Methods: Anti-IFI16 antibodies were assayed by ELISA using sera from patients with primary SS (n=133; Sjögren's International Collaborative Clinical Alliance Biorepository), SLE (n=132: Hopkins Lupus Cohort), DM (n=114; Stanford Dermatology Clinic) and healthy controls (n=47). Immunoprecipitation was used to determine whether antibodies recognized the N-or C-terminus. Expression of IFI16 in lysates made from salivary gland and skin was quantified by immunoblotting.

Results: Anti-IFI16 antibodies were present in 38/133 (29%) SS, 31/132 (23.5%) SLE, and 3/114 (2.6%) DM patients, and 1/47 (2.1%) controls (SS vs controls, $p<0.0002$; SLE vs controls, $p=0.0006$; DM vs controls, $p=1.0$). The levels of anti-IFI16 antibodies were higher in SS [median (25^{th}–75^{th} percentile): 0.334 (0.244–0.591)] as compared to SLE [0.242 (0.164–0.477); $p=0.0002$]. In SS, anti-IFI16 antibodies were associated with an abnormal Schirmer's test ($p=0.0032$), IgG> 1445 mg/dl ($p=0.0189$), ANA ≥1:320 ($p=0.0152$), germinal centers ($p=0.0130$), and higher rheumatoid factor levels [median (25^{th}–75^{th} percentile): 56.5 IU/ml (10.75–97) vs 25 (8–54), $p=0.0132$] and focus scores [3.4 (2.63–6.38) vs 2.4 (1.6–3.7), $p=0.0053$]. With the exception of germinal centers, these associations remained significant in the subgroup of 98 SS patients with positive SSA/B serology. In SLE, this specificity was associated with anti-DNA antibodies ($p=0.0017$). Among patients with high antibody levels, anti-IFI16 antibodies were directed against the C-terminus in 9/13 (69%) SS and 4/15 (26.7%) SLE patients ($p=0.056$). DNA antibodies were present in 10/11 (91%) of the SLE patients with antibodies to the N-terminus and in 1/4 (25%) of the patients with antibodies to the C-terminus ($p=0.033$). IFI16 was expressed in 4/5 (80%) of SS and 1/6 (16.7%) of control labial glands, and 4/8 (50%) of SLE skin and 0/3 (0%) of control skin biopsies.

Conclusion: Anti-IFI16 antibodies are found in primary SS and SLE with similar frequencies (24–29%), but not in DM, despite a role for interferon in the pathogenesis of all 3 diseases. These antibodies correlate with a more severe phenotype in SS and with the presence of DNA antibodies in SLE. Anti-IFI16 antibodies target different portions of the molecule in SS and SLE. Expression of IFI16 in relevant target tissues correlates with the presence of antibody to this molecule.

Sjö™, an Advanced Diagnostic Panel for Detection of Sjögren's Syndrome Autoantibodies. Mark Jasek[1], Kishore Malyavantham[2], Lakshmanan Suresh[3], Julian Ambrus Jr.[4] and Dennis Pardo[1]. [1]Nicox Inc, Fort Worth, TX, [2]IMMCO Diagnostics Inc., Amherst, NY, [3]State University of New York/Buffalo, Buffalo, NY, [4]State University of New York at Buffalo, Buffalo, NY.

Background/Purpose: Sjögren's syndrome (SS) is a complex autoimmune disease involving the salivary and lacrimal glands along with various systemic manifestations. It is a difficult disease to identify especially in its early stages. Average time from disease onset to diagnosis is 4.7 years. The serological markers suggested by the American College of Rheumatology for diagnosis of SS are antinuclear antibodies (ANA), rheumatoid factor (RF), anti-Ro, and anti-La. Novel SS autoantibodies, anti-salivary gland protein 1 (SP1), anti-carbonic anhydrase 6 (CA6) and anti-parotid secretory protein (PSP), often expressed earlier compared to traditional SS biomarkers, have been identified in animal studies and clinical trials. An approved diagnostic blood panel (Sjö™) incorporating classic and novel biomarkers was integrated as standard procedure in ophthalmic/optometric practices across 12 geographic markets.

Methods: Serum samples from patients with idiopathic dry eyes were analyzed with the Sjö™ panel through the end of May 2014. These patients had not previously been diagnosed with SS. Antibodies to RF, anti-Ro, anti-La, anti-SP1, anti-CA6 and anti-PSP were tested using enzyme linked immunosorbent assay. ANA was analyzed by indirect immunofluorescence using Hep-2 substrate.

Results: By the end of May 2014, 2306 samples had been analyzed. Of the dry eye patients analyzed, 608 (27%) turned out to be positive for SS markers. Of the positive patients, 62.6% were identified solely by the novel markers SP-1, CA6, and PSP. Only 13.2% of the patients were identified with solely the classic markers. Majority of samples were from women (88%), of whom 24% were positive for SS markers. In the subset of male dry eye patients tested (n=273), 64 were identified as positive for SS (23%).

Conclusion: The current data illustrates many patients with "idiopathic" dry eyes have autoantibodies consistent with early SS, at a frequency higher than currently reported in the literature. The majority of patients express the novel autoantibodies associated with an early stage of SS, anti-SP1, anti-CA6 and anti-PSP, without anti-Ro or anti-La. Earlier diagnosis of SS in these patients may lead to better management of their dry eye and other systemic manifestations via referral/co-management with rheumatologists and other health care providers.

Autoantibodies in Pediatric Sjogren's Patients. Lakshmanan Suresh[1], Minako Tomiita[2], Akira Hoshioka[3], Long Shen[4], Kishore Malyavantham[5] and Julian Ambrus[6]. [1]State University of New York/Buffalo, Buffalo, NY, [2]Chiba Children's Hospital, Chiba, Japan, [3]Chiba Children's Hospital,, Chiba,

Japan, [4]SUNY at Buffalo, Buffalo, NY, [5]IMMCO Diagnostics Inc., Amherst, NY, [6]University Of Buffalo, Buffalo, NY.

Background/Purpose: Sjogren's syndrome (SS) is a common autoimmune disease involving the salivary and lacrimal glands along with various other organs. It is generally seen in adult females and it is considered 'rare' in children. However, there are not a few pediatric SS patients, and their clinical features are different from those of adults. It is because pediatric patients are in early stages of the disease. The current studies were designed to characterize SS in a population of pediatric patients and whether anti-SP1, anti-CA6 and anti-PSP antibodies could be a new disease marker of early stages of SS.

Methods: Sera were obtained from 15 patients, 4 fulfilled the revised Japanese diagnostic criteria for SS and 11 who probably have SS from the Department of Allergy and Rheumatology, Chiba Children's Hospital, Chiba City, Japan. Their age range was 3–18 years with a mean age of 10.98 years. Fifty pediatric normal controls who were age and sex matched were obtained from Promedx Corporation, USA. ANA was evaluated by HEp2-IFA (Immunofluorescence), RF (Rheumatoid Factor), anti-Ro, anti-La, anti-SP1, anti-CA6 and anti-PSP by ELISA as previously described.

Results: Of the 15 pediatric patients, 11 were females (73%), 2 had SS secondary to SLE and 1 had MCTD. The majority of the patients (80%) expressed ANA and 40% RF. Anti-Ro was expressed by 7 patients of whom 2 also expressed anti-La and 1 also expressed anti-SP1 whose sialography was negative. One 6 year-old patient expressed anti-CA6 and anti-PSP without anti-Ro or anti-La. Of the 50 pediatric normal controls, ANA, anti-Ro, anti-La, anti-CA6 were all negative. Four normal controls expressed RF, 1 had a low titer for anti-PSP and one a low titer for anti-SP1.

Conclusion: Pediatric patients with SS are frequently ANA and anti-Ro positive. One patient lacking these autoantibodies expressed anti-CA6 and anti-PSP and one patient whose sialography was negative expressed anti-SP1. These antibodies may be new disease markers of SS in early stages. In general, a larger percentage of pediatric Sjogren's patients compared to adult patients were male.

The pattern of autoantibody expression in pediatric Sjogren's patients was different from what has been historically seen in adult Sjogren's patents. Further studies will be necessary to look at a larger population of pediatric Sjogren's patients over time to evaluate the progression of their disease and the pattern of their autoantibody expression.

La Positive, Ro60 Negative Subset of Primary Sjögren's Syndrome Is a Reality. Debashish Danda[1], Dat Truong[2], Marshall Shaw[3], Celia Quang[3], Kristi A. Koelsch[4], Biji T. Kurien[5], Harini Bagavant[2], Umesh Deshmukh[2] and R. Hal Scofield[6]. [1]Christian Medical College, Vellore, India, Vellore, India, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [4]Oklahoma Medical Research Foundation, Okalahoma City, OK, [5]U.S. Department of Veterans Affairs Medical Center, Oklahoma City, OK, [6]US Department of Veterans Affairs Medical Center, Oklahoma City, OK.

Background/Purpose: Twenty-nine sera from 348 primary Sjögren's syndrome patients were identified as anti-Ro60 (anti-SSA) negative and anti-La (anti-SSB) positive by immunodiffusion, line immunoassays and multiplex bead assays. We hypothesize that a significant portion of these are falsely negative for anti-Ro60.

Methods: Twenty-nine sera from primary Sjögren's syndrome patients, fulfilling four AECG criteria, were tested for the presence of antibodies directed against La and Ro60 autoantigen. Anti-La was detected on bovine La treated with or without DNAase and RNAase (to check for false positivity, since anti-La can bind DNA and RNA). Anti-Ro60 antibodies in the sera were detected using HEp-2000 substrate (in which cells are transfected with human Ro60) and HEp-2 substrate. Anti-Ro60 and Ro-52 were also tested by *in vitro*transcription/translation/immunoprecipitation assay.

Results: Out of the 29 sera, 25 were unequivocally negative on HEp-2000 (1:40 dilution). Four samples were clearly found to be Ro60 positive with a speckled pattern and three of the four continued to be positive up to 1:320 dilution, as against only two positive samples on HEp-2 at 1:40 dilution. This finding suggests false negativity for Ro60 exists in a small fraction (14 percent) of primary Sjogren's syndrome patients. However, all the samples were negative for Ro60 and Ro52 by *in vitro*transcription/translation/immunoprecipitation assay.

Conclusion: Contrary to our hypothesis, we found only a small fraction of Ro negative, La positive sera to show positive HEp-2000 pattern. This suggests that a subset of primary Sjogren's syndrome is probably a true entity with Ro60 negativity and La positivity. The clinical significance of the subset will be revealed during the follow up of our patients.

Anti-Ro/SSA Positive Incomplete Sjögren's Syndrome. R. Hal Scofield[1], Anne Igoe[2], Donald U Stone[3], Lida Radfar[4], Kimberly S. Hefner[5], David M. Lewis[4], Stephen Young[4], Judy Harris[6], Kiely Grundahl[6], Biji T. Kurien[7], Jacen Maier-Moore[8], Kristi A. Koelsch[9], James Chodosh[10], Nelson L. Rhodus[11], Raj Gopalakrishnan[11], Barbara M. Segal[12], A. Darise Farris[6], Courtney G. Montgomery[6], Christopher J. Lessard[6], Kathy L. Sivils[4] and Astrid Rasmussen[6]. [1]US Department of Veterans Affairs Medical Center, Oklahoma City, OK, [2]Metro Health, Cleveland, OH, [3]Dean McGee Eye Institute, Oklahoma City, OK, [4]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [5]Hefner Eye Care and Optical Center, Oklahoma City, OK, [6]Oklahoma Medical Research Foundation, Oklahoma City, OK, [7]U.S. Department of Veterans Affairs Medical Center, Oklahoma City, OK, [8]University of Texas at El Paso, El Paso, TX, [9]Oklahoma Medical Research Foundation, Okalahoma City, OK, [10]Massachusetts Eye and Ear Infirmary, Harvard Medical School, Boston, MA, [11]University of Minnesota, Minneapolis, MN, [12]Hennepin County Medical Center, Minneapolis, MN.

Background/Purpose: Sjögren's syndrome (SS) is a systemic disease characterized by dry eyes and mouth resulting from immune mediated damage and dysfunction of the lacrimal and salivary glands. Clinical diagnosis often takes 6–10 years, leading to a lag in potential preventive and therapeutic strategies. Research classification is most often based on the American European Consensus Group (AECG) criteria. For classification as primary SS (pSS), the AECG criteria require ≥4/6 components with at least 1 being autoantibodies or abnormal histopathology. A significant number of subjects with sicca manifestations have "incomplete" syndrome (iSS) and exhibit less than 4 AECG criteria. We describe the clinical and serologic features of a subgroup of iSS patients.

Methods: In a multidisciplinary sicca clinic, we assessed features of salivary and lacrimal gland dysfunction and autoimmunity as defined by AECG criteria, identifying 573 iSS participants. We compared the features of iSS based on the presence or absence of anti-Ro/SSA autoantibodies (Ro(+) iSS and Ro(−) iSS, respectively.

Results: Of 573 iSS participants, 467 had complete clinical and laboratory data; 19 of them were Ro(+) (4.1%), and 448 were Ro(−) (95.9%). When compared to Ro(−) iSS, Ro(+) iSS patients were younger (43 ± 5.72 vs. 53 ± 13.27 $p=0.001$) and less often Caucasian (52.6% vs. 95.7%, $p=1.95 \times 10^{-7}$); had more anti-La/SSB (+) (46.2% vs. 2.1%, $p=8.8 \times 10E\text{-}6$), hypergammaglobulinemia and lymphopenia ($p=0.02$ and $p=0.009$, respectively). Furthermore, Schirmer's I test scores, ocular surface staining, and whole unstimulated salivary flow were less abnormal than the Ro(−) iSS participants (19.05 ± 9.85 vs. 14.19 ±10.55, $p=0.05$; 1.5±1 vs. 2.84 ± 2.25, $p<0.0001$; and 5.77 ± 3.66 vs. 2.32 ± 2.3, $p<0.001$ respectively). These differences in age, race, anti-La, hypergammaglobulinemia, and lymphopenia were also statistically significant when comparing the Ro(+) iSS subjects to Biopsy(+) iSS or Ro(−)/Biopsy(−) iSS. Finally, Ro(+) iSS patients presented a variety of extraglandular manifestations: 6 had hypothyroidism and/or autoimmune thyroid disease, 5 arthritis/arthralgias, 5 leuko and/or lymphopenia, 5 low CH50, 4 hypergammaglobulinemia, 3 interstitial lung disease, 2 Raynaud's phenomenon, 2 photosensitivity, and 1 neuromyelitis optica.

Conclusion: A small percentage of patients with iSS have anti-Ro autoantibodies but do not meet the classification criteria for SS. It is possible that these patients will remain as a *forme frustre* of SS or anti-Ro positive undifferentiated connective tissue disease, but given their younger age and multiple manifestations, it is plausible that they may progress to pSS. Of any possible line of autoimmune disease prevention research, understanding the early events of the disease have the strongest potential to lead to improve-

ments in prevention, early diagnosis, and therapeutics. Thus, this group of patients warrants careful follow up to characterize the transition from iSS to full-blown pSS and pinpoint indicators of early autoimmunity that may help identify those at risk for further disease progression.

How Does a Younger Age at the Onset of Sjögren's Syndrome (pSS) Influence the Clinical Presentation and the Clinical Course of the Disease? Chiara Baldini[1], Luca Quartuccio[2], Elena Bartoloni-Bocci[3], Roberta Priori[4], Francesco Carubbi[5], Alessia Alunno[3], Roberto Gerli[3], Guido Valesini[4], Salvatore De Vita[2] and Stefano Bombardieri[6]. [1]Rheumatology Unit, Pisa, Italy, [2]DSMB, University Hospital Santa Maria della Misericordia, Udine, Italy, [3]University of Perugia, Perugia, Italy, [4]Department of Internal Medicine and Medical Specialties, Sapienza University, Rome, Italy, [5]Rheumatology Clinic, University of L'Aquila, L'Aquila, Italy, [6]Rheumatology Unit, University of Pisa, Pisa, Italy.

Background/Purpose: (1) To analyze the clinical presentation and the clinical course of Sjögren's Syndrome (pSS) in Caucasian patients with an "early-onset" pSS and (2) to compare the characteristics of the disease between this group of patients and a control group of patients with pSS and a "typical onset" of the disease.

Methods: A retrospective systematic search through an Italian computerized pSS database, including 1445 patients, was performed in order to select the patients with an "early-onset" of the disease who were defined as those patients aged below the 10th percentile at the time of pSS diagnosis. All the patients enrolled in the database have been recruited at 5 Rheumatology University Italian medical centers and the data have been systematically entered in a standardized form and updated at regular intervals during follow-up since 2009. For all patients, the following parameters were retrieved: age at diagnosis, sex, disease duration, glandular and extra-glandular disease-related manifestations, laboratory features, serological profiles, medical treatments and lymphoproliferative complications. Categorical variables were compared using chi square test; continuous variables were compared using Student's t-test. A 2-tailed value of $p < 0.05$ was taken to indicate statistical significance.

Results: The systematic search selected 1192 pSS patients out of the entire cohort (AECG 2002). Median (IQR) age at pSS diagnosis was 52 (42–62) years and the tenth percentile was 33 years. By using the tenth percentile as a cut-off, we identified 125/1192 (10.5%) as the "early-onset" group whereas the remaining 1067/1192 (89.5%) represented the control group. Median (IQR) disease duration was significantly longer in the "early-onset" group (7 (3–14) versus 3 (1–8) years, $p \leq 0.0001$). Patients with an early disease onset presented a lower frequency of subjective dry mouth ($p=0.003$) and a higher prevalence of parotid enlargement ($p \leq 0.0001$), Raynaud's phenomenon ($p=0.04$) and tubular renal disease ($p=0.04$). Moreover, patients with an "early-onset" pSS presented more frequently a positivity for rheumatoid factor (RF) ($p \leq 0.0001$), anti-Ro/SS-A ($p \leq 0.0001$), and anti-La/SS-B antibodies ($p \leq 0.0001$), low C3 levels ($p=0.006$), hypergammaglobulinemia ($p \leq 0.0001$), and leukocytopenia ($p=0.006$). No differences were detected between the two groups regarding low C4 levels, cryoglobulins, purpura, peripheral nervous system involvement and lymphoproliferative complications.

Conclusion: The age at the onset of pSS may influence the diagnostic algorithm of the disease due to the lower prevalence of subjective sicca symptoms. Parotid enlargement, kidney involvement, laboratory and serological abnormalities seemed to be distinctive features of the "early-onset" pSS. However, despite the higher frequency of parotid gland enlargement, patients with "early-onset" pSS apparently did not present a phenotype at higher risk of lymphoma.

Risk of Cervical Root and Incisal Caries in Patients with Sjogren's Syndrome. Nicola Berman[1], Jonathan S. Dunham[2], Joshua Baker[3] and Frederick B. Vivino[4]. [1]Pennsylvania Hospital, Philadelphia, PA, [2]Univ of Pennsylvania, Philadelphia, PA, [3]Philadelphia VA Medical Center, Philadelphia, PA, [4]Penn Presbyt Med Ctr, Philadelphia, PA.

Background/Purpose: Pathologic (cervical root and incisal caries) cause significant morbidity in patients with Sjogren's syndrome (SS). Identifying risk factors for pathologic caries may facilitate prevention strategies for dental complications in this population. We assessed whether primary (pSS) and secondary Sjogren's syndrome (sSS) were associated with an increased risk of pathologic caries compared with subjects with non-Sjogren's related xerostomia. We also evaluated risk factors for pathologic caries amongst SS patients with and without dental complications.

Methods: We retrospectively reviewed medical records of 225 consecutive patients with sicca symptoms who were evaluated at the Penn Sjogren's center. Subjects underwent complete physical examination, minor salivary gland biopsies, objective tests for dry eyes/dry mouth, serologic testing, and Technetium^{99} pertechnetate salivary scintigraphy. Prevalence of pathologic caries was determined by retrospective review of dental records. SS patients were diagnosed based on 2002 AECG Criteria. Subjects with Sjogren's syndrome (pSS and sSS) were compared to non-Sjogrens subjects (nSS). Patients who did not meet criteria included those with chronic sialadenitis, sclerosing chronic sialadenitis, non-specific chronic inflammation, undifferentiated connective tissue disease, or medication-induced xerostomia. We used t-tests, Wilcoxon rank sum tests and chi-squared tests to evaluate group differences. We further evaluated independent associations with pathologic caries using parsimonious multivariable logistic regression models.

Results: Compared with nSS, patients with SS were more likely to have pathological caries (57.7% vs 42.1%, $p=0.02$), abnormal scintigraphy (63.8% vs 38.6, $p=0.02$), and lower median unstimulated flow rates [0.46 (0.24, 1.06) vs 0.85 (0.30, 1.49) $p=0.005$]. There was no difference in stimulated salivary flow rates between the groups (**Table 1**). In multivariable logistic regression models adjusting for age and differences in unstimulated salivary flow, SS was associated with increased odds of pathologic caries [OR 1.81 (1.06, 3.12) $p=0.03$]. Among SS patients, only greater age was significantly associated with a greater risk pathologic caries ($p=0.03$).

Conclusion: SS is associated with an increased risk of pathologic caries compared to other causes of dry mouth. SS patients had significantly reduced unstimulated salivary flow rates and abnormal salivary scintigraphy compared with nSS patients. However, differences in caries prevalence in SS patients were not explained by differences in flow rates. Qualitative differences in saliva may be a more important cause of pathologic caries in SS than quantitative differences in flow. Further study is needed to optimize prevention strategies for caries in this group.

Table 1: Characteristics of subjects with and without Sjogren's syndrome.

	Sjogen's Syndrome	Non-Sjogrens	P Value
Number of Subjects	104	121	
Age	53.8 (13.7)	51.9 (13.2)	0.3
Female	86.4%	90.7%	0.3

Metabolic Disorders Causing Fatigue in Sjogren's Syndrome. Lakshmanan Suresh[1], Julian Ambrus[2], Long Shen[3] and Sahana Vishwanath[4]. [1]State University of New York/Buffalo, Buffalo, NY, [2]University Of Buffalo, Buffalo, NY, [3]SUNY at Buffalo, Buffalo, NY, [4]SUNY- Buffalo, buffalo, NY.

Background/Purpose: Sjogren's syndrome (SS) is a complex disorder involving both the innate and immune system. Fatigue is a common feature of the disease. Mitochondrial dysfunction has been associated with chronic inflammatory diseases, including SLE, and can result in fatigue and exercise intolerance.

Methods: We evaluated 32 patients meeting the ACR criteria for SS who presented with profound fatigue for disorders of aerobic and anaerobic metabolism. Serum lactate, carnitine and ischemic forearm tests were performed. In selected patients, muscle biopsies were done for genetic and biochemical studies.

Results: Of these SS patients, 30 had elevated lactic acid at rest and 3 had abnormal ischemic forearm tests. Nine of the patients underwent muscle biopsies. Four had mitochondrial respiratory chain abnormalities, 2 had carnitine palmitoyl transferase deficiency, 1 had very long chain acyl CoA dehydrogenase deficiency and 2 had glycogen storage diseases (myophosphorylase deficiency, lactate dehydrogenase deficiency). Appropriate treatment led to symptomatic improvement in all cases.

Conclusion: Metabolic disorders are common in patients with SS and contribute to symptoms such as fatigue and exercise intolerance. Treatment of these disorders leads to symptomatic improvement. Further studies are needed to determine the incidence of metabolic disorders in SS, the incidence of SS in patients with metabolic disorders and the mechanisms by which SS and metabolic disorders are interrelated.

Disclosure: L. Suresh, None; **J. Ambrus**, None; **L. Shen**, None; **S. Vishwanath**, None.

The Impact of Primary Sjögren's Syndrome on Female Sexual Function. Jolien F. van Nimwegen, Suzanne Arends, Greetje S. van Zuiden, Arjan Vissink, Frans G.M. Kroese and Hendrika Bootsma. University Medical Center Groningen, University of Groningen, Groningen, Netherlands.

Background/Purpose: Primary Sjögren's syndrome (pSS) is a chronic and disabling disease, characterized by sicca symptoms of the eyes and mouth as well as fatigue. Besides these well-known symptoms, multiple studies have shown that women with pSS often experience complaints of vaginal dryness and dyspareunia. Our aim was to evaluate sexual dysfunctioning and sexual distress in women with pSS compared to healthy controls, as well as to assess parameters that are associated with sexual dysfunctioning and distress in pSS.

Methods: 46 women with pSS according to the AECG criteria (mean age 46.3 ± 10.5) and 43 age-matched healthy controls (mean age 44.4 ± 11.3) were included. Median disease duration of the patients was 7 years (IQR 4–14). Participants completed self-administered questionnaires, viz. Female Sexual Function Index (FSFI), Female Sexual Distress Scale (FSDS), Multidimensional Fatigue Inventory (MFI), Hospital Anxiety and Depression Scale (HADS), Maudsley Marital Questionnaire (MMQ) and RAND 36-item health survey (RAND-36). In addition, EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) and Patient Reported Index (ESSPRI) were completed in pSS patients.

Results: Women with pSS had impaired sexual functioning compared to healthy controls (median FSFI 20.6 vs. 30.3, $p<0.001$), as reflected by significantly lower scores in the domains of desire, arousal, orgasm, lubrication and pain (figure 1). Furthermore, pSS patients experienced more sexual distress (median FSDS 7 vs. 4, $p<0.05$) and were sexually active less frequently than controls (76% vs. 93%, $p<0.05$). In total, 67% of the patients never talked about sexual problems with their rheumatologist. Sexual dysfunctioning correlated significantly with depressive symptoms (HADS), higher ESSPRI score, more symptoms of fatigue (MFI), lower mental quality of life (RAND-36) and relationship dissatisfaction (MMQ), but not with systemic disease activity (ESSDAI).

Conclusion: Women with pSS have impaired sexual function and more sexual distress compared to healthy controls. Sexual dysfunctioning and distress are associated with more patient-reported symptoms of pSS, fatigue and depression. More research is needed to obtain knowledge on the pathogenesis of vaginal sicca symptoms in pSS and the best treatment for this complaint.

Figure 1: FSFI total (A) and subscale (B) scores in patients with pSS and healthy controls. Box-and-whiskers plots (Tukey); boxes indicate medians with IQRs; whiskers indicate 1.5 times the interquartile distances; ● indicate outliers.

Primary Sjögren's Syndrome Is Associated with Significant Cognitive Dysfunction. Mehmet Engin Tezcan[1], Seminur Haznedaroglu[2], Emine Belgin Kocer[2], Cemile Sonmez[3], Ridvan Mercan[4], Aysegul Atak Yucel[2], Hale Zeynep Batur[2], Berivan Bitik[4] and Berna Goker[4]. [1]Lutfi Kirdar Kartal EA Hospital, Istanbul, Turkey, [2]Gazi University School of Medicine,, Ankara, Turkey, [3]Public Health Institution of Turkey, Ankara, Turkey, [4]Gazi University School of Medicine, Ankara, Turkey.

Background/Purpose: Primary Sjögren's syndrome (PSS) is an autoimmune exocrinopathy with multiple clinical manifestations.

We aimed to evaluate the frequency and type of cognitive dysfunction and its association with anti-ganglioside antibodies in patients with PSS.

Methods: Twenty-eight female cases with PSS fulfilling the American-European consensus criteria and 20 female control subjects matched in terms of age and education level, examined between June, 2011 and August, 2013 were enrolled into the study. The mean age was 45,7±10,6 in PSS, and 42,1±10,3 ($p=0,27$) in the control group.

Neuropsychological tests including attention, information processing speed, short term memory, long term memory, visual memory and visual-spatial perception were examined in both group. Verbal frequency functions were examined and measured by COWAT, naming concentration by BNT, verbal learning by SDLT, immediate, short term and long term verbal memory by AVLT, visual spatial perception with BJLOT, and immediate, short term and long term visual memory with RCFT. Cognitive dysfuntion was defined as "mild" if there was a deterioration in 1 or 2 test performances, and as "severe" if an impairment in 3 or 4 test performances was observed.

A standard western blot test (Euroimmun, Germany) was used to investigate IgM and IgG anti-ganglioside antibodies (GM1, GM2, GM3, GD1a, GD1b, GT1b, GQ1b) in the patients and healthy controls.

Results: Primary Sjögren's syndrome patients had lower performance in tests evaluating verbal learning, verbal memory and visual-spatial perception in SDLT and BJLOT compared to healthy controls ($p<0,01$) in PSS group (Table 1). Lower performance was also observed in the patient group in clock drawing, COWAT, PASAT, and AVLT tests, however the difference did not reach a significant level ($p>0,05$).

	Patient (n=28)	Healthy control (n=20)	P
Clock Drawing	6,71 ± 0,71	7,00 ± 0,00	0,07
COWAT	25,71 ± 10,69	28,15 ± 8,43	0,38
PASAT	46,85 ± 8,65	51,00 ± 7,07	0,10
SDLT	8,0 ± 7,34	16,50 ± 4,34	**<0,01**
AVLT			
Immediate verbal memory	6,32 ± 1,92	7,40 ± 1,84	0,78

Long term verbal memory	10,32 ± 2,34	10,75 ± 2,02	0,63
BNT	33,50 ± 1,87	32,60 ± 2,58	0,21
BJLOT	21,07 ± 3,75	24,45 ± 2,46	**<0,01**

IgM anti-ganglioside antibodies were positive in 9 patients with PSS, and 2 in healthy controls. Three PSS patient had two IgM anti-ganglioside antibody positivity (GM1-GM2, GM3-GD1b, GT1b-GQ1b). IgG anti-ganglioside antibodies were positive in 3 patients with PSS, and 1 in healthy controls.

Conclusion: We found impairment in attention, information processing speed, long term memory and short term memory in PSS patients. Anti-ganglioside IgM antibodies may play a role in cognitive dysfunction in PSS by autoimmune neuroinflammation.

Implementing detailed neuropsychological tests is helpful in assessing subclinical cognitive dysfunction in PSS and early treatment.

Renal Involvement in Primary Sjögren's Syndrome: A Multicenter French Study of 95 Biopsy Proven Cases. Benjamin Terrier[1], Magali Jasiek[2], Hélène Francois[3], Rafik Mesbah[4], Laurent Chiche[5], Anne-Laure Fauchais[6], Guillaume Moulis[7], Guillaume Le Guenno[8], Estibaliz Lazaro[9], Nathalie Costedoat-Chalumeau[1], Raphaèle Seror[10], Luc Mouthon[1], Loïc Guillevin[1], Xavier Mariette[11], Eric Thervet[12], Alexandre Karras[13] and Véronique Le Guern[1]. [1]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France, [2]Nephrology, Bicêtre Hospital, University Paris Sud, France, Paris, France, [3]1Nephrology, Bicêtre Hospital, University Paris Sud, France, PARIS, France, [4]Nephrology, Hôpital Boulogne sur Mer, France, Boulogne Sur Mer, France, [5]CHU Marseille, Marseille, France, [6]Department of Internal Medicine A, Dupuytren Hospital, Limoges University Hospital, Limoges, France, [7]Internal Medicine department, Toulouse, Toulouse, France, [8]Internal Medicine department, Clermont-Ferrand, France, [9]Hôpital Haut-Lévêque, Pessac, France, [10]Université Paris Sud, Le Kremlin Bicêtre, France, [11]Université Paris-Sud, Le Kremlin Bicêtre, France, [12]Hopital Européen Georges Pompidou, APHP, PARIS, France, [13]Hôpital Européen Georges Pompidou, APHP, Paris, France.

Background/Purpose: Renal involvement is reported in 5 to 25% of patients with primary Sjögren's syndrome (pSS). However, data on pSS-related nephropathy with renal biopsy (RB) remain scarce. This observational study was undertaken to describe the clinical and histopathological characteristics of pSS-related nephropathies and their outcomes.

Methods: We conducted a French multicenter and transdisciplinary retrospective study on pSS patients with RB-proven nephropathies. Inclusion criteria were patients diagnosed with pSS based on American-European Consensus Group (AECG) criteria or study-specific enlarged AECG criteria (presence of ≥3 of 4 AECG items), and who underwent a RB.

Results: Ninety-five patients were included (sex ratio F/M 9/1, mean age 49 years), 84% and 16% fulfilling AECG criteria and enlarged AECG criteria respectively. pSS was isolated in 88% or associated with other organ-specific autoimmune disorders (12%), including primary biliary cirrhosis, autoimmune hepatitis and thyroiditis. Renal disease was diagnosed prior to pSS for 20%, with a median interval of 17 months. For 41%, the 2 conditions were diagnosed simultaneously and, for 39%, after pSS, with a median interval of 36 months. Renal manifestations consisted of renal failure (86%), glomerular-range proteinuria (26%), electrolyte disturbances alone (18%), lithiasis (10%) and/or nephrocalcinosis (5%). RB exhibited acute or chronic tubulointerstitial nephritis (77%) with numerous plasma-cell infiltrates (69%). Glomerular lesions were found in 23%, associated with interstitial infiltrates in most patients. Glomerular disease was mainly cryoglobulinemic glomerulonephritis, focal and segmental glomerulosclerosis or membranous nephropathy. Eighty patients (84%) received corticosteroids (CS). In 21 patients (22%), standard immunosuppressive drugs (n=8) and/or rituximab (n=18) was added on top of CS in a first or a second line of treatment. Baseline mean estimated glomerular filtration rate (eGFR) was 40 mL/min/1,73m2. After a median follow-up of 53 months, eGFR improved significantly (47 mL/min/1,73m2, P=0.001), and only 3 patients progressed to end-stage renal disease. Multivariate analyses found age and tubulointerstitial lesions as significantly associated factors with poor renal prognosis, even though overall outcome was good.

Conclusion: In pSS, the main renal lesion is tubulointerstitial nephropathy associated with significant and frequent renal dysfunction. Systemic treatments can significantly improve renal function. Analysis of renal prognosis associated with the different therapeutic strategies is ongoing.

Impaired Speckle Tracking As a Marker of Subclinical Left Ventricular Dysfunction in Patients Affected By Primary Sjögren's Syndrome. Fabiola Atzeni[1], Stefano Galaverna[2], Chiara Colombo[2], Luigi Gianturco[2], Laura Boccassini[1], Piercarlo Sarzi-Puttini[1] and Maurizio Turiel[2]. [1]Rheumatology Unit, L. Sacco University Hospital, Milan, Italy, [2]Cardiology Unit, IRCCS-Galeazzi Orthopedic Institute,, Milan, Italy.

Background/Purpose: Primary Sjögren's syndrome (pSS) is a common chronic autoimmune disease that particularly affects the salivary and lachrymal glands, and leads to dry eyes and dry mouth. We have previously shown that plasma asymmetric dimethylarginine (ADMA) levels and coronary flow reserve (CFR) are impaired in patients with pSS. The aim of this study was to investigate the use of impaired speckle tracking as a marker of subclinical left ventricular dysfunction predicting congestive heart failure in patients with pSS and a normal ejection fraction.

Methods: The study involved 49 outpatients who fulfilled the American-European Consensus Criteria (AECG) criteria for pSS (14 males and 35 females; mean age 57 ±6.9 years), and 22 healthy controls matched in terms of age, gender and other anthropometric characteristics. Cardiovascular (CV) risk profiles were assessed by means of standard electrocardiography (ECG), conventional and stress trans-thoracic echocardography with the measurement of CFR, carotid ultrasonography and pulse wave velocity (PWV). Two-dimensional echocardiographic images were obtained using the apical 4-chamber view at a high frame rate of 70–80 frames/s, and three cardiac cycles were stored in cine-loop format for off-line analysis using commercially available QLAB 9 software (Philips Medical System, USA) in order to assess end-systolic LV longitudinal strain (ε).

Results: All of the patients had extra-extraglandular systemic involvement pSS: 30 were being treated with hydroxychloroquine (HCQ) 400 mg/day, 11 with azathioprine (AZA) at a mean dose of 150 mg/day (range 50–200 mg), and eight with methotrexate (MTX) at a mean dose of 7.5 mg/weekly. None of the patients showed any signs or symptoms of CV disease, pulmonary involvement, or any other complication. The patients' mean EF and E/A ratios were respectively 59.11±6.35% and 0.94±0.0.24, which were not significantly different from those of the controls; however, although within the normal range, their CFR was lower (median 2.7, IQR 2.40–2.90 *vs* 3.20, IQR 3.06–3.33; $p<0.0001$). Right and left pulse wave velocity (PWV) (PWV m/sec median 8.8, IQR 7.26–10.32 *vs* 6.86, IQR 6.66–7.10; $p<0.0001$) and right and left coronary intima media thickness (cIMT) (cIMT mm: median 0.6, IQR 0.5–0.7 *vs* 0.53, IQR 0.50–0.60; $p=0.08$) values were all higher in the pSS patients, but the differences were not statistically significant The results of the speckle tracking analysis were significantly different between the two groups, with global longitudinal strain deformation in the apical 4-chamber view (Long. ε 4c) being significantly lower in the pSS patients than in controls (Long ε 4c %: median 15.28, IQR 12.3–16.2 *vs* 19.8, IQR 19.3–20.40; $p<0.0001$).

Conclusion: LV myocardial longitudinal ε measured by means of speckle tracking echocardiography was impaired in our pSS patients in the absence of any clinical evidence of CV disease and when traditional echocardiographic evaluations were still negative, thus suggesting a myocardial alteration. However, further studies are required to define more precise methods of assessing CV disease in patients with pSS.

Presence of Germinal Centers at Baseline Is Associated with Clinical Response of Glandular Essdai Domain after Abatacept Treatment in Primary Sjogren's Syndrome. Erlin A. Haacke, Frans G.M. Kroese, Petra M. Meiners, Bert van der Vegt, Arjan Vissink, Fred K.L. Spijkervet and Hendrika Bootsma. University Medical Center Groningen, University of Groningen, Groningen, Netherlands.

Background/Purpose: Abatacept inhibits the costimulatory interaction of T-lymphocytes and antigen-presenting cells. Treatment of early and active primary Sjögren's Syndrome (pSS) with abatacept decreases disease activity. The aim of this study was to assess the histopathological changes in the parotid gland tissue after treatment with abatacept in pSS patients.

Methods: 15 patients (12 female, 3 male) were included in the open-label Active Sjögren Abatacept Pilot (ASAP) study and received 8 intravenous abatacept infusions on days 1,15, 29 and every 4 weeks thereafter. Before treatment and at 25 weeks of follow up a parotid gland biopsy was taken. Hematoxilin-eosin stains were evaluated for focus score (foci of 50 lymphocytes/4mm^2), lymphoepithelial lesions (LELs) and presence of germinal centers. A CD45 stain was used to calculate the area of lymphocytic infiltrate (Aperio ImageScope v12.0). The infiltrate was further analysed for numbers of CD20+ B-cells, CD3+ T-cells and IgA, IgG and IgM positive plasma cells using HistoQuest.

Results: At baseline 5 out of 15 patients (33%) showed presence of germinal centers in parotid gland tissue. In all these 5 patients germinal centers were absent after abatacept treatment. One patient showed only limited germinal center activity after treatment. The mean number of germinal centers decreased from 0,06 GC/mm^2 to 0,01 GC/mm^2. Importantly, the number of germinal centers/mm^2 at baseline is associated with a clinical improvement in the glandular domain of the ESSDAI. Abatacept treatment did not affect focusscore, LELs, amount of infiltrated B-cells and T-cells. Analysis of the plasma cell population is currently in progress.

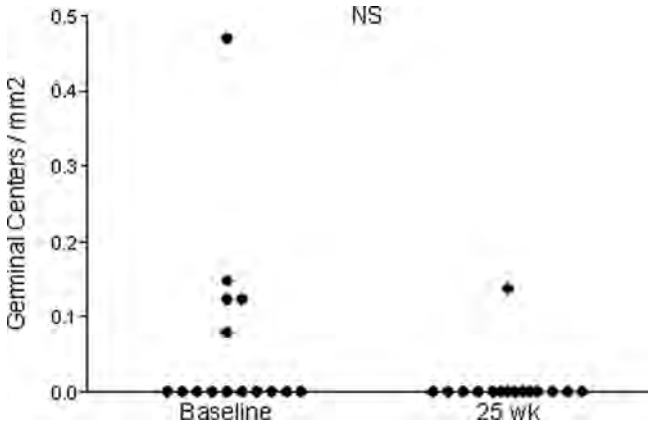

Figure 1: Number of germinal centers in parotid gland tissue decline after treatment with abatacept.

Conclusion: Presence of germinal centers at baseline in parotid gland tissue is associated with clinical respons in the glandular domain of the ESSDAI after treatment with abatacept in primary Sjogren's syndrome. Histopathological analysis of parotid gland tissue may therefore be helpfull in assessing treatment efficacy. As expected, abatacept does not affect the lymphocytic infiltrate in terms of overall numbers of T- and B-cells.

Effectiveness and Safety of Low-Dose Cyclosporine a in Patients with Primary Sjögren's Syndrome (pSS) with Articular Involvement – Results of a Pilot Study. Claudia Kedor, Jan Zernicke, Anja Hagemann, Kathrin Mattat, Gerd Burmester and Eugen Feist. Charité University Medicine, Berlin, Germany.

Background/Purpose: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease, where musculoskeletal manifestations are usually treated by symptomatic measures and different conventional DMARDs by off-label use. Cyclosporine A (CyA), as an approved DMARD for treatment of arthritic joint involvement in different rheumatic disorders, is mainly used for local treatment of keratoconjunctivitis sicca in pSS, whereas reports on systemic effects are limited to small cohorts so far. Since low-dose CyA has shown promising effects and improved tolerability in different autoimmune disorders, the aim of this pilot study was to investigate the effects of a reduced dosage on articular involvement in patients with pSS.

Methods: For this single-center, open-label, non-controlled phase II trial n=30 patients with pSS (29 females, average age 54.9 years, mean disease duration of 6 years) fulfilling the European-American Classification Criteria were included. All patients had active articular involvement with a minimum of 3 tender and/or 3 swollen joints. Oral NSAIDs and systemic steroids (£10mg/d prednisone equivalent) were permitted at stable doses for at least 4 weeks prior to inclusion. In 18 patients, at least one DMARD (not CyA) had failed prior to study entry. Primary endpoint was to evaluate the therapeutic effects of low-dose CyA (2mg/kg divided in two intakes a day) on articular involvement (reduction of tender and swollen joint counts) after 16 weeks of treatment.

Results: Introduction of low-dose CyA improved significantly joint involvement in patients with pSS. At week 16, the DAS28 decreased from 5.1 to 4.2 ($p=0.003$), the Tender Joint Count (out of 68) decreased from 17 ± 13 to 10 ± 11 ($p=0.003$), the Swollen Joint Count (out of 66) decreased from 3 ± 3 to 1 ± 3 ($p<0.001$) Furthermore, a clear treatment effect was observed on overall disease activity by the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) reduction from 5.3 ± 3.3 to 3.0 ± 3.1 ($p=0.001$). Ultrasonography of the three predominanty affected joints confirmed improvement of joint effusion and synovitis ($p<0.05$) at week 16. There was no significant effect on HAQ or sicca-symptoms measured by Schirmer- and Saxon-tests. Overall, the treatment was well tolerated and adverse events were consistent with the known safety profile of CyA (e. g. hypertension, headache, grade I creatinine increase).

Conclusion: In this pilot-study, promising effects of low-dose CyA treatment on articular involvement and disease activity were observed in patients with pSS. The safety profile was comparable to known side effects of CyA.

Compromised Volumetric Bone Density, Bone Microarchitecture and Bone Strength in Patients with Ankylosing Spondylitis: High-Resolution Peripheral Quantitative Computerized Tomography (HRpQCT) Based Study. Nisha Nigil Haroon[1], Eva Szabo[2], Janet Raboud[3], Ammepa Anton[4], Robert Josse[1], Robert D. Inman[1] and Angela Cheung[1]. [1]Department of Medicine, University of Toronto, Toronto, ON, [2]Osteoporosis Program, UHN, TOronto, ON, [3]Dalla Lana School of Public Health, University of Toronto, Toronto, ON, [4]University Health Network, Toronto, ON.

Background/Purpose: Patients with ankylosing spondylitis (AS) have high fracture risk. BMD, bone microarchitecture and strength determine fracture risk. However, in AS, DXA-based BMD measurements of the lumbar spine may be falsely normal due to the presence of syndesmophytes. Also, DXA cannot differentiate between trabecular and cortical bone. The effect of AS on bone microarchitecture and strength is also unknown. We assessed bone microarchitecture and strength in patients with AS and compared that with non-AS controls.

Methods: AS was defined by the modified New York criteria. Disease activity of AS was measured by BASDAI, mSASSS, serum ESR and CRP levels. Volumetric BMD (vBMD) and microarchitecture were measured using HRpQCT, and bone strength was estimated using finite element analysis (FEA). Multivariable linear regression was used to analyze the effect of AS on HRpQCT parameters.

Results: There were 44 cases (82% Caucasian). The mean (+SD) age and BASDAI were 44+2 and 6.3+ 1.8 respectively. Median (IQ) disease duration was 20 (7.3–27.8 years). Twenty-three subjects had mSASSS >0. Four cases (9%) reported a history of fragility fracture. Use of TNF inhibitors (none), bisphosphonates (n=2) and corticosteroids (n=2) was negligible. Mean serum ESR, CRP and SAP levels were 22.0+23.6, 12.6 +15.6 and 96.2 +43.2 IU respectively. In multivariable linear regression models adjusted for age and gender, cases (n=44) had lower vBMD (trabecular, cortical and total), cortical thickness, BV/TV, bone stiffness and stress, and higher cortical porosity and trabecular separation at the radius (Table 1) when compared to non-AS controls (n=85). Tibial vBMD, BV/TV and cortical porosity were also abnormal in cases. But trabecular architecture at tibia was not different between cases and controls.

Conclusion: This study documents abnormalities of bone structure and strength in patients with AS. Patients with AS had lower volumetric BMD and worse microarchitecture at the trabecular and cortical regions compared to controls. Bone stiffness and stress at the radius and tibia, as estimated by FEA, also tended to be lower in cases than controls. These abnormalities might partly explain the high fracture risk in patients with AS.

Table 1: Multivariable linear regression showing abnormal bone microarchitecture and strength in patients with AS (44 cases and 85 controls).

Do TNF Alpha Inhibitors Have an NSAID Sparing Effect in Real Life in Early Axial Spa? Results from the DESIR Cohort. Anna Moltó[1], Benjamin Granger[2], Daniel Wendling[3], Maxime A. Breban[4], Maxime Dougados[5] and Laure Gossec[6]. [1]GRC-UPMC 08 (EEMOIS); UPMC Univ Paris 06.AP-HP, Pitié Salpêtrière Hospital, Department of Rheumatology, Paris, France., Paris, France, [2]Université Pierre et Marie Curie - Paris 6 ; AP-HP, Paris, France, [3]CHU J Minjoz, Besancon, France, [4]Ambroise Paré Hospital, and Versailles Saint Quentin en Yvelines University, Boulogne-Billancourt, France, [5]INSERM (U1153): Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité, Paris, France., Paris, France, [6]UPMC GRC08, Paris 06 University, Pitié Salpétrière Hospital, Paris, France.

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) are the keystone in the treatment of axial Spondyloarthritis (axSpA), but have potential side effects (cardiovascular and gastrointestinal). Effectiveness of TNF alpha inhibitors (TNFi) in early axial SpA has already been established-but the NSAID-sparing-effect of TNFi in real life has not been evaluated. The aim of this study was to evaluate the effect of TNFi on NSAID intake in an early axSpA cohort over the first 2 years of follow-up.

Methods: *Study design:* prospective, multi-centre, observational study (DESIR cohort) of patients with early inflammatory back pain; management and treatment of these patients was decided by their treating rheumatologists. *Data of interest at each visit over 2 years:* NSAID intake (yes/no) and ASAS-NSAID intake score. *Statistical analysis:* matching of patients receiving a TNFi or not by a propensity score; ANCOVA of the ASAS-NSAID intake score between groups over follow-up.

Results: Of the 627 patients followed-up, 181(28.9%) received a TNFi and were matched to 181 patients receiving usual care. Baseline characteristics were comparable (mean age 34 years and 40%males)NSAID-Sparing effect:Initially, 90.2% and 90.0% of patients received an NSAID (TNFi/usual care, respectively), with a greater decrease over time in the TNFi group (Figure1. The decrease in the median NSAID intake score was significantly greater in the TNFi group (from 54.9 to 1.9 vs. 41.9 to 22.3, p=0006), and the percentage of patients that could either decrease by 50% their NSAID intake or decrease their score under 10 or discontinuate NSAID treatment was greater in the TNFi group (67.6% vs 46.2%, p=0.002) (Figure2).

Conclusion: TNFi treatment is associated with a decrease in the proportion of patients taking NSAIDS, and even with a greater decrease in the overall intake of NSAIDs, confirming the NSAID-sparing effect of TNF alpha blockers in early axSpA in real life.

The Effect of Co-Medication with Conventional Synthetic (cs)Dmards on Achieving Low Disease Activity While Persisting on Adalimumab Therapy in Patients with Ankylosing Spondylitis/Axial Spondylarthritis (AS)–Analysis from the Czech Biologics Registry Attra. Karel Pavelka[1], Jakub Zavada[2], Marketa Fojtikova[3], Sarka Forejtova[1] and Karel Hejduk[4]. [1]Institute of Rheumatology, Prague, Czech Republic, [2]Charles University, Prague, Czech Republic, [3]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [4]Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic.

Background/Purpose: The role of combined treatment with csDMARDs and anti-TNF therapy in AS is not well established.

Methods: Main goal of this study was to compare the probability of achieving low disease activity (LDA) while persisting on adalimumab (ADA) therapy in AS patients treated by either ADA alone, or by combination of ADA + csDMARDs. This analysis was conducted within the national biologics registry with mandatory registration for all patients with AS who start treatment with biologics. All patients with AS treated with ADA as a first line anti-TNF drug with available baseline BASDAI and CRP were included in the analysis. To get reimbursement for anti-TNF therapy, all AS patients had to have high baseline disease activity (defined as BASDAI >4, and CRP > 10 mg/l). LDA was defined as BASDAI < 4 and CRP <5 mg/l. Pre-specifed sensitivity analyses were conducted in patients with pure axial, and combined axial+peripheral forms of AS.

Results: Data for 481 patients were available for the analysis (table). There was no difference in the primary outcome either in the total cohort (figure 1), or in the subset of patients with combined axial and peripheral involvement. In patients with pure axial form of AS, higher probability of achieving LDA while persisting on ADA therapy was observed in some, but not all time-points of follow-up (figure 2). Patients on co-therapy with methotrexate (n=55) fared similarly as those on sulfasalazine (n=141).

Conclusion: Co-therapy with csDMARDs did not increase the overall probability of reaching LDA and drug survival on ADA in AS patients.

Is the Degree of NSAID Treatment in Early Axial Spondyloarthritis a Reflection of the physician's Diagnosic Confidence? Results from the DESIR Cohort. Anna Moltó[1], Benjamin Granger[2], Daniel Wendling[3], Maxime Dougados[4] and Laure Gossec[5]. [1]GRC-UPMC 08 (EEMOIS); UPMC Univ Paris 06.AP-HP, Pitié Salpêtrière Hospital, Department of Rheumatology, Paris, France., Paris, France, [2]Université Pierre et Marie Curie - Paris 6; AP-HP, Paris, France, [3]CHU J Minjoz, Besancon, France, [4]INSERM (U1153): Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité, Paris, France., Paris, France, [5]UPMC GRC08, Paris 06 University, Pitié Salpétrière Hospital, Paris, France.

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) are the keystone in the treatment of axial Spondyloarthritis (axSpA). Diagnosis is often not easy in early forms due to the paucity of structural/inflammatory lesions and the clinical gestalt of the physician is an important part of the treatment decision in clinical. Our hypothesis was that NSAID prescription might be a reflection of the degree of the physician's diagnostic confidence in inflammatory back pain (IBP) suggestive of axSpA. Our objective was a) to describe the population of IBP patients suggestive of axSpA that were almost never exposed to NSAID over 3 years and to compare such population to the exposed patients; b) to compare both groups with regard to the fulfillment of the ASAS criteria and physicians' diagnostic confidence and c) to explore the correlation between NSAID intake and physicians' diagnostic confidence.

Methods: *Study design and patients:* Observational prospective, multicentre study (DESIR cohort) of patients with early IBP (>3 months and < 3 years symptom duration) suggestive of axSpA, and available data over 3 years.*Diagnosis:* ASAS axSpA criteria and physician's diagnostic confidence in axSpA (from 0 to 10, where 10= highest confidence).*NSAID intake:* the almost never exposed (ANE) group was defined as the patients who had an ASAS-NSAID score < 5 at each visit over follow-up (e.g. patients who had received <6 days/6 months of diclofenac). The rest of the cohort was the exposed (E) group.*Statistical analysis:* by Chi-square and T tests and spearman correlation.

Results: Of the 606 patients, 26 (4.3%) patients were classified in the ANE group. Patient and disease characteristics were comparable in both groups, except for history of inflammatory bowel disease (IBD): 6 (23%) vs. 17 (2.9%), in the ANE and E groups, respectively (p<0.001). Diagnosticconfidence: a) baseline: the percentage of patients fulfilling the ASAS criteria at baseline (and each arm) was similar in both groups (ASAS criteria :69.2% and 72.8%, for the ANE and E groups, respectively), as was the mean physician's axSpA diagnostic confidence (7.1±2.6 and 7.1±2.5). A quite moderate correlation between physician's axSpA diagnostic confidence and NSAID intake score was found (rho= 0.15, p=0.0002); b) at 3 years: no differences were observed in the fulfillment of the ASAS criteria (69.2% and 74.9%);no differences were observed either with regard to the mean physician's axSpA diagnostic confidence at the end of follow-up, (8.11±2.5 and 7.8 ±2.8) and no correlation was found between the physician's axSpA diagnostic confidence and the NSAID intake score (rho= 0.06, p=0.183).

Conclusion: Less than 5% of patients with IBP suggestive of SpA were almost never exposed to NSAID during follow-up; these patients did not differ from the rest of the cohort, except with regard to the presence of IBD. This suggests that lack of NSAIDs exposure is more driven by the presence of IBD than the lack of diagnosis confidence.

Are We over-Treating with Nsaids Our Early Axial Spa Patients? Results from the DESIR Cohort. Anna Moltó[1], Benjamin Granger[2], Daniel Wendling[3], Maxime Dougados[4] and Laure Gossec[5]. [1]GRC-UPMC 08 (EEMOIS); UPMC Univ Paris 06.AP-HP, Pitié Salpêtrière Hospital, Department of Rheumatology, Paris, France., Paris, France, [2]Université Pierre et Marie Curie - Paris 6 ; AP-HP, Paris, France, [3]CHU J Minjoz, Besancon, France, [4]INSERM (U1153): Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité, Paris, France., Paris, France, [5]UPMC GRC08, Paris 06 University, Pitié Salpétrière Hospital, Paris, France.

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) are the keystone in the treatment of axial Spondyloarthritis (axSpA), and even in early forms, patients symptoms may lead to an over-treatment by NSAIDs. However, the current recommendation is to use NSAIDs at the lowest efficacious dose for the shortest period of time, due to safety issues (cardiovascular and gastro-intestinal side effects). The aim of our study was to describe the real-life NSAID use in an observational cohort of inflammatory back pain suggestive of axial SpA over a 3 years period of follow-up.

Methods: *Study design:* Observational prospective, multi-centre study (DESIR cohort) of patients with early inflammatory back pain (IBP) suggestive of ax-SpA. *Patients:* Patients who attended all 6 visits (every 6 months during the fist 2 years and yearly at 3 years) and for whom NSAID information was available were included in this analysis. *Data collected at every visit over 3 years:* NSAID intake and ASAS-NSAID intake score for the 6 months preceding the visit. The ASAS-NSAID intake score reflects the overall intake of NSAID during a period and ranges from 0 to 200 or more (where a 100 =150 mg of Diclofenac/day every day of the period of interest); "highly doses" were defined as score > 75. *Statistical analysis:* descriptive

analysis of the NSAID intake (as a binary variable "NSAID intake during the last 6 months" yes/no, and as a continuous variable by the ASAS-NSAID intake score for the last 6 months). Variation of the ASAS-NSAID score over time was tested by analysis of variance (ANOVA).

Results: 627 patients (46.1% males, mean age 33.7(8.7)) were assessed. 181 (28.9%) patients received a least one TNF alpha blocker during follow-up. At inclusion, 582 patients (92.8%) patients were taking NSAIDs; this proportion decreased over time, with the lowest proportion being 70.2% at 18 months. At all visits, more than 70% patients were treated with NSAIDs. Median ASAS-NSAID intake score was 36 (13–72) at inclusion, and substantially decreased to reach 7 (0–44) after 3 years ($p<0.0001$) (Figure) "Highly treated" patients represented 10% of the population at inclusion, and 4% after 3 years, with only 3 patients with a sustained score > 100 over time.

Conclusion: more than 70% of this early axSpA population received an NSAID treatment over the 3-years of follow-up, but intake significantly decreased over time, with only very few "highly treated" patients. This suggests that rheumatologists do not over-treat early axSpA patients with NSAIDS. Further studies should focus on those patients with sustained high doses of NAIDS over time.

Etanercept Increases Bone Mineral Density in Ankylosing Spondylitis, but Does Not Prevent Vertebral Fractures. M.a.C. van der Weijden[1], J.C. van Denderen[1], W.F. Lems[2], M.T. Nurmohamed[2], B.a.C Dijkmans[2] and I.E. van der Horst-Bruinsma[2]. [1]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands.

Background/Purpose: Ankylosing spondylitis (AS) is characterized by chronic inflammation often leading to ankylosis of the spine, but also by a decrease of bone mineral density (BMD) and high prevalence of vertebral fractures (VF). Treatment with TNF blocking agents decreases inflammation and has shown to be effective in increasing BMD. We studied the effects of etanercept on BMD and VF in AS patients after two years of treatment. Furthermore we studies changes in bonemarkers (CTXI, CTXII, RANKL, OPG, Osteocalcin) and radiological damage.

Methods: Patients with active AS, treated with etanercept for two years, were included. BMD lumbar spine and hips was measured at baseline and after two years, as well as the radiological damage (mSASSS, including thoracic spine), VF (Genant method) and change in bone-markers.

Results: Forty-nine AS patients were included (Table**).** After two years of etanercept, hip BMD raised with 2.2% ($p=0.014$) and lumbar spine BMD with 7.0% ($p<0.001$). The BASDAI decreased significantly ($p<0.001$) as well as CRP and ESR ($p<0.001$). Despite etanercept therapy, the number of patients with vertebral fractures more than doubled (from 6 to 15 patients, $p=0.004$) as well as the severity. Also the radiological damage mSASSS+ThSpine increased significantly over time (from 12.1 to 18.5, $p<0.001$). No significant change in bone-markers was found.

Clinical characteristics N=49	Baseline	After 2 years etanercept
Men[a]	40 (81.6)	
Age[b], years	41.8 (9.2)	
Disease duration[b], years	12.2 (9.1)	
ESR[c], (mm/hr) [<20]	20.0 (6.0–39.0)	6.5 (3.0–16.0)*
CRP[c], (mg/l) [<10]	14.0 (3.0–39.0)	2.5 (1.0–9.8)*
BASDAI[b], (0–10)	5.7 (1.6)	2.9 (2.1)*
BASFI[b], (0–10)	5.7 (2.1)	3.5 (2.9)*
BASMI[b], (0–10)	4.4 (2.3)	4.0 (2.4)
Total mSASSS[c], (0–72)	10.0 (3.8–35.5)	15.5 (5.5–42.5)*
Total mSASSS+ThSpine[c], (0–90)	12.1 (6.8–42.7)	18.5 (8.7–52.0)*
sBMD hip[b]	0.903 (0.152)	0.921 (0.146)*
sBMD L2-L4[b]	1.141 (0.203)	0.213 (0.200)*
Number vertebral fractures[a]	8 (16.3)	21 (42.9)*
Patients with vertebral fractures[a]	6 (12.2)	15 (30.6)*

[a]number (%), [b]mean (SD), [c]median (IQR), *significant change $p<0.05$

Conclusion: This prospective longitudinal observational cohort study in AS patients showed that after two years etanercept treatment, BMD of the hip and spine increased significantly. However, the number and severity of vertebral fractures increased, as well as the radiological progression, including the thoracic spine. Thus, the favourable effect of etanercept on BMD in AS is accompanied by unfavourable outcomes on vertebral fractures and radiological damage.

Vitamin D insufficiency and Deficiency in Two European Cohorts of Patients with Inflammatory Rheumatic Disorders. Alessandra Vacca[1], Giovanni Porru[1], Grazia Dessole[1], Alessandro Mathieu[1], Catherine Cormier[2], Yvonne Fulla[2], Andre Kahan[2] and Yannick Allanore[3]. [1]Unit and Chair of Rheumatology, University Hospital of Cagliari, Cagliari, Italy, [2]Rheumatology A Department, Cochin Hospital, APHP, Paris Descartes University, Paris, France, [3]Paris Descartes University, Rheumatology A Department and INSERM U1016, Cochin Hospital, Paris, France.

Background/Purpose: Vitamin D plays an important role in the modulation of immune system and epidemiologic data indicate low vitamin D levels in autoimmune diseases such as rheumatoid arthritis (RA), connective tissue disorders, inflammatory bowel diseases and multiple sclerosis. Several studies reported contradictory results regarding correlation between disease activity and vitamin D levels in these diseases. Our objective was to assess 25-OH vitamin D concentrations in 2 independent cohorts of patients affected by inflammatory rheumatic disorders (IRD) and correlations with disease activity and disability.

Methods: We retrospectively analyzed 420 patients (246 RA, 100 ankylosing spondylitis (SA), 74 psoriatic arthritis (PsA) followed at Rheumatology tertiary centers in Northern France (Paris) and Southern Italy (Cagliari). All patients underwent clinical and laboratory evaluation including serum calcium and phosphorus levels, 25-OH vitamin D and parathyroid hormone (PTH). Vitamin D concentrations < 30 ng/ml were considered insufficiency, while values < 10 ng/ml were classified as deficiency. Disease activity was assessed by DAS 28 in RA and PsA patients, and by BASDAI and BASFI in AS patients.

Results: Vitamin D insufficiency and deficiency was very high : respectively 66% and 19% in RA, 76% and 10% in AS, 83% and11% in PsA. Their incidence was comparable between the two populations in RA (68% and 20% versus 62% and 18%, P = ns, respectively in the French and Italian patients), while it was significantly higher among French compared to Italian patients in AS and PsA (86% and 23% versus 61% and 0, P = 0.005 and P = 0.002; 89% and 20% versus 55% and 3%, P = 0.002 and P = 0.02, respectively in AS and PsA). Vitamin D supplementation was statistically different only in RA patients (53% versus 34%, P = 0.003, respectively in French and Italian patients). In the combined populations, in RA patients, no correlation was observed between vit D and DAS score but treated patients with anti-TNF alpha agents had higher vitamin D levels (P = 0.01). In SA patients low vitamin D concentrations correlated with higher BASFI (R = -0,02; P < 0.05). We did not find any correlation between vitamin D levels and the other evaluated parameters.

Conclusion: A high incidence of vitamin D deficiency was found in IRD in the two populations, independently of geographic origin for RA, while a higher incidence was seen in French AS and PsA patients, suggesting a potential different influence of vitamin D on these diseases. By contrast, no correlations with disease activity were found except for disability index BASFI in AS patients. In our study, TNF alpha agents seem to improve vitamin D levels as well as disease activity, but it remains controversial if this is an effect linked to disease activity modulation or it directly depends from immunomodulatory properties of vitamin D.

This finding encourage to perform randomized controlled studies for confirming that vitamin D supplementation could reduce the risk of autoimmunity or that it eases disease activity, although there is still not a clear consensus about the optimal circulating 25-OH vitamin D levels and the supplementation dosage for maintaining immune homeostasis.

Sustained Improvements in Workplace and Household Productivity and Social Participation with Certolizumab Pegol over 96 Weeks in Patients with Axial Spondyloarthritis, Including Ankylosing Spondylitis and Non-Radiographic Axial Spondyloarthritis. Desiree van der Heijde[1], Juergen Braun[2], Martin Rudwaleit[3], Oana Purcaru[4] and Arthur Kavanaugh[5]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]Endokrinologikum, Berlin, Germany, [4]UCB Pharma, Anderlecht, Belgium, [5]University of California San Diego, La Jolla, CA.

Background/Purpose: Axial spondyloarthritis (axSpA) includes both ankylosing spondylitis (AS, meeting modified New York criteria) and axSpA with no sacroiliitis on X-ray (non-radiographic axSpA, nr-axSpA). Previous results show significant improvements in workplace and household productivity and social participation with certolizumab pegol (CZP) vs placebo (PBO) up to Week (Wk) 24 in the RAPID-axSpA study, which were continued to Wk48.[1] This report investigates the long-term effect of CZP on workplace and household productivity up to 96 wks in patients (pts) with axSpA, including AS and nr-axSpA.

Methods: The ongoing RAPID-axSpA trial (NCT01087762),[2] a 204-wk Phase 3 study in axSpA pts, is double-blind and PBO-controlled to Wk24, dose-blind to Wk48 and open-label to Wk204. Pts had active axSpA, according to ASAS criteria,[3] including both AS and nr-axSpA pts. Pts originally randomized to CZP (200mg Q2W or 400mg Q4W, following 400mg loading dose [LD] at Wks 0, 2, 4) continued on their assigned dose in the OLE; PBO pts entering dose-blind phase were re-randomized to CZP LD followed by CZP 200mg Q2W or CZP 400mg Q4W after Wk24 or, for non-responders, after Wk16. The validated arthritis-specific Work Productivity Survey (WPS; administered Q4W)[4] assessed the impact of axSpA on workplace and household productivity. WPS responses (LOCF imputation) in pts originally randomized to CZP are summarized descriptively over 96 wks.

Results: A total of 325 pts were randomized, of whom 218 received CZP (200mg Q2W or 400mg Q4W) from Wk0. Of the pts randomized to CZP at baseline (BL), 93% completed Wk24, 88% Wk48 and 80% Wk96. At BL, 72% of CZP pts were employed outside of the home. Pts randomized to CZP reported ~1 wk of paid work, ~2 wks of household duties, and mean 4.0 days of social activities affected over previous month. Employed pts in both CZP groups reported reductions in workplace absenteeism and presenteeism to Wk24, with continued improvements to Wk96 (Table). CZP pts reported continued improvements in household productivity and social participation up to Wk96 (Table). Similar improvements were observed in AS and nr-axSpA pts (Table).

Conclusion: The initial improvements with CZP in workplace and household productivity and increased participation in social/leisure activities were continued to Wk96 in axSpA, AS and nr-axSpA pts.

Low Cardio-Respiratory Fitness Is Associated with Increased Arterial Stiffness in Patients with Ankylosing Spondylitis. Inger Jorid Berg, Anne Grete Semb, Silje H. Sveaas, Camilla Fongen, Désirée van der Heijde, Tore K. Kvien, Hanne Dagfinrud and Sella A. Provan. Diakonhjemmet Hospital, Oslo, Norway.

Background/Purpose: We have previously shown that patients with ankylosing spondylitis (AS) have lower cardio-respiratory fitness (CRF) than population controls. CRF is inversely associated to risk of cardiovascular disease (CVD) in the general population. Arterial stiffness is a marker of CVD risk, and AS patients have increased arterial stiffness compared to controls. The objective was to assess associations between CRF and arterial stiffness in AS patients.

Methods: This is a cross-sectional study on AS patients (mNY criteria) where information on demographics and medication was assessed from questionnaires. Arterial stiffness (Pulse Wave Velocity (PWV) and Augmentation Index (AIx)) was recorded using the Sphygmocor apparatus (AtCor). CRF was assessed as peak oxygen uptake (VO_2peak) by a maximal walking treadmill test (modified Balke protocol). Statistics were performed using SPSS version 21. Univariate associations between lnPWV/AIx (dependent variable) and VO_2peak as well as possible confounders and factors with effect on the outcome were analyzed in separate linear regression models adjusted for age and gender. Variables with p-value<0.25 were included in backwards multivariate linear regression models.

Results: The 113 AS patients had the following characteristics: Mean (SD) age 48.4 (11.3) years, 72 (64 %) males, 18 (16%) smokers, mean (SD) BMI (kg/m^2) 25.6 (3.5), median (IQR) CRP (mg/l) 3 (2–10), 73 (65%) used NSAIDs, 24 (21%) used TNF-inhibitors, 14 (12%) used statins and 28 (25%) used antihypertensive medication. In regression models VO_2peak was significantly inversely associated with lnPWV independent of other factors (table). Similar results were found for AIx (table).

*p-value<0.05

Conclusion: CRF measured by VO_2peak was inversely associated with arterial stiffness indicating that reduced CRF can be related to increased risk

for CVD in AS patients. Studies on the effect of increasing CRF on risk of CVD in AS patients are warranted.

The Comparative One-Year Drug Survival Rate of Tumor Necrosis Factor Inhibitors in Patients with Rheumatoid arthritis and ankylosing spondylitis; results from Turkbio Registry. Ismail Sari[1], Umut Kalyoncu[2], Ahmet Mesut Onat[3], Omer Nuri Pamuk[4], Omer Karadag[2], Bunyamin Kisacik[3], Niels Steen Krogh[5], Soner Şenel[6], Fatih Saritaş[4], Ihsan Ertenli[2], Sedat Kiraz[2], Pinar Cetin[1], Fatos Onen[1] and Nurullah Akkoc[1]. [1]Dokuz Eylul University School of Medicine, Izmir, Turkey, [2]Hacettepe University School of Medicine, Ankara, Turkey, [3]Gaziantep University School of Medicine, Gaziantep, Turkey, [4]Trakya University School of Medicine, Edirne, Turkey, [5]ZiteLab Aps, Copenhagen, Denmark, [6]Erciyes University School of Medicine, Kayseri, Turkey.

Background/Purpose: Three different anti–tumor necrosis factor α (anti-TNFα) drugs (infliximab, etanercept, and adalimumab) are approved for patients with rheumatoid arthritis (RA) and particular ankylosing spondylitis (AS) in Turkey. Their efficacy has been well shown not only in randomized controlled clinical trials, but also in clinical practice setting. Comparative drug survival analyses across different diagnoses have been published in few studies. No data is yet available for the Turkish population.

The primary goal of this study was to compare the 1-year drug retention rates of TNF inhibitors in patients with AS and RA who were enrolled in the Turkish biologic registry, TURKBIO.

Methods: TURKBIO biological registry, which was established in October 2011, is a nationwide biological registry contributed by 10 different centers across Turkey. As of December 2013, 3380 patients who are receiving biologic treatment for RA (n=1355, 40.1%) or AS (n=2025, 59.9%) were enrolled in the database. However this analysis includes only 789 patients, who initiated biologic treatment after the participation of the individual centers in TURKBIO. Demographic and clinical data including age, sex, disease type, disease duration, and previous or current treatment with DMARDs and biological drug durations are stored in the database.

Results: Of the 789 patients included in this analysis, 386 patients (48.9%) were being treated for RA and 403 patients (51.1%) for AS. There were significant differences between the two groups in regard with age, gender distribution, DMARD use at baseline and DMARD use at last visit (Table). Preference for individual anti-TNF agents were also different between the RA and AS patients; infliximab, etanercept and adalimumab were used by 11.7%, 28.2% and 25.1% of the RA patients, respectively and 26.3%, 32.8% and 32.8 of the AS patients, respectively. AS patients had a shorter diagnosis duration than the RA patients. One year drug survival for the first anti-TNF agent was 60.8% for RA, and 78.3% for AS (P=0.0007).

Conclusion: The proportion of AS patients treated with biologic agents in the TURKBIO registry was slightly higher than that of RA. These results also suggest that the drug survival rate of anti-TNF agents in AS patients seems to be higher than in RA. This finding may explain the higher percentage of AS patients in the whole registry population, which included patients who had started biologics before the establishment of the TURKBIO registry.

Table 1: Demographical and clinical features of rheumatoid arthritis (RA) and ankylosing spondylitis (AS) patients at baseline and one year drug survival data

	RA (n=386)	AS (n=403)	P value
Age (years)	49 (38–58)	39 (30–46)	<0.00001
Female (%)	73.1	41.7	>0.05
Disease duration (years)	7 (3–13)	7 (3–13)	0.09
Diagnosis Duration	4 (2–10)	2 (0.75–6)	<0.00001
Biological duration (months)	9 (5–13)	10 (5–13)	>0.05
Number of biologic drugs used	1	1	>0.05
Prior DMARD use (%)	82.4	73.9	0.005
Number of DMARD use	4 (2–6)	2 (1–3)	<0.00001
DMARD use at last visit (%)	67.4	21.6	<0.00001
1-year drug retention rate of TNFi (%)	60.7	78.3	0.0007

The Distribution of Inflammatory Lesions in the Anterior and Posterior Structures of the Spine in Patients with Active Ankylosing Spondylitis and the Effect of TNF-α-Blockade. Xenofon Baraliakos[1], Kay-Geert A. Hermann[2], Stephen Xu[3], Benjamin Hsu[3] and Jürgen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Charité Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany, [3]Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: Magnetic resonance imaging (MRI) is a key tool for the assessment of inflammatory lesions used for diagnosis and the monitoring of treatment effects in patients (pts) with ankylosing spondylitis (AS). Using data from the anti-tumor necrosis factor (TNF) agent golimumab (GLM) in AS study (GO-RAISE), we analyzed the distribution and course of inflammatory spinal lesions in different parts of the axial skeleton in detail before and after treatment with GLM in pts with active AS.

Methods: Complete MR images at baseline (BL), 3 months (week 14 of the placebo [PBO]-controlled phase) and 2 years (end of open-label extension) of the study were available from 98 AS patients. Among all pts with inflammatory MRI activity at BL, the number (nr.) of spinal lesions at different time points was assessed. Both, general (total nr. of inflammatory lesions in the entire spine) and detailed (nr. of inflammatory lesions in the cervical [CS], thoracic [TS] and lumbar [LS] spine, in single vertebral units [VUs], in the upper and lower edges for anterior and posterior site of each vertebra, and in the zygoapophyseal joints [ZAJ] were assessed. Improvement in inflammation was defined as any decrease in the MRI score from baseline to year 2 of the study.

Results: Overall, evaluable inflamed VU and ZAJ lesions were seen in 81.6% and 31.6% of pts, respectively, while 22.4% of VUs/ZAJs had inf at BL. In patients showing inflammatory activity, the mean number of lesions/patient was 6.7 for VUs and 3.6 for ZAJs, with no difference between pts randomized to GLM or PBO. ZAJ inflammation without concomitant VU inflammation was present in 43 (0.97%) of all VUs and in 19 (20.9%) of patients. In detail, 7.2% of VU+ZAJ lesions were found in the CS, 27.9% in the TS and 27.9% in the LS. VU inflammation was detected more frequently in the anterior (23.5%) than in the posterior (8.5%) part of the LS. This difference was not observed in the CS and TS. The most frequently inflamed region in the CS was C7/T1, in the TS it was T8/9-T11/12 and in the LS, there was a fairly evenly distribution across VUs. After 3 months of GLM treatment, the percentage of VUs/ZAJs with inflammation decreased by 2.7%/0.7% in the CS, 17.3%/3.6% in the TS, and 17.6%/2.7% in the LS, while almost no change was observed in the PBO pts. The decreased VU/ZAJ involvement afforded by GLM treatment was sustained through 2 years. Similarly, after up to 2 years of GLM treatment, the mean number of lesions/pt showing inflammatory activity decreased to 2.7 for VUs and 2.0 for ZAJs.

Conclusion: This analysis confirms the predominance of inflammatory spinal lesions at the lower TS and the LS. While ZAJ inflammation was evident in a substantial nr. of patients it was uncommon for it to occur in isolation in a non-inflamed VU. Inflammatory lesions of VUs and ZAJs are supplementary information to MRI scoring systems and may contribute to a better understanding of clinical trial data. The already reported significance of the lower TS in the inflammatory process in AS clearly needs further study.

Ileocolonoscopic Findings in the Korean Patients with Ankylosing Spondylitis. Soo Min Ahn, Bin Yoo, Chang-Keun Lee, Yong-Gil Kim, Seokchan Hong, Seung-Hyeon Bae and Doo-Ho Lim. University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea.

Background/Purpose: The prevalence of concurrent Ankylosing spondylitis (AS) and inflammatory bowel disease, either Crohn's disease (CD) or Ulcerative colitis (UC), is estimated at 5–10%. Up to 50% of patients with AS have subclinical gut inflammation seen on ileocolonoscopy. This study was purposed to evaluate the association between reasons for ileocolonoscopy and the ileocolonoscopic findings in the patients with AS.

Methods: The retrospective study has included 108 AS patients who had ileocolonoscopy at a single tertiary hospital from January 2000 to April 2014.

Patients with a history of CD, UC, intestinal tuberculosis, or colon cancer were excluded. Patients were divided into two groups based on ileocolonoscopic results: 1) negative inflammatory lesions (including colon polyps, hemorrhoids and diverticulums) and 2) positive inflammatory lesions (including ulcers, erosion and inflammation). The clinical features including HLA-B27 profiles, inflammatory indices, and reasons for ileocolonoscopy including regular health checkup without symptoms (for screening), abdominal pain, rectal bleeding, diarrhea, constipation, anemia and positive stool occult blood were evaluated.

Results: As shown in Table, inflammatory lesions in ileocolonoscopic findings were found in 40 (37.0%) patients out of the 108 patients. Mean age was significantly lower in the group with inflammatory lesions than the group without inflammatory lesions (36.9 vs. 41.9 years, p=0.017). Mean ESR and mean CRP were significantly higher in the group with inflammatory lesions than the group without inflammatory lesions. Presence of symptoms or signs (n=34) was associated with risk of inflammatory ileocolonoscopic findings compared to for screening (n=6) (OR=3.96, 95% CI 1.46, 10.71, p=0.005). Among the patient's symptoms or signs, abdominal pain (n=13) was associated with inflammatory ileocolonoscopic findings most importantly (vs. negative abdominal pain (n=20); OR=2.47, 95% CI 0.88, 6.99, p=0.087). Among 40 patients with inflammatory lesions, 12 as CD, 1 as UC, and 4 as intestinal tuberculosis were diagnosed finally. However, most of them, 23 patients were considered as subclinical gut inflammation.

Conclusion: Considerable proportion of AS patients showed inflammatory gut lesions, even in the patients without gastrointestinal symptoms. Moreover, abdominal pain increased a possibility of inflammatory gut lesions in AS patients. Therefore, regular checkup with ileocolonoscopy could be recommended in AS patients.

Table. Patient's characteristics

	(−) inflammatory lesion (n=68)	(+) inflammatory lesion (n=40)	*p*-value
Age, mean years (SD)	41.9 (13.5)	36.9 (11.9)	0.017

The Effect of DMARD Co-Therapy on the Clinical Efficacy of Anti-TNF Medications in Patients with Axial Spondyloarthritis. Michael J. Nissen[1], Adrian Ciurea[2], Juerg Bernhard[3], Rudiger Muller[4], Giorgio Tamborrini[5], Martin Toniolo[6], Cem Gabay[7] and Axel Finckh[1]. [1]Geneva University Hospital, Geneva, Switzerland, [2]Rheumaklinik, Universitatsspital Zurich, Zurich, Switzerland, [3]Solothurn Hospital, Solothurn, Switzerland, [4]Kantonsspital St. Gallen, St. Gallen, Switzerland, [5]Bethesda Hospital Basel, Basel, Switzerland, [6]University Hospital of Zurich, Zurich, Switzerland, [7]University Hospitals of Geneva/SCQM Registry, Geneva, Switzerland, Geneva, Switzerland.

Background/Purpose: Randomized clinical trials and current recommendations suggest little role for disease-modifying anti-rheumatic drugs (DMARDs) as co-therapy with anti-TNF (aTNF) agents in patients with axial-spondyloarthritis (axSpA), although many physicians continue to prescribe this combination. Our aim was to investigate whether aTNF agents with concomitant DMARDs demonstrate superior clinical efficacy compared with aTNF monotherapy.

Methods: This is an observational cohort study of all patients in the Swiss Clinical Quality Management (SCQM) registry diagnosed with axSpA by a board-certified rheumatologist. The exposure of interest was use of aTNF monotherapy (mono) versus aTNF in combination with conventional synthetic DMARDs (combo). Exclusion criteria included aTNF initiation > 1 month prior to inclusion in the registry or missing follow-up assessments. The primary outcome was the change in BASDAI at 12 months. Secondary outcome measures were: BASDAI-50, ΔASDAS, ASDAS-CII and ASDAS-ID. When clinical outcome measures were unavailable at 12 months (+/− 3 months), we used longitudinal interpolation with mixed-effects linear regression to impute missing values. Adjustments were made for potential confounders including age, sex, disease duration, education level, number of prior aTNF agents and calendar year initiation of aTNF.

Results: We included 1310 axSpA patients with a total of 2236 aTNF treatment courses. The baseline characteristics of the mono and combo groups for all treatment courses are presented in the table. 80.1% were treated with aTNF monotherapy and 19.9% with co-therapy. The predominant DMARDs utilized were methotrexate in 69.7%, sulfasalazine in 19.3% and leflunomide in 9.6%. Disease characteristics were balanced between the 2 groups, with the exception that the co-therapy group was less frequently HLA-B27 positive, was less often ASAS criteria positive and had longer follow-up. DMARD co-therapy was prescribed significantly more often with infliximab and significantly less often with adalimumab and golimumab.

At 12 months follow-up, the mean (SD) reduction in BASDAI was 1.0 (0.8) and the mean reduction in ASDAS-CRP was 0.8 (0.7) for all treatment courses. The mean reductions in BASDAI and ASDAS-CRP for the first aTNF treatment course were 1.4 (1.6) and 1.1 (0.8) respectively. In adjusted analyses, there was no difference in the reduction in BASDAI score between the mono and the combo groups (p=0.65, CI -0.11:0.18). Similarly, there was no statistically significant benefit for DMARD co-therapy with regards to reduction in ASDAS-CRP, BASDAI-50, ASDAS-CII or ASDAS-ID.

Conclusion: This study of "real-life" patients supports the current recommendation that co-therapy with DMARDs is of no additional benefit compared with aTNF monotherapy in axSpA.

Table: Baseline characteristics. Unless otherwise stated, the values represent the mean.

	Monotherapy (n=1790) (80.1%) (n=1615)	Co-therapy (n=446) (19.9%)	p value

Spinal Mobility in the Cervical and the Lumbar Spine Correlates with Magnetic Resonance Imaging Findings in Patients with Ankylosing Spondylitis. Xenofon Baraliakos[1], Kay-Geert A. Hermann[2], Stephen Xu[3], Benjamin Hsu[3] and Jürgen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Charité Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany, [3]Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: Spinal mobility, as assessed by the Bath Ankylosing Spondylitis Metrology Index, BASMI, and imaging findings have been reported to correlate on the group level. Treatment with anti-TNF leads to improvement of both spinal inflammation as assessed by magnetic resonance imaging (MRI) and total BASMI scores. Using data from the golimumab

(GLM) in ankylosing spondylitis (AS) study (GO-RAISE), we analyzed the relationship between single components of BASMI and MRI scores of the corresponding spinal segments in anti-TNF-treated AS patients.

Methods: Complete MR imaging sets and spinal mobility data were available for 91 pts who participated in GO-RAISE. The MRI scores for active (ASspiMRI-a) and chronic changes (ASspiMRI-c) of the cervical and lumbar spine were compared to BASMI values for the cervical (cervical rotation [CR] and tragus-to-wall [TTW]) and the lumbar (lumbar flexion [LF] and lateral lumbar flexion [LLF]) spine using the linear definition. Spearman correlation coefficients were calculated for baseline scores and for changes in both BASMI and ASspiMRI-a and -c measurements of patients treated with GLM or placebo (PBO) after 14 weeks and after 2 years of GLM therapy. Subanalyses were performed with regard to age.

Results: At baseline, ASspiMRI-a scores of the cervical spine correlated with TTW ($r=0.31$, $p=0.003$) and CR ($r=0.32$, $p=0.002$) measurements, while ASspiMRI-a scores of the lumbar spine correlated with LF and LLF scores (both $r=0.41$, $p<0.0001$). In addition, ASspiMRI-c scores of the cervical spine correlated with TTW ($r=0.46$) and CR ($r=0.45$), both $p<0.0001$, while ASspiMRI-c scores of the lumbar spine correlated with LF ($r=0.34$, $p=0.001$) and LLF scores ($r=0.41$, $p<0.0001$). ASspiMRI-a scores correlated better in patients <40 years (TTW: $r=0.31$, $p=0.04$, LLF: $r=0.42$, $p=0.005$), while ASspiMRI-c scores correlated better in patients > 40 years (TTW: $r=0.35$, $p=0.015$, LLF: $r=0.48$, $p<0.001$). In contrast, no significant correlations were found in change scores (data not shown). There was a negative correlation between MRI chronicity scores and lateral lumbar flexion at 2y: $r=-0.26$, $p=0.037$.

Conclusion: Our data confirm earlier reports on patients with active AS which showed that both inflammation and structural changes contribute to impairments of spinal mobility. In addition, we demonstrate significant correlations of MRI findings with detailed spinal mobility measures before anti-TNF treatment was started. Inflammatory changes had greater impact on spinal mobility in younger patients, while structural changes had more influence on spinal mobility in older patients. The correlation of the observed changes in MRI scores and spinal mobility was significant but not high. This may be due to the different mixture of active and chronic changes in individual patients.

Vascular Endothelial Growth Factor and C-Reactive Protein Serum Levels Lack Predictive Value for Radiographic and Magnetic Resonance Imaging Outcomes in Patients with Active Ankylosing Spondylitis Treated with the Tumor Necrosis Factor-Inhibitor Golimumab.

Xenofon Baraliakos[1], Kay-Geert A. Hermann[2], Stephen Xu[3], Benjamin Hsu[3] and Jürgen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Charité Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany, [3]Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: Using data from GO-RAISE, we analyzed correlations between serum vascular endothelial growth factor (VEGF) and C-reactive protein (CRP) levels, radiographic progression and inflammation as detected by MRI.

Methods: 98 patients with active AS received golimumab or placebo up to wk16/24 and then golimumab up to 2y. All had sera, lateral spinal radiographs at baseline, wk104, and wk208 scored by the mSASSS and spinal MRIs at baseline, wk14, and wk104 scored with the ASspiMRI-a by two blinded readers. The relationship between VEGF or CRP levels and both mSASSS and MRI-a score was assessed by Spearman correlation analyses and logistic regression analyses were conducted to assess if VEGF levels conferred an increased risk of syndesmophyte formation from baseline to wk104 or wk208.

Results: CRP serum levels correlated with mSASSS scores at baseline, but not with radiographic progression or changes in MRI-a scores. No significant correlations were observed between VEGF serum levels and mSASSS at any time point. Logistic regression analyses failed to show an increased risk of changes towards syndesmophyte formation at wk104 and wk208 associated with VEGF (odds ratio, range: 0.990–1.006, all p=n.s). While a good correlation was observed between changes in ASspiMRI-a and VEGF level at wk14 ($p=0.0008$), the analysis showed that baseline and wk14 VEGF levels were not predictive of MRI-a scores including change scores at wk104

Conclusion: CRP serum levels correlated with baseline mSASSS scores but did not predict radiographic progression or remaining spinal inflammation after anti-TNF treatment. Similarly, both VEGF and CRP serum levels at baseline were not predictive of either radiographic progression or spinal inflammation in these anti-TNF treated patients. Overall, our data suggest that suppression of VEGF and CRP is not sufficient to halt new bone formation in AS.

Routine Assessment of Patient Index Data (RAPID3) Provides Similar Information Compared to Ankylosing Spondylitis Specific Indices: Analyses of the DESIR French Cohort.

Isabel Castrejón[1], Theodore Pincus[1], Daniel Wendling[2] and Maxime Dougados[3]. [1]Rush University Medical Center, Chicago, IL, [2]CHU J Minjoz, Besancon, France, [3]Université Paris René Descartes and Hôpital Cochin, Paris, France.

Background/Purpose: The Bath Ankylosing Spondylitis (AS) Disease Activity Index (BASDAI) –an index of only patient-self-report measures - has been the most widely used measure in axial spondyloarthritis (SpA). More recently the AS Disease Activity Score (ASDAS) has been developed as an algorithm that combines BASDAI elements and patient global assessment with laboratory measures. Both indices are specifically designed for AS patients. In busy clinical settings, it is more feasible to ask all patients to complete the same questionnaire, such as a multidimensional health assessment questionnaire (MDHAQ), with a Routine Assessment of Patient Index Data (RAPID3) score, which has proved useful in most of rheumatic diseases. RAPID3 may facilitate implementation of quantitative measures in routine care. This study compared RAPID3, BASDAI and ASDAS-CRP with one another and versus patient and physician global estimates.

Methods: The Devenir des Spondylarthropathies Indifférenciées Récentes (DESIR) is a prospective longitudinal cohort in France, which includes 708 patients with inflammatory back pain suggestive of SpA. 461 patients who fulfilled the Assessment of SpondyloArthritis International Society classification (ASAS) criteria for axial SpA were included in this analysis. As there is no universal gold standard to assess disease activity in AS, predefined external criteria were used based on patient and physician global estimates with 1, 3 and 6 as the specific cut points to define disease activity state: 'inactive', 'low', 'moderate', and 'high'. Additionally, patients were classified using the disease activity cut points for BASDAI (3, 3.5 and 4), ASDAS-CRP (1.3, 2.1, 3.5) and RAPID3 (3, 6 and 12). Spearman correlations were performed and the level of agreement evaluated using weighted kappas.

Results: RAPID3 showed a high correlation with BASDAI ($rho=0.84$, $p<0.001$), ASDAS-CRP ($rho=0.74$, $p<0.001$), physician global estimate ($rho=0.62$, $p<0.001$), and patient global estimate ($rho=0.90$, $p<0.001$). The percentage of patients with inactive disease ranged from 9 to 31% and with high disease ranged from 18% to 56%, according to various disease activity measures (Table). Using PATGL as reference the strength of agreement was good for RAPID3 and moderate for BASDAI and ASDAS-CRP. Using DOCGL as reference, the strength of agreement was moderate for ASDAS-CRP and fair for BASDAI and RAPID3. The strength of agreement of RAPID3 with BASDAI and ASDAS-CRP was similar.

	Disease Activity States				Level of Agreement		
	Inactive Disease	Low Disease	Moderate Disease	High Disease	PATGL % (Kappa)	DOCGL % (Kappa)	RAPID3 % (Kappa)
PATGL (1/3/6)	11%	24%	31%	34%	–	79% (0.41)	89% (0.70)
DOCGL (1/3/6)	12%	29%	42%	18%	79% (0.41)	–	77% (0.38)
BASDAI (3/3.5/4)	31%	7%	6%	56%	78% (0.51)	71% (0.37)	81% (0.55)
RAPID3 (3/6/12)	9%	17%	29%	45%	89% (0.70)	77% (0.38)	–
ASDAS-CRP (1.3/2.1/3.5)	14%	23%	45%	18%	81% (0.46)	81% (0.41)	79% (0.44)

Conclusion: RAPID3 provide a similar disease activity score as BASDAI and ASDAS-CRP, which are specific measures for AS patients. Further studies are required to evaluate different psychometric properties such as the discriminant capacity and predictive validity of these tools. A generic

measure for all rheumatic diseases such as RAPID3 may provide a feasible approach to quantitative assessment of AS patients in busy clinical settings.

Profiles of Switches in Patient with Ankylosing Spondylitis: Comparing Adalimumab, Etanercept, Infliximab, Golimumab and Certolizumab. Jean-Pierre Raynauld[1], Louis Bessette[2], Denis Choquette[1], Isabelle Fortin[3], Boulos Haraoui[1], Jean-Pierre Pelletier[4], Marie-Anaïs Rémillard[1], Diane Sauvageau[1], Edith Villeneuve[1] and Louis Coupal[1]. [1]Institut de rhumatologie de Montréal (IRM), Montréal, QC, [2]Centre d'ostéoporose et de rhumatologie de Québec (CORQ), Québec, QC, [3]Centre de rhumatologie de l'est du Québec (CREQ), Rimouski, QC, [4]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC.

Background/Purpose: As much a 40% of patients with ankylosing spondylitis will fail (BASDAI≥ 4) different non-steroidal anti-inflammatory agents and will eventually be treated with an anti-TNF agents. Response is usually satisfactory but retention on drug may vary from one agent to the other and from one patient to the other. Reasons for stopping ad/or switching are either inefficacy, intolerance or spontaneous improvement of the disease activity in a given individual. The goal of this analysis is to explore the first 6, 12 and 18 month period after first exposure to an initial agent and assess the cycling incidence from different anti-TNF agents namely adalimumab (ADA), etanercept (ETA), infliximab (INF), golimumab(GOL) or certolizumab (CERTO).

Methods: Patients with ankylosing spondylitis as diagnosed by their treating rheumatologists and exposed to either adalimumab, etanercept, infliximab, golimumab or certolizumab in first intention after failing two different non-steroidal anti-inflammatory agents for a minimum of 3 months each were extracted from the Quebec inflammatory database Rhumadata®. Demographics and baseline characteristics includes age, gender, disease duration, Hla-B27, BASDAI, BASFI, patient global (vas) and ASDAS (crp). Cycling from one agent to another was then explore at 6, 12 and 18 month time point. Proportion of patients switching vs not switching at each time point are assessed. Reason for switching at each time point (Inefficacy, AEs infections, surgery or death) are expressed in percentages.

Results: The data from 296 patients with ankylosing spondylitis and prescribed either adalimumab (114=39%), etanercept (61=21%), golimumab (31=10%) or infliximab (90=30%) as first biologic agent were extracted. These patients were treated for a period ranging from 0.4 to 173.2 months with a mean treatment duration of 44.0 (StD=36.3) months. At 6, 12 and 18 months, 11.8%, 25.7% and 35.8% of patients had either stopped or switched their medication. The reported reasons for stopping or switching medication were inefficacy (76.4%), adverse events (5.7%), surgery (14.2%) and lost to follow-up (3.6%).

Conclusion: Switches at the 6 month time point vary from 4.4% (ADA) to 9.8% (ETA). The percentage of switches increase with time for all agents except golimumab (9.7% at 12 and 18 months). A significantly higher proportion of patient stops golimumab and do not switches to another agent (51.6%). Main reason for stopping or cycling to another agent is inefficacy.

Validation of Modified Disease Activity and Functional Status Questionnaires in Spondyloarthritis. Itziar Quinzanos[1], Phat Luong[1], Sushmitha Bobba[2], J. Steuart Richards[3], Vikas Majithia[4], Lisa A. Davis[5] and Liron Caplan[6]. [1]Denver VA Medical Center, Denver, CO, [2]Department of Veterans Affairs, Denver, CO, [3]Washington DC VA and Georgetown University, Washington, DC, [4]University of Mississippi Medical Center, Jackson, MS, [5]Denver VAMC and Univ of Colorado School of Medicine, Aurora, CO, [6]Denver VA and Univ of Colorado School of Medicine, Aurora, CO.

Background/Purpose: Patients with new onset ankylosing spondylitis (AS) and those naïve to the Ankylosing Spondylitis Disease Activity Score (ASDAS) have voiced confusion over the use of the term "AS" in these instruments. Our previous abstract (EULAR 2013) compared the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) against a modified BASDAI and determined the relationship between working status and disability with Bath Ankylosing Spondylitis Functional Index (BASFI), BASDAI and modified BASDAI. It is unknown whether these tools may be applied to other forms of spondyloarthritis (SpA). In this abstract we: 1) validate slightly modified versions of the ASDAS questionnaires for use in non-AS SpA by assessing its ability to predict working status and disability; and 2) compare the disease-specific patient global assessment used in the ASDAS (PG) with the MD-HAQ version, and the disease activity scores based on these instruments.

Methods: Adult patients with SpA-associated conditions from three locations of the Program to Understand the Longterm outcomes of SpondyloARthritis (PULSAR) completed both traditional ASDAS questionnaire and modified version of the ASDAS instrument (PULSAR-modified ASDAS, [PuASDAS]) during visits with health care providers. The PuASDAS replaces references to "AS" with the term "inflammatory arthritis" and uses a non-disease specific patient global assessment that is similar to the multidimensional **health assessment questionnaire** global assessment (MD-HAQ); Scores from traditional and modified questionnaires were compared using Spearman correlations. The association of ASDAS and PuASDAS scores with disability status (according to federal program criteria) and self-reported working status were determined using logistic regression.

Results: Sixty-two patients participated in the study. Correlation between ASDAS and PuASDAS scores was high, recapitulating the previously demonstrated correlation between BASDAI and PuBaDAI (Spearman's rho=0.84, p<0.001, and Spearman's rho=0.92, p<0.001, respectively). Similarly, the PG had good correlation with the MD-HAQ (rho=0.766, p<0.001). The ASDAS (OR 1.34, 95% C.I. 1.02–1.76) and PuASDAS (OR 1.62, 95% C.I. 1.07–2.49) predicted federally-determined disability.

Conclusion: Preliminary data suggest that the PuASDAS may be used in non-AS SpA and that scores from these instruments correlate well with traditional form of the questionnaire. Correlation between the two versions of the patient's global assessments was good. PuASDAS scores predicted disability status at least as well as the ASDAS.

Table 1: Spearman correlation coefficients. *Italics indicate information previously presented at EULAR meeting 2013.*

Compared instruments	Question or total score that is compared	Corr. Coef.	p	95% CI Lower	95% CI Upper

Disease Activity and Risk of Cardiovascular Disease in Patients with Ankylosing Spondylitis with High and Low Body Mass Index. Inger Jorid Berg[1], Anne Grete Semb[1], Désirée van der Heijde[2], Tore K. Kvien[1], Hanne Dagfinrud[1], Jonny Hisdal[3] and Sella A. Provan[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Leiden University Medical Center, Leiden, Netherlands, [3]University of Oslo, Oslo, Norway.

Background/Purpose: Patients with ankylosing spondylitis (AS) have increased risk of cardiovascular disease (CVD), but the mediators of this increased risk are not known. Obesity is related to increased risk of CVD in the general population. Adipose tissue is an endocrine organ secreting pro-inflammatory cytokines which may be relevant both to the pathology of inflammatory diseases and CVD. The aim of this study was to explore the impact of body mass index (BMI) on disease activity and CVD risk in AS.

Methods: Cross-sectional study of 159 AS patients diagnosed according to the mNY criteria. Data-collection included questionnaires, blood samples and clinical examination. Carotid intima-media thickness (c-IMT) was measured by ultrasound. Height and weight were measured and BMI was calculated (kg/m^2). The patients were categorized according to the BMI, with cut-off value between normal weight and over weight: BMI<25 kg/m^2 (BMI-low) and BMI≥25kg/m^2 (BMI-high). We compared markers of disease activity and CVD risk factors between the BMI-low group and BMI-high group in linear regression models with adjustments for age, gender and smoking habits. Additional adjustments for use of non-steroidal anti-inflammatory drugs (NSAIDs) were also performed.

Results: AS patients had comparable age(years) in both groups (BMI-low vs. BMI-high), mean (SD) 50.5 (13.2) vs. 50.5 (11.3), but the BMI-low differed from the BMI-high regarding other variables: Male gender 53% vs.71%, p=0.02; CRP (mg/l), median (IQR) 2 (1–5) vs. 5 (2–13) p=0.003; use of NSAIDS, 56% vs. 74%, p= 0.01. In regression analyses the BMI-high group had higher ASDAS and BASDAI than the BMI-low group. High BMI was associated with lower high-density lipoprotein (HDL), higher triglycerides, total cholesterol/HDL ratio, systolic and diastolic pressure as well as IMT (table). Additional adjustment for use of NSAIDs did not alter results.

	BMI-low (n=81)	BMI-high (n=78)	p-value
Disease activity			
ASDAS	2.1 (1.8, 2.4)	2.6 (2.4, 2.9)	0.004
BASDAI	3.6 (3.2, 4.1)	4.3 (3.9, 4.8)	0.02
BASFI	1.9 (1.5, 2.3)	2.3 (1.9, 2.8)	0.09
$BASMI_{linear}$	3.1 (2.7, 3.5)	3.3 (2.9, 3.7)	0.54
CVD risk			
Total cholesterol (mmol/l)	5.2 (4.9, 5.5)	5.4 (5.2, 5.7)	0.15
LDL (mmol/l)	3.0 (2.7, 3.2)	3.3 (3.0, 3.5)	0.10
HDL (mmol/l)	1.7 (1.6, 1.8)	1.4 (1.3, 1.5)	<0.001
Triglycerides (mmol/l)	1.0 (0.9, 1.2)	1.5 (1.3, 1.7)	<0.001
Total cholesterol/HDL	3.2 (2.8, 3.5)	4.1 (3.8, 4.4)	<0.001
Systolic blood pressure (mmHg)	119 (116, 123)	129 (126, 133)	<0.001
Diastolic blood pressure (mmHg)	75 (72, 78)	81 (78, 83)	<0.001
c-IMT (mm)	0.62 (0.60, 0.65)	0.66 (0.64, 0.68)	0.01

Presented with estimated marginal means and 95% confidence intervals.

Conclusion: AS patients with high vs. low BMI had both worse disease activity and increased traditional CVD risk factors. Thus, obesity can be a common factor related to both disease activity and increased CVD risk and should be addressed in future observational studies in AS and considered as a potential confounding variable in future randomized controlled clinical trials.

2572

Recognition of Spondyloarthritis By General Practitioners in Daily Practice and the Effect of Education on This; A Study with Standardized Patients. Marloes van Onna[1], Simone Gorter[2], Bas Maiburg[3], Gerrie Waagenaar[3] and Astrid van Tubergen[2]. [1]Maastricht University Medical Center, division of Rheumatology, Maastricht, Netherlands, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Maastricht Univerisity, department of General Practice, Maastricht, Netherlands.

Background/Purpose: Timely recognition and referral of patients with spondyloarthritis (SpA) is challenging due to the insidious disease onset and frequently unawareness of the clinical picture by primary care physicians. The aims of this study were to assess the current practice performance of general practitioners (GPs) and GP-residents in recognizing SpA, and to investigate the influence of education on this performance.

Methods: All GP-residents and their supervising GPs were visited in two rounds by standardized patients (SPs) during their regular outpatient clinic, simulating axial SpA (axSpA), peripheral SpA (perSpA) (i.e. dactylitis) or carpal tunnel syndrome (CTS), respectively. Participants were unaware of the nature of the medical problem and purpose of the study. CTS was included as a diversionary tactic. Each case was simulated by a male and a female, in random order, according to a predefined schedule. After the 1st round, half of the GP-residents were educated about SpA, as part of the GP specialty training without referring to the actual study. The other half of the GP-residents and all GPs served as controls. Next, all participants were visited by SPs again in the 2nd round. Participants ranked their differential diagnosis based on their probabilities (rank order: 1=most likely to 3=less likely) and indicated whether referral to a hospital physician would be appropriate. Descriptive statistics and chi-square tests were used to analyse the data.

Results: Sixty-eight (38 GP-residents (mean age 27.9 yrs, 32% male) and 30 GPs (mean age 52.5 yrs, 80% male) participated. Both rounds of SP-encounters were completed by 61 (90%) and 59 (87%) participants for the axSpA and perSpA case, respectively. Table 1 shows that axSpA was ranked as the no. 1 diagnosis by 12/61 (20%) participants, whereas perSpA was correctly diagnosed by none of participants in the 1st round. Participants who received the educational intervention, were more likely to rank axSpA and perSpA as the no. 1 diagnosis in the 2nd round when compared to the control group (axSpA 72% vs. 14% (p<0.001); perSpA 21% vs 3% (p=0.017)). All 18 participants, who received the educational intervention, listed axSpA in their differential diagnosis in the 2nd round and were more likely to refer the patient or considered referral to the rheumatologist optional (axSpA 77% vs. 25% (p<0.001); perSpA 53% vs. 5% (p<0.001)).

Conclusion: Patients with SpA are not adequately recognized by general practitioners. Providing an educational programme to GP-residents markedly improved the recognition of SpA and referral of patients with SpA to the rheumatologist.

Table 1. Pre- and post-intervention results of the educational and control group regarding diagnosis and referral of patients suspected for axial and peripheral spondyloarthritis

	Educational intervention (yes vs no)	Diagnosis and referral of SPs	Round 1 (%)	Round 2 (%)
Axial SpA (n = 61)	Educational intervention (n = 18)	Ranked axial SpA as no. 1 diagnosis	4 (22)	13 (72)
		Ranked axial SpA in differential diagnosis (no. 1, 2 or 3)	12 (66)	18 (100)
		Referral rheumatologist	1 (6)	6 (33)
		Referral rheumatologist optional	0 (0)	8 (44)
	No educational intervention (n = 43)	Ranked axial SpA as no. 1 diagnosis	8 (19)	6 (14)
		Ranked axial SpA in differential diagnosis (no 1, 2 or 3)	22 (51)	33 (77)
		Referral rheumatologist	2 (5)	4 (9)
		Referral rheumatologist optional	2 (5)	7 (16)
	Educational intervention (yes vs no)	**Diagnosis and referral SPs**	**Round 1 (%)**	**Round 2 (%)**
Peripheral SpA (n = 59)	Educational intervention (n = 19)	Ranked peripheral SpA as no. 1 diagnosis	0 (0)	4 (21)
		Ranked peripheral SpA in differential diagnosis (no. 1, 2 or 3)	0 (0)	5 (26)
		Referral rheumatologist	1 (0)	8 (42)
		Referral rheumatologist optional	0 (0)	2 (11)

No educational intervention (n = 40)	Ranked peripheral SpA as no. 1 diagnosis	0 (0)	1 (3)
	Ranked peripheral SpA in differential diagnosis (no. 1, 2 or 3)	2 (5)	1 (3)
	Referral rheumatologist	2 (5)	1 (2)
	Referral rheumatologist optional	0 (0)	1 (2)

SPs = standardized patients, SpA = spondyloarthritis. Values are expressed as number (percentage) of participants.

Preferences of Patients with Spondyloarthritis for the Items of the ASAS Health Index : A Best Worst Scaling. Uta Kiltz[1], Mickaël Hiligsmann[2], D van der Heijde[3], Juergen Braun[1], Alarcos Cieza[4], Walter P Maksymowych[5], William Taylor[6] and Annelies Boonen[7]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]University of Liege, Liege, Belgium, [3]Leiden University Medical Center, Leiden, Netherlands, [4]University Southampton, Southampton, United Kingdom, [5]University of Alberta, Edmonton, AB, [6]University of Otago Wellington, Wellington, New Zealand, [7]Maastricht University Medical Center, Maastricht, Netherlands.

Background/Purpose: The ASAS Health Index (ASAS HI) is a disease-specific questionnaire aiming at measurement of health in patients with spondyloarthritis (SpA) which has been developed by Assessment of SpondyloArthritis international Society (ASAS). The 17 items of the ASAS HI address aspects of pain, emotional functions, sleep, sexual functions, mobility, self-care and community life based on the International Classification of Functioning, Disability and Health (ICF). These items can serve as the starting point to develop a disease-specific utility instrument that will enable to calculate disease specific quality adjusted life-years. To construct such utility instrument, the development steps require that the number of items should be reduced to a more manageable number of items. This selection should be based on items, which are most essential to patient's health and on items which are most preferred by patients. It is not know which aspects of health matter most to patients with SpA and also the knowledge about patient's preferences is limited. The objective is to understand the relative importance of the different items of the ASAS HI for functioning and health of patients with SpA.

Methods: A best-worse experiment was conducted using a questionnaire in patients with SpA from 20 countries worldwide. Patients answered 17 choice tasks that were constructed using the Sawtooth software. In each task, patients were asked to choose the most important item and the least important from a set of four items about their functioning and health.. The estimated hierarchical Bayes method was used to generate the mean relative importance score for each item.

Results: 206 patients (59.7% male, mean (SD) age 42.4 (13.9) years, mean (SD) BASDAI 3.8 (2.3)) with SpA completed the experiment. The five most important items are pain, sleep, standing, exhausting, and motivation to do anything that requires physical effort (figure 1). Eight items addresses concepts which are less important for the patients: toileting, sexual relations, driving, contact with people, walking outdoors, concentration, washing hair, and be able to overcome difficulties. Four items addresses concepts, which showed intermediate results addressing concepts of running, frustration, traveling, and financial changes. Subgroup analysis regarding subgroups of SpA and European versus Non-European countries showed robust results among subgroups.

Conclusion: This study provides information on the relative importance for patients with spondyloarthritis of the items of the ASAS Health Index that will be used for the development of a utility-based instrument.

2574

Do Patients with Axial Spondyloarthritis (AxSpA) Perform Enough Physical Activity? a Cross-Sectional Study of 207 Patients. Stephanie Fabre[1], Anna Molto[2], Sabrina Dadoun[2], Christopher Rein[2], Christophe Hudry[2], Sarah Kreis[2], Bruno Fautrel[2], Edouard Pertuiset[1] and Laure Gossec[2]. [1]René Dubos Hospital, Pontoise, France, [2]UPMC GRC08, Paris 06 University, Pitié Salpétrière Hospital, Paris, France.

Background/Purpose: Regular exercise is considered a cornerstone of AxSpA treatment, together with medication. Little data are available regarding the level and type of physical activity in AxSpA. The objective of this study was to assess the levels of physical activity and to explore its explanatory factors.

Methods: A cross-sectional study was performed in two tertiary care hospitals and one private practice in France. Patients had definite AxSpA according to the rheumatologist. Questionnaires evaluating the level of physical activity (International Physical Activity Questionnaire-Long form, IPAQ-L[1]) and perceived benefits of and barriers to exercising (Exercise Benefits/Barriers Score, EBBS[2]) were collected. The frequency of aerobic exercise (lasting more than 30 minutes) and the type of exercise were also investigated. Analyses included descriptive statistics and multiple logistic regression analyses to explain physical activity above 150 minutes per week (cut-off for appropriate exercise according to the World Health Organisation, WHO guidelines).

Results: In all, 207 patients had full data available: mean age, 45.9±11.5 years, 53.1% were males, mean BMI was 25.8±13.5 kg/m2. Mean disease duration was 14.6±10.2 years, mean BASDAI (0–100) 38.1±20, and mean BASFI (0–100) 29.1±26. Seventy percent were taking anti-TNF treatment, reflecting the tertiary care recruitment. The mean total level of physical activity (IPAQ) was 5409±6953 (median, 2913 [IQR 1259 to 6949]) MET-min/week: 99 (47.8%) were in the high activity category, 85 (41.1%) in the moderate and 23 (11.1%) in the low activity category. In all, 112 (54.1%) were above the recommendations of the WHO. Aerobic exercise (lasting more than 30 minutes) was performed at least once a week by 62/201 (30.8%) patients. The most frequently practiced sports included walking for at least 30 minutes (N=69, 31%), swimming and stretching ((N=43, 21% for both). The 2 main benefits of exercising were: increased acceptance from others and help to carry out normal activities without becoming tired; and the 2 main barriers: lack of encouragement of family members and people looking funny in exercise clothes. Physical activity above the WHO recommendation was not predicted by demographic variables, nor SpA activity/severity (Basdai, Basfi).

Conclusion: AxSpA patients in this study had moderate levels of physical activity. Only one half performed enough physical activity according ot the WHO recommendations. Levels of physical activity did not appear to be explained by disease-related variables but rather by other non-disease related variables. Physical activity is an important part of AxSpA management and patients should be encouraged to exercise more.

Validation of the RAPID-3 Questionnaire in a Cohort of Patients with Axial Spondyloarthritis. Maria Celeste Orozco[1], Luis Alejandro Cayetti[1], Emilce Schneeberger[2], Natalia Zamora[3], Fernando Andres Sommerfleck[1] and Gustavo Citera[1]. [1]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [2]Instituto de Rehabilitacion Psicofisica, Buenos Aires, Argentina, [3]Echeverría 955, Buenos Aires, Argentina.

Background/Purpose: RAPID3(Routine Assessment of Patient Index Data 3) is a simple index which was developed initially for RA but has been reported informative and many rheumatic diseases. A major advantage of RAPID3 over disease specific questionnaires and indices is that a single questionnaire can be completed by all patients with any diagnosis while waiting to see a rheumatologist, with minimal interference with work flow in busy clinical settings. We analyzed RAPID3 in patients with axial spondyloarthritis (axSpA).

Materials and Methods: Consecutive patients ≥ 18 years of age with diagnosis of axSpA (modified New York criteria 1987 and / or ASAS 2009) were included. Socio-demographic data (age, gender, marital status, occupation, years of education) and disease-related data (disease duration, extra-spinal manifestations, comorbidities, treatments) were recorded. All patients completed RAPID-3, ASQoL (Ankylosing Spondylitis Quality of Life), BASDAI and BASFI. Disease global assessment by both patients and physicians was determined by visual analog scale (VAS). Physical examination included 44 joint counts and evaluation of enthesitis was performed using MASES score (Maastricht Ankylosing Spondylitis Enthesitis Score). HLA -B27, and erythrocyte sedimentation rate (ESR) were collected. Ankylosing Spondylitis Disease Activity Score, was calculated (SASDAS-ESR, Clin Rheumatol 2012,31:1599–603). *Statistical analysis*: Categorical variables were compared using Fisher exact test and continuous variables by means of Mann- Whitney and Kruskal Wallis. Correlation of RAPID3 and other disease variables were assessed by Spearman Rho, and reproducibility using intraclass correlation coefficient (ICC) in a group of patients who completed the questionnaire twice. Finally, we determined the association of the preestablished cut-off values of RAPID-3 used in RA patients and preestablished cut-off values of SASDAS-ESR.

Results: 51 patients were studied, 39 males (76.5 %), with a median age of 42 years old (IQR 33–51) and a median disease duration of 20 years (IQR 10.3–27.6). 90.5 % were HLA -B27 positive. Median RAPID-3 was 9 (IQR 3–12.8), BASDAI 3.35 (IQR 1.6–6), BASFI 3.4 (IQR 1.1–5.6), ASQoL 5 (IQR 1–9), SASDAS-ESR 15.9 (IQR 8–22.6), MASES 1 (IQR 0–3). RAPID-3 proved to have an excellent reproducibility (ICC=0.97). The median time to complete it was two minutes (IQR 0.91 to 3), and the median time to calculate it ten seconds (IQR 6–15). RAPID-3 was correlated significantly with SASDAS-ESR (Rho: 0.87), BASDAI (Rho: 0.89), BASFI (Rho: 0.8) and ASQoL (Rho: 0.83) and at lower levels with MASES (Rho: 0.44). A significant association was seen between the preestablished cut points of RAPID-3 and SASDAS-ESR (Kappa: 0.5, p= 0.001).

Conclusion: RAPID-3 is a valid, reliable and reproducible questionnaire to evaluate disease activity and functional capacity in patients with axSpA, and more easily applied in busy clinical settings that axSpA specific-indices.

Diffusing Weight Magnetic Resonance Imaging May Suggest the Treatment Strategy in Ankylosing Spondylitis. Sang-Yeob Lee Division of Rheumatology, Department of Internal Medicine, Dong-A University College of Medicine, Busan, South Korea.

Background/Purpose: With the advanced MRI techniques, pathologic features can be detected at an early stage and quantitatively evaluated. resulting in the advantages of early diagnosis and prompt treatment. This study aimed to determine the value of diffusion-weighted MR imaging (DWI) in determined of ankylosing spondylitis (AS) treatment strategy and assess the role of quantitative MRI in the evaluation of AS treatment outcome.

Methods: 18 patients with the diagnosis of early AS were included in this study. Disease activity was measured according to clinical instruments and laboratory tests. For each patient, both inflamed sacroiliac (S-I) joint lesion was checked quantitatively at first diagnosis by diffusion-weighted imaging (DWI) measuring the apparent diffusion coefficient (ADC) and by dynamic contrast-enhanced imaging (DCEI) with evaluation of the enhancement factor (f_{enh}) and enhancement gradient (g_{enh}). All patients were revaluated by pelvis computer tomography (CT) for bone change in S-I joint, after two year.

Results: Clinical and quantitative MRI parameters diminished significantly with regression of the inflammatory activity. Median ADC values in AS patients were (1.118 ¡¾ 0.122) ¡¿ 10^{-3} mm^2/s in S-I joint. The high ADC (>1.118 ¡¾ 0.122) ¡¿ 10^{-3} mm^2/s, f_{enh} (>1.65) and g_{enh} (2.09 %/S) were associated severe disease activity and early administration of biologics ($p<0.05$). In each individual, the high ADC, f_{enh} and g_{enh} of S-I joint lesion was associated more severe localized pain than the other S-I joint, despite treatment ($p<0.05$). Paradoxically, early administration of biologics group who was high disease activity at the diagnosis had minimal bone change of S-I joint, compared to only NSAIDs used group who was low disease activity in pelvis CT finding two year later.

Conclusion: Diffusion-weighted imaging and DCEI were shown to be effective in quantifying changes in inflammation in S-I joint at the diagnosis of AS, and could be convenient for assessing treatment strategy. To the best of our knowledge this is the first time DWI was used to evaluate the treatment strategy and treatment outcome of AS.

The Ankylosing Spondylitis Disease Activity Score More Closely Reflects MRI Parameters of Sacroiliitis Than the Bath Ankylosing Spondylitis Disease Activity Index in Patients with Non-Radiographic Axial Spondyloarthritis. WP Maksymowych[1], S Wichuk[1], H Jones[2], A Szumski[2], L Marshall[2], J Bukowski[2] and RG Lambert[1]. [1]University of Alberta, Edmonton, AB, [2]Pfizer Inc., Collegeville, PA.

Background/Purpose: Validation of clinical measures of disease in non-radiographic axial SpA (nr-axSpA) has been limited, especially using inflammatory and structural lesions on MRI as gold standard. Ankylosing Spondylitis Disease Activity Score (ASDAS) has been proposed as an optimal outcome measure, but is less feasible than Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) due to the need to assess CRP. We assessed which clinical measures best reflect the spectrum of MRI lesions in the sacroiliac joints (SIJ) of patients with nr-axSpA, and the effect of treating with an anti-TNF agent.

Methods: Patients had axial SpA per the Assessment of SpondyloArthritis (ASAS) classification criteria, but did not meet modified NY radiographic criteria. Patients had symptoms >3 months and <5 years, BASDAI ≥4, and failed ≥2 NSAIDs. Patients were randomized to etanercept (ETN) 50 mg/wk or placebo; after 12 wks, all patients received open-label ETN 50 mg/wk. Clinical endpoints were evaluated throughout the study; MRI of SIJ and spine was performed by 2 central readers at baseline (BL), wks 12 and 48, to assess bone marrow edema using the Spondyloarthritis Research Consortium of Canada (SPARCC) SIJ score. In a post-hoc analysis, structural lesions were scored using the SPARCC SIJ structural (SSS) method, assessing fat metaplasia, erosion, backfill, and ankylosis on T1-weighted spin echo (T1WSE) MRI. Two independent readers scored BL and 48 wk T1WSE MRI scans from 187 cases blinded to outcomes and short tau inversion recovery (STIR) MRI; readers' mean scores were used. SPARCC score ≥2 for SIJ defined positive MRI evidence of inflammation. For the analysis, patients were pooled, and wk 48 change was analyzed using Spearman correlations, adjusted for treatment.

Results: Mean (SD) age was 32 (7.8) years, 60.5% were male, mean (SD) duration of symptoms was 2.5 (1.8) years. A total of 73% of patients were human leukocyte antigen B27 (HLA-B27) positive; 81% met the ASAS MRI imaging criteria at BL. A significant decrease in clinical (ASDAS, BASDAI, CRP) and MRI (SPARCC SIJ inflammation, SSS erosion) measures of active disease was noted by wk 48. There were no significant correlations at BL between BASDAI and any MRI lesion scores. There was significant BL correlation between SPARCC SIJ inflammation score and ASDAS (r=0.19, p=0.005) and CRP (r=0.22, p=0.002). Over 48 wks, there was significant correlation between change in ASDAS and changes in SPARCC SIJ inflammation (r=0.40, p<0.0001), SSS erosion (r=0.25, p=0.0007), and SSS backfill (r=-0.23, p=0.002). Change in CRP correlated significantly with changes in SPARCC SIJ inflammation (r=0.35, p<0.0001) and SSS erosion (r=0.18, p=0.02). Change in BASDAI correlated significantly with changes in SPARCC SIJ inflammation (r=0.25, p=0.0008), SSS backfill (r=-0.18, p=0.02), and SSS erosion (r=0.16, p=0.03). Correlations between ASDAS and MRI measures of sacroiliitis were strongest in the ETN group through 48 wks.

Conclusion: ASDAS is the preferred clinical measure of disease activity in nr-axSpA. Of all MRI assessments, change in SPARCC SIJ inflammation seems most closely aligned with changes in ASDAS, CRP and BASDAI, though the correlations are modest.

Disease Activity Is the Major Determinant of Quality of Life and Physical Function in Patients with Early Axial Spondyloarthritis. Results from the Esperanza Cohort.

Cristina Fernández-Carballido[1], Victoria Navarro-Compán[2], Mireia Moreno[3], Xavier Juanola[4], Juan Mulero[5] and Eugenio de Miguel[6]. [1]University General Hospital Elda, Elda (Alicante), Spain, [2]University Hospital La Paz and Leiden University Medical Center, Madrid, Spain, [3]University Hospital Parc Taulí, Sabadell, Spain, [4]University Hospital Bellvitge, Barcelona, Spain, [5]University Hospital Puerta de Hierro, Majadahonda (Madrid), Spain, [6]University Hospital La Paz - IdiPaz, Madrid, Spain.

Background/Purpose: Main objective: to describe health related quality of life (HRQoL), physical function (PF) and spinal mobility (SM) in patients with early axial Spondyloarthritis (axSpA). Second, to analyze the associations between HRQoL, PF and SM with disease activity and radiographic damage.

Methods: Baseline data from 259 patients fulfilling ASAS axSpA criteria from the Esperanza cohort were included. Validated versions of Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL) and Bath Ankylosing Spondylitis Functional Index (BASFI) were used to evaluate HRQoL and PF. SM was assessed using Bath Ankylosing Spondylitis Metrology Index (BASMI). Disease activity was measured by means of Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS), patient's global and night back pain VAS and physician' VAS, Maastricht AS Enthesitis Score (MASES) and CRP (mg/L). Radiographic damage was assessed through Bath Ankylosing Spondylitis Radiographic Index for the spine (BASRI-s) and sacroiliac joints scoring as in mNY criteria. Linear regression analyses were employed to evaluate the associations between disease activity and radiographic damage with HRQoL, PF and SM.

Results: 259 axSpA patients, 67% men, 39% AS. Mean ± SD disease duration 13.3±6.8 months; age 32.2±6.9 years; BASDAI 3.8±2.3; ASDAS 2.3±1.0; patient's global and night back pain and physician VAS 4.2±2.7, 3.8±2.9 and 2.9±2.2; MASES 0.6±1.4; CRP 9.7±13.2 mg/L and BASRI-s 1.7±1.6.

Outcome values (Mean ± SD): ASQoL 5.9±4.8; BASFI 2.4±2.3 and BASMI1.4±1.3. *HRQoL and PF* associations with all disease activity parameters (table 1) were observed in the univariable analysis, whereas HRQoL and PF associations with radiographic damage were weaker or not significant. Multivariable analysis only showed associations with disease activity for both outcomes (table 2).

Table 1: Linear regression **univariable** analysis **adjusted** for age and gender.

	ASQoL		BASFI		BASMI	
	Std Beta	**p value**	**Std Beta**	**p value**	**Std Beta**	**p value**
CRP (mg/L)	0.272	p<0.01	0.300	p<0.01	0.187	p<0.01
ESR (mmHg)	0.113	p<0.1	0.186	p<0.01	0.074	NS
VAS (0–10) physician	0.558	p<0.01	0.616	p<0.01	0.285	p<0.01
VAS (0–10) patient	0.640	p<0.01	0.650	p<0.01	0.117	p<0.1
VAS (0–10) night back pain	0.597	p<0.01	0.593	p<0.01	0.106	p<0.1
BASDAI	0.645	p<0.01	0.691	p<0.01	0.167	p<0.01
ASDAS	0.564	p<0.01	0.608	p<0.01	0.193	p<0.01
MASES	0.239	p<0.01	0.239	p<0.01	0.052	NS
BASRI spine	0.149	p<0.05	0.154	p<0.05	0.322	p<0.01
Sacroiliitis xRay	0.078	NS	0.146	p<0.05	0.282	p<0.01

Table 2: Linear regression **multivariable** analysis **adjusted** for age and gender.

	ASQoL	BASFI	BASMI			
	Std Beta	**p value**	**Std Beta**	**p value**	**Std Beta**	**p value**
CRP (mg/L)	0.107	0.07	0.126	0.02	0.032	0.7
VAS (0–10) physician	0.207	0.01	0.266	<0.001	0.246	0.02
VAS (0–10) night back pain	0.203	0.02	0.058	0.4	−0.085	0.4
BASDAI	0.336	<0.001	0.473	<0.001	0.043	0.7
MASES	0.096	0.1	0.078	0.2	–	–
BASRI spine	−0.011	0.9	−0.058	0.4	0.198	0.06
Sacroiliitis xRay	–	–	0.093	0.2	0.022	0.8

SM was mainly associated with radiographic damage (univariable), but only a trend was observed for this association in the multivariable analysis.

Conclusion: In patients with early axSpA, HRQoL and physical function are already impaired and primarily associated with disease activity.

How Should We Calculate the ASDAS If the Conventional C-Reactive Protein Is below the Limit of Detection? – an Analysis in the DESIR Cohort.

Pedro Machado[1], Victoria Navarro-Compán[2], Robert Landewé[3], Floris van Gaalen[2], Christian Roux[4] and Desirée van der Heijde[2]. [1]University College London, London, United Kingdom, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [4]Paris Descartes University, Cochin Hospital, Paris, France.

Background/Purpose: The Ankylosing Spondylitis Disease Activity Score (ASDAS) is a composite measure of disease activity in axial spondyloarthritis. It was suggested that when the conventional CRP (cCRP) is below the limit of detection, and high sensitivity CRP (hsCRP) is not available, 50% of the threshold value should be used to calculate ASDAS-CRP. However, this recommendation was not data driven and requires further testing. Our aims were to investigate the most appropriate ASDAS-C-reactive protein (ASDAS-CRP) calculation method when the cCRP is below the limit of detection, to study the arithmetic influence of low CRP values in ASDAS-CRP results and to test agreement between different ASDAS formulae.

Methods: Baseline data from the Devenir des Spondylarthropathies Indifférenciées Récentes (DESIR) cohort was used. Patients with axial spondyloarthritis and cCRP below the limit of detection (5mg/L, n=257) were selected. ASDAS-cCRP was calculated using eleven imputation strategies for the cCRP (range 0–5, at 0.5 intervals). ASDAS-high sensitivity CRP (hsCRP) and ASDAS-ESR were also calculated. Agreement between ASDAS formulae was tested. The effect of low CRP values in ASDAS-CRP results was studied.

Results: ASDAS-CRP(1.5), ASDAS-CRP(2) and ASDAS-erythrocyte sedimentation rate (ESR) had better agreement with ASDAS-hsCRP than

other imputed formulae (table). Disagreement was mainly in lower disease activity states (inactive/moderate disease activity). When the CRP value is <2mg/L, the CRP component of the ASDAS-CRP formula can take very low values that may result in inappropriately low ASDAS-CRP values.

Table: Agreement between ASDAS-hsCRP and other ASDAS formulae (ASDAS-cCRP with multiple imputation strategies and ASDAS-ESR)

	ASDAS-hsCRP			
	ASDAS values		ASDAS disease activity states	
ASDAS formulae	ICC (95% CI)	Mean difference (95%CI)	Weighted kappa (95%CI)	Disagreement (%)
ASDAS-CRP(0)	0.78 (−0.06 to 0.94)	−0.52 (−1.02 to −0.03)	0.51 (0.44 to 0.57)	46.7%
ASDAS-CRP(0.5)	0.89 (0.33 to 0.96)	−0.29 (−0.79 to 0.21)	0.73 (0.67 to 0.79)	25.0%
ASDAS-CRP(1)	0.94 (0.89 to 0.96)	−0.12 (−0.62 to 0.38)	0.73 (0.67 to 0.79)	24.4%
ASDAS-CRP(1.5)	0.95 (0.93 to 0.96)	0.01 (−0.49 to 0.51)	0.75 (0.69 to 0.81)	21.9%
ASDAS-CRP(2)	0.94 (0.90 to 0.96)	0.11 (−0.38 to 0.61)	0.76 (0.70 to 0.81)	21.8%
ASDAS-CRP(2.5)	0.92 (0.70 to 0.96)	0.20 (−0.29 to 0.70)	0.71 (0.65 to 0.77)	25.3%
ASDAS-CRP(3)	0.89 (0.37 to 0.96)	0.28 (−0.22 to 0.78)	0.66 (0.60 to 0.73)	29.1%
ASDAS-CRP(3.5)	0.86 (0.11 to 0.96)	0.35 (−0.15 to 0.85)	0.64 (0.58 to 0.70)	31.6%
ASDAS-CRP(4)	0.83 (0.00 to 0.95)	0.41 (−0.09 to 0.91)	0.61 (0.54 to 0.67)	4.3%
ASDAS-CRP(4.5)	0.81 (−0.04 to 0.94)	0.47 (−0.03 to 0.96)	0.59 (0.53 to 0.65)	35.8%
ASDAS-CRP(5)	0.78 (−0.06 to 0.94)	0.52 (0.02 to 1.01)	0.50 (0.44 to 0.57)	43.6%
ASDAS-ESR	0.91 (0.85 to 0.94)	0.13 (−0.52 to 0.79)	0.69 (0.63 to 0.76)	8.1%

Conclusion: When the cCRP is below the limit of detection or when the hsCRP is <2mg/L, the constant value of 2mg/L should be used to calculate ASDAS-CRP. There is good agreement between ASDAS-hsCRP and ASDAS-ESR; however, formulae are not interchangeable. ASDAS is increasingly being used as a measure of disease activity in clinical practice, clinical trials and observational studies. This study contributes to further standardisation of the ASDAS and to a more homogeneous and reproducible application of this new index.

A Comparison of Baseline Characteristics and Real-Life Effectiveness of Anti-TNF Therapy in Non-Radiographic Axial Spondyloarthritis Versus Ankylosing Spondylitis – a Single Center Cohort Study. Sarka Forejtova[1], Jakub Zavada[2], Michal Uher[3], Karel Hejduk[3] and Karel Pavelka[4]. [1]Institute of Rheumatology, Prague, Czech Republic, [2]Charles University, Prague, Czech Republic, [3]Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic, [4]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic.

Background/Purpose: The recent Assessment of SpondyloArthritis international Society (ASAS) classification criteria proposed the concept of axial spondylarthritis (axSpA) to enable earlier treatment not only for patients fulfilling the modified New York (mNY) criteria for ankylosing spondylitis (AS), but also for patients with non-radiographic axSpA (nr-axSpA). There is uncertainty whether the benefit of anti-TNF therapy in patients with nr-axSpA is as impressive as in patients with established AS, especially when the ASAS criteria and therapeutic recommendations are applied in real clinical practice.

Methods: Our aim was to compare the baseline characteristics and one year clinical outcome of anti-TNF therapy in axSpa patients prospectively followed in a large academic rheumatology center. This was a single center study conducted within the national biologics registry. To get reimbursement for anti-TNF therapy, all AS patients had to have high baseline disease activity (defined as BASDAI >4, and CRP > 10 mg/l). ASAS classification criteria were applied retrospectively using the data recorded in the source clinical documentation. All patients with inflammatory back pain fulfilling either ASAS criteria for nr-axSpA, or mNY criteria for AS starting treatment with anti-TNF therapy were included in the analysis.

Results: At baseline, patients with nr-axSpa had shorter disease duration, higher number of swollen peripheral joints, and were more often treated with glucocorticoids and synthetic DMARDs. There were no statistical significant differences in the effect of biologics on the improvement in BASDAI, BASFI, EUROQOL and spinal pain during first 12 months of treatment. Also, the QALY area under the curve was no different between both groups. There was significantly larger improvement in CRP in the group of AS patients, while in the nr-axSpA group there was greater change in the improvement of SJ, but these differences in range of change appeared to be caused by the ceiling effect of uneven baseline values of these measures.

Conclusion: Although there were some important baseline differences between both cohorts, the amount of improvement in axial symptoms, physical function and quality of life during the first 12 months of the anti-TNF treatment was similar in nr-axSpA and AS patients.

Acknowledgements: This work was supported by project of MHCR for conceptual development of research organization 023728.

Table: Baseline characteristics and outcome of 12 months of anti-TNF therapy in AS and nr-axSpA patients

		AS (N=275)	nr-axSpA(N=39)	p-value
Female	n (%)	68 (24.7%)	15 (38.5%)	0.069

Clinically Active Non-Radiographic Axial Spondyloarthritis Patients Who Initially Have a Negative MRI and Normal CRP May Develop a Positive MRI or Elevated CRP at a Later Timepoint. Xenofon Baraliakos[1], Joachim Sieper[2], Su Chen[3], Aileen L. Pangan[3] and Jaclyn K. Anderson[3]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Charité Universitätsmedizin Berlin, Berlin, Germany, [3]AbbVie Inc., North Chicago, IL.

Background/Purpose: Patients (pts) with non-radiographic axial spondyloarthritis (nr-axSpA) and active disease may have objective evidence of inflammation, either as bone marrow edema (BME) on magnetic resonance imaging (MRI) of the sacroiliac joints (SIJ) or spine, and/or an elevated CRP level. These pts may benefit from adalimumab (ADA) therapy. The objective was to determine whether untreated pts with clinically active disease but initially negative MRI or normal CRP, can develop objective evidence of inflammation and respond to ADA treatment.

Methods: ABILITY-1 was a phase 3, double blind (DB), randomized, controlled trial in pts with nr-axSpA who had an inadequate response, intolerance, or contraindication to NSAIDs. A 12-week (wk) DB period of ADA 40 mg every other wk (eow) or placebo (PBO), was followed by an open-label (OL) period, in which pts could receive ADA 40 mg eow for up to an additional 144 wks. MRI of the spine and SIJ were performed at baseline (BL) and wk 12. A positive MRI (MRI+) was defined as SPARCC MRI score ≥2 in either the SIJ or spine. C-reactive protein (CRP) levels were measured every 4 wks. This post hoc analysis evaluated 1) PBO-treated pts with negative MRI and normal CRP levels at BL, to determine if subsequent evidence of inflammation by MRI or CRP level occurs in untreated pts; and 2) if pts with a positive MRI or elevated CRP subsequent to the BL visit can

achieve an ASAS40 response at wk 24, similar to that observed in ADA-treated patients at wk 12.

Results: In the DB period, 9/29 (31.0%) of the PBO-treated pts with both a negative MRI of the SIJ and spine at BL, were MRI+ in either the SIJ or spine at wk 12 (table). Of the 57 PBO-treated pts with normal CRP at BL, 14 (24.6%) had elevated CRP at a timepoint between BL and wk 12. 20 PBO-treated pts had a negative MRI of the SIJ and spine and a normal CRP at BL; of these pts 10 (50.0%) had a positive MRI of either the SIJ or spine and/or an elevated CRP at ≥1 post-BL timepoint through wk 12. 5/10 (50.0%) of these pts achieved ASAS40 response at wk 24 (after 12 wks of OL ADA).

Table. Proportion of PBO patients who had a +MRI and/ or elevated CRP through wk 12, among those who had a –MRI and/or normal CRP at Baseline*

Status at Baseline N	Status at Wk 12 n (%)
Spine MRI - : 43	Spine MRI + : 11 (25.6)
SIJ MRI - : 54	SIJ MRI+ : 5 (9.3)
Spine and SIJ MRI- : 29	Spine or SIJ MRI+: 9 (31.0)
Normal CRP : 57	Elevated CRP : 14 (24.6)
Spine and SIJ MRI- and normal CRP: 20	Spine or SIJ MRI+ and/or elevated CRP: 10 (50.0)

*MRI was repeated at wk 12, CRP was repeated every 4 wks through week 12.

Conclusion: Among PBO-treated pts who did not have objective signs of inflammation at BL, but who demonstrated either a positive MRI or elevated CRP at a later timepoint, 50.0% achieved ASAS40 response after 12 wks of OL ADA treatment (wk 24). Although the sample size is small and higher response rates are expected with OL therapy, this is similar to that observed in the MRI+/elevated CRP ADA-treated population at wk 12 (41.0%). Thus, patients with clinically active disease but without objective inflammation at one point, may benefit from subsequent re-testing for inflammation, and if present, from initiation of ADA therapy.

Serum Levels of Bone Morphogenetic Protein-7 and Sclerostin Are Elevated in Ankylosing Spondylitis, but Not Linked with Structural Damage. Weiping Kong[1], Xiaotong WANG[1], Tongliang Zhou[1], Yue Jin[2], Qingwen TAO[1], Yuan Xu[1], Yingze Zhang[1], Jianming WANG[1] and Xiaoping Yan[1]. [1]China-Japan Friendship Hospital, BEIJING, China, [2]Beijing University of Chinese Medicine, BEIJING, China.

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease characterized by new bone formation that progressively leads to ankylosis and functional disability. The mechanisms of new bone formation in AS are yet to be characterized. Several biomarkers are involved in bone remodeling in AS, such as Dickkopf-1 (Dkk-1) and sclerostin, which down-regulate bone formation by inhibition of Wingless proteins (Wnt) and bone morphogenic proteins (BMPs). Wnt and BMPs are key inducers of osteoblastogenesis and new bone formation. The aim of this study was to determine serum concentrations of BMP7, Dkk-1 and sclerostin in patients with AS and to investigate their relationship to clinical manifestations and structural damage.

Methods: Serum levels of BMP-7, DKK-1, Sclerostin were detected by enzyme-linked immunosorbent assay in 40 AS patients with syndesmophyte (male: 36, female: 4, age: 32.43±7.63), 40 AS patients without syndesmophyte (male: 35, female: 5, age: 29.8±7.18) and 23 healthy controls (male: 32, female: 8, age: 31.95±9.42). Clinical manifestations such as erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score and Bath Ankylosing Spondylitis Functional Index (BASFI) score were evaluated in AS patients. Cervical and lumbar spine x-rays were performed in 80 patients to measure modified Stoke's Ankylosing Spondylitis Spine Score (mSASSS). SPSS17.0 was performed to analyze statistical difference. P-values less than 0.05 were considered statistically significant.

Results: Serum level of BMP-7 in AS patients with and without syndesmophyte (74.39±49.53 pg/ml, 89.17±83.31 pg/ml) was significantly higher than healthy control group (40.30±16.19 pg/ml, P=0.001, P=0.002). Sclerostin level in AS patients with and without syndesmophyte (184.46±316.08 pg/ml,187.79±223.53 pg/ml) was significantly higher than healthy control group (87.40±34.28 pg/ml, P=0.044, P=0.002). There was no significant differences of BMP-7 and sclerostin level in AS patients with or without syndesmophyte. No significant differences of DKK-1 level had been found in AS patients with (1174.29±863.90 pg/ml) or without syndesmophyte (971.44±677.9 pg/ml) and control group (1090.05±809.75 pg/ml). Serum DKK-1 level in AS patients was positively correlated with ESR (P=0.029). However, no biomarkers showed significant correlation with age, sex, course of disease, sacroiliitis grade, BASDAI, BASFI and structural damage (mSASSS). Furthermore, there was no correlation between three biomarkers.

Conclusion: Both osteoinductive factor BMP-7 and its inhibitor sclerostin increased in AS patients. This may reflect a counter-balancing mechanism in AS new bone formation leading to bone remodeling.

Unexpected High Prevalence of Cardiac Disease in Patients with Ankylosing Spondylitis. S.C. Heslinga[1], Thelma C. Konings[1], Irene E. Van der Horst - Bruinsma[1], M.L. John[1] and Mike T. Nurmohamed[2]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands.

Background/Purpose: Ankylosing spondylitis (AS) is associated with an increased cardiovascular (CV) risk that is caused by accelerated atherosclerosis as well as specific cardiac manifestations: valvular disease, conduction disturbances and congestive heart failure due to decreased ventricular function. In this study we investigated the prevalence of cardiac disease in AS patients with high disease activity.

Methods: We performed a cross sectional study in patients with AS eligible for treatment with TNF blocking therapy. Patients were screened for cardiac disease using standard transthoracic echocardiography that included two-dimensional, three-dimensional and M-mode echocardiography, spectral Doppler, color Doppler and tissue Doppler imaging. The ejection fraction (EF) was used to assess systolic left ventricular (LV) function, with systolic LV dysfunction defined as EF<50%. For diastolic LV function a combination of echocardiographic measurements, i.e. peak early diastolic filling velocity (E), late diastolic filling velocity (A), E/A ratio, early diastolic mitral annular velocity (E'), deceleration time (DT) and isovolumetric relaxation time (IVRT) were used. Based on these parameters diastolic LV dysfunction is graded into three categories: mild (grade I), pseudonormal (grade II) and restrictive (grade III). Valvular and aortic abnormalities were evaluated according to the current echocardiographic guidelines. Data was compared with data from literature using one-sample t-test.

Results: Forty-three consecutive AS patients were included with a mean age of 43±12 years and a mean disease duration of 10±12 years. In total, 10 out of 43 (23%) patients had diastolic LV dysfunction grade I, of which one was female. This was significantly higher compared to literature, in which the prevalence of diastolic LV dysfunction grade I is approximately 5% in an age matched control group ($p<0.01$)[1]. Two patients had a prior myocardial infarction of which one had systolic LV dysfunction, with an EF of 49%. Three patients had mild aortic regurgitation and seven other patients had mild mitral regurgitation. Five patients had mild aortic dilatation. Overall, 19 out of 43 AS patients (44%) had some form of cardiac dysfunction or disease which is substantially higher compared to the general population, as the prevalence of cardiac disease in the general population is approximately 8%[2].

Conclusion: Patients with AS have an increased prevalence of cardiac disease compared with the general population, with increased prevalence's of left ventricular dysfunction and valvular disease. This increased prevalence may increase CV risk in AS patients. As cardiac disease could be attributable to the general inflammation process affecting the heart, further studies are warranted that investigate whether or not anti-inflammatory treatment, such as TNF blockers, improves cardiac function or prevents early cardiac complications. Also, the impact of (mandatory) screening AS patients with echocardiography on CV disease should be investigated.

Smoking Is Not Associated with Response to TNF Blockers in Patients with Axial Spondyloarthritis. Anna Dellyes, Pierre Lafforgue, Vincent Pradel and Thao Pham. APHM, Aix Marseille University, Marseille, France.

Background/Purpose: Smoking has been reported as associated with increase disease activity, more functional impairment, poorer quality of life and more radiographic damages in patients (pts) with axial spondyloarthritis (SpA). However, there is little information available about a potential effect of smoking on the effectiveness of anti-rheumatic treatment such as TNF blockers. The study objective was to examine the association of smoking with clinical outcome after treatment with TNF blockers in patients with axial SpA.

Methods: A monocenter ambispective observational study in 96 patients with active axial SpA starting a treatment with a first TNF blocker. BASDAI, pain VAS, analgesics and NSAIDs consumption, and variables known as treatment response predictive factors were collected at baseline, 3, 6 and 12 months. The main outcome was the percentage of BASDAI 50 responders at M6. Secondary outcomes were BASDAI variation, pain VAS variation and NSAIDs consumption at M3, M6 and m12. We analyzed disease activity and response to treatment in current smokers vs. non-smokers using a chi-square test or one-way analysis of variance (depending on categorical/continuous variables). SPSS 17.0 version was used for the management and statistical analysis.

Results: Patients' demographic and clinical characteristics at baseline are shown in table 1. Thirty-five pts (36%) were current smokers (14.6±6.4 cigarettes/day). No significant differences were observed between current smokers and non-smokers at baseline. Patients were mainly treated with infliximab (84%). The percentage of BASDAI 50 responders at M6 was 34%(12/35) and 39%(24/61), in the smokers and the non-smokers group, respectively ($p>0.6$). No statically significant differences were observed between current smoker and nonsmokers in BASDAI variation, pain VAS variation or treatment consumption at each evaluation time.

Conclusion: Smoking status seems not to be a predictive factor of response to TNF-blockers in patients with axial SpA.

Baseline	Smokers N = 35	Non-smokers N=61	p
Gender, male (n, %)	17 (48.6%)	35 (57.4%)	0.52
Age, years, (mean, SD)	44 (14)	44 (9)	0.99
Disease duration, years, (mean, SD)	11.6 (11.1)	12.0 (9.1)	0.84

Association of Smoking with Acute Phase Reactants and Molecules Involved in Bone Formation in Patients with Ankylosing Spondylitis. Grigorios Sakellariou[1], Spyros Gerou[2], Dimitrios Oikonomou[1] and Fares Sayegh[3]. [1]424 General Military Hospital, Thessaloniki, Greece, [2]Laboratories "Analysis", Thessaloniki, Greece, [3]"Papageorgiou" General Hospital, Thessaloniki, Greece.

Background/Purpose: In patients with ankylosing spondylitis (AS), smoking is associated with increased disease activity and more radiographic damage. However, the mechanisms underlying the effects of smoking are still unknown. The aim of the study was to investigate the relationship between smoking and acute phase reactants, and serum levels of molecules involved in bone formation in patients with AS.

Methods: This was an observational, cross-sectional study. Serum samples for total Dickkopf-1 (Dkk-1), sclerostin and vascular endothelial growth factor (VEGF) were obtained from TNF inhibitor naïve patients with AS according to the modified New York criteria. Patients with at least the last 3 months use of glucocorticoids, DMARDs or high dose NSAIDs (a mean NSAIDs intake index ≥50) were excluded. C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), BASDAI, BASFI and radiographic severity (assessed by mSASSS and BASRI-s) were assessed for each patient. Demographic variables and smoking history were obtained, and smoking pack-years were calculated.

Results: Sixty-five patients were included in the study [mean age 41.3±1.5 years; duration of symptoms 13.4±1.2 years; male gender 61 patients (93.8%)]. Using Mann-Whitney U test, CRP (18.9±12.5 mg/l vs 12.4±9.3 mg/l, $p=0.019$) and VEGF levels (381.6±121.4 pg/ml vs 310.9±131.5 pg/ml, $p=0.02$) were higher in patients with current smoking compared with those without, while there was no difference for ESR and the levels of Dkk-1 and sclerostin. Ever smokers had higher VEGF levels (369.9±128.7 pg/ml vs 252.7±94.4 pg/ml, $p=0.006$) compared with never smokers, while there was no difference for ESR, CRP and the levels of Dkk-1 and sclerostin between the two groups. Among acute phase reactants and molecules involved in bone formation, only VEGF levels were correlated with smoking pack-years ($r=0.389$, $p=0.001$). In multiple linear regression analysis, which involved all demographic, clinical and radiographic variables that presented significant association with smoking pack-years in the bivariate correlations, VEGF levels were an independent variable of smoking pack-years ($\beta=0.497$, $p<0.001$).

Conclusion: It seems that VEGF levels are positively associated with smoking in patients with AS. The effect of smoking on disease activity and/or radiographic spinal progression to be mediated by increased VEGF levels could be supposed.

Which Characteristics of Inflammatory Back Pain (CBP) Forecast the Presence of Sacroiliitis on Magnetic Resonance Imaging (MRI)? Results from the Esperanza Cohort. Victoria Navarro-Compán[1], Raquel Almodóvar González[2], Azucena Hernández[3], Emma Beltrán[4], Eugenio de Miguel[5], Robert B. M. Landewé[6], Désirée van der Heijde[7] and Pedro Zarco[8]. [1]University Hospital La Paz and Leiden University Medical Center, Madrid, Spain, [2]Hospital Universitario Fundación Alcorcón, Madrid, Spain, [3]Hospital Virgen de la Salud, Toledo, Spain, [4]University General Hospital of Valencia, Valencia, Spain, [5]University Hospital La Paz - IdiPaz, Madrid, Spain, [6]Amsterdam Rheumatology Center, Amsterdam, Netherlands, [7]Leiden University Medical Center, Leiden, Netherlands, [8]Fundación Hospital Alcorcon, Alcorcon, Madrid, Spain.

Background/Purpose: CBP is often the starting point for a suspicion of axSpA. In the ASAS-criteria for axial SpA either MRI of the SI-joints or HLA-B27-testing are dominant. But, CBP is an extremely common presenting symptom and not all patients can be followed up by MRI and/or HLAB27 testing. This analysis was undertaken to investigate which characteristics of back-pain forecast a positive MRI of the SI-joints.

Objectives: To evaluate which inflammatory characteristics of CBP are associated with the presence of sacroiliitis on MRI in patients with a suspicion of axSpA.

Methods: Baseline dataset from the EsPeranza cohort (<45 years old, symptoms duration 3–24 months and with inflammatory back pain -IBP- or asymmetrical arthritis or spinal/joint pain plus ≥1 SpA features) was used. For this study, only data from all patients with axial symptoms who underwent sacroiliac joint (SIJ) MRI were analysed. Univariable and multivariable logistic regression analyses were employed to estimate odds ratio for the association between IBP characteristics (morning stiffness, improve with exercise and not with rest, alternating buttock pain, insidious onset, awakening at 2nd half of night and good response to NSAID) and their different combinations with a positive SIJ MRI (ASAS definition). Furthermore, diagnostic utility measures were also calculated.

Results: Data from 326 patients (53.7% male, 45% HLA-B27 positive, mean (SD) age 32.8 (7) years and mean (SD) symptoms duration 12.6 (6.4) months) were included in this analysis. A total of 130 (40%) patients had sacroiliitis on MRI. Table shows the association between each separate characteristic (1A) and each possible IBP definition (1B) with a positive MRI. Alternating buttock pain ($OR=3.43$;$p<0.001$), insidious onset ($OR=2.15$; $p<0.05$) and awakening at 2nd half of the night ($OR=1.71$;$p<0.05$) were significantly and positively associated with a positive MRI. The combination of these three characteristics (92%) and the addition to the ASAS-definition of IBP of alternating buttock pain (94%) or NSAID response (86%) had highest specificity, but insufficient sensitivity.

Conclusion: Alternating buttock pain is a distinguishing IBP characteristic strongly associated with a positive SIJ MRI in patients with suspected axSpA. The addition of this criterion in the decision to perform MRI of the SIJ may improve diagnostic efficiency in patients with suspected axSpA.

Acknowledgements: The EsPeranza Program has been supported by an unrestricted grant from Pfizer.

Disclosure of Interest: None declared.

Table: Association between each of the CBP characteristics and each of the possible IBP definitions with a positive MRI.

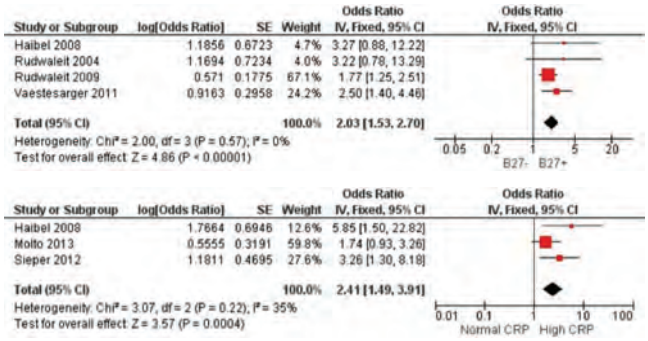
Predictors of Treatment Response to Tumor Necrosis Factor-Alpha Blockers in Spondyloarthritis: Systematic Review and Meta-Analysis. Pauline Manicki[1], Jacques Morel[1], Bernard Combe[1] and Cédric Lukas[2]. [1]Hôpital Lapeyronie, Montpellier, France, [2]Hopital Lapeyronie, Montpellier, France.

Background/Purpose: TNF blockers have demonstrated substantial clinical efficacy in spondyloarthritis patients, and are usually indicated in patients showing active disease after failure to conventional treatment with NSAIDS or conventional DMARDs in peripheral presentations of the disease. However the relevant but inconstant and "only" symptomatic efficacy of the drugs in axial disease, together with the cost and possible side effects may argue to a better selection of suitable patients before starting TNF blockers. Our objective was to identify the baseline factors potentially predictive of a good response to TNF blockers in patients with spondyloarthritis.

Methods: A systematic search of literature up to January 2014 was performed, in MEDLINE, EMBASE, the Cochrane library and abstracts from the ACR, EULAR and French national congresses from 2010 to 2013. Studies were included if they reported the response to TNF blockers based on the baseline parameters. After systematic collection of available data, a meta-analysis was conducted for every suitable outcome reported with potentially relevant baseline variables in at least 3 independent studies.

Results: The literature search identified 2340 articles and 1 congress abstract. Finally, 33 articles and one abstract could be included according the predefined requirements. The meta-analysis of data of 4 studies showed a significantly increased treatment response BASDAI 50 in patients HLA B27 positive (OR 2.03 [95%CI 1.53–2.70]). Lower BASFI was predictor of response BASDAI 50 to treatment (OR 0.88 [95%CI 0.84–0.93] per BASFI unit/10), likewise younger age (OR 0.97 [95%CI 0.96–0.98] per additional age in years) in meta-analysis of data of 4 studies, and shorter disease duration (OR 0.95 [95%CI 0.90–1.00] per additional age in years). Elevated C-reactive protein concentration was predictor of achieving ASAS 40 response (OR 2.66 [95%CI 1.39–5.08]) in meta-analysis of data from 3 studies.



Conclusion: This meta-analysis has identified increased acute phase reactants, younger age, shorter disease duration and HLA-B27 positivity as baseline predictors for achieving good clinical response to TNF-a blocking therapy. This may help clinicians in making treatment decisions in daily practice.

Which Characteristics of Inflammatory Back Pain (CBP) Forecast the Presence of HLA-B27? Results from the Esperanza Cohort. Victoria Navarro-Compán[1], Juan Jose Aznar[2], Luis F Linares[3], Eduardo Collantes-Estévez[4], Robert B. M. Landewé[5], Désirée van der Heijde[6] and Pedro Zarco[7]. [1]University Hospital La Paz and Leiden University Medical Center, Madrid, Spain, [2]Hospital de Mérida, Mérida (Badajoz), Spain, [3]University Hospital Virgen de la Arrixaca, Murcia, Spain, [4]IMIBIC/University Hospital Reina Sofía, Córdoba, Spain, Córdoba, Spain, [5]Amsterdam Rheumatology Center, Amsterdam, Netherlands, [6]Leiden University Medical Center, Leiden, Netherlands, [7]Fundación Hospital Alcorcon, Alcorcon, Madrid, Spain.

Background/Purpose: CBP is often the starting point for a suspicion of axSpA. In the ASAS-criteria for axial SpA either MRI of the SI-joints or HLA-B27-testing are dominant. But, CBP is an extremely common presenting symptom and not all patients can be followed up by MRI and/or HLAB27 testing. This analysis was undertaken to investigate which characteristics of back-pain forecast a positive HLA-B27.

Objectives: To evaluate which inflammatory characteristics of CBP are associated with the presence of HLA-B27 in patients with a suspicion of axSpA.

Methods: Baseline dataset from the EsPeranza cohort (<45 years old, symptoms duration 3–24 months and with inflammatory back pain -IBP- or asymmetrical arthritis or spinal/joint pain plus ≥1 SpA features) was used. For this study, only data from all patients with axial symptoms and HLA-B27 assessed were analysed. Univariable and multivariable logistic regression analyses were employed to estimate odds ratio for the association between IBP characteristics (morning stiffness, improve with exercise and not with rest, alternating buttock pain, insidious onset, awakening at 2nd half of night and good response to NSAID) and their different combinations with a positive HLA-B27 (local lab testing). Furthermore, diagnostic utility measures were also calculated.

Results: Data from 653 patients (54.2% male, mean (SD) age 33.0 (7.1) years and mean (SD) symptoms duration 11.0 (6.6) months. A total of 270 (41%) patients were HLA-B27 positive) were included in this analysis. Table shows the association between each separate characteristic (1A) and each possible IBP definition (1B) with a positive HLA-B27. Awakening at second half of night (OR=1.53;$p<0.05$) and good response to NSAID (OR=1.46; $p<0.05$) were significantly and positively associated with a positive HLA-B27. Among the existing criteria to define IBP, the ASAS criteria had the highest specificity (81%), but insufficient sensitivity. The addition of these two characteristics to the Calin-definition of IBP (88%) as well as the addition of NSAID response to the ASAS-definition of IBP (86%) just increased the specificity slightly.

Conclusion: Awakening at second half of night and good response to NSAIDs are distinguishing IBP characteristics associated with the presence of HLA-B27 in patients with suspected axSpA. However, the addition of these characteristics to the existing IBP definitions in the decision to test HLA-B27 does not significantly improve diagnostic efficiency in patients with suspected axSpA. Further, the most specific IBP definition for a positive HLA-B27 is the ASAS-definition.

Schett[15], Joachim Sieper[14], Simon Tarp[16], Helena Marzo-Ortega[13] and Mikkel Ostergaard[3]. [1]Medical University of Vienna, Vienna, Austria, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [4]Versailles-Saint Quentin en Yvelines University- APHP, Ambroise-Paré Hospital,, Boulogne-Billancourt,, France, [5]Versailles-Saint Quentin en Yvelines University, Boulogne-Billancourt, France, [6]Rheumazentrum Ruhrgebiet, Herne, Germany, [7]Copenhagen Center for Arthritis Research, Copenhagen, Denmark, [8]Aarhus University Hospital, Aarhus, Denmark, [9]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [10]University of Alberta, Edmonton, AB, [11]Karolinska University Hospital, Stockholm, Sweden, [12]University of Ancona, Jesi, Italy, [13]University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [14]Charité Universitätsmedizin Berlin, Berlin, Germany, [15]University of Erlangen-Nuremberg, Erlangen, Germany, [16]Copenhagen University Hospital at Fredriksberg, Copenhagen, Denmark.

Background/Purpose: Reflecting the perceived need for developing evidence-based recommendations on the use of imaging of the joints in the clinical management of spondyloarthritis (SpA) a European League Against Rheumatism (EULAR) task force was convened to develop evidence-based recommendations on the use of imaging of the joints in the clinical management of both axial and peripheral SpA.

Methods: The task force comprised an expert group of 21 rheumatologists, radiologists and methodologists from 11 countries. Twelve key questions on the role of imaging in SpA were generated using a process of discussion and consensus. Imaging modalities included conventional radiography (CR), ultrasound (US), magnetic resonance imaging (MRI), computed-, positron emission- and single photon emission computed tomography, dual-emission x-ray absorptiometry (DXA) and scintigraphy. Experts used research evidence obtained from a systematic literature review using MEDLINE and EMBASE to develop a set of 10 recommendations. The strength of recommendation (SOR) was assessed by the group members using a visual analogue scale. Quality assessment of the included studies was performed using the QUADAS-2 tool.

Results: A total of 7550 references were identified in the search process, from which 158 studies were included in the systematic literature review. Ten recommendations were produced encompassing the role of imaging in making a diagnosis of axial- or peripheral SpA, monitoring inflammation and damage, predicting outcome, response to treatment, and detecting spinal fractures and osteoporosis (OP) (Table 1). The SOR for each proposition varied, but was generally very high (mean 8.9–9.5).

Conclusion: Ten recommendations for the role of imaging in the clinical management of SpA were developed using research-based evidence and expert opinion.

LOE, level of evidence; categories of evidence: Ia, evidence for meta-analysis of randomized controlled trials; Ib, evidence from at least one randomized controlled trial; IIa, evidence from at least one controlled study without randomization; IIb, evidence from at least one other type of quasi-experimental study; III, evidence from non-experimental descriptive studies, such as comparative studies, correlation studies and case–control studies; IV, evidence from expert committee reports or opinions or clinical experience of respected authorities, or both. CRP, C-reactive protein; CT, computed tomography; DXA, dual-energy X-ray absorptiometry; MRI, magnetic resonance imaging; nr-axSpA, non-radiographic axial spondyloarthritis; SI, sacroiliac; SpA, spondyloarthritis; SOR, strength of recommendation, mean (range) of visual analogue scale; STIR, short tau inversion recovery; TNF, tumor necrosis factor alpha; US, ultrasonography.

