in SLE and reversed by vitamin D.

HAoEC network formation was not affected by vitamin D directly but media from vitamin D-treated MACs significantly increased angiogenesis toward that seen in HCs (p=0.01). There was no correlation between MAC number and angiogenesis. IP-10 has previously been reported to be anti-angiogenic and vitamin D significantly reduced IP-10 expression by MACs (p<0.001). Blockade of IP-10 in the angiogenesis model restored the angiogenic capacity of MACs (figure).

Conclusion: MACs are important for endothelial repair and are dysfunctional in SLE. The addition of vitamin D *in vitro* restores the phenotype of the cells towards that of healthy subjects. Lupus MACs show reduced angiogenic capacity and vitamin D restores this via the down-regulation of the anti-angiogenic cytokine IP-10. Restoration of endothelial repair mechanisms is an important target to reduce vascular damage in SLE and vitamin D is a novel agent to improve MAC function.

Cell Bound Complement Activation Products Have Higher Sensitivity Than Serum C3 and C4 Levels in Systemic Lupus Erythematosus. Rosalind Ramsey-Goldman[1], Richard Furie[2], Chaim Putterman[3], Anka Askanase[4], Jill P. Buyon[5], Kenneth Kalunian[6], W. Winn Chatham[7], E Massarotti[8], Kyriakos A. Kirou[9], A. Weinstein[10], Puja Chitkara[11], Susan Manzi[12], Joe Ahearn[13], Leilani Wolover[14], John Conklin[14], Tyler O'Malley[14], Claudia Ibarra[14], Derren Barken[14] and Thierry Dervieux[14]. [1]Northwestern University, Chicago, IL, [2]North Shore-LIJ Health System, Great Neck, NY, [3]Albert Einstein College of Medicine, Bronx, NY, [4]Colombia University, New York, NY, [5]New York University School of Medicine, New York, NY, [6]UCSD School of Medicine, La Jolla, CA, [7]University of Alabama at Birmingham, Birmingham, AL, [8]Brigham and Women's Hospital, Boston, MA, [9]Hospital for Special Surgery, New York, NY, [10]Washington Hospital Center, Washington, DC, [11]Sharp Memorial Hospital, San Diego, CA, [12]Division of Rheumatology, University of Pittsburgh School of Medicine, Pittsburgh, PA, [13]West Penn Allegheny Health System, Pittsburgh, PA, [14]Exagen Diagnostics, Inc., Vista, CA.

Background/Purpose: Elevated levels of cell bound complement activation products (CBCAPS) have been established as valuable biomarkers in the diagnosis of Systemic Lupus Erythematosus (SLE). In this study, we compared the sensitivity of CBCAPS to reduced complement C3 and C4 proteins levels in SLE. We also evaluated the relationship between elevated CBCAPS, reduced complement levels and SLE disease activity.

Methods: A total 288 SLE patients (mean age 41±1 years, 92% females) all meeting the 1982 American College of Rheumatology SLE classification criteria were enrolled. Serum complement C3 and C4 protein levels were determined using immunoturbidimetry while complement C4d fragment deposited on erythrocytes (EC4d) and B-lymphocytes (BC4d) were determined using flow cytometry (and expressed as net mean fluorescence intensity [MFI]). A group of 476 subjects comprising 274 patients with other rheumatic diseases and 202 healthy subjects was used to establish the cutoffs yielding 95% specificity for C3, C4, EC4d and BC4d. Among SLE subjects, disease activity was determined using the

Systemic Lupus Erythematosus Disease Activity Index SELENA Modification (SELENA-SLEDAI) subscore (without low complement and anti-dsDNA reactivity components). Difference in sensitivity (while controlling for similar specificity) was evaluated using $\chi 2$ test.

Results: Reduced C3 or C4 were both 32% sensitive for SLE (95% specific). In contrast, EC4d at a cutoff above 14 net MFI yielded 45% sensitivity (95% specific) while BC4d above 60 net MFI yielded 54% sensitivity (95% specific) ($p<0.002$). Elevated EC4d or BC4d (above their respective cutoffs as above) yielded a 22% higher sensitivity (66%) than reduced C3 or C4 (44%). Among 273 SLE patients with evaluable SELENA-SLEDAI subscores, the median subscore was 1 (range 0–23). Higher level of disease activity resulted in a higher proportion of patients testing positive for elevated CBCAPS ($p=0.027$) and reduced complement ($p=0.002$) (**Figure**). Among SLE with less active disease (SELENA-SLEDAI subscore=0) the difference in sensitivity was 26% greater for elevated CBCAPS (62%) than for reduced complement C3 or C4 (36%) ($p<0.001$). The difference in sensitivity remained higher (17%) for CBCAPS compared to low complement among SLE having a SELENA-SLEDAI subscore greater than 6 points but without reaching statistical significance ($p=0.21$).

Conclusion: Among all SLE patients, elevated CBCAPS have higher sensitivity than reduced C3 or C4. The higher sensitivity of CBCAPS is particularly significant among SLE with less active disease, and this supports the diagnostic utility of these markers for SLE

Background/Purpose: Hydroxychloroquine (HCQ) is now recognized as an important treatment of systemic lupus erythematosus (SLE). Blood HCQ levels ([HCQ]) can be quantified by high performance liquid chromatography (HPLC). [HCQ] varies widely between individual: a pharmacokinetic/pharmacodynamic (PK/PD) relation has been found in different situations, and very low [HCQ] is a simple marker of non-adherence to treatment (2). Accordingly, the interest in the [HCQ] measurement has recently grown, but little is known regarding the determinants of variation of [HCQ].

Methods: Retrospective analyses of our databases including the PLUS study (1) to determine the relationship between [HCQ] and different factors, including the daily dosage regimen, the weight and height, the renal function, the drug interactions, the smoking status and the ethnicity. Non-adherent patients ([HCQ] <200 ng/ml) were excluded.

Results: To have homogeneous pharmacological data, we restricted the analyses to the 509 patients treated with 400 mg/day. There was no correlation between [HCQ] and ethnicity or between [HCQ] and smoking. The median [HCQ] was 913 ng/ml [range: 213–2067], 951 [541–1701], and 916 [208–3316] in the patients who received enzyme inhibitors, enzyme inducers or none of these two groups of drugs respectively ($p=0.7$). Similarly, we did not find any significant differences in [HCQ] whereas the patient received or not antiacids.

In multivariate analysis, higher BMI ($p=0.008$), absence of treatment with corticosteroids ($p=0.04$), higher delay between the last tablet intake and the dosage of [HCQ] ($p=0.017$), lower platelet ($p<0.001$) and neutrophil ($p<0.001$) counts, and higher estimated creatinine clearance ($p<001$) were significantly associated with lower [HCQ].

Since patients with serum creatinine clearance lower than 60 ml/min were excluded from the PLUS study, we also studied 22 SLE patients with chronic renal insufficiency who were also treated with 400 mg/d of HCQ. Their median serum creatinine clearance was 52 ml/min [23–58]. Their median [HCQ] was significantly higher than those of the 509 patients from the PLUS study: 1338ng/ml [504–2229] versus 917 [208–3316] ($p<0.001$).

Finally, we studied 2 patients on long-term dialysis. Their [HCQ] did not change significantly after the dialysis and [HCQ] in the dialysis bath was undetectable for both patients (<50 ng/ml).

Conclusion: We report for the first time a comprehensive analyze of determinants of [HCQ]. Since this blood measurement is increasingly used, such data might be useful for clinicians.

Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics II: Approaches to Cardiac and Vascular Manifestations in Systemic Sclerosis

Monday, November 17, 2014, 4:30 PM–6:00 PM

1926

Nailfold Videocapillaroscopy Patterns Associated with Calcinosis and Acro-Osteolysis in Systemic Sclerosis. Jerome Avouac[1], Laetitia Morardet[2], Maya Sammour[3], Andre Kahan[2], Antoine Feydy[3] and Yannick Allanore[1]. [1]Paris Descartes University, Rheumatology A Department and INSERM U1016, Cochin Hospital, Paris, France, [2]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [3]Paris Descartes University, Radiology B department, Cochin Hospital, Paris, France.

Background/Purpose: Calcinosis and acro-osteolysis are frequent in systemic sclerosis (SSc). They may be related to digital vasculopathy, which can be assessed by nailfold videocapillaroscopy (NVC). Our aim was to determine whether calcinosis and acro-osteolysis are associated with specific NVC features.

Methods: Consecutive SSc patients were consecutively included during a 24-month period. NVC was performed and analysed by one investigator (JA) blinded for the results of X-Rays and classified as early, active and late pattern (2). Two independent investigators carried out radiological assessment on standard anteroposterior views of the hands and wrists (LM, MS), followed

by a consensus reading (AF and YA). Calcinosis was defined by the presence of at least one calcification in soft tissue and acro-osteolysis by the presence of the resorption of at least one digit tip. Both were classified on X-rays as mild, moderate or severe according to their extent.

Results: 155 patients were included, with a mean age of 57±13 years and a mean disease duration of 9 ± 5 years; 65 (42%) had the diffuse cutaneous subset. 15 (10%) patients had a normal, 46 (30%) an early, 47 (30%) an active, and 47 (30%) a late NVC pattern. Regarding X-ray analysis, the kappa coefficient of inter-rater agreement was 0.75. 43 (28%) patients had calcinosis, of whom 26 (17%) had moderate or severe lesions; 25 (16%) patients had acro-osteolysis; of whom 13 (8%) had severe lesions. Patients with calcinosis were more likely to have acro-osteolysis ($p=0.02$), but Cramer's V coefficient of association was 0.19, supporting low association between these variables. Patients with calcinosis and acro-osteolysis were more likely to have the late NVC pattern ($p=0.04$ and $p<0.0001$ respectively). In line with this result, significant capillary loss was observed in patients with calcinosis (4±1.9 vs. 5.5±2.4 mean capillaries/finger, $p=0.001$) and acro-osteolysis (2.8±1.3 vs. 5.6±2.27 capillaries/finger, $p<0.001$). Of note, association with the late NVC pattern was stronger ($p=0.01$)and capillary loss was more pronounced in patients with moderate or severe calcinosis ($p<0.001$).No association was observed between calcinosis and irregular enlargement of capillaries (neoangiogenesis). Conversely, neoangiogenesis was more frequently observed inpatients with severe acro-osteolysis ($p=0.03$).Multivariate logistic regression analysis confirmed the independent association between calcinosis ($p=0.03$) and acro-osteolysis ($p=0.01$) with the late NVC pattern, together with a modified Rodnan skin score >14 ($p=0.008$) and positive antitopoisomerase-I antibodies ($p=0.01$).

Conclusion: We show for the first time an independent association between calcinosis/acro-osteolysis and the late NVC pattern, and in particular, with reduced number of capillaries. This result suggests that these lesions may be related to the severe capillary loss observed at this stage. Acro-osteolysis, but not calcinosis, was associated with neoangiogenesis, which may suggest an attempt to compensate bone resorption. Further studies are now needed to determine whether capillaroscopy may predict the further occurrence or worsening of these lesions.

1927

A Retrospective Look at the Recurrence of Digital Ulcers in Patients with Scleroderma after Discontinuation of Oral Treprostinil. Ami A. Shah[1], Elena Schiopu[2], Soumya Chatterjee[3], Mary Ellen Csuka[4], Tracy Frech[5], Avram Goldberg[6], Robert F. Spiera[7], Stanford L. Peng[8] and Virginia D. Steen[9]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Michigan, Ann Arbor, MI, [3]Cleveland Clinic, Cleveland, OH, [4]Medical College of Wisconsin, Milwaukee, WI, [5]University of Utah, Salt Lake City, UT, [6]North Shore-LIJ Health System, Great Neck, NY, [7]Hospital for Special Surgery, New York, NY, [8]Benaroya Research Institute/Virginia Mason, Seattle, WA, [9]Georgetown University Medical Center, Washington, DC.

Background/Purpose: Ischemic digital ulcers (DU) occur in over 40% of systemic sclerosis (SSc) patients. Treprostinil diolamine, a newer prostacyclin analog that has been developed for oral delivery, improves cutaneous perfusion and temperature in SSc. A large randomized, double-blind, placebo-controlled clinical trial of treprostinil was conducted in SSc patients with DU. While this trial did not meet the desired endpoint (change in net ulcer burden at 20 wks), there was a significant improvement in several secondary endpoints that measured Raynaud's severity. Subjects enrolled into an open label extension study (DISTOL-EXT) after the clinical trial; after termination of DISTOL-EXT, all participants were withdrawn from oral treprostinil. We investigated whether active, indeterminate, and total DU burden increased in DISTOL-EXT participants after they discontinued treprostinil.

Methods: In this multi-center, retrospective study, medical records for the year after discontinuation of treprostinil were reviewed. Data from these routine clinical visits were abstracted into a template designed a priori to capture information on the number of active and indeterminate DU at the end of the extension study and at subsequent visits. Participants who did not have a subsequent visit with documentation of DU status were excluded. We examined the number of new DU that developed from the end of the extension study (baseline) through the first year after discontinuation of treprostinil. The number of active, indeterminate and total DU 3–6 months (time A) and >6–12 months (time B) after discontinuation of treprostinil were compared to baseline by the paired t-test.

Results: Fifty-one subjects from 9 SSc Centers were included for analysis. At the conclusion of the treprostinil extension study, the mean number of active, indeterminate and total DU was 0.25 (SD 0.63), 0.22 (SD 0.54) and 0.47 (SD 0.78), respectively. The number of active DU increased from baseline to time A (mean 1.62, $p=0.004$, $N=23$) and time B (mean 1.03, $p=0.076$, $N=30$). The number of indeterminate DU increased from baseline to time B (mean 0.42, $p=0.03$, $N=30$) but not time A. The total DU burden increased significantly from baseline to time A (mean 2.1, $p=0.002$, $N=23$) and time B (mean 1.45, $p=0.01$, $N=30$) as shown in the Figure. The majority of patients required intensive vasodilator therapy and pain medication: calcium channel blockers (60.8%), PDE 5 inhibitors (21.6%), any pain medication (58.8%), opioids (33.3%). Three patients were hospitalized for complications from digital ulcers, and 4 patients required surgical intervention. Five patients were subsequently diagnosed with pulmonary hypertension.

Conclusion: Total DU burden increased significantly after discontinuation of oral treprostinil diolamine. These data provide supportive evidence of a beneficial effect of oral treprostinil diolamine for the vascular complications of SSc.

1928

A Multicenter, Prospective Cohort Study Using Nailfold Videocapillaroscopy and Other Clinical Characteristics to Determine the Risk of Developing New Digital Ulcers in Patients with Systemic Sclerosis. Vanessa Smith[1], Maurizio Cutolo[2], Ariane Herrick[3], Oliver Distler[4], Mike Becker[5], Emma Beltran[6], Patrick Carpentier[7], Clodoveo Ferri[8], Murat Inanc[9], Panayiotis Vlachoyiannopoulos[10], Harbajan Chadha-Boreham[11], Emmanuelle Cottreel[11], Thomas Pfister[11], Daniel Rosenberg[11] and Juan Torres.on behalf of the CAP study investigators[12], [1]Ghent University Hospital, Ghent, Belgium, [2]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, [3]Centre for Musculoskeletal Research, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom, [4]Zurich University Hospital, Zurich, Switzerland, [5]Charité University Hospital, Berlin, Germany, [6]Hospital La Fe, Valencia, Spain, [7]La Tronche Hospital, Grenoble, France, [8]University of Modena & Reggio E, Moderna, Italy, [9]Division of Rheumatology, Department of Internal Medicine, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey, [10]School of Medicine, National University of Athens, Athens, Greece, [11]Actelion Pharmaceuticals Ltd, Allschwil, Switzerland, [12]Syntax for Science SL, Basel, Switzerland.

Background/Purpose: Digital ulcers (DU) are painful and disabling and affect almost 50% of systemic sclerosis (SSc) patients. Nailfold videocapillaroscopy (NVC) non-invasively assesses SSc-related micro-angiopathy and may be useful in predicting clinical progression of digital vasculopathy, especially DU.[1–4] The objective of this study was to identify NVC variables and clinical characteristics which predict the occurrence of new DU in SSc patients.

Methods: International, prospective, multicenter cohort study in SSc. Eligibility was not restricted by medication use. SSc patients (American College of Rheumatology/LeRoy and Medsger) were enrolled in two strata:

'DU History' and 'No DU History'. The No DU History patients had early disease (≤2 years).

Variables were classified into bundles for statistical analysis: demographics, SSc clinical characteristics, DU characteristics, NVC characteristics and other clinical characteristics. NVC variables for fingers II–V were evaluated locally in a standardized way. Patients were followed up to 6 months for new DUs (confirmed by the investigator). Univariable Logistic Regression (ULR) was performed on all variables and Multivariable Logistic Regression (MLR) was performed within and across bundles to assess statistical significance (Wald chi-square $p<0.15$ for linear and $p<0.05$ for quadratic) and discriminatory ability (receiver operation characteristic area under the curve [ROC AUC]). Clinical relevance to predict new DU in 6 months was portrayed by model performance characteristics in a binary risk chart and two-by-two tables at different risk probability thresholds.

Results: Of the 623 patients enrolled in 59 centers, 591 had data on DU outcome (new DU or no new DU) during the study. 468 (79%) patients had a DU history, of whom 103 (22%) developed new DU. 123 (21%) patients had no DU history, of whom 5 (4%) developed new DU. Due to low event numbers in the no DU history group, the present analysis focuses on the DU history stratum. The mean age was 54.0 years, 79.5% were females, and 59.8% patients had limited cutaneous SSc. The final model consisted of the following 3 co-variables to predict the occurrence of DU within 6 months: number of DU at baseline visit categorized into 0, 1, 2 and ≥ 3, mean number of capillaries in the middle finger of the dominant hand (evaluated on two adjacent fields in the middle of the nailfold) and presence/absence of critical digital ischemia at enrolment. AUC of this model was 0.738 (C.I. 0.681–0.795). Internal validation through bootstrap generated AUC 0.633 [C.I. 0.510–0.756]). At a probability threshold of 37.3%, the binary risk table shows a specificity of 90.6%, a sensitivity of 39.4%, a negative predictive value (NPV) of 83.8% and a positive predictive value (PPV) of 54.9%.

Conclusion: The CAP study is the first and largest prospective study producing a simple prognostic model with acceptable performance which can be useful in the management of patients with presence or history of DU.

1929

Echocardiographic Phenomics for Novel Classification of Cardiac Involvement in Systemic Sclerosis. Monique Hinchcliff, Vistasp Daruwalla, Lauren Beussink-Nelson, Sofia Podlusky, Mary A. Carns, John Varga and Sanjiv J. Shah. Northwestern University Feinberg School of Medicine, Chicago, IL.

Background/Purpose: Traditional studies of systemic sclerosis (SSc) cardiac involvement have examined one or a few echocardiographic (echo) variables; however, cardiac involvement in SSc can be multi-faceted and heterogeneous. We hypothesized that evaluation of dense quantitative echo phenotypic data using repurposed genetic analytic software would allow for novel classification of SSc cardiac involvement.

Methods: We studied 377 patients with SSc enrolled in the Northwestern Scleroderma Program. All patients underwent comprehensive echo with Doppler and tissue Doppler imaging using a standardized protocol for image acquisition and interpretation. A total of 57 unique, quantitative echo phenotypes were standardized to mean=0 and SD=±1. The quantitative phenotypic data was entered into gene expression analysis software (Cluster), and a phenotype heatmap ("pheno-map") was generated (TreeView). Cluster groups ("pheno-groups") were defined based on the resultant heriarchical dendogram. We used linear, logistic, and Cox regression analyses to determine differences in clinical, laboratory, pulmonary function testing, and survival characteristics among pheno-groups.

Results: The mean±SD age was 51±13 years, 82% were female, 51% had limited cutaneous SSc, 32% had diffuse cutaneous SSc, and 17% had other forms of SSc (e.g., overlap syndromes). Prevalence of SSc complications were as follows: PAH in 9%, ILD in 17.5%, and LV systolic dysfunction (EF<50%) in 4%. After the phenomapping analysis, 4 distinct, mutually exclusive pheno-groups were identified. The 4 groups differed significantly on clinical characteristics and outcomes. The pheno-groups did not differ by SSc subtype (limited vs. diffuse cutaneous SSc), but autoantibodies did differ by pheno-group (e.g., anti-centromere antibody was most prevalent in pheno-group #4 [38%]). PAH prevalence differed across groups (highest [18.5%] in pheno-group #1, P=0.002). Clinical ILD did not differ among groups (P=0.24), but FVC and DLCO were lowest in pheno-group #1 (P<0.001). LV, RV, and left atrial mechanics were also worse in pheno-group #1 (P<0.02 for all comparisons). Pheno-group #1 had the highest risk for death (HR 6.0, 95% CI 1.3–28.5; P=0.024 after adjustment for age, sex, SSc subtype, disease duration, ILD, and PAH).

Conclusion: Heirarchical cluster analysis of high-density, quantitative echo phenotypes results in novel, clinically relevant classification of cardiac structure/function in SSc. Further research into the identified echo pheno-groups of SSc may enhance pathophysiologic insight into SSc cardiac involvement.

The Value of Repeated Nailfold Capillaroscopy in Raynaud's Phenomenon in Daily Practice: A Follow-up Study in the Netherlands. B. de Boer[1], J. Meijs[1], J. van Aken[2], T.W.J. Huizinga[1], A.a. Schouffoer[3] and J.K. de Vries-Bouwstra[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Spaarne Ziekenhuis, Hoofddorp, Netherlands, [3]Haga Hospital, The Hague, Netherlands.

Background/Purpose: Nailfold capillaroscopy is an important tool to differentiate primary Raynaud's phenomenon (PRP) from secondary Raynaud's phenomenon (SRP). Based on possible transition from PRP to SRP (semi)annual capillaroscopy has been advocated to detect transition to SRP as early as possible.

Objective of this study is to evaluate the additive diagnostic value of repeated nailfold capillaroscopy after one year in patients with Raynaud's phenomenon (RP).

Methods: Patients with RP who underwent capillaroscopy at the outpatient clinic at least six months ago were invited for follow-up capillaroscopy. PRP was defined according to the definition of LeRoy (1); SRP was defined as RP associated with a connective tissue disease fulfilling applicable diagnostic criteria; the remaining patients were classified as suspected SRP (sSRP). The number of patients in which follow-up capillaroscopy resulted in change of diagnosis was determined.

Results: In total 107 patients with RP underwent capillaroscopy. Of these71 underwent follow-up capillaroscopy after a mean period of 12 months (range 6–25 months). At baseline, eight (11%) patients had PRP, 28 (40%) SRP and 35 (49%) sSRP. The rate of progression from PRP to SRP was 12.5% (one of eight patients). The rate of progression from sSRP to SRP was 3% (one of 35 patients). Capillaroscopy pattern changed in 21 (30%) patients: six (8%) worsened (Table 1) and 15 (21%) improved. In total five patients (7%) had a different diagnosis at follow-up, two of which based on clinical symptoms, three based on capillaroscopy pattern only: one changed from PRP to SRP, based on development of sclerodactyly, one changed from sSRP to SRP based on biopsy proven myositis, and three patients changed from sSRP to PRP due to normalization of capillaroscopy (Table 2). Thus, capillaroscopy contributed to change in diagnosis in three out of 43 patients (7%) with PRP or sSRP, all improving from sSRP to PRP.

Conclusion: Although progression from PRP to SRP was observed in 12.5% and progression from sSRP to SRP in 3%, changes in capillaroscopy did not contribute to change in clinical diagnosis in these patients.Based on the findings of this study, a follow-up capillaroscopy after one year in patients with PRP or sSRP without a change in clinical symptoms cannot be advocated. Extended follow-up in a larger population is needed to confirm this observation.

Mycophenolate Mofetil (MMF) Use in Scleroderma Patients with Pulmonary Hypertension: Observations from the Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma Cohort.

Lesley Ann Saketkoo[1], Matthew R. Lammi[2], Aryeh Fischer[3], Jerry A. Molitor[4] and Virginia D. Steen[5]. [1]Louisiana State University Health Sciences Center, New Orleans, LA, [2]Louisiana State University Health Sciences Center, Pulmonary and Critical Medicine, New Orleans, LA, [3]National Jewish Health, Denver, CO, [4]University of Minnesota, Minneapolis, MN, [5]Georgetown University Medical Center, Washington, DC.

Background/Purpose: Systemic sclerosis (SSc) related pulmonary hypertension (PH) carries a high mortality and patients with SSc-PH related to restrictive lung disease having an even worse prognosis. Speculation regarding the potential of MMF to exert anti-fibrotic and anti-remodeling effects on parenchymal lung and vascular intimal fibrosis, led us to query the possible differences in outcomes and survival between 4 groups based on forced vital capacity (FVC) and use of MMF in SSc PH.

Methods: PHAROS is a prospective registry designed to provide substantive data to recognize aspects of PH unique to SSc. For this analysis patients were stratified by an FVC of >70% or ≤ 70% predicted on spirometry at the time of PH diagnosis by right heart catheterization (RHC) and then by MMF use greater than 6 months after the diagnosis of PH. Cyclophosphamide use was exclusionary to all groups. Calculations are derived from one-way ANOVA with Tukey's post test or Kruskal Wallis with Dunn's post-test. Categorical variables were compared with Chi square. These analyses were followed by Cox and stepwise backward regression analysis to assess baseline characteristics associated with risk of death and Kaplan-Meyer analysis.

Results: 256 cases from the PHAROS database matched criteria and had baseline spirometry results coincident with diagnostic RHC, of those 173 had a baseline FVC of >70% with 23 on MMF and 150 without; and 83 had a baseline FVC≤70% with 26 on MMF and 57 without. Across groups, no differences were found in age, disease duration, racial distribution nor surprisingly in skin score, 6 minute walk test for distance or NYHA Class. No detectable differences were found between groups in 6–18 month interval change from baseline FVC% in MMF- groups or from post-RHC initiation of MMF in the MMF+ groups. Of interest, baseline mPAP and PVR were lower in both MMF+ groups regardless of FVC. Though survival is numerically worst with FVC<70 without MMF at 4 years, it did not quite reach statistical significance in Kaplan-Meier analysis at 4 (p=0.06) or 3 years (p=0.08). Survival for both MMF groups was between 70% and 82% but only 56% for the patients with a low FVC not treated with MMF. Male sex was a significant independent predictor of death in all groups especially when FVC was <70%.

Table 1. Comparison between the baseline characteristics of the four groups at time of RHC, change of FVC between baseline RHC and from 6 to 18 months from RHC and regression analyses. Values reported in mean, unless otherwise stated. * = significant. NS = not significant

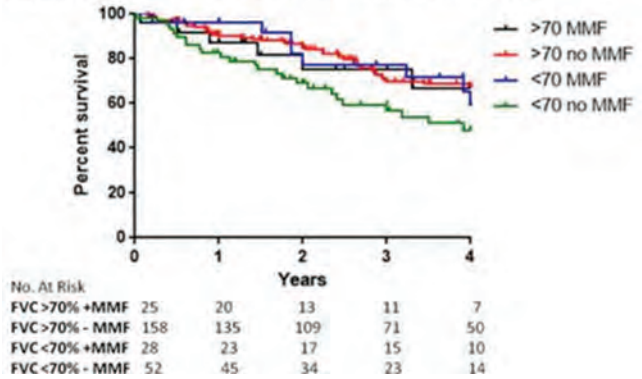
Survival at 1 year	95*	80	90	90	(p<0.05)
Survival at 3 years	82*	56	70	70	(p<0.05)
Univariate Predictors of Death in All Groups, ∧survived multivariate stepwise regression				Univariate Predictors of Death in FVC<70 group, ∧survived multivariate stepwise regression	
DLCO (p<0.0001)∧				DLCO (p = 0.005)∧	
FVC/DLCO (p<0.0001)					
6MWD (p<0.0001)				6MWD (p = 0.01)	
mPAP (p<0.0001)∧				mPAP (p = 0.003)∧	
PVR (p<0.0001)				PVR (p<0.0001)	
Male sex (p = 0.001)∧				Male sex (p = 0.007)∧	
NYHA (p<0.0001)∧				NYHA (p<0.0001)	
skin score (p = 0.04)				MMF Use (p = 0.07)	
MMF Use: (p = 0.06)					

Diagram 1. Survival across groups partitioned by FVC and MMF use.



No. At Risk					
FVC >70% +MMF	25	20	13	11	7
FVC >70% - MMF	158	135	109	71	50
FVC <70% +MMF	28	23	17	15	10
FVC <70% - MMF	52	45	34	23	14

Conclusion: The trend for improved survival in patients with PH with FVC <70 who were treated with MMF even in the absence of improvement of FVC is intriguing. Whether it has an effect on pulmonary artery remodeling should be considered. These findings warrant prospective controlled investigations of MMF in SSc PH particularly in those with restrictive lung disease.

Increasing Access to Inflammatory Arthritis Education in Rural and Remote Communities Using Telemedicine. Carol Kennedy[1], Kelly Warmington[2], Carol Flewelling[1], Rachel Shupak[1], Angelo Papachristos[3], Caroline Jones[4], Dorcas Beaton[5], Sydney Brooks[6] and Denise Linton[1]. [1]St. Michael's Hospital, Toronto, ON, [2]The Hospital for Sick Children, Toronto, ON, [3]St Michael's Hospital, Toronto, ON, [4]St. Michael's Hospital, Aurora, ON, [5]Mobility Program Clinical Research Unit, Li Ka Shing Knowledge Institute, St. Michaels Hospital, Toronto, ON, [6]The Arthritis Society, Ontario Division, Toronto, ON.

Background/Purpose: Telemedicine-based approaches to healthcare service delivery improve access to care. It was recognised that people with inflammatory arthritis living in rural areas had limited access to patient education and could benefit from the "Prescription for Education (RxEd)" program, an evidence-based inflammatory arthritis education program. (format: one-day, audience: adults with inflammatory conditions, facilitators: specialized arthritis care providers). The one-day program includes a variety of short presentations and panel discussions by the team, and small group, facilitator-led discussions.

The program was adapted to be delivered via interactive videoconferencing through two workshops for local and rural facilitators: Telemedicine Best Practices/Adult Education Principles; Improved Public Speaking.

The objective of this study was to evaluate the effectiveness of telemedicine delivery of "Prescription for Education" in improving arthritis self-efficacy and other secondary outcomes (arthritis knowledge, coping efficacy, illness intrusiveness, and effective consumer).

Methods: Two group, pre-post design comparing two methods of delivery, local (I, in-person) versus videoconferencing (R, remote using telemedicine), of the RxEd program.

Data were collected at baseline (T1), immediately following RxEd (T2), and at 6 months (T3). Self-report questionnaires served as the data collection tool. Measures included demographics, disorder-related, Arthritis Self-Efficacy Scale (SE), arthritis knowledge [ACREU RA knowledge questionnaire (AK)], coping efficacy (CE), Illness Intrusiveness (II), and Effective Consumer Scale (ECS). Analyses included: Univariate statistics for primary and secondary outcomes; Repeated measures analyses of variance (MANOVA) to assess change in primary outcome (SE) across T_{1-3} (I vs R); and Repeated measures ANOVA to assess change from pre- to immediate-post (AK) and pre- to 6-month post (CE, II, ECS) (I vs R).

Results: 123 persons completed baseline questionnaires (I n=36; R n=87), with follow-up of 81% (n=100) immediate post (T2) and 61% (n=75) at 6 months (T3). No significant baseline differences were found for: demographics, disorder-related, SE, AK, CE, II, and ECS measures.

Both groups (I and R) showed immediate effect (improved SE) after the intervention that diminished slightly over 6 months. MANOVA significant across T_{1-3} $p<0.001$ for SE. No significant differences (SE $p=0.31$) between groups (I vs R).

Both groups showed significant increase in knowledge (AK) from pre- to immediate post RxEd ($p<0.0001$), and no significant difference I vs R (ANOVA $p=0.41$). Both groups showed significant improvement in CE ($p<0.0001$), II ($p=0.03$), and ECS ($p<0.0001$) from pre- to 6-month follow-up. No significant differences (ANOVA, p-values 0.20 – 0.78) between groups (I vs R) for all secondary outcomes.

Conclusion: Improvements in arthritis self-efficacy and other secondary outcomes were equally effective in local (in-person) and remote participant groups. Access to inflammatory arthritis education in rural and remote communities is greatly increased with using Telemedicine.

Getting a Grip on Arthritis Online: Web-Based Continuing Education Supports the Dissemination of Arthritis Clinical Practice Guidelines Among Rural/Remote Primary Care Providers. Sydney Lineker[1], Mary Bell[2], Lisa Fleet[3], Elizabeth M. Badley[4], Vernon Curran[3], Marlene Del Pino[5], Fran Kirby[3], Anne Lyddiatt[6], Lynn Moore[1], Karla Simmons[3], Raquel Sweezie[1], Peter Tugwell[7] and Ed Ziesmann[1]. [1]The Arthritis Society, Toronto, ON, [2]Sunnybrook Health Sciences Ctr, Toronto, ON, [3]Memorial University, St. John's, NF, [4]Division of Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON, [5]Health Canada, Regina, SK, [6]Patient Partners in Arthritis, Toronto, ON, [7]Institute of Population Hlth, Ottawa, ON.

Background/Purpose: Primary care providers (physiotherapists, occupational therapists, nurses, family physicians) are often challenged with accessing relevant up-to-date arthritis information to enable delivery of optimal care. An online arthritis continuing health education program to disseminate arthritis clinical practice guidelines was developed, piloted, and evaluated to address this issue.

Methods: Online learning modules were developed for Osteoarthritis (OA) and Rheumatoid Arthritis (RA) based on published guidelines adapted for primary care (best practices), input from subject matter experts, and a needs assessment. The program was piloted in two rural/remote areas with high arthritis prevalence and health human resource shortages. Evaluation included 1) paired samples analyses of pre/post measurements of best practice recommendations and confidence and satisfaction with ability to manage arthritis, 2) evaluation of module content and design. Knowledge of best practice guidelines was measured by assigning one point for each best practice applied to a hypothetical case scenario and then summing the points into a total best practice score. Confidence and satisfaction were measured on 10 point numerical rating scales (0=not satisfied/not at all confident; 10=extremely satisfied/confident).

Results: Primary care providers that completed the modules (OA n=34; RA n=32) demonstrated significant improvements in best practice scores (OA pre=2.8/10, post=3.8/10, $p<0.01$; RA pre=3.9/12, post=4.6/12, $p<0.01$). More providers recommended occupational therapy/joint protection for the OA case scenario (pre=32.4%, post=58.8%, $p=0.01$) after taking the module and more providers recommended patient education for the RA case scenario (pre=46.9%, post=68.8%, $p=0.04$). Satisfaction with ability to manage arthritis also improved (OA pre=7.0, post=8.0, $p<0.01$; RA pre=6.0, post=7.0, $p<0.01$). Significant increases in confidence with different aspects of arthritis care were also observed ($p<0.05$). After taking the OA module, participants' confidence improved for the comprehensive musculoskeletal examination, prescribing/recommending corticosteroids, ordering/recommending serological tests, and managing common musculoskeletal conditions. After taking the RA module, participants' confidence improved for prescribing/recommending joint injections of the knee, DMARDs, and

corticosteroids, and managing common musculoskeletal conditions. Most respondents agreed that the modules were consistent with stated objectives (OA=97.5%; RA=97.1%), addressed learning needs (OA=87.2%; RA=94.3%) and were relevant to practice (OA=80.0%; RA=91.4%). The planned use of relevant resources in practice and with patients highlighted the participants' commitment to change.

Conclusion: With knowledge gained from the online modules, participants were able to apply a greater number of best practices and they reported an increase in both satisfaction and confidence with managing arthritis. The modules were also relevant to practice and the content addressed their learning needs. As a result of the success of the pilot evaluation, both modules were accredited and launched nationally at the end of February 2014.

Examing Why Minority Women Are Risk Averse : A Qualitative Study.
Sonal Bhalla[1], Kristin Mattocks[2] and Liana Fraenkel[3]. [1]Yale-New Haven Hospital, New Haven, CT, [2]VA Central Western Massachusetts Healthcare System, University of Massachusetts Medical School, Leeds, MA, [3]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT.

Background/Purpose: Prior research has shown that when making choices about the risks and benefits of medications, women from minority ethnic groups tend to be more risk averse compared to their Caucasian counterparts. We conducted a qualitative study to better understand how young women of three racial groups: non-Hispanic Blacks, non-Hispanic Whites and Hispanics approach trade-offs between the risks and benefits of medications.

Methods: Participants were drawn from inpatient wards and infusions centers at a large academic hospital. Women age 20–45 years, able to speak English or Spanish, who self-identified as Hispanic Black, non-Hispanic White orHispanic were eligible to particpate. We performed individual in-depth interviews following a semi-structured interview guide. In the initial prompt, all participants were asked why they think minority ethnic groups tend to be more risk averse. Interviews were audiotaped and subsequently transcribed verbatim. Transcripts were analyzed using the constant comparative method of grounded theory. Coding ended with thematic saturation (36 interviews).

Results: We coded 36 transcripts (30.6% non-Hispanic Blacks, 33.3% non-Hispanic Whites and 36.1% Hispanics). The participants' mean age (SD) was 34.8 (6.8); 66.7% had a college education or higher, 58.3% had annual income $40k or more; 41.7% were employed full-time, and 55.6% were married. The four main themes that emerged from the transcripts were the impact of 1) constrained resources (limited means, responsibilities of work and family, lack of knowledge or information); 2) deep-rooted health beliefs (familial narratives, religious beliefs, mistrust); 3) perceived discrepancies in access to high quality healthcare (access to type of care, relationship with doctors, lack of communication and disclosure) and 4) erroneous illness perceptions (perceived susceptibility to side effects, inaccurate medication beliefs) on attitudes towards treatment. References were made towards constrained resources, family responsibilities and perceived susceptibility by both African American and Hispanic women. African American women made more references to mistrust and medical experimentation and lack of education whereas Hispanic women were most often influenced by beliefs in home remedies. White women endorsed the impact of constrained resources in the minority ethnicities. Examples of illustrative quotations are provided in the table below.

Conclusion: Decision making is influenced by factors far beyond the risks and benefits of proposed medications – and this is particularly true for minority women. An increased awareness of these factors is likely to improve shared decision making in clinical practice.

Emerging Themes	Illustrative Quotes
Impact of constrained resources	"They don't want to be sitting, lying around somewhere recovering. They want to be able to go to work and pay their bills, take care of their families!"
	"We are not that risky because in the end we really cannot afford what a lot of white people can afford."
Impact of deep-rooted health beliefs	"Maybe it is the way we are raised or something", "like your grandmother use to give you these old remedies to try instead of going to the doctor."
	"Homemade remedies don't give side effects."
Impact of perceived discrepancies in access to high quality healthcare	"...clinic doctors don't look you in the face ...They don't mention the side effects. They don't mention what could happen"
	"A lot of times doctors don't have time like they use to because of the current health care system of factory working, kind of pushing people out, getting them in and out."
Impact of erroneous illness perceptions	"There is a lot to lose. I rather hear that there is no fix, stay in pain, use my knee and avoid those side effects like not being able to use it or move it."
	"more minorities have health problems.... worse health problems than the white people seem to", "I am going to be that odd number because we are that odd number for everything else."

1935

Racial Disparities in Attitude Towards Treatment in Young Women.
Raluca Cozmuta[1], Sonal Bhalla[2] and Liana Fraenkel[3]. [1]Yale University School of Medicine, New Haven, CT, [2]Yale University, New Haven, CT, [3]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT.

Background/Purpose: Previous research has found that young minority women tend to be more risk averse compared to their Caucasian counterparts. The reasons underlying these differences, however, are not well understood. The objective of this study was to examine whether factors influencing perceived treatment importance vary by minority status.

Methods: Women between the ages of 20 and 45 receiving treatment at an academic hospital either as an inpatient or in an infusion center completed a survey. The survey ascertained sociodemographic data, affect, trust in healthcare systems, and medication beliefs using validated instruments. The survey included a hypothetical scenario in which subjects were asked to rate the importance of taking a medication for a patient with joint pain, migraines and fatigue that benefits 70% of people and is well tolerated except for the rare risk (1 per 100,000) of a neurologic disease that may cause weakness, trouble with vision and numbness. Associations between patient characteristics, affect, medication beliefs, and trust with perceived importance of taking the medication were evaluated using two sample t-test, Mann Whitney U test, and Spearman correlation as appropriate. Variables found to be statistically significant ($p < 0.05$) were subsequently evaluated using multiple linear regression. Minority women were defined as women who did not self-identify as White non-Hispanic.

Results: 174 women completed the survey. Patient characteristics by minority status are summarized in the table below. Perceived importance of taking the medication varied by minority status. Among minority women, perceived medication importance was correlated with trust in healthcare systems ($r= 0.2$, $p= 0.03$), hopefulness regarding the medication ($r= 0.3$, $p= 0.002$), and difficulty paying for medications ($z= -2.3$, $p= 0.03$). The relationship between trust and perceived importance was completely mediated by hopefulness. Among non-Hispanic White women, medication beliefs ($r= -0.5$, $p= 0.001$), hopefulness ($r= 0.5$, $p< 0.001$) and worry related to the medication ($r= -0.4$, $p= 0.002$) were correlated with perceived medication importance. Hopefulness and difficulty paying for medications remained significantly associated with perceived medication importance in the multivariate regression model among minority women, as did affect and medication beliefs in non-Hispanic White women.

Conclusion: In contrast to previous findings, minority women rated the importance of taking medication higher than non-Hispanic White women. Our findings confirm the important influence of affect on decision making, and suggest that financial constraints can influence the perceived value of treatment among minority women.

Table. Patient characteristics by minority status

Variable	Non-Hispanic White	Minority	P value
Age (mean, SD)	32.8 (7.2)	33.1 (7.9)	0.80
Medication beliefs (mean, SD)	20.9 (4.8)	21.8 (4.7)	0.22
Trust (mean, SD)	28.5 (5.3)	28.7 (6.0)	0.86
Hopefulness (mean, SD)	4.1 (1.6)	3.6 (1.6)	0.05
Worry (median, range)	5 (1–7)	5 (1–7)	0.07
Important (median, range)	5 (2–7)	6 (1–7)	0.01
Some college education (%)	79.1%	51.4%	(<0.001)
Difficulty paying for meds (%)	21.2%	25.7%	0.50

1936

Ageism, Fear, and Competing Co-Morbidities - Why Older Patients May Not Seek Care for Restricting Back Pain: A Qualitative Study. Una Makris[1], Robin Higashi[2], Emily Marks[2], Liana Fraenkel[3], Joanna Sale[4] and CM Reid[5]. [1]Dallas VA Medical Ctr, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, TX, [3]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT, [4]University of Toronto, St. Michael's Hospital, Toronto, ON, [5]Weill Cornell Medical College, New York City, NY.

Background/Purpose: Back pain is highly prevalent among older adults and often undertreated. The reasons for this gap in care are poorly understood, especially in older adults from diverse racial and ethnic backgrounds. Our objective was to understand why older adults, in a racially diverse population, with restricting back pain (RBP– back pain severe enough to restrict activity), may not seek care.

Methods: We conducted one-on-one interviews and focus groups with older adults (ages ≥65 years) who reported RBP within the past 3 months. We recruited participants from 3 different sources (interviews and focus groups in Connecticut and focus groups in New York) to ensure a racially diverse sample; recruitment efforts ended once saturation was achieved. A semi-structured discussion guide was used in both the interviews and focus groups to prompt participants to discuss their experiences with RBP, including beliefs and attitudes about management. Audio recordings were transcribed and subsequently analyzed (using NVivo) in an iterative process to develop thematic categories.

Results: We conducted 23 one-on-one interviews and 16 focus groups (n=70 participants), for a total of 93 participants. Participants were mostly female (68%), older (median age=83 years), over one-half lived alone, and 46% self-identified as belonging to a minority group. We identified 3 themes for why older adults may not seek care for RBP (Table 1): (1) participant and perceived provider beliefs about age-related inevitability of RBP, (2) participants' fear of medication and/or surgery, and (3) older adults' perceived relative importance of RBP versus other comorbidities. There did not appear to be any trends in our findings based on race/ethnicity.

Conclusion: Findings demonstrated that a range of illness perceptions influence older adults willingness to seek care for RBP. Many of the barriers discussed may be addressed by improved patient-physician communication. Understanding the older adult's perspective regarding reasons they may not choose to seek care is an important step toward identifying opportunities to improve the quality of care for older adults with RBP. Providers, in turn, might benefit from clinical guidance regarding the treatment of low back pain specifically in older adults (e.g. poly-pharmacy, frailty, multiple co-morbidities), that recognizes the impact of ageist myths and assumptions, and providers' focus on medical and surgical interventions.

Theme	Sample Quotes
1. Participant and provider beliefs about inevitability of back pain in older adults	I honestly think that at this point, my body is broken, it's worn out. I mean, [chuckle] that's why I say, someone in their 70s you could help a lot more, but I honestly don't know what could be done now outside of keeping comfortable.
	I'll tell you what the doctor thinks: "you're 93 years old!" I see that all the time when I go to the office. Like everything is taken very lightly.
2. Participant fear of medication and/or surgery	They [providers] always want to give me medicine. I don't want medicine [emphasis original]! Because I don't think it helps anyÉI don't want another medication.
	That's the thing. They don't tell you much. They'd rather give you medication.
	He told me [the surgery] was a success É he said "it worked out" from the X-ray, that it looks like it's going to be successful, but the painÉthat's what to me, what I would say is successful, if I didn't have any more pain. It was not successful!
3. Relative importance of back pain compared to comorbidities	I am having back pain right now for years. Not only for months, for years. My doctorÉ I have other problemsÉ So she even told me that they are only patching me up because I have other problems; prostate, liver, heart, and all different problems. That is what she told me about this pain.
	My concentration at this point is my diabetes. I've had that and I've had that for almost 30 years. And that has presented problems along the wayÉthey know more about that than what I'm going through with my back.

Model Examining Factors Related to Physicians' Ratings of Disease Activity in Patients with RA. Julia R. Ayeroff[1], Sarah R. Ormseth[2], David Hardy[3], Michael R. Irwin[2], Michael H. Weisman[4] and Perry M. Nicassio[2]. [1]University of Southern California, Los Angeles, CA, [2]University of California, Los Angeles, Los Angeles, CA, [3]Loyola Marymount University, Los Angeles, CA, [4]Cedars-Sinai Medical Center, Los Angeles, CA.

Background/Purpose: The purpose of this study was to examine a multidimensional, integrated model describing the interrelations among rheumatoid arthritis (RA) objective disease activity, patient-rated disease activity, tender joint count, and related psychosocial factors as determinants of physician-rated disease activity (see Figure 1). It was expected that objective disease activity would be positively associated with physician-rated disease activity, both directly and indirectly through the hypothesized mediators of patient-rated disease activity and tender joint count.

Methods: The data of 105 participants satisfying the ACR classification criteria for RA were drawn from baseline of a randomized comparative efficacy trial of psychosocial interventions for RA. In the hypothesized model, objective disease activity (DAS-28 Swollen Joint Count and ESR), patient-rated disease activity (Rapid Assessment of Disease Activity in Rheumatology total joint score and disease activity VAS), physician-rated joint tenderness score serve as determinants of physician-rated disease activity. EQS 6.1 was used to evaluate the structural model, and the significance of estimated indirect effects (calculated based on the Sobel method) was taken as evidence of mediation.

Results: The hypothesized model fit the data well, $\chi^2(28) = 21.97$, $p = .079$, CFI = 0.96, RMSEA = 0.07, and the specified predictors explained 84% of the variance in physician-rated disease activity (see Figure 1). Greater objective disease activity directly predicted physician-rated disease activity and contributed to higher levels of patient-rated disease activity, which, in turn, predicted a higher tender joint count which ultimately exerted a strong positive effect on physician-rated disease activity. While objective disease activity had a strong direct effect on physician-rated disease activity, partial mediation was established because the strength of this association diminished when the model included the hypothesized predictors (as evidenced by its significant indirect effect; $\beta_{indirect} = .24$, $p < .001$). With regard to patients' self-ratings of RA symptoms, depressive symptomatology and non-white ethnicity were shown as positively associated with higher self-perceived levels of disease activity. In contrast, non-white ethnicity was associated with significantly lower physician-rated tender joint scores.

Conclusion: Findings confirmed the importance of a multidimensional framework in evaluating RA disease activity and elucidated the mechanisms that perpetuate health disparities. These results identify a specific point in the clinical encounter where an increased awareness of patients' experiences of their disease can contribute to more accurate ratings and improved outcomes.

Effects of Mesenchymal Stem Cells on Human B Cell Proliferation. Erin Collins, Maosong Qi and Gary S. Gilkeson. Medical University of South Carolina, Charleston, SC.

Background/Purpose: Human mesenchymal stem cells (MSC) are progenitor cells that have immunomodulatory properties. MSCs have been used to treat a variety of autoimmune diseases, including lupus. However, literatures have reported conflicting results of MSC function in regards to B cell biological behaviors. We tested the ability of MSCs from umbilical cords, and MSCs from healthy and lupus bone marrow in modulating the B cell functions of healthy and lupus patients.

Methods: Human MSCs were isolated from umbilical cords (UC), healthy bone marrow (HBM), and lupus patient bone marrow (LBM). Passages between 4 and 7 were used for these assays. B cells were isolated from peripheral blood of healthy and lupus donors using CD19 micro-beads, then labeled with CFSE for detection of proliferation. B cells were plated at $5x10^4$ per well in 96-well plates, with or without pre-plated MSCs, at the same number, within 24 hours. The cells were incubated at 37°C and 5% CO_2 for 96 hours ± stimulation (CpG, CD40L, IL2, and anti-human IgG/IgA/IgG). B cells were then collected and analyzed for proliferation by flow cytometry. Supernatants were collected for detection of antibodies and cytokines via ELISA.

Results: When co-cultured, UC-MSC and HBM-MSC inhibited healthy B cell proliferation better than LBM-MSC. However, only UC-MSC appeared to reduce the proliferation of lupus patient B cells. Regardless of proliferation, healthy B cells cultured in the presences of MSCs experienced increased IgM and IgG production. Supernatants of healthy B cells co-cultured with MSCs also presented increased the levels of IL-6 while having decreased amounts TNF-α when compared to the supernatants of wells with B cells alone.

Conclusion: In our experiments, MSCs obtained from umbilical cords exhibited strong activity in suppressing both healthy and lupus B cell proliferation while MSCs from healthy bone marrow suppressed healthy, but not lupus B cell proliferation. Lupus patient derived MSCs were unable to significantly suppress B cell proliferation from healthy or lupus patients. Furthermore, MSCs from all sources did not inhibit healthy B cell IgG or IgM secretion. These studies aim to improve our understanding of the *in vitro* effects of MSCs on B cell function in order to predict *in vivo* efficacy of MSCs to be used in the treatment of SLE.

Development of Cell–Based Enzyme–Linked Immunosorbent Assay for the Quantification of Anti–M–type phospholipase–a–receptor Antibodies and Its Clinical Usefulness in Patients with Membranous Nephropathy. Yasuhiro Katsumata[1], Yuko Okamoto[1], Takahito Moriyama[1], Manabu Kawamoto[1], Hirotaka Kaneko[1], Yasushi Kawaguchi[1], Takahisa Gono[1], Masanori Hanaoka[1], Tomoaki Higuchi[1], Hidenaga Kawasumi[1], Keiko Uchida[1], Kosaku Nitta[1] and Hisashi Yamanaka[2]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Better risk prediction is needed to identify patients who will benefit from immunosuppressive therapy with idiopathic membranous nephropathy (MN) due to the variable natural course of the disease–spontaneous remission occurs in 40–50% of patients. It has recently been reported that many patients with idiopathic MN, but not patients with secondary MN, have circulating antibodies against the M-type phospholipase A2 receptor (PLA2R), a transmembrane protein located on podocytes. Although measuring anti–PLA2R levels has also been suggested to be a method to follow and predict response to treatment, widely available published measuring methods are only Western blot and a semi-quantitative immunofluorescence test. We aimed to develop cell–based enzyme–linked immunosorbent assay (ELISA) for the quantification of anti–PLA2R antibodies and investigate its clinical usefulness in patients with MN. We also aimed to validate the absence of anti–PLA2R antibodies in patients with systemic lupus erythematosus (SLE).

Methods: The synthesized human PLA2R gene was transfected into the HEK293T cells using the pcDNA3.1/Hygro (+) vector. Stable cell line expressing PLA2R was generated through limiting dilution and evaluated by flow cytometry and Western blot. Using this cell line, we developed a quantitative cell–based ELISA for anti–PLA2R antibodies as follows. HEK293T cells stably expressing PLA2R were seeded and cultured in wells of a flat–bottomed 96–well tissue culture plate coated with poly–D–Lysine. After the cells were fixed, serum samples were added. Subsequently, the peroxidase–conjugated anti–human IgG and TMB were added in order, and color development was measured. The usefulness of this test was studied in 26 patients with biopsy–proven primary MN, and 16 SLE patients with pure MN. Western blots using the lysates of HEK293T cells stably expressing PLA2R were also performed with these samples. Clinical data of these patients were retrospectively evaluated. Treatment was determined by physician preference in each individual based on clinically available information without prior knowledge of anti–PLA2R antibody positivity.

Results: Stable expression of PLA2R was detected in the HEK293T cells by flow cytometry and Western blot. Anti–PLA2R antibodies were positive in 7/26 (27%) by cell–based ELISA and 7/26 (27%) by Western blot. Cohen's κ coefficient of the 2 tests was 0.61 which means there is substantial agreement. Retrospective analyses revealed that all of the 7 patients who were anti–PLA2R positive by cell–based ELISA were treated with immunosuppressive therapy. In contrast, only 5 out of 26 patients with negative results received immunosuppressive therapy. Thus, the results of cell–based ELISA were associated with physicians' decision on immunosuppressive therapy ($p < 0.001$). Renal function did not decline in any of the anti–PLA2R negative patients. All of the 16 SLE patients with pure MN were negative for both cell–based ELISA and Western blot.

Conclusion: This study showed that our cell–based ELISA is reliable and clinically useful examination for MN. Anti–PLA2R antibodies may serve as predictive biomarker in MN. The absence of anti–PLA2R antibodies in patients with SLE was reconfirmed.

A Novel Murine Model of B Cell-Mediated Glomerular Injury Is Mediated By Cytokines. Alfred Kim[1], Shreeram Akilesh[2], Ania Koziell[3], Sanjay Jain[2], Jeffrey Hodgin[4], Mark Miller[2], Jeffrey Miner[2] and Andrey Shaw[2]. [1]Washington Univ School of Med, St. Louis, MO, [2]Washington University School of Medicine, Saint Louis, MO, [3]King's College, London, United Kingdom, [4]University of Michigan, Ann Arbor, MI.

Background/Purpose: upus nephritis (LN) remains the leading cause of mortality for SLE patients, and is associated with proteinuria and foot process effacement. Podocyte foot process effacement is a feature of proteinuria, thought to be a stereotyped response of the podocyte to injury. The stimulus for podocyte injury and foot process effacement is unknown. B cell depletion therapies have demonstrated efficacy in some patients with proteinuria including those with minimal change disease. Since pathogenic antibodies are not causative, we hypothesized that a B cell derived cytokine might be capable of directly inducing podocyte injury and foot process effacement.

Methods: B cell model antigen model hen egg lysozyme (HEL) was biotinylated, complexed to avidin and injected into mice. Naive HEL-specific B cells were adoptively transferred and proteinuria assessed. Kidneys were processed for immunofluorescence and scanning electron microscopy (SEM). Cultured podocyte membrane ruffling was assessed with DIC videomicroscopy. IL-4 expression in mice was achieved by hydrodynamically injecting murine IL-4 in the piggyBac vector system. Human kidney biopsies were assessed for phospho-STAT6 by immunohistochemistry.

Results: We identified IL-4 as a B cell derived cytokine capable of altering actin cytoskeletal dynamics by stimulating podocyte membrane ruffling (lamellipodia). In addition, IL-4 generated foot process retractions on *ex vivo* fragments of renal cortex. Using a novel model of B cell induced proteinuria, B cells polarized to secrete IL-4 upon activation induced proteinuria and focal foot process effacement without antibody or complement deposition. Intravital two-photon microscopy demonstrated that HEL-specific B cells arrested trafficking within glomeruli only in the presence of glomerular-localized HEL. Inhibition of IL-4 signaling with a JAK1/3 inhibitor markedly reduced proteinuria in IL-4 overexpressing mice. A subset

of patients with steroid-sensitive nephrotic syndrome demonstrated glomerular STAT6 activation.

Conclusion: These findings suggest a potential explanation for the utility of immunosuppression and more targeted anti-B cell therapy with rituximab in the treatment of minimal change disease. These results supporting the role of IL-4 in human nephrotic syndromes and a novel therapeutic target.

Neuropsychiatric Lupus Is Substantially Unaffected By B-Cell Deficiency. Jing Wen[1], Ariel Stock[1], Haowei Wang[2], Mark Shlomchik[2], Maria Gulinello[1] and Chaim Putterman[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA.

Background/Purpose: Neuropsychiatric lupus (NPSLE) is one of the earliest clinical manifestations in human lupus. However, its mechanisms are not fully understood. In lupus, a compromised blood brain barrier may allow for the passage of circulating autoantibodies into the brain, where they can induce neuropsychiatric abnormalities. Autoantibody titers can correlate with the severity of depressive-like behavior, and injection of anti-ribsomal P or anti-NMDA receptor antibodies into the brain induces neuronal damage and memory deficits. Since antibodies play an important role in lupus pathogenesis, B-cell depletion has been proposed as a targeted treatment approach. To determine if indeed B-cells and/or autoantibodies are instrumental in the pathogenesis of murine NPSLE, we evaluated neuropsychiatric disease in constitutively B cell deficient (JhD/MRL/lpr) and conditionally B-cell deficient mice (Cre-human CD20 MRL/lpr x Rosa26-Flox-STOP-DTA MRL/lpr, referred to as hCD20-DTA MRL/lpr, inducible by tamoxifen), as compared to MRL/lpr lupus mice.

Methods: hCD20-DTA MRL/lpr mice were B cell depleted at 13–14 weeks of age with tamoxifen treatment for 5 days. Blood and cerebrospinal fluid (CSF) were collected from JhD/MRL/lpr, hCD20-DTA MRL/lpr, MRL/lpr (positive controls) and MRL/MPJ (negative controls) at 18 weeks of age. Total IgG and IgG anti-dsDNA antibody concentrations in the serum and CSF were measured by ELISA. Comprehensive neurobehavioral testing including forced swim, anhedonia, open field, object recognition, object placement, and social preference were employed to evaluate the neuropsychiatric manifestations in the B cell sufficient and deficient MRL/lpr strains.

Results: Autoantibody levels were negligible (JhD/MRL/lpr) or significantly reduced (hCD20-DTA MRL/lpr) in the serum and CSF of B cell deficient mice. Nevertheless, we found that in the forced swim test, both JhD/MRL/lpr and hCD20-DTA MRL/lpr mice showed profound depressive-like behavior, which was no different from MRL/lpr mice. However, JhD/MRL/lpr mice displayed an increase in both total track length and number of rears (standing on the hind feet) in open field. Additionally, hCD20-DTA MRL/lpr mice exhibited an increased trend in preference score in object placement. No significant differences were observed in anhedonia, object recognition and social preference tests among all three strains. Interestingly, hCD20-DTA MRL/lpr mice demonstrated a significantly reduction in cellular infiltrates in the choroid plexus compared to MRL/lpr mice.

Conclusion: We found that B-cell depleted MRL/lpr mice surprisingly had no significant attenuation of key features of neuropsychiatric disease, including depressive-like behavior and cognitive dysfunction. However, increased motor activity was observed in JhD/MRL/lpr mice. Additionally, a trend toward improved visual memory was found in hCD20-DTA MRL/lpr mice. Finally, the decreased cellular infiltrates in the brain of hCD20-DTA MRL/lpr mice indicate that B cells play an important role in facilitating the immune cell entry into the choroid plexus.

Regulation of the Responses of Human B Cell Subsets to Innate Immune Signals By Epratuzumab, a Humanized Monoclonal Antibody Targeting CD22. Natalia V. Giltiay[1], Geraldine L. Shu[1], Anthony Shock[2] and Edward A. Clark[1]. [1]University of Washington, Seattle, WA, [2]UCB Pharma, Slough, United Kingdom.

Background/Purpose: The B cell-associated receptor, CD22, functions to regulate adhesion and signaling through both the B cell receptor (BCR) and Toll-like receptors (TLRs) expressed in B cells. Epratuzumab is a humanized monoclonal antibody that targets CD22 on B cells and is currently being tested in phase 3 clinical trials in patients with systemic lupus erythematosus (SLE). This study was undertaken to determine how epratuzumab affects B cell activation through TLR and/or BCR pathways in tonsil-derived B cell subsets, which offers the opportunity to investigate the responses of B cells from human lymphoid tissue.

Methods: Purified $CD19^+CD20^+$ B cell subsets were isolated from human tonsils based on their relative expression of CD10, CD27 and other markers, and examined for CD22 expression and internalization after binding of epratuzumab using conventional flow cytometry and ImageStream® multispectral imaging cytometry. Isolated subsets were also treated with anti-IgM, R848 (a TLR7 agonist) and/or interferon (IFN)-α in the presence of epratuzumab or a human IgG_1 control. Changes in mRNA levels of a variety of genes 3 to 12 hours after activation were analyzed by qPCR. Cell proliferation was assessed by flow cytometry using CFSE staining. Cytokine production was measured by ELISA and intracellular flow cytometry after 3 days of *in vitro* culture.

Results: CD22 was expressed on all B cell subsets but $CD20^+CD10^{lo}CD27^{lo}$ mature naïve B cells expressed higher levels of CD22 (MFI 148) than $CD20^+CD27^{hi}CD10^{lo}$ memory B cells (MFI 120) or $CD10^{hi}CD27^+$ germinal center (GC)-associated B cells (MFI 130), and naïve B cells also internalized epratuzumab more uniformly compared to GC-associated B cells. Epratuzumab had no effect on IFN-α induced genes (eg. *TLR7, IRF7*) or BCR-induced genes (eg. *c-MYC*) in naïve B cells. However, epratuzumab did affect the expression of certain cytokine genes after TLR7 stimulation alone and/or in combination with anti-IgM (eg. IL-6). TLR7-driven IL-6 and IL-10 expression by naïve B cells were also differentially modulated by epratuzumab, with inhibition of IL-6 cytokine production but enhanced IL-10 expression. Finally, epratuzumab demonstrated a small but consistent enhancement of B cell proliferation induced with anti-IgM and anti-IgM+ R848.

Conclusion: These results suggest that one therapeutic effect of epratuzumab may be via down-regulation of the production of pro-inflammatory cytokines by B cells and an increase in the production of regulatory cytokines such as IL-10. These data have implications for understanding the functional consequences on B cell function of epratuzumab treatment in patients with autoimmune diseases such as SLE.

1943

***In Vivo* Effects of Epratuzumab, a Monoclonal Antibody Targeting Human CD22, on B Cell Function in Human CD22 Knock-in (Huki) Mice.** Carolin Brandl*[1], Lamia Özgör*[1], Miriam Wöhner[2], Anthony Shock[3] and Lars Nitschke[1]. [1]University of Erlangen, Erlangen, Germany, [2]Research Institute of Molecular Pathology, Vienna, Austria, [3]UCB Pharma, Slough, United Kingdom.

Background/Purpose: Epratuzumab is a humanized monoclonal antibody that targets the B cell-specific protein CD22 currently in Phase 3 clinical trials in patients (pts) with systemic lupus erythematosus (SLE). Epratuzumab does not deplete B cells but does cause long-term changes in B cell numbers (~50–60% reduction after 9–12 months) in SLE pts. The mechanism of action of epratuzumab appears to involve immunomodulation of B cells e.g. by inhibiting activation through the B cell receptor (BCR).[1] It has also been shown to modulate B cell adhesion molecule expression and responsiveness to chemokines.[2] This study aimed to understand the effect of epratuzumab on B cells *in vivo* using human CD22 knock-in (Huki) mice in which B cells express the human, instead of murine, CD22 gene.[3]

Methods: Huki mice (n=4–8) received a single intravenous injection of epratuzumab (0.5mg) or phosphate-buffered saline (PBS) and at time points up to 12 weeks (wks) B cell sub-populations (immature, transitional, mature, germinal center, marginal zone) in peripheral blood, bone marrow, spleen and lymph nodes were measured along with B cell activation markers (CD69, MHCII) and the CD62L homing marker. *Ex vivo* functional assays were also performed: Ca^{2+} flux after anti-IgM BCR stimulation, apoptosis (based on numbers of sub-G1 phase cells) and CD22 internalization on B cells were measured (flow cytometry) and the proliferation of B cell subsets assessed after 7 days *in vivo* administration of BrdU.

Results: In Huki mice, a single dose of epratuzumab did not appear to affect absolute numbers or proportions of B cell subsets in

peripheral blood or lymphoid organs at Wks 3, 5 or 12 (comparable to PBS-treated Huki mice). Similarly, there were no consistent changes in activation markers or CD62L. However Huki mice receiving epratuzumab showed human CD22 internalization in B cells from blood and all other organs. Internalization was detected at 24 hours and maintained for 8 wks; long after antibody clearance. Splenic B cells purified 10 days after receiving epratuzumab demonstrated an increased rate of apoptosis when cultured *ex vivo* relative to PBS-treated mice and decreased BCR-activated Ca^{2+} flux was demonstrated in Huki mouse splenic B cells after epratuzumab treatment *in vitro*. BrdU incorporation in several B cell subsets was unchanged 7 days after administration of epratuzumab, suggesting there was no increase in proliferation.

Conclusion: Epratuzumab administration to Huki mice induced functional effects on B cells assessed *ex vivo* in keeping with *in vitro* data using human B cells. Specifically, epratuzumab decreased CD22 expression for a long time period, increased B cell apoptosis and reduced Ca^{2+} flux upon BCR activation. Single dose epratuzumab did not seem to strongly influence B cell development or B cell populations in blood and various organs. These data have implications for understanding the effects of epratuzumab treatment on B cell function in SLE pts particularly in relation to how BCR inhibition leads to long-term changes in the survival and physiology of B cells.

Targeting CD22 with Epratuzumab Impacts Cytokine Production By B Cells. Vanessa Fleischer[1], Julia Sieber[1], Sarah J. Fleischer[2], Anthony Shock[3], Guido Heine[4], Capucine Daridon[1] and Thomas Dörner[1]. [1]German Rheumatism Research Centre Berlin, Berlin, Germany, [2]Charité University Medicine, Dept. Medicine/Rheumatology and Clinical Immunology/German Rheumatism Research Center (DRFZ), Berlin, Germany, [3]UCB Pharma, Slough, United Kingdom, [4]Charité University Medicine Berlin, Berlin, Germany.

Background/Purpose: CD22 is a negative co-receptor of the B-cell receptor (BCR) and, when targeted by epratuzumab, partially inhibits BCR signaling, for example by reducing Syk phosphorylation and Ca^{2+} flux. Cytokines produced by B cells have been described as playing important roles during certain stages of autoimmune diseases such as systemic lupus erythematosus (SLE) and their secretion is known to be driven by antigens and/or Toll-like receptor (TLR)-ligand stimulation. However, the impact of epratuzumab, a monoclonal antibody that targets CD22, on cytokine production has not yet been addressed. The current study therefore aimed to analyze the role of epratuzumab on the production of key cytokines by B cells, and compare the response of B cells from SLE patients to those from healthy donors (HD).

Methods: Peripheral blood mononuclear cells were isolated and B cells purified by Magnetic Activated Cell Sorting®. After 2 days of culture in the presence of TLR9 and/or BCR stimulation (CpG and anti-IgM/IgG, respectively), cytokine production (IL-6, TNF-α and IL-10) by B cells from SLE patients and HD was analyzed in the supernatants by bioplex. A special focus was made on IL-10-producing B cells using intracellular staining by flow cytometry. The balance between IL-10 and pro-inflammatory cytokines were assessed using the ratios of the concentrations of IL-10 to either IL-6 or TNF-α.

Results: The secretion of the pro-inflammatory cytokines TNF-α and IL-6 by anti-BCR activated HD and SLE B cells was significantly inhibited by epratuzumab co-treatment. The production of both cytokines was also inhibited by epratuzumab when B cells were stimulated concomitantly through the BCR and TLR9, although this failed to reach statistical significance for IL-6 production from HD. In contrast, the production of IL-10 in B cell supernatants was not affected by epratuzumab under any stimulation conditions; similarly, the development of IL10+ cells in culture, which was enhanced by TLR and BCR activation, was unaffected by epratuzumab. The cytokine balance between IL-10 and pro-inflammatory cytokines was influenced toward the regulatory cytokine IL-10.

Conclusion: Epratuzumab, through the targeting of CD22, inhibited the production of the pro-inflammatory cytokines IL-6 and TNF-α by B cells after stimulation through BCR and TLRs pathways, but had no effect on IL-10. This suggests that this antibody has the capacity to regulate the balance between the regulatory cytokine IL-10 and pro-inflammatory cytokines, and suggests a potential mechanism of action of epratuzumab on the effector function of B cells.

1945

Pharmacodynamic Effects of the CD22-Targeted Monoclonal Antibody Epratuzumab on B Cells in Patients with Systemic Lupus Erythematosus. Anthony Shock[1], Brian Kilgallen[2], Willem Koetse[2], Christian Stach[3], Sabine Bongardt[3] and Catrinel Galateanu[4]. [1]UCB Pharma, Slough, United Kingdom, [2]UCB Pharma, Raleigh, NC, [3]UCB Pharma, Monheim, Germany, [4]UCB Pharma, Brussels, Belgium.

Background/Purpose: Epratuzumab is a humanized monoclonal antibody (mAb) that targets the B cell-specific protein CD22 and is currently in Phase 3 clinical trials in patients (pts) with systemic lupus erythematosus (SLE). The mechanism of action of epratuzumab appears to involve immunomodulation of B cells, for example by inducing loss of B Cell Receptor (BCR)-related proteins from the cell surface, and inhibiting signaling through the BCR. The present analysis aimed to understand the effect of epratuzumab on B cells in SLE pts enrolled in the Phase 2b EMBLEM™ study (NCT00624351), and its open label extension (OLE), SL0008 (NCT00660881), in which epratuzumab produced clinically relevant, sustained improvements in disease activity in pts with moderate-to-severe SLE.[1–3]

Methods: In EMBLEM™, pts were treated with placebo or 1 of 5 cumulative doses (cd) of epratuzumab (200mg–3600mg cd over the 12-week [wk] study). In the OLE, all pts received 2400mg cd epratuzumab (1200mg at Wks 0 and 2 of repeating 12-wk cycles). Blood samples withdrawn at various time points were analyzed by flow cytometry using a panel of antibodies against cell surface markers (CD19, CD22, CD27, IgD, CD95) in order to identify B cell subsets; CD22 expression was monitored using S-HCL-1, a non-competing anti-CD22 mAb.

Results: In EMBLEM™ there was a small (10–15%) median decrease in the numbers of CD22+ naïve B cells and a quantitatively similar increase in CD22+ memory B cells in pts treated with epratuzumab but not placebo, which did not appear to be dose-dependent. During OLE, total B cell numbers continued to decline, reaching a median decrease of 50–60% after 9–12 months epratuzumab treatment before stabilizing with no further decrease. There was a rapid decrease (~80%) of CD22 expression on naïve, memory and transitional B cell subsets demonstrated at the first time point assessed (1 week) in the epratuzumab treatment groups (no changes were observed in the placebo group), which was maintained throughout the OLE. *In vitro* data demonstrated that this loss occurred primarily through epratuzumab-induced internalization of cell surface CD22. Moreover, the *in vitro* data demonstrated a bell-shaped concentration response, suggestive of bivalency. Finally, there was a gradual decline in the numbers of CD27-/IgD- B cells expressing CD95 throughout the OLE, from 41% at EMBLEM™ baseline to 27% at OLE Year 2.

Conclusion: Epratuzumab treatment of pts with SLE induced a protracted but defined reduction in the number of peripheral blood B cells over time, reaching a median reduction of 50–60% after 9–12 months treatment. CD22 expression was rapidly lost on all B cell subsets, and the loss maintained throughout the OLE. There was a gradual decline with epratuzumab treatment in the number of CD27-/IgD- B cells expressing CD95, a subset of activated memory B cells previously shown to be elevated in SLE and increased during lupus flare.[4]

CD22 Is Required for Formation of Memory B Cell Precursors within Germinal Centers. Craig Chappell, Kevin Draves and Edward Clark. University of Washington, Seattle, WA.

Background/Purpose: CD22 is a sialic-acid binding co-receptor expressed primarily on B cells that has a number of functions including adhesion, regulation of B cell homeostasis and survival, and regulation of signaling through the B cell receptor (BCR) via ITIM and ITAM signaling motifs. Mice deficient in CD22 display hyper-responsive BCR signaling, decreased numbers of marginal zone B cells and dysregulated antibody (Ab) responses to T-independent antigens. CD22 deficiency or dysregulation also has been associated with the development of autoAbs and lupus-like disease. While primary T-dependent Ab responses are normal in CD22-deficient mice, the role of CD22 in the formation of B cell memory has not been thoroughly investigated. This study was undertaken to determine the impact of CD22 deficiency on the formation of germinal centers (GC), memory B cells and secondary recall responses.

Methods: B1–8^{hi} mice that harbor B cells specific for the hapten (4-hydroxy-3-nitrophenyl)acetyl (NP) were backcrossed to CD22-deficient mice to generate Ag-specific B cells lacking CD22 for adoptive transfer studies. Wild-type (WT) and CD22-deficient Ag-specific B cells were transferred to naïve hosts which were immunized with NP-CGG in alum. Following immunization B cell expansion, GC differentiation, Ag presentation and memory B cell formation were monitored among Ag-binding B cells by flow cytometry. Anti-NP serum Ab responses were monitored by ELISA. MHCII-mediated Ag presentation by GC B cell subsets was assessed by flow cytometry. WT and CD22-deficient mice were also assessed for many of the above parameters.

Results: CD22-deficient B cells mounted anti-NP Ab responses comparable to WT B cells during the early phase of the immune response (day 35). Detailed analysis of GC B cell subsets revealed that CD22-deficient B cells failed to form a small subset of GC B cells delineated by high CXCR4 and CD38 expression. Finally, CD22-deficient GC B cells presented similar amounts of Ag on MHCII as WT GC B cells.

Conclusion: These results demonstrate that CD22 plays a critical role in the formation of memory B cells under the conditions tested, and confirm earlier reports that CD22 is not required for early T-dependent Ab responses. CXCR4^{hi}CD38^{hi} GC B cells did not develop in absence of CD22, which correlated with loss of memory B cell formation and failure to mount secondary Ab responses. These results uncover a novel role for CD22 during T-dependent Ab responses and implicate BCR signaling regulation as a critical factor for proper formation of memory B cell precursors in the GC. They also suggest CD22-based immunotherapies could be useful for inhibiting formation of autoAg-specific memory B cells (supported by NIH grants AI44257 and AI52203).

Prolactin Promotes Survival of Immature B Cells from MRL/Lpr Mice. Karina Chavez-Rueda[1], Rocio Flores-Fernández[1], Francisco Blanco-Favela[1], María Legorreta-Haquet[1], Luis Chávez-Sánchez[1], Rafael Hernández-González[2] and Emiliano Tesoro-Cruz[2]. [1]IMSS, Mexico DF, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición, Mexico DF, Mexico.

Background/Purpose: Prolactin (PRL) plays an important role in modulating the immune response. PRL is secreted by the pituitary gland as well as many other organs and cells, such as lymphocytes. In B cells, PRL enhances antibody production, including those with self-specificity; as such, PRL has been associated with B cell-triggered autoimmune diseases such as *systemic lupus* erythematosus (SLE). In this study, our aims were to determine the expression of PRL-receptor during bone marrow B cell development and whether the presence of high PRL serum concentration influences absolute numbers of developing populations and disease outcome in lupus-prone murine models.

Methods: All of the mice experiments were performed in accordance with approved guidelines established by Mexico (Norma Oficial Mexicana NOM-062-ZOO-1999). The NIH Guide for the Care and Use of Laboratory AnimalsC57BL/6 mice were purchased from Harlan, the MRL/MpJ (MRL) and MRL/MpJFAS^{lpr}(MRL/lpr) mice were purchased from the Jackson Laboratory. The pro-B, pre-B and immature B cells from the bone marrow of mice were purified by flow cytometry and were assayed for the expression of PRL receptor mRNA and protein. The nine weeks old mice were treated with metoclopramide for six weeks to induce high levels of PRL, accelerate SLE symptoms, and the absolute cell numbers of bone marrow B cell subsets were analysed.

Results: Using real time-PCR and flow cytometry, we observed that the PRL-receptor is expressed in bone marrow early B cells (pro-B, pre-B, immature); in lupus prone mice the highest level of expression was found in pro-Bs and immature cells. Immature cells from lupus-prone strains showed a decrease in the absolute numbers of cells with high PRL-receptor expression in response to PRL. Since immature B cells are permanently being subjected to anti-self-elimination mechanisms, we assessed the survival in immature B cell line and immature B cells from mice. Immature B cells incubated with an anti-IgM antibody have increased survival rates in hyperprolactinemic conditions, in the same way in immature B cells lines the mRNA expression of Bcl-xL was increased.

Conclusion: Taken together, these data indicate an important effect of PRL on B cell development, both favouring positive selection and counteracting mechanisms against self-specificity. In this scenario, increased PRL levels would result in the maturation of B cell clones with self-reactivity and an increased risk for developing auto-immune diseases.

1948

A Dual Role for IFN-γ in Development of Peripheral B Cells in Lupus-Prone MRL/*Lpr* Mice. Takeshi Machida[1], Natsumi Sakamoto[1], Gary S. Gilkeson[2] and Hideharu Sekine[1]. [1]Fukushima Medical University School of Medicine, Fukushima, Japan, [2]Medical University of South Carolina, Charleston, SC.

Background/Purpose: It had been reported previously that IFN-gamma and IFN-gamma-receptor-1 (IFNGR1) were required for auto-Ab production and development of renal disease in lupus-prone MRL/*lpr* mice. At ACR 2011, we reported that MRL/*lpr* mice deficient for the transcription factor IFN regulatory factor-4 (IRF-4), that is required for Th2/Th17 differentiation, developed granulomas in multiple organs with significantly increased numbers of IFN-gamma-producing CD4$^+$ T cells (Th1 cells) and high serum IFN-gamma levels after 12 weeks of age (Fig. 1A). Strikingly, unlike their WT littermates, they also exhibited total loss of splenic CD19$^+$IgM$^+$ B cells by 12 weeks of age. Similar B cell loss was observed in *Irf4*$^{-/-}$ MRL+/+ mice but not in *Irf4*$^{-/-}$ C57BL/6 mice, suggesting a role for IFN-gamma in survival of peripheral B cells in mice with an MRL background. This study aimed to further define roles for IFN-gamma in survival of peripheral B cells and in development of autoreactive B cells in MRL/*lpr* mice.

Methods: *Irf4/Ifng* or *Irf4/Ifngr1* double-gene knockout MRL/*lpr* mice were generated by backcrossing with C57BL/6 mice lacking corresponding genes for 8 generations. Expression levels of CD19, IgM, CD21, CD23, and IFNGR1 on splenic B cells were analyzed by flow. Splenic follicular (FO)- and marginal zone (MZ)-B cells were isolated by cell sorting and frequency of anti-dsDNA Ab-secreting cells was quantified by ELISPOT assay.