Table 1. EULAR imaging recommendations for spondylarthritis in clinical practice

		SOR	LOE
1	**Axial SpA: diagnosis** In general, X-ray of the SI joints is recommended as the first imaging method to diagnose sacroiliitis as part of axial SpA. In certain cases, such as young patients and those with short symptom duration, MRI of the SI joints is an alternative first imaging method. If the diagnosis of axial SpA cannot be established based on clinical features and X-ray, and axial SpA is still suspected, MRI of the SI joints is recommended. On MRI, both active inflammatory lesions (primarily bone marrow edema) and structural lesions (such as bone erosion, new bone formation, sclerosis and fat infiltration) should be considered. MRI of the spine is not generally recommended to diagnose axial SpA, as it provides little added diagnostic value over and above MRI of the SI joints. Other imaging modalities are not generally recommended as the first imaging choice. CT may provide additional information on structural damage if X-rays are negative and MRI cannot be performed. Scintigraphy and US are not recommended for diagnosis of sacroiliitis as part of axial SpA.	9.5 (9.2–9.8)	III
2	**Peripheral SpA: diagnosis** When SpA is suspected, US or MRI may be used to detect peripheral enthesitis, which may support the diagnosis of SpA. Furthermore, US or MRI may be used to detect peripheral arthritis, tenosynovitis and bursitis.	9.4 (9.0–9.8)	III
3	**Axial SpA: monitoring activity** MRI of the SI-joints and/or the spine may be used to assess and monitor disease activity in axial SpA, providing additional information on top of clinical and biochemical assessments. The decision on when to repeat MRI depends on the clinical circumstances. In general, STIR sequences are sufficient to detect inflammation and the use of contrast medium is not needed.	9.2 (8.8–9.6)	Ib
4	**Axial SpA: monitoring structural changes** X-ray of the SI joints and/or spine may be used for long-term monitoring of structural damage, particularly new bone formation, in axial SpA. If performed, it should not be repeated more frequently than every 2nd year. MRI may provideadditional information.	9.3 (8.8–9.8)	Ib
5	**Peripheral SpA: monitoring activity** US and MRI may be used to monitor disease activity (particularly synovitis and enthesitis) in peripheral SpA, providing additional information on top of clinical and biochemical assessments. The decision on when to repeat US/MRI depends on the clinical circumstances. US with high-frequency color or power Doppler is sufficient to detect inflammation and the use of US contrast medium is not needed.	9.3 (8.9–9.7)	Ib

6	**Peripheral SpA: monitoring structural changes** In peripheral SpA, if the clinical scenario requires monitoring of structural damage, then X-ray is recommended. MRI and/or US may provide additional information.	8.9 (8.4–9.4)	III
7	**Axial SpA: predicting outcome/severity** In patients with AS (not nr-axSpA), initial X-rays of the lumbar and cervical spine are recommended to detect syndesmophytes, which are predictive of development of new syndesmophytes. MRI (vertebral corner inflammatory or fatty lesions) may also be used to predict development of new radiographic syndesmophytes.	9.0 (8.5–9.5)	Ib
8	**Axial SpA: predicting treatment effect** Extensive MRI inflammatory activity (bone marrow edema), particularly in the spine in AS patients, may be used as a predictor of good clinical response to anti-TNF treatment in axial SpA. Thus, MRI may aid in the decision of initiating anti-TNF therapy, in addition to clinical examination and CRP.	8.9 (8.3–9.5)	Ib
9	**Spinal fracture** When spinal fracture in axial SpA is suspected, X-ray is the recommended initial imaging method. If X-rays are negative, CT should be performed, MRI is an additional imaging method to CT, which can also provide information on soft tissue lesions.	9.3 (8.9–9.7)	IV
10	**Osteoporosis** In axial SpA patients without syndesmophytes in the lumbar spine on X-ray, osteoporosis should be assessed by hip DXA and AP-spine DXA. In patients with syndesmophytes in the lumbar spine on X-ray, osteoporosis should be assessed by hip DXA, supplemented by either spine DXA in lateral projection or possibly QCT of the spine.	9.4 (9.0–9.8)	III

Comparison of Radiographic Damage Score in Ankylosing Spondylitis According to Tumor Necrosis Factor Inhibitor: Observation Study of Korean Spondyloarthropathy Registry (OSKAR) Data. Tae-Jong Kim[1], JI Hui SHIN[2], Il-Hoon Sung[2], Seunghun Lee[3], Kyung-Bin Joo[4] and Tae-Hwan Kim[2]. [1]Chonnam Nat'l University Medical School&Hospital, Gwangju, South Korea, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [3]Department of Radiology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [4]Department of Radiology, Hanynag University Hospital for Rheumatic Diseases, Seoul, South Korea.

Background/Purpose: To evaluate the influence of tumor necrosis factor (TNF) blocker on the radiographic damage in ankylosing spondylitis (AS).

Methods: A total of 610 AS patients from the Observation Study of Korean spondyloArthropathy Registry (OSKAR) data were recruited for this study. The subjects were stratified in relation to the using state of TNF blocker. We evaluated collected clinical and radiographic parameters at two different time points. Then we compared radiographic progression between groups. To use the mSASSS, cervical and lumbar spinal radiographs were examined. Univariable and multivariable regression analyses were done after adjusting for potential confounding factors, such as age, gender, disease duration, history of eye involvement, history of peripheral arthritis, juvenile onset AS, baseline CRP level, baseline mSASSS, and NSAID intakes.

Results: The mean age (SD) of the AS patients was 37.9(18.3) years, and the mean disease duration (SD) was 17.3 (18.3) years at baseline. In this data, 88.7% of the patients were male, and 96.9% were HLA–B27 positive. 40.7% of the patients had history of peripheral arthritis. Of these patients, 44.1% (269 patients) had received TNF blockers. The mean mSASSS unit (SEM) at baseline was significantly different between groups (TNF blocker naïve 17.6 ± 0.9 vs TNF blocker user 21.0 ± 1.2, $P = 0.02$). Radiographic follow-up duration from the first mSASSS assessment were comparable (4.9 ± 0.1 vs 5.1 ± 0.1, $P = 0.28$). However, Patients treated with TNF blockers had a higher CRP level (2.5 ± 0.2 vs 1.6 ± 0.1, $p < 0.01$) at baseline. On simple analysis, the TNF blocker naïve patients had comparable radiographic progression to those with TNF blocker (3.7 ± 0.5 vs 3.7 ± 0.8, $p = 0.99$). After adjustment for multiple comparisons by the Bonferroni correction, gender, history of peripheral arthritis, disease duration, baseline mSASSS, and NSAID intake had statistically significance in our registry. However, the radiographic progression between groups was no significant difference (OR 0.60, [95% CI 0.22–4.72], $P = 0.44$).

Conclusion: Treatment with TNF inhibitors has no influence on radiographic progression in AS.

Effects of Self-Management Model on the Disease-Related Knowledge, Joint Function and Quality of Life in Patients with Ankylosing Spondylitis. Pingping Zhang[1], Jun Qi[2], Zhiming Lin[3], Minjing Zhao[2] and Jieruo Gu[3]. [1]Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China, [2]The Third Affiliated Hospital of Sun Yat-sen University, guangzhou, China, [3]The Affiliated Third Hospital of Sun Yat-san University, Rheumatology, Guangzhou, China.

Background/Purpose: Ankylosing spondylitis is a kind of chronic inflammatory diseases, inflammation of the sacroiliac joint and spine attachment points are the main symptoms, as a kind of chronic disease, the patients' self-management is very importantTo investigate and evaluate the effect a new kind of health management model on disease-related knowledge, joint function and quality of life in patients with ankylosing spondylitis(AS).

Methods: 84 patients with AS Who have signed the informed consent in China were included in this study. All the patients satisfied the ACR classification criteria for AS.Doctors and AS patients co-builded a club which was a new kind of self-management model in the follow-up 6 months. In the club, the medical staff could give AS patients psychological guidance, pain guidance, dietary guidance and life guidance, patients could also give others positive impact. before and after six months of this management model of club, we evaluate the disease-related knowledge, compliance, joint function, psychological quality, and life quality by questionnaire of AS health management and Bath AS Function Index (BASFI).

Results: The questionnaire score of disease-related knowledge in AS patients increased significantly from (58.14 ± 11.62) to (74.77 ± 10.16) ($p = 0.000$); In the long process of treatment, many AS Patients despair and feel hopeless because they thought it impossible to Work like a healthy person, but after this management model, the ration has been significantly reduced from14.1% (11/84) to 3.57% (3/84)($P = 0.017$). Meanwhile, patients willing to cooperate with doctors and face life actively increased significantly from 72.62% (61/84) to 90.48% (76/84), ($P = 0.003$).Patients unwilling to insist long-term drug therapy for fear of side effects dropped significantly from 35.71% (30/84) to 4.76% (4/84) ($P = 0.000$);Patients who quit smoking and drinking, and could diet reasonably rose significantly from 45.24% (38/84) to 79.76% (67/84), ($P = 0.000$); BASFI score improved from 5.25 ± 1.93 to 3.90 ± 1.87 ($P = 0.000$); Patients with satisfaction of health education increased significantly from 72.62% (61/84) to 100% (84/84), $P = 0.000$.

Conclusion: AS club could mobilize patients' initiative, make them cooperate actively with doctors. By this new kind of management model, AS patients could gain more knowledge about health and improve their joint function; And what's more, this kind of management model also increased the patients' ability of self-management, improved their life quality.

Assessment of Spondyloarthritis International Society Endorsed Recommendations for Early Referral of Patients Suspected for Axial Spondyloarthritis. Denis Poddubnyy[1], Astrid van Tubergen[2], Robert Landewé[3], Joachim Sieper[1] and Désirée van der Heijde[4]. [1]Charité Universitätsmedizin Berlin, Berlin, Germany, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [4]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: There is a substantial gap of 5 to 8 years between the onset of symptoms (usually back pain) and the diagnosis of axial spondyloarthritis (SpA). One of the reasons for such a delay is a late referral of patients to a rheumatologist by general practitioners and other physicians encountering patients with back pain. Several referral approaches have been proposed and tested over the last 10 years, however, no universal and widely accepted referral strategy exists until now. The aim was, therefore, to develop consensual recommendations under the umbrella of the Assessment of Spondyloarthritis international Society (ASAS) for early referral of patients suspected for axial SpA by primary care physicians or non-rheumatology specialists.

Methods: Development of the ASAS endorsed referral recommendations for patients suspected for axial SpA by primary care physicians or non-rheumatology specialists consisted of the following phases: 1) systematic literature review, 2) the first Delphi round aimed at identification of unmet needs and development of the referral parameter candidate list, 3) the second Delphi round aimed at identification of the most useful combination of the referral parameters, 4) final discussion on the proposal for the recommendations and voting on it at ASAS annual meeting in 2014.

Results: The following consensus on the referral recommendation was achieved within ASAS as a result of the Delphi process and final voting.

"Patients with **chronic back pain (duration ≥3 months)** and **back pain onset before 45 years of age** should be referred to a rheumatologist if at least one of the following parameters is present:

- Inflammatory back pain;
- HLA-B27 positivity;
- Sacroiliitis on imaging if available (X-rays or magnetic resonance imaging);
- Peripheral manifestations (arthritis, enthesitis, dactylitis);
- Extra-articular manifestations (psoriasis, inflammatory bowel disease, uveitis);
- Positive family history for SpA;
- Good response to non-steroidal anti-inflammatory drugs;
- Elevated acute phase reactants."

Conclusion: A consensual ASAS endorsed referral recommendation for patients suspected for axial SpA by primary care physicians or non-rheumatology specialists was developed as a flexible and universal tool to be used in clinical practice. The diagnostic value of this tool applied in different settings should be determined in future studies.

Patients with Non-Radiographic Axial Spondyloarthritis and Ankylosing Spondylitis Demonstrate the Same Clinical Disease Course over Two Years: Results from the Gespic Cohort. Denis Poddubnyy[1], Hildrun Haibel[1], Jürgen Braun[2], Martin Rudwaleit[1] and Joachim Sieper[1]. [1]Charité Universitätsmedizin Berlin, Berlin, Germany, [2]Rheumazentrum Ruhrgebiet, Herne, Germany.

Background/Purpose: In cross-sectional studies it has been demonstrated that non-radiographic axial spondyloarthritis (nr-axSpA) does not differ from ankylosing spondylitis (AS) with respect to clinical signs of disease activity. Prospective studies comparing clinical course of the disease over time are, however, lacking. The purpose of this analysis was to investigate the clinical course of the disease over two years in patients with nr-axSpA in comparison to AS.

Methods: In total, 210 patients with early axSpA (115 with AS according to the modified New York criteria and symptom duration ≤10 years, and 95 with nr-axSpA and symptom duration ≤5 years) with complete radiographic data over 2 years from the German Spondyloarthritis Inception Cohort (GESPIC) were included. Clinical assessment, which included standard disease activity (BASDAI, C-reactive protein – CRP), function (BASFI) and spinal mobility (BASMI) assessments, as well as therapy recording, was performed at baseline and every 6 months thereafter. Starting from the visit at month 6, the ASDAS-CRP and the ASAS NSAID intake score were calculated.

Results: The majority of patients were included in GESPIC and followed-up prior to marketing authorisation of TNF blockers for AS and nr-axSpA. However, 17 AS patients (14.8%) and 5 nr-axSpA patients (5.3%) received at least one prescription of a TNF blocker during 2 years of follow-up and were excluded from the further analysis. Remaining patients with nr-axSpA (n=90) did not differ from AS patients (n=98) with respect to the BASDAI and the BASFI at any time point during 2 years of follow-up (figure). AS patients had however significantly higher level of CRP at all time points but ASDAS-CRP was significantly higher in AS at 6M only (figure).

There were also no substantial differences in the treatment between two groups. Spinal mobility (as measured by BASMI) was generally better in nr-axSpA as compared to AS, but this difference was statistically significant only at two time points (6 and 12 months).

Among all patients who did not receive a TNF-Blocker during 2 years of follow-up, 10 patients with nr-axSpA and 22 patients with AS had at baseline BASDAI≥4 and elevated CRP. Low disease activity state at at least 2 time points during 2 years of the follow-up as defined by BASDAI<4 was achieved by 57% of nr-axSpA and by 40% of AS patients, BASDAI<4 and normal CRP by 25% and 13%, BASDAI≤2 by 13% and 13%, and ASDAS inactive disease by 25% and 0% of nr-axSpA and AS patients, respectively. All differences were statistically non-significant.

Conclusion: Patients with nr-axSpA and AS demonstrated the same course of the disease over 2 years as evaluated by the level of symptoms, functional status and NSAIDs treatment (except anti-TNF). Only a small proportion of patients with nr-axSpA and AS reached a stricter definition of low disease activity over two years of follow-up without TNF-blocker treatment.

Differences in Localization and Activity of the Entheseal Involvement Between Non-Radiographic and Radiographic Axial Spondyloarthritis By the Ultrasound Assessment. Marketa Fojtikova[1], Karel Pavelka[1], Sarka Forejtova[2] and Jindra Gatterova[3]. [1]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [2]Institute of Rheumatology, Prague, Czech Republic, [3]Institute of rheumatology, Prague 2, Czech Republic.

Background/Purpose: Inflammatory involvement of peripheral enthesis belongs to an important sign of spondyloarthritis (SpA). It may occur in patients with long-term as well as newly diagnosed disease and in those with definite ankylosing spondylitis (AS) and without radiological sacroiliitis, non-radiographic axial SpA (nr-ax-SpA).

In our work we look for active and non-active entheseal changes by an ultrasound detection in four localization: Achilles tendon, patellar ligament, plantar aponeurosis and quadriceps insertion in patients suffering from newly diagnosed nr-ax-SpA and AS.

Methods: The total of 34 patients with newly diagnosed SpA (with established diagnosis maximally within 2 years) underwent the clinical and ultrasound examination. Disease activity was determined by ASDAS CRP and BASDAI. Conventional two-dimensional power Doppler ultrasonography was performed by one radiologist/musculoskeletal ultrasound specialist. Six ultrasound changes like tendon structural changes and thickening of tendon insertion, calcifications, bone erosions, bursitis, and Doppler signal was determined in four locations and Naredo et al. classification for active/non active lesions was used. The $\chi 2$ test for comparison each group, Fisher exact test and correlation for activity a tendon changes was used.

Results: Altogether, 26 nr-ax-SpA patients and 8 AS patients BASDAI 3.27±0.56 and 1.95±0.2 respectively, ASDAS CRP 1.88±0.63 and 2.07±0.29 respectively, underwent the ultrasound detection for entheseal changes.

When we look for any changes in all tested tendons there were non-active changes in only 37.90 % nr-ax-SpA compared to 71.88 % AS ($p < 0.0001$). However the active changes were distributed evenly in nr-ax-SpA and AS, 4.80 % and 7.81%, respectively.

The Doppler positive changes in any locations were found in 19.20% nr-ax-SpA and 37.5% AS (p=ns), whereas the non-active changes in 280.77% nr-ax-SpA a 100% AS (p=ns).

The Achilles tendon and the patellar ligament were the most common involved sites in both patients groups, nr-ax-SpA (32.70 and 26.92%, respectively) and AS (50.0 and 25.0% respectively), all p=ns.

There is no correlation between ASDAS CRP and/or BASDAI and active and non-active lesions in both group.

Conclusion: Our study demonstrates the usefulness of soft tissue ultrasound for active and non-active tendon changes in SpA. Interestingly, both patients with nr-ax-SpA and those with definite AS develop the same number of active entheseal changes, but non-active entheseal changes are more common AS. The presence of active and non-active entheseal changes do not correlate with disease activity.

Using Iphone Compass Application for the Assessment of Cervical Rotation in Patients with Ankylosing Spondylitis. Gokce Kenar, Berrin Zengin, Handan Yarkan, Pinar Cetin, Ismail Sari, Fatos Onen, Merih Birlik and Nurullah Akkoc. Dokuz Eylul University School of Medicine, Izmir, Turkey.

Background/Purpose: Cervical rotation reflects restriction of mobility in axial disease in ankylosing spondylitis (AS) and it can be assessed in several approaches based on the use of either an inclinometer, a goniometer or a tape measure. New generations of smartphones are equipped with a gyroscope and an accelerometer which in combination with a smartphone's operating system or specific software applications can be used for various inclinometric functions. The aim of the study was to assess the reliability and validity of using iphone built in compass application, as compared to using goniometer in the assessment of cervical rotation patients with AS.

Methods: The study sample included 20 AS patients (6 females, 14 males) with a mean age of 47.8 (± 10.2). BASMI scores were obtained from patient charts. Two examiners measured cervical rotation of each patient using iPhone4 compass application and also goniometer, twice with each method. A cap with a velcro patch on top and an iphone case with a Velcro patch on the bottom were used to stabilize the iphone's position during measurements. Intra-rater and inter-rater reliability were examined with intra-class correlation coefficients (ICC). The agreement between the two methods was assessed by by Bland-Altman method.

Results: The mean BASMI score of AS patients was 43 (± 22.7). The mean scores for BASDAI, ASDAS and BASFI were 3.7 (± 19.9), 2.9 (± 0.96) and the 3.5 (± 2.4), respectively. We observed an excellent intra and inter-rater reliability in the whole study sample for both methods (Table 1 and Table 2). Bland-Altman analysis also showed a good agreement between the two methods (iphone-goniometer) with a mean difference (bias) of −1.7 for examiner 1 (95% CI −5.9 to −2.7) and -4.6 for examiner 2 (95% CI -8.9 to -0.4). Upper and lower limits of agreement were 16.6 (95% CI 9 to 24.2) and −19.9 (95% CI −27.4 to −12.3), for examiner 1 and 13.1(95% CI 5.7 to 20.4) and -22.3 (95% CI -29.6 to -15) for examiner 2.

Conclusion: Using iPhone compass application is a simple and accessible way of measuring cervical rotation in patients with AS. Measurements obtained with iphone show excellent intra and inter-rater reliability and a very good agreement with measurements obtained with goniometer.

Table. 1 Mean cervical rotation measurements (degrees) with iPhone and goniometer and Intra-rater reliability for both methods

Method	Examiner 1				Examiner 2			
	Trial 1 (Mean ± SD)*	Trial 2 (Mean ± SD)*	ICC	95% CI for ICC	Trial 1 (Mean ± SD)*	Trial 2 (Mean ± SD)*	ICC	95% CI for ICC
Goniometer	46.8 ± 16.5	46.3 ± 16.5	0.98	0.97–0.99	46.5 ± 16.9	46.4 ± 16.6	0.98	0.97–0.99
iPhone	48.3 ± 22.1	48.1 ± 21.3	0.98	0.96–0.99	51.8 ± 21.3	50.3 ± 20.1	0.96	0.90–0.98

*Mean of the right and left cervical rotation

Table 2 Mean cervical rotation measurements (degrees) with iPhone and goniometer and inter-rater reliability for both methods

	Examiner 1 (Mean ± SD)*	Examiner 2 (Mean ± SD)*	ICC	95% CI
Goniometer	46.6 ± 16.44	46.5 ± 16.91	0.99	0.97–0.99
iPhone4	48.2 ± 21.6	51.05 ± 20.49	0.93	0.84–0.97

Similarities and Differences Between Axial and Peripheral Predominant Forms in patients with Early Spondyloarthritis (SpA): Results from the Esperanza Cohort. . Pilar del Río-Martínez[1], Victoria Navarro-Compán[2], Concepción Castillo-Gallego[2], M. Carmen Castro[3], Eduardo Collantes-Estévez[3] and Eugenio de Miguel[2]. [1]Rheumatologist, Zaragoza, Spain, [2]Rheumatologist, Madrid, Spain, [3]Rheumatologist, Córdoba, Spain.

Background/Purpose: Based on the predominant manifestation of the disease, the ASAS classification criteria for spondyloarthritis (SpA) distinguish two clinical forms:

- Axial SpA, including non-radiographic SpA and Ankylosing Spondylitis (AS).
- Peripheral SpA.

Although both forms are considered as part of the same disease, published data are limited, especially in early disease. The purpose of this study is to describe and compare the characteristics of patients fulfilling the ASAS criteria for axial SpA versus peripheral SpA in patients with recent symptoms onset.

Methods: -Population.- Baseline dataset from the early SpA ESPERANZA cohort was used, with the following referral criteria: Age <45 years, symptoms duration 3–24 months and with inflammatory back pain (IBP) or asymmetrical arthritis or spinal/joint pain plus ≥1 SpA features.

-Inclusion criteria.- Patients fulfilling the ASAS classification criteria for SpA.

-Outcome.- To compare socio-demographic and disease characteristics between patients with axial SpA and patients with peripheral SpA.

-Statistical analyses: Variables were compared using Student t test (continuous) or Chi-square test (categorical).

Results: Data from 377 patients were analysed. Two hundred ninety (77.2%) patients were classified as axial SpA (109 AS and 182 non-radiolographic SpA) and 86 (22.8%) patients as peripheral SpA. Table 1 shows the results (mean ± SD or relative frequency) for the comparison of demographic and disease characteristics between groups. Age, sex and disease activity scores were similar in both groups. However, axial SpA was more related to a delay in referral time, uveitis and positive HLA-B27 while peripheral SpA was associated with enthesitis, psoriasis, dactylitis and inflammatory bowel disease (IBD).

Conclusion: Early SpA patients with predominant axial symptoms have a higher delay in the referral to rheumathologist than patients with peripheral symptoms. However, the degree of disease activity is similar in both groups. Uveitis and HLA-B27 are more frequent in patients with predominant axial symptoms while psoriasis, enthesitis, dactylitis and IBD are more frequent in patients with peripheral involvement.

Table 1 shows mean ± SD and p value

Characteristic	Axial SpA N (%)= 291 (77.2)	Peripheral SpA N (%) = 86 (22.8)	P value
Age (years)	32.0 ± 7.0	32.8 ± 7.8	0.4
Male	191 (65.6)	50 (58.1)	0.2
Symptoms duration (months)	13.0 ± 6.7	9.3 ± 6.2	**<0.001**
Enthesitis	57 (19.6)	43 (50)	**<0.001**
Psoriasis	33 (11.3)	28 (32.6)	**<0.001**
Dactylitis	16 (5.5)	28 (32.6)	**<0.001**
IBD	9 (3.1)	10 (11.6)	**0.001**
Uveitis	23 (7.9)	1 (1.2)	**0.02**
Diarrhea, cervicitis, urethritis	11 (3.78)	5 (5.8)	0.4
Family history	101 (34.7)	31 (36)	0.8
HLA-B27	219 (75.3)	28 (32.6)	**<0.001**

CRP (mg/L)	10.8 ± 15.2	13.7 ± 31.2	0.3
ESR (mmHg)	13.6 ± 13.5	14.1 ± 13.4	0.8
SJC	0.3 ± 1.3	1.4 ± 2.4	**<0.001**
VAS (0–10) physician	2.9 ± 2.2	2.4 ± 2.1	0.1
VAS (0–10) patient	4.2 ± 2.7	3.1 ± 2.5	**<0.01**
BASDAI	3.8 ± 2.3	3.5 ± 2.3	0.2

Impact of Repeating Imaging of the Sacro-Iliac Joints over One Year on the Classification According the ASAS Axial Spa Criteria of Patients. Pauline Bakker[1], Manouk de Hooge[1], Rosaline van den Berg[1], Floris van Gaalen[1], Monique Reijnierse[1], T.W.J. Huizinga[1] and Désirée van der Heijde[2]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway.

Background/Purpose: It is known that in axial spondyloarthritis (axSpA) inflammatory lesions on MRI of the SI joints (MRI-SI) can change over time. The usefulness of repeating imaging in the diagnostic process is unclear. The aim is to investigate how patients with short-term chronic back pain are classified by the ASAS axSpA- criteria at baseline and after 1 year follow-up, with a focus on the role of imaging.

Methods: Patients in the SPACE cohort (back pain: ≥ 3 months, ≤ 2 years, onset < 45 years) with (suspicion of) axSpA underwent MRI and X-rays of the sacroiliac joints at baseline and 1 year follow-up. Only patients with complete MRI- and X-SI data at both baseline and year 1 were included in the analysis (n=80). MRI-SI and X-SI were scored independently by 3 well-calibrated readers according to the ASAS definition for a positive MRI and the mNY-criteria. Readers were blinded for patient characteristics and time sequence. Fulfillment of ASAS or mNY criteria was considered positive if 2/3 readers agreed. For each timepoint, patients were classified according the ASAS axSpA criteria and grouped in different arms (imaging arm: mNY+/− or MRI+/−; clinical arm, fulfillment of both arms and possible axSpA). In contrary to the normal application of the criteria, where a positive feature remains positive, we grouped patients according to the finding at one year, ignoring previous imaging findings.

Results: At baseline, 41/80 patients (32.8%) fulfilled the ASAS criteria (clinical arm: 22; imaging arm: 12, both arms: 7) (table). After 1 year, 3 additional patients fulfilled the criteria (2 clinical arm; 1 imaging arm). After 1 year, in 5 patients MRI-SI became positive and 1 patient fulfilled the mNY criteria. On the other hand, MRI-SI became negative after 1 year in 4 other patients. Of these patients, 3 still fulfilled the ASAS criteria (imaging arm (mNY+, n=1) or clinical arm (n=2)). Only 1 patient (classified axSpA at baseline) would be missed if imaging would have been performed at 1 year only (due to a negative MRI).

Conclusion: With one year longer symptom duration, 3/39 (8%) of the possible SpA patients could be classified additionally as axSpA because of additional SpA features (5%) or positive MRI (3%), while 1/41 (2%) of the axSpA patients would not be classified due to a normal MRI. Therefore, our data show the robustness of the axSpA criteria and does not support repeating imaging after one year.

			1 year							
			Both arms			Imagingarm				
			mNY+ MRI+	mNY+ MRI−	mNY− MRI+	mNY+ MRI+	mNY+ MRI−	mNY− MRI+	Clinical arm	Possible SpA

Disease Characteristics Associated with the Presence of Dactylitis in Patients with EARLY Spondyloarthritis: Results from Esperenza Cohort. Maria Isabel Tévar Sánchez[1], Victoria Navarro-Compán[2], Raquel Almodóvar González[3], Maria Pilar Fernández Dapica[4], Pedro Zarco[5] and Eugenio De Miguel[6]. [1]Hospital Vega Baja, Orihuela, Alicante, Spain, [2]University Hospital La Paz, Madrid, Spain, [3]Hospital Universitario Fundación Alcorcón, Madrid, Spain, [4]University Hospital 12 de Octubre, Madrid, Spain, [5]Fundación Hospital Alcorcon, Alcorcon, Madrid, Spain, [6]Department of Rheumatology, Hospital Universitario La Paz, Madrid, Spain.

Background/Purpose: Dactylitis is a typical manifestation in patients with SpA. Despite dactylitis has traditionally been related to the coexistence of psoriasis and peripheral arthritis, it was included as SpA feature for both (axial and peripheral) ASAS classification criteria. However, data supporting this is scarce, especially in patients with recent onset. The objective of this study was to determine the prevalence of dactylitis and which disease characteristics are associated with its presence in patients with early SpA.

Methods: Baseline dataset from the EsPeranza cohort (<45 years, symptoms duration 3–24 months and with inflammatory back pain -IBP- or asymmetrical arthritis or spinal/joint pain plus ≥1 SpA features) was analysed. For this study, 609 patients diagnosed of SpA by their physician were included. Logistic regression analysis was used to investigate the association between disease characteristics and the presence of dactylitis. These characteristics included family history of SpA, clinical manifestations (chronic back pain –CBP-, inflammatory back pain–IBP-, peripheral arthritis, enthesitis, uveitis, psoriasis, nail lesions, inflammatory bowel disease –IBD- and urethritis or cervicitis), activity parameters (SJC, physicianxs VAS, patientxs VAS and BASDAI), metrology (BASMI), function (BASFI), lab tests (HLA B27, ESR and CRP), and imaging (sacroiliitis on x-Ray or MRI by ASAS definition).

Results: Fifty eight (10.5%) patients had current or previous dactylitis. The presence of dactylitis was associated with peripheral arthritis, enthesitis, psoriasis, nail lesions, SJC, physicianxs VAS and CRP in the univariable analysis. Moreover, CBP, IBP and sacroiliitis were associated with absence of dactylitis. No significant differences were found for the rest of variables. In the multivariable analysis the presence of dactylitis was associated with peripheral arthritis, enthesitis, psoriasis and physicianxs VAS (Table). However, 14 (24%) patients did not have peripheral arthritis but had axial symptoms/signs.

Further, patients with dactylitis were classified as patients with dactylitis and psoriasis (n=19; 32.8%) and patients with dactylitis and no psoriasis (n=39; 67.2%). Disease characteristics were compared between both groups. Male were more frequent in the psoriasis group (84% vs 51%;$p<0.05$). The group without psoriasis had higher frequency of CBP, IBP, enthesitis, HLA-27 and sacroiliitis but these differences did not reach statistical significance.

Conclusion: Dactylitis is a frequent manifestation in patients with SpA even at early stages of the disease. Its presence is mainly associated with peripheral manifestations and psoriasis. However, the majority of patients with dactylitis do not have psoriasis and 24% of them have axial manifestations in absence of peripheral arthritis.

Table: Association between SpA characteristics and the presence of dactylitis

Characteristic	OR	95% CI
Chronic back pain	0.44	0.12 to 1.07
Inflammatory back pain	0.44	0.18 to 1.06
Peripheral arthritis	*4.83*	*2.00 to 11.7*
Enthesitis	*2.49*	*1.24 to 5.03*
Psoriasis	*3.62*	*1.63 to 8.04*
Nail lesions	0.61	0.12 to 3.18
Diarrhea, cervicitis, urethritis	2.17	0.54 to 8.77
CRP	0.99	0.97 to 1.01
ESR	1.01	0.99 to 1.03
Sacroiliitis	1.26	0.52 to 3.07
Physicianxs VAS	*0.82*	*0.70 to 0.96*

2599

Do Patients Diagnosed As Axial Spondyloarthritis (AxSpA) Who Have Primary Inefficacy to Anti-TNF Really Have AxSpA? a Five-Year Follow-up Study of 27 Patients with Primary Inefficacy to Anti-TNF. Sandra Kossi[1], Sabrina Dadoun[2], Bruno Fautrel[2], Maxime Dougados[3] and Laure Gossec[4]. [1]Hopital La Pitie Salpetrière, Paris, France, [2]UPMC GRC08, Paris 06 University, Pitié Salpétrière Hospital, Paris, France, [3]INSERM (U1153): Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité, Paris, France., Paris, France, [4]Sorbonne Universités, UPMC Univ Paris 06, GRC-08, Institut Pierre Louis d'Epidémiologie et de Santé Publique, paris, France.

Background/Purpose: The diagnosis of AxSpA is not easy and there are cases of overlap with fibromyalgia for example. Anti-TNF have been shown to have great efficacy in AxSpA, and primary inefficacy is rare. Do patients who have primary inefficacy to anti-TNF, really have a diagnosis of AxSpA?

Objective: To assess the evolution and final diagnosis of all patients with primary inefficacy to anti-TNF in AxSpA over a period of two years in one tertiary referral center, with a follow up of five years.

Methods: Systematic retrospective study of all patients receiving an anti-TNF for AxSpA in one tertiary referral centre (ref). Patients had AxSpA according to the rheumatologist and were started on a first course of anti-TNF according to usual practice. Primary inefficacy was defined by the rheumatologist's opinion after three months of treatment by anti-TNF, when the treatment was then discontinued. Five years later, these patients were recontacted and were seen in outpatient clinic if possible, filled in questionnaires including FIRST for fibromyalgia, and a final diagnosis was defined.

Results: Of 222 patients receiving a first anti-TNF for AxSpA, 27 (12.2%) were considered as having primary inefficacy to their first anti-TNF. The characteristics of these patients were slightly different from the others, with more females (48 vs 27%, p=0.04), older age (46 vs 40 yrs; p=0.04), higher BASFI (68 vs 42, p=0.001) and less increased CRP (50% vs 78%, p=0.008). Among the 27 patients, a second anti TNF was prescribed for 16 (59.2%) patients, 7 (7/16=43.7%) had primary inefficacy to the second anti-TNF and retention rate of the second anti-TNF at one year was 50%.

At the 5 year follow-up, 14 patients were seen in outpatient clinic and 9 follow-up medical files were available; 4 patients could not be evaluated (2 were lost to follow-up and 2 refused).

The diagnosis of AxSpA was confirmed for 20/23 (86.9%) patients according to the ASAS criteria and 23/23 (100%) patients according to the rheumatologist; but 16/23 (69.6%) had at least one other cause of pain/symptoms: 10 (43.5%) had osteoarthritis, 7 (30.4%) patients had depression and 3 (13.0%) had fibromyalgia.

Conclusion: Primary inefficacy to anti-TNF in AxSpA is rare, and patients with primary inefficacy have slightly different characteristics from the other AxSpA patients. Long-term follow-up indicates most of these patients have a definite diagnosis of AxSpA but often have other causes of pain/symptoms. We suggest patients with primary inefficacy to anti-TNF should be screened for comorbidities like fibromyalgia, osteoarthritis or depression that may interfere with AxSpA impact and assessment.

Gender-Attributable Differences in Outcome of Ankylosing Spondylitis: Long-Term Results from the Outcome in Ankylosing Spondylitis International Study. Casper Webers[1], Ivette Essers[1], Sofia Ramiro[2], Carmen Stolwijk[3], Robert Landewé[4], Désirée van der Heijde[5], Filip van Den Bosch[6], Maxime Dougados[7] and Astrid van Tubergen[3]. [1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Amsterdam Rheumatology Center/University of Amsterdam, Amsterdam, Netherlands, [3]Maastricht University, Maastricht, Netherlands, [4]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [5]Leiden University Medical Center, Leiden, Netherlands, [6]Department of Rheumatology Ghent University Hospital, Ghent, Belgium, [7]Paris-Descartes University, Paris, France.

Background/Purpose: In ankylosing spondylitis (AS), gender-attributable differences have been reported with respect to clinical and radiographic outcome. However, longitudinal studies exploring gender-attributable differences in the outcome of AS are scarce, and have limited follow-up. The aim of the present study was to investigate gender-attributable differences with respect to clinical outcomes (disease activity, function and quality of life (QoL)) and radiographic damage in patients with AS over time.

Methods: Clinical and radiological data from patients included in the Outcome in AS International Study (OASIS) were used. Disease activity was assessed by the Bath AS Disease Activity Index (BASDAI), the AS Disease Activity Score (ASDAS), and C-reactive protein (CRP); physical function by Bath AS Functional Index (BASFI); QoL by the Short Form-36 (SF-36), ASQoL and EuroQoL; radiographic damage by the modified Stoke AS Spine Score (mSASSS). First, cross-sectional comparative analyses were done at baseline. Second, separate models were created to assess gender-attributable differences on each outcome measure over time using time-adjusted generalized estimation equations (GEE). All analyses were performed in the total population and in those patients who completed the total 12 years of follow-up.

Results: 216 patients (154 (72.3%) men, mean age 43.6 years (SD 12.7), symptom duration 20.5 years (SD 11.8), mean follow up duration 8.3 years (SD 4.1)) were included. At baseline, male compared with female patients had lower self-reported disease activity (BASDAI 3.2 vs. 3.9, p=0.03) but more radiographic damage (mSASSS 13.8 vs. 6.5, p=0.02). No significant differences in other clinical parameters between gender were found at baseline. In univariable analysis, a significant association between male gender and better QoL (lower ASQoL and higher EuroQoL), and between male gender and more radiographic damage (higher mSASSS) over time was found.

Also in multivariable analysis, male gender was, compared with female gender, significantly associated with a better ASQoL (B= -1.10, 95%CI -2.11 to -0.09, p=0.03), and in a separate multivariable analysis also with higher mSASSS over time (B=8.52, 95%CI 4.55 to 12.50, p<0.01). Similar results were found for the 12-year completers.

Conclusion: In this longstanding observational cohort study in patients with AS, no gender-attributable differences in disease activity and function over time were found. However, male gender, compared with female gender, was found to be associated with more radiographic damage, but also better QoL. It is likely that gender differences in AS are determined by both biological and psychological factors, and that male and female patients differ in the way they cope with pain and disability.

Serum Biomarkers Associated with Changes in ASDAS and MRI Following Treatment of Ankylosing Spondylitis with Golimumab. Robert D. Inman[1], Xenofon Baraliakos[2], Kay-Geert A. Hermann[3], Jürgen Braun[2], Atul A. Deodhar[4], Désirée van der Heijde[5], Stephen Xu[6] and Benjamin Hsu[6]. [1]University of Toronto and Toronto Western Hospital, Toronto, ON, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]Charité Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany, [4]Oregon Health and Sciences University, Portland, OR, [5]Leiden University Medical Center, Leiden, Netherlands, [6]Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: Serum biomarkers that can predict subsequent clinical or imaging outcomes would aid decision-making in the management of ankylosing spondylitis (AS). Using data from the golimumab (GLM) study, GO-RAISE, in patients with active AS, we analysed correlations between multiple serum biomarkers and inflammation as detected by magnetic resonance imaging (MRI) and AS Disease Activity Score (ASDAS).

Methods: In GO-RAISE, patients with moderately to severely active AS were randomized to SC GLM 50mg, 100mg, or PBO q4wks. PBO-treated patients crossed over to receive GLM at wk16 or 24. Spinal MRIs in the sagittal plane were acquired using 1.5T scanners with T1 and short tau inversion recovery (STIR) sequences at BL and wk14. 98 patients were scored for activity (ASspiMRI-a) and structural (ASspiMRI-c) scores. Radiographs and MRIs were assessed by 2 readers who were blinded to treatment and image time order. Mean scores were used for analyses. Sera were collected from 140 patients at baseline and wk14 for analysis of markers by ELISA and/or using a multiplex platform (Rules Based Medicine). Spearman correlation analyses with Bonferoni p-value adjustment and logistic regression were conducted to assess the relationship between 76 serum biomarker levels and, ASDAS using C-reactive protein (ASDAS), ASspiMRI-a, or MRI-c score at various time points.

Results: Baseline ASDAS showed significant correlations with serum biomarkers for inflammation (IL-6, ICAM-1, haptoglobin, amyloid P) and lipid metabolism (Complement C3). BL IL-6 or TIMP-1 correlated with the reduction of ASspiMRI-a at wk14 in GLM-treated patients (Table). Wk4 change in IL-6 and C3 also showed correlation with change in ASspiMRI-a at wk14. Development of new fatty degeneration in the spine at wk14 correlated with BL biomarkers involved in lipid metabolism (leptin, C3) and tissue remodeling (TIMP-1). Previously described predictors such as insulin, MMP-3, VEGF, or bone resorption markers did not have significant correlations with clinical or imaging outcomes.

Conclusion: This analysis suggests that serum biomarkers IL-6, TIMP-1, and C3 may be linked to a reduction in spinal inflammation in AS patients following GLM treatment. In addition, ICAM-1, haptoglobin and amyloid P correlate with baseline disease activity and may implicate novel roles for these factors in AS-related inflammation.

Prevalence of Subclinical Atherosclerosis in Patients with Spondyloarthritis without Clinically Evident Cardiovascular Disease Using Carotid Intima-Media Thickness. Elena Alonso Blanco-Morales[1], Carmen Bejerano[2], Carlos Fernandez-Lopez[3], Natividad Oreiro[4], Javier De Toro[4], Francisco J. Blanco Garcia[3] and Jose A Pinto-Tasende[3]. [1]INIBIC. Complejo Hospitalario Universitario A Coruña, A Coruña, Spain, [2]INIBIC, Complejo Hospitalario Universitario A Coruña, A Coruña, Spain, [3]Rheumatology Department, Complejo Hospitalario Universitario A Coruña, A Coruña, Spain, [4]Rheumatology Department, A Coruña, Spain.

Background/Purpose: AS and PsA patients without clinically evident cardiovascular disease have a high prevalence of subclinical cardiovascular disease in form of increased carotid intima-media thickness (IMT) and carotid plaques compared to matched controls.

To evaluate subclinical atherosclerosis by determining carotid IMT and the presence of atheromatous plaques in a sample of patients with PsA and AS, and analyze its relationship with genetic, demographic, clinical and analytical characteristics.

Methods: Observational and cross-sectional study of 86 spondyloarthritis patients (48 PsA according CASPAR classification criteria and 38 AS according to the New York modified criteria) were randomly selected from our cohort in 2013. We recorded age and sex of patients, disease duration, joint count, VAS for pain and for global disease activity, BASDAI and BASFI score, ESR, CRP, HLA-B27 and Cw0602, CV risk factors as systolic and diastolic blood pressure, smoking status, glycemia, lipid profile and BMI. IMT (mm) and carotid plaques were measured in the right common carotid artery and the study was performed using high-resolution B-mode ultrasound. Continuous variables were compared using Student's *t*-test or Mann-Whitney U test. Proportions were compared by chi-square test or Fisher's exact test. Correlation between carotid IMT and continuous variables was tested via estimation of Pearson's partial correlation coefficient adjusted by age at the time of the study. Two-sided *P* values less than 0.05 were considered to indicate statistical significance. Statistical analysis was performed with the SPSS 17.0 program. It was considered $p < 0.05$ as significant.

Results: Carotid IMT was 0.66 (0.16) and correlated with age (rho = 0.444, p< 0.0001), abdominal circumference (r = 0.409, p= 0.001) and CRP level (r = 0.496, p= 0.001). Uveitis and dactylitis were associated with higher IMT (0.74 vs 0.62, p= 0.046; 0.84 vs 0.62, p 0.023). Also high blood pressure was associated with higher IMT (0.73 vs 0.59, p= 0.02). Patients with history for hypertension had higher carotid IMT (p 0.013). All the other variables were not significantly associated with IMT. Patients with PsA had slightly greater carotid artery IMT than AS (0.67 vs 0.60, p = 0.076).

Conclusion: In our patients with SAp the carotid intima-media thickness is associated with older age, hypertension, obesity, higher C-reactive protein serum levels, dactylitis and uveitis.

Short-Term Non-Steroidal Anti-Inflammatory Drug (NSAID) Use Induces Subclinical-Kidney-Injury in Spondyloarthritis Patients: Urinary Biomarker Study. Anuj Shukla, Mohit kumar Rai, Narayan Prasad and Vikas Agarwal. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background/Purpose: NSAIDs are the first-line therapy for spondyloarthritis (SpA) patients and are associated with the risk of kidney injury. Long-term NSAID use is known to cause poor urine concentrating abilities. Short-term NSAID induced subclinical-kidney-injury is not well studied. Herein, we studied the effect of short-term NSAID use on kidney injury by measuring serum and urine biomarkers.

Methods: In cross-sectional study, 40 healthy controls with minimal-NSAID-exposure (cohort-A) and 40 SpA patients on regular-NSAIDs for >3 months (cohort-B) were included. In another cohort, 17 SpA-patients with minimal baseline NSAID-exposure (cohort-C) were treated with regular-NSAIDs for 6 weeks. Urine and serum samples were collected at 0, 1 and 6 weeks. In addition, 6 healthy volunteers (cohort-D) were treated with 7 days of daily NSAID. Daily urine and weekly blood samples were collected for 14 days; including 7 days after the drug was stopped. Biomarkers like NGAL, KIM1, cystatin-C and micro-albumin (ELISA) were measured. Creatinine (Jaffe's method) was measured in all samples.

Minimal-NSAID-exposure was defined as nil in last week, <15 tablets in last month, <2 tablets/week in last year or <1000 tablets lifetime exposure. Normal-renal-function was ensured in all subjects as eGFR ≥90ml/min, <1+dipstick proteinuria and inactive urine sediments.

Results: Median age of cohort-A and B was 27 (IQR 26–35) and 30 (IQR 24–38) years respectively with male to female ratio of 3:1. Duration of NSAID use in cohort-B was 7 (IQR 5–12.5) months. There was no significant difference in serum creatinine and eGFR in both cohorts while biomarker levels were raised in cohort-B compared to cohort A (Mann-Whitney test, table).

Median age of cohort-C was 35 (IQR 28–40) years and male to female ratio of 9:8. Urine biomarker levels showed a significant rise on treatment with NSAIDs at 1 week, (Wilcoxon test) cystatin C p=0.01, NGAL p=0.02, KIM1 p=0.08 and micro-albumin p=0.1. There was a further significant rise in urine and serum levels at 6 weeks (Friedman test, table). Cohort-D showed a rise in urine and serum levels of biomarkers at 7 days followed by a fall to baseline in urine levels at 10th day while serum levels showed partial fall at 14th day.

Conclusion: Short-term NSAID use may induce subclinical-kidney-injury represented by rise of urine and serum biomarkers, even in absence of changes in serum creatinine or eGFR. These levels start rising as early as 7 days of NSAID use.

Ankylosing Spondylitis and Non- Radiographic Axial Spondyloarthritis: the Same Syndrome or Different Diseases? Analysis from Esperanza Cohort. Azucena Hernández-Sanz[1], Victoria Navarro-Compán[2], Cristina Fernández-Carballido[3], Carlos Montilla-Morales[4], Juan Mulero[5] and Eugenio De Miguel[6]. [1]H. Virgen de la Salud, Toledo, Spain, [2]University Hospital La

Paz, Madrid, Spain, [3]University General Hospital Elda, Elda (Alicante), Spain, [4]H. de Salamanca, Salamanca, Spain, [5]University Hospital Puerta de Hierro, Majadahonda (Madrid), Spain, [6]Department of Rheumatology, Hospital Universitario La Paz, Madrid, Spain.

Background/Purpose: New ASAS criteria for axial spondyloarthritis (axSpA) have two entrances: the imaging and clinical arm (presence of HLA B27). The imaging arm allows classifying patients as non radiolographic axial spondyloarthritis (nr-axSpA) and ankylosing spondylitis (AS).

The importance of the concept of nr-axSpA or the clinic arm in the classification of SpA is questioned currently, so it is interesting to investigate how homogeneous or different populations are compared to the classical AS.

Prymary objetive was to compare the characteristics of AS and nr-axSpA of recent onset. Secondary one was to compare the characteristics between groups axial SpA diagnosed by clinical and imaging arm.

Methods: Population: Baseline dataset from the ESPeranza cohort (<45 yrs, symptoms duration 3–24 months and with inflammatory back pain -IBP- or asymmetrical arthritis or spinal/joint pain plus ≥1 SpA features).

Inclusión criteria: Patiens who met ASAS criteria for axSpA.

Variables: Demographic, clinical, activity indices (BASDAI and CRP), mobility (BASMI) and physical function (BASFI) were compared.

Statistical analysis: **Results** are presented in mean ± standard deviation for continuous variables and n,(%) for categorical variables.

Results: A total of 775 patients were included in the "ESperanza" program- From these, 291 met ASAS criteria for axSpA: 194 imaging arm (43.8% nr-axSpA and 56.2 % EA), and 97 clinical arm.

Sixty five percent were male with a mean age of 32 ± 7 years and mean disease duration of 13 ± 6.7 months. Males were more frequently observed in patients with AS compared to nr-axSpA group. Only diarrhea and genito-urinary disease were more frequent in the group of nr-axSpA (Table). Mobility was more impaired in the AS group. No significant differences in the activity or other baseline characteristics were observed. Peripheral and genito-urinary disease, arthritis, enthesitis, uveitis, diarrhea, and family history were significantly more frequent in patients in the clinical arm, while physical function was more impaired in patients on image arm.

Conclusion: Patients with nr-axSpA have very similar clinical features to AS patients in the early stages of the disease, except higher frequency of males and mobility limitation in the AS group.

Patients with axial axSpA in the clinical arm presented more often peripheral involvement that the imaging arm, while no significant differences in the presence of psoriasis and inflammatory bowel disease and activity rates.

	Clinical arm n 97 (33%)	Imaging arm n 194(67%)

Profiling Ankylosing Spondylitis Patients Likely to Respond to NSAID Treatment. Mohamed Bedaiwi[1], Arane Thavaneswaran[2], Nigil Haroon[3], Ammepa Anton[4] and Robert D. Inman[5]. [1]clinical and research fellow, Toronto, ON, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, [3]Toronto Western Research Institute, Toronto, ON, [4]University Health Network, Toronto, ON, [5]Department of Medicine, University of Toronto, Toronto, ON.

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease with unpredictable course of progression. Treatment of AS thus should be tailored according to disease manifestation. There is group of patient with ankylosing spondylitis controlled with non-steroidal anti-inflammatory drugs alone, while the other subset may show high disease activity despite conventional treatments with NSAIDS and may require further therapeutic agents. The aim of study is to compare AS patients well controlled with NSAIDS alone with the other group requiring biologic therapy because of NSAID-nonresponsiveness.

Methods: This retrospective study involved data collection from the last clinic visit for 417 patients with a diagnosis of AS based on the modified New York criteria for AS. NSAID-treated patients (n=124) were defined as having a BASDAI<=4 at the last clinic visit while being treated with only NSAIDs, Biological-treated patient (n= 187) had failed to respond to a trial of ≥ NSAIDS. The comparison of NSAID treated (NS-TR) and biologic treated (B-TR) was done in relation to multiple social, clinical and laboratory variables.

Results: NS-TR patients were found to have a lower incidence of smoking (P<0.0009), lower CRP (p=0.01), lower incidence of kidney stones (P= 0.02), increase in hyperlipidemia (P= 0.02) and better spinal mobility (P<0.0001). There were no significant differences in the following variables: gender, age of onset, eye disease, hypertension, diabetes, cardiac disease, uveitis, psoriasis, inflammatory bowel disease.

Conclusion: This study showed that the NSAID-responsive AS patients tend to be non-smokers, with lower baseline CRP, and less impairment in spinal mobility at baseline. Conversely, age, gender, and B27 status which have previously been implicated as markers of severity, did not correlate with NSAID-responsiveness. This analysis begins to provide a profile of AS patients who at baseline are likely to require biologic therapy for their disease.

Table 1. Comparison of NSAID and biological treated patient with AS

Variable	Mean (sd) or Frequency (%) NS-TR N = 124	B-TR N = 187	P-value

How to Classify Spondyloarthritis after a Two Year Follow up? Results from the French Recent onset spondyloarthritis Cohort. Pierre Gazeau[1], Divi Cornec[2], Marie Agnès Timsit[1], Valerie Devauchelle[3], Sandrine Jousse-Joulin[1], Thierry Marhadour[4], Emmanuel Nowak[1], Maxime Dougados[5] and Alain Saraux[6]. [1]CHU Brest, Brest, France, [2]Brest Occidentale University, Brest, France, [3]Brest university medical school, EA 2216, Lab Ex, INSERM, IGO, UBO and CHU de la Cavale Blanche,, Brest, France, [4]CHU de la Cavale Blanche, Brest, France, [5]INSERM (U1153): Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité, Paris, France., Paris, France, [6]CHU Brest and EA 2216, UBO, Brest, France.

Background/Purpose: In early arthritis, after a two years follow up, rheumatologist diagnosis of rheumatoid arthritis agrees well with 2010 ACR/EULAR criteria (Saraux A et al. Arthritis care Arthritis Res (Hoboken). 2013;65:1227–34). Today, we do not have straightforward rules to diagnose spondyloarthritis (SpA) after a two year follow up, and we do not know the gap between rheumatologist diagnosis and SpA defined using all potential methods to classify patients having inflammatory low back pain (IBP).

Methods: We used the nationwide, longitudinal, prospective cohort (DESIR) of patients with IBP suggestive of SpA at baseline. After 2 years, patients were classified based on: imaging (MRI, X-rays), the certainty with which the rheumatologist diagnosed SpA (evaluated on 0–100 visual analogue scales), treatment used (non-steroidal anti-inflammatory drugs [NSAID] and/or TNF-alpha blockers) and classification criteria (any among axial Assessment of SpA international Society [ASAS] criteria, European SpA Study Group [ESSG] and Amor). First, we described clinical, biological and imaging characteristics, the items of all classification criteria and the diagnosis established by the rheumatologists after 2 years. Second, we evaluated the certainty in the diagnosis of SpA at inclusion and after a 2 year follow-up. Third, using ROC curves, we determined the best end point of the diagnosis certainty using the validated classification criteria (AMOR, ESSG, and ASAS) as gold standards. Then, we evaluated agreement between all potential methods to classify patients having IBP based on Cohen's kappa coefficient in the whole group and in the group having a MRI.

Results: On the 708 patients initially included, 548 had information on rheumatologist's certainty after 2 years. Using ROC curves, we found that a certainty of diagnosis ≥ 75% gave the best balance of sensitivity and specificity. This certainty of diagnosis increased with the follow up [357 of 548 (65.1%) patients had a certainty≥75% after a two year follow up versus 265 (48.3%) at inclusion]. Certainty of diagnosis≥75% after a two year follow up was statistically associated with all classification criteria (AMOR p: 0.005; ESSG p: 0.003; ASAS p<0.0001) and the ASAS criteria had the best agreement, although it was low (kappa 0.09, 0.11 and 0.25 for AMOR, ESSG and ASAS, respectively). None of the various other potential classifications items had a better agreement.

Conclusion: Rheumatologist diagnosis of SpA certainty after 2 years does not agree well with the various previously published criteria for SpA.

Fatigue in Ankylosing Spondylitis: A Multivariable Analysis Implicates Inflammation As the Key Determinant of Disability. Mohamed Bedaiwi[1], Arane Thavaneswaran[2], Nigil Haroon[3], Ammepa Anton[4] and Robert D. Inman[5]. [1]clinical and research fellow, Toronto, ON, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, [3]Toronto Western Research Institute, Toronto, ON, [4]University Health Network, Toronto, ON, [5]Toronto Western Hospital, University of Toronto, Toronto, ON.

Background/Purpose: Fatigue is one of the cardinal features of ankylosing spondylitis (AS). The clinical and laboratory correlates of fatigue in AS however are not well defined. In the current study we undertake a systematic analysis of fatigue in a longitudinal observation cohort of AS patients.

Methods: A systematic review of 950 AS patients (671 male and 279 female) followed in a longitudinal clinic which entails regular clinic visits using a standardized protocol. Fatigue was recorded using the Fatigue Severity Scales (FSS). T tests were used to compare continuous variables and Chi-Squared tests for categorical variables. Multivariate analysis was conducted using logistic regression to assess associations between FSS and various clinical features. P-value <0.05 was used to define statistical significance.

Results: In the univariate analysis there were a number of clinical variables showing association with FSS. This was followed by logistic regression analysis. Figure 1 outlines selected covariates based on a p-value<0.05 in univariate models and included in the full model. Stepwise selection was used to determine the variables most associated with (FSS). In the reduced model the clinical domains with the strongest correlation with FSS were morning stiffness, Bath AS Functional Index (BASFI), and Short Form (36) Health Survey (SF36-MCS). For patients with morning stiffness, there is an expected 2.13 increase in the FSS. For every unit increase in the BASFI, there is a 0.37 increase expected in the FSS. For every unit increase in the SF36-MCS, there is a 0.11 decrease in FSS.

Conclusion: Fatigue continues a frequent and sometimes disabling aspect of AS. The strong correlation with stiffness suggests that these two variables may reflect a common underlying process. Since morning stiffness is considered a surrogate indicator of inflammation, fatigue may fall into this conceptual framework as well. The level of disability as measured by BASFI shows stronger correlation with fatigue than with mSASSS suggesting this fatigue may impose greater functional restrictions on patients than structural progression of the disease does. The reversed SF36-MCS correlation with FSS indicates more vitality, bodily pain, emotional, social and mental health functionality impairment in fatigued AS patient.

TABLE: Linear Regression Models to Assess Variables associated with Fatigue (FSS)

	Full Model		Reduced Model	
Covariate	Estimate (SE)	p-value	Estimate (SE)	p-value

Do You Assess Gastro-Intestinal Auto-Antibodies and Symptoms in Patients with Spondyloarthritis?. Consuelo Romero Sanchez[1], Wilson Bautista-Molano[1], Viviana Parra-Izquierdo[2], Carlos Martínez[3], Ferney Garcia[3], Juliette De Avila[4], Haroldo Juliao[5], Juan Manuel Bello[1], John Londoño[6] and Rafael Valle-Oñate[1]. [1]Faculty of Medicine, Universidad Militar Nueva Granada, Bogotá, Colombia, [2]Spondyloarthritis Group. Rheumatology Department. Hospital Militar Central/Universidad de La Sabana. Bogotá. Colombia, Bogota, Colombia, [3]Coloproctology Deparment, Hospital Militar Central, Bogotá, Colombia, [4]UIBO Institute (Oral Basic Research Unit) School of Dentistry Universidad El Bosque, Bogotá, Colombia, [5]Gastroenterology Deparment, Hospital Militar Central, Bogotá, Colombia, [6]Spondyloarthritis Group. Rheumatology Department. Hospital Militar Central/Universidad de La Sabana. Bogotá. Colombia, Bogotá, Colombia.

Background/Purpose: Spondyloarthritis (SpA) are a group of chronic inflammatory rheumatic diseases. Extra-articular manifestations affect approximately 30% of patients with SpA, and gastrointestinal manifestations

(GI) represents about 5 to 10%. The relationship between gut and joint inflammation suggest that there is an increase in intestinal permeability and abnormal levels of intestinal bacteria that stimulate pathologic immune responses. The persistence of joint disease activity is primarily associated with intestinal inflammation. Therefore, the aim of this study is to investigate the association between gastrointestinal symptoms, disease activity of SpA and the presence of auto-antibodies including patients with inflammatory bowel disease (IBD).

Methods: A cross sectional study was designed, including 103 patients with SpA fulfilling ESSG classification criteria and 117 healthy subjects (HS). Twenty nine patients had a diagnosis and clinical activity compatible with IBD as confirmed by histologic examination.

Anti-*Saccharomyces cerevisiae* IgG/IgA (ASCA), 6 antigen associated with anti polymorphonuclear neutrophil (ANCA), anti-transglutaminase (tTG) IgG/IgA, anti-deaminated gliadin peptide (DGP) IgG/IgA auto-antibodies, ANAS and IgA were measured in all patients by ELISA technique. A specific questionary was applied asking for GI symptoms in the SpA and IBD group. Descriptive epidemiology was analized and association between clinical manifestations and auto-antibodies were evaluated using Chi square test and Mann Whitney U-Test as appropriate.

Results: Mean age in SpA patients was 42.2 years (SD 15.5) with a predominance of uSpA subtype (59.8 %). BASFI >4 was reported in 60.6% and BASDAI>4 in 67.7%. Respect to treatment, 49 % of patients were receiving anti-TNF therapy. HLA-B27 was positive in 39%.

ASCA IgG/IgA were positive in 28.2% of SpA patients and 75.8% of them were IgG isotype. ANCA was present in 8.8 % (six antigens evaluated), celiac auto-antibodies (1%) and ANAS (49.5%). In HS, 2.6% were ASCAS positive (50% of these were IgA subtype) and 6.8% were ANCAS positive. There was a significant difference in the frequency of autoantibodies IgG/IgA ASCAS, p-ANCAS and ANAS between SpA and HS (p=<0.001), and SpA and IBD (p=<0.001). Significant association was found between BASDAI>4 and the presence of abdominal pain (p=0,003), diarrhea (p=0.017), abdominal inflammation (p=<0.001), discomfort (p=0.004) and total IgA levels (p=0.005); as well as between abdominal inflammation and BASFI > 4 (p=0.028).

Additionally, significant difference was found in the presence of abdominal pain between SpA (54.4%) and IBD (27.5%) patients (p=0.012). Both groups (SpA and IBD) had similar frequency of mucus (30% vs 31%).

Conclusion: The presence of ASCAS IgG/IgA, p-ANCAS, ANAS, IgA and the reporting of GI symptoms, are associated with higher disease activity in SpA. There are differences in the presence of GI manifestations according to SpA subtypes, but not differences between IBD and SpA regarding the presence of mucus. It may suggest that subclinical IBD should be actively screened in Colombian SpA patients probably due to environmental conditions.

Treating Axial-Spa to Target: Prevalence of *Ankylosing Spondylitis Disease Activity Score* (ASDAS) Inactive Disease in a Cohort of Patients Treated with Anti-TNFα Agents.

Sara Monti[1], Silvia Breda[2], Francesca De Nard[2], Vittorio Grosso[3], Monica Todoerti[2], Carlomaurizio Montecucco[4] and Roberto Caporali[4]. [1]University of Pavia, IRCCS Foundation Policlinico S. Matteo, Pavia, Italy, [2]University of Pavia, IRCCS Policlinico S. Matteo Foundation, Pavia, Italy, [3]University of Pavia, Foundation IRCCS Policlinico S. Matteo, Pavia, Italy, [4]Rheumatology and Translational Immunology Research Laboratories (LaRIT), Division of Rheumatology, IRCCS Policlinico S.Matteo Foundation/University of Pavia, Pavia, Italy.

Background/Purpose: Treating disease to target is emerging as the recommended strategy also in the management of axial-SpA (axSpA) (1). Reaching remission, defined as inactive disease (ID), constitutes the ideal target in clinical practice. Using the new composite disease activity index-"*Ankylosing Spondylitis Disease Activity Score*" (ASDAS) (2) we assessed the prevalence of ID in a cohort of patients with axSpA treated with anti-TNFα agents. Potential patient- and disease-related factors influencing the status of ID were analyzed.

Methods: The study population was selected from outpatients with axSpA treated with anti-TNFα attending our Rheumatology Department. Disease activity was evaluated in terms of BASDI and ASDAS-CRP during the latest follow up visit. ID was defined as ASDAS-CRP< 1.3 (2).Statistical analysis was performed with STATA.

Results: General characteristics of the 53 enrolled patients are presented in Table 1. A BASDAI < 4 was recorded for 70% of the study population, while only 31% showed ID according to ASDAS-CRP (Figure 1). As expected, a strict correlation between the two disease activity indices was confirmed (Spearman's r = 0.76; p < 0.0001). Multivariate logistic regression demonstrated an inverse correlation of ID status with NSAIDs intake (OR 0.15; CI95% 0.45–0.54). ID achievement resulted independent from sex, disease duration, BASMI, DMARDs, type of anti-TNFα agent.

Conclusion: In our cohort of axSpA treated with biological agents, only one third achieved ID according to ASDAS-CRP. Even with the limitations of the small sample size, ID does not correlate with the principle patient- and disease-related features but is inversely associated with NSAIDs intake. Further studies are needed to optimize the targeted treatment of axSpA and to identify potential predictive factors of ID.

The Role of IL-20 in the Pathogenesis of Ankylosing Spondylitis with Peripheral Joint Involvement.

Göksal Keskin[1], Baris Mavi[2], Lale Ozisik[3], Rahsan Ilikci[4] and Mehmet Yildiz[2]. [1]Medical School of Ankara, Ankara, Turkey, [2]Diskapi Training and Research Hospital, Ankara, Turkey, [3]MD, Ankara, Turkey, [4]BC, Ankara, Turkey.

Background/Purpose: The interleukin-20 (IL-20) is a pro-inflammatory cytokine of the IL-10 family and sequence amino acid is very similar. It has been reported to be involved in the pathogenesis of several autoimmune diseases, but pathophysiological importance is poorly understood. TNF alpha plays an important role in AS patients with axial and peripheral joint involvement. It has been reported that TNF alpha induce IL-20 in macrophage and synovial cells. For this reason, we investigated serum IL-20 levels in AS patients with axial and peripheral joint involvement who had not received anti- TNF treatment.

Methods: 63 patients with AS (11 female, 52 male) and 17 healthy controls (2 female, 15 male; mean age 26.5 ± 6.9 years) were enrolled in this study. Thirty-eight of the AS patients were axial involvement (mean age; 25,9 ± 7.2 years, median disease duration 7 years) and the other 24 patients were peripheral joint involvement (mean age; 27.3 ± 6.9 years, median disease duration; 9 years). Serum IL-20 levels were determined by ELISA.

Results: The median serum IL-20 levels were 55,2 pg/ml in healthy controls, 308.5 pg/ml in the patients with peripheral joint involvement and 109.3 pg/ml in the patients with axial involvement. Serum IL-20 levels in patients with AS were significantly higher than in healthy controls ($p<0.001$). Serum IL-20 levels were significantly high in the patients with peripheral joint involvement compared with in the patients with axial involvement ($p<0.001$). in the patients with peripheral joint involvement, there are statistically significant correlation between serum IL-20 and serum CRP and ESR ($r=0.645$, $p<0.001$, and $r=0.588$, $p<0.001$ respectively). In the patients with axial involvement, it was not correlated with CRP and ESR ($r=0.262$, $p=0.298$ and $r=0.292$, $p=0.355$ respectively).

Conclusion: Serum IL-20 levels are high in the AS patients with peripheral joint involvement and, correlated with CRP and ESR. So, it may be involved in pathogenesis of the disease.

Short Term Efficacy of Tumor Necrosis Factor Inhibitors in Patients with non–radiographic Axial Spondylarthritis and ankylosing Spondylitis; Results from Turkbio Registry.

Pinar Cetin[1], Umut Kalyoncu[2], Bunyamin Kisacik[3], Ismail Sari[1], Dilek Solmaz[4], Omer Karadag[2], Ahmet Mesut Onat[3], Gezmis Kimyon[3], Levent Kilic[5], Fatos Onen[1], Sedat Kiraz[2], Merih Birlik[1], Ihsan Ertenli[2], Omer Nuri Pamuk[6] and Nurullah Akkoc[1]. [1]Dokuz Eylul University School of Medicine, Izmir, Turkey, [2]Hacettepe University School of Medicine, Ankara, Turkey, [3]Gaziantep University School of Medicine, Gaziantep, Turkey, [4]Namik Kemal University School of Medicine, Tekirdag, Turkey, [5]HacettepeUniversity School of Medicine, Ankara, Turkey, [6]Trakya University School of Medicine, Edirne, Turkey.

Background/Purpose: Axial spondylarthritis (AxSpA) has been proposed as an umbrella term for ankylosing spondylitis (AS) and non-radiographic (nr) AxSpA). This new concept makes diagnosis of AS possible at an early stage in the absence of radiographic sacroiliitis. Disease burden in AxSpA patients with or without radiographic sacroiliitis have been shown to be similar in different cohorts, which suggest that both diseases should be treated with the same approach. Recent randomized clinical trials showed that TNF inhibitors (TNFi) are effective also in treating signs and symptoms of nr-AxSpA. However, the efficacy of anti-TNF agents in patients with nr-AxSpA remains to be shown in daily rheumatology practice. The objective of this study is to compare the efficacy of TNF inhibitors in patients with AS and nr-AXSpA in daily clinical setting.

Methods: A total of 326 patients with AxSpA (195 M; 39.8 ±10.6) from four centers, who contribute to TURKBIO, a biological database in Turkey, and who could provide detailed data on imaging for patients with AxSpA, were included in this study. Of these patients 208 had AS according to the *modified New York criteria* and 118 *patients had nr-ax SPA. (20% fulfilling the clinical arm, 80% fulfilling the imaging arm)*

Results: Baseline demographics and clinical characteristics are summarized in the table-1. Patients with nr-AxSpA were significantly younger, had a shorter disease duration and had a higher female predominance than patients with AS. After three months of treatment with TNF inhibitors, mean BASDAI and ASDAS decreased significantly (Table 1). The response rates for minimal clinical improvement (ΔASDAS ≥1.1) and major clinical improvement (ΔASDAS ≥2) were similar in patients with nr-AxSpA (66% vs 72%) and those with AS (43.8% vs 39.1%). Similarly good response rates were observed for BASDAI 50 in the two groups; 56.8 % and 58.5%, respectively.

Conclusion: The results of our study suggest that TNFi, which have been clearly shown to be effective in treating signs and symptoms of AS, seem to be equally effective in the treatment of nr-AxSPA.

Table 1. Demographics and clinical characteristics of the AxSpA and AS patients.

	Non-radiographic axial spondylarthritis (n=118)	Ankylosing spondylitis (n:208)	p value

Different Performance of the Major Disease Activity Measures ASDAS and Basdai in Patients with Axial Spondyloarthritis Treated with Non-Steroidal Anti-Inflammatory Agents – Results from a Prospective Study.

Xenofon Baraliakos[1], Uta Kiltz[1], Frank Heldmann[1], Heiner Appel[2], Friedrich Dybowski[3], Manfred Igelmann[4], Ludwig Kalthoff[5], Dietmar Krause[6], Hans-Jürgen Menne[7], Ertan Saracbasi[8], Elmar Schmitz-Bortz[9] and Jürgen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Rheumatology and Nephrology Practice, Hamm, Germany, [3]Rheumatology Practice, Herne, Germany, [4]Rheumatology Practice, Bochum, Germany, [5]Rheumatology practice, Herne, Germany, [6]Rheumatology practice, Gladbeck, Germany, [7]Rheumatology practice, Dortmund, Germany, [8]Rheumatology practice, Oberhausen, Germany, [9]Rheumatology practice, Hattingen, Germany.

Background/Purpose: The ASAS/EULAR recommendations for the management of patients (pts) with axial spondyloarthritis (axSpA) have established non-steroidal anti-inflammatory agents (NSAIDs) as first choice of medical treatment in this condition. However, the outcome of this strategy has not been prospectively tested to date. Standardized measures (BASDAI, ASDAS) are routinely used to assess disease activity in pts with axSpA. Both measures are composite scores but only the ASDAS also includes CRP values as an objective measure. However, a direct comparison between ASDAS and BASDAI in axSpA pts treated with NSAIDs in a prospective study has not been performed to date. We prospectively compared the performance of BASDAI and ASDAS to identify candidates for anti-TNF therapy among patients with axSpA with high disease activity who were treated with full-dose NSAIDs over 4 weeks, as suggested in the ASAS treatment recommendations.

Methods: Consecutive patients (pts) with axSpA (both n=50 for nr-axSpA and AS, respectively) were included in a prospective study if their BASDAI level was ≥4, and if they had not received the maximally approved dose of NSAIDs nor anti-TNF agents to date. After inclusion into the study the maximal dose of NSAIDs was administered over 1wk and the dose was then adapted in case of BASDAI<4. In case of BASDAI ≥4 of in case of NSAID intolerance, the NSAID was changed and the pt was treated for another 3 wk at the maximal dose. Clinical and laboratory parameters and dosage of drugs were assessed by using the ASAS NSAID-index. Data were collected before (BL) and after 1 and 4 wk of treatment.

Results: The baseline (BL) characteristics of AS and nr-axSpA patients were similar, with exception in the mean CRP levels (nr-axSpA: 0.6±0.9 vs. AS: 1.2±1.1, $p<0.001$). Despite all patients having BASDAI ≥4 prior to treatment, an ASDAS >2.1 was found in only 74% and 76% of pts with AS and nr-axSpA, respectively. There was a significant overall decrease at both timepoints in both ASDAS-CRP (BL: 2.5±0.6, 1wk: 1.9±0.8, 4wk: 1.6±0.8) and BASDAI (BL: 5.8±1.3 1wk: 4.1±2.1 4wk: 2.1±3.1). After 4

weeks of standardized treatment with NSAIDs, there were 44% of all axSpA pts with a BASDAI ≥4 (AS 42% und % nr-axSpA 46%), while 33% of all axSpA pts (AS 32% and nr-axSpA 34%) had an ASDAS > 2.1. Overall, the two scores were in agreement in 81%. In 15% of pts, the BASDAI score would have possibly led to treatment with TNF blockers – despite an ASDAS <2.1, and, on the other hand, in 4% of cases the ASDAS would have initiated anti-TNF treatment but the not the BASDAI. In the univariate logistic regression analysis both, ASDAS (OR: 3.6, p=0.002) and BASDAI (OR: 1.8, p=0.001) predicted the eligibility for anti-TNF therapy after 4wk of NSAIDs at BL.

Conclusion: These data challenge the concept of only using the BASDAI cut-off ≥4 for the treatment decisions of initiation of TNF-blocker therapy. The question on whether BASDAI or ASDAS should be used as the appropriate cut-off for such treatment needs to also include the comparison of the subjective information on disease activity with CRP and MRI data and by assessing the predictive value of the response to NSAIDs for the response to TNF blockers in future studies.

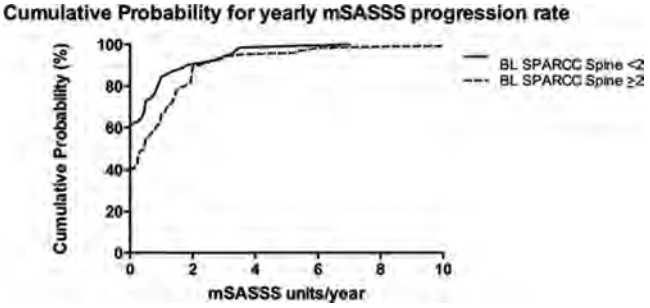
Positive Spine MRI for Inflammation Predicts Radiographic Progression in Patients with Ankylosing Spondylitis. WP Maksymowych[1], S Wichuk[1], Z Zhao[2], P Chiowchanwisawakit[3], RG Lambert[1] and Sj Pedersen[4]. [1]University of Alberta, Edmonton, AB, [2]PLA General Hospital, Beijing, China, [3]Mahidol University, Bangkok, Thailand, [4]Copenhagen Center for Arthritis Research, Copenhagen, Denmark.

Background/Purpose: Inflammation at vertebral corners on MRI has been shown to predict development of syndesmophytes in patients with AS. However, it is unclear at a patient level whether a positive spine MRI for inflammation identifies patients at higher risk for radiographic progression and whether this is also associated with the degree of spinal inflammation. We used the SPARCC MRI spine score to assess whether the proposed cut-off of ≥2 for positive spine MRI and the absolute score are predictive of radiographic progression.

Methods: Spinal inflammation was scored blinded to time point (baseline, 2 years) using the SPARCC spine score by two readers and an adjudicator using pre-specified rules for adjudication. MRI scans were assessed from a prospective cohort of 195 AS patients (mean age 40.3 years, mean symptom duration 16.6 years, 59% on anti-TNF) followed for mean 2.3 years. Two readers and an adjudicator independently scored pairs of radiographs (baseline, 2 years) from the same patients using the mSASSS. Radiographic progression was compared in patients with and without positive spine MRI (SPARCC ≥2 or <2) and the degree of spinal inflammation at baseline (absolute SPARCC score) was compared in patients with and without radiographic progression (mSASSS >0 or =0) using Mann-Whitney and cumulative probability. Multivariate regression analyses included variables significant in univariate analyses (age, sex, symptom duration, CRP, baseline mSASSS) and treatment.

Results: Radiographic progression was significantly greater in those with positive spine MRI (p=0.004) (figure), and especially in patients who only received non-biologic therapy (p=0.006). Baseline SPARCC spine inflammation scores were significantly higher in those who developed radiographic progression compared to those without (14.5 vs 8.7, p=0.002). Positive spine MRI and the degree of spinal inflammation score were both significantly associated with radiographic progression in multivariate analysis (β=0.26 (p=0.019) and β=0.006 (p=0.036), respectively).



Conclusion: Both a positive spine MRI for inflammation and the degree of spinal inflammation are significantly associated with radiographic progression in patients with AS.

Reliability of Electronic Patient Self-Assessment of Swollen and Tender Joints in Psoriatic Arthritis: A Comparison Study with B-Mode Ultrasonography, Physician and Nurse Assessments. Agnes Szentpetery[1], Muhammad Haroon[2], Eileen O'Flynn[1], Phil Gallagher[1], Shafeeq Alraqi[1] and Oliver FitzGerald[1]. [1]St. Vincent's University Hospital, Dublin, Ireland, [2]Cork University Hospital, Cork, Ireland.

Background/Purpose: 68 tender (TJC) and 66 swollen joint counts (SJC) are recommended for disease activity assessment in psoriatic arthritis (PsA). However there are time constraints and these counts may not be performed. It has been shown in rheumatoid arthritis that patient's self-reported joint counts correlate well with functional disability, pain and global disease severity. Information concerning patients' self-assessed joint counts however is limited in PsA.

The aim of this study was to evaluate the reliability of patient self-assessed joint counts versus joint counts obtained by a physician, a nurse and B-mode ultrasonography (US) in PsA.

Methods: PsA patients fulfilling the CASPAR criteria were recruited. Following a training session on the detection of tender and swollen joints by a nurse, each patient assessed their 68 joints using an electronic digital mannequin on touchscreen. A joint examination by a different nurse and a rheumatologist, both blinded to the patients' clinical data was completed. US evaluation was performed by a further consultant rheumatologist on 34 joints assessing wrists, MCPs and PIPs, ankles and MTPs, and all extensor/flexor tendons of the fingers and toes. Presence of joint effusion, synovial proliferation and tenosynovitis on grayscale (GS); and synovitis/tenosynovitis on power Doppler (PD) signal were evaluated.

Results: 50 patients (33 female and 17 male) were enrolled to the study with a mean age of 50 (±13.7) years. Patients mean GVAS was 47 (±24) mm. Focusing on the 34 joints also assessed by US, mean TJC assessed by the patients, physician and nurse was 9 (±8), 7(±7) and 7(±7), mean SJC was 4 (±6), 1 (±2) and 3 (±3) respectively. Mean number of affected (swollen or tender) joints as per patient, physician, nurse and US evaluation was 10 (±8), 7 (±7), 8 (±7) and 6 (±4.5), respectively.

Patient and nurse-assessed SJC was significantly higher than physician-counts (p=0.0005; p=0.01, respectively). Similarly, patient and nurse-assessed SJC was significantly higher compared to physician-counts when using 28, 44 or 68 joint counts.

Patients scored their number of affected joints significantly higher than physicians irrespective of using 28, 34, 44 or 68 joint counts. The number of affected joints was higher as evaluated by patients compared to US (p=0.01).

Joint effusion was detected by US in 74%, synovitis in 78% on GS and 68% on PD and 30% of the patients had tenosynovitis.

TJC did not correlate significantly with any of the US measurements irrespective of the assessors. Patients SJC significantly correlated with US-assessed joint effusion, and with synovitis (GS and PD). Physician and nurse-reported SJC correlated with US-derived synovitis scores. The number of affected joints as assessed by patients and physician correlated with the US measurements (r=0.28, p=0.04; r=0.29, p=0.04; respectively).

Conclusion: Patients scored their SJC and number of affected joints higher than physicians and US measurements. Patient-reported SJC correlated with both effusion and synovitis as detected by US suggesting that patients' self-evaluated SJC may be valid in routine clinical practice for monitoring disease activity in PsA.

Preliminary Assessment of a Multi-Biomarker Disease Activity Test for Axial Spondyloarthritis. WP Maksymowych[1], Stephanie Wichuk[1], P. Scott Eastman[2] and Eric H. Sasso[3]. [1]University of Alberta, Edmonton, AB, [2]Crescendo Bioscience, Inc., South San Francisco, CA, [3]Crescendo Bioscience Inc., South San Francisco, CA.

Background/Purpose: There has been limited validation of soluble biomarker measures of disease activity in patients with axial spondyloarthritis (SpA). C-reactive protein (CRP) is most commonly used in clinical practice but sensitivity in ankylosing spondylitis AS is only 40–50%. The Ankylosing Spondylitis Disease Activity score (ASDAS) has been proposed as a treat-to-target outcome measure for effective suppression of disease activity in patients with SpA. BASDAI has also been used but does not incorporate objective measures of disease activity. We have performed an exploratory study of the association between a multi-biomarker disease activity (MBDA) score, which measures 12 serum biomarkers and has been validated in RA, and clinically-based measures of disease activity in patients with axial SpA.

Methods: Disease activity measures based on erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), ASDAS, and BASDAI were analyzed for 40 patients with axial SpA who met modified New York criteria from a systematic, prospective follow-up cohort. The MBDA score was measured in serum samples and is based on the following 12 biomarkers: vascular cell adhesion molecule 1, epidermal growth factor, vascular endothelial growth factor A, interleukin 6, TNF receptor I, matrix metalloproteinases 1 and 3, bone glycoprotein 39 (YKL-40), leptin, resistin, serum amyloid A and CRP. These biomarkers were measured by electrochemiluminescence-based multiplexed immunoassays on the Meso Scale Discovery Multi-Array platform. The measured levels for each of the 12 biomarkers were weighted and combined using a formula validated in RA to derive the MBDA score (Vectra®DA score), which ranges from 1 to 100. Correlations between disease activity measures used Pearson correlation coefficient. Group differences were assessed using unpaired t-tests. We also determined to what degree biomarker scores reflected low and high disease activity cut-offs for the ASDAS (<1.3, >3.5) and the BASDAI (<4, ≥ 4).

Results: Patients were of mean (SD) age, 43 (11) years; number (%) males (%), 26 (65); mean (SD) disease duration, 19 (10) years; number (%) B27+, 30 (75); mean (SD) ESR, 24 (22) mm/h; mean (SD) CRP, 19 (19) mg/L; mean (SD) BASDAI, 4.2 (2.5); mean (SD) ASDAS-CRP, 2.9 (1.4); mean (SD) ASDAS-ESR, 2.7 (1.2). The MBDA score correlated significantly with the ASDAS-ESR ($r=0.63$), ASDAS-CRP ($r=0.68$) and BASDAI ($r=0.30$). The modified MBDA score calculated without CRP correlated significantly with the 12-biomarker MBDA score, which includes CRP ($r=0.98$), ASDAS-ESR ($r=0.58$), ASDAS-CRP ($r=0.63$) and BASDAI ($r=0.26$). Significant differences were observed in MBDA scores between patients with ASDAS-CRP >3.5 versus those with ASDAS <1.3 (57 vs. 25, $p=0.002$) and patients with BASDAI ≥ 4 versus BASDAI < 4 (51 vs. 37, $p=0.01$). Several of the MBDA biomarkers, including CRP, correlated strongly with the clinical composite measures. For ASDAS-CRP, serum concentrations of CRP, SAA, IL-6, TNF-R1, and YKL-40 correlated at $r > 0.5$ (range $0.51-0.71$).

Conclusion: The MBDA score was associated with available measures of clinical disease activity in patients with axial SpA and correlated most strongly with the ASDAS.

Comparison of Characteristics of Ankylosing Spondylitis in Association with Familial Mediterranean Fever with Those of Typical Ankylosing Spondylitis. Dilek Solmaz[1], Servet Akar[2], Bunyamin Kisacik[3], Sule Apras[4], Soner Senel[5], Ahmet Mesut Onat[3], Timucin Kasifoglu[6], Kenan Aksu[7], Ismail Sari[8], Mehmet Akif Ozturk[9], Mehmet Sayarlioglu[10], Ali Akdogan[4], Pinar Cetin[8] and Nurullah Akkoc[8]. [1]Namik Kemal University School of Medicine, Tekirdag, Turkey, [2]Izmir Katip Celebi University School of Medicine, Izmir, Turkey, [3]Gaziantep University School of Medicine, Gaziantep, Turkey, [4]HacettepeUniversity School of Medicine, Ankara, Turkey, [5]Kayseri Erciyes University School of Medicine, Kayseri, Turkey, [6]Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey, [7]Ege University School of Medicine, Izmir, Turkey, [8]Dokuz Eylul University School of Medicine, Izmir, Turkey, [9]GaziUniversity School of Medicine, Ankara, Turkey, [10]KahramanmarasSutçü ImamUniversity School of Medicine, Kahramanmaras, Turkey.

Background/Purpose: Several case reports and a few published studies suggest a link between Familial Mediterranean Fever (FMF) and ankylosing spondylitis (AS). There is very limited data on the clinical features of AS that develops in patients with FMF. The aim of this study is to compare the demographic and clinical features of patients with AS in association with FMF to patients with AS alone.

Methods: 73 patients with AS in coexistence with FMF (AS-FMF) who have been followed at 8 different hospitals were compared to 81 consecutive patients with AS alone from the same centers, in regard with demographic and clinical features. All of the patients fulfilled the modified New York criteria for AS and the patients with FMF additionally met the Livneh criteria for FMF. Patients' demographic and clinical data including latest disease activity (BASDAI) and functional status (BASFI) were extracted from patients' charts; MEFV genotypes, HLA B27 status and C reactive protein levels and radiographic results were also recorded if available. The independent t test was used to compare differences in continuous data. Comparisons of categorical data between groups were tested using the chi-square test.

Results: Patients in the AS-FMF group were younger and had a shorter disease duration. Gender distribution and age of onset of AS were similar in both groups; but diagnostic delay was longer and family history (for SpA) was reported more frequently in the AS group. Peripheral arthritis and heel enthesitis were more prevalent among AS-FMF patients, whereas a higher proportion of patients in the AS group had HLA-B27 and had radiographic evidence of spinal involvement. BASDAI and BASFI and the other spondyloarthritis related features were not different between the two groups. Demographic and clinical features of the patient groups are summarized in the Table below. M694V allelic variation was detected in 78.7% of the patients who had both AS and FMF.

Conclusion: Clinical characteristics of AS in association with FMF may show some differences from typical AS, such as less spinal involvement. However, this finding may also be, at least partially, explained by shorter disease duration in this group of patients. Relatively higher prevalence of M694V variant among patients who have both FMF and AS, than those reported in the historic FMF cohorts; as well as the lower prevalence of HLA-B27 in this group than those previously reported in Turkish AS patients suggest that such genetic differences may be accounted for some of the differences between the patients with AS alone and those with AS in association with FMF.

Table. Demographics, and clinical features of the patient groups

Features	AS (n:81)	FMF-AS (n:73)	P
Age, mean ± SD	45 ± 12.4	37 ± 11.9	**<0.001**

No Evidence of Accelerated Atheromatosis, Increased Arterial Stiffness or Hypertrophy in Ankylosing Spondylitis: A Systematic Case-Control Study. Aikaterini I. Arida[1], Maria Konsta[1], Alexios Iliopoulos[2], Maria Tektonidou[3], George Konstantonis[1], George D. Kitas[4], Athanasios D. Protogerou[1] and Petros P. Sfikakis[1]. [1]First Department of Propedeutic Internal Medicine, Laikon Hospital, Athens University Medical School, Athens, Greece, [2]Department of Rheumatology, Veterans Administration Hospital, Athens, Greece, [3]First Department of Internal Medicine, Laikon Hospital, Athens University Medical School, Athens, Greece, [4]The Dudley Group of Hospitals NHS Foundation Trust, Dudley, and Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom.

Background/Purpose: Chronic inflammatory arthritis is associated with increased cardiovascular disease (CVD) risk. The mechanisms behind this link include chronic inflammation, comorbidities and disease-related drugs. CV risk management according to local guidelines with aggressive suppression of inflammation for patients with RA, AS and PsA has been recommended. However, in contrast to RA where the bulk of supporting evidence exists, fewer studies have addressed CVD risk in AS. Moreover, the beneficial impact of anti-TNF agents, which are increasingly used in AS, has been extensively reported biasing somehow the link between AS *per se* and CVD risk. We aimed to compare subclinical atherosclerosis burden between AS patients to healthy controls and patients with RA.

Methods: We examined 81 consecutive non-diabetic AS patients free of clinical CVD (age 46.8±13.3, 85% men, disease duration 10 years (2–24), BASDAI 1.4 (0.4–3.2), BASFI 2.0 (0.95–2.85)). Current smokers were 62% of patients, 16% had dyslipidemia and 31% had hypertension, whereas 62% were receiving anti-TNF treatment. A subgroup of 68 AS patients could be exactly matched 1:1 with healthy controls for age, gender, smoking, dyslipidemia and hypertension. We also matched 14 AS patients with more than 10 years of disease duration 1:1 to non-diabetic RA patients, for age, gender and disease duration. Finally, we identified 24 of the 31 anti-TNF treatment-naïve patients whom we were able to match 1:1 for age and gender, smoking dyslipidemia and hypertension with 24 healthy controls. We evaluated subclinical atheromatosis in aortic and femoral arterial beds (presence of plaques), arterial hypertrophy (intimal-medial thickness adjacent to plaques when present; cross sectional area), and arterial carotid/aortic stiffness (by ultrasound and pulse wave velocity).

Results: Fewer patients with AS than controls had plaques (n=24 vs n=32, respectively, p=0.163). This observation was extended to the subgroup of 35 AS patients with more than 10 years of disease duration (n=14 vs n=22, respectively, p=0.056). Even when taking into consideration anti-TNF-naïve patients, there were no differences compared to controls. Neither BASDAI nor BASFI scores were found to be associated with the presence of plaques. Finally, and despite the small number of matched patients, presence and multiple localization of plaques were more prevalent in RA than in AS patients with more than 10 years disease duration (p=0.053 and 0.045, respectively). Notably, all indices of arterial hypertrophy and arterial carotid/aortic stiffness were comparable between AS patients and their matched controls.

Conclusion: In this group of relatively young Greek patients, AS (even long-standing disease) – in contrast to RA - does not associate with accelerated atheromatosis compared with very closely matched healthy controls. The differential CVD risk between AS and RA requires further investigation as it may have significant clinical implications in terms of prevention strategies.

Impact of Ustekinumab on Active Inflammation and Post-Inflammatory Structural Changes As Detected By Magnetic Resonance Imaging in Patients with Active Ankylosing Spondylitis: Results of a 28-Week, Prospective, Open-Label, Proof-of-Concept Study. Denis Poddubnyy[1], Kay-Geert Hermann[1], Johanna Callhoff[2], Joachim Listing[2] and Joachim Sieper[1]. [1]Charité Universitätsmedizin Berlin, Berlin, Germany, [2]German Rheumatism Research Center, Berlin, Germany.

Background/Purpose: Ustekinumab – a fully human monoclonal antibody against interleukins 12 and 23 – has been shown to be effective in reduction of symptoms of active ankylosing spondylitis (AS) in a proof-of-concept study (TOPAS) [1]. The purpose of the current work was to investigate the impact of ustekinumab on active inflammation and post-inflammatory structural changes in the sacroiliac joints (SIJ) and in the spine as detected by magnetic resonance imaging (MRI) in the TOPAS study.

Methods: In the TOPAS study, ustekinumab in a dose of 90 mg was administered subcutaneously at baseline, week 4 and week 16 in 20 patients with active AS (BASDAI score of ≥ 4 at screening) despite treatment with non-steroidal anti-inflammatory drugs. MRI of the SIJ and of the spine was performed at baseline and at week 24. Images were scored according to the Berlin scoring system for active inflammation and for chronic changes, including a detailed fatty degeneration score for SIJ, independently by two trained readers in a concealed and randomly selected order, blinded for all clinical data.

Results: Complete MRI sets (baseline and follow-up) were available in 17 patients (13 ASAS40 responders and 4 non-responders; in 3 ASAS40 non-responders no follow-up MRIs were available). There was a significant reduction of active inflammation on MRI at week 24 as compared to baseline both in the SIJ (osteitis change score -2.2±3.8 corresponding to 41% reduction) and in the spine (osteitis change score -1.2±2.3 corresponding to 31% reduction) – table. Reduction of active inflammation after 24 weeks was more prominent and statistically significant in patients with clinical response (ASAS40): osteitis change score in the SIJ was -3.1±3.8 in responders as compared to +0.6±1.3 in non-responders, p=0.015; similarly, osteitis change score in the spine was -1.9±1.9 in responders as compared to +1.0±2.4 in non-responders, p=0.023. Notably, clinical response (ASAS40) to ustekinumab was associated with higher level of inflammation at baseline in the SIJ (osteitis score 6.7±4.9 in responders vs. 2.0±1.7 in non-responders, p=0.030), and in the spine (4.9±3.6 in responders vs. 3.6±4.1 in non-responders, p=0.2).

There were no substantial changes in the scores for post-inflammatory lesions including fatty lesions in the entire group – table. However, the SIJ fatty lesion score increased significantly in patients with improvement of SIJ osteitis score by at least one point at week 24 (n=11): +0.8±1.1 vs.-0.4±0.8 in patients without osteitis improvements, p=0.022.

Conclusion: Ustekinumab effectively reduced active inflammation in the axial skeleton as detected by MRI in patients with AS after 24 weeks of treatment with a clear correlation between clinical and MRI responses. Higher level of active inflammation at baseline was associated with good clinical response.

ACR/ARHP Poster Session C

Systemic Lupus Erythematosus - Clinical Aspects and Treatment: Epidemiology, Women's Health, Cardiovascular and Central Nervous System

Tuesday, November 18, 2014, 8:30 AM–4:00PM

2619

Low Socioeconomic Status (SES) As Measured By Education Is (not) Associated with Worse Outcome in SLE: Data from the 1000 Canadian Faces of Lupus. Angela George[1], Christine Peschken[2], Earl Silverman[3], Christian A. Pineau[4], C Douglas Smith[5], Hector Arbillaga[6], Michel Zummer[7], Ann Clarke[8], Sasha Bernatsky[9], Marie Hudson[10], Carol A. Hitchon[2], Paul R. Fortin[11] and Janet E. Pope[12]. [1]University of Western Ontario, London, ON, [2]University of Manitoba, Winnipeg, MB, [3]Toronto Hospital for Sick Children, U of Toronto, Toronto, ON, [4]McGill University Health Center, Montreal, QC, [5]TOH Riverside Campus, Ottawa, ON, [6]Lethbridge Rheumatology practice, Lethbridge, AB, [7]U of Montreal, Montreal, QC, [8]U of Calgary, Calgary, AB, [9]McGill UHC/RVH, Montreal, QC, [10]McGill University, Montreal, QC, [11]Laval University, Division of Rheumatology, Centre de Recherche du CHU de Québec and Department of Medicine, Quebec City, QC, [12]St Joseph Health Care, London, ON.

Background/Purpose: To determine whether socioeconomic status, as measured by education, impacts disease activity (measured by SLAM-2,

SLEDAI-2K) or disease damage (measured by SLICC SDI) in patients with systemic lupus erythematosus (SLE).

Methods: Data from the 1000 Canadian Faces of Lupus, a multi-center, prospective cohort database included adult SLE patients from June 2005 onward. Socioeconomic status, as measured by education was defined as being either low (did not complete high school) or high (completed high school or further). The relationships between education and SLE outcomes were evaluated using one-way ANOVA and logistic regression analyses.

Results: 484 patients met inclusion criteria (mean age 47 years, 91.5% female, mean disease duration of 10 years); 80.4% had completed high school education or higher and 19.6% had not. One-way ANOVA analyses demonstrated: SLEDAI-2K ($p=0.01$), SLAM-2 ($p<0.3$) and SLICC ($p=1.0$). Proportionately more Aboriginal people were in the low education group (6.4% in high education vs. 17.9% in low education) and work disability was twice as common in low education group (13.6% vs. 28.4%). Income was higher in high education stratum. Logistic regression did not demonstrate significance between education and SLEDAI-2K when adjusting for age, sex, ethnicity, and disease duration. See table for results.

*P<0.05	High SES	Low SES
Total (% of group)	389 (80.4)	95 (19.6)
Female	360 (92.5)	83 (87.4)
Age, mean (SD), years	44.9 (12.8)	54.9 (13.2)
Ethnicity†		
Caucasian	287 (73.8)	72 (75.8)
Black	38 (9.8)	4 (4.2)
Asian	39 (10)	2 (2.1)
Aboriginal	25 (6.4)	17 (17.9)*
Work Disabled ¤	53 (13.6)	27 (28.4)*
Disease Duration	10.4 (8.9)	10.8 (9.6)
Income Level††	30 (7.7)	19 (20)
Per annum household income	47 (12.1)	8 (8.4)
<$15,000	68 (17.5)	16 (16.8)
$15,000 - $29,999	136 (35)	8 (8.4)*
$30,000-$49,999		
≥$50,000		
Disease Activity		
SLAM-	6.01 (3.8)	5. (4.1)
SLEDAI-2K	4.40 (4.1)	5.67 (5.2)
Disease Damage		
SLICC	1.34 (1.8)	1.33 (1.8)

Conclusion: This was mostly a prevalent, cohort so low income and work disability could be a result of SLE disease activity and damage. This cohort was literate and had access to lupus specialists so data may not be generalizable. Socioeconomic status, as measured by education, did not impact damage or disease activity in this cohort.

2620

Mortality and Survival in Systemic Lupus Erythematosus Patients: Trends in a Spanish Cohort from 1985 to 2013. Sergi Heredia[1], Javier Narváez[2], Andrea Zacarias[1], Milagros Ricse[1], Gloria Albert[1], Eulalia Armengol[1], Helena Borrell[1], Olga Capdevila[1], Francesca Mitjavila[1], Toni Rozadilla[1], Xavier Juanola[3] and Joan Miquel Nolla[1]. [1]Hospital Universitario de Bellvitge, Barcelona, Spain, [2]Hospital Universitario de Bellvitge. Barcelona. Spain, Barcelona, Spain, [3]University Hospital Bellvitge, Barcelona, Spain.

Background/Purpose: To study the mortality, survival and causes of death in a Spanish cohort of patients with systemic lupus erythematosus (SLE) over a 28-year period (1985–2013).

Methods: The sample comprised 219 patients with SLE treated between 1985 and 2013 at a tertiary university hospital that does not attend pediatric populations. Patients were registered in a specific database. Survival over time was studied by the Kaplan-Meier method. For patients who died or were lost to follow-up, data were censored at the last clinical visit.

Results: Mean age at diagnosis of SLE of the 219 patients recruited (189 women) was 46 ± 14 years, and mean follow-up was 8.47 ± 4.12 yrs (58% of patients were followed ≥ 10 yrs and 43% < 10 yrs).

During follow-up, 14 patients (6%) died: five due to cardiovascular disease, four of cancer, four due to infection (one invasive pulmonary aspergillosis, one *Pneumocystis jirovecii* pneumonia, one necrotizing fasciitis, and one *Pseudomonas aeruginosa*-induced sepsis), and one due to SLE activity.

The median time from diagnosis of disease to death was 106 months in patients who died of cardiovascular disease, 185 months in cases of infection, and 206.5 months in patients with cancer. Cumulative survival from onset was 99% at 5 years (95% CI 0.977–1.000), 97.6% at 10 years (0.954–1.000), 93% at 15 years (0.885–0.977), 87.8% at 20 years (0.808–0.953) and 82.1% (0.726–0.930) at 25 years. Overall mortality rate increased from 2005 to 2013. The mean age at death increased with time.

Conclusion: Long-term survival in a series of Spanish patients with SLE was high, with a cumulative survival from diagnosis of 97.6% at 10 years and 87.8% at 20 years. Cardiovascular disease (35%), infections (29%) and cancer (29%) represented the main causes of death.

2621

Health-Related Quality of Life in Patients with Systemic Lupus Erythematosus. Jin-Shei Lai[1], Karen Kaiser[1], Jennifer Beaumont[1], Sally Jensen[1], Amy H Kao[2], David Van Brunt[3] and Shih-Yin Chen[2]. [1]Northwestern University, Chicago, IL, [2]Biogen Idec, Cambridge, MA, [3]Formerly of Biogen Idec, Cambridge, MA.

Background/Purpose: Systemic lupus erythematosus (SLE) is a multi-organ chronic autoimmune disease that can negatively affect patients' health-related quality of life (HRQOL). This cross-sectional study collected HRQOL data from a sample of SLE patients using questionnaires from the Patient-Reported Outcomes Measurement Information System (PROMIS) and Quality of Life in Neurological Disorders (Neuro-QoL) to assess its association with patient-reported SLE disease severity.

Methods: Individuals with SLE were recruited via patient advocacy organizations to complete an online survey consisting of the PROMIS-29 health profile, PROMIS Psychosocial Illness Impact-Negative, and Neuro-QoL Applied Cognition. Patients self-rated their SLE disease severity to be negligible, mild, moderate, or severe. PROMIS and Neuro-QoL scores have mean=50, standard deviation (SD)=10 in the US general population. Analysis of variance was used to compare HRQOL scores between SLE disease severity groups.

Results: Of the 333 survey participants (mean age: 45 years; 92% female; 26% Black; mean disease duration=12 years), 55.6% reported their SLE disease severity as moderate or severe. Mean HRQOL scores were worse than those of the general population by half a SD or more with the greatest deficits observed in Fatigue, Applied Cognition, Psychosocial Illness Impact-Negative, Pain Interference, and Physical Function [Figure 1] [Figure 2]. Greater patient-reported SLE disease severity was associated with worse mean HRQOL scores (all $p<0.05$). Reliability exceeded 0.70 for all PROMIS and Neuro-QoL scores.

Conclusion: Relative to the general population, patients with SLE reported substantial deficits in HRQOL that correlated with their severity disease, especially in fatigue, pain, cognition, physical function and psychosocial illness impact. These deficits should be monitored in clinical practice in care for SLE patients and considered when investigating new therapies.

Figure 1. Negative HRQOL attributes by SLE severity (general population mean=50)

Background/Purpose: To describe the demographic, clinical and immunological manifestations in male patients with Systemic Lupus Erythematosus (SLE).

Methods: Patients diagnosed of SLE that were in the RELESSER data base (National Registry of Patients with Systemic Lupus Erythematosus of the Spanish Society of Rheumatology) were included. This is a multicenter retrospective cross-sectional study. We analyzed 3658 patients with SLE. All met the ACR criteria. Socio- demographic variables, comorbidities, classification, clinical and immunological manifestations were evaluated. Pearson's chi–square test, t-Student, ANOVA and multivariate logistic regression analysis were performed

Results: A total of 3658 patients were included: 353 men (9.7%) and 3298 women (90.2%), with an average onset of symptoms of 37 ± 17 and 32 ± 14 years of age respectively. In 7(0.1%) the gender was unknown. The male/female ratio was 9/1.The age of onset of symptoms and age at diagnosis was higher in men than in women (P<0.0001). Diagnosis in males was sooner than in females (P=0.04).The most common age range at diagnosis in both genders was 21–49 years(P<0.0001).

Table 1 Clinical manifestations

		MISSING N	MALE (N:353) N(%)	WOMEN (N:3298) N(%)	VALUE OF P
Systemic Manifestations	Weight loss	68	48 (13,7%)	309 (9,5%)	0,01
	Lymphadenopathy	74	49 (14%)	320 (9,9%)	0,02
	Splenomegaly	108	19 (5,5%)	99 (3,1%)	0,02
Cutaneous manifestations	Exanthema	62	190 (54,3%)	2180 (67,1%)	<0,0001
	Alopecia	86	54 (15,8%)	1229 (38%)	
Osteoarticular manifestations	Erosive arthritis	60	20 (5,8%)	342 (10,5%)	0,01
	Avascular bone necrosis	67	30 (8,5%)	121 (3,7%)	<0,0001
	Fibromyalgia	94	1 (0,3%)	223 (6,9%)	<0,0001
Pulmonary Manifestations	Pleural fibrosis	43	8 (2,3%)	25 (0,8%)	<0,0001
	Pulmonary thromboembolism	33	18 (5,1%)	86 (2,6%)	0,01
Cardiovascular manifestations	Libman Sachs endocarditis	103	7 (2%)	28 (0,9%)	0,04
	Angina or coronary bypass	52	19 (5,4%)	50 (1,5%)	<0,0001
	Acute myocardial infarction	61	24 (6,9%)	47 (1,4)	<0,0001
	Cardiomyopathy	79	20 (5,8%)	84 (2,6%)	<0,0001
	Pericarditis	52	15 (4,3%)	59 (1,8%)	<0,0001
Peripheral vascular manifestations	Claudication for more than 6 months	45	8 (2,3%)	23 (0,7%)	<0,0001
	Deep vein thrombosis	50	24 (6,9%)	119 (3,7%)	<0,0001
	Raynaud	142	80 (23,7%)	1114 (35%)	<0,0001
Renal manifestations	Lupus nephritis	89	156 (44,8%)	933 (29%)	<0,0001
	HTA in the first outbreak	182	68 (20,1%)	330 (10,5%)	<0,0001
	Hematuria	247	130 (38,70%)	908 (29,5%)	<0,0001
	Creatinine clearance = 50 irreversible	112	31 (9%)	161 (5%)	<0,0001
	Proteinuria = 3,5g/24hs	126	21 (6,1%)	114 (3,6%)	0,02
	Terminal renal insufficiency	146	16 (4,7%)	82 (2,6%)	0,03
Neuro psychiatric manifestations	Lupus headache	89	10 (2,9%)	204 (6,3%)	<0,0001
	Seizures	76	32 (9,2%)	156 (4,8%)	<0,0001
	Depression	89	36 (10,3%)	574 (17,8%)	<0,0001
Immunology	Ac anti DNA positive	99	271 (78,6%)	2342 (72,9%)	0,02
	AC anti RO positive	96	94 (27,5%)	1300 (40,8%)	<0,0001
	Positive lupus anticoagulant	1007	86 (34,11%)	547 (22,8%)	<0,0001

Women had more frequently a history of autoimmune thyroid disease (P<0.001). Males have more cardiovascular comorbidities (P<0.001). Comparing comorbidities in men with SLE by age range, it was found that SLE patients over 50 years of age had more comorbidity with p<0.05. A total of 68%(236) of males with SLE required hospitalization in comparison with 53%(1713) female (P< 0.001). During follow-up 208 patients died, 30(9.3%) were male and 178 (5.9%) women (P=0.02). On multivariate analysis, the only statistically significant variable was age. It was seen that patients over 50 year-old had a higher mortality than those under 50 year-old, regardless of gender, delay in diagnosis, risk factors and clinical features OR: 5.32 (CI: 3.61 to 7.84) P<0.001.

Conclusion: Patients with SLE older than 50 years old are at increased risk of mortality. In male patients with SLE: the age at diagnosis and the onset of symptoms is higher than in women. The diagnostic delay is lower in men than in women. Men have more cardiovascular comorbidities, especially those over 50 years-old and also more serositis, renal and cardiovascular involvement than women.

Treatment Patterns and Resource Utilization of Systemic Lupus Erythematosus Patients Newly Initiating Standard of Care: United States Commercial and Medicare Supplemental Claims Analysis. Shonda A Foster[1], Emily Durden[2], Brett Maiese[2], Sarah Al Sawah[1] and Kathleen Solotkin[1]. [1]Eli Lilly and Company, Indianapolis, IN, [2]Truven Health Analytics, Bethesda, MD.

Background/Purpose: Currently, there is not a standard treatment algorithm for the management of Systemic Lupus Erythematosus (SLE); however, there are medications that may be considered standard of care (SOC) for the treatment of SLE. Treatment may vary among patients depending on disease activity, presenting signs and symptoms, extent of organ involvement and access to care. Thus, there is a need to understand the range of treatment patterns in SLE patients.

Methods: The MarketScan®Commercial Claims and Encounters and Medicare Supplemental Databases from Truven Health Analytics were used to retrospectively analyze SLE patients newly initiating SOC treatment (i.e., antimalarials, glucocorticoids, immunosuppressants, and monoclonal antibodies). Demographic and clinical characteristics, treatment patterns (e.g., augmentation, switching, and discontinuation), all-cause healthcare resource utilization and costs (i.e., sum of patient-paid out-of-pocket costs and plan-paid amounts) were examined in the 12 months following initiation of SLE SOC treatment (index date). Included were adult SLE patients who had ≥1 prescription claim for an SLE SOC treatment between January 2008 and December 2011 (without prior SOC treatment) and continuous medical and prescription coverage ≥12 months prior to and ≥12 months following the index date.

Results: There were 8,098 patients included in the study. Mean age of the cohort was 49 (± 13.8) years, 88.3% were female, and 12.1% were insured by Medicare. Most patients (98.7%) had ≥1 comorbidity; the most frequent comorbidities in the pre-index period were hypertension (32.6%) and anemia (13.9%). At index, 26.6%, 64.0%, 2.9%, and 0.2% of patients initiated treatment with antimalarials, glucocorticoids, immunosuppressants, or monoclonal antibodies, respectively, compared to 56.6%, 63.8%, 20.3%, and 1.1% during the 12-month post-index period. At index, 6.3% of patients initiated on some combination of the classes. During the 12-month post-index period, the index medication class was discontinued by 0.5%, 29.2%, 6.8%, and 84.2% of those who received antimalarials, glucocorticoids, immunosuppressants, and monoclonal antibodies, respectively, and 24%, 31%, 26%, and 5% added another SLE SOC class, respectively. The percentages of patients who switched from the index SOC class to a different SOC class were low, ranging from 0.0% to 5.3% among index therapies. During the 12-month follow-up period, almost all patients incurred outpatient visits (99%) and laboratory and radiology services (98%). Also, 21% of patients had an inpatient admission and 40% had an emergency room visit. The mean total healthcare cost was $24,575 during the 12-month follow-up period, including $8,329 inpatient, $13,069 outpatient, and $679 in SLE-related medication costs.

Conclusion: This analysis reveals the wide range of treatment patterns and substantial healthcare resource utilization and costs in SLE patients newly initiating SOC treatment. Understanding these treatment patterns in the context of associated disease activity, symptoms, and organ involvement may assist clinicians and payers in evaluating current and future therapies in the treatment of SLE.

Impact of Provider Specialty on the Diagnosis and Management of Systemic Lupus Erythematosus in the American Indian/Alaska Native Population. John McDougall Jr.[1], Charles G. Helmick[2], S. Sam Lim[3], Caroline Gordon[4] and Elizabeth Ferucci[5]. [1]Dartmouth Hitchcock Medical Center, Lebanon, NH, [2]Centers for Disease Control and Prevention, Atlanta, GA, [3]Emory University School of Medicine, Division of Rheumatology, Atlanta, GA, [4]Rheumatology Research Group, School of Immunity and Infection, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom, [5]Alaska Native Medical Center, Anchorage, AK.

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex disease that is traditionally diagnosed and managed by specialists, typically rheumatologists. Higher SLE prevalence in racial/ethnic minorities such as American Indian/Alaska Native (AI/AN) people, often residing in areas with less access to rheumatologists, may necessitate diagnosis and management of SLE by primary care providers (PCP) in some cases. The purpose of this analysis was to identify areas of potential difference between PCP and specialist diagnosis and management of SLE in a population-based lupus registry of AI/AN people.

Methods: All individuals with SLE meeting our inclusion criteria were selected from the 2009 Indian Health Service lupus registry population. Inclusion in this analysis was limited to individuals with a final diagnosis of SLE made by a PCP or specialist (dermatologist, nephrologist or rheumatologist) and documented in the medical record. Based on medical record abstraction, SLE classification criteria were validated for each individual. Testing for biologic markers of SLE and medication use at any time during the course of the disease were also abstracted.

Results: Of the 320 patients identified with a documented physician diagnosis of SLE, 71 had been diagnosed by a PCP. SLE diagnosis by a specialist was associated with a higher median number of American College of Rheumatology (ACR) classification criteria (5 vs. 2), a higher percentage of patients meeting the definition of SLE by ACR criteria (79% vs. 22%), the Boston Weighted criteria (82% vs. 32%), and an abridged version of the Systemic Lupus International Collaborating Clinics (SLICC) criteria (83% vs. 35%) ($p<0.001$ for all comparisons). Additionally, specialist diagnosis was associated with an increased proportion with any testing for anti-double-stranded DNA antibody (93% vs 73%) and complement C3 and C4 (84% vs 52%) documented in the medical record ($p<0.001$ for all). Lastly, specialist diagnosis was associated with ever treatment with hydroxychloroquine (86% vs. 64%, $p<0.001$) as documented in the medical record at any time during their disease course.

Conclusion: Within the population studied, specialist diagnosis of SLE was associated with a higher number of SLE classification criteria met, a higher percentage of patients tested for biomarkers of disease, and a higher percentage of patients ever treated with hydroxychloroquine.

Work Productivity in Systemic Lupus Erythematosus: Relationship with Clinical Features. Micaela Ana Cosatti[1], Sebastian Muñoz[2], Paula Alba[3], Claudia Andrea Helling[4], Susana Roverano[5], Judith Sarano[6], Samanta Malm-Green[7], Anastasia Secco[8], Maria Danielsen[9], Danith Medina Bornachera[10], Analia Alvarez[11], Alicia Eimon[1], Dora Pereira[12] and Cecilia N. Pisoni[1]. [1]CEMIC, CABA, Argentina, [2]Hospital Fernandez, CABA, Argentina, [3]Hospital Córdoba, Cordoba, Argentina, [4]Omi, CABA, Argentina, [5]Hospital J. M. Cullen, Santa Fe, Argentina, [6]Instituto de Investigaciones Médicas Alfredo Lanari, CABA, Argentina, [7]Hospital Bernardino Rivadavia, CABA, Argentina, [8]Hospital Bernardino Rivadavia, Buenos Aires, Argentina, [9]Hospital Regional, Santiago del Estero, Argentina, [10]Hospital Penna, CABA, Argentina, [11]Hospital Penna, CABA, Argentina, [12]Hospital Ricardo Gutierrez, La Plata, La Plata, Argentina.

Background/Purpose: To measure work productivity and the related risk factors in patients with systemic lupus erythematosus (SLE) from Argentina.

Methods: Employment status of 171 consecutive SLE patients was assessed using a standardized data collection form. Patients fulfilled 1987 ACR criteria for SLE. Sociodemographic data, employment status, type of employment, work physical demand, disease characteristics (ACR criteria, SLE duration, SLEDAI, SLICC/ACR-DI, treatment, LupusQol) and comorbidities were collected. Work productivity and activity impairment question-

naire (WPAI) was performed. The association between clinical characteristics with work productivity was examined by standard statistical tests.

Results: 171 patients were included, 91 % women, age was 40 (SD 12.13), 39 % white, 51% mestizo and 10% afro Latin-American. Hundred and thirty six patients (80 %) had more than 12 years of education and 59 (35.5 %) had no health insurance.

SLE disease duration was: 10.3 years (SD 9.2). SLEDAI score was 2 (SD 3.2), SLICC-SDI score was 0 (range 0–7), fatigue visual analogue scale (VAS) was 4 (SD 3), pain VAS was 3.5 (SD 4.8), patients global VAS was 1.7(SD 2) and physician global VAS was 2.8 (SD 2.8). Charlson comorbidity index was 1 (1–2.5).

LupusQol in the different domains was: physical health 72.2 (SD 23.5), emotional health 64.6 (SD 23.4), burden to others 56.1 (SD33.5), intimate relationships 67 (SD32.6), body image 69.5 (SD28.3).

Eighty seven patients (51%) were working, 84 (49%) were not working (unemployed, retired, housewives and students). Seventy one patients (83 %) perform mild or sedentary jobs by Soler Pujol scale.

Absenteeism and presenteeism were measured in employed SLE patients with WPAI questionnaire. Fifty four (62%) patients did not miss hours of work in the past week, 21 (24%) of patients miss >= 8 hours of work last week. Mean of missed hours of work last week due to SLE was 2.8 (SD 7.8), the average hours worked last week was 29 (SD 20.6).

Presenteeism: 41 % of patients (n = 36) presented some degree of work impairment. The degree of work impairment performance on 0–10 likert scale was 2.4 (SD 2.8).

Employed patients with SLEDAI >=6 did not experienced significantly reduced work productivity than employed patients with SLEDAI < 6 (p=0.99), patients with SLICC-SDI >=1 did not experienced significantly reduced work productivity than employed patients with SLICC-SDI <1 (p= 0.96). Work productivity was reduced among employed SLE patients with more severe pain (p<0.001), fatigue (p<0.001) and worse scores in Lupus-Quol physical (p<0.001) and emotional domains (p<0.001).

In the multiple regression analysis considering work impairment as dependent variable (adjusting by age, disease duration, VAS pain, VAS fatigue, LupusQuol physical and emotional domains), we found the physical domain of LupusQuol (OR 0.84 CI 0.71–0.98) as unique associated variable.

Conclusion: SLE patients with worse physical domain of LupusQuol showed higher work productivity compromise. Reduction of work productivity was not associated with more active SLE neither with more damage.

2626

Relationship of Socio-Demographic and Disease Factors with Loss-to-Follow-up and Appointment Noncompliance in Indigent Patients with Systemic Lupus Erythematosus.

Angela Pham[1], Gaobin Bao[1], S. Sam Lim[2] and Cristina Drenkard[1]. [1]Emory University, Atlanta, GA, [2]Emory University School of Medicine, Division of Rheumatology, Atlanta, GA.

Background/Purpose: The relationship of medical noncompliance with poor health outcomes has been described in chronic diseases, including systemic lupus erythematosus (SLE). These outcomes are amplified in SLE due to its multi-organ involvement and high-risk immunosuppressant therapy. The association of noncompliance with socio-demographic and disease factors has been poorly studied and inconsistently identified. In past studies, noncompliance in SLE has been defined as rate of loss to follow-up (LTF) of scheduled outpatient appointments. Reported LTC rates have ranged from 24% to 48%. We investigate the relationship of socio-demographic and disease factors with noncompliance and focus on self-reported damage, health status, and depression in a predominantly indigent Black cohort.

Methods: We selected a sample of indigent SLE patients from the Grady Lupus Clinic who consented into the Georgians Organized Against Lupus (GOAL). GOAL is a longitudinal population-based cohort of patients with validated SLE from Atlanta, Georgia, who are surveyed annually on disease outcomes and access to care. Grady Lupus Clinic (GLC) is the only lupus clinic in GA that serves a large indigent population with SLE. Data on appointment compliance was abstracted from GLC electronic medical records. The first outcome, LTF, was defined as no GLC visits for the past 12 months within the past 24-month period. The second outcome, rate of appointment noncompliance, was calculated as 1 minus the rate of accomplished GLC visits in the past 12-month period. Logistic regression and multi-way ANOVA analyses examined the association of socio-demographic and disease factors with outcomes.

Result: The sample consisted of 127 patients, predominantly non-white (94%), females (91%) and living below 100% the poverty threshold (73%). Depression increased the risk of LTF, while longer disease duration and poverty protected against LTF (Table 1).

The adjusted appointment noncompliance rate was higher in patients who self-reported severe disease activity (34%; 95% CI 19–48%), compared to those with mild disease activity (18%; 95% CI 1–35%), p-value 0.058. In contrast, patients with organ damage tended to have lower appointment noncompliance (22%; 95% CI 8–26%) than those without organ damage (33%; 95% CI 16–50%), although the difference was not statistically significant (p 0.083).

Conclusion: Barriers to optimizing SLE outcomes include medical noncompliance defined as loss to follow-up and appointment noncompliance. The first step in overcoming this barrier is recognizing the associated socio-demographic and disease factors. Our data show that lower compliance is seen in patients with depression, shorter disease duration, higher income, and higher self-reported disease activity. With these factors in mind, targeted intervention for improved outcomes can be tailored for those within this vulnerable population.

Table 1 Risk factors of lost to follow-up in indigent SLE patients. Multivariable analysis

Factor	Odds Ratio	P Value
Depression (PHQ-9 score >=10)	**5.26 (1.11–24.80)**	**0.036**
Age at diagnosis (5-year increase)	1.06 (0.80–1.41)	0.67
Disease duration (1-year increase)	**0.90 (0.82–0.98)**	**0.019**
Education (3-year increase)	0.97 (0.48–1.97)	0.94
Gender (Female)	0.79 (0.12–5.29)	0.81
Below 100% the poverty threshold	**0.20 (0.05–0.73)**	**0.015**
Married/living with partner	0.96 (0.25–3.66)	0.95
No insurance or under-insured	2.50 (0.66–9.52)	0.18
Disease Activity Moderate (SLAQ = 11-16)	1.52 (0.24–9.47)	0.89
Severe (SLAQ >= 17)	1.88 (0.33–10.74)	0.53
Organ damage (SA-BILD ≥ 1)	0.58 (0.15–2.16)	0.41
Poor or fair health	0.28 (0.06–1.32)	0.11

PHQ-9 = 9-question Patient Health Questionnaire; SLAQ = Systemic Lupus Activity Questionnaire; SA-BILD = Self-Administered Brief Index of Lupus Damage.

Comparison of Disease Characteristics and Organ Damage in Patients with Juvenile and Adult-Onset Systemic Lupus Erythematosus in Large Cohort from Turkey.

Bahar Artim-Esen[1], Ozgur Kasapcopur[2], Sezgin Sahin[2], Kenan Barut[2], Ahmet Omma[1], Yasemin Sahinkaya[1], Sevil Kamali[1], Lale Ocal[1] and Murat Inanc[1]. [1]Rheumatology Division, Department of Internal Medicine, Istanbul Faculty of Medicine,Istanbul University, Istanbul, Turkey, [2]Rheumatology Division, Department of Paediatrics, Cerrahpasa Faculty of Medicine, Istanbul University, Istanbul, TURKEY, Istanbul, Turkey.

Background/Purpose: Systemic lupus erythematosus (SLE) is a multi-systemic disease that may cause a broad spectrum of clinical and immunological manifestations. Age at onset has been shown to effect the clinical course and outcome of the disease. Herein, we aimed to define the differences in clinical characteristics and organ damage between patients with juvenile-onset (jo-SLE) and adult-onset (ao-SLE) SLE followed up in two tertiary referral centres.

Methods: This analysis included 935 patients 846 of whom attended the lupus outpatient clinic at Istanbul faculty of medicine between 1975 and May 2012 and 89 of whom were followed in the paediatric rheumatology outpatient clinic at Cerrahpaşa faculty of medicine between 2004 and 2013. At the time of recruitment, all patients fulfilled the ACR classification criteria for SLE. The data presented was the cumulative clinical and serological manifestations throughout the follow-up period. jo-SLE was defined as diagnosis at the age of 18 or younger according to the Paediatric Rheumatology International Trials Organization (PRINTO). Seven hundred nineteen (76.9 %) patients with ao-SLE and 216 (23.1 %) patients with jo-SLE were examined. Demographic characteristics, clinical features, autoantibody pro-

files and damage data (SLICC damage index) were compared between the groups. Statistical analyses were performed using SPSS, version 17.

Results: Comparison of demographics revealed significant differences in age at onset (13.5 ± 3.5 vs 34 ± 11.3 years) and duration of disease (86.5 ± 96.2 vs 111.6 ± 83.9 months) between juvenile and adult groups respectively ($p<0.05$). Of clinical symptoms, photosensitivity (71.6 vs 56.5 %), malar rash (73.6 vs 45.6 % and oral ulcers (23.1 % vs 15.4 %) were significantly more frequent in jo-SLE ($p<0.05$). As was previously reported, renal involvement was significantly more prevalent in the jo-SLE affecting 53.2 % of the patients compared to patients with ao-SLE (28.9 %) ($p<0.05$). Autoimmune haemolytic anaemia (AIHA) did also occur more often in the jo-SLE (33.3 vs 9.5 %, $p<0.05$) whereas reverse was true for pleuritis (11.6 vs 18.4 %, $p<0.05$). Of the autoantibodies, a higher frequency of anti-dsDNA (78,7 vs 69 %), anticardiolipin IgG (31.9 vs 21 %) and IgM (36.6 vs 19.3 %) were observed in the jo-SLE group. However, there were significantly more patients with anti-Sm positivity in ao-SLE (19.6 vs 10.2 %, $p<0.05$). According to the SLICC damage index, renal damage was significantly more frequent in the jo-SLE (22.8 %) than the ao-SLE (8.4 %) ($p<0.05$). However, damage in musculoskeletal system, namely avascular necrosis was more prominent in the ao-SLE (14.1 vs 8.4 %, $p<0.05$).

Conclusion: Our study confirms that clinical and serological differences exist between jo-SLE and ao-SLE. jo-SLE was associated with a higher frequency of renal involvement and damage. We also report a higher frequency of cutaneous symptoms, oral ulcers, AIHA and anti-dsDNA positivity in the jo-SLE. As renal involvement is a major predictor of prognosis and outcome, this study highlights the importance of awareness of the age of onset of SLE and supports the necessity of vigilant follow-up of this subgroup.

Risk of Cancer Is Not Increased in Patients with Cutaneous Lupus Erythematosus: A Population-Based Study. Abha G. Singh, Cynthia S. Crowson, Mark Davis, Hilal Maradit Kremers, Eric L. Matteson and Vaidehi Chowdhary. Mayo Clinic, Rochester, MN.

Background/Purpose: Systemic immune dysregulation associated with chronic autoimmune diseases such as systemic lupus erythematosus (SLE) as well as immunomodulatory medications used for their treatment have been associated with an increased risk of malignancy. The pathogenesis of cutaneous lupus erythematosus (CLE) is similar to SLE. It is unclear whether CLE is associated with an increased risk of malignancy. Hence, we estimated the cumulative incidence of malignancy in a population-based cohort of patients with CLE, and compared the risk with an age- and sex-matched cohort without CLE.

Methods: Patients with subtypes of CLE (discoid, subacute cutaneous lupus, lupus panniculitis and bullous lupus) were identified from a population-based cohort in 1965–2005. Age- and sex-matched subjects without CLE were selected from the same population. Non-CLE subjects were assigned an index date corresponding to the CLE diagnosis date of the matched CLE patient. For a random sample of 66 of the 156 patients with CLE and the non-CLE subjects matched to them, data were collected on all cancers via medical record review. The cumulative incidence of cancer after CLE diagnosis was estimated using Kaplan–Meier methods. Cox models were used to estimate the relative risk of malignancy in patients with CLE as compared to non-CLE adjusted for age, sex and calendar year of index date.

Results: We identified 66 patients with CLE (mean age at time of CLE diagnosis, 55±14y; 64% females; 68% Caucasian; mean BMI, 27.3±7.2 kg/m^2; 34.8% smokers), who were followed over a median follow-up of 12.0 years (interquartile range [IQR], 8.1–17.3y). Positive antinuclear antibody, anti-SSA and anti-SSB were seen in 48%, 47% and 18% of patients with CLE, respectively. Median ESR was 11 mm/hour (IQR, 4.0–25.0) and CRP 2.9 mg/dL (IQR 1.5–3.9). Overall, we observed 14 cases of incident cancer (including 5 cases of non-melanoma skin cancer). The cumulative 1-, 5- and 10-year incidence of any malignancy after diagnosis of CLE was 3.4%, 10.9% and 14.6%, respectively. As compared to age- and sex-matched non-CLE controls, the overall risk of malignancies was not increased in patients with CLE (hazard ratio [HR], 1.09; 95% CI, 0.51–2.37; p=0.81) (Figure 1). The cumulative 1-, 5- and 10-year incidence of all malignancies except non-melanoma skin cancers in patients with CLE was 1.7%, 7.1% and 11.1%, respectively. As compared to matched controls, the risk of all malignancies except non-melanoma skin cancer in patients with CLE was not increased (HR, 0.88; 95% CI, 0.36–2.14; p=0.78).

Conclusion: The 10-year risk of any malignancy in a population-based cohort of patients with CLE is 14.6%. This risk is not increased as compared to age- and sex-matched subjects without CLE.

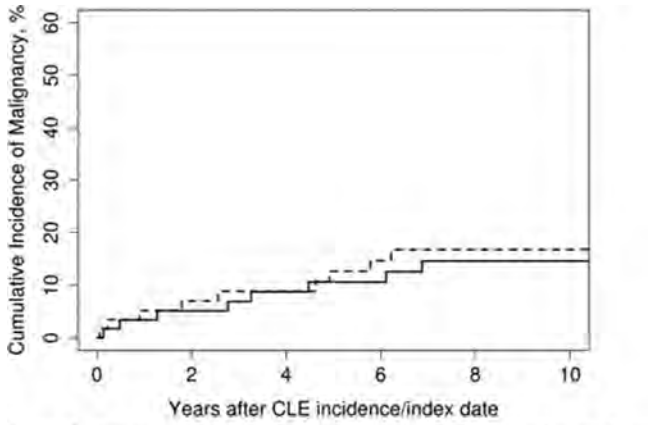

Figure 1. Cumulative incidence of malignancy in patients with cutaneous lupus erythematosus (CLE – solid line) and age- and sex-matched subjects without CLE controls (dashed line).

Childhood-Onset and Adult-Onset Systemic Lupus Erythematosus: Distinctions in an Underserved Ethnic Minority Cohort. Rebekah Neal[1], Kimberly DeQuattro[2], Elizabeth C. Ortiz[1] and Francisco P. Quismorio Jr. [3]. [1]University of Southern California, Los Angeles, CA, [2]LAC+USC Medical Center, Los Angeles, CA, [3]Keck School of Medicine, University of Southern California, Los Angeles, CA.

Background/Purpose: Previous studies suggest differences between childhood-onset SLE (cSLE) and adult onset SLE (aSLE). Whereas the prevalence of nephritis, neuropsychiatric, dermatologic, and hematologic manifestations are higher in cSLE, Raynaud's phenomenon, pleuritis, and sicca symptoms are more common in aSLE. cSLE tends to have more severe organ involvement at presentation and higher scores on damage indices. The purpose of our study is to determine whether such differences exist among an urban, poor, uninsured, ethnic minority SLE patient population in Southern California.

Methods: This is a single center, cross sectional, retrospective study of 250 consecutive SLE patients. All patients met ACR criteria for the classification of SLE and were diagnosed at < 40 years of age. cSLE and aSLE patients were defined as age at diagnosis < 18 years and ≥18 years, respectively. Gender, ethnicity, age at diagnosis, and duration of follow up were noted. Outcome measures included prevalence of nephritis, other disease manifestations, cyclophosphamide use and SLICC scores. Group characteristics were summarized by descriptive statistics and differences between groups were analyzed by the chi square test and the student's t test.

Results: There were 76 patients in the cSLE group and 174 patients in the aSLE group. Overall 76% of patients were Hispanic, 8% Black, 14% Asian, 1% Caucasian, and 1% other. Ethnic breakdown was similar between cSLE and aSLE groups as was gender (84% women, 16% men). The average age at entry into study in the cSLE group was 25.5 years (range 17–37 years) and 31.0 years (range 19–39 years) in the aSLE group. The average duration of follow up was 12.4 years and 6.8 years for cSLE and aSLE, respectively. The frequency of nephritis (54% vs 53%), neuropsychiatric lupus (9.5% vs 8.6%), cytopenias (46% vs 47%) and anti-phospholipid syndrome (6.6% vs 8.6%) were not significantly different between cSLE and aSLE, respectively, within the first two years of diagnosis. Use of cyclophosphamide was significantly higher in the cSLE group than the aSLE group (46% vs 24%, $p < 0.01$). At the time of entry into the study, cSLE patients showed a trend towards higher SLICC scores than aSLE. However, when the duration of follow up was accounted for, there were no significant differences between the two groups at 5, 10, 15, and 20 years of follow up.

Conclusion: In an underserved Hispanic and other ethnic minority SLE population, there is no difference in the frequency of nephritis, neuropsychiatric lupus, and other clinical manifestations between childhood-onset and

adult-onset SLE at presentation. This study differs from previous studies in the large proportion of Hispanic patients included and that the studied population was all adults at the time of inclusion. As these findings differ from previous, more studies are necessary within this population.

An Evaluation of Quality of Life of Patients with Systemic Lupus Erythematosus Attending Rheumatology Clinic in Kenyatta National Hospital, Nairobi, Kenya. Jackline Odhiambo University of nairobi, nairobi, Kenya.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that affects all organs of the body. Due to its chronicity SLE has been known to affect the quality of life (QoL) of those affected by it. There is minimal data on SLE in East Africa and especially in Kenya. The quality of life of SLE patients in this country has never been assessed.

Methods: Patients diagnosed with SLE as by the ACR criteria and confirmed by a rheumatologist. were recruited into the study. Informed consent (assent for minors), was obtained from all participants. The patient's demographic data and last prescription was acquired from the file. Patients clinical history was taken and a physical exam was then done looking for the presence of malar rash, discoid rash, arthritis/athralgia, serositis and photosensitivity. These were defined as per the ACR criteria. After this the patient was given the LUPUS QOL questionnaire to fill. All the patients who attended the clinic at the study period were included in the study. Demographic variables (age) were summarized into means/medians while gender, was presented using percentages. Correlation of HRQOL and age, duration of illness and medication used was done using regression analysis.

Results: Sixty two patients were recruited into the study, 96% were female. Mean age of the population was 37.3yrs (12.2), ranging from 14–17 years. All the patients had some form of education with 61% having some form of tertiary education. Mean age at diagnosis was 34.5 yrs (12.2).

Majority of the patients (88.7%) had arthritis or athralgia. This was followed by oral ulcers at 32.3%, malar rash 59.7%, photosensitivity 58.1%, serositis 32.2%, CNS involvement 27.4% The least common clinical feature was discoid rash 17.7%.

On assessment of the HRQoL, The population scored globally poor in all the domains. The domain with the highest scores was planning (63.7), followed by burden to others, (58.9), fatigue (57.5), pain (56.6), physical health (54.0), body image (47.1) and the lowest intimate relationships (41.1).

Most common drug in use was prednisone at 46(74.2%), hydroxychloroquine (HCQ) 43(69.4%), NSAIDS 34 patients (54.8), Azathioprine (37.1%), Methotrexate 14 (22.6%), Mycofenolate Mofetil (MMF) 5(8.1%), CCB 7 (11.3%), cyclosporine 2(3.2).

Quality of life scores of the population were correlated with age for each domain. Positive correlation was found between Physical health (r 0.306 p= 0.016), burden to others (r=0.272 p= 0.032) and emotional health (r=0.315, p= 0.013) and advance in age.

There was found to be no significant association between HRQOL and the duration of illness or drugs used in all the domains.

Conclusion: This study demonstrates that patients with Lupus in Kenya have a poor quality of life. Lupus affects all aspects of their lives both physically and emotionally. In this study, older patients were found to have better quality of life when it came to physical health and emotional health. They were also found to be less affected by fatigue and thought of themselves as being less of a burden to others. The drugs used by the patients and the duration since diagnosis did not affect their quality of life.

Overall Cause and Cause-Specific Mortality in a Multinational Inception Cohort of SLE. Murray B. Urowitz[1], Dafna D. Gladman[1], Nicole Anderson[2], Dominique Ibanez[1] and Systemic Lupus International Collaborating Clinics (SLICC)[3]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]Toronto Western Hospital Research Institute, Toronto, ON, [3]University of Toronto, Toronto Western Hospital (Coordinating Center), Toronto, ON.

Background/Purpose: A large multicenter multinational inception cohort was established initially to study risk factors for atherosclerosis (AS) in SLE. The aim of this study was to determine all cause and cause-specific mortality and their risk factors during the first 10 years of observation.

Methods: Patients enter the cohort within 15 months of SLE diagnosis (≥4 ACR criteria). Clinical and laboratory features of SLE and comorbidities are gathered in a standardized protocol at yearly intervals. Deaths are recorded as they occur and the cause of death was coded according to ICD9. Overall and Cause-Specific Survival curves were obtained using a Cumulative Incidence Competing Risk Analysis. Prediction models for overall survival and cause-specific for the three major causes were done using time-dependent covariate analysis for competing risks using date of birth as time zero. Variables included were geography of origin, ethnicity, sex, disease duration, disease activity, damage and medication use. The selection of variable retained was done using the stepwise approach.

Results: 1677 patients had follow-up beyond enrolment. At the time of data cut 78 patients had died. Cause of death included: atherosclerosis 11, active SLE 17, infection 27 and all other causes 23 (cancer in 5, other in 8, and unknown in 10). At enrolment 89.0% were female with a mean age at diagnosis of 34.9 ± 13.4 yrs and a disease duration of 0.5 ± 0.4 yrs. Mean SLEDAI-2K was 5.4 ± 5.4, SDI 0.12 ± 0.50 (SDI > 0: 131 (7.9%)). Patients on steroids 1167 (69.8%), on antimalarials 1124 (67.3%) and on immunosuppressives 671 (40.2%). 825 (49.2%) were Caucasian, 275 (16.4%) Black, 260 (15.5%) Hispanic, 255 (15.2%) Asian and 61 (3.6%) other. Geography of origin included USA 460 (27.4%), Canada 398 (23.7%), Europe 450 (26.8%), Mexico 160 (9.5%), and Asia 209 (12.5%). The Competing –Risk survival Analysis is presented in the Table.

	Hazard Ratio	95% Confidence Interval	P value
ALL CAUSES			
Mexico	4.02	2.30, 7.02	<0.0001
Disease Duration	0.90	0.82, 0.98	0.02
SDI	1.47	1.29, 1.66	<0.0001
On Steroids at Visit	3.97	2.01, 7.82	<0.0001
On Antimalarials at Visit	0.56	0.35, 0.89	0.01
ATHEROSCLEROSIS			
SDI excluding cardiac damage	1.56	1.17, 2.06	0.002
ACTIVE LUPUS			
Mexico	9.73	3.31, 28.59	<0.0001
Sex Male	4.40	1.51, 12.82	0.007
Disease Duration	0.70	0.55, 0.91	0.006
SDI	1.58	1.17, 2.13	0.003
INFECTION			
Hispanic	4.50	1.70, 11.92	0.002
SDI	1.59	1.32, 1.93	<0.0001
On Steroids at Visit	25.27	3.35, 190.66	0.002
On Antimalarials at Visit	0.39	0.17, 0.92	0.03
On Immunosuppressives at Visit	0.27	0.12, 0.61	0.002

Damage was an important risk factor for all cause and cause-specific mortality. Demographic factors, disease activity and treatment contribute differently to mortality both all cause and cause specific. Anti-malarials are protective for all-cause mortality and mortality due to infection.

Conclusion: Risk factors differ for all cause mortality and mortality related to active lupus, atherosclerosis and infection and all must be considered in pursuing preventive strategies.

The Cornerstone to Reasonable Allocation of Health Resource: Valuation of Health Utility in Systemic Lupus Erythematosus. Suli Wang and Liangjing Lu. Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China.

Background/Purpose: In a time of increasing economic constraints, it is crucial that health systems optimize their resource use to ensure that they generate the maximum possible health gain. Therefore, it is necessary for health interventions to be evaluated and compared across therapeutic boundaries. Undertaking such an evaluation requires a generic utility-based mea-

sure. But it remains uncertain whether the utility values obtained by direct or indirect methods are comparable and which approach is the most appropriate in Systemic Lupus Erythematosus (SLE) population. The objective of this study was to compare the utility values obtained using an indirect method based on the EuroQol scale (EQ-5D) and direct utility instruments, the standard gamble (SG) and visual analog scale (VAS), in patients with SLE.

Methods: 240 consecutive patients with stable SLE underwent assessment of disease activity SLE Disease Activity Index (SLEDAI)] and damage [Systemic Lupus Collaborating Clinics/American College of Rheumatology Damage Index (SLICC/ACR DI)] and completed a disease-specific health-related quality of life (HRQoL) measure, LupusQoL, and 3 utility measures: VAS, SG, and EQ-5D. Pearson's correlations were calculated between the LupusQol domains and the utility measures to assess validity. To assess reliability, intraclass correlations or kappa coefficients were calculated between first and second assessments, performed from 2 weeks apart, in patients without important clinical change in disease activity. Multiple regression models were performed for VAS and SG to determine predictor of utility.

Results: Disease activity from SLEDAI varied from 0 to 25 (median = 2). All domains of the LupusQoL correlated well with the VAS [r: 0.329–0.632, 95% confidence interval (CI) (0.30, 0.56)] and EQ-5D value [r: 0.299–0.757, 95%CI (0.35, 0.69)] except body image (r=0.162 and 0.165, p=0.018 and 0.016, respectively), and poorly with the SG [maximum r = 0.360, CI (0.0, 0.375); minimum r = 0.044, CI (0.0, 0.375)]. Test-retest reliability intraclass correlations for the VAS [ICC = 0.793, 95% CI (0.707, 0.856)], SG [ICC=0.770, 95% CI (0.676, 0.839)] were good. The kappa coefficient was poor (0.284) for the EQ-5D domain of Anxiety/Depression, but excellent (Mobility: 0.786; Self-care: 0.849; Usual activities: 0.972; Pain/Discomfort: 0.796) for the remaining domains. A model incorporating the SLEDAI score and LupusQoL domains of emotional health and pain were good predictors of VAS (R^2=0.56) and SG (R^2=0.221) utility measures.

Conclusion: The VAS, EQ-5D, and to some extent, SG, when compared with the disease-specific HRQoL survey LupusQoL, are valid and reliable measures to assess HRQoL in a group of patients with SLE and have emerged as promising outcome measures for future research in this population. It may also be used as a basis for further studies to obtain utility data with larger samples across SLE patients and provide helpful information to seek for theoretical basis for reasonable allocation of health resources.

Factors Associated with Damage Accrual and Survival in Chinese Patients with Systemic Lupus Erythematosus (SLE): A Prospective Cohort Analysis of 747 Patients. Chi Chiu Mok[1], Sau Mei Tse[1], Ling Yin Ho[1] and Chi Hung To[2]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Chelsea Heights, Hong Kong, Hong Kong.

Background/Purpose: To evaluate the factors associated with accrual of organ damage in a longitudinal cohort of Chinese patients with SLE

Methods: A longitudinal cohort of 747 southern Chinese patients who fulfill >=4 of the 1997 ACR criteria for SLE from 1995 to 2014 was studied. Organ damage in 12 systems was assessed by the ACR SLICC damage scores (SDI). The cumulative rate of survival was studied by Kaplan-Meier's plot. In those who died or were lost for follow-up, data were censored at the time of death and the last clinic visits, respectively. Early damage accrual was defined as occurrence of organ damage ($SDI^3$1) within the first year of SLE onset. Factors associated with damage accrual and mortality over time were studied by multivariate regression models.

Results: 747 SLE patients were studied. There were 691 women (93%) and 56 men (7%). The mean age at SLE onset was 33.0±13.5 years and the mean duration of follow-up was 111±89.1 months. Seventy-six patients (10%) died and 28(4%) patients were lost to follow-up. Early damage occurred in 191 (26%) patients. The frequency of organ damage in these patients, in decreasing order, was neuropsychiatric (29%), musculoskeletal (19%), renal (17%), dermatological (16%), pulmonary (9.4%), ocular (8.9%), cardiovascular (8.4%) and peripheral vascular (5.8%). Compared with those patients without early damage, patients with early organ damage were older at onset of SLE (37.4±15.2 vs 31.4±12.5 years; p<0.001) and were more likely to be men (13% vs 6%; p=0.009). Patients with early damage had accrued a significantly higher cumulative SDI score than those without (1.59±1.6 vs 0.84±1.5; p<0.001). Logistic regression revealed that the male sex (RR 2.20 [1.22–3.95]; p=0.008) and the age of SLE onset (RR 1.04[1.02–1.05]; p<0.001) were independently associated with early damage after adjustment for the use of corticosteroids, antimalarials and immunosuppressive agents that included cyclophosphamide, azathioprine and mycophenolate mofetil. In the entire cohort, 344 patients (46%) eventually developed organ damage ($SDI^3$1) and the median time to damage was 28 months. The cumulative survival of the patients studied was 98% at 12 months, 96% at 36 months, 94% at 60 months and 89% at 120 months. The SDI score was associated with mortality (age and sex adjusted HR for each point of increase in SDI 1.31[1.18–1.44]; p<0.001). Cox regression analysis showed that early damage (HR 6.49[3.84–11.0]; p<0.001) was independently associated with mortality after adjustment for age of SLE onset, sex and the use of medications that included prednisolone, cyclophosphamide, azathioprine, mycophenolate mofetil and hydroxychloroquine.

Conclusion: In this large longitudinal cohort of Chinese patients with SLE, the male sex and older age of onset were associated with early organ damage, which occurred most frequently in the neuropsychiatric, musculoskeletal and renal systems. The presence of early organ damage increased SLE mortality by more than 6-fold.

A Signal of Improvement in Lupus Disease Activity at 3 Months Predicts Further Valid Improvement at 6 Months. Zahi Touma, Dafna D. Gladman, Dominique Ibanez and Murray B. Urowitz. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: In patients with active disease, physicians look for an early signal in response to treatment to guide their therapeutic decisions.

Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) measures disease activity in 24 descriptors, generates a total score describing disease activity overall. SLEDAI-2K records descriptors of disease activity as present or absent. In the SLEDAI-2K Responder Index 50 (S2K RI-50), each of the 24 descriptors has a definition for a ≥ 50% improvement resulting in an appropriate 50% score for the corresponding descriptor and a total score describing disease activity overall.

We aimed to determine if a signal of improvement in disease activity at 3 months predicts further improvement at 6 months.

Methods: Consecutive active lupus patients who attended the clinic between 2012 and 2014 were screened for inclusion. Patients were included if they: 1) had at least 1 of the following 5 SLEDAI-2K clinical organ systems active (vascular, renal, musculoskeletal, serosal or skin); central nervous system was excluded and 2) started or increased prednisone therapy and/or immunosuppressants. All patients had to have a follow-up visits at 3 and 6 months.

Outcome measures: Disease activity was measured by SLEDAI-2K at all visits and by S2K RI-50 at 3 months.

Study definitions: Signal of improvement by SLEDAI-2K is defined as a decrease by ≥1 in SLEDAI-2K score at 3 months. Signal of improvement by S2K RI-50 is defined as a decrease by ≥1 in S2K RI-50 score at 3 months.

Study endpoints: Based on the change in the total SLEDAI-2K score (baseline – last visit), each of the patients at last visit were grouped as: 1) improved (SLEDAI-2K decreased by ≥4) and not improved (SLEDAI-2K decreased <4).

First, we identified the patients with SLEDAI-2K signal at 3 months and those who did not have a SLEDAI-2K signal were further evaluated for possible S2K RI-50 signal. Patients with signals were reevaluated at 6 months to determine if they had further improvement.

Results: 87 patients with mean SLEDAI-2K at baseline visit was 8.9±5.1 were studied. 90% were female, age at baseline visit was 40.0±12.4 and disease duration was 13.2±9.6 years.

Signals of improvement: Of the 87 patients, 54 (62%) had a SLEDAI-2K signal at 3 months. Of the 33 patients who did not have a SLEDAI-2K signal, a S2K RI-50 signal was identified in 11 (33%) patients.

Study endpoints: Of the 54 patients with SLEDAI-2K signal at 3 months, 28 (52%) patients improved at 6 months. Of the 11 patients with S2K RI-50 signal at 3 months, 5 (46%) improved at 6 months.

Conclusion: A signal of improvement at 3 months predicts further improvement in disease activity at 6 months. S2K RI-50 signal at 3 months, which is not discern by SLEDAI-2K, predicts improvement in half of the patients at 6 months. S2KRI-50 can identify non responders at 3 months who will respond at 6 months.

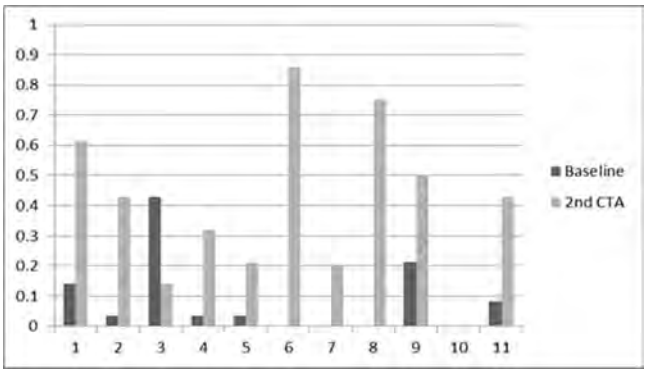
Noncalcified Plaque Progression in Systemic Lupus Erythematosus. Adnan Kiani[1], Armin Zadeh[1], Joao Lima[1], Laurence S. Magder[2] and Michelle Petri[3]. [1]Johns Hopkins University, Baltimore, MD, [2]University of Maryland, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: Coronary atherosclerosis is a major cause of morbidity and mortality in SLE. New technology, computed tomoangiography (CTA) can measure non-calcified coronary plaque (NCP), which is more inflammatory, unstable and more prone to rupture. The aim of our current study was to determine the progression of noncalcified coronary plaque in SLE.

Methods: Repeat computed tomoangiography (CTA) was done in 11 (73% female, 91% Caucasian, 9% African-American, mean age 53 years) SLE patients after a baseline CTA. The CTA scans were evaluated quantitatively by a radiologist, using dedicated software. The correlation coefficient between the overall NCP score between 2 observers was 0.93. The kappa statistic for the assessment of noncalcified plaque (present or absent) in the 71 vessel segments was 0.42. The Noncalcified plaque score was the sum of plaque severity multiplied by the plaque composition, divided by the number of vessels examined.

Results: Figure 1 shows the baseline and second CTA results in these 11 patients. Nearly all (9/11) had progression of noncalcified plaque. One patient had no NCP and one patient had regression of noncalcified plaque. Four of five patients who progressed on calcified plaque, also had progression of noncalcified plaque. Out of 11 patients, 6 were on statins, 2 mycophenolate mofetil and 1 azathioprine. All 3 on immunosuppressants progressed.

Figure 1: Noncalcified Coronary Plaque Change Over Time in SLE Patients



Statins	+	+	+			+	+				
IS*	+				+						+

***Immunosuppressive drug**

Conclusion: Noncalcified plaque – the most risky coronary plaque– progressed in the majority of SLE patients. All those with progression were under the care of a dedicated cardiologist; 5 were on statin therapy. Even the 3 on immunosuppression showed progression. This, in particular, is disappointing, as in lupus mice, mycophenolate has been proven to reduce progression of atherosclerosis. Our study proves that NCP can be the outcome in intervention trials in SLE.

Vitamin D Improves Endothelial Function in Patients with Clinically Stable Systemic Lupus Erythematosus (SLE). John A. Reynolds[1], David W. Ray[2], Terence O'Neill[3], Yvonne Alexander[4] and Ian N. Bruce[5]. [1]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Institute of Inflammation and repair, Manchester Academic Health Science Centre, The University of Manchester, United Kingdom, Manchester, United Kingdom, [2]Institute of Human Development, The University of Manchester, Manchester, United Kingdom, [3]University of Manchester, Manchester, United Kingdom, [4]Manchester Metropolitan University, Manchester, United Kingdom, [5]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Institute of Inflammation and repair, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom.

Background/Purpose: SLE patients have an increased risk of cardiovascular disease (CVD). Vitamin D deficiency has been associated with both CVD risk factors and subclinical CVD in lupus patients. There is currently no evidence that vitamin D therapy can reduce cardiovascular risk in SLE. Patients with SLE have endothelial dysfunction and restoration of vascular function may reduce CVD risk. We conducted an experimental study to determine the effect of vitamin D on endothelial function.

Methods: Clinically stable female SLE patients were recruited from a single site (Central Manchester). Serum 25(OH)D was measured by LC-MS and patients were classed as deficient (<20ng/ml) or replete (>30ng/ml). Patients were treated by their general practitioner according to local protocols (typically 400,000IU cholecalciferol over 10 days then 20,000IU weekly). Replete patients were not treated and acted as controls. Patients were assessed at baseline and after 3 months. Endothelial function was measured using flow-mediated dilatation (FMD) and expressed as endothelium dependent/endothelium independent (ED/EI) dilatation. Arterial stiffness (pulse-wave velocity, aPWV) was measured using Arteriograph. Cytokines were measured by ELISA. Disease activity was measured using the SLEDAI-2K and BILAG-2004 indices.

Results: We recruited n=22 vitamin D deficient patients and n=18 replete patients (median 25(OH)D 13.1 and 34.5ng/ml respectively). All patients were female and 36/40 (90%) had ≥4 ACR criteria. Deficient patients were younger (47.0 vs 57.9 years, p=0.007) and more likely to have a history of lupus nephritis (31.8% vs 5.6%, p=0.039) or require steroid (45.4% vs 5.6%, p=0.005) or immunosuppressant therapy (54.5% vs 11.1%, p=0.004).

FMD was strongly influenced by age and the baseline brachial arterial diameter. ED/EI in contrast was not related to either age or arterial diameter.

Serum 25(OH)D significantly increased in the deficient/treated group compared to the replete/untreated (median change 28.6 vs -0.62ng/ml, p<0.0001) and PTH significantly decreased (-8.6 vs 2.5pg/ml, p=0.039). There was no change in aPWV, disease activity, serum complement or cytokines (IL-6, TNFα, IP-10 or BAFF).

Change in 25(OH)D was strongly correlated with the change in ED/EI (r=0.650, p=0.006) in the treated group but not the replete group (r=-0.462, p=0.115) (figure). No association was seen between change in ED/EI and calcium, PTH or blood pressure. In an ordered logistic regression model the change in ED/EI remained associated with change in 25(OH)D after adjustment for age (OR 1.12 [1.02,1.24], p=0.017).

Conclusion: Increase in serum 25(OH)D significantly improved endothelial function over a short time period. This improvement was not due to changes in blood pressure or lupus disease activity. Vitamin D may be a novelvasculoprotective agent for SLE patients even in the absence of active disease.

Assessment of Plaque Thickness and Area in Patients with SLE As Measures of Atherosclerosis - Associations with Disease Activity. Sara Croca[1], Maura Griffin[2], David Isenberg[3], Andrew Nicolaides[4] and Anisur Rahman[1]. [1]University College London, London, United Kingdom, [2]Vascular Screening and Diagnostic Centre, London, United Kingdom, [3]Arthritis Research UK Centre for Adolescent Rheumatology, University College London, London, United Kingdom, [4]University of Nicosia, Cyprus, Nicosia, Cyprus.

Background/Purpose: SLE is an independent risk factor for cardiovascular disease (CVD). Traditional risk stratification tools underestimate CVD risk in patients with SLE. Previous vascular ultrasound (US) studies have reported intima-media thickness (IMT) and presence of plaques in the carotid arteries of patients with SLE. However, some patients have femoral but not carotid plaques and alternative measures such as plaque thickness (pT) and plaque area (pA) may be more sensitive and informative than IMT.

Methods: We carried out carotid and femoral US of 100 patients fulfilling ACR classification criteria for SLE with no history of CVD. Mean IMT of the common carotid artery (CCA) was measured using automated software. Plaque was defined as a focal structure of thickness >1.2 mm from media-adventitia interface to intima-lumen interface. Where plaque was present, pT was measured using manual callipers and pA measured using image analysis software.

Statistical analysis using Spearman's correlation was carried out to investigate association between IMT, pA, pT and auto-antibody profile, lipids and homocysteine levels, blood pressure (BP), treatment and smoking status. Anti-apolipoprotein A1 (anti-ApoA1) IgG and IgM and anti-HDL antibodies were measured using direct ELISA protocols. Other clinical/serological data were obtained from medical records/patient interview.

Results: No patients had thickened CCA IMT (>0.1cm) but 37 had plaque in at least one site and 15 had plaque in ≥3 sites. The factors associated with pT, pA and CCA IMT are summarized in Tables 1 and 2. Whereas CCA IMT was primarily influenced by traditional risk factors such as BP, total cholesterol and LDL, pT and pA correlated with a wider range of variables including higher disease activity, elevated homocysteine, cholesterol:HDL ratio and IgG anti-HDL level.

Table 1: Factors associated with CCA IMT

Variable	Spearman Correlation (r^2)	p-value
Age at scan (yrs)	0.55	<0.0001
Disease duration (yrs)	0.39	0.02
Systolic BP	0.4	<0.0001
Diastolic BP	0.22	0.03
Mean BP	0.32	0.001
Number of sites with plaque	0.39	<0.0001
Total plaque area (sq mm)	0.40	<0.0001
Total plaque thickness (mm)	0.40	<0.0001
Total cholesterol (mmol/l)	0.36	0.0002
LDL (mmol/l)	0.31	0.002
Anti-apoA1 IgG in early disease	0.24	0.02

Table 2: Factors associated with plaque area and thickness

Variable	Correlation with plaque area (Spearman r^2)	p-value	Correlation with plaque thickness (Spearman r^2)	p-value
Age at scan (yrs)	0.56	<0.0001	0.58	<0.0001
Disease duration (yrs)	0.29	0.004	0.32	0.0001
Systolic BP	0.27	0.007	0.29	0.004
No of sites with plaque	0.99	<0.0001	0.99	<0.0001
Mean CCA IMT	0.39	<0.0001	0.39	<0.0001
Anti-La positivity	-0.33	0.001	-0.33	0.001
Persistent moderate/high disease activity	0.21	0.035	0.18	0.07
Persistent low disease activity	-0.21	0.035	-0.18	0.07
Serum homocysteine	0.31	0.04	0.31	0.05
Serum triglyceride	0.27	0.007	0.28	0.005
Total cholesterol/HDL ratio	0.25	0.013	0.23	0.02
IgG anti-HDL	0.21	0.03	0.21	0.039
No of BILAG A flares of disease activity	0.23	0.023	0.21	0.03

Conclusion: Although some authors have hypothesised a link between disease activity and atherosclerosis in SLE, this has not been shown convincingly in studies of IMT. More sensitive measurements such as pA and pT may help in linking disease activity and serology with atherosclerosis in SLE. This could help us target CVD risk reduction therapies to appropriate patients.

The Protective Effects of Statins for Thrombosis in Patients with Systemic Lupus Erythematosus Positive for Antiphospholipid Antibodies. Toshiyuki Watanabe, Kenji Oku, Olga Amengual, Eri Sugawara, Ryo Hisada, Kazumasa Ohmura, Tomoko Fukui, Sanae Shimamura, Ikuma Nakagawa, Atsushi Noguchi, Haruki Shida, Michihito Kono, Yuka Shimizu, Takashi Kurita, Toshiyuki Bohgaki, Tetsuya Horita, Shinsuke Yasuda and Tatsuya Atsumi. Hokkaido University Graduate School of Medicine, Sapporo, Japan.

Background/Purpose: Thrombosis is one of the most frequent manifestations in patients with systemic lupus erythematosus (SLE). Although antiphospholipid antibodies (aPL) are well recognized risk factors for thrombosis in SLE, few studies have addressed the potential effect of additional factors in the development or in the prevention of thrombosis in those patients.

Objective: To identify risk and protective factors for developing thrombosis in SLE with or without aPL.

Methods: One hundred fifty two newly diagnosed consecutive patients with SLE without history of thrombotic events were recruited at Hokkaido University Hospital from April, 1997 to February, 2014. All patients, 138 woman and 14 men, fulfilled the 1997 American College of Rheumatology revised criteria for SLE. Seventy-eight patients (51.3%) had aPL. The development of thrombosis and death caused by thrombosis were defined as the study endpoint.

Results: The median follow-up period in all patients was 58 months (IQR 20–115 months). In 78 patients with aPL, the median follow-up period was 69 months (IQR 27–118 months). Fifteen patients with aPL (19.2%) developed thrombosis during the follow-up period. Cerebral infarction (CI) was observed in 6 patients, pulmonary embolism (PE) in 5 and deep vein thrombosis (DVT) in 6. Multivariate analysis with Cox's proportional hazards model showed that older age at SLE onset and anticardiolipin antibodies (aCL)-IgG positivity, (HR 1.80 for every ten age, 95%C.I. 1.11–2.94) and (HR 6.87, 95%C.I. 1.74–27.1), respectively, are statistically significant risk factor for thrombosis. Statin therapy appears as a statistically significant protective factor against thrombosis (HR 0.12, 95%C.I. 0.01–0.97) (Figure 1.). Disease activity, anti-thrombotic drug therapy and classical risk factors for atherosclerosis were not related to thrombosis. On the other hand, in 74 patients without aPL (median follow-up period 46 months, IQR 15–110 months), 7 patients (9.5%) developed thrombosis. CI was observed in 4 patients, intestinal infarction in 1, PE in 1 and DVT in 1. With Cox's proportional hazards model, older age at SLE onset represents a statistically significant risk for thrombosis (HR 2.73 for every ten age, 95%C.I. 1.17–6.37).

Conclusion: This study suggests that, in aPL positive patients, the late disease onset and the presence of aCL-IgG represent additional risk factors for thrombosis. Statin treatment appeared as a thrombotic protective factor.

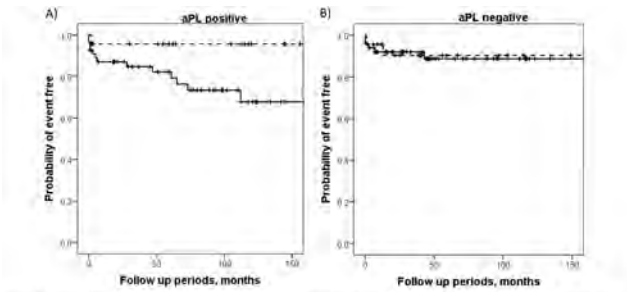

Figure 1. Kaplan-Meier survival curves for thrombotic events in patients treated (dashed line) and not treated (solid line) with statins. A) antiphospholipid antibodies (aPL) positive patients (Log-rank p=0.021) and B) aPL negative patients (Log-rank p=0.881)

Coronary-Artery Atherosclerosis in Males with Systemic Lupus Erythematosus. Juanita Romero-Díaz[1], Sergio Criales-Vera[2], Eric Kimura-Hayama[2], Roberto Ivan Acosta-Hernandez[1], Maricruz Dominguez-Quintana[1] and Jorge Sánchez-Guerrero[3]. [1]Instituto Nacional de Ciencias Medicas y Nutricion, Mexico City, Mexico, [2]Instituto Nacional de Cardiologia, Mexico City, Mexico, [3]Mount Sinai Hospital and University Health Network, Toronto Canada, Toronto, ON.

Background/Purpose: Premature coronary-artery atherosclerosis is a major cause of morbidity and mortality in females with systemic lupus erythematosus (SLE), but little is known about the frequency, extent, risk-factors, and burden of coronary-artery disease in male patients.

Methods: We studied 96 male SLE patients attending our outpatient clinic and 94 healthy males w/o preexisting coronary heart disease, matched by age and race. Patients and controls had a standardized assessment of demographic characteristics and traditional cardiovascular risk factors. In addition, patients had an evaluation of lupus characteristics, medications, and laboratory tests including immunological, extended lipid profile, homocystein, and hsCRP. All patients and healthy controls were screened for coronary-artery calcifications using a 64-slice Multidetector Computed Tomography and the extent of calcification was measured by means of the Agatson score.

Results: Mean (SD) age of lupus patients and controls was 34.9 (10.5) and 35.3 (9.8) years, respectively. Coronary-calcifications were detected in 18 patients (18.8%) and 7 (7.5%) controls (OR 2.87, 95% CI 1.07–8.53). Median calcium score in patients was 68.75 (4.6–755.6), and 7.7 (1.1–140.2) in controls. Calcifications in lupus patients and controls were detected since age 31–40 and 41–50 years, respectively. In two patients, calcifications were detected within 3 years of diagnosis. Patients had more often hypertension (39% vs 4%, P<0.001) and higher levels of homocysteine (14.4+ 10.1 vs 9.3 + 2.5, P<0.001) than controls.

In comparison to patients w/o calcifications, patients with calcifications were older (32.7 + 9.5 vs 44.8 + 7.9 years, P<0.001), had a wider waist (89.1 + 14.4 vs 96.4 + 13.7 cm, P=0.008), higher systolic blood pressure (114.9 + 9.7 vs 121.7 + 12.0, P=0.02), higher Framingham risk score [2.2(1–17) vs 7.9(1–30), P<0.001] and current smokers (14% vs 39%, P=0.04). Lupus duration was longer (7.1 + 5.7 vs 13.4 + 9.6 years, P=0.01), had accrued more damage (SDI 1.0 + 1.2 vs 2.3 + 1.6, P=0.002), higher cumulative dose of prednisone [20.1 (0–56.1) vs 49.9(8.5–106.5 grams, P=0.001], and received Azathioprine more often (51% vs 78%, P=0.04). No difference was observed in lupus activity during the course of the disease, clinical manifestations, autoantibodies, and use of anti-malarials and aspirin.

Logistic regression adjusting by disease duration showed an independent association of age (OR 1.23, 95% CI 1.04–1.45) and SLICC score (OR 3.21, 95% CI 1.31–7.86) with calcifications.

Conclusion: Coronary-artery calcifications are more common, extensive, and present at younger age in male lupus patients than in the general population. Their association to traditional risk-factors and lupus characteristics, particularly chronic damage, raise the possibility of identifying modifiable risk-factors.

Prevalence and Predictors of ECG Cardiovascular Abnormalities in Lupus Patients. Zahi Touma[1], Paula Harvey[2], Dafna D. Gladman[1], Dominique Ibanez[1], Arthy Sabapathy[1] and Murray B. Urowitz[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]Women's College Hospital, Toronto, ON.

Background/Purpose: Patients with lupus are at increased risk for cardiovascular disease. Previous studies on healthy adults showed that abnormalities detected on resting electrocardiography (ECG) are associated with an increased risk for subsequent cardiovascular (CV) events. These **ECG-CV** abnormalities are: ST-segment and/or T-wave abnormalities, left ventricular hypertrophy (LVH), left-axis deviation and bundle branch block (BBB).

We aimed to determine the prevalence of ECG-CV abnormalities in a cohort of lupus patients and to examine the factors associated with ECG-CV abnormalities.

Methods: A standard digitally recorded 12-lead resting supine ECG was performed on consecutive patients attending the Lupus Clinic between October 2012-May 2014. Coded ECGs were reviewed and interpreted by a cardiologist using the Minnesota code classification system.

The frequency of the ECG-CV abnormalities was determined. In the univariate analysis normal ECG and ECG-CV abnormalities were compared (T-test and chi-squared test). Covariates with p<0.1 in addition to age, sex and ethnicity were evaluated with a stepwise logistic regression model to predict the ECG-CV abnormalities.

Results: 461 patients were studied. Of the 461 resting ECGs, 39.5% were abnormal: 7.6% axis deviation, 3.5% atrial enlargement, 11.3% arrhythmia and 6.7% pathological Q waves. ECG-CV abnormalities were present in 120 patients and included: ST-segment abnormalities and/or T-wave abnormalities in 17.4%, LVH in 8.9%, left-axis deviation in 4.1% and BBB in 6.3%.

Of the 120 patients with ECG-CV abnormalities, 65.0% had 1 abnormality, 26.7% had 2, 6.7% had 3 and 1.7% had all 4 abnormalities.

In the univariate analysis, in the group of ECG-CV abnormalities, patients were older, had a longer lupus duration, higher damage index, higher cumulative dose of corticosteroids, history of previous CAD event, presence of Coombs', La, LE cells, SCL70 and anti phospholipid lupus antibodies (table 1).

In the multivariate analysis, older age (OR =1.03; 95% CI: 1.01, 1.05; p=0.002), presence of damage (OR= 1.33; 95% CI: 1.17, 1.52; p<0.0001) and positive Coombs' (OR=2.37; 95% CI: 1.34, 4.21; p=0.003) were associated with ECG-CV abnormalities.

Conclusion: Of 461 resting ECGs 39.5% were abnormal. 26% had ECG-CV abnormalities. Older age, damage and Coombs' test were associated with ECG-CV abnormalities. These patients are at higher risk of developing CV events.

Table 1. Comparison of normal ECG and ECG-CV abnormalities

	Normal ECG (n=279)	ECG-CV abnormalities (n=120)	p

Cardiac Magnetic Resonance Imaging in Systemic Lupus Erythematosus. Alexa Meara[1], Namrata Dhillon[2], Kimberly Fisher[3], Paul Jensen[4] and Stacy P. Ardoin[5]. [1]The Ohio State University, Columbus, OH, [2]University of Pittsburgh Medical Center, Pittsburgh, PA, [3]The Ohio State University Wexner Medical Center, Columbus, OH, [4]The Ohio State University, Nationwide Children's Hospital, Columbus, OH, [5]Ohio State University College of Medicine, Columbus, OH.

Background/Purpose: Cardiac complications of SLE are common and include both acute and chronic manifestations: pericarditis, myocarditis, valvular disease, pulmonary hypertension, atherosclerosis, ischemic and non-ischemic cardiomyopathy. Cardiovascular magnetic resonance (CMR) imaging is a non-invasive, non-radiating imaging modality which can evaluate cardiac function and structure, myocardial inflammation, ischemia, and fibrosis. In this study we sought to assess indications for CMR use and CMR findings in SLE patients.

Methods: Chart review was performed for all patients with SLE diagnosis who underwent CMR for clinical indications from 2004 to 2014 at a single academic center. CMR results, cardiac risk factors, medications, SLE history, laboratory results, SLEDAI-2K (within 30 days of CMR) were recorded. Descriptive statistics were performed.

Results: During this time period, 31 SLE patients underwent 48 CMR. The patients were 45 ± 11.7 years, 77% female, duration SLE 9.5 ± 9.5 years, SLEDAI-2K5.5 ± 5.9, and 13% had antiphospholipid antibody syndrome. (Table 1). The following cardiovascular risk factors were present: diabetes mellitus (23%), hypertension (58%), dyslipidemia (16%), congestive heart failure (16.1%), current smoker (27%), history of myocardial infarction (6%). Clinical indications for obtaining CMR were chest pain (40%), dyspnea (4%), abnormal echocardiogram (31%), arrhythmia (4%) and other/unknown (12%). Half of the patients who underwent CMR stress testing had abnormal perfusion (Table 2). The most common abnormalities on non-stress CMR testing included abnormal myocardial T2 signal (29.8%), late gadolinium enhancement (21.3%), pericardial thickening (14.6%), and valvular abnormalities (21.7% aortic, 23.9% mitral, 17.4% tricuspid).

Conclusion: Cardiac complications of SLE are common and impart significant morbidity and mortality. In this study, CMR imaging identified several abnormalities not evident on other cardiovascular (CV) imaging modalities including increased T2 signal in myocardium (suggesting myocardial inflammation) and late gadolinium enhancement (suggesting fibrosis from prior ischemia or inflammation). CMR allows simultaneous evaluation of cardiac function, structure, inflammation, and fibrosis and, with stress imaging, ischemia. As SLE cardiac complications are myriad, CMR is a promising tool to assess the breadth of potential CV complications in the SLE patient presenting with CV symptoms.

Table 1 SLE Participant Characteristics

Age, mean ± SD years	44.9 ± 11.6
Sex, no. (%) female	31 (77.4%)
SLE Characteristics	
Duration SLE mean ± SD years	9.52 ± 8.8
SLEDAI-2K (within 30 days of CMR), mean ± SD	5.5 ± 5.9
History of lupus nephritis, no. (%)	5/31 (16.7%)

Risk of Cardiovascular Events in Patients with Cutaneous Lupus Erythematosus: A Population-Based Study. Abha G. Singh, Cynthia S. Crowson, Mark Davis, Hilal Maradit Kremers, Eric L. Matteson and Vaidehi Chowdhary. Mayo Clinic, Rochester, MN.

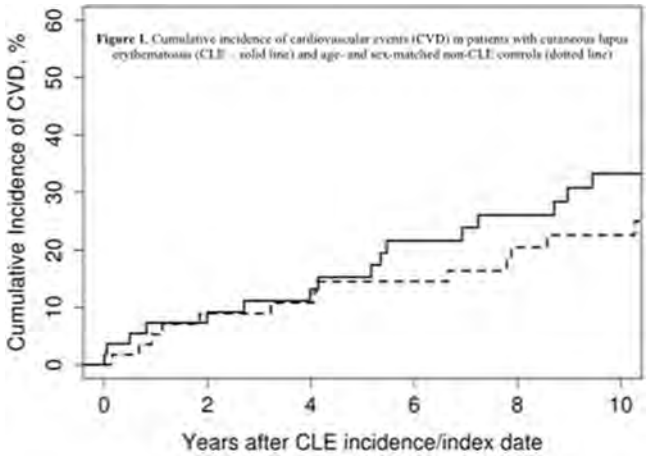
Background/Purpose: Systemic inflammation is an independent risk factor for atherosclerosis; chronic inflammatory diseases such as systemic lupus erythematosus (SLE) are associated with increased risk of cardiovascular disease (CVD). The pathogenesis of cutaneous lupus erythematosus (CLE) is similar to SLE, with complex gene-environment interactions, autoimmunity and immune-mediated cutaneous damage. It is not known whether CLE is associated with an increased risk of CVD. Hence, we estimated the cumulative incidence of CVD in a population-based cohort of patients with CLE, and compared the risk with an age- and sex-matched cohort without CLE.

Methods: Patients with subtypes of CLE (discoid, subacute cutaneous lupus, lupus panniculitis and bullous lupus) were identified from a population-based cohort from 1965–2005. Age- and sex-matched subjects without CLE were selected from the same population. Cardiovascular events (coronary artery disease [CAD], myocardial infarction, angina, heart failure, stroke,

transient ischemic attack, peripheral arterial disease) were collected via medical record review for a random sample of 66 of the 156 patients with CLE and the non-CLE subjects matched to them. The cumulative incidence of CVD was estimated using Kaplan-Meier methods. Cox models were used to estimate the relative risk of CVD in patients with CLE compared to non-CLE after adjustment for age, sex and calendar year.

Results: We identified 66 patients with CLE (mean age at time of CLE diagnosis, 55±14y; 64% females; 68% Caucasian; mean BMI, 27.3±7.2 kg/m^2; 35% current smokers), who were followed over a median follow-up of 12.0 years (interquartile range [IQR], 8.1–17.3y). Positive antinuclear antibody, anti-SSA and anti-SSB were seen in 48%, 47% and 18% of patients with CLE, respectively. Median ESR was 11 mm/hour (IQR, 4.0–25.0) and CRP 2.9 mg/dL (IQR 1.5–3.9). In this cohort, 9% were diabetic, 59% were hypertensive, 35% had hyperlipidemia and 8% had a family history of CAD; these risk factors were comparably distributed in 66 age- and sex-matched controls, except a higher prevalence of hyperlipidemia (53%, p=0.036). During follow-up, we observed 24 cardiovascular events (including 7 cases of myocardial infarction) in patients with CLE. The cumulative 1-, 5- and 10-year incidence of cardiovascular events after diagnosis of CLE was 7.3%, 15.3% and 33.2%, respectively. As compared to subjects without CLE, the risk of all cardiovascular events (hazard ratio [HR], 1.37; 95% confidence interval [CI], 0.77–2.49; p=0.29) or myocardial infarction (HR, 1.18; 95% CI, 0.77–2.49; p=0.29) was not significantly higher in patients with CLE (Figure).

Conclusion: The 10-year risk of cardiovascular events in a population-based cohort of patients with CLE is 33%. This risk is not increased as compared to age- and sex-matched non-CLE controls.



Disclosure: A. G. Singh, None; **C. S. Crowson**, None; **M. Davis**, None; **H. Maradit Kremers**, None; **E. L. Matteson**, None; **V. Chowdhary**, None.

Angiogenic and Antiangiogenic Factors in Patients with Systemic Lupus Erythematosus. Guilherme Ramires de Jesus[1], Camila Souto Oliveira[2], Flavia Cunha dos Santos[2], Nilson Ramires de Jesus[2], Luis Cristovao Porto[2], Roger A. Levy[3] and Evandro Mendes Klumb[2]. [1]Department of Obstetrics, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [2]Hospital Universitario Pedro Ernesto, Rio de Janeiro, Brazil, [3]Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil.

Background/Purpose: SLE mainly affects young women and pregnancy in these patients has significant morbidity and mortality. Clinical and laboratory findings in lupus nephritis are similar to those found in patients with preeclampsia (PE), specifically hypertension, proteinuria and edema. It has been proposed the use of angiogenic factors, such as vascular endothelial growth factor (VEGF) and placental growth factor (PlGF), and antiangiogenic factors, as soluble Fms-like tyrosine kinase-1 (sFlt-1), for the differential diagnosis between these two conditions, however available data in the literature about these cytokines in non-pregnant SLE patients are inconsistent. This study was designed to evaluate whether there are differences between serum levels of VEGF, PlGF and sFlt-1 in non-pregnant SLE patients with and without systemic disease activity and whether there are differences in these factors when comparing SLE patients with healthy women.

Methods: 54 women with SLE (according to ACR classification criteria) followed at an outpatient clinic of rheumatology were included. They had no other autoimmune disease diagnosed and were divided according to disease activity. 30 patients had inactive disease (mean SLEDAI: 0.7), and 24 had active disease (mean SLEDAI: 11.6). Twenty-three women in this latter group had active nephritis, while 20 patients with inactive disease had history of lupus nephritis. Control group consisted of 34 healthy women who attended a gynecology outpatient clinic.

Results: The mean values of VEGF, PlGF and sFlt-1 of all groups are described on Table 1. Considering the three studied cytokines, the SLE patients had significantly higher mean serum levels than the control group (VEGF: 319.0 + 226.0 × 206.2 + 119.4, p=0.02; PlGF: 42.2 + 54.1 × 13.6 + 21.6, p=0.02; sFlt-1: 107.9 + 49.2 × 70.2 + 95.0, p=0.01). The group of patients with active disease also had significantly higher mean levels of all three factors than controls (VEGF: 331.0 + 216.8 × 206.2 + 119.4, p=0.02; PlGF: 41.2 + 47.3 × 13.6 + 21.6, p=0.02; sFlt-1: 120.5 + 42.4 × 70.2 + 95.0, p=0.02), whereas no statistical difference was found between the group with inactive SLE and the control group. The mean sFlt-1 levels were higher in patients with active SLE than the mean levels of patients with inactive disease (120.5 + 54.9 × 97.8 + 42.4, p=0.02), but there was no significant difference in mean serum of VEGF and PlGF levels between these two groups.

Conclusion: Patients with active SLE have higher levels of VEGF, PlGF and sFlt-1 than controls. sFlt-1 was also higher in patients with active SLE than patients with inactive SLE. A better understanding of angiogenic and antiangiogenic factors in patients with SLE provided by this study allows the analysis of these cytokines in pregnant woman with SLE and possibly their subsequent application as differential method between PE and lupus nephritis.

Carotid Intima-Media Thickness and Plaque in Mexican Mestizos with Systemic Lupus Erythematosus: A Case-Control Study. Iris J. Colunga-Pedraza, Dionicio A. Galarza-Delgado, Alberto Cardenas-de La Garza, Ana L. Sanchez-Nuñez, Samantha L. Segarra-Linares, Rocío A. Carrillo-Palacios, David Vega-Morales, Fernando Góngora-Rivera and Mario Alberto Garza-Elizondo. Hospital Universitario UANL, Monterrey, Mexico.

Background/Purpose: Systemic lupus erythematosus (SLE) patients are at risk of premature cardiovascular disease (CVD). The specific reason of this situation is still debatable. Subclinical atherosclerosis prevalence and characteristics in Mexican mestizo patients with SLE is unknown. The objective of this study is to evaluate the presence of carotid plaque (CP) and carotid intima-media thickness (CIMT) in Mexican mestizos with SLE and to compare them to a control group.

Methods: An observational, cross-sectional study in a Mexican mestizo population was realized. 69 SLE patients, age ranging from 18 to 53 years, and 69 age-sex-diabetes-hypertension matched controls were included. Their demographic profile, biochemical, anthropometric measurements, traditional risk factors for atherosclerosis and disease-related factors were recorded. Carotid evaluation was realized by B mode carotid Doppler ultrasonography. CP was defined as presence of focal thickening at least 50% greater than that of the surrounding wall or CIMT ≥ 1.2 cm. The CIMT was measured at 1 cm proximal to the start of the carotid bulb dilatation of the common carotid artery in the far wall. The maximum CIMT value was recorded.

Results: Demographic differences between groups included a higher prevalence of CVD familiar history in the SLE group (p≤0.001), higher diastolic and systolic blood pressure in the SLE group (p≤0.001), and higher weight in the control group (p=0.013). Only 2 subjects of each group had diagnosis of hypertension, and 1 subject of each group had diagnosis of diabetes at the time of the enrollment to the study.

The mean CIM value in SLE patients was 0.514 ± 0.098 mm while the control group had a mean of 0.518 ± 0.108 mm (p=0.830). CP was found in 11 patients with SLE and 4 in the control group (p=0.360). SLE patients with CP had lower levels of total cholesterol (p=0.021), low density lipoprotein cholesterol (p=0.030) and glucose (0.003) compared with the control group with CP.

Patients in the SLE group with steroid use for more than five years were more likely to have CP or increased CIMT (p=0.023). Use of synthetic DMARD was associated with lower probability of CP or increased CIMT (p=0.048). This association was not found with biological DMARD (p=0.422).

Conclusion: Our study has shown that despite high prevalence of traditional cardiovascular risk factors among Mexicans SLE patients, the CP/CIMT findings were not completely attributable to them. These findings

agree with most previously published reports in other populations including Asians, Caucasians and African-Americans. The actual evidence suggests that SLE itself is an independent predictor of atherosclerosis. The systematic carotid evaluation could be an important surrogate biomarker of premature atherosclerosis in our patients, and we recommend their systematic use.

Long-Term Efficacy and Safety of Pulse Cyclophosphamide for Neuropsychiatric Systemic Lupus Erythematosus: A Two-Centre Experience. Antonis Fanouriakis[1], Cristina Pamfil[2], Laura O. Damian[3], Ioana Felea[3], Emmanuel Mihali[3], Ileana Filipescu[2], Theofanis Karageorgas[4], Prodromos Sidiropoulos[1], Simona Rednic[2], George Bertsias[1] and Dimitrios Boumpas[4]. [1]University of Crete, Heraklion, Greece, [2]University of Medicine and Pharmacy, Cluj-Napoca, Romania, [3]Emergency Clinical County Hospital Cluj, Cluj-Napoca, Romania, [4]"Attikon" University Hospital of Athens, Athens, Greece.

Background/Purpose: Cyclophosphamide (CYC) is often used in severe neuropsychiatric systemic lupus erythematosus. However, data on its use rely on small case series and a single randomized controlled trial with a limited number of patients and short follow-up.

Methods: SLE patients with active neuropsychiatric involvement from two tertiary European centers, who received CYC during the past 15 years and had regular follow-up were identified. Outcome at most recent follow-up visit (Likert scale from 1: remission to 6: worsening) and recurrences of the neuropsychiatric manifestation were assessed. Long-term complications of CYC therapy were also documented, with a focus on malignancies and severe infections.

Results: CYC was administered in 44 non-thrombotic neuropsychiatric events experienced by 43 patients (Table 1). Median age at NPSLE occurrence was 45 years (range 14–68 years), time lag from SLE onset was 1 year (range 0–7 years), and positivity for antiphospholipid antibodies was 42.9%. Most common indications were psychosis (9 cases), stroke (6 cases) and myelopathy, seizure disorder and polyneuropathy (5 cases each). In 95% of cases, CYC was administered as monthly intravenous pulses (the remaining 5% received oral CYC) and was chosen as first line immunosuppressive therapy in 36/44 events (81.8%). In the remaining 8 cases, CYC was used as second-line after non-response to other immunosuppressants [azathioprine (AZA) in 7/8 and steroid monotherapy in 1/8)]. The median number of CYC pulses was 8 (range 2–18) with a median cumulative dose of CYC of 7.1 gr (range 2–27 gr). After a median follow-up of 40.0 months (range 1–173), 85.4% of events had favorable outcome (Likert score <4, indicating at least moderate improvement from baseline). Recurrences of the neuropsychiatric manifestation occurred in 13.2% of events. No difference in outcome was observed when CYC was given as first or second line therapy. A total of 4 events (stroke, aseptic meningitis, myelopathy and psychosis) did not respond to CYC and were treated with rituximab as rescue therapy. In cases that responded to CYC after the induction phase, maintenance therapy consisted of AZA in 73.7%, bimonthly and quarterly pulses of CY in 21.0%, and mycophenolate mofetil in 5.3%. No malignancies were observed in our cohort, yet there were two cases of severe infections (one HBV reactivation and one fatal case of disseminated tuberculosis).

Conclusion: In a large case-series with long follow-up, cyclophosphamide was effective for severe non-thrombotic NPSLE but vigilant monitoring for infections is warranted.

Table 1

Manifestation (n)	Cumulative CYC dose (gr), median (IQR)	Duration of follow-up (months), median (IQR)	Outcome (Likert scale), median (IQR)	Major side-effects
Psychosis (9)	6.6 (6.3)	58 (99)	2.0 (2.7)	1 HBV reactivation
Stroke (6)	9.0 (9.8)	32 (100)	2.0 (3.0)	(−)
Myelopathy (5)	7.2 (8.1)	35 (69)	2.0 (1.5)	(−)
Seizures (5)	9.0 (10.3)	30 (52)	1.0 (2.0)	(−)
Polyneuropathy (5)	9.6 (10.4)	48 (35)	2.0 (1.5)	(−)
Mononeuritis multiplex (4)	4.2 (11.8)	90 (66)	1.0 (0.7)	(−)
Cranial neuropathy (3)	22.1*	67*	3.0*	(−)

Background/Purpose: Neuropsychiatric (NP) events in patients with SLE include mood disorders. We determined the frequency, characteristics, clinical and autoantibody associations of mood disorders in a large, multiethnic/racial, inception cohort of SLE patients.

Methods: A prospective study of new onset SLE patients was performed by an international network of 32 academic centers in 11 countries. Patients were evaluated at enrollment and annually for up to 14 years. Data were

collected at each assessment on demographic and clinical manifestations, medications, SLE disease activity index-2000 (SLEDAI-2K) and Systemic Lupus International Collaborating Clinics (SLICC)/ACR damage index (SDI). Nervous system events were recorded using the ACR case definitions for 19 NP syndromes. These include mood disorders, determined by clinical judgment (based on Diagnostic and Statistical Manual, DSM-IV, criteria) and consisting of: (i) major depressive-like episode, (ii) mood disorder with depressive features, (iii) mood disorder with manic features and (iv) mood disorder with mixed features. Lupus anticoagulant, IgG autoantibodies to cardiolipin, β_2-glycoprotein I, ribosomal P and NMDA glutamate receptor 2 were measured at enrollment. Pre-defined rules determined the attribution of NP events to SLE and non-SLE causes. Cox regression was used to examine the associations of various factors with the occurrence of first mood disorder and first SLE-attributed mood disorder.

Results: Of 1,827 SLE patients, 88.9% were female, 48.9% Caucasian with mean±SD age 35.1±13.3 years. At enrollment, mean SLE duration was 5.6±4.8 months, SLEDAI-2K was 5.3±5.4, SDI was 0.31±0.74. The mean follow-up was 4.73±3.45 years. Over the study 863 (47.2%) patients had 1,627 NP events of which 503 (30.9%) were attributed to SLE. Mood disorders were the second most frequent NP event: 232 patients experienced 256 mood disorders of which 98/256 (38.3%) were attributed to SLE. The predominant mood disorders were major depressive-like episodes [134/256 (52.3%)], followed by mood disorder with depressive features [114/256 (44.5%)] and the remaining two mood disorders accounted for only 8/256 (0.03%) events. The estimated cumulative incidence of any mood disorder and any SLE-attributed mood disorder after 10 years was 17.7% (95%CI=[15.1%,20.2%]) and 7.9% (95%CI=[6.0%,9.9%]), respectively. A total of 110/256 (43.0%) mood disorders occurred in isolation without other concurrent NP events. Multivariate regression revealed a greater risk of mood disorder in patients with other concurrent NP events ($p \leq 0.01$) and a lower risk with Asian race/ethnicity ($p=0.01$) and immunosuppressive drugs taken in the absence of antidepressants ($p=0.003$). No association was found between mood disorders and SLEDAI-2K, SDI scores or lupus autoantibodies, whether or not the analysis was confined to mood disorders attributed to SLE.

Conclusion: Mood disorders are the second most frequent NP event in SLE patients and about one third are attributable to lupus. The lack of association of most mood disorders with global SLE disease activity, cumulative organ damage and lupus autoantibodies emphasize their multifactorial etiology and a role for non-lupus specific therapies.

Predictors of Incident Seizure in Systemic Lupus Erythematosus. Xiangyang Huang[1], Laurence S. Magder[2] and Michelle Petri[3]. [1]Sichuan University School of Medicine, Sichuan, China, [2]University of Maryland, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: We identified the rate and risk factors for first occurrences of seizure based on a large closely followed longitudinal cohort of patients with systemic lupus erythematosus.

Methods: Rates of incident seizure were calculated overall and in subgroups defined by demographic and clinical variables. Adjusted estimates of association of risk factors were derived using pooled logistic regression.

Results: Of 2203 patients with no history of seizure prior to SLE diagnosis, 157 (7.1%) had the first seizure occurrence at the time of (37 patients, 1.63%) or after the diagnosis of (120 patients, 5.44%) SLE. The rate of incident seizure was 4.9 per 1000 person-years. The risk of seizure occurring around the time of SLE diagnosis was higher in patients with a history of malar rash ($p = 0.002$), proteinuria ($p = 0.004$), and psychosis ($p < 0.000$). Multivariable analysis of the first seizure occurring after the diagnosis of SLE showed that history of low C3 (RR = 1.763, $p = 0.0078$), psychosis (RR = 2.432, $p < 0.0001$), cranial or peripheral neuropathy (RR = 2.212, $p = 0.0043$), anti-Smith (RR = 1.518, $p = 0.0551$), renal involvement (urine dipstick protein positive 3+) (RR = 2.888, $p = 0.0177$) and current prednisone dose (RR = 9.960, $p < 0.0001$) were independently associated with a higher risk of incident seizure. SELENA-SLEDAI was not predictive and hydroxychloroquine was not protective after adjusting for the other variables in the model.

Conclusion: Seizure in SLE is multi-factorial. The risk of seizure in SLE is independently increased in those patients with prior psychosis, neuropathy, proteinuria, anti-Sm, low C3 and current corticosteroid use. Anti-Sm is of particular interest as it has also been incriminated in other CNS-SLE syndromes.

Prednisone Is a Risk Factor for Incident Depression in Systemic Lupus Erythematosus. Xiangyang Huang[1], Laurence S. Magder[2] and Michelle Petri[3]. [1]Sichuan University School of Medicine, Sichuan, China, [2]University of Maryland, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: Depression affects as many as 30% of SLE patients. Most studies of risk factors for depression among SLE patients have been cross-sectional, and thus unable to identify risk factors prospectively. The aim of this study was to identify the risk factors that preceded incident depression in a large prospective longitudinal cohort of patients without a history of depression.

Methods: A prospective study was performed using data from the Hopkins Lupus Cohort. Demographic variables, SLE manifestations, laboratory tests, Physician's Global Assessment (PGA), Safety of Estrogens in Lupus Erythematosus National Assessment-SLE Disease Activity Index (SELENA-SLEDAI), cumulative organ damage (SLICC/American College of Rheumatology Damage Index (SDI) and depression events were recorded at enrollment and each quarterly visit. A patient was considered to have depression if (1) there was a record of persistent depression (two or more mentions of depression separated by several weeks in rheumatology clinic notes) and/or a diagnosis of affective disorder was made by a psychiatric professional and (2) treatment for those symptoms with psychotherapy or antidepressant medications was documented. Rates of incident depression were calculated overall, and in subgroups defined by demographic and clinical variables. Adjusted estimates of association were derived using pooled logistic regression.

Results: The analysis was based on 1609 cohort members who did not have a history of depression prior to joining the cohort. Of these, we found that 282 (17%) experienced a first depression episode during follow-up. The incidence of depression was 29.7 episodes per 1000 person years. In the multivariable analysis, recent SLE diagnosis, non-Asian ethnicity, disability, cutaneous activity, longitudinal myelitis and higher doses of prednisone were independent predictors of incident depression (Table 1).

Table 1. Independent predictors of incident depression in the Hopkins Lupus Cohort based on a multivariate model

Variables	Comparison	Adjusted Rate Ratio (95% Confidence Interval)	P-value
Time since SLE dx	Per 10 year difference	0.7 (0.5, 0.9)	0.0006
Ethnicity	East Asian vs. others	0.1 (0.01, 0.8)	0.031
Disability	Yes vs. no	1.4 (1.0, 1.8)	0.034
Income	Income >100,000	0.7 (0.5, 1.1)	0.15
Year of enrollment	Year after 2005	0.6 (0.5, 0.8)	0.0008
Recent Cutaneous activity	Some vs. none	1.7 (1.2, 2.2)	0.0008
History of longitudinal myelitis	Yes vs. no	4.5 (1.6, 12.2)	0.0033
Recent dose of prednisone	20 mg/day+ vs. less	2.0 (1.3, 2.9)	0.0006

Conclusion: These results suggest that depression in SLE is multifactorial, with only certain types of SLE activity (skin and myelitis) playing a role. Interestingly, prednisone exposure appeared to increase the risk, even after adjustment for disease activity. This provides yet another motivation for prednisone sparing in management of SLE patients.

"Point of Care" Neurocognitive Testing for Neuropsychiatric Systemic Lupus Erythematosis (NPSLE). Debbie Rybak, Nicole Jordan, Noa Schwartz, Tamar Rubinstein, Bryan Freilich, Irene Blanco and Chaim Putterman. Albert Einstein College of Medicine, Bronx, NY.

Background/Purpose: There is currently no standardized tool to assess for NPSLE, and comprehensive neuropsychological testing can be lengthy and expensive. The Automated Neuropsychological Assessment Metric (ANAM) is a computerized battery of tests which has been successfully used to test cognitive function in SLE. The Cognitive Stability Index (CSI) is a web-based tool for assessing neurocognitive function which measures similar domains to the ANAM; however, it has not been studied in patients with SLE. Furthermore, in contrast to ANAM, CSI summary scores are not solely based on response speed, and thus may have a significant advantage over ANAM. Additionally, CSI can auto-invalidate subtests performed with insufficient patient effort. We aimed to evaluate and compare the utility of ANAM and CSI to assess NPSLE in the outpatient setting.

Methods: Subjects enrolled in the Einstein Lupus Cohort were eligible to participate. Subjects completed an NPSLE screening questionnaire (Mosca et al, 2011), with the presence of NPSLE defined by a screening score of >17 (NPSLE (+)). Subjects completed the ANAM and CSI tests (each taking ~30 minutes to complete). Eight cognitive domains were assessed by the ANAM and four by the CSI. The ANAM composite score measures average performance on all domains and is reported as a z score; four individual CSI factor scores for each cognitive domain are reported as standard scores (mean 100±15). Mann Whitney U tests assessed differences between NPSLE (+) and NPSLE (−) subjects. Pearson correlations were obtained for ANAM and CSI scores.

Results: 31 subjects completed the CSI, of which 20 also completed the ANAM. Of the 31 subjects, median age was 39 years, 94% were female, 42% were Hispanic and 63% were black. 74% were treated with corticosteroids (median prednisone dose 10 mg).

The median composite ANAM z-score, adjusted for sex/age, was −1.39 [−2.59, −0.98]. Median age-adjusted CSI standard factor scores ranged from 84–98 across the four cognitive domains. The median composite ANAM score was significantly different in the NPSLE(+) patients compared to those who were NPSLE(−) (p=0.03). Of the eight domains evaluated by ANAM, learning, attention and spatial working memory differed significantly by screening score. Of the four CSI domains, response speed and memory differed significantly between the NPSLE(+) and NPSLE(−) subjects (p=0.03 and 0.01, respectively). The composite ANAM score and CSI factor scores correlated significantly with each other. Finally, anti-dsDNA antibodies, C3, C4, SLEDAI scores, and medications were not significantly associated with NPSLE.

Conclusion: Median cognitive test scores on both ANAM and CSI fell below the standard mean for normals, independent of NPSLE status. CSI factor memory scores were significantly lower in NPSLE(+) subjects, independent of their response speed. Since this cannot be inferred from the ANAM composite score, CSI may provide a more specific assessment of cognitive functioning. Overall, NPSLE was associated with significantly lower scores on both ANAM and CSI, suggesting that these are valuable "point of care" tools that can be easily implemented in the clinical setting for the diagnosis of NPSLE.

Cognitive Impairment in SLE and Non-Criterion Anti-Phospholipid Antibodies. Michael Luggen[1], Gaurav Gulati[1], Rohan Willis[2] and Emilio B. Gonzalez[2]. [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]University of Texas Medical Branch, Galveston, TX.

Background/Purpose: The pathogenesis of cognitive impairment (CI) in patients with SLE is unknown. Anti-phospholipid antibodies (APL) have been implicated in some studies, but not in others. The APL which have been evaluated have variably included anti-cardiolipin (ACL) antibodies, lupus anticoagulant (LAC), and antibodies to beta-2 glycoprotein I (β2GPI). Few studies have examined all of the above and none has examined other APL (so-called non-criterion APL). We evaluated the association of CI with a broad spectrum of both criterion and non-criterion APL.

Methods: Subjects meeting the revised criteria for classification of SLE were recruited from 3 different patient populations. Cognitive function was assessed with the ANAM (Automated Neuropsychologic Assessment Metrics), a validated computer- based assessment tool which measures multiple cognitive domains. The TTS (total throughput score= number of correct responses/time) was used as the primary outcome measure. It was summed over 8 separate domains. Demographic, clinical, treatment, disease activity and damage information was obtained. The following APL of all three isotypes were assessed by ELISA using standardized techniques: ACL, anti-β2GPI, anti-phosphatidyl ethanolamine (aPE), anti-phosphatidyl choline (aPC), anti-phosphatidyl inositol (aPI), anti-phosphatidyl serine (aPS), anti-phosphatidyl glycerol (aPG), anti-phosphatidic acid (aPA). The data were analyzed by Fisher's exact test, Wilcoxon rank sum test, and multiple linear regression.

Results: Fifty-seven (57) patients were evaluated. Clinical characteristics are shown in Table 1. Of the 57, 12 had definite CI (<1.5 SD below the mean of an age, sex, and race matched RA population). The two groups were significantly different with regard to age, ethnicity, and family income. There was no significant difference between groups with regard to the presence or absence of any APL, or any specific APL, criterion or non-criterion. When titers of specific APL were compared with TTS, no significant correlations were found. Using multiple linear regression and adjusting for age, ethnicity, income, opioid and hydroxychloroquine use, and simple reaction time, neither the presence nor the titer of any APL significantly decreased TTS. However, the presence of aPG (IgM) (b'= 0.352, p =. 0007) and aPA (IgG) (b'=0.242,p=.02) appeared to increase TTS (model R^2=.731, p<0.0001).

Conclusion: In this cross-sectional study, neither criterion nor non-criterion APL of any isotype was associated with a significant decrease in cognitive performance as measured by the TTS of the ANAM. Somewhat surprisingly, aPG (IgM) and aPA (IgG) appeared to increase TTS, possibly reflecting protection against other pathogenic factors. Confirmation and further analysis of this finding is in progress.

Table 1.

Predictors of Therapeutic Outcomes in Patients with Neuropsychiatric Systemic Lupus Erythematosus. Kunihiro Ichinose[1], Kazuhiko Arima[2], Masataka Umeda[1], Shoichi Fukui[3], Ayako Nishino[1], Yoshikazu Nakashima[1], Takahisa Suzuki[1], Yoshiro Horai[4], Tomohiro Koga[4], Shin-ya Kawashiri[2], Naoki Iwamoto[1], Mami Tamai[1], Hideki Nakamura[1], Tomoki Origuchi[5] and Atsushi Kawakami[1]. [1]Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki,

Japan, [2]Department of Public Health, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Departments of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, Nagasaki, Japan, [4]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [5]Department of Health Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

Background/Purpose: Neuropsychiatric systemic lupus erythematosus (NPSLE) is a serious organ disorder with a variety of symptoms. Despite advances in the understanding of the immunopathogenic and clinical aspects of SLE, NPSLE remains a diagnostic and therapeutic challenge. The therapeutic outcomes among very few published controlled studies are diverse, because of the variability in the manifestations of NPSLE and the absence of appropriate diagnostic criteria.

Methods: This study was conducted to investigate the immunopathogenic and clinical aspects and treatment outcomes of NPSLE. We analyzed the laboratory data, symptoms, treatment regimen, and therapeutic outcomes 1 year after treatment, and the prognostic factors of 28 NPSLE patients admitted to our hospital in an 8-year period from 2006 through 2013 and 27 cytokine, chemokines and growth factor profiles in pretreatment samples of their cerebrospinal fluid (CSF) using the Bio-Plex Human 27-plex panel.

Results: There were 26 females (92.9%) and two male. The median age at the onset of NPSLE was 35 years, ranging from 15 to 53 years old. The median duration from SLE onset to first neuropsychiatric event was 7 years. The median Safety of Estrogens in Lupus Erythematosus National Assessment–Systemic Lupus Erythematosus Disease Activity Index (SELENA-SLEDAI) score at the disease onset of NPSLE was 13. Twelve patients were responders at 1 year post-treatment; their median age at NPSLE onset was 29 years versus 39 years in the non-responders (n=16, p=0.0260). The median duration from SLE onset of NPSLE was 1.5 years in responder versus 11 years in non-responder (p=0.0096). Patients with more than two NPSLE symptom types had significantly poorer outcomes (p=0.0159). The CSF interleukin (IL)-10, interferon (IFN)-γ and tumor necrosis factor (TNF)-α levels before the treatment were significantly higher in the non-responders (p=0.0051, p=0.0239 and p=0.0258, respectively). Ranking of the cytokines/chemokines to distinguish responder from non-responder by weighted-voting algorithm showed that the combination of IL-10, TNF-α, IL-6, IFN-γ, IL-4 and IL-13 had a highest Matthews correlation coefficient.

Conclusion: Younger, shorter disease duration and single-symptom NPSLE patients had significantly better therapeutic outcomes. The lower cytokine value of IL-10, IFN-γ and TNF-α before the treatment in CSF may provide better NPSLE outcomes. Additionally, measurement of multiple cytokines in pretreatment such as IL-10, TNF-α, IL-6, IFN-γ, IL-4 and IL-13 could distinguish responder from non-responder patients. Our findings may suggest the importance of making a diagnosis at an earlier phase for better therapeutic response and measuring multiple cytokines to predict therapeutic outcomes of NPSLE.

Headache in Patients with Systemic Lupus Erythematosus Is Associated with Reduced Cerebral Grey Matter Volume, but not with Measures of Glial Activation, Anti-NR2-, or Anti-P Antibodies. Anne B Tjensvoll[1], Maria B Lauvsnes[1], Shunsei Hirohata[2], Jan T Kvaløy[1], Mona K Beyer[3], Erna Harboe[1], Lasse G Gøransson[1], Ole J Greve[1] and Roald Omdal[1]. [1]Stavanger University Hospital, Stavanger, Norway, [2]Kitasato University School of Medicine, Sagamihara, Japan, [3]Oslo University Hospital, National Hospital, Oslo, Norway.

Background/Purpose: Headache, especially migraine, is frequent and one of the most common neuropsychiatric manifestations in systemic lupus erythematosus (SLE). A possible mechanism for this is that the threshold for migraine activation could be lower in SLE patients due to immunological, biochemical or structural disturbances or changes. Glutamatergic neurotransmission, involving the NMDA-receptor is considered important in migraine pathophysiology, and antibodies (ab) against the NR2 subtype of the NMDA receptor (anti-NR2 ab) are found in SLE patients. Ab against ribosomal P proteins (anti-P ab) are potentially neuropathogenic and associated with diffuse and complex neuropsychiatric manifestations in SLE. Protein S100B, a biomarker of astro-glial cell activation, is linked to neuropsychiatric SLE in some studies. We investigated whether structural abnormalities of the brain as revealed by MRI volumetry, or anti-NR2 ab, anti-P ab or increased protein S100B in cerebrospinal fluid (CSF) were associated with primary headaches in SLE.

Methods: Sixty-seven SLE patients, all fulfilling the ACR criteria, and 67 age- and gender matched healthy subjects, participated in the study. Headache was assessed through a structured interview and classified according to the International Classification of Headache Disorders. Anti-NR2 ab, anti-P ab and protein S100B were measured in CSF. Global volumes of grey matter (GM) and white matter (WM) were estimated from cerebral MRI images by applying the SPM8 software.

Results: SLE patients in this cohort had, in accordance with other studies, more migraine than age- and gender matched healthy subjects (36% vs 19%, P = 0.03). In logistic regression analyses, higher GM volumes in the SLE patients reduced the odds for headache in general (OR 0.98, P = 0.05) and for migraine in particular (OR 0.95, P = 0.004). This was not evident for pure tension type headache. Higher WM volumes in the patients increased the odds for migraine (OR 1.04, P = 0.007). In contrast, no associations were found between headache and brain volumes in the healthy subjects. No associations were revealed between headache or headache categories and anti-NR2 ab, anti-P ab or S100B in the SLE patients.

Descriptive data in the SLE patients

	All headache	Migraine	No headache
GM volume	549 (450–680)	544 (450–633)	566 (516–675)
Anti-NR2 ab*	0.37 (0.1–1.7)	0.33 (0.1–1.4)	0.44 (0.2–2.2)
Anti-P ab*	< 0.001 (<0.001–0.08)	< 0.001 (<0.001–0.04)	< 0.001 (< 0.001–0.13)
S100B*	228 (110–420)	222 (110–393)	190 (127–302)

Data are given as median and range; GM, grey matter; volumes are given in cm≥; * measured in CSF; anti-NR2 ab, values are given as a ratio against an internal calibrator with defined signal intensity; anti-P ab in ug/mL; S100B in pg/mL

Conclusion: SLE patients with reduced GM volumes have higher probability for migraine and headache in general. However, no associations between headache or headache categories and anti-NR2 ab, anti-P ab or protein S100B were found. These results indicate that unknown disease processes in SLE resulting in GM loss may increase headache and migraine susceptibility.

2653

Clinical Features in Patients with Anti-Triosephosphate Isomerase Antibody-Positive Neuropsychiatric Systemic Lupus Erythematosus. Shuzo Sato, Hiroshi Watanabe, Tomoyuki Asano, Hiroko Kobayashi, Hiromasa Ohira and Makiko Yashiro. Fukushima Medical University School of Medicine, Fukushima, Japan.

Background/Purpose: Although several autoantibodies of Neuropsychiatric Systemic Lupus Erythematosus (NPSLE) have been reported, none of these autoantibodies were conclusively established as pathogenic. We have reported that autoantibodies to triosephosphate isomerase (TPI), which is an important glycolytic enzyme in red blood cells or neuronal cells, are associated with NPSLE pathogenesis. We have detected the presence of anti-TPI antibodies in sera of human NPSLE patients. However, clinical features regarding anti-TPI antibody-positive NPSLE patients are not known. The aim of this study was to determine the clinical features of anti-TPI antibody-positive NPSLE patients.

Methods: Clinical data was retrospectively collected from 24 NPSLE patients (mean age: 26.41 ± 8.93 years old, 4 males and 20 females). NPSLE manifestations were determined according to the ACR case definitions for NPSLE. NPSLE patients were divided into 2 groups (anti-TPI antibody-positive or negative), and compared clinical features as follows: age, sex, disease duration, NPSLE manifestation, other SLE manifestations, SLEDAI, and laboratory data. Serum samples collected from all NPSLE patients were analyzed by Western blotting to detect anti-TPI antibodies using rabbit muscle TPI protein.

Results: 7 of 24 NPSLE patients were positive for anti-TPI antibodies (29.1%). Age, the rate of female, and SLEDAI were not significantly different between 2 groups. In Laboratory data, the platelet count was significantly elevated in anti-TPI positive NPSLE patients (221,800 vs 158,300 /μl, p = 0.047). In NPSLE manifestation, Lupus headache was more frequently observed in anti-TPI antibody-positive NPSLE patients (28.5% vs 0%, p=

0.012) (Table). The frequency of Seizure, Organic Brain Syndrome and Psychosis was similar in both groups in this study. Myelopathy and aseptic meningitis were observed only in anti-TPI antibody-negative NPSLE patients.

Conclusion: General clinical features were similar between anti-TPI antibody-positive NPSLE patients and negative patients, however, anti-TPI antibody-positive patients may have higher platelet count and higher frequency of lupus headache, compared to anti-TPI antibody-negative NPSLE patients.

Table. Clinical features of anti-TPI antibody-positive NPSLE patients.

	Anti-TPI positive	Anti-TPI negative	*p*
Clinical items number	7	17	–
Age (years old)	30.85 ± 9.7	24.58 ± 8.2	0.16
Sex (female %)	100%	76.5%	0.08
SLEDAI	16.42 ± 7.82	15.41 ± 6.51	0.76
Laboratory Data			
WBC/μL	7857 ± 7054	6688 ± 3905	0.69
Hemoglobin g/dL	11.17 ± 3.25	11.17 ± 2.40	0.99
Platelet/μL	22.18 ± 6.05	15.83 ± 7.49	0.04
C3mg/dL	67.71 ± 44.8	56.11 ± 26.98	0.54
C4mg/dL	15.14 ± 14.95	13.76 ± 9.29	0.82
NPSLE manifestation			
Seizure	42.8%	23.5%	0.17
OBS	14.3%	23.5%	0.31

Cognitive Function in Systemic Lupus Erythematosus Patients with Past History of Neuropsychiatric Manifestations : A Longitudinal Study. Yang Gao, Yi Lo, Jacky Wan, Esther YY Lau and Mo Yin Mok. University of Hong Kong, Hong Kong, Hong Kong.

Background/Purpose: Cognitive impairment is commonly reported in patients with systemic lupus erythematosus (SLE) and its associations with neuropsychiatric involvement (NPSLE) and psychiatric factors have been inconsistently reported in the literature.

Objective: To evaluate full neurocognitive function in relation to psychiatric factors including anxiety and depression in NPSLE patients longitudinally compared to matched controls.

Methods: Cognitive symptom inventory (CSI) was used to measure perceived cognitive impairment whereas full neurocognitive battery that covered 8 cognitive domains were performed by trained psychologist at 2 time-points 12 months apart. Depressive and anxiety symptoms were measured by HADS.

Results: 18 NPSLE and 18 non-NPSLE patients matched to age, sex and disease duration as well as 16 age- and sex- matched healthy subjects were recruited. NPSLE patients consistently reported more cognitive impairment and anxiety symptoms than non-NPSLE patients over both time-points. NPSLE patients had worse performance on 3 memory tests whereas non-NPSLE patients only showed significantly lower AVLT recognition compared with healthy subjects by post-hoc analysis. Applying age- and education- adjusted Chinese norms, NPSLE patients had significantly worse performance than non-NPSLE patients over 5 cognitive domains including simple and complex attention, memory, reasoning and visuospatial function which remained significant when adjusted for HADS-A. Anxiety contributed only to AVLT delay recall in regression analysis. Longitudinal analysis revealed improvement in some cognitive tests by non-NPSLE patients at re-evaluation whereas NPSLE patients did not show any difference in serial test performance.

Conclusion: Compared to non-NPSLE patients, NPSLE patients reported more cognitive and anxiety symptoms and had significantly worse cognitive functions involving simple and complex attention, memory, reasoning and visuospatial domains. Unlike non-NPSLE patients, they failed to demonstrate learning effect upon re-evaluation over 12 months.

Cerebral Small Vessel Disease in Systemic Lupus Erythematosus: Histopathological Study. Jamal A. Mikdashi[1], Rupal I. Mehta[2] and Rudy J. Castellani[3]. [1]Univ of Maryland Schl of Med, Baltimore, MD, [2]University of Maryland School of Medicine, Baltimore, MD, [3]Univeristy of Maryland school of Medicine, Baltimore, MD.

Background/Purpose: Little is known about cerebral small vessel disease (CSVD) in SLE, compared to the mounting evidence of relating cardiovascular risk factors and inflammation to lager vessel disease and atherosclerosis. Our aim is to examine the clinical features of CSVD in SLE, and determine the risk factors associated with CSVD.

Methods: This is a postmortem study of consecutive autopsy brain of subjects drawn from the Maryland Lupus Cohort, between 2002 and 2014. A total of 15 eligible patients were identified, and central nervous system and systemic autopsy histopathology were reviewed. Four patients with limited autopsy data were excluded. Histopathological evidence of CSVD included microthromboemoli, glial hyperplasia, neuronal loss, microaneuryms, lacunar infarcts, and microbleeds. Demographics, clinical SLE features, cardiovascular risk factors, neuroimaging findings and therapeutic options were examined among those with CSVD and those with no CSVD. Multivariate analysis and non parametric studies were used to determine factors associated with CSVD. SLE disease activity (SLEDAI-2k), SLE damage index (SDI) and duration of SLE were adjusted for during analyses.

Results: Only four out of 11 SLE patients (36.4 %) had histopathological evidence of CSVD [n=4, mean age = 26.4 +/− 9.2 years, 100% women, 100% African American, and mean duration of disease = 3.4 +/− 0.9 years] as compared to SLE patients with no CSVD [n=7, mean age = 26.2 +/− 8.8 years, 86 % women, 86 % African American, and mean duration of disease = 3.7 +/− 1.7 years]. CSVD patients presented with less acute CNS disease process and tended to accumulate more damage overtime as compared with no CSVD patients. Stroke and cognitive impairment were more frequent among CSVD patients compared to no CSVD group.

Histopathological CSVD findings correlated well with neuroimaging evidence of CSVD including, the presence of recent subcortical infarcts, lacunae of vascular origin, white matter hyperintensity, and brain atrophy (Pearson correlation coefficient: 0.633; p value $<$ 0.036). CSVD was manifested largely as microinfarction in the subcortical and cortical areas of the frontal and parietal regions (75 %), with volume loss (50 %), non inflammatory vasculopathy (50 %), and inflammatory vessel disease (25 %).

Independent risk factors associated with the occurrence of CSVD included, elevated dsDNA and low levels of C3 (odds ratio; 2.0; 95 % CI: 0.8–5.6, p value $<$ 0.050). This association was independent of age, hypertension, diabetes, smoking, alcohol intake, anti-phospholipid antibodies, C-reactive protein, prior use of immunosuppressive therapy, or presence of microscopic evidence of small vessel disease in other organs such as the kidney, skin, cardiac, or pulmonary systems.

Conclusion: The present study highlights the nature of CSVD in SLE which is of considerable importance related to stroke and cognitive impairment. CSVD in SLE appears to be associated with chronic inflammation in the absence of classic cardiovascular risk factors, or effective treatment of hypertension and SLE. Identifying novel risk factors that shed light on CSVD pathogenesis in SLE may offer potential therapeutic targets.

The Burden of Neuropsychiatric Symptoms in Systemic Lupus Erythematosus: Physician's and Patient's Perspectives. Chiara Tani[1], Maria Francisca Moraes-Fontes[2], Ana Carolina Araújo[2], Linda Carli[3], Manuel Pereira Gonçalves[4], Francesca Querci[1], Alexandra Mendes[5], Viola Signorini[6], Sabrina Vagnani[1], Rosaria Talarico[7], Céu Mateus[8], Stefano Bombardieri[9], Nuno Riso[2] and Marta Mosca[1]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Hospital de Curry Cabral, Centro Hospitalar Lisboa Central, Lisbon, Portugal, [3]GenOMeC PhD, University of Siena, Siena, Italy, [4]Mental Health Unit, Universidade Nova de Lisboa (UNL), Portugal, Lisboa, Portugal, [5]Clinical Psychology Unit, CHLC, Portugal, Lisboa, Portugal, [6]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [7]Rheumatology Unit, Pisa, Italy, [8]Health Economy, National School of Public Health (UNL), Portugal, Lisboa, Portugal, [9]University of Pisa, Pisa, Italy.

Background/Purpose: Neuropsychiatric symptoms (NPS) are observed in SLE with a variable prevalence depending on patient selection and

assessment methods. In 2010, a 27-item questionnaire was developed to identify NPS in SLE (1); in the present study we aim to compare the capability to detect NPS by means of this questionnaire and routine clinical assessment in SLE.

Methods: The questionnaire was administered to consecutive SLE patients from two European Countries as a physicians' administered tool in one cohort (PhQ) and a self-administered questionnaire in the other (PaQ). On the same day the routine clinical assessment was performed by a physician expert in SLE management blinded to the questionnaire result. The concordance level of NP symptoms as reported by questionnaires and clinical evaluation were calculated. The questionnaire was considered positive in presence of at least one symptom recorded.

Results: Overall, 137 patients were enrolled; the PhQ was administered to 70 patients (96% female, mean age at enrolment 42.3±12 years, disease duration 12.5±8.6 years) while the PaQ to 67 patients (92% female, mean age at enrolment 47±13 years, disease duration 14±9 years). Previous NP involvement was present in 25% of patients in PhQ cohort and in 21% in PaQ cohort. According to the clinical records and irrespectively from their attribution, NPS were reported in 23 patients (32%) in the PhQ cohort, and in 23 (34.3%) in the PaQ cohort; overall, there were neurologic symptoms in 15% and psychiatric symptoms in 14% of cases. According to questionnaires, at least one NPS was captured in 61 patients (87%) of the PhQ cohort and 62 (92%) in PaQ cohort. In the PhQ cohort, among the 61 patients with at least one symptom as captured by the questionnaire PhQ, 20 (32.7%) have also NPS recorded in the clinical chart; in all the 8 patients with negative questionnaire, no NPS were recorded in the clinical chart (agreement p=0.057). Similarly, among the 62 patients with positive PaQ, 20 (29.8%) have also NPS recorded in the clinical chart (agreement p=0.07). Cognitive impairment, depression and anxiety were the most overlooked symptoms in the clinical charts.

Conclusion: These data demonstrated that some NPS can be overlooked by the physician during routine clinical assessment. Although the clinical significance of these observations are under evaluation, this screening questionnaire can be a useful aid, for identifying patients with NPS requiring further evaluation.

Brain Gray and White Matter Volume Losses and Their Associations with Glucocorticoid Use in Patients with Newly Diagnosed Systemic Lupus Erythematosus (SLE) – a Prospective MR Study. Anselm Mak[1], Roger CM Ho[1], Hanying Tng[2] and Juan Zhou[2]. [1]National University of Singapore, Singapore, Singapore, [2]Duke-NUS Graduate Medical School, Singapore, Singapore.

Background/Purpose: Data suggest that cerebral atrophy occurs in patients with SLE as early as within 9 months after disease onset. We aimed to address (1) if cerebral atrophy occurs even earlier after disease onset and (2) if glucocorticoid use early in the course of SLE would positively impact the brain gray matter (GMV) and white matter volumes (WMV).

Methods: Whole brain analyses of T1-weighted magnetic resonance (MR) images (1.5-T Siemen scanner) obtained ≤ 3 months of diagnosis and subsequently after sufficient disease control (SLEDAI<4) from 14 patients with new onset SLE (1997 ACR classification criteria) without clinically overt neuropsychiatric symptoms, traditional cardiovascular risk factors and antiphospholipid antibodies were performed. MR images of 14 demographically and intelligent-quotient matched healthy controls (HC) were used for comparison. An optimized voxel-based morphometry protocol was used to analyse the images. With thresholding at p<0.01 family-wise error (FWE) corrected, GMV and WMV between patients at diagnosis and HC were compared by 2-sample t-tests on 2-subject level probabilistic maps, while changes of GMV and WMV within the SLE group at diagnosis and after achieving sufficient disease control were compared by paired t-tests. Cumulative glucocorticoid doses were correlated with the changes of GMV and WMV of the regions of interest (ROI) within the SLE group.

Results: The mean±SD age of the patients at diagnosis and HC were 39.38±13.9 and 34.07±14.4 years respectively. The mean±SD SLEDAI and daily prednisolone dose were 9.93±5.7 and 15.32±18.4mg respectively. The mean±SD interval between diagnosis and the first MR scan was 36.86±35.5 days. Second MR scans in lupus patients were performed after a mean±SD of 504.92+267.0 days of treatment, with significant improvement of mean±SD SLEDAI and daily prednisolone dose to 2.64±1.4 (p<0.001) and 3.82±3.5mg (p=0.023) respectively. The mean±SD cumulative prednisolone was 1.76±2.10gm. Demonstrated in the first scans, lupus patients had significant GMV losses in both middle cingulate cortices and middle frontal gyrus, right rolandic operculum and the right supplementary motor area (lower panel of figure), and significant WMV losses in both superior longitudinal fasciculus, corticospinal tract, cingulum cingulate gyrus and inferior fronto-occipital fasciculus (upper panel of figure) as compared with HC. On ROI analyses, cumulative glucocorticoid dose was significantly correlated with improvement of brain volumes in the left inferior temporal gyrus, left cerebellum, and both anterior thalamic radiation in the SLE patients (all p<0.05).

Conclusion: In SLE patients, significant gray and white matter losses occurred as early as within a mean of 36.9 days of diagnosis. Glucocorticoid use early in the disease course improved GMV and WMV in certain areas, suggesting the potential benefit of glucocorticoids in brain plasticity and connectivity in early SLE.

Cognitive Symptoms and Associated Disease and Non-Disease Related Factors in Patients with Systemic Lupus Erythematosus : A Longitudinal Study. Yang Gao, Yi Lo and Mo Yin Mok. University of Hong Kong, Hong Kong, Hong Kong.

Background/Purpose: Cognitive impairment is commonly reported in patients with systemic lupus erythematosus (SLE). Its associated disease and non-disease related factors have been inconsistently reported.

Objective: To examine cognitive symptoms and its relation to disease related factors including disease activity, antiphospholipid antibody, previous neuropsychiatric history (NPSLE) and non-disease related factors such as anxiety and depression over time.

Methods: Cognitive symptoms inventory (CSI) was used to measure perceived cognitive impairment serially at 3 time-points 12 months apart. Disease activity was measured by SLEDAI. Depressive and anxiety symptoms were measured by HADS-D and HADS-A respectively.

Results: 304 SLE patients were recruited at baseline (T0) among whom 144 had first re-evaluation (T1) and 34 had second re-evaluation (T2) at 12-month interval. Majority (73.5%, 25/34) of patients had stable CSI whereas 5.9% (2/34) of patients had persistently worsened CSI over 24 months. At T0, multivariate analysis revealed that higher CSI was associated with history of NPSLE (p=0.005) and psychiatric disease (p=0.04), higher HADS-A (p<0.001) and HADS-D (p<0.001) scores. CSI of active patients (SLEDAI>6) was not different from inactive patients and did not change despite regression of disease activity in 12 months. There was no difference in CSI between T0 and T1 regardless of history of NPSLE, psychiatric history, change in depressive status at T1 (HADS-D>11 as cutoff) but CSI was significantly different in patients who demonstrated change in anxiety status at T1 (HADS-A>11 as cutoff) (p=0.03). Multivariate linear regression analysis revealed change in HADS-A as the only significant predictive factor of change in CSI over time (β=0.774, 95% CI 0.43 – 1.12, p<0.001).

Conclusion: 5.9% of unselected SLE patients reported persistent cognitive symptoms. Patients with history of NPSLE and psychiatric illness, high

anxiety and depressive symptoms had worse CSI than those without these conditions. CSI was sensitive, but modestly, to change in anxiety symptoms over time.

Neurofilament H Is Associated with White Matter Lesions in Childhood-Onset Systemic Lupus Erythematosus. Aline T. Lapa[1], Mariana Postal[1], Nailu A. Sinicato[1], Lucas Ferreti Silveira[1], Fernando Cendes[1], Roberto Marini[1] and Simone Appenzeller[2]. [1]State University of Campinas, Campinas, Brazil, [2]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: Imaging findings in systemic lupus erythematosus (SLE) patients are diverse; and diffuse or regional atrophy and white matter hyperintensities (WMH) have been described in variable frequency. Studies have shown that the subunit of high molecular weight neurofilament (NF-H) is more resistant to degradation and therefore can be found in large quantities in the serum of patients with CNS injury. However the prevalence and clinical significance of WMH and it′s association with serum NF-H levels in childhood-onset SLE (cSLE) is still unknown. We aimed to determine if serum NF-H protein levels are associated with WMH in cSLE patients.

Methods: We included consecutive cSLE patients (disease-onsebefore the age of 18)followed in a cohort at the Pediatric Rheumatology Unit at the StateUniversity of Campinas. The control group was consisted by age and sex matched healthy individuals. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Neurological manifestations were analyzed according to the ACR classification criteria. MRI scans were obtained through a standardized protocol (3Tessla Philips). WMH were analyzed in T2-weighted images using a semiautomated computer program developed in our laboratory (Neuroline) and validated against standard MRI segmentation programs. Disease activity was measured by the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and cumulative SLE-related damage was determined using the Systemic Lupus International Collaborating Clinics (SLICC)/ACR Damage Index (SDI) at time of blood withdrawal. NF-H protein levels were measured by enzyme-linked immunosorbent assay using commercial kits from BioVendor, Inc (Czech Republic). Data were compared by non-parametric tests.

Results: We included 70 consecutivecSLE patients [63(90%) female; median age=16 years (range 9–30)]. The median disease duration was 3 years (range 0–13 years). At time of study entry, 30 (42.5%) cSLE patients had active disease (SLEDAI $\geq$3) and 28 (40%) had a history of neuropsychiatric (NP) manifestations. Eighteen (25.7%) cSLE had cumulative damage [SDI scores$\geq$1 (range 1–3].The white matter lesions were identified in 63 (90%) patients. WMH lesions occurred more frequently in the subcortical WM. The median NF-H protein levels were significantly increased in cSLE(55.1 pg/mL; range 1.00–330.3) when compared to controls (60.68pg/mL; range 16.1–76.7; $p<0.001$).

Conclusion: The vast majority of cSLE patients presented WMH using an objective quantitative MRI method. The presence of WMH was associated withhigher NF-Hprotein levels, suggesting that these lesions are a result of CNS injuryand should be followed carefully.

Metabolic Syndrome Features Can Influenciate Cognitive Functions and Brain Lesions in Childhood-Onset Systemic Lupus Erythematosus. Nailu A. Sinicato[1], Aline T. Lapa[1], Mariana Postal[1], Bruna Bellini[1], Paula T Fernandes[1], Roberto Marini[1] and Simone Appenzeller[2]. [1]State University of Campinas, Campinas, Brazil, [2]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: The underlying factor for an association between the metabolic syndrome (MetS) and cognitive decline might be a subclinical inflammation. Inflammatory mechanisms are hypothesized to be involved in the pathogenesis of cognitive impairment (CI) and in the development of diabetes and atherosclerosis. We aimed to correlate MetS, cognitive function and white matter hyperintensities (WMH) lesions in childhood-onset systemic lupus erythematosus (cSLE).

Methods: We performed a cross sectional study of 63 consecutive cSLE patients followed at the Pediatric Rheumatology Unit of the State University of Campinas and 63 age and sex matched healthy controls. All individuals were assessed for anthropometric and MetS features according to International Diabetes Federation (IDF) criteria. Body mass index (BMI) was calculated and blood was collected for the measurement of glucose, lipid profile including total cholesterol, high-density lipoprotein cholesterol (HDL-c), low-density lipoprotein cholesterol (LDL-c), triglycerides (TG), after a standard 12-hour fasting in all subjects. cSLE patients were further assessed for clinical and laboratory manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SLICC)], current and cumulative drug exposures. Cognitive evaluation was performed in all participants using Wechsler Intelligence Scale for children (WISC-III) and Wechsler Intelligence Scale for adults (WAIS), according to age and validated in Portuguese. Cognitive impairment (CI) was defined when scores were $\leq$2 standard deviations from controls in 1 or more subtests. Magnetic resonance imaging (MRI) scans were performed in a 3T Phillips®scanner using a standardized protocol and T2 weighted images were used for analyze. Quantification of lesion load and volume of WMH were performed by using a semiautomatic computer program (Neuroline®). Non-parametric tests were used for statistical analysis.

Results: MetS was observed in 11 (17.4%) cSLE patients and in none of the controls ($p<0.001$). We observed a higher hip circumference ($p=0.030$), waist-to-hip ratio ($p<0.001$) and hypertriglyceridemia ($p=0.005$) in cSLE patients when compared to controls. Controls had a higher height ($p=0.003$) and higher levels of HDL ($p=0.004$). We observed an inverse correlation between height and total corticosteroid dose adjusted by weight in cSLE patients ($r=-0.285;p=0.022$). CI was present in 32 (50.8%) cSLE. No association between Mets and CI was observed ($p=0.3$). Rey complex picture on memory subtest correlated with BMI ($r=-0.249$; $p=0.05$) and TG levels ($r=0.282;p=0.028$) and Boston Naming Test had an inverse correlation with total cholesterol levels ($r=-0.258;p=0.047$). WMH were observed in 53 (82.5%) cSLE patients and in 4 (6.3%) controls. The presence of WMH lesions was associated with sera glucose levels ($p=0.039$).

Conclusion: MetS features such as lipid profile and glucose levels were associated with some cognitive functions and with WMH in cSLE. This findings suggest that MetS complications go beyond the cardiovascular risk factors and should be routinely screened and treated.

Serum Neuronal Biomarkers and Brain Atrophy in Childhood-Onset Systemic Lupus Erythematosus. Aline T. Lapa[1], Mariana Postal[1], Nailu A. Sinicato[1], Renata Barbosa[2], Fernando Cendes[1], Roberto Marini[1] and Simone Appenzeller[3]. [1]State University of Campinas, Campinas, Brazil, [2]Faculdade de Ciencias Medicas, Universidade Estadual de Campinas, Campinas, Germany, [3]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: We aimedto investigate the association of serum biomarkers and regional and diffuse brain atrophy in cSLE.

Methods: We included consecutive cSLE patients (disease-onset before the age of 18) followed in a cohort at the Pediatric Rheumatology Unit at the State University of Campinas and age and sex matched healthy controls. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Neurological manifestations were analyzed according to the ACR classification criteria. Disease activity was measured by the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and cumulative SLE-related damage was determined using the Systemic Lupus International Collaborating Clinics (SLICC)/ACR Damage Index (SDI). Magnetic resonance imaging (MRI) scans were obtained through a standardized protocol (3Tessla Philips) and normalized volumetric 1mm Tl weighted images were used for manual volumetric measurements. Volumes $\leq$2 standard deviation from the means of controls were considered abnormal. Serum biomarkers (S100β, NF-H and antiribossomal P (Anti-P) and anticardiolipin antibodies levels were measured by enzyme-linked immunosorbent assay using commercial kits from BioVendor, Inc(Czech Republic). Anti-double stranded DNA (dsDNA) antibodies were determined by indirect immunofluorescen-

ceusingCrithidia as substrate and considered positive if ≥ 1:20.Precipitating antibodies to extractable nuclear antigens (ENAs),including Ro (SSA), La (SSB), and Sm were detected by a standardizedELISA method, and considered positive if higher than 1:40.Anticardiolipin antibodies (aCL) of theIgG and IgMisotypes were measured by an ELISA method. Thelupus anticoagulant (LA) activity was detected by coagulation assaysin platelet-free plasma obtained by double centrifugation. Non-parametric-tests and correlation were used for statistical analysis.

Results: We included 76 cSLE patients (69 women; median age 16 years; range 9–30), with median disease duration was 3 years (range 0–13 years). Neuropsychiatric manifestations were observed in 32 (42.1%). Structural brain abnormalities were identified in 51 (67%) cSLE patients and in in none of the controls ($p<0.001$). Cerebral atrophy was identified in 18 (23.7%), corpus callosum atrophy in 20 (26.3%) and hippocampal atrophy in 46 (60.5%). We did not observe an association between structural brain abnormalities and S100β, NF-H and anti-P protein. The presence of cerebral atrophy was associated with cumulative corticosteroid dose ($p=0.026$), active disease (SLEDAI≥3) ($p=0.044$), aCL ($p=0.024$), anti-dsDNA ($p=0.022$) and anti-Smith ($p=0.049$) antibodies. The presence of corpus callosum atrophy was associated with low complement levels ($p=0.011$). Hippocampal atrophy was associated with low complement levels ($p=0.014$) and LA ($p=0.019$).

Conclusion: Regional and diffuse brain atrophy is frequently observed in cSLE patients. We did not observe an association with neuronal biomarkers, however aPL, LA, low complement levels and cumulative corticosteroid dose were associated with atrophy in this cohort.

Attribution Protocol and Clinical Significance of Neuropsychiatric Manifestations in Childhood-Onset Systemic Lupus Erythematosus. Renata Barbosa[1], Karina Oliveira Peliçari[2], Aline T. Lapa[2], Nailu A. Sinicato[2], Mariana Postal[2], Roberto Marini[2], Marcelo Govoni Sr.[3] and Simone Appenzeller[4]. [1]Faculdade de Ciencias Medicas, Universidade Estadual de Campinas, Campinas, Germany, [2]State University of Campinas, Campinas, Brazil, [3]University of Ferrara, Ferrara, Italy, [4]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: Systemic lupus erythematosus (SLE) is caused by an imbalance of the immune system and may lead to injury and dysfunction of various systems and organs, including the central nervous system. Different attribution protocols have been developed in adult-onset SLE, however, none has been validated for childhood-onset SLE (cSLE). This study aimed to validate an attribution protocol for NP manifestations and to determine clinical significance of NP manifestations in cSLE.

Methods: A complete clinical, laboratory and neurological evaluation was performed in all subjects. Neurological manifestations were analyzed according to the ACR classification criteria. Cognitive evaluation was performed in all participants using Wechsler Intelligence Scale according to age and validated in Portuguese. Mood disorders were determined through Becks Depression and Becks Anxiety Inventory. Disease activity was measured by the Systemic Lupus Erythematosus Disease Activity Index and cumulative damage was determined using the Systemic Lupus International Collaborating Clinics Damage Index (SDI). Serum biomarkers (antiribossomal P anticardiolipin Anti-double stranded DNA, Ro (SSA), La (SSB), Sm, anticardiolipin lupus anticoagulant were evaluated. Dose of corticosteroids and other immunosuppressant medications were obtained by review of the medical charts. The protocol was developed and validated in adult-onset SLE by one of the authors (MG). In this protocol each NP manifestations is categorized in unrelated to SLE, uncertain relation to SLE and as definitively related to SLE according to disease duration, disease activity and antibody profile. According to our chart review some modifications were made to the original protocol, such as inclusion of macrophage activation syndrome.

Results: A total of 161 NP were observed in 80 (73 female, mean age 19.13 SD± 4.57 years of 99 (80.8%) patients. Mean disease duration was 6.92(SD± 5.16) years. 39 (48.75%) of patients presented NPSLE during the first 6 months of disease. In decreasing order we observed the following NP manifestations: 68(85%) headache, 22(31.25%) cognitive impairment, 19 (23.75%) mood disorder, 16 (20%) seizure, 12 (15%) cerebrovascular disease, 12 (15%) anxiety, 3 (3.75%) acute confusional state, 3 (3.75%) psychosis, 2(2.5%) corea, 1 (1.25%) cranial neuropathy, 1 (1.25%) aseptic meningitis, 1 (1.25%) demyelinating syndrome and 1 (1.25%) polyneuropathy. Positive anticardiolipin antibodies were identified in 27 (27.27%), positive LA in 28 (28.28%) and positive anti-P in 9/34 (26.47%) cSLE patients. Using the attribution protocol NP manifestations were classified as unrelated to SLE in 1(1.25%) events, uncertain expressions to SLE in 47(58.75%) and as definitively related to SLE 32 (40.0%) events. The NPSLE were associated with azathioprine ($p = 0.011$), current age ($p = 0.006$), disease duration ($p=0.023$) and corticosteroid use (p 0.019).

Conclusion: Neuropsychiatric manifestations are prevalent in cSLE, however only 40% are definitively attributed to SLE. Results are similar to adult-onset SLE. This protocol has to be further validated in other cohorts, but may be useful in clinical practice.

Sense of Smell, Anti-Ribosomal P Antibodies and Neuropsychiatric Manifestations in Systemic Lupus Erythematosus. Fernando Augusto Peres[1], Karina Oliveira Peliçari[1], Nailu A. Sinicato[1], Mariana Postal[1], Aline T. Lapa[1], Lilian Costallat[2] and Simone Appenzeller[3]. [1]State University of Campinas, Campinas, Brazil, [2]State University of Campinas, Campinas, United Kingdom, [3]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: Neuropsychiatric manifestations occur in 12–95% of SLE patients. Recent studies have demonstrated the high specificity of antiribosomal P antibodies for SLE. Antiribosomal P antibodies are able to bind to neuronal cells in areas of the limbic system which are responsible to the olfactory. We aimed to analyze the prevalence of olfactory disorder in SLE, correlate olfactory with presence of neuropsychiatric manifestations, disease activity and the presence of antiribosomal P antibodies.

Methods: Consecutive SLE patients followed at the rheumatology unit of the State University of Campinas were enrolled in this study. The control group was consisted by age and sex matched healthy individuals. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Neurological manifestations were analyzed according to the ACR classification criteria. Mood and anxiety disorders were determined through Becks Depression and Becks Anxiety Inventory. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage (Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index). Antiribosomal P antibody was performed by Enzyme Linked Immuno Sorbent Assay. Olfactory functions were evaluated using the Sniffin' Sticks test, in 3 stages: threshold, discrimination, and identification of different odors (TDI).

Results: We included 120 SLE patients (93.3% female; mean age 40.3 years; SD±11.3 years) and 135 healthy volunteers (91.1% female; mean age 37.6 years; SD±12.4 years). Anxiety was observed in 81(67.5%) SLE patients and in 49 (39.2%) controls ($p<0.001$). Depression was identified in 56 (46.6%) SLE patients and in 39 (28.8%) controls ($p=0.004$). Antiribosomal P antibodies were identified exclusively in SLE patients and were present in 13 (10.8%) of them ($p<0.001$). Olfactory changes were observed in 62 (51.6%) SLE patients and in 40 (29.6%) controls ($p=0.001$). SLE patients had significantly lower mean in all phases of the olfactory assessment. The olfactory was also inversely associated with anxiety ($p=0.004$, $R=-0.18$), depression ($p=0.01$, $R=-0.232$), cumulative damage ($p=0.002$, $R=-0.282$) and age ($p<0.001$, $R=-0.353$). The TDI was correlated with a CNS involvement, and patients with NP manifestations [mean of 28.35 (SD ± 5.30)] points, whereas patients without NP manifestations had a mean TDI of 30.8 (SD ± 4.51) points ($p<0.001$). Antiribosomal P antibodies were not associated with CNS involvement ($p=0.730$), but when we analyzed each manifestation separately, we observed an association between the presence of antiribosomal P antibodies and psychosis ($p<0.046$). We also observed an association between antiribosomal P antibodies and disease activity ($p=0.036$).

Conclusion: SLE patients have a significant decrease of smell when compared to healthy controls. Olfactory changes are associated with a history of neuropsychiatric symptoms, anxiety, depression, cumulative damage, and age. Antiribosomal P antibodies were exclusively observed in SLE patients compared to healthy controls and they were associated with psychosis and disease activity.

Increased Risk of Hematological Malignancies in Children Born to Women with SLE. Evelyne Vinet[1], Ann E. Clarke[2], Christian A. Pineau[3], Susan Scott[3], Robert W. Platt[4] and Sasha Bernatsky[3]. [1]McGill University Health Center, Montreal, QC, [2]University of Calgary, Calgary, AB, [3]McGill University Health Centre, Montreal, QC, [4]McGill University, Montreal, QC.

Background/Purpose: Patients with SLE have an increased risk of hematological malignancies, particularly non-Hodgkin lymphoma, compared to the general population. Recently, in utero exposures, such as chronic maternal autoimmune conditions, have been associated with the development of childhood hematological malignancies. However, until now, no one has assessed the risk of hematological cancers in children born to women with SLE. Thus, in a large population-based study, we aimed to determine if SLE offspring have an increased risk of hematological malignancies, versus controls.

Methods: The "Offspring of SLE mothers Registry (OSLER)" includes all women who had ≥1 hospitalization for delivery after SLE diagnosis, identified through Quebec's universal healthcare databases (1989–2009). OSLER also includes a randomly selected control group of women, matched at least 4:1 for age and year of delivery, who did not have a diagnosis of SLE prior to or at the time of delivery. We identified children born live to SLE mothers and their matched controls, and ascertained hematological malignancies based on ≥1 hospitalization or physician visit with a relevant diagnostic code, through to end of database follow-up.

We performed multivariate logistic regression analyses, using generalized estimating equations, to adjust for maternal demographics and comorbidities, sex of child, and gestational diabetes. In a subsample analysis of children with maternal drug coverage throughout pregnancy, we further assessed relevant in utero medication exposures.

Results: 509 women with SLE had 719 children, while 5824 matched controls had 8493 children. Mean maternal age and follow-up were respectively 30.3 (SD 5.0) and 9.1 (SD 5.8) years. Children born to women with SLE experienced more hematological malignancies (9/719) compared to controls (38/8493) [1.25% (95% CI 0.61, 2.45) versus 0.45% (95% CI 0.32, 0.62), difference 0.80% (95% CI 0.14, 2.01)]. The most frequent type of hematological cancer in both groups was acute lymphoblastic leukemia. Of note, primary non-Hodgkin lymphoma of bone was observed in 2/719 SLE offspring as opposed to 6/8493 control children [0.28% (95% CI 0.05, 1.12) versus 0.07% (95% CI 0.01, 0.16), difference 0.21% (95% CI -0.04, 1.05)]. In multivariate analyses (n=9212), children born to women with SLE appeared to have an increased risk of hematological cancers versus controls (OR 2.80, 95% CI 1.33, 5.92).

In the subsample of children with drug coverage (n=1925), in utero medication exposures were rare in the 10 hematological cancer cases: none was exposed to antimalarials, corticosteroids, or immunosuppressants.

Conclusion: Our data suggest that compared to children from the general population, children born to women with SLE may have an increased risk of hematological malignancies. However, it must be emphasized that this outcome is extremely rare, and our findings remain to be confirmed by other study methods. The lack of association with in utero drug exposures may be viewed as somewhat re-assuring, though this too is preliminary.

Risk of Hydrocephalus and/or Macrocephaly in Children Born to Mothers with SLE. Catherine Huang[1], Sasha Bernatsky[2], Christian A. Pineau[2], Susan Scott[2], Ann E. Clarke[3], Robert W. Platt[1] and Evelyne Vinet[4]. [1]McGill University, Montreal, QC, [2]McGill University Health Centre, Montreal, QC, [3]University of Calgary, Calgary, AB, [4]McGill University Health Center, Montreal, QC.

Background/Purpose: Evidence suggests that both hydrocephalus and macrocephaly could be potential manifestations of neonatal lupus. In a recent study of 87 children born to mothers with anti-Ro antibodies (Boros et al., *Arthritis Rheum*, 2007), prevalence of hydrocephalus was high at 8.0% and mean head circumference was substantially larger than the age-matched normal values. Although up to 40% of women with SLE display anti-Ro antibodies, to date, no one has assessed the occurrence of hydrocephalus and/or macrocephaly in SLE offspring. Thus, in a large population-based study, we aimed to determine if children born to women with SLE have an increased risk of hydrocephalus and/or macrocephaly compared to children born to women without SLE.

Methods: The "Offspring of SLE mothers Registry (OSLER)" includes all women who had ≥1 hospitalization for delivery after SLE diagnosis, identified through Quebec's universal healthcare databases (1989–2009). OSLER also includes a randomly selected control group of women, matched at least 4:1 for age and year of delivery, who did not have a diagnosis of SLE prior to or at the time of delivery. We identified children born live to SLE mothers and their matched controls, and ascertained hydrocephalus and macrocephaly based on ≥1 hospitalization or physician visit with a relevant diagnostic code, through to end of database follow-up. We performed multivariate logistic regression analyses, using generalized estimating equations, to adjust for maternal demographics and comorbidities, sex of child, and gestational diabetes.

Results: A total of 719 children were born to 509 women with SLE, and 8493 children were born to the 5824 matched controls. Compared to controls, children born to women with SLE showed only a slight trend towards more records of hydrocephalus and/or macrocephaly diagnosis [8 per 1000 persons (95% CI 4, 18) versus 6 per 1000 persons (95% CI 5, 8), difference 2 per 1000 persons (95% CI -3,13)]. Similarly there was only a slight trend towards younger age at time of hydrocephalus and/or macrocephaly diagnosis in SLE offspring versus controls [respectively 0.6 year (95% CI 0.2, 1.0) and 1.1 years (95% CI 0.5, 1.7)]. Of note, among the 6 cases of hydrocephalus and/or macrocephaly identified in SLE offspring, none had a diagnosis of cardiac conduction disturbance, suggesting no strong association with neonatal lupus. In multivariate analysis, the point estimate for the outcome was consistent with a trend for higher risk of hydrocephalus and/or macrocephaly in SLE offspring compared to controls, although the confidence interval was wide and precluded definitive conclusions (OR 1.37, 95% CI 0.58, 3.22).

Conclusion: Compared to children from the general population, there was a slight trend for higher frequency (and earlier age at diagnosis) of hydrocephaly and/or macrocephaly among children born to mothers with SLE, but the results do not strongly suggest an important increase in the risk of hydrocephalus and/or macrocephaly.

Causes of Stillbirths in Women with SLE. Evelyne Vinet[1], Geneviève Genest[2], Susan Scott[2], Christian A. Pineau[2], Ann E. Clarke[3], Robert W. Platt[4] and Sasha Bernatsky[2]. [1]McGill University Health Center, Montreal, QC, [2]McGill University Health Centre, Montreal, QC, [3]University of Calgary, Calgary, AB, [4]McGill University, Montreal, QC.

Background/Purpose: It is believed that pregnant women with SLE face an increased risk of stillbirths, although there are few precise or recent estimates of the magnitude of the effect. As well, no one to date has investigated the causes of stillbirths in SLE pregnancy. Using the "Offspring of Systemic Lupus Erythematous Registry (OSLER)", we examined stillbirths and the cause of their death in SLE mothers versus those without SLE.

Methods: OSLER is a large population-based cohort, which includes all women who had one or more hospitalizations for delivery after SLE diagnosis, identified through Quebec's healthcare databases (1989–2009). OSLER also includes a randomly selected control group of healthy women, matched at least 4:1 for age and year of delivery. We identified stillbirths (defined as intrauterine deaths occurring at or after 20 weeks of gestational age) from SLE mothers and their matched controls and ascertained the cause of death as indicated on the death certificate. We performed a multivariate logistic regression analysis, using generalized estimating equations, to estimate the risk of stillbirths in SLE offspring versus controls, adjusting for maternal education, comorbidities (i.e. hypertension, diabetes, asthma, depression), and multiple births.

Results: 509 women with SLE had 729 births, including 9 stillbirths (1.4%), while 5829 matched controls had 8541 births including 47 stillbirths (0.6%). Compared to controls, women with SLE had an increased risk of having a stillbirth (adjusted OR 2.16, 95% CI 1.05, 4.44). Among women having a stillbirth, median maternal age was identical for both SLE and control mothers [respectively 31.0 years (IQR 29.0, 32.0) and 31.0 years (IQR 26.5, 30.5)]. There was a trend for more female stillbirths born to women with SLE (6 of nine stillbirths were female) compared to controls (22/47) (OR 2.27, 95% CI 0.54, 9.41). In addition, stillbirths in SLE mothers occurred at a younger median gestational age compared to controls [29 weeks (IQR 28, 31) versus 35 weeks (IQR 27, 38)].

Causes of death in SLE and control stillbirths are illustrated in Table 1. We observed a trend for higher risk in SLE mothers versus controls for stillbirths due to maternal hypertensive disorders and placental abruption [respectively OR 6.43 (95% CI 0.8, 53.3) and OR 4.19 (95% CI 0.59, 29.72)].

Conclusion: Compared to women from the general population, women with SLE appear to have an increased risk of stillbirths, although it must be emphasized that most pregnancies in SLE are not complicated by this event. Stillbirths in mothers with SLE might be more often caused by maternal hypertensive disorders and placental abruption compared to stillbirths in mothers without SLE.

First-Trimester Disease Activity Does Not Predict Pre-Eclampsia in SLE Pregnancy. Khaled Alderaan[1], Laurence S. Magder[2] and Michelle Petri[3]. [1]King Fahad Specilaist Hospital, Dammam, Saudi Arabia, [2]University of Maryland, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: Preeclampsia complicates up to 35% of lupus pregnancies compared to 8% of general population pregnancies. SLE has up to a 3-fold increased rate of preeclampsia. The aim of this cohort study was to determine whether variables measured in the first trimester could help predict which women will develop pre-eclampsia.

Methods: Only pregnancies with a clinic visit during the first trimester were included. All women were diagnosed with SLE either before or during the pregnancy, according to the American College of Rheumatology (ACR) revised classification criteria. Preeclampsia was defined according to the American College of Gynecology (ACOG), as follows: systolic blood pressure of 140 mm Hg or higher or diastolic of 90 mm Hg or higher in patients with previously normal blood pressure, taken on two occasions, measured after 20 weeks of gestation; and proteinuria, defined as urinary protein excretion of more than 0.3 g in a 24-hour urine collection. Rates of pre-eclampsia were calculated in subgroups defined by variables measured in the first trimester, defined as the first 13 weeks of pregnancy.

Results: A total of 280 pregnancies from 234 different women were included in this analysis. The patients were 62% Caucasian, 28% African American, and 10% other ethnicities. Twenty-nine (10%) of the pregnancies met the definition of preeclampsia. Table 1 shows the rates of pre-eclampsia by patient subgroups. There was not strong evidence of an association between lupus-related variables such as anti-dsDNA, low complement, global disease activity and risk of pre-eclampsia. Also, there was no strong evidence of a relationship between medications such as prednisone, hydroxychloroquine and risk of pre-eclampsia.

Conclusion: Preeclampsia development in SLE patients cannot be predicted in the first trimester. Disease activity, serologic activity, proteinuria, antiphospholipid antibodies and prednisone are not predictive.

Maternal Clinical Characteristics of SLE and Pregnancy: Hopkins Lupus Pregnancy Cohort. Michelle Petri[1], Amanda Eudy[2], Marcy Powell[2], Greg Giguere[2], Qinggong Fu[2] and Deanna Hill[2]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]GlaxoSmithKline, Research Triangle Park, NC.

Background/Purpose: Systemic lupus erythematosus (SLE) typically presents in women of childbearing age. As such, it is important to understand how the clinical characteristics of SLE affect pregnancy outcomes. This research question is being assessed in a secondary analysis of the Hopkins Lupus Pregnancy Cohort.

Methods: Data from the Hopkins Lupus Pregnancy Cohort for pregnancies occurring on or after 01 Jan 2000. Maternal clinical characteristics in the 6 months prior to or during pregnancy that were analyzed included comorbidities (pregnancy-induced hypertension, placental abruption, preeclampsia, gestational diabetes, proteinuria, hypertension and thrombocyto-

penia), concomitant medications (corticosteroids, other immunosuppressants, NSAIDs, anti-malarials and heparin) and lab tests (low C3/C4, anticardiolipin antibodies and anti-dsDNA+). We evaluated whether maternal clinical characteristics were associated with low birth weight (LBW; <2500 g) pregnancy outcome for live births. Fischer exact p-values were calculated in this analysis (WEUKBRE5887 & WEUKBRE4566; 114256).

Results: In this analysis, there were 213 pregnancies in 190 women (median age: 30 years; median SLE duration: 5.5 years; 51% white, 37% black, 12% other). There were 16 (7.5%) spontaneous miscarriages, 6 (2.8%) stillbirths and 188 (88.3%) live births (median gestational age: 38 weeks). The outcome was unknown in three of the pregnancies. Of the live births, 38 (20.2%) were preterm, 15 (8.0%) were small for gestational age (SGA; defined as weight <10th percentile for gestational age) and 41 (21.8%) were LBW. Compared to mothers of infants with normal birth weight (Table 1), mothers of infants with LBW had a greater frequency of hypertension (34.1% vs. 17.0%; p=0.01), proteinuria (12.2% vs. 3.4%; p=0.03) and higher dose steroid use (≥7.5 mg/day) in the 6 months prior to or during pregnancy (63.4% vs. 47.6%; p=0.03).

Table 1 Association of maternal clinical characteristics[1] and low birth weight pregnancy outcome in the Hopkins Lupus Pregnancy Cohort

	Total Live Births n=188 n (%)	Normal Birth Weight (≥2500g) n=147 n (%)	Low Birth Weight (<2500g) n=41 n (%)	Fischer Exact p-value

IgA	3 (1.6)	2 (1.4)	1 (2.4)	0.4
Anti-dsDNA+	100 (53.2)	78 (53.1)	22 (53.7)	0.1

[1]Observation period defined as the 6 months prior to and/or during pregnancy
[2]Medication use ever in the observation period
[3]Corticosteroid use categories are mutually exclusive. Patients with higher dose (≥7.5 mg/day) ever during the observation period were not included in the low dose (<7.5/mg day) category.
[4]NSAIDS: nonsteroidal anti-inflammatory drugs

Conclusion: In this analysis, certain maternal clinical characteristics were associated with LBW in infants born to mothers with SLE. Although a greater frequency of higher dose steroid use was observed in mothers of infants with low birth weight, it is possible that treatment with higher dose steroids (≥7.5 mg/day) was a proxy for more active SLE in the 6 months prior to or during pregnancy, rather high dose steroid use having a direct effect on low birth weight. Data from this analysis will complement planned analyses for the Belimumab Pregnancy Registry, an ongoing international, prospective cohort study of women exposed to commercially-supplied belimumab within 4 months prior to and/or during pregnancy (WEUKBRE6076; clinicaltrials.gov ID NCT01532310; 114256).

Systemic Lupus Erythematosus and Lactation: Factors Affecting Infant Feeding Choices in Women with SLE. Sara Wasserman and Megan E. B. Clowse. Duke University Medical Center, Durham, NC.

Background/Purpose: Breastfeeding has been shown to improve maternal and infant wellbeing and long-term health, but it is currently unknown how often it is pursued in the SLE population. We sought to determine the rate of breastfeeding and factors that promote or discourage this in the postpartum period for women with SLE.

Methods: Lupus patients enrolled in a prospective pregnancy registry completed questionnaires about infant feeding intentions at enrollment and infant feeding practices post-partum. Throughout the pregnancy and postpartum, medications and disease activity were evaluated using the SLE pregnancy disease activity index (SLEPDAI).

Results: 86 pregnancies occurred in women who met the 2012 SLICC criteria for SLE. Of these, 13 resulted in a miscarriage or termination and 10 were lost to follow-up; postpartum feeding data is available for 51 pregnancies. 28 (54.9%) of pregnancies were in Caucasian women, 20 (39.2%) in African-American and 3 (5.9%) in Asian women. The average maternal age was 29.8yrs (SD 4.8), with a range from 21.5 to 42.2yrs. At study entry, 53 (64.6%) planned on breastfeeding, 19 (23.2%) planned on using formula, and 10 (12.2%) had no feeding plan.

By 6 weeks postpartum, 26 (51.0%) were formula feeding exclusively and 25 (49.0%) were breastfeeding. Of the women breastfeeding, 7 (28%) were supplementing with formula. Compared to women who formula fed only, those who were breastfeeding were older and had less disease activity post-partum (see table). Breastfeeding mothers also had deliveries that were more likely to be at term and their infants were less likely to have spent time in the intensive care unit.

African-American women were more likely to plan to use formula (45.0% AA vs 22.2% Caucasian, p=0.12) and to only use formula (65.0% AA vs 42.9% Caucasian, p=0.15). African-American women were also more likely to have high SLE activity post-partum (47.4% AA vs 15.6% Caucasian, p=0.04). In multivariate logistic regression, post-partum SLE activity (p=0.02) and whether breastfeeding was planned in pregnancy (p=0.03), but not race (p=0.6), predicted breastfeeding.

The key reasons that women breastfed included to keep the baby healthy (91.7%), to bond with the baby (66.7%), to keep infant feeding costs low (66.7%), to lose weight (58.3%), and for convenience (33%). The main reasons that women did not breastfeed were concern over medication effects on the infant (36%); 7 (27%) of the non-breastfeeding women were taking contraindicated medications (methotrexate, mycophenolate, or azathioprine) post-partum.

Conclusion: About half of women with lupus breastfeed for at least 6 weeks. Factors that influence this decision include pre-delivery intention to breastfeed, maternal age, SLE activity, and medications. Given the myriad of maternal and infant benefits seen with breastfeeding, finding approaches that facilitate this choice for women with SLE is an important goal.

	Breastfeeding	Formula Only	p-value

Premature Delivery in Patients with Systemic Lupus Erythematosus. Valeria Arturi, Pierina Sansinanea, Mariana Alejandra Pera, Adrian Pablo Salas, Josefina Marcos, Ana Carolina Costi, Claudia Elizabeth Pena and Mercedes Argentina García. HIGA San Martín La Plata, La Plata, Argentina.

Background/Purpose: Premature delivery (PD) is one of the most important difficultiess in perinatology. An incidence on developing countries of around 19% and 5–7% in developed nations is estimated. In Systemic Lupus Eritematosus (SLE) preterm delivery and stillbirth are still concerns, particularly in relation to pregnancies in patients with renal involvement, the presence of antiphospholipid antibodies (a-PL) or anti Phospholipidic Syndrome (APS). The aim of this study was to evaluate the prevalence of PD in patients with SLE and analyze the relationship between different factors related to the disease with fetal outcomes and neonatal mortality.

Methods: Patients with SLE (1997 ACR criteria) with ≥ 1 pregnancy between 1987–2011 were analyzed. Premature delivery was defined as live birth before 37 weeks of gestation. We compared the outcomes among PD pregnancies versus term pregnancies. The statistical analysis was performed with Chi-square test or test of Student as appropriate.

Results: 166 pregnancies were recorded in 124 SLE patients. In 132/166 (79.5%) pregnancies were live birth. 46/132 (34.8%) were PD. Main causes of PD were: premature rupture of fetal membranes (21.7%), gestosis (19.6%) and placental insufficiency with intrauterine growth restriction (13%). Eight preterm newborn (17.4%) died in the neonatal period, 4 of them were part of the seven cases of extreme preterm birth (< 32 weeks of gestation).

	Preterm 46	Term 98	p	OR	CI
APS	51%	32.65%	0.65	2.063	0.94–4.49
Previous nephropathy	32.6%	30.6%	1.000	1.063	0.46–2.39
Infections	24%	18.3%	0.505	1.39	0.54–3.52
Proteinuria	43.75%	10.2%	0.002	3.85	1.42–10.51
a-PL	77%	52.6%	0.006	3.06	1.27–7.49
Hydroxychloroquine	37%	40%	0.855	0.887	0.40–1.93
Pre-eclampsia	19.6%	11.2%	0.201	1.92	0.66–5.54
Cesarean delivery	58.7%	47%	0.212	1.61	0.74–3.48
Low birth weight	82.6%	10%	<0.0001	41.8	13.9–132
Neonatal Death	17.4%	4%	0.019	4.94	1.24–20.9

Conclusion: 34.8% of the 132 live newborns from mothers with SLE were preterm deliveries. Proteinuria during the course of the pregnancy and anti-phospholipid antibodies were significantly associated with PD. Patients with PD had increased the risk of having a newborn with low birth weight as well as increased mortality in the neonatal period, especially when the delivery occurred before 32 weeks of gestation.

2671

Impact of Glucocorticoid Dose on Maternal and Fetal Outcomes in Lupus Pregnancies. Dafhne Miranda[1], Miguel A. Saavedra[2], Eduardo Gomez[3], Alberto Daniel Rocha Muñoz[4], Jorge Gaspar Ramos[1] and Luis Javier Jara[5]. [1]Rheumatology Unit, Hospital de Especialidades. Centro Médico La Raza, IMSS, Distrito federal, Mexico, [2]Hospital de Especialidades Centro Médico La Raza, IMSS, Mexico City, Mexico, [3]Institute for Research in Rheumatology and Musculoskeletal System, Guadalajara, Mexico, [4]Institute for Research in Rheumatology and Musculoskeletal System, Guadalajara, Jalisco, Mexico, [5]Instituto Mexicano del Seguro Social, D.F., Mexico.

Background/Purpose:

- Lupus flares during pregnancy can be treated with short courses of low to moderate doses of glucocorticoids (GCs). GCs are associated with several maternal and fetal complications during pregnancy, however information about the role of the dose in the development of these complications is limited
- To analyze the role of GCs in the development of maternal and fetal complications in women with systemic lupus erythematosus (SLE) and if these complications are dose-related

Methods: We prospectively studied a cohort of pregnant women with SLE (ACR 1997) between January 2009 and August 2013. The patients were assessed every 4 to 6 weeks and postpartum by a rheumatologist and a gynecologist. Clinical, biochemical and immunological characteristics of women, along with maternal and fetal complications, were recorded. For analysis, the patients were first assigned to one of two groups: pregnancies exposed to GCs vs those not exposed. Secondly, to evaluate the dose effect of GCs, we compared three dose ranges throughout pregnancy: prednisone £10 mg daily, prednisone >10–24 mg daily and prednisone ≥25 mg daily. Statistical analysis included descriptive statistics, chi square, Student t test, Fisher's exact test, ANOVA and Scheffe's test as post-hoc and logistic regression; relative risk (RR) with confidence intervals (CI) of 95% were calculated. For the analysis each pregnancy was considered as an independent event.

Results:

- We included 143 pregnancies in 136 patients. There were 111 pregnancies exposed to GCs and a greater exposure to azathioprine (55% vs 21.9%, p=0.001) in comparison with those not exposed to GCs. There were no differences in maternal complications in the analyzed groups by dose ranges. Major fetal complications were dose-related: low weight, low height, and preterm birth. In the multivariable analysis, the use of prednisone >25mg daily was associated with preterm birth (RR 3.3, CI 95% 1.39–8.04, p=0.0002), low birth weight (RR 3.25, CI 95% 1.37–7.18, p=0.0001).

Conclusion:

- This study suggests that fetal complications associated with the use of prednisone are dose-related (>25 mg). The use of low to moderate doses of prednisone during pregnancy is safety.

Characteristics of the Reproductive System in Systemic Lupus Erythematosus: A Cross-Sectional Survey with Pair-Matched Controls. Maria N. Antoniol[1], Cecilia Reimundes[1], Cecilia Catoggio[1], Analia V. Longo[2], Analia P. Alvarez[2] and Carlos Perandones[1]. [1]CEMIC, Buenos Aires, Argentina, [2]Hospital Penna, Buenos Aires, Argentina.

Background/Purpose: Patients with Systemic Lupus Erythematosus (SLE) present factors associated with the reproductive system that can increase the risk of the disease, but the literature is controversial.

The reproductive system variables are influenced by multiple social, ethnic, economic and cultural factors that can function as confounding variables. For this reason, the optimal SLE population control should be matched by age and sociodemographic features.

We compared reproductive variables of a group of women with SLE with pair-matched healthy controls.

Methods: A case-control study was performed using a cross-sectional survey to analyze variables of the reproductive system in patients with SLE. We included women over 18 years-old with SLE according to ACR criteria. Each case was matched with a healthy control belonging to her sociocultural environment and having her age ± 5 years.

The survey included multiple demographic and disease variables, as well as reproductive system features: age of menarche and menopause, number of pregnancies and fetal losses, and contraceptive methods. Paired t test and McNemar's test or Fisher exact test were applied for continuous and categorical variables, respectively.

Results: We included 83 cases with a mean age of 39.2 ± 10.8 years (range19–66) and the mean age at SLE diagnosis was 26.9 ± 10.3 years. Previous treatments were as follows: 91% hydroxychloroquine, 32% cyclophosphamide, 31% azathioprine, 24% mycophenolate mofetil, and 16% methotrexate.

	Cases	Controls	
Menarche (age ± SD)	12.8 ± 1.7	12.4 ± 1.4	paired t test p 0.15
Menopause (age ± SD)	43.12 ± 6.4	50.23 ± 3.7	paired t test p 0.01
Previous Oral Contraceptives (%)	42%	50%	McNemar's test 1.25 (p 0.26)
Pregnancies (mean ± SD)	1.7 ± 1.6	1.9 ± 1.9	paired t test p 0.34
Fetal Loss (%)	28	28	
Fetal Loss (mean ± SD)	0.43 ± 0.8	0.43 ± 0.8	paired t test p 1.0
Children (mean ± SD)	1.25 ± 1.2	1.45 ± 1.4	paired t test p 0.24
Gestational Age (weeks) (mean ± SD)	37.8 ± 3.1	37.9 ± 3.3	t test p 0.8
Infertility Treatment (%)	6.02	9.6	Fisher exact test p 0.17

When cyclophosphamide was analized as a risk factor for early menopause there were no difference between exposed and non exposed patients

Conclusion: There were no differences in the age of menarche, previous oral contraceptives, number of pregnancies, fetal losses and children, and the need of infertility treatment between SLE patientes and pair-matched controls.

The age of menopause is significantly different but cannot be related only to cyclophosphamide.

ACR/ARHP Poster Session C
Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: T and B Cell Signaling and Genetic Variants
Tuesday, November 18, 2014, 8:30 AM–4:00 PM

2673

High-Throughput Sequencing of 219 Candidate Genes for Identification of SLE-Associated Risk Variants. Fabiana Farias[1], Maria Wilbe[1], Johanna Dahlqvist[1], Dag Leonard[2], Sergey Kozyrev[1], Gerli Pielberg[1], Maija-Leena Eloranta[2], Lars Rönnblom[2] and Kerstin Lindblad-Toh[1]. [1]Uppsala University, Science for Life Laboratory, Uppsala, Sweden, [2]Department of Medical Sciences, SciLife Lab, Rheumatology, Uppsala University, Uppsala, Sweden, Uppsala, Sweden.

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease, believed to arise from environmental triggering events in genetically predisposed individuals. To date, more than 50 genes have been associated with SLE through genome-wide association studies. However, only about 15% of the heritability of SLE is explained by these findings. In this study we aimed to identify novel rare genetic variants of functional importance for SLE.

Methods: One hundred and forty Swedish SLE patients, fulfilling the ACR classification criteria for SLE, and 12 healthy controls were included in the study. We sequenced the exons, promoter regions and putative regulatory regions of 219 genes selected on basis of their role in immune response, autoimmunity or known association with SLE or SLE-related disease complex in dogs. Selected gene regions were targeted using Roche NimbleGen capture array and the DNA samples were then divided into 10 pools according to the disease manifestations of the patients, with the 12 healthy controls in a separate pool. The pools were paired-end sequenced using Illumina HiSeq2000 reaching approximately 250x coverage per individual.

Results: We detected 4276 novel single-nucleotide polymorphisms (SNPs; not present in 1000genomes or dbSNP137) out of which 1258 SNPs were case-only variants. Seventeen genes showed ≥ 5 novel variants private to cases. Of these, three genes have previously been associated with human SLE and 14 are novel candidate genes. Six SNPs (allele frequencies 0.01–0.03 in patients) located in non-coding sequences with potential regulatory function were selected for further studies based on their characteristics in terms of conservation, DNAse hypersensitivity, ENCODE data on histone marks and ChIP-Seq peaks. The SNPs were validated by genotyping in all patients and in 96 additional healthy controls, to confirm their increased frequency in the patient cohort. Using electrophoretic mobility shift assay, binding of protein complexes was investigated for all six SNPs and they are currently evaluated for their effect on gene expression. The clinical disease manifestations of the patients harboring each of the six SNPs are being analyzed in order to identify any phenotype-genotype correlations.

Conclusion: This proof-of-principle study highlights the importance of analysis of non-coding putative regulatory DNA regions for the identification of rare variants associated with complex disease.

The Effect and Mechanisms of Icaritin on Regulating Foxp3/IL17a Expression in CD4$^+$ T Cells from SLE. Jieyue Liao[1], Yu Liu[2], Ming Zhao[3], hai Jing Wu[4] and Qianjin Lu[1]. [1]Department of Dermatology, Second Xiangya Hospital, Central South University, Changsha, China, [2]Department of Dermatology, Second Xiangya Hospital, Central South University, shangcha, China, [3]Department of Dermatology, Second Xiangya Hospital, Central South University, changsha, China, [4]Department of Dermatology, Second Xiangya Hospital, Central South University, sahngsha, China.

Background/Purpose: Systemic lupus erythematosus (SLE) is a female predominant autoimmune disease characterized by overproduction of autoantibodies. The pathogenesis of SLE is complex. Several studies have revealed that the balance between Treg cells and Th17 cells is destroyed in autoimmune diseases such as SLE.

Icaritin (ICT) is an active ingredient extracted from Chinese herbals Epimedium genus. It has been used as an aphrodisiac, tonic and antirheumatic in China. Our previous studies have found that ICT has a wide range of pharmacological and biological activities, including inhibiting T cell activation and enhancing Treg cells suppressive activities. In this study, we explored the the effect and mechanisms of Icaritin on regulating Foxp3/IL17a expression in systemic lupus erythematosus.

Methods:

1. CD4$^+$ T cells were isolated from SLE patients by positive selection using magnetic beads. CD4$^+$ T cells were treated with 40uM/L ICT for 72h. Foxp3 and IL17a mRNA levels were determined by real-time RT-PCR. Foxp3 protein level was examined by western blotting. Detection of IL17a level was performed by ELISA.
2. Amounts of H3K4me3 AH3K9me3 and H4 acethlation within the foxp3 and IL17a promoter were analyzed by chromatin immunoprecipitation (ChIP) and real-time PCR.
3. The transcription factor regulating both Foxp3 and IL17a expression was determined by microarray. STAT5b-siRNA and control-siRNA were transfected into CD4$^+$ T cells by transient electroporation. Then CD4$^+$ T cells were treated with 40uM/L ICT for 24h. STAT5b, Foxp3 and IL17a mRNA were evaluated by real-time PCR. STAT5b protein levels were examined by western blotting.

Results:

1. Compared to control group, Foxp3 mRNA and protein level were significantly increased in ICT- treated group, while IL17a mRNA and protein level were significantly decreased in ICT-treated group.
2. Compared to control group, H3K4me3 enrichment at the Foxp3 promoter was significantly increased in ICT-treated group; H3K9me3 enrichment at the IL17a promoter was significantly increased in ICT-treated group. There was no significant difference in H4 acethlation level at Foxp3 and IL17a promoter region.
3. Compared to control-siRNA group, STAT5b mRNA level and protein level were significantly decreased. After down-regulating STAT5b expression, Foxp3 and IL17a had no significant changes in ICT-treated group.

Conclusion:

1. ICT can increase the expression level of Foxp3 while decrease IL17a gene expression in CD4$^+$T cells from SLE.
2. ICT can increase H3K4me3 enrichment at the foxp3 promoter and H3K9me3 enrichment at the IL17a promoter in CD4$^+$T cells from SLE.
3. Down-regulating STAT5b in CD4$^+$ T cells can inhibit the effect of ICT on the modulation of Foxp3/ IL17a balance in CD4$^+$T cells from SLE.

The Selective Loss of SLAMF4$^+$ CD8$^+$ T Cells Contributes to the Decreased Cytotoxic Capacity Observed in Systemic Lupus Erythematosus. Katalin Kis-Toth, Denis Comte, Maria Karampetsou, Lakshmi Kannan and George C. Tsokos. Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA.

Background/Purpose: Signaling lymphocytic activation molecule family member 4 (SLAMF4) engagement by its ligand SLAMF2 can mediate the cytotoxicity of CD8$^+$ T cells and natural killer cells. SLE CD8$^+$ T lymphocytes are reportedly defective in cytotoxicity. The aim of this study was to investigate the expression and function of SLAMF4 on SLE CD8$^+$ T cells.

Methods: The expression of SLAMF4 and its adaptor SAP in healthy and SLE T cells were measured by Q-PCR, flow cytometry and western blot. T cells were treated by immobilized anti-SLAMF4 antibodies and the cytotoxic capacity of the T cells was monitored by the cell surface expression of CD107a, reflecting exocytosis of lytic granules.

Results: We found significant downregulation of SLAMF4 and the adaptor molecule SAP gene and protein expression in SLE T cells compared to normal controls. Characterization of the T cell subsets revealed that SLE patients have significantly less $SLAMF4^+$ $CD8^+$ T cells compared to normal control T cells, switching the $SLAMF4^+/SLAMF4^-$ ratio in the favor of $SLAMF4^-$ $CD8^+$ T cells which have less SAP expression and decreased cytotoxic capacity. SLAMF4 engagement triggers the degranulation of $CD8^+$ T cells and SLE T cells have decreased degranulation capacity compared to normal controls. In the effort to explain the loss of $SLAMF4^+$ $CD8^+$ T cells in SLE we found that these cells are more likely become double negative T cells and/or die by apoptosis.

Conclusion: Based on our results we conclude that the selective loss of $SLAMF4^+$ $CD8^+$ T cells may contribute to the ineffective capacity of fighting against infections in SLE.

The E3 Ligase Casitas B Lineage Lymphoma b (Cbl-b) Modulates Peripheral Regulatory T Cell Function Via $p27^{kip1}$ in Patients with Systemic Lupus Erythematosus. Diana Gómez-Martín[1], Jorge Romo-Tena[2], Javier Merayo-Chalico[1], Ana Barrera-Vargas[1] and Jorge Alcocer-Varela[1]. [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico city, Mexico.

Background/Purpose: The interplay between effector and regulatory T cells (Tregs) is a key element among peripheral tolerance mechanisms in Systemic Lupus Erythematosus (SLE). Resistance to suppression has been recently acknowledged as part of the defects shown by T cells from SLE patients. The E3 ligase Cbl-b has been shown to modulate T cell unresponsiveness in SLE. However its potential role in the regulation of peripheral Tregs tolerance has not been fully addressed. The aim of this study was to assess the expression of Cbl-b and its relationship to the resistance to suppression phenotype in SLE patients.

Methods: We included 25 patients with SLE (10 in remission and 15 with active untreated disease) according to the classification criteria of the American College of Rheumatology and 25 age and gender-matched healthy controls. PBMCs were isolated by density gradient and effector ($CD4^+CD25^-$) and Tregs ($CD4^+CD25^+CD127^-$) were purified by magnetic selection. The expression of Cbl-b and $p27^{kip1}$ was analyzed by Western blotting. Interaction between Cbl-b and $p27^{kip1}$ was addressed by immunoprecipitation (IP). Proliferative responses were assessed in allogeneic and autologous cocultures by CFSE. Differences were assessed by t Student test. $p<0.05$ was considered as statistically significant. In all cases, an informed consent was obtained, and the ethics committee approved this study.

Results: We found diminished Cbl-b expression in Tregs from SLE patients in comparison to healthy controls (1.3 ± 1.0 vs 2.8 ± 1.8, $p=0.002$), which was associated with resistance to suppression in proliferation assays ($r=0.553$, $p=0.041$). Moreover, this phenomenon was related to deficient expression of the cell cycle regulator $p27^{kip1}$ in Tregs from SLE patients when compared to healthy controls. We also found by IP assays, that $p27^{kip1}$ interacts with Cbl-b in Tregs. We found no significant differences regarding to disease activity.

Conclusion: Our data suggest that the ligase Cbl-b is able to regulate the interplay between effector and Tregs, particularly, the resistance to suppression via ubiquitination of $p27^{kip1}$ in SLE patients. To our knowledge, this is the first study to demonstrate that $p27^{kip1}$ is able to interact with Cbl-b, which might constitute another mechanism by which this ubiquitin ligase is able to modulate the T cell receptor activation threshold.

Decreased Levels of SRSF1 (Serin/Arginine-Rich Splicing Factor1) Induced Lower Levels of RasGRP1 in T Cells from Patients with Systemic Lupus Erythematosus. Takashi Kurita[1], Shinsuke Yasuda[1], Vaishali Moulton[2], Yuka Shimizu[1], Michihito Kono[1], Hideyuki Koide[1], Kenji Oku[1], Toshiyuki Bohgaki[1], Olga Amengual[1], Tetsuya Horita[1], George C. Tsokos[3] and Tatsuya Atsumi[1]. [1]Hokkaido University Graduate School of Medicine, Sapporo, Japan, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [3]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA.

Background/Purpose: Down-regulation of MAP kinase pathway has been recognized in T cells from patients with SLE that results in hypo-methylation of DNA. RasGRP1 is an intracellular signaling protein highly expressed in T cells and activates the Ras signaling pathway downstream of TCR engagement. RasGRP1 deficient mice develop late-onset lymphoproliferative autoimmune syndrome. Previously we reported that defective (alternatively spliced) RasGRP1 transcripts correlate with lower levels of RasGRP1 protein in SLE T cells. Serin/arginine-rich splicing factor1 (SRSF1) is a member of the serine arginine family of splicing proteins that binds pre-mRNA to regulate alternative splicing. For instance, SRSF1 binds to the 3'UTR of CD3 zeta and enables normal splicing of this signaling protein. (Moulton V et.al. J Biol Chem. 2010). The purpose of this study is to determine the relationship between aberrant splicing of RasGRP1 and SRSF1 expression in SLE T cells.

Methods: Forty-five SLE patients and eighteen healthy subjects were included in this study. T cells were collected from peripheral blood of each subject and RNA was isolated. Expression levels of SRSF1, normally spliced RasGRP1 and DNMT1 transcripts were assessed by real time quantitative PCR. Immunoprecipitations (IP) were performed to confirm the direct binding of SRSF1 to RasGRP1 mRNA. SRSF1 specific siRNA was used to supress the expression levels of the RasGRP1 in Jurkat T cell.

Results: Expression levels of SRSF1 transcripts were significantly lower in SLE patients compared with healthy subjects ($p=0.001$, t-test). In patients with SLE, expression levels of SRSF1 correlated with those of normally spliced RasGRP1 and DNMT1 ($r=0.517$, $p=0.023$ [RasGRP1]; $r=0.557$, $p=0.013$ [DNMT1]). IP studies suggested that SRSF1 binds directly to RasGRP1 exon11 RNA. RasGRP1 protein level was decreased in Jurkat T cell when exposed to SRSF1 specific siRNA (Figure).

Conclusion: SRSF1 binds to RasGRP1 mRNA and controls its expression. Low SF2/ASF levels in SLE T cells correlate with the expression levels of RasGRP1 and DNMT1. We propose that SRSF1 regulates the alternative splicing of important genes in SLE T cells including RasGRP1 and CD3 zeta. (2238+250 < 2750 characters, one figure = 250 characters)

UC-MSCs Inhibit T Cell Autophagy and Apoptosis in Patients with Systemic Lupus Erythematosus through Mitochondrial Transfer. Jinyun Chen, Xuebing Feng and Lingyun Sun. The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China.

Background/Purpose: This study is aimed to investigate the role of umbilical cord derived mesenchymal stem cells (UC-MSCs) on autophagy and apoptosis in T cells from SLE patients, and to explore the underline mechanisms involved in this process.

Methods: Peripheral blood mononuclear cells (PBMC) were isolated from SLE patients and healthy donors, and cultured under stimulation with anti-CD3/28 antibodies in the presence or absence of autophagy inhibitor 3-MA (5mM for 6h) or activator rapamycin (50nM for 48h). Autophagy levels and apoptotic rates were measured by flow cytometry with the detection of LC3IIB and Annexin V respectively. To determine the effects of MSCs on T cell autophagy and apoptosis, UC-MSCs were cocultured with T cells at the ratio of 1:10 directly or in transwell system. To observe the changes of pathways upstream of autophagy after MSC treatment, an AMPK activator was added to the cocultures. Meanwhile, mitochondria transmembrane potential (¦¤¦Øm), which was closely related to APPK activation, was marked and measured in MSCs and T cells by MitoTracker Deep Red (MDR).

Results: T cells from SLE patients had both elevated autophagy level and apoptotic rate compared with those from normal controls, which were further increased after anti-CD3/CD28 stimulation. Apoptotic rate of T cells significantly correlated with autophagy level ($r=0.570$, $p<0.0001$ for CD4+T; $r=0.508$, $p=0.0001$ for CD8+T). Inhibition of autophagy with 3-MA decreased the apoptotic rate of T cells, whereas activation of autophagy with rapamycin increased the apoptotic rate. UC-MSCs significantly inhibited T cell autophagy (22.5±2.4 vs. 36.4±6.3 for CD4+T; 27.2±1.9 vs. 39.2±5.4 for CD8+T, both $p<0.05$) and T cell apoptosis (22.2±2.6% vs. 49.1±5.7 % for CD4+T; 23.3±2.4% vs. 53.2±2.3 % for CD8+T, both $p<0.05$) after cell-to-cell contact coculturing, yet the effect was diminished in transwell system. When AMPK activator added to the cultures, the ability of UC-MSCs to regulated T cell apoptosis was greatly impaired. As shown in Figure 1, mitochondria in UC-MSCs could be transferred to SLE T cells when directly cocultured. Consequently, the elevation of ¦¤¦Øm in T cells was downregulated after MSC treatment (242.5±8.4 vs. 315.8±5.5, $p=0.003$ for CD4+T; 139.8±23.5 vs. 199±35.7, $p=0.06$ for CD8+T), along with the reduction of AMPK.

Conclusion: Autophagy levels are elevated in T cells from SLE patients, leading to aberrant apoptosis. UC-MSCs may inhibit T cell autophagy and apoptosis through mitochondrial transfer.

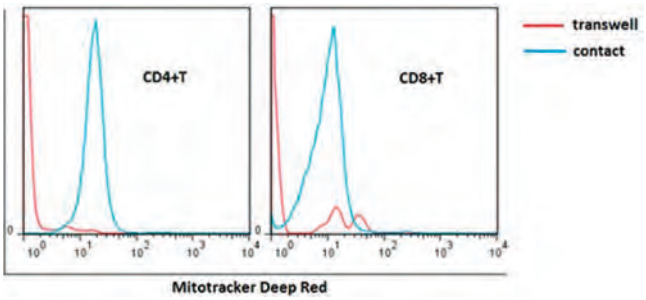

Figure 1 Transfer of MSC mitochondria to lupus T cells. Mitochondria in MSCs were marked by MitoTracker Deep Red. After cell-to-cell contact coculture, MSC-derived mitochondria were detectable in T cells.

Mucosal-Associated Invariant T Cell Deficiency in Systemic Lupus Erythematosus. Jeong-Hwa Kang, Young-Nan Cho, Hye Mi Jin, Hyun-Ju Jung, Sung-Ji Lee, Seung-Jung Kee and Yong-Wook Park. Chonnam National University Medical School and Hospital, Gwangju, South Korea.

Background/Purpose: Mucosal-associated invariant T (MAIT) cells contribute to protection against certain microorganism infections and play an important role in mucosal immunity. However, the role of MAIT cells remains enigmatic in autoimmune diseases. Here, we examined the level and function of MAIT cells in patients with rheumatic diseases.

Methods: MAIT cell, cytokine and programmed death-1 (PD-1) levels were measured by flow cytometry.

Results: Circulating MAIT cell levels were significantly reduced in systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) patients. In particular, this MAIT cell deficiency was more prominent in CD8+ and double-negative T cell subsets, and significantly correlated with disease activity, such as SLE disease activity index (SLEDAI) and 28-joint disease activity score (DAS28). Interestingly, MAIT cell frequency was significantly correlated with natural killer T (NKT) cell frequency in SLE patients. Interferon-γ production in MAIT cells was impaired in SLE patients, but it was preserved in RA patients. In SLE patients, MAIT cells were poorly activated by α-galactosylceramide-stimulated NKT cells, thereby showing the dysfunction between MAIT cells and NKT cells. Notably, an elevated expression of PD-1 in MAIT cells and NKT cells was associated with SLE. In RA patients, MAIT cell levels were significantly higher in synovial fluid than in peripheral blood.

Conclusion: Our study primarily demonstrates that MAIT cells are numerically and functionally deficient in SLE. In addition, we report a novel finding that this MAIT cell deficiency is associated with NKT cell deficiency and elevated PD-1 expression. These abnormalities possibly contribute to dysregulated mucosal immunity in SLE.

DNA Hydroxymethylation Changes in CD4+T Cells from Patients with Systemic Lupus Erythematosus. Ming Zhao, Wei Liao, Bochen Zhu, Ruifang Wu and Qianjin Lu. Department of Dermatology, Second Xiangya Hospital, Central South University, Changsha, China.

Background/Purpose: Recent studies have uncovered 5-hydroxymethylcytosine (5hmC) as the sixth base of the genome, and that the Ten-eleven translocation (TET) family proteins is responsible for the generation of 5hmC from 5mC in mammalian cells. 5hmC may function as another epigenetic mark by altering chromatin structure or contributing to the recruitment or exclusion of other DNA-binding proteins that affect transcription. However, the report about DNA hydroxymethylation in CD4+ T cell or SLE is poor, though DNA hypomethylation has been confirmed to contribute to SLE. In this study, we will investigate DNA hydroxymethylation in genome-wide in lupus CD4+ T cells.

Methods: 36 SLE patients and 36 healthy controls were recruited. CD4+ T cells were isolated by magnetic beads. The age and sex are matched. All patients fulfilled at least 4 of the SLE classification criteria of ACR. The content of 5hmC in genome was detected by dot blot. hMeDIP-NimbleGen Human 3×720K Promoter Plus CpG Island Arrays was completed for identification of genes with different 5hmC modifications between SLE CD4+ T cells and normal controls. mRNA expression levels were measured by real-time RT-PCR. Gene ontology (GO) was analyzed by the Database for Annotation, Visualization and Integrated Discovery (DAVID). Student's t-test for equality of means was used to compare values. P-values < 0.05 were considered as significant.

Results: Compared with normal controls, the content of 5hmC was increased significantly in lupus CD4+ T cells according to the result of dot blot. hMeDIP-chip and data analysis showed 2753 genes with increased 5hmC and 50 genes with decreased 5hmC within their promoter regions in lupus CD4+ T cells. Through the integrated analysis of DNA hydroxymethylation data with DNA methylation data from our previous study, we found 404 genes with increased 5hmC and decreased 5mC in promoter regions in lupus CD4+ T cells, such as UBE2A, IRF1, JUND. In addition, the integrated analysis of DNA hydroxymethylation data with gene expression data from our previous study showed 211 genes with increased promoter hydroxymethylation and expression in lupus CD4+ T cells, such as TNFRSF4, IL15RA and NR2F6, in which some significant GO enrichments, including T cell proliferation and cytokine-mediated signaling pathway, were observed. Furthermore, the results from real-time PCR showed that mRNA expression levels of TET2, TET3, UBE2A and JUND were up-regulated signficantly in CD4+T cells of SLE patients compared with normal controls. The positive correlation was observed between TET2 or TET3 and UBE2A or JUND expression levels.

Conclusion: The increased 5hmC may contribute to DNA demethylation and overexpression of some genes in lupus CD4+ T cells, which suggest DNA hydroxymethylation play an important role in the aberrant epigenetic mechanisms of SLE.

Activated SLE-T Cells Enhance the Interferon-Alpha Production By Plasmacytoid Dendritic Cells Stimulated By RNA-IC. Dag Leonard[1], Maija-Leena Eloranta[1], Niklas Hagberg[1], Olof Berggren[1], Karolina Tandre[1], Gunnar Alm[2] and Lars Rönnblom[1]. [1]Department of Medical Sciences, SciLife Lab, Rheumatology, Uppsala University, Uppsala, Sweden, Uppsala, Sweden, [2]Department of Biomedical Sciences and Veterinary Public Health, Swedish University of Agricultural Sciences, Uppsala, Sweden, Uppsala, Sweden.

Background/Purpose: A prominent interferon-α (IFNα) signature is seen in several autoimmune diseases including systemic lupus erythematosus (SLE). Plasmacytoid dendritic cells (pDCs) are the main IFNα producing cells and produce large amounts of IFNα in response to immune complexes containing nucleic acids (ICs). Produced IFNα activates the immune system in a number of ways, including polarization of naïve T helper cells to Th1 cells, expansion and activation of cytotoxic CD8+ T cells and enhanced B-cell differentiation and antibody production. Thus, once pDCs are activated they strongly promote the adaptive immune response. However, much less is known about the effects on pDCs by different adaptive immune cells. Therefore, we asked if T cells can promote the IFNα production by pDCs stimulated by RNA containing ICs.

Methods: Human T cells were activated by anti-CD3/CD28 antibodies. T cells or supernatant from T cell cultures were co-cultured with pDCs stimulated with ICs containing U1 snRNP particles and SLE-IgG (RNA-IC). Cells were analyzed by flow cytometry and cytokines in supernatants were depleted or blocked by monoclonal antibodies. Supernatants were analyzed for IFNα and other cytokines.

Results: Activated T cells or supernatants from activated T cells increased the IFNα production by pDCs stimulated by RNA-IC >20-fold. The frequency of pDCs expressing intracellular IFNα increased when co-cultured with activated CD4+ T cells (5.8%) or CD8+ T cells (6.8%) compared to pDC cultured alone (0.2%). When cytokines were added to the RNA-IC stimulated pDCs at the same concentration as in the supernatant from activated T cells, both GM-CSF and IL-3 demonstrated a strong stimulatory effect on the IFNα response. The combination of both cytokines increased the IFNα production as much as supernatants from activated T cell. The stimulatory effect of supernatants was significantly reduced after depletion of GM-CSF (81%), blocking of GM-CSF (92%) or its receptor subunits CD131 and CD116 (55–81%), (all $p<0.05$). Blocking of IL-3 or its receptor subunit CD123 also reduced the stimulatory effect of the supernatant (31% and 32%, respectively). Supernatant from activated T cells increased the frequency of CD80 and CD86 expressing pDC from 6% to 35% ($p<0.05$) and 10% to 26% ($p<0.01$), respectively. Furthermore, when RNA-IC was added to pDCs cultured with GM-CSF and IL-3, an increased frequency of CD80 and CD86 ($p<0.05$) expressing pDCs were observed. Activated SLE T cells enhanced the IFNα production to the same extent as T cells from healthy controls. Detectable levels of serum-GM-CSF was found in 31% of SLE patients ($n=51$), who had a more active or severe disease.

Conclusion: Activated T cells enhance the IFNα production by RNA-IC stimulated pDCs via GM-CSF and IL-3, which induce maturation of the pDCs. Previous findings of activated T cells in patients with SLE and our observation of a subset of SLE patients expressing increased levels of serum-GM-CSF suggests that T cells contribute to the activated type I interferon system in SLE. Thus, a bidirectional crosstalk between the type I IFN system and the adaptive immune system seems to exist in SLE.

Serine Arginine-Rich Splicing Factor 1 (SRSF1) Regulates Transcriptional Activation of the T Cell Receptor CD3 Zeta Chain in Human T Cells. Vaishali Moulton[1], Andrew R. Gillooly[1] and George C. Tsokos[2]. [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA.

Background/Purpose: T cells from patients with systemic lupus erythematosus (SLE) express reduced amounts of the critical CD3 zeta signaling chain, and are poor producers of the vital cytokine interleukin (IL)-2. Using oligonucleotide-pulldown and mass spectrometry approaches, we previously identified the serine arginine-rich splicing factor 1 (SRSF1) binding to the 3'UTR of CD3 zeta mRNA. We showed that SRSF1 regulates alternative splicing of the CD3 zeta 3'UTR to promote a full length 3'UTR over an unstable splice variant, and thus promotes expression of CD3 zeta chain. SLE T cells exhibit reduced expression of SRSF1, more so patients with worse disease as evidenced by higher SLE disease activity index (SLEDAI). SRSF1 and the serine arginine (SR) proteins have recently been suggested to regulate transcription, in addition to regulating post-transcriptional events in gene expression such as alternative splicing, mRNA stability and translation. CD3 zeta is regulated by the Ets transcription factor family member E-74-like factor (Elf)-1 via two Ets binding sites (EBS) within the CD3 zeta promoter. In this study, we asked whether SRSF1 could activate CD3 zeta transcription and if this involved the transcription factor Elf-1.

Methods: T cells were isolated by negative selection from peripheral blood of healthy individuals, and patients with SLE. Primary T cells were transfected with an SRSF1 or empty expression plasmid by nucleofection. mRNA and protein expression were assessed by real time quantitative pcr and immunoblotting respectively. To measure transcriptional activity, CD3 zeta promoter-luciferase constructs were co-transfected with increasing amounts of SRSF1 into 293T cells or into primary T cells, and luciferase activity measured using the dual luciferase assay system. Reporter chromatin immunoprecipitation (R-ChIP) assays were used to assess recruitment of proteins to the CD3 zeta promoter-luciferase construct. Specific antibodies were used to immunoprecipitate SRSF1, HA (tag present in the SRSF1 plasmid), and Elf-1 proteins. Quantitative real time pcr was performed to assess enrichment, and normalized to values obtained from inputs.

Results: We show that SRSF1 expression directly correlates with CD3 zeta chain expression in T cells from patients with SLE. Overexpression and silencing of SRSF1 in primary T cells results in corresponding increase and decrease in total CD3 zeta mRNA expression. SRSF1 increases activity of the CD3 zeta promoter-luciferase in a dose dependent manner. SRSF1 overexpression leads to increased Elf-1 expression in T cells. Recruitment of SRSF1 and Elf-1 (a known transcriptional activator of CD3 zeta) to the CD3 zeta promoter is observed in T cells that overexpress SRSF1 compared to control transfected cells.

Conclusion: Our results reveal a novel transcriptional mechanism by which SRSF1 regulates CD3 zeta and may represent a molecular mechanism that contributes to the reduced CD3 zeta expression in SLE.

The Discovery of Novel Splicing Variants of Neurogranin and Their Role in the Pathogenesis of Systemic Lupus Erythematosus. Xiaofang Luo, Xuelan He, Chaonan Wu, Juan Ni, Ling li Dong and Shouxin Li. Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.

Background/Purpose: Systemic lupus erythematosus (SLE) is a prototypic autoimmune disease with a diverse array of clinical manifestations that is characterized by the production of antibodies to components of the cell nucleus. Neurogranin(Ng), a calmodulin binding protein, was thought to be a neural-specific factor involved in learning and memory, while, its ectopic expression was found in peripheral blood cells, like T lymphocytes, B lymphocytes, etc. And its role in SLE has not been reported yet. Our aim was to compare the expression and structure of Ng in peripheral blood and central nervous system (CNS), and to explore its role in SLE.

Methods: Thirty-four patients with SLE and 22 healthy controls were enrolled. Splicing variants of Ng gene in peripheral blood mononuclear cells(PBMCs) were screened with reverse transcription polymerase chain reaction (RT-PCR) combined with T/A clone, DNA sequencing, and reconfirmed using the primer-specific PCR. Expression of Ng splicing variants mRNA was detected by qRT-PCR. All subjects gave written informed consent prior to enrollment in the study, which was approved by the ethics committee of our hospital.

Results: Three splicing variants of Ng gene were cloned from SLE PBMCs, and two of which, named as Ng-mu1 and Ng-mu2 respectively, were not been reported yet. Compared to wild type of Ng (Ng-WT), Ng-mu1 containing of a 55 bp intron retention insertion with 256–392 base sites deleted, Ng-mu2 with second exon partially deleted and termination codon early emerged. The IQ motifs of Ng-mu1 which is the binding site of calmodulin were impaired (Fig 1). The ratio of Ng-WT to Ng-mu1 in healthy control PBMCs was lower than human brain total RNA. Further analysis showed the up-regulation of Ng-WT mRNA and the elevated ratio of Ng-WT to Ng-mu1 in SLE PBMCs, and the expression of Ng-WT was positively correlated with SLE disease activity index (SLEDAI) (Fig 2).

Conclusion: The novel splicing variants of Ng and their ectopic expression in PBMCs may contribute to the pathogenesis of SLE through mediating Ca2+ signal transduction.

Association of Adam33 Polymorphisms with Systemic Lupus Erythematosus. Seong-Wook Kang[1], Seung-Taek Song[1], Su-Jin Yoo[1], Mi-Kyoung Lim[2], Dong-Hyuk Sheen[2], In-Seol Yoo[1], Jinhyun Kim[1] and Seung-Cheol Shim[1]. [1]Chungnam National University School of Medicine, Daejeon, South Korea, [2]Eulji University Hospital, Daejeon, South Korea.

Background/Purpose: A Disintegrin and Metalloprotease 33 (ADAM33) is a member of a family of genes that encode membrane-anchored proteins with a disintegrin and a metalloprotease domain, and is located on chromosome 20p13. Recently, the polymorphisms in Adam33 have been found to be associated with asthma. Among the rheumatic diseases, systemic lupus erythematosus (SLE) is a prototypic Th2-mediated autoimmune disease like allergic disorders.

To assess whether genetic functional variants of ADAM33 are associated with susceptibility to SLE or development of specific phenotypes in patients with SLE.

Methods: We have identified 48 SNPs, and nine SNPs were selected with regard to the LD pattern. Genotyping for g.10918G>C, g.12433T>C and g.13506C>G in the ADAM33 gene was conducted with PCR RFLP methods, and genotyping for g.-330C>T, g.517 A>G, g.8227 G>A, g.9511 G>T, g.12462 C>T, g.12988 C>A polymorphisms was performed by single-base extension (SBE), using the ABI Prism SNaPshot Multiplex kit (Applied Biosystems). We conducted an association study for ADAM33 polymorphisms in 190 SLE patients, 469 healthy controls, and 390 rheumatoid arthritis (RA) patients as a disease control. Haplotype analyses of related variants were performed as well.

Results: Significant associations of ADAM33 polymorphisms with susceptibility to SLE were found at g.8227 G>A, g.12988 C>A, and g.13506 C>G (*P* value were all below 0.001). Polymorphisms at g.8227 G>A was associated with the ANA titers among SLE patients ($P = 0.012$). In addition, we analysed the haplotype, and found a positive association of susceptibility to SLE with the major haplotype CGCG ($P = 3.5E\text{-}11$). There was no association between ADAM33 polymorphisms and RA as expected.

Conclusion: ADAM33 polymorphisms were strongly associated with susceptibility to SLE and the development of specific clinical manifestations.

Ten-Eleven Translocation 2 Protein Down-Regulates DNA Methylation of Interleukin-17A Promoter and Induces Its Expression in CD4$^+$t Cells of Patients with Systemic Lupus Erythematosus. Duo Li, Qian Tang, Lina Tan, Ming Zhao, Gongping Liang, Yang Yang and Qianjin Lu.Department of Dermatology, Second Xiangya Hospital, Central South University, Changsha, China.

Background/Purpose: Recent evidence indicates that IL-17A plays a key role in the pathogenesis of autoimmune diseases, such as systemic lupus erythematosus (SLE). SLE patients have a higher serum level of IL-17A which correlates with disease activity. However, the exact mechanisms of increased IL-17A level remain uncertain. Ten-eleven translocation (TET) family of dioxygenases catalyze the conversion of 5-methylcytosine into 5-hydroxymethylcytosine, and regulate DNA methylation and gene expression dynamicly. Our previous results showed that both TET1 and TET2, particularly TET2 were increased in SLE CD4$^+$T cells, which suggests TET2 may play a role in the pathogenesis of SLE. In this study, we aim to explore the effect of TET2 on IL-17A expression and the underlying mechanisms in SLE CD4$^+$T cells.

Methods: Fifteen SLE patients and fifteen healthy controls were recruited. All patients fulfilled at least 4 of the SLE classification criteria of the American College of Rheumatology. Naive T cells or CD4$^+$T cells were isolated by Ficoll-Hypaque density gradient centrifugation and magnetic sorting. The IL-17A levels in serum or culture supernatant were measured by ELISA kits. Bisulfite sequencing was done to assess the methylation status of the IL-17A promoter. Th17 cells were induced from Naive T cells of healthy donors in vitro. TET2-siRNA or TET2-expressing plasmid was transfected into CD4$^+$T cells by transient electroporation. The mRNA levels of IL-17A and TET2 were examined by real-time PCR.The protein levels of IL-17A and TET2 were measured by flow cytometric analysis or western blot, respectively. The enrichment of TET2 in the promoter region of IL-17A gene was investigated by chromatin immunoprecipitation and real-time PCR.

Results: Compared to controls, both the serum IL-17A levels and IL-17A mRNA levels in CD4$^+$T cells were elevated in SLE patients ($p<0.05$; $p<0.05$), the levels of Tet2 mRNA and protein were also increased in lupus CD4$^+$T cells ($p<0.05$; $p<0.05$). The IL-17A promoter region in SLE CD4$^+$T cells were found to be demethylated, which negatively correlated with the increased IL-17A mRNA expression ($r=0.725$; $p<0.05$). TET2 enrichment at IL-17A promoter was increased in SLE CD4$^+$T cells ($p<0.05$).Both IL-17A mRNA and protein levels were increased under the Th17 induction treatment on naive CD4$^+$T cells ($p<0.05$; $p<0.05$). TET2 mRNA and protein levels were also increased in a time-dependent manner during the process of Th17 differentiation($p<0.05$; $p<0.05$). IL-17A mRNA and protein levels were decreased in SLE CD4$^+$T cells transfected with TET2-siRNA ($p<0.05$; $p<0.05$), while increased in normal CD4$^+$T cells overexpressed TET2 ($p<0.05$; $p<0.05$). The methylation levels of IL-17A promoter were up-regulated in SLE CD4$^+$T cells transfected with TET2-siRNA ($p<0.05$), while down-regulated in normal CD4$^+$T cells overexpressed TET2 ($p<0.05$). TET2 enrichment at IL-17A promoter was reduced in SLE CD4$^+$T cells transfected with TET2-siRNA ($p<0.05$), while elevated in normal CD4$^+$T cells overexpressed TET2 ($p<0.05$).

Conclusion: Our results indicate that TET2 promotes IL-17A expression through demethylation of its promoter in SLE CD4$^+$T cells.

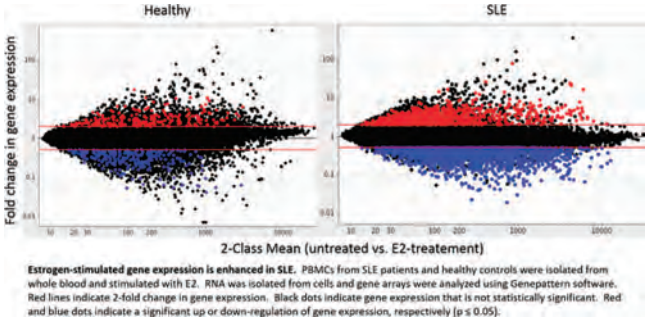
Gene Array Analysis Reveals Unique Estrogen Signature in Peripheral Blood Mononuclear Cells of Patients with Systemic Lupus Erythematosus. Stephanie Amici[1], Nicholas A. Young[2], Lai-Chu Wu[2], Mireia Guerau[1] and Wael N. Jarjour[2]. [1]The Ohio State University, Columbus, OH, [2]The Ohio State University Wexner Medical Center, Columbus, OH.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disorder predominately affecting females in the reproductive age range. Estrogen is present at higher levels in this population compared to pre-pubertal and postmenopausal women and has been shown to influence immune cell function by regulating the expression of multiple genes through activation of estrogen receptors (ER) a and b. Recent work using a chromatin immunoprecipitation with ERa has shown that this list may be much larger than what has been characterized to date. In this study, the effects of E2 were examined by comparing gene array expression in peripheral blood mononuclear cells (PBMCs) from premenopausal women with SLE and in healthy premenopausal individuals.

Methods: SLE patients meeting the revised criteria of the American College of Rheumatology and healthy volunteers were recruited through approved IRB protocols. Whole blood was collected into heparnized tubes and PBMCs were isolated. Cells were cultured with or without 10 nM of 17b-estradiol (E2) for 48 hours. PBMCs were then collected and purified as total RNA and submitted for gene array analysis using HG-U133 Affymetrix® Human Gene Chips. Untreated PBMC arrays served as the internal baseline control for each individual sample and was subtracted from the E2-treated expression values; thus, only the estrogen mediated effect was reported. Data was analyzed using the Multiplot function within the Genepattern software program and with Ingenuity Pathway Analysis Software.

Results: While over 1000 genes were significantly up-regulated over 2-fold in SLE samples when treated with E2, only 236 were identified in corresponding healthy controls. Furthermore, E2 stimulation significantly down-regulated 2530 genes in PBMCs from SLE patients, but only 244 in healthy samples under the same conditions. In concordance, 525 and 1629 genes were found to be uniquely up or down-regulated with E2 treatment in SLE, respectively. Significant E2-mediated regulation of several methyltransferases, including PCMTD1 and RG9MTD3, was identified in this analysis. Using Ingenuity Pathway Analysis Software, our results identified these gene sets to be associated with several pathways, including post-translational modification.

Conclusion: These results establish a clear estrogen effect over many genes to produce an estrogen signature, including several genes known to be associated with post-translational modification, and further reveals enhanced regulation in SLE patients when compared to healthy controls.



Estrogen-stimulated gene expression is enhanced in SLE. PBMCs from SLE patients and healthy controls were isolated from whole blood and stimulated with E2. RNA was isolated from cells and gene arrays were analyzed using Genepattern software. Red lines indicate 2-fold change in gene expression. Black dots indicate gene expression that is not statistically significant. Red and blue dots indicate a significant up or down-regulation of gene expression, respectively ($p \leq 0.05$).

Estrogen-Mediated STAT1 Activation By Estrogen Receptor a Induces TLR8 Expression: A Novel Pathogenic Mechanism in Systemic Lupus Erythematosus. Nicholas Young[1], Giancarlo Valiente[2], Lai-Chu Wu[2], Michael Bruss[2], Stacy Ardoin[2], Craig Burd[3] and Wael N. Jarjour[2]. [1]Ohio State University, Columbus, OH, [2]The Ohio State University Wexner Medical Center, Columbus, OH, [3]The Ohio State University, Columbus, OH.

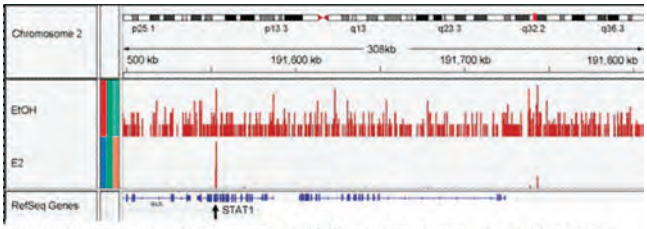
Background/Purpose: Many autoimmune disorders, including Systemic Lupus Erythematosus (SLE) display female gender predominance. Previous studies have demonstrated significant hormonal contributions to SLE pathogenesis, including estrogen, which influences gene expression by binding to

estrogen receptors (ERα and ERβ). E2 has been shown to regulate Signal Transducer and Activator of Transcription (STAT) 1 function and we have previously defined E2-mediated Toll-like receptor 8 (TLR8) expression in SLE. This study examined E2-induced STAT1 expression human peripheral blood mononuclear cells (PBMCs) and characterized the downstream effect on TLR8 expression.

Methods: Putative ERα binding sites in the human genome were identified from ChIP-seq data of MCF-7 cells stimulated with E2 for one hour. SLE patients and healthy controls were recruited for this study through approved IRB protocols. PBMCs were isolated and stimulated with a physiological dose of 17-b estradiol (E2). Radio-labeled probes were used in EMSA analysis to examine DNA-protein complex formation with recombinant ERα and in a human monocytic cell line (THP-1). STAT1 expression was blocked by siRNA with E2 treatment in THP-1 cells.

Results: ChIP-seq data identified an intragenic ERα binding peak within the STAT1 locus and EMSA analysis using this DNA sequence with recombinant ERα protein demonstrated enhanced DNA-protein complex formation. Levels of STAT1 were significantly elevated in SLE patients relative to healthy controls and E2 stimulation of both SLE and healthy PBMCs significantly induced STAT1 expression. In THP-1 cells, blocking STAT1 with siRNA significantly reduced TLR8 induction by E2. Using a *bona fide* STAT1 binding region located 24 kb from the 3'end of the TRL8 genetic locus, EMSA analysis showed enhanced DNA-protein complex formation with E2 stimulation in THP-1 cells.

Conclusion: E2 stimulates the expression of STAT1 in PBMCs, which could contribute to SLE pathogenesis by promoting TLR8 expression. These results identify a novel molecular target to inhibit the TLR8 inflammatory pathway; thus presenting a significant therapeutic opportunity.



Chromatin immunoprecipitation sequencing (ChIP-seq) identification of a putative estrogen receptor α (ERα) binding peak proximal to the STAT1 genetic locus. MCF7 cells were treated with vehicle (EtOH) or estrogen for 45 min and ChIP enriched DNA was sequenced on the Illumina platform. When compared to vehicle, the putative ERα binding peak is indicated with an arrow.

Comparison of Systemic Lupus Erythematosus and Healthy Anti-Nuclear Antibody Positive African-Americans Reveals Distinct Differences in T Cell and Progenitor Populations. Rufei Lu[1], Samantha Slight-Webb[2], Holden T. Maecker[3], Paul J. Utz[3], Joel M. Guthridge[2] and Judith A. James[2]. [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Stanford University School of Medicine, Stanford, CA.

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disorder which arises from both genetic and environmental factors that likely affect phenotypic and functional characteristics of multiple cell lineages. Further, almost all SLE individuals are antinuclear antibody positive (ANA+) although ANA positivity does not obligate autoimmune disease. The differences in cellular physiology between ANA+ healthy individuals and individuals that go on to develop SLE remains a critical goal in the understanding of SLE development. A comprehensive view of immune cell phenotypes in disease is often challenging to ascertain due to limits of assay parameters and proper visualization tools to display cellular hierarchy for high-dimensional data sets. Using mass cytometry, we visualize the expression of 33 cell surface markers through hierarchical clustering using spanning-tree progression analysis of density-normalized events (SPADE) to provide a comprehensive view of the immune system between ANA- and ANA+ healthy controls and ANA+ patients with SLE.

Methods: Blood specimens and information on disease activity were collected from eight African American SLE patients. Patients were matched by age (±5 years), race, and gender to healthy individuals positive for ANA without classifiable lupus (ANA+, n=8) and ANA negative healthy controls (ANA-, n=8). Single-cell analysis of cell surface markers was completed by mass cytometry and cellular heterogeneity was analyzed using SPADE. Significant differences in cell population frequencies were determined using ANOVA and Wilcoxon rank test. Plasma samples isolated from patients at time of draw were analyzed for 51 cytokines using a multiplex immunoassay.

Results: Compared to both ANA+ and ANA- healthy controls, SLE patients had lower frequencies of cytotoxic CD8+ T cells, regulatory CD4+ T cells and early progenitor cell populations ($P<0.05$). Significant differences in progenitor cells nodes were found in CD4 and CD8 negative CD3+ T cells and surface marker null progenitor cells. Concentrations of serum sCD40 ligand were significantly lower in patients with SLE compared with ANA+ and ANA- healthy controls ($p<0.05$). Interestingly, sCD40L production positively correlated with a decrease in regulatory CD4+ T cell populations ($p<0.01$). Further, IL-7 levels were lower in both ANA+ controls and SLE patients compared with ANA- healthy individuals ($p<0.05$).

Conclusion: Our results indicate that early differences in progenitor cell populations may contribute to decreased levels of regulatory CD8+ and CD4+ T cells important for controlling systemic inflammation. Further, the decreased production of IL-7, which is important for the differentiation of hematopoietic stem cells into lymphoid progenitors, in SLE patients and ANA+ patients may contribute to early immune defects in progenitor lymphoid populations leading to loss of tolerance in autoimmunity.

The CUL4^{CRBN} E3 Ubiquitin Ligase Modulator CC-220 Induces Degradation of the Transcription Factors Ikaros and Aiolos: Immunomodulation in Healthy Volunteers and Relevance to Systemic Lupus Erythematosus. Peter H. Schafer, Ying Ye, Lei Wu, Jolanta Kosek, Zhihong Yang, Liangang Liu, Michael Thomas, Maria Palmisano and Rajesh Chopra. Celgene Corporation, Summit, NJ.

Background/Purpose: CC-220 is an immunomodulatory compound that binds to cereblon (CRBN), part of the CUL4^{CRBN} E3 ubiquitin ligase complex, which has been shown to ubiquitinate the transcription factors Ikaros (IKZF1) and Aiolos (IKZF3). Polymorphisms at the IKZF1 and IKZF3 loci have been associated with risk of systemic lupus erythematosus (SLE). We explored CRBN, IKZF1, and IKZF3 gene expression in peripheral blood mononuclear cells (PBMC) from SLE patients, the effect of CC-220 on Ikaros and Aiolos protein levels and SLE autoantibody production in vitro, and the impact of CC-220 on immunological parameters in a phase 1, double-blinded, placebo-controlled, single ascending dose, healthy volunteer study.

Methods: CRBN, IKZF1, and IKZF3 gene expression was measured by qRT-PCR. Ikaros and Aiolos protein levels were measured by western blot and flow cytometry. Anti-dsDNA and anti-phospholipid autoantibodies were measured from SLE PBMC cultures treated for 7 days with CC-220. In the phase 1 healthy volunteer study, 56 subjects were randomized and enrolled in 7 cohorts, with 6 subjects per cohort receiving a single oral dose of CC-220 (0.03 to 6 mg) and 2 subjects per cohort receiving placebo. CD19+ B cells, CD3+ T cells, and intracellular Aiolos were measured by flow cytometry. IL-2 and IL-1β production were stimulated with anti-CD3 or lipopolysaccharide, respectively, in the TruCulture ex vivo whole blood assay system.

Results: Compared to normal PBMC, SLE PBMC expressed significantly higher levels of CRBN (1.5-fold), IKZF1 (2.1-fold), and IKZF3 (4.1-fold). CC-220 treatment of whole blood significantly reduced Ikaros and Aiolos protein levels in B cells, T cells, and monocytes, but not in granulocytes. In cultures of SLE PBMC, CC-220 inhibited anti-dsDNA and anti-phospholipid autoantibody production with an IC_{50} of ≈10 nM. Following administration of single doses of CC-220 to healthy volunteers, there was a treatment-related decrease in intracellular Aiolos, with minimum mean percent of baseline values of ≈12% to 28% in B cells and ≈0% to 33% in T cells for 0.3 to 6 mg. There was also a treatment-related decrease in absolute CD19+ B cells and CD3+ T cells, with minimum mean percent of baseline values of ≈41% to 67% for B cells and ≈66% to 73% for T cells for 2 to 6 mg. CC-220 administration also resulted in increased IL-2 (maximum mean percent of baseline values ranging from 247% to 1,896% for 0.1 to 6 mg), and a decrease in IL-1β (minimum mean percent of baseline values of ≈11% for 6 mg).

Conclusion: These results demonstrate that CRBN, IKZF1, and IKZF3 mRNA are overexpressed in PBMC from SLE patients. Targeting the CUL4^{CRBN} E3 ubiquitin ligase with CC-220 resulted in a potent reduction in Ikaros and Aiolos protein levels in B cells, T cells, and monocytes, and inhibited autoantibody production. Administration of single doses of CC-220 (0.3 to 6 mg) reduced intracellular Aiolos protein expression in B cells and T cells, reduced absolute B cell and T cell counts in the peripheral blood,

increased T cell-derived IL-2 production, and decreased LPS-induced IL-1β production in whole blood ex vivo. These findings support the further development of CC-220 for the treatment of SLE and other autoimmune diseases.

Autoregulatory Function of IL-10 Producing Pre-Naïve B Cells Is Defective in Systemic Lupus Erythematosus. Ji-Hyun Sim[1], Hang-Rae Kim[1], Soog-Hee Chang[1], In Je Kim[2], Peter E. Lipsky[3] and Jisoo Lee[2]. [1]Seoul National University, Seoul, South Korea, [2]Ewha Womans University School of Medicine, Seoul, South Korea, [3]AMPEL BioSolutions, Charlottesville, VA.

Background/Purpose: Pre-naive B cells represent an intermediate stage in human B cell development with some functions of mature cells, but their involvement in immune responses is unknown. The aim of this study was to determine the functional role of normal pre-naive B cells and possible abnormalities in systemic lupus erythematosus (SLE) that might contribute to disease pathogenesis.

Methods: Pre-naïve, naïve and memory B cells from healthy individuals and SLE patients were stimulated through CD40 and were analyzed for IL-10 production and co-stimulatory molecule expression, and their regulation of T cell activation. Autoreactivity of antibodies produced by pre-naïve B cells was tested by measuring IgM autoantibodies in culture supernatants after differentiation.

Results: CD40-stimulated pre-naive B cells produce large amounts of IL-10, but did not suppress $CD4^+$ T cell cytokine production. Activated pre-naive B cells demonstrated IL-10 mediated ineffective promotion of $CD4^+$ T cell activation, and IL-10 independent impairment of co-stimulatory molecule expression and TNF-a and IL-6 production. IgM antibodies produced by differentiated pre-naive B cells were reactive to ssDNA. SLE pre-naive B cells were defective in producing IL-10, and co-stimulatory molecule expression was enhanced, resulting in promotion of robust $CD4^+$T cell activation.

Conclusion: There is an inherent and IL-10 mediated mechanism that limits the capacity of normal pre-naïve B cells from participating in cellular immune response, but these cells can differentiate into autoantibody secreting plasma cells. In SLE, defects in IL-10 secretion permit pre-naive B cells to promote $CD4^+$ T cell activation, and may, thereby, enhance the development of autoimmunity.

A Novel $CD123^-CD11c^-$ Dendritic Cell Subset Increased in Relation to Disease Activity in Patients with Systemic Lupus Erythematosus. Satoshi Kubo, Shingo Nakayamada, Naoki Yunoue, Maiko Yoshikawa, Kunihiro Yamaoka and Yoshiya Tanaka. University of Occupational and Environmental Health, Japan, Kitakyushu, Japan.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by overproduction of autoantibodies by B cells and breaking self-tolerance of T cells and dendritic cells (DCs). However, little is known about the relationship between these immune cells in the etiology of SLE. Here, we found a novel DC subset and investigated the interaction among immune cell subsets in SLE.

Methods: Peripheral blood mononuclear cells were obtained from 44 patients with SLE, 20 with rheumatoid arthritis (RA), and 8 healthy donors (HD). Circulating B cells, T cells and DCs were defined based on comprehensive flow cytometric analysis for human immune system termed 'the Human Immunology Project' by NIH/FOCIS.

Results: The proportion of central memory B cells, effector B cells, and plasmablasts was higher ($p=0.04$, $p=0.001$, respectively), whereas the proportion of IgM memory B cells was lower ($p<0.001$) in SLE, compared to HD and RA. For T cell subsets, the proportion of effector memory T cells was highest in SLE ($p=0.04$). For DCs which were defined as $CD3^-CD14^-CD19^-CD20^-HLA\text{-}DR^{hi}$, the percentage of $CD11c^+$ myeloid DCs significantly decreased in SLE ($p<0.001$), while that of $CD123^+$ plasmacytoid DCs was comparable among SLE, HD and RA ($p=0.48$). Interestingly, DCs that expressed neither CD11c nor CD123 were detected exclusively in SLE but not in the control or RA ($p<0.001$). To assess pathological relevance of this double-negative DC subset in SLE, we calculated the Pearson product-moment correlation coefficient among immune cell subsets and also conducted correlation clustering analysis. Among them, Double-negative DCs characteristically clustered with the central memory B cells and plasmablasts, and was correlated positively with plasmablasts ($p=0.04$) and negatively with myeloid DCs ($p<0.001$) and plasmacytoid DCs ($p=0.04$). Furthermore, the percentage of double-negative DCs was correlated with scores of Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and the British Isles Lupus Assessment Group (BILAG) index in patients. In 13 patients with treatment-naive in this cohort, the percentage of double-negative DCs was correlated positively with scores of SLEDAI and BILAG index as well as serum anti-dsDNA antibody levels and negatively with CH50 levels.

Conclusion: These results suggest that a novel $CD123^-CD11c^-$ DC subset characteristically increased in relation to central memory B cells and plasmablasts in patients with treatment-naïve SLE. Furthermore, the frequencies of novel DC subsets were correlated with scores of SLEDAI and BILAG and serum levels of anti-dsDNA antibody, indicating that this DC subset may contribute to disease activity and autoantibody production. Although further studies are required, our findings would shed light on the activation mechanism of autoantibody production through the interaction between a novel DC subset and central memory B cells/plasmablasts in SLE and could be potentially useful in the design of new therapeutic strategies.

Up-Regulated Expression of CXCR4 on Circulating B Cells in Patients with Systemic Lupus Erythematosus. Hironari Hanaoka, Yuka Okazaki, Akinori Hashiguchi, Hidekata Yasuoka, Tsutomu Takeuchi and Masataka Kuwana. Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: It is increasingly appreciated that circulating B cells are functionally altered and are involved in pathogenic process in patients with systemic lupus erythematosus (SLE). We previously reported that anti-dsDNA antibody-secreting B cells and plasma cells were recruited into circulation in active disease phase in SLE patients. In this study, we evaluated roles of circulating B cells in pathogenic process of SLE by focusing on chemokines.

Methods: We studied peripheral blood samples from 38 patients with SLE and 13 healthy donors. We recorded the disease activity index (SLEDAI) at blood sampling by a retrospective chart review. According to the previous report, active disease was defined as SLEDAI ≥ 5. Peripheral blood mononuclear cells (PBMCs) were obtained by density gradient centrifugation and analyzed by flow cytometry for expression or mean fluorescence intensity of CXCR4, CXCR5 and CCR7 on CD19+ B cells. The concentration of serum CXCL12, which is a ligand for CXCR4, was also measured by enzyme immunoassay. Chemotaxis assay was conducted to test the chemotactic responsiveness of B cells toward the CXCL12. Infiltration of CD19+ B cells with expression of CXCR4 in renal tissue from patients with lupus nephritis ISN/RPS class IV was semi-quantitatively assessed by immunohistochemistry. In this experiment, renal specimens from patients with IgA nephropathy were used as a disease control.

Results: Seventeen active and 21 inactive patients with SLE were enrolled. Flow cytometric analysis revealed that expression of CXCR4 was higher in patients with SLE than normal healthy controls ($p = 0.035$). In patients with SLE, the expression of CXCR4 was higher in those with active disease than in those with inactive ($p = 0.001$). The expression levels of CXCR5 and CXCR7 were not different between patients with SLE and normal healthy controls. In contrast, there was no difference in circulating concentration of CXCL12 between patients with active and inactive disease (2113 vs 2201 pg/ml, $p = 0.263$). Migration ability of B cells toward CXCL12 was enhanced in SLE patients compared with normal healthy controls (33.9 vs 19.4 %, $p = 0.005$). Moreover, SLE patients with active disease represented more prominent chemotaxis towards CXCL12 than did

those with inactive disease (52.9 vs 27.6 %, p = 0.004). Finally, infiltration of CXCR4-expressing CD19+ B cells into the renal interstitium was more prominent in lupus nephritis than IgA nephropathy (p = 0.003).

Conclusion: In SLE patients with active disease, B cells with up-regulated expression of CXCR4 and enhanced chemotaxic responsiveness towards CXCL12 were increased in circulation. These aberrant B cells may be involved in the pathogenic process of SLE by infiltrating into the inflamed organs such as kidneys.

Hyporesponsiveness to TLR9 in Term of Cytokines Production By B Cells in SLE-Patients. Julia Sieber[1], Capucine Daridon[1], Sarah J. Fleischer[1], Vanessa Fleischer[1], Falk Hiepe[1], Tobias Alexander[1], Guido Heine[2], Gerd Burmester[3], Simon Fillatreau[4] and Thomas Dörner[1]. [1]Charité University Medicine, Dept. Medicine/Rheumatology and Clinical Immunology/ German Rheumatism Research Center (DRFZ), Berlin, Germany, [2]Charité University Medicine, Dept. Dermatology, Venerology and Allergology, Berlin, Germany, [3]Charité University Medicine, Dept. Medicine/ Rheumatology and Clinical Immunology, Berlin, Germany, [4]German Rheumatism Research Center (DRFZ), Berlin, Germany.

Background/Purpose: The role of B cells in immunity has been mainly related to the generation of antibodies and formation of immune complexes. However, B cells can exert additional functions, such as antigen presentation, activation of T cells, formation of lymphoid organs and secretion of cytokines which has not been comprehensively explored in human autoimmunity. In systemic lupus erythematosus (SLE), which is a prototypic autoimmune disease characterized by a breakdown of tolerance toward nuclear antigens, cytokine production induced by toll-like receptor (TLR)9 is of great interest. It remains unclear to what extent B cells from SLE patients are able to produce cytokine in reaction to TLR9 stimulation.

Methods: Peripheral B cells from 18 SLE patients and 13 healthy donors (HD) were purified from peripheral blood mononuclear cells (PBMCs) by Magnetic Activated Cell Sorting and were stimulated with CpG 2006 *in vitro* for 48 hours. Subsequently, cell culture supernatants were tested for 28 cytokines (Bio-Plex). In a subgroup of subjects (6 SLE, 10 HD), activation status (CD38 expression), proliferation (% $Ki67^+$ B cells) and IL-10 producing B-cells were studied by flow cytometry after 48h of TLR9 stimulation of PBMCs. The response of B cells from SLE patients and HD upon TLR9 stimulation was compared regarding proliferation, activation and cytokine production and correlated with disease activity, anti-dsDNA titers and B cells subsets.