Results: The splenic B cell loss observed in *Irf4*$^{-/-}$ MRL/*lpr* mice was restored in *Irf4*$^{-/-}$*Ifng*$^{-/-}$ and *Irf4*$^{-/-}$*Ifngr1*$^{-/-}$ MRL/*lpr* mice even after 12 weeks of age (Fig. 1B).

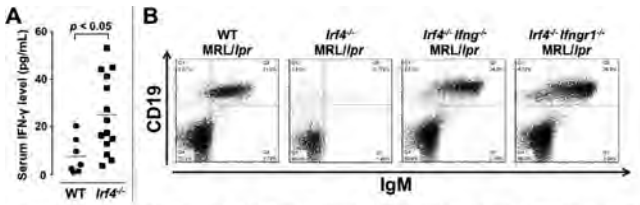

Fig. 1. Serum IFN-γ levels (A) and splenic CD19$^+$IgM$^+$ B-cell populations (B) of 12 weeks old MRL/*lpr* mice.

CD21^{hi}CD23^{lo} MZ-B cells of WT MRL/*lpr* and MRL+/+ mice showed high IFNGR1 expression levels compared to their CD21^{lo}CD23^{hi} FO-B cells. In contrast, MZ- and FO-B cells of C57BL/6 mice showed minimal IFNGR1 expression (Fig. 2A). MZ-B cells of MRL/*lpr* mice showed significantly increased frequency of anti-dsDNA IgM-secreting cells compared to their FO-B cells or MZ/FO-B cells of C57BL/6 mice (Fig. 2B).

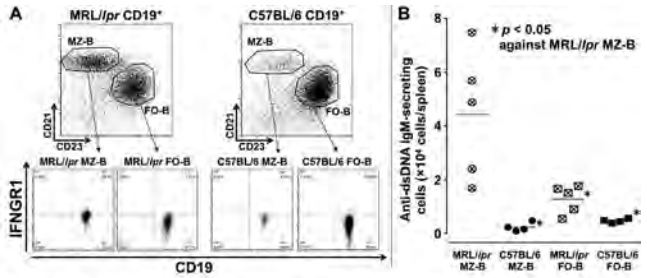

Fig. 2. A, Expression levels of IFNGR1 on splenic MZ- and FO-B cells. B, The numbers of anti-dsDNA IgM-secreting splenic MZ- and FO-B cells estimated by ELISPOT.

Conclusion: Our results suggest a dual role for IFN-gamma in peripheral B-cell development in murine lupus: expression of IFNGR1 on splenic B cells, especially on MZ-B cells, is required for development of autoreactive B cells whereas high levels of serum IFN-gamma impact on their survival.

Defective PTEN Regulation and Function Contributes to B Cell Hyper-Responsiveness in Systemic Lupus Erythematosus. Xiangni Wu[1], Yanxia Ye[1], Jingwen Niu[1], Yang Li[1], Xin Li[1], Xin You[1], Hua Chen[1], Lidan Zhao[1], Xiaofeng Zeng[1], Fengchun Zhang[1], Fulin Tang[1], Wei He[1], Xuetao Cao[2], Xuan Zhang[1] and Peter E. Lipsky[3]. [1]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [2]School of Basic Medicine, Peking Union Medical College, and Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, Beijing, China, [3]NIH, Charlottesville, VA.

Background/Purpose: PTEN regulates normal signaling through the B cell receptor (BCR). In systemic lupus erythematosus(SLE), enhanced BCR signaling contributes to increased B cell activity. We, therefore, examined whether abnormalities in PTEN might contribute to increased B cell activity in SLE.

Methods: We mainly used B cells from peripheral blood of newly diagnosed untreated SLE patients (vs. HC) to determine whether PTEN plays a critical role in the immunodysregulation in patients with SLE. The expression of PTEN protein, and the phosphorylation of Akt and/or STAT3 were examined by flow cytometry and/or western blotting. Expression of candidate microRNAs that could regulate PTEN was identified by TargetScan prediction, and confirmed using a dual luciferase reporter gene assay with a reporter construct containing the *PTEN* 3' UTR. To determine whether the abnormal expression of PTEN and its regulation by these microRNA contribute to B cells function in SLE, we electroporated peripheral B cells with pre-microRNA or an microRNA antagomir in the presence or absence of siPTEN. The levels of PTEN mRNA and microRNAs were assessed by real-time PCR, and the intracellular calcium levels were assessed by Fluo4-AM and then measured by flow cytometry.

Results: By FACS analysis, we found all SLE B cell sub-sets, except for memory B cells, showed decreased expression of PTEN, and the level was inversely correlated with disease activity. Notably, IL-21 induced PTEN expression and also suppressed Akt phosphorylation induced by anti-IgM and CD40L stimulation in normal but not SLE B cells. However, IL-21-induced STAT3 phosphorylation was intact and IL-21 up-regulated PTEN mRNA in SLE B cells. Therefore, expression of candidate microRNAs that could regulate PTEN was examined and SLE B cells were found to express increased levels of miR-7, 21 and 22. These microRNAs down-regulated expression of PTEN, and IL-21 stimulation increased expression of miR-7 and 22 in both normal and SLE B cells. Decreased expression of PTEN in SLE B cells was associated with augmented calcium signaling induced by BCR engagement as well as increased IL-21-mediated B cell proliferation and plasma cells differentiation, and these abnormalities were corrected by a miR-7 antagomir. Moreover, knockdown of PTEN with siRNA significantly increased the baseline calcium signal, and this increase was not altered by either an miR-7 agomir or antagomir. In addition, IL-21-mediated inhibition of the BCR-induced calcium signal as well as Akt phosphorylation was altered when PTEN was knocked down in a very similar manner to that caused by miR-7.

Conclusion: Defective miR-7 regulation of PTEN contributes to B cell hyperresponsiveness in SLE and could be a new target of therapeutic intervention.

1950

Circulating $CD19^+CD38^+CD43^+$ B Cell Subset in SLE Patients Have More Cell Cycle Related Genes Than Healthy Controls. Hiroshi Fujii, Tomoaki Machiyama, Kanae Akita, Yukiko Kamogawa, Ryu Watanabe, Yoko Fujita, Yuko Shirota, Shinichiro Saito, Tomonori Ishii and Hideo Harigae. Tohoku University, Sendai, Japan.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic inflammatory disease associated with deposition of autoantibodies such as anti DNA antibody. After activation of B cells in lymphoid tissues, B cells circulate in the blood as "plasmablast", migrate to bone marrow and reside as plasma cells which produce antibodies. Specific targeting of circulating plasmablast might be a novel strategy for SLE treatment. Recently, $CD19^+CD38^+CD43^+$ B cell subset from healthy control (HC) are reported to be "pre-plasmablast" phenotype based on gene expression profiling. The clarification of biological properties of $CD19^+CD38^+CD43^+$ B cell subset in SLE patients might provide us a clue to specific targeting to this population. In this study, we analyzed the gene profiling of the circulating $CD19^+CD38^+CD43^+$ B cells in HC and SLE using Agilent based microarray technologies.

Methods: Naïve B cell ($CD19^+CD27^-CD38^-CD43^-$), memory B cell($CD19^+CD27^+CD38^-CD43^-$) and $CD19^+CD38^+CD43^+$ B cell were sorted with FACS AriaII from HC and SLE (n=4, respectively). Total RNA were isolated and labelled, then mRNA was analyzed with Aglinet microarray. Gene profiling data was analyzed with GeneSpring and Ingenuity Pathway Analysis software. Statistic analysis was performed by Fisher's exact test in upregulator, canonical pathway and gene function analysis, and by modified t-test in comparative analysis between HC and SLE or each B cell subset.

Results: Comparison of gene profiling of $CD19^+CD38^+CD43^+$ B cell and naïve/memory B cell showed that genes differentially expressed in $CD19^+CD38^+$ $CD43^+$ B cell were significantly regulated by several transcriptional factors which play roles in cell cycle and proliferation, such as E2F1, MYC E2F3 ($p=4.47 \times 10^{-19}$, 1.69×10^{-16}, 3.73×10^{-9}, respectively) in addition to XBP-1, PRDM and PAX5 which are well known to function in differentiation from B cell to plasma cells. In comparison of each B cell subset between HC and SLE patients, 2467 genes were significantly changed in $CD19^+CD38^+CD43^+$ B cell. Among them, 1967 genes were changed only in $CD19^+CD38^+CD43^+$ B cell and 123 genes were changed commonly in $CD19^+CD38^+CD43^+$ B cell, naïve and memory B cell. Canonical pathway analysis showed that interferon signaling was significantly up-regulated in the commonly changed genes ($p=1.35 \times 10^{-6}$), in contrast, cell cycle related pathways, such as Role of BRCA1 in DNA Damage Response, Mismatch Repair in Eukaryotes and Cell Cycle Control of Chromosomal Replication were significantly increased ($p=7.41 \times 10^{-7}$, 3.09×10^{-6}, 2.82×10^{-5}, respectively) in only $CD19^+$ $CD38^+$ $CD43^+$ B cell increased genes. 266 genes were cell cycle related genes among 1516 genes up-regulated in $CD19^+$ $CD38^+$ $CD43^+$ B cell.

Conclusion: Gene profiling analysis suggested that $CD19^+CD38^+$ $CD43^+$ B cell have more proliferating properties than naïve, memory B cell subsets and this population of SLE patients express more cell cycle related genes than HC.

1951

A Novel $CD27^{(-)}$ Spleen Tyrosine Kinase (Syk) Bright Memory B-Cell Subset Is Expanded in SLE. Sarah Fleischer[1], Claudia Giesecke[1], Henrik Mei[1], Peter E. Lipsky[2], Capucine Daridon[3] and Thomas Dörner[3]. [1]Charité University Medicine Berlin, CC12, Dept. Medicine/Rheumatology and Clinical Immunology and German Rheumatism Research Center Berlin (DRFZ), Berlin, Germany, Berlin, Germany, [2]Peking Union Medical College Hospital, Beijing, China, [3]Charité University Medicine Berlin, Berlin, Germany.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease known to be associated with a breakdown of self-tolerance, B-cell hyperactivity and disturbed B-cell homeostasis of peripheral B-cell subsets. To analyze in more detail the extent to which the B- cell antigen receptor (BCR) proximal spleen tyrosine kinase (Syk) contributes to B-cell abnormalities in SLE, comprehensive functional and phenotypic analyses on SLE B-cells were performed.

Methods: B-cells from healthy donors (HD) and SLE patients were analyzed by flow cytometry to assess basal expression of Syk and phosphorylated (p-)Syk. B-cell subsets expressing distinct levels of Syk were identified and characterized phenotypically by flow cytometry, microscopy and molecularly to assess IgVH rearrangements. Their functions were analyzed by *in vitro*differentiation assays into plasma-cells and Syk induction by cytokines.

Results: A significantly increased frequency of $CD27^{(-)}$ B-cells with enhanced expression of Syk (Syk^{++}) was found specifically in SLE patients. $CD27^{(-)}Syk^{++}$ B-cells showed a substantially increased Syk and basal p-Syk expression as well as an increased cytoplasmic Syk accumulation and increased Syk phosphorylation upon BCR engagement compared to $CD27^{(-)}Syk^{+}$ B-cells. Furthermore, $CD27^{(-)}Syk^{++}$ B-cells were characterized as $CD38^{(-)}$ as well as $CD19^{++}$, $CD20^{++}$ and mainly $CD21^{(-)}$ with reduced ABC-B1 transporter activity and exhibited somatically mutated IgVH rearrangements. $CD27^{(-)}Syk^{++}$ B-cells showed an enhanced differentiation into IgG secreting plasma-cells in contrast to $CD27^{(-)}Syk^{+}$ cells. Finally, Syk^{++} B-cells were inducible *in vitro* by stimulation with IFN-γ, LPS or TNF-α.

Conclusion: SLE patients exhibit an increased frequency of a novel $CD27^{(-)}Syk^{++}$ subset of B-cells with memory B-cell characteristics which candidate as a source of increased plasma-cells characteristic of SLE patients. Moreover, the evidence indicates that the use of intracellular markers, such as Syk, permitted a distinction between naïve and memory B-cell subsets within the $CD27^{(-)}$ B-cells and and a more precise delineation of the $CD27^{(-)}$ memory B-cell subset.

1952

Elucidation of Molecular Mechanisms of Breg Induction in Autoimmune Diseases. Shun-ichiro Ota, Hiroaki Niiro, Naoko Ueki, Yuri Hirosaki, Hirofumi Tsuzuki, Kumiko Noda, Siamak Jabbarzadeh-Tabrizi, Atsushi Tanaka, Hiroki Mitoma, Mitsuteru Akahoshi, Yojiro Arinobu, Hiroshi Tsukamoto and Koichi Akashi. Department of Medicine and Biosystemic Science, Kyushu University Graduate School of Medical Sciences, Fukuoka, Japan.

Background/Purpose: The advent of B-cell depletion therapy in autoimmune diseases identifies a novel B cell population, referred to as regulatory B cells (Bregs), that exerts regulatory functions via IL-10 production. We previously showed that human Bregs are strongly induced in IgM-memory B cell subsets following TLR9 stimulation and Breg induction is significantly impaired in systemic lupus erythematosus (SLE). The underlying mechanisms of these findings, however, remain largely elusive. In the present study we have sought to elucidate how Bregs are induced and their function is crippled in SLE patients.

Methods: Gene expression and protein production in B cells were assessed by quantitative PCR, ELISA and flow cytometry analysis. Bregs were co-cultured with T cells, and proliferation and IFNγ production of T cells were assessed. The knock-down vector of Blimp-1 was generated and transfected into B cells.

Results: We first tested the function of Bregs in healthy controls and SLE patients. TLR9-induced Bregs from healthy controls inhibited proliferation and IFN γ production of T cells, while such Bregs from SLE patients exerted less regulatory effects on the function of T cells. A previous study in the mouse system suggested that Breg induction is associated with plasma cell differentiation of B cells. In light of a critical role of Blimp-1 in plasma cell differentiation, we generated Blimp-1 knocked down B cells and found that Breg induction is impaired by Blimp-1 silencing. Intriguingly, fleshly-isolated B cells from SLE patients exhibited higher basal levels of Blimp-1 and IL-10 expression, while further induction of Blimp-1 by TLR9 stimulation was significantly abrogated along with less IL-10 production, highlighting the induction of Blimp-1, but not its levels, in Breg induction.

Conclusion: Together, these findings provide not only a better understanding of molecular mechanisms of Breg induction in humans, but also a novel clue to revitalizing Bregs for the treatment of SLE.

1953

Circulating Plasmablasts from Patients with Systemic Lupus Erythematosus Produce Autoantibodies Reactive to Epstein-Barr Virus. Yangsheng Yu[1], Song Li[1], Run Fan[2], Yinshi Yue[1], Hongyan Liao[1], Zhixin Wang[1], Lin Huang[1], Qin Wang[3], Michelene Hearth-Holmes[1], Amy Cannella[1], W. Winn Chatham[2], Robert Kimberly[2], James O'Dell[1], Lynell Klassen[1], Robert Carter[2], Zhixin Zhang[1] and Kaihong Su[1]. [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Shanghai Jiao Tong University, Shanghai, China.

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by the over-production of high affinity autoantibodies. It is not clear how such autoantibodies are generated during the course of lupus. The purpose of this study was to analyze the antibody repertoire in circulating plasmablasts in adult SLE patients and explore the molecular basis for the generation of such antibodies in SLE.

Methods: Eight patients with active SLE and seven healthy controls were recruited for the study. Recombinant antibodies were cloned from circulating plasmablasts by single cell RT-PCR analyses. Auto and poly-reactivities of these antibodies were measured by indirect immunofluorescent anti-nuclear antibody assays (IFA-ANA) and ELISAs using a panel of antigens (dsDNA, ssDNA, insulin, and LPS) respectively. Anti-Epstein-Barr Virus (EBV) reactivity of antibodies was examined by ELISAs using EBV viral capsid antigen (VCA) as capturing antigens.

Results: In patients with active SLE, the relative frequencies of circulating plasmablasts were significantly increased compared to those of healthy controls (10.6% vs 1.0%, $p=0.0013$, n=8). Circulating plasmablasts from SLE patients, but not healthy controls, predominantly produced auto/polyreactive antibodies (autoreactive: 24.8% vs 4%, $p<0.0001$, n=8; polyreactive: 58.5% vs 11.3%, $p<0.0001$, n=8). Sequence analyses revealed excessive receptor editing and enrichment of V_H replacement products in immunoglobulin (Ig) genes derived from SLE patients (20.6% vs 7.9%, $p=0.0012$, n=8). Interestingly, 76.7% of the V_H replacement products derived from plasmablasts of SLE patients encoded auto/polyreactive antibodies. Furthermore, about 20% of circulating plasmablast-derived antibodies from SLE patients reacted with EBV VCA antigens. These SLE-derived anti-EBV antibodies cross-reacted with dsDNA and other nuclear antigens. V_H replacement products were also significantly enriched in Ig heavy chain genes encoding anti-EBV antibodies.

Conclusion: The elevated frequencies of auto/polyreactive antibodies, enrichment of V_H replacement products, and production of anti-EBV-VCA antibodies in plasmablasts from SLE patients indicate that autoreactive B cells in active SLE patients are positively selected by EBV antigens. This finding supports the hypothesis that preventing EBV infection is a beneficial intervention to limit active disease in SLE patients.

1954

Successfull Long-Term Depletion of Memory Plasma Cells Requires a Combined Depletion of Plasma Cells and Their Precurors in NZB/W Mice. Adriano Taddeo[1], Laleh Khodadadi[1], Qingyu Cheng[2], Andreas H. Radbruch[1], Falk Hiepe[3] and Bimba F. Hoyer[2]. [1]Deutsches Rheumaforschungszentrum, Berlin, Germany, [2]Charité University Medicine, Department of Medicine/Rheumatology and Clinical Immunology and German Rheumatism Research Centre Berlin (DRFZ), Germany, Berlin, Germany, [3]Charité – University Hospital, Berlin, Germany.

Background/Purpose: Autoantibodies contribute significantly to the pathogenesis of systemic lupus erythematosus (SLE). **T**he long-lived plasma cells (LLPC) secreting such autoantibodies are unfortunately refractory to conventional immunosuppressive treatments. Although generated long before the disease becomes clinically apparent, the kinetic of their generation in established disease is unclear. Here, we analyze the generation of autoreactive LLPCs in lupus-prone NZB/W F1 mice over their lifetime, and LLPC regeneration after depletion.

Methods: BrdU-pulse chase experiments over two weeks in mice of different age were used to analyze the generation of LLPC. Treatments were performed using Bortezomib, cyclophosphamide and a combination of both for very short (36h), short (5 days) and "longterm" treatment (15 and 30 days). Plasma cell numbers were quantified using flowcytometry. Autoreactive plasma cells were analyzed using ELIspot.

Results: Autoreactive LLPCs are established in the spleen and bone marrow of lupus-prone mice very early in ontogeny, before week 8 and before the onset of symptoms. The generation of LLPCs then continues throughout life. LLPC counts in the spleen plateaued by week 10, but continued to increase in the bone marrow. After depletion of LLPCs by the proteasome inhibitor bortezomib, their numbers regenerate within two weeks. A persistent, therapeutic depletion of LLPCs was achieved only by combining a short treatment with bortezomib with a longterm depletion of plasma cell precursors.

Conclusion: In lupus-prone NZB/W F1 mice, autoreactive LLPCs are generated throughout life. Their sustained therapeutic elimination requires both, depletion of LLPCs and the inhibition of their regeneration by specific depletion of their precursors.

1955

Disparity in Internalisation of Monoclonal Antibodies Targeting B Cell Antigens and Regulation By Fc Gamma Receptor IIb: Implications for Targeted Therapy in SLE. Venkat Reddy[1], Geraldine Cambridge[2], David A. Isenberg[2], Mark Cragg[3] and Maria J. Leandro[2]. [1]Centre for Rheumatology Research, Division of Medicine, University College London, London, United Kingdom, [2]Centre for Rheumatology, Department of Medicine, University College London, London, United Kingdom, [3]Southampton University, Southampton, United Kingdom.

Background/Purpose: Monoclonal antibodies (mAbs) targeting B cell antigens CD20 and CD22 are used to treat patients with SLE either in the clinic or in clinical trials whilst anti-CD19mAbs have been studied *in vitro*. The main mechanisms of action of these mAbs are depletion and immunomodulation. Internalisation of antigens bound to mAbs is key to immunomodulatory action whereas retention of mAbs on cell surface evokes immune effector mechanisms triggering depletion.

Methods: We studied internalisation of anti-CD19 mAb (RFB9), type1 anti-CD20 mAb (Rituximab), type2 anti-CD20mAb (BHH2, glycosylated GA101), anti-CD22 mAb (4KB128) and anti-CD38mAb (AT13/5h) in 11 patients with SLE. Internalisation of mAbs was assessed using the surface fluorescence-quenching assay on isolated B cells. We used AT10, a mAb against the Fcgamma receptor II (CD32), to assess whether it regulated internalisation of mAbs. Isolated B cells were incubated with mAbs +/− AT10. Paired "t' test or Mann-Whitney U test was used to compare groups, as appropriate.

Results: We performed surface fluorescence-quenching assay in 11 patients with SLE, assessed internalisation of mAbs after 6 hours of incubation with mAbs (5 mcg/mL), with or without prior incubation with AT10 (50mcg/mL) in 6/11. The median % of surface accessible mAbs was 68, 48, 71, 23 and 76 for anti-CD19, type1 anti-CD20, type2 anti-CD20, anti-CD22 and anti-CD38, respectively. However, prior incubation with AT10 significantly reduced internalisation of *only*anti-CD20 antibodies, a mean reduction of 12% and 4% for type1 and type2, respectively (Figure 1.A). A remarkable variability between patients in both the extent of internalisation and reduction in internalisation with AT10 was noted for rituximab, but not BHH2 (type2 anti-CD20mAb).

Internalisation of type1 and 2 anti-CD20mAbs in B cell subpopulations Internalisation of type1, but not type2, anti-CD20mAbs was significantly lower for post-switched cells (IgD-CD27+) when compared with other B cell subpopulations (naïve, IgD+CD27+; unswitched, IgD+CD27+; and double negative, IgD-CD27-) ($p<0.05$ for all). AT10 reduced internalisation of type1, but not type2, mAb in all B cell subpopulations (Figure 1.B). Internalisation was also 9% greater for IgD+ vs IgD- Bcells ($p<0.005$) suggesting a role for IgD in internalisation of mAbs, probably in synergy with Fcgamma receptor IIb (as B cells predominantly express the inhibitory Fcgamma receptor IIb)(Figure 1.C).

Conclusion: Disparity in internalisation of mAbs occurs, with a high rate for anti-CD22mAb, probably related to its high physiological rate of endocytosis and less so for type1 anti-CD20 mAbs. Disparity between B cell subpopulations in internalisation of type 1 anti-CD20 mAbs may occur due to differential expression of IgD and Fcgamma receptor IIb. Therefore, internalisation of mAbs poses important therapeutic implications for targeted therapy in SLE.

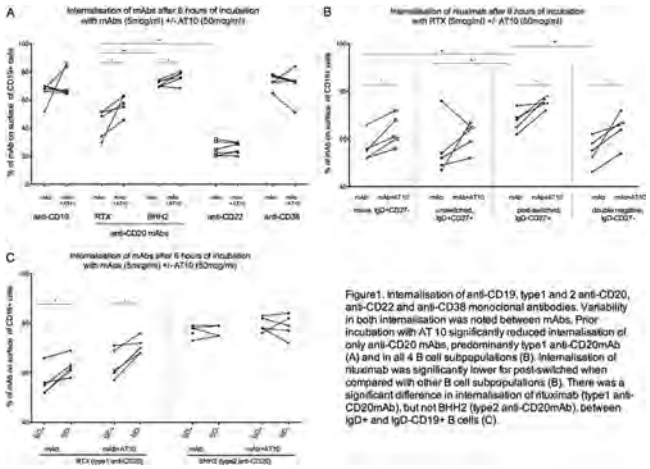

Figure1. Internalisation of anti-CD19, type1 and 2 anti-CD20, anti-CD22 and anti-CD38 monoclonal antibodies. Variability in both internalisation was noted between mAbs. Prior incubation with AT 10 significantly reduced internalisation of only anti-CD20 mAbs, predominantly type1 anti-CD20mAb (A) and in all 4 B cell subpopulations (B). Internalisation of rituximab was significantly lower for post-switched when compared with other B cell subpopulations (B). There was a significant difference in internalisation of rituximab (type1 anti-CD20mAb), but not BHH2 (type2 anti-CD20mAb), between IgD+ and IgD-CD19+ B cells (C).

Increased IL-6 Production By Effector B Cells in Giant Cell Arteritis and Polymyalgia Rheumatica. Kornelis S.M. van der Geest[1], Wayel H. Abdulahad[1], Gerda Horst[1], Abraham Rutgers[1], Annemieke M.H. Boots[2] and Elisabeth Brouwer[3]. [1]University Medical Center Groningen, Groningen, Netherlands, [2]University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [3]UMCG, Groningen, Netherlands.

Background/Purpose: The role of B cells in auto-immunity may extend beyond the production of auto-antibodies. B cells can influence T cell responses via antigen presentation and secretion of cytokines. Pathogenic T cell responses are critical in giant cell arteritis (GCA) and polymyalgia rheumatica (PMR). Cytokine-producing B cells with distinct effects on T cells have been described. $B_{regulatory}$ cells suppress T cell responses via IL-10, whereas $B_{effector}$ cells promote inflammation via secretion of TNF-α and/or IL-6. IL-6 is currently considered important in the pathogenesis of GCA and PMR. Little is known on the contribution of $B_{effector}$ and $B_{regulatory}$ cells to the immunopathology of GCA and PMR. Here, we studied the distribution of $B_{effector}$ cells and $B_{regulatory}$ cells in GCA and PMR patients before and after corticosteroid treatment.

Methods: Circulating B cells were analyzed in 34 newly-diagnosed, non-treated patients with GCA and PMR, and in 44 follow-up samples of GCA and PMR patients receiving corticosteroids for 2 weeks and 3 months. For comparison, 40 age-matched, healthy controls (HCs) were included. Serum BAFF levels were determined by ELISA and temporal arteries were studied by immunohistochemistry. Intracellular staining for TNF-α, IL-6 and IL-10 was performed after stimulating B cells with PMA and Ca2+ ionophore in the presence of Brefelin A for 4 hours.

Results: Newly-diagnosed GCA and PMR patients had decreased numbers of circulating CD19+ B cells when compared to HCs. B cell numbers recovered rapidly in treated GCA and PMR patients in remission. This recovery was not achieved by compensatory hyperproliferation or enhanced bone marrow production. The low B cell counts in newly-diagnosed GCA and PMR patients were associated with an increase in serum levels of the B cell growth factor BAFF. Serum BAFF levels diminished upon the return of B cells during remission. Functional characterization of the B cells showed that circulating numbers of IL-10 producing $B_{regulatory}$ cells remain normal in GCA and PMR patients, irrespective of disease activity and treatment. In contrast, circulating numbers of TNF-α producing $B_{effector}$ cells were profoundly decreased in newly-diagnosed GCA and PMR patients, but recovered during remission. Moreover, the returning $B_{effector}$ cells in GCA and PMR patients demonstrated an enhanced capacity to produce IL-6. Few B cells were found in temporal artery biopsies of GCA patients.

Conclusion: Our combined data indicate that $B_{effector}$ cells, but not $B_{regulatory}$ cells, are redistributed during active disease and quickly return upon remission. These $B_{effector}$ cells are characterized by an enhanced capacity to produce IL-6. The role of these IL-6 producing $B_{effector}$ cells in GCA and PMR warrants further investigation, as B cells and IL-6/IL-6R are potential targets for treatment.

Dysregulation of CC Chemokines at Microvascular Endothelial Cells of Blood and Lymphatic Vessels Under Inflammatory Conditions. Lisa Rump-Goodrich[1], Ayman Askari[2], Derek Mattey[3] and Jim Middleton[4]. [1]Keele University, Gobowen, United Kingdom, [2]Robert Jones and Agnes Orthopaedic Hospital, Gobowen, United Kingdom, [3]Keele University, Stoke-on-Trent, United Kingdom, [4]Bristol university, Bristol, United Kingdom.

Background/Purpose: Inflammation in the rheumatoid arthritis (RA) synovium is directly associated with inflammatory cell migration across microvasculature endothelial cells (ECs), and their persistence within the synovium.

It has been shown that lymphatic vessel chemokine presentation increases in RA and so should increase the removal of the interstitial fluid containing the invading inflammatory cells which are at significant levels within the fluid. However, dysregulation of chemokine presentation between RA blood vessel and lymphatic vessel ECs may lead to reductions in removal of the ever increasing joint interstitial fluid and persistance of the inflammatory cells.

Methods: Immunohistochemistry was performed on human synovial tissue to using the pan-endothelial cell marker von-Willebrand factor, and the lymphatic EC marker LYVE-1 to assess the presence of CCL7, CCL14, CCL16 and CCL22.The number of vessels positive for each marker and the chemokine were counted to a maximum if 15 vessels over three fields of view (FOV) from 8 RA and 6 on-RA samples. Transmigration of mononuclear cells isolated from RA blood was performed over confluent human dermal lymphatic EC (HDLEC) monolayers in response to human CCL7 and analysed by FACS analysis. Inflammatory conditions were stimulated by activating overnight with 100ng/mL 100ng/mL TNF-α with 100ng/mL IFN-γ.

Results: Significant increases in CCL14 and CCL22 were obsereved in RA blood vessel ECs compared to non-RA ECs (P=0.0041 and 0.014 respectively). A significant decrease in CCL7 in RA lymphatic ECs compared to non-RA lymphatic ECs was observed ($p = 0.011$). Furthermore, significant increases in RA monocyte migration were observed in response to CCL7 ($p = 0.002$). The greatest increase to be at 250ng/ml CCL7 ($p = 0.013$) with a significant increase in monocyte migration also seen at 100ng/ml CCL7 ($p = 0.037$) compared to 0ng/ml.

Conclusion: The significant decrease of CCL7 in lymphatic ECs, combined with it having the greatest chemotactic ability for monocytes for the tested chemokines suggests CCL7 may be of importance in lymphatic removal of infiltrates in the inflamed RA synovium. Reduction in CCL7 may therefore be functional in leukocyte persistence and accumulation in the RA synovium.

1958

Pyrrolopyrimidine Derivatives That Inhibit Binding of BAFF to Its Receptor, BR3, Are Drug Candidates for Primary Sjögren's Syndrome. Keiko Yoshimoto[1], Eriko Ishioka[1], Katsuya Suzuki[1], Takahiro Itou[2], Tomohiro Sugano[2], Hajime Yamada[2], Ayumu Okuda[2], Hiroyuki Ishiwata[2], Takeshi Doi[2], Takatsugu Hirokawa[3] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Kowa Co., Ltd., Higashimurayama-City, Japan, [3]National Institute of Advanced Industrial Science and Technology (AIST), Koto-ku, Japan.

Background/Purpose: We have been investigating the possible involvement of BAFF (B cell activating factor of TNF family) in the pathogenesis of primary Sjögren's syndrome (pSS). We found that soluble BAFF (sBAFF) robustly increased IL-6 production in vitro by peripheral monocytes of patients with pSS, and that the expression level of a BAFF receptor (BR3) was significantly elevated in pSS monocytes compared to that of normal monocytes. Additionally, the proportion of BR3-positive monocytes to total monocytes was positively and significantly correlated with the sBAFF-induced IL-6 production and the serum IgG level of pSS patients. These data collectively suggest that the elevated expression of BR3 on monocytes is involved in the pathogenesis of pSS. Consequently, our findings suggest that BR3 is a therapeutic target to treat pSS. However, no compounds except antibodies were reported to have inhibitory activities against BAFF signaling so far. In this study, we show some of our latest data about drug discovery for pSS aiming at BAFF signaling pathway.

Methods: High-throughput screening (HTS) of a chemical library was carried out to search for compounds that block binding of sBAFF to BR3. To this end, BR3 expressing CHO-K1 cells were established by transfection of a full-length cDNA of human BR3. Transfectants were cultured in the presence of FMAT Blue-labeled sBAFF and each compound in 384-well plates, and the binding of sBAFF to the cells was monitored by an Applied Biosystems 8200 Cellular Detection System.Hit compounds were further screened as follows: IFN-γ-stimulated THP-1, a human acute monocytic leukemia cell line, was cultured in vitro with sBAFF and each compound for 96 hr, and the cumulative amount of IL-6 produced by the cells was measured by ELISA. Cytotoxicities of the compounds were analyzed by measuring LDH in culture supernatants. The expression level of NF-κB in the cells was analyzed by quantitative PCR.

Results: A total of 18,562 compounds were examined for inhibitory activities of sBAFF binding to BR3. To eliminate false positives, inhibitory activities of the HTS-hits against IL-6 production by sBAFF-stimulated THP-1 were measured. Their cytotoxicities, which result in the reduction of IL-6 production, were also examined. As a result, two pyrrolopyrimidine derivatives, BIK12 and BIK13, showed substantial inhibition of sBAFF-binding. IC_{50} values for BIK12 and 13 were 11 and 6 μM, respectively. sBAFF-induced IL-6 production by THP-1 was significantly suppressed by these compounds in a dose dependent manner, while the compounds had no cytotoxicities. Additionally, the expression of NF-κB in the cells was also repressed by BIK12 and 13. These results collectively suggest that these compounds suppress IL-6 production by THP-1 through an inhibition of binding of sBAFF to its receptor, BR3, and possibly subsequent BAFF signaling pathway.

Conclusion: We have successfully discovered low molecular weight compounds which have inhibitory activities against BAFF signaling. Although IC_{50} values were not so low, these compounds may provide not only lead compounds for therapeutic drugs of pSS, but also novel tools to explore the pathological mechanism of pSS.

Interaction of PDE4 and β-Arrestin Reverses Anti-Inflammatory Effects of Catecholamine-Producing Cells in Chronic Arthritis Via Adrenoceptor Switching from Gαs to GαI Signalling. Zsuzsa Jenei-Lanzl[1], Janika Zwingenberg[2], Torsten Lowin[3] and Rainer Straub[2]. [1]1Laboratory of Experimental Rheumatology and Neuroendocrine Immunology, Regensburg, Germany, [2]University Hospital Regensburg, Regensburg, Germany, [3]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, University Hospital of Regensburg, Regensburg, Germany.

Background/Purpose: In recent studies, we confirmed the anti-inflammatory effects of tyrosine-hydroxylase (TH)-positive catecholamine producing synovial cells in chronic arthritis. Other studies described that inhibitors of the cAMP-degrading enzyme, phosphodiesterase 4 (PDE4), exhibit anti-inflammatory effects (see FDA-approved therapy with apremilast). Furthermore, Lefkowitz et al.[1] demonstrated that the interaction of PDE4 with β-arrestin at β-adrenoceptor can result in a catecholamine receptor switching from Gαs to Gαi signalling with subsequent ERK1/2 activation. Therefore, the aim of our study was to investigate whether and how PDE4 and catecholamine signaling interact and possibly influence inflammatory responses in chronic arthritis.

Methods: Immunostaining of PDE4 and β-arrestin and visualization of presumed PDE4/β-arrestin interaction (via proximity ligation assay) was performed in synovial tissue and in synovial cell culture of rheumatoid arthritis (RA) and osteoarthritis (OA) patients. Synovial cells were cultivated under normoxic or hypoxic conditions (the microenvironment of inflamed joints is hypoxic) with/without PDE4 inhibitor and/or different concentrations of catecholamine receptor agonists, adenosine receptor agonists, and/or blocker of Gαi-mediated pathways (pertussis toxin, ERK1/2 blocker). After 24 hours, supernatants were collected, cytokine concentrations were determined, and activation of ERK1/2 signaling was analyzed.

Results: Both, PDE4 and β-arrestin were detected in the synovial tissue and in synovial cell culture of OA and RA patients. Moreover, the interaction of PDE4/β-arrestin was demonstrated with proximity ligation assay. Under hypoxia, Gαs-coupled adrenoceptor agonists decreased TNF release in both OA and RA synovial cell culture. In contrast to normoxia, hypoxic incubation with PDE4 inhibitor alone and co-incubation with PDE4 inhibitor and catecholamine receptor agonists with Gαs-protein pathway increased TNF release, which was reversed by pertussis toxin or by ERK1/2 blocker. Western blot analyses demonstrated an increased ERK1/2 activation after treatment with Gαs-coupled adrenoceptor agonist alone or after co-incubation with PDE4 inhibitor and Gαs-coupled adrenoceptor agonist.

Conclusion: In summary, this study presents that PDE4 and b-arrestin interact at catecholamine receptors in human arthritic synovial tissue inducing catecholamine receptor switching from Gαs to Gαi signalling, which results in the reversal of catecholamine-induced anti-inflammatory effects at high neurotransmitter concentrations. This phenomenon might be responsible for possible reduced efficacy of PDE4 inhibitor treatment in some chronic arthritic diseases.

1960

NF-κB-Inducing Kinase (NIK) Is Expressed in Synovial Endothelial Cells in Early Arthritis Patients and Correlates with Local Disease Activity and Systemic Markers of Inflammation. Karen I. Maijer[1], Ae-Ri Noort[2], Maria J. H. de Hair[1], Christiaan van der Leij[2], Katinka P.M. van Zoest[2], Danielle M. Gerlag[3], Mario Maas[2], Paul-Peter Tak[1] and Sander W. Tas[2]. [1]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [3]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands.

Background/Purpose: The NF-κB family of transcription factors is strongly involved in synovial inflammation. We have previously shown that NF-κB-inducing kinase (NIK) is a key regulator of inflammation-induced angiogenesis in rheumatoid arthritis (RA) synovial tissue (ST). In this study we investigated the expression of NIK in ST of early arthritis patients and in autoantibody-positive individuals at risk for developing RA, and correlated this with both systemic markers of disease activity (ESR and CRP) and with local disease activity in DMARD-naive early arthritis patients including magnetic resonance imaging (MRI) inflammation scores of the biopsied joint.

Methods: Arthroscopic ST biopsy samples were obtained from 154 early arthritis patients (arthritis duration less than 1 year, disease-modifying antirheumatic drug (DMARD) naïve; RA (n=64), unclassified arthritis (UA; n=61), crystal arthropathy (n=11), osteoarthritis (n=4) and spondyloarthritis (n=14)) and from 54 IgM-rheumatoid factor and/or anti-citrullinated peptide antibody positive individuals at risk for developing RA, who never had any evidence of arthritis upon physical examination. ST sections were stained for the expression of NIK and evaluated by digital image analysis. In addition, measures of disease activity such as ESR, CRP and swelling of the biopsied joint (score of 0 (no swelling) – 3 (severe swelling)) were collected. In a subset of these patients contrast enhanced MRI was performed in the same joint and scored for effusion, synovitis, edema, cartilage degeneration and erosions, each in 4–6 compartments. A score of 0–3 for each compartment was given and a total MRI score was calculated (0–81).

Results: In early arthritis patients, NIK was predominantly expressed in endothelial cells (EC) of small blood vessels. No significant difference in NIK expression was observed between baseline diagnosis groups. However, NIK^+ EC were significantly increased in UA patients that remained undifferentiated after 2 years. Furthermore, we observed that NIK^+ EC may correlate better with disease activity than vWF^+ EC, since NIK expression correlated with ESR ($r=0.184$; $p=0.024$), CRP ($r=0.194$; $p=0.017$), swelling of the biopsied joint ($r=0.297$; $p<0.001$), MRI effusion ($r=0.665$; $p<0.001$), MRI synovitis ($r=0.632$; $p<0.001$) and MRI total score ($r=0.569$; $p<0.001$). NIK expression did not significantly correlate with edema, cartilage damage and erosion scores. In 18.5% of autoantibody-positive individuals NIK^+ EC were present in the synovium before the clinical onset of arthritis, but this did was not predictive for the development of arthritis.