Results: SLE patients had a lower frequency of proliferating B cells upon TLR9 stimulation than HD ($p<0.05$). B cells from HD significantly up-regulated CD38, resulting in a 3-fold increase after TLR9 stimulation, while the response of B cells from SLE patients was significantly lower ($p<0.05$). Even though, the profiles of cytokine secretion observed in the supernatants of cultured B cells from SLE patients and HD were largely similar; the production of IL-6, IL-1ra, and VEGF by B cells was significantly reduced in active SLE patients (SLEDAI ≥ 6) compared to HD. In addition, correlation analyses of individual cytokines revealed significant inverse correlations between the SLEDAI and inducible amounts of IL-6, IL-9, IL-17A, IFN-γ, IP-10, MIP-1α, MIP-1β, TNF-α, and VEGF of TLR9-activated SLE B cells and between the serum anti-dsDNA titers as well as levels of IL-1ra, IL-6, IL-9, IL-17A, IFN-γ, MIP-1α, -1β, TNF-α, and VEGF produced by TLR9-activated SLE patients B cells. The secretion of IL-10 was also numerically reduced, although it just failed statistical significance ($p=0.051$). The generation of IL-10 producing B cells was not reduced in cultures of B cells from SLE patients.

Conclusion: The data show that TLR9-induced cytokine production by B cells is less efficient with increasing disease activity and either suggests exhaustion or loss of responsiveness of peripheral blood B cells in SLE.

B Lymphocyte Stimulator (BLyS) Promotes Dysregulated Monocyte Function in Systemic Lupus Erythematosus(SLE). Eoghan M. McCarthy[1], Joan Ní Gabhann[2], Siobhán Smith[2], Lorraine O' Neill[3], Eamonn S. Molloy[4], Donough Howard[1], Paul G. O'Connell[1], S. Donnelly[5], Grainne M. Kearns[1] and Caroline Jefferies[2]. [1]Beaumont Hospital, Dublin, Ireland, [2]Royal College of Surgeons in Ireland, Dublin, Ireland, [3]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [4]St. Vincent's University Hospital, Dublin 4, Ireland, [5]Mater Misericordiae University Hospital, Dublin 7, Ireland.

Background/Purpose: SLE involves complex interactions between the innate and adaptive immune systems. Monocytes are increasingly recognised to play a key role in the dysregulated immune response seen in SLE whilst more recently BLyS has been demonstrated to play a key role in the pathogenesis of SLE. Despite the fact that monocytes are one of the key producers of BLyS, the effect of BLyS on monocyte function in health and SLE is poorly understood. The aim of this study was to investigate the effect of BLyS on monocyte signalling and activation in healthy controls and to determine its role in the pathogenesis of SLE.

Methods: Signalling pathways following BLyS stimulation were investigated by Western Blotting in monocytes from healthy controls and SLE patients. qPCR was utilised to investigate pro-inflammatory gene expression. Monocyte supernatant and serum levels of proinflammatory cytokines were measured by ELISA. CD 14+ monocyte activation was assessed by Flow Cytometry. Differences between groups were examined using the Mann Whitney.

Results: Following stimulation with BLyS an increase in phosphorylated levels of STAT1, AKT, p42/44 MAPK and p38 MAPK was observed in healthy controls indicating BLyS signals via a number of pathways in monocytes. A corresponding decrease in total IkB levels was observed. Strikingly SLE patients exhibited significantly enhanced responses to BLyS stimulation compared to controls for the phospho-p42/44 MAPK, AKT and STAT pathways.

qPCR analysis revealed significant increases in BLyS, IL-6 and IFN-γ gene expression in SLE patients following stimulation, a finding that was not replicated in controls. Subsequent ELISA confirmed significantly enhanced IL-6 production in the supernatant of SLE patient monocytes compared to controls following BLyS stimulation. Furthermore the SLE patients exhibited significantly higher levels of IL-6 in their serum.

With regard to BLyS receptors, SLE patient monocytes demonstrated a significant upregulation of TACI expression following stimulation. Increased levels of BAFF-R were also seen in both patients and controls following stimulation.

With respect to monocyte activation SLE patients expressed significantly more CD80, CD86 and HLA-DR in the resting state compared to healthy controls. Despite this baseline hyperactivated state, BLyS stimulation resulted in significant increases in CD80, CD86 and MHC Class II in SLE patients. In contrast the healthy control volunteers failed to significantly upregulate any of the surface markers following BLyS stimulation indicating that SLE patients monocytes are more responsive to the effects of BLyS. Interestingly SLE patients with evidence of immunological activity (dsDNA +ve/Low C3/C4) exhibited enhanced HLA-DR and CD86 expression following BLyS stimulation compared to patients without evidence of such activity.

Finally co-culture of BLyS treated monocytes with T lymphocytes resulted in enhanced expression of the T cell activation marker CD69 on both CD8 and CD4+ T Cells, a finding that was significant in SLE patients.

Conclusion: BLyS promotes dysregulation of monocyte activation and signalling pathways in SLE with consequential excess production of pro-inflammatory cytokines and enhanced T cell activation.

Alterations in B Cell Subsets and BAFF Levels in Autoimmune Rheumatic Diseases Treated with B Cell Depletion Therapy: Rituximab. Pamela M.K. Lutalo[1], David P. D'Cruz[2] and Jo Spencer[3]. [1]King's College London School of Medicine, London, United Kingdom, [2]Guy's and St Thomas' Hospital NHS Foundation Trust, London, United Kingdom, [3]King's College London, School of Medicine, London, United Kingdom.

Background/Purpose: Systemic lupus erythematosus (SLE) and granulomatosis with polyangiitis (GPA) are autoimmune diseases which develop secondary to immune self-tolerance failure. Both diseases are characterised in part by the production of pathogenic autoantibodies. Although they are different clinically, genetically and immunologically, SLE and GPA may be treated successfully with rituximab, an anti-CD20 monoclonal antibody B cell depleting drug.

The repopulation of B cells post-rituximab is of interest as the timing may differ in different autoimmune diseases and may be associated with serum factors, such as B cell activating factor (BAFF), which promotes B cell survival or with characteristics of specific B cell subsets.

Methods: A prospective longitudinal study of 12 patients with SLE and 12 patients with GPA pre-rituximab and at set intervals post-rituximab with matched autoimmune controls was conducted. Demographic, clinical and laboratory data was obtained in all patients with comparison to healthy controls.

Flow cytometry analysis of transitional B cell, naive mature B cell and memory B cell subsets was conducted in experiments staining isolated peripheral blood mononuclear cells with antibodies to CD19, IgD, CD27, CD24 and CD38. The expression of $\alpha4\beta7$ integrin by B cell subsets was analysed. Plasma BAFF levels were measured by ELISA at baseline, 3 months and 6 months post-rituximab. Statistical analysis was done using GraphPad Prism version 5.

Results: B cells were found to repopulate the blood earlier after rituximab in some cases of SLE compared to GPA. There was no statistically significant difference between the pre-rituximab CD19+ B cell percentage of total lymphocytes in SLE and GPA [$p=0.37$], however at 3 months and 6 months post-rituximab SLE patients had a greater population of CD19+ B cells in the peripheral blood compared to GPA patients [$p=0.02$, $p=0.001$, respectively]. Early repopulation was found to be independent of serum factors, but was related to the expression of $\alpha4\beta7$ integrin by subsets of B cells. $\alpha4\beta7$ integrin expression by T1 and T2 transitional B cells, naive mature B cells and memory B cells was significantly lower in SLE patients compared to GPA patients pre-rituximab [$p<0.0001$, $p=0.0003$, $p=0.0008$ and $p=0.0005$, respectively]. A separate analysis revealed significantly lower $\alpha4\beta7$ integrin expression in the early repopulation group, defined as B cell count >5 cells/μl ≤ 3 months post-rituximab, compared to SLE patients who repopulated the peripheral B cell pool later [$p=0.004$, $p=0.004$ and $p=0.003$, $p=0.7$ respectively].

Plasma BAFF levels were elevated in SLE and GPA patients pre-rituximab compared to HC [$p=0.008$, $p=0.001$ respectively] with a rise in BAFF levels detected in SLE 3 months post-rituximab [$p=0.006$] but no difference in SLE 6 months post-rituximab [$p=0.25$]. Plasma BAFF levels did not change significantly in the GPA cohort post-rituximab. Plasma BAFF levels were positively correlated with percentage transitional B cells [$r=0.44$, $p=0.04$].

Conclusion: There may be an association between the early repopulation of the peripheral blood B cell pool, $\alpha4\beta7$ integrin by subsets of B cells and rise in BAFF levels in a cohort of SLE patients.

Relationship Between Soluble sCD23 and B Cell Activation Factor in Patients with Systemic Lupus Erythematosus before and after Rituximab. Laura Heretiu[1], Maria J. Leandro[2], Venkat Reddy[3], David A. Isenberg[2] and Geraldine Cambridge[2]. [1]'Sf. Maria' Clinical Hospital, Bucharest, Romania, [2]Centre for Rheumatology, Department of Medicine, University College London, London, United Kingdom, [3]Centre for Rheumatology Research, Division of Medicine, University College London, London, United Kingdom.

Background/Purpose: CD23 is the low-affinity receptor for IgE (FceRII). The soluble form, sCD23 is released into the circulation and in vitro this is consistent with cleavage from naive B cells and expression of CD27 (a marker of memory B cells). BAFF (B cell activation factor) is a survival factor for predominantly naive B cells and is involved in B-cell proliferation, plasma cell differentiation and, with APRIL, also class switching. High levels of sCD23 and of BAFF can be present in sera from patients with Systemic Lupus Erythematosus (SLE) and other autoimmune diseases. The interrelation between sCD23 and BAFF has not been studied in relation to Rituximab (RTX) treatment.

Aim To investigate the relationship between sCD23 and serum BAFF at baseline and after RTX in patients with SLE.

Methods: Twenty eight patients with SLE (diagnosed according to the 1982 ACR revised criteria) were studied before B cell depletion therapy (BCDT) based on RTX and 18 SLE patients after RTX treatment. Twenty eight healthy controls (HC) were also included. Serum sCD23 (normal range given by manufacturers; 1235–5024pg/ml;) and BAFF levels were determined using ELISA. Results were analysed in relation with C3 level, anti-ds DNA titer, IgA, IgG, IgM level and CD19+ B cell count.

Results: Before RTX, sCD23 levels were positively correlated with serum BAFF ($p=0.05$, r^2 0.47). There was no correlation between sCD23 levels with C3, anti ds-DNA, total serum IgA, IgG or IgM. In HC, sCD23 levels did not correlate with serum BAFF ($r^2=0.23$: $p=0.10$). Further, in patients with levels of sCD23 above the normal range (>5024pg/ml; $n=7$) median BAFF levels were significantly higher than those with sCD23 within normal limits ($n=21$) (median BAFF levels: 3.37 and 1.35 ng/ml respectively).

In the 15/28 SLE patients with active disease (BILAG score), there was an even stronger correlation between sCD23 levels and serum BAFF ($r^2=0.56$, $p=0.001$) but no correlation between sCD23 and anti-ds-DNA, IgA, IgG or IgM levels. There was a tendency towards lower C3 values in those patients with sCD23 above the normal range. Median BAFF levels were significantly higher in this group ($n=6$; 5.75 ng/ml) compared to patients with sCD23 within the normal range ($n=9$; median BAFF: 1.25 ng/ml) ($p=0.001$).

After RTX, in 10 patients from whom serial samples were available, sCD23 decreased by a median of 39% at 3 months and 56% at 3–6 months consistent with removal of the majority of circulating B cells but levels did not fall below the normal range.

Conclusion: *In vitro*, the addition of BAFF to B cell cultures stimulated through either Toll-like receptors and the B-cell receptor significantly increases sCD23 cleavage from the B cell surface. Before RTX, serum BAFF levels were related to levels of sCD23 above the normal range in patients with SLE, most markedly in patients with active disease. Serum BAFF is raised in some SLE patients due to changes in availability of BAFF-R, B-cell lymphopenia, BAFF production, or induction by interferons. Germinal center structure is also disturbed in SLE, possibly related to high BAFF levels, which may result in decreased stringency for naïve B cell differentiation into memory phenotype, accompanied by release of sCD23. Levels of sCD23 may be a useful measure of B cell maturation *in vivo*.

Gender Disparities in Lung Transplantation in Patients with Systemic Sclerosis-Related Interstitial Lung Disease and Pulmonary Hypertension. Elizabeth Volkmann[1], Daniel E. Furst[2], Rajeev Saggar[3], Philip J. Clements[4], Bryant Torres[5], Lynne Yoder[1] and Rajan Saggar[1]. [1]University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, CA, [2]University of California, Los Angeles, CA, [3]University of Arizona College of Medicine, Phoenix, AZ, [4]University of California, Los Angeles, Department of Medicine, Los Angeles, CA, [5]Rollins School of Public Health, Emory University, Atlanta, GA.

Background/Purpose: Lung transplantation is often the most viable option for patients with severe systemic sclerosis (SSc)-associated interstitial lung disease (ILD) that is unresponsive to pharmacologic intervention. This study investigates gender differences in lung transplantation rates in patients with SSc-ILD with concomitant precapillary pulmonary hypertension (PH).

Methods: SSc patients with right heart catheterization (RHC)-diagnosed precapillary PH (mean pulmonary artery pressure (mPAP) $\geq$25 mmHg, pulmonary capillary wedge pressure (PCWP) $\leq$15 mmHg, and pulmonary vascular resistance (PVR) $\geq$240 dynesxsecond/cm^5) were included. All patients had extensive ILD based on review of high-resolution computed tomography (HRCT) chest imaging and spirometry. Independent t-tests and Fisher's Exact Test were used to compare differences in continuous and

categorical variables, respectively. Logistic regression was used to identify variables associated with lung transplantation.

Results: Of 71 patients with SSc-PH-ILD, 70% were women and 30% were men. Baseline characteristics (ethnicity, SSc type, SSc disease duration), co-morbidities (hypertension, coronary artery disease, diabetes mellitus), and hemodynamic and pulmonary parameters (mPAP, PCWP, PVR, FVC/DL_{CO}Ratio) were similar for men and women with the exception of age (Mean age (years): Women 56 vs. Men 50, p=0.03). There were no gender differences in median follow up time (All patients: 26 months). In all patients who underwent transplantation, the mPAP was 36.6 (SD 7.7) and the mean forced vital capacity (FVC)% predicted was 50.5 (SD 17.4); there were no differences in mPAP and FVC% predicted between patients who underwent transplantation and those who did not (all p-values =0.2). More men (38%) underwent transplantation than women (12%), p=0.016. The median time to transplantation from RHC was longer for women (21 months) than for men (10 months), p=0.09. In the logistic regression model, male gender (OR 2.3; p=0.02) was the only factor significantly associated with transplantation, even after controlling for severity of ILD and PH.

Conclusion: Among all patients with RHC-diagnosed precapillary PH and extensive ILD, there were no significant differences in mPAP and FVC% predicted between patients who underwent lung transplantation and those who did not. Lung transplantation occurred earlier and more frequently in men than in women with SSc-PH-ILD, even after accounting for severity of ILD and PH.

Survival in Systemic Sclerosis-Pulmonary Arterial Hypertension By Serum Autoantibody Status. Monique Hinchcliff[1], Saira Khanna[1], Jungwha Lee[1], Orit Almagor[2], Rowland W. Chang[1], Virginia D. Steen[3] and Lorinda Chung[4]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Georgetown University Medical Center, Washington, DC, [4]Stanford University School of Medicine, Palo Alto, CA.

Background/Purpose: Previous studies have shown that anticentromere (AC) and isolated nucleolar (NUC) antibodies are the most common autoantibodies in patients with systemic sclerosis (SSc) and World Health Organization (WHO) group 1 pulmonary arterial hypertension (PAH). The goal of the present study was to determine the association between serum autoantibodies and survival in patients with newly diagnosed PAH who are enrolled in the PHAROS (**P**ulmonary **H**ypertension **a**nd **R**ecognition of **O**utcomes in **S**cleroderma) Registry.

Methods: We evaluated patients from the multi-center, prospective, observational PHAROS registry who had definite PAH diagnosed by right-heart catheterization (RHC) (mean pulmonary artery pressure (mPAP) ≥ 25mmHg and pulmonary capillary wedge pressure (PCWP)[2] 15mmHg) within 6 months of enrollment. Medical history, laboratory (including serum autoantibodies), pulmonary function test, echocardiogram, 6-minute walk distance, and RHC data were collected at baseline and biannually or as clinically indicated. Mortality data were collected from participating centers' electronic medical records and/or the Social Security Death Index. Kaplan-Meier estimates for survival were determined for 6 different autoantibody groups. Multivariable Cox regression analyses were performed to assess risk of death by hazard ratios (HR) in each autoantibody group, controlling for age, sex, SSc disease duration (defined as duration since first Raynaud symptom), forced vital capacity (FVC) % predicted, and skin score.

Results: 163 PHAROS subjects met WHO group 1 PAH criteria and had serum autoantibody information available (7 missing autoantibody data, 7 with negative autoantibody test). More than half had either AC or NUC; 61 (36%) subjects had AC, 39 (23%) NUC, 11 (6%) Scl70, 28 (16%) had mixed/other, 9 (5%) RNA polymerase III (RNApol), 8 (5%) U1RNP autoantibodies. The mean SSc disease duration at PAH diagnosis was longest for AC (19.3±13.4y) and shorter for NUC patients (12.2±9.8, compared to AC p=0.02). Thirty-two (21%) subjects died over a mean follow-up time of 2.4±1.7 (median 2.0, range 0–7.2) years. 1-, 3-year survival across all antibody groups was 93% and 77%; 1- and 3-year survival estimates were 94% and 72% for AC; 94% and 79% for NUC; 89% and 63% for Scl70; 100% and 86% for U1RNP; 92% and 79% for mixed/other. No patient with RNApol or negative autoantibodies died over the follow-up period. For all autoantibody groups, unadjusted and adjusted HR revealed no statistically significant association between risk of death and autoantibody positivity.

Conclusion: Anticentromere and NUC autoantibodies are prevalent in SSc patients with PAH. PAH may be a late complication in AC patients, but may occur earlier in SSc patients with other autoantibodies. There does not appear to be a significant association between SSc antibody type and survival in patients with PAH.

Table 1: Clinical Characteristics for World Health Organization Group 1 (PAH) Patients

Optimizing Scleroderma Centers of Excellence: Perspectives from Patients and Scleroderma (SSc) Experts. Veronika K. Jaeger[1], Andrew Aubin[2], Nancy Baldwin[3], Kim Fligelstone[4], Robyn Sims[5], Joep Welling[6], Ryan Burrill[7], Kerri Connolly[7], Tracy Frech[8], Jessica K. Gordon[9], Tanaka Ngcozana[10], Monika Kowalczyk[11], Matthew R. Lammi[12], Ulrich A. Walker[1] and Lesley Ann Saketkoo[13]. [1]Department of Rheumatology, University Hospital Basel, Basel, Switzerland, Basel, Switzerland, [2]Louisiana State University School of Medicine, New Orleans, LA, [3]Scleroderma Foundation-Chicago Support Group, Chicago, IL, [4]Royal Free Hospital, Scleroderma Unit and Scleroderma Society, London, United Kingdom, [5]Scleroderma Australia, Victoria, Australia, [6]The Dutch Patient Organization for Systemic Autoimmune Diseases, Utrecht, Netherlands, [7]Scleroderma Foundation, Boston, MA, [8]University of Utah, Salt Lake City, UT, [9]Hospital for Special Surgery, New York, NY, [10]Royal Free hospital, London, United Kingdom, [11]Tulane University School of Medicine, New Orleans, LA, [12]Louisiana State University Health Sciences Center, Pulmonary and Critical Medicine, New Orleans, LA, [13]Louisiana State University Health Sciences Center, New Orleans, LA.

Background/Purpose: SSc is a complex, diffuse, devastating health condition of vascular injury, inflammation and fibrosis resulting in multiple organ-system derangements with high impact on survival and quality of life. Demonstrated research activity tends to define SSc Centers of Excellence (SCoE) certification. However, SSc complications require coordinated high-level multi-specialty expert care. The Scleroderma Foundation in partnership with Scleroderma Australia and Scleroderma Society UK engaged SSc patients and SSc health providers (HPs) in a multi-tiered process to assess priorities in recognition of SCoEs.

Methods: A mixed methods design ensured comprehensive item collection in addressing 'important qualities and services in a certified SSc Center of Excellence'. A core of 35 patients, SSc HPs from 8 countries initiated the study through an iterative process using nominal group technique with rounds of item collection modification and review until saturation and satisfaction of proposed survey content was achieved and subsequently field-tested with a 5 point scale (critical to low importance). Participation was screened and 'gate-controlled' with online survey access through a unique one-time link. Telephone interview was offered for accessibility. Responses from SSc

patients and HPs were compared by Pearson's X2 or Fisher's exact tests as appropriate.

Results: Initial phases yielded a 54 item survey that was field-tested in 15 SSc patients and HPs. 400 patients and SSc HPs received surveys of which 299 from 19 countries (75% response rate) were completers. Expert care superseded research as a priority of 'critical importance' by HPs and patients respectively at 69% and 48% (p=0.02) and by 94% and 89% (p=0.8) when 'critical to very important' were collapsed. 3 questions provided internal cross-validation of this query. "SCoEs should engage in research" received 57% of patients and 48% of HPs (p=0.37) as being critical. Further, education, rehabilitative services and support networks were consistently highly rated items with topics stratified by ratings (tables 1 & 2). Discrepant areas of importance between patients and HPs are highlighted in tables.

Conclusion: Participation was robust in all project stages emphasizing the perceived global importance of this effort. Though research is of clear importance, quality expert care incorporating rehabilitative and educational provisions is a SCoE operational priority. These findings signal the need to redefine SCoE certification standards and provide a roadmap to SCoE development.

Table 1. Selected survey items. 5-point scale represented under 3 categories: 1. Critical importance, 2. Very important and 3. Moderate importance to not important collapsed. P value = between groups.

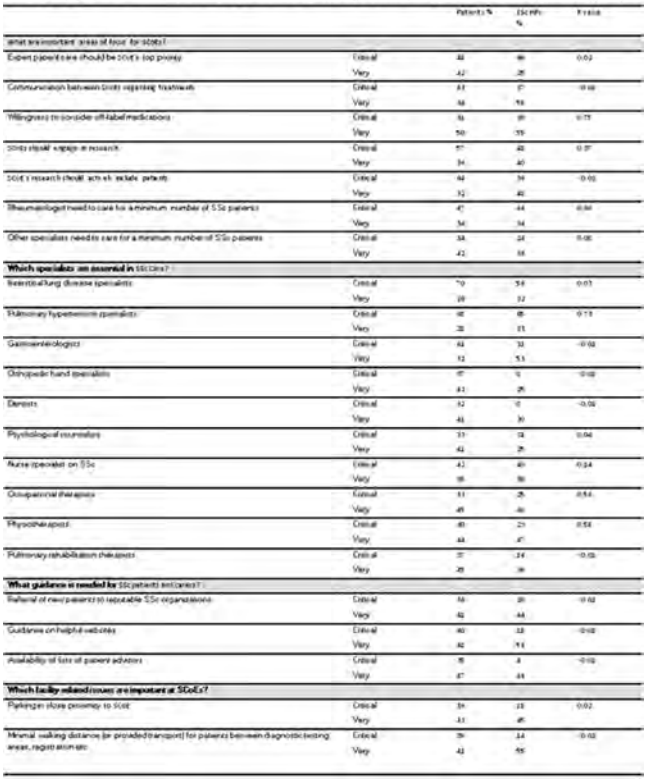

Table 2. Priority of Perceived Educational Needs

	Patients	HPs	Overall
'Red Flag Symptoms' to help patients recognize when to seek medical attention	54%	28%	49%
Overview of available treatments for SSc (with associated risks and benefits)	48%	17%	43%
Stress reduction, cold management, pain management strategies, and exercise	46%	21%	42%
Dietary/nutritional strategies to ease symptoms	38%	15%	34%
Current clinical trials available	36%	28%	35%
Over-the-counter medications or preparations for relieving symptoms	35%	13%	31%
Specialized treatment options (like hand surgeries or stem cell transplants)	34%	11%	30%
'Helping' tools and devices for assistance with daily living	31%	15%	28%

Clinical Phenotype of Systemic Sclerosis Patients with Anti-RNA Polymerase III Antibodies: A New French Cohort, Systematic Review and Meta-Analysis. Vincent Sobanski[1], Luc Dauchet[2], Guillaume Lefèvre[3], Marc Lambert[4], Sandrine Morell-Dubois[5], Thierno Sy[5], Eric Hachulla[1], Pierre-Yves Hatron[6], Sylvain Dubucquoi[7] and David Launay[8]. [1]Service de médecine interne, Centre National de Référence de la Sclérodermie Systémique, Hôpital Claude Huriez, CHRU Lille, Lille, France, [2]INSERM U744, LILLE, France, [3]EA 2686, Lille, LILLE, France, [4]Internal Medicine University Lille Hospital, Lille, Lille, France, [5]CHRU Lille, LILLE, France, [6]Internal Medicine, Lille, France, [7]Institut d'Immunologie, Centre de Biologie-Pathologie-Génétique, CHRU Lille, Lille, France, [8]EA 2686, Lille, Lille, France.

Background/Purpose: Anti-RNA polymerase III antibodies (anti-RNAP III) are one of the most frequent antinuclear antibodies identified in systemic sclerosis (SSc), with an estimated prevalence of 11% (95% CI: 8–14) (1). Anti-RNAP III has been associated with some clinical characteristics linked with a poor prognosis such as diffuse cutaneous involvement or renal crisis. More recently, anti-RNAP III have been suggested to play a role in immunological response to cancer (2). This study aimed to (i) confirm this clinical phenotype in a new French cohort followed by a systematic review and meta-analysis of the literature; (ii) test whether unknown clinical associations could be highlighted by a meta-analysis.

Methods: One hundred and thirty tree consecutive and unselected SSc patients were tested for anti-RNAP III. Clinical characteristics were retrieved from our database. PubMed and EMBase were searched for all references providing clinical characteristics of anti-RNAP III positive and negative (controls) SSc patients. Meta-analysis was performed using number of anti-RNAP III positive and controls patients, clinical characteristics and organ involvement.

Results: Twelve patients were found to be anti-RNAP III positive in our cohort. Anti-RNAP III was associated with diffuse cutaneous involvement (p=0.02), myositis, renal crisis and cancer (p=0.01). The systematic review retrieved 112 abstracts from 2003 references, which were read in full-text. Forty-five studies were finally included in the meta-analysis. The number of studies providing data for each clinical association was comprised between 4 and 26; between 256 to 1098 anti-RNAP III positive patients and 2088 to 6612 controls were included in analysis. Anti-RNAP III were positively associated with diffuse cutaneous involvement, joint involvement, renal crisis, heart involvement and cancer; and negatively associated with female sex. There was no association between anti-RNAP III and esophageal involvement, pulmonary hypertension, interstitial lung disease, digital ulceration, and myositis (Table 1).

Conclusion: This meta-analysis confirmed that SSc patients with anti-RNAP III are at higher risk of severe skin extension, renal crisis and cancer. Merging results from numerous studies also highlighted less known association such as joint and heart involvement. Patients carrying anti-RNAP III should benefit from an appropriate screening of these potentially severe complications.

Relevance of the 6-Minute Walking Test in Assessing the Severity and Outcome of Pulmonary Arterial Hypertension Associated with Systemic Sclerosis, without Extensive Interstitial Lung Disease. Sébastien Sanges[1], David Launay[1], Rennie L. Rhee[2], Olivier Sitbon[3], Eric Hachulla[1], Luc Mouthon[4], Loïc Guillevin[4], Laurence Rottat[3], Pierre Clerson[5], Jean-Francois Cordier[6], Steven M. Kawut[2], Gérald Simonneau[7] and Marc Humbert[3]. [1]Université Lille Nord de France, Faculté de Médecine Henri Warembourg, Lille, Lille, France, [2]University of Pennsylvania, Philadelphia, PA, [3]Université Paris-Sud, Faculté de Médecine, Le Kremlin-Bicêtre, Le Kremlin-Bicêtre, France, [4]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France, [5]Orgametrie, Roubaix, France, [6]Division of Pneumology, Hôpital Louis-Pradel, Hospices Civils de Lyon, Lyon 1, Lyon, France, [7]INSERM U999, Centre Chirurgical Marie-Lannelongue, LabEx LERMIT, Le Plessis-Robinson, Le Plessis-Robinson, France.

Background/Purpose: In pulmonary arterial hypertension (PAH) associated with systemic sclerosis (SSc), no study has yet evaluated the correlation between the 6-minute walking test (6MWT) distance and the right-heart catheterization (RHC) hemodynamic data. This is an important matter, since the 6MWT is used as an outcome measure in SSc-PAH clinical trials, and can be biased by various comorbidities caused by the systemic disease. In this work, we assessed whether there is a correlation between the 6MWT and the RHC parameters at baseline and during follow-up, in SSc-PAH patients without extensive interstitial lung disease (ILD).

Methods: Patients with definite SSc (according to ACR 1987 and/or Leroy criteria), RHC-proven pre-capillary PAH and no extensive ILD on thoracic CT or pulmonary function tests (PFT) were included. Several data were collected regarding the clinical status (age, sex, BMI, NYHA class, SSc subtype), the 6WMT (total distance, heart rate and ΔHR, SaO_2 and ΔSaO_2, Borg score), the RHC (mRAP, mPAP, sPAP, dPAP, cardiac index (CI), PVR, TPR, stroke volume), the PFT and the transthoracic echocardiography, at baseline and during follow-up. The correlation of the 6MWT total distance with each hemodynamic parameter was studied, both at baseline and during follow-up, by linear regression.

Results: The statistical analysis was primarily conducted on a derivation cohort (83 patients from the French National SSc-PAH prospective network), and then confirmed on an independent validation cohort (329 patients from the FDA CTD-PAH register).

At baseline

In the derivation cohort, the univariate analysis showed that the 6MWT total distance was significantly correlated with all the RHC parameters, especially mPAP ($p=0.005$) and CI ($p=0.0001$), and with the NYHA class ($p<0.0001$). In multivariate analysis, the 6WMT total distance was significantly and independently correlated with the CI ($R^2=0.21$, $p=0.0002$) and NYHA classes 3&4 ($R^2=0.12$, $p=0.002$). In this regression model, the hemodynamic status explained only 21% of the distance walked during the test, suggesting the important weight of the confounding comorbidities. Those results were confirmed in the validation cohort, in which a significant, but weaker, correlation with the CI was also found ($R^2=0.08$, $p=0.0001$).

During follow-up

In the univariate analysis conducted on the derivation cohort, the Δ6MWT total distance was non-significantly and weakly correlated with ΔmPAP ($r = -0.20$, $p = 0.15$) and with ΔPVR ($r = -0.17$, $p = 0.22$). Similar results were found on the validation cohort, but reached statistical significance (ΔmPAP : $r = -0.20$, $p = 0.03$; ΔPVR : $r = -0.29$, $p= 0.008$). There were no correlation between Δ6MWT total distance and ΔCI in both cohorts.

Conclusion: To our knowledge, this study is the first to prove a correlation between the baseline 6MWT total distance and the RHC hemodynamic parameters, in SSc-PAH patients without extensive ILD. As the CI explains only 8–21% of the distance, the weight of confounding comorbidities remains important in this test. During follow-up, a weak correlation persists between Δ6MWT and ΔmPAP, but not with ΔCI. These results question the relevance of the 6MWT as an outcome measure for SSc-PAH patients.

Key Roles for Mir-155 and Mir-21 in Progressive Lung Fibrosis Associated with Systemic Sclerosis (SSc-ILD). Romy Christmann[1], Percival D Sampaio-Barros[2], Claudia Borges[3], Carlos Carvalho[4], Ronaldo A Kairalla[5], Edwin R. Parra[4], Giuseppina Stifano[6], Avi Spira[7], Robert W. Simms[7], Vera L. Capelozzi[4] and Robert Lafyatis[8]. [1]Arthritis Center/Rheumatology, Boston, MA, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [3]CEUMA University, Sao Luis do Maranhao, Brazil, [4]University of Sao Paulo School of Medicine, Sao Paulo, Brazil, [5]University of Sao Paulo, Sao Paulo, Brazil, [6]Boston University Medical Center, Boston, MA, [7]Boston University School of Medicine, Boston, MA, [8]Boston University, Boston, MA.

Background/Purpose: We have already reported that macrophage activation, and up-regulation of TGF-beta- and interferon-regulated genes are involved in progressive SSc-ILD. Micro-rnas (miRNA) are a class of small noncoding RNAs that control gene expression and are eventually involved in most biological processes. Therefore, we analyzed simultaneously mRNA and miRNA in the same prospective cohort of SSc-ILD patients in order to explore their complex network and the miRNA's involvement in progressive lung disease.

Methods: Lung tissue was obtained by open lung biopsy in 22 consecutive SSc-ILD patients (11 diffuse and 10 limited cutaneous SSc patients; 5 controls). High-resolution computerized tomography (HRCT) was performed on baseline and 2–3 years after treatment that was based on lung histologic classification. Microarray analysis (mRNA and miRNA) was performed and the results correlated (Pearson's) with changes in HRCT score (FibMax). MirConnX software was used to explore the gene regulatory network between mRNA and miRNA. The study was approved by the Institutional Review Boards from both universities (Brazil and USA).

Results: As already shown, despite treatment, most of SSc-ILD patients progressed based on delta FibMax ($p< 0.01$). Lung miRNA microarray analysis distinguished SSc-ILD from controls (FDR-corrected, $q<0.25$) with 185 miRNA genes (present in ≥25%) that had significant differential expression. The mRNA microarray analysis also confirmed the altered expression of hundreds of genes in our SSc-ILD cohort and MirConnX simultaneous analysis of mRNA and miRNA showed 4 relevant miRNAs in the center of this multifaceted regulation (graphic): mir-182, mir-141, mir-155, and mir-195 (graphic). Pearson's correlation between miRNAs and the top-50 most upregulated mRNAs in SSc-ILD compared to controls showed that mir-155 was strongly correlated ($r>0.5$) with 32/top-50 genes, such as IL13Ra2 ($r=0.75$) and TOP2A ($r=0.68$), mir-21 was the second most correlated (22/top-50 genes), followed by mir-195 (21/top-50 genes), mir-141 (22/top-50 genes), and mir-182 (19/top-50 genes). Mir-155 and mir-21 were also strongly negatively correlated with several top-downregulated mRNA genes, including IL12A, with r=-0.70. A heatmap of the most informative miRNAs showed mir-155 clustering together with mir-21, a known miRNA involved in idiopathic lung fibrosis; and both mir-155/mir-21 expression were strongly correlated ($r^2=0.6$). Surprisingly, only 4 miRNAs were correlated to the delta FibMax: mir-155 (r=0,65), mir-182 (r=0.49), mir-27a (r=0.49), and mir-21 (r=0.47).

Conclusion: Mir-155 and mir-21 were the center of this complex altered gene expression in the lungs of SSc-ILD. More importantly, these miRNAs were key for the progression of the lung fibrosis based on a CT score. Together, anti-miRNA therapy might be a novel target to prevent progressive SSc-ILD.

Elevated Serum Levels of Endostatin in Mixed Connective Tissue Disease - Association with Pulmonary Fibrosis and Digital Ulcers. Silje Reiseter[1], Ragnar Gunnarsson[2], Torhild Garen[2], May Brit Lund[3], T. Mogens Aalokken[4], Anna-Maria Hoffmann-Vold[2], Øyvind Molberg[1] and Thor Ueland[5]. [1]Institute of Clinical Medicine, University of Oslo, Oslo, Norway, [2]Department of Rheumatology, Oslo University Hospital Rikshospitalet, Oslo, Norway, [3]Department of Respiratory Medicine, Oslo University Hospital Rikshopitalet, Oslo, Norway, [4]Department of Radiology, Oslo University Hospital Rikshospitalet, Oslo, Norway, [5]Research Institute for Internal Medicine, University of Oslo, Oslo, Norway.

Background/Purpose: Mixed Connective Tissue Disease (MCTD) is a chronic, immune-mediated disorder defined by the combined presence of serum anti-RNP antibodies and selected clinical features of Systemic Sclerosis (SSc), Systemic Lupus Erythematosus and Polymyositis. Previous studies have revealed increased values of endostatin and Vascular Endothelial Growth Factor (VEGF) in MCTD (1) and SSc (2), suggesting that an altered angiogenic balance might play a pathogenic role in both diseases. The aim of this study was to examine the serum levels of endostatin and VEGF in MCTD, compared to SSc and Healthy Controls (HC).

Methods: Sera of MCTD patients (N=169) from the cross-sectional nationwide Norwegian MCTD cohort (n=136) and the Norwegian Systemic Tissue Disease and Vasculitides Registry (NOSVAR) (n=33) were assessed. SSc patients (N=310) were included from NOSVAR. Age- and sex-matched healthy blood donors were included as HC (N=100). Clinical parameters examined in MCTD patients were; digital ulcers (N=136), pulmonary fibrosis (N=158) and Forced Vital Capacity (FVC) % of predicted value (N=142). Pulmonary fibrosis was defined according to the Fleischner Society classification system for high-resolution CT Abnormalities. Serum levels of endostatin and VEGF were assessed by ELISA and compared by Means (M) and Standard Deviation (SD) in all groups. Statistical differences were analyzed by the independent sample t-test with significance level $P \leq .05$.

Results: The levels of endostatin were higher in the MCTD group M(SD) 83.0(24) ng/ml compared to HC 65.1(12) ng/ml ($P<.001$), but lower compared to SSc 93.0(37) ng/ml, ($P<.001$). The levels of VEGF in MCTD were not different compared to HC and SSc. However, levels of VEGF were elevated in SSc vs. HC (251.8(185) vs. 186.1(130) pg/ml, $P<.001$). MCTD patients with digital ulcers had higher endostatin levels (90.4(26) ng/ml) than MCTD patients without digital ulcers (79.6(21) ng/ml, $P<.05$). Mean endostatin levels were increased in MCTD patients with pulmonary fibrosis 90.5(33) ng/ml compared to MCTD without pulmonary fibrosis 79.9(20) ng/ml ($P<.05$). Correspondingly, MCTD patients with FVC< 80% had higher endostatin levels 94.5(33) ng/ml than MCTD patients with FVC ≥80% 81.8(21) ng/ml ($P<.05$).

Conclusion: MCTD patients have significantly elevated serum levels of endostatin, but not elevated serum levels of VEGF. Increased circulating levels of endostatin can indicate dysregulation of angiogenesis in MCTD, particularly in patient subgroups with digital ulcers and pulmonary fibrosis.

Fatigue in Systemic Sclerosis. Didem Uzunaslan[1], Caner Saygin[1], Tufan Torun[2], Mehmet Ozdemir[2] and Gulen Hatemi[3]. [1]University of Istanbul, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey, [2]Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey, [3]Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey.

Background/Purpose: Fatigue is a frequently reported disabling symptom for patients with systemic sclerosis (SSc). It has a major impact on overall quality of life including work, family and social life. Our aim is to evaluate the frequency of fatigue among SSc patients compared to healthy and diseased controls and to delineate the factors associated with fatigue.

Methods: We included SSc and rheumatoid arthritis (RA) patients who visited our outpatient clinic for their routine follow-up and healthy controls recruited from hospital staff. Comprehensive physical examination with nailfold capillaroscopy and assessment of Rodnan skin score (RSS) were performed by a single physician. Health assessment questionnaire disability index (HAQ-DI), multidimensional assessment of fatigue (MAF) scale, fatigue severity scale (FSS), fatigue impact scale (FIS), and Beck depression inventory (BDI) were filed by all participants. Having a score of ≥5 in FSS was tabulated as having fatigue for statistical analysis. Multivariate regression analysis was performed to determine the factors associated with high fatigue scores in SSc.

Results: Seventy patients with SSc, 52 RA patients and 100 healthy controls were included in this study. MAF scores were significantly higher among RA patients ($p<0.0001$), followed by SSc patients ($p=0.013$) compared to healthy controls. Similarly, RA patients had higher FSS scores ($p<0.0001$), followed by SSc patients ($p<0.0001$) compared to healthy controls. FIS and BDI scores were highest in SSc patients ($p<0.0001$), followed by patients with RA ($p<0.0001$) and these were also significantly higher than healthy controls. The frequency of fatigue, determined by FSS score, was significantly higher with 77% among RA patients (40 out of 52 scored ≥5 in FSS) ($\chi^2=14.758$, df:2, $p<0.0001$), followed by SSc patients of whom 60% (42 out of 70) reported high FSS scores ($\chi^2=9.402$, df:1, $p=0.002$). SSc patients who experienced fatigue had higher frequency of skin pigmentation (72.9% vs. 45.5%, $p=0.02$), GI involvement (70% vs 35%, $p=0.007$), and higher HAQ (1.26 vs 0.54) and BDI scores (24.7 vs 12.1, $p<0.001$). The components of HAQ-DI which were significantly higher among SSc patients with fatigue were VAS-Raynaud (1.53 vs 0.32), VAS-digital ulcer (1.36 vs 0.32), VAS-GI (1.2 vs 0.39), and VAS-general (1.87 vs 0.76). In multivariate analysis, RSS ($p=0.016$, $\beta=0.365$, 95%CI=0.28–0.45), pulmonary arterial hypertension ($p=0.043$, $\beta=0.258$, 95%CI=0.009–0.504), VAS-digital ulcer ($p=0.036$, $\beta=0.339$, 95%CI=0.009–0.271), and VAS-GI ($p=0.016$, $\beta=0.169$, 95%CI=0.032–0.297) were independent predictors of fatigue.

Conclusion: Around two-thirds of our SSc patients reported higher levels of fatigue. This increase in fatigue correlated with the extent of skin sclerosis, pulmonary hypertension and patient-reported digital ulcer and gastrointestinal involvement severity.

	Systemic sclerosis (n=70)	Rheumatoid arthritis (n=52)	Healthy controls (n=100)	p value
Mean age, yrs	46.95 ± 11.96	54.07 ± 14.84	45.97 ± 10.39	<0.0001
Female/male ratio	65/5 (13)	40/12 (3.3)	96/4 (16)	0.001
Multidimensional assessment of fatigue scale	24.1 ± 14.08	33.9 ± 14.4	16.8 ± 6.06	<0.0001
Fatigue severity scale	4.61 ± 1.87	5.1 ± 1.8	3.97 ± 1.43	<0.0001
Fatigue impact scale	63.6 ± 39.4	61.69 ± 38.16	35.03 ± 28.67	<0.0001

Reduction of Cerebral and Corpus Callosum Volume in Systemic Sclerosis. a Volumetric Magnetic Resonance Imaging Study. Sergio Dertkigil[1], Tiago N. Amaral[1], Aline T. Lapa[1], Fernando Peres[1], Renan Frittoli[1], Ana Paula del Rio[1], João Francisco Marques-Neto[2] and Simone Appenzeller[3]. [1]State University of Campinas, Campinas, Brazil, [2]University of Campinas, Campinas, Brazil, [3]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: Systemic sclerosis (SSc) is a systemic disease characterized by cutaneous and visceral fibrosis, presence of autoantibodies and vasculopathy. The central nervous system has, however, been rarely studied. Therefore the aim of this study is to determine cerebral and corpus callosum abnormalities in SSc and to determine the possible relationship between atrophy and SSc related features.

Methods: A total of 41 SSc patients (37 female; mean age=50.8; SD=13.2) and sixty-six health age and sex matched volunteers (57 female; mean age=51.4; SD=12.3) were included. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Cognitive evaluation was performed using the Montreal Cognitive Assessment (MoCA). Individual with scores≤26 were considered impaired. Mood disorders were determined through Beck′s Depression and Beck′s Anxiety Inventories. SSc patients were further assessed for clinical and laboratory SSc manifestations, disease activity (Valentini Activity Index), severity activity (Medsger Severity Index). Total dose of corticosteroids and other immunosuppressant medications used since the onset of the disease were calculated. MRI scans were performed in a 3T Phillips® scanner. Sagittal T1 weighted were used for manual volumetric measurements. Volumes ≤ 2 standard deviations from the means of controls were considered abnormal. Non-parametric tests and correlation were used for statistical analysis.

Results: We included 27 (65.9%) limited SSc (lSSc) and 14 (34.1%) diffuse SSc (dSSc) with mean disease duration of 10.4 (SD 6.9) years. Active disease was identified in 12 (29.3%), abnormal neurological exam in 27 (65.8%) and cognitive impairment in 36 (87.8%) SSc patients. Mood disorders were identified in 25 (60.9%) SSC patients. All controls had normal neurological examinations. In SSc, cerebral (mean volume=8975.4 $cm^{3;}$; SD= 165.1) and corpus callosum (mean volume = 96.2 $cm^{3;}$; SD= 8,7) were significantly smaller when compared to cerebral (mean volume = 9514.2 $cm^{3;}$; SD= 176.1; p= 0.03) and corpus callosum (mean volume=114.3 $cm^{3;}$; SD=8,4 ; p=0.02) volumes of controls. When analyzed separately dSSc had significantly smaller cerebral and corpus callosum volumes than lSSc. Depression correlated with cerebral volume in dSSc (r=-0.31, p=0.03) and corpus callosum volume in both dSSc (r=-0.34, p=0.03) and lSSc (r=-0.30, p=0.04). Anxiety correlated with cerebral volume in dSSc (r=-0.30, p=0.02) and corpus callosum volume in both dSSc (r=-0.35, p=0.02) and lSSc (r=-0.26, p=0.04). MoCA scores correlated with corpus callosum volume in dSSc (r=0.57; p=0.002) and lSSc (r=0.29; p=0.04). No correlation was found between disease activity and cerebral volume (r=-0.05; p=0.14) or corpus callusum volume (r=-0.06; p=0.14).

Conclusion: dSSc have significant smaller cerebral and corpus callosum volumes when compared to lSSc and healthy controls. Structural abnormalities are observed in SSc patients with cognitive impairment and mood disorders. Disease activity and organ damage showed no correlation with cerebral volume and corpus callosum volume in this population.

Ulnar and Radial Stenosis in Systemic Sclerosis. María Eugenia Lara[1], Mariano Rivero[1], Julia Romero[1], Guadalupe Palacios[1], Ignacio Carrillo[2], Claudia L. Giraldo[3], Amalia Schiel[1], Hugo Armando Laborde[1], Marina Khoury[1], Saez Diego[1], Gustavo Citera[2], Oscar L. Rillo[4] and Juan C. Barreira[1]. [1]British Hospital, Buenos Aires, Argentina, [2]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [3]Hospital Gral. de Agudos Dr. E. Tornú, Buenos Aires, Argentina, [4]Hospital General de Agudos Dr. E. Tornú, Buenos Aires, Argentina.

Background/Purpose: Systemic sclerosis (SSc) is a chronic, autoimmune disease. Endothelial damage has been recognized as the initial pathogenic factor. The involvement of the microvasculature is well defined, whereas the prevalence of large vessels disease is still unknown. We aim to describe the frequency of ulnar and radial stenosis in SSc patients and analyze the correlation between arterial stenosis and digital ulcers.

Methods: We included 57 SSc consecutive patients who fulfilled ACR 1980 classification criteria, and 21 healthy controls. SSc patients were classified in two groups: those with present or past digital ulcers and those without them. We collected demographic, clinical and laboratory information. The control group was constituted with voluntaries who attended spontaneously to our hospital to make an image study. All participants have done an arterial ecodoppler of both arms, looking for ulnar and radial stenosis. Statistical analysis: Mann-Whitney, Fisher test $p<0.05$, Odds Ratio (OR), Forward Stepwise, Hosmer and Lemeshow test.

Results: The presence of stenosis in at least one ulnar artery was observed in 18 of 57 patients with SSc (31%) and in none of the 21 controls (p=0.003). Stenosis occurred in at least one radial artery in 9 of 57 SSc patients (15%) and in one of 21 controls (p=0.19). Univariate analysis is shown in Table 1. In the multivariate model, the best predictors of digital ulcers were age at onset of Raynaud phenomenon before 40 years (OR 5.3 95%CI 1.54–18.22, p=0.008) and presence of late SD pattern (OR 4.4 95%CI 1.29–15.63, p=0.018). The area under ROC=0.76 and the Hosmer and Lemeshow test was not significant (p=0.54). Ulcers probability calculated by the model and observed in the sample by combining groups with different predictors is presented in Table 2.

Conclusion: In the present series, ulnar stenosis was observed frequently in SSc patients. However, the size of the sample did not allow adjusting for potential confounders. Stenosis of large vessels in SSc patients was not associated with presence or history of digital ulcers. The best predictors of digital ulcers were age at onset of Raynaud phenomenon before 40 years and the presence of late SD pattern.

Table 1. Clinical features between SSc patients with present or past digital ulcers (A) versus those without them (B).

	A % (n=25)	B % (n=32)	p value	OR (95% CI)
Age > 45 years	20 (5)	34 (11)	**0.02**	4.2 (1.22–14.64)
Male	16 (4)	12 (4)	0.4	
Age at first non–Raynaud symptom years ± SD	37 ± 14	50 ± 9	**0.0018**	
Raynaud phenomenon onset <40 years=“ “ b=” ”>	28 (7)	46 (15)	**0.005**	**5.3 (1.68–17)**
Radial stenosis	12 (3)	18 (6)	0.4	0.59 (0.13–2.64)
Ulnar stenosis	32 (8)	31 (10)	0.9	1 (0.33–3.18)
Esophageal involvement	52 (13)	50 (16)	0.5	
Rodnan skin score >14	28 (7)	34 (11)	0.079	2.8 (0.88–8.87)

Systemic Sclerosis Related Calcinosis: Patients Provide What Specialists Want to Learn. Angela Christensen[1], Samara Khalique[2], Sophia Cenac[3], Kim Fligelstone[4], Anne Mawdsley[5], Tracy Frech[6], Jessica K. Gordon[7], Murray Baron[8], Evan Busman[9], Virginia D. Steen[10] and Lesley Ann

Saketkoo[2]. [1]Tulane University School of Medicine, New Orleans, LA, [2]Louisiana State University Health Sciences Center, New Orleans, LA, [3]Louisiana State University Health Science Center, New Orleans, LA, [4]Royal Free Hospital, Scleroderma Unit and Scleroderma Society, London, United Kingdom, [5]Raynaud's & Scleroderma - Care and Support UK, Cheshire, United Kingdom, [6]University of Utah, Salt Lake City, UT, [7]Hospital for Special Surgery, New York, NY, [8]Jewish General Hospital, Montreal, QC, [9]Atlanta Scleroderma Support Group, Atlanta, GA, [10]Georgetown University Medical Center, Washington, DC.

Background/Purpose: Calcinosis is a disabling, rarely discussed manifestation of SSc for which the natural history and management is poorly understood. Last year, the Scleroderma Clinical Trials Consortium (SCTC) established a task force to develop a calcinosis specific patient reported measure (PROM). This investigation is the 1st phase of a multi-tiered project.

Methods: Four focus groups and individual interviews in the US and UK were recorded and transcribed verbatim. To capture both pathophysiologic and life impact, 2 questions were asked: 1. Since developing calcinosis how has your life changed over time? 2. How has the calcinosis changed over time? Patients were also asked to frame questions to help a physician learn if calcinosis was better, worse or the same.

Transcripts each underwent an iterative inductive process (no preconceived coding, content drives coding and analysis) by at least 5 independent analysts including at least one research team member with SSc. Concepts were triangulated to identify a comprehensive set of meaningful concepts with occurrence quantified per participant.

Results: Twenty-three patients (22/23 female, 19/23 white, with mean disease duration 14.8 years) were consented and interviewed. Responses spanned broadly to include concepts of self-management strategies and recurrent hypotheses relating calcinosis development to trauma, Raynaud's and cold exposure. We identified discrete concepts which are described in Table 1 along with the proportion of patients declaring personal relevance.

Cold exposure and Raynaud's were a perceived association to calcinosis severity - "when they are cold mine always open back up". Several described a disabling core body phenomenon involving decreased core temperature with a rapid physical decline requiring prolonged recovery potentially lasting hours – "it's like intense - it racks your whole body". Calcinosis tended to present along with or soon after SSc diagnosis and remained throughout disease duration.

A majority of patients engage in strategies to extrude calcinosis with either pressure +/− soaking or at home surgical techniques. "I actually have homemade surgical tools to get these out."

The following anchors were consistently indicated to assess calcinosis severity: pain level, size, frequency, number and functional impairment.

Conclusion: Patient observations and self-management behavior provide opportunities to learn from and to preemptively educate physicians and patients. Patients are eager for self-management guidance. These concepts provide the groundwork for PROM development. However, as suggested by patients, a composite of scales anchored in pain, size, frequency, number and related impairment may reasonably serve as an interim instrument for SSc calcinosis until that time.

Table 1. Concepts from patient focus groups and interviews. The participants not represented by either affirmations or denials did not discuss the designated issue.

Patient Characteristics			
Raynaud's (%)	100%		
Gender (female)	96%		
Race (white)	82%		
Time from Diagnosis (mean)	14.8 years		
Cold exposure decreases core body temperature with sensation of systemic symptoms	26%		
Patient Report	**Yes %**	**No %**	**Quotes**
Location			
Fingers	87%	–	"I got a spreading infection in there and then I had it amputated"

Post-Occlusive Reactive Hyperemia (PORH) Test Mirrors Vascular Changes in Systemic Sclerosis (SSc):a Laser Speckle Contrast (LASCA) Study. Alessandra Della Rossa[1], Anna d'Ascanio[1], Massimo Cagnoni[1], Chiara Stagnaro[1], Alice Parma[1], Marta Mosca[2] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Rheumatology Unit, University of Pisa, Pisa, Italy.

Background/Purpose: Vascular involvement is a key feature of Systemic sclerosis (SSc) and involves both the micro and macrovasculature. Vascular changes are central in the disease's pathogenesis and the assessment of vascular involvement has a prognostic value, therefore vascular assessment has a pivotal significance, both for research and clinical purpose.

A non invasive technique to monitor cutaneous vascular function is the response to a physiological challenge using laser speckle contrast imaging. This technique has proven effective and reproducible for the assessment of skin blood flow in SSc patients, either with or without dynamic challenge.

The aim of our study was to evaluate post-occlusive reactive hyperemia test (PORH) in consecutive SSc patients and to test whether PORH is a useful tool to discriminate different disease subsets within SSc population.

Methods:

Patients

Starting from to april 2011 to June 2014, 54 consecutive SSc patients were enrolled (mean age 56 ±15 years, F/M =18). Patients were divided into limited SSc (n=29), Diffuse SSc (n=8) and Very early SSc (VEDOSS) (n=17) according to literature definition.

Laser Speckle Contrast Analysis

Cutaneous blood flow was measured throughout the experiments using a high frame rate LSkI (Pericam PSI system, Perimed, Jarfalla). The occlusive/ischemic test was performed by inflating for 4 minutes a cuff placed on the left arm to 30 mm Hg above the systolic pressure. The recovery time (time needed to recover the basal flux after occlusion in seconds), the peak flux (hyperemic peak reached after occlusion) and the area under the hyperemic curve were recorded.

Statistical analysis

Correlation between clinical data and laser measurements were performed by non parametric tests and contingency tables for cathegorical variables (Stat-View, SAS). In view of the high number of comparisons involved, only p values equal or below 0,01 were considered significant.

Results: A statistical significant difference was detected in the post-ischemic hyperemic peak flow between very early SSc and established SSc (424 vs 137% p = 0,0001). PORH peak flow decreased according to capillaroscopic pattern (early=435%, active=173%, Late=145% P<0,005). Moreover a strong correlation between capillary density and peak flow was unveiled (rho=0,56, p < 0,0001).

Conclusion: These data show a different pattern of vascular involvement in early SSc as compared to established disease that mirror capillaroscopic changes. In this context, functional features of early and established disease seem to be the physiologic counterpart of abnormalities detected by capillaroscopy. POHR test might be a useful aid for further characterization of vascular involvement in SSc.

Could a Fibroblast-Free Environment Protect the Microcirculation in Systemic Sclerosis? Evidence from Retinal Vascular Imaging Research. Evaggelia K. Aissopou[1], Vasiliki-Kalliopi Bournia[1], Athanase D. Protogerou[1], Stylianos Panopoulos[1], Theodore G. Papaioannou[2], Panayiotis G. Vlachoyiannopoulos[1], Marco Matucci-Cerinic[3] and Petros P. Sfikakis[1]. [1]First Department of Propedeutic Internal Medicine, Laikon Hospital, Athens University Medical School, Athens, Greece, [2]Biomedical Engineering Unit, First University Dept. of Cardiology, Hippokration Hospital, Athens University Medical School, Athens, Greece, [3]University of Florence, Florence, Italy.

Background/Purpose: A primary endothelial cell dysfunction is thought to be involved in systemic sclerosis (SSc)-associated fibroproliferative vasculopathy of the microcirculation and small arterioles, even in sites not affected by fibrosis. Since, (i) the role of resident fibroblasts in the pathologic modifications and vascular wall remodeling is still unclear, and (ii) a fibroblast–free environment, such as the retina, provides a unique opportunity to assess the microcirculation, we systematically evaluated the retinal vessels in patients with SSc.

Methods: Digital retinal images were obtained from both eyes of 93 consecutive patients with fully characterized SSc and 29 healthy controls effectively matched 1:1 for age and gender with 29 selected patients without diabetes, hypertension history, or anti-hypertensive treatment. Internal microvascular calibers (erythrocyte column width in micro-m) by central retinal arteriolar and venular equivalents and arteriolar to venular ratio were measured using validated software.

Results: Arterioral and venular calibers were similar in patients and their matched controls (mean±SEM of 187±2 vs 184±3, p=0.444 and 211±2 vs 216±3, p=0.314, respectively). Both arterioral and venular calibers and their ratio in SSc patients were not associated with disease duration, the extent of skin involvement, the presence of pulmonary fibrosis, digital ulcers or absorptions, amputations, digital capillaroscopic findings, inflammatory indices, or autoantibodies.

Conclusion: The strong evidence that retinal microcirculation is spared in SSc suggests that the fibroproliferative vasculopathy depends on resident fibroblasts and/or other specific cellular or soluble factors not present in the retinal environment.

The New ACR-EULAR 2013 Systemic Sclerosis Classification Criteria Show Good Performance in a Capillaroscopy Clinic. Patricia E. Carreira[1], M Jesus Garcia de Yebenes[2], Beatriz E. Joven[1], Estibaliz Loza[2] and Loreto Carmona[2]. [1]Rheumatology Department. Hospital Universitario 12 de Octubre, Madrid, Spain, [2]Instituto de Salud Musculoesqueletica, Madrid, Spain.

Background/Purpose: To analyze the validity of the new 2013 ACR-EULAR Systemic Sclerosis (SSc) classification criteria versus SSc clinical diagnosis in patients from a capillaroscopy clinic.

Methods: All patients seen for capillaroscopy between Jan2010 and Oct2013 (before criteria publication) were included. Having as gold standard the SSc diagnosis done by a rheumatologist, the performance (sensitivity, specificity, likelihood ratios) of the ACR-EULAR 2013 criteria, in full, and by items was analyzed. Receiver Operating Characteristic (ROC) curve and area under the curve (AUC) were calculated for global score, and best cut-off for the criteria score obtained

Results: The study included 327 patients (84% women, 48±16 y). Reasons for capillaroscopy were Raynaud (40%), SSc evaluation (27%), other CTD with Raynaud (13%), CTD suspicion (10%), ischaemic lesions (1%) and others (9%). Final diagnosis was SSc in 106 (32%), idiopathic Raynaud (39%), SLE (13%), myopathy (8%), vascular related (6%), primary SS (3%) and others (30%).

The performance of the individual items in the criteria varied, being the best sclerodactily and capillaroscopic changes. The full criteria showed very high validity, with 98% sensitivity, 95% specificity and 18.6 positive likelihood ratio (Table 1). The best cut-offs of the criteria as a score were ≥8, ≥9 or ≥10 (Table 2). Finally, ROC curve showed an elevated discriminatory capacity for diagnosis of SSc, with AUC of 0.993 (Figure 1)

Conclusion: The new ACR-EULAR 2013 SSc classification criteria show high validity and discriminatory capacity for SSc clinical diagnosis done by rheumatologists in a capillaroscopy clinic setting

Table 1. Validity indexes for new ACR-EULAR 2013 SSc classification criteria global score, and by items and subitems

Criteria	Se (%)	Sp (%)	PPV (%)	NPV (%)	LHR+
Proximal and distal scleroderma	66.3	98.6	95.6	86.2	46.2

Joint and Tendon Involvement Predict Severe Disease Progression in Systemic Sclerosis: A Prospective Study. Jerome Avouac[1], Ulrich Walker[2], Eric Hachulla[3], Gabriela Riemekasten[4], Giovanna Cuomo[5], Patricia E. Carreira[6], Paola Caramaschi[7], Lidiya P. Ananieva[8], Marco Matucci-Cerinic[9], Laszlo Czirjak[10], Christopher P. Denton[11], Ulf Muller-Ladner[12] and Yannick Allanore[13]. [1]Paris Descartes University and INSERM U1016, Rheumatology A department, Cochin Hospital, Paris, France, [2]Department of Rheumatology, Basel University, basel, Switzerland, [3]National Scleroderma Centre, Lille CEDEX, France, [4]Charité – University Hospital, Berlin, Germany, [5]Second University of Naples, Naples, Italy, [6]Rheumatology Department. Hospital Universitario 12 de Octubre, Madrid, Spain, [7]Rheumatology Unit, Azienda Ospedaliera Universitaria Integrata, Verona, Italy, [8]Research Institute of Rheumatology RAMS, Moscow, Russia, [9]University of Florence, Florence, Italy, [10]University of Pécs, Pécs, Hungary, [11]Centre for Rheumatology, Royal Free and University College Medical School, London, United Kingdom, [12]Univ Giessen/Kerckhoff-Clinic, Bad Nauheim, Germany, [13]Paris Descartes University, Rheumatology A Department and INSERM U1016, Cochin Hospital, Paris, France.

Background/Purpose: Joint involvement is frequent and strongly contributes to impaired quality of life in systemic sclerosis (SSc). In a previous cross-sectional study, synovitis and tendon friction rubs (TFRs) were associated with systemic inflammation and disease activity. Therefore, the aim of the present study was to determine whether joint synovitis and TFRs can predict the progression of SSc over time.

Methods: We included patients from the EUSTAR database (MEDS online) with early disease duration (first non Raynaud's symptom equal or less than 3 years) and with a follow-up of at least two years. We extracted data regarding the presence or not of synovitis and TFRs and data related to disease progression. Skin progression was defined by a ≥30% worsening of the modified Rodnan skin score (mRSS). Lung progression was defined by the new onset of pulmonary fibrosis on high resolution CT scan, or the deterioration of lung volume (≥10% of forced vital capacity, FVC). Cardiovascular worsening was defined for skin by new ischemic digital ulcers (DU), for lung by pre-capillary pulmonary arterial hypertension (PAH) on right heart catheterization, and for heart by the reduction of the left ventricular ejection fraction below 50% on echocardiography. Renal progression was defined by the occurrence of scleroderma renal crisis. Overall disease progression was defined according to the occurrence of at least one organ progression.

Results: From the 9165 patients included in the database, 1301 patients (1079 females) met our inclusion criteria (mean ± SD age of 55±15 years, mean ± SD follow-up: 4.5±2.2 years). During the follow-up period, 579 patients (45%) experienced skin and/or lung and/or cardiovascular progression with a mean time to development of 3.2±1.9 years.

Joint synovitis (Hazard Ratio, HR: 1.26, 95% confidence interval, CI, 1.01–1.59) and TFRs (HR: 1.32, 95%CI 1.03–1.70) were both independently predictive of overall disease progression, as were also the diffuse cutaneous subset (HR: 1.30, 95%CI 1.05–1.61) and positive antitopoisomerase-I antibodies (HR: 1.25, 95%CI 1.02–1.53).

The mean change of mRSS over the follow-up period was 9.4±4.11, and 99/123 patients (80%) had a progression of at least 5 points. Joint synovitis (HR: 1.63, 95%CI 1.05–2.55) and TFRs (HR: 1.67, 95%CI 1.01–2.75) were independently predictive of skin progression.

Joint synovitis was predictive of the occurrence of new digital ulcer(s) (HR: 1.45, 95%CI 1.08–1.96) and decreased left ventricular ejection fraction (HR: 2.20, 95%CI 1.06–4.57); TFRs were confirmed to be an independent predictor of scleroderma renal crisis (HR: 2.33, 95% CI 1.03–6.19).

Conclusion: This first report of the prospective follow-up of EUSTAR patients identified for the first time the merit of baseline synovitis and extended previous data for tendon friction rubs in early SSc patients. These results obtained through the largest worldwide database support the use of these easily detected clinical findings for the risk stratification of SSc patients. These parameters might be used in the future to select high-risk patients, guide therapies and might be regarded as potential surrogate markers for severity.

Nailfold Videocapillaroscopy in Healthy Children and Adolescents: Description of Patterns of Normality. Daniela Piotto[1], Juliana Sekiyama[2], Cristiane Kayser[3], Mariana Yamada[4], Claudio A. Len[5] and Maria Teresa Terreri[6]. [1]Assistant Doctor, Universidade Federal de São Paulo/UNIFESP, São Paulo, Brazil, [2]Universidade Estadual de Campinas, Campinas, Brazil, [3]Universidade Federal de São Paulo, São Paulo, Brazil, [4]Pediatric Resident, São Paulo, Brazil, [5]Universidade Federal de São Paulo/Escola Paulista de Medicina, São Paulo, Brazil, [6]Universidade Federal de São Paulo/UNIFESP, São Paulo, Brazil.

Background/Purpose: Video capillaroscopy (VCP) allows for the evaluation of capillary dimensions and to quantify the degree of microangiopathic alterations in autoimmune diseases. However, studies in healthy subjects and specially in children and adolescents are limited. To describe the normal pattern of capillaries by VCP in healthy children and adolescents, and to evaluate the inter and intraobserver concordance in capillary measurements.

Methods: Cross-sectional study of 100 healthy participants aged 5 to18 years by VCP. The capillary dimensions (capillary loop length, capillary width and inter capillary distance) and the number of capillaries/mm were evaluated under 100x magnification, acquiring three consecutive images of nine capillaries per individual, totaling 900 capillaries examined and photographed. Four age groups were studied: 5–7 years (17 individuals); 8–10 years (24 individuals); 11–14 years (30 individuals) and 15–18 years (29 individuals). The intra and inter observer concordance was tested in 25% of subjects by two professionals with experience in this method.

Results: The capillary dimensions (mean ± SD) were: capillary loop length 278.6 ± 60.3 μm, inter capillary distance 124.1 ± 28.1 μm, capillary width 15.0 ± 2.6 μm and 7.8 ± 1.5 number of capillaries /mm. The only significant difference between males and females was the inter capillary distance which was higher in girls ($p = 0.011$). When comparing the four age groups, only the intercapillary distance remained constant over time ($p=0.088$). Teenagers between 15 and 18 years had longer and thicker capillaries (318.7 ± 64.4 μm) and (16.2 ± 3.3 μm) resp. when compared to other age groups ($p < 0.001$ and $p = 0.012$ respectively). We also found an increase in the number of capillaries/mm with age: 6.1 capillaries/mm (5–7 years); 7.0 (8 to 10 years); 8.0 (11–14 years) and 9.3 (15–18 years) ($p < 0.001$). There was a good intra and interobserver concordance in the analysis of capillary dimensions and the number of capillaries/mm by VCP. In VCP, 11% had enlarged capillary (capillary width percentile> 97.5) and 10% avascular areas (inter capillary distance percentile> 97.5). There was a negative correlation between the distance and the number of capillaries/mm.

Conclusion: This study evaluated the normal pattern of VCP in healthy children and adolescents and stratified patients by age groups. The number of capillaries /mm, the length and thickness of the capillary increased with age, while the intercapillary distance was maintained over the years.

The Relationship of Patient Reported Skin Symptoms to the Scleroderma HAQ, the Modified Rodnan Skin Score and Skin Pathology.. Jessica Ziemek, Ada Man, Robert W. Simms and Robert Lafyatis. Boston University School of Medicine, Boston, MA.

Background/Purpose: Changes in skin are a cardinal feature of systemic sclerosis (SSc). However, there are no SSc specific patient reported outcome measures validated for use to measure changes in skin. Some of the current measures used for SSc are the Modified Rodnan Skin Score (MRSS), SHAQ, SF-36, and PROMIS-29. In addition, several PROs have been developed for use in other skin diseases such as Skindex-29. Our goal was to evaluate some of these current measures to determine their correlations with specific skin symptoms and skin pathology in diffuse cutaneous systemic sclerosis patients.

Methods: Patients were recruited from the Boston University Scleroderma Center. Data collection occurred between December 2005 to April 2014 and data collected included the SHAQ, Skindex-29, MRSS, and a skin symptom assessment questionnaire developed for this study. The Skin Symptom Assessment (SSA) consisted of patients' self-evaluation of six skin symptoms over the past week, each scored on a 5-level Likert Scale (tight, painful, red, rigid/stiff, itchy and overall). Correlations using Spearman's rho were assessed between SSA, SHAQ, MRSS, and Skindex-29, only when the compared measures were completed on the same date. A subgroup of patients had a skin biopsy from the same visit as the MRSS, SSA, and SHAQ ($n=20$), and the relationships between these measures, histological features and myofibroblast staining were evaluated. The first time point the subject completed each patient reported outcome measure was used for analysis.

Results: 99, 42, 99, and 45 patients completed the SHAQ, Skindex-29, MRSS, and SSA, respectively. In the 99 patients who had a SHAQ and MRSS from the same date, the SHAQ moderately correlated with MRSS ($r=0.403$, $p<0.001$). SSA had weak to moderate correlations with the MRSS ($n=45$): the MRSS correlated most highly with tight ($r= 0.410$, $p=0.0052$), rigid/stiff ($r=0.535$, $p=0.0002$), and overall skin symptoms ($r=0.389$, $p=0.0083$). In contrast, the SHAQ correlated most highly with painful ($r=0.524$, $p=0.0003$) skin symptoms ($n=43$). In the 20 patients with skin biopsies along with concurrent measures, the MRSS correlated strongly with hyalinized collagen ($r=0.679$, $p=0.001$), but the SHAQ did not correlate significantly with any of the histologic measures (inflammation, myofibroblast infiltration, or hyalinized collagen).

With the SSA, tight skin moderately correlated with myofibroblast infiltration ($r=0.485$, $p=0.030$), while rigid/stiff skin moderately correlated with inflammation ($r=0.514$, $p=0.02$), myofibroblast infiltration($r=0.450$, $p=0.036$) and hyalinized collagen($r=0.539$, $p=0.014$).

The three domains of Skindex-29, Symptoms, Emotions and Functioning did not correlate significantly with MRSS but did so moderately with SHAQ ($r=0.464$, $r=0.502$, and $r=0.472$ respectively all with $p<0.05$).

Conclusion: Patient reported skin symptoms correlate with both clinical and pathological measures. However, this Skin Symptom Assessment was exploratory, as it was not developed through the formal methodology needed for validation of a patient reported outcome measure. Further research is required to develop a patient reported skin symptom measure that is both validated and sensitive to change.

Application of the 2013 ACR/EULAR Classification Criteria for Systemic Sclerosis in Korean Patients with Raynaud Phenomenon. Jin Su Park, Hee-Jin Park, You Jung Ha, Yong-Beom Park, Soo-Kon Lee and Sang-Won Lee. Yonsei University College of Medicine, Seoul, South Korea.

Background/Purpose: The American College of Rheumatology (ACR) and the European League Against Rheumatism (EULAR) suggested the 2013 ACR/EULAR classification criteria for systemic sclerosis (SSc), due to the lack of sensitivity for early and limited SSc of the 1980 ACR classification criteria.

The aim of this study was to determine how many patients with Raynaud phenomenon are reclassified as SSc by the 2013 ACR/EULAR classification criteria for SSc and to analyze the predictive variables of the new classification criteria in those patients.

Methods: We applied the 2013 ACR/EULAR classification criteria for SSc to 60 patients who had been diagnosed as SSc according to the 1980 ACR classification criteria (SSc group) and 64 patients who presented Raynaud phenomenon with or without autoimmune disease, but did not fulfill the 1980 ACR classification criteria (Raynaud phenomenon group). We analyzed the discrepancy between the previous and the new classification criteria when subjects were categorized as those with SSc.

Results: All patients who were diagnosed as SSc according to the previous classifications criteria fulfilled the new criteria. Furthermore, 17 of 64 patients (26.5%) in Raynaud phenomenon group were reclassified as SSc by the new criteria. Reclassified SSc patients in Raynaud phenomenon group significantly showed less frequency of scleroderma, sclerodactyly, finger pitting scar, interstitial lung disease and higher frequency of telangiectasia than those in SSc group (Table 1). Eleven of 17 patients who were reclassified as SSc (64.7%) had anti-centromere antibody. But none of 17 patients had anti-topoisomerase 1, meanwhile 29 of 60 patients who had been diagnosed as SSc (43.8%) had anti-topoisomerase 1 (Table 1). On multivariate linear regression analysis using variables with significance, puffy finger, sclerodactyly and telangiectasia were significant predictive values for the new classification as SSc in Raynaud phenomenon (RR=23.7, 29.5, 14.2; p value=<0.001, 0.015, 0.031).

Conclusion: 26.5% patients, who presented Raynaud phenomenon but did not fulfill the 1980 ACR classification criteria for SSc, were reclassified as SSc according to the 2013 ACR/EULAR classification criteria. Also, we suggest that physicians should pay attention to puffy finger, sclerodactyly and telangiectasia in patients with Raynaud phenomenon for the early diagnosis of SSc.

Table 1. Comparison of characteristics, clinical manifestations and autoantibodies between reclassified systemic sclerosis patients in Raynaud phenomenon group (New SSc) and patients in systemic sclerosis group (SSc).

Variables	New SSc (n=17)	SSc (n=60)	*P* value
RP duration (years)	3.4 ± 2.4	9.6 ± 6.7	<0.001
Disease duration (years)	1.25 ± 1.25	6.4 ± 5.8	<0.001
2013 ACR/EULAR score	10.8 ± 1.8	19.1 ± 5.2	<0.001

Scleroderma (N(%))	0 (0)	40 (66.7)	<0.001
Puffy finger (N(%))	12 (70.5)	27 (45.0)	0.062
Sclerodactyly (N(%))	6 (35.3)	55 (91.6)	<0.001
Digital tip ulcer (N(%))	2 (11.8)	20 (33.3)	NS

Reliability and Validity of the Duruöz Hand Index in an Argentinian Population with Scleroderma. Vanesa Duarte, Gloria Crespo, Maritza Manzano, María Victoria Martire, Santiago Scarafia, Lucila Marino, Felix Romanini, Marta Mamani and Anastasia Secco. Hospital Bernardino Rivadavia, Buenos Aires, Argentina.

Background/Purpose: The Duruöz Hand Index (DIH) is a reliable tool for the evaluation of hand′s function in patients with scleroderma. The aim of our study was to adapt and to validate the DHI questionnaire in an Argentinian population with scleroderma.

Methods: For validation, 3 rheumatologists adapted and translated to Spanish the original version in French and the final version was re-translated to French by a bilingual person. To evaluate the construct validity, we used the patient global visual analogue scale (VAS), VAS for questions for the same activity, the health assessment questionnaire (HAQ) and the Rodnan. A subsample attended a second visit to evaluate reproducibility, with no modifications in the treatment in relation to the previous visit. Continuos variables were expressed as mean and standard desviation (SD) or medians with their interquartile range (IQR). Spearman′s correlation coefficient was used to quantify the degree of correlation between the different VAS, HAQ and Rodnan with the total score. The intraclass correlation coefficient(ICC) was used to assess reproducibility and Cronbach′s alfa to evaluate internal consistency.

Results: 45 patients diagnosed with scleroderma were included in the study. 84,44% were women, mean age of 51±13,72 years (SD), 48,89% were Mestizos, while 46,67% were Caucasians with a disease duration of 24 months (IQR: 18–60). 64,44% patients had diagnostic of limited scleroderma; 77,78% were right handed and 53,33% had extra cutaneous manifestations. Raynaud was present in 93,33%, pitting scars in 33,33% and digital ulcers in 26,67%. The median score of the total questionnaire was 4,5 (IQR: 0–26), of the global VAS 49 (IQR: 10–50), of HAQ 0,3 (IQR: 0–1) and of Rodnan 5 (IQR:2–11). The correlation between the total score of DHI and the patient global VAS was 0,58, with the HAQ was 0,63 and with Rodnan 0,08. The correlation coefficient between the VAS and each group of questions for the same activity in the DHI questionnaire, indicated good correlation for the questions that refer to activities of **kitchen** (0,60;0,71;0,67;0,67;0,59;0,62; 0,55), as well as for **dressing** (0,69;0,65;057), for **hygiene** (0,61;0,56), and for **the office** questions (o,56;0,73). There was excellent level of correlation with those related to **fine motor activities** with a maximun r value of 0,78. The reproducibility was 0,88 (CI 95% 0,76–0,99) and the internal consistency according to Cronbach′s alfa was 0,98.

Conclusion: The results from this study show the DHI to be a reliable and valid test for this Argentinian population with scleroderma.

Development of a "Renal Crisis Prevention Card" As an Educational Tool Aimed at Improving Outcomes in High-Risk Patients with Systemic Sclerosis. Lee S. Shapiro[1], Lesley Ann Saketkoo[2], Jessica F. Farrell[1] and Kim Fligelstone[3]. [1]The Center for Rheumatology, Albany, NY, [2]Louisiana State University Health Sciences Center, New Orleans, LA, [3]Royal Free Hospital, Scleroderma Unit and Scleroderma Society, London, United Kingdom.

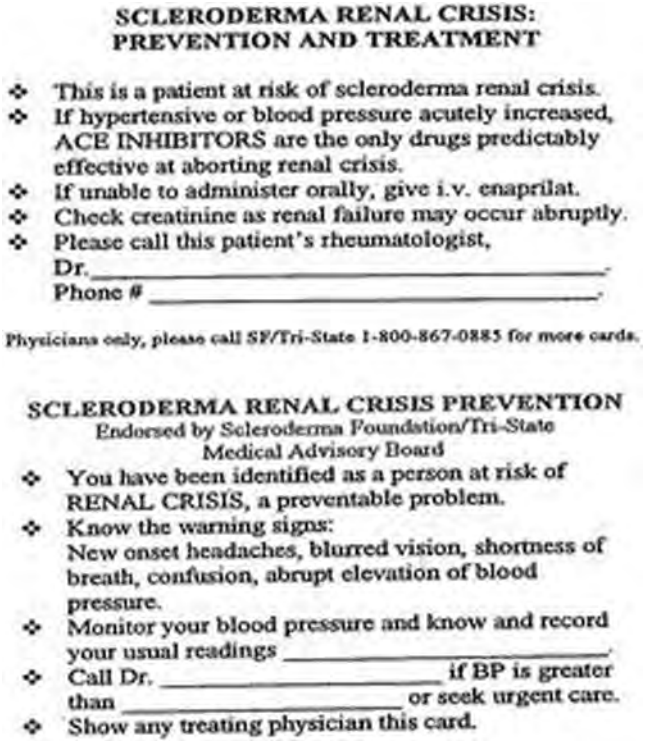
Background/Purpose: Scleroderma renal crisis (SRC) is a devastating complication of SSc. The introduction of effective treatment with ACE inhibition (ACE-I) in 1979 dramatically reduced death as a near-immediate consequence of SRC. However, poor outcomes still occur with great frequency including chronic or temporary dialysis or death. Individuals with early, rapidly progressive diffuse disease and RNA polymerase III antibody positivity are at high risk for SRC. Prophylactic use of ACE-I in high risk patients has not demonstrated improved outcomes and may have negative consequences. Our goals were to identify associative causes of poor outcome and develop a targeted preventive intervention to address in accordance with findings.

Methods: A retrospective chart review at Royal Free Hospital scleroderma clinic between 1994–1999 identified and stratified 44 cases of SRC for long term outcomes (death, long-term dialysis, short-term dialysis, and no dialysis). Cases were then assessed for factors potentially related to outcomes: onset of symptoms, time to medical attention, and therapeutic management. Results directed development of SRC preventive intervention.

Results: Death or long-term dialysis was the outcome in approximately 50% of the cases reviewed. Three subgroups emerged as associative with poor outcomes:

1. SSc patients with no previously established SSc diagnosis presenting as "malignant hypertension"
2. SSc patients with an established SSc diagnosis but uninformed about SRC and misinterpreted symptoms or failed to recognize the urgency of seeking medical attention
3. SSc patients who presented promptly for urgent outpatient medical care informing physician of SSc diagnosis, but were incorrectly treated with therapies other than ACE-I or initiation of ACE-I was without sufficiently rapid dose adjustment to achieve blood pressure control.

Poor outcomes were correlated to delayed therapy, rather than drug failure. All patients in the 'no dialysis/death' group were treated with ACE-I according to protocol. From these findings, a "scleroderma renal crisis prevention card" was developed. See image.



SCLERODERMA RENAL CRISIS:
PREVENTION AND TREATMENT

- This is a patient at risk of scleroderma renal crisis.
- If hypertensive or blood pressure acutely increased, ACE INHIBITORS are the only drugs predictably effective at aborting renal crisis.
- If unable to administer orally, give i.v. enaprilat.
- Check creatinine as renal failure may occur abruptly.
- Please call this patient's rheumatologist,
  Dr. _____.
  Phone # _____.

Physicians only, please call SF/Tri-State 1-800-867-0885 for more cards.

SCLERODERMA RENAL CRISIS PREVENTION
Endorsed by Scleroderma Foundation/Tri-State
Medical Advisory Board

- You have been identified as a person at risk of RENAL CRISIS, a preventable problem.
- Know the warning signs:
  New onset headaches, blurred vision, shortness of breath, confusion, abrupt elevation of blood pressure.
- Monitor your blood pressure and know and record your usual readings _____.
- Call Dr. _____ if BP is greater than _____ or seek urgent care.
- Show any treating physician this card.

Conclusion: Despite availability of effective therapy, SRC is associated with poor outcomes often consequential to treatment delay and lack of knowledge of initial treating physicians. A "renal crisis prevention card" may improve health outcomes of high-risk patients as a method of educating patients and health care providers.

Comparison of PROMIS® survey Between Scleroderma Patients in an Academic Center and Patient-Based Scleroderma Foundations. Vivek Nagaraja[1], Veronica Berrocal[1], Kerri Connolly[2], Ann Kennedy[3], Daniela Seelmann[4] and Dinesh Khanna[1]. [1]University of Michigan, Ann Arbor, MI, [2]Scleroderma Foundation, Boston, MA, [3]Federation of European Scleroderma Associations, Tournai, Belgium, [4]Universidad de Los Andes, Santiago, Chile.

Background/Purpose: The National Institutes of Health Patient-Reported Outcomes Measurement Information System (PROMIS®) roadmap initiative is a cooperative research program designed to develop, evaluate, and standardize item banks to measure patient-reported outcomes (PROs) across different medical conditions as well as the US population (www.nihpromis.org). It has comprehensive items banks that assess physical, mental, and social well-being. The aim of this study was to compare the PROMIS survey between the scleroderma patients at an academic center and patient-based foundations as this has implications for large epidemiological studies (such as Scleroderma Patient Intervention Network).

Methods: A study titled 'PROMIS in rheumatology' was created in the Assessment center website. This study contained 13-PROMIS instruments. Patients seeking care in the academic Scleroderma clinic were approached to participate in the PROMIS survey. Patients were also recruited from the Scleroderma patient-based foundations (SF) namely – the Scleroderma Foundation and the Federation of European Scleroderma Associations, through the respective social media pages and e-newsletters. Average T-scores of the patient-based foundation scleroderma cohort were compared with those of the UM scleroderma patient cohort.

Results: Thirty-six patients at UM and 241 patients from SF have so far completed the survey. In both groups, the T-scores in the following domains were approximately 1 standard deviation worse than the United States (US) general population (GP) – fatigue, physical function, pain interference, satisfaction in roles and activities. Anger and social isolation banks were comparable to US GP. In comparison to the UM scleroderma cohort, the T-scores of the SF patient cohort was significantly worse for pain behavior and social isolation (Table, $p < 0.05$); however, the differences were not clinically meaningful.

Conclusion: The patients with SSc have decrements in health-related quality of life on PROMIS measures when compared to the US general population. There were no meaningful differences in the two cohorts, suggesting that patients from scleroderma clinic and patient foundations can be approached for non-pharmacologic intervention trials.

Table 1: Comparison of T-scores of UM and SF patient cohorts

	UM Scleroderma		Scleroderma patient foundations		
PROMIS item banks	**N**	**Mean**	**N**	**Mean**	**p-value**
Anger	36	51.4	238	52.0	0.75
Anxiety	36	55.1	238	54.5	0.57
Depression	36	54.4	241	54.5	0.57
Fatigue	35	60.4	240	60.9	0.49
Pain behavior	36	56.4	238	56.6	**0.04**
Pain interference	36	59.3	240	60.4	0.48
Physical function*	36	39.5	239	37.8	0.59
Physical function with mobility aid*	36	41.7	238	38.8	0.56
Satisfaction in roles and activities*	36	43.8	238	41.9	0.65
Sleep Disturbance	36	56.7	239	56.5	0.29
Sleep related impairment	36	58.1	239	56.8	0.19
Social activities (Ability to participate)*	36	45.2	238	43.8	0.74
Social isolation	36	48.7	238	50.8	**0.04**

* Lower score (T-score <50) means worse than average

The UCLA Gastrointestinal Tract Questionnaire (GIT)2.0 and GI Visual Analogue Scale(GI-VAS) Reflect Different Aspects of GI Involvement in Systemic Sclerosis. Yossra Suliman[1], Yasser Shaweesh[2], Suzanne Kafaja[3], Lewei Duan[4] and D. E. Furst[5]. [1]David Geffen School of Medicine, University of California Los Angeles,, Los Angeles, CA, [2]David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, [3]University of California, Los Angeles, Department of Medicine, Los Angeles, CA, [4]David Geffen School of Medicine, University of California School of Medicine, Los Angeles, CA, [5]University of California at Los Angeles, Los Angeles, CA.

Background/Purpose: UCLA GIT2.0 is a validated measure for assessing the severity of gastrointestinal involvement in systemic sclerosis patients (SSc) patients; GI VAS is also a widely used measure of GI effect in patients as a component of SSc health assessment questionnaire (SHAQ). GIT2.0 includes 34 questions in 7 domains (reflux, distension, soilage, diarrhea, social function, emotional wellbeing and constipation). GI VAS is a 100 mm VAS that asks the patient; how much GI symptoms interfere with patient function. Both are measures of present state.

Objectives

1) Is there a correlation between GI-VAS and total GIT2.0?
2) Is a correlation between GI-VAS and GIT2.0 domains?
3) Does total GIT2.0 or GI-VAS predict patient global.

Methods: We extracted baseline data in 98 consecutive SSc patients, with respect to: age, sex, SSc subtype, disease duration, HAQ-DI, VAS for: pain, raynaud's, ulcer, breathing, GIT2.0 domains and patient global.

Analysis:-Correlation between GI VAS and GIT 2.0 (total and individual domains) by Pearson correlation Coefficient. Univariable linear regression using patient global as dependent variable against total GIT2.0 or GI-VAS as separate independent elements. Independent variables were: SSc subtype, age, gender, disease duration, VAS for: raynaulds, finger ulcers and breathing in each model.

Results: Of total 98 patients available for analysis, 84 were females, 59 were diffuse subtype, mean age 54.6 (SD 14), mean disease duration 9.6 years (7.6), total GIT2.0 mean0.51 (0.49) - moderate, GI-VAS mean2.34 (2.77)-mild, HAQ-DI mean 0.98 (0.76) and patient global mean 3.77(2.69). Correlation between GI VAS and GIT2.0 (total and individual domains) are listed in **table1**. Even though the correlation between GIT2.0 and GIT VAS is ($r=0.6$) and weighted kappa is 0.59 –moderate, thirty four percent of the patients showed disagreement between the two measures by at least 1 category (total of four categories). Linear regression analysis demonstrated that GIT2.0 and GI-VAS were independent predictors of patient global as were VAS for breathing and ulcer ($p<0.007$). Adjusted r squared for GIT2.0 was 0.49and for GI-VAS was0.51.

Table 1. Correlation between GI VAS and GIT2.0 (total and individual domains)

	GIT2.0	Reflux	Distension	Soilage	Diarrhea	Constipation	Social function	Emotional wellbeing
GI VAS	0.61	0.56	0.54	0.32	0.26	0.33	0.58	0.49

Conclusion: GIT2.0 and GI VAS reflect GIT involvement. Each separately is an independent predictor of patient global. They disagree sufficiently frequently that they may reflect different aspects of GI involvement and might be considered separately in clinical GI evaluation of SSc patients.

Performance of the New ACR Criteria in Systemic Sclerosis: A Multicenter Study. Necati Cakir[1], Omer Nuri Pamuk[2] and Mehmet Ali Balci[2]. [1]Fatih Sultan Mehmet State Hospital, Istanbul, Turkey, [2]Trakya University Medical Faculty, Edirne, Turkey.

Background/Purpose: Reliable and validated classification criteria are needed to conduct high quality clinical research in systemic sclerosis (SSc). The most widely used classification criteria for SSc are ACR criteria published in 1980. Recently, ACR and EULAR Collabarative Initiative has prpposed a new set of criteria for the classification of SSc. In our study, we aimed to compare the sensitivity and specificity of the new ACR/EULAR criteria to the ACR criteria in our SSc population.

Methods: Two rheumatology centers from Turkey participated in this study. The features present at disease onset in patients with SSc seen between 2008–2013 were retrospectively reviewed. For the evaluation of specificity, patients admitted to each center between the same time period for conditions other than SSc, in whom ANA was deemed necessary within the diagnostic work-up, were included as controls.

Results: Onehundredandtwo SSc patients (93 females, 9 males, mean age: 47.9 ± 13.9) and 80 controls (70 females, 10 males, mean age: 48.4 ± 11.6) were included into the study. ANA was positive in 89.2%,

anti-Scl-70 in 31.7%, and anti-centromere in 21.6% of the patients. Digital ulcers were present in 34.7% of SSc patients, pulmonary hypertension in 42.2%, interstitial lung disease in 38.3%, and renal crisis in 2%.

The sensitivity of ACR&EULAR and ACR1980 criteria were, respectively, 92.2% and 78.4%. The specificity of ACR/EULAR and ACR1980 criteria were, respectively, 89.3% and 76.7%. According to the new critera göre 10 patients were misclassified, and according to ACR1980 criteria 18 patients were misclassified. The sensitivity of ACR 1980 criteria was significantly better in SSc patients with interstitial lung disease when compared to others (91.7% vs. 74.%1, p=0.036). According to the New criteria set, however, the sensitivity tended to be higher in the group with anti-Scl-70 positivity (91.7% vs. 74.1%, p=0.09). The sensitivity and the specificity of the criteria were not different in patients with certain other clinical features or other antibody positivities.

Conclusion: We observed that the new ACR/EULAR SSc classification criterianın had better sensitivity and specifity in our SSc patients; and it led to misclassification in a less number of patients.

Prevalence and Features of Metabolic Syndrome in Systemic Sclerosis. Tiago N. Amaral[1], Karina Pereira[2], Nailu A. Sinicato[1], Sandra Gasparini[1], Fernando Augusto Peres[1], Maria Carolina de Souza[1], Ana Paula del Rio[1], João Francisco Marques-Neto[3] and Simone Appenzeller[4]. [1]State University of Campinas, Campinas, Brazil, [2]State University of Campinas, Limeira, Brazil, [3]University of Campinas, Campinas, Brazil, [4]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disease characterized by initial vascular injuries and resulted fibrosis of skin and internal organs. Vascular impairment in SSc involves both micro and macrovascular circulation and maybe a sign of endothelial dysfunction. Metabolic syndrome (MetS) is defined as a set of metabolic abnormalities which commonly manifests together and are considered to be cardiovascular risk factors. Each component by itself increases the risk for cardiovascular disease (CVD), however, when combined, a 1.5 – 2.5 increase in CVD mortality is observed.

Objective: To determine the prevalence and features of metabolic syndrome (MetS) in SSc.

Methods: We screened consecutive SSc patients followed in a longitudinal cohort from 2011 to 2013 and age and sex matched controls. We excluded patients with overlapping rheumatic diseases. Predefined outcome measures were collected. This included demographics (age, gender, disease duration), physical examination [skin score, joint count, blood pressure, height, weight, waist circumference (WC) and hip circunference (HC)], disease activity (Valentini Disease Activity Index) and severity (Medsger Disease Severity Scale) scores and laboratory data (total and fractions of cholesterol, fasting glucose levels, basal insulin, C3, C4, erythrocyte sedimentation rate and hemoglobin/hematocrit levels). MetS was assessed using the definition recommended by the 2009 Joint Interim Statement (JIS). Nonparametric tests and correlation were used for statistical analysis.

Results: A total of 131 SSc (121 female; mean age = 51.70; SD=13.12) and 79 health subjects (69 female; mean age=40.66; SD=13.38) (p=0.41) were included in the study. Seventy-eight (59.54%) patients had limited SSc (lSSc); 42(32.06%) had diffuse SSc (dSSc) and 11(8.4%) SSc sine scleroderma disease (ssSSc). Active disease was observed in 18(13.74%) SSc (10 lSSc and 8 dSSc) patients. Hypertension was identified in 35 (26.72%)SSc and in 3 (3.8%) controls (p<0.001), diabetes mellitus in 16 (12.21%) SSc patients and in 3 (3.8%) controls (p=0.04) and lipid profile abnormalities in 83 (63.36%) SSc patients and in 10 (12.6%) controls (p<0.001). Increased LDL [94 (71.76%)], increased triglycerides [49 (37.40%)] and reduced HDL [75 (57.25%)] were the lipid abnormalities more often observed in SSC when compared to controls (p<0.01). Abnormal abdominal circumference was observed in 105 (80.15%) SSc patients and in 54 (68.35%) controls (p=0.05). MetS was identified in 52 (39.69%) SSc patients and 7 (8.86%) controls (p<0.001). We did not observe an association between MetS and SSc subtype (p=0.76), disease activity (p=0.66), prednisone use (p=0.093) and severity index (p=0.1).

Conclusion: This is the first study to determine the prevalence and features of MetS in SSC. MetS is frequently observed in SSc and not associated with disease related features in this cohort. However MetS should be routinely screened since it can influence atherosclerosis and cardiovascular mortality in SSc.

Patients' Perspective of Skin Involvement in Systemic Sclerosis. Ada Man[1], Amy Wu[1], Jessica Ziemek[1], Romy Christmann[1], Robert W. Simms[1], David T. Felson[1] and Robert Lafyatis[2]. [1]Boston University School of Medicine, Boston, MA, [2]Boston University, Boston, MA.

Background/Purpose: Skin tightness and other abnormalities of the skin are the hallmark features of systemic sclerosis (SSc). While skin involvement may significantly impact a patient's quality of life, this impact is not well understood since current measures of SSc disease activity only address the objective measure of skin thickness (modified Rodnan skin score), and non-skin related SSc health status (scleroderma HAQ, SSc-GIT). We sought to identify key items of concern as related to skin disease in SSc from the patient's perspective.

Methods: Three directed focus groups with diffuse and limited cutaneous SSc patients (N=15) were conducted to facilitate free discussion around the patients' experience with skin-related quality of life in SSc. Transcripts were qualitatively analyzed using a Grounded Theory approach and emerging items of concern were coded with the aid of data analysis software (NVivo 10, QSR International). The items were sorted according to their frequency of citation combining all three focus sessions. We identified major constructs that formed a unifying conceptual framework for the items.

Results: The top cited concerns by patients included difficulty with gripping and moving parts of the body due to skin tightness, feeling self-conscious about the skin's appearance, uncomfortable skin tightness/restrictiveness, and difficulty opening and closing the mouth. Some skin-related concerns such as hand function may overlap with musculoskeletal involvement in SSc. Four major constructs were identified (in descending order of cited frequency): physical limitations imposed by skin tightness, physical skin effects, emotional effects, and social effects.

Conclusion: The subjective effects of skin involvement on SSc patients' quality of life are multidimensional and some important patient concerns such as discomfort from skin tightness, itch, and reduced mouth opening are not captured by existing disease outcome instruments in the dermatology and rheumatology literature. Hand function was a frequently cited skin-related concern and points to a possible need for SSc specific hand function assessment instruments as well.

Table 1. Top 20 concerns cited by systemic sclerosis patients (N=15) during three focus sessions relating to how skin affects their quality of life

Construct	Item	Number of times cited
Physical limitations	Difficulty with grip/fist	46
Physical limitations	Difficulty moving parts of the body	26
Emotional effects	Self-conscious	24
Physical skin effects	Tight or Restrictive	21
Physical limitations	Reduced ability to close or open mouth	18
Physical limitations	Difficulty with fine motor skills	18
Emotional effects	Fear of not knowing how disease will progress	14
Physical limitations	Difficulty putting on clothes and shoes	11
Physical skin effects	Itchy	11
Physical skin effects	Skin darkening	10
Physical skin effects	Swelling of skin on hands and fingers	10
Physical skin effects	Dry	7
Physical skin effects	Tingling or burning	6
Emotional effects	Depressed	6
Emotional effects	Different sense of self	6
Physical limitations	Difficulty opening hands	5
Physical skin effects	Change in facial appearance	5
Social effects	Decreased ability to work	5
Emotional effects	Feel misjudged by looks	4
Physical limitations	Change in ability and comfort in doing sports	4

Rapamycin Corrects GATA-3 Deficiency in Lupus Treg. Hiroshi Kato and Andras Perl. SUNY Upstate Medical University, Syracuse, NY.

Background/Purpose: As demonstrated by the negative correlation between Treg frequency or suppressive function and SLE disease activity index score, it is tempting to speculate that a Treg defect contributes to dysregulated immune response in SLE. GATA-3 is not only indispensable for Th2 differentiation, but also plays critical roles in homeostasis and function of Tregs as exemplified when Treg-specific deletion of GATA-3 leads to spontaneous development of inflammatory disorder. GATA-3 deficient Tregs have reduced FoxP3 expression and are poised to express IL-17 in the presence of IL-6. However, roles of GATA-3 in lupus Treg biology remain undefined.

Methods: $CD3^+$ T cells were isolated from 9 pairs of matched SLE and healthy control (HC) subjects. A part of the $CD3^+$ T cells were stained with CD4, CD8, and CD25 followed by GATA-3 and FOXP3. The rest of the cells were cultured in RPMI culture media with 10% FCS, 1% Penicillin/Streptomycin, and 1% L-glutamine for 3 days in the presence of plate-bound anti-CD3 and soluble anti-CD28 with or without 100 nM rapamycin. After 3 days of culture period, cells were stained as previously described. GATA-3 expression by $CD4^+$, $CD8^+$, and $CD4^-CD8^-$ double-negative (DN) T cells as well as $CD4^+CD25^+FOXP3^+$Treg was assessed by flow cytometry. Mean fluorescence intensity was normalized to that of HC samples on day 0. Frequency of GATA-3^+ cells was determined after 3-day T-cell-receptor stimulation.

Results: GATA-3 was overexpressed in freshly isolated SLE $CD3^+$ T cells (Relative MFI: 1.22±0.08, p=0.013), $CD8^+$ T cells (Relative MFI: 1.26±0.09, p=0.012), and DN T cells (Relative MFI: 1.70±0.33, p=0.033), whereas it was reduced in freshly isolated SLE Tregs (Relative MFI: 0.81±0.09, p=0.032). After 3-day T-cell-receptor stimulation, rapamycin suppressed GATA-3 expression by $CD3^+$ T cells in HC (% GATA-3^+ cells: 51.8±1.7% in rapamycin-untreated cells, 49.7±2.2% in rapamycin-treated cells, p=0.006), which appears to be the case in SLE (% GATA-3^+ cells: 49.8±5.6% in rapamycin-untreated cells, 48.1±6.9% in rapamycin-treated cells). In contrast, rapamycin augmented GATA-3 expression by Tregs in HC (% GATA-3^+ cells: 63.1±4.6% in rapamycin-untreated cells, 69.4±3.7% in rapamycin-treated cells, p=0.003) and appears to have restored that in SLE (% GATA-3^+ cells: 61.1±6.3% in rapamycin-untreated cells, 62.8±7.6% in rapamycin-treated cells).

Conclusion: The data points to GATA-3 deficiency in SLE Treg as a potential mechanism underlying the functional incompetence. Rapamycin may correct Treg function by restoring GATA-3 expression in SLE.

Programmed Death 1 Inhibits T-Cell Adhesion By Regulating Rap1. Inbar Alfaguter[1], Marianne Strazza[1] and Adam Mor[2]. [1]NYU, New York, NY, [2]NYU Langone Medical Center, New York, NY.

Background/Purpose: Programmed Death-1 (PD-1) is an inhibitory co-receptor that is highly expressed in T lymphocytes. The binding of PD-1 to its ligands, PD-L1 or PD-L2, is vital for the physiologic regulation of the immune system. Likewise, a major function of the PD-1 signaling pathway is the inhibition of self-reactive T cells, which serve to protect against autoimmune disease. PD-1 transmits its inhibitory effects by dephosphorylation of physically associated proximal signaling molecules that are downstream of the T cell receptor complex. At the cellular level, PD-1 activation can leads to depression of T-cell proliferation, impaired survival, and decreased interleukin-2 release.

Methods: Preliminary studies have shown that PD-1 also inhibits T cell adhesion, but little is known how this is mediated. In order to fill this gap, we investigated the role of PD-1 in T-cell adhesion by analyzing the major players in its TCR signaling pathway. We hypothesized that PD-1 inhibited adhesion by inhibiting Rap1, a small GTPase vital for effective T cell motility and adhesion.

Results: We identified that when PD-1 binds to its ligand PD-L2 there is an inhibition of Rap1 activation and LFA-1 mediated adhesion. We continued to show that C3G, a vital component of activating Rap1 and a more upstream element in the TCR signaling cascade, is dephosphorylated by PD-1.

Moreover, this was mediated by the phosphatases SHP-1 and SHP-2. Interestingly, we did not see these results downstream the inhibitory co-receptors, CTLA-4, proving that PD-1 works by a distinct mechanism.

Conclusion: We concluded that PD-1 inhibits Rap1 mediated adhesion by dephosphorylation of C3G utilizing the phosphatases SHP-1 and SHP-2. Further studies are underway to further characterize the regulation of these enzymes by PD-1.

Deficiency of Ro52/TRIM21 in Different Subsets of Peripheral Blood Mononuclear Cells from Patients with Inflammatory Myopathies. Angeles Shunashy Galindo-Feria, Diana Gómez-Martín, Ana Barrera-Vargas, Javier Merayo-Chalico and Jorge Alcocer-Varela. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.

Background/Purpose: The detection of Ro52/TRIM21 autoantibodies has been considered an independent prognostic marker in different rheumatic conditions. However, the information about the expression of Ro52/TRIM21 in subsets of peripheral blood mononuclear cells (PBMCs) in autoimmune diseases is scant. Specifically, its role in idiopathic inflammatory myopathies (IIM) has not been elucidated, and the evaluation of its expression in these diseases is the aim of the present study.

Methods: We included active, untreated patients with recent diagnosis (<1 month) of IIM according to Bohan and Peter's criteria, who attended a tertiary care center from March 2013 to April 2014. Patients with diagnosis of dermatomyositis (DM), polymyositis (PM) and antisynthetase syndrome (AAS), as well as age and gender-matched healthy controls were recruited. All subjects gave informed consent and the study was approved by the institutional ethics committee. PBMCs were isolated by Ficoll-Hypaque method and different subsets of PBMCs ($CD4^+$, $CD8^+$, $CD14^+$) were purified by magnetic selection. The expression of Ro52/TRIM21 was evaluated by Western Blot. Descriptive statistics are shown with mean and standard deviation. Student's T test or Mann-Whitney U test was used to analyze differences between groups.

Results: We included 14 patients with IIM (1 PM, 3 AAS, 10 DM), as well as 14 healthy controls. Sixty percent of subjects were female, with a mean age of 43±15 years. CPK levels at diagnosis were 4534±2235 UI/L and lymphocyte count was 1021±170 cells/uL. The presence of myositis-specific and associated autoantibodies was assessed by ELISA. The autoantibodies found in DM patients were anti-Ro52 (20%) anti-PL7 (20%), anti-Ku (20%), anti-PL12 (10%), anti-SRP (10%) and anti-Mi2 (10%). In AAS patients, anti-Ro52 (33.3%), anti-Jo1 (33.3%) and anti-PMScl75 (33.3%) were identified. We did not find any specific nor associated autoantibodies in the patient with PM. Patients with IIM showed decreased protein expression of Ro52/TRIM21 in comparison to healthy controls in different PBMC subsets: total PBMC (0.971±0.603 *vs* 1.849±0.927, p=0.016), $CD4^+$ lymphocytes (0.797±0.540 *vs* 2.413±0.786 p=0.017), and monocytes (0.875±0.358 *vs* 1.890±0.209 p<0.001). $CD8^+$ lymphocytes from IIM patients also showed a trend towards lower Ro52/TRIM21 expression (0.902±0.708 *vs*1.610±0.540, p=0.133). We did not find significant differences among each of the IIM groups.

Conclusion: Our findings suggest that patients with IIM are characterized by deficient expression of the ubiquitin ligase Ro52/TRIM21 in different PBMC subsets ($CD4^+$ lymphocytes and monocytes). Further insights into the function of this protein will have profound implications for the understanding of its role in IIM. TRIM21 deficiency could be particularly related to decreased IRF ubiquitination and degradation, which could enhance type 1 interferon signaling.

Enhanced Expression of CCL25 to Facilitate Increased Numbers of CCR9-Expressing Tfh-like Cells in Salivary Glands of Primary Sjögren's Syndrome Patients. S.L.M. Blokland[1], M.R. Hillen[1], A.a. Kruize[1], A. Kislat[2], S. Meller[2], B. Homey[2], G.M. Smithson[3], J. Zalevsky[4], T.R.D.J. Radstake[1] and J.a.G. van Roon[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]University of Düsseldorf, Medical Faculty, Düsseldorf, Germany, [3]Takeda Pharmaceuticals International, Chicago, IL, [4]Takeda California, San Diego, CA.

Background/Purpose: In primary Sjögren's syndrome (pSS) B cell activation and autoantibody secretion are hallmark immunopathological features. Specific lymphoid organization (including germinal centers) is associated with increased risk for development of extraglandular manifestations and lymphoma. Thus better understanding of the cellular and molecular pathways that underlie formation of ectopic lymphoid structures is of pivotal importance. Tfh cells, expressing ICOS and cytokines like IL-21 play a critical role in the formation of such structures and in activation of B cells. Recently, a novel subset of CD4+ T cells found to have Tfh-like characteristics was found to be specifically attracted to mucosal sites by CCL25, the ligand for CCR9.

Objective: To investigate the presence of CCL25 and CCR9-expressing Tfh-like cells in pSS patients.

Methods: Levels of CCL25 were measured in the serum of patients with pSS (n=13), non-Sjögren's sicca (nSS, n=15) and healthy controls (HC, n=6). Also, the correlation of CCL25 with other inflammatory mediators as assessed by Luminex was determined. Secretion of CCL25 by labial salivary gland (LSG) biopsy samples from pSS (n=14) and nSS (n=14) patients was assessed and CCL25 mRNA was quantified (n=9 vs n=9). CCR9-expressing cells were assessed in the circulation of HC and pSS patients and expression of Tfh markers including CXCR5, ICOS and PD-1 was analyzed.

Results: Increased CCL25 levels were observed in serum of pSS and nSS patients as compared to HC (pSS 2984 ± 286, nSS 2692 ± 177, HC 2140 ± 154, $p = 0.02$ and $p = 0.03$ resp). CCL25 serum levels in pSS correlated with the presence of chemokines involved in formation of ectopic lymphoid structures CXCL13 and CCL19 ($r=0.594$, $p=0.04$) and proinflammatory cytokines IL-12 ($r=0.615$, $p=0.03$) and TWEAK ($r=0.621$, $p=0.03$). In addition, pSS patients displayed a 10 fold increase in CCL25 mRNA levels in LSG ($p<0.05$) and an increase in CCL25 protein levels in LSG washouts compared to nSS patients (2029 ± 2986 vs 974 ± 188 pg/mL, $p=0.03$), correlating with CXCL13 ($r=0.832$, $p<0.001$). pSS patients had enhanced numbers of CCR9-expressing T cells in the circulation as compared to HC (14.1% vs 7.9%, $p=0.05$). Interestingly, comparable to Tfh a substantial proportion of CCR9+ cells expressed CXCR5, PD-1 and ICOS.

Conclusion: Our results suggest that enhanced expression of CCL25 in the labial salivary gland might promote elevation of CCR9-expressing Tfh-like cells at the site of inflammation. Considering the expression of ICOS and the capacity of CCL25 to induce proinflammatory cytokine secretion this suggests that the CCL25/CCR9-axis might play a role in the immunopathology of pSS, representing a novel therapeutic target in this disease.

CD28null T Cells from Polymyositis Patients Are Cytotoxic to Autologous Muscle Cells *in Vitro* Via Perforin-Dependent Mechanisms. Jayesh Pandya[1], Paulius Venalis[1], Lubna Al-Khalili[2], Mohammad Shahadat Hossain[1], Ingrid E. Lundberg[1], Vivianne Malmström[1] and Andreas E. R. Fasth[1]. [1]Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Solna, Karolinska Institutet, Stockholm, Sweden, [2]KTH - Royal Institute of Technology, Stockholm, Sweden.

Background/Purpose: Inflammatory infiltrates of muscles in polymyositis are dominated by CD4+CD28null and CD8+CD28null T cells. In contrast to conventional CD28+ T cells, these cells have a restricted T cell-receptor repertoire, rapidly release large amounts of IFN-γ and TNF, and can kill tissue cells by granzyme-B and perforin upon activation. Although their presence in myositis muscles have been demonstrated recently, their effect on muscle cells has not been clarified. Aim of the study was to investigate the potential myotoxic effect of CD28null T cells on muscle cells from patients with polymyositis, in a fully autologous co-culture system.

Methods: Muscle stem cells were extracted from biopsies from 6 patients with polymyositis (classified according to Bohan and Peter criteria) and differentiated into myotubes. T cell subsets from the same patients were isolated from peripheral blood by flow-cytometry. Co-cultures of autologous muscle cells were performed with un-stimulated or stimulated T cell subsets for 24–36 hours. Dead myotubes were quantified by calcein release assay and flow-cytometry. Blocking experiments were performed using relevant blocking antibodies to the co-cultures.

Results: CD28null T cells were spontaneously cytotoxic to autologous muscle cells in culture. The median cytotoxicity (induced muscle cell death) at 5:1 T cells-muscle cells ratio was 23.5% for CD4+CD28null and 22.3% for CD8+CD28null T cell subsets (n=4). In comparison, conventional CD4+ and CD8+ T cells displayed lower cytotoxicity (median CD4+CD28+ 10.3%, CD8+CD28+ 11.4%, n=4). Upon co-culture in stimulatory environment, both CD28null T cell subsets significantly induced more cell death in autologous muscle cells than CD28+ counterparts (n=5). Not only CD8+CD28null but also CD4+CD28null T cells displayed perforin polarization towards muscle cells and secreted higher levels of granzyme-B and IFN-γ in co-culture than CD28+ subsets (n=4). By blocking perforin, the myotoxicity was reduced by a median of 52% with CD4+CD28null T cells and by 56% in cultures with CD8+CD28null T-cells (n=3). TNF or IFN-γ did not induce death of muscle cells in the absence of T cells, but did upregulate HLA class I and II on muscle cells (n=3–5). Blockade of IFN-γ and TNF in co-cultures with T cells reduced the level of dead muscle cells by 46% (CD4+CD28null) and 53% (CD8+CD28null) (n=3). The reduced myotoxicity is likely attributed to reduced HLA expression, as HLA blockade resulted in a comparable reduction in myotoxicity, 61% (CD4+CD28null) and 55% (CD8+CD28null) (n=5).

Conclusion: The myotoxic effect by CD28null T cells in polymyositis may be mediated by perforin-dependent killing and regulated by IFN-γ-induced HLA expression by muscle cells. Together, this suggests that CD28null T cells are key effector cells directly contributing to the muscle cell damage in polymyositis, hence represent target candidate for future therapies

T Cells Trigger Interstitial Pneumonia in Polymyositis. Akira Takeda[1], Yasutsugu Fukushima[2], Takaji Matsutani[3], Yoichiro Haji[1], Chisun Min[1], Ryo Rokutanda[1], Yasuhiro Suyama[1], Mitsumasa Kishimoto[1], Ken-ichi Yamaguchi[1] and Masato Okada[4]. [1]St. Luke's International Hospital, Tokyo, Japan, [2]Dokkyo University School of Medicine, Mibu, Japan, [3]Wakayama Medical University, Ibaraki, Japan, [4]St. Luke's International Hospital, tokyo, Japan.

Background/Purpose: The lung is frequently affected in connective tissue diseases (CTDs). Polymyositis (PM) is a major CTD characterized by idiopathic inflammatory lesions of muscle and other organs including critical pulmonary involvement. Interstitial lung diseases, mainly interstitial pneumonia (IP), have been recognized in 30–70% of PM patients, which often have a poor prognosis and a high risk of mortality. While the presence of myositis-specific autoantibodies suggests an autoimmune etiology of PM, the pathogenesis of PM-associated IP remains unclear. The aim of this study was to elucidate the role of T cells in this pulmonary complication. Lung tissue was utilized in this study with the approval of the IRB.

Methods: We had advantage of a rare opportunity to be able to precisely study the lung tissues which were obtained for the pathodiagnostic purpose by video-assisted thoracoscopy from the cases of earliest-stage IP associated with PM: one patient with IP of early usual IP (UIP) pattern and another patient with IP of nonspecific IP (NSIP) pattern. It lead us to immunohistochemically characterize the phenotype of lung-infiltrating lymphocytes from the lung biopsy specimens, and to analyze T-cell receptor α-chain (TCR Vα) and TCR β-chain (TCR Vβ) variable region repertoires of T-cells infiltrating the lung tissues using a validated adaptor ligation polymerase chain reaction (PCR)-based microplate hybridization assay, comparing these to peripheral blood lymphocytes (PBL). We considered it important to perform TCR analysis from lung tissue in the earliest stage of IP because TCRs diversify with disease progression due to "determinant spreading" in which autoreactive T-cell responses, initiated by a single antigenic epitope, evolve into multiepitopic responses.

Results: The study with lung tissues of the initial stage of IP demonstrated substantial pulmonary CD3+ predominated T cell infiltrates. In both cases, patient A (early UIP pattern) and patient B (NSIP pattern), most of the mononuclear cells were CD3+ T-cells, accompanied by a subtle infiltration of B-cells (CD20+), and a minimal number of monocytes (CD19+). Of infiltrating T-cells, more CD4+ than CD8+ cells (in the ratio of four to one) were noted in both patients. The usage of repertoires of TCR Vα/Vβ in the lung differed from those in PBL, with certain TCR V gene families detected more frequently in lung tissue, suggesting a pivotal role for T cells in the pathogenesis of IP associated with PM. This is the first robust demonstration of selective TCR repertoire usage and its differential expression in lung tissue

versus PBL. As expected, no TCR signals were detected from non-IP lung tissue controls.

Conclusion: These findings clearly suggest a pathogenic contribution of organ-specific oligoclonal T cell accumulation through antigen-driven immune responses, implying potential elucidation of causative antigens as well as development of immuno-specific treatments such as molecular-targeted therapies.

Reduction of MAIT Cell Frequency Associated with Reduced Cell Proliferation and Enhanced Cell Death in Systemic Lupus Erythematosus. Asako Chiba, Naoto Tamura, Eri Hayashi, Ran Matsudaira, Yoshinari Takasaki and Sachiko Miyake. Juntendo University School of Medicine, Tokyo, Japan.

Background/Purpose: Mucosal-associated invariant T (MAIT) cells are innate-like lymphocytes which are restricted by the MHC-related molecule-1 (MR1) and express a semi-invariant TCRα chain: Vα7.2-Jα33 in humans and Vα19-Jα33 in mice. MAIT cells uniquely recognize microbial-derived vitamin B metabolites presented by MR1. Like other innate-like lymphocytes, MAIT cells have been suggested to play both proinflammatory and regulatory roles in autoimmune models. Although MAIT cells are rare in mice, human MAIT cells are more abundant and constitute approximately 5% of peripheral blood T cells, suggesting possible roles of MAIT cells in human autoimmune diseases. Previously we have revealed that the frequency of MAIT cells was reduced and reflected the disease activity in multiple sclerosis. In this study, we sought to investigate whether MAIT cells are involved in the pathogenesis of systemic lupus erythematosus (SLE).

Methods: Whole blood samples or peripheral blood mononuclear cells (PBMC) of SLE patients as well as healthy volunteers were stained with anti-human monoclonal antibodies(mAb) against CD3, $\gamma\delta$TCR, Vα7.2TCR, CD161, CD45RA, CCR7, CD69, CD95(FAS) and 7-AAD. MAIT cells were identified as $CD3^+\gamma\delta TCR^-V\alpha7.2TCR^+CD161^{high}$cells by FACS LSR Fortessa. In some experiments, costaining of intracellular active caspase-3 of MAIT cells was performed. MAIT cells and other T cell subsets were single-cell sorted by using FACS Aria II, and the usage of Vα7.2-Jα33 TCR of single-cell sorted cells was examined by PCR. PBMC labeled with Cell Trace Violet Dye were stimulated with anti-CD3mAb and anti-CD28mAb or IL-15, and the cell proliferation was analyzed by FACS.

Results: As previously reported, the frequencies of $\gamma\delta$T cells were slightly reduced in SLE. The percentages of MAIT cells from SLE patients were markedly decreased and about 7-fold lower compared with those from healthy subjects. Single-cell PCR analysis indicated that the decrease of lupus MAIT cells was not a result of downmodulation of surface markers. The proliferative capacity was slightly reduced in lupus MAIT cells. MAIT cells from lupus patients with active disease expressed high levels of CD69, and lupus MAIT cells had higher percentages of FAS^{high} cells, active caspase-3 or 7-AAD positive cells. These result suggest that more MAIT cells are undergoing activation-induced cell death in SLE. Activated MAIT cells failed to expand in a long term culture. Although the frequencies of naïve cells were increased in lupus $\gamma\delta$T cells, most MAIT cells displayed an effector memory phenotype and there was no increase of naïve cells among lupus MAIT cells.

Conclusion: This study demonstrates that the frequency of MAIT cells was significantly reduced in SLE. The increased cell death and reduced cell prolifeation of activated MAIT cells were in part responsible for the decrease of MAIT cells in SLE. The limited recruitment of recent thymic emigrants of naïve MAIT cells also contributed the profound reduction of these cells in SLE.

To Live or Let Die... the Battle Between PD-1 and OX40 on SLE T Cells. Julie Kristine Laustsen[1], Stinne Greisen[1], Bent Deleuran[2] and Tue Kruse Rasmussen[1]. [1]Aarhus University, Aarhus C, Denmark, [2]Aarhus University Hospital, Aarhus, Denmark.

Background/Purpose: Programmed cell death 1 (PD-1) is a co-inhibitory receptor, which inhibits T cell proliferation and survival by inhibiting IL-2 signalling. By this PD-1 has been speculated as a key player in maintaining and restoring self-tolerance. In contrast, OX40 is a surface receptor that induces IL-2R expression and OX40 has been suggested to allow possible autoreactive effector T cells to develop into memory T cells. These two molecules could therefor represent two opposite sides of the balance in immune regulation -a balance crucial for maintaining peripheral tolerance. In systemic lupus erymathosus (SLE) this balance is disrupted, and disease progression is characterized by antibody production and autoreactive lymphocytes. In this study, we investigated cellular expression and soluble (s) levels of PD-1 and OX-40.

Methods: Plasma levels of sPD-1 and sOX40 from SLE patients (n=19) and healthy controls (HCs) (n=18) were quantified by ELISA. PBMCs from SLE patients and HC were stained with monoclonal antibodies against PD-1, OX40, CD4 and CD8. Cells where analyzed by flow cytometry. Skin biopsies from SLE patients and HCs were stained with anti-OX40 and anti-PD-1 antibodies and analyzed by confocal microscope. Statistics were assessed by Mann-Whitney's test, and Spearman's ranked correlation. Data are expressed as median (IQR).

Results: In SLE patients, sPD-1 was significantly increased (445 pg/ml (319 pg/ml – 897 pg/ml)) compared to HCs (244 pg/ml (173 pg/ml – 343 pg/ml), $p<0.001$) and correlated positively with the SLE disease activity score SLEDAI ($\rho=0.69$, $p=0.01$). Soluble OX40 was decreased (7.3 pg/ml (7.3 pg/ml – 16.4 pg/ml)) compared with HC (53,5 pg/ml (41.9 pg/ml – 72.5 pg/ml) $p<0.001$). Furthermore, did levels of sPD-1 and sOX40 inter-correlate positively in SLE patients ($\rho=0.59$, $p= 0.005$), which was not the case in HCs. Co-expression of PD-1 and OX40 was seen on (9.5%) $CD4^+$ T cells in SLE compared with (5.2%) in HCs ($P<0.01$). Immunofluorescence revealed that PD-1 and OX40 co-expressing cells were present in SLE skin, further supporting that the same cell expresses both PD-1 and OX40 (Fig 1).

Conclusion: In this study, we show that T-cells expressing both PD-1 and OX40 are increased in SLE, and that the levels of the soluble isoforms intercorrelate. We also show that sPD-1 correlates strongly with SLEDAI, suggesting sPD-1 as a marker of inflammation in SLE. The observed co-expresssion of the death receptor PD-1 and the survival receptor OX40, could in part explain why autoreactive effector T cells survive, despite receiving apoptosis signals, and help elucidate the lack of self-tolerance in SLE patients.

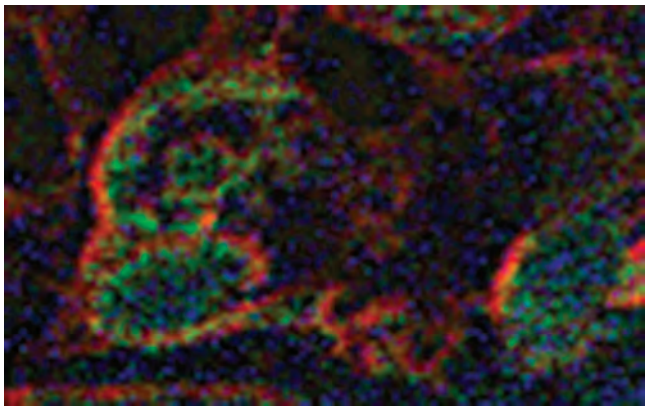

Fig 1: co-expression of PD-1 (green) and OX-40 (red)

FcγRIIIa Ligation in Human Peripheral $CD4^+$ T-Cells Generate T_H17 like Population. Anil K. Chauhan[1], Terry Moore[2] and Chen Chen[1]. [1]Saint Louis University, St. Louis, MO, [2]St Louis University, Saint Louis, MO.

Background/Purpose: Cytokines produced during T_H17 response, IL-17A and IL17F drive inflammation and autoimmunity. They also act as a bridge between adaptive and innate immunity. Immune deposits are formed in vascular sites in autoimmunity and often demonstrate the excessive presence of immune complexes (ICs) and activated complement products. ICs drive nephropathic changes in SLE. Thus, we examined whether these immune reactants can activate naive $CD4^+$ T-cells to generate T_H17 like cells. Furthermore to elucidate the mechanism by which ICs triggered the generation of T_H17 like population, we also examined the presence of low affinity Fc-receptors on activated naïve $CD4^+$T-cells.

Methods: Naïve $CD4^+CD45RA^+$ T-cells obtained from SLE patients were activated using plate bound ICs (10 mg/ml) and soluble C5b-9 (2.5 mg/ml) in the presence of anti-CD3 (0.25 mg/ml). Post activation cells were cultured in the presence of IL-1β (25 ng) IL-2 (10 ng), IL-6 (50 ng), IL-23 (25 ng), and TGF-β1 (10 ng) in each ml of RPMI. On day 9th culture soups were analyzed for cytokines and flow analysis was performed for IL-17A, IL-17F, IL-21, and IL-22. qRT-PCR was performed for *rorc and ifng* IFN pathway genes were analyzed using qRT-PCR IFN-arrays (Applied Biosystems). Activated cells were analyzed for binding to labeled ICs and expression of *fcgr3a* gene transcripts.

Results and Conclusion: Our results demonstrate that ICs via FcγRIIIa ligation on activated naïve $CD4^+$ T-cells generate T_H17 like population. We observed increased expression of *rorc* transcripts and statistically significant increase in IL-17A, IL-17F, IL-21, and IL-22 in the culture supernatant and an increase in cytokine producing population in flow analysis in response to ICs treatment. In addition IC mediated signal in $CD4^+$ T-cells also generated an IFN-γ^{high+} population. ICs and complement provided a co-stimulatory signal that was strong and divergent from the traditional CD28 co-stimulatory signal. $CD4^+$ T-cells activated using anti-CD3+ICs+C5b-9 induced expression of *fcgr3a* transcripts and membrane FcγRIIIa protein. These activated cells showed statistically significant increase in binding to labeled ICs and AHG in flow analysis. These results for the first time demonstrate a possible role for FcγRIIIa in the generation of T_H17 like cells. Our IFN array analysis also showed increase in type 1 IFN genes. In autoimmune disease a co-operation between type 1 IFNs and T_H17 has been observed. Our data suggest that both of these responses are driven by ICs and complement in $CD4^+$ T-cells. Generation of T_H17 like population and IFN-γ producing cells will contribute to the development of lupus nephritis, which could occur locally in the kidney. These findings are important in that the activating membrane co-stimulatory signal from CD28 and ICOS are counteracted by CTLA4 and PD1 inhibitory signal during immune contraction. An activating signal from ICs and complement in immune contraction can tip the balance in favor of activating signal that may lead to breakdown of peripheral tolreance. Thus the data present identifies a new pathway by which ICs and complement will drive the autoimmune pathology.

Th1 and Th17 Cytokines Drive Takayasu Arteritis Inflammation. David Saadoun[1], Marlène Garrido[2], Cloé Comarmond[3], Anne-Claire Desbois[4], Fanny Domont[4], Léa Savey[5], Benjamin Terrier[6], Michelle Rosenzwajg[2], David Klatzman[7], Pierre Fourret[8], Philippe Cluzel[9], Laurent Chiche[10], Julien Gaudric[11], Fabien Koskas[12] and Patrice Cacoub[13]. [1]DHU 2iB Internal Medicine Referal Center for Autoimmune diseases Pitie Hospital, Paris, France, [2]UMR 7211, INSERM U959, Hôpital Pitié-Salpêtrière, Paris, France, [3]Internal Medicine and Clinical Imunology, Hôpital Pitié Salpétrière, Paris, France, [4]Hôpital Pitié-Salpêtrière, Internal Medicine and Clinical Immunology, Paris, France, [5]Hôpital Pitié-Salpêtrière, Internal Medicine and Clinical Immunology, P, France, [6]Cochin Hospital, Paris, France, [7]UPMC Université Paris 06, UMR 7211, Paris, France, [8]Hôpital Pitié-Salpêtrière, Anathomopathology, Paris, France, [9]Vascular and Interventional Imaging Department, Paris, France, [10]Vascular Surgery, Paris, France, [11]Department of Vascular surgery GHPS, Paris, France, [12]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France, [13]Groupe Hospitalier Pitié Salpétrière, Service de Médecine Interne, DHU i2B, Paris, France.

Background/Purpose: Takayasu arteritis (TA) is a large-vessel vasculitis inducing damage of the aorta and its branches. Glucocorticoids remain the gold standard of therapy in TA. However, the nature of T cell driving vascular inflammation and the effects of glucocorticoids on the systemic components of TA are not understood.

Methods: T cell homeostasis and cytokines production were analyzed in peripheral blood and aorta inflammatory lesions using Luminex, flow cytometry, and immunohistochemistry analysis. The study included 41 TA patients fulfilling the ACR criteria [17 active (aTA) and 24 in remission (rTA)], 30 giant cell arteritis (GCA) patients (disease control) and 20 age and sex-matched controls.

Results: We first demonstrated the promotion of Th1 and Th17 responses that correlates with TA activity. We determined whether serum from TA patients was able to modulate T cell differentiation in healthy controls. The addition of serum from active TA patients in sorted $CD4^+$ T cells culture of healthy donors induced a significant production of IFN-g and IL-17A. We demonstrated the the strong expression of IFN-g, and IL-6 producing T cells within vascular inflammatory infiltrates of TA. Glucocorticoid therapy were associated to decreased circulating Th1 cytokines with significantly lower IL-2 (mean±SEM; 2812±690.1 vs. 7228±1536 pg/ml, p=0.0196), IFN-g (1437±367.3 vs. 7124±1818pg/ml, p=0.0019) and TNF-a (643.3±106.4 vs. 1438±196.6pg/ml, p=0.01) in steroid treated TA compared to steroid free TA patients, respectively. However, glucocorticoids essentially left unaffected Th17 cytokines (i.e. IL-1b, IL-6, IL-17 and IL-23).

Conclusion: Our data provided the first evidence that Th1 and Th17 immunity seems to be important in driving TA inflammation, both systemically and in the blood vessels. In addition, only one of these pathways was amendable to glucocorticoid-mediated suppression. Glucocorticoids are associated to decrease Th1 cytokines and spared Th17 cytokines in TA.

Massive Ex Vivo Expansion of Functionally Stable Behcet's Patient-Derived Regulatory T Cell Clones. Johannes Nowatzky, Olivier Manches, Yusuf Yazici and Juan Lafaille. New York University School of Medicine, New York, NY.

Background/Purpose: Adoptive transfer of regulatory T cells (Treg) is a promising strategy for the treatment of human autoimmune diseases. Most currently tested approaches focus on the polyclonal expansion of human thymus-derived Treg (tTreg), and are limited by potentially harmful and efficacy-limiting co-expansion of effector T cells (Teff). We hypothesized that the ex vivo isolation and massive expansion of $CD4^+/CD25^{high}/CD127^{low}/FoxP3^+/Helios^+$ tTreg clones results in maximal purity of the generated cellular product, preserving its suppressor function stability over several re-expansion cycles while yielding cell numbers sufficient for pre-clinical and clinical testing.

Methods: To validate our approach for a human rheumatic disease in which antigen-specific T effector responses have been implicated in target organ damage (uveitis), we chose to identify and expand Behcet's disease patient-derived tTreg clones. $CD4^+/CD25^{high}/CD127^{low}$ T cells were isolated by magnetic bead separation, subsequently cloned in a limiting dilution approach and massively expanded in at least four re-expansion cycles. Suppression was tested in suppression assays of CD3/CD28-stimulated effector T cells at repeated expansion cycles over at least 8 weeks. Clonality was demonstrated by Vβ staining.

Results: Cloning efficiency was 2–5/100 seeded cells. Treg clones were homogeneously $CD4^+/CD25^{high}/FoxP3^+/Helios^+$ and stained positive for one unique TCR Vβ chain. Clones maintained around 80% suppression at 1:4 Treg:Teff ratios over as long as 11 weeks in culture and at least 4 re-expansion cycles. Proliferation was in the 10^8 to 10^9-fold range at day 50. When compared to tTreg clones generated from healthy human donors there were no significant differences in suppressive capacity, suppressor function stability, or phenotype.

Conclusion: Our results suggest that tTreg are not intrinsically dysfunctional in Behcet's disease, and they deliver proof of principle that the massive monoclonal expansion of antigen-specific human Treg clones from patients with a rheumatic disease is possible and yields a functionally stable, ultra-pure cellular product for pre-clinical and clinical testing.

Decreased CXCR3+CCR4-CCR6+ CD4+ Effector Memory T Cells in Patients with Granulomatosis with Polyangiitis. Lucas L. Lintermans, Coen A. Stegeman, Abraham Rutgers, Peter Heeringa and Wayel H. Abdulahad. University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: Persistent expansion of circulating $CD4^+$ effector memory T cells (T_{EM}) in patients with Granulomatosis with polyangiits (GPA) suggest their fundamental role in disease pathogenesis. The functional phenotype of these $CD4^+$ T_{EM} cells in GPA-patients is not known. Recent studies have shown that 4 distinct functional subsets of $CD4^+$ T_{EM} cell can be identified based on the expression pattern of the chemokine receptors CXCR3, CRTh2, CCR4, and CCR6. The current study aimed to identify

functionally reported different phenotypes within the expanded $CD4^+$ T_{EM} cell population in peripheral blood of GPA-patients.

Methods: Peripheral blood of 43 GPA-patients in remission and 16 healthy controls (HCs) was stained immediately after blood withdrawal with fluorochrome-conjugated antibodies for cell surface markers (CD3, CD4, CD45RO) and chemokine receptors (CCR4, CCR6, CCR7, CRTh2, CXCR3) followed by flow cytometry analysis. Positively and negatively stained populations were calculated by dot plot analysis, determined by the appropriate isotype controls. Expression patterns of chemokine receptors $CXCR3^+CRTh2^-CCR4^-CCR6^-$, $CXCR3^-CRTh2^+CCR4^+CCR6^-$, $CXCR3^-CRTh2^-CCR4^+CCR6^+$, and $CXCR3^+CRTh2^-CCR4^-CCR6^+$ were used to distinguish Th1, Th2, Th17, and Th1/17 cells, respectively.

Results: The percentage of $CD4^+$ T_{EM} ($CD3^+CD4^+CD45RO^+CCR7^-$) cells was significantly increased in GPA-patients in remission compared to HCs (median 41,93% vs 31,52%). Chemokine receptor co-expression analysis within the $CD4^+$ T_{EM} cell population demonstrated similar percentages of Th1 and Th2 cells between GPA-patients and HCs. Interestingly, the analysis revealed a significant decrease in the frequency of Th1/17 cells (median 9,28% vs 16,53%) with a concomitant significant increase in the Th17 cells (median 21,14% vs 16,93%) in GPA-patients compared to HCs. However, differences between these $CD4^+$ T_{EM} cell subsets were not related to generalized or localized disease, ANCA positivity at the time of inclusion, nor to immunosuppressive treatment regimens.

Conclusion: Based on chemokine receptor co-expression analysis we demonstrate an aberrant distribution in the $CD4^+$ T_{EM} cell compartment in GPA-patients. The identification of different phenotypes within the expanded $CD4^+$ T_{EM} cell population revealed a distinction between Th1/17 cells and Th17 cells. Interestingly, it has been described that the functional and molecular signature of Th1/17 cells is associated with a strong pathogenicity of this subset and may be important in mediating chronic inflammation. Analyzing the migration capacity of Th1/17 cells might reveal their distinct tissue homing characteristic to inflamed lesions in GPA-patients.

B55β Regulates T Cell Survival through the Modulation of AKT during Cytokine Deprivation. José C. Crispin[1], Sokratis A. Apostolidis[1], Noe Rodriguez Rodriguez[1], Tran Nguyen[1] and George C. Tsokos[2]. [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA.

Background/Purpose: The abundance of cytokines controls the length of immune responses through poorly defined mechanisms. B55β is a molecule that triggers apoptosis in activated T cells when cytokine levels decrease. T cells from a subset of patients with systemic lupus erythematosus (SLE) exhibit resistance to apoptosis that is associated to failure to express B55β. The aim of this study was to determine the molecular mechanisms through which B55β controls the survival of activated T cells.

Methods: Most experiments were performed in human primary T cells obtained from healthy donors. MCF7 cells were used in some experiments. T cells were activated with anti-CD3 and anti-CD28 (1 μg/mL). After day 3, fresh RPMI and IL-2 (100 U/mL) were replenished every 48 hours. Apoptosis was induced at day 10 by transferring the cells to fresh RPMI devoid of IL-2, in the presence of IL-2 blockade (anti-human IL-2). Apoptosis was quantified by flow cytometry (Annexin V/ propidium iodide staining). Forced expression and knockdown of B55β was induced by transducing activated T cells with lentiviruses encoding human B55β or B55β-specific shRNAs, respectively. Protein phosphorylation status was assessed by flow cytometry and Western blotting. Induction of pro-apoptotic genes was quantified by real time PCR.

Results: Maximal expression of B55β (protein) was reached after 2 hours of IL-2 deprivation. This induction was associated to dephosphorylation of AKT S473 and T308 that occurred 4 hours after IL-2 withdrawal. IL-2 deprivation-induced AKT dephosphorylation was abrogated in T cells infected with lentivirus encoding B55β-specific shRNA. Accordingly, apoptosis was significantly reduced by B55β knockdown. Complementary experiments showed that forced expression of B55β caused apoptosis of activated T cells that was associated to dephosphorylation of AKT S473. Simultaneous forced expression of AKT annulled apoptosis induced by B55β indicating that B55β induces cell death through inactivation of AKT. To determine the effects of IL-2 deprivation on the PI3K-AKT-mTOR axis, we assessed the phosphorylation status of 18 members of the pathway using an intracellular signaling array. The results confirmed that AKT is dephosphorylated by IL-2 deprivation but that the pathway is not uniformly downregulated. mTORC1 and its substrates were mostly not affected whereas other AKT substrates, in particular the pro-apoptotic protein Bad and the transcription factors FoxO1 and 3a, were activated by dephosphorylation. Accordingly, induction of pro-apoptotic genes regulated by FoxO factors was observed. Further experiments confirmed that B55β overexpression activates the FoxO factors inducing the upregulation of pro-apoptotic genes, in particular Noxa, Puma and HRK.

Conclusion: B55β is a key regulator of AKT. Upon its induction by IL-2 deprivation, it causes AKT dephophorylation triggering programmed cell death through the induction and activation of the BH3-only pro-apoptotic proteins Bad, Noxa, Puma, and HRK. Our results demonstrate a novel mechanism of how AKT is regulated in activated T cells in response to cytokine abundance.

Association of a-Kinase Anchoring Protein-79 (AKAP79) to PKC Mediates Inhibition of IL2 Transcription and Erk Activation in T Cells. Gabriel Criado, María J. Pérez-Lorenzo, María Galindo, Jose L. Pablos and Abel Suarez-Fueyo. Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain.

Background/Purpose: A-Kinase anchoring Protein AKAP79 associates to and regulates the activity of PKA, PKC and calcineurin, key regulators of T cell activation. We have previously described that AKAP79 is overexpressed in T cells from systemic lupus erythematosus lupus patients and inhibits IL2 transcription in Jurkat T cells (Criado et al., A&R 63 (Suppl10): S916). In the present study, we aim to analyze the effect of AKAP79 levels on IL2 production in SLE and normal T cells and characterize the role of the associations to PKA, PKC and calcineurin in T cell activation and IL2 transcription.

Methods:T cells were isolated by negative selection from SLE patients and healthy controls (HC). RNA was purified, retrotranscribed to cDNA and levels of AKAP79 and β-actin transcripts were quantified by quantitative real-time PCR using Sybr Green technology. AKAP79 protein expression was quantified in T cell lysates by ELISA. AKAP79 mutants deficient for association to PKA (ΔPKA-AKAP79), PKC (ΔPKC-AKAP79) and calcineurin (ΔCN-AKAP79) were generated with QuickChange Site Directed Mutagenesis kit and confirmed by sequencing. Jurkat T cells were transduced with dual promoter pRRL-AKAP79/GFP- or control pRRL-GFP-expressing lentiviruses. For functional assays, T cells were stimulated with plate-bound anti-CD3 and soluble anti-CD28 antibodies or PMA/ionomycin. RNA was isolated, IL2 transcripts quantified by quantitative real-time PCR (qPCR) and results calculated as fold change over non-stimulated cell (Mean +/− SEM). Statistical differences between groups were analysed by ANOVA and non-parametric Mann-Whitney U test, using GraphPad Prism software.

Results: IL2 transcription induced by anti-CD3/CD28 stimulation was not significantly different between SLE (n=6) and HC (n=6) T cells. However, a negative correlation between levels of AKAP79 protein and induction of IL2 transcription was found in T cells, regardless of their origin (R^2= 0.53, **p=0.0076). This was confirmed in Jurkat T cells by transduction with different amounts of AKAP79 (R^2= 0.57, *p=0.03, n= 8). Complementation of anti-CD3/CD28 stimulation by PMA, but not ionomycin, restored IL2 transcription in Jurkat cells overexpressing AKAP79, suggesting that inhibition of PKC by AKAP79 was responsible for the observed reduction of IL2 transcription. Consistent with this interpretation, overexpression of ΔPKC-AKAP79 partially rescued IL2 transcription when compared to WT-AKAP79 but ΔPKA-AKAP79 and ΔCN-AKAP79 had no significant effect (GFP: 11.59 +/− 2.21, AKAP79: 1.67 +/− 0.61, ΔPKC-AKAP79: 4.86 +/− 1.24, ΔPKA-AKAP79: 0.73 +/− 0.29, ΔCN-AKAP79: 0.88 +/− 0.35). Likewise, analysis of the kinetics of Erk activation in response to antiCD3/CD28 showed that Erk activation was blocked by AKAP79 overexpression and was recued by ΔPKC-AKAP79.

Conclusion: Overexpression of AKAP79 inhibits IL2 transcription and Erk activation in a PKC-dependent manner. Thus, targeting AKAP79-PKC interaction could provide a therapeutic approach to modulate T cell activation.

Female Specific Increase in T Cell Glycosylation in Lupus. Gabriela Gorelik and Bruce Richardson. University of Michigan, Ann Arbor, MI.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune inflammatory disease characterized by altered T cell signaling. SLE is characterized by epigenetic mechanisms that cause hypomethylation of the inactive X-chromosome predisposing females to the disease, and a global T cell DNA hypomethylation, which causes overexpression of immune-related genes.

OGT (O-linked N-acetylglucosamine transferase) is an X-linked gene overexpressed in female lupus T cells. OGT causes posttranslational modifications to proteins by adding β-N-acetyl-glucosamine (O-GlcNAc) to Ser or Thr residues in competition with phosphorylation. OGT mRNA and protein levels and O-GlcNAc-modified proteins are increased in CD4+ experimentally demethylated T cells and in T cells from active women with lupus.

Recent evidence shows that OGT plays a critical role in chromatin structure through O-GlcNAcylation of histones *in vivo* and *in vitro*, and GlcNAc is considered now part of the histone code.

Hypothesis: OGT overexpression in female lupus alters T cell signaling affecting posttranslational modifications of histones, thereby regulating chromatin remodeling and modifying gene expression.

Methods: PBMC from healthy donors were PHA-stimulated and treated with 5-azaC for 72 h. Then CD4+ T cells were isolated by negative selection and stimulated with PMA/Ionomycin for 6 h. T cells from lupus patients were activated with PMA/Ionomycin for 6 h. Cell fractions were obtained by using a nuclear extract kit (Active Motif) and the chromatin-bound proteins were isolated from the insoluble nuclear fraction. Subcellular fractions were subjected to SDS-PAGE gel electrophoresis followed by immunoblot. To detect glycosylated proteins we used CTD110.6 antibody (Abcam) and histone glycosylation was specifically detected by using anti-Histone H2B (glcnac S112) antibody (Abcam). T cells were nucleofected with 2μg of OGT siRNA using a nucleofector device (Amaxa).

Results: OGT and GlcNAcylated protein levels were increased in the nuclear fraction which correlates with translocation of OGT to the nucleus after lymphocyte activation, and the increment was higher in experimentally demethylated T cells, (OGT: $p=0.047$ control vs 5-AzaC T cells; GlcNAcylated proteins: $p=0.047$ control vs 5-AzaC T cells). OGT levels in T cells from males did not show any significant difference regardless of the treatment and/or cell fraction. We also found OGT bound to chromatin-bound proteins. H2B was GlcNAcylated at Ser112 in T cells and increased in women patients with active lupus with respect to healthy female donors (mean $\pm$ SEM: 2.85 ± 0.95; $p<0.05$ vs healthy donors; $n=3$). Histone glycosylation was inhibited in T cells transfected with OGT siRNA by $81 \pm 11\%$, indicating the specificity of the effect.

Conclusion: These results support our hypothesis that OGT overexpression in lupus T cells causes modifications in histone glycosylation that may result in altered gene expression.

Microrna-155 Suppresses IL-21 Signaling and Production in Systemic Lupus Erythematosus. Tue K. Rasmussen[1], Thomas Andersen[1], Rasmus Bak[1], Gloria Yiu[2], Kristian Steengaard-Petersen[3], Jacob G. Mikkelsen[1], Paul J. Utz[2], Christian Holm[1] and Bent Deleuran[3]. [1]Aarhus University, Aarhus C, Denmark, [2]Stanford University School of Medicine, Stanford, CA, [3]Aarhus University Hospital, Aarhus, Denmark.

Background/Purpose: IL-21 is a key regulator of B cells functions and autoantibody production and is mainly produced by follicular T helper cells. The purpose of this study is to investigate the signaling capacity of interleukin (IL)-21 in T and B cells and assess its possible regulation by microRNA-155 and its target gene suppressor of cytokine signaling 1 (SOCS1) in systemic lupus erythematosus (SLE).

Methods: The signaling capacity of IL-21 was quantified by stimulating PBMCs with IL-21 and measuring phosphorylation of (p)STAT3 in CD4+ T cells, B cells, and NK cells. Induction of miR-155 by IL-21 was investigated by stimulating purified CD4+ T cells with IL-21 and measuring miR-155 expression levels. The functional role of miR-155 was assessed by overexpressing miR-155 in PBMCs from SLE patients and HCs and measuring its effects on STAT3 and IL-21 production in CD4+ and CD8+ T cells.

Results: Induction of pSTAT3 in CD4+ T cells in response to IL-21 was significantly decreased in SLE patients compared to HCs ($p<0.0001$). Further, expression levels of miR-155 were significantly decreased and SOCS1 correspondingly increased in CD4+ T cells from SLE patients. Finally, overexpression of miR-155 in CD4+ T cells increased STAT3 phosphorylation in response to IL-21 treatment ($p<0.01$) and differentially increased IL-21 production in SLE patients compared to HCs ($p<0.01$).

Conclusion: We demonstrate that SLE patients have reduced IL-21 signaling capacity, decreased miR-155 levels, and increased SOCS1 levels compared to HCs. The reduced IL-21 signaling in SLE could be rescued by overexpression of miR-155, suggesting an important role for miR-155 in the reduced IL-21 signaling observed in SLE.

Shk-186, a Kv1.3 channel inhibitor That Targets Effector Memory T Cells: Safety and Tolerability in Humans and Its Evaluation in a Model of Rapidly Progressive Glomerulonephritis. Ernesto J. Muñoz-Elías[1], Kayla Norton[1], John B. Grigg[1], Liz Bromley[1], David W. Peckham[1], Eric J. Tarcha[1], Jared Odegard[2], James Qin[2], Megan Yuasa[3], Anne Stevens[4], Wayel H. Abdulahad[5], Galina Schmunk[6], K. George Chandy[6] and Shawn P. Iadonato[1]. [1]Kineta Inc., Seattle, WA, [2]Benaroya Research Institute at Virginia Mason, Seattle, WA, [3]Seattle Children's Research Institute, Seattle, WA, [4]Seattle Children's Hospital, Seattle, WA, [5]University Medical Center Groningen, Groningen, Netherlands, [6]UC Irvine, Irvine, CA.

Background/Purpose: The voltage-gated potassium channel Kv1.3 is a novel target for the treatment of autoimmune disorders including psoriatic and rheumatic diseases. ShK-186 is an exquisitely specific, highly potent peptide inhibitor of Kv1.3 on activated effector memory T cells that has just entered clinical development. Here, we report on ShK-186's safety and tolerability in phase I trials and on the evaluation of its therapeutic potential in an autoimmune kidney disease model.

Methods: To evaluate the safety, tolerability and pharmacokinetics (PK) of ShK-186, we conducted single ascending dose and multiple ascending dose doubled-blind, placebo-controlled phase I trials in healthy volunteers. In the single ascending dose trial, individuals were given increasing doses of ShK-186 subcutaneously and characterized after a single dose of drug; in the multiple ascending dose trial, individuals were given 9 doses of drug twice weekly over 4 weeks and characterized throughout. To investigate ShK-186's potential therapeutic application in autoimmune kidney disease, we evaluated the drug in a glomerular basement membrane animal model of autoimmune glomerulonephritis. Moreover, we have begun evaluating peripheral blood and urine samples from patients with autoimmune kidney disease for expression of Kv1.3 and production of cytokines in the presence and absence of ShK-186.

Results: ShK-186 was well tolerated with no serious adverse events reported. PK analysis revealed that the doses and dose regimens evaluated provided drug exposure in plasma surpassing the predicated therapeutic range based on therapeutic drug exposures in preclinical models of disease. Supporting the therapeutic potential of ShK-186 to treat chronic autoimmune kidney diseases, we showed that ShK-186 could lower kidney disease parameters such as urine protein and creatinine in a model of autoimmune glomerulonephritis, as well as significantly reduced histopathological changes associated with disease such as crescent formation and inflammatory cellular infiltrate. *Ex vivo*immunophenotyping and functional studies of blood and urine from autoimmune kidney disease patients showed that Kv1.3 is present in effector memory T cells.

Conclusion: This first-in-human clinical trial suggests that ShK-186 is a well-tolerated drug when given at doses expected to provide a therapeutic benefit. In addition to previously described indications where Kv1.3 has been implicated including multiple sclerosis and rheumatoid arthritis, we provide evidence to support extending its therapeutic scope to the treatment of chronic kidney autoimmune diseases.

SHP-1 Regulates the Activation Threshold of iNKT Cells. Meng Zhao[1] and Mitchell Kronenberg[2]. [1]UC-San Diego, La Jolla, CA, [2]La Jolla Institute for Allergy and Immunology, La Jolla, CA.

Background/Purpose: Autoreactive invariant Natural Killer T (iNKT) cells have been implicated in several rheumatic diseases, including Systemic lupus erythematosus and Rheumatoid arthritis. iNKT cells are a unique subgroup of lymphocytes that recognize glycolipids presented by CD1d, and that express an invariant T cell Ag receptor (TCR) a chain. As a result of activation, iNKT cells secrete copious amount of cytokines, including IFNγ, IL-4, IL-17 and IL-21 and they mediate immune responses in various pathological conditions. Although several potential lipid self-antigens for iNKT cell development and activation have been identified, the mechanism by which iNKT cells react to CD1d-self-antigen is not understood yet. Our discoveries therefore will help identify novel drug targets for potential translational intervention in patients with SLE, RA and other autoimmune diseases in which abnormal activation of iNKT cells is observed.

Methods: In detecting autoreactivity, instead of iNKT cell hybridomas that have many limitations, we will use primary cultured mouse iNKT cells. Sorted as αGalCer-CD1d tetramers$^+$ TCRb$^+$, iNKT cells grow exponentially *in vitro*, and can be transduced by retroviruses in order to modulate differential expressions of important regulators. Microarray was carried out to identify new regulators of iNKT cell autoreactivity.

Results: Our data show that the cultured iNKT cells have a greatly increased sensitivity to CD1d-lipid complexes derived from multiple sources, including soluble CD1d molecules produced in insect or mammalian cells, CD1d transfected cultured cells, and bone marrow-derived DCs. APCs that express a tail-deleted form of CD1d have a strongly diminished ability to stimulate the iNKT cell lines, indicating that the lines, like their primary cell counterparts *in vivo*, recognize auto-Ags loaded onto CD1d in endo/lysosomal compartments. Our results show that the iNKT cell lines preferentially respond to the auto Ags described previously when compared to the closely related homologs, despite their very different structures. Microarrays comparing the expression profiles of cultured and freshly isolated iNKT cells identifies SHP1/PTPN6, a tyrosine phosphatase that regulates TCR signaling, is down regulated in the iNKT cell lines. Reconstitution of the lines with the wild type but not the catalytically inactive SHP1 decreases the auto reactivity of the iNKT cell lines.

Conclusion: We hypothesize that iNKT cell TCR is intrinsically autoreactive, and instead of requiring a special autoantigens, many autologous Ags are capable of stimulating iNKT cells. The threshold of activation for iNKT cells are controlled during development and immune responses through key regulators, so that in the situation when this threshold is lowered, iNKT cells are activated by common lipid antigens that are present in the DP thymocytes or APCs. In the present study, taking advantage of a new system, we show the autoreactivity of polyclonal iNKT cells and we discover the protein tyrosine phosphatase SHP-1 (Ptpn6) is a critical regulator of the activation threshold of iNKT cells.

Microbiota Modulate Intraepithelial Lymphocyte Presence and Function. Kristine A. Kuhn and Sean P. Colgan. University of Colorado School of Medicine, Aurora, CO.

Background/Purpose: Microbiome studies in autoimmune diseases including rheumatoid arthritis and inflammatory bowel disease demonstrate alterations in relative abundance of specific bacterial species (dysbiosis). The immunologic influence of dysbiosis is only now being appreciated as important in disease pathogenesis. As intraepithelial lymphocytes (IELs) are anatomically positioned in intimate association with epithelial cells, it is intriguing to consider how the commensal flora might impact IEL function. In contrast to IELs of the small intestine, which have been better studied, the role of IELs in the colon during health and disease remains unclear.

Methods: Epithelial cells were harvested from wild type C57Bl/6 mice, lymphocytes stained for T cell surface markers, and cells evaluated by flow cytometry. IELs were also magnetically sorted from the epithelial cell harvest and stimulated ex vivo for five hours with PMA and ionamycin. Then IEL RNA was purified and analyzed by qRT-PCR. To model dysbiosis, mice were treated with 1 mg/ml ampicillin, metronidazole, and neomycin and 0.5 mg/ml vancomycin in the drinking water for one week. Recolonization of mice occurred by cohousing antibiotic treated mice with unmanipulated littermates. Trafficking of IELs was studied using the KiKGR transgenic mouse in which violet light exposure via colonoscopy photoconverts green fluorescent cells to red.

Results: Our studies demonstrate that the major subpopulation of IELs in the colon (52%) is CD3+ CD4- CD8- TCRβ+ (versus the small intestine where 72% are CD3+ CD8$\alpha\alpha$+ TCR$\gamma\delta$+). These colonic double negative IELs express cell surface markers consistent with activated lymphocytes (CD44+ CD69+ CD62L-) and produce a balance between inflammatory and regulatory cytokines. We next aimed to understand the role of colonic microbiota in shaping this population of cells. Treatment of mice with broad-spectrum antibiotics significantly decreased the number of IELs and shifted cytokine expression to a more pathogenic phenotype. Not only did the number of mature, activated T cells significantly decrease by about 75%, but also the remaining IELs expressed significantly more IL-17 (nearly 70-fold higher) in the antibiotic treated mice compared to untreated controls. The impact of antibiotics was reversible, as recolonization of mice resulted in normalization of the IEL numbers, phenotype, and cytokine expression. Finally, using a transgenic mouse in which colonoscopy-guided green-to-red photoconverstion labels IELs in the distal colon, we demonstrate that IELs traffic to extraintestinal sites, including the spleen, lung, and liver.

Conclusion: These data strongly support our hypothesis that colonic microbiota dynamically influence IEL function which, in turn, influences downstream systemic immune responses. By understanding the development and function of colonic IELs in health and disease, we hope to identify a potential pathway for the development of autoimmunity.

The Role of Fli1 in Lupus T Cell Function and Nephritis. Thirumagal Thiyagarajan[1], Ivan Molano[1] and Tamara K. Nowling[2]. [1]Medical University of South Carolina, Charleston, SC, [2]Medical University of South Carolina and Ralph H. Johnson VA Medical Center, Charleston, SC.

Background/Purpose: The Ets factor Fli1 is implicated as a key modulator of lupus disease expression. Over-expressing Fli1 in healthy mice, results in the development of an autoimmune kidney disease similar to that observed in lupus. Lowering the global levels of Fli1 in two lupus mouse models significantly improved kidney disease and prolonged survival. Lowering the levels of Fli1 in hematopoietic cells in MRL/lpr lupus mice resulted in significantly improved kidney disease. We recently demonstrated that lowering the global levels of Fli1 in the MRL/lpr lupus model has specific effects on T cells, including reducing their activation and IL-4 production when stimulated through the T cell receptor. We further showed that this was likely a result of decreased glycosphingolipid (GSL) metabolism, specifically decreased Neuraminidase1 (Neu1) expression and activity and decreased lactosylceramide (LacCer) in T cells. GSLs are a heterogeneous class of lipids in the sphingolipid family that play a role in the regulation of cellular processes. LacCer is a GSL to which sialic acid residues are added by ganglioside synthases to generate gangliosides in the GSL synthesis pathway. Sialic acids are then removed by NEUs from gangliosides in the GSL catabolic pathway. Lipids with distinct chain lengths are thought to possess distinct biological activities. We now demonstrate that lowering Fli1 levels significantly decreases the number of CXCR3+ T cells, T cell migration to the kidney and GSL metabolism in the kidney of MRL/lpr lupus prone mice.

Methods: Kidney and/or spleen were harvested from 11, 14 and 18 week-old MRL/lpr Fli1+/+ and Fli1+/− mice. Kidneys and/or T cells isolated from spleen by negative selection were analyzed by flow cytometry. Supercritical Fluid Chromatography coupled with tandem mass spectrometry was performed on kidney cortex homogenates. Gene expression was analyzed by real-time RTPCR on RNA isolated from kidney cortex. Matrix-assisted laser desorption/ionization-imaging mass spectrometry (MALDI-IMS) imaging and immunohistochemistry (IHC) for LacCer was performed on frozen kidney sections.

Results: LacCer levels, which are elevated in the kidneys of MRL/lpr mice compared to controls, are significantly reduced by 50% in age-matched MRL/lpr mice that are heterozygote for Fli1 (Fli1+/−). This reduction in LacCer expression is observed across the kidney using MALDI-IMS. Although Neu1 expression and NEU activity is decreased in T cells, their levels are unchanged in the kidney of Fli1+/− compared to Fli1+/+ MRL/lpr mice. The percentage of T cells expressing CXCR3 is significantly reduced by ~30% in Fli1+/− compared to Fli1+/+ MRL/lpr mice and the percentage and overall number of T cells in the kidney are significantly reduced by ~50%.

Conclusion: Our results demonstrate that one mechanism by which reducing Fli1 levels may be protective in lupus kidney disease is to decrease GSL metabolism in T cells, reducing T cell activation, production of IL-4, expression of CXCR3, a receptor shown to be important in T cell migration

to the kidney in lupus, and migration to the kidney. This likely contributes to the decreased inflammation and GSL metabolism in the kidney and improved kidney disease of MRL/lpr Fli1+/− mice.

Polymorphisms in the Slam Family of Molecules Play a Role in the Development and Function of Invariant Natural Killer T Cells in New Zealand Black Mice. Yuriy Baglaenko[1], Kieran Manion[1], Nan-Hua Chang[2] and Joan E. Wither[3]. [1]University of Toronto, Toronto, ON, [2]Toronto Western Research Institute, Toronto Western Hospital, Toronto, ON, [3]Toronto Western Research Institute, Toronto Western Hospital, University of Toronto, Toronto, ON.

Background/Purpose: The family of signaling lymphocyte activating molecules (SLAM) have been shown to play a key role in the development of autoimmunity in spontaneous and induced mouse models. Previous work by others has shown that expression of two SLAM family members, CD150 and Ly108, plays a critical role in the development of Natural Killer T (NKT) cells, an innate-like semi-invariant population of lymphocytes, which quickly respond to lipids presented on non-classical MHCs. However, the impact of SLAM polymorphisms on NKT function is less clear. **The aim of this study was to characterize both the development and function of NKT cells in B6 congenic mice with an NZB chromosome 1 interval that is known to have polymorphisms in the SLAM family of molecules.**

Methods: NKT development and marker expression were examined by flow cytometry of *de novo* splenocytes and thymocytes. NKT cell function was examined by *in vivo* stimulation with 2μg of αGalCer, injected intravenously. Production of IFNγ and IL-4 was measured by intracellular flow cytometry. Bone marrow derived dendritic cells (BMDCs) were generated by 7–10 day culture with recombinant human FLT3 ligand.

Results: Congenic mice had significantly fewer splenic NKT cells when compared to B6 controls. However, NKT cell frequencies in the thymus did not differ. The frequency of double positive thymocytes, critical for homotypic interactions between NKT cell precursors, was also unchanged. In support of previous findings, cell surface expression of SLAM family members on this cell population was altered. When compared to control animals, NZB congenic mice had significantly decreased expression of positive signaling Ly108 and CD150 molecules and increased expression of the negative SLAM signaling molecule, Ly9. Since NKT cells have been shown to play a role in autoimmunity through production of cytokines such as IL-4 and IFNγ, the capacity of these cells to secrete cytokines was assessed. Upon stimulation with αGalCer, the prototypic NKT cell stimulating lipid, NKT cells from NZB congenic mice produced significantly less IL-4 and IFNγ when compared to control mice. Consistent with this being the result of the SLAM polymorphisms, analysis of subcongenic NZB strains with shorter chromosome 1 intervals revealed that both of these phenotypes localized to a small region between 171–177Mb containing the SLAM family. To determine whether the reduced NKT cytokine production in NZB congenic mice was due to altered antigen presentation or impaired NKT cell function, adoptive transfer experiments were conducted with αGalCer pulsed BMDCs from control or congenic mice. The results revealed that injection of BMDCs generated from either strain could equivalently stimulate IL- 4 and IFNγ production by NKT cells in control animals, whereas injection of control BMDCs into NZB congenic mice resulted in impaired production of these cytokines.

Conclusion: These data suggest that polymorphisms in the SLAM family result in reduced peripheral NKT cell numbers and an intrinsic NKT cell functional defect.

CD27 Is a Key Regulator of T Cell Responses. Michael Scully[1], Nicole Wunderler[2], Holger Babbe[1], Yevgeniya Orlovsky[1], Galina Obmolova[2], Ann Cai[1], Heath Guay[3], Jacqueline Benson[3] and Tatiana Ort[1]. [1]Immunology Research, Janssen Research and Development, LLC, Spring House, PA, [2]Janssen Research and Development, LLC, Spring House, PA, [3]Estrela Lupus Venture, Janssen Research and Development, LLC., Spring House, PA.

Background/Purpose: CD27 is a member of the TNF superfamily of receptors that is expressed on a majority of natural killer (NK) cells, T cells, memory B cells and antibody-secreting plasma cells in humans. CD70 is the only known ligand for CD27 and is transiently expressed on activated dendritic cells, B cells and T cells. Much of our understanding of the immunological role of CD27 comes from studies with mouse models, which suggest that CD27 is a key regulator of NK cell, T cell and B cell responses. Here, we used an in-house generated neutralizing, antagonistic antibody to evaluate the role of CD27 in regulating human and primate immune responses using in vitro and in vivo models.

Methods: To examine the role of CD27 in immune cell biology, we generated a neutralizing, antagonistic and non-depleting human anti-human CD27 antibody. To assess the contribution of CD27 signaling to human immune responses in vitro, we examined the effects of CD27 blockade on Ig-production by B cells, proliferation of naive $CD4^+$ T cells and cytokine production by healthy volunteer PBMCs in vitro. To understand the role of CD27 on immune responses in vivo, we examined the effects of CD27 blockade on T and B cell responses in a cynomolgus monkey Delayed Type Hypersensitivity (DTH) model. To further explore the contribution of CD27 to human T cell responses in vivo, we examined the effects of CD27 blockade on human T cell engraftment in the NSG (NOD/SCID IL-2R$\gamma^{-/-}$) human $CD45^+$ peripheral blood cell → mouse GVH model.

Results: We found that neutralizing the CD27 pathway inhibited CD70-induced Ig-secretion by activated human B cells, whereas blockade of CD27 in an autologous T cell:B cell co-culture model did not impact Ig-secretion in vitro (despite expression of CD70 on cells in this system). Treatment with an anti-CD27 antibody dose-dependently attenuated CD70-mediated induced proliferation of primary human $CD4^+$ T cells and decreased the production of pro-inflammatory cytokines by healthy control PBMCs in vitro. Treatment with an anti-CD27 antibody reduced human $CD45^+$ $CD4^+$ and $CD8^+$ cell numbers in the spleen and peripheral blood of host mice in the human cell → NSG mouse GVH model. Blockade of CD27 reduced T cell infiltration into the challenge site in response to a neo-antigen, but did not impact antigen-specific antibody titers in a cynomolgus monkey DTH model.

Conclusion: These data demonstrate that CD27 can promote Ig-production by human B cells, but may play a redundant role in some types of B cell responses. In contrast, CD27 appears to play a critical role in the generation of both $CD4^+$ and $CD8^+$ T cell responses. These data suggest that the CD27 pathway modulates the activity of multiple human immune cell types, and that blockade of the CD27 pathway may present a novel therapeutic strategy for the treatment of immune mediated diseases.

Mi-RNA Profile of Active Vascular BEHÇET'S Patients. Ahmet Mesut Onat[1], Ozan Gerenli[2], Bunyamin Kisacik[1], Mustafa Ulasli[2], Gezmis Kimyon[1], Yavuz Pehlivan[3] and Serdar Oztuzcu[2]. [1]Gaziantep University School of Medicine, Gaziantep, Turkey, [2]Gaziantep UniversitySchool of Medicine, Gaziantep, Turkey, [3]Uludag University, School of Medicine, Bursa, Turkey.

Background/Purpose: Behçet's Disease (BD) is a systemic vasculitis that predominantly presented with oral aphtous ulcers and additionally at least two of the following findings like genital ulcers, eye involvement, skin lesions and pathergy reaction. Vascular involvement is devastating face of BD and thrombosis of the arterial and venous system and aneurismatic arterial disease is not rare. The flares are the typical nature of BD and the pathology of the disease is mostly constructed on vasculitis. However the satisfied mechanism of BD remains unknown. We herein tried to evaluate the micro RNA (miRNA) behavior in BD.

Methods: Eighty-five BD patients were enrolled in to the study group, which were divided to 3 groups of 20–20 and 25 with active vascular disease, active mucocutaneous disease and patients with at least 6 months remission, respectively. Additional 25 volunteers were the healthy controls and the 4 of the groups have no difference in the characteristics. The whole study population was male, due to difficulties of finding active women BD patients.

Serum samples were analyzed for miRNA with PCR assay and the data were analyzed statistically. Active vascular patients had significantly higher CRP and ESR results than active mucocutaneous ones and they both had significantly higher levels than remission and healthy groups.

	Active vasculer BD	Active mucocutaneous BD	Remission BD	Healthy controls
Age	32.60 ± 4.57	32.60 ± 6.36	35.72 ± 9.21	32.20 ± 1.71
Disease duration	4.30 ± 2.71	4.25 ± 3.31	4.68 ± 3.21	
CRP (mg/l)	29.35 ± 36.47	22.53 ± 21.38	4.92 ± 3.11	3.1 ± 1.8
ESR (/hour)	34.90 ± 26.46	30.0 ± 24.03	15.56 ± 11.85	10.02 ± 4.21

Results: There was no difference for any miRNA between BD patients with remission and healthy controls. The comparison of active BD patients and healthy controls revealed lower levels of miR-17-5p, miR-451A, miR-106b-5p, miR-16-5p, miR-19b-3p, miR-26b-5p, miR-93-5p, miR-20b, miR-25-3p in the disease activity. miR26b-5p was found lower only in mucocutaneous group inspite of vasculars.

Conclusion: The miRNA profile of active BDs especially the vascular group was remarkable. These miRNAs were related mainly with T and B lymphocytes and some apoptotic genes. miRNA studies might be beneficial for detecting better targets for treating the disease in the future.

Disclosure: A. M. Onat, None; **O. Gerenli**, None; **B. Kisacik**, None; **M. Ulasli**, None; **G. Kimyon**, None; **Y. Pehlivan**, None; **S. Oztuzcu**, None.

Plasma of Patients with Active Behçet′s Disease (BD) Increases Neutrophil Extracellular Trap Formation, Oxidative Metabolism and NADPH-Oxidase Expression in Normal and BD Neutrophils, and Carries Several Neutrophil Stimulating Factors. Sandro F. Perazzio[1], Paulo Vitor Soeiro Pereira[2], Alexandre W. S. de Souza[3], Antonio Condino-Neto[2] and Luis Eduardo C. Andrade[3]. [1]Fleury Medicine and Health, Sao Paulo, Brazil, [2]ICB IV - Universidade de São Paulo, São Paulo, Brazil, [3]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil.

Background/Purpose: Plasma factors seem to play a role in Behçet's disease (BD) pathogenesis, especially by increasing phagocyte oxidative profile. No data exists regarding neutrophil extracellular trap (NET) formation. We investigate the effect of plasma from patients with active BD (aBD) and inactive BD (iBD) on NET formation and oxidative burst, and searched for candidate soluble factors.

Methods: Neutrophils, peripheral blood mononuclear cells (PBMC) and plasma were obtained from patients with aBD (n=30), iBD (n=31), and healthy controls (HC; n=30). H_2O_2 and O_2^- production was determined by luminol/lucigenin luminescence with or without stimulation with phorbol myristate acetate (PMA), *Streptococcus pneumoniae, Streptococcus sanguinis*, *Candida albicans* or human plasma (from HC, iBD or aBD). Gene expression for the five NADPH-oxidase subunits was determined by qRT-PCR in resting cells, and protein expression by flow cytometry before and after stimulation with PMA or human plasma. NET formation was quantified after stimulus with PMA or human plasma, followed by labeling with anti-histones antibody, anti-neutrophil elastase antibody and Sytox Orange.

Results: Neutrophil production of O_2^-/H_2O_2 (Table 1) and NADPH-oxidase expression (Table 2) was higher after stimulus with aBD or iBD plasma than with HC plasma. PBMC displayed equivalent results. Resting and pathogen-stimulated phagocytes presented equivalent O_2^-/H_2O_2 production and NADPH-oxidase expression. NET formation was constitutively increased in aBD and iBD, compared to HC neutrophils (Table 3). Similarly, neutrophils from aBD and iBD produced more extensive NET than neutrophils from HC when stimulated with iBD plasma. In neutrophils from each group, aBD plasma induced greater NET formation than iBD or HC plasma. Eighteen soluble factors had increased concentration in aBD or BD plasma, and six were increased in both (Table 3). There was no significant difference in medication use between aBD and iBD patients.

Conclusion: Plasma from patients with aBD exerts a strong stimulus on NET formation and phagocyte oxidative burst. Increased concentration of MIP-1β, TNFα and other soluble plasma factors might be associated with neutrophil hyperactivity in BD. These findings warrant further studies in order to identify possible metabolic pathways involved in neutrophil activation in BD.

The Importance of the Serum Visfatin Levels in Behcet's Disease Patients. M. Emin Enecik[1], Zeynep Ozbalkan[2], Goksal Keskin[3], Sevinc Can Sandikci[1] and Yasar Karaaslan[2]. [1]M.D., Ankara, Turkey, [2]Ankara Numune Education and Research Hospital, Ankara, Turkey, [3]Prof., Ankara, Turkey.

Background/Purpose: It's a known fact that serum levels of the tumor necrosis factor Alfa (TNF-α) interleucin-6 (IL-6) and other proinflammatory cytokines which are released from the adipose tissue are increased in Behcet's disease (BD). In BD adipose tissue is nor a passive energy depot, it is an active endocrine organ and releases adipositokines. Visfatine is one of them. Visfatin is realted to TNF-α and IL-6, IL-1 beta, co-stimulators like CD40, CD54 and CD 80 and endothelial ICAM-1 and ICAM-2. We aimed to search the relation among levels' of visfatin with activity of BD.

Methods: 60BD (30 patients were in active state and 30 were in remission) patients diagnosed according to The Criteria of Working Group on International BD and 20 health subjects as controls were involeved in to the study. The study of groups detected visfatin levels were compared among groups.

Results: Visfatin levels were significantly higer in both group of patients compared to the control group (both p<0,001). Serum visfatin levels in patients with active than in inactive patients were found statistically significantly higher (p <0.001). The same way in all cases statistically significant correlation between visfatin and CRP (p <0.001) and visfatin and ESR (p<0.01). Only according to the symptoms of the patients in the active group compared to visfatin levels in patients with genital aphth visfatin levels, a statistically significantly higher than in patients without genital aphth were detected (p<0,001).

Conclusion: Serum visfatin levels in patients with active and inactive causes are higher than the control group; visfatin proinflammatory cytokines have a role in chronic inflammatory reaction, and to sustain the cellular expression of the inflammatory stokinlerin concluded that induce or be due to different reasons.

Identification of Potential Serum Biomarkers for Behcet Disease By High Resolution Quantitative Proteomic Analysis. Yongjing CHENG Jr.[1], Xiaolin Sun[2], Yuling Chen Jr.[3], Cibo Huang[4], Haiteng Deng[3] and Zhan-Guo Li[5]. [1]Beijing Hospital, Ministry of Health, Beijing, China, [2]People's hospital,Peking University, Beijing, China, [3]Tsing hua University, Beijing, China, [4]Beijing hospital, Beijing, China, [5]Peking University People's Hospital, Beijing, China.

Background/Purpose: Behcet's disease (BD) is a chronic, multisystemic vasculitis, pathogenesis of BD remains enigmatic. Diagnosis of BD is sometimes difficult, and until now, no specific serological markers have been established. Identification of antigens incorporated into CICs provides information that may be helpful in developing diagnostic and treatment strategies for autoimmune diseases, and such information might be more relevant than information on free antigens. The purpose of this study is to seek candidate autoantigens in CIC in BD, analyze autoantiges through Orbitrap mass spectrometry, and detect antibody levels of candidate autoantigens through ELISA in different autoimmune diseases.

Methods: A novel proteomic strategy (immune complexome analysis) was developed, in which circulating immune complexes (CICs) were separated from pooling serum sample of 10 BD patients and 10 healthy controls, digested directly with trypsin, and then subjected to Orbitrap mass spectrometry for identifying and profiling antigens in CICs. Anti-tubulin- a -1C antibody level were detected by Enzyme-linked immunosorbent assay (ELISA) in sera of 44 BD, 51 SLE, 51 SSc, 40 RA, 51 SS, 22 RAU, 13 TA, 25 AASV and 59 healthy volunteers.

Results: A totle of 22 antigens incorporated into CICs were found in CICs of BD patients, but not in RA and HC, including TAOK3, BAG3 and Tubulin-a-1C et al. The auto-antibody to one of the identified proteins, Tubulin-a-1C, was investigated by ELISA using a recombinant protein. The auto-antibody to Tubulin-a-1C were detected positive in 26 (59.0%) of the 44 patients with BD, 14 (27.5%) of the 51patients with SLE, 14 (27.5%) of the 51patients with SSc, 3 (7.5%) of the 40 patients with RA, 3(23.1%) of 13 TA, 1(4%) of 25 AASV and 2 (3.39%) of 59 HC. The sensitivity and specificity of Tubulin-a-1C antibody in the diagnosis of BD were 59.0% and 82.7% respectively. Further analysis demonstrated that Tubulin-a-1C antobody was correlated with complications of deep venous thrombosis and erythema nodosum of BD(p<0.05), and meanwhile, levels of anti- Tubulin-a-1C antibody were correlated with levels of ESR, CRP and BVAS(p<0.05).

Conclusion: Anti- Tubulin-a-1C antibody may be helpful in diagnosis and severity evaluation of BD, CIC relevant antigens may benefit understanding of the pathogenesis of venous thrombosis and erythema nodosum of BD.

Microparticles May Play a Role in Causing Thrombosis in Behçet's Syndrome and Act As a Biomarker for Risk Management. Emon Khan, Nicola Ambrose, Michael A. Laffan and Dorian O. Haskard. Imperial College, London, United Kingdom.

Background/Purpose: Thrombosis occurs in 20% of patients with Behçet's Syndrome (BS) and leads to significant morbidity. There is no robust association between thrombosis in BS and the presence of hereditary thrombophilia or raised inflammatory markers. It remains a challenge to distinguish those at risk of thrombosis potentially requiring aggressive preventative therapy and those whose therapy can be reduced. There is a clear need to develop biomarkers for diagnosis and risk management in BS.

Plasma cell membrane derived microparticles (MPs) are released from cells undergoing apoptosis or activation. MPs are known to promote thrombosis in malignancy and cardiovascular disease, as a result of surface expression of phosphatidylserine (PS) and other cell surface markers, in particular tissue factor (TF). The aim of this study was to assess whether MPs are associated with thrombosis in Behçet's Syndrome (BS).

Methods: MPs were prepared following venepuncture of 88 BS patients who fulfilled International Study Group Criteria for diagnosis, 21 of whom had a history of thrombosis, and 39 healthy controls (HC). MPs were identified using flow cytometry by gating for particles less than 1μm in size and staining positively with Annexin V, which binds PS, giving a total MP count. Antibodies to CD14 (monocytes), TF, CD62P (platelets), CD144 (endothelial cells) and CD66b (neutrophils) were used to identify cellular origin. Endogenous thrombin potential (ETP) and peak thrombin (PT) were measured using calibrated automated thrombography, allowing analysis of the thrombotic potential of MPs.

Results: BS patients had higher total (4.3×10^5/ml vs 2.3×10^5/ml, $p=0.0072$), CD14+(2.7×10^5/ml vs 8.5×10^3/ml, $p<0.0001$), TF+ (4.5×10^4/ml vs 5.9×10^3/ml, $p<0.0001$) and CD14+TF+ (1.9×10^4/ml vs 4.5×10^3/ml, $p<0.0001$) MPs compared to HCs. Thrombotic BS (TBS) patients had higher total (8.8×10^5/ml vs 3.2×10^5/ml, $p=0.0028$), CD14+ (2.9×10^4/ml vs 2.5 x10^4/ml, $p=0.042$), TF+ (6.1×10^4/ml vs 4.3×10^4/ml, $p=0.041$) and CD14+ TF+ (2.6×10^4/ml vs 1.5×10^4/ml, $p=0.047$) than non-thrombotic BS (NTBS) patients.

BS patients also had higher CD62P+ (1.2×10^5/ml vs 4.7×10^4/ml, $p=0.0152$) and CD66b+ (1.9×10^4/ml vs 8.8×10^3/ml, $p=0.0389$) MPs than HCs. CD144 MPs were not significantly higher in BS patients than HCs (1.9×10^4/ml vs 1.1×10^4/ml, $p=0.0769$). TBS patients had higher CD62P+ (2.3×10^5/ml vs 7.1×10^4/ml, $p=0.0111$), CD144+ (3.8×10^4/ml vs 1.5×10^4/ml, $p=0.0342$) and CD66b+ (4.8×10^4/ml vs 1.7×10^4/ml, $p=0.0237$) MPs than NTBS patients.

ETP was significantly higher in BS patients than HCs (515.13 vs 383.52, $p=0.013$), but there was no difference in ETP between TBS and NTBS patients. PT was significantly higher in BS patients (20.08nM vs 9.92nM, $p=0.0022$) compared to HCs and in TBS (27.06nM vs 16.73nM, $p=0.041$) compared with NTBS patients, but did not correlate with MP numbers.

Conclusion: MPs are found in higher numbers in BS patients than in HCs, in particular in TBS patients. It is interesting that PT was raised in TBS compared with NTBS patients. These results suggest that MP counts and PT may be useful biomarkers in combination and may provide a scoring system for identifying patients at risk of thrombosis and risk management in patients with BS.

The Clinical Course of Acute Deep Vein Thrombosis of the Legs in Behçet's Syndrome. Melike Melikoglu[1], Yesim Ozguler[2], Serdal Ugurlu[3], Firat Cetinkaya[4], Koray Tascilar[2], Emire Seyahi[3], Vedat Hamuryudan[3] and Hasan Yazici[1]. [1]Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey, [2]University of Istanbul, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey, [3]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [4]Colormed Radiology Center, Istanbul, Turkey.

Background/Purpose: To determine the prospective clinical course of lower extremity deep vein thrombosis (LEDVT) in patients with Behçet's syndrome (BS).

Methods: Consecutive BS patients with an acute episode of LEDVT were prospectively studied. Clinical examination and lower extremity Doppler ultrasonography (US) were done at 1, 3, 6, 18 and 24 months after the index event. A relapse was defined as a new episode of LEDTV and/or a superficial vein thrombosis (SVT).

Results: 40 patients (6F, 34M) with LEDVT were followed for a mean=33.2 ± 10.8 months. The mean age was 30.2 ± 7.3, and the median disease duration since disease onset was 33.3 months (IQR=8.0–60.8). A total of 50 relapses were observed in 27 patients. This was in the form of solo SVT in 8 patients, solo LEDVT in 10 and LEDV+SVT in 9 patients. Cox regression analysis revealed that a recanalization rate of $\geq$ 50% in LEDVT observed by US at month 3 was significantly associated with a lower relapse rate (HR=0.23; 95% CI =0.092–0.59).

The first line treatment had been with azathioprine (AZA) with moderate doses of glucocorticoids (0.5 mg/kg/d) in 34 (85%) patients, interferon-alpha (IFN-alpha) in 4 and cyclophosphamide in 2 patients (also with pulmonary vasculitis). 19 out of 34 (55%) remained on AZA, 10 were switched to IFN-alpha for resistant or recurrent disease during follow up. 8 of these 10 patients did not experience relapses after switching to IFN-alpha. 16 patients treated with IFN-alpha (including 3/4 initially treated with IFN-alpha) during follow-up and 12 of 16 (75%) patients were still on IFN-alpha therapy without relapses.

Conclusion: Relapses and resistant disease are frequent 27/40 (67.5%) in LEDTV in BS and is significantly associated with a failure to recanalize at 3 months. IFN-alpha can justifiably be tried in the treatment of LEDVT, refractory to AZA and glucocorticoid use.

Background/Purpose: Vascular involvement (VI) is one of the major causes of mortality and morbidity in Behcet's Disease (BD). There are no controlled studies for the management of major vascular involvement in BD. According to the EULAR recommendations for the management of BD, only immunosuppressive (IS) agents such as corticosteroids, azathioprine, cyclophosphamide or cyclosporine A are recommended for VI. In this study, we aimed to investigate the effects of anticoagulant (AC) treatment on the development of new vascular events in patients with BD followed up for vascular disease (VBD), retrospectively.

Methods: In this retrospective study, 637 patients with BD (F/M: 283/354, mean age: 38.5 ± 11.1 years) classified according to ISG criteria from 8 Rheumatology centers in Turkey, were included. The demographic data, clinical characteristics of first vascular event and relapses, treatment protocols and data about complications were acquired from files, retrospectively.

Results: Two hundred eighty-one BD patients (44.1%) were of mucocutaneus type, whereas 356 patients (55.9%) had major organ involvement [Uveitis: 42.4% (n=270), neurologic involvement: 6.9% (n=44), gastrointestinal involvement 1.9%(n=12)]. VBD developed in 20.6% (N=131) patients during the follow-up. When the first vascular event developed, the mean disease duration was 3.5 (0–28) years and mean age 33.2±8 years. After the first vascular event, IS treatment was given to 88.5% (n=105) and AC treatment to 62.6% (n=76) of the patients. Minor hemorrhage (as a complication related to AC treatment) was observed in 3 (3.9%) patients. A second vascular event developed in 35.9% (n=47). The rate of new vascular event development was similar between the patients taking only ISs and AC+IS treatments after first vascular event (27.2% vs 29.6%, p=0.78). Relapse rate was significantly higher in group taking only ACs (91.6%, p=0.002). During follow-up, a third vascular event developed in 23.4% (n=11) patients. The rate of new vascular event development was again similar between the patients taking only IS and AC+IS treatments. There was no relationship between the total duration of AC treatment and number of vascular events. However, total number of vascular events negatively correlated with the age during the first vascular event (r:−0.215, p=0.02).

Conclusion: In this study, we did not find any additional positive effect of AC treatment used in combination with ISs in the course of vascular involvement in patients with BD. Severe complications related to AC treatment were also not detected. Our results suggest that short-duration of IS treatments is the major problem in BD patients associated with vascular relapses during follow-up.

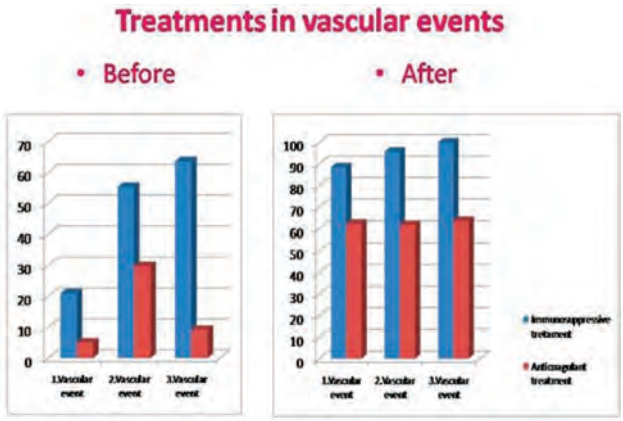

Figure 1: Immunosuppressive and anticoagulant treatment rates before and after vascular events.

18F-FDG PET/CT in Vascular Disease Due to Behçet's Syndrome.
Emire Seyahi[1], Metin Hallac[2], Betul Vatankulu[1], Serdal Ugurlu[1], Melike Melikoglu[3], Sebahattin Yurdakul[1] and Hasan Yazici[3]. [1]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [2]Cerrahpasa Medical Faculty, University Of Istanbul, Istanbul, Turkey, [3]Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey.

Background/Purpose: 18F-fluorodeoxyglucose (FDG) positron emission tomography (PET)/CT is considered as a useful tool in assessing active vascular inflammation in large vessel vasculitis. Lower extremity vein thrombosis is the most common type of vascular disease in BS followed by vena cava thrombosis, pulmonary artery involvement and peripheral arterial aneurysms. Pulmonary artery involvement is mainly manifested by pulmonary artery aneurysms and solely by 'in situ' pulmonary artery thrombosis. Varying and multiple pulmonary parenchymal lesions such as nodules, consolidations and cavities make part of this involvement as well (1). Apart from a few case reports, information on the diagnostic value of PET/CT in vascular disease of BS is limited (2–3). We investigated the potential of PET/CT to evaluate the extent and activity of disease in vascular disease due to BS.

Methods: Thirty-three (30 M/3 F) patients with BS between March 2012 and April 2014 were studied. The mean age and the mean disease duration were 32±7 and 4±3 years, respectively. All patients had one or more type of large vessel disease such as: deep vein thrombosis of lower extremities (n=31), pulmonary artery involvement (n=14), vena cava superior (n=1) or inferior thrombosis (n =9) and Budd-Chiari syndrome (n=5). FDG PET/CT studies were performed within the first 2 weeks of diagnosis in 23 patients. In the remaining 10, scans were obtained for activity assessment during the follow-up. Maximum standardized uptake values (max SUVs) and visual analyses were used to interpret the FDG PET/CT images. In addition, non-enhanced CT findings obtained during FDG PET/CT were recorded.

Results: FDG PET/CT was positive (SUV ≥ 2; equal to or greater than liver uptake) in 15 (45 %) patients. These included 11 patients with pulmonary artery involvement (11/14, 79 %). Among these 11 patients, FDG uptake was observed in the lung parenchyma (in the form of nodules, consolidations or cavities) in 8, in the hilar region suggesting lymphadenopathy in 6 patients and in 1 patient, suggesting thrombus of a pulmonary artery aneurysm. Among the 19 patients with major venous vessel involvement, FDG uptake was observed in 4 patients (4/19, 21 %) and these was in the femoro-popliteal vessels.

Conclusion: This preliminary survey showed that in BS, FDG uptake was mainly observed at the pulmonary parenchyma while pulmonary arteries did not show increased uptake. Disease in peripheral major veins, on the other hand, can only occasionally be discerned by FDG PET/CT. Further studies might still be needed among immunosuppressive naïve patients.

Budd-Chiari Syndrome Due to Behçet's Syndrome: Some Patients Present without Liver Related Symptoms and Have a Better Outcome.
Emire Seyahi[1], Erkan Caglar[2], Serdal Ugurlu[1], Fatih Kantarci[3], Vedat Hamuryudan[1], Abdullah Sonsuz[4], Melike Melikoglu[5], Sebahattin Yurdakul[1] and Hasan Yazici[5]. [1]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [2]Bakirkoy Research and Training Hospital, Istanbul, Turkey, [3]Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey, [4]Cerrahpasa Medical Faculty of Istanbul University, Istanbul, Turkey, [5]Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey.

Background/Purpose: Behçet's syndrome (BS) is a well recognized cause of Budd–Chiari syndrome (BCS), however, information about its clinical characteristics and outcome is limited. We had presented the outcome of 40 patients with BCS due to BS at the ACR 2013 meeting (1). In further analyses, we better understood that there were patients in whom BCS could exist without the presence of any liver related symptoms/signs. In the current study we compared demographic, clinical, radiologic and prognostic characteristics of these patients to those presented with overt liver related symptoms.

Methods: We reviewed the records of about 9000 patients with BS who were registered at the multidisciplinary Behçet's syndrome outpatient clinic at Cerrahpasa Medical Faculty between July 1977 and October 2013. We identified 43 (40 male/ 3 female) patients who were diagnosed as having BCS. Their outcome was evaluated between September 2012 and October 2013.

Results: 43 (40 male/ 3 female) patients with BCS were identified. Thirty-three patients (77 %) had presented with liver related symptoms such as ascites and abdominal swelling for a median duration of 1 month [IQR:0.5–2.5 months]. These patients were defined as Group I. On the other hand, 10 (21%) were silent for liver disease at presentation and were found to have BCS while being investigated for fever (n=4), bilateral diffuse leg swelling (n = 4), and pulmonary symptoms like hemoptysis or dyspnea (n =4). None had liver dysfunction related symptoms/signs. These patients were classified as Group II. All were diagnosed after 1990. Group II patients were somewhat older (mean age: 32.2 vs 28.7, p=0.26) and had longer disease duration of BS at the onset of BCS (median: 5.1 vs 2.7, p =0.18) than Group I patients. The level of hepatic venous outflow obstruction in Group II

involved less frequently the combined IVC and hepatic veins (30 %) while was more likely to involve isolated hepatic veins (30 %) or isolated IVC (40 %) when compared to Group I (76 %, 26 % and 3 %, respectively) ($p = 0.05$). Besides that, the anatomical distribution of vessels other than those involved in BCS, and the clinical characteristics of BS were not very different than Group I. By the end of the survey, there was only 1 death in Group II, which was not due to hepatic failure. Mortality was significantly lower among Group I patients (1/10) as compared to Group II (19/33, 58 %), ($p = 0.025$).By the end of the survey, only 1 (1/13) in Group I, had ascites, while in the remaining surviving patients in Group I ascites had resolved within 6 to 8 months after the first visit. A final hepatic Doppler USG indicated that, the frequency of recanalisation and collateral formation was similar between the patients in Group I and II.

Conclusion: There is subgoup of patients in whom, BCS may exist without the presence of liver related symptoms/signs and these patients have a good prognosis. These patients could pass unnoticed, unless one looks carefully for hepatic veins or intra or suprahepatic segments of the IVC. The fact that, 8 of these10 patients were diagnosed after 2000, suggests that this subgroup was recognized after the recent availability of imaging techniques.

Reduced Heart Rate Variability in Patients with Behcet's Disease. Joung-Wook Lee[1], Seung-Geun Lee[2], Eun-Kyoung Park[2] and Geun-Tae Kim[3]. [1]Divsion of Rheumatology, Department of Internal Medicine, Busan St. Marys center, Busan, South Korea, [2]Divsion of Rheumatology, Department of Internal Medicine, Pusan National University School of Medicine, Pusan National University Hospital, Busan, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Kosin University College of Medicine, Busan, South Korea.

Background/Purpose: The autonomic nervous system, including the sympathetic and parasympathetic nervous systems, has an important role in the triggering of ventricular arrhythmias and sudden cardiac death.

The aim to this study was to investigate autonomic regulations by means of heart rate variability(HRV), influence of conventional cardiovascular risk factors, and relationship with the disease activity in patients with Behcet's disease (BD).

Methods: 50 patients with BD (Age : 43.8 ± 18.6, female : 40) and 50 age-and sex-matched healthy controls were included in this study. All the participants were screened for basic cardiovascular risk factors.

BD activity was studied with Behcet's disease current activity form (BDCAF) and acute phase indices. HRV was calculated by time domain measures, frequency domain measures and nonlinear/complexity-based measures on 24 hours recording.

Results: Patients with BD had decreased HRV in comparison to healthy controls as reflected by decrease of the standard deviation of normal R-R intervals(SDNN) (74.0 ± 37.5 vs. 136.2 ± 62.3ms, respectively, $p < 0.01$) and of the high frequency(HF) power (130.0 ± 89.9 vs. 383.5 ± 154.2 ms2, respectively, $p < 0.005$).

SDNN ($r = -0.45$, $p < 0.005$ and $r = -0.37$, $p < 0.04$) and HF ($r = -0.42$, $p < 0.01$ and $r = -0.35$, $p < 0.02$) were significantly correlated with BDCAF and CRP, respectively.

Conclusion: HRV was shown to be significantly decreased, compared to healthy controls, among BD patients. Patients with BD had impaired autonomic cardiac regulation which is related to the disease activity and presence of systemic inflammation and which could contribute to the increased cardiovascular risk in these patients.

Predictors of Quality of Life in Behçet's Syndrome. Selma Bozcan[1], Yesim Ozguler[1], Koray Tascilar[1], Caner Saygin[1], Didem Uzunaslan[1] and Gulen Hatemi[2]. [1]University of Istanbul, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey, [2]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey.

Background/Purpose: Quality of life is commonly impaired in patients with chronic inflammatory diseases. The disease itself as well as the drugs used may be responsible for this impairment. Behçet's syndrome (BS) is a multisystem vasculitis with a wide variety of manifestations including oral ulcers, genital ulcers, nodular lesions, papulopustular lesions, arthritis, uveitis, venous thrombosis, arterial aneurysms, neurologic and gastrointestinal involvement. Determining the factors affecting quality of life in BS patients, would help developing effective management strategies.

Methods: Behçet Disease Quality of Life (BDQoL) and Short- Form 36 (SF-36) questionnaires were filled by consecutive BS patients attending our outpatient clinic. Socioeconomic factors, each type of organ involvement during the disease course, during the previous 4 weeks, disabilities caused by each, treatment modalities and overall disease activity were tested with regression analysis as possible determinants of quality of life. Men and women were also analyzed separately.

Results: 322 patients (M/F: 166/156, mean age: 37.9 ± 11.1 years) were included. 157 patients had eye involvement, 72 patients had vascular involvement, 67 patients had joint involvement, 20 patients had neurologic involvement, 2 patients had gastrointestinal involvement and 93 patients had only mucocutaneous involvement without major organ involvement. Determinants of BDQoL in the whole group were BSAS, household income, work disability, perception of insufficient income, neurologic damage (R^2:0.47, F: 48.76, $p<0.001$). Among women they were BSAS, perception of insufficient income, neurologic and mucocutaneous involvement (R^2:0.40, F: 19.75, $p<0.001$). Among men they were work disability, BSAS, household income, perception of insufficient income, vascular involvement during the last 4 week and damage caused by neurologic involvement (R^2:0.56, F: 29.70, $p<0.001$). SF-36 scores were well correlated with BDQoL scores ($r=-0.69$ for physical component and $r=-0.63$ for mental component).

Conclusion: In addition to overall disease activity and neurologic damage, mucocutaneous involvement in women and recent eye and vascular events in men seem to impair quality of life in BS. These findings are important for developing management strategies and outcome measures.

Disease Activity and Quality of Life in BEHÇET'S Disease: The Role of Patients Reportedoutcomes. Elena Elefante[1], Rosaria Talarico[1], Chiara Stagnaro[2], Anna d'Ascanio[3], Antonio Tavoni[4], Chiari Tani[1], Chiara Baldini[1], Marta Mosca[5] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Rheumatology Unit, University of Pisa, Pisa, Italy, [3]University of Pisa, Pisa, Italy, [4]Immunoallergology Unit, Pisa, Italy, [5]S. Chiara, Pisa, Italy.

Background/Purpose: Behçet's disease (BD) is a systemic vasculitis, typically characterised by recurrent oro-genital ulcers, ocular inflammation and skin manifestations; articular, vascular, gastro-enteric and neurological involvement may also occur. Since BD has a chronic-relapsing course and it can be very severe, debilitating and potentially life-threatening, it may without any doubt affect the quality of life of the patients. Moreover, it is well known that patient's perception of own disease represents an useful tool to help physicians to improve the understanding and management of the disease itself. The primary aim of this study was to explore the role of quality of life patients reported outcome (PRO) in better identifying the global status of BD.

Methods: The study enrolled 120 patients, all fulfilling the International Study Group (ISG) criteria for BD. The male/female ratio was 1.6:1, with a mean disease duration of 11 ± 6 years. Their mean age was 42 ± 8 years (min:18, max:77), while the mean age at disease onset was 24 ± 5 years. The primary end-point was to study any potential correlation between quality of life and disease activity. Disease activity was evaluated by means of the Behçet's Disease Current Activity Form (BDCAF), while the Italian version of the Short-form-36 (SF-36) was used to evaluate quality of life. Disease activity was compared with the global SF-36 score and with each dimension, that includes: physical functioning, physical disability, body pain, general health, vitality, social functioning, emotional disability, mental health. The statistical analysis was performed using Student t-test, Mann-Whitney-U test, ANOVA and Pearson correlation.

Results: At time of evaluation, according BDCAF, 47 BD patients (39%) had clinically active disease (18 ocular involvement, 8 joint involvement, 4 neurological involvement, 2 gastro-enteric, 15 muco-cutaneous involvement). As expected, the overall SF-36 scores were significantly lower in patients

with clinically active disease. Moreover, female BD patients had statistically significant lower scores in all SF-36 domains compared with male patients. When each domain of SF-36 was evaluated, we found that physical disability (p=0.004), body pain (p=0.006), general health (p=0.001), and vitality (p=0.001) were significantly lower in patients with disease activity. Notably, vitality (p=0.001), physical disability(p=0.004), social functioning (p=0.001), emotional disability (p=0.003) and mental health (p=0.001) were significantly lower in patients with muco-cutaneous active disease, compared with the other patients with active disease.

Conclusion: The clinicians who take care of any chronic disease would like to correctly know the current status of a patient to manage him properly. In this regard, the combination data of PRO measures and disease activity have been demonstrated to add more information compared to the evaluation of disease activity alone. These consideration suggest that the correct assessment of BD need a multi-dimensional approach, that fairly includes disease activity, disease damage and quality of life.

Treatment of Mucocutaneous Manifestations in Behçet's Disease with Anakinra: A Pilot Open-Label Study. Peter C. Grayson[1], Yusuf Yazici[2], Elaine Novakovich[3], Elizabeth Joyal[3], Raphaela T. Goldbach-Mansky[3] and Cailin H. Sibley[3]. [1]National Institutes of Health, Bethesda, MD, [2]New York University School of Medicine, New York, NY, [3]National Institutes of Health Clinical Center, Bethesda, MD.

Background/Purpose: IL-1 blocking therapy shows promise in the treatment of Behçet's eye disease, but its effect on mucocutaneous manifestations is unknown.

Methods: 6 patients with Behçet's disease as determined by International Study Group criteria and active oral or genital ulcers for ≥2 months were enrolled in this open label phase I/II study. 2 patients had a history of inactive uveitis (anterior, panuveitis). Study duration was 3 months with extension up to 16 months (range 4–16). All were treated with anakinra 100mg subcutaneous daily with the option to escalate dose to 200mg in partial responders after 1 month and 300mg after 6 months. Patients recorded the number and severity of oral and genital ulcers in daily diaries. The primary outcome was remission defined as no ulcers on physical exam for 2 consecutive monthly visits from months 3–6. Secondary outcomes included the number of ulcers, the number and severity of patient-reported ulcers, patient/physician global scores, and standardized disease activity scores.

Results: 2 of 6 patients achieved the primary outcome of remission from months 3–6. All but 1 had improvement in the number of oral ulcers at month 3 (primary endpoint). Mean number of oral ulcers at baseline, month 3 and month 12 were 3.3, 1.5 and 0.5 and mean number of genital ulcers were 0.8, 0 and 0. Over the entire study, patients reported ≥1 oral and ≥1 genital ulcer on 665 (66%) and 139 (14%) days, respectively. Non-statistically significant improvements were seen in secondary outcomes including physician and patient visual analog scores and scores for Behcet's disease current activity form (BDCAF) patient index, and Behcet's disease quality of life (BDQOL). Behcet's syndrome activity scale (BSAS) showed significant changes at 3 and 9 months. (**Table**). Dose escalation to 200mg occurred in all patients prior to month 3 and was further increased in 3 to 300mg after month 6. 2 patients on baseline prednisone of 40mg and 20mg were tapered to 20mg and 0mg, respectively. On anakinra 200mg vs. 100mg, patients reported fewer days with oral ulcers (65% vs 74% days, p=0.02) and genital ulcers (10% vs 22% days, p<0.001) and milder ulcer severity (p<0.01). Increase of anakinra to 300mg did not result in fewer ulcers or milder ulcer severity. No ocular flares occurred during the study; however, 2 ocular flares (anterior uveitis, periorbital inflammation) occurred within a month after discontinuation of anakinra in the 2 patients with prior eye disease. Adverse events included a serious adverse event of pulmonary hypertension suspected prior to the study and frequent viral infections.

Conclusion: In this open-label pilot study, anakinra, at an optimal dose of 200mg daily, demonstrated partial efficacy in treatment of resistant oral and genital ulcers in Behçet's disease. Organ-specific differential effects of IL-1 blockade are likely.

Background/Purpose: Behçet's disease (BD) is a systemic large vessel vasculitis with recurrent genital and oral ulceration, uveitis, cardiovascular, joints, neurological or gut symptoms. Treatment of BD is dependent of the nature and the severity of clinical manifestations. Increased levels of TNF alpha and soluble TNF receptors have been found in the serum, plasma and in the aqueous humor of patients with BD. Although, anti-TNF alpha have proved effective in refractory uveitis, few data are available relative to its efficacy in extraocular manifestations of BD. The aim of this study is to report on the efficacy and the safety of anti-TNF alpha in BD.

Methods: We performed a retrospective multicenter study of main characteristics and outcomes of 122 patients with BD treated with anti-TNF alpha.

Results: One hundred twenty two observations were collected in 21 centers. Mean ± SD age at the anti-TNF alpha introduction was 35 ±12 years with 47% of men. Ninety one (75%) patients received at less one immunosuppressive therapy before the use of anti-TNF alpha.

The main indications of anti-TNF alpha were uveitis (n=80, 66%), mucocutaneous manifestations (n=26, 21%) [oral (n=21) and genital ulcerations (n=13)], articular (n=29, 24%), neurologic (n=12, 10%), cardiovascular (n=5, 4%) and digestive manifestations (n=9, 7%). Infliximab was frequently used (61%), followed by adalimumab (30%), etanercept (8%) and golimumab (1%). Associated therapy included prednisolone (84%), azathioprine (28%), mycophenolate mofetil (6%), and methotrexate (10%). Median duration of follow up was 31 months [11–55]. 96% and 81% of BD patients achieved a complete or partial response of uveitis and extraocular manifestations, respectively. Relapse free survival was similar regardless of anti-TNF alpha used. Anti-TNF alpha had a significant corticosteroid sparing effect (daily prednisolone dose of 40mg at time of introduction of anti-TNF alpha vs 10mg and 5mg at 6 and 12 months, respectively; p<0,0001). The median time for clinical improvement was 62 days [31–92]. Adverse events were reported in 28% of patients, mainly with infliximab (infliximab 61%, adalimumab 32%; p=0.02). They mainly included infections (52%) and

hypersensitivity reactions (16%). Serious adverse events were reported in 13% of patients and required treatment interruption in all cases.

Conclusion: These results show that TNF alpha inhibitors are highly and rapidly efficient in all BD manifestations. Although tolerance seems satisfactory, infliximab is associated with more frequent and more serious side effects.

Predictive Factors for the Response to Infliximab Therapy in Patients with Behçet's Disease. Salvatore D'Angelo, Pietro Leccese, Angela Padula, Angelo Nigro, Michele Gilio, Antonio Carriero, Carlo Palazzi and Ignazio Olivieri. Rheumatology Department of Lucania, San Carlo Hospital of Potenza and Madonna delle Grazie Hospital of Matera, Potenza, Italy.

Background/Purpose: To identify the clinical factors predicting a good clinical response to Infliximab (IFX) therapy after 12 months in patients with Behçet's disease (BD) refractory to conventional therapy.

Methods: Patients receiving IFX (5 mg/kg intravenously at weeks 0, 2, 6, and every 6–8 weeks subsequently) for BD unresponsive to conventional therapy (corticosteroids plus at least two different immunosuppressive drugs) were prospectively included. Clinical response to IFX therapy was based on the expert opinion and was graded as follows: remission, response, no response and worsening. Remission was defined as the complete disappearance of symptoms and signs of inflammation and response as at least 50% of improvement. Univariate and multivariate analyses were performed to identify factors associated with IFX good response (remission, response) at 12 months. Logistic regression analysis was performed to analyse which of the following measures at the start of treatment were associated with a good response: sex; age; disease duration; HLA-B51 status; indication for IFX treatment including uveitis, CNS involvement, severe mucocutaneous manifestations or others including arthritis, intestinal and vascular involvement; concomitant drugs including steroids (Ster), colchicine (Col), azathioprine (AZA) or cyclosporine (CSA).

Results: The study included 73 BD patients (47 M/26 F; mean age 33.6±10.7 yrs; mean disease duration 12.3±9.3 yrs; 71.2% HLA-B51 positive). Indication for IFX treatment were uveitis in 38 patients, severe mucocutaneous manifestations in 13, CNS involvement in 16, intestinal involvement in 2, arthritis in 2, vascular involvement in the remaining 2. At 12 months, 56 patients (76.7%) had a good response to IFX, 4 (5.5%) patients had stopped for adverse events, and 13 (17.8%) had stopped for primary or secondary inefficacy. In the univariate analysis concomitant use of AZA (95.8% vs 67.3%, $p < 0.01$) was the only factor associated with a good response. In a multivariate logistic regression analysis concomitant use of AZA was independently associated with a good therapeutic response (OR = 34.2; 95% CI 2.7–435.8; $p = 0.007$). None of the other variables analysed predicted response to treatment.

Conclusion: This study has, for the first time, shown that concomitant use of AZA at the start of IFX treatment is a factor that seems to influence the probability of achieving a good therapeutic response in patients with refractory BD. Further support from larger studies is necessary so as to optimize the management of BD patients treated with IFX.

Anti-TNF Treatment for Refractory Vascular Involvement of Behçet's Syndrome. Vedat Hamuryudan[1], Emire Seyahi[1], Melike Melikoglu[2], Serdal Ugurlu[1], Gulen Hatemi[1], Sebahattin Yurdakul[1] and Hasan Yazici[2]. [1]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [2]Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey.

Background/Purpose: The optimal management of major vascular involvement in patients with Behçet's syndrome (BS) is still a challenge.

Methods: We reviewed the charts of 16 BS patients (15 men) with vascular involvement who had been treated with anti-TNF agents following an inadequate response to traditional immunosuppressives (cyclophosphamide or azathioprine combined with glucocorticoids).

Results: Ten patients had pulmonary artery involvement (PAI), 5 had major vein involvement (multiple thromboses of vena cavae, deep veins and dural sinuses) and 1 had renal artery aneurysm. PAI was in the form of pulmonary artery aneurysm (PAA) in 2 patients, pulmonary artery thrombosis (PAT) in 6 patients and the combination of PAA with PAT in 2 patients. Six patients (5 with PAI) also had intracardiac thrombi formation. All patients were using immunosuppressives at the time of initiation of anti TNF therapy (for 11 ± 7 SD months in patients with PAI and for 50 ± 51 SD months in patients with other types of vascular involvement). The initial anti TNF agent was infliximab (5mg/kg) in 15 patients and adalimumab (40 mg eow) in 1 patient who had PAA and PAT in combination. Additionally, all patients used varying dosages of glucocorticoids and 10 used immunosuppressives (azathioprine = 7).

At the time of survey closure (December 2013) all patients were being followed, with all but 3 being still on anti TNF therapy. None of the patients experienced an exacerbation or new development of vascular involvement under anti TNF therapy during a mean of 16±13.6 SD months for PAI patients and 19.5±14.9 SD months for patients with other vascular involvement. Anti TNF treatment (all infliximab) had been discontinued in 5 patients (4 with PAI). In 3 patients (2 with PAI) this was due to stable disease after a mean of 22.7±12 SD months treatment. One of these patients with PAA is on maintenance treatment with azathioprine and is symptom free 8 months after withdrawal. The second patient with PAT experienced hemoptysis due to development of a new PAT 3 years after withdrawal. He responded to re-institution of infliximab, which was switched to adalimumab because of anaphylaxis during the second infusion. The third patient with extensive venous involvement developed new venous thrombosis and secondary amyloidosis 1 year after withdrawal. His clinical status improved with re-institution of infliximab but he was also switched to adalimumab because of the development of anaphylaxis. In the 2 remaining patients with PAI infliximab was withdrawn because of serious infections (lung tuberculosis and fungal infection). The patient developing tuberculosis is still receiving treatment for tuberculosis with no immunosuppressives and the second patient with fungal infection was subsequently prescribed interferon alpha.

Conclusion: Our uncontrolled experience suggests that anti TNF therapy effectively suppresses signs and symptoms of major vascular involvement in BS. Relapses can be seen after withdrawal. The development of serious infections underline the importance of close follow-up.

Interferon Alfa-Associated Depression in Patients with Behçet's Syndrome. Yasin Keskin[1], Emire Seyahi[1], Cagri Poyraz[2], Serdal Ugurlu[1], Yilmaz Ozyazgan[3] and Hasan Yazici[4]. [1]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [2]Cerrahpasa Medical Faculty, University Of Istanbul, Istanbul, Istanbul, Turkey, [3]Cerrahpasa Medical Faculty University of Istanbul, Istanbul, Turkey, [4]Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey.

Background/Purpose: Interferon (IFN) is an effective immunemodulatory agent in the medical management of eye disease of Behçet's syndrome (BS). The agent is frequently associated with psychiatric adverse events, such as depressive disorders and suicide attempts are the most feared complication (1). We evaluated psychiatric status of a group of BS patients in whom IFN was used for the first time. As a control group we studied BS patients who started to use drugs other than IFN.

Methods: We studied BS patients who were seen between January 2012 and January 2014 at the Behçet's syndrome outpatient clinic at Cerrahpaşa Medical Faculty. Patients who have a history of psychiatric illness, who use illicit drugs/alcohol, or who have parenchymal neurological involvement due to BS were not included in the study. Patients who started to use IFN for the first time (Group 1) and those who started to use drugs other than IFN (Group 2) were studied. Beck Depression Inventory (BDI) and Hospital Anxiety and Depression Scale (HADS) were used to measure status of depression at baseline and at week 12.

Results: Group 1 included 17 (14 M, 3F) while Group 2 included 21 (13 M, 8 F) patients. During 12 weeks of follow-up, in Group 1, 6 patients used corticosteroids while 3 used colchicine in addition to IFN. Drugs that were started in Group 2, were azathioprine and cyclosporine combination (n=5), infliximab (n=2), methotrexate (n=1), azathoprine alone (n=6) and colchicine (n=7). Patients who used IFN were more likely to be male, to have longer disease duration and to have eye disease. Besides that, demographic, socio-economical and clinical characteristics were similar between the Groups. Among patients who used IFN, both BDI and HADS scores increased significantly after 3 months of follow-up. These scores did not change among patients who used other drugs (Table 2). (Table 1). Additionally, those who answered (I have thoughts of killing

myself but I would not carry them out) to question no: 9 was more common in the IFN group at week 12 (35 % vs 10 %, p =0.053). These were 24 % vs 10 %, respectively, (p = 0.24) at baseline.

Conclusion: We found that the depression scales increased among IFN users after 12 weeks of follow-up compared to those who used other drugs. Additionally, after 12 weeks of follow-up, the frequency of those with suicidal ideation also increased among the IFN users. A recent survey indicated that BS patients with major organ involvement have already increased risk for depression and suicidal behavior (2). Physicians should be cautious while using IFN in BS, since this drug may further increase this risk.

Table 1. Depression scales at baseline and at week 12

	Interferon, n = 17			Other drugs, n=21		
	Baseline	Week 12	p	Baseline	Week 12	p
BDI, mean ± SD	11.4 ± 8.7	14.7 ± 9.0	0.05	10.9 ± 9.6	10.0 ± 8.0	0.39
HADS, mean ± SD	5.0 ± 4.5	7.1 ± 4.2	0.04	5.5 ± 4.2	5.3 ± 3.2	0.71

BDI: Beck Depression Inventory; HADS: Hospital Anxiety and Depression Scale

2761

Increased Risk of Parenchymal Neurological Involvement in Behcet's Syndrome Patients with Panuveitis. Berivan Bitik[1], Berna Goker[1], Kubilay Sahin[2], Yesim Sucullu Karadag[2], Ridvan Mercan[1], Abdurrahman Tufan[1], Mehmet Akif Ozturk[1], Fikri Ak[2], Yasar Karaaslan[3] and Seminur Haznedaroglu[1]. [1]Gazi University School of Medicine, Ankara, Turkey, [2]Ankara Numune Education and Research Hospital, Ankara, Turkey, [3]Hitit University, Corum, Turkey.

Background/Purpose: Behcet's Syndrome (BS) is a systemic vasculitis which may involve multiple organ systems simultaneously. Most frequently, clinical findings in BS fit into well recognized patterns such as the association between papulopustular skin lesions and arthritis. Neurological involvement in BS is a serious condition which could lead to significant disability. It could either be parenchymal or vascular. The pathogenesis of these two types of Neuro-Behcet's Syndrome (NBS) are suggested to be different. The purpose of this study is to evaluate the association between the parenchymal Neuro-Behcet's Syndrome and panuveitis.

Methods: We retrospectively reviewed the clinical records of 288 patients with BS, who met the international classification criteria for BS, diagnosed at two major rheumatology clinics from 2000 to 2014. Patient demographics, ophthalmic examinations, clinical and radiologic patterns of neurological involvement were recorded. Pearson's Chi-square test was used for analysis.

Results: In this cohort of a total of 288 patients, 93 developed panuveitis and 38 had NBS (28 men and 10 women, median age 33 (28–54)). Of the 38 patients with neurological involvement, 28 had parenchymal and 10 had vascular disease. Venous sinus thrombosis was the only vascular involvement in NBS patients. Those with panuveitis were significantly more likely to have parenchymal neurological involvement compared to those without panuveitis (22.6% vs 3.6 %, p =0.001) (Table). 21 of the 28 parenchymal NBS patients had panuveitis either prior to or during the course of neurological involvement. Panuveitis was significantly associated with parenchymal-NBS (OR 7.83 95% CI 3.19–19.21).

Table. The association between panuveitis and parenchymal neurological involvement in patients with BS.

BS Patients		Parenchymal neurological involvement: Present	Absent	P-value
Panuveitis	Present	21	72	0.001
	Absent	7	188	

Conclusion: Among our 288 patients with BS, over one out of five cases with panuveitis had neurological involvement during their disease course. Our findings suggest a significant association between these two major organ involvements. This association might also be defined as a recognized clinical pattern, similar to the association of papulopustular skin lesions with arthritis. BS patients with panuveitis should be educated about possible signs and symptoms of neurological involvement which could progress quite rapidly and early initiation of treatment is the key for success.

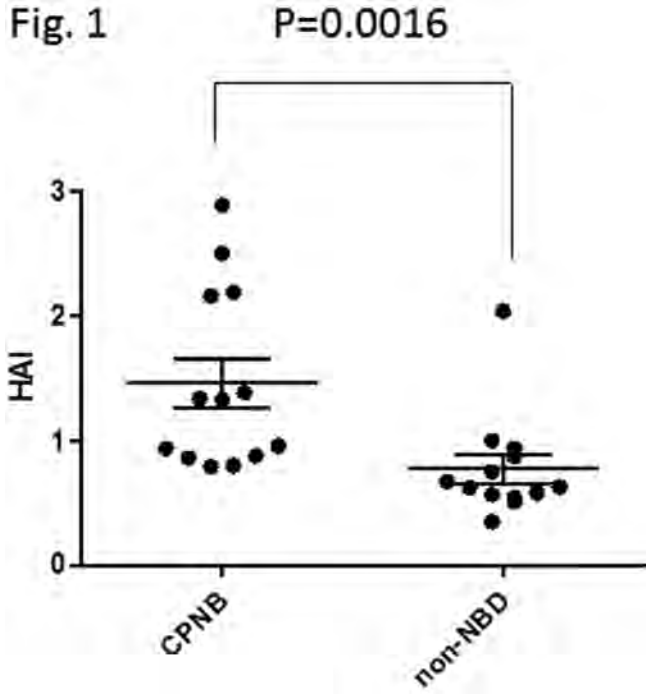
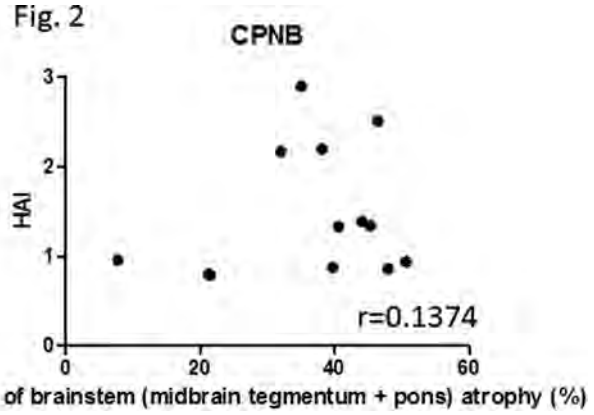
Atrophy of Hippocampal Region in Chronic Progressive Neuro-Behçet's Disease. Hirotoshi Kikuchi[1], Kurumi Asako[1], Maki Takayama[1], Yoshitaka Kimura[1], Akiko Okamoto[1], Toshihiro Nanki[2], Hajime Kono[1] and Shunsei Hirohata[3]. [1]Teikyo University School of Medicine, Tokyo, Japan, [2]Teikyo University, Tokyo, Japan, [3]Kitasato University School of Medicine, Sagamihara, Japan.

Background/Purpose: Central nervous system involvement in Behçet's disease, usually called neuro-Behçet's disease (NB), can be classified into acute NB (ANB) and chronic progressive NB (CPNB) based upon the differences in clinical courses and responses to corticosteroid treatment. Previous studies demonstrated that brainstem atrophy was significantly more frequently observed in CPNB than in ANB or non-NB. Noteworthy, in addition to truncal ataxia, neurobehavioral changes are frequently observed in CPNB, which cannot be accounted for by brainstem atrophy. In the present study we examined the volumes of hippocampus in order to determine the responsible lesions for neurobehavioral changes in CPNB.

Methods: A total of 26 patients were studied, including 13 patients with CPNB (11 males and 2 females, age 51.2 ± 12.1 [mean ± SD]) and 13 non-NBD (10 males and 3 females, age 54.4 ± 11.4). All the patients satisfied the international classification criteria for Behçet's disease. CPNB was defined as intractable, slowly progressive neurobehavioral changes and/or ataxia accompanied by the persistent elevation of cerebrospinal fluid of IL-6 more than 20 pg/mL on two different occasions at intervals of at least 2 weeks (3). The sagittal sections of T1-weighted images on brain MRI were obtained from each patient. Severity of gray matter loss in the hippocampal region and whole brain were investigated by the software for Voxel-Based Specific Regional Analysis System for Alzheimer's Disease (VSRAD) (Eisai Co., Ltd), calculating the indicators of the degrees of hippocampal region atrophy (HAI) and those of whole-brain atrophy (WBAI). The areas of midbrain tegmentum and pons were measured on mid-sagittal sections of T1-weightened images of brain MRI using image analysis software Image J (NIH, U.S.).

Results: The VSRAD analysis showed that HAI was significantly increased in CPNB (1.46 ± 0.70 [mean ± SD]) compared with in non-NB (0.77 ± 0.40) (p=0.0016) (Fig. 1). Although less markedly, WBAI was significantly higher in CPNB (10.6 ± 5.0) than in non-NB (6.9 ± 1.7) (p=0.0240). Neither HAI nor WBAI was correlated with age. Whereas all the patients with CPNB showed brainstem atrophy, there was no significant correlation between HAI and the rate of brainstem atrophy (Fig. 2).





Conclusion: These results indicate that hippocampus, in addition to brainstem, is a commonly affected lesion in CPNB, accounting for progressive neurobehavioral changes. The lack of correlation between brainstem atrophy and hippocampal atrophy suggest that there might be some predisposing factors determining the preference of affected lesions in CPNB.

2763

Long-Term Outcome of Chronic Progressive Neurological Manifestations in Behcet's Disease. Shunsei Hirohata[1], Hirotoshi Kikuchi[2], Tetsuji Sawada[3], Hiroko Nagafuchi[4], Msataka Kuwana[5], Mitsuhiro Takeno[6] and Yoshiaki Ishigatsubo[7]. [1]Kitasato Univ School of Med, Kanagawa, Japan, [2]Teikyo University School of Medicine, Tokyo, Japan, [3]Tokyo Medical University, Tokyo, Japan, [4]St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan, [5]Keio University School of Medicine, Tokyo, Japan, [6]Yokohama City University Hospital, Yokohama, Japan, [7]Yokohama City Grad Schl of Med, Yokohama, Japan.

Background/Purpose: Chronic progressive neurological manifestations in Behcet's disease (BD) is characterized by progressive deterioration leading to disability either with or without a history of previous attacks, thus called chronic progressive neuro-Behcet's disease (CPNBD). Although high doses of steroids, including steroid pulse therapy, cyclophosphamide and azathioprine have been anecdotally used in the treatment of CPNBD, the prognosis of the patients treated with such drugs have been usually miserable. Notably, methotrexate has been found effective for CPNBD in a prospective open trial with a small number of patients. However, its influences on the long-term outcome in a larger population remain unclear. The present study was designed to explore the effects of various treatment regimens, including methotrexate, on the prognosis of patients with CPNBD.

Methods: Thirty-seven patients, who met the international classification criteria for BD, and developed chronic progressive manifestations of NBD after 1988, were followed up until October 2013. The effects of various treatment regimens on prevention of death or severe disability of bedridden state were examined by Kaplan-Meier analysis and Cox's proportional hazard model.

Results: In 37 patients with CPNBD, 28 patients (75.7%) received methotrexate. Among the 28 patients with methotrexate, no patients died and only 5 patients progressed to disability with bedridden state. By contrast, among the 9 patients without methotrexate, 5 patients died and 3 patients progressed to the bedridden state. Thus, methotrexate significantly improved the survival of patients with CPNBD (HR 0.0507, 95% CI: 0.0077–0.334, p=0.020 as calculated by Mantel-Cox test) (figure), but any of steroid pulse, azathioprine or cyclophosphamide did not. Methotrexate also significantly reduced the proportion of the patients who were progressed into the bedridden state or death (HR 0.0694, 95% CI: 0.0047–0.7327, p=0.0258 as determined by multivariate analysis in Cox proportional hazard model).

Conclusion: These results indicate that methotrexate, but not high doses of steroids, azathioprine or cyclophosphamide, is effective to prevent the progression of CPNBD. Thus, it is recommended that methotrexate should be started as soon as possible the diagnosis of CPNBD is made.

S100B Astrocyte Protein May Serve As a Prognostic Factor in Reversible Cerebral Vasoconstrictive Syndromes. Juan J. Maya[1], Vikram Puvenna[2], Chanda Brennan[2], Seby John[1], Ken Uchino[1], Leonard H. Calabrese[1], Damir Janigro[2] and Rula Hajj-Ali[1]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Cleveland Clinic Lerner College of Medicine, Cleveland, OH.

Background/Purpose: Reversible Cerebral Vasoconstriction Syndromes (RCVS) are a group of disorders characterized by acute onset of recurrent thunderclap headaches with or without neurologic deficits. Radiologically, RCVS is characterized by reversible vasoconstriction; however at a molecular level the pathophysiology is poorly understood. Blood-Brain Barrier Disruption has been linked to a variety of neurological disorders. S100B is as an astrocytic protein considered to be an important peripheral blood marker of Blood-Brain Barrier Disruption and correlates with the presence or absence of enhancements on MRI scans. S100B serum levels have been used to study Blood-Brain Barrier Disruption after traumatic brain injury, and are even being used in emergency department settings to detect traumatic brain injury. Consequently, we assessed Blood-Brain Barrier Disruption in patients with RCVS by measuring the serum levels of S100B, and tested this protein for prognostic utility and risk stratification.

Methods: A total of 10 patients with RCVS from the Cleveland Clinic RCVS Biologic Repository were included in this study. A sample from each patient had been obtained during the ictal phase and samples of 3 patients were also obtained during the resolution of the vasoconstriction. S100B measurements were performed using S100B ELISA (Diasorin, Stillwater, MN). RCVS data was compared to age and gender matched historical controls, and subanalyses were performed using the data from the RCVS patients with ischemic stroke (n=5), and the RCVS patients with intracranial hemorrhages (n=4).

Results: Mean S100B level in RCVS patients during the ictal phase was statistically higher than the mean level in the control group (mean = 0.3644 vs. mean = 0.072, $p < 0.0001$). When the mean S100B level of RCVS patients with ischemic stroke (mean = 0.6588) was independently compared with the control group (mean = 0.072) and with RCVS patients with intracranial hemorrhages (mean = 0.048), the level was also statistically higher ($p < 0.0001$ for both comparisons). There was no statistical difference in the mean level of S100B between the control group and the group with intracranial hemorrhage ($p = 0.7271$). The levels of S100B in 2 out of 3 patients decreased when the initial levels were compared with the follow-up levels, in average from 0.08 to 0.05. The patient with the highest S100B level (> 3 SD above the mean) had multiple ischemic strokes and ultimately expired.

Conclusion: The elevation in S100B protein levels that was observed in RCVS patients implies that this condition can cause an alteration in the permeability of the Blood-Brain Barrier. S100B levels were higher in the ischemic stroke group as compared to the hemorrhagic group and to controls. This information implies that S100B may serve as a prognostic factor in a subgroup of RCVS patients. Furthermore, RCVS patients with intracranial hemorrhage did not have a significant increase in S100B levels, which is different from what other authors have observed in non RCVS intracranial hemorrhages. Further studies with larger number of subjects are needed in order to validate and further explore this data.

2765

Putative Blood Biomarkers of Reversible Cerebral Vasoconstriction Syndrome. Seby John, Belinda Willard, Leonard H. Calabrese, Ken Uchino, Tariq Hammad, Stewart Tepper, Mark Stillman and Rula A Hajj-Ali. Cleveland Clinic Foundation, Cleveland, OH.

Background/Purpose: The pathophysiology and molecular mechanisms of Reversible Cerebral Vasoconstriction Syndrome (RCVS) are unknown. Objective of the study was to identify putative biomarker proteins for RCVS.

Methods: Patients were recruited from our institution's prospective RCVS registry. Plasma samples were collected from 6 patients with RCVS during the acute cerebral vasoconstrictive phase, 2 patients at 6-month follow-up after resolution of vasoconstriction, and 4 patients with CNS vasculitis.

Plasma samples were immune-depleted for the most abundant plasma proteins, precipitated, and then digested overnight with trypsin and analyzed by liquid chromatography tandem mass spectrometry (LC-MS/MS). These LC-MS/MS experiments were carried out on a high resolution Orbitrap-Elite FT-MS system that allows the relative quantity of the proteins in these samples to be determined by a label free quantitative method. The quantitation is performed by searching the data with the programs Mascot and Sequest. These search results were then uploaded into the program Scaffold. The quantitation was performed by comparing the normalized spectral counts (SC) for the samples. The data was filtered based on several parameters including two matching peptides, a FDR of 1.0%, a protein threshold of 95%, and identified in at least 3 of the samples. The relative quantity of these proteins was determined by using the spectral counting method that has been described previously In order for a protein to be considered as a putative biomarker, the relative abundance needs to be at least two fold different with the T-test derived p-value less than 0.05.

Results: A total of 228 proteins were identified. Three, 5 and 4 proteins were found to be of higher abundance in a) follow-up samples of RCVS compared to baseline, b) CNS vasculitis samples compared to baseline RCVS, and c) baseline RCVS samples compared to CNS vasculitis respectively (Table 1).

Conclusion: This is a preliminary study looking at proteomic analysis of RCVS plasma samples. Results of this study show proteins that might be potential biomarkers for RCVS and which could help differentiate RCVS from its mimic CNS vasculitis. Further studies with larger number of patients are needed to assess reproducibility. The function and the pathways of these differentially expressed proteins should be further explored.

Table 1: List of differentially expressed proteins identified in LC-MS/MS analysis comparing i) Baseline vs follow-up RCVS and ii) Baseline RCVS vs CNS vasculitis

Protein	Average nSC Baseline RCVS	Average nSC Follow-up RCVS	Ratio Follow-up/ Baseline	T-Test P-Value

Mycophenolate Mofetil in the Treatment of Primary Central Nervous System Vasculitis. Carlo Salvarani[1], Robert D. Brown Jr.[2], Teresa J. H. Christianson[2], John Huston III[2], Francesco Muratore[1], Caterina Giannini[2] and Gene G. Hunder[2]. [1]Arcispedale S Maria Nuova, Reggio Emilia, Italy, [2]Mayo Clinic, Rochester, MN.

Background/Purpose: The optimal management of primary central nervous system vasculitis (PCNSV) remains unclear. Cyclophosphamyde (CYC) in combination with glucocorticoids (GCs) or GCs alone are the most commonly used therapies. It is not proven if other immunosuppressants, used in other vasculitides, such as azathioprine (AZA), methotrexate (MTX) and mycophenolate mofetil (MMF), that are less toxic than CYC, can be used as induction and/or maintenance therapies. The aim of the study was to determine the efficacy and safety of MMF in PCNSV.

Methods: The study cohort consisted of 163 consecutive patients with PCNSV seen at Mayo Clinic (Rochester, MN) from 1983 to 2011. The diagnosis of PCNSV was based on findings of brain or spinal cord biopsy, cerebral angiography, or both. To assess treatment response, we used the treating physician's global opinion about the response to therapy. The degree of disability was defined using the modified Rankin scale. Outcomes, relapses, treatment response and ability to discontinue treatment at last follow-up were compared between patients treated with MMF and those receiving other therapies.

Results: 159/163 patients were treated at the time of diagnosis: 68 received GCs alone, 72 GCs and CYC, 2 CYC alone, 10 MMF and GCs, 6 AZA and GCs, and 1 rituximab and GCs. 6 more patients were treated with MMF after obtaining remission with CYC. In total, 16 patients were treated with MMF: 7 males and 9 females with a median age of 45.5 years (range: 20–72 years). Cerebral biopsy was performed in 10 and was positive in 9 (3 associated cerebral amyloid angiopathy). Clinical manifestations at presentation were: headache (9 patients), altered cognition (9 patients), persistent neurologic deficit or stroke (8 patients), seizures (6 patients) and 1 had intracranial hemorrhage. Cerebral MRI showed infarctions in 10 patients (bilateral in 7) and prominent leptomeningeal enhancement in 4 patients. CSF abnormalities were observed in 14/16 patients. The median duration of follow-up was 34 months (range: 10–78 months). Cerebral angiography was positive in 7/11 patients and large vessel involvement was observed in 4. The median dosage of MMF was 2 grams (range: 0.5–3 grams) and the median therapy duration 14.9 months (range: 1–31.6 months). Rankin disability scores at diagnosis were similar between patients treated with MMF and those receiving other therapies (Rankin score, 0–3: 68.7% versus 69.9%; Rankin score, 4–6: 31.3% versus 30.1%; p = 1.000). A significantly lower proportion of patients treated with MMF had severe disability at last follow-up compared to those receiving other therapies (Rankin score, 4–6: 0 versus 25.1%, p=0.023). No statistically significant differences were observed in patients treated with MMF compared to those receiving other therapies regarding relapses [7/16 (43.7%) versus 37/143 (25.9%), p = 0.146], ability to discontinue therapy at last follow-up [4/16 (25%) versus 36/142 (25.3%), p = 1.000], and treatment response [15/15 versus 111/142 (78.1%), p = 0.075]. Only 1 patient suspended MMF for a severe adverse event (leukopenia).

Conclusion: In this retrospective study of a small number of PCNSV patients, MMF was an effective and safe therapy.

Core Outcome Domains and Potential Measurement Instruments in polymyalgia Rheumatica (PMR) Using Omeract Filter 2.0. Sarah Mackie[1], Toby Helliwell[2], Rodney Hughes[3], E Brouwer[4], Colin T. Pease[5], Christian Mallen[6], Maarten Boers[7] and John R. Kirwan[8]. [1]University of Leeds, Leeds, United Kingdom, [2]Keele University, Staffordshire, United Kingdom, [3]St. Peters Hospital, Chertsey Surrey, United Kingdom, [4]University Medical Center Groningen, Groningen, Netherlands, [5]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [6]Keele University, Keele, United Kingdom, [7]VU University Medical Center, Amsterdam, Netherlands, [8]Bristol Royal Infirmary, Bristol, United Kingdom.

Background/Purpose: The OMERACT PMR specialist interest group was established to develop a core outcome measurement set for PMR using the methods of OMERACT filter 2.0. This work builds on previous work undertaken to identify potential domains, which were presented at OMERACT 11.

Methods: A three-round Delphi survey was undertaken to identify domains of importance (Figure1). Additionally, meetings of patient and clinician participants were convened in order to scrutinise and finalise the candidate core domain set. A review of the PMR literature was undertaken to identify outcome measures and instruments used in previous PMR research. The candidate domains and identified instruments were presented and discussed at OMERACT 12.

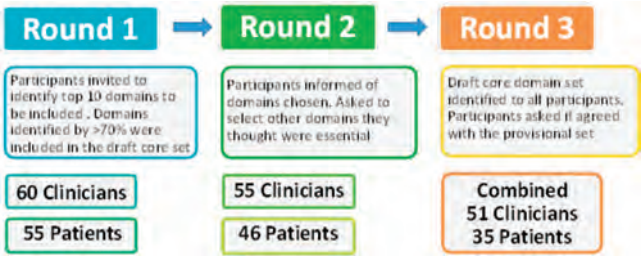

Figure 1.

Results: The literature review identified 28 studies for full review. The identified domains from the Delphi survey and corresponding measurement instruments are presented in Table 1.

Table 1.

Life Impact		Pathophysiological Manifestations		Rare/serious or adverse events	
Domain	Instrument used (N)	Domain	Instrument used (N)	Domain	Instrument
Pain/ache	VAS (11)	Blood tests	CRP or ESR (26)	Death	SAE reporting
Fatigue	VAS (2)	Physician Global	VAS (3)	Giant Cell Arteritis	Clinical diagnosis
Patient Global	VAS (3)	Stiffness	Duration (min) (7)	'Glucocorticoid AE'	None identified
Quality of Life	SF36 (2)				
ADL	HAQ (4)				

N: Number of studies; VAS: Visual analogue scale; CRP: C-reactive protein; ESR: Erythrocyte sedimentation rate; SAE: Serious adverse event; AE: Adverse event; SF36: Short Form-36; ADL: Activities of daily living; HAQ: Health Assessment Questionnaire Disability Index

No study reported any patient involvement in the development of the outcome measures used. The candidate core domain set emerging after discussion at the OMERACT 12 PMR special interest group is shown in figure 2. Two studies undertook instrument validation and demonstrated poor test-retest reliability for fatigue VAS, morning stiffness duration, and SF36 mental component score and that the HAQ performed well for PMR.

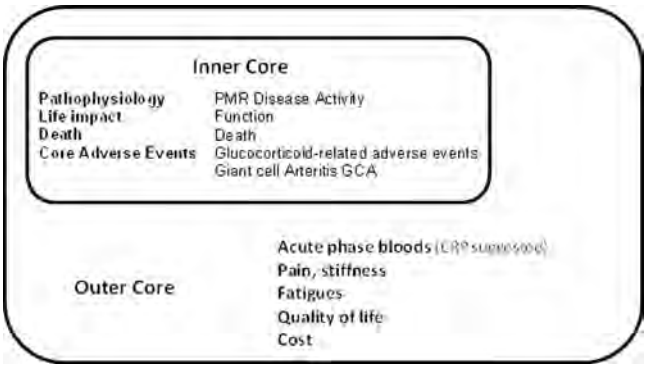

Figure 2.

Conclusion: The concern over glucocorticoid (GC) adverse effects (AEs) warrants their inclusion in the core set. No accepted measurement instrument for GC AEs was identified. GC AEs were not routinely reported in the studies identified. Review work by a EULAR Task Force found little evidence of their prevalence and severity at different daily and cumulative doses. Low dose GCs remain the cornerstone of PMR treatment and so the reporting of relevant associated AEs should be routine. The candidate core domain set is supported by substantial patient and clinician contributions, and by the previous use of these domains. Full evaluation of the instruments would now be worthwhile.

Patient Reported Outcomes and Acute Phase Reactants in Polymyalgia Rheumatica in Patients Treated with Prednisone Versus Modified-Release Prednisone. Mauro Betelli, Giulia Erba, Massimo Ricci, Carlo Valena, Elisabetta Allevi, Marta Riva, Giorgia Grosso, Simona Barbarossa, Federica Bonomi and Maria Rosa Pozzi. Rheumatology Outpatient Clinic - San Gerardo Hospital – Milano-Bicocca University, Monza, Italy.

Background/Purpose: Polymyalgia rheumatica (PMR) is a chronic inflammatory disorder of the elderly, characterised by morning stiffness, pain and aching in the hip and shoulder girdles and acute phase reactants increase. The response to low-dose prednisone (Pd) is marked and fast on both Patient Reported Outcomes (PROs) and acute phase reactants, but most patients require a treatment course of 1–3 years. A new modified-release delivery system Prednisone adapts the release of the administered glucocorticoid to the circadian rhythms and proved to be useful for morning stiffness, fatigue and disease activity control in Rheumatoid Arthritis. We compared Prednisone (Pd) to modified release Prednisone (MR-Pd) on PROs and acute phase reactants in Polymyalgia Rheumatica.

Methods: We studied 15 patients (5 men, mean age 70 years, SD 8.25) with newly diagnosed PMR and previously untreated. They received the same tapering dose of prednisone starting from 15 mg: 8 patients received a MR-Pd tablet, and 7 a Pd tablet. We observed no drop-outs but only ten patients have completed the 16-week assessment period by now (3 men, mean age 72 years, SD 5.48). CRP/ESR, VAS for stiffness duration/intensity and fatigue and HAQ-DI (PROs) were obtained at baseline and at week 4 and 16. We used Standardized Response Means (SRM), a measure of responsiveness, to evaluate acute phase response and clinical parameters improvement at week 4 and 16.

Results: The mean relative changes of the CRP/ESR and PROs from baseline to 4th and 16th week were not statistically different between Pd and MR-Pd ($p > 0.05$), confirming their same efficacy at the same dosage. We noticed that after 4 weeks CRP, fatigue, stiffness duration and HAQ assessment showed a better response in the group treated with modified release CS (CRP SRM 1.03–0.71, fatigue SRM 1.25–0.80; stiffness duration 1.40–0.40, HAQ SRM 1.74–1.10 for modified and immediate release Prednisone respectively). However at week 16 there were no significantly differences between CRP and HAQ (SRM 0.56 – 0.67 and 1.83 – 1.82 respectively), whereas fatigue and stiffness duration improved in patients treated with Pd (SRM 1.12– 7.03 and 0.72 – 1.01). Otherwise impact on stiffness intensity was constantly better in patients treated with Pd (after 4 and 16 weeks respectively: SRM 1.70–1.15 and 4.19–1.16).

Conclusion: Modified-Release Prednisone and Prednisone showed the same overall efficacy on Patient Reported Outcomes and acute phase reactants in patients with PMR, but with different timings and impacts on various disease aspects.

Validation of New 2012 EULAR/ACR Classification Criteria for Polymyalgia Rheumatica: Comparison with the Previous Criteria in a Prospective Multi-Center Study. Gulsen Ozen[1], Seda Bas[1], Ali Ugur Unal[1], Gezmis Kimyon[2], Ahmet Mesut Onat[2], Meryem Can[3], Alperen Mengi[3], Ali Sahin[4], Sema Yilmaz[5], Havva Keskin[6], Sadiye Murat[6], Ayse Balkarli[7], Veli Cobankara[7], Omer Nuri Pamuk[8], Yonca Cagatay[9], Neslihan Yilmaz[9], Ilker Yagci[1], Pamir Atagunduz[1], Sibel Z. Aydin[10], Nevsun Inanc[1] and Haner Direskeneli[1]. [1]Marmara University School of Medicine, Istanbul, Turkey, [2]Gaziantep University School of Medicine, Gaziantep, Turkey, [3]Fatih Sultan Mehmet Education and Research Hospital, Istanbul, Turkey, [4]Cumhuriyet University Faculty of Medicine, Sivas, Turkey, [5]Selcuk University School of Medicine, Konya, Turkey, [6]Goztepe Medeniyet University Faculty of Medicine, Istanbul, Turkey, [7]Pamukkale University School of Medicine, Denizli, Turkey, [8]Trakya University School of Medicine, Edirne, Turkey, [9]Bilim University Faculty of Medicine, Istanbul, Turkey, [10]Koc University Faculty of Medicine, Istanbul, Turkey.

Background/Purpose: To evaluate the diagnostic and discriminative ability of the new 2012 European League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) polymyalgia rheumatica (PMR) classification criteria compared to previous four diagnostic/classification criteria for PMR in a multi-centre prospective study.

Methods: One-hundred and five patients older than 50 years of age, presenting with new onset (symptom duration ≤12 weeks) bilateral shoulder pain with elevated acute phase reactants were enrolled from 9 rheumatology clinics in Turkey. Patients were prospectively followed and the diagnosis of PMR was established when the diagnosis was maintained without an

alternative diagnosis at 6 months of follow-up. Those who were diagnosed as other than PMR at the 6thmonth were designated as control group. All patients were classified by each of the five different criteria for PMR and 2010 ACR/EULAR RA classification criteria.

Results: Of the 105 patients with new-onset (mean symptom duration 9.9±7.0 weeks) bilateral shoulder pain 65 (61.9%) patients were diagnosed as PMR and 40 (38.1%) were diagnosed as nonPMR (15 were RA). The discriminative ability as estimated by the area under the receiver operating characteristic (ROC) curve, was better for the Chuang criteria (0.86) than 2012 EULAR/ACR clinical criteria for PMR (0.69), Jones (0.67), Bird (0.66) and Nobunaga (0.75) criterias (Table 1). The 2012 EULAR/ACR clinical criteria for PMR had a sensitivity of 90.8% and a specificity of 47.5%. Jones and Chuang criteria had the highest specificity (90% and 92.5%, respectively). The specificity of the new 2012 EULAR/ACR clinical criteria for PMR further decreased to 40% in RA patients. Although the new 2010 ACR/EULAR RA classification criteria classified only 2 out of 65 PMR patients as RA, the new 2012 EULAR/ACR clinical criteria for PMR classified 9 out of 15 RA patients as PMR.

Conclusion: The new 2012 EULAR/ACR clinical classification criteria for PMR can classify PMR patients with high sensitivity, however, its ability to discriminate PMR from other inflammatory conditions with shoulder pain, especially RA is poor. Another criteria set, Chuang criteria, despite involvement of similar clinical parameters, perform better in discriminating PMR from RA and other inflammatory/noninflammatory articular diseases. This difference may be attributed to the involvement of a cut-off for ESR as 40 mm/h, exclusion of other diagnoses as criteria and classification of patients as PMR when all criteria are fulfilled unlike the new 2012 EULAR/ACR clinical criteria which require just four 4 points. Our results, therefore, suggest that in seronegative patients with bilateral shoulder pain and acute-phase response, differential diagnosis of PMR and RA may require imaging or biomarker studies.

Table 1. Sensitivity and specificity of each set of PMR criteria

Criteria	Sensitivity (%)	Specificity (%)	AUC (95% CI)	Specificity (%)	AUC (95% CI)
	PMR vs Total Cases			*PMR vs RA*	
Chuang	80	92.5	0.86 (0.78–0.93)	93.3	0.86 (0.77–0.96)
Bird	92.3	40	0.66 (0.54–0.77)	13.3	0.52 (0.36–0.69)
Jones	44.6	90	0.67 (0.57–0.77)	93.3	0.69 (0.56–0.81)
Nobunaga	73.8	77.5	0.75 (0.65–085)	80	0.76 (0.63–0.90)
EULAR/ACR	90.8	47.5	0.69 (0.58–0.80)	40	0.65 (0.48–0.82)

Polymyalgia Rheumatica Relapse and 'Silence' Large Vessel Vasculitis. Is There Any Association? Stavros Chrysidis[1], Philip Rask Lage-Hansen[1] and Andreas P. Diamantopoulos[2]. [1]Department of Rheumatology, Hospital of Southwest Denmark, Esbjerg, Denmark, [2]Hospital of Southern Norway Trust, Kristiansand, Norway.

Background/Purpose: Large Vessel Vasculitis (LVV) can present with heterogeneous clinical manifestations, which range from general symptoms (fever, loss of weight) to the classic symptoms of Giant Cells Arteritis (GCA) (headache, jaw claudication, visual manifestations). Around 40% of GCA patients have concomitant Polymyalgia Rheumatica (PMR) and up to 40% of PMR patients have a positive biopsy of the temporal artery (TAB).

Studies evaluating ultrasound (US) as a diagnostic tool in GCA have reported a high sensivity and specificity.

The aim of this study was to investigate the association between disease's relapse and co-existing "silence" LVV in patients with pure PMR.

Methods: Patients with PMR who relapsed under corticosteroid (CS) tapering In Esbjerg Hospital, Denmark in the period of April 2013 to June 2014 have been prospectively included. In patients with PMR who relapsed under corticosteroid (CS) tapering, US examination of temporal (AT), axillary (AA), subclavian (AS) and carotid (AC) arteries was performed. US images were recorded and evaluated by an ultrasonographer experienced on vascular ultrasound (AD), who was blinded to patients' clinical and laboratory data.

US was considered positive when a homogeneous hypoechoic thickness >1.5 mm in AC and AS and >1mm in AA, in transverse and longitudinal view was observed. For the AT, the typical sign of halo (arterial wall swelling in transverse and longitudinal view) was considered as vasculitis. Relapse was defined as the reappearance of PMR clinical symptoms in addition to elevated ESR or CRP (ESR> 40 mm/h, CRP>10mg/lt) or persistent increased CRP/SR without any other explanation. All patients with positive US findings underwent a TAB.

Results: On a period of 14 months, 17 patients had been evaluated. All patients fulfilled the Bird's classifications criteria for PMR and all the patients responded appropriately to CS treatment at baseline. None of the patients had GCA- related clinical symptoms either on baseline or during the relapse. No significant differences were observed between the two groups of patients (PMR + LVV and PMR - LVV) in age, diseases duration, initial CRP/SR levels and initial CS dose (prednisolon 15–25mg).

Seven out of 17 (41%) patients had ultrasonographic sign of vasculitis. All patients had affection of the AA (6 of them bilateral), 3 of the AS, 1 of the AT none of the AC. The patient with the positive US of the AT was the only who had a positive TAB.

Conclusion: In our study, the relationship between PMR relapse and concomitant "silence" LVV has been evaluated. More than one-third of PMR patients who relapsed had a co-existing LVV. Thus, we recommend the use of vascular US in all patients with PMR suffering a relapse to investigate the possible co-existence of LVV.

PET-CT Imaging and Association of Ferritin Autoantibodies in Polymyalgia Rheumatica. Niklas Thomas Baerlecken[1], Torsten Witte[2], Marco Amedeo Cimmino[3] and Dario Camellino[4]. [1]MD, Hannover, Germany, [2]MD, Hanover, Germany, [3]Università di Genova, Genova, Italy, [4]Clinica Reumatologica, Genova, Italy.

Background/Purpose: Previously we described antibodies against ferritin heavy chain peptide (anti-FHCP) in sera of patients with giant cell arteritis (GCA) and/or polymyalgia rheumatic (PMR) before glucocorticoid treatment was initiated. In that study, it remained unclear however, whether the PMR patients may have suffered from additional undiagnosed GCA. Therefore, we now measured antibodies against FHCP in PMR patients in whom GCA had been excluded by FDG-PET scan.

Methods: Sera of 63 patients were studied that presented initially with symptoms of PMR. A PET-CT had been performed in all patients and revealed large vessel vasculitis in 27 of these patients (GCA/PMR), whereas 36 had no signs of vasculitis (PMR). In a single-blinded study, we measured anti-FHCP in these patients and in a control group of patients with rheumatic diseases (RD, n=26), malignant diseases (MD, n=15) and infectious febrile diseases (IFD, n=22).

In the ELISA 3 peptides of the ferritin heavy chain were used as antigens: A19–45 (AAINRQINLELYASYVYLSMSYYFDRF), A79–104 (GRIFQDIKKPCDDWESGLNAMECA) and A105–143 (LHEKNVNQSLELHKLATDKNDPHLCFIETHYLNEQVK).

Results: The frequency of antibodies against A19–45 were 38/63 (60%) in all PMR patients and 14/63 (22%) in controls ($p<0.0001$), of antibodies against A79–104 30/63 (48%) in all PMR patients and 9/63 (14%) in controls ($p=0.0001$) and of antibodies against A105–143 38/63 (60%) in PMR and 12/63 (19%) in controls ($p<0.0001$). There were no differences within the controls considering all antigens.

Comparing the patients with and without vascular involvement in PET-CT, the frequencies of antibodies against A19–45 (18/27 (67%) and 20/36 (56%), ($p=0.53$)), against A79–104 (14/27 (52%) and 16/36 (44%) ($p=0.74$)) and against A105–143 (19/27 (70%) and 19/36 (53%) ($p=0.25$)) were not different.

Conclusion: This single-blinded study confirms the frequency of anti-FHCP in a different cohort. Anti-FHCP are associated with both GCA/PMR and PMR only.

Disclosure: N. T. Baerlecken, None; **T. Witte**, None; **M. A. Cimmino**, None; **D. Camellino**, None.

The Use of Imaging in the Diagnosis of Polymyalgia Rheumatica: Systematic Literature Review and Meta-Analysis. Sarah Mackie[1], Gouri Koduri[2], Catherine L. Hill[3], Andrew Hutchings[4], Richard J. Wakefield[5], Bhaskar Dasgupta[6] and Jeremy Wyatt[1]. [1]University of Leeds, Leeds, United Kingdom, [2]York Teaching Hospital NHS Foundation Trust, York, United Kingdom, [3]University of Adelaide, Adelaide, Australia, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [6]Southend University Hospital, Essex, United Kingdom.

Background/Purpose: ACR/EULAR provisional classification criteria for polymyalgia rheumatica (PMR) incorporate musculoskeletal ultrasound of shoulder and hip (bursitis and synovitis given equal weight). Our objective was to systematically review diagnostic accuracy of imaging features of PMR: the reference standard was rheumatologist diagnosis.

Methods: Data sources were MEDLINE, EMBASE and PubMed searches; hand-searching; and experts in the field. Two authors independently reviewed search outputs and discussed disagreements. 1764 citations yielded 23 eligible studies. Data were extracted by two authors independently. Methodological quality was assessed by 3 authors using QUADAS-2. Hierarchical summary receiver operating curve (HSROC) models were constructed where appropriate, and positive/negative likelihood ratios (LR+/LR-) calculated.

Results: 23 studies with data from 2328 patients were evaluated: musculoskeletal ultrasound (9 studies), vascular ultrasound (6), magnetic resonance imaging (MRI) (6), and positron emission tomography (PET) (2). One further article (musculoskeletal ultrasound) was published during the preparation of this review. Internal and external validity varied, as did the clinical spectrum. All but one of the studies had a diagnostic case-control design. The most useful imaging features were subacromial-subdeltoid bursitis (SAB) on one or both sides (4 ultrasound studies: LR+ 2.5 (1.6 to 3.8); LR− 0.30 (0.11 to 0.81)), bilateral SAB (4 ultrasound studies: LR+ 6.2 (1.2 to 32); LR− 0.38 (0.15 to 0.97)), and presence of trochanteric bursitis (2 ultrasound, 1 MRI and 1 PET study: LR+ 5.4 (3.3 to 8.8), LR− 0.076 (0.002 to 2.8)). Hip or shoulder synovitis LRs were closer to the non-informative ratio of 1.0. Interspinous bursitis (LR+ 4.5 (1.5 to 13), LR− 0.26 (0.093 to 0.73)) and ischiogluteal bursitis (LR+ 3.6 (1.5 to 8.8), LR− 0.19 (0.05 to 0.69)) were detected by PET scans rather than ultrasound.

Conclusion: Based on current evidence, the most useful imaging features for the diagnosis of PMR appear to be SAB, bilateral SAB and trochanteric bursitis, rather than shoulder or hip synovitis.

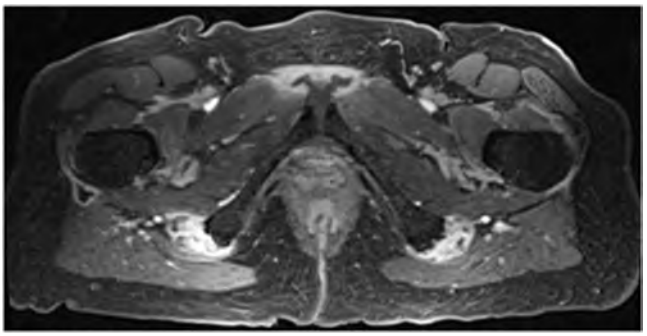
Whole-Body MRI Reveals Characteristic Extracapsular Pattern of Inflammation in Polymyalgia Rheumatica. Sarah Mackie[1], Colin T. Pease[2], Eiki Fukuba[3], Paul Emery[4], Richard J. Hodgson[4], Jane E. Freeston[5] and Dennis McGonagle[6]. [1]University of Leeds, Leeds, United Kingdom, [2]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [3]Faculty of Medicine, Shimane University, Shimane, Japan, [4]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [5]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds., United Kingdom, Leeds, United Kingdom, [6]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom.

Background/Purpose: Polymyalgia rheumatica (PMR) is a disease of widespread musculoskeletal inflammation characterized by pain and stiffness in shoulder and hip girdles. Here we report the first use of whole-body MRI to study the clinical spectrum of PMR in the rheumatology clinic. We hypothesized that PMR is characterized by an extracapsular pattern of inflammation.

Methods: 38 participants underwent whole-body MRI: 22 consecutive cases of clinically-diagnosed, active PMR identified by two rheumatologists with a special interest in PMR and followed up for a mean of 21 months; and 16 patients (controls) selected from a larger inflammatory arthritis (RA) cohort. 4 of the PMR patients did not have gadolinium enhancement, due to contra-indications. Anonymised gadolinium-enhanced MRI scans were consensus scored in axial view using semi-quantitative grading, and the features best discriminating PMR from RA were identified. Patients were treated after the MRI with 15mg prednisolone and then asked at follow-up whether they now felt back to normal.

Results: A characteristic pattern suggesting PMR was classified as "PMR pattern" by the blinded scorers; this could be identified both on the gadolinium-enhanced and non-enhanced scans. The features best discriminating PMR from RA were inflammation in the following sites: extending up around the rim of the acetabulum ("peri-acetabular"); around the ischial tuberosity; within the hip joint; around the greater trochanter; and around the symphysis pubis (Figure). Of all the MRIs performed in patients with a clinical diagnosis of PMR, "PMR pattern" was significantly associated with patient-defined glucocorticoid responsiveness ($p=0.01$).



Conclusion: A characteristic, extracapsular pattern of inflammation in PMR can be identified, and defines a subgroup of the clinical spectrum of PMR with excellent patient-reported glucocorticoid responsiveness. MRI is particularly useful in assessing inflammation of structures around the pelvis.

Why Leg Ulcers Do Not Heal? a Prospective Study Showing High Proportion of Small Vessel Vasculitis. Vinod Ravindran[1], Sunil Rajendran[2] and Ranjish Vijayan[2]. [1]National Hospital, Kozhikode, Kerala, India, [2]PVS Hospital, Kozhikode, India.

Background/Purpose: Non healing cutaneous ulcers of lower limbs can have several different aetiologies [1]. It is likely that the patients with such ulcers would be treated with empirical therapies and may also undergo (unnecessary) venous procedures. Small vessel vasculitides (leucocytoclastic or non leucocytoclastic) are one of the important causes of non healing cutaneous leg ulcers [2]. The primary objective of this prospective study was to ascertain the cause of non healing cuatneous ulcers of the lower limbs.

Methods: Between May 2010 and April 2013 (3years) consecutive adult patients (age 18 to 75 years) who had one or more persistent leg ulcers (with or without a history of recurrent ulcerations in legs) for more than 2 years presenting to us were prospectively enrolled. Relevant details were extracted using a predefined proforma and included: demographic details, drug history, comorbidities, clinical features, investigations including ANCA, complement levels, cryoglobuilins, HIV and Hepatitis viral serology etc. and venous and arterial Dopplers, microscopy and culture of the ulcer swab in instances of infected looking ulcers. Previous biopsies were reveiwd and fresh biopsies were obtained from the ulcer edges and also from the nonulcerated sites where suitable skin lesions were also present. In cases of ulcers deemed to be a manifestation of a primary systemic vasculitis based on the EMEA classification, BVAS was used to assess disease activity.

Results: A total of 51 patients were assessed. Mean age was 53 ± 10.3 years and 39 (76%) were male. Eight (16%) patients were diabetic. History of some type of venous surgery was present in 30 (59%) and 9 had such procedures more than once. Biopsy confirmed small vessel vasculitis of various types in a majority (76%) of patients (table 1). Drug induced cutaneous vasculitis was not present in this cohort.

Table 1

Aeitiology	n(%)	Comments
Small vessel Vasculitis	39 (76%)	All biopsy proven
Chronic infections	4 (8%)	Mainly Stap. epidermidis
No apparent single cause	8 (16%)	Likely mixed aetiology

In 9 (18%) patients the leg ulcers were one of the manifestations of a primary systemic vasculitis i.e GPA (4), EGPA(2), MPA(2) and PAN (1). Leg ulcers in these patients ran an indolent course with a variety of low to moderate grade of activity features reflected also in the BVAS range of 9 to 15. All patients with small vessel vasculitis were treated with immunosuppressive therapy including glucocorticoids with good effect [complete healing of ulcer(s) in 21 patients with no relapse in 24 weeks of follow up period].

Conclusion: In this cohort of patients with chronic non healing leg ulcers small vessel cutaneous vasculitis emerged as the leading cause and majority benifitted from subsequently instituted specific measures of treatment.

2775

Cutaneous Vasculitis Associated with Severe Bacterial Infections. Study of 27 Patients from a Series of 766 Cutaneous Vasculitis. Leyre Riancho-Zarrabeitia[1], Javier Loricera[1], Ricardo Blanco[1], Jose L. Hernández[1], Vanesa Calvo-Río[1], Francisco Ortiz Sanjuan[1], Cristina Mata-Arnaiz[1], Javier Rueda-Gotor[1], Lino Álvarez[1], Carmen Gonzalez-Vela[1], Marcos A. González-López[1], Susana Armesto[1], Trinitario Pina Murcia[2], Montserrat Santos-Gómez[1] and Miguel A. González-Gay[1]. [1]Hospital Universitario Marqués de Valdecilla. IDIVAL. Santander. Spain, Santander, Spain, [2]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IDIVAL, Santander, Spain.

Background/Purpose: To assess the clinical spectrum of severe bacterial infections presenting as cutaneous vasculitis (CV) in a defined population.

Methods: Unselected series of 766 patients with CV diagnosed at a single university referral center.

Results: An underlying severe bacterial infection was diagnosed in 27 (22 men/5 women; mean age±SD: 53±18 years) of 766 cases presenting with CV (3.5%). These infections were: pneumonia (n=8), endocarditis (n=6), meningitis (n=4), intra-abdominal infections (n=3), septic arthritis (n=2), septicemia (n=2), septic bursitis (n=1), and urinary tract infection (n=1). All the patients were admitted for suspected CV. The median delay from admission to the diagnosis of infection was 4 days. A typical palpable purpura without relevant visceral vasculitic involvement was the main clinical manifestation. Patients with severe bacterial infections were older, with male predominance, had more frequently fever, constitutional symptoms, focal infectious features, and leukocytosis with left shift and anemia than the remaining patients with CV. Although antibiotics were prescribed in all the patients, seven of them also required the use of low-dose corticosteroids to achieve complete resolution of cutaneous lesions. Most patients experienced full recovery but two of them underwent prosthetic cardiac valve replacement, and another two died due to infection-related complications.

Conclusion: CV may be the presenting manifestation of a severe underlying bacterial infection. Physicians should keep in mind this fact to make an early diagnosis of infection and, consequently, prevent life-threatening complications.

Drug-Associated Cutaneous Vasculitis: Study of 239 Patients from a Single Referral Center. Montserrat Santos-Gómez[1], Francisco Ortiz Sanjuan[1], Ricardo Blanco[1], Jose L. Hernández[1], Vanesa Calvo-Río[1], Javier Loricera[1], Carmen Gonzalez-Vela[1], Trinitario Pina Murcia[2], Hector Fernandez-Llaca[1], Susana Armesto[1], Victor Martínez-Taboada[1], Javier Rueda-Gotor[1], Leyre Riancho-Zarrabeitia[1] and Miguel A. González-Gay[1]. [1]Hospital Universitario Marqués de Valdecilla. IDIVAL. Santander. Spain, Santander, Spain, [2]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IDIVAL, Santander, Spain.

Background/Purpose: The 2012 International Chapel Hill Consensus Conference on the Nomenclature of Vasculitides defined drug-associated immune complex vasculitis as a distinct entity included within the category of vasculitis associated with probable etiology. In the present study we assessed the clinical spectrum of patients with drug-associated cutaneous vasculitis (DACV).

Methods: Case records of patients with DACV attending to a tertiary referral hospital over a 36-year period were reviewed. A diagnosis of DACV was considered if the drug was taken within a week before the onset of the disease.

Results: 239 (30.9%) patients (133 men and 106 women with a mean age of 36 years) from a series of 773 unselected cutaneous vasculitis were diagnosed with DACV. Antibiotics (n=149; 62.3%) -mainly β-lactams-, and non-steroidal-anti-inflammatory drugs (NSAIDs) (n=24; 10%) were the most common drugs. Besides skin lesions (100%), the most common clinical features were joint (51%) and gastrointestinal (38.1%) manifestations, nephropathy (34.7%), and fever (23.8%). The most remarkable laboratory data were increased erythrocyte sedimentation rate (40.2%), presence of serum cryoglobulins (26%), leukocytosis (24.7%), positive antinuclear antibodies (21.1%), anemia (18.8%), and positive rheumatoid factor (17.5%). Despite drug discontinuation and bed rest, 108 patients (45.2%) required medical treatment, mainly corticosteroids (n=71) or immunosuppressive drugs (n=7). After a median follow-up of 5 months, relapses occurred in 18.4% of patients, and persistent microhematuria or renal insufficiency in 3.3% and 2.9%, respectively.

Conclusion: DACV is generally associated with antibiotics and NSAIDs. In most cases it has favorable prognosis, although a small percentage of patients may develop residual renal damage.

Clinical-Biological Spectrum and Therapeutic Management of Hypocomplementemic Urticarial Vasculitis: Data from a French Nationwide Study on 57 Patients. Marie Jachiet[1], Alain Le Quellec[2], Alban Deroux[3], Pascal Godmer[4], Mikael Ebbo[5], Leonardo Astudillo[6], Beatrice Flageul[7], Nicolas Dupin[8], Selim Aractingi[1], Loïc Guillevin for the French Vasculitis Study Group[9], Luc Mouthon[9] and Benjamin Terrier[1]. [1]Cochin Hospital, Paris, France, [2]Division of internal Medicine, Hôpital Saint-Eloi, Centre Hospitalier Universitaire de Montpellier, Montpellier, Montpellier, France, [3]CHU Grenoble, Grenoble, France, [4]Department of Internal Medicine, Centre Hospitalier Bretagne Atlantique de Vannes, Vannes, France, [5]CHU, Marseille, France, [6]CHU, Toulouse, France, [7]Saint Louis, Paris, France, [8]Service de Dermatologie, Hôpital Cochin, AP-HP, Paris, France, [9]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France.

Background/Purpose: Hypocomplementemic urticarial vasculitis (HUV), an uncommon vasculitis of unknown etiology, is rarely reported. It is also called anti-C1q vasculitis in the 2012 revised International Chapel Hill Consensus Conference Nomenclature for Vasculitis. Information on its presentation and therapeutic management is scarce.

Methods: To analyze the clinical spectrum and therapeutic management of HUV patients, we conducted a French nationwide retrospective and transdisciplinary study on behalf of the FVSG that included 57 patients with chronic urticaria, histological leukocytoclastic vasculitis and hypocomplementemia as inclusion criteria.

Results: The 57 identified patients had a median age at diagnosis of 45 (range 15–83) years, and 42 (74%) were women (sex ratio 2.8). HUV was

isolated in 43 (75%) patients, while the remaining 14 (25%) were associated with systemic lupus erythematosus (n=10), primary Sjögren's syndrome (n=2), systemic sclerosis and lung cancer (n=1 each). Urticarial lesions were typically erythematous papules, more pruritic than painful, associated with angioedema (51%), purpura (35%) and/or livedo reticularis (14%). Extracutaneous manifestations included constitutional symptoms (56%), musculoskeletal (82%), ocular (56%), pulmonary (19%), gastrointestinal (18%) and/or kidney involvement (14%). HUV patients typically had low C1q-complement and normal C1-inhibitor levels, with 55% of them also having anti-C1q antibodies. Patients with anti-C1q antibodies had more frequent systemic HUV, angioedema, livedo reticularis, ocular, musculoskeletal and/or kidney involvement(s), and less frequent pulmonary and/or gastrointestinal involvement(s). Hydroxychloroquine (HCQ) or colchicine seemed to be as effective as corticosteroids as first-line therapy. For patients with relapsing and/or refractory HUV, higher cutaneous and immunological response rates were obtained with immunosuppressants, particularly azathioprine (AZA), mycophenolate mofetil (MMF), cyclophosphamide or rituximab (RTX)-based regimens, with the latter apparently more effective. Finally, cutaneous and immunological responses were strongly associated.

Conclusion: HUV is an uncommon systemic and relapsing vasculitis with various manifestations, mainly musculoskeletal and ocular. Half of the patients have anti-C1q antibodies. HCQ and colchicine should be the first-line therapy, whereas corticosteroids alone or combined with an immunosuppressant, preferentially AZA, MMF or RTX, could be alternative therapeutic options for relapsing and/or refractory disease.

Non-Systemic Vasculitic Neuropathy: Presentation, Therapeutic Management and Outcome. Benjamin Terrier[1], Fleur Cohen[2], Aude Rigolet[3], Jean-Emmanuel Kahn[4], Alice Berezne[5], Olivier Benveniste[6], Alain Créange[7], Thierry Maisonobe[8], Zahir Amoura[9], Luc Mouthon[10] and Loïc Guillevin for the French Vasculitis Study Group[10]. [1]Cochin Hospital, Paris, France, [2]Pitié-Salpétrière, Paris, France, [3]Assistance Publique - Hôpitaux de Paris, Pitié-Salpêtrière University Hospital, Paris, France, [4]Internal Medicine, Foch Hospital, Suresnes, France, [5]Paris Descartes University, Internal Medicine department, Cochin Hospital, Paris, France, [6]Sorbonne Universités, University Pierre et Marie-Curie-Paris 6, INSERM, Paris, France, [7]Henri Mondor, Créteil, France, [8]Pitie-Salpetriere Hospital, Paris, France, [9]Pitié-Salpêtrière Hospital (AP-HP), Paris, France, [10]National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, Paris, France.

Background/Purpose: Non-systemic vasculitic neuropathy (NSVN) is a small-to-medium–sized vessel vasculitis limited to the peripheral nervous system. It can be considered a single-organ vasculitis, as recently defined in the revised International Chapel Hill Consensus Conference Nomenclature of Vasculitides in 2012. NSVN is probably an underdiagnosed entity that has rarely been reported. This descriptive study was undertaken to ascertain its presentation, therapeutic management and outcome.

Methods: We retrospectively analyzed 18 patients with NSVN fulfilling criteria proposed by Collins in 2010, including: 1) peripheral neuropathy, 2) vasculitis histologically proven on neuromuscular biopsy, 3) possible constitutional symptoms, and 4) absence of systemic manifestations or laboratory markers suggestive of systemic vasculitis or connective tissue disease.

Results: Ten women and 8 men, median age 51 (range 27–83) years, were included. Neurological manifestations were characterized by acute onset (78%), mononeuritis multiplex (88%), polyneuropathy (12%), sensory impairment (100%) and motor impairment (88%). Neurological manifestations were painful (88%) and asymmetrical (78%). Nerve trunks involved were external popliteal (94%), internal popliteal (44%), ulnar (33%), radial (17%) and median (11%). General symptoms included asthenia and weight loss >10% (22% each), arthralgias (12%) and fever (6%). Only 2 patients had elevated inflammatory parameters. Neuromuscular biopsy showed, in muscle or nerve, medium-sized-vessel vasculitis (56%) or small-sized-vessel vasculitis (44%), with fibrinoid necrosis (88%). Corticosteroids were prescribed to 94%, and their NSVN regressed significantly (65%), stabilized (2%) or progressed (24%). Cyclophosphamide was added to corticosteroids for refractory patients. Relapsing patients received methotrexate or azathioprine, with 3/4 patients showing improvement. After median follow-up of 47 months, neurological sequelae were noted in 83%, including sensory sequelae in 15 patients and motor sequelae in 6.

Conclusion: The results of this study describing NSVN presentation, therapeutic management and outcome indicated that acute onset, painful and asymmetrical manifestations are suggestive of NSVN. Half of the patients required immunosuppressive agents because of relapsing and/or refractory disease. Sensory and motor sequelae were common, suggesting that early diagnosis and initiation of therapy are critical.

Background/Purpose: To describe characteristics, treatment and outcome of patients with systemic inflammatory or autoimmune diseases (SAID) and myelodysplastic syndrome (MDS).

Methods: For this retrospective study, a questionnaire was sent to SNFMI, CRI and GFM to report patients with SAID and MDS, concomitantly or successively. SAID were classified according to usual diagnostic criteria. Exclusion criteria included 1) MDS diagnosed > 12 months after immunosuppressive treatment for SAID 2) infectious, drug-related or neoplasm-related SAID. MDS characteristics, outcome, survival were compared between patients with MDS associated SAID and a cohort of 665 MDS without SAID diagnosed at Avicenne's university hospital between 2003 and 2013.

Results: 123 patients with both MDS and SAID (mean age, 70±13 years; 41 females and 82 males, baseline characteristics in table 1) were included. SAID was systemic vasculitis in 39 cases (32%), connective tissue diseases in 31 cases (25%), inflammatory arthritis in 28 cases (23%), neutrophilic disorder in 12 cases (10%) and unclassified in 13 cases (11%). Complete diagnostic SAID criteria were fulfilled in 66% of cases, remained incomplete

in 21% and SAID was unclassified in the remaining patients. The diagnosis of SAID and MDS was concomitant in 38 (31%) cases, diagnosis of SAID preceded MDS in 46 (37%) cases and was made after MDS in 39 (32%) cases, with the time between the diagnoses of the 2 diseases being 8.6±52 months. Apart from significant association between Chronic myelomonocytic leukemia (CMML) and systemic vasculitis (p=0.0024), no correlation was seen between specific types of SAID and of MDS. A response to SAID first line treatment (mainly steroids), was observed in 83% of the 118 treated cases, including 80% for steroids alone. A second-line treatment was required for steroid dependence or relapse in 48% of the patients. Among treated patients who received biologic targeted treatments at any time (n=27), overall response of SAID (partial or complete) was noted in 9/20 (45%) patients. Among 16 patients treated by azacytidine for their MDS, SAID remission was seen at 3 months in 75% of the cases, with a significant decrease of acute-phase reactants and steroid amounts required. At last follow-up, 37 patients (67%) with stable MDS had remission of SAID, and among patients with MDS progression, 23 patients (56%) also had active SAID (p=0.2).

Conclusion: The spectrum of SAID associated to MDS is variable, many cases remain difficult to classify. Presence of SAID has no impact on the overall survival of MDS patients. Azacitidine can improve SAID in 75% of the patients. Because of frequent steroid dependence and relapse of SAID, better therapeutic strategies with biological targeted drugs are required, while larger use of MDS specific dugs like azacitidine must be assessed prospectively.

Table 1. Baseline characteristics of patients with MDS-associated to SAID and MDS without SAID.

	MDS with SAID N=123	MDS without SAID N=665
Age (years)	70 ± 13	73 ± 11*

Effectiveness of a Sequential Treatment with Intravenous Prostaglandins Followed By Bosentan in Patients with Buerger Disease and Severe Ischemic Lesions: A Case Series. Helena Borrell[1], Javier Narváez[2], Milagros Ricse[1], Eulalia Armengol[1], Andrea Zacarias[1], Sergi Heredia[1], Carmen Gomez Vaquero[1] and Joan Miquel Nolla[1]. [1]Hospital Universitario de Bellvitge, Barcelona, Spain, [2]Hospital Universitario de Bellvitge. Barcelona. Spain, Barcelona, Spain.

Background/Purpose: Buerger disease or tromboangitis obliterans (TAO) is a distinct form of systemic vasculitis of unknown etiology though strongly linked to cigarette smoking. It affects the small and medium-sized arteries and veins in the extremities of the limbs, frequently requiring amputation. Tobacco withdrawal is the only known effective treatment. Endothelial dysfunction appears to be of relevance in this condition and a report has even found that high serum levels of endothelin correlate with the presence of necrosis.

This prelimary study assessed the effectiveness and safety of a sequential treatment with intravenous prostaglandins followed by bosentan in patients with severe TAO.

Methods: A series of patients with TAO and severe ischemic ulcer or gangrene were treated with intravenous alprostadil (PGE-1) for 21 days, followed by bosentan p.o at dose of 62.5 mg twice daily during the first month, which was thereafter up-titrated to 125 mg twice daily. Bosentan was administered on a compassionate-use basis. The study endpoints were clinical improvement of the pain and trophic lesions and the need of amputation.

Results: To date, 4 patients have been included, all of them fulfilling the diagnostic criteria proposed by *De Olin (Current Opin Reumatol 2006;18: 18–24)*. Two patients were male and 2 women, with a mean age of 45 years. All patients were current smokers and withdrawn tobacco during follow-up as well as received antiaggregants.

In all cases a complete healing was achieded within the first 4 months after starting the sequential treatment, with disappearance of pain and complete healing of the ischemic lesions in the patient's toes. None of the patients required amputation. Bosentan could be stopped after a mean of 12 months (SD: 4.22, range 10–14), without relapses. After discontinuation of bosentan, patients were followed for a median of 21 months (4.54; 14–24) and none developed new ischemic lesions.

In all patients bosentan was well tolerated, without any observed adverse reaction.

Conclusion: This preliminary data suggest that a sequential treatment with intravenous prostaglandins followed by bosentan may be considered a therapeutic option for patients with TAO and severe ischemic lesions. Larger studies are required to confirm these results.

2781

Cost-Effectiveness of Adding Etanercept Vs. Sulfasalazine and Hydroxychloroquine to Methotrexate Therapy: A Randomized Noninferiority Trial. Nick Bansback[1], Ciaran Phibbs[2], Huiying Sun[3], James R. O'Dell[4], Mary Brophy[5], Edward C. Keystone[6], Sarah Leatherman[7], Ted R. Mikuls[4] and Aslam H. Anis[3]. [1]University of British Columbia, Vancouver, BC, [2]Palo Alto VA Health Care System, Menlo Park, CA, [3]Centre for Health Evaluation and Outcome Sciences, Vancouver, BC, [4]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [5]VA Boston Heathcare System, Boston, MA, [6]University of Toronto, Toronto, ON, [7]VA Boston Heatlhcare System, Boston, MA.

Background/Purpose: To estimate the incremental cost-effectiveness of etanercept plus methotrexate versus a triple regimen of disease-modifying anti rheumatic drugs (methotrexate, sulfasalazine, and hydroxychloroquine) over 24 weeks and 48 weeks in patients with active rheumatoid arthritis despite methotrexate therapy (RACAT).

Methods: In this double blind, noninferiority trial 353 patients were randomized to etanercept plus methotrexate or a triple regimen. After 24 weeks of treatment patients not achieving a DAS28 improvement of 1.2 were switched in a blinded fashion to the other therapy. Quality Adjusted Life Years (QALYs) were estimated using US societal values from the EQ-5D instrument which was measured every 24 weeks. Costs of drugs, hospitalizations, procedures, tests, visits and lost productivity were prospectively tracked and monetized from a societal perspective in 2014 US dollars. Incremental cost-effectiveness ratios were calculated using standard procedures assuming an intent-to-treat analysis, with missing data analyzed using multiple imputation and uncertainty assessed using bootstrapping.

Results: Both strategies showed significant improvements in EQ-5D, with etanercept providing marginally more accumulated QALYs (0.358 vs 0.354 over 24 weeks, and 0.742 vs 0.726 over 48 weeks for etanercept and triple regimen strategies respectively). The etanercept strategy accumulated

substantially higher drug costs even considering the switches between treatements at 24 weeks ($11,286 vs $369 cumulative costs from 0 to 24 weeks, and $19,625 vs $3,721 cumulative costs from 0 to 48 weeks for etanercept and triple regimen respectively). The differences in other health care and productivity costs across strategies were negligible. The resultant incremental cost-effectiveness ratios for etanercept vs. triple regimen were $2.7 million/QALY (95%CI 0.87 to ∞) gained over 24 weeks and $0.95 million/QALY (95%CI 0.41 to ∞) over 48 weeks.

Conclusion: This economic evaluation based on a prospective tracking of resource use and QALY measurement in a blinded, randomized trial demonstrates that the additional costs associated with using etanercept prior to a triple regimen does not provide good value for money at generally acceptable willingness to pay thresholds. A limitation of the study is its short time frame. However, even when considering the long-term perspective, since the incremental benefits are so small, even under the most optimistic scenarios imaginable, etanercept has only a small probability of being cost-effective compared to triple therapy. Given the opportunity cost associated with all health care spending, adapting a triple regimen prior to etanercept would free up scarce health dollars for use on alternative health care interventions that provide greater health benefits.

Klassen[2], James R. O'Dell[4], Zhixin Zhang[1] and Kaihong Su[1]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [3]University of Nebraska Medical Center, Lincoln, NE, [4]Veteran Affairs Nebraska Western Iowa Health Care System and University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: Anti-citrullinated protein antibodies (ACPAs) are highly specific for rheumatoid arthritis (RA) and also believed to play a pathogenic role in RA. *Porphyromonas gingivalis* (*P. gingivalis*), a Gram negative oral pathogen associated with periodontitis, has long been speculated as a trigger for the anti-citrulline autoimmune responses in RA patients. However, the detail relation between ACPA and *P. gingivalis* is still unclear.

Methods: In this study, we made 195 recombinant monoclonal antibodies from anti-cyclic citrullinated peptide (CCP)-positive RA patients (N=6), 23 recombinant monoclonal antibodies from CCP-negative RA patients (N=1), and 110 recombinant monoclonal antibodies from healthy controls (N=4) using a single cell-based antibody cloning approach. All the 7 RA patients satisfied the 2010 ACR classification criteria. Monoclonal ACPAs were determined by commercial anti-CCP test and fine specificity with 3 synthesized citrullinated peptides. Cross-reactivity of ACPA to *P. gingivalis* was tested by ELISA against *P. gingivalis* outer membrane protein and citrullinated peptide from *P. gingivalis* enolase. Immunoglobulin genes of 5 ACPAs were reverted to the germ line sequences and the corresponding antibodies were also expressed for the above tests.

Results: The relative frequencies of circulating plasmablasts were significantly higher in RA patients than in healthy donors ($p = 0.0015$). About 19.5% of circulating plasmablast-derived recombinant antibodies from CCP-positive RA patients, but none from the CCP-negative RA patient or healthy donors, specifically recognized citrullinated RA autoantigens ($p = 0.0001$). The immunoglobulin genes encoding these ACPAs were highly mutated with increased replacement/silent mutation ratios, suggesting that the generation of ACPAs involved active antigen selection. Interestingly, 63% of these ACPAs cross-reacted with the outer membrane antigens and/or citrullinated enolase from *P. gingivalis*. Germ-line reversions of some ACPAs completely eliminated their reactivity to citrullinated RA autoantigens but retained their reactivity to *P. gingivalis* antigens.

Conclusion: These results suggest that circulating plasmablasts in RA patients produce ACPAs and this process may be, in part, initiated by the anti-*P. gingivalis* immune responses.

Effect of Synovitis, Effusion and Bone Marrow Lesions on Development of Sensitization in Knee OA: The Multicenter Osteoarthritis Study.

Tuhina Neogi[1], Michael C. Nevitt[2], Joachim Scholz[3], Lars Arendt-Nielsen[4], Clifford Woolf[5], Laurence A. Bradley[6], Emily K. Quinn[7] and Laura Frey-Law[8]. [1]Boston University School of Medicine, Boston, MA, [2]UCSF (University of California, San Francisco), San Francisco, CA, [3]Columbia University, New York, NY, [4]Center for Sensory-Motor Interaction, Aalborg, Denmark, [5]Children's Hospital Boston, Boston, MA, [6]Univ of Alabama-Birmingham, Birmingham, AL, [7]Boston University, Boston, MA, [8]University of Iowa, Iowa City, IA.

Background/Purpose: Alterations in the peripheral and central nervous systems including sensitization are thought to play an important role in the pain experience in knee OA. While sensitization could occur due to an underlying predisposition, it is hypothesized that joint inflammation and/or tissue injury in OA could provide sufficient peripheral nociceptive input to cause sensitization. We previously reported that radiographic knee OA severity or duration do not appear to be related to sensitization. However, whether specific MRI lesions related to inflammation (e.g., synovitis, effusion), or mechanical load or remodeling related to noninflammatory tissue injury (e.g., bone marrow lesions (BMLs)) are risk factors for development of sensitization is not yet known.

Methods: The Multicenter Osteoarthritis (MOST) Study is a NIH-funded longitudinal cohort of persons with or at risk of knee OA. Subjects had x-rays and MRIs (1.0 T) of each knee obtained at each study visit, and a standardized somatosensory evaluation of mechanical temporal summation and pressure pain thresholds (PPT) at the patella at 60- and 84-months. Temporal summation was defined by increased pain during repeated mechanical stimulation (1 Hz × 30-sec) with a 60g monofilament. PPT was assessed with an algometer (1 cm^2 tip, 0.5 Kg/sec) as the point at which the subject felt the pressure change to slight pain. Lower PPT indicates more sensitivity. Synovitis, effusion and BMLs on MRIs were scored using WORMS (one knee per person); these lesions were considered to be present if their score was ≥1 in any subregion. In sensitivity analyses, we assessed the sum of BML scores across all knee subregions as a measure of BML burden. We assessed the relation of presence of synovitis, effusion, and BMLs at 60-mo to incident temporal summation in the same knee at 84-mo among those who did not have temporal summation at 60-mo, and to change in PPT in the same knee between 60- and 84-mo in the whole sample using logistic and linear regression, respectively, adjusted for relevant potential confounders, including OA severity.

Results: There were 1111 subjects (mean age 66.9, mean BMI 29.7, 62% female) in the whole sample. 22.6% developed incident temporal summation at the 84-mo visit, and the range in change of PPT between the 60- and 84-mo visits was −7.35 to 7.15 kg/cm^2. Presence of synovitis was associated with a significant decrease in PPT (i.e., more sensitized) over 24 mo, while effusion was significantly associated with incident temporal summation (**Table**). BML presence or burden were not associated with temporal summation or PPT.

Conclusion: Inflammation, as evidenced by synovitis or effusion, may drive the occurrence of sensitization in knee OA. In contrast,

BMLs do not appear to contribute to sensitization in knee OA. Early targeting of inflammation in knee OA may be a reasonable strategy to test for its ability to prevent occurrence of sensitization, thereby reducing pain severity in knee OA.

MRI Lesion at 60-mo	Incident Temporal Summation at 84-mo (N=716)		Change in PPT (60- to 84-mo) (N=1111)	
	Prevalence of MRI Lesion	Adjusted* OR (95% CI)	Prevalence of MRI Lesion	Adjusted* Beta (95% CI)
Presence of synovitis	62%	1.12 (0.75, 1.66), p=0.6	60%	−0.30 (−0.52, −0.08), p=0.01
Presence of effusion	67%	1.54 (1.01, 2.36), p=0.04	66%	−0.04 (−0.28, 0.19), p=0.7
Presence of BMLs	79%	0.92 (0.56, 1.49), p=0.7	79%	0.03 (−0.25, 0.31), p=0.8
Sum of BMLs ('BML burden') (per unit increase)	Range: 0–19	1.00 (0.92, 1.07), p=0.9	Range: 0–19	−0.01 (−0.05, 0.04), p=0.8

Contribution at the Spinal Level of Innate and Adaptive Immunity to the Development of Persistent Post-Inflammatory Mechanical Allodynia in Arthritic Mice. Sarah Woller[1], Cody Ocheltree[1], Tony Yaksh[1] and Marpiat Corr[2]. [1]UCSD, La Jolla, CA, [2]University of California at San Diego, La Jolla, CA.

Background/Purpose: Individuals with arthritis frequently develop persistent pain despite adequate treatment of synovitis. There is a need to better understand the mechanisms underlying pain occurring with arthritis. Recently, it has been shown that Toll-like receptor 4 (TLR4) mediates the transition from acute to chronic pain in a murine model of arthritis. Rather than developing persistent pain, animals deficient in TLR4 showed an attenuation of the late phase of pain. This receptor is unique in signaling through both MyD88-dependent and independent pathways. In order to further understand the role of TLR signaling, we examined the development of arthritis and persistent pain in mice deficient in these adaptor proteins.

Methods: Adult arthritic K/BxN mice were bled and the sera pooled. 100μl of the pooled sera was injected into recipient mice on Days 0 and 2. Clinical arthritis scores and mechanical reactivity, using the up-down method of von Frey testing, were assessed over a period of 28 days in male C57Bl/6, *Tlr4*$^{-/-}$, *Trif*^{lps2}, *Myd88*$^{-/-}$, *Tnf*$^{-/-}$, and *Ifnar1*$^{-/-}$ mice. Spinal cords were collected from WT and *Tlr4*$^{-/-}$ arthritic mice and changes in gene expression were measured using nanoString™ nCounter™ analysis. Behavioral data were analyzed using repeated measures ANOVAs, and Duncan New Multiple Range *post-hoc* analyses when appropriate.

Results: As shown previously, WT mice develop a persistent increase in mechanical reactivity that outlasts the period of inflammation; the 50% withdrawal thresholds dropped from 1.66 at baseline to 0.74 on day 28. In addition, *Tlr4*$^{-/-}$ mice develop an initial increase in reactivity, which resolves concurrent with inflammation (WT AUC 13.2 and TLR4 AUC 9.7, $p<.05$). MyD88 and TRIF play distinct roles in the development of pain: mice lacking MyD88 do not develop swelling or allodynia (AUC 2.6, $p<0.01$), while those deficient in TRIF develop a *prolonged* allodynia (AUC 12.2), similar to WT animals and outlasting the period of inflammation. NanoString™ nCounter™ analysis of 516 immune genes in the spinal cords of WT and *Tlr4*$^{-/-}$ mice harvested on Day 10 of arthritis showed differences in expression levels of IL2, RANKL, IFNβ, and TNF transcripts. Therefore, we also examined the development of pain resulting from arthritis in *Rag1*$^{-/-}$, *Ifnar1*$^{-/-}$, and *Tnf*$^{-/-}$ mice. In the *Tnf*$^{-/-}$ mice there was an attenuated development of pain (AUC 8.0, $p<.001$), the Rag1 (10.0, $p<.05$) mice developed pain, which resolved with the resolution of inflammation similar to *Tlr4*$^{-/-}$ mice and *Ifnar1*$^{-/-}$ mice developed pain that was not different than the WT mice (AUC 12.2).

Conclusion: These results suggest that pain can persist after resolution of inflammation. The innate and adaptive immune systems appear to have distinct roles in the development of the chronic pain state, and this pain cannot be attributed solely to increased TNF or IFNβ transcription.

Joint Specific Positional Differences in Coding and Noncoding Transcriptome of Synovial Fibroblasts As a Determinant of the Susceptibility of Synovial Joints to Rheumatoid Arthritis. Caroline Ospelt[1], Maria Armaka[2], Giancarlo Russo[3], Anna Bratus[3], Michelle Trenkmann[4], Emmanuel Karouzakis[1], Christoph Kolling[5], Renate E. Gay[4], George Kollias[2], Steffen Gay[1] and Mojca Frank Bertoncelj[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Biomedical Sciences Research Center 'Alexander Fleming', Vari, Greece, [3]Functional Genomics Center Zurich, ETH Zurich and University of Zurich, Zurich, Switzerland, [4]Zurich University Hospital, Zurich, Switzerland, [5]Schulthess Clinic, Zurich, Switzerland.

Background/Purpose: The molecular mechanisms underlying the topographic differences in the susceptibility of synovial joints to develop rheumatoid arthritis (RA) are unknown. Positional embryonic expression of Hox genes along proximal-distal and anterior-posterior body axes is critical for proper limb development. Adult skin fibroblasts retain the positional embryonic Hox code and exhibit major anatomic differences in their transcriptome, defining their unique positional identities. Synovial fibroblasts (SF) in the joints of RA patients drive joint destruction and inflammation locally. We hypothesized that SF from different joints show a joint specific, positional gene expression pattern, which can predispose joints to develop certain types of arthritides, like RA or osteoarthritis (OA).

Methods: SF were derived from knees, shoulders and metacarpophalangeal joints (MCPs) of RA and OA patients (n=9 each) undergoing joint replacement surgery. SF were obtained also from front paws, ankles and knees of wildtype (wt) and TNF transgenic (TNFtg) mice (n=7 each). Total RNA was extracted and RNA sequencing was performed with the Illumina HiSeq 2000 sequencing system followed by hierarchical clustering. Functional annotation clustering of mRNAs was done using Database for Annotation, Visualization, and Integrated Discovery (DAVID). Positionally expressed RNAs were validated by qPCR.

Results: Unsupervised hierarchical cluster analysis showed clustering of SF according to anatomic joint localization rather than disease. The positional embryonic HOX code was retained in SF, clearly differentiating between different joints. Among the Hox cluster residing long noncoding RNAs, HOTTIP was expressed in distal, MCP-derived SF and HOTAIR in posterior, knee-derived SF. Several positionally expressed mRNAs, e.g.HOXC8 and HOXD13, were differentially expressed in MCP-derived RA and OA SF. DAVID analysis showed positional enrichment of GOTERM limb development, anterior/posterior patterning, cartilage development, extracellular region part, cell adhesion, regulation of transcription. While some outliers where found when clustering was based on mRNA expression, clustering of SF into knee, shoulder and MCPs was perfect when based on miR expression. For example, miR-24 was positionally expressed in shoulder, miR-34c in MCP, and miR-137 in knee-derived SF, irrespective of disease. The positional expression of these miRs was confirmed in wt and TNFtg mice. Interestingly, miR-204 and miR-146a were positionally expressed in MCPs of OA but not of RA patients. These miRs were indeed positional also in wt mice but their MCP specific expression in humans correlated to ankle specific expression in wt mice. In addition, their expression was significantly changed in ankles of TNFtg compared to wt mice.

Conclusion: SF from joints of different anatomic sites exhibit particularly different mRNA and miR expression patterns suggesting that functionally unique subsets of SF populate different joints. The existence of positionally imprinted "risk" signatures of SF may account for the susceptibility of certain synovial joints to develop RA in humans and mice and may have major implications for synovial disease pathways operating early in RA.

Aortitis: Outcomes from a Cohort of 196 Patients. Alison Clifford, Amr Arafat, Jahanzaib Idrees, Eric Roselli, Carmela D. Tan, E. Rene Rodriguez, Lars Svensson, Eugene Blackstone and Gary S. Hoffman. Cleveland Clinic Foundation, Cleveland, OH.

Background/Purpose: Idiopathic aortitis is a rare diagnosis that may occur in the context of a primary systemic vasculitis, as part of a systemic autoimmune disease, or in isolation. In patients with focal isolated aortitis

(FIA), surgery alone may be curative; however, new vascular lesions have been reported to develop in between 5–47% of cases. The risk of progression to systemic disease and optimal management strategy for FIA patients is uncertain.

Methods: Patients with biopsy-proven aortitis, diagnosed following thoracic aortic surgery at the Cleveland Clinic between 1996 and 2012, were retrospectively reviewed. Patients were classified into clinical subgroups [Giant cell arteritis (GCA), Takayasu's arteritis (TAK), Focal Isolated Aortitis (FIA) or Other] at the time of surgery using pre-defined criteria. Symptoms, pathology, laboratory and imaging results were recorded at surgery and over time using a standardized database. Patients with FIA at surgery were followed for progression to systemic disease and outcomes of clinical subgroups were compared.

Results: Of 7,551 patients who underwent thoracic aortic surgery between 1996–2012, 196 patients with biopsy-proven aortitis were identified for review. Median age at surgery was 69 years (range 15–88) and 67% were female. At the time of surgery, 129 (65.8%) patients met criteria for FIA, 42 (21.4%) for GCA, 14 (7.1%) for TAK, and 11 (5.6%) for Other. A minimum of 6 months of clinical follow-up was available for 73 FIA patients. During follow-up (median 45 months, range 6–201 months), 14/73 (19.2%) FIA patients developed symptoms of systemic disease, 17/40 (42.5%) developed elevated inflammatory markers, 29/65 (44.6%) developed new vascular lesions on imaging, 30/73 (41.1%) required a second vascular surgery, 7(9.6%) dissected and 9 died (12.3%.) Ultimately 23 of 73 (31.5%) with FIA progressed to have features of a systemic disease: 21 GCA, 1 TAK, and 1 Other. When compared to patients with known systemic disease at surgery, patients with FIA were less likely to develop symptoms ($p=0.01$) but no different with respect to development of elevated inflammatory markers ($p=0.19$), new vascular lesions by imaging ($p=0.92$), need for further vascular surgery ($p=0.84$), dissection ($p=0.40$) or death ($p=0.76$) over time. Only 12 patients with FIA at surgery received immunosuppressive therapy post-operatively. Over time, 0/11 treated FIA patients with follow-up imaging developed aneurysms, but 2 (18.2%) developed new stenoses. Among the 54 untreated FIA patients with imaging available, 27 (50%) developed new lesions (23 aneurysms and 5 stenoses.) Additional tissue obtained after subsequent surgery in 2 untreated FIA patients revealed persistent inflammation in the distal aorta.

Conclusion: Over time, nearly one third of patients classified as FIA at the time of surgery progressed to have features of a systemic autoimmune disease. Patients with FIA are less likely to develop overt symptoms, but equally likely to develop elevated inflammatory markers or new vascular lesions on imaging when compared to GCA, TAK and Others. These patients require regular clinical follow-up and serial imaging to assess for progression.

Identification of Urinary Biomarkers for Lupus Nephritis. Carolina Landolt-Marticorena[1], Stephenie Prokopec[2], Heather Reich[3], James Scholey[4], Carmen Avila-Casado[3], Paul R. Fortin[5], Paul Boutros[2] and Joan Wither[6]. [1]Toronto Western Hospital, Toronto, ON, [2]Ontario Institute for Cancer Research, Toronto, ON, [3]University Health Network, Toronto, ON, [4]The Toronto Western Hospital, Toronto, ON, [5]Laval University, Division of Rheumatology, Centre de Recherche du CHU de Québec and Department of Medicine, Quebec City, QC, [6]University of Toronto, Toronto, ON.

Background/Purpose: Lupus nephritis (LN) is a major determinant of morbidity and mortality in Systemic Lupus Erythematosus (SLE). Variability in clinical course, underlying renal injury, and response to treatment pose therapeutic challenges. Management of LN would be served by the discovery of biomarkers that accurately reflect changes in disease activity, aiding in the prompt identification of flares and evaluation of response to therapy. Renal biopsy is the most reliable way to determine the extent and nature of renal injury, with serologic changes (anti-dsDNA antibodies) or measures of renal dysfunction (proteinuria) faltering in the diagnosis of impending flares and/or assessment of therapeutic response. We used a proteomics approach to identify potential urinary biomarkers associated with LN.

Methods: Urine was obtained from 60 LN patients within 2 weeks of biopsy, 25 active non-LN SLE patients, and 24 controls. The mean age and proportion of females (83–88%) was similar in the 3 groups. 128 distinct analytes were quantified by Luminex and normalized by scaling to urinary creatinine levels. Data was analyzed by hierarchical clustering using divisive analysis (DIANA), linear modeling, and non-parametric statistics, with appropriate corrections for multiple comparisons.

Results: LN and non-LN SLE patients had comparable SLEDAI-2K scores (13.8 ± 7.6 and 11.1 ± 3.9, respectively), with the majority of the SLEDAI-2K in LN patients arising from the renal indices (renal SLEDAI = 8 ± 4.3). The distribution of the renal biopsy classes (ISN-RPS) for the LN patients was: I – 1; II-3; III or III/V-12; IV or IV/V-32; V-9; VI-2; TIN-1. The mean biopsy activity and chronicity scores biopsy were 6.68 (range 0–19) and 3.13 (range 0–10), respectively. Following hierarchical clustering, significant clustering was seen for LN as compared to non-LN SLE patients and healthy. Linear modeling was used to determine the urinary proteins whose abundance differed significantly between disease states (SLE vs healthy control) and between the presence or absence of LN (active LN vs active non-LN). There were 9 analytes that differed significantly (q value <0.01) between SLE patients and controls and 42 between LN and non-LN, of which 37 differed only in LN patients as compared to active non-LN patients. A number of proteins, not previously proposed as urinary LN biomarkers (e.g., MMP-2, TIMP-1), and known candidate LN biomarkers (e.g., adiponectin), were identified, with several of the novel biomarkers showing an enhanced ability to discriminate between LN and non-LN patients over potential biomarkers reported in the literature. Ten proteins were found to significantly correlate with the activity score on renal biopsy ($q < 0.01$), 5 of which (IP-10, vWF, adiponectin, IL-16 and PAI-1) strongly discriminated between active proliferative and non-proliferative/chronic renal lesions.

Conclusion: Using a proteomics approach we identified promising urinary biomarkers that correlated with the presence of active renal disease and/or renal biopsy changes. Experiments to assess the ability of these candidate biomarkers to fluctuate over time and predict clinically significant changes in renal disease activity and outcome are ongoing.

Preliminary Population- Based Incidence and Prevalence Estimates of SLE: The California Lupus Surveillance Project. Maria Dall'era[1], Kurt Snipes[2], Miriam Cisternas[3], C. Gordon[4] and Charles G. Helmick[5]. [1]University of California, San Francisco, San Francisco, CA, [2]California Department of Public Health, Sacramento, CA, [3]MGC Data Services, San Diego, CA, [4]Medical School, Birmingham, United Kingdom, [5]Centers for Disease Control and Prevention, Atlanta, GA.

Background/Purpose: Previous estimates of prevalence and incidence of systemic lupus erythematosus (SLE) in the United States have varied widely. The California Lupus Surveillance Project (CLSP) is part of a national effort funded by the Centers for Disease Control and Prevention (CDC) to determine more credible estimates of incidence and prevalence of SLE, with a special focus on Hispanics and Asians.

Methods: The CLSP is a population-based registry designed to determine the incidence and prevalence of SLE in San Francisco County, California. Sources of cases included hospitals, rheumatologists, nephrologists, commercial laboratories, and state population databases. Over 15,000 potential SLE patients were identified after the initial queries, and trained abstractors performed detailed medical chart reviews on the >5,500 patients who met the catchment criteria of residence in San Francisco County within the years of 2007–2009. Cases were defined as patients with documentation of $>$ 4/11 of the ACR Classification Criteria for SLE. Using SAS 9.3, we calculated prevalence and incidence rates and associated 95% confidence intervals (CI). Denominators for all rates were obtained from the U.S. Census data (revised 2000–2009 intercensal population files) for San Francisco County.

Results: Preliminary overall crude prevalence and incidence of SLE in San Francisco County were 90.4/100,000 and 5.1/100,000 respectively. The highest prevalence of disease was observed in Black women (430.6/100,000), followed by Hispanic and Asian (163.8/100,000 and 158.9/100,000, respectively), and White (111.3/100,000) women (Table I).

Table I: Preliminary Prevalence and Incidence Rates (per 100,000) of SLE in San Francisco County, CA

Race/ethnicity, sex	Prevalence (2007) # cases	Prevalence (2007) Crude rate (95% CI)	Incidence (2007–2009) # cases	Incidence (2007–2009) Crude rate (95% CI)
Overall	704	90.4 (84.0–97.3)	121	5.1 (4.3–6.1)
Women	623	162.0 (149.8–175.2)	112	9.6 (8.0–11.5)
Men	81	20.6 (16.5–25.5)	9	0.7 (0.4–1.4)
Black	138	243.0 (205.7–287.0)	27	15.9 (10.9–23.1)
Women	121	430.6 (360.5–514.2)	25	29.9 (20.3–44.2)
Men	17	59.2 (37.0–94.9)	2	2.3 (0.6–8.4)
White	255	58.1 (51.4–65.7)	43	3.2 (2.4–4.3)
Women	230	111.3 (97.8–126.6)	38	6.0 (4.4–8.3)
Men	25	10.8 (7.3–15.9)	5	0.7 (0.3–1.7)
Asian	264	95.8 (84.9–108.1)	39	4.6 (3.4–6.3)
Women	233	158.9 (139.8–180.7)	37	8.3 (6.0–11.4)
Men	31	24.0 (16.9–34.1)	2	0.5 (0.1–1.9)
Hispanic	99	87.7 (72.1–106.8)	17	4.9 (3.1–7.8)
Women	87	163.8 (132.9–202.0)	16	9.8 (6.0–15.9)
Men	12	20.1 (11.5–35.1)	1	0.5 (0.1–3.1)

Conclusion: The CLSP uses more complete case finding methods to provide current estimates of prevalence and incidence in a racially and ethnically diverse population. Racial and ethnic disparities in SLE were confirmed with the highest burden of disease in Black women, followed by Hispanic and Asians, and, finally, White women.

Medical Marijuana Related Outcomes in Patients with Systemic Lupus Erythematosis. Basmah Jalil[1], Wilmer Sibbitt Jr[2], Romy Cabacangun[3], Clifford Qualls[3], Arthur Bankhurst[4] and Roderick Fields[5]. [1]University of New Mexico, Albuquerque, NM, [2]University of New Mexico HSC, Albuquerque, NM, [3]UNM, Albuquerque, NM, [4]University of NM Med Ctr, Albuquerque, NM, [5]University of New Mexico School of Medicine, Albuquerque, NM.

Background/Purpose: Medical cannabis is used extensively in the United States, usually in the form of smoked marijuana. There is growing research regarding the immunomodulatory effects of cannabinoids and the cannabinoid receptor system as a possible therapeutic target. Despite the increasing use of medical marijuana, almost all studies report short–term subjective effects of medical cannabis with little to no real outcome data in medical disease and systemic lupus erythematosus (SLE) in particular. Randomized, controlled trials of smoked cannibis are generally considered ethically problematic. This study determined whether cannabis was associated with important outcomes in SLE, including mortality and morbidity.

Methods: This is an analysis of a prospective de-identified 5 year longitudinal outcome study of a cohort of SLE patients at the University of New Mexico with a sample size of 276 patients with 30.4% using marijuana and 69.5% with no marijuana use. All patients had signed informed consent, but additional IRB approval was obtained prior to analyzing the de-identified database in relation to cannabis. Inclusion criteria were any patient with SLE, age 18–80. Exclusion criteria were any patient with a diagnosis other than SLE, age < 18 years, age > 80 years. The population sample was diverse and included all social and ethnic backgrounds, with Hispanics and Whites being the dominant participants. This analysis was supported by the University of New Mexico. Outcomes were determined at 5 years after enrollment in the study.

Results: No significant difference was observed in age, gender, SLE disease duration, SLE criteria, ANA titer, dsDNA titer, antiphospholipid Ig G, M, A, RF, anti-ribosomal P, incidence of Sjogren's syndrome between marijuana and non-marijuana users. Ethnically these groups were also similar.

However marijuana users were more likely to use opiate analgesics (p value 0.008), even though no differences were reported between pain scores, prednisone use, SLEDAI or joint pain/stiffness between the 2 groups. With marijuana use there was a 39% increase in neuropsychiatric SLE ($p=0.04$), a 85% increase in end-stage renal disease requiring dialysis ($p<0.006$) and a 40% increase in mortality ($p<0.12$). With multivariate analysis, the association of marijuana on the increase in ESRD could be explained completely by an increase in non-compliance/nonadherence to recommended therapy (non-marijuana: 3% noncompliance vs. marijuana use: 95% non-compliance, p value < 0.001).

Conclusion: This 5 year outcome study indicates that marijuana use in SLE is not associated with reduced pain, use of prednisone, narcotic analgesics or SLE disease activity. However, marijuana use in SLE is associated with an increased incidence of neuropsychiatric SLE, death, narcotic use, end stage renal disease, and noncompliance/nonadherence to recommended therapy. These epidemiologic data are not supportive of a beneficial role for medical cannabis in SLE.

CMR with Quantitative T2 Mapping in Patients with Active SLE. Stacy P. Ardoin[1], Wael Jarjour[2], Subha V. Raman[2], Amanda Kibler[2] and Tam Tran[2]. [1]Ohio State University College of Medicine, Columbus, OH, [2]Ohio State University, Columbus, OH.

Background/Purpose: Cardiovascular (CV) disease is an important cause of morbidity in systemic lupus erythematosus (SLE). Myocarditis is considered an uncommon complication of SLE but autopsy studies suggest prevalence of up to 40%. With this study we used cardiac magenetic resonance (CMR) quantitative T2 mapping to assess for subclinical myocardial involvement during SLE flare.

Methods: Consecutive patients with active SLE (defined by SLEDAI $>$ 5 and clinician's intention to change therapy due to disease activity) without bias to CV symptoms were enrolled at a single academic center. Clinical, demographic and laboratory data were collected. CMR was performed on 1.5 Tesla scanner and included cine imaging, T2 mapping in long and short axes. Late gadolinium enhancement was assessed after contrast administration if GFR > 30. Left ventricular (LV) end diastolic volumes, end systolic mass and peak circumferential strain were measured. All images were scored by an experienced, blinded reader. To reduce artifactual findings, T2 mapping was limited to the 6 mid cardiac segments, and involvement of $\geq$2 mid-segments was considered abnormal. Based upon myocarditis literature, T2 scores > 59 ms were considered abnormal. Descriptive statistics were performed; means were compared using Student's t-test and correlation assessed with Pearsons' coefficient.

Results: 27 patients underwent CMR: mean age 32.4 years, 82% female, 44% black, mean SLEDAI-2K 10.4, mean SLICC DI 0.52 (see Table 1). 12/27 (44%) of patients had $\geq$ 2 mid cardiac segments with elevated T2 signal (Table 2). The mean T2 signal for mid cardiac segments was elevated compared to 40 historical healthy controls (57.0 ms $\pm$ 5 vs. 54.5 ms $\pm$ 2.2; $p= 0.010$) The mean LV circumferential strain was $-15.2\% \pm 5.4$ which is lower than accepted normal values (-20%). SLEDAI-2K scores positively correlated with mean mid cardiac T2 signal ($r = 0.57$); and mid cardiac maximum T2 signal ($r = 0.65$). Only 2/27 (7%) patients had positive LGE.

Conclusion: In this cohort of active SLE patients, CMR with quantitative T2 mapping identified a high prevalence (44%) of patients with abnormal T2 signal in $\geq$2 mid cardiac segments, suggesting subclinical myocardial inflammation may be common in SLE flare. Both mean and max mid segment T2 showed correlation with SLE disease activity measured by SLEDAI scores. Mean LV circumferential strain was lower than normal, suggesting impaired LV function. Very few CMR showed evidence of myocardial fibrosis as measured by LGE enhancement. Further study is needed to determine if abnormal quantitative T2 mapping during SLE flare foreshadows longer term CV complications.

Table 1: Patient Characteristics

Age, mean $\pm$ SD years	32.4 $\pm$ 9.7

Lung Cancer in SLE. Sasha Bernatsky[1], Rosalind Ramsey-Goldman[2], Michelle Petri[3], Murray B. Urowitz[4], Dafna D. Gladman[4], Edward H. Yelin[5], Christine Peschken[6], John G. Hanly[7], James E. Hansen[8], Jean-Francois Boivin[1], Lawrence Joseph[1], Patrice Chrétien Raymer[9], Mruganka Kale[10], Ann E. Clarke[11] and Systemic Lupus International Collaborating Clinics (SLICC)[12]. [1]McGill University, Montreal, QC, [2]Northwestern University, Chicago, IL, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]University of Toronto, Toronto Western Hospital, Toronto, ON, [5]University of California, San Francisco, San Francisco, CA, [6]University of Manitoba, Winnipeg, MB, [7]Dalhousie University and Capital Health, Halifax, NS, [8]Yale University, New Haven, CT, [9]McGill University Health Centre, Montreal, QC, [10]RI McGill Univ Health Ctr, Montreal, QC, [11]University of Calgary, Calgary, AB, [12]Systemic Lupus International Collaborating Clinics (SLICC), ON.

Background/Purpose: Lung cancer is 50% more common in SLE patients than their sex and age-matched counterparts. Our objective was to assess lung cancer risk in SLE, comparing demographics, drug exposures, and disease activity.

Methods: We used data from a very large multi-site international SLE cohort; this preliminary analysis is based on 6 centres: Halifax, Toronto, Montreal, Winnipeg, San Francisco, Baltimore. We used Cox proportional hazards regression to calculate the hazard ratio (HR) for lung cancer risk in SLE, relative to smoking, demographics (sex, age, race/ethnicity and time-dependent drug exposures and cumulative disease activity (based on adjusted mean SLEDAI-2K scores, assessed at baseline and annually). The adjusted mean SLEDAI score was assessed both as a continuous variable and (to aid in interpretation) and categorized using quartiles. Time zero for the observation interval was SLE diagnosis, so that our analyses adjusted for SLE duration. We included observation time and lung cancer events occurring after entry into the lupus cohort and up to the time of cohort exit (death, cancer, or date of last visits). Those developing a cancer other than lung during the interval, were censored at that time.

Results: Within the cohort (N=4,667) 34 lung cancers (7 male, 27 female) occurred. Versus SLE controls without cancer, lung cancer cases tended to be white (85.3% versus 63.3% in controls), and older at cohort entry (mean 52.3 years, median 52.9; versus mean 38.4, median 36.9 in controls). Among lung cancer cases 61.8% had high disease activity (highest SLEDAI quartile) at baseline (95% CI 43.6, 77.8), in contrast to only 40.1% (95% CI 38.6, 41.5) of SLE patients that went on to remain free of lung cancer. The vast majority (78.8%) of the lung cancer cases in SLE were ever-smokers, versus 40.7% of the SLE patients who did not develop lung cancer. The drug profiles seemed similar (in terms of steroids, immunomodulators, NSAIDs) in the SLE patients who developed lung cancer versus those who did not (though of note, none had been exposed to cyclophosphamide prior to a lung cancer). In both univariate and multivariate models, the principal factors associated with lung cancer risk were ever smoking and age. The adjusted analyses did suggest a trend for greater cancer risk in SLE patients with higher cumulative disease activity over time (HR 1.81, 0.90, 3.63) although the CI included the null value. The estimated adjusted effects of all drugs were relatively imprecise.

Conclusion: There was a trend for greater cancer risk in SLE patients with higher cumulative disease activity over time, although we saw no definite adverse effects of drugs on lung cancer risk in SLE. In particular we did not note prior cyclophosphamide exposure in the lung cancer cases. However, drug estimates were relatively imprecise. Smoking appears to be the most significant modifiable risk factor for lung cancer in SLE.

Methotrexate Prevents Inflammatory Osteolysis By Activation of the Adenosine a_{2A} Receptor (A2AR). Aranzazu Mediero[1], Tuere Wilder[1] and Bruce N. Cronstein[2]. [1]NYU School of Medicine, New York, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Prior studies demonstrate that adenosine, acting at A2AR, mediates the anti-inflammatory effects of methotrexate (MTX) in models of both acute and chronic inflammation. We have previously reported that adenosine A2AR ligation diminishes wear particle-driven osteolysis. We asked whether MTX treatment could prevent bone resoprtion due to inflammatory osteolysis.

Methods: MTX (1mg/kg) was administered intraperitoneally to C57B/6 mice on a weekly basis starting 2 weeks prior to surgery. Control mice were injected with 0.9% saline. 1cm midline sagittal incisions were made over calvaria in 6–8 wk old C57Bl/6 mice. Calvaria were exposed to 20μl of PBS containing 3mg of UHMWPE followed by daily injections of either vehicle (Control and MTX) or ZM241385 1μM (A2AR antagonist) (n=5 each) for 14 days. XenoLight Rediject Bone Probe was injected IV and fluorescence of calvaria measured (IVIS) to assay bone formation. MicroCT and immunostaining for osteoclast and osteoblast markers were performed.

Results: XenoLight imaging revealed an 80±10% increase in bone formation after exposure to MTX when compared to UHMWPE alone ($p<0.001$, n=5) and ZM241385 completely reversed this effect (11±5% increase vs. control, p=NS, n=5). microCT analysis revealed increased porosity in particle-exposed mice that was inhibited by MTX treatment (54±6% decreased compared to saline treatment, $p<0.001$, n=5) an effect abrogated by ZM241385. MTX significantly increased bone volume/total volume (BV/TV) (9.54±0.1 vs 8.68±0.2, $p<0.05$), BV (5.31±0.3 vs 4.15±0.2, $p<0.05$), TV (5.90±0.2 vs 3.76±0.2, $p<0.001$) and Bone Mineral Density (BMD) (153.75±0.4 vs 144.63±1, $p<0.001$) when compared to WT, and ZM241385 completely reversed this effect. Histological examination of particle-exposed mouse calvarias demonstrated an inflammatory infiltrate on the bone surface that was significantly reduced by MTX and treatment with ZM241385 completely reversed this effect.

Conclusion: These results indicate that treatment with MTX, a well-tolerated and commonly used anti-inflammatory drug, may provide a novel therapeutic approach to enhance orthopedic implant survival, delaying or eliminating the need for revision arthroplasty surgery.

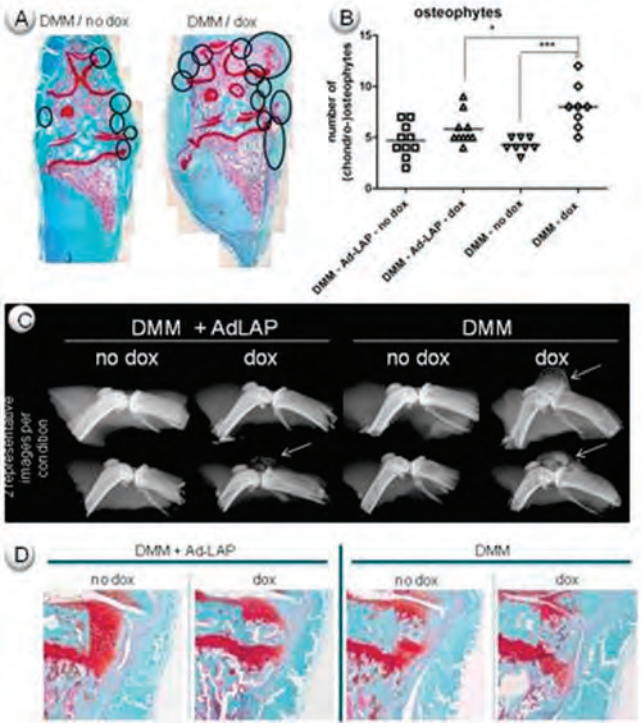
BMP2 Requires TGF-Beta to Induce Osteophytes during Experimental Osteoarthritis. Esmeralda Blaney Davidson[1], Arjen Blom[2], Arjan van Caam[1], Elly Vitters[2], Miranda Bennink[1], Wim van den Berg[2], Fons van de Loo[1] and Peter van der Kraan[2]. [1]Radboud university medical center, Nijmegen, Netherlands, [2]Radboud University Medical Center, Nijmegen, Netherlands.

Background/Purpose: Osteophytes are a major hallmark of osteoarthritis (OA). Both TGF-beta and BMP2 can induce osteophytes in murine knee joints. We demonstrated that TGF-beta could induce chondrogenesis in mesenchymal stem cells when BMPs were inhibited but not vice versa. This suggested that BMP2 might require a trigger like TGF-beta to induce initial stages of chondrogenesis. Therefore, we investigated whether BMP2 was still able to induce osteophyte formation in experimental OA when TGF-beta activity was blocked.

Methods: We made a unique transgenic mouse (Col2a1-rtTA-BMP2) expressing BMP2 under control of the Col2a1 promoter, only when exposed to doxycycline (dox) which results in only chondrocytes producing BMP2. These mice were fed dox-food up to 8 weeks to investigate BMP2 effects on osteophyte formation. We induced the DMM-model and investigated whether BMP2 augmented osteophyte formation. We combined the DMM-model with intra-articular injection of an adenovirus overexpressing TGF-beta-inhibitor LAP with or without dox. Knee joints were isolated 4 weeks after DMM for histology.

Results: There was no significant difference in osteophyte formation between dox and non-dox treated Col2a1-rtTA-BMP2 mice. However, dox treatment increased the number of osteophytes (8.0) during DMM compared to DMM non-dox (4.25). These "new" osteophytes were larger than DMM-induced osteophytes. The lack of osteophytes by dox compared to DMM+dox implied that DMM provided a trigger enabling BMP2-induced osteophyte formation. To investigate whether TGF-beta was that trigger, we injected Ad-LAP one day after DMM-induction. Without TGF-beta, BMP2 no longer augmented the number of osteophytes during DMM. Strikingly, inhibition of TGF-beta significantly reduced the pace of osteophyte formation. This was completely abolished by the presence of BMP2 restoring the speed of osteophyte formation and maturation.



Conclusion: Our data show that BMP2 is capable of inducing osteophyte formation, but is dependent on an additional trigger to achieve this, as present in OA. In OA conditions, BMP2 can severely aggravate osteophyte formation, both in number and size. However, when TGF-beta is blocked BMP2 is no longer capable of aggravating osteophyte formation during DMM. Strikingly, early inhibition of TGF-beta during OA impaired the speed of osteophyte formation, which could be compensated by the presence of BMP2. Our data show for the first time that BMP2 is dependent on TGF-beta to induce de novo osteophyte formation. This provides novel insight into the mechanism behind osteophyte formation and provides clues for future therapeutic application for osteophyte formation in OA.

Deletion of the Inhibitory Receptor Motif, ITIM, on DC-STAMP Alters Osteoclast Differentiation and Function. Yahui Grace Chiu[1], Edward M. Schwarz[1], Dongge Li[1], Yuexin Xu[1], Minsoo Kim[1] and Christopher T. Ritchlin[2]. [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY.

Background/Purpose: DC-STAMP (Dendritic Cell-Specific Transmembrane Protein), a 7-pass transmembrane protein essential for cell-to-cell fusion during osteoclast (OC) differentiation, is expressed on the cell surface of OC precursors (OCP). DC-STAMP knock-out (KO) mice form only mononuclear OC and have mild osteopetrosis due to the absence of functional multinucleated OC with bone erosion activity. Previously, we identified an Immunoreceptor Tyrosine-based Inhibitory Motif (ITIM) on the cytoplasmic tail of DC-STAMP, which suggested the potential role of DC-STAMP in signaling during osteoclastogenesis. A major hurdle in DC-STAMP research, however, is the absence of a known ligand. To overcome this barrier, we engineered DC-STAMP:Rhodopisn chimeric molecules that can be activated by light (photo-activatable). This approach enabled us to investigate the downstream events of DC-STAMP activation, and examine the importance and function of the ITIM in osteoclastogenesis.

Methods: DNA constructs were generated in which the four extracellular domains of DC-STAMP were replaced with the photo-activatable extracellular domains of rhodopsin. The functionality of two DC-STAMP chimeras (WT: original ITIM; TD: ITIM-deleted) was confirmed by: (1) activation of a calcium signal by 505-nm light, a wavelength that specifically excites rhodopsin; and (2) expression of mCherry protein (red), which was fused to the C'-terminus of DC-STAMP during engineering. These 2 chimeras were transfected into either murine 293T cells, or mouse bone marrow-derived macrophages (BMM) isolated from the DC-STAMP KO mice. To assess the role of the ITIM in signaling, we assessed the dynamic intracellular Ca^{2+} flux known to occur during normal osteoclastogenesis between the WT and TD transfected cells. Bone erosion was assessed by the bone wafer assay.

Results: The studies with the transfected chimeric molecules revealed the following. First, deletion of ITIM on DC-STAMP resulted in a significant and continuous (non-pulsatile) elevation (3-fold >WT DC-STAMP) in the intracellular Ca^{2+} level after light activation. Second, ITIM-deleted DC-STAMP did not complement the deficiency of cell-cell fusion in DC-STAMP KO cells, which was fully corrected and restored by the WT DC-STAMP. Most cells expressing ITIM-deleted DC-STAMP were unable to fuse, although rare cells with 3 nuclei were observed. Third, In contrast to an even distribution of wild-type DC-STAMP on the cell surface, ITIM-deleted DC-STAMP was expressed on the cell surface in a clustered and punctate distribution fashion. Fourth, bone resorption was decreased in cells expressing TD compared to WT DC-STAMP.

Conclusion: Our results suggest that the ITIM on the cytoplasmic tail of DC-STAMP functions (1) to induce pulsatile intracellular Ca^{2+} flux required for osteoclastogenesis after DC-STAMP activation; (2) to trigger cell-to-cell fusion between OCPs and form multinucleated mature OC; (3) to maintain an even distribution of DC-STAMP on the cell surface; (4) to support bone erosion activity of OC. Blocking the ITIM on DC-STAMP by targeted inhibition might serve as a novel strategy to inhibit pathologic bone resorption by OC in inflammatory and metabolic bone disorders.

Blockade of IL-6R Signaling by Sarilumab Suppressed Circulating Markers of Bone Resorption and Synovial Damage in Rheumatoid Arthritis Patients from a Phase 3, Randomized, Double-Blind, Placebo-Controlled, International Study. Anita Boyapati[1], Jérôme Msihid[2], Emmanuelle Cousin[2], Ling Cai[3], Janet van Adelsberg[1], Jennifer D Hamilton[1], Neil Graham[1], Tanya Momtahen[4] and Stefano Fiore[4]. [1]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [2]Sanofi R&D, France, Chilly-Mazarin, France, [3]Sanofi R&D, China, Beijing, China, [4]Sanofi, Bridgewater, NJ.