Conclusion: We demonstrate that NIK^+ EC are already present in the earliest phase of synovial inflammation and may be indicative of high angiogenic activity in the inflamed synovial tissue. Therefore, NIK^+ EC may play an important role in the persistence of synovial inflammation. Collectively, our data underscore the importance of angiogenesis in synovial inflammation and identify NIK as a potential therapeutic target in arthritis to prevent the switch from acute to chronic inflammation.

1961

Chemokine-like Receptor 1 (CMKLR1) is Expressed on Synoviocytes and Proinflammatory Monocytes in Arthritis and is Predominantly Regulated By β arrestin 2 and G Protein Coupled Receptor Kinase (GRK) 6. D. Stephen Serafin[1], Maria F. Sassano[2], Daniel Mattox[1], Roman Timoshchenko[1], Matthew J. Billard[1], David P. Siderovski[3], Bryan Roth[2] and Teresa K. Tarrant[1]. [1]Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Dept. of Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]West Virginia University School of Medicine, Morgantown, WV.

Background/Purpose: Chemokine-like receptor 1 (CMKLR1) is a G protein-coupled receptor (GPCR) expressed by inflammatory monocytes and up-regulated in fibroblast-like synoviocytes (FLSs), both of which are pathogenic in osteoarthritis (OA) and rheumatoid arthritis (RA). Its cognate ligand, chemerin, is a chemoattractant for invading inflammatory cells and is present in the synovial lining of arthritis patients. In OA and RA, chemerin/CMKLR1 signaling contributes to disease pathogenesis via recruitment of inflammatory leukocytes and stimulates breakdown of cartilage matrix by metalloproteases.

CMKLR1, like most GPCRs, is desensitized by recruitment of G protein receptor kinases (GRKs) and β-arrestins. Due to the significant role of chemerin/CMKLR1 interaction in human inflammatory arthritis, we examined the mechanism of CMKLR1 regulation by G protein receptor kinases (GRK) 2, 3, and 6 and β-arrestin-2.

Methods: De-identified, healthy, OA, and RA human FLSs were cultured for measurement of relative gene expression by qRT-PCR of CMKLR1, GRK2, GRK3 and GRK6 as compared to housekeeping gene IDUA (ΔCt).

A modified Tango assay was used to measure β-arrestin-2 recruitment to CMKLR1. HTLA cells were over-expressed with CMKLR1 and GRK2, GRK3, or GRK6 via calcium phosphate precipitation and stimulated with increasing concentrations of chemerin. After 24 hours, luminescence was measured on a Promega Glomax Multi+ Detection System.

Peritoneal activated monocytes/macrophages from C57Bl/6 wildtype (WT) and transgenic mice deficient in GRK2, GRK3, GRK6, or β-arrestin-2 (−/−) were studied *ex vivo* for CMKLR1 receptor internalization and migration. Calcein-labeled monocyte migration to media alone, SDF-1, or chemerin was examined using the FalconTM HTS FluoroBlok 96-Multiwell Insert System (3 μm pore-size) and a Fluoroskan Ascent Microplate Fluorometer. To measure CMKLR1 internalization, receptor surface expression was measured by flow cytometry at 30 sec, 1 min, 5 min and 10 min post-stimulation with chemerin and mean fluorescence intensity (MFI) normalized relative to 0 min on F4/80 positive cells.

Results: Relative gene expression of CMKLR1 is increased in both OA and RA FLS samples compared to normal controls. In addition, RA FLS show increased GRK2, -3, and -6 relative gene expression compared to controls. β-arrestin-2 recruitment to ligand-activated CMKLR1 is preferentially mediated by GRK6 as compared to GRK2 and -3. Additionally, GRK6−/− and β-arrestin-2 −/− murine peritoneal macrophages have enhanced chemotaxis to chemerin, as well as significantly decreased receptor internalization after ligand stimulation when compared to controls.

Conclusion: Chemerin/CMKLR1 signaling has an important role in the pathogenesis of OA and RA through the activation of cells within the joint, as well as recruiting proinflammatory monocytes to sites of inflammation. Chemerin-induced migration of proinflammatory monocytes and CMKLR1 receptor internalization is predominantly regulated by GRK6 phosphorylation and β-arrestin-2 recruitment.

1962

Inflammatory Properties of Inhibitor of DNA Binding 1 As a Unique Fibroblast Derived Nuclear Protein. Gautam Edhayan[1], Christine M. Ha[1], Ray A. Ohara[1], Takeo Isozaki[1], M. Asif Amin[1], Ali Arbab[2], Pei-Suen Tsou[3], Phillip L. Campbell[1], Elena Schiopu[3], Dinesh Khanna[3], Rachel Morgan[1], Sean C. Friday[1], David A. Fox[1] and Jeffrey Ruth[1]. [1]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI, [2]Georgia Regents University, Augusta, GA, [3]University of Michigan Scleroderma Program, Ann Arbor, MI.

Background/Purpose: Inhibitor of DNA binding 1 (Id1) is a nuclear protein containing a basic helix-loop-helix (bHLH) domain that regulates cell growth by selective binding and prevention of gene transcription. Id1 has shown pleiotropic effects: important in vasculogenesis in endothelial progenitor cells (EPCs), and important in angiogenesis in mature endothelial cells (ECs). Our group was the first to report that rheumatoid arthritis (RA) synovial fluid contains elevated amounts of Id1, and histologic analysis of RA synovial tissue (ST) revealed that Id1 is highly expressed in the vasculature of RA. We later found that the primary source of Id1 in STs were activated fibroblasts. Once released, Id1 acts as a potent inducer of angiogenesis, suggesting that Id1 may contribute to vasculogenesis as well as angiogenesis by independent mechanisms. This suggests that hyperproliferating fibroblasts produce Id1 that induces blood vessel growth. What is still unknown is the method of release of Id1 by synovial fibroblasts, as well as the potential importance of Id1 in other rheumatic diseases such as scleroderma (SSc).

Methods: Synovial fibroblasts from RA, osteoarthritis (OA), normal (NL), and dermal fibroblasts from NL and SSc patients were plated and cultured without cytokines or stimulated with tumor necrosis factor-α (TNF-α), CXCL16, Interleukin-17 (IL-17), transforming growth factor-β (TGF-β), or platelet-derived growth factor (PDGF). Supernatants were measured for Id1 expression by ELISA. Fibroblast supernatants were subjected to rate zonal centrifugation to isolate and purify exosomes. Whole and lysed (0.5% Triton X-100) exosome fractions were also measured for Id1 by ELISA. For signal transduction analysis, human dermal microvascular endothelial cells (HMVECs), EPCs, and synovial fibroblasts were plated and stimulated with human Id1. Western blot analysis was used to determine the kinetics of protein phosphorylation in cell lysates. Finally, we assessed the effects of Id1 signaling on angiogenesis using silencing RNA (siRNA) to inhibit HMVEC signaling pathways in the mouse Matrigel plug assay.

Results: NL and RA synovial fibroblasts increased Id1 production with stimulation by TGF- β. Similarly, dermal fibroblast supernatants from NL and SSc patients showed a marked increase in Id1 production after stimulation with PDGF and TGF-β. We assessed the role of exosomes to determine the mechanism of Id1 transport outside the cell. We found that Id1 is encapsulated by fibroblast exosomes and that 80% of the Id1 released by RA synovial fibroblasts is contained within exosomes. Cell signaling assays following stimulation by recombinant human Id1 showed the JNK pathway was upregulated in HMVECs, EPCs, and RA synovial fibroblasts, while P38 phosphorylation was increased in only EPCs. Furthermore, we show that inhibiting HMVEC associated JNK with siRNA reverses Id1 induced HMVEC vessel formation in Matrigel plugs.

Conclusion: Id1 is a pleotropic molecule that has significant effects on angiogenesis, vasculogenesis, and fibrosis. Our data shows that Id1 is not only an important nuclear protein, but also that it can be released from fibroblasts in exosomes, thus expanding its role in the orchestration of inflammatory lesions.

1963

Hierarchical Role of PI3K/Akt/mTOR Signaling Cascade on: Tissue Inflammation, Organization and Angiogenesis in Autoimmune Arthritis. Siba Raychaudhuri[1], Anupam Mitra[2], Ananya Datta Mitra[2], Christine Abria[2] and Smriti K. Raychaudhuri[2]. [1]Univ California Davis/VA Sac, Davis, CA, [2]VA Sacramento Medical Center, Mather, CA.

Background/Purpose: The PI3K/Akt/mTOR signaling proteins are pro-growth/pro-survival and thus likely to regulate inflammatory cascades in autoimmune diseases (1). The key pathologic outcome in psoriatic arthritis (PsA) and rheumatoid arthritis (RA) is 'uncontrolled proliferation' of synovial fibroblasts (FLS), endothelial cells (EC) and T cells. To identify the regulatory role of the PI3K/Akt/mTOR kinase cascade in FLS proliferation, immune response and neoangiogenesis in PsA and RA here we investigated the functional role of this kinase cascade in the target pathologic cells (FLS, EC, T cells) of these diseases.

Methods: Using the MTT assay we compared the antimitotic effect of Perifosine (Akt inhibitor), GDC-0941 (PI3K inhibitor), Rapamycin, NVP-BEZ235 (PI3K & mTOR inhibitor) and OSI-027 (mTORC1 & mTORC2 inhibitor) on FLS, T cells and human umbilical vein endothelial cells (HUVEC). FLS were derived from synovial tissues and T cells were obtained from the PBMC of PsA (n=5) and RA (n=5) patients. FLS were treated with PDGF and the T cells were activated with anti-CD3/CD28 cocktail. RTPCR was done to determine the effects of these mTOR inhibitors on regulation of genes associated with proliferation (MKI67), inflammation (IL-8, MMP3) and T cell activation (IFNG and IL2).

Results: All the inhibitors significantly inhibited PDGF induced FLS proliferation in RA and PsA (Figure 1). The dual mTOR inhibitor OSI-027 had a maximum inhibitory effect. In HUVEC and T cells the maximal inhibitory effect was noticed with PI3K inhibitor GDC-094. RTPCR results showed marked inhibition of the proliferation marker MKI67 mRNA in all the cell lines, inhibition of MMP3 gene expression in FLS and inhibition of IFNG and IL2 genes in T cells.

Conclusion: Dual inhibitor of mTORC1/mTORC2 and proximal kinase inhibitors (Akt or PI3K) have more potent antimitotic effect on FLS, HUVECs and T cells compared to Rapamycin. These observations open up a new paradigm in respect to the regulatory role of mTOR kinase cascade in inflammatory arthritis and provide novel targets for these diseases. Inhibition of mTORC1 by rapamycin results in an unopposed activation of mTORC2 and thus induces a positive feedback to the PI3K/Akt pathway and reduces its clinical efficacy. To overcome the therapeutic failure of rapamycin (mTORC1 inhibitors) here we have explored whether an alternative effective therapeutic approach could be a dual inhibition of mTORC1 and mTORC2 or more proximal inhibition of the mTOR cascade by targeting either Akt or PI3K.

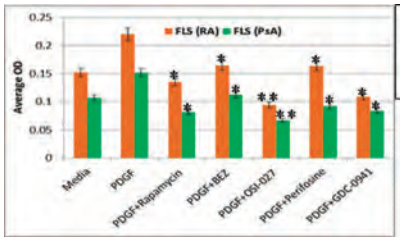

Figure 1: mTOR inhibitors significantly inhibited PDGF induced FLS proliferation in autoimmune arthritis. (*=p<0.01, **=p<0.001, ANOVA, as compared to PDGF)

Changes in Soluble CD18 Reflect Latency in the Immune System and Predict Radiographic Progression in Early Rheumatoid Arthritis. Tue Wenzel Kragstrup[1], Babak Jalilian[1], Kresten Krarup Keller[2], Kristian Stengaard-Pedersen[3], Merete Lund Hetland[4], Kim Hørslev-Petersen[5], Peter Junker[6], Mikkel Østergaard[4], Ellen Margrethe Hauge[3], Malene Hvid[1], Thomas Vorup-Jensen[1] and Bent Deleuran[2]. [1]Aarhus University, Aarhus, Denmark, [2]Aarhus University Hospital, Aarhus, Denmark, [3]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark, [4]Glostrup University Hospital, Glostrup, Denmark, [5]Research Unit at King Christian X Hospital for Rheumatic Diseases, Graasten, Denmark, [6]Odense University Hospital, Odense, Denmark.

Background/Purpose: In early rheumatoid arthritis (RA), clinical disease characterized by swollen and painful joints is caused by synovitis. However, presence of autoantibodies may precede the clinical onset of RA by several years, and joint damage can progress despite clinical remission. Therefore, early and aggressive synovitis suppression has become the principal goal in "treat-to-target" strategies. However, the temporal changes of immune system abnormalities during therapy and their significance remain poorly understood. Previously, we found a negative consequence of having low levels of the soluble form of CD18 (sCD18) in patients with chronic RA and spondyloarthritis[1,2]. Here, we study changes in plasma sCD18 levels in patients with early RA during a treat-to-target strategy (the OPERA regimen)[3], during

arthritogenesis in a murine model of chronic inflammatory polyarthritis (the SKG model) and in RA mononuclear cell cultures.

Methods: The level of sCD18 in plasma was analyzed with a time-resolved immunoflourometric assay in a study population of 152 patients with early treatment naïve RA at baseline and after 3, 6, and 12 months of treatment and during induced arthritogenesis in SKG mice. In vitro, synovial fluid mononuclear cells (SFMCs) and peripheral blood mononuclear cells (PBMCs) from 9 RA patients were cultured with either TNFα (40 ng/ml) or adalimumab (5μg/ml) for 48 hours. Data are expressed as median and IQR.

Results: Plasma levels of sCD18 were decreased in early RA patients at baseline (958.7 (766.2–1243) mU/ml) compared with healthy controls (HC) (1001 (872.0–1355) mU/ml) ($P<0.05$). The sCD18 plasma levels decreased further by 11% after 3 months ($P<0.05$), but after 12 months of treatment the levels returned to those of HC. The sCD18 increment between 3 and 12 months was most pronounced in patients who achieved an early ACR response compared with non-responders ($P<0.05$). Changes in plasma sCD18 between baseline and 12 months associated inversely with progression in total Sharpe score (rho=-0.18, $P<0.05$) and joint space narrowing (rho=-0.23, $P<0.01$) at the 24-month radiographic follow-up. Similarly, the serum level of sCD18 was decreased in SKG mice 6 weeks after arthritis induction (249 (151–282) mU/ml) compared with control SKG mice (334 (313–403) mU/ml) ($P<0.05$) and exhibited a biphasic course after arthritis induction with an initial increase above baseline ($P<0.05$) followed by a decline to levels below baseline ($P<0.05$). In vitro, shedding of CD18 from RA SFMC and RA PBMC cultures were increased 2–3 fold by TNFα (both $P<0.01$) and decreased by adalimumab ($P<0.05$ and $P<0.01$, respectively).

Conclusion: Concordant biphasic temporal patterns of sCD18 were observed in early RA and in a murine model of chronic inflammatory polyarthritis. The late increase in sCD18 was particularly pronounced in patients who achieved and early ACR response and may reflect latency in immune system restoration pertaining to the course of future radiographic progression.

1965

Characterization of the Thyroid Hormone System in Rheumatoid Arthritis.

Anna-Sophia Pörings[1], Torsten Lowin[2], Luise Rauch[1], Tanja Späth[1], Angelika Graeber[2] and Rainer Straub[3], [1]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, Regensburg, Germany, [2]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, University Hospital of Regensburg, Regensburg, Germany, [3]University Hospital Regensburg, Regensburg, Germany.

Background/Purpose: Chronic inflammation is characterized by an energy appeal reaction supporting high energy demand of the activated immune system. Thyroid hormones are strongly associated with catabolic effects and are therefore important mediators of energy allocation. Until now, the role of thyroid hormones in the locally inflamed joint is unknown. This study investigates metabolism of thyroid hormones in the joint and demonstrates expression and regulation of thyroid hormone regulating elements in rheumatoid arthritis (RA) and osteoarthritis (OA).

Methods: Typical thyroid gland –related autoantibodies were detected in order to exclude patients with autoimmune thyroid disease. TSH and thyroid hormones in serum were detected by ELISA. Thyroid hormone receptors TRα, TRβ, TA-1, deiodinases DIO1/DIO2/DIO3 and thyroid transporter MOT-8 were stained immunohistochemically in paraffin embedded synovial tissue samples. Influences of cytokines on above-mentioned thyroid hormone related proteins were detected by cell-based ELISA. Thyroid receptor-related signaling was analyzed by proteome profiling.

Results: In RA and OA, serum levels of reverse triiodothyronine (rT3), the degradation product of T3, is higher in synovial fluid than in plasma which is opposite for T3 and thyroxine (T4). Serum rT3 relative to free T3 was higher in RA than OA. rT3 levels in superfusate of synovial tissue were higher in RA compared to OA. Staining of synovial tissue revealed expression of thyroid converting enzymes DIO1–3, transporter MOT-8 and nuclear receptors TRa and TRb. The addition of TNF or IL-1β to RA or OA synovial fibroblast cultures increased protein levels of DIO1, DIO3 and TRα. Furthermore, high expression of TA-1, a receptor for the degradation product of T3, iodothyronamine, was detected. In addition, synovial fibroblast MAP kinase signaling and IL-6 production was altered by thyroid hormones.

Conclusion: Our data demonstrated that thyroid hormones are metabolized locally in the inflamed joint. This local inactivation is more pronounced in RA than OA (higher rT3 levels). Since cytokines alter the expression of DIO convertases and thyroid receptors, the thyroid hormone system might become dysregulated in the joint during chronic inflammation.

CTLA4-Ig (abatacept) Modulate *in Vitro* the ICAM1 and VEGFR-2 Expression in Human Endothelial Cells.

Maurizio Cutolo[1], Paola Montagna[2], Stefano Soldano[2], Paola Contini[3], Barbara Villaggio[4], Alberto Sulli[1], Sabrina Paolino[1], Carmen Pizzorni[1], Bruno Seriolo[1], Giuseppe Zampogna[2], Marco A. Cimmino[1] and Renata Brizzolara[2]. [1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, [2]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy, [3]Division of Clinical Immunology, Department of Internal Medicine, University of Genova, Genova, Italy, [4]Research Laboratory of Nephrology, Department of Internal Medicine, University of Genova, Genova, Italy.

Background/Purpose: CTLA4-Ig (abatacept) is employed as biological agent in rheumatoid arthtritis (RA) treatment and interacts with the costimulatory molecule CD86 expressed by different cells involved in synovitis [1,2]. The presence of CD86 has been shown on endothelial cell (EC) surface and their dysfunction is involved in the angiogenetic processes characterizing RA synovitis [3,4]. Since, ICAM1 (intercellular adhesion molecule 1) and VEGFR-2 (vascular endothelial growth factor receptor 2) are relevant molecules for the inflammatory and angiogenetic processes, their expression was evaluated *in vitro* on activated ECs at protein and gene expression level, following CTLA4-Ig treatment.

Methods: ECs (human microvascular endothelial cells, HMVECs, Lonza, Switzerland) were induced by gamma-IFN (500 U/ml for 48 hours) to activate and to express CD86. The cells were then treated for 24 hrs with CTLA4-Ig (10, 100, 500 micrograms/ml), and the protein expression levels for CD86, ICAM1 and VEGFR-2 were evaluated by flow cytometric analysis (FACS). After 3 and 24 hrs of CTLA4-Ig treatment, the protein expression levels of both ICAM1 and VEGFR-2 were also evaluated by Western blot analysis (WB) and their respective gene expression was evaluated by quantitative real time PCR (qRT-PCR). The statistical analysis was performed using the Mann-Whitney non-parametric t test.

Results: Activated ECs, after CTLA4-Ig treatment (10, 100, 500 μg/ml; 24 hrs), decreased their CD86-positivity at FACS by 66%, 59% and 51%, respectively, versus 68% of untreated cells (cnt), suggesting CTLA4-Ig/CD86 interaction and CD86 masking. All activated ECs, analysed by FACS, strongly expressed ICAM1 (99%) and VEGFR-2 (79%). Interestingly, after 24 hrs of CTLA4-Ig treatment, ECs showed a dose-dependent decrease in the mean fluorescence intensity for ICAM1, while VEGFR-2 positivity resulted unchanged. However, WB showed a significant decrease after CTLA4-Ig 500 μg/ml treatment for both ICAM1 and VEGFR-2 ($p<0.05$ at 3 and 24 hrs) while a significant decrease after CTLA4-Ig 100 μg/ml treatment was observed only for VEGFR-2 at 3 hrs ($p<0.05$). Similarly, qRT-PCR showed a significant decrease after CTLA4-Ig 500 μg/ml treatment for VEGFR-2 ($p<0.05$ at 3 and 24 hrs) and a significant decrease after CTLA4-Ig 100 μg/ml treatment for VEGFR-2 at 3 hrs ($p<0.05$). qRT-PCR at 3 hrs seemed to late to detect ICAM1 changes.

Conclusion: suggest a significant modulation by CTLA4-Ig of the gene expression and protein synthesis for ICAM1 and VEGFR-2 in cultured human ECs, which seems mainly due to the interaction between CTLA4-Ig and CD86 on activated ECs, possibly involving NFkB pathway downregulation, as previously reported [2]. Therefore, in the presence of chronic inflammatory reaction, such as in RA synovitis, ECs might be considered among other cells a further possible target for CTLA4-Ig modulation.

1967

Transforming Growth Factor Beta Is a Major Regulator of Micro-RNA Synthesis in Rheumatoid Arthritis Synovial Fibroblasts. Anna Engler[1], Emmanuel Karouzakis[1], Christoph Kolling[2], Renate E. Gay[3], Steffen Gay[1] and Caroline Ospelt[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Schulthess Clinic, Zurich, Switzerland, [3]Zurich University Hospital, Zurich, Switzerland.

Background/Purpose: Transforming growth factor beta (TGFβ) modulates microRNA (miRNA) biogenesis in a variety of cell types. The expression of miRNAs is deregulated in the synovial fibroblasts from patients with rheumatoid arthritis (RASF). However, the role of TGFβ in the regulation of miRNAs in RASF was not investigated so far. The aim of the current study was to investigate the role of TGFβ in the regulation of miRNAs and in the inflammatory and matrix-destructive properties of RASF. Moreover, the effects of TGFβ on TNFα-induced signaling were analyzed.

Methods: Synovial tissues were obtained from RA patients undergoing joint replacement surgery. RASF (n=6) were stimulated with 10 ng/ml TGFβ, 10 ng/ml TNFα or with TGFβ and TNFα together in cultivation medium supplemented with 5% FCS for 24, 48 or 72 hours. Total RNA was isolated using Qiagen miRNeasy Kit. Global expression of miRNAs was analyzed by human miRNA Array analysis (Card A, Life Technologies) and verified by measurement of single miRNAs using real-time PCR with miRNA-specific TaqMan primers. The levels of interleukins (ILs) and matrix metalloproteinases (MMPs) were detected by Real-time TaqMan and SYBR green PCR.

Results: The global miRNA expression profile was altered by stimulation of RASF with TGFβ after 48h in all patients. The expression of 29 miRNAs was downregulated by 25–70% whereas the levels of 32 miRNAs were upregulated by 50–800%. TGFβ induced changes in several miRNAs that were previously reported to be deregulated in RASF. In particular, the levels of miR-155, miR-221, miR-222 and miR-335 were downregulated, while the expression of miR-18a, miR-22, miR-145 and miR-203 was significantly increased. We then investigated whether TGFβ can modify the effects of TNFα. Stimulation with TNFα alone increased the levels of miR-155 by 8.2-fold$\pm$1.2 (p=0.01), while the co-stimulation with TNFα and TGFβ resulted only in 4.3-fold$\pm$0.5 (p=0.03) increase in miR-155 levels. Treatment with TNFα decreased the expression of miR-145 by 0.7-fold$\pm$0.1 (p=0.03). However, co-stimulation with TNFα and TGFβ reversed this effect completely and increased the levels of miR-145 by 2.0-fold$\pm$0.3 (p=0.03). In contrast, TGFβ amplified TNFα-induced reduction in the expression of miR-222 and miR-335. Stimulation with TGFβ or TNFα alone already significantly reduced the expression of these miRNAs and co-stimulation with TGFβ and TNFα together led to a further decrease in the levels of miR-222 (by 0.35-fold$\pm$0.05, p=0.03) and miR-335 (by 0.4-fold$\pm$0.08, p=0.02). Moreover, TGFβ mitigated the matrix-destructive activities of RASF that were induced by TNFα by strongly decreasing TNFα-induced MMP1 expression (by 16-fold, p=0.04). In contrast TNFα-initiated IL6 production was increased by TGFβ(by 1.7-fold, p=0.03).

Conclusion: In the current study we found that TGFβ modulates the expression of miRNAs involved in the pathogenesis of RA. Moreover, TGFβ influences the inflammatory and matrix-destructive activities of RASF by reduction of TNFα-induced MMP1 expression and by enhancement of TNFα-initiated IL6 production. Thus, TGFβ has dual effects in the regulation of RASF and exhibits pro-inflammatory as well as anti-matrix-destructive properties.

1968

Highly activated IL-23/Th17 axis and JAK2/STAT3 signal pathway in PBMC of active AS patients involve in pathogenesis of AS. Hongxiao Liu[1], Peng Chen[2], Yingyan Zhou[2], Junyao Song[2], Benyong Liu[2], Xiaoyan Feng[2] and Xinghua Feng[2]. [1]Guang□'anmen Hospital, China Academy of Chinese Medical Sciences, Bei Jing, China, [2]Guang'anmen Hospital, China Academy of Chinese Medical Sciences, Bei Jing, China.

Background/Purpose: T helper cell(Th17), the third lineage of CD4+T cells, has been determined its important role in pathogenesis of AS, and its main effector, IL-17, has a critical effect on mediating AS inflammation. Survival and function of Th17 is dependent on induction of IL-23. And JAK2/STAT3 signal pathway works on IL-23 signal transduction essentially. Here we investigate the role of JAK2/STAT3 signal pathway and IL-23/Th17 in pathogenesis of AS.

Methods: A total of 30 AS patients(average age, 27.6$\pm$ and 30 healthy controls(average age, 23.5$\pm$ without any tissue diseases participated in the experiments. All patients were diagnosed with AS by experienced rheumatologists and met with the modified New York criteria(Bath Disease Activity Score $\geq$4). The serum level of IL-17 and IL-23 in peripheral serum were detected by enzyme-linked immunosorbent assay(ELISA), the percentage of Th17 were detected by flow cytometry, the protein levels of JAK2/STAT3 signal pathway mainly involved in IL-23R, JAK2, pJAK2, STAT3, pSTAT3 and RORc(the lineage-specific transcription factor of Th17) were detected by Western blotting, and the mRNA level of RORc was detected by real-time quantitative PCR(qPCR).

Results: The serum IL-23 and IL-17 levels were significantly higher of active AS patients than that of the healthy controls(IL-23:p$\leq$¼0.001; IL-17: p$\leq$¼The frequency of Th17 in PBMCs were also elevated(p$\leq$¼as higher in PBMCs of AS patients than that of the healthy controls (p$\leq$¼s of JAK2 and STAT3 in PBMCs between AS patients and healthy controls(JAK2:p=0.538; STAT3:p=0.0.554), the phosphorylated levels of JAK2 and STAT3 were critically higher(pJAK2:p$\leq$¼; pSTAT3:p$\leq$¼Besides, the protein level and mRNA level of RORc were both significantly higher in PBMCs of AS patients than that of the healthy controls(protein level: p$\leq$¼0.001; mRNA level: p$\leq$¼0.001).

Conclusion: Our findings showed the exist of high serum IL-23 level, high activity degree of JAK2/STAT3 signal pathway and high protein and mRNA level of RORc in active AS patients. Important as IL-23 for Th17's differentiation and function, STAT3 phosphorylated by IL-23 signal can not only promote the expression of RORc, acting on differentiation of Th17, but bind to IL-17's promoter, being a direct regulator of IL-17. That's to say, high serum IL-23 level and its active JAK2/STAT3 signal pathway play a critical role in resulting in high serum IL-17 level and high frequency of Th17 existed in active AS patients. In this way, our results suggest the possible role of JAK2/STAT3 signal pathway and IL-23/Th17 axis in pathogenesis of AS.

Neurotrophin Receptor p75 (CD271) Defines a Distinct Synovial Fibroblast Subset in Rheumatoid and Osteoarthritic Synovial Tissues with Enhanced Proinflammatory Potential. Manuel J. Del Rey[1], Regina Faré[1], Gabriel Criado[1], Alicia Usategui[1], Vanessa Miranda[1], Juan D. Cañete[2] and Jose L. Pablos[1]. [1]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain, [2]Hospital Clínic of Barcelona, Barcelona, Spain.

Background/Purpose: Synovial mesenchymal or stromal cells constitute a heterogeneous cell population difficult to characterize *ex vivo* due to a paucity of cell markers and are usually named synovial fibroblasts (SF). CD271, the low affinity receptor for neurotrophin nerve growth factor (NGF),

is considered a mesenchymal stem cell marker that is expressed by a small fraction of SF *ex vivo*. We have analyzed the location and relative proportion of CD271+ cells in synovial tissues from rheumatoid arthritis (RA), osteoarthritis (OA) and normal (N) individuals as well as their *ex vivo* functional properties in CD271+/− SF sorted cultures.

Methods: CD271 expression was analyzed by immunohistochemistry (IHC) in synovial tissues, and by flow cytometry (FC) in SF cultures from RA (n=10), OA (n=10), and normal synovial tissues (n=6). Isolation of CD271+ and CD271- OA SF (n=3) was carried out by magnetic beads sorting in passage 0 from OA explants. Supernatants of sorted CD271+/− SF were analyzed for IL-6, IL-8, MCP-1, MMP-1, MMP-3 and VEGF production by multiplex ELISA array (RayBiotech, Norcross, GA, USA). IL-6 data were confirmed by single specific ELISA. Quantitative data were analyzed by Mann-Whitney or ANOVA test where appropriate.

Results: CD271+ cells were observed by IHC in all types of synovial tissues with a perivascular distribution partially resembling pericytes. The number of CD271+ cells per area was significantly increased in both RA and OA tissues compared to normal synovial tissues (772±206, 802±221 and 206±100 per mm^2 respectively, $p<0.0001$ ANOVA). The frequency of CD271+ cells in SF cultures was highly variable but a trend towards a higher proportion of CD271+ cells in OA compared to RA and normal established SF cultures was observed (5.1±4.0%, 1.4±0.9% and 1.5±0.8% respectively). In individual OA SF cultures, cell passaging from passage 0 to 5 induced a progressive decrease in the percentage of CD271+ cells. OA CD271+ SF cultures sorted at passage 0 released significantly more IL-6 (3.1-fold increase) and metalloprotease MMP-1 (8.1-fold increase) than CD271- SF. A non-significant trend towards more IL-8, MMP-3 and VEGF production in CD271+ SF was also observed. MCP-1 production was similar in both SF subsets.

Conclusion: Our results demonstrate an expansion of CD271+ perivascular cells in inflammatory RA and OA synovial tissues. Cultured CD271+ SF showed increased production of proinflammatory factors *ex vivo* compared to CD271- SF. These data suggest that CD271+ stromal cells could play a proinflammatory role in OA and RA synovium.

1970

T_H17 Inflammatory Responses Occur in a Subset of Patients with Erythema Migrans or Lyme Arthritis, but Are Not Predominant Responses in Joints. Klemen Strle, Elise E. Drouin and Allen C. Steere. Massachusetts General Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Lyme disease usually begins with an expanding skin lesion, erythema migrans (EM), whereas arthritis is a late disease manifestation. The infection usually resolves with appropriate antibiotic therapy, but post-infectious symptoms following EM or persistent synovitis despite antibiotic therapy (antibiotic-refractory arthritis) may occur. Control of the infection in humans is attributed predominantly to innate and adaptive T_H1 immune responses, whereas the role of T_H17 responses is not yet well characterized. We recently showed that high levels of IL-23, a T_H17-associated cytokine, occur in a subset of European patients with EM, and are associated with more frequent post-infectious symptoms and autoantibody responses. Here, we characterized these responses in a large cohort of American patients with EM or Lyme arthritis to elucidate the role of T_H17-mediated immunity throughout the infection.

Methods: The levels of 20 cytokines and chemokines, representative of innate and adaptive T_H1 and T_H17 immune responses, were assessed by Luminex in matched acute and convalescent serum samples from 106 culture-positive patients with EM, in matched serum and synovial fluid (SF) samples from 159 patients with antibiotic-responsive or antibiotic-refractory arthritis, and in serum samples from 57 healthy control subjects.

Results: Compared with healthy subjects, acute-phase sera from EM patients contained significantly higher levels of the T_H17-associated mediators (IL-6, IL-17A, IL-17F, IL-21, IL-22, IL-23, IL-25 and IL-27; P≤0.01). With the exception of IL-27, which down-regulates T_H17 responses, the levels of other T_H17-associated mediators remained elevated in convalescent sera obtained at the conclusion of antibiotic therapy. The levels of IL-23, the most highly induced T_H17 cytokine, correlated directly with antibody levels to the *B. burgdorferi* VlsE antigen (P=0.04) in both acute and convalescent samples, suggesting a role for T_H17-associated mediators in control of the infection. In patients with Lyme arthritis, the serum levels of IL-23 and other T_H17-associated mediators were generally lower than in patients with EM, and the levels of these mediators were only minimally concentrated, if at all, in SF. In contrast, innate (IL-8) and T_H1 mediators (CXCL9 and CXCL10) were 50-fold higher in SF than in serum. Compared with antibiotic-responsive patients, there was a trend toward higher levels of most of the T_H17-associated mediators, particularly IL-23, in SF in patients with antibiotic-refractory arthritis, and toward a greater frequency of autoantibody responses to human endothelial cell growth factor, the first known target of T and B cell responses in this disease.

Conclusion: A subset of patients with Lyme disease develops T_H17 immune responses. T_H17-associated mediators seem to be highest early in the infection and may play a role in control of the infection. In addition, T_H17 mediators may be one factor in shaping an immune response early in the illness in which autoantibody responses are more common, thereby contributing to subsequent antibiotic refractory Lyme arthritis.

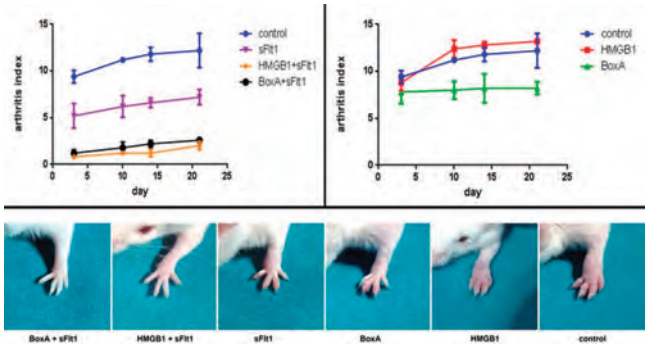
1971

The Role of the Proinflammatory Mediator High-Mobility Group Box Protein 1 (HMGB1) in Anti-Collagen-Antibody-Induced Arthritis Is Dependent on Vascular Endothelial Growth Factor (VEGF). Federico Biscetti[1], Andrea Flex[2], Giovanni Pecorini[2], Flavia Angelini[2], Vincenzo Arena[3], Egidio Stigliano[3], Barbara Tolusso[1], Elisa Gremese[1] and Gianfranco Ferraccioli[1]. [1]Division of Rheumatology, Institute of Rheumatology and Affine Sciences, Catholic University of the Sacred Heart, Rome, Italy, [2]Laboratory of Vascular Biology and Genetics, Catholic University School of Medicine, Rome, Italy, [3]Department of Pathology, Catholic University School of Medicine, Rome, Italy.

Background/Purpose: High-mobility group box 1 (HMGB1) is a non-histone nuclear protein that is released extracellulary and has been implicated in rheumatoid arthritis (RA) and angiogenesis. Although HMGB1 is abundantly expressed throughout the inflamed synovium, the mechanism by which this protein is involved in the development of RA is still not well known. The aim of this study was to better define the role of HMGB1 in the synovial angiogenesis and pathogenesis of RA.

Methods: Balb/c mice were injected with monoclonal anti-collagen antibody cocktail followed by lipopolysaccharide. Animals were evaluated every 3 days after the infusion of the antibody cocktail for arthritis incidence and each paw was evaluated and scored individually on a scale of 0–4, with 4 indicating the most severe inflammation. An arthritis index (AI) that expressed a cumulative score for all paws was calculated for each animal. To investigate the role of HMGB1 in pathological synovial angiogenesis in RA, three groups of mice were studied: mice treated with HMGB1, mice treated with HMGB1 inhibitor BoxA and untreated control mice. To further define and clarify the HMGB1 –VEGF interaction, additional groups of mice were treated with BoxA and with vascular endothelial growth factor (VEGF) inhibitor, the sFlt-1 plasmid.

Results: Immunohistochemical and ELISA analyses confirmed overexpression of HMGB1 and VEGF in the areas of the synovium where more inflammation and neoangiogenesis were present. Interestingly, the selective blockade of HMGB1 or of VEGF alternatively resulted in a lower severity of arthritis evaluated by AI ($p=0.003$ and $p=0.001$) (**Figure**).



Furthermore, exogenous HMGB1 administration caused a worsening of arthritis, associated with VEGF up-regulation and increased synovial angio-

genesis. Surprisingly, the selective inhibition of VEGF resulted in the lack of induction of arthritis also in mice receiving exogenous HMGB1 ($p<0.001$). ELISA analyses performed on peripheral blood and synovial fluid demonstrated a significant reduction of IL-1b ($p<0.001$), IL-6 ($p<0.001$) and TNF-a ($p<0.001$) in mice where HMGB1 and VEGF pathways were blocked. Interestingly, the selective blockade of HMGB1 and VEGF resulted in an increase of the peripheral IL-17A concentration ($p<0.001$).

Conclusion: The development of arthritis mediated by HMGB1 and the synovial angiogenesis can be blocked by inhibiting the VEGF activity. The pro-inflammatory and pro-angiogenic cytokine IL-17A is increased when HMGB1 is inhibited, but the synovial angiogenesis is nevertheless reduced in this model of arthritis. These data confirm that the blood vessels neoformation at the synovial level is dependent on VEGF. Taken together, these findings shed new light on the role of this nuclear protein in the pathogenesis of arthritis in an RA-like model.

Analysis of Anakinra in Primary Human Cell Systems Reveals an in Vitro Signature for Skin-Related Side Effects. Ellen L. Berg, Alison O'Mahony and Mark A Polokoff. BioSeek, South San Francisco, CA.

Background/Purpose: The therapeutic options for treatment of rheumatic diseases have grown and now include a variety of inflammatory pathway inhibitors, with diverse mechanisms, but having both shared and unique side effects. Understanding side effect mechanisms is important for guiding patient treatment choices and also for developing improved next generation therapies. We have successfully employed high throughput primary human cell-based models of tissue and disease, BioMAP Systems, to study failed and approved drugs and have previously identified in vitro activities that correlate with certain side effects. Here we compare the activity profiles of adalimumab (TNF inhibitor), MTX and anakinra (IL1RA) to test if activities can be correlated with differences in efficacy or safety.

Methods: BioMAP systems model disease biology in early-passage human primary cells and have been used extensively to characterize compounds based on phenotypic signatures. A panel of 12 BioMAP systems, including mono- and co-cultures of vascular, immune, and tissue cell types were used to generate profiles of anakinra, adalimumab, and MTX. Changes in protein-based and clinically relevant endpoints (biomarkers, including inflammatory, immune, tissue remodeling and hemostasis-related endpoints) as well as other cellular events (e.g., proliferation, cell cytotoxicity) were evaluated. For select activities, a comparison to a large reference database of approved and failed drugs, experimental chemicals, and other agents, was performed to elucidate potential mechanisms.