Background/Purpose: Rheumatoid arthritis (RA) patients develop bone and joint damage due to chronic inflammation mediated by critical cytokines, eg, IL-6. Pre-clinical studies have implicated IL-6 signaling in regulation of osteoclasts and fibroblast-like synoviocytes (FLS) to increase levels of bone resorptive molecules like receptor activated NF kB ligand (RANKL) and joint destructive proteins, such as matrix metalloproteinases (MMPs). Blockade of IL-6R signaling by sarilumab significantly reduced structural damage in RA patients, as measured by the modified van der Heijde total Sharp Score, including the erosion score and joint space narrowing components in the Phase 3 part of the MOBILITY study (NCT01061736). Most common TEAEs included infections and injection site reactions. A higher incidence of serious infections was observed with sarilumab. Lab abnormalities included decreases in neutrophils and increases in transaminases and lipids. To elucidate mechanisms of clinical reduction of bone and joint damage by sarilumab, we evaluated a panel of serum markers associated with bone resorption (RANKL and osteoprotegerin [OPG]), bone turnover (CTX-1 and C1M), osteoblast formation (osteocalcin [OC]), synovium (MMP-3 and C3M) and cartilage degradation (C2M) in patients enrolled in MOBILITY B.

Methods: Sera were analyzed from 128 patients treated with placebo (Pbo) + methotrexate (MTX), and 131 patients receiving subcutaneous 200 mg sarilumab every other week (q2w) + MTX. Serum biomarkers levels were measured by ELISA. All biomarkers were analyzed at baseline, and post-treatment at Wks 2 and 24, with the exceptions of CTX-1 and OC, which were analyzed at baseline, Wks 24 and 52 post-treatment. A mixed effect model with repeated measures on % change from baseline (after rank transformation) was performed for all biomarkers (ANOVA-type method). Treatments were compared at each visit. For samples above the limit of quantitation (LOQ), the LOQ was used in analyses, for samples below the LOQ, half the LOQ was used.

Results: Sarilumab + MTX treatment significantly reduced levels of MMP-3 and MMP generated fragments of collagen type 1 and type 3 (C1M and C3M) compared to Pbo + MTX at all timepoints analyzed (Table). RANKL levels were also reduced at Wk 24 in the sarilumab + MTX group, however approximately 15% of values were above the LOQ. In contrast, OC increased from baseline in the sarilumab 200 mg q2w + MTX group compared to Pbo + MTX but did not reach significance (Wk 52, p=0.0571).

Table Median percent change from baseline

Serum Biomarker	Tissue of Origin	Wk 2		Wk 24	
		Pbo + MTX (N=128)	Sarilumab 200 mg q2w + MTX (N=131)	Pbo + MTX (N=128)	Sarilumab 200 mg q2w + MTX (N=131)
C1M	Bone	2.30	−50.10*	−8.10	−60.30*
RANKL	Bone	0	−3.95†	0	−23.90†
OPG	Bone	0	−5.60	−1.80	−1.55
C3M	Synovium	−0.35	−23.75*	−5.25	−31.50*
MMP-3	Synovium	−0.35	−5.35†	−2.65	−44.20*
C2M	Cartilage	2.40	−4.30†	0	−4.35
		Wk 24		Wk 52	
CTX-1	Bone	−7.80	−6.65	−6.95	−7.70
OC	Bone	2.10	10.85	0.10	13.20

p-values generated for Sarilumab 200 mg q2w + MTX vs. Placebo + MTX comparison at each timepoint: * p<0.0001, † p<0.05.
Note: for RANKL, 15% of values were above the upper LOQ

Conclusion: Sarilumab reduced bone resorption and joint damage markers, and increased OC, a marker of bone formation, in RA patients. This is the first report that IL-6 inhibition leads to RANKL reduction in RA patients. This data supports a mechanism whereby increased IL-6 signaling promotes structural damage through osteoclasts and FLS and by reducing osteoblast bone formation.

A Novel Mouse Model of Osteochondromagenesis By Deleting NFATc1 in Mesenchymal Progenitors and Postnatal Chondrocytes. Xian-Peng Ge, Susan Y. Ritter, Julia F. Charles, Kelly Tsang and Antonios O. Aliprantis. Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Osteochondromas are the most common benign bone tumor and are characterized by cartilage-capped bony projections from the external surface of bone. These lesions may cause pain, deformity, fracture and neurovascular compromise, and rarely undergo malignant transformation. The pathogenesis of osteochondroma remains poorly understood. Since we recently reported that transcription factor nuclear factor of activated T cells c1 (NFATc1) suppresses osteoarthritis in mice, we hypothesized that it controls other aspects of chondrocyte biology. The objective of this study was to further characterize potential roles of NFATc1 in mesenchymal progenitors and chondrocytes.

Methods: To investigate the role of NFATc1 in mesenchymal progenitors of the limb bud and in postnatal chondrocytes, *Nfatc1*$^{fl/fl}$ mice were bred to *Prx1-Cre* (hereafter *Nfatc1*^{Prx1}) or tamoxifen-inducible *Aggrecan-CreER*^{T2} (hereafter *Nfatc1*$^{Aggrecan\text{-}CreER}$) mice, respectively. *Nfatc1*$^{Aggrecan\text{-}CreER}$ mice were analyzed on either an NFATc2-sufficient (*Nfatc2*$^{+/-}$) or deficient (*Nfatc2*$^{-/-}$) background to check for redundancy among NFAT family members. *Nfatc1* was deleted in *Nfatc1*$^{Aggrecan\text{-}CreER}$ chondrocytes by administration of tamoxifen at 8 weeks or 12 weeks of age. The skeletal and joint phenotypes of these strains were determined by a combination of micro-CT and histology.

Results: *Nfatc1*^{Prx1} mice displayed ectopic cartilage and bone formation around the knee joints (osteochondromatosis) at 16 weeks of age. Similarly, within 1 month of tamoxifen injection, all *Nfatc1*$^{aggrecan\text{-}creER}$*Nfatc2*$^{+/-}$ mice displayed ectopic cartilage formation at the tibial attachment site of the medial collateral ligament. Three months after the administration of tamoxifen, *Nfatc1*$^{aggrecan\text{-}creER}$*Nfatc2*$^{+/-}$ mice showed clear osteochondroma-like exostoses at the ligament-bone attachment site, characterized histologically by cartilage-capped bony protrusions continuous with underlying bone. In some *Nfatc1*$^{aggrecan\text{-}creER}$*Nfatc2*$^{+/-}$ mice, cartilaginous protrusions outgrew from the epiphyses of knee joints at this time point. Lastly, the osteochondromagenesis previously reported around the hip joints in *Nfatc2*$^{-/-}$ mice, was exacerbated in *Nfatc1*$^{aggrecan\text{-}creER}$*Nfatc2*$^{-/-}$ double knockout mice.

Conclusion: Our data indicate that NFATc1 constitutively represses chondrogenesis and the formation of exostoses in mice. Reducing NFATc1 expression in mesenchymal progenitors or postnatal aggrecan-expressing chondrocytes represents a novel animal model of osteochondromagenesis.

Anti-Citrullinated Proteins Antibodies Promotes Osteoclastogenesis and Bone Destruction in Rheumatoid Arthritis. Akilan Krishnamurthy[1], Vijay Joshua[1], Heidi Wähämaa[1], Catia Cerqueira[1], Lars Klareskog[2], Vivianne Malmström[3], Jimmy Ytterberg[1] and Anca I Catrina[1]. [1]Rheumatology Unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institute, Stockholm, Sweden, [3]Rheumatology Unit, Karolinska University Hospital, Solna, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Presence of anti-citrullinated protein antibodies (ACPA) is a major risk factor for bone erosion in rheumatoid arthritis (RA) and antibodies against modified citrullinated vimentin induce osteoclast (OC) formation from monocytes. Besides monocytes, dendritic cells (DC) are potent osteoclast precursors. We aimed to further characterize DC derived osteoclastogenesis and to explore the effect of pooled and individual monoclonal ACPAs on this pathway.

Methods: ACPA positive and negative IgGs were isolated from synovial fluid (SF, n=26) and peripheral blood (PB, n=38) samples of RA patients. $CD14^+$ monocytes from PB of $ACPA^+$ RA patients and healthy individuals were first cultured in the presence of GM-CSF and IL-4 to generate DC or M-CSF to generate MΦ, and then further differentiated to OC in the presence of RANKL and M-CSF. In parallel, cells were grown on osteoassay surfaces and bone resorption area was quantified by computer assisted image analysis. In house generated anti-citrullinated monoclonal antibodies obtained from SF B-cells were also tested. Cytokines were measured by cytometric bead arrays in cultures supernatants. Mass spectrometry analysis was performed on different stages of differentiation of DC derived OC. Immunohistochemistry (IHC) was used to stain the OCs with biotinylated ACPA IgG and monoclonal anti-citrullinated proteins antibodies. The effect of PAD inhibition (C.I.amidine) and IL-8 inhibition was tested in the osteoclasts cultures.

Results: SF derived ACPAs enhanced osteoclastogenesis and bone resorption from both DC (fold increase of 1.6±0.2 for osteoclasts number and 2.0±0.3 for bone resorption area) and MΦ (fold increase of 1.6±0.4 for osteoclasts number and 2.0±0.6 for bone resorption area) of healthy donors. Similar effect was observed when the precursor cells were derived from ACPA+ RA patients in both DC (fold increase of 2.3±0.9 for osteoclasts number and 2.6±0.1 for bone resorption area) and MΦ (fold increase of 1.8±0.6 for osteoclasts number and 2.3±0.7 for bone resorption) assays. PB

derived ACPAs were equally effective with SF ACPAs. Principal component analysis confirmed distinct proteomic profiles during osteoclasts maturation from DC and MΦ, respectively. Vimentin significantly increased during DC-OC maturation, with citrullinated vimentin peptides detectable in matured osteoclasts. Increased osteoclastogenesis was associated with significantly higher levels of IL-8 levels in cultures supernatants of both DC (fold increase of 2.4±0.5) and MΦ (fold increase of 2.0±0.5). Two of the tested anti-citrullinated monoclonal antibodies had similar effects, while a third one had no such effect. Fab fragments of these monoclonal antibodies retained similar effects. Binding of these antibodies on OC was confirmed using IHC. Both PAD activity and IL-8 appear to be required for ACPAs effects.

Conclusion: SF and PB derived ACPA IgGs with broad specificities enhanced osteoclastogenesis from both DC and MΦ. This effect appears to be restricted to certain ACPAs specificities and at least partially mediated through a Fab mediated mechanism.

***C5orf30* a Novel Regulator of Inflammation and Tissue Damage in Rheumatoid Arthritis.** Munitta Muthana[1], Sarah Hawtree[1], Holly Davies[1], Hannah Roberts[1], Sachin Khetan[1], Mohammed Akil[2], Fiona Wright[1], Barbara Ciani[1], Ursula Fearon[3], DJ Veale[4] and Anthony G. Wilson[5]. [1]University of Sheffield, Sheffield, United Kingdom, [2]Rheumatology Department, Sheffield South Yorkshire, United Kingdom, [3]Translational Rheumatology Research Group, Dublin, Ireland, [4]St. Vincent's University Hospital, Dublin, Ireland, [5]University College Dublin, Dublin, Ireland.

Background/Purpose: A recent genome wide association study identified the variant rs26232 in the first intron of the uncharacterized gene, *C5orf30*, as a rheumatoid arthritis (RA) susceptibility variant[1]. In addition, it has been associated with severity of radiological joint damage suggesting a role in tissue breakdown[2]. To date there is no function assigned for *C5orf30* and neither the gene or protein show homology to any known functional sequences. However, C5orf30 is highly conserved in chimpanzee, dog, cow, mouse, chicken, and zebrafish (orthologs).

Purpose - To determine the biological roles of *C5orf30* in rheumatoid arthritis.

Methods: Immunohistochemistry on synovial samples was used to determine expression of C5orf30 using anti-C5orf30 and antibodies to macrophages (CD68), fibroblasts (5B5), T (CD3) & B (CD19) cells. Real time PCR and western blotting were used to examine C5orf30 transcript and protein levels in RA PBMCs and fibroblast-like synovial cells (RASF) treated with TNF & hypoxia. To investigate gene function siRNA was used to knockdown (KD) either *C5orf30* or a non-targeting control (NTC) in RASF *in vitro*. After knockdown cell migration, invasion, and global gene expression (Illumina BeadChip array) were assessed. The disease-modulating activity of siRNA designed to silence C5orf30 was also investigated *in vivo*in a mouse model of collagen-induced arthritis (CIA). Clinical scores of CIA were measured daily (days 0–49) and the bones were analysed using a microCT scanner.

Results: Confocal microscopy revealed C5orf30 to be strongly expressed in the cytoplasmic compartment of RA synovial lining cells including macrophages and RASF but not T & B cells. C5orf30 was undetectable in arthroscopy sections obtained from osteoarthritis (OA) or OASFs. C5orf30 was found to be up-regulated by hypoxia (8-fold) and down-regulated by TNF treatment (0.5-fold) in RASF. We found that $C5orf30^{KD}$ increased the invasiveness of FLS assayed using Matrigel (N=6 p=0.01) and increased FLS migration in a scratch-wound assay (N=6 p=0.02). Gene profiling studies also revealed $C5orf30^{KD}$ resulted in upregulation of cell migration, adhesion, angiogenesis, and immune and inflammatory pathways. Finally, in mice with CIA, siRNA designed to inhibit C5orf30 strongly induced joint inflammation (n=10, p=0.0001) and bone erosion compared to irrelevant NTC siRNA.

Conclusion: Our data, in both RA and murine inflammatory arthritis, reveals C5orf30 to be a novel negative regulator of tissue breakdown modulating the autoaggressive phenotype that is characteristic of rheumatoid synovial fibroblasts.

The Differential Impact of Obesity on the Pathogenesis of RA or Preclinical Models Is Contingent on the Disease Status. Zhenlong Chen[1], Seung-jae Kim[1], Abdul Essani[1], Michael V. Volin[2], Suncica Volkov[1], William Swedler[1], Shiva Arami[1], Giamila Fantuzzi[1], Nadera J. Sweiss[1] and Shiva Shahrara[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]Chicago College of Osteopathic Medicine Midwestern University, Downers Grove, IL.

Background/Purpose: Studies were performed to determine the significance of obesity in the pathogenesis of rheumatoid arthritis (RA) and experimental arthritis models.

Methods: Chronic and acute preclinical models of arthritis were utilized to examine the impact of obesity on different disease stages. Inflammatory mediators were identified in RA and mouse adipose condition media using ELISA. Role of IL-8/MIP2 was investigated in disease onset employing neutrophil chemotaxis. RA and mouse myeloid cells as well as ankle joints from preclinical arthritis models were utilized to assess the importance of proinflammatory M1 macrophage differentiation in disease remission using real-time RT-PCR, histology and Western blotting.

Results: We document that early onset of collagen induced arthritis (CIA) was impacted by high fat diet (HFD) on days 26, 28 and 30 post onset compared to mice fed with regular diet (RD). To elucidate the mechanism by which obesity affects the early stage of RA, inflammatory factors were quantified in adipose condition media extracted from RA synovial tissue and obese mouse gonadal adipose tissue. We uncovered that a great number of neutrophil (CXCL1, CXCL5 and IL-8/MIP2) and monocyte chemaoattractants (TNF-a, IL-17, IL-1b, CCL2) are present in RA and mouse adipose condition media, however levels of IL-8/MIP2 exceeded all other factors. We found that early arthritis exacerbated by obesity is due to elevated IL-8/MIP2 protein levels in the obese joint, as blockade of IL-8/MIP2 dysregulates neutrophil chemotaxis in response to RA and mouse adipose media, in contrast, neutralization of CXCL1 and CXCL5 was ineffective in this process. To elucidate the effect of obesity on arthritis progression, we chose to utilize the TLR4 induced arthritis model. We found that in the first 48h, TLR4 driven joint inflammation progresses similarly in obese and lean mice. Thereafter while arthritis resolves in the lean mice, ankle swelling is sustained in the obese mice at 72h post LPS injection. Histological studies confirm that mice on HFD have markedly greater joint inflammation and lining thickness compared to RD group. Corroborating with the higher levels of monocyte chemoattractants detected in the obese mice (TNF-a, IL-17, CCL20 and IL-6), joint myeloid cell recruitment was potentiated in the HFD arthritic mice compared to RD group. To better understand how obesity prolongs arthritis, joint myeloid cell phenotype was evaluated in the obese and the lean arthritic mice. We show that the obese arthritic mice, predominately express iNOS+ M1 macrophages; while iNOS+ cells are reduced and Arginase+ M2 macrophages are strongly expressed in the lean mice. Consistently, employing RA and mouse adipose condition media we show that RA or mouse naïve cells can be transformed into M1 macrophages. Hence, our results exhibit that obesity can sustain arthritis by reconstructing the newly recruited joint myeloid cells into proinflammatory M1 macrophages.

Conclusion: We show for the first time that early and late RA is impacted by obesity through differential mechanism of function.

Tofacitinib Regulates Synovial Angiogenesis in Psoriatic Arthritis through Induction of Negative Feedback Inhibitors. Wei Gao, Jennifer McCormick, Carl Orr, Mary Connolly, Ursula Fearon and Douglas J. Veale. Translational Rheumatology Research Group, Dublin, Ireland.

Background/Purpose: Psoriatic Arthritis (PsA) is a common, chronic immune-mediated inflammatory disease, characterised by synovitis, progressive destruction of articular cartilage/bone, and is associated with psoriasis. Janus Kinase and Signal Transducer and Activator of Transcription (JAK/STAT), a critical signalling pathway involved in inflammatory mechanisms, has been implicated in the pathogenesis of PsA. This study was to examine the mechanistic effect of Tofacitinib (A novel JAK inhibitor CP-690,550) on pro-inflammatory pathways using *ex vivo* and *in vivo* models of PsA.

Methods: PsA whole tissue synovial explant cultures were established from PsA biopsies obtained under direct visualisation at arthroscopy. This explant model maintains the architecture and cell-cell contact of the synovial tissue, spontaneously releases pro-inflammatory mediators and therefore closely reflects the *in vivo* inflamed microenvironment. Primary PsA synovial fibroblasts (PsASFC) were also isolated from PsA synovial biopsies. Phospho-STAT3 (p-STAT3), phospho-STAT1 (p-STAT1), Suppressor of Cytokine Signaling 3 (SOCS3) and Protein Inhibitor of Activated Stat 3 (PIAS3) expression were quantified by Western Blot in PsA synovial explants and PsASFC following culture with Tofacitinib (1μM) or vehicle control. Cytokine expression of IL-6, IL-8 and IL-10 in *ex vivo* culture synovial explants in response to Tofacitinib (0.5μM-1μM) were assessed by ELISA. Furthermore the effect of Tofacitinib (0.5μM-1μM) on PsASFC migration, invasion, matrigel network formation and MMP2/9 were quantified by wound repair assays, transwell invasion chambers and zymography.

Results: Tofacitinib significantly decreased p-STAT3 and p-STAT1 expression in PsA synovial tissue explant cultures *ex vivo* and in primary PsASFC ($p<0.05$). In contrast Tofacitinib induced SOCS3 and PIAS3 expression in both models ($p<0.05$). In parallel Tofacitinib significantly decreased spontaneous secretion of IL-6 ($p<0.05$), IL-8 ($p<0.05$) and induced IL-10 ($p<0.05$) expression in PsA explant cultures. Functionally, PsASFC invasion, matrigel network/tube formation, migration, and pro-MMP-2/-9 activities, were inhibited in the presence of Tofacitinib ($p<0.05$).

Conclusion: This is the first study to demonstrate Jak/STAT signaling and the effect of Tofacitinib on these pathways in PsA synovial tissue and primary PsA synovial fibroblasts. Tofacitinib mediated specific JAK-STAT signaling components, inhibited key pro-inflammatory cytokines and invasion/migrational mechanisms. Thus this data further supports the use of JAK-STAT inhibition as a potential therapeutic agent for the treatment of PsA.

IL-38: A New Factor in Rheumatoid Arthritis. Shinjiro Kaieda[1], Katsuya Kanezaki[2], Naomi Yoshida[1], Yukiko Kunitake[1], Hiroaki Ida[1] and Tomoaki Hoshino[1]. [1]Kurume University School of Medicine, Kurume, Japan, [2]Nagata orthopedic hospital, Omuta, Japan.

Background/Purpose: IL-38 (IL-1F10) was originally described as an IL-1 family cytokine, and named IL-1HY2. The *IL-38* gene is located in the *IL-1* family cluster on chromosome 2, next to the genes encoding the IL-1 receptor antagonist (IL-1Ra) and the IL-36 receptor antagonist (IL-36Ra). IL-38 shares 37% homology with IL-1Ra, 43% homology with IL-36Ra, and has a three-dimensional structure similar to IL-1Ra. IL-38 was recently shown to inhibit *Candida albicans*-induced IL-17 and IL-22 production by human memory T cells. However, the role of IL-38 in inflammatory diseases such as RA remains unclear.

Methods: We established several clones of mouse anti-human IL-38 mAb. One anti-human IL-38 mAb (H127C, mouse IgG2a) can be used for sandwich ELISAs and immunohistochemistry. To determine the expression pattern of the *IL-38* gene, a panel of cDNA derived from normal lung, pancreas, spleen, muscle, synoviocyte samples and peripheral blood mononuclear cells (PBMCs) was analyzed by quantitative real time-PCR (qRT-PCR), using primers specific to human IL-38. The serum levels of IL-38 in 137 RA and 26 OA patients, and in 56 healthy donors, were determined by ELISA. Synovial tissue samples were also obtained from 7 RA and 3 OA patients. We used immunohistochemistry to identify IL-38, prolyl-4-hydroxylase-positive fibroblasts, and CD68-positive macrophages. Arthritis was initiated in mice lacking IL-38, as well as their wild-type littermates, via intraperitoneal administration of K/BxN mouse serum. Total RNA was isolated from mouse ankle joints and *IL-1β* and *IL-6* mRNA were quantified by qRT-PCR.

Results: The *IL-38* transcripts were strongly expressed in the lung, spleen, and synoviocytes, and at a lower level in the pancreas and muscle**.** Further, strong mRNA expression of the *IL-38* gene was also observed in PBMCs obtained from 2 healthy donors**.** The serum levels of IL-38 were 5.7 $\pm$ 0.4 pg/mL, 2.8 $\pm$ 0.8 pg/mL, and 2.8 $\pm$ 0.7 pg/mL in RA patients, OA patients, and healthy donors, respectively. Twenty-one of the 137 RA (15.3%) patients, 1 of the 26 OA patients (3.9%), and 5 of the 56 controls (8.9%) had IL-38 levels that were above the limit of detection of our ELISA system (10 pg/mL). Further, IL-38 protein was strongly expressed in the synovial lining of RA synovium. Serial sections indicated that synovial fibroblasts highly expressed IL-38 protein; CD68-positive macrophages barely expressed IL-38 in the RA synovium. In contrast, IL-38 protein was barely expressed in the synovial lining of OA synovium. Moreover, we found that IL-38-deficient mice exhibited significant exacerbation of their arthritis clinical scores, compared with their wild-type littermates. Correspondingly, histological measures of arthritis were also exacerbated, and accompanied by increased *IL-1β* and *IL-6*gene expression in the ankles.

Conclusion: Our present study is the first to identify the presence of soluble IL-38 protein in the serum and its expression in the synovium of RA patients. IL-38 may play a role as an inhibitor in the pathogenesis of RA.

Non-Canonical NF-Kappab Signaling Promotes Angiogenesis in a Novel 3D Spheroid Model of Rheumatoid Arthritis Synovial Inflammation. Chrissta X. Maracle[1], Boy Helder[1], Ae-Ri Noort[1], Corine van der Horst[2] and Sander W. Tas[1]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Arthrogen BV, Amsterdam, Netherlands.

Background/Purpose: Angiogenesis is regarded as a switch from acute to chronic inflammation and thus plays a crucial role in rheumatoid arthritis disease progression. This process is highly complex, involving interactions between several cell types in the inflamed synovium. Many of the current *in vitro* models of angiogenesis focus solely on endothelial cells (EC) and do not include interactions with other cell types. RA synovial fibroblasts (RASF) are important contributors to angiogenesis in synovial inflammation, and therefore a model including both RASF and EC would more accurately represent the pathophysiology of RA angiogenesis. We previously demonstrated that NF-κB inducing kinase (NIK) dependent non-canonical NF-κB signaling can induce angiogenesis in EC. This has not yet been studied in a co-culture model of angiogenesis.

Objective: To develop a 3D *in vitro* model to study the interaction between RASF and EC and to further delineate the role of the non-canonical NF-κB pathway in pathological angiogenesis.

Methods: We developed a novel 3 dimensional (3D) model in which human umbilical cord vein EC and RASF were labeled with green or orange cell tracker dye, respectively, and incubated overnight to form spheroids. Subsequently, the spheroids were harvested and plated in a collagen solution, and medium with or without lymphotoxin $\alpha1\beta2$ (LT) or LIGHT (both stimuli that induce non-canonical NF-κB signaling via the lymphotoxin beta receptor (LTβR)) or pro-angiogenic growth factors (bFGF/VEGF) was added. After 48 hours, spheroids were fixed and imaged through confocal microscopy. Cumulative EC sprout length and the number of sprouts was quantified using Leica QWin Plus software. To demonstrate NIK dependency of this process, EC were transfected with non-targeting or NIK targeting siRNA before addition into the model and subsequent sprout formation was quantified.

Results: Confocal analysis of the 3D model showed spheroids containing HUVEC and RASF formed sprouts under all conditions. Both LT and LIGHT caused significant increases in cumulative sprout length ($p<0.05$). Interestingly, the total number of sprouts formed by each spheroid also increased significantly. LT and LIGHT induced sprout formation was significantly decreased by siRNA-mediated knockdown of NIK in EC as compared to the non-targeting siRNA controls.

Conclusion: Our novel 3D model demonstrates that activation of the non-canonical pathway induces angiogenesis in spheroids of EC and RASF and that this process is strictly NIK dependent. This suggests that NIK targeting therapeutics may be able to reduce pathological angiogenesis in synovial inflammation and possibly halt disease progression. Further studies to test this, including the use of small molecule pharmacological NIK inhibitors, are currently underway. Of interest, the current 3D model is also optimized to include different subsets of immune cells in order to study their contributions to inflammation-induced angiogenesis, which makes this model a valuable tool for future studies.

Methotrexate Impacts the Effects of Tofacitinib, but Not Tocilizumab, on Clinically Relevant Biomarkers in Human Primary Cell–Based BioMAP® Disease Models: Can We Utilize in Vitro Models to Predict Clinical Outcomes? Alison O'Mahony[1], Ellen L. Berg[1], Xitong Li[1], Markus R. John[2], Kandeepan Ganeshalingam[2] and Ernest H. Choy[3]. [1]BioSeek, South San Francisco, CA, [2]F. Hoffmann-La Roche, Basel, Switzerland, [3]Cardiff University, Cardiff, United Kingdom.

Background/Purpose: A number of trials have shown that adding MTX benefits some, but not all, biologics and small molecules to treat RA. Specifically, though treatment of RA with an anti-TNF+MTX has been shown to be more beneficial than with the biologic alone,[1–3] the same was not consistently observed with tocilizumab (TCZ)+MTX.[4,5] Thus, it remains a challenge to determine whether cotreatment with MTX is a better option for patients. We have previously reported that BioMAP activities detected with TCZ alone were highly similar to those of TCZ+MTX, whereas the effects of adalimumab (ADA) alone differed from those of ADA+MTX.[6] Here we evaluate whether MTX alters the pattern of BioMAP activities of tofacitinib (TOF) in order to predict whether the effects of this drug can be modulated by cotreatment with MTX.

Methods: Human primary cell–based BioMAP disease models[7,8] were used to generate phenotypic activity profiles for compounds alone and in combination with MTX at concentrations that cover their clinical C_{max} ranges[9–11]: TCZ, 200 mg/mL; TOF_1, 1.1 mM; TOF_2, 0.12 μM; MTX, 10 mM. Agents and combinations were tested under standard[7] and soluble interukin-6 receptor–stimulated conditions. Changes in protein-based, clinically relevant end points (biomarkers)[7] and proliferation were evaluated by *t*-test and other statistical methods to determine whether activities of the combinations differed from those of the individual agents.

Results: Several activities detected with TOF_1+MTX or TOF_2+MTX were statistically significantly different ($p<0.01$) from those of TOF_1 or TOF_2 profiled alone. Cytokine and chemokine levels (M-CSF, G-CSF), inflammation markers (VCAM-1, E-selectin, and IP-10), and tissue-remodeling activities (thrombomodulin and PAI-1) were all modulated differently by TOF+MTX vs TOF alone. In contrast, the profile of TCZ+MTX was not significantly different from that of TCZ alone, with only MTX-mediated antiproliferative effects on endothelial cells (3C) and B cells (BT) contributing to the pattern of TCZ activities.

Conclusion: These data show that though TCZ has diverse effects on inflammatory responses, cotreatment with MTX elicits few additional activities and does not impact TCZ effects. In contrast, TOF+MTX impacts immune function, inflammation markers, and matrix-remodeling end points in human primary cell disease models differently than does TOF or MTX alone. The pharmacodynamic interactions between TCZ and MTX in BioMAP are significantly less pronounced than those between TOF and MTX. These data are consistent with the comparable efficacy of TCZ in monotherapy and combination therapy seen in some clinical trials[4,5] and in real life[12] and suggest that TOF could be more beneficial in combination with MTX.

Rituximab in IgG4-Related Disease: A Large Single-Center Experience. Zachary Wallace, Mollie Carruthers and John H. Stone. Massachusetts General Hospital, Boston, MA.

Background/Purpose: IgG4-related disease (IgG4-RD) is an immune-mediated multiorgan, fibroinflammatory disease often associated with an elevated serum IgG4 concentration. The diagnosis hinges on characteristic histopathologic features. Glucocorticoids (GC) are an effective but non-curative treatment with many known toxicities, and many patients relapse on low doses. We report here an experience with the use of B cell depletion in 58 patients with biopsy-proven IgG4-RD.

Methods: All 58 patients were treated and followed for at least three months in the Massachusetts General Hospital Center for IgG4-RD. Patients' medical records were reviewed for details regarding demographics, clinical manifestations, prior treatment, response to treatment, and complications of treatment. The IgG4-RD Responder Index (IgG4-RD RI) was used to assess clinical improvement. Rituximab (RTX) (1gm) was administered on days 0 and 15. Three fourths of the patients in this cohort received no treatment except for RTX.

Results: Fifty-eight patients were included. Their mean age was 56 years (range: 32–83). The mean number of organs involved was 2.2 (range: 1–6). Thirty-two patients (55%) had an elevated serum IgG4 concentration at baseline (mean 712 mg/dL; range 154–4780; normal < 135 mg/dL). Thirty-two (55%) of the patients had undergone treatment courses – GC in 24 (41%) – prior to treatment with B cell depletion. The mean duration of follow-up after the first RTX infusion was 597 days (range: 90–1770). Forty-three (74%) of the patients were treated with RTX alone.

Clinical improvement was observed in 88% of patients following RTX administration. Among the 25 patients with post-RTX imaging studies, 24 (96%) demonstrated either improvement (68%) or stability (28%) in the radiologic features. Among the 15 (26%) patients on GC at the time their RTX began, 11 (73%) were able to discontinue GC completely following RTX treatment and 4 (27%) were able to taper the dose to below 5 mg/day of prednisone. Among the patients with an elevated serum IgG4 concentration before RTX, the value declined to a mean of 248 mg/dl (range: 20–985) after RTX among the 29 patients with follow up values assessed; the value normalized in only 13 patients (44%).

Among 33 patients followed for more than one year, 18 (55%) experienced disease flares, an average of 10 months (range 5–27) after the first RTX infusion. Nineteen patients received more than one course of RTX (a total of 36 re-treatments, 24 for flares and 12 for remission maintenance). RTX was well tolerated; there were 15 adverse events among 13 patients. Infusions reactions (4) and infection (4) were the most common adverse events.

Conclusion: RTX appears to be an effective and well-tolerated treatment for IgG4-RD. The majority of patients treated with RTX require no concomitant GC therapy. Serum IgG4 concentrations improve but the majority do not normalize following RTX treatment, despite clinical improvement.

IgG4-Related Disease: Baseline Features in 100 Patients with Biopsy-Proven Disease. Zachary Wallace[1], Vikram Deshpande[1], Hamid Mattoo[2], Vinay Mahajan[2], Mollie Carruthers[1], Maria Kulikova[1], Shiv Pillai[1] and John H. Stone[1]. [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: IgG4-related disease (IgG4-RD) has emerged as an immune-mediated disease that links multiple fibro-inflammatory conditions through common pathology and pathophysiologic mechanisms. Most of the literature on IgG4-RD is comprised of case reports and small case series focused on individual organ manifestations. We report detailed clinical features of the first 100 patients with IgG4-RD evaluated at our center.

Methods: We reviewed the cases of the first 100 patients included in a database maintained by the Massachusetts General Hospital Center for

IgG4-RD. All patients had biopsy-proven disease and 75 were on no immunosuppression at the time of evaluation yet had active disease. Clinical and laboratory data were extracted from the electronic medical record. An IgG4-RD responder index score > 3 defined active disease. Serum IgG4 concentrations were determined by nephelometry after serial dilution to prevent the prozone effect. Circulating plasmablasts and SLAMF7+ CD4+T cells were measured by flow cytometry.

Results: The average ages at evaluation and disease onset were 55 years (range: 24–83) and 49.9 years (range: 12–82), respectively. The majority of patients were white (75%) and male (63%); the mean number of organs affected was 2.8 (range 1–7). The most commonly involved organs were the submandibular glands, orbit, lymph nodes, pancreas, and retroperitoneum; fifty-five patients had sustained permanent damage due to IgG4-RD **(Table 1)**.

Forty-seven patients had received glucocorticoid therapy and all had either failed treatment or required ongoing treatment to maintain disease control. Only 38 (53%) of the 75 patients on no treatment at baseline had an elevated serum IgG4 concentration. Elevated serum IgG4 levels correlated with an inflammatory phenotype (increased acute phase reactants) and multi-organ disease. Regardless of the serum IgG4 concentrations, patients had elevated levels of circulating SLAMF7+ CD4+ T cells and plasmablasts. Male patients had a higher average serum IgG4 concentration (597mg/dL versus 233mg/dL; P=0.03) but neither the proportion with an elevated baseline value nor the number of organs involved differed. Patients with renal disease, lymphadenopathy, and retroperitoneal fibrosis represented distinctive subtypes on the basis of complement levels, serum IgG4 concentrations, number of organs involved, and inflammatory markers.

Conclusion: We report the baseline features of our first 100 patients with biopsy-proven IgG4-RD. The majority of the patients were on no treatment at the initial assessment, permitting insights into the pre-treatment features of IgG4-RD. Our study stands in contrast to all IgG4-RD publications to date as this is the first study to describe the clinical and laboratory features of a large, diverse cohort with IgG4-RD.

Characteristic Phenotype of Peripheral Blood Lymphocytes in Patients with IgG4-Related Disease, Comparing to Primary Sjögren Syndrome and Healthy Controls. Shintaro Hirata, Shingo Nakayamada, Satoshi Kubo, Maiko Yoshikawa, Naoki Yunoue, Kazuhisa Nakano, Kunihiro Yamaoka, Kazuyoshi Saito and Yoshiya Tanaka. University of Occupational and Environmental Health, Japan, Kitakyushu, Japan.

Background/Purpose: IgG4-related disease (IgG4-RD) is a systemic disease that is characterized by the infiltration of IgG4-positive plasma cells and T cells into various organs. However, the characteristic and pathological role of immune cell subsets remains unclear. We have characterized peripheral blood immune cell subsets in patients with IgG4-RD by comparing with patients with primary Sjögren syndrome (pSS) and healthy controls (HC).

Methods: PBMCs were obtained from 8 IgG4-RD and 4 pSS patients as well as from 8 HC. The phenotype of immune cells was analyzed by 8-color staining flow cytometry. T helper cells were categorized as naive, central memory, effector memory and effector T cells by expression of CCR7 and CD45RA. B cells were categorized as naive, IgM memory, switched memory, effector B cell and plasmablast (PB) by expression of IgD, CD27 and CD38. DCs were categorized as myeloid and plasmacytoid DC by expression of CD11c and CD123. The proportion of immune cell subsets was assessed for correlations with serological parameters, including serum IgG, IgG4, and CRP.

Results: Baseline characteristics of patients with IgG4-RD (mean Â± SD) were; age 56 Â± 20 year, symptom duration 16.3 Â± 19.2 months, serum IgG4 628 Â± 549 mg/dl, CRP 1.3 Â± 2.6 mg/dl, respectively. There was no difference in the proportion of T helper cells (Th1, Th2, Th17, Treg), B cells or DC subsets between IgG4-RD, and pSS, HCï¼Œwhereas $CD3^+CD4^+CXCR5^+CD45RA^-$ Tfh cells were significantly higher in IgG4-RD than HC (p=0.033). In contrast, the proportion of $CD3^+CD4^+CCR7^-CD45RA^+$ effector T cells and $CD19^+CD27^+CD20^-CD38^+$ plasmablasts significantly increased in IgG4-RD compared to pSS and HC (*p* values: 0.008 and 0.013, respectively). Importantly, the proportion of $CD3^+CD4^+CCR7^-CD45RA^-$ effector memory T helper cells was strongly correlated with the ratio of serum IgG4/IgG ratio (rho=0.90, *p*=0.002), whereas it was not with that of plasmablasts (rho=0.17, p=0.67).

Conclusion: These results revealed that the higher proportion of effector T cells including Tfh cells and the increase of plasmablasts possibly induced by Tfh are characteristically observed in IgG4-RD, but not in pSS. Moreover, serum IgG4/IgG ratio was strongly correlated with ratio of effector memory T cells, but not plasmablasts. Taken together, IgG4 overproduction may be conducted by matured effector phase helper T cells, suggesting a pivotal role of effector phase T cells in pathogenesis of IgG4RD, especially in IgG4 specific production. Further studies are required to elucidate the detailed role of effector phase T cells in the pathogenesis of IgG4-RD.

2807

Comparison of Outcomes in Septic Arthritis Caused By MRSA and MSSA. Deepa Panikkath[1], Sian Yik Lim[2], Swetha Gadwala[3], Ragesh Panikkath[3] and Kenneth Nugent[2]. [1]Texas Tech University of Health Sciences, Lubbock, LUBBOCK, TX, [2]Texas Tech University Health Sciences Center, Lubbock, TX, [3]Texas Tech University of Health Sciences, Lubbock, TX.

Background/Purpose: Staphylococcus aureus is the most common cause of adult septic arthritis and the incidence of methicillin-resistant Staphylococcus aureus (MRSA) infections continues to rise. There is a relative lack of information on clinical presentations and outcomes in MRSA septic arthritis and how it differs from methicillin-sensitive Staphylococcus aureus (MSSA) septic arthritis. Our aim was to evaluate the differences in clinical features and outcomes between patients with MRSA and MSSA septic arthritis.

Methods: This is a retrospective chart review study performed at a tertiary level referral hospital. We queried the electronic database for patients with a discharge diagnosis of pyogenic arthritis between Jan 1st 2000 and Dec 31st2013. We only included native joint septic arthritis. We collected data on patient demographics, clinical information, and patient outcomes. Statistical analysis was performed using SPSS staistics 20.0. The institutional review board at Texas Tech University approved this study.

Results: We identified 274 patients with native joint septic arthritis. Staphyloccocus aureus caused 122 cases. MRSA caused septic arthritis in 45 patients; MSSA caused septic arthritis in 77 patients. Patient characteristics, clinical features and outcomes of MRSA septic arthritis patients and MSSA septic arthritis patients are summarized in Table 1. MRSA and MSSA septic arthritis occurs predominantly in males. There were no differences between the two groups in mean age. MRSA septic arthritis patients had more comorbidities than MSSA septic arthritis patients. There were no statistically significant differences in the initial clinical presentation between both groups (fever, leukocytosis, presence of bacteremia, polyarticular involvement, mean leucocyte count on synovial analysis). Only 77.8% of MRSA patients were treated initially for MRSA. The MRSA septic arthritis patients had a higher mean number of joint surgeries and longer hospital lengths of stay. They also had worse patient and joint outcome and higher rates of development of osteomyelitis adjacent to the joint.

Conclusion: We recorded a significant number of MRSA septic arthritis cases from the year 2000 to 2013. MRSA septic arthritis affects patients with multiple comorbidities and is associated with worse outcomes. Only 77.8% of MRSA septic arthritis patients were covered empirically for MRSA on initial presentation. Since MRSA is an emerging clinical entity in septic arthritis, rheumatologists have to consider this pathogen in patients with septic arthritis and more research is needed to improve patient outcomes.

Human Papilloma Virus and Chlamydia Trachomatis Infections in Rheumatoid Arthitis Under Anti-TNF Therapy. Mariana G Waisberg[1], Ana C.M. Ribeiro[2], Wellington M. Candido[1], Poliana B. Medeiros[1], Cezar N. Matsuzaki[1], Mariana C. Beldi[1], Maricy Tacla[1], Helio H. Caiaffa-Filho[1], Eloisa Bonfá[1] and Clovis A Silva[3]. [1]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [2]University of Sao Paulo, Sao Paulo, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: Cervical human papillomavirus (HPV) infection has been observed in 28% of rheumatoid arthritis (RA) patients in a cross-sectional study with no available data regarding *Chlamydia trachomatis* (CT) infection. Anti-TNF blockage may increase the risk of these gynecologic complications, in spite of a few case reports of HPV infection in chronic inflammatory arthritis and psoriasis under this therapy. Therefore, the purpose of our study was to evaluate HPV and CT infections in RA patients pre- and 6 months post-TNF blocker. The possible associations among these infections, demographic data, sexual function, disease parameters and treatment were also analyzed.

Methods: Fifty female RA patients (ACR criteria), who were eligible to anti-TNF therapy, [n=50 at baseline (BL) and n=45 after 6 months of treatment (6M)] and 50 age-matched healthy controls were prospectively enrolled. All RA patients and controls had previous sexual activity. Exclusion criteria were: current pregnancy, early post-partum period, diabetes mellitus, psychiatric diseases and cervical cancer. They were assessed for demographic data, gynecologic, sexual, cervical cytology and histological evaluations, disease parameters and current treatment. HPV DNA and CT DNA testing in cervical specimens were done using Hybrid Capture II assays.

Results: At BL, the median current age of RA patients and controls was 49(18–74) vs. 49(18–74) years, p=1.0. A trend of lower frequency of HPV infection was observed in AR patients pre anti-TNF compared to controls (14% vs. 30%, p=0.054). None of patients had genital warts. Further evaluation of AR patients with and without HPV infection before anti-TNF therapy showed that the former group had a higher frequency of sexual intercourses (100% vs. 48%, p=0.014), higher median number of sexual partners [1(1–1) vs. 0(0–1), p=0.032] and higher frequency of abnormal cervical cytology (43% vs. 7%, p=0.029). Current age, disease duration, physician and patient visual analogue scales, DAS 28, ESR, CRP and treatments were alike in both groups (p>0.05). At 6M after TNF blockage, HPV infection remained unchanged in five patients, whereas two became negative and one additional patient turn out to be positive (McNemar′s test p=1.0). None of them had cervical cancer in Pap smear. CT infection was uniformly negative in RA patients pre- and post-TNF blockage and in controls.

Conclusion: To our knowledge, this was the first study to assess prospectively genital infections in RA patients under TNF blockage therapy. Anti-TNF does not seem to increase short-term risk or severity of HPV and CT infections in RA patients.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Clinical Aspects V: Mortality and Other Outcomes
Tuesday, November 18, 2014, 2:30 PM–4:00 PM

2810

Reduced Mortality Risk in Rheumatoid Arthritis: Findings from Two UK Inception Cohorts. Sam Norton[1], Elena Nikiphorou[2], Lewis Carpenter[2], David Walsh[3], Patrick Kiely[4], Josh Dixey[5] and Adam Young[6]. [1]King's College London, London, United Kingdom, [2]University of Hertfordshire, Hatfield, United Kingdom, [3]University of Nottingham, Nottingham, United Kingdom, [4]St. Georges Healthcare NHS Trust, London, United Kingdom, [5]New Cross Hospital, Wolverhampton, United Kingdom, [6]ERAS, St Albans City Hospital, St Albans, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) is associated with a 20 to 30% increased risk of mortality from all-causes compared to the general population. The aim of the present study is to examine whether, as observed in the general population, mortality rates in RA have decreased over the past 25 years. Furthermore, to assess whether changes are due to a potentially milder disease at presentation or change in treatment practise.

Methods: Data from 32 centres in the UK that recruited 2763 patients to two inception cohorts between 1986 and 2012 were combined for the analysis: Early RA Study and Early RA Network. Both recruited DMARD naïve patients at presentation to the rheumatology clinic. Death certificates were provided by the NHS central register. All-cause mortality was standardised against population rates (stratified by age, sex and calendar year) to examine whether excess mortality risk had changed with time. Pooled logistic survival models estimated the relative yearly reduction in mortality hazard. Marginal structural modelling was used to examine the effect on methotrexate on survival, adjusting for confounding by indication of the treatment effect.

Results: The excess mortality risk in RA compared to the general population reduced over time. Restricting the analysis to deaths within 10 years of onset, for ERAS (recruitment 1986 to 2001) the all-cause standardised mortality ratio (SMR) was significantly increased (1.21; 95%CI 1.10 to 1.34), whereas for ERAN (recruitment 2002 to 2012) it was non-significant (1.04; 95%CI 0.88 to 1.22). The difference between SMR's for the two cohorts was non-significant. Combining the two cohorts, year of symptom onset was significantly associated with all-cause mortality risk (HR = 0.96, p<.001; 95%CI. 95 to. 98). Controlling for demographic and clinical features at baseline did not reduce the magnitude of the effect for year of onset (HR = 0.95, p<.001; 95%CI. 93 to. 97). Extending the model to control for treatment using a marginal structural modelling approach, the use of methotrexate (use of which increased dramatically over the period of recruitment) was associated with a 60% reduction in the risk of death (HR = 0.40, p<.001; 95%CI. 25 to. 64). After controlling for methotrexate use the effect of year of onset was reduced to non-significant (Hazard ratio = 0.98, p<.001; 95%CI. 96 to 1.01).

Conclusion: Substantial gains in life expectancy have been observed for people with RA in the UK over the last 25 years. The excess mortality risk appears to have been greatly diminished. This is probably due to changes in treatment practise, rather than RA becoming milder at presentation.

Improvements in Rheumatoid Arthritis Related Fatigue Are Driven By Reductions in Pain, Not Disease Activity – Results from the British Society for Rheumatology Biologics Register for Rheumatoid Arthritis.
Katie L Druce, Gareth T Jones, Gary J. Macfarlane and Neil Basu. University of Aberdeen, Aberdeen, United Kingdom.

Background/Purpose: Rheumatoid Arthritis (RA) patients commonly report reductions in fatigue after commencing Anti-TNF therapy. The mechanisms behind such reductions have not been determined, although it is assumed that changes in disease activity drive improvements. Nevertheless, to promote improvement in this patient priority, the true pathways to change in fatigue must be elucidated. Using Structural Equation Modelling (SEM), this study aimed to be the first to determine the pathways to improvement in fatigue among RA patients commencing Anti-TNF therapy.

Methods: Participants recruited to a long-term cohort study (the British Society for Rheumatology Biologics Register for RA) provided information on fatigue (SF 36 Vitality), disease activity (DAS 28) and other putative mediators of fatigue change (including disability, pain and mental health) at Anti-TNF therapy commencement and 6 month follow-up. A SEM path model, using the data of 2652 participants with high baseline fatigue (SF 36 Vitality ≤12.5,), was constructed employing a model generation approach. The total, direct and indirect effects of each putative mediator on improvement in fatigue were quantified using path co-efficients. Where indirect effects accounted for more than 50% of total effect, the variable was considered to be mediated by other variables in the model.

Results: Significant pathways to improvement in fatigue (Figure 1) were shown to originate from changes in disease activity, pain, mental health, and disability, as well as a history of depression and participant sex. The model accounted for 40% of the variance in change in fatigue and demonstrated a good model fit (χ^2=0.18, df=3,p=0.98). The largest absolute improvements in fatigue were associated with a one standard deviation improvement in pain and mental health (0.31 and 0.28 unit improvement in fatigue, respectively). As 82% of the total effect of change in disease activity was indirect, the variable was mediated by other variables in the model. Specifically, 50% of the indirect effect was mediated through a change in pain and an additional 14% through pain and mental health improvement.

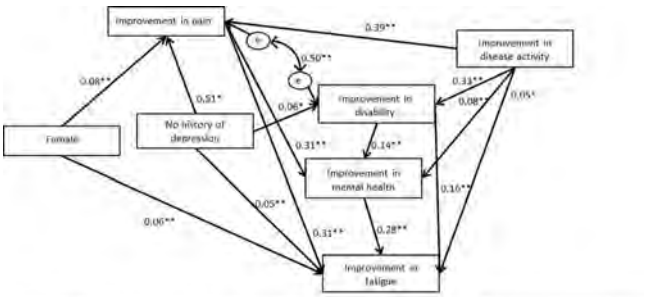

Figure 1. Path model diagram with standardized coefficients determining direct and indirect effects to improvement in fatigue (SF36 Vitality 0-100). e; 'error term' (unmeasured variable) p<0.01, **p<0.001

Conclusion: Improvement in RA related fatigue after commencing Anti-TNF therapy is driven by reductions in pain, rather than directly from disease activity. In addition, mental health and disability are important mediators in the pathway to fatigue improvement and should be targeted, in an attempt to further improve this patient priority.

Is Rheumatoid Arthritis the Same Disease in Women and Men?- Joint Damage in Patients with EARLY Rheumatoid Arthritis at 10 YEARS after Diagnosis.
Juha Asikainen[1], Kalevi Kaarela[2], Heidi Mäkinen[3], Hannu Kautiainen[4], Pekka Hannonen[5], Tuomas Rannio[6] and Tuulikki Sokka[7]. [1]Jyvaskyla Central Hospital, Jyväskylä, Finland, [2]Jyväskylä Central Hospital, Jyväskylä, Finland, [3]Tampere University Hospital, Tampere, Finland, [4]Medcare Oy, Äänekoski, Finland, [5]Jyväskylä Central Hospital, Jyvaskyla, Finland, [6]Kuopio University Hospital, Kuopio, Finland, [7]Jyvaskyla Central Hospital, Jyvaskyla, Finland.

Background/Purpose: Rheumatoid arthritis (RA) is suggested to be a more severe disease in women than in men as disease activity appears higher in women, and men meet remission criteria more often.

Long-term severity of RA can be analyzed from permanent joint damage in radiographs. Our purpose was to study possible differences in the extent of radiographic joint damage between women and men in an early RA cohort at 10 years after diagnosis.

Methods: Our early RA cohort includes 990 patients from a single clinic with a clinical diagnosis of early RA in 1997 – 2004. Radiographs of hands and feet were taken at a 10 year follow-up visit after diagnosis and were analyzed according to the Larsen score (0–100) including MCP I-V, wrists, and MTP II-V.

Results: Baseline characteristics of 990 patients were: the mean (SD) age 57(16) years, 67% female, 61% seropositive (RF/CCP+ any time over 10 years) and median (IQR) duration of symptoms before diagnosis 6(3, 12) months; 657(66%) patients were available for a 10 year follow up. Reasons for non-attendance among 333 patients included death (52%), high age, multi-comorbidity or institutionalization (10%), moving from the area (12%); 8% declined, 4% were lost to follow-up and 14% miscellaneous reasons. Thus, radiographs were available in 462 women and 195 men with a similar percentage of 66% being seropositive among genders. In seropositive patients, the mean (SD) Larsen score was 7.7(10) in women and 8.1(11) in men, p=0.12. The probability plot was similar for women and men (Figure 1). In seronegative patients, the mean (SD) Larsen score was 1.9(3.8) in women and 2.3(4.5) in men, p=0.29.

Conclusion: At 10 years after diagnosis, RA joint damage appears similar in both genders. RA severity is comparable between women and men.

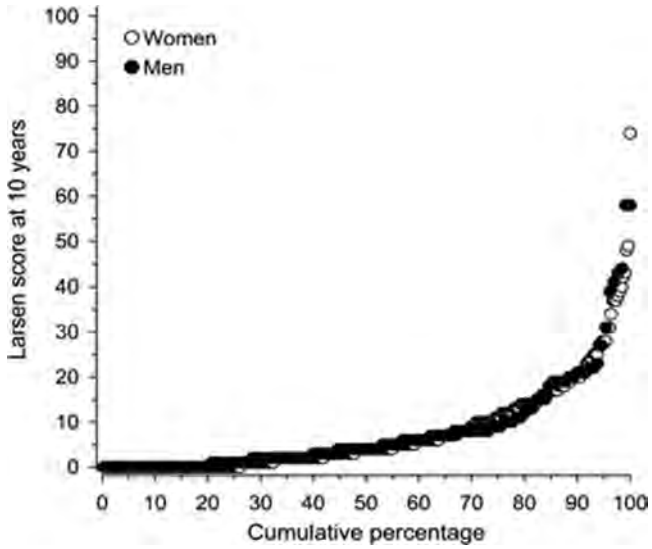

Figure. Larsen score in seropositive women and men with early RA at 10 years after diagnosis.

Correlation of Morning Stiffness with Measures of Higher Disease Activity in a Large US Registry Population of Rheumatoid Arthritis Patients. Vibeke Strand[1], Robert J. Holt[2], Katherine C. Saunders[3], Jeffery D. Kent[4], Ping Xu[5], Amy Y. Grahn[4], Marc Mason[3] and Carol J. Etzel[3]. [1]Stanford University, Palo Alto, CA, [2]University of Illinois - Chicago, Chicago, IL, [3]Corrona, LLC., Southborough, MA, [4]Horizon Pharma, Inc., Deerfield, IL, [5]Axio Research LLC, Seattle, WA.

Background/Purpose: Morning stiffness may not be specifically queried by rheumatologists in the course of their regular interactions with rheumatoid arthritis (RA) patients. This analysis investigated whether morning stiffness was correlated with measures of disease activity.

Methods: Data from the Corrona RA Registry included RA patients who initiated a new therapy: non-biologic or biologic DMARD, whether as monotherapy or in combination, and remained on treatment for ≥ 90 days. Patients were evaluated at initiation, 1 and 2 years after initiation and time of last visit. Correlations of measures of disease activity with presence and change in morning stiffness were modeled at the patients' last Corrona visit between January 2013 and February 2014. For patients with ≥ one visit during this interval, propensity score (PS) trimming of the top and bottom 5% was used to obtain comparable populations with and without morning stiffness. Thus data from 90% of RA patients (5379 subjects) were utilized to examine the association of measures of disease activity: remission (CDAI ≤2.8); low disease activity (2.8>CDAI≤10); moderate disease activity (10<CDAI≤22) and high disease activity (CDAI>22) with presence/absence of morning stiffness, after PS trimming at time of last visit.

Results: At baseline those with morning stiffness (n=9688) were less likely to be working, more likely to have received biologic therapy, Medicaid insurance, and to have higher measures of disease activity than those without (n=2865): CDAI high: 34.1 vs 10.3%; remission/low: 31.6 vs 66.3%, p<0.0001. At one year after initiation of treatment, these differences persisted (with morning stiffness (n=6148) without (n=2597), including statistically significantly higher mHAQ scores: 0.5 ± 0.5 vs 0.1 ±0.3, p<0.0001; more reporting disabled work status: 21.7 vs 5.2%, p<0.0001 and CDAI high: 21.7 vs 5.2%; remission/low: 48.0 vs 80.2% p<0.0001. These differences persisted even after 2 years of follow-up (with morning stiffness (n=4466) without (n=1895): mHAQ scores unchanged; disabled: 29.2 vs 9.4%; CDAI high:19.3 vs 3.9%; remission/low: 51.4 vs 82.0, all p<0.0001. At time of last Corrona visit, higher CDAI, mHAQ and patient reported fatigue were significantly associated with presence of morning stiffness and increased persistence of morning stiffness (Figure 1).

Conclusion: In this registry analysis, presence and persistence of morning stiffness consistently reflected higher disease activity associated with more impairment of physical function and self reported work disability.

Time-to-Remission, Time-to-Relapse and Disease Severity at the Time of Relapse in RA- Results from the Ontario Best Practices Research Initiative (OBRI). Bindee Kuriya[1], Xiuying Li[2], Binu Jacob[2], Pooneh Akhavan[3], Jessica Widdifield[1], Mark Tatangelo[1], Janet E. Pope[4], Edward Keystone[5] and Claire Bombardier[6]. [1]University of Toronto, Toronto, ON, [2]University Health Network, Toronto General Research Institute, Toronto, ON, [3]Early Rheumatoid Arthritis Program, Mount Sinai Hospital and University of Toronto, Toronto, ON, [4]Western University, London, ON, [5]Mount Sinai Hospital, University of Toronto, Toronto, ON, [6]Institute for Work & Health, Toronto, ON.

Background/Purpose: Clinical remission in RA is the desired goal, however the ability to sustain remission and the timing and severity of relapse is not well known. We aimed to describe time to remission, time-to-relapse and disease activity at the time of relapse.

Methods: We performed a longitudinal data analysis of patients enrolled in the Ontario Best Practices Research Initiative (OBRI), a clinical registry of RA patients followed in routine care. The prevalence of a first occurrence of clinical remission according to the DAS28-ESR <2.6 or CDAI </=2.8 following cohort entry (baseline) was determined as was the average time-to-remission. Patients achieving remission with >/= 1 follow-up visit (typically spaced 3 to 6 months apart) were observed for the average time until relapse, defined as a DAS28 >2.6 or CDAI >2.8. The baseline disease activity level of those achieving remission and the disease activity level at the time of relapse was examined.

Results: The total cohort (N=2305) was 78% female with mean (SD) age 57 (13) years, disease duration 8.6 (9.6) years and mean DAS28 score 4.5 (1.5) at baseline. Remission was achieved in 1081 patients (47%); 140 of these patients had low baseline disease activity, 516 had moderate and 369 had high disease activity at baseline. The median time to remission was 279 days (interquartile range [IQR] 146 – 482) and remission was reached significantly faster among those starting with low disease activity (median 218 days, IQR 148–385) at baseline compared to more severe disease (median 357 days, IQR 173–563) (P<0.001). Nine hundred eighteen patients (85%) had continued follow up after remission and 582 (59%) went on to experience a relapse. The median time-to-relapse was 197 days (IQR 126–363). The majority switched from a state of remission to mild or moderate disease activity, in contrast to the moderate to severe levels of disease activity they experienced at baseline (Table).

Conclusion: Clinical remission in routine care is achievable and occurs fastest in those with low to moderate levels of disease activity at baseline. Remission is not sustained in the majority of individuals and relapse occurs, on average, by 7 months. Further work examining the predictors and characteristics of patients who relapse to a low disease state (which may be an acceptable substitute to remission) vs. relapse to a high disease state is needed to determine the nature and timing of therapeutic intervention that may be required to prevent and manage disease flares.

Table. Disease activity according to DAS28 or CDAI at time of relapse according to baseline level disease activity.

RA disease at baseline	Disease Activity at Time of Relapse (N=552)*		
	Low (N=257)	Moderate (N=245)	High (N=50)
Low (N=55)	26	25	4
Moderate (N=284)	140	127	17
High (N=213)	91	93	29

* 30 of the 582 patients were missing information at follow up to calculate disease activity

Better Functional Ability with Less Biologicals 2 years after Induction with Combination DMARD Therapy versus methotrexate Monotherapy. T. Martijn Kuijper[1], J.J. Luime[1], P.H.P. de Jong[1], A. H. Gerards[2], D. van Zeben[3], I. Tchetverikov[4], P.B.J. de Sonnaville[5], M. van Krugten[6], B. Grillet[7], J.M.W. Hazes[8] and A.E.a.M. Weel[9]. [1]Erasmus University Medical Center,

Rotterdam, Netherlands, [2]Vlietland Hospital, Schiedam, Netherlands, [3]Sint Franciscus Gasthuis, Rotterdam, Netherlands, [4]Albert Schweitzer Hospital, Dordrecht, Netherlands, [5]Admiraal de Ruyter Ziekenhuis, Goes, Netherlands, [6]Admiraal de Ruyter Hospital, Vlissingen, Netherlands, [7]ZorgSaam Hospital, Terneuzen, Netherlands, [8]Erasmus MC, Rotterdam, Netherlands, [9]MD, PhD, Rotterdam, Netherlands.

Background/Purpose: To assess differences in frequency of biological therapy use and functional ability in early RA patients two years after starting induction therapy according to three different treatment regimens.

Methods: Data were used from patients with recent-onset arthritis participating in a single-blinded clinical trial (Treatment in the Rotterdam Early Arthritis CoHort (tREACH))(1) in which three induction therapy strategies were compared: (A1) combination therapy (methotrexate (MTX) + sulfasalazine + hydroxychloroquine) with glucocorticoids (GCs) intramuscularly; (A2) combination therapy with an oral GC tapering scheme and (B) MTX with oral GCs similar to B. As no difference in disease activity scores (DAS) was found between groups A1 and A2 at 3 and 12 months of follow-up(1), these groups were combined for this analysis (group A). Disease activity scores (original DAS) were assessed every 3 months. Functional ability was assessed using the Health assessment questionnaire (HAQ). Data were analysed using simple descriptive statistical techniques.

Results: 281 patients (91 men, 190 women; mean baseline DAS 3.3, median baseline HAQ 1.00) were initially randomized. Data on medication use at 2 years were available from 248 patients (88%), see figure 1. At 2 years, 24% of patients in group A versus 43% in group B were using a biological DMARD. Biological use and DAS over time are demonstrated in figure 2.

Equal mean DAS of 1.66 (95%CI 1.54–1.78) at 24 months was observed for the initial treatment groups at 24 months (group A: 1.58 (95%CI 1.43–1.73), group B: 1.80 (95%CI 1.58–2.02). DAS remission (DAS<1.6) was achieved by 53% of patients.

The median disability score (HAQ (min-max)) was 0.38 (0–2) for all patients but varied in the treatment groups: A. 0.25 (0–1.9) and B. 0.63 (0–2.1) (p=0.042).

Conclusion: We observed lower use of biological therapy and better functional ability in induction triple therapy compared to induction monotherapy MTX with GC bridging at 2 years of follow-up in the treat-to-target tREACH study. No differences were found for disease activity scores.

Distinctive DNA Methylome Signatures in Early Rheumatoid Arthritis (RA) Synoviocytes Compared with Longstanding (RA) and Other Inflammatory Arthritides. Rizi Ai[1], John W. Whitaker[2], David L. Boyle[3], Paul Peter Tak[4], Danielle M. Gerlag[5], Wei Wang[6] and Gary S. Firestein[3]. [1]UC San Diego, La Jolla, CA, [2]UCSD, San Diego, CA, [3]University of California at San Diego School of Medicine, La Jolla, CA, [4]Academic Medical Center / University of Amsterdam, Department of Clinical Immunology and Rheumatology & GlaxoSmithKline, Amsterdam, Netherlands, [5]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [6]UCSD, La Jolla, CA.

Background/Purpose: Epigenetics influences pathogenic mechanisms in autoimmunity. Recently, a stable RA DNA methylation signature in fibroblast-like synoviocytes (FLS) was defined in 2375 genes. The present study compared the DML patterns of early RA (ERA) and other inflammatory arthritides to the patterns in longstanding RA (LRA) and OA.

Methods: Genomic DNA from FLS was isolated from arthroscopic biopsies in ERA (1–13 months of symptoms; n=4), undifferentiated arthritis that progressed to RA (UA; n=2) and ACPA+ arthralgia that did not develop arthritis (Arthralg; n=2). FLS lines were obtained from juvenile idiopathic arthritis (JIA; n=3) and spondyloarthritis (SpA; n=2) at arthroplasty. Methylation was measured using the Illumina HumanMethylation450 chip. Hierarchical clustering using Pearson correlation as the metric was performed on the methylomes of 11 LRA and 11 OA FLS lines. Principle component analysis (PCA) assessed the relationships between the different FLS types. Feature selection was determined by random forest to define ERA and LRA differences. Pathway enrichment analysis was evaluated using Kyoto Encyclopedia of Genes and Genomes (KEGG).

Results: Differentially methylated loci (DMLs) for LRA and OA segregated from each other based on the methylation pattern of 15,220 DMLs. Other non-inflammatory arthritis FLS lines clustered with LRA rather than OA. Within the non-OA cluster, LRA were highly similar to each other. DML patterns for ERA FLS were closely related to each other, but differed from the LRA. FLS from other diseases, including UA, SpA and JIA had an intermediate pattern. They were more closely related to LRA but formed subgroups within the non-OA hierarchical clustering. PCA confirmed distinct methylation patterns for LRA and OA. ERA and LRA patterns partially overlapped, which could be consistent with a transition of ERA to LRA methylation. UA was in the center of the LRA region while SpA and JIA primarily localized at the edges of LRA. The 2 Arthalg FLS lines did not conform to either OA or LRA patterns. Feature selection was performed and showed that the difference between LRA and ERA was due to 317 CpG loci. Pathway analysis suggested that DML genes in ERA involving focal adhesion, chemokine signaling, complement and coagulation are differentially methylated compared with LRA, indicating that cell recruitment in synovium evolves during the transition from early to late disease.

Conclusion: These data show a methylation signature in longstanding RA, with patterns that could be differentiated from SpA and JIA. UA patients who ultimately develop RA have a longstanding RA pattern. Most interesting, early RA had a distinct but overlapping DML pattern compared with longstanding RA with changes in cell recruitment pathways that might indicate a change in how cells enter the joint as disease progresses. Therefore, differential methylation of RA FLS occurs early and evolves over time. Understanding the transition from early and established disease provides clues identifying targets causing disease progression.

Histone Deacetylase One Contributes to the Auto-Aggressive Phenotype of Rheumatoid Arthritis. Sarah Hawtree[1], Munitta Muthana[1], J. Mark Wilkinson[1], Anthony G. Wilson[1] and Mohammed Akil[2]. [1]University of Sheffield, Sheffield, United Kingdom, [2]Rheumatology Department, Sheffield South Yorkshire, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, autoimmune, inflammatory disease that affects synovial joints. A key characteristic of RA is hyperplasia of fibroblast-like synoviocytes (FLS) which develop a stable, auto-aggressive phenotype that augments tissue destruction. It is unknown how this phenotype is stably maintained, however epigenetic changes have been implicated. Histone acetylation is a major epigenetic mechanism (HDACs). The objective of the study is to determine the role of histone deacetylates (HDACs) in regulating the auto-aggressive phenotype of RA FLS.

Methods: Real time-qPCR was used to compare levels of HDAC1–11 in RA compared with osteoarthritis (OA) FLS. Joint biopsies were co-stained with anti-HDAC1 and anti-fibroblast antibodies. HDAC1 and a non-targeting control (NTC) siRNA were transfected *in vitro* into RA FLS. Cell proliferation, migration and invasion after siRNA knockdown (KD) were assessed by using tritiated thymidine, a scratch assay and a matrigel invasion assay respectively. An Illumina BeadChip (47,000 transcripts) was used to analyse global gene expression changes after KD. The *in vivo* effect of $HDAC1^{KD}$ was investigated in a mouse model of collagen-induced arthritis (CIA) using *in vivo*siRNA. Clinical scores of CIA were measured daily (days 0–49) and the bones were analysed using a microCT scanner.

Results: The mRNA levels of HDACs 1–11 are higher in RA compared to OA FLS, with HDAC1 levels showing a 4.2-fold increase ($p=0.03$, n=7–10). $HDAC1^{KD}$ reduced FLS proliferation ($p=0.04$, n=6), migration ($p=0.01$, n=6) and invasion ($p=0.02$, n=6) compared to the NTC. Cluster analysis of the microarrays (n=3) revealed significant changes in genes involved in apoptosis ($p\leq0.009$, n=21), migration ($p\leq0.008$, n=4) and proliferation ($p\leq0.009$, n=9). In mice with CIA, $HDAC1^{KD}$ significantly inhibited joint inflammation ($p=0.0001$, n=10) and reduced bone erosion compared to the NTC.

Conclusion: Our data implicates HDAC1 in controlling the autoaggressive phenotype of FLS in RA and our data in murine inflammatory arthritis supports targeting HDACi as a potential therapy in RA.

SH2 Domain-Containing Phosphatase 2 Promotes Aggressiveness of Rheumatoid Fibroblast-like Synoviocytes. Stephanie M. Stanford[1], German R. Aleman Muench[1], Cristiano Sacchetti[1], Lifan Zeng[2], David L. Boyle[3], Gen-Sheng Feng[4], Zhong-Yin Zhang[2], Maripat Corr[3], Gary S. Firestein[3] and Nunzio Bottini[1]. [1]La Jolla Institute for Allergy and Immunology, La Jolla, CA, [2]Indiana University School of Medicine, Indianapolis, IN, [3]University of California at San Diego School of Medicine, La Jolla, CA, [4]University of California at San Diego Division of Biological Sciences, La Jolla, CA.

Background/Purpose: In rheumatoid arthritis (RA), fibroblast-like synoviocytes (FLS) that line joint synovial membranes aggressively invade the extracellular matrix, destroying cartilage and bone. Although this cell type mediates RA pathogenesis, it is currently untapped as a drug target. Signal transduction in FLS is mediated through multiple pathways involving protein tyrosine phosphorylation, thus we sought to identify the protein tyrosine phosphatases (PTPs) regulating the aggressiveness of FLS from RA patients (RA FLS). We previously profiled the expression of all PTPs in FLS from RA and osteoarthritis (OA) patients, and found that the *PTPN11* gene, encoding the PTP SHP-2, is overexpressed in RA FLS. We also reported that SHP-2 promotes the aggressiveness of RA FLS by enhancing sensitivity of these cells to stimulation by platelet-derived growth factor (PDGF) or tumor necrosis factor (TNF). Here we sought to further explore the role of SHP-2 in mediating pathogenesis of RA.

Methods: Inhibition of SHP-2 enzymatic activity was achieved using a cell-permeable small-molecule chemical inhibitor. FLS migration was assessed in transwell assays in response to 5% fetal bovine serum. Inducible *in vivo* deletion of *Ptpn11* in hematopoietic cells was achieved by breeding *Ptpn11* floxed mice with mice expressing Cre recombinase under the *Mx1* promoter. Prior to experiments, deletion of the floxed alleles was induced by treating mice with 3 administrations of 300 μg poly(I:C) 2 days apart. *In vivo* inhibition of SHP-2 activity was achieved by administering mice with 7.5 mg/kg SHP-2 inhibitor once daily. Severity of arthritis in female mice was assessed every 2 days by ankle swelling in the K/BxN passive serum transfer arthritis mouse model following administration of 150 μl arthritogenic serum.

Results: We found that RA FLS migration was reduced 86% upon treatment with 25 μM SHP-2 chemical inhibitor (Median [IQR] % maximum cells per field: 56.58 [41.45–72.37] for vehicle-treated FLS and 7.90 [3.29–15.13] for SHP-2 inhibitor-treated FLS; $p<0.0001$ by Mann-Whitney test). Using the K/BxN mouse arthritis model, we found that inducible deletion of SHP-2 in hematopoietic cells led to >50% reduction in arthritis severity (Median [IQR] change in ankle thickness after 8 days: 3.62 [3.08–3.78] for Cre^- mice and 0.46 [0.11–1.69] for Cre^+ mice; $p<0.0001$ by two-way ANOVA test of 14-day arthritis course). Global inhibition of SHP-2 activity by daily administration of 7.5 mg/kg SHP-2 inhibitor also led to reduced arthritis severity (Median [IQR] change in ankle thickness after 8 days: 2.650 [1.81–3.27] for vehicle-treated mice and 2.14 [0.70–2.73] for inhibitor-treated mice; $p<0.01$ by two-way ANOVA test for 14-day arthritis course).

Conclusion: These data indicate that SHP-2 promotes the aggressiveness of RA FLS, a role that is dependent on the catalytic activity of the phosphatase. Both global inhibition and inducible deletion of SHP-2 in hematopoietic cells caused a reduction in arthritis severity, suggesting SHP-2 could be a potential target for therapy for RA.

The YAP Pathway Regulates Fibroblast-like Synoviocyte Invasion. Beatrix Bartok. University of California, San Diego, La Jolla, CA.

Background/Purpose: Fibroblast like synoviocytes (FLS) in RA possesses unique transformed phenotype, such as cartilage invasion that is maintained independent of cytokines and other inflammatory cells. However-.the molecular mechanisms that regulate FLS behavior in RA are poorly understood. The transcriptional coactivator Yes-associated protein (YAP) was recently shown that is dysregulated in RA compared with OA FLS. Increased YAP activity might contribute to persistent activation and pathogenic behavior of RA FLS. Therefore, we assessed role of YAP in synoviocyte invasion.

Methods: We used siRNA knock down and chemical inhibition to assess effect of YAP iactivation on RA FLS invasion. We used Verteporfin to inhibit YAP transcriptional activity. For siRNA knockdown, YAP and control siRNA were transfected using AMAXA technology. FLS invasion was studied using Matrigel coated transwells, 3 days following transfection. YAP inhibitor or vehicle was added to the upper chamber and PDGF was used as chemoattractant in the lower chamber. The cytoskeleton and focal adhesions were visualized with confocal microscopy using Rhodamin phalloidin and anti-Vinculin staining. MMP expression was measured using qPCR.

Results: The YAP inhibitor Verteporfin significantly decreased number of invading cells in a concentration dependent manner, with 65+5% inhibition at 0.1 uM ($p< 0.02$, n=3). Similar results were obtained when YAP was knockdown by siRNA. Cells with reduced YAP activity displayed 52+6% ($p< 0.04$, n=3) decrease in invasion through Matrigel matrix compared with scramble control. To determine effect of YAP inactivation on cytoskeleton and focal adhesion formation, cells were stained with phalloidin and anti-Viculin. RA FLS treated with the YAP inhibitor Verteporfin displayed diminished stress fiber formation and decrease in focal adhesion formation by 56+5% ($p<0.04$, n=3) visualized with confocal microscopy. Similar findings were obtained when YAP was inactivated by siRNA knock down. To determine the effect on MMP production cells were stimulated with TNF and qPCR was performed for MMP1, 2, 3, 9 and MT1MMP. mRNA levels for MMP1 and MMP3 were significantly lower in YAP deficient cells compared with scramble control ($P<0.03$ and $p<0.05$, n=3), while MMP2,9 and MT1MMP mRNA were unchanged. Similar findings were obtained using chemical inhibition with Verteporfin.

Conclusion: YAP is a major regulator of RA FLS invasion by modulating focal adhesion formation and MMP production. These observations, together with our previous findings that increased YAP activity in RA FLS compared with OA suggest that YAP activity might contribute to persistent activation and pathogenic behavior of RA FLS. Therefore, modulating YAP pathway might represent a novel therapeutic approach for RA.

Dual Role for B Cells in Promoting Bone Erosion in Rheumatoid Arthritis Via Effects on Osteoclast and Osteoblast Differentiation. Nida Meednu, Hengwei Zhang, Teresa Owen, Lianping Xing and Jennifer H. Anolik. University of Rochester, Rochester, NY.

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease that often leads to joint damage, a process mediated by an imbalance between bone resorption and bone formation. Additional evidence implicates the role of B cells in joint destruction including the presence of B cell aggregates in RA synovium and subchondral bone and the efficacy of B cell depletion therapy in halting radiographic progression. However, B cell effects on bone have been described as mediated via indirect influences on other immune cell such as T cells. Whether B cells directly affect bone homeostasis in RA is not known. In this study we investigated the effects of B cells on osteoclast (OC) and osteoblast (OB) functions in RA.

Methods: Isolated B cells from peripheral blood of healthy controls (HC) or RA patients were stimulated with α-CD40 and PMA for 96 h, and RANKL and TNF production was assessed by flow cytometry, ELISA, and qPCR. Stimulated and un-stimulated B cells were fixed then co-cultured with CD14+ monocytes isolated from HC along with M-CSF and sub-optimal levels of exogenous RANKL (10ng/ml). OC formation *in vitro*was examined by TRAP staining. For OB differentiation assays, stimulated and un-stimulated B cells were co-cultured in Transwells with human mesenchymal stem cells (hMSCs) (Lonza, #PT-2501) for 24 h and the expression of OB transcription factor RUNX2 and Notch signaling molecules, Hes1 and Hey1 in hMSCs was detected by qPCR.

Results: HC B cells stimulated with α -CD40 and PMA produce significant amounts of RANKL as compare to un-stimulated B cells (%RANKL+: 4.9±0.94 *vs.* 0.413±0.095, $P<0.0001$). Stimulated HC B cells promoted more OC formation than that of un-stimulated B cells (#OC/well: 66±8 *vs.* 4±1, $P<0.0001$), which can be blocked by RANKL neutralizing antibody (#OC/well: 66±8 *vs.* 21±3, $P<0.0001$). Notably, stimulated RA B cells induced significantly more OC formation in comparison to HC B cells (using the same donor for OCP) (#OC/well: RA: 60±7 *vs.* HC: 12±7, $P<0.001$). In parallel, RA memory B cells expressed higher RANKL than memory B cells from HC (%RANKL+: 20.4±1.68 *vs.* 11.25±3.15, $P<0.05$). In addition to RANKL, stimulated B cells produce TNFα (91±11.6 pg/ml, n=4) a cytokine that we reported recently to inhibit OB differentiation of murine CD45- MSCs via up-regulating the Notch signaling pathway. In co-culture with hMSCs, stimulated RA B cells significantly reduced RUNX2 expression in hMSCs as compared to un-stimulated B cells (Runx2/actin: 0.21±0.01*vs.* 1±0.04 $P=0.002$, n=3), which was associated with increased levels of Hes1 and Hey1. In agreement with this finding, RA CD45- cells (MSC-enriched cells) isolated from peripheral blood have reduced expression of RUNX2 and increased expression of Hes1 and Hey1 compared to HC (n=11 for RA, n=14 for HC), suggesting abnormal OB function *in vivo*.

Conclusion: Our finding suggest that B cells play a critical role in promoting bone erosion in RA both by directly enhancing osteoclastogenesis and inhibiting osteoblast differentiation.

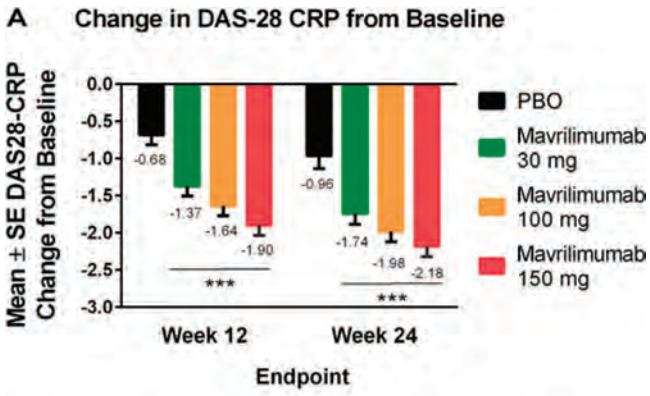
Efficacy and Safety/Tolerability of Mavrilimumab, a Human GM-CSFRá Monoclonal Antibody in Patients with Rheumatoid Arthritis.

Gerd Burmester[1], Iain B. McInnes[2], Joel M. Kremer[3], Pedro Miranda[4], Mariusz Korkosz[5], Jiri Vencovsky[6], Andrea Rubbert-Roth[7], Eduardo Mysler[8], Sara Sandbach[9], Matthew A. Sleeman[9], Alex Godwood[9], David Close[9] and Michael Weinblatt[10]. [1]Charité - University Medicine Berlin, Berlin, Germany, [2]University of Glasgow, Glasgow, United Kingdom, [3]Albany Medical College and the Center for Rheumatology, Albany, NY, [4]Centro de Estudios Reumatologicos, Santiago, Chile, [5]Malopolskie Centrum Medyczne, Krakow, Poland, [6]Charles University Institute of Rheumatology, Praha, Czech Republic, [7]University of Cologne, Koln, Germany, [8]OMI, Buenos Aires, Argentina, [9]MedImmune Ltd, Cambridge, United Kingdom, [10]Brigham & Women's Hospital, Harvard Medical School, Boston, MA.

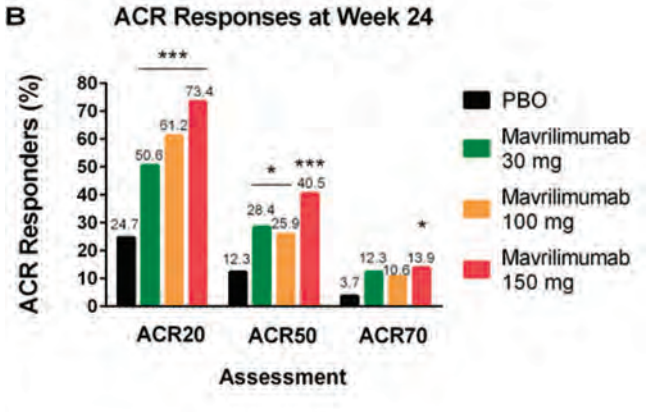
Background/Purpose: Granulocyte-macrophage colony-stimulating factor (GM-CSF) is implicated in RA pathogenesis via myeloid and granulocyte cell lineage activation. In a prior Phase 2a study (NCT01050998), mavrilimumab, a first-in-class inhibitor of the GM-CSF receptor α showed a rapid and sustained effect over the 12-week study duration. Here, we present results of a 24-week Phase 2b randomized, double-blind, placebo (PBO)-controlled, parallel-group, multicenter study (NCT01706926) that evaluated the efficacy and safety of mavrilimumab in patients with moderate-to-severe adult-onset RA.

Methods: Patients (18–80 years; inadequate response to ≥1 DMARD; DAS28-CRP ≥3.2; ≥4 swollen joints; receiving methotrexate [MTX]) were randomized 1:1:1:1 to receive 1 of 3 subcutaneous mavrilimumab doses (30, 100, 150 mg) or PBO every 2 weeks plus MTX (7.5–25.0 mg/week) for 24 weeks. Co-primary endpoints were change in DAS28-CRP (day 1 to week 12) and ACR20 response rate (week 24). Safety and tolerability were measured through assessment of adverse events (AEs) and pulmonary parameters. **Results** were analyzed using the modified intent-to-treat population.

Results: In total, 326 patients from Europe, South America and South Africa (mean [SD] age 51.8 [11.1] years; female 86.5%; mean [SD] DAS28-CRP 5.8 [0.9]; RF/ACPA+ 81.9%) were randomized to PBO or mavrilimumab 30, 100, or 150 mg (n=81, 81, 85, 79, respectively). At week 12, a statistically significant difference in DAS28-CRP ($p<0.001$) was seen for all doses of mavrilimumab vs PBO (Figure A). At week 24, a significantly higher percentage of all mavrilimumab-treated patients also met the ACR20 co-primary endpoint vs PBO (Figure B). A significant ($p<0.001$) separation vs PBO for these parameters was seen as early as week 1 for mavrilimumab 150 mg, which was also associated with significantly higher ACR50 and ACR70 response rates vs PBO at week 24 (Figure B). A dose response effect was observed across multiple secondary endpoints, with separation vs PBO evident from week 1 and 1 dose. The most common treatment-emergent AEs were headache (2.5%, 6.2%, 4.7%, 7.6%), nasopharyngitis (7.4%, 4.9%, 3.5%, 7.6%) and bronchitis (7.4%, 3.7%, 1.2%, 5.1%) for PBO and 30, 100, or 150 mg, respectively. There was no increase in pulmonary AEs for mavrilimumab vs PBO (6.2%, 3.5%, 6.3% vs 9.9%). No serious infections were observed in the 100 and 150 mg groups; 2 cases of pneumonia were seen (30 mg and PBO groups). There were no deaths or anaphylaxis, and no apparent dose relationship for AEs. >90% patients entered a long-term open-label study.



***p<0.001, mavrilimumab vs PBO
Mean [95% CI] adjusted difference from PBO at week 12: 150 mg -1.22 [-1.60, -0.84]; 100 mg -0.96 [-1.33, -0.58]; 30 mg -0.69 [-1.06, -0.31]
PBO, placebo; SE, standard error



*p<0.05, mavrilimumab vs PBO
***p<0.001, mavrilimumab vs PBO
PBO, placebo

Conclusion: This second Phase 2 study demonstrates the potential benefit of inhibiting macrophage activity via the GM-CSFRα pathway on RA disease activity. The study met both co-primary endpoints with a clear dose response effect. An acceptable tolerability profile was demonstrated over the 24-week study period.

2822

Safety and Efficacy of Baricitinib through 128 Weeks in an Open-Label, Long-Term Extension Study in Patients with Rheumatoid Arthritis.

Edward C. Keystone[1], Peter C. Taylor[2], Mark C Genovese[3], Douglas E. Schlichting[4], Inmaculada De La Torre[5], Scott D. Beattie[4] and Terence Rooney[4]. [1]Mount Sinai Hospital, Toronto, ON, [2]University of Oxford, Oxford, United Kingdom, [3]Stanford University Medical Center, Palo Alto, CA, [4]Eli Lilly and Company, Indianapolis, IN, [5]Eli Lilly and Company, Alcobendas, Spain.

Background/Purpose: Baricitinib is an oral inhibitor of JAK1/JAK2 being investigated as a treatment for rheumatoid arthritis (RA). In a phase 2b study, baricitinib treatment resulted in significant clinical improvements over 24 wks[1]. The safety and efficacy findings of baricitinib treatment in RA patients (pts) up to 128 wks are reported here.

Methods: Pts were randomized to placebo (PBO) or 1, 2, 4, or 8 mg baricitinib QD for 12 wks (Part A). Pts assigned to 2, 4, or 8 mg continued assigned treatment and pts assigned to PBO or 1 mg were reassigned to 4 mg QD or 2 mg BID for an additional 12 wks of blinded treatment (Part B). Pts completing Part B were eligible to enter a 52 wk open-label extension (OLE; Wks 24–76, Part C), where pts in the 8 mg group continued to receive 8 mg QD and all other pts received 4 mg QD. During Part C, doses could be escalated to 8 mg QD at 28 or 32 wks at the investigator's discretion when ≥6 tender and ≥6 swollen joints were present. Pts completing Part C were eligible to enter an additional 52 wk OLE (Wks 76–128, Part D) where pts received 4 mg QD regardless of previous dose.

Results: Of 204 pts at sites participating in Part C, 201 (99%) were treated and 169 (84%) completed 52 wks. Among pts who remained on 4 mg (N=108) in Part C, TEAEs occurred in 63%, SAEs in 16%, infections in 35%, and serious infections in 5%. Among pts who received 8 mg at any time (N=93) in Part C, TEAEs occurred in 68%, SAEs in 13%, infections in 40%, and serious infections in 3%. Of 150 pts at sites participating in Part D, 144 (96%) were treated and 133 (92%) completed an additional 52 wks. Among pts who remained on 4 mg (N=79) in Part D, TEAEs occurred in 53%, SAEs in 6%, infections in 32%, and serious infections in 3%. Among pts who decreased to 4 mg (N=65) in Part D, TEAEs occurred in 55%, SAEs in 6%, infections in 28%, and serious infections in 3%. The exposure-adjusted incidence rates for adverse events for all baricitinib groups in Part D were similar to or lower than those rates observed in Part C (Table 1). No opportunistic infections, tuberculosis cases, or lymphomas were observed through 128 wks. One death due to myocardial infarction occurred in the 8 mg group in Part C. Among all pts combined, the proportions of pts achieving ACR20 or disease improvement at Wk 24 were similar or increased at Wks 76 and 128 (Table 2).

Conclusion: Among pts completing 128 wks of a phase 2b study, clinical improvements observed at Wk 24 were maintained or improved through Wk 128. In addition, safety data collected during the OLE were consistent with previous baricitinib findings[1].

2823

Comparable Efficacy with Sarilumab Plus Methotrexate in Biologic-Experienced and Biologic-Naïve Patients with Moderate-to-Severe Rheumatoid Arthritis from a Phase 3, Randomized, Double-Blind, Placebo-Controlled, International Study.

Roy Fleischmann[1], Dennis L. Decktor[2], Chunpeng Fan[3], Hubert Van Hoogstraten[3] and Mark C Genovese[4]. [1]Metroplax Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, [2]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [3]Sanofi, Bridgewater, NJ, [4]Stanford University Medical Center, Palo Alto, CA.

Background/Purpose: For patients with prior exposure to tumor necrosis factor-α inhibitor (TNF-I), the likelihood of response to subsequent treatment with a TNF-I declines with the increasing number of previous treatment failures.[1] Sarilumab, a fully human monoclonal antibody directed against interleukin-6R, has shown efficacy in a study of adult rheumatoid arthritis (RA) patients with moderate-to-severe disease and an inadequate response to methotrexate (MTX).[2] Sarilumab's safety and efficacy has been demonstrated at subcutaneous doses of 150 mg or 200 mg q2w + MTX. A further analysis of the clinical efficacy and safety of sarilumab in patients with/without prior biologic use (physician-reported) from this study is reported here. In the total population, 21.2% were exposed to biologics, of which 50% had received prior-TNF-I.

Methods: This was a subanalysis of the ACR20 (primary efficacy endpoint) and ACR50 and ACR70 responses, reduction of DAS28-CRP, and CDAI scores in patients with/without prior biologic use in the intention-to-treat population of the Phase 3 aspect of the MOBILITY study. Patients previously nonresponsive to biologic treatment were excluded from study participation.

Results: Both doses of sarilumab resulted in a statistically significant ACR20 response at Wk 24 vs placebo ($p<0.0001$); ACR50 and ACR70 responses were also statistically significant at Wk 24 (Fig 1). Statistically significant improvements in DAS28-CRP reduction were observed, with mean reductions at Wk 52 of –1.85, –2.80, and –3.15 in the placebo, sarilumab 150 mg, and 200 mg q2w groups, respectively, in patients with prior use of biologics, and –1.93, –3.24, and –3.29 in biologic-naïve patients (Figure 2). Similar improvements were seen in CDAI scores, with mean reductions at Wk 52 of –23.23, –28.45, and –28.81 in the placebo, sarilumab 150 mg, and 200 mg q2w groups, respectively, in patients with prior use of biologics, and –24.52, –31.35, and –30.33 in biologic-naïve patients (Fig 2). Most common TEAEs included infections and injection site reactions. A higher incidence of serious infections was observed with sarilumab. Lab

abnormalities included decreases in neutrophils and increases in transaminases and lipids.

Conclusion: Independent of prior use of a biologic, treatment with sarilumab resulted in clinically meaningful and statistically significant responses; given the modest number of biologic-experienced participants and the exclusion of prior non-responders, additional research is warranted.

2824

A Profile of the Efficacy of Sarilumab Plus Methotrexate in Rheumatoid Arthritis Patients: Results of a 52-Week, Phase 3, Randomized, Double-Blind, Placebo-Controlled, International Study. Arthur Kavanaugh[1], Dennis L. Decktor[2], Chunpeng Fan[3], Janet van Adelsberg[2], Renata Martincova[4] and Mark C. Genovese[5]. [1]University of California San Diego, La Jolla, CA, [2]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [3]Sanofi, Bridgewater, NJ, [4]Sanofi Czech Republic, Prague, Czech Republic, [5]Stanford University Medical Center, Palo Alto, CA.

Background/Purpose: Interleukin-6 (IL-6) regulates a diverse array of activities that may underlie systemic and local symptoms of rheumatoid arthritis (RA). The efficacy of sarilumab, a fully human monoclonal antibody (mAb) directed against IL-6R, has recently been investigated in the randomized, double-blind, placebo(pbo)-controlled, multicenter, phase 3 part of the MOBILITY study.[1] This analysis expands the profile to the entire 52-week duration of the trial.

Methods: Adults with active, moderate-to-severe RA and inadequate response to methotrexate (MTX) were randomized 1:1:1 to pbo + MTX, sarilumab 150 mg or 200 mg q2w + MTX for 52 wks. 3 co-primary endpoints associated with RA activity (signs & symptoms, physical function, and structural damage) were investigated: proportion of patients achieving ACR20 response at Wk 24; change from baseline in HAQ-DI at Wk 16; and change from baseline in mTSS at Wk 52. Secondary efficacy endpoints included major clinical response at Wk 52, ACR50 and ACR70 responses, reduction in DAS28-CRP, and CDAI.

Results: Sarilumab 150 mg and 200 mg q2w + MTX provided statistically significant, clinically meaningful improvement in all co-primary efficacy endpoints (ACR20, HAQ-DI, and mTSS) and secondary efficacy endpoints vs pbo + MTX (Table). ACR 20 response rates increased by Wk 2 and remained significantly higher in both sarilumab + MTX groups vs pbo + MTX through Wk 52 ($p<0.0001$). Change from baseline in the ACR core set of disease activity measures, swollen and tender joint counts, was significantly higher in the sarilumab + MTX groups vs pbo + MTX (Table). A significantly higher proportion of patients in the sarilumab + MTX groups maintained CDAI remission vs pbo + MTX (Wks 4–52; $p<0.0001$). DAS28-CRP scores were significantly improved vs pbo + MTX at Wks 2–52 ($p<0.0001$) in sarilumab + MTX-treated patients, who achieved DAS28-CRP remission at Wks 24 and 52 (Table). The proportion of HAQ-DI responders at Wks 16, 24 and 52 was significantly higher ($p<0.0001$) with sarilumab + MTX vs pbo + MTX at each timepoint (Table). Mean change from baseline in mTSS at Wk 52 with sarilumab + MTX was significantly higher vs pbo + MTX (Table). Most common TEAEs included infections and injection site reactions. A higher incidence of serious infections was observed with sarilumab. Lab abnormalities included decreases in neutrophils and increases in transaminases and lipids.

Conclusion: These additional analyses of patients with active RA and an inadequate response to MTX showed that treatment with subcutaneous sarilumab at 150 mg and 200 mg q2w + MTX improved the full range of reported outcomes in a robust and durable manner that was maintained over this 52 week-trial.

A Randomized, Double-Blind, Phase 3 Equivalence Trial Comparing the Etanercept Biosimilar, HD203, with Etanercept (Enbrel®), in Combination with Methotrexate (MTX) in Patients with Rheumatoid Arthritis (RA). Sang-Cheol Bae[1], Jinseok Kim[2], Jung-Yoon Choe[3], Won Park[4], So-Ra Lee[5], Yongho Ahn[6] and Yunjeong Seo[5]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Jeju National University, Jeju, Korea, South Korea, [3]Catholic University of Daegu School of Medicine, Daegu, South Korea, [4]Inha University Hospital, Incheon, South Korea, [5]Hanwha Chemical, Seoul, South Korea, [6]Hanwha Chemical, Daejeon, South Korea.

Background/Purpose: Etanercept is a recombinant fusion protein that blocks TNF activity. HD203 is a biosimilar of etanercept. In a double-blind, randomized study in healthy volunteers, HD203 and a reference etanercept were comparable with regards to pharmacokinetics, safety and tolerability. The aim of this study was to evaluate the equivalence in efficacy and to compare the safety of HD203 (biosimilar etanercept) and a reference etanercept, in combination with MTX in patients with RA. (ClinicalTrials.gov identifier NCT01270997).

Methods: Patients (male or female aged ≥20 years) with active RA were randomly assigned (1:1) to 25 mg HD203 or reference etanercept, administered subcutaneously twice weekly with MTX for 48 weeks. The primary endpoint was the proportion of patients achieving ACR20 at week 24. Secondary endpoints included ACRn, change in DAS28, and EULAR response at week 24 and 48, safety and immunogenicity. Efficacy and safety were evaluated at screening, week 0, 2, 4, 8, 12, 16, 20, and 24. Immunogenicity, efficacy and safety were also evaluated at week 36 and 48.

Results: In total, 294 patients were randomized: 147 to HD203 and 147 to reference etanercept. The proportion of patients achieving ACR20 at week 24 (primary endpoint) was not significantly different for HD203 and reference etanercept (Table) and equivalence in efficacy was demonstrated within predefined margins. In addition, there were no statistically significant differences between proportions achieving ACR20 at weeks 12 and 48. Similar trends were seen for ACR50 and ACR70, however the proportion of patients achieving ACR50 at week 24 and 48 was higher with HD203 than with reference etanercept. There were no statistically significant differences between the groups for ACRn, change in DAS28, and EULAR response at week 24 and 48.

Table: Proportion of patients achieving ACR20 at week 24 and week 48

	HD203	Reference etanercept	Difference (95% CI)	P-value
24-week PPS	83.48% (96/115)	81.36% (96/118)	2.12 (–7.65,11.89)	0.6706†
FAS	79.10% (106/134)	75.56% (102/135)	3.55 (–6.45,13.55)	0.4870†
48-week PPS	86.27% (88/102)	81.90% (86/105)	4.37 (–5.57,14.31)	0.3905†

CI, confidence interval; PPS, per-protocol set; FAS, full analysis set; †Pearson's chi-square test

Analysis of the safety set (HD203, n=147; reference etanercept, n=146) revealed no statistically significant difference in the number of treatment-emergent (all-causality) adverse events (AEs): HD203 76.87% vs. reference etanercept 78.08% (p=0.8040). Furthermore, no statistically significant differences between HD203 and reference etanercept were observed with regards to adverse drug reactions, serious AEs, or discontinuations due to AEs. No unexpected AEs were observed, and few patients tested positive for anti-drug antibodies.

Conclusion: The study met the primary endpoint of demonstrating equivalence in efficacy of HD203 compared with a reference etanercept. HD203 was well tolerated, with a safety profile comparable to that of the reference etanercept in this population of Korean patients with RA.

2826

A Phase 2b, Randomized, Double-Blind, Parallel-Group, Placebo-Controlled, Dose-Finding, Multi-Center Study to Evaluate the Safety and Efficacy of ASP015K in Moderate to Severe Rheumatoid Arthritis Subjects Not on Concomitant Methotrexate. Mark C. Genovese[1], Maria Greenwald[2], Christine Codding[3], Mario H. Cardiel[4], Anna Zubrzycka-Sienkiewicz[5], Alan J. Kivitz[6], Steve Wisseh[7], Kathyjo Shay[8] and Jay P. Garg[8]. [1]Stanford University Medical Center, Palo Alto, CA, [2]Desert Medical Advances, PALM DESERT, CA, [3]Health Research of Oklahoma, Oklahoma City, OK, [4]Centro de Investigacion Clinica de Morelia, Morelia, Mexico, [5]ARS Rheumatica sp. Zo.o, Reumatika, Warszawa, Poland, [6]Altoona Center for Clinical Research, Duncansville, PA, [7]Biocis, Chicago, IL, [8]Astellas Pharma Global Development, Northbrook, IL.

Background/Purpose: ASP015K is a novel oral Janus kinase (JAK) inhibitor in development for the treatment of rheumatoid arthritis (RA). ASP015K inhibits JAK 1/3 with relative selectivity over JAK2 and can be dosed once daily (QD). This study evaluated the efficacy, safety and dose response of once daily ASP015K in patients (pts) with moderate to severe rheumatoid arthritis (RA) with an inadequate response/intolerance to DMARDs and not currently on concomitant methotrexate (MTX) (Clinical Trials Registration: NCT01565655).

Methods: In this 12-week, double-blind, placebo (PBO)-controlled study, pts 18 years or older who met ACR criteria for RA, were not on concomitant MTX, and had active RA (defined as either CRP [*** :possibility of New Font being added]' 0.8 mg/dL or ESR [*** :possibility of New Font being added]' 28 mm/hr and [*** :possibility of New Font being added]' 6 tender and swollen joints) were randomized 1:1:1:1:1 to ASP015K 25 mg, 50 mg, 100 mg, 150 mg or PBO. Allowed concomitant DMARD therapies were anti-malarials and/or sulfasalazine. The primary endpoint was ACR20 response at week 12.

Results: 289 pts (82% female; mean age 53.9 years) were randomized and dosed. Approximately half the subjects (48%) were enrolled in the U.S. and the remainder from Europe (41%) and Mexico (11%). 48% had used a biologic, with 36% exposed to ≥ 2. Mean baseline values: disease duration, 10.4 y, tender joint count 25.7 (of 68), swollen joint count 16.3 (of 66), CRP 1.69 mg/dL, ESR 44.36 mm/hr, DAS28-CRP 5.83, and DAS28-ESR 6.64. A statistically significant dose-response at week 12 was seen for ACR20 with the highest response seen in the ASP015K 100 mg and 150 mg groups. ACR50/70 response and DAS28-CRP remission were also higher in the 2 highest ASP015K dose groups as compared to PBO. Dose-dependent improvement in DAS28-CRP was seen, with statistically significant differences shown in the two highest dose groups as early as week 4. The incidence of adverse events (AEs) was similar between combined ASP015K groups and PBO (41.6% vs 43.1%). The most frequently reported AEs in the combined ASP015K groups as compared to PBO were upper respiratory tract infection (5.5% vs 3.9%), nausea (5.0% vs 0%), and diarrhea (3.8% vs 2.0%). The overall incidence of infections and serious adverse events was similar between ASP015K and PBO (13.4% vs 13.7% and 4.2% vs 3.9%, respectively). No meaningful differences in absolute neutrophil and lymphocyte counts or hemoglobin were seen between ASP015K and PBO. The safety profile was generally comparable among the ASP015K dose groups, except for a higher incidence of dyspepsia, headache, and blood creatinine phosphokinase increased (transient without associated symptoms) in the 100 mg and/or 150 mg groups.

Conclusion: In a population of RA pts with long-standing disease and previous treatment with multiple DMARDs, 12 weeks of treatment with ASP015K was well tolerated and efficacious, with the highest response seen at the 100 and 150 mg doses. These data support further development of ASP015K for the treatment of RA.

Cervical Spine Fracture and Mortality in Ankylosing Spondylitis. Katherine D. Wysham, Sara G. Murray, Nancy K. Hills, Edward H. Yelin and Lianne S. Gensler. University of California, San Francisco, San Francisco, CA.

Background/Purpose: Little data exist regarding mortality in Ankylosing Spondylitis (AS) patients. We performed a population-based study of diagnoses associated with hospital mortality in AS.

Methods: Data were abstracted from the Healthcare Cost and Utilization Project-National Inpatient Sample (HCUP-NIS) between 2007–2011. We identified hospital discharges with AS using a validated administrative definition. The primary outcome was mortality and we performed a subset analysis on cervical spine fracture (CSFX) associated conditions and fracture level. Chi-square and Wilcoxon rank sum tests were used when appropriate to identify diagnoses associated with mortality. Multivariable logistic regression, including socio-demographic variables, significant covariates and co-morbidities, was performed to identify independent factors associated with in-hospital mortality.

Results: There were 12,493 AS admissions, 422 CSFXs and 276 deaths between 2007–2011. The mean age of all hospitalized AS patients was 59.2±16.4 years, 71% were males and 24% were electively admitted. The mean age of those with CSFX was 67.8±15.1 years, 91% were males and 11% were electively admitted. The mean age of those who died was 73.0±12.9 years, 78% were males and 10% were electively admitted. In the multivariable model, bacteremia and CSFX were the diagnoses with the highest odds of death, 7.28 (95% CI 5.36–9.88) and 5.70 (95% CI 3.63–8.95), respectively. Of those with CSFX, 66% also had a diagnosis of fall, though there was no interaction between CSFX and falls in predicting mortality. Motor vehicle accidents accounted for another 16% of CSFX cases. The majority of CSFX occurred at the lower cervical spine (75%). Regardless of level of fracture, 11% of patients died with associated CSFX.

Conclusion: The diagnoses most strongly associated with mortality in hospitalized AS patients, were bacteremia and CSFX. CSFX appears to be most commonly associated with falls and the majority of fractures occur in the lower cervical spine. This is the first population-based study describing the significant mortality associated with CSFX in AS patients.

Table 1. Multivariable model of predictors of mortality in AS hospitalizations

Variable	Adjusted OR*	95% CI	P value
Age (per 1 year)	**1.05**	**1.03–1.06**	**<0.001**

A Physically Demanding Job May Amplify the Effect of Disease Activity on the Development of Syndesmophytes in Patients with Ankylosing Spondylitis. Sofia Ramiro[1], A.M. van Tubergen[2], Robert Landewé[3], Annelies Boonen[2], Carmen Stolwijk[2], Maxime Dougados[4], Filip Van den Bosch[5] and Desiree van der Heijde[6]. [1]Amsterdam Rheumatology Center/University of Amsterdam, Amsterdam, Netherlands, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [4]Université Paris René Descartes and Hôpital Cochin, Paris, France, [5]Ghent University Hospital, Ghent, Belgium, [6]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: We have recently shown that disease activity is longitudinally associated with radiographic progression in AS. In animal models, it has recently been shown that mice that were tail suspended, in order to prevent mechanical loading on paws, had less new bone formation, thus providing a proof-of-concept that mechanical strain drives new bone formation in spondyloarthritis. Our aim was to investigate the complex relationship between inflammation, mechanical stress and radiographic progression in patients with ankylosing spondylitis (AS), using job type as a proxy for continuous mechanical stress.

Methods: Patients from OASIS were followed-up for 12 years, with 2-yearly assessments. Two readers independently scored the x-rays according to the mSASSS. Disease activity was assessed by the ASDAS-CRP. The relationship between ASDAS and spinal radiographic progression was investigated with longitudinal analysis, with job type at baseline (physically demanding ('blue collar') vs sedentary ('white collar') labor as a potential factor influencing this relationship. The effects of smoking status and socio-economic factors were also investigated.

Results: In total, 184 patients were included in the analyses (70% males, 83% HLA-B27 positive, 39% smokers, 48% blue-collar workers (65/136 patients in whom data on job type were available)). The relationship between disease activity and radiographic progression was significantly and independently modified by job type: In 'blue-collar' workers vs 'white collar' workers every additional unit of ASDAS resulted in an increase of 1.2 vs 0.2 mSASSS-units/2-years (p=0.014 for the difference between blue collar and white collar workers). In smokers vs non-smokers every additional unit of ASDAS resulted in an increase of 1.9 vs 0.4 mSASSS-units/2-years. Personal income also significantly modified the relationship ASDAS-mSASSS, but education and family income did not (Table).

Conclusion: Physically demanding jobs may amplify the driving effects of inflammation on radiographic progression, thus supporting the theory that mechanical stress leads to bone formation in AS. Smoking and personal income are likely classic confounders of this relationship but a separate detrimental effect of smoking on radiographic progression could not be excluded. If confirmed, these findings may have implications for our commonly given advice to patients with SpA to strenuously exercise.

Table: Effects of disease activity (one ASDAS-unit increase) on radiographic progression in subgroups

	2-year increase in mSASSS [units, (95% CI)]
A: Occupation: 'Blue collar' (n = 65)	1.19 (0.58; 1.79)
A: Occupation: 'White collar' (n = 71)	0.20 (−0.23; 0.64)
B: Smoking: Smokers (n = 49)	1.94 (1.00, 2.87)
B: Smoking: Non-smokers (n = 78)	0.35 (0.04; 0.65)
C: Education: 'non-university' (n = 167)	0.74 (0.41; 1.07)
C: Education: 'University' (n = 14)	−0.18 (−1.91, 1.55)
D: Personal income: <€1588 (n = 105)	0.93 (0.45, 1.41)
D: Personal income: ≥€1588 (n = 56)	0.14 (−0.21, 0.50)
E: Family income: <€3176 (n = 90)	0.49 (0.09, 0.89)
E: Family income: ≥€3176 (n = 21)	0.15 (−0.35, 0.65)

Spondyloarthritis Is Associated with Increased Cardiovascular and Cerebrovascular Mortality. Nigil Haroon[1], Nisha Nigil Haroon[2], Ping Li[3], Michael Paterson[3] and Robert D. Inman[4]. [1]Toronto Western Research Institute, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]Institute of Clinical Evaluative Sciences, Toronto, ON, [4]University of Toronto and Toronto Western Hospital, Toronto, ON.

Background/Purpose: OnSpA is a population-based study of spondyloarthritis (SpA) based on a provincial population of over 13 million. Patients with SpA are thought to be at increased risk of cardiovascular disease but it is unknown if they have excess vascular mortality. We explored risk of vascular mortality and the contributing factors in AS.

Methods: We performed a population-based, retrospective cohort study on incident SpA patients, age 15 or above, living in Ontario, Canada between April 1995 and March 2011. There were 21,878 SpA cases and 87,504 controls (matched for age, gender and socioeconomic status). The primary outcome was a composite event of cardiovascular or cerebrovascular deaths coded as the primary cause on death certificates. Considering the large size of the cohorts, we used standardized differences to compare the baseline characteristics of those with AS and their matched controls. Cox proportional hazards model was used to estimate differences in vascular mortality between cases and controls. Crude and adjusted hazard ratios (HR) were calculated and adjustments were made for coronary and cerebrovascular disease (CAD, CVD), cancer, diabetes, dementia, inflammatory bowel disease, hypertension, chronic kidney disease (CKD) and peripheral vascular disease (PVD). Additionally, we used a separate model in those with AS to identify covariates associated with vascular mortality. Finally, we constructed survival curves using the Kaplan-Meier (KM) method and tested for survival differences among groups using the Log-Rank test.

Results: In the SpA cohort 53% were male, with a mean age of 46 ±16 years, and a follow-up of 169,307 patient-years. Follow-up for controls was 692,499 patient-years. Crude and adjusted HR (95%CI) for vascular deaths were 1.49 (1.26–1.77) and 1.36 (1.14–1.63) respectively, indicating a 36–49% higher risk of vascular mortality in AS. Crude HR (95%CI) in males and females were 1.63 (1.31–2.03) and 1.31(1.00–1.71) respectively. Cases and controls had similar prevalence of CAD, CVD, PVD, dementia and diabetes, but IBD (6% *vs* 4%), hypertension (24% *vs* 18%) and CKD (2% *vs* 0.8%) were more common in SpA. The predictors of vascular death were age, male sex, low income, CKD and PVD apart from CAD and CVD. The KM curve showing an increase in vascular mortality in AS patients is shown in figure 1.

Conclusion: This is the first population-based study to demonstrate SpA is associated with significantly risk of vascular mortality. These new findings should prompt a comprehensive strategy to screen and treat modifiable vascular risk factors in SpA patients.

Progression to and Type of Orthopaedic Surgery in Juvenile *Vs.* Adult-Onset Ankylosing Spondylitis. Deepak R. Jadon[1], Gavin Shaddick[2], Amelia Jobling[2], Athimalaipet V Ramanan[3] and Raj Sengupta[1]. [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]University of Bath, Bath, United Kingdom, [3]University of Bristol Hospital Trust, Bristol, United Kingdom.

Background/Purpose: Juvenile-onset ankylosing spondylitis (JoAS) and adult-onset ankylosing spondylitis (AoAS) are subtypes of ankylosing spondylitis (AS) that may have different clinical outcome. We compared cohorts of JoAS and AoAS in terms of: (1) clinical characteristics; (2) clinical outcomes; (3) proceeding to and types of AS-related orthopaedic surgery.

Methods: A cohort study was conducted of all patients attending a dedicated AS clinic in a teaching hospital. Patients aged ≤16 years at symptom onset were categorised as JoAS, and ≥17 years as AoAS. Demographics, clinical parameters, composite indices ≤6 months of census, biological use, and history of AS-related orthopaedic surgery to the spine, root or peripheral joints were recorded. Univariate, multivariate logistic regression, and survival analyses were performed.

Results: 553 AS cases were studied: 162 JoAS; 391 AoAS. On univariate analyses (*Table 1*), no statistically significant differences were found between JoAS and AoAS in terms of *HLA-B*27 positivity, smoking, occurrence at any time of inflammatory bowel disease, psoriasis, enthesitis, or uveitis. JoAS cases had higher scores for two Bath AS Functional Index (BASFI) domains: bending forward from the waist (p=0.03); doing physically demanding activities (p=0.04).

On multivariate analyses adjusted for significant covariates (*Table 2*), compared to JoAS cases the AoAS cases were less likely to have: proceeded to surgery (odds ratio, OR 0.31; p<0.001); had a hip procedure (resurfacing or arthroplasty; OR 0.374; adjusted p=0.001); had a hip arthroplasty (OR 0.43; adjusted p=0.01). JoAS and AoAS were equally likely to have had hip resurfacing, bilateral hip arthroplasty, hip arthroplasty revision, hip arthroplasty re-revision, spinal orthopaedic surgery, and several (≥3) procedures.

Kaplan-Meier survival curves (log-rank test p=0.001) and Cox regression also demonstrated a significant difference in not having surgery between JoAS and AoAS (p=0.002) (*Figure 1*). A history of smoking was not associated with surgery. AS cases with older age at symptom onset were far less likely to have surgery than those with younger onset, in a non-linear manner.

Conclusion: JoAS are more likely than AoAS cases to proceed to AS-related orthopaedic surgery, especially hip resurfacing and arthroplasty.

Table 1. Comparison of clinical parameters and outcomes: Juvenile vs. adult-onset ankylosing spondylitis

		Juvenile-onset AS (n=162) n (%)	Adult-onset AS (n=391) n (%)	Odds Ratio	95% CI	p-value*

Development of New Radiographic Vertebral Fractures in Patients with Ankylosing Spondylitis during 4 Years of TNF-α Blocking Therapy: Results from the Glas Cohort. Fiona Maas[1], Anneke Spoorenberg[1], Elisabeth Brouwer[2], Reinhard Bos[3], Rizwana N. Chaudhry[1], Freke Wink[3], Hendrika Bootsma[4], Eveline van der Veer[1] and Suzanne Arends[4]. [1]University Medical Center Groningen, Groningen, Netherlands, [2]University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [3]Medical Center Leeuwarden, Leeuwarden, Netherlands, [4]University Medical Center Groningen, University of Groningen, Groningen, Netherlands.

Background/Purpose: Previous studies have shown that the risk of vertebral fractures is increased in patients with ankylosing spondylitis (AS). Prospective longitudinal data about radiographic vertebral fractures are scarce and little is known about the effect of tumor necrosis factor-alpha (TNF-α) blocking therapy on the development of vertebral fractures in AS.

Our objective was to determine the prevalence of radiographic vertebral fractures in patients with AS before start of TNF-α blocking therapy and to investigate the incidence of vertebral fractures after 4 years of follow-up.

Methods: Consecutive AS patients from the Groningen Leeuwarden AS (GLAS) cohort with available thoracic and lumbar radiographs at baseline and after 4 years of TNF-α blocking therapy were included. Patients fulfilled the modified New York criteria for AS and the ASAS criteria to start with TNF-α blocking therapy. Vertebral fractures were assessed by two independent readers using the Genant method and were defined as ≥20% reduction in vertebral height (grade 1 (mild), 20–25% reduction; grade 2 (moderate), 25–40% reduction; grade 3 (severe), >40% reduction). Bone mineral density (BMD) was measured with DXA and spinal radiographic damage with the modified Stoke AS Spine Score (mSASSS).

Results: 105 AS patients were included: 72% male, mean age 42±11 years, median symptom duration 16 years (range 1–47), and 83% HLA-B27 positive. In 27 (26%) of 105 patients, vertebral fractures were observed at baseline (average 1.7 fractures per patient). These patients were significantly older, had larger occiput-to-wall distance, and more spinal radiographic damage.

After 4 years of follow-up, 21 (20%) patients had new vertebral fractures. Most fractures were mild and occurred in the thoracic spine. Older age, higher BASFI, low lumbar spine BMD, use of anti-osteoporotic treatment, and presence of moderate vertebral fractures at baseline were significantly associated with the development of new fractures. Lumbar spine and hip BMD increased significantly during treatment. Patients with new vertebral fractures showed significantly less improvement in lumbar spine BMD than patients without new fractures (median change in Z-score 0.4 vs. 0.8).

Conclusion: The prevalence of radiographic vertebral fractures was 26% in AS patients with active disease before start of TNF-α blocking therapy. Although a significant increase in BMD was found, 20% of patients developed new vertebral fractures during 4 years of TNF-α blocking therapy.

2832

The Effect of Co-Medication with Conventional Synthetic Disease Modifying Anti-Rheumatic Drugs on TNF Inhibitor Drug Survival in Patients with Ankylosing Spondylitis: Results from a Nationwide Prospective Study. Elisabeth Lie[1], Lars Erik Kristensen[2], Helena Forsblad-d'Elia[3], Johan Askling[4] and Lennart T. Jacobsson[3]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Lund University, Malmö, Sweden, [3]Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, [4]Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: For rheumatoid arthritis it is well established that co-medication (co-med) with methotrexate (MTX) increases the efficacy and drug survival of TNF inhibitors (TNFi), while there has been little evidence of such a beneficial effect of co-med for ankylosing spondylitis (AS). The purpose of this study was to assess the effect of co-med with conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) on retention to TNFi therapy in AS.

Methods: Data on patients (pts) with AS starting adalimumab (ADA), etanercept (ETN) or infliximab (IFX) as their first TNFi from Jan 2003 through Dec 2010 were extracted from the Swedish Biologics Register ARTIS, including use of csDMARD co-med at baseline. Follow-up data through Dec 2011 were available at the time of analysis. Additional covariate data were obtained by linkage to the National Patient Register and Statistics Sweden. We analysed 5-year drug survival by multivariable Cox regression, including covariates that were selected a priori (Table). Additional potential confounders (ESR, CRP, patient global, 28-swollen joint count (SJC), and history of uveitis, psoriasis and inflammatory bowel disease) were also tested in the model.

Results: 1365 pts with AS were included (605 IFX, 406 ADA, 354 ETN). At baseline 557 pts (40.8%) used csDMARD co-med (429 used MTX), and co-med was more often given with IFX (55.4%) than with ADA (28.1%) or ETN (30.5%). Patients on co-med had higher levels of ESR and CRP and more often ≥1 swollen joint at baseline, and remained on therapy longer vs. pts on TNFi monotherapy. Estimated median survival time (based on Kaplan-Meier of overall drug survival) was 6.0 vs. 4.2 years (log rank test $p<0.001$). By separate analyses per drug (Kaplan-Meier with log rank test), statistically significantly better survival rates in pts on co-med were observed for IFX ($p=0.015$), ADA ($p=0.015$) and ETN ($p=0.020$). The multivariable Cox regression model is shown in the Table. The hazard ratio (HR) for TNFi discontinuation for pts on csDMARD co-med was 0.71 vs. those not on co-med. We also found statistically significant associations between drug survival and ESR, CRP, patient global, 28-SJC and uveitis, respectively, while the association with csDMARD co-med remained highly statistically significant ($p<0.001$) with a HR of 0.58–0.70 in the models with additional adjustments (data not shown). We also tested csDMARD co-med as MTX vs. other csDMARDs vs. no csDMARD in the model shown in the Table: MTX vs. no csDMARD HR (95% CI) 0.74 (0.61–0.91) ($p=0.004$), and other csDMARDs vs. no csDMARD 0.59 (0.41–0.83) ($p=0.002$).

Table. Multivariable Cox regression analysis of 5-year drug survival

	HR (95% CI)	p-value
Age (per 10 years)	1.01 (0.94–1.09)	0.739
Sex (ref. female)	0.66 (0.55–0.80)	**<0.001**
csDMARD co-medication (ref. none)	0.71 (0.59–0.85)	**<0.001**
TNFi type		**0.037**
ADA vs. IFX	0.90 (0.73–1.11)	0.317
ETN vs. IFX	0.75 (0.60–0.93)	**0.010**
Start year 2007–2010 vs. 2003–2006	1.22 (1.01–1.48)	**0.037**
Hospital days*	1.01 (1.00–1.01)	**0.008**
Number of outpatient visits*	1.02 (1.00–1.03)	**0.010**
Disposable income (per 1000 €)†	0.99 (0.99–1.00)	0.146
Education‡		0.087
10–12 years vs. ≤9 years	0.93 (0.73–1.17)	0.532
>12 years vs. ≤9 years	0.78 (0.60–1.01)	0.060
Missing vs. ≤9 years	2.55 (0.62–10.4)	0.192

*Number of days/visits the 2 years prior to TNFi start; data from the National Patient Register
†Income the year prior to TNFi start; data from Statistics Sweden
‡Data from Statistics Sweden

Conclusion: AS patients who received csDMARD co-med with their first TNFi remained on therapy significantly longer than those who were not on co-med. The association remained statistically significant when adjusting for potential confounders.

ACR Concurrent Abstract Session
Systemic Lupus Erythematosus - Clinical Aspects and Treatment: Novel Therapies for Systemic Lupus Erythematosus
Tuesday, November 18, 2014, 2:30 PM–4:00 PM

2833

SM101, a Novel Recombinant, Soluble, Human FcγIIB Receptor, in the Treatment of Systemic Lupus Erythematosus: Results of a Double-Blind, Placebo-Controlled Multicenter Study. Sascha Tillmanns[1], Claudia Kolligs[1], David P. D'Cruz[2], Andrea Doria[3], Eric Hachulla[4], Reinhard E. Voll[5], Michael Tansey[1] and Klaus Schollmeier[1]. [1]SuppreMol GmbH, Martinsried, Germany, [2]Louise Coote Lupus Unit, Guy's and St Thomas' Hospital, London, United Kingdom, [3]University of Padova, Padova, Italy, [4]Lille University, Lille, France, [5]University Hospital Freiburg, Freiburg, Germany.

Background/Purpose: SM101, which represents the human soluble non-glycosylated version of the Fcγ receptor IIB, binds to the Fc part of autoimmune complexes and inhibits the binding of immune complexes to cell-standing Fcg receptors. It has undergone preclinical and clinical safety and efficacy investigation, with evidence of efficacy in primary immune thrombocytopenia. The mode of action could make SM101 a safe and effective treatment for systemic lupus erythematosus (SLE).

Methods: The objectives of this phase IIa randomised, double-blind, placebo-controlled parallel-group study were to evaluate the safety, tolerability and efficacy of placebo and 2 doses of SM101 (6mg/kg and 12mg/kg), randomised 1:2:2, in patients with SLE. The main inclusion criteria were a diagnosis of SLE, evidence of serological activity (high anti-dsDNA activity or low C3), and a SELENA-SLEDAI score ≥ 6 points, with stratification to include patients with lupus nephritis (LN). Concomitant immunosuppressive therapy with corticosteroids, mycophenolate mofetil (MMF) or azathioprine and adjuvant SLE medication were allowed at constant doses during the study. Eligible patients received an infusion of study drug once a week for the first 4 weeks; study duration was 24 weeks. Data were reviewed regularly by an independent safety monitoring board. Response was measured at 24 weeks according to the SLE Responder Index (combination of SELENA-SLEDAI response ≥ 4 points, no BILAG A or 2 × B flares and no PGA score worsening).

Results: Fifty one eligible patients, 14 with LN, from 8 European countries and Australia, were randomized and received at least one dose of active investigational drug or placebo. Concomitant medications were corticosteroids (96% of patients), MMF (45%), azathioprine (20%) or combinations thereof. Patient numbers per group and response rates are shown in Table 1. The SLE Responder Index response rate was twice as high in the SM101-treated patients compared with placebo, and response in patients with LN was proportionately greater. The response rate on SM101 remains the same after exclusion of 15 patients who received rescue medication. The main clinical drivers for response were improvement in arthritis and in skin eruption (present in 75% and 50% patients respectively) according to the BILAG scale. Both worsened or remained unchanged in placebo patients; in SM101-treated patients improvement or resolution occurred in 57% with arthritis and 45% with skin eruption. No safety signals which could be attributed specifically to SM101 were reported, and no serious adverse events were probably or possibly related to the drug. No anti-drug antibodies were detected.

Conclusion: The encouraging results of this early phase study indicate that the novel biological SM101 warrants further investigation as a treatment for patients with SLE, including patients with LN.

Table 1. Percentage of Patients Responding According to the SLE Responder Index and its Components

Correlation of Laboratory and Clinical Parameters with British Isles Lupus Assessment Group Response in an Open-Label Extension Study of Epratuzumab in Systemic Lupus Erythematosus. Richard A. Furie[1], Michelle A. Petri[2], Caroline Gordon[3], Vibeke Strand[4], Catrinel Galateanu[5], Sabine Bongardt[6], Willem Koetse[7] and Daniel J. Wallace[8]. [1]North Shore - Long Island Jewish Health System, Great Neck, NY, [2]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [3]Rheumatology Research Group, School of Immunity and Infection, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom, [4]Biopharmaceutical Consultant, Portola Valley, CA, [5]UCB Pharma, Brussels, Belgium, [6]UCB Pharma, Monheim, Germany, [7]UCB Pharma, Raleigh, NC, [8]Cedars-Sinai Medical Center, Los Angeles, CA.

Background/Purpose: Epratuzumab is a monoclonal antibody in development for the treatment of systemic lupus erythematosus (SLE) that binds CD22, promoting the natural inhibitory function of CD22 on the B-cell receptor.[1,2] In EMBLEM™ (dose-ranging Phase 2b study [NCT00624351]), and its open-label extension (OLE; SL0008 [NCT00660881]), epratuzumab produced sustained, clinically relevant improvements in patients (pts) with moderate-to-severe SLE as measured by British Isles Lupus Assessment Group (BILAG) response. BILAG response forms the basis of BILAG-Based Composite Lupus Assessment (BICLA), described elsewhere.[3] This study aimed to correlate BILAG response with clinical and laboratory parameters during epratuzumab open-label therapy, and to examine maintenance of improvements in BILAG organ systems.

Methods: All EMBLEM™ pts completing 12 weeks (wks) of blinded treatment, or who discontinued due to lack of efficacy but completed ≥8 wks, were eligible for OLE entry, in which all pts received 1200mg epratuzumab at Wks 0 and 2 of repeating 12-wk cycles. Post-hoc analysis evaluated changes from EMBLEM™ baseline in clinical and laboratory parameters in BILAG responders (R) vs non-responders (NR) (OLE Wks 48 and 96). BILAG response was defined as BILAG A to B/C/D, all Bs to C/D, no new BILAG A or ≥2 new B scores; non-response as lack of improvement, worsening or withdrawal prior to assessment. Achievement and maintenance of a low disease activity state was defined as disease activity improvement in all systems with BILAG A or B scores at EMBLEM™ baseline to C or D in the OLE, with no categorical deterioration from baseline levels prior to improvement, and no reversion to baseline A or B levels once improvement had occurred.

Results: 203 pts entered the OLE; 80 (39%) achieved a BILAG response at Wk48, and 72 (36%) achieved a BILAG response at Wk96. At both timepoints, responders had significantly greater reductions in Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), Physician Global Assessment (PGA) and Patient Global Assessment (PtGA) scores, and improvements in greater numbers of BILAG organ domains than non-responders (Table). At Wk48, responders had greater reduction in concomitant steroid doses (not significant at Wk96 [Table]). Laboratory parameters associated with BILAG response are shown in the table. Improvements in individual BILAG organ systems were maintained in >50% of pts in 4/9 body systems.

Conclusion: BILAG responders in the OLE were more likely to achieve improvements in a range of clinical and laboratory parameters, including SLEDAI, PGA and PtGA scores, and show changes in absolute B-cell (CD19+) and T-cell (CD3+) counts. Additionally, improvements in individual body organ systems were maintained.

2835

A Phase 2, Multicenter, Randomized, Double-Blind, Placebo-Controlled, Proof-of-Concept Study to Evaluate the Efficacy and Safety of Sirukumab in Patients with Active Lupus Nephritis. Cynthia Aranow[1], R. van Vollenhoven[2], Brad H. Rovin[3], Carrie Wagner[4], Bei Zhou[4], Robert Gordon[4] and Benjamin Hsu[4]. [1]The Feinstein Institute, Manhasset, NY, [2]The Karolinska Institute, Stockholm, Sweden, [3]Ohio State University Medical Center, Columbus, OH, [4]Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: IL-6 is a pro-inflammatory cytokine that is over-expressed in lupus nephritis(LN). This proof-of-concept study examined the efficacy and safety of sirukumab, an anti-interleukin-6 monoclonal antibody, in patients (pts) with active, ISN/RPS class III or class IV lupus nephritis (LN).

Methods: Pts were enrolled if they had class III or IV LN on renal biopsy within 14 mo of randomization, persistent proteinuria (≥ 0.5 g/d) despite immunosuppression (MMF or AZA ± corticosteroids), and stable renin-angiotensin system blockade. Pts were randomized to IV sirukumab 10 mg/kg (n=21) or placebo (Pbo, n=4) q4wks through wk 24. Primary endpoint was % reduction from baseline in proteinuria (protein/creatinine (P/C) ratio in a 12hr urine collection) at wk 24; major secondary endpoints included the proportion of pts with: 1) ≥50% reduction of baseline proteinuria; 2) meaningful reduction in proteinuria; 3) no worsening of glomerular filtration rate (GFR) based on serum creatinine levels (defined as <15% decrease from baseline rate); all at any time through wk 24, as well as 4)% change from baseline in Patient's and Physician's Global Assessments of Disease Activity over time.

Results: Median time from biopsy collection to randomization was 116 days. 76% of pts (19/25) completed 2-wks of treatment. No median reduction in proteinuria at wk 24 (primary endpoint) was observed in the sirukumab group. In contrast, the Pbo group demonstrated median 43.3% increase in proteinuria(Table), largely driven by 1 Pbo-treated pt. Secondary endpoints indicated 20% (4/20) and 15% (3/20) of sirukumab-treated pts, vs 0% of Pbo-treated pts, demonstrated a ≥50% reduction or a meaningful reduction, respectively, in proteinuria at wk 24 (Table). In contrast, at wk 24, 10/18 (56%) of sirukumab-treated pts and 3/4 (75%) of Pbo-treated pts had no worsening in GFR (Table). Neither Physician nor Patient Global Assessment scores improved in either treatment group. Among the 12 sirukumab-treated pts positive for anti-dsDNA at baseline, there was a mean 62.3% reduction in anti-dsDNA at wk 24. Among 6 pts who discontinued study agent, 5 did so because of an adverse event(AE)(anaphylactic reaction, increased liver enzymes, neutropenia, pneumonia, and LN worsening). No deaths occurred. Approximately half (47.5%, 10/21) of sirukumab-treated pts had ≥1 serious AE, the majority of which were infections. No serious AE occurred with Pbo-treated pts, although 4/37 (10.8%) screen-failed pts had 1 or more SAEs during the 8 wk screening period.

Conclusion: IL-6 inhibition with sirukumab in pts with active LN did not result in a median improvement in proteinuria, however approx 15–20% of treated pts did show a notable reduction in proteinuria. A high frequency of serious AE was observed in this population of immunosuppressed pts with refractory LN.

Table. Summary of primary and major secondary efficacy endpoints at wk 24

	Placebo	CNTO 136
Modified intent-to-treat pts	4	20[a]
Proteinuria % change from baseline at wk24[a]		
Median		0.00
(95% CI)	43.3	(−61.8, 39.6)
Pts with decrease ≥50% in proteinuria at wk24[a]	0	4/20 (20.0%)
95% confidence interval		(5.7, 43.7)
Pts with meaningful reduction in proteinuria at wk24[a,b]	0	3/20 (15.0%)
95% confidence interval		(3.2, 37.9)
Pts with no worsening in GFR at wk24	3 (75.0%)	10/18 (55.6%)
95% confidence interval		(30.8, 78.5)

[a]A last-observation-carried-forward procedure was used to impute missing proteinuria values if a pt had data for ≥1 post- baseline evaluation. Of 21 randomized pts, 20 were included in the efficacy analyses.
[b]Meaningful reduction in proteinuria was defined as P/C (protein/creatinine) ratio < 0.5 for non-nephrotic pts; and ≥50% reduction in P/C ratio and P/C ratio < 3.0 for nephrotic pts.

Effects of Blisibimod, an Inhibitor of B Cell Activating Factor, on Patient Reported Outcomes and Disease Activity in Patients with Systemic Lupus Erythematosus. Michelle Petri[1], Renee S. Martin[2], Colin Hislop[2], Morton A. Scheinberg[3] and Richard Furie[4]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Anthera Pharmaceuticals Inc, Hayward, CA, [3]Rheumatology Hospital Abreu Sodre Pesquisa Clínica, São Paulo, Brazil, [4]North Shore - Long Island Jewish Health System, Great Neck, NY.

Background/Purpose: To conduct secondary endpoint analyses of the effects of subcutaneously-administered blisibimod (A-623, AMG 623), an inhibitor of B-cell activating factor (BAFF), on patient-reported outcomes and indices of disease activity in patients with systemic lupus erythematosus (SLE) during the phase 2b clinical trial PEARL-SC (NCT01162681).

Methods: 547 SLE patients who met the ACR classification criteria, and had anti-double-stranded DNA or anti-nuclear antibodies, and SELENA-SLEDAI score ≥6 at baseline, were enrolled into the PEARL-SC study, and randomized 1:1 to receive placebo or blisibimod administered at 1 of 3 dose levels, 100 mg weekly (QW), 200 mg QW, or 200 mg every 4 weeks for up to 52 weeks (with a median of 37 weeks) or until the last subject completed 6 months of study drug therapy. Patient self-reported outcomes were evaluated using the Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue scale, and disease activity evaluated within SELENA-SLEDAI organ domains.

Results: Significant improvements in measures of disease activity, including the SLE responder Index-8 (SRI-8) in subjects with severe baseline disease (defined at SELENA-SLEDAI score≥10 and receiving steroids), especially at the highest blisibimod dose of 200mg QW were reported previously (Furie et al. 2014). Approximately 76% of subjects had SELENA-SLEDAI musculoskeletal organ involvement at enrollment, and 89% of subjects had mucocutaneous organ involvement. At Week 24, approximately 12% and 39% of subjects randomized to the 200mg QW blisibimod arm had musculoskeletal or mucocutaneous organ involvement, compared with approximately 15% and 42% respectively in the placebo arm ($p<0.2$ to $p<0.05$ across manifestations evaluated over Weeks 12 through 24). A concomitant tendency toward improved self-reported fatigue was observed amongst subjects randomized to blisibimod based on the FACIT-Fatigue scale, especially in the 200mg QW group (N=80) where a mean 6.9-point improvement from baseline was reported at Week 24 ($p=0.065$) compared with 4.4 with placebo (N=229). Based on exploratory statistical analyses, the

effects of blisibimod on FACIT-fatigue were significantly better than placebo ($p<0.05$) as early as Week 8.

Blisibimod was safe and well-tolerated at all dose levels with no meaningful imbalances in serious adverse events or infections between blisibimod and placebo. Amongst the commonly-reported AEs, imbalance was observed only with injection site reactions (200mg QW blisibimod=15%, matched placebo=7%), but these were not serious or severe.

Conclusion: Fatigue remains a debilitating manifestation of lupus. In this trial, blisibimod showed a tendency toward improved mucocutaneous and musculoskeletal disease activity as well as patient self-reported fatigue. These data support further evaluation of blisibimod in patients with SLE.

Induction of Clinical Remission By Low-Dose Interleukin-2 in Refractory SLE. Jens Y. Humrich[1], Caroline von Spee-Mayer[1], Elise Siegert[1], Angelika Rose[1], Tobias Alexander[1], Falk Hiepe[1], Andreas Radbruch[2], Gerd Burmester[3] and Gabriela Riemekasten[1]. [1]Charité – University Hospital, Berlin, Germany, [2]German Rheumatism Research Centre Berlin (DRFZ), an institute of the Leibniz Association, Berlin, Germany, [3]Charité University Medicine, Dept. Medicine/Rheumatology and Clinical Immunology, Berlin, Germany.

Background/Purpose: Interleukin-2 (IL-2) is crucial for the growth and survival of regulatory T cells (Treg), and thus for the control of autoimmunity. In previous studies we have proven a causal relationship between an acquired IL-2-deficiency, defects in Treg biology and the development of systemic lupus erythematosus (SLE). Accordingly, we showed that compensation of IL-2 deficiency by IL-2 therapy corrects associated Treg defects and ameliorates already established disease in lupus-prone mice, providing the rationales for an IL-2-based immunotherapy of SLE in order to restore Treg activity an thus to re-establish endogenous mechanisms of tolerance that can counteract autoimmunity.

Here we report a rapid and robust reduction of disease activity in parallel to a remarkable expansion of the Treg population by an off-label therapy with low-dose IL-2 in two patients with a long-term history of SLE and increased disease activity refractory or intolerant to a large variety of approved and experimental therapies.

Methods: The therapeutic regimen consisted of four treatment cycles each with daily subcutaneous injections of recombinant human IL-2 (aldesleukin; Proleukin®) at single doses of 1.5 or 3.0 million IU on five consecutive days separated by washout-periods of 9–16 days and followed by a 9-week follow-up period. Disease activity was determined by the SLEDAI at defined time points during the study. Cells from peripheral blood were analyzed by flow cytometry at the indicated time points. Written informed consent was obtained from the patient prior to the initiation of the off-label treatment with IL-2.

Results: In the first treated patient, disease activity rapidly decreased already after one treatment cycle, while in the second patient a reduction in disease activity was observed two weeks later. During the following treatment cycles disease activity further decreased or remained low due to disappearance of clinical manifestations such as arthritis, myositis and skin rash. In addition and unexpectedly levels of anti-dsDNA-antibodies considerably declined in both patients. The clinical response was associated with cyclic and treatment-related increases of the CD25hiFoxp3+CD127lo Treg population in the peripheral blood. The therapy was very well tolerated and adverse events were generally mild and transient.

Conclusion: These data provide the first evidence for the clinical efficacy of low-dose IL-2-therapy in conjunction with the boosting of Treg activity in SLE and strongly support the rationales of this selective biological treatment strategy.

Exploratory Analysis of Pharmacokinetic Effects of Atacicept in Patients with Moderate to Severe Systemic Lupus Erythematosus. David Wofsy[1], Caroline Gordon[2], Yong Li[3], Stephen D. Wax[4] and David Isenberg[5]. [1]Division of Rheumatology, University of California, San Francisco, CA, [2]Rheumatology Research Group, School of Immunity and Infection, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom, [3]R&D Global BioStatistics, EMD Serono, Billerica, MA, [4]Global Clinical Development Center - Immunology, EMD Serono Inc, Rockland, MA, [5]Centre for Rheumatology Research, University College Hospital London, London, United Kingdom.

Background/Purpose: Atacicept is a fusion protein that inhibits B-cell stimulating factors BLyS and APRIL. We previously reported the clinical effects of atacicept in lupus patients with active disease (the APRIL-SLE study). Here we report the exploratory analysis between mean drug concentration and clinical outcome in those subjects.

Methods: Patients with active SLE (≥1 BILAG A and/or B) were treated with corticosteroid taper for 12 weeks. Subjects reaching BILAG C or D at weeks 10 and 12 were randomized 1:1:1 to receive placebo (PLC), atacicept 75 mg (A75) or 150 mg (A150) twice weekly for 4 weeks then weekly for 48 weeks. All patients received standard of care. As previously reported, A150 reduced the frequency of BILAG A and B flares but was discontinued prematurely due to two infection-related deaths. This post-hoc analysis was performed among subjects in all groups randomized at least 52 weeks prior to discontinuation of A150 and who had an opportunity to complete the protocol (n=81, 84, and 81 for PLC, A75, and A150, respectively). For this analysis subjects in the two treatment arms were divided into four quartiles based on mean atacicept concentration, the 1st being the group with the lowest concentration.

Results: Subjects with the highest atacicept concentrations (3rd and 4th quartiles) experienced fewer flares during treatment compared to subjects with lower concentrations (1st and 2nd quartiles) and subjects in the PLC group (60, 63, 61, 49, and 29% in the PLC, 1st, 2nd, 3rd, and 4th quartiles, respectively). Similarly, the proportions of subjects using high-dose corticosteroids was lowest among subjects with higher concentrations of atacicept (32, 24, 17, 22 and 15% in the PLC, 1st, 2nd, 3rd and 4th quartiles). Time to first new flares was also longer for atacicept than the PLC. Despite their higher atacicept concentrations subjects in the 4th quartile experienced similar proportions of treatment-emergent serious or severe infectious adverse events vs PLC (4.9 vs 3.7%). Subjects with baseline free BLyS and APRIL concentrations both ≥median experienced fewer flares in the groups with higher atacicept concentrations (2nd, 3rd and 4th quartiles). Results are summarized in the Table 1. The two subjects in the A150 group who died due to infection had mean and max trough levels that were near or below the 25th percentile concentration.

Conclusion: Subjects in the APRIL-SLE study who achieved the highest concentrations of atacicept showed a reduced risk of SLE flares and increased time to flare. Atacicept was also associated with a reduction in corticosteroid use. Subjects with free BLyS and APRIL levels above median at baseline had an increased flare risk in the PLC group; among these subjects, there was an even greater treatment effect seen in the atacicept groups. These post-hoc results warrant further studies to assess the safety and efficacy of atacicept in SLE patients.

BCL-2 As a Potential Therapeutic Target in Human Lupus Tubulointerstitial Inflammation. Kichul Ko[1], Denisse Yanez[1], Natalya Kaverina[1], Vladimir M. Liarski[1], Yahui Peng[2], Li Lan[1], Stuart Perper[3], Annette Schwartz[3], Liz O'connor[3], Andrew Souers[4], Steven Elmore[4], Lisa Olson[3], Maryellen L. Giger[1], Li Chun Wang[3] and Marcus R. Clark[1]. [1]University of Chicago, Chicago, IL, [2]Beijing Jiaotong University, Beijing, China, [3]AbbVie Inc, AbbVie Bioresearch Center, Worcester, MA, [4]AbbVie Inc, North Chicago, IL.

Background/Purpose: Lupus nephritis (LuN) is the most common, severe manifestation of systemic lupus erythematosus (SLE). We have previously shown that glomerulonephritis appears to be a manifestation of systemic autoimmunity while tubulointerstitial inflammation (TII) is associated with additional, *in situ* adaptive immune cell networks that might amplify local inflammation and tissue damage. Furthermore, patients with significant TII are more likely to fail conventional therapy and progress to renal failure. Therefore, understanding the mechanisms of *in situ* adaptive immunity in lupus TII might provide new therapeutic opportunities for treating LuN. In mice, BCL-2 family proteins are key regulators of immune cell apoptosis and forced expression of BCL-2 in B cells promotes lupus-like nephritis. We hypothesized that dysregulated expression of the BCL-2 family proteins in human LuN TII might contribute to local adaptive immunity, inflammation and disease pathogenesis.

Methods: Frozen renal biopsy specimens from 26 patients with SLE (ISN/RPS Class III, IV or V LuN), 10 mixed cellular renal allograft rejection (MR) biopsy specimens and tonsil samples from healthy subjects and kidneys from IFNα-induced NZB/W F1 lupus mice were stained with antibodies specific for CD20, CD4, BCL-2, MCL-1 or BIM. Images were acquired using scanning laser confocal microscopy. IFNα-induced NZB/W F1 mice were treated daily with vehicle or 30 mg/kg of ABT-199 and analyzed for survival and the development of proteinuria.

Results: A recently developed imaging tool (*Science Translational Medicine* 2014, 6:230) was used to quantify the frequency of $CD20^+$ B and $CD4^+$ T cells expressing the anti-apoptotic molecules BCL-2, MCL-1 and the pro-apoptotic molecule BIM. In primary follicles of normal tonsils, both B and T cells frequently expressed BCL-2. However, upon entry into germinal centers (GC), BCL-2 was down-regulated and MCL-1 was induced. In marked contrast, in LuN and MR TII biopsies, the frequency of $BCL\text{-}2^+$ cells was increased in B and T cells while $MCL\text{-}1^+$ cells were rare. Observed differences between tonsil GC lymphocytes versus TII in LuN and MR for both BCL-2 and MCL-1 were highly significant ($p<0.001$). These expression differences were confirmed by laser capture microscopy coupled to qPCR. In contrast, the frequency of BIM^+ cells did not significantly vary among tissues. Consistent with these findings, BCL-2, but not MCL-1 expressing cells were detected in the inflamed kidney in IFNα-induced NZB/W F1 lupus mice. Furthermore, administration of ABT-199, a BCL-2 selective inhibitor, prevented the development of lupus nephritis by depleting intra-renal B and T cells in these animals.

Conclusion: Frequent BCL-2, but not MCL-1, expressing cells were present in LuN, MR TII tissues and IFNα-induced NZB/W F1 lupus mice. Treatment of these mice with the BCL-2 selective inhibitor ABT-199 resulted in the loss of renal B and T cells and the preservation of renal function. These data indicate that BCL-2, which is dysregulated in TII, is an attractive therapeutic target in cases of lupus nephritis manifesting tubulointerstitial inflammation.

Targeting the RhoA-Rock Pathway to Reverse T Cell Dysfunction in SLE. Cristina T. Rozo, Laura Leuenberger, Kyriakos A. Kirou, Margaret Robotham, Sanjay Gupta, Reena Khianey, Alessandra B. Pernis and Jane E. Salmon. Hospital for Special Surgery, New York, NY.

Background/Purpose: Aberrant expansion of T_H-17 cells and deregulated production of IL-17 and IL-21 are involved in the pathogenesis of SLE. Production of IL-17 and IL-21 is critically dependent on the transcription factor, IRF4 (Interferon Regulatory Factor 4). Rho-associated protein kinases (ROCKs) can phosphorylate IRF4 and regulate its activity. The finding that ROCK activity is elevated in SLE patients and is associated with human T_H-17 differentiation, coupled with the ability of ROCK inhibitors to ameliorate autoimmunity in murine models of lupus suggest that targeting the ROCK pathway might be a novel therapeutic strategy for the treatment of SLE. ROCK activation can be inhibited by Y27632 (a nonselective ROCK inhibitor that inhibits both ROCK isoforms, ROCK1 and ROCK2) or by statins (which inhibit ROCKs by interfering with their major upstream activator, RhoA). Here, we examined the ability of Y27632 and simvastatin to inhibit the production of IL-17 and IL-21 by human T_H-17 cells and SLE T cells.

Methods: We assessed the capacity of Y27632 (60uM–90uM) and simvastatin (0.2uM) to decrease ROCK activation and IL-17 and IL-21 production by cord blood $CD4^+$ T cells cultured under T_H-17-skewing conditions (5ng/mL TGFb, 10ng/mL IL1-b, 20ng/mL IL-6, 50ng/mL IL-23, 5ug/mL anti-IL-4 and 10ug/mL anti-IFN-g). We also assessed the ability of Y27632 and simvastatin to diminish IL-17 and IL-21 production by stimulated SLE $CD4^+$T cells. ROCK activation was determined by an ELISA-based ROCK activity assay. Plasma levels of IL-17, IL-21, and CCL20 were measured by ELISA. qPCR was used to determine gene expression of IRF4. All patients (N=24) met ACR criteria for SLE. Demographics and clinical features were as follows: mean age 37 ± 11 years, 96% female, 8% Asian, 21% African American, 21% Caucasian, 50% Hispanic, SLEDAI score 6 ± 4, and 42% with nephritis.

Results: Compared to T_H0 cells, cord blood $CD4^+$ T cells cultured under T_H-17-skewing conditions exhibited elevated ROCK activity that was inhibited by both Y27632 and simvastatin. IL-17 production was decreased by 60% in cord blood T_H-17 cells treated with either inhibitor. IL-21 production was decreased by 83% (90uM Y27632) and 65% (0.2uM simvastatin) in cord blood T_H-17 cells. Neither Y27632 nor simvastatin decreased IRF4 gene expression suggesting that their effects on IL-17 and IL-21 were not secondary to effects on cell viability. Both Y27632 and simvastatin decreased IL-17 and IL-21 cytokine production by purified SLE $CD4^+$T cells but neither treatment altered IFN-g protein production. We also confirmed our

previous findings that in a subset of SLE patients PBMCs showed elevated ROCK activity compared to PBMCs from healthy controls. In this new cohort, the majority (79%) of the SLE patients had ROCK values that were at least 2SD above the mean ROCK value for the healthy controls.

Conclusion: These data indicate that the production of IL-17 and IL-21 by SLE T cells can be selectively inhibited by targeting the RhoA-ROCK pathway providing a rationale to inhibit the ROCKs as a means to reverse T cell dysfunction in SLE.

Identifying Novel Lupus Severity Risk Variants through Identification of Alleles with High Ethnic Variability Worldwide. Belinda A. Waltman[1], Kimberly E. Taylor[1], Julio Molineros[2], Sarah French[1], Joanne Nitiham[1], Jennifer Kelly[2], Adam Adler[2], Judith A. James[2], Swapan Nath[2], Marta Alarcon-Riquelme[2] and Lindsey A. Criswell[1]. [1]University of California, San Francisco, Rosalind Russell / Ephraim P. Engleman Rheumatology Research Center, San Francisco, CA, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: Substantial epidemiologic evidence demonstrates that SLE disproportionately affects minority patients in terms of incidence, prevalence, and disease severity. European ancestry has been associated with a lower risk of developing renal disease in SLE. We developed an approach to identify novel SLE risk variants that may influence disease severity by searching for single nucleotide polymorphisms (SNPs) with high ethnic variability worldwide and testing them in our multiethnic SLE cohort.

Methods: The Human Genome Diversity Project (HGDP) characterized the allele frequency of 650,000 SNPs in 938 people from 53 populations worldwide. Our multiethnic cohort of SLE patients was genotyped on the Illumina Immunochip (I-chip), covering over 160,000 SNPs across 185 autoimmune genes plus select non-autoimmune genes and ancestry informative markers. There were 32,907 SNPs common to the HGDP and I-chip. We selected the top 2% of those SNPs that met both an absolute mean frequency difference and a t-test criteria between Europeans and Non-Europeans. We tested these SNPs in our multiethnic cohort of 1427 SLE patients for severe disease outcomes (renal disease by ACR renal criterion, severe renal disease on biopsy or end-stage renal disease, and production of dsDNA antibodies) stratified by ethnicity: Caucasian, African American, Hispanic, and Asian. Logistic regression was performed, adjusting for disease duration and gender. Ethnic strata were refined via STRUCTURE analysis of 878 I-chip SNPs, excluding subjects with substantial ancestry outside of their self-identified ethnicity.

Results: This approach identified 13 SNPs with ethnicity-disease outcome associations (unadjusted p value < 0.001). Two SNPs, rs2099365 and rs2163882, which are in high linkage disequilibrium (LD) ($r2 = 0.98$) in Hispanics, also had significant false discovery rate p values (0.014) for association of renal disease in Hispanics (odds ratio 2.90). Both SNPs are 20kb from the 3' end of the endomucin (EMCN) gene, a glycoprotein involved in cell adhesion. These SNPs are predicted to disrupt 3–4 regulatory motifs. The EMCN gene is a non-autoimmune gene on the I-chip, not previously associated with SLE, but recently reported to be associated with susceptibility to RA. The association of the 2 SNPs with renal disease in Hispanics is consistent with an estimated 5.7 odds of renal disease per 100% Amerindian ancestry ($p = 3.5e\text{-}06$) compared to 0.23 odds per 100% European ancestry ($p=1.1e\text{-}22$) based on I-chip data. To validate the EMCN association results, we examined available EMCN gene SNPs in a large cohort of Hispanic patients, confirming an association with renal disease (5 SNPs with p values < 0.001, most significantly 4.5e-05).

Conclusion: Here we describe an approach to identify novel SLE severity risk variants. Testing these candidate alleles in our multiethnic SLE cohort identified 2 SNPs in high LD that were significantly associated with renal disease among Hispanic SLE patients. These SNPs are near the EMCN gene, a gene never before associated with SLE. Additional investigation is warranted to further validate these results and better characterize the association of this gene with renal disease in SLE.

An Anti CD123 Monoclonal Antibody (CSL362) Depletes Plasmacytoid Dendritic Cells and Inhibits CpG Upregulated IFNα Production and IFNα-Inducible Gene Expression in Peripheral Blood Mononuclear Cells from Patients with Systemic Lupus Erythematosus. Shereen Oon[1], Nicholas Wilson[1] and Ian Wicks[2]. [1]The University of Melbourne, Melbourne, Australia, [2]The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia.

Background/Purpose: Plasmacytoid dendritic cells (pDCs) contribute to systemic lupus erythematosus (SLE) pathogenesis by producing Type 1 interferon (IFN), most likely induced by endosomal Toll like receptor (TLR) activation by immune complexes. In healthy donors, pDCs are known to express high levels of CD123, the IL3 receptor alpha chain. CSL362 is a novel monoclonal antibody (mAb) that binds to CD123, neutralizing IL3 signaling and causing antibody dependent cell mediated cytotoxicity (ADCC) of CD123 bearing cells. This study of SLE and healthy donors evaluates - 1) CD123 expression on pDCs and other cell types, 2) CSL362 mediated depletion of pDCs, and 3) the effect of CSL362 on IFNα production and IFNα-inducible gene expression from peripheral blood mononuclear cells (PBMCs) *in vitro*.

Methods: Quantitative flow cytometry with Quantibrite PE beads and an anti-CD123-PE antibody was used to assess CD123 expression on cell types from peripheral blood of SLE and healthy donors ($n=15$). PBMCs from SLE ($n=13$) and healthy ($n=10$) donors were isolated by Ficoll gradient centrifugation and incubated for 24 hours *in vitro* with CSL362, the Fab portion of CSL362 (Fab', which neutralizes IL3 signaling, but does not effect ADCC), or an isotype control mAb. The percentage of viable pDCs was enumerated by flow cytometry. PBMCs from SLE ($n=7$) and healthy ($n=6$) donors were pretreated with CSL362, Fab' or isotype control mAb for 24 hours, then stimulated with CpG, a TLR9 agonist, for 18 hours. IFNα production from culture supernatant was assessed by ELISA. A novel 'IFN gene score', based on 11 IFNα-inducible genes, was incorporated into a customized gene array, to serve as a 'gene signature' to stratify patients and assess drug efficacy. This score was evaluated by performing quantitative PCR on RNA extracted from SLE ($n=17$) and healthy ($n=9$) donor whole blood. The average of the log2 fold change for the 11 genes in the SLE patients was compared to healthy donors. This score was also evaluated in PBMCs ($n=2$ SLE, $n=2$ healthy) after CSL362 pretreatment followed by CpG stimulation. The average of the log2 fold change for the 11 genes of the treated samples was compared to the untreated samples.

Results: CD123 expression levels were highest on pDCs compared to other cell types. pDCs were depleted after *in vitro* culture with CSL362 ($8.3 \pm 2.4\%$ [mean $\pm$ SEM], $p < 0.0001$) compared to isotype control but were not depleted by Fab' ($96.8 \pm 5.5\%$, $p = 0.17$). In addition, CpG-induced IFNα production from PBMC was inhibited by CSL362 pretreatment ($1.1 \pm 0.8\%$, $p < 0.0001$) compared to isotype control, but was not inhibited by pretreatment with Fab' ($122.3 \pm 27.7\%$, $p = 0.78$). The IFN gene score was elevated in SLE (3.31 ± 0.46) compared to healthy (1.49 ± 1.1, $p = 0.07$) donors. CpG-induced upregulation of the IFN gene score (3.9 ± 0.9) was reduced by pretreatment of PBMC with CSL362 (-0.9 ± 1.9, $p = 0.12$).

Conclusion: A mAb targeting CD123 (CSL362) depletes pDCs and decreases CpG-induced IFNα production and IFNα-inducible gene expression from SLE and healthy donor PBMCs. These effects were not seen with IL3 blockade alone or isotype control mAb. Cytoreductive therapy with CSL362 may therefore represent a novel treatment strategy in SLE.

SLE Patients Carrying a Disease-Associated *PTPN22* R620W Variant Show Reduced Interferon-Inducing Capacity. Yaya Wang, David Ewart, Ami Yamamoto, Emily C. Baechler, Parastoo Fazeli and Erik J. Peterson. University of Minnesota, Minneapolis, MN.

Background/Purpose: Type 1 interferons (IFN) are implicated in the pathogenesis of systemic lupus erythematosus (SLE). Increased expression of IFN-regulated genes, termed the IFN-signature, correlates with autoantibodies and disease activity in SLE. Likely sources of type 1 IFN in SLE include plasmacytoid dendritic cells (pDC), which produce IFNα following Toll-like receptor 7 (TLR7) activation. A coding variant in the protein tyrosine phosphatase nonreceptor type 22 (*PTPN22*) gene is associated with SLE. *PTPN22* encodes lymphoid tyrosine phosphatase (Lyp). We showed previ-

ously that Lyp is required for TLR-driven type 1 IFN production in myeloid cells. Variant *PTPN22* encodes an R620W bearing protein ("LypW"). We recently established that LypW is associated with impaired TLR-driven type 1 IFN production and type 1 IFN-dependent immunity. However, the functional consequences of LypW carriage in human SLE patients remain unclear. The current study was designed to address the effect of LypW carriage on interferogenic TLR signaling in SLE patients.

Methods: Caucasian SLE patients satisfying 1987 ARA diagnostic criteria were genotyped for *PTPN22* LypW variant carriage. Plasma IFNα concentrations in 15 LypW carriers and 21 non-carriers were determined by ELISA. IFN gene signature in whole blood was also determined by quantitative PCR (qPCR). PBMC were stimulated with R848, a TLR7/8 agonist, and IFNα2 and TNFα expression in pDC ($Lin^{-}HLA\text{-}DR^{+}CD123^{+}$) were detected by FACS. We measured IFNα protein levels in the supernatant from R848-stimulated SLE PBMC by ELISA. We compared STAT1 activation in SLE PBMC from carriers and non-carriers by phospho-flow.

Results: In both LypW carrier and non-carrier SLE patients, we observed comparable IFNα protein in plasma and type 1 IFN gene "signatures" in whole blood. We found that the percentage of pDC that produce IFNα2 after R848 simulation was significantly reduced in LypW carrier SLE patients, while the percentage of pDC producing TNFα was comparable to that observed in non-carrier patients. Further, we observed that IFNα2 expression in pDC was decreased in LypW carriers. Supernatant IFNα protein levels from R848-stimulated PBMC were significantly reduced in LypW carriers. Moreover, activation of type 1 IFN-driven STAT1 was impaired in LypW carrier PBMC after R848 stimulation.

Conclusion: LypW carrier SLE patients have reduced capacity for TLR-induced type 1 IFN production, even as they exhibit elevated whole blood type 1 IFN signatures similar to those observed in non-carrier patients. The findings suggest that LypW carriage may identify a subset of SLE patients who harbor defects in type 1 IFN-dependent host defense or anti-inflammatory functions.

Intracellular Complement C3 Is Exposed on the Cell Surface upon Apoptosis Induction and Participates in the Clearance of Apoptotic Cells By Phagocytes. Lucrezia Colonna[1], Christian Lood[1], YuFeng Peng[1], Xizhang Sun[1], Lena Tanaka[1], Sandip Panicker[2] and Keith B. Elkon[1]. [1]University of Washington, Seattle, WA, [2]True North Therapeutics, South San Francisco, CA.

Background/Purpose: The complement system has been viewed as a predominantly serum-derived host defense mechanism with multiple functions, including clearance of apoptotic cells. Defective function of the complement pathways have been implicated in the pathogenesis of systemic lupus erythematosus (SLE). Recently, intracellular complement C3 storage was demonstrated in many different cell types, and C3 activation products were shown to participate in the survival and effector cell differentiation of murine and human lymphoid cells. Despite the known role of serum-derived C3 activation products in the removal and immunosuppressive properties of dying cells, the role of intracellular C3 in clearance of apoptotic cells has never been explored. Thus, we asked whether human cells expose C3 and/or C3 activation products on their surface upon cell death induction, and whether such exposure functionally participates in their phagocytic clearance, independently of serum complement factors.

Methods: Apoptosis and secondary necrosis of human lymphoid cells was induced by both UV irradiation and serum starvation. C3/C3b/C3bi surface and intracellular expression on live and apoptotic human T and B primary cells as well as cell lines was monitored by flow cytometry (FACS), western blot and confocal microscopy. Macrophages were derived from circulating CD14+ monocytes by culture with M-CSF. Phagocytosis of apoptotic cells in presence or absence of serum was quantified by microscopy (phagocytic index) and by FACS with the aid of fluorescently labeled apoptotic cells.

Results: We observed that live human primary T and B cells, and human T and B cell lines expressed intracellular but not cell surface C3/C3bi. However, upon apoptosis induction, C3 activation products were exposed on the surface of dying cells in a time dependent manner. Detection of C3/C3bi correlated with later stages of apoptosis characterized by cell shrinkage and loss of membrane integrity (Annexin V+ PI+ cells). Confocal microscopy of unfixed cells revealed detection of C3/C3bi in a granular distribution, possibly in blebs and/or other endosomal compartments. To determine whether surface exposed C3/C3bi had functional relevance, we blocked the macrophage C3bi receptors CR3 and CR4 with antibodies, and compared phagocytosis of apoptotic cells in the absence of serum. Strikingly, functional blockade of CR3 and CR4 on human macrophages in the absence of serum specifically reduced the uptake of C3bi+ late apoptotic cells, and not that of latex beads (with an inhibition of 19.3% for CR3, 24.1% for CR4, and 48% for CR3+CR4 blockade; p= 0.182, 0.066; and 0.043, respectively).

Conclusion: Our results suggest that we have uncovered a novel function of intracellular complement C3 activation products in the removal of dying cells. C3 is a very large protein of 185,000 molecular mass and penetration into tissues is likely to be limited. Cell intrinsic, serum-independent, C3-mediated clearance of apoptotic cells may therefore be of particular relevance in tissues where there is accumulation of dead cells as observed in patients with SLE, as well as under other conditions such as hypoxia reperfusion injury and stroke.

Altered Plasticity of Inflammatory CD4 T Cells Contributing to Th17 Shift in Rheumatoid Arthritis. Jan Leipe, Fausto Pirronello, Simon Hermann, Matthias Witt, Hendrik Schulze-Koops and Alla Skapenko. University of Munich, Munich, Germany.

Background/Purpose: Whereas T helper (Th) cell subsets were previously regarded as irreversibly differentiated endpoints, evidence suggests that Th cell differentiation is a plastic process in response to appropriate stimulation. Mechanisms leading to the pathogenetic important predominance of Th17 cells in rheumatoid arthritis (RA) are not yet understood. We hypothesized that an altered T cell plasticity contributes to the shift towards the Th17 phenotype in RA.

Methods: A unique cohort of 35 patients with early, active and untreated RA (to exclude effects of immunosuppressive drugs on T cells) and 33 age- and sex- matched healthy controls (HC) were studied. Viable *in vivo*-originated Th1, Th2 and Th17 cells were FACS-sorted and trans-differentiated under Th1-, Th2- or Th17-inducing conditions. The cytokine secretion profile of the trans-differentiated cells was assessed by flow cytometry. Analysis of histone modifications in *IL17* and *RORC* gene loci was performed by ChiP assay. The relative expression of cytokine and transcription factor genes was measured by qRT-PCR.

Results: Of interest, Th17 cells from RA patients demonstrated a strikingly diminished re-differentiation capacity into both Th1 and Th2 directions. Under Th1 conditions, RA Th17 cells retained significantly more IL-17-producing cells, whereas frequencies of newly generated Th1 cells in RA were diminished. Similarly, under Th2 conditions, frequencies of newly generated Th2 cells were significantly reduced in RA. Vice versa, RA Th1 and Th2 cells demonstrated an enhanced capacity to re-differentiate into Th17 cells. In order to analyze underlying mechanisms leading to increased re-differentiation of Th1 to Th17 cells in RA, expression of RORC was investigated. We found that *RORC* expression was higher after re-differentiation of Th1 cells. Moreover, in the *IL17* and *RORC* loci an overrepresentation of the permissive histone modification H3 actetylation over the repressive H3K27 methylation was found in T cells from RA patients. Investigation of the SGK1/ FOXO1/ IL23R pathway, known to be important for Th17 stability, revealed higher expression of SGK1 and IL23R in RA after re-differentiation of sorted Th1 cells.

Conclusion: Together these data indicate that in RA *in vivo*-originated Th17 cells are resistant to changes in their phenotype, whereas other Th subsets are prone to Th17 cell re-differentiation. Increased RORC expression and the presence of a permissive histone modification state at the RORC gene locus might contribute to the altered Th plasticity in RA, thereby forcing Th17 cell-mediated immunity of the disease.

CaMK4 Inhibition Ameliorates the Development of Th17 Driven Inflammatory Diseases By Preventing Recruitment of IL-17 Producing Cells to Target Organs. Tomohiro Koga[1], Kotaro Otomo[2], Masayuki Mizui[2], Nobuya Yoshida[2], José C. Crispin[2], Atsushi Kawakami[1] and George C. Tsokos[3]. [1]Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [3]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA.

Background/Purpose: IL-17 producing T helper (Th17) cells have been closely associated with the development of organ damage in inflammatory and autoimmune diseases. We have previously reported that Calcium/calmodulin-dependent protein kinase IV (CaMK4) plays a crucial role in Th17 cell differentiation *invitro* and *invivo* and suggested that CaMK4 inhibition ameliorates clinical and pathological findings in experimental autoimmune encephalomyelitis (EAE) and MRL/*lpr* mice (1). We have also shown that Il-17 is important in the expression of anti-glomerular basement membrane Ab-induced glomerulonephritis (AIGN) (2). However, the effect of CaMK4 on recruitment of pathogenic T cells to target tissues in inflammatory settings has not been studied.

Methods: To determine the role of CaMK4 in the infiltration of inflammatory cells to target tissues, we induced experimental AIGN in *Camk4* sufficient or deficient mice and compared the kidney injury including the number of IL-17 producing cells in both groups. We also evaluated the effect of KN-93, a compound of CaMK4 antagonist in this AIGN model.

Results: *Camk4* deficient mice displayed less glomerular injury and less proteinuria at day 14 and at day 21 after induction of AIGN. Kidney infiltration by Th17 producing CD4 T cells was decreased significantly in *Camk4* deficient mice, suggesting that CaMK4 facilitated AIGN damage by promoting local inflammatory cells accumulation. In line with these observations, KN-93 treatment improved clinical and pathological finings in mice induced AIGN at dose dependent manner.

Conclusion: Collectively, our results indicate that CaMK4 inhibition might be a novel therapeutic strategy of Th17 cells-mediated inflammatory diseases.

Survivin Co-Ordinates Formation of Follicular T-Cells in Rheumatoid Arthritis. Maria Bokarewa[1], Karin Andersson[2], Malin Erlandsson[2], Mattias Svensson[2], Nicola Cavallini[3] and Mikael Brisslert[2]. [1]University of Goteborg, Goteborg, Sweden, [2]University of Gothenburg, Gothenburg, Sweden, [3]University of Göteborg, Göteborg, Sweden.

Background/Purpose: Survivin is a proto-oncogene that regulates cell division and apoptosis. Recently, survivin has emerged as a biomarker of persistently active and joint destructive rheumatoid arthritis (RA). High serum levels of survivin are frequently associated with antibodies against cyclic citrullinated epitopes (ACPA).

Here we study the role of survivin in the formation of follicular T-cells and in the antibody production in RA.

Methods: The intracellular expression of survivin and Bcl-6 was studied in RA patients (age 21–71 years, disease duration 1–49 years) by flow cytometry and qPCR. DNA binding of survivin and Bcl-6 was studied in stimulated PBMC by chromatin immunoprecipitation.

The effect of survivin modulation on the follicular T-cells and on production of antigen-specific and autoantibodies was studied in collagen-immunized arthritis (CIA) mice, where Survivin transcription was inhibited by shRNA-lentiviral construct (shSurv, 10^6–10^7 particles/mouse). In separate experiments, CIA mice were vaccinated with survivin-peptides before the CII immunization. Control CIA mice received non-targeting transduction particles or were vaccinated with irrelevant peptides.

Results: The sSurv+RA group (n=76) was characterized by higher frequency of RF+ and ACPA+ patients, as well as by higher levels of ACPA compared to sSurv-RA (n=68). Intracellular survivin was present in the effector (CD45RA+CD27-) CD4+ T cells. Survivin co-expressed with Bcl-6 on lymphocytes of arthritic mice and in RA patients. Bcl-6+ subset comprised 7–38% of surv+CD4+ T-cells and was also CXCR5+. Bcl6+Surv+ subset of CD4 T cells and mRNA levels of Bcl-6 were lower in blood of sSurv$^+$patients.

Follicular (CXCR5+PD-1+) CD4 population in spleen and lymph nodes of arthritic DBA1 mice were mostly surv+Bcl6+. Mice vaccinated with survivin-derived peptides developed the phenotype similar to sSurv+RA patients and had high serum levels of survivin and higher levels of aCII and RF antibodies. Surv-vaccinated mice had significantly increased survivin expression and the subset of surv+Bcl-6+ within CXCR5+CD4+ cells in LN. shSurv-treated mice had reduced CD4+surv+ and CD19+surv+ populations in spleens, and smaller CXCR5+CD4+ and CXCR5+B220+ populations, while Bcl-6 gene transcription was increased. Inhibiting survivin led to lower levels of anti-CII antibodies and lower RF, suggesting insufficient Bcl-6 and poor Tfh development. Chromatin immunoprecipitation showed that survivin binds within Bcl-6 responsive element of Blipm-1 promoter potentially controlling transcriptional activity of Bcl-6.

Conclusion: In this study we demonstrate that RA patients have co-expression of survivin and Bcl-6 in the follicular T helper cells. Changes in survivin transcription modulate formation and function of the follicular T cells by regulating transcriptional activity of Bcl-6, essential factor of germinal center formation and autoantibody production.

T-Cell Signaling Defects Can be Corrected By Manipulating 'TCR Signal Fine-Tuning Molecules' That Are Altered Due to Increased Ubiquitination in Systemic Autoimmune Disease. Julia Pinkhasov and Ram Raj Singh. UCLA, Los Angeles, CA.

Background/Purpose: T-cell selection in the thymus is primarily determined by the avidity of T cell receptor (TCR) for self-ligand-MHC. Since this process is dependent on the somatically generated receptors against the internal antigenic environment, all T-cells are inherently self-reactive to some degree. Hence, a signaling threshold must be established whereby overtly high self-avidity, potentially pathogenic, T-cells are removed, while allowing other lower self-avidity T-cells to survive. Using a avidity-based TCR transgenic model system, we found that besides the TCR, there are other signal regulating molecules that play a role in establishing signal threshold during a process known as TCR *tuning*, which modulates the intensity of TCR signaling (Pinkhasov et al, manuscript in preparation). Here, we determined the expression of potential TCR signal *fine-tuning* (TFT) molecules in a model of multi-system autoimmune disease, and investigated their role in T-cell signaling defects and mechanisms of their alteration.

Methods: The availability of murine strains that develop autoimmune disease resembling human SLE enables one to study the preclinical events in the pathogenesis. Here, we used MRL/MpJ-*Fas*$^{+/+}$ (MRL+/+) mice that develop SLE at 8–10-months of age, congenic MRL/MpJ-*Fas*$^{lpr/lpr}$ (MRL/lpr) mice that develop accelerated SLE due to a mutation of the *fas* gene, and MHC-matched C3H control mice. To analyze TFTs in antigen-specific T cells, studies were repeated in MRL/lpr, MRL+/+ and healthy B10.BR mice carrying the *AND* TCR transgene.

Results: We found the altered expression patterns of a battery of TFTs on thymocytes from MRL/lpr and MRL+/+ mice compared to C3H controls; specifically, negative regulator TFTs were reduced, while a positive regulator was increased. Thymocytes from young MRL+/+ and MRL/lpr mice showed increased activation and phosphokinase signal upon ex vivo stimulation, which were restored to near normal levels in the presence of a CD5 agonistic antibody. Unexpectedly, we observed a drastic reduction of TFTs in activated peripheral T-cells after disease onset. The reduced levels of negative TFTs correlated with increased responsiveness to TCR stimulation and to weak antigenic ligands. The reduced expression of TFTs in periphery was not due to their decreased transcripts, but rather, to activation-induced post-translational modification due to increased ubiquitination leading to targeted protein degradation. This was associated with an altered expression of E3 ubiquitin ligases *cbl-b*, *traf6*, *grail* and *itch* in MRL mice.

Conclusion: These results suggest that T-cells are able to tune the expression levels of TFTs post-development, likely by targeted protein degradation using the ubiquitin cycling pathway. We propose that the ability of T-cells to alter their internal signal threshold by altering TFT expression is a novel mechanism for

T-cells to escape peripheral tolerance and perpetuate autoimmune disease. Restoration of TCR signals to normal upon increased signaling through a TFT raises hope for a new avenue of treating systemic autoimmune diseases.

Involvement of CD8$^+$ T Cells in the Pathogenesis of Giant Cell Arteritis and Polymyalgia Rheumatica. Maxime Samson[1], Sylvain Audia[1], Malika Trad[2], Marion Ciudad[2], Hervé Devilliers[3], Alexandrine Gautheron[2], Valérie Quipourt[4], Francois Maurier[5], Nadine Meaux Ruault[6], Patrick Manckoundia[4], Paul Ornetti[7], Jean-Francis Maillefert[8], Jean-François Besancenot[3], Christophe Ferrand[9], Philippe Saas[9], Laurent Martin[10], Nona Janikashvili[2] and Bernard Bonnotte[1]. [1]INSERM UMR 1098, Besançon ; University of Burgundy, Faculty of Medicine, IFR100 ; Department of Internal Medicine and Clinical Immunology, Dijon, France, [2]INSERM UMR 1098, Besançon, Dijon, France, [3]Department of internal medicine and systemic diseases, Dijon, France, [4]Department of Geriatric Internal Medicine, Dijon, France, [5]Department of Internal Medicine, Metz, France, [6]Department of Internal Medicine, Besançon, France, [7]Department of Rheumatology, Dijon, France, [8]University Hospital Dijon, Dijon, France, [9]INSERM UMR1098, Besançon, France, [10]INSERM UMR 1098, Besançon ; University of Burgundy, Faculty of Medicine, IFR100 ; Department of Pathology, Dijon, France.

Background/Purpose: Previous studies have demonstrated the implication of CD4$^+$ T cells, especially T helper (Th1) and Th17 cells, in the pathogenesis of giant cell arteritis (GCA) and polymyalgia rheumatica (PMR). However, very little is known concerning CD8$^+$ T cells. This study aimed to investigate their implication in the pathogenesis of GCA and PMR.

Methods: Thirty patients suffering from GCA (n=23) or PMR (n=7) and 21 age-matched healthy volunteers were enrolled. Blood samples were collected at diagnosis and after 3 months of glucocorticoid (GC) treatment. Percentages of circulating cytotoxic T lymphocytes (CTL) (CD3$^+$CD8$^+$Perforine$^+$ GranzymeB$^+$), Tc1 cells (CD3$^+$CD8$^+$IFN-γ^+), Tc17 cells (CD3$^+$CD8$^+$IL-17$^+$) and the expression of CD63, HLA-DR, CCR5, CCR6, CCR7, CD62L and CXCR3 by CD8$^+$ T lymphocytes were assessed by flow cytometry analysis. Levels of soluble Granzyme A, Granzyme B, CCL2, CCL20, CXCL9, CXCL10 and CXCL11 were determined by ELISA or Luminex® technology. Temporal artery biopsies (TAB) were stained for CD3, CD4 and CD8. Data are expressed by mean±SEM and *P* value is the result of the Mann Whitney U test or Wilcoxon matched-pairs signed rank test, when appropriate.

Results: Percentages of circulating CTL and Tc17 in total CD8$^+$ T cells were significantly increased in patients compared to controls: 36.6±4.1 vs. 16.3±3.1% (P=0.0004) and 0.59±0.11 vs. 0.15±0.03% (P<0.0001), respectively. The level of Tc1 cells was not different between two groups. CD63 expression, that is expressed at the membrane once CTL have degranulated, was higher in patients than in controls (29.3±3.5 vs. 14.8±2.9%; P=0.003). Levels of Granzyme A and B were also significantly increased in the serum of patients when compared to controls: 20.6±4.4 vs. 11.6±2.7 pg/mL (P=0.02) and 3.2±1.3 vs. 0.95±0.49 pg/mL (P=0.004), respectively. After 3 months of GC treatment, percentages of circulating CTL, Tc17 and soluble levels of Granzyme A and B were significantly decreased, whereas the percentages of Tc1 and CD63$^+$cells in total CD8$^+$ T lymphocytes remained stable. Expression of chemokine receptors was comparable between patients and controls except for CXCR3 that was expressed at a higher level by CD8$^+$ T cells from patients: 48.1±3.6 vs. 28.5±3.5% (P=0.0004). Levels of CXCR3 ligands were increased in the serum of patients compared to controls: 629.8±194.7 vs. 92.81±19.2 pg/mL (P<0.0001) for CXCL9, 31.4±6.9 vs. 9.2±1.5 pg/mL (P<0.0001) for CXCL10 and 12.0±4.1 vs. 3.5±2.7 pg/mL (P=0.0094) for CXCL11. Importantly, the levels of these 3 chemokines were decreased after 3 months of GC treatment. Immunohistochemical analyses of TAB (5 GCA patients) revealed a strong infiltration by CD4$^+$ and CD8$^+$ T cells in all the layers of the artery.

Conclusion: This study provides the first data that demonstrate an implication of CD8$^+$ T cells in the pathogenesis of GCA and PMR. In untreated patients, CD8$^+$ T cells, that infiltrate lesions of vasculitis, have an activated phenotype that is partly corrected by GC treatment. CXCR3 is upregulated on CD8$^+$ T cells from GCA and PMR patients while levels of CCL9, −10 and −11 are increased in the serum of patients, which argues for the implication of CXCR3 in the homing of CD8$^+$ T cells in the lesions of GCA.

MiR-125a Is Critical Regulator for Controlling Autoimmunity in Multiple Autoimmune Diseases through Stabilizing Treg Mediated Immune Homeostasis. Wan Pan[1], Shu Zhu[1], Dai Dai[1], John Harley[2] and Nan Shen[1]. [1]Institute of Health Sciences, Shanghai Institutes for Biological Sciences (SIBS), Chinese Academy of Sciences (CAS) & Shanghai Jiao Tong University School of Medicine (SJTUSM), Shanghai, China, [2]The Center for Autoimmune Genomics and Etiology (CAGE), Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio, United States of America, Cincinnati, OH.

Background/Purpose: Although different autoimmune diseases show distinct clinical phenotypes, common cellular and molecular immune pathways have been shown to be intimately involved in the autoimmune pathogenesis. Treg cells suppress inflammation and maintain immune homeostasis. Impairment of the development and function of Treg cells is a common immune defect that contributes to the development of multiple autoimmune diseases. MicroRNAs as novel epigenetic regulator of immune response play critical role on T cell mediated immune regulation. In this study we focus on defining the cellular and molecular mechanisms underlying microRNA(miR) mediated dysregulation of Treg cells on multiple autoimmune diseases and explore therapeutic potentials of miRs based intervention for re-program immune homeostasis on these disease relevant mouse models.

Methods: miR profiling for CD4+ T cells of multiple autoimmune diseases and their relevant mouse models were done by ABI miR array. miR125a KO and transgenic mice have been generated for testing Treg cell phenotype and function. EAE and T-cell mediated colitis models were conducted on both genetically modified mice and B6 controls mice for evaluating role of miR125a on Treg cell mediated tissue inflammation. mRNA profiling, IPA bioinformatics tool and several microRNA databases were used for miR targets predication. 3UTR report gene assay, western blot and FACS were used for miR125a targets's validation. We administrated miR 125a agomir(chemical modified miRNA mimics) into EAE and Lpr/MRL mice for evaluating its efficacy.

Results: Frist we identified a commonly down-regulated miRNA, miR-125a, in peripheral CD4+ T cells of multiple autoimmune diseases including systemic lupus erythematosus, multiple sclerosis, and Crohn's diseases, as well as their relevant mouse models. Although the common dysregulation implied a shared mechanism of autoimmune pathogenesis, a function for miR-125a in either driving or constraining autoimmune pathology was still unclear. By using miR-125a deficient mice, we identified miR-125a as a key regulator that stabilizes the commitment and immunosuppressive capacity of Treg cells by restraining the differentiation programs of effector lineages, thus contributing to the suppression of inflammation, as well as the maintenance of immune homeostasis. Deficiency of miR-125a may ultimately result in more severe pathogenic consequences of T-cell mediated colitis and EAE development. Analysis of the genome-wide targets of miR-125a revealed that it suppressed several effector T cell factors that are detrimental to Treg cell differentiation, including Stat3, Il13 and Ifng. Moreover, manipulation of miR-125a level by chemically synthesized analogue of miR-125a showed therapeutic potentials to re-program the immune homeostasis and contributed to certain disease prevention or treatment in clinically-relevant animal models.

Conclusion: Our finding identify miR-125a as a commonly down-regulated miRNA critical for controlling autoimmune diseases through stabilizing Treg mediated immune homeostasis by repressing effector programs. miR-125a could be promsining therapeutic traget for treating multiple Treg cells mediated autoimmune diseases.

The Relationship of ARMS2 Genotype with Idiopathic Inflammatory Vasculitis. Christopher Mecoli[1], Fan Wang[2], Christopher Pappas[3], Peter C. Grayson[4], David Cuthbertson[5], Simon Carette[6], Christian Pagnoux[6], Gary S. Hoffman[7], Nader A. Khalidi[8], Curry L. Koening[9], Carol A. Langford[10], Carol

McAlear[11], Paul A. Monach[12], Larry W. Moreland[13], Philip Seo[14], Ulrich Specks[15], Steven R. Ytterberg[15], Rui Feng[1], Gregory Hageman[3] and Peter A. Merkel[11]. [1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, OK, [3]University of Utah School of Medicine, Salt Lake City, UT, [4]National Institutes of Health, Bethesda, MD, [5]University of South Florida, Tampa, FL, [6]University of Toronto, Toronto, ON, [7]Center for Vasculitis Care and Research, Cleveland Clinic Foundation, Cleveland, OH, [8]St. Joseph's Hospital, McMaster University, Hamilton, ON, [9]University of Utah, Salt Lake City, UT, [10]Center for Vasculitis Care and Research, Cleveland Clinic, Cleveland, OH, [11]Vasculitis Center, University of Pennsylvania, Philadelphia, PA, [12]Vasculitis Center, Boston University School of Medicine, Boston, MA, [13]University of Pittsburgh, Pittsburgh, PA, [14]Johns Hopkins Vasculitis Center, Johns Hopkins University, Baltimore, MD, [15]Mayo Clinic, Rochester, MN.

Background/Purpose: Patients with age-related macular degeneration (AMD), a leading cause of irreversible blindness, have a 10-fold increased prevalence of abdominal aortic aneurysms. Single nucleotide polymorphisms (SNPs) in a number of genes, including Complement Factor H (CFH) on chromosome 1 and age-related macular susceptibility protein 2 (*ARMS2)* and HTRA Serine Peptidase 1 *(HTRA1)* on chromosome 10, are strongly associated with increased risk for developing AMD. These AMD-associated loci are also strongly associated with vasculopathies, including choroidal neovascularization, polypoidal choroidal vasculopathy, and retinal angiomatous proliferation in both Caucasians and Japanese. These finding raise intriguing possibilities of a potential association between vascular pathology and AMD-associated genes. This study tested the hypothesis that AMD-associated gene variants may also be involved in the development of vasculitis, especially the large-vessel vasculitides (LVV), giant cell arteritis (GCA) and Takayasu's arteritis (TAK).

Methods: A candidate gene study was performed to investigate the relationship between AMD-associated variants and vasculitis. In a preliminary study, SNPs within CFH (rs1061170), Complement Component 3 (*C3*; rs2230199), *IL2/IL21* (rs1065489), *ARMS2* (rs10490924) and *HTRA1* (rs11200638) were examined for association with six phenotypes of vasculitis: GCA, TAK, granulomatosis with polyangiitis (Wegener's, GPA), microscopic polyangiitis (MPA), eosinophilic granulomatosis with polyangiitis (Churg-Strauss, EGPA), and polyarteritis nodosa (PAN). Among these 5 SNPs rs10490924 had the strongest association with the vasculitides and this SNP was pursued in the full analysis. The study included samples from 1196 patients with vasculitis and 1248 healthy controls matched for age, sex, race, and ethnicity. Additive p-values were calculated for each subtype of vasculitis.

Results: The main results of the study are reported in the Table. The controls had a minor allele frequency (MAF) of 21% for rs10490924. Overall there was a significant association of all vasculitis types with rs10490924 (p=0.0449). Large-vessel vasculitides were significantly associated with rs10490924 (p-value of 0.0177). The GCA and MPA groups were each independently associated with rs10490924 (p-values of 0.0199 and 0.039, respectively).

Conclusion: This candidate gene study demonstrated a significant association between variants in *ARMS2* and idiopathic forms of vasculitis, including large-vessel vasculitides. While further validation is needed, this study suggests the possibility of a common pathogenesis between aortic pathology in AMD and large-vessel vasculitis.

Association of rs10490924 with Vasculitis

Type of vasculitis	Cases, n	MAF in cases	MAF in controls	Additive OR (95% C.I.)	Additive p-value

Evaluation of KIR3DL1/KIR3DS1 Association with Behçet's Disease in Turkish Individuals. Burak Erer[1], Elaine F. Remmers[1], Masaki Takeuchi[1], Colleen Satorius[1], Duran Ustek[2], Ilknur Tugal-tutkun[3], Emire Seyahi[4], Yilmaz Ozyazgan[5], Ahmet Gul[3], Daniel L. Kastner[6] and Michael J. Ombrello[7]. [1]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, [2]Institute of Experimental Medicine, Istanbul University, Istanbul, Turkey, [3]Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey, [4]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [5]Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey, [6]National Human Genome Research Institute, Bethesda, MD, [7]National Institute of Arthritis Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD.

Background/Purpose: The Behçet's disease (BD)-associated HLA-B type, HLA-B*51 (B*51), is a ligand for a pair of allelic killer immunoglobulin-like receptors (KIR) present on cytotoxic cells —KIR3DL1, which inhibits their cytotoxicity, and KIR3DS1, which activates their cytotoxic activity. KIRs are inherited in evolutionarily conserved haplotypes in which KIR3DL1 and KIR3DS1 are mutually exclusive. We therefore tested the hypothesis that KIR-regulated cytotoxic mechanisms contribute to BD by testing for association between the presence of KIR3DL1 and KIR3DS1 alleles in Turkish individuals.

Methods: Turkish BD patients (n = 1,900) and controls (n = 1,779) were genotyped for the KIR3DL1 and KIR3DS1 alleles with two sequence-specific PCR assays. Genotypes of 6,994 SNPs from the HLA region were determined with the Immunochip (Illumina) and used to impute the individuals' HLA types using SNP2HLA and a reference panel of 5,225 European individuals. A chi squared test for association was used to evaluate the contribution of KIR3DL1 and KIR3DS1 to BD. A P-value less than 0.05 was considered significant.

Results: Classical HLA types were determined by imputation in all samples and types with posterior probability greater than 0.9 were included in analyses. KIR3DL1 and KIR3DS1 genotypes were determined for 1799 of the cases and 1710 of the controls. In these subjects, presence of the killing activating KIR3DS1 allele did not differ significantly between cases and controls (42.7% vs 41.0%, P = 0.29). Furthermore, the activating allele did not appear to interact with HLA-B alleles. It was present at similar frequencies in B*51-positive cases and controls (44.3% vs 43.0%, P = 0.63), in Bw4-positive cases and controls (43.0% vs 41.1%, P = 0.31), and in cases and controls bearing the Bw4 motif with isoleucine at position 80 (43.7% vs 41.4%, P = 0.32). Similarly, no disease association was found for the inhibitory KIR3DL1 allele in all the samples or in any of the HLA-B subsets.

Conclusion: We found no association of BD with the presence of the KIR3D activating (KIR3DS1) or inhibitory (KIR3DL1) receptors, which together regulate cytotoxic cell activity through binding of a subset of HLA class I molecules, including the BD-associated HLA-B*51. Due to the complexity of this locus (i.e. sequence variation, copy number variation), lack of association between BD and the presence/absence of KIR3DS1 or KIR3DL1 does not exclude a role for KIRs in the pathogenesis of BD. Further studies of KIR3DL1/KIR3DS1 types and copy number variants, as well as of other KIRs, are warranted.

Background/Purpose: To compare the efficacy of infliximab (IFX) versus adalimumab (ADA) as first biologic drug in refractory uveitis due to Behçet's disease (BD) for 1-year period.

Methods: Multicenter study of patients with BDxs uveitis refractory to conventional treatment including high-dose corticosteroids and at least one standard immunosuppressive agent. IFX (3–5 mg/kg at 0, 2, and 6 weeks and then every 4–8 weeks) was used in 75 cases and ADA (usually 40 mg every 2 weeks) in 50 cases. The main comparative outcome measures were improvement of visual acuity (VA) (at least 20%), complete inactivity of anterior chamber inflammation, vitritis, and retinal vasculitis as well as macular thickness <250 microns. A bivariate and logistic regression analysis was performed for every previous outcome between ADA vs IFX (SPSS20.0 package).

Results: We studied 125 patients (223 affected eyes). No statistically significant differences at baseline were observed between IFX vs ADA groups in sex (♂/♀; 41/34 vs 29/21; p=0.71), mean age (39.2±9.39 vs 36.14±12.7 years; p= 0.12), HLA-B51 positive (75% vs 75%), uveitis duration before anti TNFα onset (median [IQR]; 36 [12–71] vs 24 months [12–60]; p=0.4), VA (0.47±0.26 vs 0.52±0.27; p=0.29), anterior chamber cells (median [IQR]; 0.5 [0–2] vs 1.5 [0–2]; p=0.2), retinal vasculitis (73.2% vs 75%; p=0.95); macular thickness (285.90±90.15 vs 312.02±106.57; p=0.25), combined treatment (82.7% vs 77.6%; p= 0.481), basal degree of immunosuppression (mean±SD; 11.35± 5.67 vs 9.65±4.68; p= 0.09). After 1 year of therapy**,** ADA yielded a non-statistically significant increased frequency of improvement of VA, complete inactivity of anterior chamber inflammation, and macular thickness < 250 microns when compared with IFX. In contrast, a slight increased frequency of inactive vitritis and improvement of retinal vasculitis was observed in IFX-treated patients but the difference was not statistically significant **(Table).**

Conclusion: After 1 year of therapy ADA and IFX do not show differences in the visual outcome of patients with refractory uveitis due to BD.

Table: Treatment results at 1 year of therapy: Differences between ADA and IFX

	ADA/IFX (%)	Crude Odds ratio (95% confidence interval)	p	Adjusted Odds ratio*	p
Visual acuity improvement (>20%)	66.7%/48.2%	2.148 (0.879–5.250)	0.094	1.84	0.214
Inactive anterior chamber inflammation	67.6%/61.2%	1.324 (0.528–3.323)	0.550	1.669	0.346
Inactive Vitritis	60.5%/66.7%	0.767 (0.330–1.782)	0.537	0.867	0.765
Improvement of retinal vasculitis	85.2%/93%	0.431 (0.089–2.099)	0.298	0.340	0.217
Macular thickness < 250 microns	36.8%/21.7%	2,100 (0.539–8.185)	0.285	1.447	0.620

* adjusted for age, sex, and disease duration.

Effect of Apremilast on Quality of Life and Physical Function in Patients with Behçet's Syndrome. Gulen Hatemi[1], Melike Melikoglu[1], Recep Tunc[2], Cengiz Korkmaz[3], Banu Turgut Ozturk[4], Cem Mat[5], Peter A. Merkel[6], Kenneth Calamia[7], Lilia Pineda[8], Ziqi Liu[8], Randall M. Stevens[8], Hasan Yazici[1] and Yusuf Yazici[9]. [1]Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey, [2]Necmettin Erbakan University, Meram Medical Faculty,Division of Rheumatology, Konya, Turkey, [3]EskiÅŸehir Osmangazi University, EskiÅŸehir, Turkey, [4]Selçuk University, Konya, Turkey, [5]Istanbul University, Cerrahpasa Medical Faculty, Dermatology, Istanbul, Turkey, [6]Vasculitis Center, Division of Rheumatology, University of Pennsylvania, Philadelphia, PA, [7]Mayo Clinic Health System in Waycross, Waycross, GA, [8]Celgene Corporation, Warren, NJ, [9]New York University School of Medicine, New York, NY.

Background/Purpose: The oral ulcers in Behçet's syndrome (BS) can be painful, causing difficulty in eating and speaking, and can impair the quality of life. Apremilast is an oral phosphodiesterase 4 inhibitor that modulates inflammatory pathways. A clinical trial demonstrated a beneficial effect on oral ulcers with this agent. For this study, we aimed to assess whether apremilast is effective in improving quality of life in patients with BS.

Methods: This was a phase 2, multicenter, controlled study of 111 patients with BS, without major organ involvement but with ≥2 oral ulcers, who were randomized to apremilast 30 mg BID or placebo for 12 weeks, followed by a 12-week active-treatment period for all patients. The primary outcome, which was the number of oral ulcers at Week 12, and secondary outcomes at Week 12, including oral ulcer pain, number of genital ulcers, number of patients with a complete or partial response, number of genital ulcers, and disease activity assessed by the BS activity scale (BSAS) and Behçet's disease current activity form, have already been reported. We now report the results of health related quality of life measurements from the trial as assessed using the Behçet's disease quality of life (BDQoL) questionnaire and the 36-item Short-Form Health Survey version 2 (SF-36v2). Patients in the trial completed each of these instruments at baseline and at Week 12.

Results: The mean ± SD BDQoL score showed a significantly greater improvement from baseline at Week 12 with apremilast vs. placebo (−4.5 ± 7.61 vs. −1.6 ± 5.30; p=0.0397). The mean ± SD SF-36v2 physical

component summary scores were significantly higher (improved) at Week 12 with apremilast vs. placebo (4.72 ± 9.45 vs. −1.70 ± 7.78; P=0.0011). The mean scores were significantly improved with apremilast for the SF-36v2 subscales of physical function, bodily pain, and general health perceptions at Week 12.

Conclusion: Treatment with Apremilast improved quality of life and physical function in patients with BS.

Scarlato Hospital, Scafati, Salerno, Italy, [14]Università Politecnica delle Marche, Ancona, Italy, [15]UNIVERSITY OF TURIN (ITALY), TURIN, Italy, [16]Univ Modena Reggio Emilia, Modena, Italy, [17]Rheumatology Unit, University of Pisa, Pisa, Italy, [18]Internal Medicine Unit, Policlinico San Marco, Bergamo, Italy, [19]Istituto di Malattie Infettive e Tropicali, Università di Milano c/o Ospedale L. Sacco, Milano, Italy.

Background/Purpose: Two independent controlled randomized trials recently reported the efficacy and safety of rituximab (RTX) monotherapy in severe cryoglobulinemic vasculitis (CV) (1, 2), with one reporting a follow-up lasting two years (1). The aim of this study is to report the very long term efficacy and safety of a retreatment regimen with RTX administered at clinical relapse after the end of the abovementioned trial (1).

Methods: Long term follow up data of a trial of RTX in severe CV (1) were analysed, by considering patients managed with retreatent with RTX at clinical relapse. During this follow-up, only RTX monotherapy was used. Number of retreatments, disease activity at last follow up, adverse events and causes of deaths were registered. Clinical response was evaluated at the last follow-up visit, as follows: i) complete response (remission), partial response (response < 50% of at least one manifestation among glomerulonephritis, severe neuropathy or skin ulcers) (1), and active disease despite treatment.

Results: After the end of the 24-month controlled trial (1), follow-up data were analysed in 30 patients, all positive for hepatitis C virus infection. The mean follow up after the beginning of RTX therapy (1) was 72.6±20.4 months, including 24 (80%) patients followed for more than 4 years and 6 (20%) patients followed for 2.4–4 years. Of them, 21 patients were still under an active follow up, 3 patients were lost from follow-up shortly after the end of the trial, and 6 patients died. Survival of RTX regimen was 7.6±0.3 yrs (mean±standard error). Seventeen out of 30 (56.7%) patients needed a retreatment for relapse; of them, 6/30 were retreated during the trial, 10/30 only after the end of the trial and 1/30 during both follow-up periods, accounting for 25 retreatments in total, the first one at a mean of 22.3 ± 12.1 months from last RTX cycle during the trial. Patients were retreated for nephritis (7/25), neuropathy (12/25), skin ulcers (6/25) or widespread purpura (6/25). Of the 17 patients retreated, 6/17 (35.3%) showed complete response at the last follow-up, 5/17 (29.4%) a partial response, while 6/17 (35.3%) had an active disease. Interestingly, of the remaining 13/30 patients undergoing only one single course of RTX during the follow-up, 6/13 were still in active follow-up and in clinical remission at the last follow-up. Recurrent infections occurred in three patients (10%; urinary and upper respiratory), related to severe hypogammaglobulinemia (IgG < 3 g/l) in 2/3. Death occurred in 6 patients. However, only 2/6 deaths were linked to relapsed vasculitis, with new onset of intestinal vasculitis.

Conclusion: A long-term RTX monotherapy with a retreatment at relapse regimen is effective and safe in cryoglobulinemic vasculitis, with low rate of severe hypogammaglobulinemia. Clinicians should be aware to promptly recognize and treat clinical relapse, as well as concomitant infections. Relapses with life-threatening manifestations (i.e. intestinal vasculitis) were uncommon. Further investigation may be required to select patients where maintenance RTX therapy may be the best choice.

Update on Long-Term Outcomes after Reversible Cerebral Vasoconstriction Syndrome (RCVS). Seby John[1], Aneesh Singhal[2], Leonard H. Calabrese[1], Ken Uchino[1], Tariq Hammad[1], Stewart Tepper[1], Mark Stillman[1] and Rula A Hajj-Ali[1]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Massachusetts General Hospital, Boston, MA.

Background/Purpose: RCVS is characterized by acute onset of severe headaches, with or without neurologic deficit with evidence of reversible cerebral vasoconstriction. We have previously reported data on long-term outcome on 20 patients with RCVS. Herein, we are validating our previous report by including data from two large academic centers.

Objectives:

i) To assess stroke and headache outcomes using validated measures ii) To determine the impact of RCVS on health related quality of life (QoL).

Methods: The following validated questionnaires were mailed to patients recruited from RCVS registries of Cleveland Clinic and Massachusetts General Hospital: Headache screening form, Headache Impact Test (HIT-6), Migraine Disability Assessment Test (MIDAS), Barthel Index (BI), EuroQoL (EQ-5D-5L) and Patient Health Questionnaire (PHQ-9).

Results: Of the 191 patients in the RCVS registries, 109 could be contacted and 45 responded to the questionnaires. This included 41 (91%) females, with a median follow-up time after symptom onset of 78 months (range 4–254 months). Forty six % had prior migraine, 31% developed ischemic stroke, 18% intracerebral hemorrhage, and 44% had convexal subarachnoid hemorrhage. After RCVS resolution, 24 (53%) patients continued to have headache, but the majority (88%) reported improvement in its severity. Five (14%) patients reported severe impact on activities of daily living from headaches as measured by the HIT-6 and MIDAS scales. The majority (97.5%) of patients were functionally independent based on their BI scores. EQ-5D-5L measurements showed that patients did better in the domains of mobility, self-care and usual activities, as compared to pain and anxiety/depression. Patients with persistent headache had significantly higher levels of pain as measured by EQ-5D-5L. Depression assessment using the PHQ-9 revealed only 1 (3%) patient reporting severe depression. There was a trend towards greater patients with persistent headache having more severe degrees of depression. There was no difference among all the outcome measures between the two centers.

Conclusion: More than half of patients with RCVS will continue to have headache long-term. They are not similar to the RCVS onset headache and are markedly improved from the initial headache. Although close to two-thirds of patients suffered from an initial ischemic or hemorrhagic stroke, almost all were independent with little functional disability. However, pain and anxiety/depression might be associated with lower QoL Headache may be a potential factor aggravating pain and anxiety/depression in those patients with persistent headache. This larger data from two different centers validate our previous report.

2857

Restricting Back Pain Is Strongly Associated with Disability in Community-Living Older Persons over the Course of 13 Years. Una Makris[1], Liana Fraenkel[2], Ling Han[3], Linda Leo-Summers[3] and Thomas M. Gill[4]. [1]Dallas VA Medical Ctr, Dallas, TX, [2]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT, [3]Department of Medicine, New Haven, CT, [4]Yale University, New Haven, CT.

Background/Purpose: Although back pain is common and costly, few longitudinal studies have evaluated the association between back pain severe enough to restrict activity [hereafter referred to as restricting back pain (RBP)] and the development of disability. The objective of this study is to evaluate the association between RBP and subsequent episodes of disability in basic, instrumental, and mobility activities, respectively.

Methods: Participants included the 754 members of the Precipitating Events Project (median age 78 y, 64.6% women), a prospective study of community-living persons, aged 70+ years, who completed monthly telephone assessments of RBP and disability, and who were at risk for developing new and recurrent disability episode(s) for up to 159 months. RBP was defined as staying in bed for at least 1/2 day and/or cutting down on one's usual activities due to back pain. Disability was defined as needing help with/inability to complete ≥1 of the activities, listed in the Table, in any given month for each of the three outcome categories. The event rates for the three disability outcomes were estimated using a GEE Poisson model. A recurrent events Cox model was used to evaluate the association between RBP and each of the three disability outcomes. The model was adjusted for fixed-in-time (sex, education, ethnicity) and time-varying covariates (listed in Table) (age, chronic conditions, BMI, depressive symptoms, cognitive impairment, physical frailty) that were updated every 18 months.

Results: For the basic, instrumental and mobility activities, the disability event rates were: 3.6 per 100-person months (95% CI 3.37, 3.89), 8.5 per 100-person months (95% CI 8.05, 8.98), and 9.38 per 100-person months (95% CI 8.98,9.81), respectively, with a median duration of 2 months per disability episode for each of the three outcomes. The unadjusted and adjusted associations of restricting back pain with the 3 disability outcomes are listed in the Table.

Conclusion: In this longitudinal study, RBP was independently associated with disability in basic, instrumental and mobility activities among older persons. Interventions directed at preventing or decreasing RBP may reduce the likelihood of disability in activities across three key domains of function.

Disability Outcome	Activities Involved	Hazard Ratio: Association of Restricting back Pain with Disability	95% CI
Essential activities (N=754)	Bathing, dressing, walking inside house, transferring from chair	Unadjusted 3.83 Adjusted* 3.47	3.35, 4.37 3.01, 3.99
Instrumental activities (N=703)	Housework, meal preparation, shopping	Unadjusted 2.32 Adjusted* 2.33	2.05, 2.62 2.08, 2.61
Mobility activities (N=709)	Walking 1/4 mile, climbing flight of stairs, lifting or carrying 10 lb	Unadjusted 3.53 Adjusted* 3.23	3.13, 3.97 2.87, 3.64

*The model was adjusted for fixed (sex, education, ethnicity) and time-varying covariates (age, chronic conditions, body-mass index, depressive symptoms, cognitive impairment, and physical frailty) updated every 18 months.

Education Effects on Outcome Expectations for Exercise in Adults with Knee Osteoarthritis. Tressa Gamache, Lori Lyn Price, Jeffrey B. Driban, William F. Harvey and Chenchen Wang. Tufts Medical Center, Boston, MA.

Background/Purpose: Outside of a clinical trial setting, higher outcome expectations for exercise, more education, and greater physical activity are inter-related, and outcome expectations may partly explain why education level is associated with physical activity. In clinical trials with exercise interventions, where participants tend to have higher outcome expectations, it would be informative to know if these associations still hold true. Therefore, we assessed if higher education is associated with higher outcome expectations and if outcome expectations mediate the relationship between education and physical activity.

Methods: We conducted a secondary analysis of all baseline data from a randomized trial comparing Tai Chi and Physical Therapy among people with knee osteoarthritis (KOA) as defined by the ACR criteria. Participants completed the Outcome Expectations for Exercise (OES), CHAMPS Activities Questionnaire for Older Adults (CHAMPS), and demographics self-report questionnaires. The OES is a 9-item questionnaire, in which higher mean scores indicate higher expectations for exercise with a range from 1 to 5, CHAMPS is a 40-item questionnaire that measures physical activity, and education was categorized into the following: high school diploma or less, some college/trade school, college degree, graduate school.

We performed an analysis of variance (ANOVA) with OES as the dependent variable to explore the differences among education groups with graduate school as the reference group. We also performed a multivariable analysis to adjust for age and sex.

To examine the role of OES as a mediating factor between education and physical activity, we performed a mediation analysis between education and physical activity with OES as the mediator using a commonly accepted method (Baron & Kenney).

Results: Our analysis included data from 282 participants with an average age of 59.7 years (SD=10.4); 69% female, 51% white, 35% black, 29% working at least part time, 72% completed at least some college, and an average body mass index of 32 kg/m^2. In the ANOVA, participants with high school or less had lower OES than participants who completed graduate school (Table 1). Higher education attainment was associated with increased OES after adjusting for age and sex (p=0.002). Criteria were not met for the mediation analysis because education did not predict physical activity and OES did not predict physical activity when controlling for education.

Conclusion: Education is associated with OES; however, OES is not a mediator between education and physical activity among individuals with KOA who are enrolled in a clinical trial with an exercise intervention. The lack of mediation may be in part because the participants recruited into this trial had higher OES and most had at least some college education, therefore were not reflective of the general population.

Table 1. ANOVA with OES as Dependent Variable (p=0.003)

Variable	N	OES Mean	SD	p-value
High School or less	50	3.66	0.85	<0.01
Some College/Trade School	91	3.96	0.88	0.06
College Degree	51	4.13	0.50	0.75
Graduate School	64	4.24	0.55	Ref.

Randomized Controlled Trial of Postoperative Care Navigation in Total Knee Arthroplasty Patients: Does One Size Fit All? Elena Losina, Jamie E. Collins, John Wright, Meghan E. Daigle, Laurel Donnell-Fink, Doris Strnad, Vladislav Lerner, Stanley Abrams and Jeffrey N. Katz. Brigham and Women's Hospital, Boston, MA.

Background/Purpose: A number of TKA recipients have suboptimal improvements after surgery. Our objective was to establish the efficacy of a motivational-interviewing (MI)-based telephone intervention aimed at improving functional outcomes post-TKA and to identify subgroups especially likely (or unlikely) to benefit from the intervention.

Methods: We conducted the RCT to compare functional status in TKA recipients randomized to one of two strategies: 1) enhanced postoperative care with frequent follow-up by a care navigator; 2) usual postoperative care. Those who were randomized into the care navigation arm received ten calls from a trained non-clinician care navigator over the first 6 months post-TKA. The trained navigator used theory driven MI to engage TKA recipients in discussions about their rehabilitation goals, including plans for and confidence in achieving those goals. Patients in the usual care arm received standard postoperative care. Patients in both arms were assessed at baseline, 3 and 6 months post-TKA. The study enrolled subjects 40+ years of age with OA who were scheduled for TKA. Primary outcome was the difference between the arms in WOMAC function score change, over the 6 months post-TKA.

We defined a satisfactory functional improvement as either achieving WOMAC function scores <15 or reducing pre-operative functional score by 19+ points, suggested as MCID in TKA patients (Escobar, 2007). We examined whether sex, obesity and pain catastrophizing affected the efficacy of the care navigator intervention.

Results: We enrolled 309 TKA recipients, average age 67 years; 60% female, 84% Kellgren-Lawrence Grade 4, 50% obese (BMI>=30kg/m^2). Mean pre-operative WOMAC function score was 40 (18), on a 0–100 scale, 100-worst. Baseline characteristics did not differ between study arms. At 6 months, participants in care navigation arm improved by 29.4 (16.1) points compared to 26.1 (18.3) in control arm (p=0.1126). Overall, 21% of study participants did not achieve satisfactory functional improvements, with similar rates across arms. Greater pain catastrophizing led to less improvement overall and its association with poor outcome was more prominent among females compared to males (p value for interaction = 0.002). Further analysis, restricted to females, showed that greater pain catastrophizing modified the impact of the intervention: females with a low degree of pain catastrophizing improved by 8 points more (33 vs. 25) in the navigation arm than in the control arm, while females with a high degree of pain catastrophizing improved by five points less in the navigation arm than in the control arm (p-value for interaction= 0.0233).

Conclusion: The results of this RCT did not show benefits of the MI based enhanced postoperative care navigation in functional improvements in TKA recipients. The negative overall result could be explained by differential effect of intervention among females with high and low levels of pain catastrophizing. Greater focus on understanding the determinants of and effective therapies for reducing pain catastrophizing could improve the efficacy of interventions focused on better functional outcomes in TKA recipients.

Randomised Comparison of the Effectiveness of a Non-Pharmacological Multidisciplinary Face-to-Face Group-Based Treatment Program Vs. a Telephone-Delivered Treatment Program on Daily Function in Patients with Generalized Osteoarthritis. Nienke Cuperus[1], Thomas Hoogeboom[2], Clarinda Kersten[1], Leonie Rietveld[1], Alfons den Broeder[1], Thea Vliet Vlieland[3] and Cornelia H.M. van den Ende[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]CAPHRI school for public health and primary care, CCTR centre for Care Technology Research, Maastricht University, Maastricht, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Generalized osteoarthritis (GOA) is a widely accepted and prevalent OA phenotype characterized by the involvement of multiple joints. However, current research and clinical practice mostly examine OA populations for a specific OA localization. The effectiveness of non-pharmacological interventions for GOA is therefore largely unknown. In addition, there is no evidence concerning the optimal mode of care delivery. Therefore, we compared the effectiveness of a non-pharmacological multidisciplinary face-to-face group-based treatment program versus a telephone-delivered treatment program on daily function for patients with GOA, until one year after treatment.

Methods: In this single blind randomized clinical superiority trial, individuals clinically diagnosed with GOA were randomly allocated to either a six week multidisciplinary face-to-face group-based treatment program or a six week telephone-delivered treatment program. Both programs aimed to improve daily function and to enhance self-efficacy to control the disease. The programs had comparable content but critically differed in mode of delivery and intensity. Primary (daily functioning; HAQ-DI) and secondary outcome measures were assessed at baseline, 6, 26 and 52 weeks. The 6-week time point was used to assess the short-term effects of both interventions. The average score obtained from the 6, 26 and 52 time points was used to assess the long-term effects. Directly after finishing the treatment patient satisfaction was measured. Multiple imputation was used to estimate missing values. Differences in effectiveness between both treatment programs were analysed using linear regressions adjusted for baseline, sex and age.

Results: Of 158 randomized patients (mean (SD) age 60 (8); female 85%), 147 (93%) completed at least the baseline measurement and were included in the intention to treat analysis. Of these patients, 75 were allocated to the face-to-face treatment program and 72 to the telephone-delivered treatment program. No difference in effectiveness between both treatment groups was found on the HAQ-DI at both the short (p = 0.59) and long-term (p = 0.65). Moreover, no differences in effectiveness between the two modes of care delivery on the secondary outcomes were found (p > 0.05). Patient satisfaction was significantly higher in the face-to-face treatment program than in the telephone-delivered treatment program.

Conclusion: In this trial we found no differences in effectiveness between two modes of delivery of non-pharmacological care for patients with GOA. Therefore, our results imply that the choice of mode of treatment delivery i.e. face-to-face versus telephone-delivered could be based on patients' preferences and/or costs.

Changes in Knee Kinematics from a 6-Week Hip and Trunk Strengthening Program for Persons with Patellofemoral Osteoarthritis. Lisa Hoglund[1], Laura Pontiggia[1], John Kelly IV[2], Mark Arnott[1], Olumide Babalola[1], Andrew Gushen[1] and James Carey[2]. [1]University of the Sciences, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Patellofemoral (PF) osteoarthritis (OA) is prevalent in middle-aged adults. Aberrant lower extremity (LE) biomechanics is one etiology of knee OA. Reduced peak knee flexion angles and increased peak tibial abduction angles were reported during sit-to-stand (STS) in persons with general knee OA and with PF OA, respectively. Additionally, reduced strength of the hip abductor, hip extensor, and knee extensor muscles was reported in PF OA, which may impact LE biomechanics. Studies have reported improved knee and hip biomechanics in persons with PF pain when treated with proximal LE strengthening. It is unknown if a proximal LE strengthening program with pelvic/abdominal stabilization training will alter LE kinematics, improve symptoms, and improve function in persons with PF OA. This study examined the impact of a 6-week hip and trunk muscle strengthening and stabilization program on knee and hip kinematics during STS and a step-down (StDn) task and self-reported symptoms and function in persons with PF OA.

Methods: Six female subjects with PF OA and anterior knee pain, median age (interquartile range [IQR]): 52 years (48–56 years) participated in the study. Subjects attended a biomechanical evaluation, 10 supervised exercise treatment sessions, and a reevaluation. Biomechanics of the most painful LE were examined during STS from a stool and StDn on a 3-step staircase. Subjects were treated with hip and abdominal/trunk strengthening exercises. In addition, subjects were instructed in proper LE position and pelvic stability. Outcome measures included triplanar knee and hip joint peak angles and the Knee Injury and Osteoarthritis Outcome Score (KOOS). Data analysis included group medians (IQR) and Wilcoxon Signed Rank tests.

Results: Peak knee flexion angle during STS increased: Initial: 76° (67, 86), Final: 93° (87, 97), p=.03. Peak knee extension angle during STS decreased: Initial: 2° (0.4, 9), Final: −7° (−11, −4), p=.03. Peak knee extension angle during StDn decreased: Initial: −0.2° (−5, 0.5), Final: −11° (−16, −6), p=.03. KOOS-Symptoms score improved: Initial: 62 (54, 68), Final: 75 (68, 89), p=.03. KOOS-Function score improved: Initial: 69 (47, 76), Final: 84 (79, 85), p=.03.

Conclusion: A hip and trunk strengthening program with education in proper LE alignment and pelvic stability resulted in increased knee flexion angles and reduced knee extension angles during two tasks that increase PF joint stress. In addition, subjects reported significant improvement in symptoms and function. The intervention may have improved subjects' ability to tolerate loading the PF compartment in activities requiring knee flexion. This may be one method to improve symptoms and function in persons with PF OA.

Satisfaction Following Total Knee Replacement: Journey or Destination? Jeffrey N. Katz[1], Yan Dong[1], Jamie E. Collins[1], John Wright[1], David Dalury[2], Kirk Kindsfater[3] and Elena Losina[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Townson Orthopedics, Maryland, Baltimore, MD, [3]Orthopedic Center for the Rockies, Ft. Collins, CO.

Background/Purpose: Total knee replacement (TKR) outcome is often assessed with measures of pain and function (fxn), but there is no consensus on whether surgery should be evaluated as extent of improvement on these scores ("journey") or final score ("destination"). We addressed this question

by evaluating whether improvement (journey) or final score (destination) is more closely associated with patient satisfaction with TKR.

Methods: We analyzed data from a prospective, multicenter cohort undergoing TKR. Subjects completed the WOMAC Pain and Fxn scales (0–100, 100 worst) preoperatively and 6 months postoperatively. At 6 months patients also completed a question on satisfaction with results of TKR. We defined the journey criterion as improvement by the minimal clinically important difference following TKR, ≥23 points on the WOMAC Pain or ≥19 on WOMAC Fxn Scale (Escobar et al). The destination criterion was the Patient Acceptable Symptom State following TKR, <31 on WOMAC Fxn (Tubach et al). We calculated the number of subjects who achieved the journey criterion, the destination criterion, both or neither. In each group, we calculated the proportion who reported being dissatisfied, somewhat satisfied and very satisfied with surgery. We used ordinal logistic regression to examine independent effects of achieving journey or of achieving destination criteria on satisfaction with TKR.

Results: 329 subjects were included, mean age 66, 57% female. Mean preoperative WOMAC Pain and Fxn scores were 40 (sd 18) and 42 (sd 17) respectively. 238 subjects (72%) met both journey and destination criteria for success while 10 (3%) met neither criterion. 63 subjects (19%) achieved the destination criterion but not journey, while 18 patients (5%) achieved the journey criterion but not destination. Among subjects who achieved the destination but not the journey criteria, 59% were very satisfied and only 6% were dissatisfied (Figure). Among those who achieved the journey but not the destination criteria, 44% were very satisfied and 33% were dissatisfied. In ordinal logistic regression models that adjusted for age, sex and baseline WOMAC Fxn, achieving the destination criterion had a stronger association with satisfaction (OR 7.7, 95% CI 3.2, 18) than the journey (OR 2.2, 95% CI 1.0, 4.7). This finding was essentially unchanged when we excluded the 30 subjects with preoperative WOMAC Fxn scores < 19, who were not eligible to achieve the journey criterion.

Conclusion: Improvement in outcome score (journey) and final score (destination) are distinct metrics for assessing results of surgery. In this TKR cohort, both metrics were associated with patient satisfaction with the results of TKR, with destination having a stronger association than journey. These data suggest that both journey and destination criteria should be integrated into patient-centered assessment of TKR.

ACR Concurrent Abstract Session
Antiphospholipid Syndrome
Tuesday, November 18, 2014, 4:30 PM–6:00 PM

2863

IgG Antiphospholipid Antibodies Enhance Stroke Damage: An in Vivo Ischemia/Reperfusion Study. Charis Pericleous[1], Valerie Taylor[2], Lauren Bourke[3], Daniel Stuckey[2], Jed Wingrove[4], Mark Lythgoe[2], Silvia S. Pierangeli[5], Anisur Rahman[4], Ian Giles[1] and Yiannis Ioannou[6]. [1]Centre for Rheumatology, University College London, London, United Kingdom, [2]Centre for Advanced Biomedical Imaging (CABI), University College London, London, United Kingdom, [3]Centre for Rheumatology Research, University College London, London, United Kingdom, [4]University College London, London, United Kingdom, [5]University of Texas Medical Branch, Galveston, TX, [6]Centre for Rheumatology Research, University College Hospital London, London, United Kingdom.

Background/Purpose: Circulating pathogenic antiphospholipid antibodies (aPL) are the hallmark of antiphospholipid syndrome (APS) and a major risk factor for ischemic stroke, with up to one third of stroke cases in patients under 50 years of age due to APS. Additionally, stroke is the most common recurrent thrombotic manifestation in APS. While aPL are convincingly prothrombotic in both venous and arterial *in vivo* vessel thrombosis models, their effect upon stroke size post ischemia remains unexplored. We therefore employed an established rat model of ischemic / reperfusion (I/R) stroke injury utilizing transient endovascular filament middle cerebral artery (MCA) occlusion to assess the pathogenicity of APS-derived IgG.

Methods: Polyclonal IgG was purified from sera of two female patients with APS (triple positive for lupus anticoagulant, IgG anti-cardiolipin (aCL) and anti-beta-2-glycoprotein I (aβ_2GPI)) and four female healthy controls (HC). Two pooled IgG populations, APS-IgG and HC-IgG, were prepared at a final concentration of 1mg/ml and confirmed to be endotoxin-free (<0.1EU/mg).

Male Sprague-Dawley rats (200–215g) were injected once intravenously with 1mg APS-IgG or HC-IgG (5 rats per group). After 15min, a filament inserted through the common carotid artery was positioned so as to occlude the right MCA for 30min. The filament was then removed to allow reperfusion. After 24hr reperfusion, rats were sacrificed and histology was performed to determine brain infarct size, quantified by analyzing digital images scanned from 1mm brain slices stained with triphenyl tetrazolium chloride (TTC) which identifies metabolically active tissue. A small portion of the brain was kept for analysis of intracellular pathways by Western blot. Blood was collected prior to occlusion and at sacrifice. Researchers administering the IgG and performing TTC analysis were blinded to the groups.

Results: APS-IgG induced significantly larger infarcts compared to HC-IgG (mean infarct area as a percentage of total brain area ± SD: APS-IgG 32.2±4.6% versus HC-IgG 14.3±4.5%, $p<0.01$).

Reduced phosphorylation of the pro-survival kinase Akt was seen in brain tissue lysates of rats injected with APS-IgG compared to HC-IgG (ratio of phosphorylated : total Akt protein ± SD: APS-IgG 0.4±0.2 versus HC-IgG 0.9±0.2, $p=0.03$). Interestingly, there was a strong negative correlation between infarct size and the level of Akt activation ($r=-0.9$, $p<0.01$). Brain tissue lysates showed no difference in phosphorylation of ERK, JNK or p38-MAPK between APS-IgG and HC-IgG groups. Human IgG aCL/aβ_2GPI activity was present in the sera of rats treated with APS-IgG at sacrifice; human IgG was detected in brain tissue lysates from animals treated with APS-IgG and HC-IgG with no difference between the groups.

Conclusion: This study is the first to directly demonstrate the ability of APS-IgG to exacerbate stroke severity post I/R injury, causing larger infarcts compared to rats treated with HC-IgG. Furthermore, this finding correlated with inhibition of the pro-survival kinase Akt and warrants further validation studies to confirm Akt dependency and dissect mechanisms through which this inhibition may occur.

Markers of Thrombotic Events in Autoimmune Diseases:Comparison of Antiphospholipid Score (aPL-S) and Global Anti-Phospholipid Syndrome Score (GAPSS). Kenji Oku, Olga Amengual, Ryo Hisada, Kazumasa Oomura, Ikuma Nakagawa, Toshiyuki Watanabe, Toshiyuki Bohgaki, Tetsuya Horita, Shinsuke Yasuda and Tatsuya Atsumi. Hokkaido University Graduate School of Medicine, Sapporo, Japan.

Background/Purpose: Recently, new scoring systems to quantify the probability for the diagnosis of antiphospholipid syndrome (APS) have been proposed in sequence: the Antiphospholipid Score(aPL-S) and the Global Antiphoshpholipid Syndrome Score (GAPSS). They are derived from the combinations of independent risks for thrombosis particularly focused on antiphospholipid antibodies profiles(aPL-S) or centered on the existence of each antiphospholipid antibodies taking into account with conventional cardiovascular disease risks (GAPSS). These scores, as well as tools for diagnosis, function as index for predicting future thrombosis in autoimmune diseases.

Methods: This study comprised 411 patients with autoimmune diseases who visited Hokkaido University Hospital Rheumatology Clinic between 2002 and 2003. Demographic, clinical data and cardiovascular risk factors were obtained from the medical charts. Lupus Anticoagulant (LAC) assays and IgG/M anticardiolipin antibodies, IgG/M anti-β_2-glycoprotein I antibodies and IgG/M phosphatidylserine dependent antiprothrombin antibodies were performed in all subjects. Among all the patients, 257 (62.5%) patients with follow-up period of more than 5 years (median follow-up periods: 126(IQR 92.5,133) months) were eligible. The disease profile of these patients was as follows; 17(7%) primary APS, 25(10%) APS with systemic lupus erythematosus(SLE), 84(33%) SLE (without APS), 45(18%) rheumatoid arthritis and 85 patients with other autoimmune diseases.

To evaluate the diagnostic powers for GAPSS and aPL-S, area under the curve (AUC) of receiver operating characteristic (ROC) curves were calculated. To evaluate the powers of the two scores for thrombosis prediction, Cox proportional hazard regression analyses were performed separately for each score with the cut off derived om the ROC curve. Each risk factor for the multivariate Cox analyses were assessed through separate univariate Cox regression test. To evaluate and compare the predictive powers of the two scores, Somer's d coefficient was calculated.

Results: Thirty-seven patients newly developed thrombosis during the observation period; 23 arterial thrombosis and 23 venous thrombosis. The ROC curve of GAPSS showed higher AUC than that of aPL-S (0.693 vs 0.656, respectively, $p<0.05$) indicating that GAPSS has better ability of diagnosing APS (GAPSS vs aPL-s: 0.693 vs 0.656, $p<0.05$).The cut off values of GAPSS and aPL-S for predicting future thrombosis were 10 and 31, respectively. The Cox multivariate proportional hazard regression analyses revealed that both scores, with appropriate cut off levels, accurately reflected the risks of the future thrombosis with statistic significance(GAPSS$>$10 $p=0.01$, aPL-S$>$31 $p<0.0001$). The aPL-S showed higher Somer's coefficient than GAPSS (0.497 vs 0.412, respectively, $p<0.05$).

Conclusion: The aPL-S and GAPSS accurately reflected the diagnosis of APS and the risk for future thrombotic events in patients with autoimmune diseases in our cohort. GAPSS may have relatively high potential for APS diagnosis and aPL-S might be superior to GAPSS in predicting future thrombosis.

The Cellular Effects of ANTI-Factor Xa Antibodies Isolated from Patients with Antiphospholipid Syndrome ARE Inhibited By Factorxa Inhibitors, Hydroxychloroquine and Fluvastatin. Bahar Artim-Esen[1], Natalia Smoktunowicz[2], Vera M. Ripoll[3], Charis Pericleous[3], Rachel Chambers[2], Ian Mackie[4], David Isenberg[5], Anisur Rahman[6], Yiannis Ioannou[5] and Ian Giles[3]. [1]Rheumatology Division, Department of Internal Medicine, Istanbul Faculty of Medicine,Istanbul University, Istanbul, Turkey, [2]Respiratory Research Unit, University College London, London, United Kingdom, [3]Centre for Rheumatology, University College London, London, United Kingdom, [4]Haemostasis Research Unit, University College London, London, United Kingdom, [5]Centre for Rheumatology Research, University College Hospital London, London, United Kingdom, [6]University College London, London, United Kingdom.

Background/Purpose: Recently we showed that FXa reactive IgG in patients with the antiphospholipid syndrome (APS) displayed higher avidity binding to FXa and had greater functional effects upon the coagulant functions of FXa compared to patients with anti-FXa IgG isolated from patients with systemic lupus erythematosus (SLE) without APS. FXa signalling has been observed in many cell types via activation of protease-activated receptors (PAR) which stimulate an increase in intracellular calcium (Ca^{2+}) levels. Given that cellular responses elicited through activation of PARs are important in influencing pathways responsible for inflammation, tissue repair and haemostasis, FXa-reactive IgG may be important in the pathogenesis of SLE and APS. Therefore, we characterised the interaction between FXa and human umbilical vein endothelial cells (HUVEC) and the cellular effects of anti-FXa IgG isolated from patients with APS and SLE without APS.

Methods: IgG was purified from patients with APS (n=14) and SLE/no APS (n=14) who had medium or high serum levels of anti-FXa IgG and healthy controls (HC) (n=8). The effect of IgGs on FXa-mediated intracellular calcium release was measured using the fluorescent image plate reader (FLIPR). HUVECs were seeded in 96-well plates, for 48 hours until confluent and then incubated with Fluo-4AM calcium binding dye for one hour. Alterations in intracellular calcium release were monitored for 10 minutes following stimulation with α-Thrombin (Thr) or FXa +/− IgGs. PAR inhibitors, agonist peptides (AP), hydroxychloroquine (HCQ), fluvastatin and desensitisation experiments were also performed to characterise responses.

Results: We observed a dose-dependent induction of Ca^{2+} transients by FXa in HUVEC. FXa was a weaker agonist than Thr but the kinetics of response was different with a longer lag-time and duration. APS IgG significantly potentiated the FXa-induced Ca^{2+} release compared to SLE/no APS IgG ($p=0.04$), HC IgG ($p<0.05$) and FXa alone ($p<0.05$). FXa-mediated Ca^{2+} release was significantly reduced by PAR-1 inhibitors. When PAR-1 receptors were desensitised by Thr (10 nM) and cells were stimulated by PAR-2 AP, PAR-2 response was reduced by 47.5%. When Thr-desensitised cells were stimulated by FXa, response was reduced by 66% and residual response was not inhibited by PAR-1 or completely by 2 inhibitors. When cells were treated with: Antistasin, a specific FXa inhibitor; Hydroxychloroquine; or fluvastatin - FXa induced and IgG potentiated intracellular Ca^{2+} release was significantly reduced.

Conclusion: We confirmed FXa stimulation of HUVEC to be mediated mainly via PAR1 and 2 dependent signalling mechanisms that may be acting as a unit and this effect was enhanced by FXa-reactive APS-IgG. These effects were blocked by a FXa inhibitor which raises the exciting prospect that anti-FXa IgG positivity may be used as a novel biomarker to predict response to treatment with FXa inhibitors in patients with APS. Despite the need for the specificity to be investigated further, results also suggest that HCQ and fluvastatin may be beneficial in patients with APS.

2866

External Validation of the Global Anti-Phospholipid Syndrome Score in Comparison to IgG Antibodies Directed Against Domain I of β_2-Glycoprotein I. a Prospective Multicentre Cohort Study. Stephane Zuily[1], Bas De Laat[2], Veronique Regnault[3], Pierre Kaminsky[4], Hilde Kelchtermans[5], Zakera Shums[6], Roger Albesa[6], Gary L Norman[6], Philip de Groot[7], Anne-Christine Rat[8], Jacques Ninet[9], Nadine Magy-Bertrand[10], Jean-Louis Pasquali[11], Marc Lambert[12], Bernard Lorcerie[13], Thomas Lecompte[14], Francis Guillemin[15] and Denis Wahl[16]. Background/Purpose: Our objectives were 1- to perform an external validation of the Global Anti-Phospholipid Syndrome Score (GAPSS) and 2- to compare prognostic significances of GAPPS and a novel assays IgG antibodies directed against domain I of β_2-glycoprotein I (antiDI) in patients with antiphospholipid antibodies (aPL) and/or systemic lupus erythematosus (SLE).

Methods: We performed a prospective cohort study in French University Hospitals. Consecutive patients with aPL and/or SLE according to ACR classification without ongoing anticoagulant treatment were enrolled. The outcome was the time to the first incident thrombotic event. Blood was drawn at baseline. ELISA antiDI and anti-phosphatidyl/prothrombin antibodies assays were performed together with traditional assays (lupus anticoagulant,

anticardiolipin and anti-β_2-glycoprotein I antibodies). GAPSS was computed for each patient.

Results: One hundred and thirty eight patients (median age 43.5±15.3 years; 108 women) were followed-up for a mean duration of 43±20.7 months (493.9 patient-years). Thrombosis during follow-up occurred in 16 patients (3 strokes, 1 myocardial infarction, 1 splanchnic arterial thrombosis, 3 pulmonary embolisms, 3 deep vein, 5 small vessels thromboses). Higher values of GAPSS were seen in patients who experienced thrombosis compared to those without (10.9±4.8 vs 7.9±5.4, p=0.03). While triple positivity (HR=2.38 [CI95%; 0.83–6.80], p=0.11) and GAPSS above 10 (HR=1.56 [CI95%; 0.55–4.47], p=0.41) were not predictive of further incident thrombotic events, GAPSS above 16 (HR=5.27 [CI95%; 1.16–23.93], p=0.03) and high levels of antiDI above the 90th percentile of patients (HR=5.64 [CI95%; 1.94–16.42], p=0.002) were highly predictive of incident thrombotic events.

Conclusion: GAPSS and high levels of antiDI are significant predictors of thrombosis in aPL/SLE patients. These antibodies seem to add a substantial improvement in risk prediction of thrombosis independently of clinical variables assessed by GAPSS' components.

Antiphospholipid Antibodies Promote the Release of Neutrophil Extracellular Traps: a New Mechanism of Thrombosis in the Antiphospholipid Syndrome. Srilakshmi Yalavarthi[1], Levi F. Mazza[1], Alexandra E. Morris[1], Carlos Núñez-Álvarez[2], Diego Hernández[2], Paula L. Bockenstedt[1], Antonio R. Cabral[2] and Jason S. Knight[1]. [1]University of Michigan, Ann Arbor, MI, [2]Instituto Nacional de Ciencias Medicas y Nutricion, Mexico City, Mexico.

Background/Purpose: Antiphospholipid antibodies (aPL), especially those targeting beta-2-glycoprotein I, are known to activate endothelial cells, monocytes, and platelets, with prothrombotic implications. However, the interaction of aPL with the most abundant leukocyte in human blood, the neutrophil, has only rarely been considered. Neutrophil extracellular trap (NET) release—a form of neutrophil cell death that results in the externalization of decondensed chromatin decorated with granular proteins—has recently been recognized as an important activator of the coagulation cascade, as well as an integral component of deep vein thrombi in both humans and animals. Here, we hypothesized that aPL activate neutrophils to release NETs, thereby predisposing to thrombosis.

Methods: Neutrophils, sera, and plasma were prepared from patients meeting criteria for primary antiphospholipid syndrome (APS) by the revised Sapporo classification criteria (n=50), or from healthy volunteers. Circulating NETs were quantified in sera and plasma by a myeloperoxidase-DNA sandwich ELISA. Neutrophils from APS patients were scored for their ability to release NETs by both immunofluorescence microscopy and fluorescence-based quantification of extracellular DNA. Neutrophils from healthy volunteers were stimulated with APS patient sera, purified IgG, or aPL monoclonal antibodies, and NET release was quantified; dependence on generation of reactive oxygen species was also determined. Expression of known aPL receptors, beta-2-glycoprotein and annexin A2, was measured on the neutrophil surface.

Results: Sera and plasma from APS patients have elevated levels of NETs as compared to healthy volunteers (2.7-fold increase when comparing means; p=0.0279). Neutrophils isolated from patients with primary APS are predisposed to spontaneous NET release when compared to healthy volunteers (p=0.0143). Importantly, APS-patient sera and IgG purified from patients with aPL, stimulate NET release from healthy-volunteer neutrophils (p=0.004 and 0.0187, respectively). Human aPL monoclonal antibodies, especially those that target beta-2 glycoprotein I, also enhance NET release; this enhancement can be abrogated by blockade of reactive oxygen species formation. At baseline, both APS-patient neutrophils and healthy-volunteer neutrophils display beta-2 glycoprotein I on their surface.

Conclusion: APS patients have more circulating NETs than healthy volunteers, even between thrombotic episodes. APS-patient neutrophils are predisposed to NET release, probably through exposure to aPL, since aPL can trigger NET release from healthy volunteer neutrophils *in vitro*. Future experiments will explore the role of annexin-A2/Toll-like-receptor-4 pathways in aPL-mediated NET release, while also assessing the thrombotic implications of APS NETs. Neutrophil netting warrants further investigation as a novel therapeutic target in APS patients.

Antiphospholipid Syndrome Alliance for Clinical Trials and International Networking (APS ACTION) Clinical Database and Repository Initial Analysis. Doruk Erkan[1], Danieli Andrade[2], Maria Tektonidou[3], Amaia Ugarte[4], Alessandra Banzato[5], Angela Tincani[6], Pier-Luigi Meroni[7], Ricard Cervera[8], Paul R. Fortin[9], Roger A. Levy[10] and On Behalf of APS Action[11]. [1]Hospital for Special Surgery, New York, NY, [2]University of São Paulo, São Paulo, Brazil, [3]First Department of Internal Medicine, Laikon Hospital, Athens University Medical School, Athens, Greece, [4]Hospital Universitario Cruces, Bizkaia, Spain, [5]Department of Cardiac Thoracic and Vascular Sciences, University of Padua, Padua, Italy, [6]Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia, Italy, [7]University of Milan, Milano, Italy, [8]Hospital Clinic, Barcelona, Spain, [9]Laval University, Division of Rheumatology, Centre de Recherche du CHU de Québec and Department of Medicine, Quebec City, QC, [10]Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [11]APS ACTION, New York, NY.

Background/Purpose: APS ACTION International Clinical Database and Repository ("Registry") was created to study the natural course of disease over 10 years in persistently aPL-positive patients with/without other systemic autoimmune diseases. The objective of this preliminary analysis is to report the baseline characteristics of currently enrolled patients.

Methods: A secure web-based data capture system is used to store patient information including demographics, aPL/APS history, and aPL data. The inclusion criteria are positive lupus anticoagulant (LA) test based on the ISTH recommendations, medium-to-high titer (> 40U and/or > 99th percentile) anticardiolipin antibody (aCL) IgG/M/A, and/or medium-to-high titer anti-β_2Glycoprotein-I (aβ_2GPI) IgG/M/A tested at least twice within one year prior to enrollment. Clinical and blood collection (for core laboratory aPL confirmation and mechanistic studies) are performed once a year, or when patients develop new events. We used chi-square or Fisher's exact test for group comparisons, and linear-by-linear association test to analyze for trend.

Results: As of June 2014, 408 patients have been recruited from 17 centers globally (mean age at entry: 43.7±12.8y; female: 310 [76%]; white: 261 [69%]; and other systemic autoimmune diseases: 130 [32%]). Table shows the distribution of the aPL-related events (historically and/or at registry entry) as well as the association between the aPL-related events and the aPL profile (triple, double, or single positivity based on inclusion tests). The results did not change when the single aPL group was restricted to LA-positive patients only (data not shown). The percentages of patients tested for LA, aCL, and aβ_2GPI were 93%, 100%, and 76%, respectively in the double aPL-positive group; and 97%, 99%, and 77% in the single aPL-positive group. The percentages of the patients with positive LA, aCL, and aβ_2GPI were 65%, 89%, and 39%, respectively in the double aPL-positive group; and 72%, 23%, and 5% in the single aPL-positive group.

aPL-related Events (# of Patients)	Triple aPL	Double aPL	Single aPL	p-value*
N: 403 (5 excluded-pending aPL entry)	135 (34%)	123 (30%)	145 (36%)	
aPL, No Criteria Met (n:85)	30 (35%)	28 (33%)	27 (32%)	0.88
Thrombotic APS (n:221)	76 (34%)	64 (29%)	81 (37%)	0.21
Obstetric APS only (n:40)	12 (30%)	13 (33%)	15 (38%)	0.77
Thrombotic & Obstetric APS (n:57)	17 (30%)	18 (32%)	22 (39%)	0.57
Venous Thrombosis (n:169)	59 (35%)	44 (26%)	66 (39%)	0.34
Arterial Thrombosis (n:143)	47 (33%)	47 (33%)	49 (34%)	0.29
Catastrophic APS (n:3)	3 (100%)	0 (0%)	0 (0%)	*0.044*
Microthrombosis without CAPS (n:23)	9 (39%)	9 (39%)	5 (22%)	0.23
Fetal Loss (n:76)	25 (33%)	22 (29%)	29 (38%)	0.60
Premature Birth (EC/PEC/PI) (n:42)	13 (31%)	13 (31%)	16 (38%)	0.95
3 Consecutive Embryonic Losses (n:17)	4 (24%)	7 (41%)	6 (35%)	0.72
Livedo reticularis/racemosa (n:59)	19 (32%)	13 (22%)	27 (46%)	0.16
Persistent Thrombocytopenia[1] (n:73)	24 (33%)	28 (38%)	21 (29%)	0.22

Autoimmune Hemolytic Anemia (n:23)	9 (39%)	8 (35%)	6 (26%)	0.31
Cardiac Valve Disease[2] (n: 34)	18 (53%)	10 (29%)	6 (18%)	*0.02*
aPL-associated Nephropathy[2] (n:11)	2 (18%)	7 (64%)	2 (18%)	0.053
Skin Ulcers (n:21)	5 (24%)	8 (38%)	8 (38%)	0.58
Cognitive Dysfunction[3] (n: 10)	3 (30%)	4 (40%)	3 (30%)	0.27
MRI White Matter Changes (n:57)	18 (32%)	16 (28%)	23 (40%)	0.22

PEC: preeclampsia; EC: eclampsia; PI: placental insufficiency; (1) <100,000/mcL twice at least 12w apart; (2) Based on APS Classification Criteria Definitions; (3) neuropsychological test proven. * similar results with linear-by-linear association test for p-value trend.

Conclusion: Our preliminary analysis suggests that: a) there is no association between the aPL-related events and aPL profile (triple, double, or single positivity), except for Catastrophic APS and cardiac valve disease, based on a small number of patients; and b) LA positivity is the most important determinant of event risk in aPL-positive patients. Further analysis of the APS ACTION registry, i.e., detailed aCL/aβ_2GPI titers, potential confounders, and core laboratory aPL profile, will clarify if triple, double, and single aPL profiles are associated with different risk profiles.

TLR7 Influences Autoreactive B Cell Selection in the Germinal Center. Weiqing Huang[1], Megan Woods[1], Alexis Boneparth[2], Ramalingam Bethunaickan[1], Ranjit Sahu[1] and Anne Davidson[1]. [1]Feinstein Institute for Medical Research, Manhasset, NY, [2]Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ.

Background/Purpose: TLR7 is required for the generation of anti-RNA antibodies and excess TLR7 confers a SLE-like phenotype in mice. Recent studies have shown that TLR7 expression in B cells is sufficient for this phenotype and that TLR7 excess enhances germinal center (GC) maturation. The goal of this study was to determine how TLR7 influences the GC derived autoreactive B cell repertoire.

Methods: TLR7 deficiency was crossed into NZW mice for 13 generations. The 3H9 IgVH transgene that confers anti-DNA and anti-cardiolipin specificity was introduced into NZW/BXSB.Yaa and NZW.TLR7+/−/BXSB.Yaa lupus prone mice. The Yaa locus confers an extra copy of TLR7 in males and an accelerated lupus phenotype and NZW.TLR7+/−/BXSB.Yaa mice retain the Yaa locus but carry only one copy of TLR7. To create a physiologic setting in which autoreactive B cells compete for survival with non-autoreactive B cells, we generated 50% 3H9/50% wild type bone marrow chimeras in which transferred male 3H9. TLR7+/+ or TLR7+/−cells are GFP+ and can be easily identified. Mice were followed clinically and sacrificed at the onset of fixed proteinuria. Spleen cells were phenotyped and GC B cells were analyzed by single cell PCR for the repertoire of Vk light chains associated with the 3H9 heavy chain. Full length Vk5–43 encoded light chains were resequenced and their mutation frequency analyzed.

Results: Disease onset occurred with the same kinetics in TLR7+/+ and TLR7+/− chimeras and spleens from both sets of chimeras were phenotypically indistinguishable. We have previously shown a preferential selection of Vk5–43 and Vk5–48 light chains into the GCs of 3H9 SLE prone mice; these light chains confer anti-chromatin activity in their germline configuration whereas anti-DNA and anti-cardiolipin activity is acquired as a result of somatic mutations. We found that Vk5–48/Jk4 encoded light chains that have a high affinity for chromatin were preferentially selected into the GCs when 3H9 TLR7+/+ cells were transferred together with their non-3H9 counterparts but were found rarely when 3H9 TLR7+/− cells were transferred. By contrast, Vk5–43 encoded light chains were selected into the GCs in both TLR7+/+ and TLR7+/− chimeras. We therefore examined the frequency of somatic mutations in these light chains. The frequency of somatic mutations was significantly less in Vk5–43 light chains from 3H9+ GC cells from TLR7+/− chimeras than in 3H9+ GC cells from TLR7+/+ chimeras. Finally 3H9+ B cells were significantly more expanded in the GCs of TLR7+/+ than TLR7+/− chimeras.

Conclusion: We have demonstrated that TLR7 influences selection of autoreactive B cells into the GC, as well as their expansion and the frequency of somatic mutations. Our results suggest that TLR7 influences proliferation in the dark zone of the GC since this is linked to mutation frequency. These effects of TLR7 are independent of other genes in the Yaa locus.

B Cell-Intrinsic Deletion of the Type 1 Interferon Receptor Does Not Impact the Development of Murine Lupus. Shaun W. Jackson, Nicole Scharping, Socheath Khim and David Rawlings. Seattle Children's Research Institute, Seattle, WA.

Background/Purpose: Type 1 interferon (IFN) is strongly implicated in lupus pathogenesis, and patients with SLE frequently express a "type 1 IFN gene signature". Type 1 IFN promotes B cell activation *in vitro* suggesting a direct role for type 1 IFN in humoral autoimmunity. However, it is unclear whether type 1 IFN impacts lupus pathogenesis via B cell-intrinsic or –extrinsic mechanisms. We previously described the Wiskott Aldrich syndrome (WAS) model of B cell-driven autoimmunity (Becker-Herman et al., *JEM* 2011, Jackson et al. *J Immunol* 2014). An important advantage of the WAS chimera model is that dysregulated immune responses are limited to the B cell compartment, allowing genetic manipulation in a B cell-intrinsic fashion. In the current study, we describe the impact of B cell-intrinsic deletion of the type 1 interferon receptor (*ifnar*) in the WAS chimera model.

Methods: Proliferation of wild-type (WT), *was*−/−, *ifnar*−/− and double-deficient *was*−/−.*ifnar*−/− marginal zone B cells was quantified after stimulation with LPS (TLR4 agonist), R848 (TLR7 agonist) and CPG (TLR9 agonist) +/− IFN-β. To test the impact of B cell-intrinsic type 1 IFN activation in lupus pathogenesis *in vivo* we established bone marrow chimeras in which B cells were WT, *was*−/−, or *was*−/−.*ifnar*−/−; hereafter be referred to as B^{WT}, $B^{WAS-/-}$, and $B^{W/IFNAR-/-}$. Chimeras were analyzed for autoantibodies, immune activation and development of immune-complex glomerulonephritis by ELISA, flow cytometry and immunohistochemistry.

Results: We previously showed that autoimmunity in the WAS chimera model is dependent on B cell-intrinsic TLR7 activation (Jackson et al. *J Immunol* 2014). *Ifnar*-deficient B cells demonstrated a specific defect in TLR7-induced proliferation, while TLR4 and TLR9 responses were unaffected. In addition, recombinant IFN-β enhanced TLR7 responses, without impacting TLR4/TLR9 activation. These data suggest a role of B cell-intrinsic type 1 IFN signals in lupus pathogenesis. To test this hypothesis, we generated chimeras with B cells double-deficient in *was* and *ifnar*. Surprisingly, although type 1 IFN promoted B cell TLR7 activation *in vitro*, autoantibodies to RNA-associated antigen sm/RNP were equivalent in $B^{WAS-/-}$ and $B^{W/IFNAR-/-}$ animals. Further, B cell-intrinsic *ifnar* deletion had no impact on immune activation manifest by: splenomegaly; CD4+ T cell expansion; and generation of T follicular helper cells and germinal center B cells. Finally, we demonstrate that B cell-intrinsic *ifnar* deletion does not impact immune-complex glomerulonephritis.

Conclusion: The importance of type 1 IFN in the pathogenesis of SLE has been well established by both human studies and murine lupus models. Type 1 IFN promote TLR7-mediated B cell activation *in vitro*, suggesting a direct role for type 1 IFN on B cells in lupus pathogenesis. Despite these *in vitro* data, we demonstrate that TLR7-dependent humoral autoimmunity can develop independently of B cell-intrinsic *ifnar* activation. To our knowledge, this is the first study to directly address the impact of B cell type 1 IFN activation in murine lupus, of relevance to both the understanding of disease pathogenesis and to efforts to target type 1 IFN therapeutically in SLE.

Break of Anergy in Human Autoreactive B Cells By T Helper Signals Restores B Cell Receptor Signaling Capacity and Is Dependent on Upregulation of CD45 Phosphatase Activity-a Possible Novel Mechanism of Breech of B Cell Tolerance in Rheumatic Diseases. Peter Szodoray[1], Stephanie M. Stanford[2], Nunzio Bottini[2] and Britt Nakken[1]. [1]Institute of immunology, Rikshospitalet, Oslo University Hospital, Oslo, Norway, [2]La Jolla Institute for Allergy and Immunology, La Jolla, CA.

Background/Purpose: We recently identified a human B cell population, which is naturally autoreactive and tolerized by functional anergy. This population was naïve, fully mature, negative for surface IgM and expressing only IgD BCR (BND cells: naïve, D-only). The BND cells have antibody variable region genes in germline configuration and a proportion of anergic cells exhibit natural reactivity to antinuclear antigens and dsDNA. Break of B cell tolerance leading to presence of autoantibodies in rheumatic diseases may cause the initiation and perpetuation of various autoimmune processes. The aim of this study was therefore to investigate if anergy in BND cells could be overcome by T cell mediated signals as has been reported in murine systems, and furthermore, study the molecular mechanisms underlying this process.

Methods: Untouched naive and BND human B cells from healthy blood donors were purified and cultured in the presence of T cell help (e.g. IL-4 and CD40L) followed by various functional assays such as Ca2+-flux, phosphoflow (pSyk, pLyn) and standard flow cytometry measurements of intracellular and surface B cell markers. Finally, CD45 phosphatase activity was measured utilizing fluorescent peptide-based assay.

Results: Stimulation mimicking T cell help broke anergy and forced BND cells to fully respond to antigenic stimulation by restoring normal signaling through the BCR. This was dependent on *de novo* protein synthesis as opposed to direct crosstalk between the BCR, IL-4 and CD40 signaling pathways. We traced the restoration of BCR signaling from downstream signaling stages such as intracellular calcium release to phosphorylation of Syk and Lyn kinase, which is located proximal to the BCR. We observed an inability of activation of Lyn in BND cells upon BCR-stimulation, while subsequent to IL-4/CD40L treatment, the activation state of Lyn was restored. Lyn kinase activity is principally regulated by CD45 phosphatase (activating) and Csk kinase (inactivating). By inhibition studies, we identified CD45 phosphatase as a key component in the process of restoration of BCR signaling by T cell mediated signals. As a next step, we therefore investigated if T helper signals regulate CD45 expression in anergic B cells. A modest upregulation of CD45 surface expression on B cells stimulated with T cell mimicking signals was observed. Since CD45 is a complex molecule with many possible isoforms exhibiting different levels of phosphatase activity, quantitation of CD45 phosphatase activity of B cells upon T cell stimulation was performed. These analyses showed enhanced CD45 phosphatase activity upon T cell help in BND cells as well as in naive B cells, pinpointing CD45 as a key regulator of BCR signaling thresholds mediated by T cell help.

Conclusion: Our findings reveal a novel connection between T cell help, increased CD45 phosphatase activity and BCR signaling in human primary anergic and naïve B cells, and further implies that anergic BND cells may represent the precursors of autoantibody secreting plasma cells in B cell driven autoimmune conditions. Our data provide new insight in the break of humoral immune tolerance with possible diagnostic and therapeutic implications in patients with systemic autoimmune and rheumatic diseases.

B-Cell Autoepitope and Tetramer Analysis Reveals Expansion of Apoptotic Autoantigen La and snRNP Reactive B Cells in BXD2 Mice. Jennie Hamilton[1], Jun Li[1], Qi Wu[1], PingAr Yang[1], Bao Luo[1], Hao Li[1], Troy Randall[1], John Edwin Bradley[1], Justin J. Taylor[2], John D. Mountz[3] and Hui-Chen Hsu[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Fred Hutchinson Cancer Research Center, Seattle, WA, [3]Birmingham VA Medical Center, Birmingham, AL.

Background/Purpose: Systemic lupus erythematous (SLE) is characterized by production of highly pathogenic IgG autoantibodies (autoAbs). While serum autoAb profiling is standard, it remains challenging to isolate authentic autoreactive B cells that give rise to these autoAbs. Similar autoAbs are spontaneously produced in lupus-prone BXD2 mice that display apoptotic cell clearance defects and heightened type I interferon (IFN) signals. The purpose of this study is to develop a comprehensive autoepitope and tetramer strategy to identify the dominant autoantigens (autoAg) and the underlying mechanisms promoting the development of autoreactive B cells in BXD2 mice.

Methods: A PEPperPRINT Autoimmunity Microarray covering 3,653 database derived, linear B-cell autoepitopes was probed with B6 and BXD2 serum to determine IgM and IgG binding reactivity. Top peptides were selected for 3D crystal structural analysis. A panel of over 50 peptide epitopes were verified by ELISA and ELISPOT. Two epitopes from RNA-binding lupus La and 70 kDa U1snRNP were used to generate B cell tetramers for characterization of Ag-specific subpopulations of B cells.

Results: The dominant epitopes recognized by BXD2 autoAbs are those commonly found in human SLE patients. Many immunodominant epitopes are located in cryptic regions of the native protein. The strongest autoAb response was observed with nuclear peptides from RNA binding proteins (RBP) including lupus La_{13-27} LEAKICHQIEYYFGD, $U1snRNP_{357-373}$ SHRSERERRRDRDRDRD, and $SmD1_{97-111}$RGRGRGRGRGRGRG. Other nuclear autoAgs include histones, centromere, and RNA polymerase III. Tetramer analysis revealed a significant expansion in La^+ and $snRNP^+$ memory B cells and marginal zone precursor (MZ-P) B cells in BXD2 vs. B6 in both the circulation and the spleen. Phenotype analysis of $tetramer^+$MZ-P B cells showed upregulation of type I IFN inducible activation molecules CD69 and CD86 in BXD2 mouse spleens.

Conclusion: The bona fide presence of RBP cryptic autoAgs that were not predicted by Ag prediction programs is consistent with the previous finding that defective clearance of apoptotic blebs in BXD2 mice leads to production of autoepitopes that break B cell tolerance. The potential activation of the TLR7 pathway by RBPs in combination with the upregulation of type I IFN response in Ag-specific MZ-P B cells further suggest that expanded $tetramer^+$ MZ-P B cells may be a result of apoptotic cell clearance defects. In light of our previous findings that MZ-P B cells are exceptional apoptotic Ag delivery $MHCII^{hi}$, $CD86^{hi}$cells and can stimulate CD4 T cells, these results suggest that specific targeting on TLR7 and type I IFNs may be important to eliminate autoAg-specific B cells.

Epratuzumab Induces Broad Inhibition of B Cell Receptor Proximal Signaling but Has Opposing Effects on Distal Signaling in B Cell Subsets: A Profile of Effects on Functional Immune Signaling By Single Cell Network Profiling. Alison Maloney[1], Drew Hotson[2], Stephen Rapecki[1], Gianluca Fossati[1], Simon Lumb[1], David Rosen[2], Santosh Putta[2], Nikil Wale[2], David Spellmeyer[2], Alessandra Cesano[2], Rachael Hawtin[2] and Anthony Shock[1]. [1]UCB Pharma, Slough, United Kingdom, [2]Nodality Inc., South San Francisco, CA.

Background/Purpose: Epratuzumab is a humanized monoclonal antibody targeting the B cell-specific protein CD22 and is in Phase 3 clinical trials in patients with systemic lupus erythematosus (SLE). Epratuzumab does not deplete B cells, rather, the mechanism of action centers on CD22 regulatory activity of B cell receptor (BCR) modulation, via inhibition of specific BCR-driven phosphorylation events (Syk, PLCγ2) and Ca^{2+} flux.[1] The aim of this study was to assess the effects of epratuzumab on receptor activation and BCR signaling across multiple B cell subsets in peripheral blood mononuclear cells (PBMC) from a large cohort of healthy donors.

Methods: Single Cell Network Profiling (SCNP) is a multiparametric, flow cytometry-based technology that enables simultaneous analysis of signaling networks in multiple immune cell subsets.[2] BCR modulated signaling (anti-IgG/anti-IgM) was profiled by SCNP in PBMC from 60 healthy donors (HD) across naïve (CD27-/IgD+), switched memory (CD27+/IgD-) and unswitched memory (CD27+/IgD+) B cell subsets. Surface receptor (CD22, CD19), proximal (Syk, Slp76, BTK, PLCγ2) and distal (Akt, Erk, S6, p38, IkBa, NFκB-p105) signaling was interrogated 5 or 15 minutes post modulation in the presence and absence of epratuzumab (10mg/ml), which had been pre-incubated with cells for 1 hour.

Results: On-target epratuzumab activity in B cells was identified as induction of $pCD22\ Tyr^{807}$, most pronounced in naïve B cells ($p<0.001$). Broad inhibition of all examined BCR-proximal signaling ($p<0.0001$) was observed in the whole B cell population with the most pronounced effects observed in the switched memory population. Strong inhibition of BCR modulated pCD19 ($p<0.001$) was also seen in this population, which may contribute to inhibition of BCR activation events. Inhibition of distal signals was demonstrated specifically in the switched memory B cell population whilst conversely, in the naïve B cell subset, evidence for activation of distal signaling ($p<0.0001$) was observed. Interestingly, weak activation of pAkt was observed in both naïve and switched memory B cells.

Conclusion: Broad analysis of functional immune signaling across B cell subsets identified epratuzumab inhibition of BCR-proximal signaling, supporting an inhibitory role in BCR activation. Opposing effects on distal

signaling were identified in the naïve and memory populations. In switched memory B cells inhibition of pCD19 and downstream signals was demonstrated. In contrast, in naïve B cells activation of distal signals was observed. These data have implications for understanding the functional consequences of epratuzumab treatment on B cell pathologic activity in patients with autoimmune diseases such as SLE.

Pro-Inflammatory FcRL4+ Memory B Cells in Joints of RA Patients: Immunoglobulin Gene Characteristics and Antigen Specificity. Khaled Amara[1], Lorraine Yeo[2], Natalie Sippl[1], Philip Titcombe[1], Andrew Filer[3], Karim Raza[3], Dagmar Scheel-Toellner[2] and Vivianne Malmström[4]. [1]Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Karolinska Institutet, SE-17176 Solna, Stockholm, Sweden., Stockholm, Sweden, [2]Rheumatology Research Group, Centre for Translational Inflammation Research, College of Medical and Dental Sciences, University of Birmingham, Birmingham B15 2TT, UK, Birmingham, United Kingdom, [3]Rheumatology Research Group, MRC Centre for Immune Regulation, School of Immunity and Infection, University of Birmingham, Birmingham, United Kingdom, [4]Rheumatology Unit, Karolinska University Hospital, Solna, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Our recent findings identified a subset of pro-inflammatory memory B cells in the RA synovium characterized by the expression of the surface protein Fc receptor like 4 (FcRL4)[1]. FcRL4+ve B cells produce RANKL, and express high levels of TNF mRNA, indicating a destructive, pro-inflammatory role for this B cell subpopulation. It is however unclear how synovial FcRL4+ve B cells develop, whether they have undergone hypermutation in germinal centers and the nature of their relationship with FcRL4-ve B cells at the same site. The aim of this project was to investigate whether autoreactive features would accumulate in the FcRL4+ve subset by investigating the antigen-specificity and Ig gene characteristics of FcRL4 +ve versus -ve B cells from both synovial tissue and fluid of RA patients.

Methods: Single FcRL4+ve and -ve memory B cells were sorted from synovial tissue (n=2) and synovial fluid (n=5) of patients with active RA. Their Ig variable region genes were sequenced and subsequently expressed to generate recombinant monoclonal antibodies. Antigen-specificities of the generated monoclonal antibodies were determined by ELISA.

Results: In total, we have cloned and sequenced B cell receptors from 332 individual B-cells (171 from FcRL4+ and 160 from FcRL4- cells). The Ig gene sequence analyses demonstrated that the Ig repertoire was highly diverse with no major differences in the *IGH* and *IGK* or *IGL* gene segment usage or *IGH*CDR3 features between FcRL4+ and FcRL4- memory B cells. From the sequenced clones we have so far generated 38 recombinant monoclonal antibodies (from both FcRL4+ve and FcRL4–ve B cells) and determined their specificity for citrullinated candidate autoantigens. We found no difference in the frequency of autoreactive Ig in the FcRL4 +ve versus -ve cells. 13 antibodies reacted to citrullinated antigens (including α-enolase, fibrinogen, and vimentin) without recognizing the unmodified arginine control peptides.

Conclusion: We conclude that the FcRL4+ve and FcRL4-ve memory B cells, while functionally and phenotypically distinct, are both post-germinal center hypermutated B cell subsets with similar Ig gene features. We have not identified a clonal relationship, but overall both B cell receptor characteristics and antigen specificities suggest that the two B cell subpopulations may originate from similar immune responses differentiating into functionally distinct subsets.

Macrophage Expression of Hypoxia-Inducible Factor-2 Alpha Promotes Rheumatoid Arthritis Progression. Munitta Muthana[1], William Jacob Hardy[1], Sarah Hawtree[1], Fiona Wright[1], Ursula Fearon[2], DJ Veale[3], Mauro Perretti[4] and Anthony G. Wilson[5]. [1]University of Sheffield, Sheffield, United Kingdom, [2]Translational Rheumatology Research Group, Dublin, Ireland, [3]St. Vincent's University Hospital, Dublin, Ireland, [4]Barts and the London School of Medicine, London, United Kingdom, [5]University College Dublin, Dublin, Ireland.

Background/Purpose: Hypoxia exists in many diseased tissues including arthritic joints, atherosclerotic plaques and malignant tumours. Macrophages accumulate in these hypoxic sites where they possess broad pro-inflammatory, destructive and remodelling potential leading to inflammation and joint destruction. Macrophages respond to hypoxia by up regulating the hypoxia inducible transcription factors– HIF-1 and −2, which leads to the up-regulation of genes involved in proliferation, angiogenesis, and glucose metabolism.

The purpose of our study was to characterise the HIF-2 expressing macrophage populations in response to joint hypoxia, and in particular to dissect out the effects of HIF-2 in a murine model of arthritis.

Methods: Arthroscopy sections from RA patients with mild (~40mmHg) or severe (~3mmHg) joint hypoxia were immunostained with anti-HIF 2 and co-localised with the pan-macrophage marker CD68 as well as other M1 and M2 macrophage markers. Cell-specific RNA was purified from CD68+ve macrophages in RA tissue by laser capture microdissection (LCM) and differential gene expression was determined using the RT^2 Profiler PCR inflammatory arrays. The significance of HIF-2 was also evaluated in the K/BxN serum transfer model in mice bearing a targeted deletion of HIF-2 in myeloid cells including macrophages (HIF2fl/fl; LysM-Cre+' mice). Arthritis was assessed clinically and histologically.

Results: In patients with severely hypoxic joints macrophages predominately expressed HIF-2 as well receptors for VEGF (Flt1), angiopoietin 'Tie2' and mannose 'CD206' markers associated with M2-skewed macrophages. However, expression of CXCL-2, −4, −5, IL-1a, IL-6 IL-8 & TNFa were also all up regulated compared to macrophages from mildly hypoxic joints. *In vivo*, macrophages lacking HIF2 significantly suppressed disease development indicating an indispensable role for HIF2 in supporting macrophages in K/BxN serum-transfer arthritis.

Conclusion: HIF-2 expressing macrophages have an M1 & M2-like phenotype in patients with severely hypoxic joints and loss of HIF-2 in macrophages suppressed arthritis in mice. Collectively, our data identify HIF-2 as an important regulator of macrophage function, suggesting it may be a useful therapeutic target for treating RA.

Interleukin-10 Receptor Blockade during Lcmv Infection Results in Macrophage Activation Syndrome-like Disease in Mice. Lehn K. Weaver[1] and Edward M. Behrens[2]. [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Childrens Hospital of Philadelphia, Philadelphia, PA.

Background/Purpose: Macrophage activation syndrome (MAS) is the rheumatic disease-associated member of a group of hyperinflammatory syndromes characterized by uncontrolled cytokine storm manifest as unremitting fevers, cytopenias, splenomegaly, hepatitis, coagulopathy, multisystem organ failure, and death in its most severe form. The clinical features of MAS are shared with other hyperinflammatory syndromes, of which genetic defects in cytotoxicity have provided insight into the pathogenesis driving viral-triggers of disease. However, severe defects in cellular cytotoxicity have not been found in patients with MAS making it unclear how viral infection can trigger hyperinflammation in this condition.

Methods: C57Bl/6, interferon (IFN)$\gamma^{-/-}$, and IFN$\alpha^{-/-}$mice were infected with LCMV Armstrong and treated with or without interleukin (IL)-10 receptor blockade. Survivial, weight loss, splenomegaly, cytopenias, and serum cytokine levels were measured after viral infection.

Results: Wildtype mice treated with IL-10 receptor blockade succumbed to MAS-like hyperinflammation manifest as weight loss, splenomegaly, bicytopenias, and hypercytokinemia during LCMV infection. IFN$\gamma^{-/-}$ and IFN$\alpha^{-/-}$mice were not protected from LCMV-induced disease in this model, as they developed severe weight loss, splenomegaly, cytopenias, hypercytokinemia, and more severe mortality when IL-10 receptor was blocked.

Conclusion: IL-10 receptor blockade leads to heightened immunopathology in the setting of LCMV infection similar to MAS-like hyperinflammatory disease. Unlike other hyperinflammatory syndromes, this immunopathology is independent of IFNγ and IFNα, and highlights the capacity of other inflammatory mediators to cause viral-induced hyperinflammation during IL-10 receptor blockade. Furthermore, these data highlight a novel mechanism that could contribute to MAS-like disease whereby defects in IL-10 production and/or sensing could exacerbate hyperinflammatory immunopathology induced by viral infection without genetic defects in cellular cytotoxicity.

2877

Novel Function of Tocilizumab As a Modulator of Interleukin-27-Mediated Anti-Inflammatory Responses. Misato Hashizume[1], Jun Kikuchi[2], Keiko Yoshimoto[2] and Tsutomu Takeuchi[2]. [1]Chugai Pharmaceutical Co., Ltd., Gotemba, Japan, [2]Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: The immunological roles of interleukin 27 (IL-27) have been reported in the function of regulatory T cells (Treg), monocytes and osteoclasts, and these cells are involved in various autoimmune diseases, such as rheumatoid arthritis (RA), lupus, systemic sclerosis, and psoriasis. There was a paucity of information about how the function of IL-27 is regulates in autoimmune disease. IL-27 is a heterodimeric cytokine composed of IL-27p28 and EBI3, which are analogous to IL-6 and soluble IL-6 receptor (sIL-6R) respectively. In this study, we investigated whether a possible role of sIL-6R in regulating IL-27 function.

Methods: CD14$^+$ cells were isolated from peripheral blood in RA patients. MCP-1 was measured by ELISA in the culture supernatant of incubated with TNF-α, IL-27, sIL-6R, anti-IL-6 antibody and anti-IL-6R antibody (tocilizumab). In the experiments of osteoclasts, CD14$^+$cells were cultured with RANKL and M-CSF in the presence of IL-27, sIL-6R, anti-IL-6 antibody and tocilizumab for 4 days and the number of osteoclasts was counted. Consecutive RA patients who received 8mg/kg of tocilizumab every 4 weeks as first biologics between March 2010 and April 2012 after giving a written informed consent were included in this study (n=39). The proportions of Treg and monocytes at base line, week 24 and week 52 were sequentially measured by using the expression levels of differentiation markers, activation markers and co-stimulatory molecule markers in T cells and monocytes defined in previous report.

Results: Whereas IL-27 reduced MCP-1 production by CD14$^+$ cells stimulated with TNF-α, further addition of sIL-6R restored the production of MCP-1. To clarify which is an important unit either IL-6 or sIL-6R for modulating IL-27 function, we measured MCP-1 production in the presence of anti-IL-6 antibody or tocilizumab. Tocilizumab, but not an anti-IL-6 antibody, inhibited TNF-α-induced MCP-1 production in the presence of IL-27 and sIL-6R. RANKL-mediated osteoclast formation was suppressed by IL-27, and sIL-6R antagonized the activity of IL-27. Tocilizumab, but not anti-IL-6 antibody inhibited osteoclastgenesis in the presence of IL-27 and sIL-6R. Over the treatment with tocilizumab, the proportions of Treg and HLA-DR$^+$ activated Treg were significantly increased from baseline (Treg: $p=0.0034$, activated Treg: $p=0.0008$ by Wilcoxon rank test). The proportions of HLA-DR$^+$CD14$^+$ activated monocytes, CD69$^+$CD14$^+$ activated monocytes and CD16$^+$CD14$^+$ non-classical monocytes were significantly decreased from baseline to 52 weeks after treatment (HLA-DR$^+$ activated monocytes: $p=0.0006$, CD69$^+$activated monocytes: $p<0.0001$, non-classical monocytes: $p<0.0001$).

Conclusion: Our results suggest that sIL-6R antagonizes the IL-27 signaling, and blocks IL-27-mediated anti-inflammatory effects. In addition, tocilizumab, but not an anti-IL-6 antibody rescued IL-27-mediated anti-inflammatory effects in the presence of sIL-6R. And in vivo study demonstrates that tocilizumab showed differential effects on the proportions of circulating Treg and monocytes in RA patients. These data suggest that tocilizumab may be involved in modulating the anti-inflammatory responses of IL-27.

G Protein Signaling Modulator 3 (GPSM3) Deficiency Is Protective in Inflammatory Arthritis Models and Altered GPSM3 Gene Products Correlate with Single Nucleotide Polymorphisms in Humans. Teresa K. Tarrant[1], D. Stephen Serafin[1], Elizabeth Sugg[1], Roman Timoshchenko[1], Matthew J. Billard[1], David P. Siderovski[2] and Kristy Richards[3]. [1]Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]West Virginia University School of Medicine, Morgantown, WV, [3]Dept. of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background/Purpose: GPSM3, a newly described regulator of heterotrimeric G protein signaling, is selectively expressed in hematopoietic cells with high expression in monocytes. We have shown that *Gpsm3* deficient (−/−) mice are protected from Collagen Antibody Induced Arthritis due in part to their attenuated monocyte responses, including decreased *ex vivo* migration to the chemokines CX3CL1, CCL2, and chemerin, and enhanced apoptosis, which leads to an observed decrease in proinflammatory intra-articular *IL-6* and *IL-1b* transcripts in the joint. Given the restricted expression of *GPSM3* in leukocytes and the functional phenotypes observed in immune cells lacking *GPSM3* expression, we chose to examine effects of *GPSM3* deficiency in Collagen Induced Arthritis (CIA) and to analyze whether single nucleotide polymorphisms (SNPs) within the human *GPSM3* gene locus, associated with a decreased incidence of autoimmunity, correlate with altered *GPSM3* gene products.

Methods: *Gpsm3*−/− and *Gpsm3*+/+ DBA1-J mice were immunized with heterologous type II collagen in Freund's Adjuvant with a booster immunization at day 21 per published protocols. Arthritis was assessed by a blinded observer for paw swelling and clinical disease score (0–4). Paws were processed at day 42 for histopathology. Serum B-cell activating factor (BAFF) was measured by commercial ELISA (R&D Systems) per manufacturer's instructions on day 14. DNA and RNA was isolated from healthy human subject blood using Qiagen purification reagents. Genotyping for SNP (A (minor)/G (major) transition substitution) was performed using commercially available TaqMan SNP Genotyping Assay (SNP ID = rs204989) from Applied Biosystems by Life Technologies. qRT-PCR primers for known *GPSM3* transcripts *−001*, *−002*, *−003*, and *−004* were designed from NCBI (−001 and −002) and Ensembl (−003 and −004) databases, and validated by gel electrophoresis for sequence length, sequencing, melt curve analysis, and PrimerBlast. qRT-PCR of cDNA from healthy human subject blood was performed using a Biorad CFX96 Real-Time System and standard protocols. Data was calculated as relative expression compared to the housekeeping gene *IDUA*(ΔCt).

Results: *Gpsm3*−/− mice are protected from CIA and have significantly decreased serum BAFF levels. Healthy human subjects carrying protective SNP alleles that correlate with a decreased incidence of rheumatoid arthritis (RA) and four other autoimmune diseases have decreased levels of transcripts *GPSM3-001*, *−002*, and *−004*, but significantly increased levels of the transcript *GPSM3-003*, which is thought to be subjected to nonsense-mediated decay.

Conclusion: Our goal from these studies is to determine whether GPSM3 has immune system-modulating potential for the treatment of autoimmune diseases with particular focus on inflammatory arthritis. *Gpsm3*−/− mice are protected from two models of inflammatory arthritis through mechanisms involving monocyte function. *GPSM3* has altered mRNA transcripts in healthy human subjects with SNPs that correlate with decreased RA and other autoimmune diseases, suggesting differential gene regulation.

Disclosure: T. K. Tarrant, None; **D. S. Serafin**, None; **E. Sugg**, None; **R. Timoshchenko**, None; **M. J. Billard**, None; **D. P. Siderovski**, None; **K. Richards**, None.

Epigallocatechin-3-Gallate (EGCG) Suppresses IL-1β-Induced IL-6 and IL-8 Synthesis By Selectively Inhibiting TAK1 Activation in Human Rheumatoid Arthritis Synovial Fibroblasts. Anil Singh[1], Sharayah Riegsecker[2], Sadiq Umar[1] and Salahuddin Ahmed[1]. [1]Washington State University, Spokane, WA, [2]University of Toledo, Toledo, OH.

Background/Purpose: In rheumatoid arthritis (RA), the role of interleukin-1β (IL-1β) signaling proteins (IRAK-1/TAK-1/TRAF-6) proximal to IL-1 receptor in mediating proinflammatory response is not completely understood. Using IL-1β-induced IL-6 and IL-8 production in RA synovial fibroblasts (RA-FLS), we examined the role of key signaling molecules critical in mediating its inflammatory response. We also tested if EGCG, a potent anti-inflammatory compound, inhibits IL-1β signaling protein to suppress IL-6 synthesis in RA-FLS.

Methods: RA-FLS were treated with IL-1β for different time alone or in the presence of EGCG. Western blotting analysis was utilized to study activation/phosphorylation of different IL-1β signaling proteins. In vitro kinase activity of IRAK-1 was determined using ADAPTA kinase assay. Changes in the ubiquitination patterns of IL-1β-stimulated RA-FLS was studied using immunoprecipitation (IP) assay. Using chemical inhibitors or siRNA for IRAK-1, TAK-1 or TRAF-6, their respective roles were examined in IL-1β-induced IL-6 and IL-8 expression by ELISA and qRT-PCR methods. Therapeutic effect of EGCG on these signaling events was evaluated.

Results: IL-1β-induced IL-6 and IL-8 production in RA-FLS was significantly inhibited by EGCG (2.5–20 μM) in a dose-dependent manner ($p<0.01$; $n=5$). IL-1β induced rapid degradation of IRAK-1 within 1–5 min followed by the activation of TAK-1 phosphorylation in RA-FLS. Using the chemical inhibitors for TAK-1, IRAK-1, and TRAF-6, our novel findings showed a complete blockade of IL-1β-induced IL-6 and IL-8 production by TAK-1, but only a modest inhibition with IRAK-1 or TRAF-6 inhibitors ($p<0.01$ for TAK-1; $n=4$). Confirmatory studies using siRNA method also showed a marked inhibition of IL-6 production by TAK-1 or IRAK-1 siRNA. Although EGCG inhibited *in vitro* IRAK-1 kinase activity by almost 65%, it did not prevent the IL-1β-induced proteasomal degradation of IRAK-1 in RA-FLS. To our surprise, EGCG selectively inhibited IL-1β-induced TAK-1 phosphorylation in a dose-dependent manner ($p<0.05$; $n=4$). Interestingly, we observed that the levels of TRAF-6 remained unchanged upon IL-1β stimulation. IP of RA-FLS cell lysates with global FK2 ubiquitin antibody and further Western blotting analysis showed that IL-1β activated TRAF-6 ubiquitination was not modulated by EGCG, suggesting TAK-1 as a potential therapeutic target in IL-1β signaling.

Conclusion: Our study provides a novel evidence of an important mediatory role of TAK-1 in IL-1β signaling in RA-FLS and warrants further testing of EGCG or it synthetic analogs as TAK-1 inhibitors for the treatment of RA.

Elevated Levels of Soluble Inflammatory Mediators and Lupus-Specific Connective Tissue Disease Questionnaire Scores Discern Unaffected First Degree Relatives of Lupus Patients from Unaffected Individuals Not Related to Lupus Patients. Melissa E. Munroe[1], Kendra A. Young[2], Jennifer Fessler[1], Dustin Fife[1], Diane L. Kamen[3], Joel M. Guthridge[1], Timothy B. Niewold[4], Michael H. Weisman[5], Mariko L. Ishimori[5], Daniel J. Wallace[5], David R. Karp[6], John B. Harley[7], Gary S. Gilkeson[3], Jill M. Norris[2] and Judith A. James[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Colorado School of Public Health, Aurora, CO, [3]Medical University of South Carolina, Charleston, SC, [4]Mayo Clinic, Rochester, MN, [5]Cedars-Sinai Medical Center, Los Angeles, CA, [6]UT Southwestern Medical Center, Dallas, TX, [7]Cincinnati Children's Hospital Medical Center; US Department of Veterans Affairs Medical Center, Cincinnati, OH.

Background/Purpose: Identifying populations at risk of SLE is essential to curtail inflammatory damage and select individuals for prevention trials. First-degree relatives (FDRs) of lupus patients have an increased risk of developing SLE. Using a unique resource of SLE patient family members with longitudinal samples available, the goal of this study is to determine factors that distinguish FDRs who remain unaffected over time from unrelated, unaffected individuals.

Methods: We evaluated plasma samples from 154 unaffected FDRs of known SLE patients with samples available from previous genetic studies and who remained unaffected at follow-up evaluation (mean time to follow-up 6.8 years). FDRs were matched 2:1 by gender, race and age ($\pm$5 years) to 77 unaffected individuals unrelated to SLE patients (Controls). FDRs and Controls provided clinical and demographic information, and completed the SLE-specific portion of the Connective Tissue Disease Screening Questionnaire (CSQ) at baseline (BL) and follow-up (FU). BL and FU plasma samples were assessed for autoantibody production (ANA, anti-dsDNA, aCL, Ro, La, Sm, nRNP, and ribosomal P antibodies) and for 52 soluble inflammatory mediators (BLyS, APRIL, cytokines, chemokines, and shed TNF receptors). Logistic regression modeling of CSQ scores, number of autoantibody specificities, and select soluble mediators (via Random Forest) was utilized to evaluate whether certain factors distinguished unaffected FDRs from Controls.

Results: FDRs had significantly higher BL and FU CSQ scores than Controls ($p<0.0001$); CSQ scores were higher in female FDRs vs. male FDRs or female Controls ($p<0.0001$). No significant difference in the number of positive autoantibody specificities were noted between FDRs and Controls. FDRs had significant ($p\leq0.01$) alterations in 38 (of 52) soluble mediators compared to Controls, including innate and adaptive mediators of inflammation, chemokines, and TNF superfamily members. APRIL and BLyS, IFN-associated chemokines IP-10, MIG and MIP-1α, as well as the regulatory mediators IL-10 and TGF-β, were significantly higher in FDRs at BL and FU ($p\leq0.002$). A number of mediators (14 at BL and 18 at FU) found to best separate FDRs from Controls by Random Forest strongly correlated with CSQ scores ($p\leq0.0002$). Of these, levels of MIP-1α ($p=0.008$), MIG ($p=0.019$), GROα ($p=0.001$), ICAM-1 ($p=0.007$), and VEGF ($p=0.004$), along with CSQ scores ($p=0.010$), best distinguished FDRs from Controls in logistic regression models.

Conclusion: Unaffected FDRs of SLE patients demonstrate significantly altered levels of soluble inflammatory, as well as regulatory, mediators compared to matched, unrelated, unaffected Controls. These alterations are present despite lack of progression to classified SLE, suggesting that multiple perturbations in immune-mediated inflammatory processes present in family members of SLE patients may be offset by inhibitory factors, providing unique insights for potential autoimmune disease prevention or SLE disease treatment.

The Center of Excellence in Musculoskeletal Care and Education: A Sustainable Interprofessional, Multidisciplinary Programmatic Innovation Developed with the Department of Veterans Affairs. Michael J. Battistone, Andrea M. Barker, Marissa Grotzke, Peter Beck, Jeffery Berdan, Caroline Milne, JoAnn Rolando and Grant W. Cannon. Salt Lake City VA and University of Utah, Salt Lake City, UT.

Background/Purpose: While musculoskeletal (MSK) problems are common in primary care, the current formal education in the evaluation and management of these conditions is inadequate. Through funding from the Veterans Affairs (VA) Office of Academic Affiliations, we developed an interprofessional, interdisciplinary, mixed-method program to enhance the clinical education of medical students, residents, fellows, and trainees of other health professions.

Methods: The week-long course begins with didactics, is reinforced through technology-enhanced simulation and peer-teaching in small-group settings, and culminates in supervised ambulatory clinical experiences and reflective practice.

Participants learn to perform, describe, and document a systematic physical exam of the shoulder and knee, interpret these findings, and develop patient-centered management options in a framework of high value care. Faculty represent Internal Medicine (IM) (Primary Care, Rheumatology, Endocrinology), Orthopaedics, and Physical Medicine and Rehabilitation (PM&R) disciplines. Course assessments include written surveys, 2-station Objective Structured Clinical Examination, and individual exit interviews.

Results: Student and trainee participants in the 2013–14 academic year are summarized below. Survey response rate was 89%. Post-course competency in examining the shoulder and knee, and in reporting, interpreting, and managing the case using a framework of high-value care, was confirmed with 2-station OSCE.

Table 2

Discipline/ Profession	Post-Graduate Trainees							Students		
	IM	Rheum	Geri	Neuro	Ortho	PM&R	Occ Med	Med	APRN	PA
Number of Trainees	34	1	2	1	4	5	1	4	9	10

	Pre-MSK COE Week	Post-MSK COE Week
Able to evaluate and manage shoulder complaints	16%	98%
Able to evaluate and manage knee complaints	35%	94%
Competent to aspirate/inject knee or subacromial space	18%	76%

Conclusion: The MSK Intensive Education Week provides an interdisciplinary and interprofessional environment to teach trainees from multiple backgrounds in the evaluation and management of patients with complex MSK diseases through a cooperative practice model and evaluates their competency to practice in this system.

Using Decision-Based Learning to Highlight Rheumatic Disease for Third-Year Medical Students. Karen Law[1], J Richard Pittman[1] and Chad Miller[2]. [1]Emory University School of Medicine, Atlanta, GA, [2]Tulane University Health Sciences Center School of Medicine, New Orleans, LA.

Background/Purpose: Opportunities for exposure to rheumatology are limited in medical school, especially during the clinical years. In addition, because the rheumatic diseases represent a small portion of the National Board of Medical Examiners Subject Examination (SHELF exam) for the Internal Medicine clerkship, clerkship directors are reluctant to devote limited class time to rheumatology.

This project aims to improve medical student exposure to rheumatology during the third-year Internal Medicine Clerkship via Decision-Based Learning (DBL), a simulated case-based teaching technique. Learners work in teams on a challenging clinical case. Teams are given a description of the patient's history and physical examination; each team collaborates to generate a differential diagnosis, then order tests and studies to work up the case. A simulated "bank" of tests and studies is available, with each test coming with a "price" that the team is charged. The teams compete to solve the case by ordering and interpreting studies while also spending the least amount of money. Because of the cost-conscious and competitive nature of the exercise, learners are incentivized to employ prudent hypothesis testing and diagnostic reasoning to decide what is "the next best step" to arrive at the diagnosis.

DBL facilitates rheumatology exposure within the broad context of internal medicine, a format more appropriate for the medical student level than typical disease-specific rheumatology curricula. In addition, the DBL format highlights the diagnostic complexity of rheumatic cases. Students also practice critical thinking and cost consciousness, areas of medical education that are frequently lacking.

Methods: The project introduced DBL to third year medical students during their clerkship in Internal Medicine. Control sessions consisted of usual lecture-style didactics. Learners were given a survey after each session to rate their learning experience.

Results: Student feedback for DBL sessions was significantly higher than control didactic sessions ($p < 0.01$). 67% of learners rated DBL a "10" on a 10-point Likert scale compared to 35% for control ($p < 0.01$). Positive responses to DBL were also noted in the survey comments:

- "Really productive exercise; thought provoking"
- "Very high-yield, learned lots of new things"
- "Made us think about what to order & why- I don't feel we have gotten much experience with that during the rotation"

Conclusion: A novel case-based teaching technique facilitated medical student exposure to rheumatology during their clerkship in Internal Medicine. DBL resulted in significantly higher ratings of didactic sessions compared to traditional lecture-style didactics. Learners found the DBL sessions to be engaging and educationally valuable. This interactive teaching method can enhance the learning experience during the Internal Medicine clerkship; the realistic context in which Rheumatology topics are addressed may make it more appealing for Clerkship Directors to adopt. These findings support future evaluation of DBL with a case-control study to determine efficacy in the principal areas of Rheumatology-specific knowledge, diagnostic reasoning, and cost awareness.

Rheumatology-Specific Milestones for a Musculoskeletal Radiology Curriculum. Michelle Newkirk[1], Liem Mansfield[1], Jay B. Higgs[2] and Daniel Battafarano[1]. [1]San Antonio Military Medical Center, JBSA - Ft Sam Houston, TX, [2]San Antonio Military Medical Center, JBSA - Fort Sam Houston, TX.

Background/Purpose: In 2012, the Accreditation Council for Graduate Medical Education (ACGME) announced the required implementation of standardized milestones with entrustable professional activities (EPAs) for the semi-annual evaluation of resident/fellow performance which must be implemented by November 2014. However, little guidance was rendered as to the incorporation of these milestones and EPAs into the curriculum of a subspecialty training program. Our rheumatology fellowship has had a formal musculoskeletal (MSK) radiology rotation for the past five years as part of its core curriculum and has integrated internal medicine subspecialty curricular milestones with MSK radiology specific EPAs into this curriculum.

Methods: Utilizing a modified Delphi technique via e-mail, faculty and current fellows from the program established a consensus on EPAs for MSK radiology. The EPAs were individually rated using a nine-point Likert scale, with 1 being disagreement with the EPA and 9 being the most agreement. Agreed upon EPAs were then used as a foundation for the development of curricular milestones. These milestones were designed using a 5-level Dreyfus model which were defined as novice/critical deficiency, advance beginner, competent, proficient/ready for unsupervised practice, and expert/aspirational. The milestones were then incorporated into the core curriculum, with an emphasis placed on the "proficient" level and above for teaching purposes.

Results: Six faculty members and 2 rheumatology fellows participated in the process. Six EPAs were initially developed, and after two rounds of comments with rewording and scoring, all six EPAs rated in the highest agreement scores (see table). Curricular milestones for MSK radiology were then established in keeping with these EPAs. These curricular milestones were integrated into our core MSK radiology lecture series.

Entrustable Professional Activities (EPAs)	Mean Likert Score
1. Order and utilize appropriate diagnostic imaging studies for evaluation and management of patients with rheumatic disease.	8.9
2. Identify the optimal imaging modalities for patients with rheumatic disease within the context of patient comorbidities, preferences, treatment goals, financial considerations and insurance requirements.	8.3
3. Interpret signs of acute and/or chronic musculoskeletal disease on radiography and know when to consult a radiologist for further evaluation and interpretation.	7.7

4. Understand the written interpretation reports of radiography, computed tomography, ultrasound, magnetic resonance imaging, scintigraphy and bone mineral density studies and utilize the results to optimize the care of the patient with rheumatic disease.	8.6
5. Communicate directly with consulting radiologists when necessary to determine the optimal diagnostic studies to evaluate and manage patients with rheumatic disease.	8.1
6. Effectively communicate with patients their diagnostic imaging options, indications, alternatives and results in a clear and easily understood manner.	8.6

Conclusion: The interpretation and application of MSK radiology is critical in the training of a rheumatology fellow. Incorporating a dedicated radiology rotation which addresses specific milestones and EPAs is one way of ensuring trainees are exposed to a quality, uniform curriculum that meets the ACGME's next accreditation system requirements.

Training the Rheumatologists of Tomorrow: The Canadian Experience. Alfred Cividino[1], Volodko Bakowsky[2], Susan Barr[3], Louis Bessette[4], Nader Khalidi[5], Christian A. Pineau[6], Janet E. Pope[7], David Robinson[8], Kam Shojania[9], Elaine Yacyshyn[10], Lynne Lohfeld[1] and Diane Crawshaw[1]. [1]McMaster University, Hamilton, ON, [2]Dalhousie University, Halifax, NS, [3]Heritage Medical Research Bldg, Calgary, AB, [4]Laval University, Québec, QC, [5]Division of Rheumatology, McMaster University, Hamilton, ON, [6]McGill University Health Center, Montreal, QC, [7]St Joseph Health Care, London, ON, [8]University of Manitoba, Winepeg, MB, [9]University of British Columbia, Vancouver, BC, [10]University of Alberta, Edmonton, AB.

Background/Purpose: Many countries face a shortage of rheumatologists. Based on an accepted benchmark of 1 specialist per 50,000 people as the number needed for effective patient care[1], recent figures show severe shortages in the U.S.[2]and Canada.[3]This qualitative environmental scan was designed to identify what faculty, administrators and learners associated with Canadian postgraduate rheumatology programs identify as appropriate means and messages that programs could use to attract future trainees.

Methods: Individual-level data from program faculty (F), administrators and learners (L) across Canada (n = 103) were collected via an online survey (n=78) and interviews (n = 25). Data were subjected to Thematic Framework Analysis to identify commonalities across sites to determine ways to address the rheumatology manpower shortage. Quotes are provided as examples.

Results: ***Participants:*** There were 103 respondents from nine programs including learners (medical students, junior residents (PGY1–3) rheumatology residents (PGY4–6) or new graduates); program and division directors and their assistants; and faculty in academic centres or community practices. Two-thirds of the survey respondents were female.

Ways to Increase Interest in Rheumatology: The need for rheumatologists was widely recognized. Respondents advocated targeting both undergraduates (*"People who influenced me were* [role models] *I had as a medical student"* [F]) and junior residents in Internal Medicine. Proposed methods included increasing exposure to rheumatology in undergraduate programs through formal lectures and courses, clinical skills and other hands-on training sessions, faculty available to shadow or mentor learners and postgraduate weekend information and training sessions, mandatory rotation for Internal Medicine residents, internships and career counseling.

Messaging to Promote Rheumatology: Messages to brand rheumatology as an attractive specialty included the intellectual challenge (*"This field fascinates me"* [L]; *"novel immunotherapies make it very exciting"* [F]), stimulating workday (*"nice mix of procedural and cerebral work"* [L]), positive relationships with colleagues and patients (*"According to a recent survey we are the happiest specialists"* [F]), alleviating suffering (*"We know how to treat arthritis now"* [L]), good quality of life and excellent job prospects (*"the health care system needs you"* [F]).

Conclusion: We found consensus on the need to inform potential trainees about rheumatology early in their education through a variety of messages and methods. Because of the shortage of rheumatologists it is important to increase awareness and information about the field by selectively using limited resources. The next step would be to collaboratively develop, test and evaluate tools designed to help increase the number of future rheumatologists, which will be applicable in many locales.

Clinical Training Opportunities in Two Innovative Ambulatory Resources: The Primary Care Musculoskeletal Clinic and Center of Excellence Multidisciplinary Clinic. Michael J. Battistone, Andrea M. Barker, Marissa Grotzke, Peter Beck, Jeffery Berdan, Phillip Lawrence and Grant W. Cannon. Salt Lake City VA and University of Utah, Salt Lake City, UT.

Background/Purpose: While musculoskeletal (MSK) problems are common in primary care, current training models do not adequately prepare primary care providers (PCP) to deal with these issues. With funding from the Veterans Affairs (VA) Office of Academic Affiliations (OAA), we developed a Center of Excellence (COE) for MSK Care and Education to meet this training need for health care professional trainees.

Methods: Two new weekly outpatient clinics, the Primary Care MSK (PC-MSK) and the Multidisciplinary (COE-MSK) Clinics were developed as key components of the COE. The PC-MSK is staffed by a rheumatologist and a physician assistant (PA) with orthopaedic experience. The COE-MSK is attended by a rheumatologist, endocrinologist, orthopaedic surgeon, physiatrist, and a PCP. All categorical internal medicine (IM) interns, orthopaedic interns, PM&R residents, and rheumatology fellows participate in this clinic over the course of the academic year. Additional IM residents, medical students, nurse practitioner students and physician assistant students are also included as space allows.

Results: In 2013–14, 80 trainees participated in the PC-MSK and COE-MSK clinics. The distribution of disciplines and professions represented in this multi-level cohort are shown in Table 1.

Table 1

	Post-Graduate Trainees							Students		
Discipline/Profession	**IM**	**Rheum**	**Geri**	**Neuro**	**Ortho**	**PM&R**	**Occ Med**	**Med**	**APRN**	**PA**
Number of Trainees	39	4	2	1	4	6	1	4	9	10
Percentage of Cohort	49%	5%	3%	1%	5%	8%	1%	5%	11%	12%

Since June 2013, 330 patients have been seen in these clinics. As shown in Table 2, most are referred from primary care, mainly by providers in non-resident clinics. Most non-resident referrals were to the PC-MSK clinic, all others tended to request the multidisciplinary COE-MSK clinic.

Table 2

		Referral Destinations	
Referral Sources	**Total**	**COE**	**MSK**
All Patients (n, %)	330 (100)	191 (58)	139 (42)
Primary Care	217	110	107
Resident Continuity Clinics	73	47	26
Faculty and Staff Clinics	138	60	78
Women's Clinics	6	3	3
Specialty Care	36	28	8
Medicine Subspecialties	25	18	7
Surgery	11	10	1
PC-MSK + COE-MSK (self-referrals)	23	19	4
Other	54	34	20
Procedures Performed (n, % of patients referred)	115 (35%)	43 (23%)	72 (52%)
Days to Consult Completion (mean, st.dev.)	47 (31.7)	55 (36.3)	36 (19.8)

Conclusion: These clinics provide unique and innovative opportunities for a broad range of trainees in a rich interdisciplinary and interprofessional educational environment. Additionally, these clinics are a valuable resource to primary care providers, specialty physicians, and patients for prompt and comprehensive care for veterans with either limited or complex MSK problems.

Assessing Rheumatology Fellows' Teaching Skills Using the Objective Structured Teaching Exercise (OSTE). Eli M. Miloslavsky[1], Marcy B. Bolster[1], Kenneth S. O'Rourke[2] and Lisa G. Criscione-Schreiber[3]. [1]Massachusetts General Hospital, Boston, MA, [2]Wake Forest School of Medicine, Winston-Salem, NC, [3]Duke University Health System, Durham, NC.

Background/Purpose: The interaction between rheumatology fellows and Internal Medicine residents in the setting of a consult offers an important opportunity for resident learning. However, teaching in the setting of a consult interaction can be challenging due to time constraints and lack of a longitudinal relationship between the resident and fellow. Fellows' teaching skills in the setting of the consult interaction have not been evaluated. We conducted a pilot study utilizing the Objective Structured Teaching Exercise (OSTE)[1] to evaluate rheumatology fellows' teaching skills.

Methods: First and second year rheumatology fellows from 5 training programs participated in a one-station OSTE during a 7 station rheumatology Objective Structured Clinical Examination (OSCE) in February 2014. Following the OSCE format, fellows were given 10 minutes to teach a standardized resident in the setting of a simulated consult and relay their consult recommendations, followed by 2 minutes of feedback. Prior to beginning the station fellows were given written instructions on the objectives of the exercise as well as a resident admission note describing the patient (32 year old male with monoarthritis). The OSTE was proctored by 3 faculty members (including author [EMM]) and utilized 3 standardized residents. Each fellow was evaluated by one faculty member and the standardized resident using an 8-point instrument adapted from a validated OSTE rating tool.[1] Prior to the OSTE, faculty and standardized residents received written materials describing the station and the rating tool and underwent a 30–60 minute training.

Results: Nineteen rheumatology fellows participated in the OSTE (11 first years and 8 second years). Fellows' overall teaching effectiveness had a mean score of 3.75 out of 5 (Table). Of seven specific skills evaluated, fellows were rated highest on their ability to present organized material. The lowest rated skills were evaluating residents' factual knowledge, evaluating residents' ability to synthesize knowledge and giving feedback. No differences in teaching skill ratings were detected between first and second year fellows. Ratings of the two evaluators had a high degree of correlation for all items (0.85–1.0).

Skill evaluated	Average rating * (range)	Standard deviation
Listened to learner	3.95 (2–5)	0.90
Encouraged learner to participate actively in the discussion	3.75 (2–5)	0.95
Evaluated learner's knowledge of factual medical information	3.53 (1–5)	1.15
Evaluated learner's ability to analyze or synthesize knowledge	3.18 (1–5)	0.93
Presented well organized material	4.00 (2–5)	0.71
Paced the session well	3.92 (2–5)	0.70
Explained to learner why he/she was correct/incorrect	3.38 (1–5)	0.96
Overall teaching effectiveness	3.75 (2–5)	0.91

* Scores ranged from "1" as the lowest rating to "5" as the highest rating.

Conclusion: Rheumatology fellows may benefit from programs designed to improve their teaching skills, particularly in the consult setting where time pressure and lack of a longitudinal relationship with learners impede the teaching interaction. Such interventions should focus on improving fellows' ability to engage in learner-centered teaching and feedback. Our pilot study suggests that the OSTE may be a useful tool in assessing fellows' teaching skills.

Post-Menopausal Factors and the Risk of Seropositive and Seronegative Rheumatoid Arthritis Phenotypes: Results from the Nurses' Health Study. Camilla Bengtsson[1], Susan Malspeis[2], Jeffrey A. Sparks[2], Karen H. Costenbader[2] and Elizabeth W. Karlson[2]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Among women, the peak incidence of rheumatoid arthritis (RA) is reported to be 45–74 years of age. In addition, it has been suggested that the post-menopausal transition, especially at younger ages (Pikwer, Ann Rheum Dis, 2012), is related to an increased risk of RA, but the literature is scarce. Whether menopause has different impact on seropositive/seronegative RA phenotypes remains to be elucidated. Our aim was to explore whether age and menopausal factors were independently associated with subsequent development of serologic RA phenotypes in 2 prospective cohorts.

Methods: Data were analyzed from Nurses' Health Study (NHS, 1976–2010) and NHSII (1989–2011). In NHS 121,701 female nurses aged 30–55and in NHSII 116,430 female nurses aged 25–42 were followed via biennial questionnaires on lifestyle factors and disease outcomes. In total, 1,089 incident RA cases were confirmed by questionnaire and chart review. Seropositive RA was defined as +RF or ACPA by chart review or lab measurement. We used Cox proportional hazards models to obtain HR (95% CI) of seropositive or seronegative RA associated with menopausal status, age at menopause, type of menopause, severity of hot flashes and ovulatory years, adjusting for age, income, BMI, smoking, breast-feeding, and parity.

Results: Women aged 45 or more had an increased risk of seronegative RA in all age-groups, compared with women aged 25–44, with peak HR at ages 55–59. Women aged 50 or more had an increased risk of seropositive RA, with peak HR at ages 55–59, but the risk attenuated after age 60. Post-menopausal women had an increased risk of seronegative RA after adjusting for age and other potential confounders (NHS: HR 1.8, 95% CI 1.1–3.0; NHSII: HR 2.5, 95% CI 1.5–4.2; pooled HR 2.1, 95% CI 1.5–3.1) without marked differences according to type of menopause. Early age at menopause associated with an increased risk of seronegative RA (NHS: HR 2.0, 95% CI 1.2–3.4; NHSII: HR 3.0, 95% CI 1.7–5.1; pooled HR 2.4, 95% CI 1.6–3.5), regardless of type of early menopause. Moderate/severe hot flashes was mainly associated with an elevated risk for seronegative RA (NHS HR=2.4, 95% CI 1.4–4.3; NHSII: 3.7, 95% CI 2.0–6.8; pooled HR 3.0, 95% CI 2.0–4.5). None of the menopausal factors were significantly associated with seropositive RA.

Conclusion: In these prospective cohorts, women of older ages have an increased risk of both RA phenotypes, but this risk attenuates after age 60 for seropositive RA. Post-menopausal factors are strongly associated with seronegative RA, but not seropositive RA, suggesting potential differences in disease etiology.

Table. Age and menopausal factors and the relative risk of seropositive RA and seronegative RA in the NHS (1976–2010) and NHSII (1989–2011) cohorts

	NHS I	NHS II	Pooled (NHS+NHSII)		
Factors	Seropositive RA (n=457)	Seronegative RA (n=267)	Seropositive RA (n=694)	Seronegative RA (n=395)	Seronegative RA (n=662)

Amount of Smoking, Duration of Smoking Cessation, and Their Interaction with Silica Exposure in the Risk of Rheumatoid Arthritis: Results from the Swedish Epidemiological Investigation of Rheumatoid Arthritis Study. Xia Jiang[1], Camilla Bengtsson[1], Henrik Källberg[1], Lars Klareskog[2] and Lars Alfredsson[3]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Karolinska University Hospital, Stockholm, Sweden, [3]The Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Exposure to silica is a well-defined inhalation exposure, and is known to be associated with moderately increased rheumatoid arthritis (RA) risk, with the effect confined to anti-citrullinated protein/peptide antibody (ACPA) positive RA. The interaction between silica exposure and current smoking, but not past smoking, in the etiology of ACPA-positive RA has also been described. Whereas the overall association of current smoking status, silica, and their interaction in RA could be regarded as established, considerably less is known about how much smoking is needed to bring about this synergistic effect, that is, the influence from cumulative dose (pack-years) among current smokers and the influence from cessation duration among past smokers. This study is to explore the interaction between silica exposure and smoking dose on one hand, as well as duration of smoking cessation on the other, with regard to the risk of developing RA defined by the presence/absence of ACPA.

Methods: We analyzed 927 incident male RA cases (fulfill 1987 ACR criteria) and 1403 randomly selected male controls, aged 18–70, from the Swedish EIRA study, a population based case-control study. Information on silica exposure and cigarette smoking were collected through self-reported questionnaires at the inclusion. Men with a history of having occupations as rock drilling and stone crushing were defined as silica exposed. Additive interaction (attributable proportion due to interaction (AP) and 95% confidence interval (95%CI)) between silica exposure, pack-years of smoking, and duration of smoking cessation (years after quit smoking) were calculated. ACPA status among cases was determined.

Results: A high risk of developing ACPA-positive RA was observed among silica-exposed current smokers (OR=8.03 (95%CI: 4.47–14.03)), and a statistically significant additive interaction was present (AP=0.41 (95%CI: 0.04–0.77)). The magnitude of the estimated silica-smoking interaction increased as the pack-year of smoking increased, with the highest AP observed for smoking ≥ 29 pack-years (AP=0.62 (95%CI: 0.29–0.94)). Although a relevant high risk of developing ACPA-positive RA was also observed for silica-exposed ex-smokers in general, no significant interaction was revealed (OR=4.09 (95%CI: 2.46–6.82); AP=0.07 (95%CI: −0.45–0.60)). Through further analysis, we found those ex-smokers who quit smoking no more than 10 years ago had a similarly high silica-smoking AP as current smokers (AP=0.46 (95%CI: −0.02–0.95), p=0.06). No significant interaction was observed after 10 years after smoking cessation. No statistically significant results were found for ACPA-negative RA.

Conclusion: Silica exposure and smoking interact significantly in a dose dependent manner regarding risk of developing ACPA-positive RA among men. It might take up to 10 years after smoking cessation for the diminishment of the smoking-silica interaction effect, and even longer for the main effect of smoking to return to the baseline. Since silica dust is hard to get rid of once in the lung, it is yet another reason to advise silica exposed persons not to start smoking, smoke less, and to quit smoking as early as possible.

The Association Between Changes in Inflammation and High Density Lipoprotein Cholesterol Efflux Capacity in Rheumatoid Arthritis. K P Liao[1], Martin Playford[2], Michelle A. Frits[1], Christine K. Iannaccone[1], Jonathan S. Coblyn[1], Michael E. Weinblatt[1], Nancy A. Shadick[3] and Nehal N. Mehta[4]. [1]Brigham and Women's Hospital, Boston, MA, [2]National Heart, Blood, and Lung Institute, Bethesda, MD, [3]Brigham and Women's Hospital/Harvard University, Cambridge, MA, [4]University of Pennsylvania, Philadelphia, PA.

Background/Purpose: High density lipoprotein (HDL) cholesterol efflux capacity measures the functional ability of HDL to remove cholesterol from atherosclerotic plaque. Low HDL efflux capacity is associated with an elevated risk of cardiovascular disease (CVD) independent of HDL levels and traditional CV risk factors in the general population. Recent cross-sectional studies suggest that inflammation is associated with impaired HDL efflux capacity. The objective of this study was to examine whether longitudinal changes in inflammation are associated with a change in HDL efflux capacity in rheumatoid arthritis (RA).

Methods: We conducted this study in a single center longitudinal RA cohort from a large academic center with RA clinical data, CRP and blood samples collected annually. We randomly selected 100 patients who experienced a reduction in inflammation defined as >10mg/L CRP decrease between any two time points one year apart. The first time point was defined as the baseline. Subjects on statin therapy one year before baseline or during the one-year follow-up period were excluded. We measured HDL efflux capacity in serum samples at baseline and one year follow-up quantified using a validated ex vivo system involving the incubation of macrophages with apolipoprotein B-depleted serum. We used the paired t-test to determine significant differences between baseline and follow-up HDL cholesterol efflux values. We assessed the correlation between the change in CRP levels [natural log (baseline CRP-1 year follow-up CRP)] with percentage (%) change in HDL cholesterol efflux capacity using a Spearman's correlation.

Results: We studied 92 subjects who experienced a reduction in inflammation as measured by CRP between baseline and one year follow-up with adequate serum volume. The mean age was 57.7 (SD 12.3), 89.3% were female, 78.5% were ACPA positive. The mean baseline CRP was 48.4mg/L (SD 59.3), and HDL efflux capacity was 1.04 (SD 0.17). At one year follow-up, the mean reduction in CRP was 41.0mg/L (SD 54.6). We observed an increase in HDL cholesterol efflux capacity of 6.7% (p<0.0001). A reduction in CRP was significantly correlated with an increase in HDL cholesterol efflux capacity (r=0.24, p=0.02) (Figure).

Conclusion: Although HDL cholesterol efflux capacity is considered to be a stable measure of HDL function over time in the general population, in RA subjects we observed a concomitant improvement in HDL function by efflux capacity with reductions in inflammation. These findings highlight a potential mechanism linking inflammation and CV risk in RA.

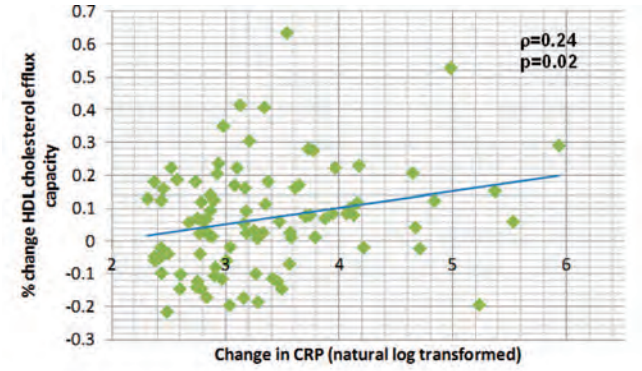

Figure. The correlation between reduction in CRP (natural log transformed) and percentage change in HDL cholesterol efflux capacity. (*Note:* A higher number change in CRP represents a larger reduction in CRP between baseline and one-year follow-up).

Does a Family History of RA Influence the Clinical Presentation and Treatment Response in RA? Thomas Frisell[1], Saedis Saevarsdottir[2] and Johan Askling[3]. [1]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology Unit, Karolinska University Hospital, Stockholm, Sweden.

Background/Purpose: Since family history of RA is among the strongest risk factors for developing the disease, individuals suspected to have RA are routinely asked about their relatives' disease history. Being a summary measure of a range of genetic and non-genetic risk factors, it would seem likely that family history of RA carries information not only on risk of onset of RA, but also on prognosis, and/or that it may be more strongly associated to certain clinical features of this heterogenic criteria based syndrome. Despite the potential clinical value, and great interest from patients, the role of family history of RA as a clinical marker has been little studied, probably due to the difficulty in ascertaining valid information on familial RA and clinical outcomes.

Methods: We performed a cohort study using prospectively recorded data from Swedish nationwide registers. The cohort was defined as all early RA patients (symptom onset <12 months before inclusion) with a diagnosis of seropositive or seronegative RA in the Swedish Rheumatology register, who started methotrexate monotherapy as first DMARD treatment 2000–2011, and who had parents registered in the Swedish multi-generation register. First degree relatives of cohort members were identified through the Swedish Multi-Generation Register, and the presence of RA among relatives was assessed through the National Patient Register.

The association of RA in one or more first degree relatives to baseline clinical characteristics and treatment response (according to the DAS28-based EULAR response criteria), treatment switch, and change in disease activity measures at 3 and 6 months was estimated using linear regression and generalized logistic regression models.

Results: In our cohort, 380 (9%) of 4210 patients had a first degree relative with RA by their time of RA diagnosis. RA patients with compared to without a family history of RA were more often seropositive (75%/69%), but there were no other significant differences in baseline clinical characteristics (e.g., mean HAQ 0.95/1.01, mean DAS28 5.04/5.06, mean disease duration 0.48/0.49 years). Neither were there any significant differences in treatment response or disease progression at 3 or 6 months, a lack of association that remained after adjustment for sex, age, birth year, and disease duration, and also when further adjusting for baseline DAS28, HAQ, and CRP (Table).

Conclusion: Using a large population-based cohort, we found that despite being a strong predictor of RA itself, family history of RA is not associated with a more severe presentation of RA, nor with short term response to methotrexate monotherapy. Future studies could consider whether family history may be a predictor of long term prognosis or response to treatment other than methotrexate, and what this negative finding implies for the possibility of RA risk genes to also influence disease severity and treatment response.

Table. Association of family history of RA and response to methotrexate monotherapy at 3 and 6 months

Inflammatory Genes Are Associated with Autoantibodies in Rheumatoid Arthritis-Free Individuals Who Are at-Risk for Future Disease. Ryan W. Gan[1], Kendra A. Young[1], M. Kristen Demoruelle[2], Michael H. Weisman[3], Jane H. Buckner[4], P. K. Gregersen[5], Ted R. Mikuls[6], James R. O'Dell[6], Richard M. Keating[7], Elizabeth W. Karlson[8], Kevin D. Deane[2], V. Michael Holers[2] and Jill M. Norris[1]. [1]Colorado School of Public Health, Aurora, CO, [2]University of Colorado School of Medicine, Aurora, CO, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]Benaroya Research Institute at Virginia Mason, Seattle, WA, [5]Feinstein Institute Medical Research and North Shore-Long Island Jewish Health System, Manhasset, NY, [6]Veteran Affairs Nebraska Western Iowa Health Care System and University of Nebraska Medical Center, Omaha, NE, [7]Scripps Clinic, La Jolla, CA, [8]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: We previously found that presence of rheumatoid arthritis(RA)-related autoantibodies is associated with systemic inflammation, and that decreased consumption of anti-inflammatory omega-3 fatty acids (n-3 FA) is associated with RA-related autoantibody positivity. We examined whether selected genes in inflammatory pathways in which n-3 FA also play a role are associated with the presence of RA-related autoantibodies in individuals without RA but at future risk for the disease.

Methods: Participants were enrolled in The Studies of the Etiology of RA (SERA), which is a multisite observational study following a cohort of first-degree relatives of RA probands and a cohort enriched with the HLA-DR4 genetic variant, both of which are RA-free at their baseline visit. Participant DNA was screened at the Benaroya Research Institute for specific shared epitope subtypes of HLA-DR4 and HLA-DR1. Participants were positive for the shared epitope if they were either DR4 or DR1 subtype positive. Serum was measured for the following autoantibodies: anti-cyclic citrullinated peptide version 2 (CCP2), CCP3.1 (in a subset), rheumatoid factor (RF) by nephelometry, and RF isotypes (RF-IgM, RF-IgG, RF-IgA). Participants were considered positive for RA-related autoantibodies if they tested positive for any of these autoantibodies at their baseline visit.

Participants were typed for single nucleotide polymorphisms (SNPs) in *Cox-2, TNFA, NF-KB, IkBkB, PPARA, and PPARG* at the Broad Institute using the Sequenom platform. The association between RA-related autoantibody positivity and inflammatory genes was assessed using logistic regression, accounting for the correlation within family members, and adjusting for age at visit, sex, and race.

Results: Demographic characteristics were similar between autoantibody positive (n=306) and autoantibody negative (n=1,576) participants (Table 1). We observed a significant association between increasing number of minor alleles for *Cox-2* and *NF-KB* and autoantibody positivity (Table 2).

Conclusion: Our results suggest that *Cox-2* and *NF-KB* could be associated with an increased likelihood of developing RA-related autoantibodies. The association observed with *Cox-2* is of interest due to the enzyme's role in producing inflammatory lipid molecules, while the association observed with *NF-KB* is of interest given the potential roles that NF-KB has in the RA disease process, including cytokine production and stimulating B cell differentiation to immunoglobulin-producing B cells. These results need to be explored in further detail.

Table 1: Demographic characteristics at baseline by autoantibody (Ab) positivity

Demographic	Ab Positive (n=306)	Ab Negative (n=1576)	p
Age at baseline visit (Mean ± SD)	43.9 ± 15.3	42.9 ± 13.4	0.22
Sex (% female)	71.6	68.2	0.25
Race (% NHW)	75.2	78.9	0.14
Ever Smoke (% Yes)	39.9	37.4	0.42
Current Smoker (% Yes)	12.1	10.9	0.55
Pack Years (Mean ± SD)	3.6 ± 6.8	3.5 ± 7.0	0.70
Shared Epitope (% Pos)	51.8	52.9	0.74
First-degree Relative of RA patient (%)	70.9	67.1	0.20

Table 2: Association between autoantibody positivity (CCP2, CCP3.1, or any RF) at baseline and increasing number of minor alleles (additive model). Adjusted for age, sex, and race, accounting for family correlation

The Relative Risk of Incident NON-Ischemic Heart Failure in Prevalent Rheumatoid Arthritis. Ängla Mantel[1], Marie Holmqvist[2], Johan Askling[3], Lars Lund[4] and Daniel Andersson[5]. [1]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Solna, Sweden, [2]Unit of Clinical Epidemiology, Department of medicine, Stockholm, Sweden, [3]Clinical Epidemiology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [4]Unit of Cardiology section for Heart Failure. Department of Medicine, Stockholm, Sweden, [5]Unit of Cardiology section for heart failure. Department of Medicine, Stockholm, Sweden.

Background/Purpose: Patients with rheumatoid arthritis (RA) may be at increased risk of developing heart failure (HF). Inflammatory activity has been linked to the pathogenesis of HF by inducing structural changes of the myocardium. Despite these indications of a potential link between RA-related factors and non-ischemic HF, the relative risk of non-ischemic HF in contemporary patients with RA has not yet been assessed. The objective of this study was therefore o assess the relative risk of incident non-ischemic heart failure in contemporary patients with prevalent RA.

Methods: Using the Swedish nationwide patient register, a cohort of patients with prevalent RA was identified between 2006 and 2012 and matched with up to 10 general population comparators based on sex, age and area of residency. An index-date, defined as the second visit listing RA (comparators received the same index-date as their corresponding case), was assigned to all study subjects and all study participants with ischemic heart disease (IHD) and/or HF prior to the index-date were excluded. Thereafter all study subjects were followed for the outcome, defined as a first-time hospitalization or outpatient visit listing a main diagnosis of HF. All subjects were followed until outcome, death, incident IHD, first emigration or 31 December 2012, whichever occurred first. Crude rates were calculated and presented as number of events per 1000 person-years. Cox regression models were used to assess the relative risk of HF in patients with RA and adjusted for potential confounders.

Results: In total, 41982 patients with RA and 360763 general population comparators free of IHD and HF at the index-date were identified. During the follow-up period (median follow-up for RA-patients 4.6 years [iqr 2.4–6.0] and comparators 4.8 years [iqr 2.5–6.1]), 630 (1.5 %) of patients with RA and 3058 (0.8%) of the comparators were registered with incident HF. The rate of HF was 3.6 HF/1000 person-years among the RA-patients and 2.0 HF/1000 person-years among the comparators. The corresponding risk increase of incident HF among the patients with RA was approximately 70% (Crude HR 1.69 [95% CI 1.56–1.85]) and remained statistically significantly increased after adjusting for potential confounders (Adjusted HR 1.53 [95% CI 1.40–1.67]). Stratifying RA patients by RF-positivity at index-date did not reveal any major differences between these two subgroups (Crude HR RF-positive subjects 1.66 [95% CI 1.51–1.84]; Crude HR RF-negative subjects 1.78 [95% CI 1.52–2.07]).

Conclusion: Patients with prevalent RA have an increased risk of developing non-ischemic HF. Our results support the proposed involvement of RA-related factors in the pathogenesis of HF, independent of vascular disease. The role of autoantibodies and other markers of RA disease is an important subject for further research.

ACR Concurrent Abstract Session
Osteoarthritis - Clinical Aspects II: Osteoarthritis Risk Factors and Therapies

Tuesday, November 18, 2014, 4:30 PM–6:00 PM

2893

Genome-Wide Association Study of Osteoarthritis Progression: Results from the Osteoarthritis Initiative. Michelle S. Yau[1], Laura M. Yerges-Armstrong[1], Youfang Liu[2], David J. Duggan[3], Joanne M. Jordan[2], Braxton D. Mitchell[1], Rebecca D. Jackson[4] and Marc C. Hochberg[1]. [1]University of Maryland School of Medicine, Baltimore, MD, [2]University of North Carolina, Chapel Hill, NC, [3]Translational Genomics Research Institute, Phoenix, AZ, [4]The Ohio State University, Columbus, OH.

Background/Purpose: Most genome-wide association (GWA) studies have focused on OA prevalence, but few have focused on OA progression. GWA studies of OA progression may help reveal new biology and drug targets that can be used to develop treatments that slow disease progression in OA patients.

Methods: We used an agnostic GWA analysis of ~8 million 1000 genomes imputed single nucleotide polymorphisms (SNPs) to identify genetic variation associated with structural knee OA progression. Our analyses were conducted in Caucasian participants from the Osteoarthritis Initiative (OAI), a multi-center natural history study of individuals who have or are at high risk for developing radiographic knee OA. A total of 1,756 participants who returned for a follow-up exam and had evidence of radiographic OA (Kellgren-Lawrence (KL) grade ≥ 2) in one or more knees at baseline were included in the analyses (54% female, mean age=67±9 years). We defined progression as worsening of KL grade or progression to total joint replacement (TJR). As a secondary phenotype, we exclusively evaluated progression to TJR. Participants were followed annually for four years. About 27% had worsening of KL grade and 6% had TJR at follow-up. For these analyses, we used logistic regression models adjusted for age, sex, study site, and population stratification and assumed additive genetic models.

Results: We identified two SNPs that reached genome wide significance ($P < 5\times10^{-8}$). One SNP on chromosome 18, rs9964107 (OR=1.6, 95% CI=1.4–1.7, $P=3.2\times10^{-8}$), is associated with worsening of KL grade and another SNP on chromosome 4, rs76964101 (OR=10.8, 95% CI=10.0–11.7, $P=4.4\times10^{-8}$), is associated with progression to TJR. Both SNPs are located within intergenic regions, where rs9964107 is closest to *SYT4* and rs76964101

is closest to *SRD5A3* and *KDR*. *SYT4* encodes synaptotagamin 4, which is expressed in the brain and may play a role in calcium dependent vesicular trafficking and exocytosis. There is some evidence that this protein may be involved in body weight regulation through negative regulation of oxytocin release. *SRD5A3* encodes steroid 5 alpha-reductase 3, which is involved in maintenance of the androgen receptor activation pathway. *KDR* encodes a kinase insert domain receptor, which is a receptor for vascular endothelial growth factors and promotes proliferation, survival, migration, and differentiation of endothelial cells. There was no evidence for association of either SNP with OA prevalence, suggesting that these SNPs may be uniquely associated with OA progression.

Conclusion: We have identified two genome-wide significant SNPs that may be associated with structural knee OA progression. These SNPs reveal that neuronal regulation of obesity, androgen signaling, and vascular endothelial growth factors may play an important role in OA progression. None of these SNPs are associated with OA prevalence. Further work is ongoing to replicate these associations and identify the causative signal.

2894

Relationship of Dermal Advanced Glycation End Products and Hand OA. Charles Eaton[1], Jeffrey Driban[2], Bing Lu[3], Mary Roberts[4] and Timothy E. McAlindon[2]. [1]Center for Primary Care and Prevention, Memorial Hospital of Rhode Island, Providence, RI, [2]Tufts Medical Center, Boston, MA, [3]Brigham and Women's Hospital, Foxboro, MA, [4]Center for Primary Care and Prevention, Pawtucket, RI.

Background/Purpose: Hand Osteoarthritis (HOA) is characterized by the progressive destruction of articular cartilage and bony changes and is strongly and positively associated with age but the mechanism by which aging contributes to this increased susceptibility is largely unknown. Recently the hypothesis that accumulation of advanced glycation endproducts (AGEs) that are associated with oxidative stress and aging might explain some or most of this association has been suggested. We compared skin autofluorescence as a measure of dermal AGEs and its association with the prevalence of HOA, symptomatic HOA, and the number of finger joints with osteophytes and joint space narrowing (JSN) as a measure of severity.

Methods: We performed a cross-sectional analysis of a purposeful sample of the Osteoarthritis Initiative (OAI) from a single site who had dermal AGEs measured by skin autofluoresence using SCOUT DS machine (Vera light Inc., Albuquerque, New Mexico) at the 36 month visit. We used an excitation wavelength of 375nm and emission wavelengths of 435–660nm. This wavelength is correlated with cross-links of collagen, FAD, and NADH. A mathematical algorithm is applied to spectrum results to adjust for age, hemoglobin, skin pigmentation and light scattering. Hand x-rays from the dominant hand were read for definite osteophytes with JSN at 48 months. We classified a person as having radiographic HOA if their hand x-ray had two or more finger joints (DIP, PIP, MCP) affected on different fingers. Symptomatic HOA was defined as having radiographic HOA and presence of hand/finger pain, aching or stiffness for more than half the days in past 30 days. Simple T tests or Pearson correlation coefficients were used to evaluate the the mean number of finger joints involved by tertiles of dermal AGE levels. Then Analysis of Covariance was performed to adjust for age and gender. T-tests comparing levels of dermal AGEs between those with and without HOA and with and without symptomatic HOA were performed.

Results: In a sub-sample from the OAI (n=200)with equal proportions of participants with and without abdominal adiposity had hand x-rays read. Of this sample, 171 had dermal AGEs measured and analyses performed. Mean levels of AGEs were greater both for those with radiographic HOA (n=114) [29.3(4.8) vs. 27.1(5.0), p = 0.005], and symptomatic HOA(n=35) [30.5(5.2) vs. 28.1(4.8), p=0.01] compared to those without HOA or symptomatic HOA. Furthermore level of AGEs correlated significantly with the number of joints affected per hand (r= 0.25, p<0.001) and exhibited a dose-response relationship in categorical analysis(with 2.34, 2.70 and 3.59 joints involved by increasing tertiles of dermal AGE levels after adjustment for age and gender (p trend <0.001).

Conclusion: Non-enzymatic glycation of dermal tissues as a proxy for the accumulation of AGEs in articular cartilage is associated with HOA, symptomatic HOA and the severity of HOA as measured by the number of finger joints affected in this cross-sectional study. Replication of these findings in prospective cohort studies and understanding of metabolic pathways that may modify or mediate the relationship of AGEs with HOA are indicated.

Habitual Running Any Time in Life Is Not Detrimental and May be Protective of Symptomatic Knee Osteoarthritis: Data from the Osteoarthritis Initiative. Grace H. Lo[1], Jeffrey B. Driban[2], Andrea Kriska[3], Kristi Storti[3], Timothy E. McAlindon[2], Richard Souza[4], Charles B. Eaton[5], Nancy J. Petersen[6] and Maria E. Suarez-Almazor[7]. [1]Michael E. DeBakey VA Medical Center, Baylor College of Medicine, Houston, TX, [2]Tufts Medical Center, Boston, MA, [3]University of Pittsburgh, Pittsburgh, PA, [4]University of California, San Francisco, San Francisco, CA, [5]Memorial Hospital of Rhode Island, Pawtucket, RI, [6]Baylor College of Medicine, Houston, TX, [7]The University of Texas, MD Anderson Cancer Center, Houston, TX.

Background/Purpose: Controversy exists regarding whether habitual running is beneficial versus harmful to the knee. Chronic mechanical overloading could potentially physically damage structures within the knee. Alternatively, runners have a lower body mass index (BMI), protective of knee osteoarthritis (OA). Most existing studies evaluating running and knee osteoarthritis (OA) have focused on elite male athletes, not generalizable to most of the population. Therefore, we aimed to evaluate the relationship of habitual running with symptomatic knee OA in the Osteoarthritis Initiative (OAI), a cohort recruited from the community not based on elite running status.

Methods: This is a cross-sectional study of OAI participants with knee x-ray readings, symptom assessments, and completed surveys on lifetime physical activity. At the 96-month visit, a modified version of the Lifetime Physical Activity Questionnaire (LPAQ) asked participants to identify the top 3 most frequently performed physical activities (≥ 20 times in life) from ages 12 – 18, 19 – 34, 35 – 49 and >50 years old. Those indicating running as an activity were defined as a runner in that time period. Running at any time in life included runners from all time periods. Posterior-Anterior semi-flexed knee radiographs were obtained at OAI 48-month visit and scored for Kellgren-Lawrence (KL) grade (0–4). Radiographic OA (ROA) was defined as KL ≥ 2. Frequent knee pain within a person required at least one knee have frequent knee pain at the OAI 48-month visit. Symptomatic radiographic OA (SOA) required that at least one knee had both ROA and frequent knee pain. Anyone with a total knee replacement was classified as having SOA.