Results: The profiles for both anakinra and adalimumab show anti-inflammatory activities across the panel of BioMAP systems, including reduction in leukocyte recruitment molecules IL-8, E-selectin and MCP-1. Anakinra was more effective in blocking responses in a co-culture system of monocyte-driven (TLR4) vascular inflammation (LPS system) and differentially active in a model of T cell-dependent B cell activation (BT system), reducing IL-17A, IL-17F, and IL-6. In contrast, adalimumab was more effective in co-cultures driven by T cell or macrophage (TLR2) activation (SAg and/Mphg systems). The profile for MTX was distinct, reducing T cell proliferation (SAg system) and IgG production (BT system). Interestingly, in a fibroblast model of wound healing (HDF3CGF system), anakinra, but not adalimumab or methotrexate increased the levels of VCAM-1 and I-TAC (CXCL11). VCAM-1 and I-TAC (CXCL11) mediate recruitment of inflammatory lymphocytes into sites of inflammation. This combination of activities is an unusual feature, shared by MEK and p38 MAPK inhibitors, that we have previously associated with the potential for skin rash side effect.

Conclusion: Profiling of anakinra across a panel of primary human cell systems reveals an activity signature that has been correlated with skin side effects, and may be related to the cutaneous side effects observed with anakinra in patients. This signature is shared by inhibitors of MEK and p38 MAPK and suggests a common pathway mechanism. A better understanding of side effect mechanisms can help in the design and selection of novel therapies, or combinations.

Ectopic Lymphoid Neogenesis Is Strongly Associated with Activation of the IL-23/IL-17 Pathway in Rheumatoid Synovitis. Nataliya Yeremenko[1], Raquel Celis[2], Leonie M. van Duivenvoorde[1], Julio Ramirez[3], Iris C. Blijdorp[1], Sara Marsal[4], Jose L. Pablos[5], Raimon Sanmarti[3], Juan D. Cañete[3] and Dominique L. Baeten[1]. [1]Department of Clinical Immunology and Rheumatology and Department of Experimental Immunology, Academic Medical Centre/University of Amsterdam, Amsterdam, Netherlands, [2]Arthritis Unit, Rheumatology Dpt, Hospital Clinic of Barcelona and IDIBAPS, Barcelona, Spain, [3]Hospital Clínic of Barcelona, Barcelona, Spain, [4]Vall d'Hebron Hospital Research Institute, Barcelona, Spain, [5]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain.

Background/Purpose: The functional relevance of synovial ectopic lymphoid neogenesis (ELN) in rheumatoid arthritis (RA) remains unknown. As ELN correlates with the degree of tissue inflammation we investigated whether ELN was associated with specific cytokine profiles.

Patients and Methods: Paired synovial tissue (ST) (n=63) and fluid (SF) (n=44) was obtained from the inflamed knee joints of RA patients. Synovial inflammation and ELN was determined by immunohistology. CD21L was used as molecular marker of ELN. Cytokine expression was determined by ELISA and quantitative PCR in SF and ST, respectively.

Results: 48% of ST displayed ELN by histology. ELN+ samples had increased T and B lymphocyte infiltration ($p<0.001$) and CD21L expression ($p=0.014$). SF analysis showed higher expression of IL-23 ($p=0.018$) and IL-17F ($p=0.028$) in ELN+ versus ELN- samples, with a similar trend for IL-22 ($p=0.070$). Other cytokines, including IL-17A, IL-6, TNFa, Th1 cytokines and Th2 cytokines, were not different. In ST, IL-23 ($p=0.030$) mRNA levels were increased in ELN+ samples. Moreover, CD21L expression as molecular marker of ELN correlated significantly with mRNA expression of IL-23 ($r=0.70$), IL-17F ($r=0.42$), IL-21 ($r=0.30$) and IL-22 ($r=0.33$), but not IL-17A. The strong correlation between CD21L and IL-23, IL-17F, IL-21 en IL-22 was confirmed in an independent RA ST sample set (n=36). IFNγ and IL-2, but not IL-6 and TNFα, also showed some correlation with CD21L expression.

Conclusion: Synovial ELN in RA is strongly associated with increased expression of IL-23/IL-17-related cytokines. Whether patients depicting synovial ELN respond differently to therapeutic targeting of this pathway remains to be determined.

1974

Sex Steroids, Interleukin-1, and Interleukin-10 Inhibit interferon–gamma (IFN-γ) Induced B Cell Activating Factor of the Tumor Necrosis Factor Family (BAFF) in Human Synovial Fibroblasts. Georg Pongratz, Marina Bäuml, Tanja Späth, Rainer Straub and Torsten Lowin. University Hospital Regensburg, Regensburg, Germany.

Background/Purpose: B cell activating factor of the tumor necrosis factor family (BAFF) is a cytokine important for the stimulation and survival of autoreactive B cells and therefore might play a role in several autoimmune disease, e.g. autoimmune arthritis. In psoriasis arthritis, BAFF correlates with disease activity and inversely with testosterone, but only in male patients, suggesting a role for sex hormones in the regulation of BAFF. It is also known that synovial fibroblasts (SFs) are capable of producing BAFF following INF-γ stimulation and that SFs possess sex hormone receptors. Therefore, we wanted to better characterize inflammatory stimuli that modulate BAFF in SFs and then test the hypothesis that sex steroids directly regulate BAFF production in SFs.

Methods: Fibroblasts isolated from synovial tissue of RA (n=10) and OA (n=10) patients were cultured in the presence or absence of different stimuli (IFN-γ, interleukin (IL)-1, lipopolysaccharide (LPS), tumor necrosis factor (TNF), cortisol, dihydrotestosterone, and estradiol). BAFF was determined by ELISA. Levels of phosphorylated and total STAT1 and STAT3 were determined by western blotting.

Results: IFN-γ in a concentration-dependent manner best induced BAFF in RA ($p<0.001$) and OA ($p<0.001$) fibroblasts. Since inflammation usually leads to hypoxic conditions, we also compared IFN-γ-induced BAFF production in RA (n=7) and OA (n=16) SFs under normoxic and hypoxic (oxygen content 2%) culture conditions. INF-induced BAFF is increased in hypoxic conditions in RA SFs ($p=0.015$) but not OA SFs ($p=0.362$) as

compared to the normoxic situation. In hypoxic ($p=0.005$) but not normoxic conditions ($p=0.471$), RA SFs produce more BAFF when exposed to the same IFN stimulation than OA SFs. IFN leads to a strong phosphorylation of STAT1 but to a reduction in phosphorylated STAT3. However, it has been suggested that concomitant phosphorylation of STAT3 further augments BAFF production. Therefore, we wanted to test if concomitant IL-1 or IL-10, which both lead to phosphorylation of STAT3, further increase IFN-induced BAFF in SFs. However, in the presence of IL-1 or IL-10, INF-induced BAFF was inhibited in a concentration dependent manner independent of oxygen content in both, OA ($p<0.001$) and RA ($p<0.001$) fibroblasts. Furthermore, inhibition of pSTAT3 resulted in further augmentation of IFN-induced BAFF. Finally, in the presence of dihydrotestosterone and estrogen, IFN-induced BAFF production in SFs was inhibited in a concentration dependent manner.

Conclusion: Taken together, BAFF production in synovial fibroblasts is induced by IFN-γ and pronounced under hypoxic conditions. STAT3 inducers like IL-1 and IL10 inhibit IFN-induced BAFF production. Also, the sex steroids dihydrotestosterone and estrogen inhibit BAFF production in OA and RA SFs. Therefore, the known correlation of endocrine factors with disease activity in arthritis might be in part mediated by regulating IFN-dependent BAFF production in SFs.

1975

Profiling 14-3-3η in Human Primary Cell Based BioMAP® Disease Models Reveals a Unique Pro-Inflammatory Phenotypic Signature Consistent with RA-Inflammation Biology. Alison O'Mahony[1], Ellen L. Berg[1], WP Maksymowych[2], Yuan Gui[3] and Anthony Marotta[3]. [1]BioSeek, South San Francisco, CA, [2]University of Alberta, Edmonton, AB, [3]Augurex Life Sciences Corp., North Vancouver, BC.

Background/Purpose: 14-3-3 proteins represent a highly conserved seven-member family of ubiquitously expressed intracellular chaperonins that perform a broad range of signaling functions. The 14-3-3 eta (η) protein is an emerging diagnostic and prognostic biomarker for RA driving inflammation and joint erosion.[1] Elevated levels of the η isoform have been reported in synovial fluid and serum from patients with joint inflammation[2], but not with other diseases including psoriasis, osteoporosis, SLE, Crohn's and MS. Here we evaluate the impact of this RA-associated biomarker on the levels of clinically relevant biomarkers across a panel of human primary cell-based disease models in the BioMAP®platform.

Methods: BioMAP® systems model disease biology in primary human cells cultured alone or with different stimulus combinations and have been used extensively to characterize compounds based on phenotypic signatures.[2,3]Phenotypic activity profiles were generated for eight concentrations of 14-3-3η observed in RA patients (0.25–50 ng/ml) across a panel of 13 BioMAP systems modeling vascular, immune, inflammation and tissue remodeling biology relevant for various human diseases. Changes in protein-based, clinically relevant endpoints (biomarkers), cell proliferation and cytotoxicity were evaluated to identify activities of 14-3-3η relative to vehicle control. The resultant 14-3-3η BioMAP profile was analyzed and compared in a similarity search with more than 3000 compounds in the BioMAP database to identify common mechanistic signatures using Pearson's correlation.

Results: 14-3-3η messenger RNA (mRNA) is highly expressed in all BioMAP Diversity Plus Systems with stimulus coupled increases detected in B cell and Fibroblast based systems. The activity profile for 14-3-3η in BioMAP shows highly selective effects in two systems: 1. HPNo, a non-stimulated vascular endothelial cell-PBMC co-culture; 2. BT, a stimulated co-culture of $CD19^+$ B cells plus PBMC modeling T-cell dependent B cell activation. 14-3-3η caused an increase in levels of VCAM-1 and TNFα in HPNo and sIL-6 production in BT, activities consistent with an inflammatory phenotype. Comparison of the profile to the BioMAP database identified mechanistic matches with several pro-inflammatory TLR-like agonists including Pam3CSK4, a TLR-2/-1 agonist ($r = 0.735$), Flagellin, a TLR-5 agonist ($r = 0.723$) and HKLM, a TLR-2 agonist ($r = 0.721$). Of interest, the BioMAP profile of 14-3-3η was not similar to LPS, a potential bacterial endotoxin contaminant of biological preparations that also has TLR-agonist activities.

Conclusion: The BioMAP profile for 14-3-3η is consistent with activation of B cell responses that correlates with pro-inflammatory activity associated with disease-relevant biomarkers. This data supports the hypothesis that 14-3-3η may serve both as a diagnostic marker in early RA as well as an important target for therapeutic intervention.[5]

1976

Elevation and Functional Activity of Interferon Omega in Human Systemic Lupus Erythematosus. Jarrat Jordan[1], Jessica Schreiter[1], Hao Liu[2], Sreedevi Adhikarakunnathu[2], Chichi Huang[3] and Jacqueline Benson[1]. [1]Estrela Lupus Venture, Janssen Research and Development, LLC., Spring House, PA, [2]Immunology Research, Janssen Research and Development, LLC., Spring House, PA, [3]Biologics Research, Janssen Research and Development, LLC., Spring House, PA.

Background/Purpose: IFNα is emerging as a clinically validated target in SLE yet it is currently unclear if other type I IFNs are contributing to the IFN signature present in many SLE patients. In this study we analyzed SLE patient sera and plasma for the presence of IFNω protein and compared the biological effects imparted by recombinant IFNα and IFNω on human cells. We further examined the effects of blocking IFNα alone versus dual blockade of IFNα and ω using SLE patient-derived IFN stimuli in vitro.

Methods: SLE patient sera and plasma were analyzed for the presence of IFNα and IFNω using a multiplex ELISA. SLE sera or conditioned media from cells exposed to SLE patient immune complexes were utilized as stimuli in an ISRE reporter gene assay (RGA) with selectively neutralizing mAbs to IFNα or IFNω or isotype control. To examine the effects of IFNω treatment, PBMCs from 6 healthy human donors were treated with either recombinant IFNαA or ω and gene and protein expression were analyzed by microarray and, Luminex or ELISA, respectively. To assess the individual contribution of IFNα and IFNω on the IFN signature, unstimulated SLE whole blood from patients having an elevated IFN signature was treated with neutralizing mAbs to IFNα, IFNω or the combination of both and qPCR analysis was performed. A fully-human monoclonal antibody targeting IFNω and multiple subtypes of IFNα was developed and tested for its ability to neutralize IFNα and IFNω-induced IP-10 release in whole blood.

Results: IFNω and IFNα were found to be elevated in the plasma and serum of a subset of SLE patients. IFNω protein was also detected in conditioned media from SLE patient immune complex-stimulated PBMCs. Combined blockade of IFNα and IFNω resulted in further suppression of IFN activity in comparison to IFNα blockade alone using these endogenous preparations of type I IFN. Microarray data from IFN-treated PBMCs indicated that 99.25% of genes modulated by IFNαA treatment versus untreated control were modulated by IFNω at 24h. IFNω exhibited indistinguishable qualitative gene expression responses as compared to IFNαA-treated cells using a 21 gene IFN signature. IFNαA and IFNω treatment induced TLR7, IP-10 and BLyS gene expression. IFNω-mediated BLyS and IP-10 induction was confirmed at the protein level. To determine the impact of various IFN inhibitors on the IFN signature present in SLE donor whole blood, neutralizing antibodies targeting IFNα, IFNω, or the combination of both were added to unstimulated blood. Gene expression analysis by qPCR indicated that combined blockade of IFNα and IFNω resulted in greater reduction of multiple IFN-inducible genes than IFNα blockade alone. We further demonstrate a fully-human monoclonal antibody capable of dose-dependently inhibiting IP-10 release induced by both IFNω and IFNα.

Conclusion: IFNω antagonism enhanced the ability of IFNα antagonists to suppress IFN activity in SLE patient sera, SLE immune complex-induced preparations of IFN and the IFN signature in SLE patient whole blood in vitro. IFN signatures induced by recombinant IFNω and IFNα were found to be indistinguishable and our current data lends compelling support to the hypothesis that IFNω may contribute to the total type I IFN activity and signature present in some SLE patients.

The Proangiogenic Function of the Epigenetic Regulator EZH2 in Synovial Tissue Is Mediated By Fibroblasts in Rheumatoid Arthritis. Michelle Trenkmann[1], Steffen Gay[2], Douglas J. Veale[1] and Ursula Fearon[1]. [1]Translational Rheumatology Research Group, Dublin, Ireland, [2]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: The histone methyltransferase Enhancer of Zeste 2 (EZH2) is overexpressed in solid tumors and is associated with invasion, malignancy and tumor angiogenesis. EZH2 expression is upregulated in rheumatoid arthritis (RA) synovial fibroblasts (SF) whose activated phenotype drives them to invade and destroy articular cartilage. Another hallmark of the inflamed rheumatoid joint is angiogenesis and RASF are important regulators of this pathway secreting proangiogenic molecules and providing a molecular scaffold for blood vessel formation. Here, we studied the role of EZH2 in the interplay of RASF and endothelial cells in RA.

Methods: Fresh biopsies of synovial tissue (ST) from RA patients were stimulated with tumor necrosis factor alpha (TNFα, 10ng/ml) for 24h (explant culture) and RNA was isolated (n=3). Human microvascular endothelial cells (HMVEC) were stimulated with proinflammatory stimuli, Toll-like receptor (TLR) ligands or synovial fluid (2%, 5% and 10%) for different periods of time (n=3). RASF (n=4) were transfected with siRNA targeting EZH2. After 72h and 96h, cells were analyzed for EZH2, interleukin (IL)-6, IL8 and vascular endothelial growth factor (VEGF) expression at mRNA (by quantitative real-time PCR) and protein levels (by ELISA).

Results: *Ex vivo*, TNFα induced the expression of EZH2 in RA ST (1.8$\pm$0.3-fold) which was accompanied by an increase in the expression and copious secretion of proinflammatory and proangiogenic mediators, namely IL6 (from 77$\pm$88 ng/ml to 197$\pm$163 ng/ml) and IL8 (from 105$\pm$53 ng/ml to 220$\pm$30 ng/ml). Since RA ST explant cultures maintain the synovial architecture with cell-cell and cell-matrix contacts thus mimicking the *in vivo* situation, these data indicate that chronic inflammation within the RA synovium upregulates EZH2 expression *in vivo*. Our previous work demonstrated that TNFα upregulates EZH2 in RASF. Silencing of EZH2 in RASF changed the expression and secretion of IL6 and VEGF into cell culture supernatants whereas no significant changes were observed for IL8. Specifically, IL6 and VEGF were downregulated by EZH2 knockdown both under basal (by 39$\pm$17% and 29$\pm$8%) and TNFα-stimulated (by 30$\pm$18% and 38$\pm$6%) conditions which was confirmed at the protein level by ELISA. To elucidate whether other cell types show the same EZH2 expression pattern, HMVEC were studied for their response to pathogenetically relevant stimuli. No significant changes in EZH2 expression, however, were observed following proinflammatory stimuli (TNFα, IL-1β, IL-17), TLR stimulation (TLR2, 3 and 4) or treatment with synovial fluid, ruling out a direct effect of inflammation-induced EZH2 on endothelial cell behaviour.

Conclusion: Here we show that TNFα induces the expression of the epigenetic regulator EZH2 in RA ST explants *ex vivo*. *In vitro*, TNFα regulates EZH2 expression in RASF but not in endothelial cells. Silencing of EZH2 in RASF decreased the expression and secretion of IL6 and VEGF. These data imply that induction of EZH2 by TNFα in synovial tissue and RASF drives proinflammatory and proangiogenic mechanisms in RASF.

1978

Role of Monocytes Subsets in the Pathology of Rheumatoid Arthritis: Involvement in Endothelial Dysfunction and Proinflammatory Profile. Chary Lopez-Pedrera, Patricia Ruiz-Limon, Carlos Perez-Sanchez, Rosario Carretero, Yolanda Jiménez Gómez, Ángeles Aguirre Zamorano, Jerusalem calvo-Gutierrez, Eduardo Collantes-Estevez, Alejandro Escudero-Contreras and Nuria Barbarroja. IMIBIC-Reina Sofia University Hospital, Cordoba, Spain.

Background/Purpose: Different frequency of monocytes subsets has been reported in rheumatoid arthritis (RA).Human monocytes are divided into three main subpopulations according to expression of the surface markers CD14 and CD16:'classic' CD14brightCD16- monocytes, 'non-classic' CD14dimCD16bright cells and 'intermediate' CD14brightCD16bright subpopulation.

Aim: to functionally characterize the different monocytes subsets in RA patients and analyze their role in the endothelial dysfunction, altered oxidative status and proinflammatory/prothrombotic profile associated to RA.

Methods: Thirty RA patients and 15 healthy donors were included in the study. Endothelial function was measured through post occlusive hyperaemia (PORH) using the Laser-Doppler linear Periflux 5010. Classic, intermediate and non-classic monocytes were characterized by flow cytometry. Different proinflammatory cytokines and peroxides levels were analyzed by flow cytometry in the three different subsets.CD14brightCD16- and CD16+ cells were isolated using immuno-magnetic selection.mRNA expression of inflammatory cytokines,endothelial adhesion markers and oxidative enzymes were analyzed in the two monocytes subsets.Correlation studies between clinical parameters, endothelial function and markers of inflammation and endothelial adhesion expressed by the different monocytes subsets were performed.

Results: CD16+(intermediate and non-classic)monocytes were extended in RA patients.These subsets had increased protein expression of TF, IKK and TNFa and lower peroxide levels compared to CD14brightCD16-.CD16+ monocytes displayed higher mRNA expression of TF, TNFa, TLR4, PPARg and MCP-1.In contrast, CD14brightCD16- cells had increased expression of IL8 and oxidative enzymes. All these parameters were significantly increased in RA patients. RA patients had impaired endothelial function, with a reduced perfusion value after ischemia.

Clinical parameters such as evolution time, CRP, anti-CCPs antibodies and rheumatoid factor levels strongly correlated with endothelial dysfunction, decreased percentage of classic monocytes and increased number of non-classic and intermediate subsets.Furthermore, higher expression of proinflammatory/prothrombotic molecules and endothelial adhesion markers in these CD16+ cells correlated with the alteration in endothelial function and the clinical parameters.

Conclusion: RA patients display an increased number of intermediate and non-classic monocytes directly associated to the autoimmune and inflammatory profile, the progression of the disease and the altered microvascular function. Therefore, CD16+ subpopulation might play a key role in the atherothrombotic pathogenesis of RA.

1979

Pseudostarvation By AMPK Activator Therapy Is Associated with Reduced Disease Activity and Downregulation of Pro-Inflammatory Responses in Rheumatoid Arthritis (RA). Lorna Gallagher[1], Ursula Fearon[2], Douglas J. Veale[3], David Kane[1], Luke A. O'Neill[4] and Ronan Mullan[1]. [1]Department of Rheumatology, Tallaght Hospital, TCD, Dublin 24, Ireland, [2]Translational Rheumatology Research Group, Dublin, Ireland, [3]St. Vincent's University Hospital, Dublin 4, Ireland, [4]School of Biochemistry and Immunology, Dublin, Ireland.

Background/Purpose: AMP-activated protein kinase (AMPK) is a highly conserved, regulator of cellular energy status. In inflammation, AMPK inactivation is associated with increased glucose consumption through aerobic glycolysis, and up-regulation of pro-inflammatory effector responses. Pseudostarvation of cells through AMPK activation by hypoglycaemic therapy reverses these effects through downregulation of pro-inflammatory transcription factors, including NFκB/HIF-1α. Here we demonstrate AMPK upregulation in RA synovial tissues (RAST) after successful treatment, and inhibition of pro-inflammatory responses following pharmacological AMPK activation by metformin/phenformin *in vitro*.

Methods: RAST from RA patients during arthroscopy pre and 3/12 post treatment with anti-TNF therapy, were stained by immunohistochemistry for activated AMPK (pAMPK) and inactive AMPK (AMPK). Primary Human Microvascular Endothelial Cells (HMVEC) and K4 Synovial fibroblasts (K4 SF) were stimulated with LPS/TNFα (10ng/ml) in the presence of AMPK activators metformin/phenformin (0.5–2 mM). Culture supernatants were evaluated for IL-6 and IL-8 by ELISA. pAMPK and AMPK expression in K4 SF protein lysates were analysed by Immunoblotting normalized against β-actin.

Results: pAMPK was differentially expressed with low expression in highly inflamed RAST pre-treatment, and high expression post-treatment, in concert with a reduction in clinical disease activity.

In LPS and TNFα stimulated K4 SF, IL-6 and IL-8 production is decreased in the presence of metformin and phenformin in a dose dependent manner, with phenformin the more potent effect ($P < 0.0001$).

In LPS stimulated HMVEC, the production of IL-6 was also decreased in the presence of metformin or phenformin, dose dependent manner, with phenformin the more potent; 2428pg/ml (LPS) reduced to 2263pg/ml (Metformin 0.5mM), 149pg/ml (Metformin 1mM, $P=0.0005$), 1387 (Metformin 2mM, $P<0.0001$); 917pg/ml (Phenformin 0.5mM, $P<0.0001$), 629pg/ml (Phenformin 1mM, $P<0.0001$) and 306pg/ml (Phenformin 2mM, $P<0.0001$). Decreased production of IL-8 was seen with phenformin; 12572pg/ml (LPS) reduced to 8270pg/ml (0.5mM, $P<0.0001$), 5731pg/ml (1mM, $P<0.0001$) and 409pg/ml (2mM, $P<0.0001$). IL-8 production was not decreased in LPS stimulated cells in the presence of Metformin.

By immunoblot, pAMPK expression was strongly upregulated in the presence of metformin or phenformin (2mM) compared to unstimulated K4 SF cells indicating a role of both drugs in activating AMPK.

Conclusion: AMPK activation is associated with reduced RA disease activity and down-regulation of pro-inflammatory effector responses. AMPK activating drugs, such as Metformin, may be suitable as an additional therapeutic agent in the treatment of RA.

1980

Thrombospondin-1 Is Elevetad in the Plasma of Patients with Antiphospholipid Syndrome and Is Correlated with Soluble Fas Ligand and Free Active TGF-B levels. Markos Patsouras, Marina Sikara, Athanasios G. Tzioufas and Panayiotis Vlachoyiannopoulos. School of Medicine, National University of Athens, Athens, Greece.

Background/Purpose: Antiphospholipid syndrome (APS) is an acquired thombophillia characterized by recurrent thromboembolism and pregnancy morbidity. Thrombospondin (TSP-1) is a matricellular glycoprotein with antiangiogenic and proapoptotic properties, which is secreted by platelets upon activation. It has been described to promote apoptosis through activation of caspases or induction of Fas ligand (sFasL) expression. Furthermore, TSP-1 is considered as the major activator of TGF-beta by releasing it from the Latency Acossiated Peptide. Herein, we sought to study the involvement of TSP-1 in antiphospholipid syndrome

Methods: Plasma, serum and platelets obtained from 90 patients fulfilling the diagnostic criteria of APS, 46 healthy individuals (healthy controls: HC) and 26 SLE patients, that served as disease controls were studied.

Human Umbilical Vein Endothelial Cells (HUVECs) were isolated from 2 APS patients and 3 HCs upon full term vaginal delivery by a standard protocol. HC-HUVECs were cultured in the presence of 10% plasma from HC ($n=10$) or APS patients ($n=20$) for 20 hours. Then, culture supernatants (SPN) were removed, cells were washed twice with HBS and fresh medium was added and left for two hours (hr). The 2 hr SPNs were collected and kept at $-20°C$ till use. Furthermore, HUVECs from APS patients were cultured in medium supplemented or not with their own plasma. TSP-1, soluble FasL (sFasL) and active cell-free TGF-b were determined by ELISA in plasma and cell culture SPNs.

Results: APS patients had significantly higher plasma levels of TSP-1, compared to HCs and SLE patients [Mean ng/ml [intarquartile range]: 390.0 [95.90–437.7] in APS patients vs 144.3 [46.3–236.6], $p<0.0001$, and: 153.0 [8.2–267.2], $p=0.029$ in HCs and SLE patients, respectively). TSP-1 was found to strongly correlate with sFasL and active TGFβ levels (Spearman $r=0.8785$, $p<0.0001$ and $r=0.827$, $p<0.0001$ respectively). Significantly higher levels of TSP-1 were detected in culture SPNs obtained from HUVECs treated with plasma from APS patients compared to those from HCs (mean concentration: 139.4 ng/ml in APS vs 22.8 ng/ml in HCs, $p=0.0009$). The analysis of correlations with clinical features, revealed that lower TSP-1 levels (mean value 130.1 ng/ml) were associated with pregnancy morbidity alone, whereas higher levels (403.2 ng/ml) with thromboembolic events with or without misacarriages ($p<0.05$).

Conclusion: Our findings implicate TSP-1 in APS pathogenesis, and associate it with the levels of sFasL and active TGF-b in the plasma of patients. Further studies are needed to clarify the exact role of TSP-1.

1981

A Qualitative Analysis of Methotrexate Injection Videos on Youtube. Rebekah Rittberg[1], Tharindri Dissanayake[2] and Steven J. Katz[2]. [1]University of Manitoba, Winnipeg, MB, [2]University of Alberta, Edmonton, AB.

Background/Purpose: Methotrexate (MTX) is one of the most commonly prescribed disease modifying antirheumatic drugs for rheumatoid arthritis. While data suggests subcutaneously administered methotrexate is more efficacious, there are many potential patient barriers to its use. Video assisted teaching has been shown to be an effective supplementary method for subcutaneous MTX education. This review evaluates the quality of video resources available for patients on YouTube for learning to self-administer subcutaneous MTX.

Methods: Using the search term "Methotrexate injection" on YouTube, 2 independent clinical reviewers in 2 different geographic locations analyzed the first 3 pages of search results (60 videos). Discrepancies were evaluated and resolved by a 3rd independent reviewer. Source and search rank of videos, audience views video duration and time since video was uploaded to YouTube were recorded. Videos were classified as useful, misleading or a personal patient view. Videos were rated for reliability using the DISCERN reliability tool (0–5, 5 being the most reliable), comprehensiveness (0–4; 1 point each as follows: needle preparation, MTX withdrawal, injection demonstration, needle disposal) & global quality scale (GQS; 1=poor video quality, 5= excellent video quality). Reasons for misleading videos were documented, and personal patient view videos were recorded as being either positive or negative towards MTX injection.

Results: A total of 51 English videos overlapped between the two geographic locations; 10 videos were classified as useful (19.6%), 14 as misleading (27.5%) & 27 as personal patient view (52.9%). Total views of videos were 161,028: 19.2% useful videos, 72.8% personal patient view videos, & 8.0% misleading videos. Mean GQS was 4.2 ($\pm$ 1.0) for useful videos, 1.6 ($\pm$ 1.1) for misleading videos & 2.0 ($\pm$ 0.9) for personal patient videos ($p<0.0001$). Mean reliability was 3.3 ($\pm$ 0.6) for useful videos, 0.9 ($\pm$ 1.2) for misleading videos, & 1.0 ($\pm$ 0.7) for personal patient videos ($p<0.0001$). Comprehensiveness was 2.2 ($\pm$ 1.9) for useful videos, 0.1 ($\pm$ 0.3) for misleading videos, & 1.5 ($\pm$ 1.5) for personal patient view videos ($p = 0.0027$). Of the personal patient view videos, 77.8% were positive, & 22.2% were negative. No significant correlation was found between the number of video views and quality of the video. The most common reason for a video being misleading was video content being unrelated to MTX injection. Of the 10 videos (19.6%) from university or professional organizations, 80% were useful and 20% misleading, while 72.7% of the 11 medical advertisements/for-profit organizations videos were misleading.

Conclusion: A qualitative review of MTX injection videos posted on YouTube shows a minority of useful videos for MTX injection, with the majority of viewers watching patient created videos. While many of these demonstrate MTX injection positively, this does not necessarily correlate with appropriate and safe technique. While web video may be an additional educational tool available for patients, clinicians need to be familiar with specific resources to help guide and educate their patients to ensure best outcomes.

1982

Final Year Medical Students Prefer E-Reading Content to Interactive Case-Based Quizzes in a Pediatric Rheumatology E-Learning Module. Taunton R. Southwood. Institute of Child Health, University of Birmingham and Birmingham Children's Hospital. Birmingham, United Kingdom.

Background/Purpose: Traditional medical student learning and teaching methods, such as lectures and bedside teaching, maybe inadequate for providing core knowledge and clinical skills in rheumatology, paediatrics and paediatric rheumatology, with reduction in undergraduate time allocated to paediatrics and increasing medical student numbers. To supplement paediatric knowledge and improve access to essential clinical skills, an e-learning module, "paediatric rheumatolog-e", was developed within a Canvas(c) learning management system. The design promoted revision of basic sciences (e.g. musculoskeletal anatomy,

inflammation and immunological processes), in the context of clinical sciences (e.g. pharmacology, rheumatology and child development). Learning content comprised videos of patient and family narratives, clinical skills and layered information on 4 key learning outcomes: joint swelling, limb pain, back pain and the limping child. Optional information on juvenile idiopathic arthritis was provided. Core knowledge was consolidated using interaction, reflection and formatively assessed case-based quizzes.

The aim of this study was to assess final year medical student use and acceptability of an e-learning module in paediatric rheumatology.

Methods: 341 final year medical students were notified of the e-learning module by email at the beginning of the academic year, and again 3 months later. Students beginning their paediatric rotation were reminded in the introductory lecture and written course materials. Use of the module was assessed 4 months into the academic year, after 3 blocks of medical students (193 students, 53% of the year) had undertaken a paediatric rotation. Canvas(c) embedded in-course analytics were used and acceptability was ascertained through online feedback and an email questionnaire.

Results: 187 students (55%) accessed the e-learning module (a mean of 14.8 pages per student, range 1–270, 28% 3); of these only 20 (11%) answered at least one clinical quiz. Higher median quiz scores were found in the joint swelling quiz and back pain quiz. Qualitative feedback indicated that the students found the quizzes took too much time and effort compared with reading through the other learning content and watching the clinical videos. There was a preference for accessing the module during a paediatric rotation (74/193 students to date, 62%). Time for completion of the module was 1–1.5 hours. Student acceptability of the entire module was high, with comments such as "thorough" and "engaging", and requests for more e-learning modules.

Conclusion: An e-learning module in a paediatric speciality was widely used and found to be acceptable by final year medical students. Students preferred written and video content to interactive clinical case quizzes due to the perceived time-inefficiency of clinical quizzes.

1983

Improving Resident Confidence with the Musculoskeletal Exam through a Rheumatology-Dedicated Musculoskeletal Workshop. Kimberly Fisher[1], Alexa Meara[2], Brian LaMoreaux[2], Hareth Madhoun[1], Irving Rosenberg[2], Xiaokui Mo[1], Lisa G. Criscione-Schreiber[3] and Nicole Bundy[4]. [1]The Ohio State University Wexner Medical Center, Columbus, OH, [2]The Ohio State University, Columbus, OH, [3]Duke University Health System, Durham, NC, [4]OSU Medical Center, Columbus, OH.

Background/Purpose: Musculoskeletal (MSK) complaints are among the most common complaints evaluated by primary care physicians. Thus, it is imperative that Internal Medicine (IM) residents learn how to perform and interpret a thorough MSK exam. Research suggests that IM residents lack confidence in performing a detailed MSK exam. If physicians find performing a procedure or exam difficult, they tend to avoid that behavior, which in the case of MSK complaints, could lead to over imaging and unnecessary referrals. Formalized clinical education has been shown to improve resident exam skills. To help improve IM residents' competence and confidence in the MSK exam, a dedicated MSK workshop was performed by the Rheumatology fellows at The Ohio State University with a Rheumatology faculty attending supervisor.

Methods: A single, 3 hour quality improvement workshop for IM residents was conducted by Rheumatology fellows supervised by an attending Rheumatologist. The residents were broken into small groups and rotated through twenty minute stations focusing on joint exams of the knee, hip, shoulder, wrist and hand. A validated pre-test survey created by Dr. Lisa Criscione-Schreiber assessing confidence and ability in the MSK exam was given to the residents in paper form prior to the workshop. The survey consisted of 10 questions, with 1–6 ranking system (1 being the lowest or no confidence in the listed skill). The same survey, in an on-line version was then administered to the residents 1 month after the workshop in to assess a change in proficiency. The data was analyzed by ANOVA with repeated measures since each subject answered 10 questions. The primary tests compare the scores between post and pre-workshop for question 1 and question 9. Multiplicities were adjusted by the Bonferroni method.

Results: 40 residents completed the pre-test and 20 residents completed the post-test. As shown in Table 1, there is a statistically significant improvement in confidence scores from the pre and post survey ($P < 0.05$) in most questions one through ten after completing this work shop.

Conclusion: Comfort and confidence in performing the MSK exam is an essential tool for Internists. There is a need for an efficient and cost effective way to teach IM residents clinical skills during their busy schedules. Using a validated survey created at Duke University, we found that a short, dedicated MSK exam workshop performed by Rheumatologists improved IM residents' confidence and ability to perform an MSK exam in statistically significant matter. Limitations were the small size of our study group and poor response rate to the post-survey evaluation. We were also unable to collect a sufficient number of responses from residents who did not participate in the workshop for a control comparison. We hope to perform this workshop on a larger scale with adequate control groups.

Table 1:

Survey Questions	Pre-test Average Ranking	Post-test Average Ranking	Adjusted p-value
Question 1: Identifying and naming common musculoskeletal deformities	3.4	4.3	0.014
Question 2: Taking a MSK pain history from a patient with pain in the following joints:			
Knee	3.6	4.7	0.0007
Spine	3.7	4.5	0.0162
Shoulder	3.4	4.3	0.0032
Hand/Wrist	3.4	4.4	0.0008
Hip	3.4	4.5	0.0004
Question 3: Describing the basic structure and function of the following joints:			
Knee	3.6	4.7	0.0007
Spine	3.6	4.5	0.0036
Shoulder	3.4	4.2	0.0089
Hand/Wrist	3.5	4.3	0.0091
Hip	3.6	4.5	0.0015
Question 4: Identifying the important surface markings when examining the following joints:			
Knee	3.1	4.7	<.0001
Spine	3.2	4.5	<.0001
Shoulder	3.0	4.4	<.0001
Hand/wrist	3.0	4.5	<.0001
Question 5: Assessing the following joint area for soft tissue swelling and/or effusion:			
Knee	3.5	4.9	<.0001
Spine	3.1	3.8	0.029
Shoulder	3.1	4.1	0.0005
Hand/wrist	3.2	4.8	<.0001
Question 6: Assessing the stability of the following joints:			
Knee	3.3	4.7	<.0001
Shoulder	3.0	4.4	<.0001
Question 7: Assessing the following joints for range of motion:			
Knee	3.8	5.0	<.0001
Spine	3.7	4.8	0.0001
Shoulder	3.6	4.7	0.0005
Hand/wrist	3.4	4.8	<.0001
Hip	3.6	4.7	0.0005
Question 8: Using information gained from physical exam of the following joint areas to make diagnoses:			
Knee	3.1	4.6	<.0001
Spine	3.1	4.0	0.0064
Shoulder	2.9	4.2	<.0001
Hand/Wrist	3.0	4.2	<.0001
Hip	3.0	4.0	0.0003
Question 9: Using information gained from physical exam of the following joint areas to guide medical decision making:			
Knee	3.1	4.7	<.0001
Spine	3.2	4.3	0.0021
Shoulder	2.9	4.5	<.0001
Hand/Wrist	3.0	4.4	<.0001
Hip	3.0	4.3	<.0001
Question 10: Performing and interpreting special diagnostic maneuvers on the following joints:			
Knee	3.0	4.5	<.0001
Spine	2.9	4.1	0.0001
Shoulder	2.8	4.3	<.0001
Hand/Wrist	2.9	4.0	<.0001
Hip	2.9	4.1	<.0001
Net Average All Questions	3.2	4.4

1984

Implementation and Performance of an Objective Structured Clinical Examination (OSCE) in a National Certification Process of Trainees in Rheumatology. Two Years of Experience. Virginia Pascual Ramos[1], Gabriel Medrano-Ramírez[1], Eunice Solis-Vallejo[1], Ana Bernard-Medina[2], Diana Flores[1], Margarita Portela Hernandez[1], Lilia Andrade-Ortega[1], Olga Lidia Vera-Lastra[1], Rolando Espinosa-Morales[1], Juan Miranda-Limón[1], M Maldonado-Velázquez[1], Luis Javier Jara[3], Luis M. Amezcua-Guerra[1], Judith Lopez-Zepeda[1], Miguel Angel Saavedra[1] and Cesar Alejandro Arce[1]. [1]Mexican Board of Rheumatology, Mexico City, Mexico, [2]Antiguo Hospital Civil de Guadalajara - Fray Antonio Alcalde, Mexico City, Mexico, [3]Hospital de Especialidades. Centro Médico La Raza, IMSS, Mexico City, Mexico.

Background/Purpose: We developed and conducted an OSCE to assess clinical skills of trainees in rheumatology (TRs) and determine its performance at two consecutive annual evaluations of the National Board of Rheumatology (NCR) certification.

Methods: Thirty-two (in 2013) and 38 (in 2014) TRs, underwent an OSCE and a 300-questions examination (MCQ). MCQ was annually developed by faculty and experienced test questions writers NCRS–certified members, who submitted questions based on pre-specified content areas. Each question was reviewed by a committee of 4 NCR members.