We performed logistic regression analyses where the predictor was running any time in life and running in the specific age ranges. The outcomes were ROA, frequent knee pain, and SOA; adjusted analyses included covariates age, sex and BMI.

Results: 2439 participants were included, 55% were female, mean age was 64.7 (9.0) years and BMI was 28.5 (4.9) kg/m^2. 28% ran at some time in their lives; of those, 49%, 31%, 15% and 5% identified running in 1, 2, 3, and 4 of the time periods respectively. From lowest to highest BMI tertile, 35%, 28%, and 24% were runners at any time in life.

Table: Odds Ratios of Prevalent Symptomatic Knee Osteoarthritis (SOA) for Runners compared to Non-Runners

Running Time Period	Prevalence of SOA	Unadjusted Odds Ratios	Adjusted Odds Ratios*
Any time in Life			
No (n = 1528)	29.3%	Referent	Referent
Yes (n = 626)	22.7%	0.84 (0.76 – 0.94)	0.89 (0.79 – 1.00)
Ages 12 – 18 years old			
No (n = 1924)	27.7%	Referent	Referent
Yes (n = 212)	23.6%	0.81 (0.58 – 1.12)	0.94 (0.66 – 1.34)
Ages 19 – 34 years old			
No (n = 1806)	28.3%	Referent	Referent
Yes (n = 332)	22.0%	0.71 (0.54 – 0.94)	0.78 (0.58 – 1.05)
Ages 35 – 49 years old			
No (n = 1794)	28.2%	Referent	Referent

Yes (n = 374)	22.5%	0.74 (0.56 – 0.97)	0.85 (0.63 – 1.13)
Ages > 50 years old			
No (n = 1881)	28.2%	Referent	Referent
Yes (n = 221)	22.2%	0.73 (0.52 – 1.01)	0.85 (0.60 – 1.20)

*Adjusted for Age, Sex, and BMI.

For outcomes of frequent knee pain and ROA, the results were similar to that of SOA.

Conclusion: Our findings suggest an exposure to non-elite running at any time in life is not associated with a higher odds of prevalent ROA, knee pain, and SOA. Those with the lowest BMI were most likely to identify running as a habitual activity. These findings were observed in a cohort recruited from the community not based on elite running status making these findings potentially more applicable to a broader population. Non-elite running at any time in life does not appear detrimental, and may be protective of SOA.

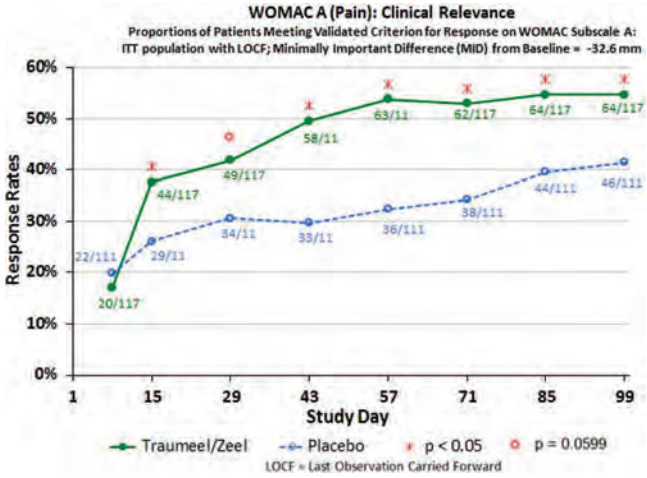
A Multi-Center Double-Blind, Randomized, Controlled Trial (db-RCT) to Evaluate the Effectiveness and Safety of Co-Administered Traumeel® (Tr14) and Zeel® (Ze14) Intra-articular (IA) Injections Versus IA Placebo in Patients with Moderate-to-Severe Pain Associated with OA of the Knee.

Carlos Lozada[1], Eve del Rio[2], Donald Reitberg[3], Robert Smith[3], Charles Kahn[4] and Roland W. Moskowitz[5]. [1]University of Miami Miller School of Medicine, Miami, FL, Miami, FL, [2]Rio Pharmaceutical Services, LLC, Bridgewater, Afghanistan, [3]Rio Pharmaceutical Services, LLC, Bridgewater, NJ, [4]South Florida Rheumatology, Hollywood, FL, [5]University Hospitals Case Medical Center, Cleveland, OH.

Background/Purpose: Tr14 & Ze14 is a combination of dilute biological and mineral extracts administered IA for painful knee OA. In response to clinician impressions of positive outcomes, a db-RCT to assess efficacy and safety compared to IA saline was deployed in the US.

Methods: Pts with moderate-to-severe chronic knee OA were randomized to 3 weekly IA injections of either Tr14 & Ze14 or saline by clinical investigators experienced with use of the IA injection route. The primary efficacy variable was change in knee pain from Baseline to End-of-Study (Week 17) as measured by the WOMAC OA Pain Subscale (Section A, 1–5) 100 mm VAS. Secondary measures included Total WOMAC and subscores for stiffness (B), and physical function (C), change in pain following a 50 ft walk (100 mm VAS), patient and physician global assessments. Clinical relevance was assessed by comparing proportions of patients with reductions from baseline in WOMAC A scores greater than a validated benchmark Minimal Clinically Important Difference (MCID). This was chosen as −32.6 mm (the most conservative value) based on a study of outpatients with knee or hip OA where WOMAC VAS MCIDs ranged from −7.9mm to −32.6mm [see reference 59 Tauback et al., *Ann Rheum Dis.* 2005; 64(1):29–33 in the description of the WOMAC index published by ACR]. Safety was assessed by monitoring of vital signs, physical examinations of the target knee, adverse events and concomitant medications.

Results: 232 patients were randomized and treated (All Tr14 & Ze14, n=119, All Placebo, n=113; Intention-to-Treat (ITT) Tr14 & Ze14, n=117, Placebo, n= 111). Treatment arms were well balanced across demographic and baseline characteristics. Tr14 & Ze14 did not discriminate for WOMAC A Pain as expected after only 1 of 3 injections on Day 8 (p=0.3715), but subsequently was significantly different (p<0.05) on Days 15, 43, 57, 71, 85 and 99 (primary endpoint day), and approached significance on Day 29 (p=0.0686). Logistic regressions showed the proportion of MCID responders was not significant on Day 8. As this was an expected finding, it served as a no-effect internal-model-validation. Tr14 & Ze14 was significantly different (p<0.05) on all subsequent days except Day 29 (approached significance, p=0.0599, Figure 1). 50' walk pain was similarly discriminating as was the physician global assessment. Total WOMAC and subscores B&C were directionally consistent with WOMAC A. There were no related SAEs. AEs were generally mild and unrelated to treatment. Local knee-related AEs, lab assessments, ECGs and vital signs were unremarkable and similar between treatments.



Conclusion: Tr14 & Ze14 provided statistically significant and clinically relevant pain relief on days 15 to 99 in comparison to placebo. In this double-blind, randomized, controlled trial, a biological/mineral multi-extract combination was shown to be a safe and effective treatment for pain in moderate-to-severe knee OA.

Exercise Therapy and/or Manual Therapy for Hip or Knee Osteoarthritis: 2-Year Follow-up of a Randomized Controlled Trial.

J. Haxby Abbott[1], Cathy Chapple[1], Daniel Pinto[2], Alexis Wright[3] and Jean-Claude Theis[1]. [1]University of Otago, Dunedin, New Zealand, [2]Northwestern University, Chicago, IL, [3]High Point University, High Point, NC.

Background/Purpose: Although both exercise therapy and manual therapy have evidence supporting their effectiveness in people with hip and knee osteoarthritis (OA), few clinical trials have reported their incremental effectiveness compared with usual medical care, or their long-term effects.

Methods: In this randomized controlled trial with 2-year follow-up, adults meeting the American College of Rheumatology criteria for hip or knee OA were randomly allocated to receive either a] exercise therapy; b] manual therapy; c] combined exercise therapy and manual therapy; or d] no trial intervention in addition to usual medical care. Groups a-c were provided 10 treatment sessions: 7 sessions within the first 9 weeks plus 3 booster sessions (2 at 4 months and 1 at 13 months). Assessors blinded to group allocation reassessed participants at 2 years. The primary outcome measures were the Western Ontario and McMaster (WOMAC) osteoarthritis index (24 questions, 0–10 scale, total range 0–240) and physical performance tests (timed up-and-go, 40m fast-paced walk, 30 second sit-to-stand).

Results: 186 (90.3%) of 206 participants recruited were retained at 2 years follow-up. At baseline, mean age was 66 years (range 37 to 92) and mean WOMAC was 100.8 (SD 53.8). Missing data were replaced using multiple imputation. Intention-to-treat analysis of covariance (ANCOVA) showed improvements in WOMAC at 2 years were superior for all three intervention groups compared with the usual care group (2-sided p<0.05). Participants receiving exercise therapy in addition to usual care showed gains of 31.7 WOMAC points (95% CI 10.0, 53.3); effect size 0.57 (Cohen's d; 95% CI. 17,. 97). Participants receiving manual therapy in addition to usual care showed gains of 30.1 (8.9, 51.3); effect size 0.55 (.16,. 94). Participants receiving combined exercise therapy and manual therapy in addition to usual care did not meet the *a priori* threshold for clinical significance (28 points), but were 26.2 (6.1, 46.3) WOMAC points better than usual care only, for a clinically significant effect size of 0.52 (.11,. 91). The exercise therapy group showed greater mean changes on most physical performance tests than did the other groups.

Conclusion: Both exercise physiotherapy and manual physiotherapy provided incremental benefit over usual care alone at 2 years follow-up. Physical performance test outcomes significantly favoured the exercise therapy group.

New Insights into the Primary Care Osteoarthritis Consultation with Implications for Practice. Zoe Paskins, Tom Sanders, Peter Croft and Andrew Hassell. Keele University, Keele, United Kingdom.

Background/Purpose: Osteoarthritis (OA) is the commonest long term condition in primary care. Existing international guidance suggests that much can be done to improve patient outcomes but existing research suggests doctors and patients are pessimistic about OA treatment. How important is the primary care consultation in shaping and influencing this incongruity? Our study used innovative methods, a combination of video recorded consultations and post consultation interviews using video to prompt recall, to uncover what happens when patients with OA present to their General Practitioners (GPs). The study took place in the context of a programme of translational research and also aimed to characterise any unmet patient need to which interventions could be targeted.

Methods: With ethical approval, 15 GPs consented to have two routine consultation sessions video recorded. GP consultations with 190 consenting patients aged ≥ 45 were video recorded. 20 consultations contained reference to OA, and 17 of these patients and their GPs (n=13) consented to participate in post consultation interviews, during which the video was played to stimulate recall. Analysis involved comparing and contrasting patient and GP interviews with the matched consultation findings, using thematic analysis. The results in this abstract relate predominantly to the consultation findings.

Results: Four overarching themes emerged from analysis: complexity, heterogeneity, dissonance and the lack of a biomedical construct for OA. OA arises in the primary care consultation in complex contexts of multimorbidity, multiple and varied patient agendas which are often not explicit, and against a background of clinician agendas including time pressures, multiple guidelines and service commissioner requirements. Dissonance between doctors and patients was both observed and reported and was often underpinned by patient perception of lack of empathy and validation of their symptoms. Doctors and patients favour a 'lay' construct of OA where joint pain is seen as a normal part of life; this influences doctor and patient behaviour and acts as a significant barrier to formal recognition and hence treatment of the condition.

Conclusion: OA appears to be experiencing an identity crisis, with doctors and patients uncertain, (both consciously and subconsciously), of what constitutes OA and when to use the term 'osteoarthritis'. Further work is needed to establish whether primary care should adopt a more biomedical construct of OA in order to bring OA more in line with other long term conditions such as cancer or heart disease, which have clearer clinical pathways. The need for public health messages regarding OA and optimal models of primary care for these patients also needs to be explored.

High Dose Aspirin for Treating Kawasaki Disease – Outdated Myth or Effective Aid? Gil Amarilyo[1], Yael Koren[2], Dafna Brik Simon[1], Maskit Bar-Meir[3], Hilla Bahat[4], Mona Hanna Helou[5], Amir Mendelson[6], Yackov Berkun[7], Eli Eisenstein[7], Yonatan butbul Aviel[5], Galia Barkai[8], Yoav Bolkier[8], Shai Padeh[8], Philip J. Hashkes[3], Riva Brik[5], Liora Harel[1] and Yosef Uziel[6]. [1]Schneider Children's Medical Center of Israel, Petach Tikvah, Israel, [2]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [3]Shaare-Zedek Medical Center, Jerusalem, Israel, [4]Assaf Harofeh Medical Center, Zerifin, Israel, [5]Rambam Medical Center, Haifa, Israel, [6]Meir Medical Center, Kfar Saba, Israel, [7]Hadassah Hebrew University Medical Center, Jerusalem, Israel, [8]Sheba Medical Center, Tel-Hashomer, Israel.

Background/Purpose: Kawasaki disease (KD) is generally treated with intravenous immunoglobulin (IVIG) together with high anti-inflammatory doses of acetyl salicylic acid (ASA), which is subsequently switched to low, anti-thrombotic dose ASA. However, there is still no evidence whether adding high dose ASA to IVIG increases the efficacy of the latter, especially concerning coronary artery outcome. We aimed to compare the efficacy and safety of IVIG+ anti-inflammatory high dose ASA regimen to IVIG with low dose ASA in a multicenter, national, retrospective study.

Methods: Medical record review of KD patients from our Pediatric Rheumatology Study Group units was conducted. Some hospitals do not use anti-inflammatory high dose ASA routinely, but rather add low dose ASA therapy to IVIG. Demographic data, clinical manifestations, coronary involvement, ASA and IVIG doses and adverse events were recorded. The primary efficacy outcome was defined as coronary aneurism 2–4 weeks after fever onset. Secondary outcomes were time from beginning of therapy to fever resolution and disease recurrence (defined as recurrence of fever after >72 hours). High dose and low dose ASA groups were compared using the Student's t-test for continuous variables and the Pearson Chi-square test for categorical variables.

Results: 336 KD patients, 287 in the high dose ASA group and 49 in the low dose ASA group were included. There were no demographic, clinical, or laboratory differences between the groups. In the high dose ASA group, 8% had coronary aneurisms, while no aneurisms were reported in the low dose ASA group ($P<0.2$). Regarding mild coronary findings, 22.8% of the high dose ASA group developed coronary ectasia 2–4 weeks after KD onset, compared to 3.6% in the low dose ASA group ($p<0.02$). No significant statistical differences were noted between the groups in time until fever resolution in days (high dose ASA 0.77 ± 1.84; low dose ASA 1.1 ± 3.34; $P=0.34$) or in KD recurrence (high dose ASA 32/287 (11%); low dose ASA 7/49 (14%); $P=0.58$). The need for use of rescue medications was similar in both groups. The number of adverse events in both groups were similar ($P=0.86$).

Conclusion: The efficacy and safety of treatment with IVIG and low-dose ASA was similar to that of IVIG and high dose ASA in patients with KD. We suggest that the routine use of high-dose ASA in addition to IVIG, will be re-evaluated in a prospective controlled study.

Clinically Inactive Disease in Juvenile Dermatomyositis – a Proposed Revision to the Pediatric Rheumatology International Trials Organisation Criteria. Beverley Almeida[1], Raquel Campanilho-Marques[2], Katie Arnold[2], Lucy R. Wedderburn[3], Clarissa A Pilkington[1] and Kiran Nistala[4]. [1]Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom, [2]UCL Institute for Child Health, London, United Kingdom, [3]UCL, UCLH, GOSH NHS Trust, London, United Kingdom, [4]University College London, London, United Kingdom.

Background/Purpose: Juvenile dermatomyositis (JDM) affects 3 children/million/year with myositis and skin disease being the typical features. The Pediatric Rheumatology International Trials Organisation (PRINTO) have recently established criteria to classify JDM patients who are clinically inactive by meeting at least 3 out of the following 4 conditions – Creatine Kinase (CK) ≤150 U/L, Childhood Myositis Assessment Score (CMAS) ≥48, Manual Muscle Testing of 8 groups (MMT8) ≥78 and physician global Visual Analogue Scale (PGA) ≤0.2. CK, CMAS and MMT8 all measure muscle involvement, only PGA includes skin or other organ involvement. The hypothesis that these criteria may fail to detect patients who have active skin disease but normal muscle parameters was tested. The aim was to demonstrate the prevalence of clinically inactive disease in the UK JDM Cohort and Biomarker Study and to identify whether skin disease is still present in these patients on the basis of the PRINTO criteria.

Methods: Data were analysed from children who were recruited and met Bohan-Peter criteria. Data from patient episodes (either a clinic visit or hospital admission) were assessed using the PRINTO criteria. Using the PRINTO rules stipulating 3 of 4 criteria are required, all data entries were divided into 2 groups based on the criterion that was omitted. Each case was analysed to determine whether skin disease was present or absent.

Results: 682 data entries (DE) from 321 patients were identified as clinically inactive. 255 (37.4%) of these DE (119 patients) met all 4 criteria. 21.2% of DE had skin rash and 10.5% had nailfold changes (Table 1) at the time of assessment. 427 of the total DE (202 patients) met 3 of the 4 criteria. Of these, 320 (74.9%) had clinically inactive based on the 3 muscle criteria (PGA was not met). 61.6% of this group had ongoing skin rash present. Among the 107 remaining DE, which were clinically inactive by 3 criteria of which one was PGA, the frequency of skin changes was lower. The differences between the 3 groups were statistically significant in terms of rash (χ2 111.5, p<0.0001), nailfold changes (χ2 65.5, p<0.0001) and calcinosis (χ2 22.07, p<0.0001).

Table 1: Frequency of skin changes in JDM patients meeting PRINTO criteria (number of episodes, % in brackets)

No. of criteria met (DE=data entries, n=number of patients)	Rash	Nailfold changes	Calcinosis
All 4 criteria met (255 DE, n 119)	54 (21.2)	27 (10.5)	19 (7.5)
3 criteria met, but PGA not met (320 DE, n 131)	197 (61.6)	114 (35.6)	60 (18.8)
3 criteria met of which one was PGA (107 DE, n 71)	25 (23.3)	9 (8.4)	6 (5.6)

Conclusion: This study is one of the first to test the PRINTO criteria in a large independent cohort of JDM patients. When clinically inactive disease is defined by "muscle-based" criteria, without PGA, there is a greater frequency of skin disease. As a revision, we propose that PGA should be included as an essential criterion together with 2 of the 3 muscle criteria. This would prevent skin disease being overlooked in the clinical assessment which is important since it is often recalcitrant to treatment and may be associated with poor long-term disease outcomes. A revision of the criteria would need testing in independent cohorts.

Predictors of Relapse after Discontinuing Systemic Treatment in Childhood Autoimmune Chronic Uveitis. Gabriele Simonini[1], Claudia Bracaglia[2], Marco Cattalini[3], Andrea Taddio[4], Alice Brambilla[1], Cinzia DeLibero[5], Denise Pires Marafon[6], Roberto Caputo[5] and Rolando Cimaz[1]. [1]Anna Meyer Children's Hospital-University of Firenze, Florence, Italy, [2]Division of Rheumatology, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy, [3]Pediatric Immunology and Rheumatology Unit, Brescia, Italy, [4]Institute of Child Health, IRCCS Burlo Garofolo, University of Trieste, Trieste, Italy, [5]Anna Meyer Children's Hospital, Florence, Italy, [6]Ospedale Pediatrico Bambino Gesù, IRCCS, Roma, Italy.

Background/Purpose: Information regarding the natural clinical history of a child on systemic treatment due to auto-immune chronic uveitis would be helpful in driving duration therapy. Aim of our study was to assess the time on remission after discontinuing systemic therapy in a retrospective, comparative, multi-centre, cohort study of childhood non-infectious chronic uveitis.

Methods: 40 patients (30 F, 10 M; median age: 11.6 years, 31 JIA, 9 Idiopathic Chronic Uveitis [IdCU]) from 4 different paediatric rheumatology centres, with previously refractory, vision threatening, non-infectious *inactive* uveitis, which discontinued all related treatments for at least 3 months were enrolled. 23 children previously received Methotrexate, 17 TNF inhibitors. Primary outcome was to assess, once remission was achieved, the time on remission up to the first relapse after discontinuing treatment. Time to remission once systemic not-steroid treatment was started, time to steroid discontinuation, number of relapses before achieving remission and time on remission on therapy before discontinuing all treatments were also considered. Statistical Analysis. Mann–Whitney U-test, Wilcoxon signed-rank test for paired samples, c-square tests, and Fisher's exact test, when appropriate, were used to compare data. Pearson and Spearman correlation tests were used to determine correlation coefficients for different variables. In order to identify predictors of outcome Cox regression model and Kaplan–Meier curves were constructed, each one at mean of enter ed covariates.

Results: Median follow-up time on remission without treatment was 9 months (range 1–59 months). At last available follow-up after 1 year from discontinuation of treatment [49 months, range 15–168], 11/39 (28.2%) children maintained a complete remission over a median period of 18 months. At 49 months of follow-up, 6/8 children with IdCU (75%) compared to 5/31 children with JIA (16.1%) were still on remission without treatment (p<0.003). A higher probability of maintaining uveitis remission after discontinuing treatment was shown in IdCU compared to JIA group (Mantel-Cox c2 7.62, p<0.006) (Figure). ANA positivity was associated with a higher probability of flare in overall population (Mantel-Cox c2 6.68, p<0.01), but not in sub-analysis limited to JIA (Mantel-Cox c2 0.78, p=0.37) and IdCU (Mantel-Cox c2 1.18, p=0.27). None clinical variable, including time on remission on therapy, total length of treatment, and type of treatment, resulted significant predictors of long-lasting remission without therapy.

Conclusion: Even if limited to a relatively small group in retrospectively study design, our results suggest that type of disease, rather than the type or the length of treatment, can predict different duration of uveitis remission without systemic therapy.

2902

The Health Status of Patients with Juvenile Idiopathic Arthritis (JIA) Significantly Worsens after Transfer from Pediatric to Adult Care. Kirsten Minden[1], Jens Klotsche[2], Martina Niewerth[2], Angela Zink[3] and Gerd Horneff[4]. [1]Charité University Medicine, Berlin, Germany, [2]German Rheumatism Research Center, Berlin, Germany, [3]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany, [4]Asklepios Klinik Sankt Augustin, Sankt Augustin, Germany.

Background/Purpose: A minority of patients with polyarticular JIA enter adulthood in drug free remission. Thus, patients are in need of care beyond adolescence. There is little information how patients' health status changes after discharge from pediatric care. We therefore investigated changes in the patients' health status before and after the transfer from pediatric to adult health care.

Methods: Data from patients were considered who were prospectively followed in the JIA biologic register BiKeR and in the follow-up register JuMBO for at least two additional years**.** Disease activity (physicians' global assessment on a numerical rating scale 0–10 [NRS]) and patient-reported outcomes (PROs; i.e. global assessment of disease activity, pain, overall well-being on NRS, functional status by CHAQ/HAQ) were assessed from inclusion in BiKeR up to the last follow-up in JuMBO.

Results: The eligible 654 patients were enrolled in BiKeR with a mean disease duration of 5.6 years (ys) at the start of a biologic (66.8%) or non-biologic DMARD (33.2%). The whole observation period of patients comprised 8.2 ys. During the years (mean 2.6) in pediatric care, i.e. from enrollment until the last visit in BiKeR, all PROs significantly improved: overall well-being from 4.5 to 2.1 (mean), pain level from 4.6 to 1.9, functional status (CHAQ-score) from 0.75 to 0.35. In contrast to this trend towards a steady improvement in patients' health state in pediatric care, PROs significantly worsened after discharge from pediatric care ($p < 0.001$). At the last follow-up in JuMBO, when patients were at the age of 23 ys (mean) and had a disease duration of 14.2 ys, the mean disease activity was 2.6, pain level 2.8, and overall well-being 2.9. At that time, more patients had an active disease (NRS0; 71 vs. 57%) and reported pain (78 vs. 56%) and restrictions in overall well-being (86 vs. 58%) than at the last visit in pediatric care.

Adult health care providers rated the patients' disease activity at first documentation in JuMBO lower than pediatric rheumatologists at the last visit in pediatric rheumatology care (1.8 vs. 2.1), which is in contrast to patients' self-reports. They also rated the disease activity lower than the patients did at last observation in JuMBO (1.9 vs. 2.6). The correlation between physician and patient scores for disease activity was better during pediatric than adult care (0.56 vs. 0.51).

Conclusion: The health state of patients with long-standing JIA significantly worsens after discharge from pediatric care. The reasons for this have to be explored. In addition, there are larger discrepancies between physician- and patient-reported outcomes in adult care than in pediatric care.

Early Outcomes in Pediatric Antineutrophil Cytoplasmic Antibody (ANCA) Associated Vasculitis (AAV). Kimberly Morishita[1], Susanne Benseler[2], Rae S.M. Yeung[3], Thomas Mason II[4], Dawn Wahezi[5], Kenneth N. Schikler[6], Erica F. Lawson[7], Susan Nielsen[8], Sirirat Charuvanij[9], Paul Dancey[10], Susan Shenoi[11], Linda Wagner-Weiner[12], Angelyne Sarmiento[1], David A. Cabral[1] and For the PedVas Initiative[1]. [1]BC Children's Hospital and University of British Columbia, Vancouver, BC, [2]Department of Pediatrics/University of Calgary, Calgary, AB, [3]The Hospital for Sick Children and University of Toronto, Toronto, ON, [4]Mayo Clinic, Rochester, MN, [5]Children's Hospital at Montefiore, Bronx, NY, [6]Univ of Louisville Schl of Med, Louisville, KY, [7]University of California, San Francisco, San Francisco, CA, [8]Rigshospitalet, Copenhagen, Denmark, [9]Siriraj Hospital, Bangkok, Thailand, [10]Janeway Children's Hospital, St. John's, NL, [11]Seattle Childrens Hospital, seattle, WA, [12]University of Chicago Hospital, Chicago, IL.

Background/Purpose: Childhood AAV is rare and outcome studies are limited. The PedVas Study is an international initiative collecting clinical data (to A Registry of Childhood Vasculitis -ARChiVe) and biological samples from children with primary systemic vasculitis. This is the largest study to date reporting early outcomes in pediatric AAV.

Methods: Patients diagnosed with granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), eosinophilic granulomatosis with polyangiitis (EGPA) and ANCA-associated pauci-immune glomerulonephritis before 18 years of age and with 12-month follow up data were included. Diagnoses were verified by applying a pediatric modification of the European Medicines Agency algorithm for classifying AAV (incorporating EULAR/PRINTO/PRES classification criteria). Descriptive statistics were used for baseline characteristics, remission-induction medications, and rates of remission at 4–6 months (post-induction) and at 12-months. Remission (on or off medications) was defined by a Pediatric Vasculitis Activity Score (PVAS) of 0. Relapse was defined as recurrence or new onset of disease activity (an increase in PVAS $\geq$1, from 0) attributable to active inflammation. Major relapse was defined as the recurrence, or new onset of potentially organ-or life-threatening disease activity requiring increased treatment, additional to corticosteroids (CS). Other relapses were considered minor.

Results: Among 40 patients eligible for inclusion in June 2014, 39 had verified AAV (35 GPA, 3 MPA, 1 EGPA), one patient became "unclassified" following verification. Median age at diagnosis was 12.4 years. 64% of patients were female. Median PVAS score at the time of diagnosis was 14 (IQR 11,19). 20 patients (51%) achieved remission 4–6 months after diagnosis and 25 patients (64%) were in remission at 12-months. 6 relapses occurred in 20 (30%) patients following remission, all were minor. At 12-months two patients were dialysis dependent and two patients had received renal transplants. No deaths occurred.

Primary treatments used for remission induction were: cyclophosphamide (CYC) in 29 (74%), methotrexate in 8 (21%), and rituximab (RTX) in 2 (5%). Plasmapheresis was used in conjunction with CYC or RTX in 8 patients. The most common maintenance treatments were azathioprine (38%), methotrexate (36%), and mycophenolate mofetil (18%). 37 (95%) of patients received CS in addition to their primary treatments. At 12-months, 22 patients (56%) were off (n=14) or on a low dose $\leq$ 0.1mg/kg/day (n=8) CS.

Following time-of-diagnosis, 20 patients required 31 hospitalizations: 16 in relation to underlying disease; 7 due to infection; 7 due to health problems unrelated to vasculitis; 1 due to medication effects.

The median score of a pediatric modification of the vasculitis damage index (pVDI) score completed for 21 patients at 12-months was 1 (range 0–5).

Conclusion: A significant proportion of children with AAV do not achieve remission following remission induction treatment, or at 12-months despite aggressive therapy. Compared to adults with AAV, remission rates may be lower in children and about half of children remain on corticosteroids at 12 months.

Clinical and Radiological Features of Down's Arthropathy. Charlene Foley, Orla Killeen and Emma Jane MacDermott. The National Centre for Paediatric Rheumatology, Dublin, Ireland.

Background/Purpose: The 'Arthropathy of Down syndrome' was first described in 1984. Three decades on we still have limited literature on the clinical & radiological features of this arthritis, despite the fact that it is thought to be 3–6 times more common than Juvenile Idiopathic Arthritis (JIA) in the general paediatric population. Down's Arthropathy (DA) is rarely recognised at onset, & remains under-diagnosed & largely under-reported in this population group. Ireland has one of the highest Trisomy 21 (T21) birth rates in Europe (1/547), and therefore provides an ideal setting for such a study.

Research Questions

1. What are the clinical & radiological features of DA?
2. Is DA missed, leading to a delay in diagnosis?

Objectives

To perform a musculoskeletal examination on children with T21, aged 0–18 years & document;

1. Presence of features to suggest old and/or present arthritis.
2. Radiological findings.

Methods: From May 2013 to September 2014, Children with T21 (aged 0–18 years) were invited to attend a screening clinic. Screening involved completion of a health questionnaire & musculoskeletal examination. Suspected cases of DA were invited to attend the National Centre for Paediatric Rheumatology (NCPR) for investigation, treatment & follow-up as per normal clinical practice.

Results: 370 children with T21 enrolled in the study, 56% Male. 17 new cases of DA were detected, only 3 (17.6%) of which were referred with suspected arthritis. In total, 28 children with DA now attend the NCPR for management of their arthritis, the largest cohort ever reported in the literature. We estimate the Point Prevalence of DA in Ireland to be 17–18/1000. For

comparison, the UK Prevalence of JIA is 1–2/1000. Table 1 compares characteristics of our DA cohort to a JIA comparison group.

Table 1: Comparison of Study Characteristic by Diagnosis

Characteristic		DA (n=28)		JIA (n=21)		p value
Small Joint Involvement	Mean (sd)	4.46 (1.95)		3.05 (2.29)		p<0.01
Time to Diagnosis	Mean (sd)	1.71 (1.47)		0.74 (0.86)		p<0.05
Characteristics		**n**	**(%)**	**n**	**(%)**	**p value**
Gender	Male	14	50.0	11	52.4	ns
	Female	14	50.0	10	47.6	
Rx MTX		8	28.5	7	33.3	ns
MTX Nausea		6	75.0	1	14.3	p<0.05

Features of DA – Summary of our findings

- Polyarticular Rheumatoid Factor negative presentation (69% of DA cohort).
- Finger involvement (77% of DA cohort) – significantly greater proportion than seen in the JIA comparison group.
- Erosive changes noted on X-Ray at presentation (27% of cohort).
- Methotrexate nausea common, but a good response to steroid intra-articular joint injections observed.
- General lack of awareness about the increased risk of arthritis in children with T21.

Conclusion: Children with T21 are at increased risk of developing arthritis, however there is often a delay in diagnosis. Reasons for this are multifactorial and include, failure of the child to express and localise pain, and changes in mobility attributed to the Down syndrome rather than a Rheumatological cause. Early diagnosis & treatment of DA is key to preventing irreversible joint destruction & long-term functional impairment. Methotrexate nausea is a significant barrier to successful treatment of DA with this DMARD. However, a good response to steroid joint injections has been observed. We advocate that children with T21 have an annual musculoskeletal assessment as part of their Health Screening Programme.

The IL-6/Th17 Axis Promotes Autoantibody-Associated Autoimmune Valvular Carditis in Mice. Jennifer L. Auger, Brianna J. Engelson, Yaya Wang, Erik J. Peterson and Bryce A. Binstadt. University of Minnesota, Minneapolis, MN.

Background/Purpose: Autoimmune valvular carditis occurs in patients with systemic lupus erythematosus, rheumatoid arthritis and rheumatic fever, but the pathogenic mechanisms remain incompletely defined. Spontaneous autoimmune valvular carditis develops in the K/BxN T cell receptor transgenic mouse model of autoantibody-dependent inflammatory arthritis. CD4 T helper (Th) cells and macrophages cooperate to promote carditis in this model. We investigated which effector Th cell population was the predominant driver of cardiovascular pathology in K/BxN mice.

Methods: We first used RT-PCR to measure key cytokine transcript levels in cardiac valves of arthritic K/BxN mice and controls. We then used anti-cytokine blocking antibodies and gene knockout mice to determine which Th effector cells and cytokines were most critical for valve inflammation.

Results: We found increased expression of the genes encoding the Th17 differentiation factor IL-6 and IL-17A itself in K/BxN mitral valves relative to controls; IL-4 and IFNγ transcript levels were not different. Antibody blockade of IL-6 or IL-17A reduced the severity of valve inflammation, whereas blocking IL-4 had no effect. Genetic deficiency of IFNγ did not affect carditis severity. K/BxN mice lacking the key Th17 transcription factor RORγt had delayed onset of arthritis and were protected from valvular carditis.

Conclusion: Th17 cells are key drivers of autoimmune valvular carditis in K/BxN mice. We suggest a model in which autoantibodies engage Fc receptors on macrophages, leading to IL-6 production, which in turn promotes the differentiation of valve-infiltrating Th17 effector cells. Our results provide new insight into the mechanisms of valvular carditis in systemic autoantibody-mediated rheumatic diseases. More broadly, these findings may help guide the selection of therapies to reduce cardiovascular morbidity and mortality among patients with rheumatoid arthritis and systemic lupus erythematosus.

Systemic Delivery of Short Hairpin RNA Targeting Calcium Release-Activated Calcium Channel 3 Down-Regulates Severity of Collagen-Induced Arthritis. Shuang Liu[1], Takeshi Kiyoi[2], Shohei Watanabe[3] and Kazutaka Maeyama[1]. [1]Informational Biomedicine, Ehime University Graduate School of Medicine, Toon-shi, Ehime, Japan, [2]Integrated Center for Sciences, Ehime University, Ehime, Japan, [3]Japan Community Health Care Organization Uwajima Hospital, Ehime, Japan.

Background/Purpose: In recent years, one widespread and potentially important Ca^{2+} channel, store-operated Ca^{2+}-release-activated Ca^{2+} (CRAC) channel is raised in drug discovery for rheumatoid arthritis (RA). Ca^{2+} entry through CRAC channels drives exocytosis, stimulates mitochondrial metabolism, activates gene expression and promote cell growth and proliferation in non-exitable cells. Downregulation of the CRAC channels lead to irregular functions of T cells, B cells and osteoclasts, which contribute to RA pathogenesis. The present study was undertaken to investigate the feasibility and efficiency of partially regulation of the Ca^{2+} influx via CRAC channel by CRACM3 gene-silencing for the treatment of RA.

Methods: We evaluated the therapeutic potential of CRACM3 gene-silencing by systemic delivery of lentivirus expressing CRACM3-shRNA (Lenti-M3shRNA) in a collagen-induced arthritis (CIA) mouse model. The inflammatory response was assessed by measuring the levels of inflammatory cytokines in joint and serum. The cytokine profile of T cells stimulated with autoantigen was also determined. Mature osteoclast function was analyzed using tartrate-resistant acid phosphatase (TRAP) staining and pit formation assay.

Results: The intraperitoneal injection (10^9 particles/7 days) of Lenti-M3shRNA was highly effective in treating CIA. Ca^{2+} influxes in splenocytes, thymocytes, and synovial cells were partially blocked by gene-silencing of CRACM3. CIA mice showed significant regression of the disease after Lenti-M3shRNA treatment. The autoimmune response, which was assessed using self-reactive Th1 cell activity and autoantibody production, was significantly suppressed by M3shRNA administration. Low level of the resorptive capacity in mature osteoclasts was also observed in Lenti-M3shRNA treated CIA mice according to the results of TRAP staining and pit formation assay.

Conclusion: Our findings indicate that *in vivo* gene-silencing CRACM3 by systemic delivery of Lenti-M3shRNA may have beneficial therapeutic effects on RA. Our findings provide valuable insight into the potential ways that CRACMs could contribute to RA pathogenesis and support the idea that targeting CRAC channels might offer an effective strategy for the treatment of RA.

Loss of microRNA-146a Exacerbates Inflammatory Arthritis. Victoria Saferding[1], Antonia Puchner[1], Eliana Goncalvesalves[1], Birgit Niederreiter[1], Silvia Hayer[1], Gernot Schabbauer[2], Marije Koenders[3], Josef S. Smolen[1], Kurt Redlich[1] and Stephan Blueml[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University Vienna, Vienna, Austria, [3]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.

Background/Purpose: MicroRNA (MiR-) 146a is a key regulator of the innate immune response and has also been shown to suppress cancer development in myeloid cells. Elevated expression of miR-146a has been detected in synovial tissue of rheumatoid arthritis patients, but its role in the development of inflammatory arthritis is yet unknown.

Methods: We induced K/BxN serum transfer arthritis in wild type and miR-146a$^{-/-}$ mice. As a second inflammatory arthritis model we crossed miR-146a deficient into hTNFtg mice. Disease severity was assessed clinically and histologically in both arthritis models. Blood of arthritis animals was analyzed by flow cytometry. Serum cytokine levels were measured by Elisa.

Results: Absence of miR-146a leads to increased clinical signs of the induced serum transfer arthritis. In line, higher serum levels of the proinflammatory cytokines IL12 and TNF were measured in miR146a deficient mice compared to wt mice. When we crossed miR-146a$^{-/-}$ mice into hTNFtg mice, while detecting no clinical difference between hTNFtg and miR-146a/hTNFtg mice, we found a significant increase in circulating CD11b^{+} myeloid cells as well as CD11c^{+} dendritic cells in blood of miR-146a$^{-/-}$/hTNFtg mice compared to hTNFtg mice. Histological examination revealed a significant increase in synovial inflammation miR-146a$^{-/-}$/hTNFtg mice compared to hTNFtg mice. Even more striking, miR-146a$^{-/-}$/hTNFtg mice displayed a more than twofold increase in local bone destruction which was due to increased generation of osteoclasts in the tarsal joints of the mice. Measuring cytokine levels in serum, we show that IL-1β levels are increased in mice lacking miR-146a.

Conclusion: These data clearly demonstrate a negative regulatory role of the miR-146a in inflammatory arthritis. During arthritis, miR-146a is centrally involved in the regulation of proinflammatory cytokines as well as local bone destruction. These results identify an important anti-inflammatory role of miR-146a, which might possibly be exploited for therapeutic purposes.

Flip Deficiency in Dendritic Cells Promotes Spontaneous Arthritis Mediated By Reduced Treg and Increased Autoreactive CD4^{+}t Cells. Qiquan Huang[1], Harris R. Perlman[1], Robert Birkett[1], Renee E. Doyle[1], Deyu Fang[1], G. Kenneth Haines[2], William H. Robinson[3], Syamal K. Datta[1], Hyewon Phee[1] and Richard M. Pope[4]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Mount Sinai Hospital School of Medicine, New York, New York, NY, [3]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [4]Northwestern University Feinberg school of Medicine, Chicago, IL.

Background/Purpose: *Flip (CFLAR)* has been identified as a rheumatoid arthritis (RA) risk allele and is important in preventing death receptor mediated apoptosis of dendritic cells (DCs). To examine the *in vivo*role of Flip in DCs in maintaining immune homeostasis, mice deficient in Flip in conventional DCs were generated (DC-Flip-KO). The DC-Flip-KO mice spontaneously develop erosive, inflammatory peripheral arthritis, resembling rheumatoid arthritis (RA). These studies were conducted to define the mechanisms that contribute to the development of arthritis in these mice.

Methods: Immune cell phenotyping was performed by flow cytometry. DC function was examined by antigen presentation and T regulatory cell (Treg) induction. Thymic T cell development, selection and tolerance were examined. T cell autoreactivity was determined by the syngeneic mixed lymphocyte response *in vitro* and by adoptive transfer *in vivo*, monitored by dilution of CFSE labelled T cells. Treg function was examined by suppression of CD4^{+} T cell proliferation. Autoantibodies to joint components were identified by immunoblotting. DC-Flip-KO mice were crossed with *Rag*$^{-/-}$ to generate DC-Flip-KO-*Rag*$^{-/-}$double mutant lines and arthritis was evaluated. All data are analyzed comparing indicated genotypes in age and gender matched groups.

Results: CD11c-cre mediated Flip deficiency resulted in consistent reduction of the CD11c^{+}CD8α^{+} subset of DCs in central and peripheral lymphoid organs before or after the onset of arthritis. No defects in thymic central tolerance were identified, however, increased autoreactive CD4^{+} T cells and plasmablasts are identified in the lymph nodes draining the inflamed joints, and both were positively correlated with the severity of arthritis. The DC-Flip-KO mice possessed autoantibodies specific for joint components. Further, Tregs were reduced in the thymus and spleen of DC-Flip-KO mice in a setting of lymphopenia. In addition, the number of Tregs in the spleen inversely correlated with the severity of the arthritis and adoptive transfer of Tregs ameliorated joint inflammation. DCs isolated from the DC-Flip-KO mice effectively presented antigen but were deficient in promoting the induction of Tregs. Supporting the role of T and B cells, DC-Flip-KO-*Rag*$^{-/-}$ mice, which lack of both T and B cells, develop significantly milder and self-resolving arthritis compared with the DC-Flip-KO-*Rag*$^{+/-}$mice.

Conclusion: Flip plays a key role in the survival of the CD8α^{+}CD11c^{+} DC subset *in vivo*. The loss of this subset impairs the generation and/or maintenance of Tregs, which in turn permits the expansion of antoreactive CD4^{+}T cells and autoantibody producing B cells, resulting in autoimmune arthritis. Our observations suggest that the DC-Flip-KO mouse is a novel model of RA that may provide important insights and permit in depth interrogation of the pathogenesis of RA.

Tolerogenic Splenic IDO+ Dendritic Cells from the Mice Treated with Induced-Treg Cells Could Suppress Collagen-Induced Arthritis. Jie Yang[1], Huahua Fan[2] and Hejian Zou[1]. [1]Division of Rheumatology, Huashan Hospital, Fudan University, Shanghai 200040, China, Shanghai, China, [2]Blood Engineering Laboratory, Shanghai Blood Center, Shanghai 200051, China, Shanghai, China.

Background/Purpose: As well known, Foxp3+ regulatory T cells play a crucial role in maintaining immune tolerance. It was reported that TGF-β-induced Tregs (iTregs) could retain Foxp3 expression and immune suppressive activity in the collagen-induced arthritis (CIA). However, the mechanisms whereby transferred iTregs suppressed immune response, especially the interplay between iTregs and DCs *in vivo*, remained incompletely understood. In this study, whether splenic DCs were involved in iTreg-based suppression and how these DCs further inhibited CIA were determined.

Methods: *In vitro*, iTregs were induced by TGF-β and adoptive transferred into established CIA mice. After 7 days, splenic CD11c^{+}DCs were isolated, termed 'DC_{iTreg}'. The phenotype, the expression of cytokines and function-associated molecules, the immunogenicity and the suppression on CD4/CD8 T cell differentiation of DC_{iTreg} were assessed. To determine the suppression *in vivo*, 5×10^5 of DC_{iTreg} were re-infused into the new CIA mice. Clinical and histopathologic scores, cytokine and anti-CII antibody secretion in serum were analyzed. And it also was determined the expression of Foxp3 and function of Tregs after IDO^{+}DCs transferred. Additionally, the role of IDO in the inhibitory effect of DC_{iTreg} was determined by 1-MT blocking *in vitro*and in CIA mice.

Results: After iTregs adoptive transferred, isolated DC_{iTreg} exhibited a series of tolerogenic characteristics. Compared with splenic DCs isolated from CIA mice (DC_{CIA}), DC_{iTreg} expressed obviously lower levels of MHC molecule (IA-IE) and co-stimulatory molecules (CD80, CD86 and CD40). And IL-12p40 and IL-6 production by DC_{iTreg} were negligible, while high levels of IL-10 and TGF-β were expressed; especially enhanced level of IDO by DC_{iTreg} was detected, and CD11b^{+}DCs were found as a major contributor of IDO expression in iTreg-treated CIA mice. In the proliferation assay, DC_{iTreg} showed the poor ability to expand effector T cells and had the effective inhibitory potency. Meanwhile, after CD11b^{+}IDO$^{+}DC_{iTreg}$ re-infused, a remarkable anti-arthritic activity, improved clinical scores and histological end-points were found. Also, serological levels of TNF-α, IL-6, IL-17 and anti-CII antibodies showed significantly low and TGF-β production was high in the DC_{iTreg}-treated group. Conversely, DC_{CIA} could not suppress CIA completely. And IDO^{+}DCs could induce the generation and proliferation of functional Foxp3^{+}Tregs *in vitro* and in CIA mice. Moreover, DC_{iTreg}lost the inhibitory ability on CIA when they pretreated 1-MT.

Conclusion: These findings suggested that iTregs could inhibit CIA via tolerogenic splenic DCs formation. These tolerogenic splenic DCs could further effectively dampen the severity and progression of CIA in the IDO-dependent manner, which was associated with modulation of inflammatory cytokine and anti-CII antibody secretion and induction of new iTregs. Thus, the potential therapeutic effect of iTreg in CIA and RA is likely to be maintained, even enlarged by their effects on DCs *in vivo*.

Tofacitinib Facilitates the Expansion of Myeloid-Derived Suppressor Cells and Ameliorates Arthritis in SKG Mice. Keisuke Nishimura, Jun Saegusa, Fumichika Matsuki, Kengo Akashi, Goichi Kageyama and Akio Morinobu. Kobe University Graduate School of Medicine, Kobe, Japan.

Background/Purpose: Myeloid-derived suppressor cells (MDSCs) are a heterogeneous population of cells that are characterized by the co-expression of Gr1 and CD11b in mice. MDSCs suppress T cell responses by producing arginase I (Arg I) and inducible nitric oxide synthase (iNOS). Tofacitinib is a Janus kinase (JAK) inhibitor that inhibits JAK1 and JAK3. Tofacitinib currently represents a novel therapeutic for treating rheumatoid arthritis. However, the anti-rheumatic effects of tofacitinib, especially its influence on

myeloid cells, are not fully understood. The aim of this study was to evaluate the effects of the Janus kinase inhibitor tofacitinib on MDSCs in a mouse model of rheumatoid arthritis.

Methods: Arthritis was induced in SKG mice by zymosan A (ZyA) injection. MDSCs isolated from the bone marrow (BM) of donor arthritic SKG mice were adoptively transferred to recipient arthritic mice. In a separate experiment, tofacitinib was administered to SKG arthritic mice subcutaneously via osmotic pump, in some cases followed by injection of an anti-Gr1 monoclonal antibody (mAb). BM cells from untreated mice were cultured for 5 days with granulocyte/macrophage colony-stimulating factor (GM-CSF), with or without tofacitinib, and then analyzed by flow cytometry.

Results: The BM and spleens of ZyA-treated mice contained increased numbers of $CD11b^{+}Gr1^{+}$ MDSCs, whereas polymorphonuclear (PMN)-MDSCs ($CD11b^{+}Ly6G^{+}Ly6C^{low}$) were significantly increased in the spleen of ZyA-treated mice. The number of monocytic-MDSCs ($CD11b^{+}Ly6G^{-}Ly6C^{high}$) was also significantly increased in the BM of ZyA-treated mice, although they represented only a small proportion of the BM cells. The BM cells from ZyA-treated SKG mice also expressed higher levels of iNOS and Arg I compared to untreated SKG mice. The adoptive transfer of MDSCs to recipient arthritic mice reduced disease severity compared to the untreated controls. Continuous administration of tofacitinib significantly ameliorated the arthritic scores of SKG mice. Tofacitinib treatment significantly increased the numbers of total- and PMN-MDSCs in the BM of arthritic mice. Furthermore, the anti-arthritic effect of tofacitinib was abrogated when MDSCs were depleted by anti-Gr1 mAb. *In vitro*, tofacitinib facilitated the differentiation of BM cells to MDSCs, and inhibited their differentiation to dendritic cells. Moreover, tofacitinib-treated BM cells were incapable of enhancing T cell proliferation, compared to mock-treated BM cells.

Conclusion: MDSCs play crucial roles in the regulation of SKG arthritis, and a JAK inhibitor, tofacitinib, enhances their expansion. Our results suggest a novel mode of anti-arthritic action for tofacitinib and a critical role for JAKs in the differentiation of MDSCs.

Clinical Outcomes of Early RA after 7 Years – Does T2T Approach Overcome Delay of Therapy? Tuulikki Sokka[1], Hannu Kautiainen[2], Tuomas Rannio[3], Juha Asikainen[1] and Pekka Hannonen[1]. [1]Jyvaskyla Central Hospital, Jyväskylä, Finland, [2]Medcare Oy, Äänekoski, Finland, [3]Kuopio University Hospital, Kuopio, Finland.

Background/Purpose: Early vs. delayed referral/start of therapy within 3–4 months has been shown beneficial for outcomes in rheumatoid arthritis (RA) (Lard et al. AM J Med 2001, Gremese at al. ARD 2013, Ehrmann Feldman et al. Rheumatology 2013). However, in a real world setting, this applies for a minority of RA patients. In the FIN-RACo study, a delay of 4 months significantly influenced a 2-year remission rate in the monotherapy arm (remission rate was 11% vs 35%) while in the combination arm, 42% were in remission regardless of a delay indicating that early intensive therapy may overcome a delay (Möttönen et al. A&R 2002). Therefore, our aim was to study whether a delay of starting therapy in early RA affects long-term outcomes in a clinic with a T2T approach including preferring methotrexate based combinations over monotherapy, long-term low dose glucocorticoids over bridging, intra articular glucocorticoid injections to all swollen joints at every visit, patient education by specialist nurses, and routine monitoring including disease activity and self-reported outcomes.

Methods: A clinical database in a district of 275.000 population was analyzed for patients with a new diagnosis of RA in 1993–2013. Variables included demographics, clinical course, outcomes, medications and the date of first symptoms of RA, a question which was asked from the patient at the first visit and recorded in the database. Duration of symptoms (delay) at initiation of therapy was categorized as 0–3mo, 4–6mo, 7–12mo, 13–24mo, and >2yr. Outcome variables and medication data were available in 60–68% of patients at a mean of 7.3 years after diagnosis.

Results: In 1993–2013, 2374 patients (mean age 56yr, 67%F, 59%RF/CCP+) were diagnosed and treatment started with a median delay of 5.5mo (4.5mo in 2005 to 7.4 in 2003 with no trend of delay over years). Existing musculoskeletal disease and younger age were associated with longer delay, adjusted for sero+/−, gender, and year of diagnosis. Overall, 32%, 24%, 24%, 10%, and 10% of patients had a delay of 0–3mo, 4–6mo, 7–12mo, 13–24mo, and >2yr, respectively (in 98 patients delay data was missing).

After a mean follow-up of 7 years, the mean swollen and tender joint count (28JC) was <1, the mean ESR and CRP were normal, symptom level was low, functional capacity well maintained, and 66% of patients met the DAS28 remission (Table). No significant differences in outcomes and treatments were observed between the delay groups.

Conclusion: Clinical outcomes were good after 7 years in patients with early RA who were treated extensively using a T2T approach, including 66% of patients in DAS28 remission. Delay of treatment start did not influence outcomes in this clinic. Further analyses will include radiographic outcomes and work disability.

Background/Purpose: There is limited data on adherence to treat-to-target (T2T) strategies in RA in real world-practice and the impact of failure to adopt this best practice on clinical outcomes. We aimed to assess the impact of failure to adhere to T2T across 10 countries participating in the RA BIODAM program.

Methods: RA BIODAM is an international multicenter (35 sites, 620 patients) 2-year prospective study aimed at the clinical validation of biomarkers. Active RA patients are assessed for disease activity every 3 months with a prompt to make major treatment changes in order to achieve a DAS target

of ≤2.4. An internet-based data entry and management system (IDEMS) was designed to automate calculation of the DAS and alert sites to the requirement for treatment change. If a treatment change was not made a reason for that decision was required. RA outcomes (HAQ, RAID, SF36) and attainment of remission (DAS, CDAI, SDAI, ACR Boolean) were compared by adherence to T2T and according to treatment category (DMARD, anti-TNF).

Results: As of June 2014, 500 patients have been recruited of whom 172 have completed at least 15 months follow-up. Adherence to T2T was 52% and non-adherence 42% for at least 1 study visit (*the T2T failure visit*). Reasons for non-adherence were: physician decision that current treatment was acceptable (69%), physician decision (other) (14%), patient decision (9%), physician decision due to concern for adverse event (2%), other non-specific (6%). Starting at 6 months of follow up and continuing to diverge though 15 months, all outcomes were superior in T2T adhered patients: improvement in SJC/TJC, patient/physician global, HAQ, RAID, SF36. Remission at 15 months follow up was more frequent in T2T adhered patients at 75% (DAS), 41% (CDAI), 41% (SDAI), 40% (ACR Boolean) compared to non-adhered patients at 30% (DAS), 12% (CDAI), 13% (SDAI), 15% (ACR Boolean) irrespective of therapy (standard DMARD, anti-TNF). Median data for DAS components at *the T2T failure visit* was 9 and 4 for TJC and SJC, 5 for patient global, and 16 for ESR (40.0% with ESR >20). At the subsequent visit, there was still no change in treatment in 37% despite DAS > 2.4: median was 10 and 4 for TJC and SJC, 5 for patient global, and 22.5 for ESR (54.0% with ESR >20).

Conclusion: Adherence to T2T is associated with consistent improvement in RA outcomes and increased rates of remission. However, there remains a substantial gap in implementation even in protocol-specified clinical settings.

Does Corticosteroid Therapy at Disease Onset Influence Disease Progression of RA? Results from the Swiss Prospective Observational Cohort.

Ruediger Mueller[1], Nazim Reshiti[2], Toni Kaegi[1], Axel Finckh[3], Hendrik Schulze-Koops[4], Michael H. Schiff[5] and Johannes von Kempis[6]. [1]Kantonsspital St. Gallen, St. Gallen, Switzerland, [2]Division of Rheumatology, St. Gallen, Switzerland, [3]Geneva University Hospital, Geneva, Switzerland, [4]University of Munich, Munich, Germany, [5]University of Colorado, Denver, CO, [6]St. Gallen Hospital, CH-9007 St.Gallen, Switzerland.

Background/Purpose: Anti-inflammatory and disease-modifying properties of glucocorticoids (GCs) have been demonstrated in patients with rheumatoid arthritis (RA). Better outcomes in trials by combinations of synthetic DMARDs plus GCs versus DMARD monotherapy might be due GC. Since GCs are associated with adverse events, tapering of GCs is recommended in guidelines. There is almost no information on the benefits of GC in early arthritis outside the limitations of a clinical study.

To analyse whether initial GC therapy influences the course of the disease in early arthritis patients.

Methods: We included all patients from the Swiss RA registry SCQM with recent onset arthritis, (disease duration ≤1 year). Patients were categorized into two groups depending on their initial GC use. The primary outcome of this study was RA disease progression, as assessed by the evolution of disease activity (DAS28), radiographic erosion (Ratingen score) and HAQ-DI as a patient cantered outcome. The baseline disease characteristics were compared using standard descriptive statistics. The effect of initial glucocorticoid use on DAS 28 and HAQ-DI scores during follow up was estimated using linear mixed models with random slope and random intercept, and adjusted for various baseline factors in a univariate fashion. Slopes were compared between groups using the Mann-Whitney U-test.

Results: A total of 592 patients (pts) with early disease were available. Of these, 363 pts were initially treated with GC and 228 pts without (no-GC). DAS 28 (4.6 vs. 4.3, $p = 0.011$) and the HAQ-DI (0.94 vs. 0.82, $p = 0.0122$) were higher at the inclusion visit in GC patients, whereas average levels of CRP, swollen/tender joint counts, and erosion scores (Ratingen), presence of ACPA or rheumatoid factor at disease onset were not statistically different. Neither DAS 28, nor HAQ-DI, or the development of joint erosions differed between the two groups during follow up. Initial GC treatment was stopped in 201 patients during follow up after 680 days (mean). In parallel, GC treatment was initiated in 48 of the initial no-GC patients after 662 days (mean). Escalation of treatment employing biologics was documented in 18.0% of the no-GC patients and 27.3% of the GC patients ($p = 0.0097$). No differences in the number or kind of concomitant diseases were found.

We examined the probability of taking GC on the basis of baseline, parameters in a propensity score analysis. Even after adjusting for this propensity score, patients with and without use of GC did not have statistically significantly different DAS 28 (difference 0.04 on average, $p = 0.67$), erosion (0.75 higher Ratingen score with GC, $p = 0.29$), or HAQ-DI (0.03 higher with GC, $p = 0.47$).

Conclusion: It could be argued that initial GC use is not necessary in early RA patients, since disease progression, patient centred outcome, and the radiographic progression were comparable during follow up. Is has to be taken into consideration, however, that the patients with initial GC treatment had bad prognostic factors for the further disease course. Therefore we conclude that the treating rheumatologists have counterbalanced these factors by earlier and more frequent use of GC and subsequently by biologics.

The Clinical and Radiographic Course of Early Undifferentiated Arthritis Under Treatment Is Not Dependent on the Amount of Erosions at Diagnosis. Results from the Swiss Prospective Observational Cohort.

Ruediger Mueller[1], Toni Kaegi[1], Sarah Haile[2] and Johannes von Kempis[3]. [1]Kantonsspital St. Gallen, St. Gallen, Switzerland, [2]University of Zurich, Switzerland, Zurich, Switzerland, [3]St. Gallen Hospital, CH-9007 St.Gallen, Switzerland.

Background/Purpose: To analyse whether early arthritis patients who do not fulfil the ACR/EULAR 2010 classification criteria for rheumatoid arthritis (RA) have a different course of the disease dependent on whether they can or cannot be classified as RA because of radiographic disease (as recently defined by the EULAR task force) at diagnosis.

Methods: For this observational study within the Swiss RA cohort SCQM, we included patients with early undifferentiated arthritis (disease duration ≤1 year), as diagnosed by the treating rheumatologist, who had not received any previous DMARDs. 2010 ACR/EULAR criteria negative patients were separated into 2 groups (radiographic vs. non radiographic arthritis) depending on whether or not they had radiographic changes recently defined as erosive disease by a EULAR task force (≥3 joints with erosions). The primary outcome measure was the radiographic progression detected employing the Ratingen erosion score. HAQ and DAS 28 were used as secondary outcome measures. The average observation period was 4 years.

Results: A total number 592 patients was analysed. 240 were not classifiable as RA by application of the 2010 ACR/EULAR criteria at baseline. 133 of these patients had radiographic arthritis and 50 non-radiographic arthritis. In 57 patients radiographs at the first visit were not available. Treatment was initiated in all patients with DMARDs, mostly MTX. There were no significant differences in the therapeutic strategies between radiographic and non-radiographic patients. No differences in DAS 28 and HAQ scores were found during follow up over 4 years. The average erosion scores were higher among patients with initially radiographic arthritis throughout the study. The progression of erosion scores over time, however,

was higher in initially non radiographic arthritis patients (3.3 erosions/year vs. 0.4, resp., $p<0.0001$).

Conclusion: The clinical and radiographic course of early undifferentiated arthritis under treatment was not dependent on the presence of erosions in 3 or more joints (i.e. the definition of radiographic disease by the EULAR taskforce) at diagnosis in our cohort.

Effects of Methotrexate on Anti-TNF Treatment in Rheumatoid Arthritis: An in-Depth Analysis of a Prospective Observational Study with Adalimumab. Marc Schmalzing[1], Frank Behrens[2], Eva C. Scharbatke[1], Michaela Koehm[3], Bianca Wittig[4], Gerd Greger[5], Harald Burkhardt[2] and Hans-Peter Tony[1]. [1]University of Würzburg, Würzburg, Germany, [2]Goethe-University Frankfurt, Frankfurt, Germany, [3]Fraunhofer Institute for Molecular Biology and Applied Ecology IME, Project Group Translational Medicine & Pharmacology TMP, Frankfurt/Main, Germany, [4]Abbvie Deutschland GmbH & Co. KG, Wiesbaden, Germany, [5]AbbVie GmbH & Co KG, Wiesbaden, Germany.

Background/Purpose: Methotrexate (MTX) is currently the most frequently used drug in the treatment of rheumatoid arthritis (RA). MTX co-medication can improve the therapeutic benefit of adalimumab (ADA) in biologic-naïve RA patients. However, the impact of concomitant MTX has not been fully characterized in patients pretreated with biologics. Similarly, the influence of adding MTX to established ADA monotherapy has not been fully characterized.

Methods: We analyzed data from a large German multicenter, prospective, observational study of patients with active RA who are treated with ADA during routine clinical care. The effect of therapy on mean DAS28 scores was evaluated at baseline (month 0) and at months 3, 6, and 12 for patients receiving continuous ADA monotherapy, continuous ADA + MTX combination therapy, and MTX added to ADA therapy at 6 months (ADA monotherapy for the first 6 months and ADA + MTX combination therapy for months 6–12). Subgroup analyses for ADA monotherapy vs ADA + MTX were performed on biologic-naïve versus biologic-experienced patients. Stepwise forward and backward regression analyses were performed for identifying significant predictors.

Results: Combination therapy with ADA + MTX resulted in lower mean DAS28 scores at month 12 and a significant reduction in DAS28 scores from baseline than ADA monotherapy (Table). DAS28 improvements in patients who began the observation period on ADA monotherapy and added MTX at month 6 were similar to those receiving ADA + MTX continuously for 12 months. Subgroup analysis by prior biologic therapy indicated that both biologic-naïve and biologic-experienced patients achieved lower mean DAS28 scores with ADA + MTX than with ADA monotherapy ($p<0.0001$). However, patients treated previously with biologics did not show as much improvement in DAS28 scores as biologic-naïve patients, irrespective of MTX use.

Conclusion: Adding MTX to ADA monotherapy at month 6 resulted in DAS28 decreases similar to those observed with continuous ADA + MTX therapy, although patient numbers were small. Both biologic-naïve and biologic-experienced patients achieved lower DAS28 scores with ADA + MTX than with ADA monotherapy. These findings support the addition of MTX to ADA therapy for all patient populations.

Table 1. Effect of concomitant MTX on therapeutic response during ADA-treatment

Patient population	Therapy[a]	n	Mean DAS28 scores Month 0	Month 3	Month 6	Month 12	Mean DAS28 change at month 12[b]
All patients	Continuous ADA monotherapy	438	5.98	4.31	4.09	4.14	−1.85
	Continuous ADA + MTX	858	5.87	4.14	3.82	3.78	−2.08
	MTX added to ADA monotherapy at 6 months	51	5.84	4.31	3.83	3.70	−2.14
Biologic-naïve patients	Continuous ADA monotherapy	300	5.91	4.10	3.88	3.98	−1.93
	Continuous ADA + MTX	593	5.85	3.98	3.64	3.64	−2.21
Patients treated with ≥1 prior biologic	Continuous ADA monotherapy	138	6.15	4.77	4.55	4.47	−1.68
	Continuous ADA + MTX	265	5.90	4.51	4.21	4.10	−1.80

[a]Patients were considered to receive continuous therapy if they were recorded as receiving the stated therapy at each visit during the first 12 months of the observational study.
[b]Mean value calculated from the difference between DAS28 at month 12 and DAS28 at month 0 for each individual patient.

Effects of Exercise on Body Composition, Cardiovascular Fitness, Muscle Strength, and Cognition in Patients with Rheumatoid Arthritis: A Randomised Controlled Trial of a Patient-Specific Exercise Programme. Maha Azeez[1], Ciara Clancy[2], Tom O'Dwyer[2], Fiona Wilson[2] and Gaye Cunnane[1]. [1]St James's Hospital and Trinity College Dublin, Dublin, Ireland, [2]Trinity College Dublin, Dublin, Ireland.

Background/Purpose: Rheumatoid Arthritis (RA) patients have lower levels of physical activity compared to their non-RA counterparts. Large proportions of patients with RA are overweight or obese, and exhibit poor cardio-respiratory fitness and reduced muscle strength. These factors have been associated with poor function and increased mortality. A less well studied but important co-morbidity that affects RA patients is cognitive impairment, which can have a negative impact on patients' ability to manage their disease. We aimed to investigate the effects of a specifically designed exercise programme on body composition, aerobic capacity, muscle strength and cognition in RA patients.

Methods: Sixty-six patients with RA were randomised on a 1:1, case: control ratio. Assessments included body composition (waist circumference), fitness (VO_2max), muscle strength (hand-grip) and cognitive testing (Montreal Cognitive Assessment), in addition to disease related measures. Patients in the intervention group were enrolled for a three-month exercise programme. The control group received standard care.

Results: Twenty-eight cases and 24 controls attended for baseline testing. Seven patients were subsequently lost to follow up (4 cases and 3 controls). There were significant improvements in several measured outcomes in the intervention group compared to controls after three months. Median waist circumference was significantly reduced in cases, with median value 94.0 cm (range 67.3–124.5) at 0 months, compared to 91.4 cm (range 66.0–124.5) at 3 months, (2.8% reduction, $p<0.0001$). Aerobic capacity, as measured by VO2max, for cases was 23.2 ml/kg/min at 0 months compared to 27.6 ml/kg/min at 3 months (19% increase, $p=0.002$). Median right grip strength was 12kg (0–23) at 0 months, compared to 13kg (0–30) at 3 months (8.3% increase, $p=0.025$). For left grip strength, the median value was 8kg (0–20) at 0 months, compared to 10kg (0–32) at 3 months (25% increase, $p=0.005$). There was a significant improvement in cognitive function for cases, with median Montreal Cognitive Assessment value 25.5 (20–30) at 0 months compared to 28.0 (22–30) at 3 months (10% increase, $p=0.001$). There was also a significant reduction in C-reactive protein (median 2.8, range 1.0–27.4 at 0 months compared to 1.9, 1.0–18.4, at 3 months, equating to a reduction of 32.1%, $p=0.025$). Fatigue scores, measured by Global Fatigue Index were reduced from median 13.2 (range 6.4–34.1) at 0 months, to 10.9 (6.5–37.5) at 3 months ($p=0.047$). There was a significant reduction in trunk fat at 3 months (median 37.3, range 16.3–56.9) compared to 36.2, range 16.3–56.5 ($p=0.004$). For all above measures, there was no significant difference in median control values at 3 months.

Conclusion: There are significant benefits associated with physical activity for both general health and RA-related parameters, as evidence by the current data. This study has demonstrated for the first time that exercise has a significant impact on cognitive function in RA. We can conclude that physical activity is safe and effective in RA patients and should be a vital component of management protocols.

Inhibition of PAD4 Activity and the Formation of Neutrophil Extracellular Traps Via PTPN22, but Not Its Rheumatoid Arthritis-Prone W620 Variant. I-Cheng Ho[1], Hui-Hsin Chang[1], Nishant Dwivedi[1], Hsiao-Wei Tsao[1] and Anthony Nicholas[2]. [1]Brigham and Women's Hospital, Boston, MA, [2]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: One unique feature of rheumatoid arthritis (RA) is the presence of anti-citrullinated protein antibody (ACPA). Protein citrullination, a process mediated by peptidyl arginine deiminases, such as PAD4, not only yields antigens recognized by ACPA but also contributes to RA through several other mechanisms including promotion of neutrophil extracellular traps (NET) formation. A C-to-T single nucleotide polymorphism (SNP) located at position 1858 of human PTPN22, a protein tyrosine phosphatase, carries an odds ratio of 2–3 and, together with HLA alleles containing shared epitopes, synergistically increases the risk of RA 20- to 30-fold. The effect of this SNP is limited to ACPA+ RA. An explanation for this unique association is still lacking. We postulate that PTPN22 and the C1858T SNP, which converts an arginine (R620) to a tryptophan, influence protein citrullination.

Methods: The level of citrullinated proteins in wild type and PTPN22-deficient cells, as well as PBMC from healthy donors carrying or not carrying the risk T allele was examined with Western blotting using F95 antibody and anti-citrullinated histone H3. Co-immunoprecipitation was used to examine the physical interaction between PTPN22 and PAD4. The formation of neutrophil extracellular traps was analyzed with Sy-tox uptake and immunocytochemistry.

Results: Impaired expression of PTPN22 resulted in hypercitrullination in mouse and human immune cells. This effect was partly mediated by PAD4. PTPN22 did not regulate the expression or tyrosine phosphorylation of PAD4. Instead, PTPN22 physically interacted with and suppressed the activity of PAD4 independently of its phosphatase activity. Conversion of the R620 to a tryptophan disrupted the interaction between PTPN22 and PAD4, and completely ablated the ability of PTPN22 to suppress protein citrullination. Accordingly, the risk T allele is associated with hypercitrullination in PBMC and heightened propensity to form NET in healthy donors.

Conclusion: PTPN22 is a natural inhibitor of PAD, and the R620 is critical for this non-phosphatase function of PTPN22. The C1858T-mediated conversion of R620 to tryptophan increases the risk of ACPA+ RA through hypercitrullination and heightened propensity to form NET. Our data also identify a novel pathway regulating PAD activity and establish a molecular connection between the two RA risk genes PTPN22 and PAD4.

Fine-Mapping Major Histocompatibility Complex Associations in ACPA-Positive Rheumatoid Arthritis Identified Shared HLA Amino Acid Polymorphisms in Asian and European Populations. Yukinori Okada[1], Kwangwoo Kim[2], Buhm Han[3], Nisha E. Pillai[4], Rick T-H. Ong[4], Woei-Yuh Saw[4], Ma Luo[5], Lei Jiang[6], Jian Yin[6], So-Young Bang[7], Hye-Soon Lee[7], Matthew A. Brown[8], Sang-Cheol Bae[9], Huji Xu[10], Yik-Ying Teo[4], Paul IW. de Bakker[11] and Soumya Raychaudhuri[3]. [1]Tokyo Medical and Dental University, Tokyo, Japan, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [4]National University of Singapore, Singapore, Singapore, [5]University of Manitoba, Winnipeg, MB, [6]The Second Military Medical University, Shanghai, China, [7]Hanyang University Guri Hospital, Guri, South Korea, [8]University of Queensland Diamantina Institute, Brisbane, Australia, [9]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [10]Shanghai Changzheng Hospital, Shanghai, China, [11]University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Rheumatoid arthritis (RA) risk is strongly associated with variations within the major histocompatibility complex (MHC) region, and in particular to *HLA-DRB1* alleles. We aimed to fine-map RA risk alleles within the MHC in Asian populations and conduct trans-ethnic risk comparison to those in European populations.

Methods: We analyzed 2,782 anti-citrullinated protein antibodies (ACPA)-positive RA cases and 4,315 controls from Chinese and Korean populations. We applied HLA imputation to infer genotypes at eight class I and II HLA genes (*HLA-A*, *HLA-B*, *HLA-C*, *HLA-DRB1*, *HLA-DQA1*, *HLA-DQB1*, *HLA-DPA1*, *HLA-DPB1*) using SNP2HLA software and a newly constructed pan-Asian imputation reference panel.

Results: We obtained highly accurate imputation of HLA classical alleles with this reference panel (95.1% and 82.4% concordance for two and four digit classical alleles respectively). We observed the most significant association in HLA-DRβ1 at amino acid position 13 ($P_{omnibus} = 6.9\times10^{-135}$), located outside the classical shared epitope (SE). The individual residues at position 13 have relative effects that are consistent with published effects in European populations (His>Phe<Arg>Tyr≈Gly>Ser) – but Asian effects are generally smaller. Applying stepwise conditional analysis, we identified additional associations at positions 57 (conditional $P_{omnibus} = 2.2\times10^{-33}$) and 74 (conditional $P_{omnibus} = 1.1\times10^{-8}$). Outside of HLA-DR$\beta$1, we observed independent effects for amino acid polymorphisms within HLA-B (Asp9, conditional $P = 3.8\times10^{-6}$) and HLA-DPβ1 (Phe9, conditional $P = 3.0\times10^{-5}$) concordant with European populations. While a common set of amino-acid residue effects in three HLA genes are shared between European and Asian populations, these same effects can induce different classical allelic associations (e.g. *HLA-DRB1*09:01*) in the two populations due to differences in allele frequencies.

Conclusion: Our trans-ethnic study reveals that a common set of amino-acid residue effects in three HLA genes are largely shared between European and Asian populations. Our study illustrates the value of high-resolution imputation for fine-mapping causal variants in the MHC.

The Novel Rheumatoid Arthritis (RA) Risk Gene, *LBH*, Is Regulated By TGFβ and PDGF and Modulates Cell Growth in Fibroblast-like Synoviocytes. Anna-Karin Ekwall[1], Deepa Hammaker[2], John W. Whitaker[3], William Bugbee[4], Wei Wang[5] and Gary S. Firestein[6]. [1]UC San Diego, La Jolla, CA, [2]University of California San Diego, La Jolla, CA, [3]UCSD, San Diego, CA, [4]Scripps Clinic, La Jolla, CA, [5]UCSD, La Jolla, CA, [6]University of California at San Diego School of Medicine, La Jolla, CA.

Background/Purpose: RA fibroblast-like synoviocytes (FLS) display an aggressive phenotype, such as increased cytokine production and cell growth. Currently no therapeutics specifically target FLS. To this end, we have taken an unbiased integrative omics approach to identify therapeutic candidate gene by combining three different genome-wide assays: (i) GWAS in RA, (ii) differentially expressed genes in RA vs. osteoarthritis (OA) FLS and, (iii) differential DNA methylation in RA vs. OA FLS. We identified and characterized one gene present in all three databases, namely *limb bud and*

heart development (LBH). LBH is a conserved putative protein with largely unknown functions.

Methods: FLS cultures were established from RA and OA synovial tissues from joint replacement surgery. Gene expression was measured by qPCR. *LBH* gene expression was silenced using siRNA (mean 91% decrease) or over-expressed (mean 13 fold increase) using an LBH expression vector. Differentially expressed genes of 4 RA FLS lines with modified *lbh* expression were determined by microarray. The affected pathways were identifed using Ingenuity Pathway Analysis. Effects of modified *lbh*gene expression were assessed by cell migration (scratch-wound assay), cell growth (MTT), apoptosis (caspase 3/7 activity) and TNF-stimulated gene expression.

Results: LBH is constitutively expressed in RA FLS as determined by qPCR. TGFβ stimulation (1 ng/ml, 18 hr) significantly increased *LBH* mRNA by 5.0±0.4 fold *(P*=0.02) and PDGF-BB (0.1 ng/ml,12 hr) significantly decreased *LBH* mRNA expression by 5.7±1.7 fold (*P*=0.04). Stimulating FLS with TNF, Wnt1, Wnt3a or Wnt 5a had no effect on *LBH* gene expression. LBH was then knocked down using siRNA, with no effects on cell migration or TNF-induced MMP3 or IL-6 expression. To determine potential functions, microarrays were performed using LBH-deficient FLS. Pathway analysis of gene expression profiles in LBH^{low} compared to control FLS identified "Cellular growth and proliferation" as the most significantly enriched pathway. Therefore, we performed cell growth assays. LBH-deficiency increased FLS proliferation by 92±15% (p=0.025). Conversely, LBH-overexpressing FLS significantly inhibited cell growth by 62±10% (*P*=0.018). LBH did not alter apoptosis.

Conclusion: We identified *LBH* as a candidate gene for RA by integrating multiple omics datasets. Microarray experiments focused our attention on cell growth as a potential LBH-regulated function, and this was confirmed using functional assays. Furthermore, the gene is highly regulated by growth factors that modulate the cell cycle. The data suggest that LBH contributes to synovial intimal hyperplasia and joint damage in RA.

Contraceptive Factors Are Associated with Serum Antibodies to Citrullinated Protein Antigens in Women at Elevated Risk for Future Rheumatoid Arthritis. Sonia Khatter[1], Mark C. Parish[1], Marie L. Feser[1], Jason R. Kolfenbach[1], Ryan W. Gan[2], Michael H. Weisman[3], James R. O'Dell[4], Ted R. Mikuls[5], Richard M. Keating[6], Peter K. Gregersen[7], Jane H. Buckner[8], V. Michael Holers[1], Kevin D. Deane[1], Jill M. Norris[2] and M. Kristen Demoruelle[1]. [1]University of Colorado School of Medicine, Aurora, CO, [2]Colorado School of Public Health, Aurora, CO, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]Veteran Affairs Nebraska Western Iowa Health Care System and University of Nebraska Medical Center, Omaha, NE, [5]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [6]Scripps Clinic, La Jolla, CA, [7]Feinstein Institute for Medical Research, Manhasset, NY, [8]Benaroya Research Institute at Virginia Mason, Seattle, WA.

Background/Purpose: The preclinical period of rheumatoid arthritis (RA) development is characterized by elevations of serum RA-related autoantibodies (Abs) including Abs to citrullinated protein antigens (ACPA) and rheumatoid factor (RF). Serum ACPAs are highly predictive of future inflammatory arthritis (IA) classifiable as RA, and recent data suggesting that ACPAs are directly pathogenic in joint disease highlight the need to understand the etiology of ACPA development. In addition, it remains unknown why RA disproportionately impacts women compared to men, and data suggest hormonal factors may influence the risk of developing RA. Importantly, prior data from our group identified that oral contraceptive pill (OCP) use was associated with a decreased risk for serum RF positivity in the absence of IA (Bhatia 2007). Therefore, we hypothesize that contraceptive factors will be associated with serum ACPA positivity among arthritis-free women at increased risk for RA.

Methods: In the Studies of the Etiology of RA (SERA) project, 1243 first degree relatives (FDR) of probands with RA are enrolled who are women. Of these FDRs, we studied women who at their baseline visit had serum ELISA testing for ACPA using anti-CCP3.1 (IgG/IgA, INOVA) and a detailed prior contraceptive and pregnancy history obtained using a standardized questionnaire (N=336). To avoid familial correlation, we also randomly selected only one subject per family; therefore, our final analyses included 297 FDRs. All subjects were without clinical IA at the time of serum testing. In cross-section, associations of ACPA and subject factors were analyzed using chi-squared and logistic regression.

Results: In multivariate analyses, prior use of OCPs was associated with a decreased risk of serum ACPA positivity (OR=0.34; 95% CI 0.15–0.79; adjusted for age, race and smoking). In addition, there was an increased risk of ACPA positivity in women who had a history of intrauterine device (IUD) use (OR=2.68; 95% CI 1.11–6.47; adjusted for age, race and smoking). ACPA(+) FDRs were slightly older than ACPA(−) FDRs, but were similar in race, smoking and shared epitope status (Table). No significant association was seen between ACPA positivity and pregnancy or breastfeeding.

Conclusion: Prior OCP use was associated with a decreased risk of ACPA positivity in these FDRs, and these results are in line with our prior findings of OCP use associated with a decreased risk of RF positivity. Of interest was the association of an increased risk of ACPA positivity with IUD use. While the mechanisms that link contraceptive factors to ACPA generation are unknown, unlike OCPs, IUDs have been shown to generate endometrial inflammatory responses. Therefore, the association of IUD use and ACPA suggest that IUD-induced endometrial inflammation may be a potential mucosal trigger of RA-related Abs. Mechanisms by which OCPs could protect and IUDs could increase risk for RA-related autoimmunity need further study.

Table. Contraceptive and Other Risk Factors for ACPA Positivity in Women at Elevated Risk for Future RA

	ACPA (+) (N=34)	ACPA (−) (N=263)	p-value*	Unadjusted OR (95% CI)	Adjusted OR (95% CI)**

Association of Single Nucleotide Polymorphisms of PADI4 Gene with Susceptibility to Rheumatoid Arthritis-Related Lung Disease. Seong-Wook Kang, Seung-Taek Song, Song Soo Kim, Ji Young Kim, So Young Lee, Su-Jin Yoo, In-Seol Yoo, Jinhyun Kim and Seung-Cheol Shim. Chungnam National University School of Medicine, Daejeon, South Korea.

Background/Purpose: Rheumatoid arthritis (RA) causes a myriad of pulmonary complications, including bronchiolitis and bronchiectasis, pleuritis, and interstitial lung disease (ILD). Recently, several studies have shown the association of rheumatoid arthritis-related lung disease (RA-LD) with the high titers of rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) which are the most specific serologic marker for RA. Single nucleotide polymorphisms (SNPs) in a citrullinating (or deiminating) enzyme, peptidyl arginine deiminase type IV (PADI4) have been reproducibly associated with RA susceptibility in several populations.

The aim of the present study is to investigate if the SNPs in PADI4 gene are associated with RA-LD.

Methods: A total of 103 consecutive RA patients, who satisfied the 1987 American College of Rheumatology classification criteria, were genotyped for two nonsynonymous (padi4_89 and padi4_92) and one synonymous (padi4_104) SNPs in PADI4. RA-LD was diagnosed using high-resolution computed tomography of the chest. The following data were collected from medical records: Age, sex, disease duration, smoking history, use of disease-modifying anti-rheumatic drugs (DMARDs), RF, and ACPA. We used the t-test for continuous variables and the chi-square or Fisher's exact test for categorical variables. Multivariate logistic regression analysis was performed to assess the relationship between the SNPs in the PADI4 gene and RA-LD.

Results: Of the 103 RA patients, 8 (7.8%) had interstitial lung disease (ILD) and 33 (32.0%) had small airway disease (AD). High titers of ACPA (≥80 U/mL; p=0.022) and RF (≥ULN×3; p=0.008) were significantly associated with susceptibility to RA-LD (Table 1). SNPs and genotypes in exon-3 (padi4_92) of PADI4 showed significant association with susceptibility to RA-LD (p=0.013, p=0.004, respectively) (Table 2)(Table 3). No statistically significant differences were seen between RA patients with LD and those without LD with respect to sex, smoking history, anti-Ro antibody, and use of DMARDs.

Conclusion: Our results suggest that SNPs and genotypes in exon-3 (padi4_92) of PADI4 are associated with susceptibility to RA-LD. Further studies are warranted to clarify the mechanisms by which SNPs in the PADI4 gene affect the development of RA-LD.

Table 1 Clinical characteristics of RA patients with or without lung disease

Characteristics	RA-no LD (n = 69)	RA-LD (n = 34)	*p*-value
Age (yrs)†	51.77±9.25	58.50±8.26	**0.001**
Female	62 (89.9)	30 (88.2)	1.000
RA duration (yrs)†	10.49±7.84	7.11±7.14	**0.037**
Smoking history	6 (9.1)	1 (3.1)	0.421
Positive ACPA	53 (77.9)	30 (88.2)	0.208
ACPA titer (U/mL)†	204.51±201.33	300.74±201.07	**0.025**
High-titier ACPA (≥80 U/mL)	40 (59.7)	28 (82.4)	**0.022**
Positive RF	53 (76.8)	30 (88.2)	0.168
RF titer (IU/mL)†	58.36±70.37	89.35±87.51	0.056
High-titer RF (≥ULN×3)	20 (20.9)	19 (55.9)	**0.008**
Positive anti-Ro Ab	12 (18.8)	4 (11.8)	0.567
anti-Ro titer	0.71±1.39	0.53±1.27	0.520
Use of DMARDs			
Biologic agents	17 (24.6)	11 (32.4)	0.408
Methotrexate	66 (95.7)	27 (79.4)	0.14
Leflunomide	7 (10.1)	4 (11.8)	1.000
Hydroxychloroquine	37 (53.6)	17 (50.0)	0.729
Sulfasalazine	5 (7.2)	2 (5.9)	1.000

Values are the number (%), †; (mean±SD). RA-LD group encompasses the interstitial lung disease (ILD) and small airway disease (AD). RA-no LD group includes RA patients without ILD or small AD. Smoking history is defined as positive for current or former smokers. In biologic agents, anti-tumor necrosis factor-α inhibitors (such as Etanercept, Adalimumab, and Golimumab), Abatacept, and Tocilizumab were included. Significance was determined by means of the independent *t*-test for continuous variables and the chi-square or Fisher's exact test for categorical variables.
RA, rheumatoid arthritis; ACPA, anti-citrullinated protein antibodies; RF, rheumatoid factor.

Table 2 Association of the alleles of *PADI4*SNPs with RA-LD susceptibility

SNP	Allele	RA-no LD	RA-LD	OR (95% CI)	*p*-value
padi4_89	A	0.52	0.61	1	0.418
	G	0.48	0.39	0.749 (0.372–1.508)	
padi4_92	C	0.18	0.41	1	**0.004**
	G	0.82	0.59	0.319 (0.147–0.692)	
padi4_104	C	0.61	0.67	1	0.809
	T	0.39	0.33	0.914 (0.441–1.896)	

Values are frequency. Age, sex-adjusted odds ratios (ORs) and *p* values for carriers of minor susceptibility alleles versus noncarriers were calculated by multivariate logistic regression. SNP, single nucleotide polymorphism; RA, rheumatoid arthritis; 95% CI, 95% confidence interval.

Table 3 Association of *PADI4*SNP genotypes with RA-LD susceptibility

SNP	Genotype	RA-no LD	RA-LD	OR (95% CI)	*p*-value
padi4_89	AA	0.25	0.39	1	0.087
	AG/GG	0.75	0.61	0.429 (0.162–1.132)	
padi4_92	CC	0.14	0.39	1	**0.004**
	CG/GG	0.86	0.61	0.195 (0.065–0.589)	
padi4_104	CC	0.32	0.46	1	0.081
	CT/TT	0.68	0.54	0.429 (0.166–1.110)	

Values are frequency. Age, sex-adjusted odds ratios (ORs) and *P*values for carriers of minor susceptibility alleles versus noncarriers were calculated by multivariate logistic regression. SNP, single nucleotide polymorphism; RA, rheumatoid arthritis; 95% CI, 95% confidence interval.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy VI: Biomarkers and Predictors of Rheumatoid Arthritis Disease Response and Outcomes
Tuesday, November 18, 2014, 4:30 PM–6:00 PM

2923

Protein Quantification Using Mass Spectrometry Methods to Predict Response to Abatacept and Methotrexate Combination Therapy in Rheumatoid Arthritis. A Obry[1], P Cosette[1], T Lequerré[2], Maria-Antonietta d'Agostino[3], C Gaillez[4], M Le Bars[5] and O Vittecoq[2]. [1]UMR 6270 CNRS, PISSARO Proteomic Facility, IRIB, Normandy University, University of Rouen, Rouen, France, [2]Rouen University Hospital, Rouen, France, [3]AP-HP Ambroise Paré Hospital, Boulogne-Billancourt, France, [4]Formerly of Bristol-Myers Squibb, Rueil-Malmaison, France, [5]Bristol-Myers Squibb, Rueil-Malmaison, France.

Background/Purpose: Targeted biologic therapies with different mechanisms of action are commonly used in RA. Abatacept is a recombinant fusion protein that inhibits T-cell co-stimulatory molecules required for T-cell activation. Overall, 57.1% of patients reached LDA (DAS28 [CRP] ≤3.2) after 6 months of treatment with abatacept and MTX in the open-label abatacept Power Doppler Ultrasonography APPRAISE study, in patients with RA and inadequate MTX response.[1] Treatment choice may be optimized by the identification of predictive protein markers of patient response to treatment. The aim of this study was to identify, by mass spectrometry-based quantification methods, a protein signature from peripheral blood mononuclear cells (PBMC) to predict abatacept/MTX response.

Methods: In total, 104 patients with active RA and inadequate MTX response were treated with approved doses of abatacept and MTX. For this analysis, patients were categorized as abatacept responders (DAS28 ≤3.2 [LDA]) (n= 30) or abatacept non-responders (DAS28 >3.2) (n=6) following 6 months of treatment. Proteins extracted from PBMCs from responders and non-responders at baseline and 6 months were analyzed. A 'label-free' approach was designed to compare the whole PBMC proteome for the 72 samples; the proteome of each sample was extracted and then in-gel digested. The resulting peptides were analyzed by high-resolution mass spectrometry (MS). Protein quantification was performed by comparing extracted ion currents with dedicated software for quantitation from MS data. Three differential analyses were conducted: (i) between responders and non-responders before treatment; (ii) between responders before and after treatment; (iii) between non-responders before and after treatment.

Results: These investigations revealed 30 proteins exhibiting differential expression between responders and non-responders before treatment: 28 proteins were down-regulated and 2 proteins were up-regulated in responders compared with non-responders. In our cohort, this combination of potential biomarkers could predict a good treatment response with 86.67% sensitivity and 66.67% specificity. In our second analysis, after 6 months of abatacept/MTX treatment 29 proteins were down-regulated in responders, while 30 proteins were up-regulated in non-responders, without overlap between these two sets of proteins. Several pathways were recruited in responders, including focal adhesion or leukocyte trans-endothelial migration, whereas immune system response was the main pathway among the over-expressed proteins in non-responders.

Conclusion: Our investigations identified a combination of potential biomarkers able to predict patient response to abatacept/MTX treatment in this dataset. We also demonstrated a decrease in the expression of proteins involved in cell migration in treatment responders and an enhanced immune response in treatment non-responders from our dataset. These exploratory findings require further validation and confirmation in another trial.

Clinical Utility of Random Anti-TNF Drug Level Testing and Measurement of Anti-Drug Antibodies on Long-Term Treatment Response in Rheumatoid Arthritis. Meghna Jani[1], Hector Chinoy[1], Richard B. Warren[2], Christopher E.M Griffiths[2], Ann W. Morgan[3], Anthony G. Wilson[4], Kimme L. Hyrich[1], John Isaacs[5], Darren Plant[1] and Anne Barton[6]. [1]Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom, [2]Dermatology Centre, University of Manchester, Manchester, United Kingdom, [3]University of Leeds, Leeds, United Kingdom, [4]University College Dublin, Dublin, Ireland, [5]Institute of Cellular Medicine, University of Newcastle, Newcastle, United Kingdom, [6]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Science Centre, Manchester, United Kingdom.

Background/Purpose: Up to 40% of RA patients on anti-TNF treatment fail to respond either due to primary inefficacy or loss of response. One explanation is immunogenicity leading to the development of anti-drug antibodies (ADAb) and low drug levels, however the clinical utility of pharmacological monitoring is debated. One challenge is the practicality of obtaining trough drug levels in patients and the impact that would have on service delivery. Our aim was to evaluate whether the presence of ADAb and/or non-trough drug levels may predict treatment response in patients with RA treated with anti-TNF drugs.

Methods: 331 patients were selected from the Biologics in RA Genetics and Genomics Study Syndicate prospective cohort [n=160 adalimumab (ADL); n=171 etanercept (ETA)]. Serum samples were collected at 3, 6 and 12 months following initiation of therapy. ADAb were measured using RIA and drug levels using ELISA assays at 3, 6 and 12 months. Disease activity (DAS28) scores were measured at each visit. Multiple linear regression, logistic regression, generalised estimating equation and ROC curves were used to test the association and predictive value of ADAb and/or non-trough drug levels on treatment response as assessed by the change in DAS28 score between pre-treatment and 12 months post-treatment (ΔDAS28).

Results: 835 serial samples were suitable for pharmacological testing (n=414 ADL; n=421 ETA). Mean age: 56±13 years; 75% female; baseline DAS28 score 5.9±0.8; median BMI 27.5 (IQR 23.6–32.3). 85% were on a DMARD (56% MTX). ADAbs to ADL were detected in 24.8% (31/125 patients at ≥1 time points by 12 months) and in none of the ETA patients. The presence of ADAbs were significantly associated with lower ADL drug levels (ADAb titres>100AU p=0.0041; Spearman's rho −0.66). At 3 months, ADAb formation and low ADL levels were a significant predictor of no EULAR response at 12 months [ROC curve analysis, area under curve (AUC) 0.71, 95% confidence intervals (CI) 0.57–0.85]. Patients who developed ADAbs received lower median doses of concomitant MTX therapy (15mg/wk [IQR 10–20]) and had longer disease duration (14.0 years [6.7–19.4]) *vs.* patients who did not (20mg/wk [15–20] p= 0.01); (7.7 years [3.6–16.0] p=0.03). ADL drug level was the most significant independent predictor of ΔDAS28 at all time points after adjusting for confounders (p=0.003, regression coefficient (RC) 0.12, CI: 0.06–0.18). Patients on ETA with higher drug levels (>15μg/mL) were more likely to achieve a good EULAR response than patients with sub-therapeutic levels (<0.035 μg/mL) (p=0.01). However low ETA levels at 3 months were not a significant predictor of no EULAR response at 12 months (AUC 0.51; CI 0.41–0.61). BMI was the strongest predictor of low drug levels (ETA, p<0.001, RC −5.97; CI −8.75 to −3.19; ADL, p<0.001, RC −3.86; CI −5.72 to −2.00). Patients with a BMI>30 had significantly lower drug levels compared to those with a BMI<30 in both ADL and ETA cohorts (p<0.01).

Conclusion: Pharmacological testing in anti-TNF initiated patients is clinically useful even in the absence of trough levels. At 3 months ADAb formation and low ADL drug levels are a significant predictor for poor treatment response at 12 months. Patients with a BMI<30 were less likely to have therapeutic drug levels.

2925

Serum MMP-3 Predicts a Subgroup with No Radiographic Progression in Rheumatoid Arthritis Patients with Low-Dose Methotrexate (MTX) Monotherapy. Kazuko Shiozawa[1], Takashi Yamane[1], Miki Murata[1], Chihiro Tanaka[1], Noriaki Yo[1], Ryosuke Yoshihara[1], Yasushi Tanaka[1], Ken Tsumiyama[2] and Shunichi Shiozawa[2]. [1]Kohnan Kakogawa Hospital, Kakogawa, Japan, [2]Kyushu University Beppu Hospital, Beppu, Japan.

Background/Purpose: Studies have shown that treating rheumatoid patients with methotrexate (MTX) monotherapy initially and later providing an option to step up to combination therapy produces outcomes similar to those seen with combination therapies of conventional drugs and/or biologics provided immediately (O'Dell JR et al. Arthritis Rheum 65:1985, 2013). In their study, approximately 30% of the patients treated with MTX monotherapy did not require subsequent combination therapy. However, this subgroup was clinically and radiographically indistinguishable from those who required it.

The purpose of the present study was to assess the efficacy of low-dose MTX monotherapy, a regimen which is commonly prescribed in Japan, and to identify a subgroup of patients whose radiographic progression is halted in response to MTX monotherapy. In the present study, 161 rheumatoid patients were treated continuously with low-dose MTX monotherapy continuously for 3 yrs until significant adverse events or radiographic progression were suspected.

Methods: Rheumatoid patients treated with low-dose MTX monotherapy (n=161) were followed prospectively for 3 yrs. Their disease activity and radiographic progression were evaluated with reference to disease activity score 28 (DAS28), modified health assessment of questionnaire (mHAQ) and others and by the change in van der Heijde-modified total Sharp score per year (f¢TSS), by classifying patients into subgroups showing structural remission (REM; f¢TSS≤0.5), radiographic progression (f¢TSS>3) or rapid radiographic progression (RRP; f¢TSS>5).

Results: Disease activity was improved yearly, from baseline to 3 yrs: DAS28-ESR (3) improved from 5.2±1.1 to 3.9±1.4 (p<0.0001), %DAS28 remission from 1% to 19%, mHAQ from 0.54±0.47 to 0.18±0.32 (p<0.0001), mHAQ remission rate (f¢mHAQ<0.5) from 16% to 60%, and Boolean remission from 0.8% to 24.0%. During the 3-yrs of MTX monotherapy, the ratio of the patients classified into the REM group increased from 38.5% to 50.4% (p=0.0466), those in ΔTSS>3 decreased from 34.2% to 20.4% (p=0.0095), and those in RRP decreased from 21.7% to 10.9% (p=0.0190). In particular, the patients with active disease who required biologics arose mostly from the RRP group, followed by the CRRP group. This was, however, not the case when the patients were classified according to disease activity, i.e., DAS28. Receiver operating characteristic (ROC) curve analyses showed that serum matrix metalloproteinase-3 (MMP-3) levels of below 103.7 ng/ml at baseline predict a patient subgroup with no radiographic progression.

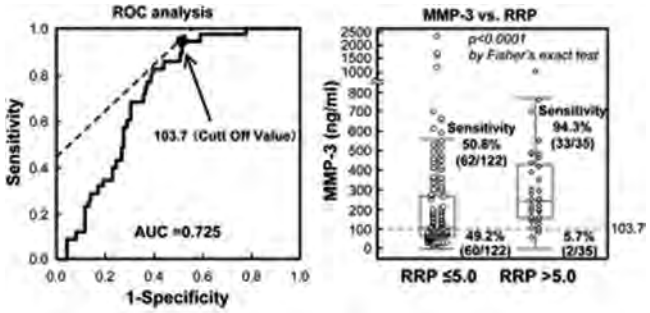

Fig.1 MMP-3 as a redictor identifying radiographic non-progression: cut off value for RRP and non-RRP

Conclusion: Approximately half of the patients given low-dose MTX monotherapy showed no radiographic progression over 3 yrs. A subgroup with no radiographic progression was predicted at outset by lower serum MMP-3.

Calprotectin Serum Levels Reflect Residual Inflammatory Activity in Patients with Rheumatoid Arthritis and Psoriatic Arthritis on Clinical Remission or Low Disease Activity Undergoing TNF-Antagonists Therapy. Jose Inciarte-Mundo[1], M. Victoria Hernández[1], Sonia Cabrera-Villalba[1], Julio Ramirez[1], Andrea Cuervo[1], Virginia Ruiz-Esquide[1], Azucena González Navarro[1], Jordi Yagüe[2], Juan D. Cañete[1] and Raimon Sanmarti[1]. [1]Hospital Clínic of Barcelona, Barcelona, Spain, [2]Hospital Clinic Barcelona, Barcelona, Spain.

Background/Purpose: Calprotectin is a major S100 leucocyte protein, is associated to disease activity in rheumatoid arthritis (**RA**) and Psoriatic Arthritis (**PsA**) patients. Calprotectin is a potentially biomarker more sensitive of disease activity than conventional acute-phase proteins.

Objective: To analyze the relationship between calprotectin serum levels and inflammatory disease activity in patients with RA and PsA patients in clinical remission or low disease activity treated with TNF-antagonists. To correlate calprotectin levels with serum trough levels of TNF-antagonists.

Methods: Prospective cohort study of patients diagnosed with RA (ACR 1987 criteria) or PsA (CASPAR criteria) treated with adalimumab (**ADA**), etanercept (**ETN**) or infliximab (**IFX**) for ≥ 3 months in clinical remission or with low disease activity measured by DAS28-ESR in ≥ 2 consecutive visits. Clinical and laboratory data were analyzed. Calprotectin serum levels (using kits from Calpro AS, Norway) and TNF-antagonist serum trough levels, anti-drug antibodies (**Abs**) (using kits from Promonitor®, Progenika SA) were determined at 0, 4, 8 and 12 months of follow-up. We present the results at study entry (visit 0).

Results: 103 patients (47 RA, 56 PsA) were included. 61% female, mean age 58±12 years, mean DAS28-ESR 2.1±0.58, 76% were in clinical remission and 24% in low disease activity, 48% on monotherapy, 44% receiving reduced dosage of biologic (ADA 18 patients, ETN 22 patients and IFX 5 patients). Calprotectin levels were significantly lower in PsA than in RA patients (1.4±1 vs. 2.2±1, p=0.006). Patient on clinical remission (DAS28<2.6) showed lower calprotectin levels to those observed in those with low disease activity (1.2±1 vs. 3.4±1, *p<0.0001*), even when distributed by the most stringent remission criteria (patients with SDAI 3.3 1.9±2, p=0.005). Calprotectin strongly correlates with DAS28-ESR and SDAI in both RA (r_s=0.744, *p<0.0001* and r_s=0.328, *p=0.025* respectively) and PsA (r_s=0.777, *p<0.0001* and r_s=0.419, p=0.001 respectively), whereas no correlation was found between CRP serum levels or ESR with DAS28-ESR and SDAI in both populations. A trend for higher calprotectin levels in patients with low serum trough levels of ADA was showed (n=17, r_s=-0.413, p=0.09), that was statistically significant in those patients with RA treated with adalimumab at standard dose (r_s=-0.767, p=0.026). No correlations between calprotectin and serum trough levels ETN or IFX were observed.

Conclusion: Calprotectin was found to have high accuracy to discriminate RA or PsA patients in remission from those in low disease activity undergoing TNF-antagonists therapy, reflecting ongoing inflammatory activity. A strong correlation between disease activity measured by DAS28 and SDAI and calprotectin, but not with CRP or ESR, was found. No clear correlation between calprotectin levels and TNF-antagonists serum through levels was observed. Calprotectin emerges as a very useful biomarker to detect residual inflammatory activity in these patients.

Baseline Serum Interferon Beta/Alpha Ratio Predicts Response to Tumor Necrosis Factor Alpha Inhibition in Rheumatoid Arthritis. Priyanka Vashisht[1], Jessica M. Dorschner[2], Mark A. Jensen[2], Beverly Chrabot[3], Theresa Wampler Muskardin[2], Marlena Kern[4], Tetrad Investigators[5], ABCoN Consortium[6], S. Louis Bridges Jr.[7], P.K. Gregersen[8] and Timothy B. Niewold[2]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Mayo Clinic, Rochester, MN, [3]University of Chicago, Chicago, IL, [4]Feinstein Institute for Medical Research, Manhasset, NY, [5]AL, [6]NY, [7]University of Alabama at Birmingham, Birmingham, AL, [8]The Feinstein Institute for Medical Research, Manhasset, NY.

Background/Purpose: Response to tumor necrosis factor alpha (TNF-α) inhibition is variable in rheumatoid arthritis (RA). Previous studies have suggested that circulating type I interferon (IFN) levels may predict treatment response to TNF-α inhibitors and other biological agents in RA. Prediction of likely responders prior to initiating therapy would represent a major advance in biological treatment strategies for RA.

Methods: We studied a test set of 32 RA patients from the ABCoN registry and a validation set of 80 RA patients from the TETRAD registry. All subjects had serum available prior to treatment with a TNF-α inhibitor. In the test set, only those with a good response or no response at 14 weeks by EULAR criteria were included. In the validation set, subjects were included from the EULAR good, moderate, and non-response categories defined at 12 weeks post-treatment. Pre-treatment total serum type I IFN activity as well as IFN-α vs. IFN-β activity were measured using a functional reporter cell assay.

Results: In the test set, an increased ratio of IFN-β/IFN-α >1.3 in the pre-treatment serum sample was associated with lack of response by EULAR criteria at 14 weeks (p=0.009), and a receiver-operator curve supported a ratio of 1.3 as the optimal cut-off. Similarly, higher IFN-β/IFN-α ratio was positively correlated with higher DAS score at 14 weeks in the test set (Spearman's rho= 0.57, p=0.0075). In the validation set, subjects with an IFN-β/IFN-α ratio >1.3 were significantly more likely to have non-response by EULAR criteria at 12 weeks (p=0.0035), and no patient with this ratio or greater achieved a good response. In meta-analysis, IFN-β/IFN-α ratio >1.3 was a strong discriminator of good response vs. non-response at 12–14 weeks (OR = 18.0, $p=7.4\times10^{-5}$), and also a significant predictor of non-response vs. either moderate or good response at 12–14 weeks (OR = 4.34, p=0.0014). Anti-CCP antibody titer and mechanism of action (mAb vs etanercept) of TNF-α inhibitor did not influence this relationship.

Conclusion: Increased pre-treatment serum IFN-β/IFN-α ratio was strongly associated with non-response to TNF-α inhibition by EULAR criteria at 12–14 weeks. This blood test may be useful in making treatment decisions using TNF-α inhibitors in RA and other diseases.

Serum IL-33 Level Is Increased in Rheumatoid Arthritis and Predicts Response to Rituximab in Combination with High Serum IgG Level and Autoantibody Positivity: An Open-Label, Prospective, Multicentre Biological Trial. Jérémie Sellam[1], Houria Chavez[2], Stéphanie Rouanet[3], Nathalie Vernet[3], Bineta Ly[4], Sandrine Marion-Thore[5], Bernard Combe[6], Jean Sibilia[7], Jacques Tebib[8], Gilles Chiocchia[9], Maxime Dougados[10], Yassine Taoufik[2] and Xavier Mariette[11]. [1]AP-HP, Saint-Antoine Hospital, Rheumatology Department and DHU i2B, Paris, France, [2]Hopital Bicetre, Université Paris Sud, AP-HP, Kremlin Bicetre, France, [3]Roche France, Boulogne-Billancourt, France, [4]Universite Paris-Sud, Kremlin Bicetre, France, [5]Université Versailles Saint-Quentin, Montigny le Bretonneux, France, [6]Hôpital Lapeyronie, Montpellier, France, [7]University Hospital of Strasbourg, Strasbourg, France, [8]University Hospital Lyon, Lyon, France, [9]Université Versailles-Saint Quentin, Montigny le Bretonneux, France, [10]INSERM (U1153): Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité, Paris, France., Paris, France, [11]Université Paris-Sud, Le Kremlin Bicêtre, France.

Background/Purpose: The recent discovered cytokine interleukin-33 (IL33) could be involved in B-cell activation as well as in RA pathophysiology. After a whole-blood transcriptomic analysis showing that baseline IL-33 mRNA upregulation was associated with clinical response to rituximab (RTX) (1), we investigated whether the serum level of IL-33 was associated with RA features and whether it may predict response to RTX.

Methods: We used ELISA to quantify serum IL-33 level and assessed B-cell–activation biomarkers (rheumatoid factor [RF], anti-CCP antibodies, free light chains, IgG, IgA, IgM, and BAFF levels), serum CXCL12, CXCL13 and CCL19 levels (all log transformed for analysis) in 205 RA patients before receiving a 1st course of RTX (1g on days 1 and 15) in the SMART trial and 63 controls (CT). Uni and multivariate analyses were performed to identify factors associated with a EULAR response 24 weeks after RTX.

Results: Serum IL-33 level was higher in patients with RA than in CT (median [interquartile range]: 258 [75;1345] *vs* 35 [22;664] pg/mL; p≤0.001) as well as in anti-CCP positive compared with anti-CCP negative patients (359 [87–1619] vs 102 [39–368] pg/mL, p=0.001). A similar result was observed for RF status (p=0.001). Serum IL-33 level was uncorrelated neither with DAS28 nor with CRP level. Unexpectedly, serum IL-33 level was highly correlated with CCL19 (r=0.7 ; p<0.0001) and CXCL13 levels (r=0.15 p=0.003). There were 146 (71%) responders (i.e. 44 good and 102 moderate). Using ROC curve analyze, 249 pg/mL was the optimal serum IL-33 level cut-off to discriminate responders from non-responders. Multivariate analysis indicated that IL33 level was independently associated with subsequent response to RTX (odds ratio [95% confidence interval]: 2.25 [1.14;4.43]; p=0.02), as well as the presence of anti-CCP antibodies or RF (OR: 2.76 [1.24;6.15]; p=0.01), with a similar trend for IgG level (OR: 2.00

[0.97;4.11]; p=0.059). These 3 parameters acted synergistically on the RTX response prediction since their simultaneous presence, observed in 20% of RA patients in SMART, frankly increased the likelihood of response (OR: 13.6 [3.2;57.9]) (Figure).

Conclusion: Serum IL-33 level, intrinsically increased in RA, represents a simple marker predicting accurately clinical response to RTX, independently of and synergistically with auto-antibodies and serum IgG level.

ACR Concurrent Abstract Session
Sjögren's Syndrome I: Clinical Perspectives
Tuesday, November 18, 2014, 4:30 PM–6:00 PM

2929

Molecular Diagnostics for Patient Subsetting in Sjögren's Syndrome. John C. Hall[1], Alan N. Baer[1], Mi Y. Lam[2], Lindsey A. Criswell[3], Antony Rosen[1] and Livia Casciola Rosen[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of California San Francisco, San Francisco, CA, [3]University of California, San Francisco, Rosalind Russell/Ephraim P. Engleman Rheumatology Research Center, San Francisco, CA.

Background/Purpose: Sjögren's syndrome (SS) is a chronic autoimmune disease which targets exocrine glands, particularly salivary and lacrimal glands. While all SS patients have abnormal secretory function and inflammatory infiltration of their salivary glands, there is significant heterogeneity in terms of disease features, pathology and clinical course. Elucidating the inflammatory pathways which are active in pathologic tissues has important implications for defining disease subsets and monitoring disease activity. With the increasing availability of therapies which target specific immune pathways, defining the activity of distinct molecular pathways in target tissues will be important for selecting therapy. The type I and type II IFNs, which are implicated in SS pathogenesis, are particularly relevant in this regard.

Methods: Clinical data and a frozen labial salivary gland was obtained from each of 82 participants enrolled in the Sjögren's International Collaborative Clinical Alliance registry (NIH/NIDCR contract HHSN26S201300057C) with the following characteristics: (i) 53 individuals meeting ACR criteria for primary SS; (ii) 29 age and sex-matched controls lacking serologic and pathologic evidence of SS, of which 14 exhibited evidence of dry eye disease (OSS ≥3 for either eye). Protein lysates were generated from SS and control labial salivary glands, proteins were separated by SDS-PAGE and immunoblotted with specific markers of type I or type II IFN activity. Protein expression was normalized to the level of a loading control within the same sample and subject to hierarchical clustering to define patterns of IFN activity (high vs low). Correlations between IFN activity and categorical SS phenotypic features were analyzed using Fisher's exact test. Continuous phenotypic characteristics were compared between groups using a Wilcoxon rank sum test.

Results: IFN activity was low or absent in controls and detected at high levels in 31 of 53 (59%) SS patients. While patterns consistent with type I-predominant (n=9), type II-predominant (n=11) and mixed I/II (n=11) IFN activity were evident, these patients were indistinguishable in regards to key SS phenotypic features, except focus score which was highest in type II-predominant patients (p=0.024). Stratification of SS patients by high vs low IFN activity revealed associations of high IFN activity with high titer ANA (p=0.0016) and SSA (p=0.0161) antibodies, hyperglobulinemia (IgG ≥1445 mg/dl, p=0.0005; IgA ≥400 mg/dl, p=0.0335) and higher focus scores (p<0.0001). Additionally IFN high patients demonstrated greater evidence of glandular dysfunction as determined by a decreased ability to produce saliva (UWS; 0.164 vs 0.549 ml/5min, p=0.0003) and tears (Schirmer; 4 vs 6.5 mm/5min, p=0.0368).

Conclusion: Our data indicate that the parent phenotype in SS (chronic exocrine gland dysfunction, inflammatory infiltration and autoimmunity) includes distinct molecular subtypes, segregated by magnitude and pattern of IFN responses. While the resulting disease subtypes are clinically similar, therapies targeting type I and/or type II IFN may need to be selected based on prior analyses of which specific IFN pathway(s) are active *in vivo* in individual patients.

Precisely Quantified Fibrosis in Labial Salivary Glands Predicts Sjögren's Syndrome Classification in a Multiple Regression Model. Kerry M. Leehan[1], Michael Brown[2], Courtney Montgomery[2], Astrid Rasmussen[2], David M. Lewis[1], Lida Radfar[1], Donald U. Stone[1], Stephen Young[1], R. Hal Scofield[1], Kathy L. Moser Sivils[2] and A. Darise Farris[2]. [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: Primary Sjögren's Syndrome (pSS) is a systemic, progressive autoimmune exocrinopathy that presents diagnostic challenges. Focal lymphocytic infiltrates in labial salivary gland (SG) biopsies, serum autoantibodies, objective measures of dryness, and patient-reported symptoms are used to classify pSS. Because focus score (FS) may vary with course of disease, we asked whether precisely quantified SG fibrosis can distinguish pSS from non-SS sicca.

Methods: Formalin-fixed biopsy sections (4–6 glandular cross-sections per subject) collected from symptomatically dry individuals attending the Oklahoma Sjögren's Syndrome Center of Research Translation clinic were stained with hematoxylin/eosin, imaged and digitally reconstructed. American European Consensus Group (AECG) classification status (n=50 pSS; n=28 non-SS) was blinded in order to eliminate bias by the scorer. AECG pSS exclusions were applied to all subjects. Fibrosis was quantified using a digital grid overlay; sections were scored and reported as average percent area per individual. Relationship of degree of fibrosis with age, focus score, whole unstimulated salivary flow, stimulated parotid flow, van Bijsterveld score and Schirmer's score was evaluated using Spearman correlations. Logistic regression was implemented using rank-transformed fibrosis scores to assess their predictive value for disease classification.

Results: Fibrosis was significantly increased (p=0.0004, Mann-Whitney U) in pSS salivary glands (median 25.39%, range 1.788%-70.45%) compared to non SS sicca subjects (median 15.52%, range 8.876%-31.38%). Among pSS subjects, fibrosis correlated with age (p=0.029, r=0.307), lip biopsy focus score (p=0.01, r=0.360) and van Bijsterveld Score (vBS, p=0.02, r=0.310). No significant correlation between fibrosis and salivary flow or Schirmer's score was observed. In a predictive model including fibrosis and age, degree of labial salivary gland fibrosis predicted disease classification with 68% accuracy irrespective of age (fibrosis, $p=3.91\times10^{-5}$; age, p=0.63).

Conclusion: Although age is associated with salivary gland fibrosis, multiple regression analysis suggests that labial salivary gland fibrosis is a significant feature of primary Sjögren's syndrome regardless of age.

Longitudinal Examination with Salivary Gland Ultrasonography (SGUS) of Patients with Primary Sjogren's Syndrome: A Single Center Experience. Chiara Baldini[1], Nicoletta Luciano[1], Francesca Sernissi[1], Daniela Martini[1], Francesco Ferro[1], Marta Mosca[2] and Stefano Bombardieri[2]. [1]Rheumatology Unit, Pisa, Italy, [2]Rheumatology Unit, University of Pisa, Pisa, Italy.

Background/Purpose: Recently, convincing data have been published on the diagnostic value of salivary gland ultrasonography (SGUS) in primary Sjögren's syndrome (pSS). However, a limited number of information are available on the contribution of SGUS in the patients' prognostic assessment and in the monitoring of the response to therapy during the follow-up. Aim of the study was to prospectively evaluate if SGUS might have a role in the prognostic stratification and in the monitoring of the disease activity in patients with pSS over the follow-up.

Methods: The study population consisted of consecutive patients with a diagnosis of pSS (AECG 2002) who prospectively underwent clinical, laboratory and SGUS assessment at baseline, at 12 and at 24 months. An experienced rheumatologist scored the EULAR Sjögren's Syndrome Activity Index (ESSDAI) at each follow-up time point. Patients received the "best-available-therapy" according to the clinical practice. SGUS was performed by the same radiologist blinded to the rheumatologist clinical assessment. The parotid and submandibular glands were scanned on both sides by using a real-time US scanner (Esaote Technos MPX) with a 7.5–12.5 MHz transducer and the following US parameters were recorded: size, parenchymal echogenicity and inhomogeneity in the parotid and submandibular glands on both sides. A previously reported ultrasound scoring system (De Vita *et al* 1992) was used to grade the echostructure alterations of the salivary glands. Baseline, 12 months and 24 months SGUS results were compared using the non-parametric Friedman test for multiple comparisons. Correlation between SGUS and ESSDAI changes throughout the follow-up period was assessed using the Spearman linear correlation coefficient. Statistical significance was accepted at $p<0.05$.

Results: From January 2012 and January 2014, 68 pSS patients were enrolled in this study (median (IQR) age: 54 (45–64) years). At the baseline 28/68 (41.2%) presented a SGUS score ≥2. These patients, when compared to the group of patients with a SGUS score <2, presented more frequently low C4 levels ($p=0.04$), positivity for anti-Ro/SSA ($p<0.0001$) and higher mean ESSDAI scores, with the ESSDAI positively correlating with the SGUS score ($r=0.571$, $p<0.0001$). Over the follow-up we still observed a positive correlation between the changes in the ESSDAI and the changes in the SGUS score ($r=0.490$, $p<0.0001$). However, no statistically significant differences were detected over the follow-up in the SGUS score across the multiple test performed and at the end of the study patients with grossly inhomogenous glands still presented evident inhomogeneities.

Conclusion: This study highlighted the positive correlation between SGUS score and pSS disease activity. However, further research is needed before a conclusion can be made regarding the possibility of using SGUS in the assessment of the response to therapy in pSS.

2932

Increased Risk of Deep Vein Thrombosis and Pulmonary Embolism in Sjögren's Syndrome: A General Population-Based Cohort Study. Marko Yurkovich[1], Hyon K Choi[2], Eric C. Sayre[3], Kamran Shojania[1] and J. Antonio Avina-Zubieta[3]. [1]University of British Columbia, Vancouver, BC, [2]Boston University School of Medicine, Boston, MA, [3]Arthritis Research Centre of Canada, Richmond, BC.

Background/Purpose: There is limited data available on the risk of deep venous thrombosis (DVT) and pulmonary embolism (PE) in Sjögren's Syndrome (SjS). We estimated the population-based risk of **newly recorded DVT and PE** among **incident cases with SjS** compared to controls from the general population using physician-billing and hospitalization databases that cover the entire population of the province of British Columbia, Canada (~ 4.4 million).

Patients and Methods: Our data include all visits to health professionals and all hospital admissions from Jan 1, 1990 to Dec 31, 2010 and all dispensed medications from Sept 1, 1995 to Dec 31, 2010 for all individuals. We conducted a retrospective matched cohort study among patients satisfying at least one of the following criteria: **a)** diagnosis of SjS in adults on at least two visits within a two-year period between Jan 1996 and Dec 2010 by a non-rheumatologist physician; **b)** diagnosis of SjS on at least one visit by a rheumatologist or from hospitalization. To increase specificity we excluded cases that were not confirmed by a rheumatologist if they were seen at a later point. Ten non-SjS controls matched by birth year, sex and calendar year of follow-up were selected from the general population for each case. Outcomes: **incident PE, DVT, and PE or DVT** events based on hospitalization records (for PE and DVT), outpatient visits (DVT) or death certificates (all outcomes). For non-fatal outcomes, we also required the use of anticoagulant medication within six-months of the event as part of all outcome definitions. We estimated relative risks (RRs) comparing SjS with age-, sex- and entry time-matched comparison cohorts, adjusting for potential risk factors for PE and DVT. Sensitivity analyses were conducted to assess for unmeasured confounders.

Results: Among 1175 incident SjS cases, 14, 10 and 19 developed a first time PE, DVT, and PE or DVT event, respectively (incidence rates = 3.8, 2.7 and 5.2 per 1,000 person years, respectively) (**see table**). Compared with the age, sex, and entry-time-matched controls, the RRs were 4.1 (95% CI; 2.0 – 7.7), 3.0 (95% CI; 1.3 – 6.1) and 3.1 (95% CI; 1.8 – 5.3) for PE, DVT, and DVT or PE, respectively. After adjusting for covariates the results remained similar (**see table**). The risk of developing DVT, PE or either event was highest within the first year following diagnosis of SjS, decreasing over time to become not significantly increased after 5 years. Our results remained statistically significant after adjusting for the potential impact of an unmeasured confounder (adjusted RRs ranging between 1.58 – 1.98 in all sensitivity analyses).

Conclusion: This large population-based study indicates an increased risk of DVT and PE in patients with SjS. Our results support the need for increase monitoring for these complications in SjS patients.

Table: Risk of Incident PE, DVT or DVT or PE according to SjS Status

	PE		DVT		PE or DVT

Metabolic Syndrome, Adipocytokines and Inflammation in Sjögren's Syndrome. Kristopherson Lustosa Augusto[1], Eloisa Bonfá[2], Rosa M. R. Pereira[1], Cleonice Bueno[1], Vilma S. T. Viana[3] and Sandra G. Pasoto[1]. [1]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [2]University of Sao Paulo, Sao Paulo, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: Systemic inflammation has been linked to increased frequency of metabolic syndrome (MetS) in autoimmune diseases. However, there are no studies concerning the frequency of this complication and adipocytokine sera profile in Primary Sjögren's syndrome (SS).

The aim of this study was to evaluate the frequency of MetS and serum levels of inflammatory cytokines, B-cell activating factor (BAFF) and adipocytokines in SS patients.

Methods: Seventy-one female SS patients (American-European Consensus Group Criteria), aged 18–65 years and 71 healthy women matched for age and race were enrolled in this case-control study. Clinical data were collected by a standardized questionnaire and physical examination at inclusion. Serum levels of glucose, total cholesterol, low density lipoprotein (LDL), high density lipoprotein (HDL), triglycerides, interleukin-1 beta (IL-1b), IL-6, BAFF, insulin, leptin, adiponectin, visfatin, resistin, ghrelin and plasminogen activator inhibitor-1 (PAI-1) were determined for all patients and controls. MetS (International Diabetes Federation) and disease activity [(EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI)] were also determined.

Results: Patients and controls were comparable regarding mean age (47.6 ± 10.3 vs. 47.2 ± 10.3 years, $p=0.833$), ethnicity (white: 77.5 vs. 77.5 %, $p=1.000$), body mass index (BMI) (27.6 ± 6.4 vs. 26.7 ± 3.6 kg/m^2, $p=0.783$), smoking ($p=0.538$), sedentary lifestyle ($p=0.847$) and menopause

(p=0.502). In contrast, MetS (39.4 vs. 16.9%, p=0.005), hypertension (32.4 vs. 11.3%, p=0.004) and dyslipidemia (22.5 vs. 4.2%, p=0.002) were more frequent in patients than controls in spite of similar abdominal and hip circumferences (p>0.05). No differences were observed regarding glucose (p=0.062), insulin (p=0.271) and HOMA-IR (p=0.662). Serum levels of IL-1b (p=0.008), IL-6 (p<0.0001), BAFF (p<0.0001), resistin (p<0.0001) and adiponectin (p=0.001) were higher in patients than in controls. Further analysis showed that SS patients with (n=28) and without (n=43) MetS were similar regarding age (p=0.111) and race (p=0,773). In contrast, the first group had higher BMI, abdominal circumference, cholesterol/LDL/VLDL, triglycerides, insulin and leptin levels, HOMA-IR score, and higher frequencies of hypertension and diabetes (p<0.05). ESSDAI (p=0.240), prednisone use (35.7 vs. 23.3%, p=0.289), current (3.0 ± 4.5 vs. 1.6 ± 3.2 mg/day, p=0.299) and cumulative dose (p=0.495) were similar in both groups. Otherwise, IL-1b levels were higher in SS patients with MetS than those without MetS (83.1 ± 187.6 vs. 8.4 ± 27.7 pg/mL, p=0.046). Multivariate analysis with adjustment for age, ethnicity, current and cumulative prednisone doses and usage time revealed that MetS group had higher values of hypertension (p=0.010), HOMA-IR (p=0.001), LDL (p=0.041), VLDL (p=0.001), triglycerides (p=0.001), glucose (p=0.045), insulin (p=0.006), leptin (p=0.008) and IL-1b (p=0.048).

Conclusion: This study identified a high frequency of MetS and an abnormal adipocytokine profile in SS patients. The interesting association of MetS with elevated IL-1b suggests that inflammation plays an important role in its pathogenesis in SS.

Abatacept reduces Circulating Effector Memory T-Helper Cells in Patients with Primary Sjögren's Syndrome. Gwenny Verstappen[1], Wayel H. Abdulahad[2], Petra M. Meiners[1], Suzanne Arends[1], Silvia Beijer-Liefers[1], Arjan Vissink[1], Frans G.M. Kroese[1] and Hendrika Bootsma[1]. [1]University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [2]University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: In an open-label proof of concept study, Abatacept has been identified as an effective and safe treatment modality in primary Sjögren's syndrome (pSS). Abatacept is a fully human fusion molecule of IgG-Fc and CTLA-4 that modulates the costimulatory interaction between APCs and T-lymphocytes, thereby inhibiting full T-cell activation. Modifying T-helper (Th-) cell homeostasis may contribute to the therapeutic effect of Abatacept as Th-cell subset imbalances are involved in the emergence of autoimmune diseases. Therefore, the aim of this study was to assess Th-cell homeostasis in peripheral blood of pSS patients in response to Abatacept treatment.

Methods: Fifteen patients with pSS, diagnosed according to the revised American-European Concensus Group criteria, were treated with Abatacept on days 1, 15, 29 and every four weeks thereafter for five months (≈10 mg/kg of body weight i.v.). Absolute numbers and frequencies of circulating Th-cell subsets ($CD3^+CD4^+$) were examined in fresh blood samples by flow cytometry at baseline and 4, 12, 16, 24, 36 and 48 weeks after the first dose. Expression patterns of chemokine receptors CCR7 and CD45RO were used for distinction between naive, central memory, effector memory and terminally differentiated Th-cells. Generalized estimating equations (GEE) were used to analyze the presence of different subsets over time within subjects, viz. on treatment (week 0–24) and off treatment (week 24–48). Currently, the extent to which different subsets of effector memory Th-cells are affected by Abatacept is under investigation.

Results: On Abatacept treatment, numbers of peripheral blood $CD4^+$ T-cells did not significantly differ from baseline values. However, absolute numbers and frequencies of total memory Th-cells decreased significantly over time on treatment (p=0.001 and p<0.001, resp.). This was mainly a result of a decrease in effector memory Th-cells. On treatment, both absolute numbers and frequencies of effector memory Th-cells decreased significantly over time (p=0.011 and p=0.001, resp.), with the largest decrease seen at week 24. On the contrary, frequencies of naive Th-cells increased over time on treatment (p<0.001). From week 24 to week 48 (off treatment), a trend towards increased absolute numbers and frequencies of effector memory Th-cells was observed. Decrease and repopulation of this T-cell subset correspond to changes in disease activity as assessed with ESSDAI.

Conclusion: CTLA-4Ig treatment with Abatacept decreases the presence of circulating effector memory Th-cells of pSS patients. The observation that decrease and repopulation of effector memory Th-cells correspond to changes in disease activity suggests that these cells are -at least partially- responsible for the effects of Abatacept treatment seen in pSS patients.

Spondylarthropathies and Psoriatic Arthritis V - Clinical Aspects and Treatment
Tuesday, November 18, 2014, 4:30 PM–6:00 PM

2935

Attainment of Minimal Disease Activity Using Methotrexate in Psoriatic Arthritis. Barry J. Sheane, Arane Thavaneswaran, Dafna D. Gladman and Vinod Chandran. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Methotrexate (MTX) is used as first-line treatment in psoriatic arthritis (PsA); however, the extent of the disease-modifying effect of MTX on PsA, if any, is not established. Randomized controlled trials examining the efficacy of MTX have been either under-powered or have used dosages that may be sub-optimal. While TNF inhibitors (TNFi) are used as second-line therapies in PsA, they have proven efficacy and disease-modifying effect. Minimal disease activity (MDA) is achieved at 24 weeks in 39% and 52% of patients treated with adalimumab and infliximab, respectively. There is a need to establish the treatment effect of MTX. An international task force recently recommended that disease remission or MDA be the target of treatment and should be attained within 6 months of initiating medication.

The aims of this retrospective study were to: a) establish the percentage of PsA patients that achieve MDA after 6 months of treatment with MTX, and b) identify the dose of MTX most likely to achieve MDA.

Methods: All patients attending a large, tertiary referral centre for PsA who initiated MTX and were naïve to biological medication on or after January 2004 up until April 2014 were assessed for inclusion. The primary outcome was the achievement of MDA after 6 months of MTX. MDA is defined as: the presence of at least 5 out of the following 7 domains: tender joint count ≤ 1, swollen joint count (SJC) ≤ 1, Psoriasis Area Severity Index (PASI) ≤ 1 or body surface area ≤ 3%, tender entheseal points ≤ 1, Health Assessment Questionnaire score ≤ 0.5, patient global disease activity Visual Analogue Scale (VAS) score ≤ 20 and patient pain VAS ≤ 15.

Of 204 patients identified, 29 had insufficient duration on MTX to accurately assess outcome. These were excluded, leaving 175 for analysis. Of these, 167 patients had sufficient data for analysis at 6 months.

Results: Of 204 patients, 54% were male. At the start of MTX use (all mean (SD)), age was 47.1 (13.5) years, duration of PsA 6.2 (8.0) years, PASI 5.5 (8.0), tender joint count 10.2 (10.7) and swollen joints 6.0 (7.4). Oral MTX was prescribed in 77.5%; 22 (10.8%) had been prescribed a DMARD in the past.

After 6 months on MTX, 29 patients (17.4%) achieved MDA, despite 97 patients (58.1%) achieving a SJC ≤ 1 and 138 (82.6%) a PASI ≤ 1; Patient-reported outcomes were less responsive, with only 22 (13.2%) achieving the outcome for disease activity. For patients achieving MDA, mean dose was 17.8 (4.2) mg/week by 6 months, with 58.6% taking ≥ 17.5 mg/week (76% were taking oral MTX). This dose was similar in those not achieving MDA. Back pain (both inflammatory and mechanical) and dactylitis were associated with a lower probability of achieving MDA.

Conclusion: Based on this analysis, MTX use achieves the recommended treatment target of MDA by 6 months in less than 20% of patients. This low rate of achievement is explained by failure of response in the patient-reported outcome components of the MDA criteria. Adequately-powered randomized controlled trials are needed to establish the efficacy of MTX as a first line drug in PsA.

Is Ankylosing Spondylitis a Risk Factor for Cardiovascular Diseases, and How Does These Risks Compare to Those in Rheumatoid Arthritis?. Johan Askling[1], Lennart Jacobsson[2] and Jonas Eriksson[1]. [1]Clinical Epidemiology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]sahlrenska academy, gothenburg, Sweden.

Background/Purpose: Patients with RA are at increased risk of cardiovascular (CV) diseases, including acute coronary syndromes (ACS), deep venous thromboembolism (DVT) and pulmonary embolism (PE), and cerebrovascular diseases. Evidence suggests that traditional CV risk factors alone do not account for the entire risk increase. Instead, RA disease activity has been proposed to be of critical importance. Ankylosing Spondylitis (AS) is a chronic inflammatory disease with a different gender- and age-distribution, pathology, and phenotype yet often with a pronounced systemic inflammation. In contrast to the literature on CV risks in RA, data on CV risks in AS are less well studied, and because of the age/sex-differences between RA and AS, not directly comparable. The aim of this study was therefore to assess and compare CV risks, by CV phenotype, between prevalent patients with AS, RA and the general population, taking age and sex-differences into account.

Methods: We performed a nationwide population-based cohort study based on register linkage of prospectively recorded data from the Swedish Patient, Death, and Population Registers 2006–2011. We identified one cohort of prevalent patients with RA (n=37,245), one with AS (N=5,358) and one with general population comparator subjects (n=185,153). These cohorts were followed through 2011 for first ever occurrence of ACS, DVT/PE, and stroke, respectively (individuals with a history of the outcome were excluded). Age- and sex-specific rates for each outcome were calculated; rates were then standardised to the age/sex-distribution of the AS cohort.

Results: Crude rates were the lowest for AS. However, assuming all populations had the same age/sex distribution as the AS cohort, the rate for ACS was 30% higher among patients with AS, and 60% higher in patients with RA, than in the general population (Table). For stroke, the rate was 20% higher among patients with AS, and 30% higher in patients with RA, than in the general population. For thromboembolic events, the rate was 30% higher among patients with AS, and 80% higher in patients with RA, than in the general population.

Conclusion: Prevalent patients with AS in a population-based cohort are at a 20–30% increased risk of CV events compared to the general population. Whilst increased, the level of increase is around half that seen in the corresponding age/gender groups in RA.

Table. Crude rates of ACS, stroke, and DVT/PE in AS, RA and general population cohorts, and the corresponding standardised rates using the AS population as standard

	Acute Coronary Syndrome			Stroke			Thromboembolic events

Evaluation of Referral Models for Axial Spondyloarthritis in Primary Care in the Spondyloarthritis Caught Early Cohort. Ozair Abawi, Rosaline van den Berg, Désirée van der Heijde and Floris van Gaalen. Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Several models have been proposed to refer patients (pts) with possible axial spondyloarthritis (axSpA) from primary care to the rheumatologist. Aim of the study was to evaluate performance of referral models for axSpA in the SPondyloArthritis Caught Early (SPACE) cohort.

Methods: Ten referral models were found in literature and tested in the *Leiden* SPACE cohort, including pts with back pain (≥3 months, ≤2 years, onset <45 years; n=192) referred to the rheumatology outpatient clinic of the LUMC. Imaging was omitted from all models if included as a referral parameter, as it is unfeasible for screening in primary care. **[table 1]**

Table 1. Characteristics of referral models. IBP, inflammatory back pain; IBD, inflammatory bowel disease

Model	Criteria	Refer if
Brandt I	HLA-B27, IBP (based on 3 criteria[1]; positive if 1/3 criteria fulfilled)	≥1 out of 2 positive
Brandt II	HLA-B27, IBP (positive if 2/3 criteria fulfilled)	≥1 out of 2 positive
Brandt III	HLA-B27, IBP (positive if 3/3 criteria fulfilled)	≥1 out of 2 positive
Braun[2]	Psoriasis, buttock pain, improvement of back pain by exercise (if ≤1 positive answer, HLA-B27 is tested)	≥2 positive or ≤1 positive and HLA-B27 positive
Braun alt.	Psoriasis, alternating buttock pain, improvement of back pain by exercise (if ≤1 positive answer, HLA-B27 is tested)	≥2 positive or ≤1 positive and HLA-B27 positive
MASTER[3]	HLA-B27, IBP, family history for ankylosing spondylitis, good response to NSAIDs	≥2 out of 4 positive
RADAR[4]	HLA-B27, IBP, family history for SpA, good response to NSAIDs, extra-articular manifestations (uveitis, psoriasis or IBD)	≥2 out of 5 positive
RADAR 2/3	IBP, good response to NSAIDs, extra-articular manifestations (uveitis, psoriasis or IBD)	≥2 out of 3 positive
CaFaSpA 1 pt[5]	IBP (ASAS), family history for SpA, good response to NSAIDs	≥1 out of 3 positive
CaFaSpA 2 pt	IBP (ASAS), family history for SpA, good response to NSAIDs	≥2 out of 3 positive

Performance of the models was evaluated (sensitivity, specificity, positive predictive value, positive likelihood ratio) using classification by ASAS axSpA criteria as external standard. For pts not fulfilling the ASAS criteria who are referred, post-test probability for axSpA was calculated based on the LR product for presence of SpA features. A LR product ≥78 equals a post-test probability ≥80% and was used as cut-off for probable axSpA. Pts who were incorrectly not referred met the ASAS axSpA criteria by fulfilling the clinical arm only or the imaging arm (imaging arm only or both arms). [table 2]

Table 2. Performance of referral models. Sens, sensitivity; Spec., specificity; PPV, positive predictive value; LR+, positive likelihood ratio; PTP, post-test probability

In SPACE: 74 patients fulfilling axSpA criteria 118 patients not fulfilling axSpA criteria							
Model	LR+	PPV	Referred patients fulfilling axSpA criteria n (sens.)	Referred patients not fulfilling axSpA criteria n (spec.)	Referred patients not fulfilling axSpA criteria with ≥80% axSpA n	Patients not referred but fulfilling axSpA criteria: imaging arm	Patients not referred but fulfilling axSpA criteria: clinical arm only
Brandt I	1.08	0.40	73 (0.99)	108 (0.08)	7	1/1	–
Brandt II	1.27	0.44	71 (0.96)	89 (0.24)	7	3/3	–
Brandt III	1.87	0.54	60 (0.82)	52 (0.56)	6	13/13	–
Braun	1.90	0.54	63 (0.85)	53 (0.55)	7	11/11	–
Braun alt.	3.04	0.66	61 (0.82)	32 (0.73)	6	13/13	–
MASTER	2.67	0.63	52 (0.70)	31 (0.74)	5	21/22	1/22
RADAR	2.27	0.59	64 (0.86)	45 (0.62)	6	10/10	–
RADAR 2/3	1.52	0.49	43 (0.58)	45 (0.62)	4	23/31	8/31
CaFaSpA 1 pt	1.27	0.44	69 (0.93)	87 (0.26)	6	5/5	–
CaFaSpA 2 pt	2.18	0.58	41 (0.55)	30 (0.75)	3	26/33	7/33

Results: In total, 74/192 pts fulfilled ASAS axSpA criteria; 48 with positive imaging (n=15 radiographic sacroiliitis). Most models performed well regarding sensitivity/specificity. Braun alt. model has the most balanced sensitivity/specificity and highest LR+. All models that include HLA B27 miss axSpA pts with positive imaging, 14–23% with radiographic sacroiliitis (depending on the model). PPV of the models is low, indicating that many pts are referred despite not fulfilling axSpA criteria. However, 6–16% (depending on the model) of these pts have a post-test probability ≥80% for axSpA. This reflects that these pts are rightly referred, despite not fulfilling the axSpA criteria.

Conclusion: Most referral models performed well in the SPACE cohort. However, this cohort includes pts already referred from primary care, probably causing overestimation of performance of all models. All models miss pts fulfilling the ASAS imaging arm, 14–23% of which have radiographic sacroiliitis, which is highly undesirable. Moreover, large numbers of pts referred unnecessarily might lead to a burden for health care systems. Further studies should be conducted in primary care to evaluate these models in their target population.

A Randomized, Double-Blind, Placebo-Controlled, 16-Week Study of Subcutaneous Golimumab in Patients with Active Nonradiographic Axial Spondyloarthritis. J Sieper[1], D van der Heijde[2], M Dougados[3], W Maksymowych[4], J Boice[5], G Bergman[5], S Curtis[5], A Tzontcheva[5], S Huyck[5]

and HH Weng[5]. [1]University Clinic Benjamin Franklin, Berlin, Germany, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Paris-Descartes University, Paris, France, [4]University of Alberta, Alberta, AK, [5]Merck & Co., Inc., Whitehouse Station, NJ.

Background/Purpose: Axial spondyloarthritis (axSpA), including ankylosing spondylitis and nonradiographic axial SpA (nr-axSpA), is a chronic inflammatory disease marked by back pain and progressive spinal stiffness. The goal of GO-AHEAD was to determine if golimumab (GLM) is superior to placebo (PBO) in patients with nr-axSpA.

Methods: GO-AHEAD was a Phase 3b, double-blind, randomized, PBO-controlled trial that evaluated subcutaneous (SC) GLM 50 mg vs PBO in patients aged 18–45 years with active nr-axSpA (Assessment of SpondyloArthritis international Society [ASAS] criteria and centrally-read SI joint X-rays; disease duration ≤5 years; chronic back pain; high disease activity [total back pain ≥40 mm on a 0–100 mm VAS and Bath Ankylosing Spondylitis Disease Activity Index {BASDAI} ≥4 cm]; and inadequate response or intolerance to NSAIDs). Patients were randomized 1:1 to GLM or PBO SC injections every 4 weeks. The primary endpoint was ASAS 20 attainment at week 16. Key secondary endpoints were ASAS 40, ASAS partial remission, and BASDAI 50 attainment; and Spondyloarthritis Research Consortium of Canada (SPARCC) magnetic resonance imaging (MRI) sacroiliac (SI) joint score change. AS Disease Activity Score based on C-reactive protein (ASDAS) was assessed. Treatment group differences for all patients-as-treated and the target populations (signs of inflammation by MRI or elevated CRP at baseline) were compared using the stratified Miettinen and Nurminen method for responder endpoints and the Mann-Whitney test for MRI SI joint score.

Results: Of 198 patients enrolled, 197 were treated (GLM=97; PBO=100). Mean age was 31 years; 57% were male. At baseline, mean BASDAI was 6.5 cm (SD=1.5), SPARCC MRI SI was 11.3 (SD=14.0), and ASDAS was 3.5 (SD=0.9). The primary endpoint was achieved by significantly more GLM patients (71.1%) than PBO patients (40.0%; table). Significantly more GLM patients also attained ASAS 40, ASAS partial remission, and BASDAI 50 (table). Mean ASDAS improvements were greater with GLM than PBO (−1.7 vs −0.6, respectively; P <.0001). Mean SPARCC MRI SI joint score improvements from baseline to week 16 were greater with GLM than PBO (−5.3 vs −0.9, respectively; P <.0001); improvements for the target population were −6.4 vs −1.2, respectively (P<.0001).

Table. Primary and Key Secondary Outcomes, Week 16

	All Patients as Treated			Target Population		
	GLM N=97 n (%)	PBO N=100 n (%)	Difference vs PBO,* % (95% CI)	GLM N=78 n (%)	PBO N=80 n (%)	Difference vs PBO,* % (95% CI)
ASAS 20	69 (71.1)	40 (40.0)	31.2 (17.5, 43.6) P <.0001	60 (76.9)	30 (37.5)	39.6 (24.6, 52.6) P <.0001
ASAS 40	55 (56.7)	23 (23.0)	33.8 (20.4, 46.1) P <.0001	47 (60.3)	18 (22.5)	37.9 (23.0, 51.2) P <.0001
ASAS Partial Remission	32 (33.0)	18 (18.0)	15.2 (3.2, 27.1) P =.0136	27 (34.6)	15 (18.8)	16.1 (2.5, 29.6) P =.0204
BASDAI 50	56 (57.7)	30 (30.0)	28.0 (14.4, 40.6) P <.0001	46 (59.0)	23 (28.8)	30.5 (15.4, 44.3) P <.0001

*Differences derived from the statistical model.

Adverse events (AEs) occurred in 41% of GLM and 47% of PBO patients. Serious AEs occurred in 1 GLM (female partner reported fetal death) and 2 PBO patients (cholelithiasis, back pain). There were no serious infections, serious opportunistic infections, active tuberculosis, malignancies, serious systemic hypersensitivity, or deaths.

Conclusion: Patients with active nr-axSpA treated with GLM had significantly greater improvements in disease activity and inflammation on MRI than patients treated with PBO. GLM was well-tolerated and generally had a favorable benefit-risk profile.

Increased Diagnosis of Spondyloarthritis in Female Patients Started in the Early Biologic Era: Data from the Ontario Spondyloarthritis (OnSpA) Study. Nisha Nigil Haroon[1], Ping Li[2], Michael Paterson[2] and Nigil Haroon[3]. [1]Department of Medicine, University of Toronto, Toronto, ON, [2]Institute of Clinical Evaluative Sciences, Toronto, ON, [3]Toronto Western Research Institute, Toronto, ON.

Background/Purpose: The health and economic impact of spondyloarthritis is considerable and growing. Over the past decade or more, there have been two major changes in this field that could potentially affect the diagnosis of new AS patients. The first was the introduction of Tumor Necrosis Factor inhibitors (TNFi), which dramatically changed the treatment paradigm in AS. The second was the introduction of a new entity called non-radiographic axial Spondyloarthritis (nr-AxSpA), defined based on the presence of MRI changes and HLA-B27, but without classic X-ray changes of AS. We studied the changes in incidence and prevalence of spondyloarthropathies (SpA) over time in Ontario, Canada.

Methods: We performed a population-based, retrospective cohort study on patients with SpA, age 15 or above, living in Ontario between 1995 and 2010. We used a stringent SpA definition of 2 outpatient claims within 2 years with at least one inpatient or rheumatologist claim. Incidence ratios, prevalence rates and confidence intervals were calculated using Poisson regression. The incidence of SpA in men and women were compared in the pre-biologic era (1995–2000), early biologic era (2000–2005) and late biologic era (2005–2010).

Results: A total of 21,878 SpA patients were identified. The age, sex and local health integration network (LHIN) standardized prevalence rates (per 100,000) for SpA were 79 in 1995, 132 in year 2000, 173 in 2005 and 213 in 2010. The male: female ratio was 1.7 in 1995, which progressively dropped to reach 1.25 by 2010. A significant increase in the diagnosis of female AS patients but not male patients occurred between 2000–2005. The male; female ratio in incident cases decreased from 1.3 in 1995 to 1.0–1.1 by 2005–2010. In both sexes, the incidence rates rose uniformly in all age groups (15–44 years, 45–64 years and above 65 years) with time.

Conclusion: In this large population-based study, the period specific adjusted prevalence of SpA progressively increased. More female patients were diagnosed with SpA from 2000 onwards which correlates with the introduction of TNFi therapy in AS. Thus the trend of increasing female SpA patients predates the introduction of MRI and the new ASAS classification criteria for axial SpA.

Do Patients with Non-Radiographic Axial Spondyloarthritis and Ankylosing Spondylitis Respond Similarly Well to Nsaids? – a Prospective Study Including Magnetic Resonance Imaging. Xenofon Baraliakos[1], Uta Kiltz[1], Frank Heldmann[1], Heiner Appel[2], Friedrich Dybowski[3], Manfred Igelmann[4], Ludwig Kalthoff[5], Dietmar Krause[6], Hans-Jürgen Menne[7], Ertan Saracbasi[8], Elmar Schmitz-Bortz[9] and Jürgen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Rheumatology and Nephrology Practice, Hamm, Germany, [3]Rheumatology Practice, Herne, Germany, [4]Rheumatology Practice, Bochum, Germany, [5]Rheumatology practice, Herne, Germany, [6]Rheumatology practice, Gladbeck, Germany, [7]Rheumatology practice, Dortmund, Germany, [8]Rheumatology practice, Oberhausen, Germany, [9]Rheumatology practice, Hattingen, Germany.

Background/Purpose: Patients classified as axial spondyloarthritis (axSpA) may have ankylosing spondylitis (AS) or non-radiographic axSpA (nr-axSpA). Treatment recommendations for AS consider non-steroidal anti-inflammatory drugs (NSAIDs) as first-line therapy. After an unsatisfactory response to at least 2 non-steroidal anti-inflammatory drugs (NSAIDs) within 4 weeks (wk), anti-TNF agents are to be considered. However, it is unknown whether patients with nr-axSpA and AS respond similarly well to NSAIDs.

Methods: Consecutive patients (pts) with axSpA (both n=50 for nr-axSpA and AS, respectively) were included in a prospective study if their BASDAI level was ≥4, and if they had not received the maximally approved dose of NSAIDs nor anti-TNF agents to date. After inclusion into the study the maximal dose of NSAIDs was administered over 1wk and the dose was then adapted in case of BASDAI<4. In case of BASDAI ≥4 of in case of NSAID intolerance, the NSAID was changed and the pt was treated for another 3 wk at the maximal dose. Clinical and laboratory parameters and dosage of drugs were assessed by using the ASAS NSAID-index. Magnetic resonance images (MRI) of the sacroiliac joints including STIR sequences were performed and scored by the Berlin score. Data were collected before (BL) and after 1 and 4 wk of treatment.

Results: Nr-axSpA pts were more often female (48% vs. 30%), younger (mean age 37.6±11.0 vs. 41.9±12.3 years), and had a shorter symptom duration than AS pts (7.3±9.1 vs. 14.6±11.8 years) but were similarly often HLA-B27+ (80% vs. 74%), respectively. Significant differences were found in the mean CRP levels (0.6±0.9 vs. 1.2±1.1) and mean SIJ-MRI scores (3.1±3.0 vs. 6.7±5.4) in nr-axSpA vs. AS pts, respectively (both $p<0.001$). Prior to treatment, an ASDAS-CRP >2.1 was found in 76% and 74% and a positive MRI was seen in 70% and 78% of pts with nr-axSpA and AS, respectively. Both groups responded similarly well to NSAIDs: after wk1 and wk4, the NSAID-index increased similarly in both groups. Significant improvement after 4 wks were found for all assessments with the exception of CRP levels and MRI-a scores, where almost no changes were observed. Between wks 1 and 4, the ASAS20% response rate increased in the entire group from 40% to 52%. At wk 4, there was a slight difference between pts with nr-axSpA and AS: 46% vs. 58% ($p=0.23$), and ASAS partial remission was only found in 16% (14% nr-axSpA and 18% AS, $p=0.59$). However, a BASDAI ≥4 was found in 49% and 44% of pts at wks 1 and 4, respectively, while, in comparison, an ASDAS-CRP of ≥2.1 was found in 37% and 33% at wk 1 and 4. Overall, there were no major differences in response to treatment between nr-axSpA and AS pts.

Conclusion: This study confirms that there are no major differences between pts with AS and nr-axSpA in most clinical aspects. For the first time we show that pts with nr-axSpA and AS show similar response rates to NSAIDs in recommended doses. Importantly, almost 50% of pts with axSpA still have BASDAI levels ≥4 after 4wk of NSAIDs and would, thus, be eligible for anti-TNF therapy. Bone marrow edema on MRI and CRP levels were not influenced by NSAIDs.

Physical Function Is Independently Associated with Mortality Among Individuals with Knee and/or Hip OA: The Johnston County Osteoarthritis Project. Rebecca Cleveland[1], Todd Schwartz[1], Jordan B. Renner[2], Joanne M. Jordan[3] and Leigh F. Callahan[4]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina Department of Radiology, Chapel Hill, NC, [3]University of North Carolina Dept of Epidemiology, Chapel Hill, NC, [4]University of North Carolina, Chapel Hill, NC.

Background/Purpose: Declining physical function (PF) is a common consequence of osteoarthritis (OA), and poor PF is associated with death. It is possible that the resulting reduction in physical activity may increase an individual's risk of development or progression of life-threatening chronic diseases such as CVD and diabetes; however, we previously found that individuals with severe knee and/or hip OA were more likely to die, independent of comorbidities. We therefore sought to explore whether poorer PF among those with OA was associated with death at subsequent follow-up, independent of comorbidities associated with reduced PF.

Methods: Data were from 1,525 individuals aged 45 or older with radiographically confirmed (KL grade ≥2) knee and/or hip OA (rOA) who entered the cohort during the original study enrollment (1990–1997) and newly enrolled individuals recruited during the cohort enrichment (2003–2004). Vital status was assessed at first follow up period (1999–2004 for original participants; 2007–2010 for new enrolls). Severe rOA was defined as a KL grade ≥3; symptomatic OA (sxOA) was a subset of those with rOA and symptoms in the same joint. PF assessment was the 8-ft (2.4-m) walk test. Average number of steps needed to complete the walk and average times to the nearest tenth of a second across two trials were computed. Dichotomous variables based on medians were used for walk time (<3.4 sec and ≥3.4 sec) and number of steps (<5.5 steps and ≥5.5 steps). Multilevel logistic regression models controlling for the primary sampling unit (PSU) were used to estimate odds ratios (OR) and 95% confidence intervals (CI) for the associations between each PF measure at baseline and whether death occurred by the first follow-up evaluation. All models were adjusted for age, race, sex, BMI, smoking, depression, stroke, diabetes and CVD.

Results: Our sample was mostly women (63%), Caucasian (67%) and had a mean age of 65 years. At first follow-up, 18% of our sample had died. Walking time and number of steps above their medians were associated with about a doubling in the odds of death among those with knee and/or hip rOA (Table 1). Similar associations were observed when restricted to individuals with sxOA, and slightly attenuated ORs among those with severe disease that failed to reach statistical significance, possibly due to a smaller sample size. The highest odds of death with greater walking times were seen among individuals who had hip rOA whether with knee rOA (OR=2.33; 95% CI=1.20–4.51) or without knee rOA (OR=2.40; 95% CI=1.25–4.61).

Conclusion: Our findings suggest that poor PF among a cohort of individuals with knee and/or rOA is associated with death, findings which are independent of comorbidities linked to increased mortality. We observed associations with death were particularly strong for individuals with hip rOA, therefore suggesting a potential survival benefit through intervention among those individuals.

A Longitudinal Population-Based Study 1994–2010 of Age, Period, and Cohort Effects in the Prevalence of Arthritis: The Effect of Improving Socioeconomic Status and Increasing Obesity over Time. Elizabeth M. Badley[1], Mayilee Canizares[2], Anthony V. Perruccio[2], Sheilah. Hogg-Johnson[2] and Monique A.M. Gignac[2]. [1]Toronto Western Research Institute, Toronto, ON, [2]University of Toronto, Toronto, ON.

Background/Purpose: To examine birth cohort and period effects in the age-trajectories of reported arthritis from 1994 to 2010 in a representative sample of Canadians; and to determine whether any birth cohort or/and period effects in reported arthritis are associated with differences in SES (education and income), smoking, physical activity, or obesity over time.

Methods: Data from the Canadian Longitudinal National Population Health Survey, a nationally representative community sample followed every 2 years for 18 years. We used data for four birth cohorts (n =8,809 at baseline): World War II generation, born 1935–1944; older baby boomers, born 1945–1954; younger baby boomers, born 1955–64; and generation X, born 1965–74. Data at each interview included self-reported arthritis diagnosed by a health professional, years of education, household income, smoking, index of physical activity, and height (m) and weight (kg) (used to calculate body mass index (BMI: wt/ht^2)). Multilevel growth models were used to estimate the age-trajectory for reported arthritis for each cohort accounting for period. Once the age-trajectory was established, education, household income, smoking, physical activity, and BMI were separately introduced into the models to examine their influence on arthritis.

Results: There was a trajectory of increasing prevalence of arthritis with increasing age in all cohorts, with younger cohorts having successively greater prevalence. After accounting for period effects the cohort effect was no longer apparent. There were marked population-level cohort effects for increasing education, income, physical activity, and BMI and decreasing smoking from the youngest to oldest cohorts, which were much reduced (education, smoking, and physical activity) or removed (income and BMI) once period was taken into account. Including these variables in a multi-level growth model showed the prevalence of arthritis was significantly lower ($p<.001$) in those with higher education (OR: 0.54; 95% CI: 0.44 – 0.65: >16 years vs <12 years of school) or higher income (OR: 0.60; 95% CI: 0.53 – 0.68: highest vs lowest quartile) and the prevalence was significantly higher for obese individuals (OR: 2.63; 95% CI: 2.20 – 3.14: BMI>=35 vs normal

BMI (18.5–24.9) and current smokers vs non-smokers (OR: 1.63; 95% CI: 1.42 – 1.88). Physical activity was not significantly associated with arthritis. Further analysis showed that the population-level effects of increasing education and income on reducing the arthritis prevalence were almost counter-balanced by effects of increasing BMI (obesity).

Conclusion: The findings suggest that the cohort effect of more arthritis in younger cohorts is explained by period effects such that the potential benefits of increased education and income in reducing the prevalence of arthritis have been partially offset by increases in BMI over time. Our understanding of the impact of BMI on arthritis is therefore likely to be an underestimate. The cohort effect of increased arthritis in younger cohorts also suggests that previous population projections may be underestimated.

Severity of Foot Pain Is Linked to the Prevalence of Depressive Symptoms: The Framingham Foot Study. Arunima Awale[1], Alyssa B. Dufour[2], Patricia P. Katz[3], Virginia A. Casey[1] and Marian T. Hannan[4]. [1]Hebrew SeniorLife, Boston, MA, [2]Hebrew SeniorLife, Harvard Medical School & Beth Israel Deaconess Medical Center, Boston, MA, [3]University of California, San Francisco, CA, [4]Institute for Aging Research, Hebrew SeniorLife, Dept. of Medicine Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.

Background/Purpose: While a number of risk factors for foot pain are established, the relation between depression and foot pain has not been well studied. The purpose of this study was to examine the associations of foot pain and severity of foot pain with depressive symptoms in a population-based study of older adults.

Methods: A validated foot assessment and the 20-item CES-D questionnaire were administered to Framingham Foot Study (2002–08) participants. Age (years) and body mass index (BMI, kg/m^2) were also collected. Foot pain was queried: "On most days, do you have pain, aching or stiffness in either of your feet?" Severity of foot pain was categorized as: none (referent), mild, moderate or severe pain. CES-D scores ≥ 16 were considered indicative of significant level of depressive symptoms. Sex-specific logistic regression was used to calculate odds ratios and 95% confidence intervals for the association of foot pain (y/n or severity of foot pain) with depressive symptoms (y/n) adjusting for age and BMI. In a subset of participants, further models adjusted for leg pain (hip, knee, ankle), back pain, or other joint pain (neck, shoulder, elbow, wrist).

Results: Of the 3321 participants (mean age: 66 ± 10 years), 1464 were men (BMI: 28.9 ± 4.7 kg/m^2) and 1857 were women (BMI: 28.0 ± 6.0 kg/m^2). 21% men and 27% women had depressive symptoms (CES-D score ≥ 16). Men with moderate foot pain vs. none had 2-fold increased odds (Table) of reporting depressive symptoms; men with severe foot pain had a 4-fold increased odds, independent of age and BMI. Women showed a similar trend in which women with moderate foot pain had 2-fold increased odds of depressive symptoms, and women with severe foot pain had 3-fold odds, independent of age and BMI. For both men and women, mild foot pain showed increased odds (ratios of = 1.3 and 1.4 respectively), but was only statistically significant for women (p =. 046). Models considering other regions of pain attenuated the odds ratios (Table); pain variables were non-significant for men, while in women, back pain (p =. 007), other pain (p =. 019) but not leg pain (p =. 775) added to the model.

Conclusion: Severity of foot pain, adjusting for age and BMI, was significantly associated with the prevalence of depressive symptoms in our study (i.e., those reporting worse foot pain were more likely to report depressive symptoms). Adding joint pain at other regions attenuated but did not change the pattern of results. Future studies should investigate the longitudinal aspects of the severity of foot pain and depressive symptoms in older adults.

Table: Odds ratios and 95% confidence intervals for the association between severity of foot pain and depressive symptoms, stratified by sex, and adjusted for age and BMI.*

	Men (n = 1464)		Women (n = 1857)	
	n (%)	OR (CI)	n (%)	OR (CI)

Sedentary Time Is an Independent Risk Factor for Disability Onset Among Adults at Elevated Risk: Prospective Cohort Study. Jungwha Lee[1], Jing Song[1], Barbara Ainsworth[2], Rowland W. Chang[1], Linda S. Ehrlich-Jones[3], Christine Pellegrini[1], Pamela Semanik[4], Dorothy D. Dunlop[1] and Leena Sharma[5]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Arizona State University, Pheonix, AZ, [3]Rehabilitation Institute of Chicago, Chicago, IL, [4]Rush University, Chicago, IL, [5]Northwestern University, Chicago, IL.

Background/Purpose: Disability threatens personal independence and is a major driver of health care costs. Physical activity has been shown to prevent disability. Sedentary behavior, already associated with poor health outcomes, may have a unique relationship to the development of disability or simply reflect limited recommended moderate/vigorous physical activity (MVPA). If a separate and distinct risk factor, reducing sedentary behavior may provide an additional strategy to reduce disability among older adults.

Methods: Prospective multi-site cohort of 1680 community dwelling adults aged 49 years or older were at elevated risk to develop disability due to knee osteoarthritis or having knee osteoarthritis risk factors. Baseline sedentary and non-sedentary (e.g., light, moderate, vigorous) time were objectively measured using accelerometers. Participants were classified into sedentary time quartiles groups. Disability was ascertained from limitations in instrumental and basic activity of daily living (IADL/ADL) at baseline and two years. Hazard ratios for disability onset over 2 years follow-up were estimated from discrete time proportional hazards model controlling MVPA time, socioeconomic factors (age, sex, race/ethnicity, education, income), health factors (function, comorbidity, Center for Epidemiological Studies Depression score, body mass index category, current smoking, knee pain, knee OA severity, knee symptoms, knee injury, other lower extremity joint pain, gait speed).

Results: Incident disability was 147 versus 69, 62, and 72 per 1000 person-years over 2-years follow-up in the most sedentary quartile group (>11.5 sedentary hours per day) compared to the three less sedentary quartile groups, irrespectively. Less sedentary time was significantly associated with decreased risk of incident disability independent of moderate/vigorous minutes and other covariates (hazard ratios comparing three less sedentary quartiles vs. the most sedentary quartile, 0.62, 0.52, 0.57, irrespectively) (Figure). The average of the three less sedentary quartiles compared to the most sedentary quartile was associated with 44% decreased risk of disability (HR=0.56 [95% CI, 0.37–0.81], P=0.003). From further analyses using an isotemporal model, replacing one hour sedentary time with one hour light activity (e.g. walking) was associated with 51% decreased risk of disability onset for those in the most sedentary quartile group, independent of potential confounders and time spent in other activities (HR=0.49 [95% CI, 0.29–0.85], P=0.01; not shown in Figure).

Conclusion: Sedentary time appears to be a separate and distinct risk factor for incident disability among adults at elevated risk for disability. In addition to increasing MVPA physical activity, these findings suggest decreasing sedentary time may be an additional strategy to prevent disability onset.

Foot Structure and Function Show Associations with Lower Extremity Physical Function. Yvonne M. Golightly[1], Marian T. Hannan[2], Patricia P. Katz[3], Howard J. Hillstrom[4], Alyssa B. Dufour[5] and Joanne M. Jordan[1]. [1]University of North Carolina Dept of Epidemiology, Chapel Hill, NC, [2]Institute for Aging Research, Hebrew SeniorLife, Dept. of Medicine Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [3]University of California, San Francisco, San Francisco, CA, [4]Hospital Special Surgery (HSS), New York, NY, [5]Hebrew SeniorLife & Boston Univ, Boston, MA.

Background/Purpose: Foot pain is associated with poorer physical function in older adults, but few studies have examined how foot structure (high / low arches) and foot function (supination / pronation) are related to lower extremity physical function. The purpose of this cross-sectional study was to evaluate whether foot structure and function were associated with self-reported and performance-based physical function in a community-based study of Caucasian and African American men and women 50+ years old.

Methods: During the 2006–2010 exam of the Johnston County Osteoarthritis Project, foot pressure scans were obtained and physical function of participants was assessed via self-report and performance tests. Physical function measures included: the