OSCE circuits were developed over a 10-month period by a trained NCR committee. At first, NCR members selected and designed stations using public core skills which included history-taking, physical examination, problem solving, studies interpretation, intra-articular injection (using a model) and capillaroscopy test; then, an expert consensus panel of rheumatologists validated each station (≥80% agreement); appropriated consented patients were selected and trained, as were examiners and each one was assigned to a particular station; finally, a pilot OSCE was performed by 3 certified rheumatologists who served as the "gold standard" control participants. Feedback was obtained. Final circuits consisted of 12 (in 2013) and 15 (in 2014) 8-minutes-stations, respectively, with 4 (2013) and 5 (2014) additional rest stations. Stations were scored by the same examiner in a previously validated check-list.

A composite OSCE score was obtained from each participant. Inter-station correlation was calculated using Pearson′s correlation coefficient. Concurrent validity was established by correlating MCQ scores and composite OSCE scores within each TR (Pearson′s correlation coefficient), by comparing OSCE scores between TRs and certified rheumatologists (Student t test) and by comparing distribution of TRs with MCQ pass scores among TRs with/without OSCE pass score (Wilcoxon rank sum).

Results: In 2013, mean (±SD) OSCE score in all the participants was 7.1(±0.6) and none received a failing score, meanwhile mean MCQ was 6.5(±0.6) and 7 TRs (21.9%) received a failing score (<6). In 2014, mean (±SD) OSCE score was 6.7(±0.6) and 3 TRs (7.9%) received a failing score (

In 2013, there was a significant correlation between MCQ score and composite OSCE score (r=0.44, p=0.006) meanwhile in 2014 correlation was not significant. At both consecutive years, certified rheumatologist had significantly higher OSCE scores than TRs. There were more TRs with a MCQ pass score among TRs with an OSCE pass score than among TRs with an OSCE failing score: 86% vs. 67%, p=0.02. TRs with an OSCE failing score were more frequently distributed in the bottom 2 quartiles on the MCQ (p=0.07).

Nine stations were applied at 2013 and 2014 OSCE circuits, and their (mean±SD) scores showed good correlation, r from 0.81 to 0.95, p≤0.01.

Conclusion: The OSCE was a valid and reliable tool to assess clinical skill competency in TRs.

1985

Rheumatology Learning Management System. Rodney Tehrani, Rochella A. Ostrowski and Baltazar Espiritu. Loyola University Medical Center, Maywood, IL.

Background/Purpose: A learning management system (LMS) is software that facilitates the development, management, and tracking of training and education. To date, web based learning is a method of teaching that has been under-utilized in medical training. It has the advantage of being an efficient and easily accessible educational tool. We implemented a Rheumatology LMS for Internal Medicine residents. We hypothesized that the LMS would enhance the education and training of Internal Medicine residents in regard to Rheumatology through the use of dynamic and interactive software.

Methods: Five rheumatologic modules were created covering antiphospholipid syndrome, crystal arthritis, giant cell arteritis, myositis and rheumatoid arthritis in the LMS. All first year Internal Medicine residents completed the modules during dedicated educational time. Attendance and completion was mandatory. Modules were completed either in small groups or individually based on the preference of the learner. Residents completed the modules after their first Internal Medicine In-Training Examination (ITE) and prior to their second. We then analyzed the ITE performance of the first year Internal Medicine residents on the Rheumatology subsection to determine whether there was a statistical improvement in their scores compared from previous year residents who did not have access to the LMS.

Results: In the previous 2 years of residents who had not completed the modules, ITE mean examination scores in the rheumatology content changed from 58% to 53% and from 45% to 62%. National percentile ranking changes were 16% to 25% and 18% to 16% for the 2 groups respectively. Thirty four residents completed the modules. Mean examination scores improved from 48% correctly answered items on the year 1 ITE to 63% on the year 2 ITE (p value <0.0005). National percentile rank improved from 27% to 46% respectively. Twenty-eight residents had a rheumatologic experience defined as a clinic or rotation in rheumatology during their PGY1 year. Differences in examination scores before and after the module completion remained statistically significant even when stratifying residents according to whether or not they had a clinical rheumatologic experience.

Conclusion: The development and implementation of a LMS can enhance the education and training of Internal Medicine residents to the field of Rheumatology.

1986

Ambulatory Rheumatology Curriculum: Effect of Multimodal Curriculum Enhancement. Susan Kroop[1], Cecilia P. Chung[2], Mario Davidson[1], Laura Skaug[1], D. Alan Johnstone[1] and Charlene M. Dewey[1]. [1]Vanderbilt University School of Medicine, Nashville, TN, [2]Vanderbilt University, Nashville, TN.

Background/Purpose: Evidence suggests that Internal Medicine (IM) residents are not confident in basic rheumatologic skills (history taking, exams, and procedures). To improve IM residents' confidence in rheumatologic skills, we implemented and evaluated a multimodal simulation training session (MSTS) using standardized patients and mannequins to enhance Post Graduate Year (PGY) 1 IM residents' rheumatologic skills. To assess the utility and effectiveness of the MSTS enhancement, we conducted pre/post self-assessment of residents completing the curriculum.

Methods: We developed and implemented our MSTS for all PGY1 IM residents rotating on the 1 week ambulatory rheumatology block during the 2014 academic year. The two-part training consisted of a live standardized patient (SP) and deliberate practice with a mannequin for knee aspirations with feedback for both. PGY 1 residents performed a rheumatologic history and exam on a SP presenting with monoarticular inflammatory knee arthritis and practiced knee joint aspiration using a mannequin under the direct supervision of an attending rheumatology faculty member.

All PGY 1 residents completed an online, self-assessment survey on self-confidence (0=not confident, 100=extremely confident) in performing a rheumatologic history, physical examination and common rheumatologic procedures pre/post their rheumatology block as well as a separate MSTS evaluation form. Pre/post-rotation assessments were analyzed and 2014 results compared to the 2013 academic year, a historical control using the Wilcoxon Signed Rank test. IRB approval and consent was obtained prior to completing the survey.

Results: In 2013 and 2014, 22/27(81%) and 39/43 (91%) of PGY1 IM residents completed pre/post surveys respectively. Both cohorts significantly increased (p<0.05) their self-assessed confidence ratings from pre to post rotation in all variables other than trochanteric bursa injection in the 2013 cohort (Table 1). The 2014 cohort had significantly greater changes in self-assessed confidence ratings than the 2013 historical controls. The difference in the median in rheumatology history was 12, exam was 11, knee aspiration was 37 and knee injection was 34 (Table 1). 35/43 (81%) PGY1 IM residents strongly agreed and 8/43 (19%) agreed that the MSTS was a valuable training exercise.

Conclusion: Our results indicate that our MSTS enhanced curriculum improves residents' self-confidence in performing a rheumatologic history and exam and knee injection and aspiration techniques when compared to an unenhanced prior curriculum. Further study is required to assess if these results are sustained over time and whether this translates into IM residents performing more procedures competently during their training.

Table 1. Median Self-Assessed Confidence Levels for PGY 1 Residents with and without MSTS

	2013 Median (IQR)* Historical Control			2014 Median (IQR)* MSTS Curriculum			
Self-Assessed Confidence in Performing:	Pre-Rotation	Post-Rotation	P Value	Pre-Rotation	Post-Rotation	P Value	Difference in Median (95% CI)
Rheumatology History Taking	50 (27–62)	64 (53–79)	<0.001	34 (19–49)	70 (61–81)	<0.001	12 (2–22)
Rheumatologic Exam	36 (23–50)	63 (52–74)	<0.001	31 (12–39)	71 (59–83)	<0.001	11 (2–22)
Knee Injection	10 (2–33)	22 (6–36)	<0.05	9 (2–36)	60 (50–74)	<0.001	34 (20–46)
Knee Aspiration	13 (2–20)	28 (10–42)	<0.005	9 (0–30)	63 (56–75)	<0.001	37 (25–49)
Shoulder Injection	7 (1–13)	12 (5–27)	<0.05	7 (0–19)	27 (16–42)	<0.001	6 (−1–14)
Trochanteric bursa injection	7 (2–14)	13 (5–26)	<0.071	7 (0–19)	25 (8–52)	<0.001	9 (0–19)

Visual Analog scale (0, not confident-100, extremely confident).

1987

Simulation in Continuing Education: Improving Evidence-Based Decisions for Rheumatoid Arthritis Management. Nimish Mehta[1], Martin Warters[2] and Douglas Blevins[2]. [1]Medscape, LLC, New York, NY, [2]Theraasim, Durham, NC.

Background/Purpose: In many patients with rheumatoid arthritis (RA), the disease is not adequately controlled, and only a minority of patients attain the goal of consistent remission or low disease activity. Underlying clinical practice gaps and educational needs were identified and a study was conducted to determine if online, simulation-based educational interventions could improve competence and performance of rheumatologists in managing patients with RA.

Methods: A cohort of US-practicing rheumatologists who participated in simulation-based educational interventions was evaluated. The interventions consisted of four cases presented in a platform that allowed physician learners to choose from numerous lab tests and assessment scales as well as thousands of diagnoses, treatments, and procedures. The clinical decisions made by the participants were analyzed using an artificial intelligence technology, and instantaneous or delayed clinical guidance was provided employing current evidence-based and expert faculty responses. Participant decisions were collected after clinical guidance and compared with each user's baseline data using a 2-tailed paired T-test to provide *P* values for assessing the impact of simulation-based education on the clinical decisions made by participants.

Results: The assessment sample consisted of185 rheumatologists who made at least one clinical decision within the simulation and proceeded to the end, debrief section. As a result of clinical guidance provided through simulation, significant improvements were observed in several areas of management of patients with RA, specifically:

- 32% improvement in the selection of a biologic agent in a patient with inadequate response to methotrexate (62% post intervention vs 30% baseline, $P<.001$)
- 11% improvement in recommendations for corticosteroids (77% post intervention vs 66% baseline, $P=.044$)
- 10% more participants correctly ordered clinical disease activity index and C-reactive protein to determine the level of disease activity (84% post intervention vs 74% baseline, $P<.03$)
- 16% improvement in selection of non-TNF biologic agent in a patient with RA not adequately controlled on methotrexate plus trials of etanercept and then adalimumab (60% post intervention vs 44% baseline; $P=.004$)
- 21% more participants selected an appropriate biologic in a patient failing an initial anti-TNF agent. (57% post-intervention vs 36% baseline, $P<.001$)

Conclusion: This study demonstrated the success of simulation-based educational interventions on improving the evidence-based practice patterns of rheumatologists in the management of patients with RA. Simulation-based instructions that lead to improvement in physician performance in a consequence-free environment can result in more evidence-based clinical decisions for RA and improvement in patient outcomes.

1988

Process Outcomes and Community-Wide Efficacy of the Amigo Inter-Institutional Mentoring Initiative within Pediatric Rheumatology. Lakshmi N. Moorthy[1], Eyal Muscal[2], Meredith P. Riebschleger[3], Kelly A. Rouster-Stevens[4], Polly J. Ferguson[5], Rayfel Schneider[6], Marisa Klein-Gitelman[7], Hermine I. Brunner[8], Anna Huttenlocher[9] and Peter A. Nigrovic[10]. [1]Robert Wood Johnson Medical School-Rutgers University, New Brunswick, NJ, [2]Texas Children's Hospital, Houston, TX, [3]University of Michigan, Ann Arbor, MI, [4]Emory University School of Medicine, Atlanta, GA, [5]University of Iowa Carver College of Medicine, Iowa City, IA, [6]The Hospital for Sick Children, Toronto, ON, [7]Anne & Robert H Lurie Childrens Hospital of Chicago, Chicago, IL, [8]PRCSG, Cincinnati, OH, [9]Univ of Wisconsin Schl of Med, Madison, WI, [10]Brigham and Women's Hospital/Harvard University, Cambridge, MA.

Background/Purpose: Mentoring is considered a critical contributor to career success in academic medicine. Recognizing that pediatric rheumatologists may experience limited access to mentoring due to the small size of most clinical programs, the American College of Rheumatology (ACR) and Childhood Arthritis and Rheumatology Research Alliance (CARRA) cooperatively developed a subspecialty-wide inter-institutional mentoring program, entitled the ACR/CARRA Mentoring Interest Group (AMIGO). We report outcomes of this initiative three years after its inception as a small pilot program in 2011.

Methods: Two distinct sets of surveys were conducted: (1) AMIGO participants in the pilot phase were surveyed 17 months after matching to characterize mentor-mentee contact, and results compared with a subsequent survey of all participants following full program implementation. (2) All US/Canadian pediatric rheumatologists were surveyed before and after implementation of AMIGO to identify global changes in mentorship over this interval.

Results: (1) Participants in the pilot phase (19 dyads) and general implementation phase (112 dyads) reported comparable experiences with AMIGO, including success in establishing contact and suitability of mentor-mentee pairing. Pilot and general roll-out participants reported similar anticipated benefit from the program. (2) Respondents in the community wide surveys included 180 pediatric rheumatologists in 2011 and 177 in 2014, with comparable demographics. Among survey respondents, 31/36 fellows (86%), 17/58 junior faculty (29%), and 37/61 (61%) senior faculty reported participation in the AMIGO program. Over the interval from 2011 to 2014, overall satisfaction with mentoring increased for fellows ($p=0.01$) but not junior faculty. AMIGO mentees reported that participation in AMIGO provided benefit in the domains of research/scholarship (30/51, 61%), career development (35/51, 71%), work-life balance (21/51, 43%), and connectedness to the pediatric rheumatology community (33/61, 56%).

Conclusion: The AMIGO program has expanded successfully from its pilot phase and now serves the large majority of US and Canadian pediatric rheumatology fellows as well as many junior faculty members. AMIGO mentees reported benefit in the domains of research, career development, and work-life balance. Institution of AMIGO was associated with improved satisfaction with mentoring among fellows, where program penetration was greatest. These results confirm that a subspecialty-wide inter-institutional mentoring program is feasible and can translate into concrete gains measurable at the level of the whole community.

Application of an Experiential Learning Framework for Clinician Scholar Educator Training in a Rheumatology Fellowship. Reena Khianey[1], Jessica Berman[2], Stephen A. Paget[2], Anne R. Bass[1] and Juliet Aizer[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY.

Background/Purpose: Rheumatology training programs rely on capable clinician scholar educators to sustain the rheumatology workforce. No program for rheumatology fellow clinician scholar educator (CSE) training has been described in the literature. We describe application of iterative cycles of Kolb's experiential learning in a mentored rheumatology fellow CSE experience as a proof-of-concept model.

Methods: With mentorship from a faculty CSE, a second year rheumatology fellow at Hospital for Special Surgery contributed to implementation

of a learning module on fracture risk for New York Presbyterian Hospital (NYPH) internal medicine (IM) residents.

Applying an experiential framework (learning through experience), the fellow refined the fracture risk module through cycles of Reflective Observation (review of faculty-led sessions), Abstract Conceptualization (identification of effective techniques), Active Experimentation (enactment of proposed teaching vignettes), and Concrete Experience (teaching parts of sessions).

The fracture risk module itself was built on the same experiential framework; IM residents recalled patients with fractures, identified fracture risk factors, formed clinical approaches, and estimated fracture risk. From July 2013-June 2014, IM residents completing a rheumatology rotation participated.

Following sessions, the fellow and faculty CSE reflected on module content and format, and on the teaching experience. Verbal and written prompts elicited impact, challenges, and key elements.

Results: The fellow attended 24/36 (66.7%) sessions, and taught in 21/24 (87.5%) of attended sessions.

The fellow found the experience valuable and feasible. Confidence related to clinical mastery and self-efficacy regarding curricular design and teaching abilities increased. The fellow cited increasing comfort and ease preparing to teach sessions and answering questions from IM residents.

The fellow's suggestions were consistent with experiential learning techniques, demonstrating application of new knowledge. Greater knowledge of the clinical subject (fracture risk) was evident in increased ability to respond to residents' questions. The fellow's knowledge and scholarly approach resulted in publication of a review article.

Challenges included competing clinical and research demands. Key elements identified for the fellow's learning included longitudinal faculty mentorship, establishment of fellow's content expertise, shared curricular development, explicit application of an educational framework, iterative learning cycles around a recurring teaching module, and flexibility in involvement to allow for other research experiences.

Conclusion: This descriptive analysis demonstrates the utility and feasibility of rheumatology fellow CSE development. Application of an experiential framework to fellow teaching in a recurring teaching module promoted iterative cycles of learning. Fellow self-efficacy and knowledge related to both rheumatology and education increased. This model may be adapted to support rheumatology fellow CSE development more broadly and systematically as a programmatic element.

1990

Pilot Musculoskeletal Workshop for Internal Medicine Residents. Sonali Khandelwal, Narender Annapureddy, Joel A Block, Andem Ekpenyong and Richard I Abrams. Rush University Medical Center, Chicago, IL.

Background/Purpose: Musculoskeletal (MSK) complaints in primary care are common but often underemphasized in residency training. There are few reports of methods residency programs have reported to address this need. Wilcox et. al reported an intervention for residents consisting of a monthly experience, and Houston et. al reported the experience of residents in a community clinic precepted by general internists. Both these interventions were scheduled as multi-week curricula. With limitation of work hours, residents spend less time on sub-specialty rotations such as Rheumatology, and so it becomes challenging to incorporate adequate exposure to the MSK examination. To address this need for more dedicated MSK teaching while remaining sensitive to the constraints of limited contact hours, a pilot MSK workshop consisting of a single 90 minute session was initiated.

Methods: As part of the ambulatory medicine curriculum for medicine residents at Rush University a MSK workshop was initiated. The workshop consisted of a lecture followed by assessment of preselected patients with MSK complaints. The residents assessed each patient through a focused history and dedicated musculoskeletal exam. Prior to the workshop a multiple choice pretest was administered. Subsequently, a post-test with different questions and an anonymous survey was completed. Informed consent was obtained from the patients. Paired t-test was used to compare pre-test and post-test scores. One-way ANOVA with Bonferroni correction was used to compare mean pre-test and post-test scores across PGYs.

Results: 45 medicine residents participated in the workshop. The mean±SD pretest score was 68.44 % ± 20.21. Post test scores are available for 26 residents. There was significant improvement in post test scores overall for PGY2 and PGY3, but none for PGY1s (table). One-way ANOVA with Bonferroni correction revealed no baseline differences at any PGY, but significant improvement among PGY2 and PGY3 compared to PGY1. Post workshop survey results are available for 19 residents. 92.9% of residents strongly agreed or agreed that the workshop was helpful and clinically useful. 89.3% strongly agreed or agreed that they were applying what they learned in their evaluation of patients in their continuity clinics and they felt more confident with their skills. Notwithstanding the PGY1 test results, there was no difference in their overall acceptance of the workshop compared to PGY2 or PGY3s.

	Pre-test Percentage (±SD)	Post-test Percentage (±SD)	P-Value
All PGY (n=26)	69.2 (21.3)	87.7 (12.7)	**0.001**
PGY1 (n=9)	64.4 (26.0)	77.8 (12.0)	0.111
PGY2 (n=8)	70.0 (18.5)	92.5 (10.3)	**0.0002**
PGY3 (n=9)	73.3 (20.0)	93.3 (10.0)	**0.003**
PGY1 vs. PGY2	66.7 vs. 66.7 (p-value =1.000)	77.8 vs.92.5 **(p-value=0.031)**	
PGY1 vs. PGY3	66.7 vs.72.0 (p-value=1.000)	77.8 vs.93.3 **(p-value=0.017)**	
PGY2 vs. PGY3	66.7 vs. 72 (p-value=1.000)	92.5 vs. 93.3 (p-value=1.000)	

Conclusion: These data suggest that an intervention requiring a single session may result in substantial and durable improvement in testable knowledge among PGY2 and PGY3 residents. The lack of improvement in post-test scores among PGY1 residents may indicate that this group needs more dedicated sessions. This is the first report to indicate that residents apply what is learned longitudinally in their long-term continuity experiences and a single session led them to feel more confident with their skills.

1991

Integration of Nailfold Capillary Microscopy and Dermoscopy into the Rheumatology Fellows Curriculum. Daniele Lerner[1], Stephen A. Paget[2], Maurizio Cutolo[3], Vanessa Smith[4], Robert F. Spiera[1] and Jessica K. Gordon[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [3]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, [4]Ghent University Hospital, Ghent, Belgium.

Background/Purpose: Microvascular damage is an intrinsic and early pathological event in Systemic Sclerosis (SSc) and can be observed using nailfold capillaroscopy (NFC). NFC can be performed using different techniques, including dermoscopy, widefield microscopy, and videocapillaroscopy. Abnormal nailfold capillaries are part of the 2013 diagnostic criteria for systemic sclerosis and may be observed in other connective tissue diseases (CTD) as well. With the support of our Academy of Medical Educators, we developed and assessed an educational curriculum to teach adult and pediatric rheumatology fellows the techniques and skills required for NFC.

Methods: Our curriculum had three programmatic elements. First, the fellows were provided with dermatoscopes and were given the opportunity to learn both the normal exam and abnormal capillary patterns. They were then given a one-hour didactic session and workshop where they used dermoscopy and widefield microscopy to examine the normal and abnormal patterns on themselves and an SSc patient. The third part of the curriculum involved a full-day course given by two experts in NFC that incorporated videocapillaroscopy and patient cases. Tests of usage and interest were taken at three time points – prior to giving the dermatoscopes, following the one-hour didactic session, and following the full-day course. Tests of knowledge were given to attendees of the full-day course before and after and included fellows, rheumatology attendings, and others. Comparisons were made using Fischer Exact Tests.

Results: In our institution there are 12 pediatric and adult rheumatology fellows. Response rates were 100%, 83% and 75% at the 1st, 2nd and 3rd timepoints- respectively. At all time points 100% of fellows noted interest or strong interest in learning NFC techniques. After the course 67% felt confident in their ability to perform NFC while before the course only 17% felt confident, $p = 0.03$. Prior to the completion of the curriculum 25% of fellows responded that they used NFC frequently when they performed rheumatologic consultation compared to 67% after the course, $p = 0.09$.

Before and after the one-day course participants were asked to look at photographs of normal and abnormal NFC using a web-based application via

SurveyMonkey. Response rates were 36/70 (51%) prior and 19/70 (27%) after. In the pre-test 74% answered all questions correctly and 95.5% answered all questions correctly in the post-test. Improved identification of normal NFC was observed: 18/36 (50%) before the course and (18/18) 100% after the course on one question, $p<0.001$. Improved identification of neoangiogenesis was observed, 18% pre versus 77% post, $p<0.001$.

Conclusion: NFC is an area of interest for rheumatology trainees and attendings. This curriculum was feasible and led to improved ability of learners to distinguish normal from abnormal and to recognize and describe SSc-specific NFC changes that identify validated patterns of disease progression. This curriculum also led to improved confidence in examining nailfold capillaries and increased use of this skill in rheumatologic consultation.

1992

Resident's Guide to Rheumatology Mobile Application: An International Needs Assessment. Evelyn V. Rozenblyum[1], Niraj Mistry[1], Tania Cellucci[2], Tina Martimianakis[3] and Ronald M. Laxer[4]. [1]University of Toronto, Toronto, ON, [2]McMaster Children's Hospital, Hamilton, ON, [3]Hospital for Sick Children, Toronto, ON, [4]The Hospital for Sick Children, University of Toronto, Toronto, ON.

Background/Purpose: "A Resident's Guide To Pediatric Rheumatology" (the Guide) is a widely accepted resource for pediatric rheumatologists and trainees. In preliminary assessments, uptake of the Guide was broader than intended and it was used by trainees to help with clinical decision-making, learning and teaching. Users of the Guide suggested that it be developed into a mobile application (app).

The Technology Acceptance Model (TAM) provides a framework to assess the perceived usefulness and ease of use of a tool to predict future acceptance and use.

Objectives: (1) To determine the International demand amongst pediatric professionals and current trainees for a mobile app format of the Guide.

(2) To determine user preferred features, functions, and format to be included in a mobile app using the TAM.

Methods: An electronic survey was developed and distributed to pediatric residents at SickKids hospital and to both faculty and trainee members of the international Pediatric Rheumatology list server. The survey included respondent demographics, perceived usefulness, perceived ease of use, and behavioural intention to use the app based on the TAM. Data were analyzed using descriptive statistics.

Results: The survey was distributed to 75 pediatric residents and 1132 members of the Pediatric Rheumatology listserver and 135 (12% response rate) completed the survey. The majority of respondents were rheumatologists (53%), while the remainder consisted of Fellows (17%), Pediatric Residents (16%), and other allied health professionals (5%). 93% owned a smartphone and 58% owned a tablet. Most had medically related apps (75%) compared to e-books (38%), but had similar use for each- one to several times per week for 1–15 minutes each time on average.

The most useful features of an app would be clinical pictures (e.g. skin rashes), radiology images (e.g. joint x-rays), and definitions of key terms. Least useful features were games and multiple-choice questions. Additional features included a searchable index and links to journal articles.

Looking at the TAM, the vast majority of respondents thought that the mobile app would enhance trainees' learning and teaching effectiveness. Greater than 80% of respondents consistently supported its perceived ease of use. 55% stated that they were likely to use the app often.

86% felt it was important for the app to be developed. If the app was not available for free, a majority (43%) of respondents were willing to pay for the app with a most willing to pay up to $5.00, and 10% willing to pay up to $10 for access to the app.

Conclusion: Development of the Guide app was well supported with adding features such as clinical photographs, radiology images, definitions and searchable index. TAM showed the intention to use the app in the future will be most determined by the perceived ease of use which was consistently high in the survey. Interestingly, users were willing to pay for the app if it was not free.

Future steps include a qualitative study ultilizing focus groups to assess the perceived functionality, usability, facilitators and barriers in using the Guide app prototype to create the most targeted, user friendly app.

1993

Does Psychological Safety Impact Learning Environments Among Rheumatology Fellows: Findings from Veterans Affairs Learners' Perception Survey. Joe Gamboa[1], Karina Marianne D. Torralba[1], Chau Nguyen[1], Grant W. Cannon[2], Samuel Baz[3] and T. Michael Kashner[4]. [1]Loma Linda University, Loma Linda, CA, [2]Salt Lake City VA and University of Utah, Salt Lake City, UT, [3]Loma Linda University Medical Center, Loma Linda, CA, [4]Office of Academic Affiliation, VA Loma Linda Healthcare System, Loma Linda, CA.

Does Psychological Safety Impact Learning Environments among Rheumatology Fellows: Findings from Veterans Affairs Learners' Perception Survey

Gamboa JR, Torralba KD, Nguyen CN, Cannon GW, Baz S, Kashner TM

Background/Purpose: Each year, over 35% of all U.S. residents will rotate through a U.S. Department of Veterans Affairs (VA) medical center as part of their clinical training. The VA Learners' Perceptions Survey (LPS) was created to assess VA's performance in furthering its professional education training mission.

Objective: The purpose of our research is to assess how Rheumatology fellows rate psychological safety (PS) and their experiences with VA faculty/preceptor, along with clinical, learning, working, and personal environments.

Methods: The LPS is a validated instrument that measures health professions trainee satisfaction with clinical programs. We explored data from 70 Rheumatology fellows who responded to the LPS from July 2011 to January 2014 at 29 VA medical centers across the US. PS was assessed on a 5-point Likert scale ("strongly agree," "agree," "neither," "disagree," and "strongly disagree") with: "members of the clinical team of which I was a part are able to bring up problems and tough issues." This question accounted for 85% of the cumulative variance with other question formats: "I feel free to question decisions or actions of those with more authority," and "It is safe to take a risk on this clinical team."

Results: There were 44 (67%) of 66 respondents who were female, 36 (52%) of 69 were international medical school graduates, 37 (53%) of 70 were PGY 4. Among all 70 fellows, 66 (94%) reported satisfaction with their clinical learning environment, 65 (93%) with preceptors, and 64 (91%) with working, 65 (93%) personal, 66 (94%) clinical, and 61 (87%) medical systems environments. Of the 70 fellows, 67 (96%) agreed or strongly agreed that members of the fellow's clinical team could bring up problems and tough issues. Among those strongly agreeing their VA experience was psychologically safe, 35(79%) of 45 also rated being very satisfied with their clinical learning (versus 8 (32%) of 25 otherwise, $x^2(4)=16.272$ $p=.003$); 35 (80%) of 44 with the preceptors (versus 31% otherwise, $x^2(4)=20.089$ $p<.001$); 36 (84%) of 43 with working (versus 26%, $x^2(4)=24.364$ $p<.001$), 38 (81%) of 47 personal (versus 21%, $x^2(4)=22.993$ $p<.001$), 36 (82%) of 44 clinical environment (versus 27%, $x^2(3)=21.145$ $p<.001$), and 36 (84%) of 43 medical systems (versus 20%, $x^2(3)=27.044$ $p<.001$.

Conclusion: Our data suggests that Rheumatology fellows were satisfied with their VA clinical learning experience, and that psychological safety was strongly associated with the fellow's satisfaction of their VA learning, working, and clinical training environments.

Table 1. Overall ratings at VA facility by Rheumatology fellows 2001–2014 across major domains in LPS survey

	Very Satisfied		Somewhat satisfied		Not Satisfied		
Domain	Total N	N (%) strongly psychologically safe	Total N	N (%) strongly psychologically safe	Total N	N (%) strongly psychologically safe	x^2
Learning environment	45	35(78%)	21	8 (38%)	4	0 (0%)	$x^2(4)=16.3$, $p=0.003$
Preceptors	44	35 (80%)	21	7 (33%)	5	1 (20%)	$x^2(4)=20.1$, $p<.001$
Clinical environment	44	36 (82%)	22	6 (27%)	4	4 (33%)	$x^2(3)=21.145$, $p=0.000$
Physical environment	37	32 (87%)	28	11 (39%)	4	0 (0%)	$x^2(2)=22.144$, $p=0.000$
Working environment	43	36 (84%)	21	6 (29%)	6	1 (17%)	$x^2(4)=24.364$, $p=0.000$
Personal experience	47	28 (81%)	18	4 (22%)	5	1 (20%)	$x^2(3)=22.993$, $p=0.000$
Timeliness of staff and services	40	35 (88%)	24	7 (29%)	6	1 (17%)	$x^2(4)=27.443$, $p=0.000$
Quality of staff and services	41	31 (85%)	28	8 (29%)	1	0 (0.0%)	$x^2(2)=24.266$, $p=0.000$
System and process in dealing with medical errors	43	36 (84%)	18	4 (22%)	7	1 (14%)	$x^2(3)=27.044$, $p=0.000$

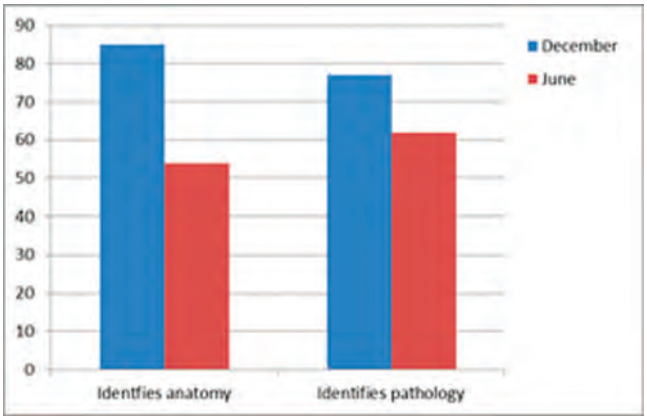
1994

Incorporation of Musculoskeletal Ultrasound Curriculum and 6-Month Assessment of Knowledge Retention into the 2nd Year of Medical Student Training. Kiley Toder[1], William Rennie[2], Ruth L. Marder[3] and Maria L. Barilla-LaBarca[4]. [1]Northshore LIJ, Great Neck, NY, [2]Hofstra North Shore LIJ School of Medicine, Hempstead, NY, [3]North Shore LIJ Health System, Great Neck, NY, [4]Hofstra North Shore LIJ Health System, Great Neck, NY.

Background/Purpose: Few medical schools offer a formal curriculum in musculoskeletal ultrasound (MSUS); the success of such a program in terms of skills and knowledge acquisition and durability of response has not been clearly documented. The purpose of this study was to assess second year students' ability to identify the presence of pre-loaded suprapatellar effusions using a cadaver model following a formal MSUS curriculum and assess their skill and knowledge retention rate at 6 months.

Methods: As part of a longitudinal US curriculum at Hofstra NSLIJ SOM, 3 sessions were reserved for MSUS during the 2nd year of study. There were pre-assigned readings prior to each session. The 1st session reviewed probe selection, patient positioning, and recognition of tissues (tendon, muscle, bone, cartilage, etc). The 2nd session demonstrated normal and pathologic knee anatomy on a cadaveric model. Multiple choice question style pre-assessment was given prior to this session. In the 3rd session, students performed a standard knee US exam with the guidance of MSUS-trained faculty. The summative assessment evaluated the students' ability to perform a standard knee exam, label knee anatomy on acquired images, and identify a suprapatellar "effusion" in a cadaver preinjected with a gelatin mixture. This exercise was repeated 6 months later in a smaller, voluntary group of students to assess retention of skills and knowledge.

Results: In the pre-assessment 22/57 (38.5%) students correctly identified the US image with a knee effusion although only 2 students could label it correctly compared to 37/57 (67%) in the summative assessment ($p = .003$ correct answer and $p < .0001$ labeling). Thirteen students volunteered to participate in the 6 month extension; they did not prepare in advance nor have significant opportunities for MSK US in the intervening months. Eleven of these students (84.6%) had identified the anatomy and 10 (76.9%) had identified the effusion during the summative assessment in December. In June, a decrease in both knowledge (table) and skills (84.6% of images were of poor quality or taken in non-standard locations) was found although the majority (61.5%) was still able to identify the pathology.



Conclusion: Following a formal MSUS curriculum, the majority of the 2nd year medical students were able to demonstrate their skill in the acquisition of images, distinguish pathologic from normal findings, and identify knee structures by US. However the retention rate for quality images and identifying anatomical structures decreased at 6 months. Yet, a majority of students identified fluid and bone in the knee that helped to obtain their respective images and assess the location and nature of the effusion. Thus, although anatomy would have to be further reinforced, student's identification of effusions was durable at 6 months.

1995

Design and Implementation of a Clinical Teaching Tool for Approach to Children with Suspected New Rheumatologic Diagnosis. Kristen Hayward and Jennifer Hrachovec. Seattle Children's Hospital, Seattle, WA.

Background/Purpose: Approximately 1 in 1000 children suffer from a rheumatologic disorder. Despite the relative frequency of these conditions, there is a shortage of pediatric rheumatologists and many children with rheumatologic conditions will present to primary care providers for initial evaluation and management. Unfortunately, there is strong evidence that graduating pediatric residents are ill equipped to recognize and treat these children. In the University of Washington Pediatric Residency Program, exposure to rheumatology occurs through a month long, largely inpatient rotation. The inpatient focus presents an educational challenge to provide residents with fundamental concepts involved in the care of a primarily ambulatory patient population.

Methods: A literature search was conducted to identify previous relevant work. Although there are existing curricula for pediatric rheumatology electives, no curricula were identified to specifically address inpatient based pediatric rheumatology education. A clinical teaching tool was developed based on types of rheumatology admissions commonly available for pediatric resident involvement, as well as a desire to teach broad based concepts involved in evaluation of rheumatologic disorders. An evidence-based literature search identified supporting evidence for relevant clinical questions. The tool consists of a clinical pathway activated by an electronic medical record (EMR) based orderset which guides users through initial assessment and treatment considerations. The orderset is linked to a visual algorithm outlining the recommended approach. An accompanying web-based educational module has been developed along with an assessment tool designed to gauge changes in learner's knowledge and attitudes after completion of the module. Initial content validity for the assessment tool was developed through peer review by additional pediatric rheumatology providers at our institution.

Results: The Rheumatology New Diagnosis Pathway was implemented in Nov. 2011. The web-based educational module was added in March 2014. EMR derived utilization data reflects high acceptance from pediatric residents with an average of 10 patients on pathway per fiscal quarter (range 2–18). Informal feedback has been positive in terms of facilitation of order entry and appreciation of general concepts presented.

Conclusion: Given the scarcity of pediatric rheumatologists, it is imperative to provide pediatric residents with quality education about rheumatologic conditions. Given the constraints of current residency experiences, novel curricular developments are required to address this educational need. This teaching tool addresses the management of children admitted to the rheumatology service. By focusing on broad concepts involved in initial diagnosis and treatment of childhood rheumatologic disorders, this teaching tool offers a foundational model which can be translated to future patient encounters. Additional work is planned to assess the impact of the tool on trainee knowledge of and comfort with evaluation of children with rheumatologic conditions as well as potential for dissemination to additional institutions.

1996

Improvement in Basic Bone Health Knowledge Among VA Primary Care Practitioners during a Focused Musculoskeletal Mini-Residency. Mathilde Pioro[1], Nancy Fisher[1], Marissa Grotzke[2], Grant W. Cannon[3] and Michael Battistone[4]. [1]Cleveland Veterans Affairs Medical Center, Cleveland, OH, [2]Salt Lake CIty Veterans Affairs Medical Center, Salt Lake CIty, UT, [3]Salt Lake City VA and University of Utah, Salt Lake City, UT, [4]University of Utah Health Sciences Center, Salt Lake City, UT.

Background/Purpose: Osteopenia and osteoporosis are common yet underrecognized in the veteran population.

Methods: We tested basic bone health related knowledge among Veterans Affairs (VA) primary care providers (PCPs) before and after a 3 day intensive musculoskeletal mini-residency. Principles and practice of bone health were reviewed during 6 hours of small group sessions led by a practicing VA endocrinologist with expertise in osteoporosis. Topics included dietary calcium, vitamin D supplementation, and screening for osteoporosis. Self-reported satisfaction with the program was evaluated at the conclusion. An 8-item medical

knowledge examination was administered at the beginning of the program (pre-test) and at the end (post-test). The post-test composite score was compared to the pre-test composite score for all participants.

Results: 17 full-time PCPs participated. 71% were female, with mean age 48.3 years (range 27–58), and mean number of years in practice 14.6 (range 1–23). 47% were physicians, 41% nurse practitioners, and 12% physician assistants. 79% practiced in community-based outpatient clinics and 29% at the associated tertiary care referral facility (Cleveland VA Medical Center).

Question	% correct PRE	% correct POST
Screening age for osteoporosis in men in the absence of risk factors (70 years)	25%	94%
Screening age for osteoporosis in women in the absence of risk factors (65 years)	47%	88%
Content of calcium in one cup of milk (300mg)	24%	31%
Recommended daily vitamin D intake for men over 70 years (1200mg)	65%	53%
Serum 25 (OH) D3 level minimally sufficient for bone health (30 ng/ml)	73%	94%
Identification of suitable candidates for FRAX screening algorithm	59%	71%
Significant level for 10 year probability of major hip fracture per FRAX algorithm (3%)	20%	47%
Significant level for 10 year probability of major osteoporotic fracture per FRAX algorithm (20%)	14%	35%

FRAX *www.shef.ac.uk/FRAX/tool.aspx*

The program evaluation showed 100% very satisfied with the training experience and over 95% reporting the program as applicable to their clinical practice. 77% of participants improved their overall composite bone health knowledge score at the end of the program. Non-MDs had better baseline knowledge than MDs for recommended screening age for osteoporosis in women and recommended daily vitamin D intake. Areas of persistent knowledge deficit at the end of the residency included dietary calcium content and interpretation of the FRAX osteoporosis screening algorithm.

Conclusion: Participants demonstrated an increase in overall bone health knowledge after a mini-residency program. Not all areas improved. Further educational efforts should be directed to VA PCPs to further address methods to improve basic identification and treatment of osteopenia and osteoporosis. Particular emphasis should be directed to the use and interpretation of the FRAX screening algorithm.

1997

Structured Integrative Rheumatology Modules (SIRM). Sonia Manocha, Ingrid Cobb, Sobia Hassan, Stanley P Ballou and Marina N. Magrey. Case Western Reserve University, MetroHealth Medical Center, Cleveland, OH.

Background/Purpose: Medical students and internal medicine residents frequently rotate through the division of rheumatology, but there have been inconsistencies in specialty-based training. We hypothesized that the development of a structured curriculum is an effective and consistent method of improving students' and residents' core content knowledge of rheumatology during the elective. Our aim was to develop a comprehensive curriculum with structured, appropriate and timely information.

Methods: Utilizing rheumatology textbooks, relevant journal articles and educational websites, such as the American College of Rheumatology (ACR) website (Rheumatology Image Bank, Clinical Practice Guidelines and Rheum2Learn), we created a series of modules that address key learning objectives in rheumatology. The modules were organized into a series of interactive lectures for one hour three times a week. In addition to the lectures, rotators were required to attend clinic and give a presentation at the completion of their rotation.

To measure the effectiveness of this structured, module-based curriculum, we created a 25 question multiple-choice exam that was administered at the start of the rotation (pre-test) and again at completion of the rotation (post-test). Both pre-test and post-tests were scored together at the end of the rotation.

Pre and post-test results were analyzed using a two-tailed paired T-test.

Rotators were given a survey at the completion of their elective. It was comprised of questions relative to the teaching sessions as well as open-ended questions related to further improvement of the curriculum.

Results: Twenty-two rotators completed both pre-test and post-test examinations and were included in the data analysis. Rotators that did not complete both pre-test and post-test were excluded.

The mean post-test score (21.77, SD 3.23) showed significant improvement from the mean pre-test score (17.59, SD 3.66) at a p-value of 0.00024 as shown in figure 1.

In the final survey, rotators consistently expressed that the dedicated teaching sessions were a helpful addition to the rotation. They also suggested that we continue to expand and include more topics.

Conclusion: A comprehensive structured curriculum with consistent information for rheumatology helps to improve core content knowledge of rheumatic diseases and aids in consolidation of the clinical experience for medical students and residents during their rheumatology elective.

pGALS Training Increases Kenyan Pediatric Residents' Confidence in Performing a Musculoskeletal Exam. Tanya Glushko[1], Ines Colmegna[2], Helen Foster[3], Sasha Bernatsky[1], Carol Hitchon[4] and Rosie Scuccimarri[1]. [1]McGill University, Montreal, QC, [2]McGill University - Royal Victoria Hospital, Montreal, QC, [3]Newcastle University, Newcastle, United Kingdom, [4]University of Manitoba, Winnipeg, MB.

Background/Purpose: Musculoskeletal (MSK) manifestations are a common reason for outpatient consults accounting for 6–9% of pediatric clinic visits in developed countries. Patients are initially evaluated by primary care practitioners, general pediatricians and emergency physicians. It has been suggested that low confidence in pediatric MSK assessment is a key factor contributing to diagnostic delays and poor outcomes.

pGALS (pediatric Gait, Arms, Legs, Spine) is a simple tool for MSK assessment, which facilitates early recognition and prompt referral of patients with joint problems. When performed by non-pediatric specialists and compared with pediatric rheumatologists, pGALS has been shown to have excellent sensitivity (97–100%) and specificity (98–100%) for detecting abnormal joints.

We undertook this study to evaluate pediatric residents' confidence in conducting an MSK evaluation and the effect that a pGALS training session had on enhancing this perception.

Methods: Pediatric residents working at the two training centers in Nairobi, Kenya (Aga Khan University Hospital and Kenyatta National Hospital) participated in a 60 minute hands-on session on pGALS given by a pediatric rheumatologist. Written anonymized questionnaires performed prior and post training assessed the participants' level of confidence in examining the MSK system.

Results: Sixteen residents with an average of 2.9 ± 0.8 years of training completed the survey. Ten out of 16 (63%%) reported previous MSK exam training. None of the participants had been trained in pGALS before. A third of residents (31%) were not comfortable examining the MSK system, while the remaining felt comfortable in some aspects only. The level of confidence in examining the MSK system was significantly lower than that for all of the following systems: cardiovascular, respiratory, abdominal and neurological ($p<0.005$).

Ninety four percent of the residents reported increased level of confidence ($p<0.001$) following the pGALS training session. Most physicians considered the training session extremely beneficial (75%) or very beneficial (25%). Ten residents (63%) reported planning to use this tool for all patient visits, 4 (25%) in patients with minimal joint complaints and 2 (12%) in those with

obvious joint concerns. In their clinical setting, the residents thought that office posters (63%) and pocket cards (63%) would be more useful than web-based video demonstrations (25%) to facilitate the use of the pGALS in clinical practice. They felt that the best way to increase confidence in the MSK exam was with one-on-one bedside coaching (81%) rather than web-based video demonstrations (50%) and workshops (44%).

Conclusion: pGALS training together with routine reminders to facilitate pGALS incorporation into the regular exam translates into increased physician confidence, which may lead to earlier recognition of rheumatic diseases in children. pGALS teaching materials may need to be tailored to the clinical setting that they will be used in.

1999

Internal Medicine Resident Confidence in Rheumatologic and Musculoskeletal Diseases: A Needs Assessment Survey. Cristina Savasta, Deborah Korenstein and Yousaf Ali. Icahn School of Medicine at Mount Sinai, New York, NY.

Background/Purpose: Small studies have demonstrated a lack of confidence and competency in the areas of rheumatology and musculoskeletal diseases among internal medicine physicians at various levels of training. This can lead to a delay in the diagnosis of rheumatologic disease and may result in suboptimal patient outcomes and increased morbidity. Increasing time devoted to teaching the subject has been shown to increase resident confidence, suggesting that an intervention could have a significant impact on residents' ability to diagnose and manage rheumatologic diseases. We aim to assess resident confidence in rheumatologic and musculoskeletal topics and skills in order to evaluate the need for an educational intervention.

Methods: We emailed a survey to the 137 residents in the Department of Medicine at a large, urban university hospital. The survey included 6 questions on a 5-point Likert scale measuring self-assessed knowledge of rheumatology topics and confidence in musculoskeletal exam skills. Questions regarding non-rheumatologic topics were included to control for increased confidence across post-graduate years related solely to increased experience.

Results: Seventy-one responses were collected for a response rate of 51.8%. Resident confidence in rheumatology was generally low. Fewer than 60% of respondents agreed or strongly agreed that they were confident diagnosing and managing musculoskeletal and joint diseases. Fewer than 50% of respondents reported confidence in skills such as interpreting rheumatologic serologies, performing a musculoskeletal exam or performing a joint aspiration or injection. This is in contrast to the more than 77% of respondents who reported confidence in diagnosing and managing hyperthyroidism or coronary artery disease. Similarly, more than 73% of respondents reported confidence in interpreting electrocardiograms or thyroid function tests. While confidence related to non-musculoskeletal diseases tended to improve from first to third year of training, confidence related to musculoskeletal diseases tended to remain poor despite increased experience. Respondents reported interest in receiving further training in musculoskeletal topics in which they lacked confidence.

Conclusion: Internal Medicine residents at our hospital have low self-assessed knowledge and skills in the areas of rheumatologic and musculoskeletal diseases. We believe our hospital is representative of residency training in the United States, and a dedicated educational curriculum to fill these gaps in training could improve resident confidence and knowledge. Ultimately, we hope this will impact patient care and improve rheumatologic outcomes.

Percentage of respondents who agreed or strongly agreed they were confident in the following topics or skills:

	Overall (n=71)	PGY*-1 (n=21)	PGY-2 (n=27)	PGY-3 (n=23)
Crystal-induced arthritis	59.2%	57.1%	63%	56.5%
Infectious arthritis	40.8%	47.6%	33.3%	43.5%
Autoimmune disorders	32.9%	28.6%	33.3%	36.4%
Spondyloarthropathies	7.0%	4.8%	7.4%	8.7%
Interpreting rheumatologic serologies	42.3%	38.1%	29.6%	60.9%
Musculoskeletal/joint physical exam	29.6%	23.8%	37%	26%
Joint injection/aspiration	9.9%	9.5%	3.7%	17.4%

*PGY: Post graduate year

2000

The Effect of a Rheumatology Ambulatory Rotation for Medical Residents on Documentation of Musculoskeletal Complaints. Deana M. Lazaro[1], David Ozeri[2], Jenna Checchi Gibilaro[2] and Deena Hassuna[3]. [1]Brooklyn VA, Brooklyn, NY, [2]SUNY Downstate Medical Center, Brooklyn, NY, [3]SUNY Downstate Medical Center, Brooklyn, Algeria.

Background/Purpose: Musculoskeletal (MSK) complaints are commonly the reason for visits to Primary Care offices. Therefore, it is important to teach residents to recognize and manage them. Passive learning techniques such as reading may improve knowledge but do not necessarily teach residents to synthesize and apply that knowledge in a clinical encounter. The purpose of this study is to determine if an enriched rheumatology curriculum, using active learning techniques, leads to better assessment and management of MSK complaints in a primary care setting among medical residents.

Methods: This pilot study is a blinded, retrospective, case-controlled trial comparing residents who participated in a rheumatology elective in comparison to residents who had passive learning about rheumatology. Medical residents were assigned to rheumatology or another subspecialty elective. All residents were assigned rheumatology reading in preparation for a post-test and objective structured clinical examination (OSCE). Rheumatology elective residents were taught using active learning techniques such as arthrocentesis simulation and small group teaching for MSK examination. They attended rheumatology clinic for an average of 3 sessions weekly for 4 weeks. The other residents viewed videos on arthrocentesis and MSK physical examination.

Fifty medical records from Primary Care continuity clinic were analyzed for evaluation of MSK complaints. The selected outpatient records had MSK-related chief complaints and were completed within 18 months from the writers' rheumatology teaching in both groups. The performance of the residents was assessed using a predetermined grading system by two blinded evaluators. Evaluators reviewed specifics regarding history (10 points), physical examination (5 points), assessment (2 points) and management (2 points) for a possible total of 19 points. Evaluators also gave each record a summary score for documentation of history, physical examination, assessment or plan (possible total of 4 points) regarding the chief complaint.

Results: Results are displayed in Table 1. A 2-tailed T-test was performed comparing the total scores by evaluator 1 and evaluator 2; p values were 0.14 and 0.28 respectively.

Table 1 Mean scores with +/− standard deviation for chart review by evaluator 1 and evaluator 2

	Evaluator 1		Evaluator 2	
Resident assignment	**Rheumatology**	**Non-Rheum**	**Rheumatology**	**Non-Rheum**
History	4.2 (2.0)	4.7 (2.0)	4.3 (2.1)	4.4 (2.4)
Exam	1.2 (1.3)	1.8 (1.1)	1.2 (1.2)	1.9 (1.0)
Assessment	1.8 (0.9)	1.4 (0.9)	0.8 (0.6)	1.0 (0.7)
Management	1.8 (0.5)	1.6 (0.7)	1.7 (0.5)	1.6 (0.6)
Total	8.1 (3.2)	9.5 (3.3)	8.0 (3.1)	8.9 (3.3)
Summary score	3.2 (0.7)	3.6 (0.7)	3.2 (1.0)	3.5 (0.8)

Conclusion: We found no significant difference in documentation of medical care for MSK complaints between medical residents who had a rheumatology elective with active learning and medical residents who had passive learning for rheumatology. These results indicate that passive learning through reading and videos is as effective as small group teaching, at least for 4 week long elective experiences. Improvement in outcomes may require reinforcement over a longer period of time and in different clinical settings.

The Musculoskeletal Mini-Residency Collaborative Network: A National Department of Veterans Affairs Interdisciplinary and Interprofessional Educational Innovation for Primary Care Providers. Michael J. Battistone[1], Andrea M. Barker[1], Marissa P. Grotzke[1], J. Peter Beck[1], Anna Quan[2], Michal Hose[2], Victoria Seligman[3], Roneka Ravenell[4], Pushpa Pavuluri[4], W. Neal Roberts[4], Mathilde Pioro[5], Nancy Fisher[5], Vanessa Osting[6], Betty Prihar[6], Joanne Hackman[7], Susan Kirsh[7] and Grant W. Cannon[1]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]San Diego VA, San Diego, CA, [3]Denver VA Medical Center, Denver, CO, [4]Louisville VA,

Louisville, KY, [5]Cleveland VA, Cleveland, OH, [6]Tampa VA, Tampa, FL, [7]Office of Specialty Care Transformation, Patient Care Services, VHA Central Office, Washington, DC.

Background/Purpose: To address the problem of insufficient training in Musculoskeletal (MSK) diseases by practicing primary care providers (PCPs), the Veterans Affairs (VA) Office of Specialty Care Transformation provided pilot funding through a competitive, peer-reviewed process, to develop and support a "MSK Mini-Residency" to train PCPs in evaluation and management of common MSK diseases.

Methods: The 3 day MSK mini-residency curriculum intersperses didactic lectures with small group workshops, as well as case based interactive small-group practice sessions and technology-enhanced simulation (see full schedule, Table 1). Participants' competency in performing and interpreting the physical examination of the shoulder and knee is evaluated by a 2-station Objective Structured Clinical Examination (OSCE), to ensure sufficient preparation for assessing patients in clinic. Course evaluation was conducted using the Kirkpatrick's model of assessing educational effectiveness, and Phillip's concept of Return on Investment. Table 1

Results: From 2012–2014, the 3-day MSK Mini-Residency course has been presented at 12 VA medical centers, serving catchment areas centered in Los Angeles, San Francisco, Denver, Omaha, Louisville, Cleveland, Philadelphia, Tampa, Orlando, and Boston. Table 2 shows the distribution of participants by professional credential, as well as their pre- and post-course self-assessments of their ability and preparation to evaluate and manage shoulder and knee pain in their clinics.

Table 2

MSK Mini-Residency Participants	**Total**	**Physician**	**NP**	**PA**	**Unspecified**
Number, %	241 (100)	148 (61)	75 (32)	15 (6)	3 (1)
			Pre Course		**Post Course**
Able to evaluate and manage shoulder complaints			25%		99%
Able to evaluate and manage knee complaints			31%		98%
Prepared to aspirate/inject knee or subacromial space			29%		66%

Post course competency in examining the shoulder and knee, and in reporting, interpreting, and managing the cases using a framework of high-value care, was confirmed with 2-station OSCE. Course evaluations were extremely positive across all sites: over 95% of participants anticipate that the training will impact their job performance and would recommend the course to others.

Conclusions: The MSK Mini-Residency is an effective model for training and evaluating primary care providers in the diagnosis and management of common musculoskeletal diseases.

2002

Implementation of a Collaborative Rheumatology and Physiatry Musculoskeletal Ultrasound Training Program. Minna J. Kohler[1], Chloe Slocum[2], Imran Siddiqui[2], Kevin O'Connor[2] and Marcy B. Bolster[1]. [1]Massachusetts General Hospital/Harvard Medical School, Boston, MA, [2]Spaulding Rehabilitation Hospital/Harvard Medical School, Charlestown, MA.

Background/Purpose: Rheumatology musculoskeletal ultrasound (MUS) certification has been established and MUS teaching is rapidly being incorporated into U.S. rheumatology fellowship training programs. Similarly, MUS use by physiatrists is growing, and exposure to MUS and rheumatology teaching is now mandatory in physical medicine and rehabilitation (PM&R) residency programs. At this time, no standardized rheumatology MUS curriculum is required, but competency criteria are currently under discussion.

Methods: We describe the implementation of a novel, collaborative rheumatology/physiatry MUS training program at a single academic center. The program was developed by a rheumatology MUS expert in conjunction with the program directors of both rheumatology fellowship and PM&R residency to adequately expose fellows to MUS, and fulfill both rheumatology and MUS training requirements for residents. A self-assessment survey of the participating fellows and residents was obtained post-implementation, using a 3-point Likert formatted scale (1=no knowledge to 3= extensive knowledge).

Results: All 1st year rheumatology fellows (n=2) were required to participate in a twice monthly ½ day faculty-mentored, MUS clinic over one year. For 2nd year rheumatology fellows with a demonstrated interest in MUS (n=1), additional training included: longitudinal, weekly, faculty-mentored MUS clinics, participation in the USSONAR program, and MUS research. All PGY-3 PM&R residents (n=9) were required to participate in a 1-month rotation of faculty-mentored MUS clinics, 3 days per week. All rheumatology fellows and PM&R residents (n=12) participated in an introductory MUS lecture to review basic knobology, image acquisition, and reasonable use of MUS. Every other month, hands-on sessions reviewed anatomy and scanning protocols. Both groups had access to US equipment for self-directed learning. In the clinic, fellows/residents evaluated patients referred for musculoskeletal pain in a one-stop approach where MUS and guided injections may be performed, as indicated. All fellows and residents completed the survey (Table 1). Post-curriculum, 100% of participants felt they had adequate exposure to MUS and adequate MUS knowledge/ability. Ten of the 12 (84%) trainees participated in self-directed learning. The average range of MUS exams performed by all participants was 11–20; MUS-injections also ranged from 11–20. Six of the 12 trainees (50%) participated in MUS research activities.

Conclusion: Implementation of a collaborative MUS training program is beneficial to the education of both rheumatology fellows and PM&R residents. Improvement in MUS knowledge and ability was shown in both groups. A combined program can adequately fulfill the educational and research needs for both specialties, especially when the number of trained MUS instructors may be limited.

Table 1. Post-Implementation Survey (3-point Likert Scale)

Fellow/Resident Self-Assessment	**Pre-curriculum (mean)**	**Post-curriculum (mean)**
Basic MUS anatomy knowledge	1.36	2.55
Level of ability to optimally image structures	1.27	2.36
Level of ability to interpret MUS images	1.18	2.09
Ability to perform MUS-guided procedures	1.18	2.27
Understanding of indications for reasonable use of MUS	1.45	2.33

2003

Pilot Study of a Web-Based Module on Gout. Bernadette Siaton[1], Elizabeth Clayton[2], Alexandra Kueider[3] and Matthew Rietschel[4]. [1]University of Maryland Medical System, Baltimore, MD, [2]University of Maryland, Baltimore, MD, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [4]University of Maryland School of Nursing, Baltimore, MD.

Background/Purpose: The majority of internal medicine trainees complete residency with little exposure to rheumatology. We aimed to create a validated, self-directed, web-based, core curriculum in rheumatology for residents. The first module focused on gout. We also aimed to assess the efficacy of this educational product utilizing the script concordance testing (SCT) method. SCT assesses clinical data interpretation and decision making.

Methods: We obtained IRB exemption to perform this study that included internal medicine trainees at the University of Maryland Medical Center. Pre-test and post-test questions were examined for item validity. Pre- and post-test scores were compared to the scores of the expert panel, which was made up of 2 rheumatology fellows, 9 academic rheumatologists, and 1 community rheumatologist. Baseline knowledge was assessed via a pre-test on the Blackboard learning management system, followed by the educational intervention, an interactive didactic presentation on gout. The module included gout pathophysiology, clinical presentation, and therapeutic management. Immediate post-testing was performed. An ANOVA was used to compare trainee and expert groups as well as pre- and post-test scores. Cronbach's alpha was used to calculate test reliability. An effect size was calculated using Cohen's d.

Results: Ten trainees completed paired pre-and post-tests for analysis. The 20-case SCT achieved high reliability (Cronbach alpha for all 20 cases $>$ 0.75). At baseline, the trainees' average SCT score was 32 points ($M=32.45$, $SD=1.99$); whereas the experts' average SCT score was 40 points ($M=40.65$, $SD=1.72$). After the didactics, trainees' SCT scores increased by an average of 2.83 points $F(1, 18) = 9.33$; ($p<.01$). Cohen's d showed a strong effect size ($d=1.13$). Expert SCT scores were an average of 8.2 points ($SD = 0.81$) higher than trainee pre-test scores. Expert SCT scores were an average of 5.4 ($SD = 0.84$) points higher than trainee post-test scores. Both of these differences were statistically significant ($p<.0001$).

Conclusion: Trainee test scores significantly increased after the educational intervention in this pilot study. Expert SCT scores were higher at baseline and remained higher after the didactics, which lends support to the construct validity of the tool as the experts had higher clinical competence. The effect of the educational intervention will be tested on a larger group of internal medicine trainees. Future plans include subgroup analysis by post-graduate year, implementation of self-efficacy evaluations, and possible re-testing at 6 or 12 month intervals to assess durability of knowledge. Additional modules for the core curriculum will be developed.

2004

Osteoporosis Screening and Fracture Risk Assessment Tool Usage Among House Staff. Jordan Brodsky[1], Meghan Greenfield[2] and Erin Patton[2]. [1]Albert Einstein College of Medicine, Woodmere, NY, [2]Beth Israel Medical Center, New York, NY.

Background/Purpose: Despite increased awareness of the magnitude and consequences of osteoporosis and the availability of recommendations for screening and treatment by multiple organizations, osteoporosis is still under diagnosed and inadequately managed in the United States. Identifying patients at risk, making a timely diagnosis, implementing prevention measures and initiating pharmacologic therapy for appropriate patients can all help to minimize fracture risk. Academic hospitals with resident-led outpatient primary care providers are an area where there may be under-utilization of evidence-based fracture risk assessment tools, such as the Fracture Risk Assessment Tool (FRAX) score.

Methods: House staff of the Internal Medicine department at Beth Israel Medical Center where given an anonymous questionnaire. The goal was to assess the resident's knowledge of current practice guidelines and recommendations for osteoporosis and the utilization of the FRAX score.

Results: 48 residents of Internal Medicine, levels PGY 1, 2 and 3, filled out the questionnaire. 63% of residents estimated their female patient population was greater than 65 years old and 31% of their male patient population was greater than 70 years old. 77% of residents performed age appropriate DEXA scans on their patients. 58% of residents had knowledge of what the FRAX score was and 48% of resident knew the appropriate use in patient care. 62% used the FRAX score to identify patients who met criteria for the initiation of treatment for osteoporosis. 29% could identify the modifiable risk factors and 31% identified the non modifiable risk factors which calculate the FRAX score. 33% of residents said they would use the FRAX score on woman less than 65 years old. 79% of residents wanted to receive more information on the FRAX score and its appropriate applications.

Conclusion: Appropriate identification and prevention are imperative to reducing the risk of osteoporosis and osteoporosis-related fractures in individuals. Our study concluded that Internal Medicine residents at one academic medical center are following the current guidelines for screening for osteoporosis with DEXA scans, however, the use of the FRAX score for the identification of patients at high risk for fracture requiring the initiation of treatment for osteoporosis, is highly underutilized. There was also a discrepancy between the resident's knowledge of the FRAX score and its application in clinical practice. Further training and education regarding osteoporosis screening and the use of the FRAX score in a resident led outpatient primary care setting will be beneficial to resident providers and their patients.

2005

Multimedia Patient Education Tool for Patients with Osteoporosis. Maria A. Lopez-Olivo[1], Aparna Ingleshwar[1], Robert Volk[1], Andrea Barbo[1], Maria Jibaja-Weiss[2], Heather Lin[1] and Maria E. Suarez-Almazor[1]. [1]The University of Texas, MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX.

Background/Purpose: Patient education materials incorporating video modelling can be effective in improving patients' outcomes. We conducted a randomized control trial to test the efficacy of a multimedia-patient education tool (MM-PtET) for patients with osteoporosis, including storylines and narratives.

Methods: 224 patients were recruited from three outpatient clinic systems and through advertisement. Inclusion criteria were: (i) diagnosis of osteoporosis/osteopenia, (ii) female gender, (iii) age $\geq$50 years (iv) at least 3 years post-menopausal, (v) adequate cognitive status, and (vi) ability to communicate in English or Spanish language. Participants were given materials to review based on randomization (Intervention=MM-PtET; Control=written booklet with same content as MM-PtET). All participants completed pre-post self-report questionnaires. Primary outcome measures included: a) Disease knowledge and, b) Decisional Conflict Scale- "Informed" and "Values clarity" scales. Secondary outcomes included: a) Ottawa Acceptability Instrument and b) Evaluation of the educational tool. Baseline demographic information and health literacy level were also obtained. Mean differences in knowledge scores (pre-post randomization) and between group differences in the Ottawa Acceptability and tool evaluation measures were calculated.

Results: 111 patients were randomly allocated to the MM-PtET intervention and 113 to the control booklet. Mean age of participants was 64 ± 9 years and 82% had adequate health literacy. Knowledge scores significantly increased in both groups, post randomization (MM-PtET: 9.5 ± 4.2 vs 12.8 ± 3.2 and Control: 9.1 ± 4.2 vs 12.5 ± 3.2; $p<0.05$ for both groups). Post randomization, participants in both groups had significantly lower "Informed" scores (pre vs post; Intervention: 55.3 ± 38.7 vs 15.8 ± 25.6 and Control: 54.0 ± 38.1 vs 17.7 ± 30.8; $p<0.05$ for both groups; lower scores=more informed) and "Values clarity" scores (pre vs post; Intervention: 49.8 ± 40.9 vs 16.9 ± 30.6 and Control: 55.1 ± 40.8 vs 18.6 ± 29.3; $p<0.05$ for both groups; lower scores=more values clarity). Compared to controls, participants in the MM-PtET group rated better explanation of the medical facts ($p=0.03$), and the understanding of the potential side effects ($p=0.03$). Similarly, when asked about the balance of the material (slanted towards self-care/lifestyle options, slanted toward medical therapies, balanced), greater number of intervention group participants found the material to be "balanced" ($p=0.004$).

Conclusion: The results of our study indicate that, when compared to standard written materials, the MM-PtET was better rated and was comparable in improving knowledge in women with osteopenia/osteoporosis.

Multiple Joint Osteoarthritis: Patient Preferences for a Generic Exercise and Self-Management Programme. Nicola E. Walsh[1], Geeta Patel[2] and Rachael Gooberman-Hill[3]. [1]University of the West of England Bristol, Bristol, United Kingdom, [2]University of the West of England, Bristol, Bristol, United Kingdom, [3]University of Bristol, Bristol, United Kingdom.

Background/Purpose: In the UK approximately 1.75 million people age 45 and over are diagnosed with multiple, peripheral joint osteoarthritis (OA), a figure that would increase significantly with the inclusion of degenerative spinal pain. Exercise and self-management are recommended core treatment strategies for OA, but evidence is generally based on single site presentations and interventions. In clinical practice patients frequently consult with either pain in more than one joint, or re-consult over time when symptoms manifest in other joints. We developed a 6-week group programme to Facilitate Activity and Self-management in Arthritis (FASA) for people with multisite OA of the hip, knee and/or lower back. The aim of FASA was to teach an exercise programme for these joints, and provide education regarding multiple joint pain management. This qualitative study, embedded within a randomised controlled trial (RCT), presents data from a focus group analysis to determine perceived benefits and acceptability of the intervention.

Methods: Nine semi-structured, focus group interviews facilitated by a researcher independent of the RCT were conducted with patients with OA who had participated in the FASA programme, and had completed their primary end point assessment at 6 months post-intervention. The interviews were audio-recorded, transcribed and analysed using thematic analysis. A second researcher independently coded a selection of transcripts to establish accuracy of interpretation.

Results: Forty-five participants (28 female), age 53–85 years (mean=68 years) with multisite OA joint pain participated in the focus groups. Thematic analysis demonstrated that individuals reported benefits from gaining confidence and knowledge of how to self-manage pain in other joints should it manifest. They also found it beneficial to undertake exercises that took into account their multisite presentations. Gaining insight of how others coped with their pain, irrespective of site, was also considered positive; participants also talked about valuing the shared pain experience. Whilst the majority of participants valued the more general joint pain approach, three people with lower back pain found it difficult to relate to those who did not experience back pain, and expressed a preference for a specific intervention tailored to their presentation.

Conclusion: An exercise and self-management intervention for multisite OA was perceived as beneficial and acceptable to the majority of participants, who reported increased confidence and knowledge for self-management. Further consideration regarding the suitability of integrating back pain patients into these generic sessions may be necessary. Embedding a qualitative analysis into an RCT enhances our understanding of interventions and provides valuable insight from a patient perspective.

2007

Using Photovoice Techniques to Empower Lupus Patients and Create Public Awareness: A Program Evaluation. Jessica Rowshandel and Diane Gross. S.L.E. Lupus Foundation, New York, NY.

Background/Purpose: *Lupus through the Lens* is a photography project for people with lupus to capture, in pictures, what it means to live with lupus. Created by the S.L.E. Lupus Foundation, it borrows from photovoice, a socially-engaged photography technique based on community-based participatory research and visual narrative inquiry. To our knowledge, photovoice has not been used within the lupus community. The Foundation's goals for the program were: 1. create public awareness about the shared lived experience of lupus since it is often misunderstood by both lay people and healthcare professionals, 2. aid participants in coping with their illness, and 3. aid viewers with lupus to feel less isolated and more validated in their experience through identification with photos and respective captions.

Methods: This was a 7-week workshop that met over 4 months with 6 participants, all with lupus. Participants were integral in developing project content: through group discussions, they chose the program title and photos to include on the project website; they developed captions, which further defined the meaning of their work. Participants were loaned cameras, and a participant with photography experience gave lessons on camera use and photography techniques. To create public awareness, photos were displayed on a dedicated website and via social media.

Results: Of 803 photos, 53 were selected for the project website. The Foundation's goals were met. Awareness is measured by website traffic; within its first 6-weeks, there were 26,000 views. Participants were aided in coping with their illness, as reported in their final evaluation indicated by a sense of pride, camaraderie, socialization, and self-expression; a new way to share lupus with others; and a deeper understanding of the personal impact of one's own lupus. Based on responses on the project website, Facebook, email and in-person communication, viewers shared that the project gave their experience a voice and they related to the photos on an emotional level.

Conclusion: The project resulted in powerful images and new ways to convey what it is like to live with lupus. The participants themselves defined it as a success. While the program is time-intensive, it is an inexpensive program that can be replicated by other lupus groups. The Foundation will continue in-person workshops, and the project will also grow through online submissions. Based on participants' feedback, the program has the potential to help reduce feelings of isolation and depression, and increase self-esteem and a sense of self-efficacy. More data are needed to confirm participants' reported outcomes. In the future, variables like self-efficacy, self-esteem, depression, and quality of life will be incorporated into the evaluation.

2008

Personalized Risk Education for Rheumatoid Arthritis Improves Self-Perceived Risk Accuracy and Risk Factor Knowledge in First-Degree Relatives. Jeffrey A. Sparks[1], Maura D. Iversen[2], Rachel Miller Kroouze[1], Nellie A. Triedman[1], Taysir G. Mahmoud[1], Sarah S. Kalia[1], Michael L. Atkinson[1], Robert C. Green[1] and Elizabeth W. Karlson[1]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Having a first-degree relative (FDR) with RA increases personal RA risk by four-fold. Other RA risk factors include demographics, genetics, auto-antibodies, and behaviors. We aimed to develop a personalized RA risk tool incorporating these risk factors, suitable for use in RA education trials. We explored changes in self-perceived RA risk and RA knowledge after personalized RA risk education among a group at increased RA risk due to having a relative affected with RA.

Methods: We conducted a pilot study on RA self-perceived risk, knowledge, and attitudes among FDRs recruited at a large academic hospital. Eligible participants had a FDR with RA. We developed a web-based interactive tool, the Personalized Risk Estimator for RA (*PRE-RA*), which provided RA education and calculated lifetime RA risk based on demographics, genetics (HLA shared epitope), auto-antibodies (RF and ACPA), and

behaviors (smoking, overweight/obesity, low fish intake, and dental health). RA knowledge and attitudes were assessed before and 6 weeks after the intervention: *PRE-RA* and health education. RA risk factor knowledge was evaluated by whether subjects agreed that an established risk factor, supported by literature, increased RA risk. An RA knowledge index was calculated by the total number of established factors agreed to increase RA risk. Self-perceived lifetime RA risk before and after the intervention was compared to the *PRE-RA*calculated lifetime RA risk using Wilcoxon rank-sum test. RA knowledge and attitudes before and after intervention were compared by Fisher's exact or Wilcoxon rank-sum tests.

Results: A total of 37 subjects enrolled in the study and 14 completed the *PRE-RA* tool with health education. Median age was 44 years (range 20–70) and 76% were female. Using demographics, behaviors, genetics, and auto-antibodies, the median personalized lifetime calculated RA risk was 5% (range 1–56, mean 12.4, SD 14.7; **Table**) and was significantly lower than self-perceived risk at baseline (median 50%, range 0–85, mean 38.6, SD 23.7; $p=0.0002$). After intervention, self-perceived risk approached the calculated *PRE-RA* risk but remained significantly higher (median 14%, range 1–80, mean 25.1, SD 26.5; $p=0.04$). RA knowledge index significantly improved after the *PRE-RA* tool (median 8, mean 8.6, SD 0.5) compared to baseline (median 6, mean 5.4, SD 1.6; $p<0.0001$). Only 20% agreed that smoking was a risk factor for RA at baseline, but 100% agreed after the intervention ($p<0.0001$).

Conclusion: We developed an interactive RA risk education tool, *PRE-RA*, personalized to demographics, behaviors, genetics, and auto-antibodies suitable for use in RA risk education trials. Subjects in our study had high self-perceived RA risk, compared to calculated risk, that became more accurate after personalized RA risk education. Knowledge of RA risk factors was low prior to intervention and significantly increased after the *PRE-RA* tool and health education.

Table. RA risk self-perception, knowledge, and attitudes at baseline and after the Personalized Risk Estimator for RA (*PRE-RA*) tool and health education among RA first-degree relatives.

Self-perceived vs. calculated lifetime RA risk

	Self-perceived lifetime RA risk (n = 37)	Calculated *PRE-RA* tool lifetime RA risk (n = 14)	*P* value
Baseline lifetime % RA risk, median (range)	50 (0–85)	5 (1–56)	**0.0002**
Post-intervention lifetime % RA risk, median (range)	14 (1–80)*	5 (1–56)	**0.04**

Baseline vs. 6-weeks after intervention

	Baseline (n = 37)	After *PRE-RA*tool and health education (n = 14)	*P* value
Lifetime % RA risk, median (range)	50 (0–85)	14 (1–80)	**0.043**
Smoking is a risk factor for RA, % agree	20%	100%	**<0.0001**
Diet is a risk factor for RA, % agree	53%	67%	0.68
Dental health is a risk factor for RA, % agree	7%	67%	**0.003**
Obesity is a risk factor for RA, % agree	40%	89%	**0.033**
RA knowledge index, median (range)	6 (3–8)	8 (7–9)	**<0.0001**
>45% lifetime RA risk for average person, % agree	16%	0%	0.17
18% lifetime risk of RA is low or very low, % agree	51%	36%	0.36

*A total of 14 subjects provided self-perceived risk after the *PRE-RA* tool and health education.

2009

Development of Multimedia Patient Education Tools (MM-PtET) for Osteoarthritis (OA), Osteoporosis (OP) and Rheumatoid Arthritis Patients (RA). Maria A. Lopez-Olivo[1], Aparna Ingleshwar[2], Robert Volk[1], Andrea Barbo[1], Maria Jibaja-Weiss[3] and Maria E. Suarez-Almazor[1]. [1]The University of Texas, MD Anderson Cancer Center, Houston, TX, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, [3]Baylor College of Medicine, Houston, TX.

Background/Purpose: The purpose of our study was to develop and perform usability testing of Multimedia Patient Education Tools (MM-PtET) for patients with knee osteoarthritis, osteoporosis and rheumatoid Arthritis.

Methods: We developed three MM-PtETs following an Edutainment Model (one for each disease). The goals were designed to make the programs both didactic and entertaining and the navigation and graphical user interface as simple as possible. Entertainment education was provided via a storyline with several episodes linked to the consecutive learning modules which emphasized the content of the episodes. Learning objectives were drafted for each MM-PtET topic. After segments of the scenes were developed, we pre-tested them to ascertain that the stories had the appropriate cultural context and lifestyle. Refinements were made to the program after pre-testing to ensure accuracy. Ten cognitive interviews per disease were conducted to identify potential language and imagery issues in the MM-PtDA. Once the MM-PtET was finalized patients (20 per disease) were shown the tool and were interviewed. Their disease knowledge was tested with a self-report questionnaire (before and after viewing the MM-PtET).

Results: The general sequence of content was: (i) overview of the disease, (ii) description of treatments, (iii) testimonial I, (iii) description of the harms and benefits of each option (iv) testimonial II, (v) review of key facts and suggestions for questions to ask of the patient's doctor, and vi) testimonial III. Both the content and the instructions were narrated, and visual cues were provided to reach patients who are poor readers or who cannot read. We created both English and Spanish-language versions. After cognitive interviewing, 4 of the 10 patients suggested adding more content: for knee osteoarthritis, information on knee replacement and rehabilitation after surgery; for osteoporosis, providing more information on the difference between osteoporosis and osteoarthritis; and for rheumatoid arthritis: (i) including more information on nutrition to prevent anemia and bone decalcification and (ii) exercises to help with the stiffness. In the pilot testing, 60 participants were interviewed and in terms of acceptability, most patients in all disease groups found the length and amount of information presented in the MM-PtETs to be "just right", and the presentation as 'balanced". In terms of comprehension, all participants provided a favorable evaluation of the MM-PtET; all found the video easy to use, the vocabulary easy to understand and the material to be well organized. All participants felt they: 1) gained "clarity" on disease duration, symptoms, and time medication takes to start acting, 2) were "encouraged to see their doctor regularly", and 3) were more aware about taking their medications. Statistically significant differences were observed in pre-post knowledge questionnaire scores (OA, p=0.03; OP, p=0.001; RA, p<0.0001).

Conclusion: Multimedia tools that incorporate video modeling can help patients better understand and manage their disease. Patient involvement in the development process is essential to ensure relevant content and usability.

2010

Reaching out to Physical Therapists: Results of a Survey on Physical Therapists Preferences for Learning about Evidence-Based Community Programs. Jennifer Hefelfinger[1], Teresa J. Brady[2], Jennifer Berktold[3], Marc Goldstein[4], Erika Bonilla[5], Mari Brick[6], Erica Odom[2], Angela Oliver[2] and Penney Cowan[7]. [1]National Association of Chronic Disease Directors, Atlanta, GA, [2]Centers for Disease Control and Prevention, Atlanta, GA, [3]Westat, Inc, Rockville, MD, [4]American Physical Therapy Association, Alexandria, VA, [5]Westat, Inc, Rickville, MD, [6]National Association of Chronic Disease Directors, Voorheesville, NY, [7]American Chronic Pain Association, Rocklin, CA.

Background/Purpose: Community resources such as evidence-based physical activity (PA) and self-management education (SME) programs, with their documented health benefits, can complement clinical care. These clinical-community linkages can be strengthened by Physical Therapists (PTs) awareness and recommendation of these resources to their patients. The purpose of this study was to explore PTs awareness of, and attitudes towards the use of arthritis-appropriate PA and SME programs, and factors that would influence their decision and facilitate a recommendation of these programs to their patients.

Methods: A stratified random sample of 10,000 members from the geriatrics, home health, orthopedics, and private practice sections of American Physical Therapy Association (APTA) received e-mail invitations to participate in an on-line survey exploring awareness of and preferences related to evidence-based community PA and SME programs. Inclusion criteria included PTs in clinical practice with > 50% adult patients. The survey questions and response options were based on earlier qualitative interviews and refined through pilot-testing.

Results: 1180 PTs responded to the invitation (response rate 11.6%), 84% of respondents met eligibility criteria; a total of 973 PTs participated in the survey. 67% of PTs surveyed were aware of some PA programs in the community; only 22% were aware of community SME programs. Willingness to refer to evidence-based programs was high (over 90% were somewhat or very likely to refer to PA and SME programs). PTs preferred to learn about these resources via means they can access at their convenience (e-mail-82%,

website-51%, direct mail-42%). The tool considered most helpful to facilitate a recommendation was patient handout materials (84%); the most desired patient materials were pamphlets (86%), flyers (57%), and website (57%). 81% would provide information about evidence-based community programs both during treatment and at discharge. Preferred sources of information were APTA (91%) and Arthritis Foundation (68%).

Types of information PTs needed to recommend a community program differed somewhat by program type. For both PA and SME programs, opportunity for post therapy PA (74%, 75% respectively), offered by credible organizations (76%, 69%), and evidence-base (71%, 69%) were important. For PA programs, coverage of techniques to exercise safely (81%), and certified instructors (77%) were most critical; for SME programs, helping patients take an active role in managing their chronic condition (75%) was essential.

Conclusion: Although awareness of PA and SME programs differed by program type, large number of PTs expressed willingness to recommend arthritis-appropriate evidence-based programs in the community, both during therapy and at discharge. PTs need patient materials to facilitate these recommendations, preferably brochures, flyers, or website. Preferred channel to receive program information was via website. These results can be used to shape methods, materials, and messages to encourage PTs to recommend evidence-based community programs and improve patient outcomes.

Disclosure: J. Hefelfinger, None; **T. J. Brady**, None; **J. Berktold**, None; **M. Goldstein**, None; **E. Bonilla**, None; **M. Brick**, None; **E. Odom**, None; **A. Oliver**, None; **P. Cowan**, None.

2011

What Do State Legislators Think about Arthritis? Results of Focus Groups with State Legislators. Mari Brick[1], Erica Odom[2], Teresa J. Brady[2], Carol McPhillips-Tangum[3], Angela Oliver[2], Dana Heyl[4] and Jennifer Hefelfinger[5]. [1]National Association of Chronic Disease Directors, Voorheesville, NY, [2]Centers for Disease Control and Prevention, Atlanta, GA, [3]Experion HealthCare Group LLC, Atlanta, GA, [4]Consultant, Atlanta, GA, [5]National Association of Chronic Disease Directors, Atlanta, GA.

Background/Purpose: Arthritis affects > 1 in 5 American adults, and is the most common cause of disability. Nearly ½ of people with diabetes or heart disease also have arthritis. Public health interventions such as community-based physical activity (PA) and self-management education (SME) programs have demonstrated health benefits among people with arthritis, yet availability is limited. State legislation addresses other chronic diseases, yet arthritis receives little attention. The purpose of this qualitative research was to explore state legislators' attitudes towards arthritis, factors influencing their attention to health issues, and potential legislative actions to increase availability of arthritis-appropriate community PA and SME programs.

Methods: The National Conference of State Legislatures (NCSL) invited a purposive sample of 20 state legislators and 2 legislative staff to participate in focus groups (FGs) that preceded the NCSL 2013 Legislative Summit. Selection criteria included: leadership of NCSL's Health Committee, appointment by presiding officers, or attendance at an arthritis education session at the 2012 Legislative Summit. 2 FGs were held; group assignment balanced Democrats and Republicans, men and women, geographic region, and previous education session attendance.

Each FG was conducted by an experienced moderator using a structured guide. The two moderators coded each FG transcript independently and met to identify key findings.

Results: 16 Legislators and 2 staff participated (82% response rate). The legislators were: 56% Democrat, 38% Republican, and <1% Independent. Legislators were both interested in and surprised by the national and state level arthritis statistics, but not compelled to take action (i.e. legislation, health benefit design). Participants identified perceived seriousness (particularly mortality) and belief that state action would save money as key factors influencing their health action decisions. Participants reported that advocacy groups could influence their thinking on health issues; yet few participants recalled any contact with arthritis advocates.

Arthritis was not perceived as a serious health issue warranting state legislator attention. Participants believed the most effective way to address arthritis was to include it with higher priority health conditions (e.g., heart disease, diabetes).

Participants were unaware of evidence-based PA or SME programs offered in the community, and had trouble distinguishing them from clinical interventions. There was no support for including these interventions in state-covered Medicaid benefits, but some support for including them in state employee benefit packages.

Conclusion: Arthritis is an invisible problem to state legislators; they are unaware of arthritis statistics and have not been contacted by arthritis advocates. Arthritis alone is not compelling enough to motivate legislator action. Attention to arthritis could be increased by educating state legislators on the role arthritis plays in complicating management of other chronic diseases, developing promising policy options, and addressing arthritis within the context of other chronic diseases.

2012

Moving Social Media Beyond Health Education and into Patient Engagement. Xiaohui Yan and R. Paola Daly. Lupus Foundation of America, Washington, DC.

Background/Purpose: During Lupus Awareness Month, Lupus Foundation of America conducted several social media-specific activities, including sharing facts with the end goal of increasing health knowledge in people with lupus, their friends and family. Topics ranged from lupus in different organ systems to coping strategies.

This abstract will evaluate social media as a means for engaging individuals in their health through Facebook conversation (thread) about mild cognitive dysfunction. We expect that individuals who responded at higher levels of engagement have the tools to better manage this aspect of lupus. More than 80% of patients with lupus present subjective complaints of cognitive difficulties (Wallace, 2013) and symptoms include feelings of confusion and memory loss. The causes are unknown.

Engagement is an indicator that links social media to action. Levels range from low (showing a preference) to medium (creating & sharing content) to high (engaging in offline events) (Neiger et al., 2012). Patients who are highly activated in their health are more likely to report higher quality of life & satisfaction with care (Mosen et al., 2007) and may show an increase in improved health behaviors (Hibbard et al., 2007).

Methods: Comments in the thread were collected and sorted into broad themes, assigning one or more theme to each comment. The thematic analysis yielded the following categories: validation, sharing experience/advice and increased knowledge.

Engagement actions, including number of likes, comments and shares, were obtained through Facebook Insights and categorized as low, medium or high levels.

Results: The thread resulted in 336 comments over the span of six days. 284(84%) comments were on-topic. Examples of statements of validation include "Thank you for addressing this. . .It's frustrating, embarrassing at times but now I know I am not alone." A characteristic response of increased knowledge was "I attributed it to my medications. I'll pay more attention now to see if it worsens."

Table 1: Thematic Analysis

Comment Theme	# of comments (%)
Validation	54 (20%)
Sharing experience/advice	239 (84%)
Increased knowledge	12 (4%)
Two or more categories	21 (8%)

Overall, the post reached 326,528 people. 263,808 (80%) people saw the post through others' engagement actions. Levels of engagement are listed in Table 2.

Table 2: Engagement Actions

Engagement Action	Number of Actions	Engagement Level
Comments	948	Medium
Shares	3620	Medium
Likes	5892	High

Conclusion: Results suggest that in addition to being an effective platform for health promotion and education, social media may also serve as an informal support system by providing validation of experiences and symptoms. Future studies will target specific health behaviors, measure outcomes of interest through pre and post testing, and potentially include an off-line component to promote high level of engagement.

Disclosure: X. Yan, Lupus Foundation of America, 3; **R. P. Daly**, Lupus Foundation of America, 3.

2013

Quality Appraisal of Educational Websites on Osteoporosis and Bone Health. Maria A. Lopez-Olivo[1], Noha Abdel-Wahab[1], Abhinav Dodeja[2], Gregory Pratt[1] and Maria E. Suarez-Almazor[1]. [1]The University of Texas, MD Anderson Cancer Center, Houston, TX, [2]The University of Texas Health Science Center, School of Public Health, Houston, TX.

Background/Purpose: Osteoporosis, like many other chronic diseases, can have better outcomes when informed patients get involved in self-management, resulting in better ourtcomes. Bone health education publicly available through the Internet, if evidence-based and unbiased, could help patients to deal with issues such as decision making, maintaining healthy lifestyles, using medications correctly, and improving their communication with health professionals. The current study aimed to assess the quality of websites providing bone health-related information on the Internet.

Methods: We performed an environmental scan of the currently available osteoporosis and bone health patient education information on the World Wide Web. The sample websites were identified by using three separate search tools: Google Advanced, Bing, and Ask.com. We used the phrases "bone health" and "osteoporosis" in titles of Web pages and reviewed the first 100 results in each of the following domains: .gov, .org, & .com, plus links to 50 .edu websites. Only patient education websites were included. Websites that were part of clinical guidelines were excluded. Two independent investigators collected data regarding: information provided (accuracy and completeness), design, disclosures and references provided. Literacy was evaluated using the Flesch Grade Level readability formula.

Results: We identified 29 websites (92% non-profitable). Most websites were focused on risks factors of osteoporosis, preventive measures, screening recommendations, and topics to discuss with the physician. All websites provided adequate information describing treatment options; however, only 10.3% had information addressing duration of treatment, what happens when treatment stops, and the benefits and risks of various treatments. Only 50% of the websites had their content updated to 2014. Reading levels ranged from 7.8 to 14.8 (higher than the recommended 6-grade level). Ninety percent of the sites were static websites with no interactive features in their design; 94% were linear. Only 33% included an adequate disclosure statement and 25% cited their sources of information to support their content.

Conclusion: Websites with information about bone health and osteoporosis commonly fail to report adequate disclosure statements and sources of information. While they commonly present information about initial treatment choices, most fail to address risk-benefit issues, and common barriers than can occur throughout the course of the disease. In addition, most websites are written at a 9-grade level or above, rendering them unsuitable for low-literacy populations.

ACR/ARHP Poster Session C
Epidemiology and Public Health: Rheumatoid Arthritis Pathogenesis and Treatment
Tuesday, November 18, 2014, 8:30 AM–4:00 PM

2014

Performance of Self-Reported Measures for Periodontitis in Rheumatoid Arthritis and Osteoarthritis. Brian Coburn[1], Harlan Sayles[2], Jeffrey Payne[3], Robert Redman[4], Jeffery Markt[1], Mark Beatty[3], Garth Griffiths[5], David McGowan[6] and Ted R. Mikuls[2]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [3]University of Nebraska Medical Center, Lincoln, NE, [4]Veterans Affairs Medical Center (VAMC), Washington, DC, [5]Dallas VA and University of Texas Southwestern, Dallas, TX, [6]George E. Wahlen VA Medical Center, Salt Lake City, UT.

Background/Purpose: Periodontitis (PD) is associated with many chronic health conditions including rheumatoid arthritis (RA). Affecting one-third to one-half of the US population, the high prevalence of PD underscores its potential impact. PD may play a role in initiating or worsening RA. Yet, studies are often hindered by resource intensive full-mouth exams required for PD diagnosis whereas new self-report methods can reduce cost. Many studies indicate that PD has a different presentation in RA patients. It is unknown whether this difference affects performance of self-report measures. The purpose of this study was to evaluate self-report against the reference standard of clinically-defined PD in RA and osteoarthritis (OA) patients after accounting for factors associated with PD.

Methods: Six self-report PD questions were evaluated in RA and OA patients. All RA patients met ACR criteria and OA patients were classified based on physician diagnosis or corresponding x-ray results. Self-report questions were validated against a reference standard of severe or moderate-to-severe PD based on full-mouth examination. Multivariable logistic regression was used to evaluate the performance of: 1) self-report alone; 2) age, sex, education, and smoking status; and 3) a combination of the above. Model performance was assessed using the c-statistic. Convergent validity of self-reported 'bone loss/deep pockets' and 'loose teeth' was assessed; associations of self-report with RA disease characteristics were explored.

Results: Self-report performed similarly in RA and OA, with individual specificity for PD $\geq$ 68% and sensitivity between 10% and 45%. Question-only models yielded c-statistics of 0.66–0.72 while risk factor-only models yielded c-statistics of 0.74–0.79. The best performing models incorporated both self-report questions and PD risk factors with c-statistics $\geq$0.79. Greater radiographic alveolar bone loss was observed among participants reporting 'bone loss or deep pockets' ($p<0.001$) and 'loose teeth' ($p<0.001$). Among RA patients, 'loose teeth', but not other self-report items, was associated with rheumatoid factor positivity ($p=0.047$) and higher disease activity ($p<0.001$).

Table 1. Logistic Regression for Final Models after Backward Stepwise Selection

Variables	Overall (n=592)		RA (n=275)		OA (n=317)

Final Model AUC	0.82	0.81	0.79	0.80	0.83	0.81

All odds ratios displayed have a p-value less than 0.05. Separate models are presented for each group: rheumatoid arthritis (RA), osteoarthritis (OA) and overall. Each group is analyzed by the severe and moderate-to-severe periodontitis (PD) definitions. Area under the curve (AUC). AUCs for question-only models: Overall & Severe PD – 0.70; Overall & Mod-Sev PD – 0.67; RA & Severe PD – 0.70; RA and Mod-Sev PD – 0.66; OA & Severe PD – 0.72; OA and Mod-Sev PD – 0.68. AUCs for risk factor-only models: Overall & Severe PD – 0.76; Overall & Mod-Sev PD – 0.76; RA & Severe PD – 0.74; RA and Mod-Sev PD – 0.72; OA & Severe PD – 0.76; OA and Mod-Sev PD – 0.77.

Conclusion: Patient self-report, when combined with other risk factors, performs well in identifying PD among patients with RA and OA. Self-report questions related to alveolar bone loss exhibit excellent convergent validity in these patient subsets.

Fine Particulate Air Pollution and Systemic Autoimmune Rheumatic Disease in Two Canadian Provinces. Sasha Bernatsky[1], Audrey Smargiassi[2], Cheryl Barnabe[3], Lawrence W. Svenson[3], Allan Brand[4], Marie Hudson[5], Steven M. Edworthy[6], Ann E. Clarke[3], Paul R. Fortin[7], Patrick Belisle[8] and Lawrence Joseph[9]. [1]McGill University Health Centre, Montreal, QC, [2]Université de Montréal, Montréal, QC, [3]University of Calgary, Calgary, AB, [4]Institut national de santé publique du Québec, Montreal, QC, [5]Lady David Institute for Medical Research and Jewish General Hospital, Montreal, QC, [6]The University of Calgary, Calgary, AB, [7]Laval University, Division of Rheumatology, Centre de Recherche du CHU de Québec and Department of Medicine, Quebec City, QC, [8]Research Institute of the McGill University Health Centre, Montreal, QC, [9]McGill University, Montreal, QC.

Background/Purpose: To estimate the degree to which fine particulate (PM2.5) air pollution is associated with systemic autoimmune rheumatic diseases (SARDs).

Methods: We used population-based administrative data from Alberta (1993–2007) and Quebec (1989–2010). The SARD case definition was based on at least 2 physician billing claim codes, or at least 1 rheumatology billing code, or at least 1 hospitalization diagnostic code (for systemic lupus, Sjogren's Syndrome, scleroderma, polymyositis, dermatomyositis, or undifferentiated connective tissue disease). Bayesian hierarchical latent class regression models estimated the probability that any given resident was a SARD case, given our three case definitions. Mean 2001–2006 residential exposures to ambient PM2.5 levels were assigned using satellite-derived data for Dissemination Area regions in Alberta, and *Local Community Services*-Centre (CLSC) regions in Quebec (both assigned from postal code of residence). The sum of individual level probabilities provided the total cases per region in each province, according to age, sex, urban-versus-rural residence, income, and PM2.5 levels. In Alberta, we also stratified by First-Nations(FN) status, which in Alberta represents about 3% of the population (Blackfoot, Cree, Chipewyan, Dene, Sarcee, Stoney/Nakoda Sioux, and others). The hierarchical model generated odds ratio (OR) estimates for being a SARD case, based on age, sex, urban-versus-rural residence, income, and PM2.5 levels. The model accounted concurrently for these characteristics, as well as an interaction term between age and sex. The model generated Bayesian 95% credible intervals (CrI, which are similar to the non-Bayesian confidence interval) for the OR estimates.

Results: The probability of being a SARD case was higher among females versus males and for residents aged > 45 versus younger, with the highest ORs for older females. Independently, the odds of being a SARDs case increased with PM2.5 levels. In Alberta, the effect was slightly greater for FN residents. Specifically, in Alberta, when we used a continuous variable for PM2.5, the adjusted OR (interpreted as increase in SARDs per unit increase in PM25) in FN residents was 1.38 (95% CrI 1.14, 1.68) whereas in non-FN Alberta residents the adjusted OR was 1.05 (95% CrI 1.01, 1.08). In Quebec, where information on FN status (1% of the Quebec population) was not available, the adjusted OR for PM2.5 as a continuous variable, was 1.05 (95% CI 1.05, 1.06).

Conclusion: Adjusting for demographics, exposure to PM2.5 is associated with an increased risk of SARDs. Our data suggest that FN populations may be particularly vulnerable to this effect. Improving air quality across the continent appears to be an important way to reduce chronic disease burden, not only for respiratory and cardiac disease, but also systemic autoimmune rheumatic diseases.

2016

Occupation and Risk of Developing Rheumatoid Arthritis. Anna Ilar[1], Pernilla Wiebert[1], Lars Klareskog[2], Lars Alfredsson[3] and Camilla Bengtsson[1]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institute, Stockholm, Sweden, [3]The Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: The role of environmental factors in the etiology of rheumatoid arthritis (RA) is still fairly unknown. Finding occupations associated with the risk of disease could generate knowledge about occupational hazards that might be involved in disease development. The objective was to study the association between different occupations and the risk of developing anti-citrullinated protein antibodypositive (ACPA+) RA or anti-citrullinated protein antibody-negative (ACPA−) RA in men and women.

Methods: The Epidemiological Investigation of Rheumatoid Arthritis (EIRA) study is a population-based case-control study, which enrolls newly diagnosed cases of RA in defined geographical areas of Sweden. Participants were 18–70 years of age. In total, 3,295 cases and 4,912 controls participated in the study. A questionnaire was collected to obtain information on environmental/lifestyle factors, including occupational history. Blood samples were taken for serologic analyses. Occupations were coded according to the Nordic Classification of Occupations and divided into 69 occupational groups. We compared the last occupation before onset of disease symptoms with the rest of the workforce for occupations with at least 5 controls by calculating odds ratios (ORs) together with 95% confidence intervals (CIs) for ACPA+ RA or ACPA- RA, respectively, by means of logistic regression with adjustment for age and county. Potential confounding from smoking was also considered.

Results: Among women, *Nurses* had a reduced risk (OR: 0.7, 95 % CI 0.5–1.0) whereas *Assistant nurses & attendants in psychiatric care* (OR: 1.4, 95 % CI: 1.2–1.6) and *Rubber & plastic workers* (OR: 2.9, 95 % CI: 1.1–7.4) had an increased risk of ACPA+ RA.

Among men, *Technical, Physical & biological workers* (OR: 0.7, 95 % CI: 0.5–1.0) and *Clerical workers* (OR: 0.7, 95 % CI: 0.5–1.0) had a reduced risk whereas *Smelters & metal foundry workers* (OR: 2.8, 95 % CI: 1.0–7.4), *Bricklayers & concrete workers* (OR: 2.6, 95 % CI: 1.3–4.9), *Material handling & related equipment operators* (OR: 2.5, 95 % CI: 1.4–4.3) and *Electrical & electronics workers* (OR: 1.8, 95 % CI: 1.0–3.1) had an increased risk of ACPA+ RA.

For ACPA− RA, male *Administrators & managers* had a reduced risk (OR: 0.3, 95 % CI: 0.2–0.8), while *Shop managers & assistants* (OR: 1.9, 95 % CI: 1.2–3.1) and *Electrical & electronics workers* had an increased risk (OR: 2.1, 95 % CI: 1.1–4.0). Adjustment for smoking had a small effect on the estimates and mainly reduced the risk of ACPA+ RA.

Conclusion: The study found associations between several occupations and onset of RA. Among women, mainly occupations within the health care sector were associated with RA, whereas increased risks among men were detected in mechanical and technical occupations.

2017

Fish Consumption and Risk of Rheumatoid Arthritis Among Women in Large Prospective Cohorts. Jeffrey A. Sparks, Shun-Chiao Chang, Bing Lu, Susan Malspeis, Karen H. Costenbader and Elizabeth W. Karlson. Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Prior studies have suggested a protective effect of fish intake on RA. However, these studies were limited by potential recall bias, short follow-up, and small sample sizes. We aimed to evaluate the effect of fish consumption on RA development in two large cohorts, the Nurses' Health Study (NHS) and NHSII.

Methods: We examined the effect of fish consumption on RA risk among women in two large, prospective cohorts. NHS is composed of 121,700 US nurses followed since 1976; NHSII is composed of 116,430 nurses followed since 1989. Lifestyle and environmental exposures were collected through biennial questionnaires. Diet and fish intake were assessed by a semi-quantitative food frequency questionnaire completed every 4 years. Participants who provided fish data at baseline in each cohort were analyzed. Incident RA cases were identified by screening questionnaire and validated by medical record review according to the 1987 ACR RA criteria. Cumulative average fish intake prior to RA development was used to represent long-term fish intake. Cox regression models estimated hazard ratios (HR) and 95% confidence intervals (CI) of fish intake and RA risk, adjusted for confounders, including age, total energy intake, smoking, body mass index, alcohol, and soda intake. HRs from the two cohorts were meta-analyzed using a random effects model.

Results: We validated 652 incident RA cases among 86,135 women in NHS and 322 incident RA cases among 92,984 women in NHSII with diet data. For women in NHSII, modest fish consumption (1–2 fish servings per week) was associated with a protective effect on RA (age-adjusted HR 0.63, 95% CI 0.42–0.96, **Table**) compared to never/rare fish consumption that was nearly significant in the multivariable model (HR 0.66, 95% CI 0.44–1.01). However, for women in NHS, modest fish consumption was not associated with RA (HR 0.86, 95% CI 0.57–1.32) compared to never/rare fish intake. In meta-analysis of the results, there was a suggestion of a protective effect for modest fish intake that was nearly statistically significant (HR 0.76, 95% CI 0.56–1.02). More frequent fish consumption was not statistically associated with RA (HR 0.94 for 2 to <3 servings/week; HR 0.88 for ≥3 servings per week compared to never/rare intake) and there was no statistically significant trend for fish consumption on RA risk.

Conclusion: In these large prospective studies of nearly 180,000 women, there was a suggestion of a protective effect of modest fish consumption (1–2 fish servings per week) on RA development compared to never/rare fish intake. This protective effect of fish intake on RA risk was more pronounced in NHSII than NHS, but was not statistically significant in meta-analysis of both cohorts. Cohort differences, such as age, secular diet trends, and age at RA onset, may explain these results or they may be due to chance. Further studies of nutritional components of fish, such as omega-3 fatty acids, may clarify the effect of fish intake on RA risk.

Table. Hazard ratios for RA development by categories of cumulative average updated fish intake serving frequency in NHS (n = 86,135), NHSII (n = 92,984), and meta-analysis of both cohorts

Do Mediterranean or Vegetarian Diets Influence Risk of Rheumatoid Arthritis? Kari Johansson[1], Maria Sandberg[2], Saedis Saevarsdottir[3], Martin Neovius[1], Lars Alfredsson[2], Johan Askling[1] and Camilla Bengtsson[2]. [1]Clinical Epidemiology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]The Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Lifestyle factors are of major importance for development of RA. Yet, regarding the role of diet surprisingly little is known. The Mediterranean diet, rich in fish, plant food, mono- and polyunsaturated fat, and including moderate wine consumption, has been suggested to protect against e.g. cardiovascular disease, but its effect on RA development has only been studied to a limited extent. The aim of this study was to investigate whether Mediterranean or vegetarian (vs. Western) diet influences the risk of developing RA.

Methods: In the Swedish case-control study Epidemiological Investigation of Rheumatoid Arthritis (EIRA), 1296 incident RA cases and 2661 randomly selected controls matched by age, sex and residential area were enrolled between 2005 and 2012. Type of diet the year before enrolment was ascertained by a single question in a food-frequency-questionnaire, including Western diet, Mediterranean diet, vegetarian diet, vegan diet, or other specified diet. Odds ratios (OR) were estimated for RA overall, and also stratified for anti-citrullinated peptide autoantibodies (ACPA) and rheumatoid factor (RF) status. Adjustments were made for the matching factors in the crude model and additionally for BMI, smoking, formal education and, physical activity in the adjusted model.

Results: 9% of the RA-cases (n=122/1269) reported to consume a Mediterranean diet the year before enrolment compared with 12% (309/2661) of the controls, and 4% (n=47/1269) of the RA-cases and 3% (80/2661) of the controls reported to consume a vegetarian diet. After adjustment for the matching factors, a Mediterranean diet was associated with a statistically significant decreased risk of RA compared with Western diet (OR 0.76; 95%CI 0.62–0.97; **Table**). However, after additional adjustment the association did not remain statistically significant (OR 0.86; 95%CI 0.68–1.08). The results did not change when stratifying by ACPA or RF-status, although there was a tendency towards lower risk with Mediterranean diet in ACPA+ and RF+ patients. Vegetarian diet was not associated with development of RA, neither overall nor in the stratified analysis (Table).

Conclusion: Self-reported Mediterranean diet was in itself associated with a lower RA risk, but this association disappeared after adjustment for the selected potential confounders. A tendency towards lower risk with Mediterranean diet in ACPA+ and RF+ patients was observed. No association was observed for a vegetarian diet.

Table. Mediterranean or vegetarian diet and risk of RA, stratified by ACPA and RF-status

Antibodies to Citrullinated Clusterin, Filaggrin, Vimentin, and Fibrinogen Are Associated with Blood Pressure in First-Degree Relatives of Rheumatoid Arthritis Patients: The Studies of the Etiology of Rheumatoid Arthritis. Jan M. Hughes-Austin[1], Ryan W. Gan[2], Kevin D. Deane[3], Peter K. Gregersen[4], Michael H. Weisman[5], Joachim H. Ix[1], Jeremy Sokolove[6], William H. Robinson[7], V. Michael Holers[3] and Jill M. Norris[2]. [1]University of California, San Diego, La Jolla, CA, [2]Colorado School of Public Health, Aurora, CO, [3]University of Colorado School of Medicine, Aurora, CO, [4]The Feinstein Institute for Medical Research, Manhasset, NY, [5]Cedars-Sinai Medical Center, Los Angeles, CA, [6]VA Palo Alto Healthcare System and Stanford University, Palo Alto, CA, [7]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA.

Background/Purpose: Hypertension is common in rheumatoid arthritis (RA), but it is unclear whether this prevalence is due to RA-related medications or to the disease process itself. Prior work in first-degree relatives (FDR) of RA patients without clinically apparent RA, and thus without RA-related medications, has shown that markers of endothelial dysfunction were associated with antibodies to citrullinated protein antigens (ACPA), suggesting that ACPA may be involved in vascular injury. Thus, we sought to investigate associations between ACPA and systolic and diastolic blood pressure in FDRs.

Methods: In the Studies of the Etiology of RA (SERA) (a multicenter prospective study of preclinical RA), we evaluated associations between ACPA and systolic (SBP) and diastolic blood pressure (DBP) in 89 FDRs of RA patients. A panel of 15 ACPA were measured using a Bio-Plex bead-based assay; and were dichotomized as positive/negative based on pre-specified cut-offs in 200 RA patients and 98 blood bank controls. These cutoffs were developed using receiver operating characteristic (ROC) curves giving >90% specificity. Seventeen FDRs lacked ACPA measurements and were excluded, leaving 72 FDRs for analysis. SBP and DBP were measured 3 times and averaged. ANCOVA was used to evaluate associations between ACPA positivity and SBP and DBP, adjusting for age, sex, race, body mass index (BMI), pack-years of smoking, high sensitivity C-reactive protein (CRP), and current use of anti-hypertensive medications.

Results: Average age was 51 years, and 69% were female. Mean SBP was 119 ± 18 and DBP was 74 ± 9 mmHg. 46% of FDRs were positive for any ACPA; these individuals were younger and had lower BMI, more pack-years of smoking, and higher levels of hsCRP, and had marginally higher DBP. (Table) Positivity for antibodies to cit-fibrinogen A (211–230) was associated with 11.52 mmHg higher SBP; to cit-filaggrin was associated with 13.9 mmHg higher SBP; to cit-clusterin, cit-filaggrin, and cit-vimentin were associated with 7–8 mmHg higher DBP. Positivity for each additional ACPA was significantly associated with a 0.98 mmHg increase in SBP, and a 0.66 mmHg increase in DBP.

Conclusion: In FDRs without RA, ACPA positivity is associated with higher SBP and DBP, independent of risk factors and medications for hypertension. While cit-fib and cit-vimentin have been implicated in subclinical CVD in RA, these findings suggest ACPA play a role in the vascular changes leading to hypertension prior to RA.

Table. Proportion of SERA FDRs with ACPA, and associations of ACPA with blood pressure

		Systolic Blood Pressure		Diastolic Blood Pressure	
	n (%) positive	β (SD)	p	β (SD)	p

Circulating Carotenoids and Subsequent Risk of Rheumatoid Arthritis. Yang Hu[1], Karen H. Costenbader[2], Elizabeth W. Karlson[2] and Bing Lu[2]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Antioxidant components in food may be biologically relevant to the prevention of rheumatoid arthritis (RA). Evidence from prospective cohort studies regarding the relationship between blood levels of food source antioxidants and risk of RA is limited. The aim of present study was to examine the association between circulating carotenoids and RA risk.

Methods: We conducted a nested case-control study consisting of 228 incident RA cases and 674 matched controls with prospectively measured plasma carotenoids (α-carotene, β-carotene, β-cryptoxanthin, lycopene and lutein/zeaxanthin) levels in the Nurses' Health Study (NHS) and Nurses' Health Study II (NHS II). Incident RA cases were diagnosed >3 months after blood draw, matched on birth year, race, menopausal status/hormone use, time of day and fasting status, with 3 controls. Smoking, alcohol intake, dietary data, body mass index (BMI) and physical activity were from the questionnaire prior to blood draw. Seropositive RA was defined as positive RF or ACPA by chart review or measurement. Logistic regressions models estimated odds ratios (OR) and 95% confidence intervals (CI) for RA risk associated with each circulating carotenoid.

Results: The median follow-up time from blood draw until RA diagnosis was 8.6 years (0.3 to 19 years). In the multivariable models, no significant associations were found between any plasma carotenoids and risk of all RA, or of seropositive RA. In contrast, we found circulating α-carotene, β-carotene, β-cryptoxanthin and total carotenoids were inversely associated with seronegative RA risk. Women in the highest quartile of α-carotene were associated with a 52% reduction in seronegative RA risk (OR=0.48; 95% CI, 0.25–0.92). The risk reduction of the highest quartile of β -carotene was 51% (OR=0.49; 95% CI: 0.24–1.00). Circulating β-cryptoxanthin was also associated with the reduced risk of seronegative RA (p trend 0.05). Being in the highest quartile of total plasma carotenoid concentration was associated with a 58% reduced seronegative RA risk (OR=0.42, 95% CI: 0.22–0.81, *p*trend 0.03). There was no significant inverse association of lycopene with seronegative RA.

Conclusion: Circulating carotenoid metabolites were associated with a reduced risk of seronegative RA, but not seropositive RA, suggesting different mechanisms for development of these two RA phenotypes. Further studies are needed to confirm our finding.

Table. The association between circulating carotenoids (quartiles) and risk of seropositive and seronegative RA (Odds ratio and 95% confidence interval)*

	Q1	Q2	Q3	Q4	P trend
Seropositive RA (n=135)					
Lutein/zeaxanthin	1.00	1.08 (0.62,1.89)	1.32 (0.76,2.28)	1.36 (0.79,2.37)	0.47
β-cryptoxanthin	1.00	0.87 (0.51,1.49)	1.00 (0.58,1.72)	1.17 (0.67,2.03)	0.93
Lycopene	1.00	1.40 (0.81,2.42)	1.53 (0.90,2.62)	1.20 (0.69,2.10)	0.74
α-carotene	1.00	0.96 (0.56,1.67)	1.09 (0.63,1.88)	1.28 (0.74,2.22)	0.82
β-carotene	1.00	1.50 (0.87,2.59)	1.10 (0.61,1.98)	1.72 (0.98,3.03)	0.44
Total carotenoids**	1.00	1.26 (0.72,2.22)	1.67 (0.97,2.90)	1.51 (0.85,2.69)	0.44
Seronegative RA (n=93)					
Lutein/zeaxanthin	1.00	1.43 (0.80,2.57)	0.81 (0.42,1.55)	0.64 (0.32,1.28)	0.07
β-cryptoxanthin	1.00	0.82 (0.46,1.45)	0.52 (0.27,0.99)	0.54 (0.28,1.05)	0.05
Lycopene	1.00	1.16 (0.63,2.12)	0.89 (0.47,1.70)	1.01 (0.55,1.88)	0.87
α-carotene	1.00	0.50 (0.27,0.91)	0.63 (0.34,1.14)	0.48 (0.25,0.92)	0.07
β-carotene	1.00	0.77 (0.42,1.39)	0.87 (0.48,1.58)	0.49 (0.24,1.00)	0.07
Total carotenoids**	1.00	0.37 (0.20,0.71)	0.62 (0.35,1.11)	0.42 (0.22,0.81)	0.03

* Total carotenoids were the sum of lutein/zeaxanthin, β-cryptoxanthin, total lycopene, α-carotene and β-carotene.
** Adjusting for matching factors (age, menopausal status, postmenopausal hormone use, and day, time, and fasting status at the time of collection), smoking status (never, past, current) and body mass index. Additional adjustment for alcohol consumption, healthy eating index, physical activity and total calories intake did not change the results.

The Association Between Rheumatoid Factor and Cardiovascular Disease in Healthy Adults. Chisun Min[1], Mitsumasa Kishimoto[1], Gautam A. Deshpande[2], Shunya Kaneshita[1], Masei Suda[1], Yuri Ohara[1], Yoichiro Haji[1], Ryo Rokutanda[1], Yasuhiro Suyama[1], Hisanori Shimizu[1], Tokutaro Tsuda[1], Ken-ichi Yamaguchi[1], Akira Takeda[3], Yukio Matsui[1] and Masato Okada[1]. [1]St. Luke's International Hospital, Tokyo, Japan, [2]St. Luke's Life Science Instutute, Tokyo, Japan, [3]International University of Health and Welfare Hospital, Nasu-shiobara, Japan.

Background/Purpose: Rheumatoid arthritis (RA) has been shown to be a risk factor for cardiovascular disease (CVD). Both elevated rheumatoid factor (RF) and anti-citrullinated protein antibodies have been reported to be associated with substantially higher risk of CVD and mortality among RA patients. However, the correlation between RF and CVD in the general population remains unclear. This study examines whether RF is associated with CVD in apparently healthy individuals.

Methods: All participants presenting to the Center for Preventive Medicine at St. Luke's International Hospital in Tokyo, Japan from April 2004 to March 2013 for an annual health screening were included in this retrospective, cross-sectional study. The goals of this employer-mandated screening program are early detection of chronic disease and identification of risk factors. In addition to various CVD risk factors, RF is also routinely measured for early detection of rheumatoid arthritis.

Participants were divided into two groups by the presence of self-reported CVD. Using this as the primary outcome, we compared several parameters including RF positivity (15 IU/ml), age, male gender, height, weight, body-mass index (BMI), waist circumference (WC), body fat percentage, systolic blood pressure (SBP), diastolic blood pressure (DBP), lipid profile, HbA1c, fasting blood glucose (FBG), uric acid (UA), C-reactive protein (CRP), percentage of ever-smokers and ever-drinkers, presence of self-reported CVD risk factors including dyslipidemia (DL), diabetes mellitus (DM) and hypertension (HTN), and family history of CVD. We evaluated whether whether RF positivity was independently associated with CVD using multivariate regression analysis.

Results: Of 111,021 individuals presenting for health checkup during the study period, 110,856 (99.9%) provided complete datasets regarding our parameters of interests. Of these, mean age was 46.0±12.0 (48.9% men) and 1,863 (1.7%) reported a history of CVD.

On univariate analysis, individuals with CVD were more likely to be male (70 vs. 48.5%), older (62.7 vs. 45.8 years), and have RF positivity (12.4 vs. 8.9%). Those with CVD also had poorer metabolic markers including BMI (23.7 vs. 22.3), WC (85.3 vs. 79.9cm), SBP (128 vs. 117mmHg), DBP (77.9

vs. 72.3mmHg), cholesterol ratio (3.7 vs. 3.4), HbA1c (5.9 vs. 5.5%), FBG (108 vs. 99mg/dl), CRP (0.19 vs. 0.12mg/dl). Health history was also suboptimal in the CVD group, including ever-smoking (57.8 vs. 40.0%); history of CVD risk factors such as DL, DM and HTN (22.3 vs. 4.4%, 2.4 vs. 0.3% and 35.9 vs. 7.1%, respectively); and family CVD history (37.1 vs. 22.2%). p-value < 0.001 for all.

On multivariate analysis, however, RF positivity was not correlated with CVD (1.06, 95%CI 0.91–1.22), in either men (1.03, 95%CI 0.85–1.23) or women (1.10, 95%CI 0.86–1.42) after adjustment for clinically established risk factors.

Conclusion: Despite its association with CVD in individuals with RA, RF does not appear to be correlated with CVD and appears to be inappropriate for use as a CVD screening test in apparently healthy individuals. Further investigations to clarify the reason for this discrepancy between RA patients and general population are warranted in the future.

First Nations Persons Have an Increased Risk of Developing Rheumatoid Arthritis with an Early Onset Age but Are Seen Less Frequently By Rheumatologists: A Population Based Study. Carol A. Hitchon, Sazzadul Khan, Brenda Elias, Hani S. El-Gabalawy, Alan Katz and Christine A. Peschken. University of Manitoba, Winnipeg, MB.

Background/Purpose: High global prevalence rates of rheumatoid arthritis (RA) have been reported in First Nations (FN). For our regional population of 1.2 million, health care is universally covered, and health services and diagnoses based on International Classification of Disease codes (ICD-9CM) are recorded in the Population Health Research Database (PHRD) from 1984. As a first step to addressing RA care in FN, we validated case definitions for RA for use with the PHRD and described the incidence, prevalence, and health care use for RA.

Methods: Records from April 1, 1995 to March 31, 2010 were accessed. FN people were identified using linkage with the Federal Indian Registry File (FIRF) which records all registered FN for the purposes of entitlement. Identification was expanded to include non-status Indians otherwise eligible (Metis, Inuit). Residents who resided in the province for $\geq$2 years were identified as having RA if they had $\geq$5 physician visits or hospitalizations with (ICD)-9-CM/ICD-10 codes 714/M05, M06 recorded. Persons resident for $<$2 years were identified as having RA if they had $\geq$3 such claims. This definition was validated for the years 2000–2010 by linkage with the Arthritis Centre database (includes self-identified nonFN, FN, Metis; RA n=2281; nonRA n=7044; definition sensitivity 77.12, specificity 90.30 Youden statistic 67.42). Crude and age standardized prevalence rates for FN and nonFN in 2000–2010 were determined. Onset age, (age at first RA code), was compared in prevalent cases. Using a 5 year run-in time to eliminate prevalent cases, incident RA cases were identified and compared between FN and non-FN using logistic regression and odds ratios with 95% CI reported. Physician visits and hospitalizations were compared between FN and nonFN from 2000–2010.

Results: While both crude and age standardized overall prevalence rates of RA increased from 2000–2010 (crude prevalence 0.34% to 0.65%), FN had higher rates than nonFN in each year. In 2009–2010, crude rates were 0.85% vs. 0.63% for FN vs. nonFN, while age adjusted rates were 1.0% vs. 0.4%; for a rate that was 2.48 times higher in FN than non-FN in 2009–2010 (95%CI 2.471–2.472; $p<0.0001$). The age standardized annual incidence of RA decreased from 0.07% in 2000 to 0.02% in 2010. The overall incidence of RA was higher in FN than nonFN at most years with FN having 2.23 times higher incidence of RA in 2009–2010 (CI 2.22–2.23; $p<0.0001$). RA onset age was earlier in FN than non-FN (41 vs. 55 years; $p<0.001$). Despite greater physician visits (110 vs 99; $p<0.0001$) (all rates are per person over 10 years) and more hospitalizations (3.4 vs 1.9 $p<0.0001$), FN had fewer rheumatologist visits (6.9 vs 8.2 $p<0.0001$), non-rheumatology specialist visits (15 vs 23 $p<0.0001$) and surgeries (3.7 vs 5.3 $p<0.0001$) than non FN.

Conclusion: While overall provincial RA incidence is decreasing, FN have more than twice the risk of developing RA, with a prevalence of 1% in 2009–2010, as well as an onset age 10 years earlier than the general population. When combined with generally more severe disease in FN and fewer rheumatology visits this demonstrates a significant care gap highlighting the need to optimize rheumatology care delivery to this population, particularly in view of the rapid growth of this population.
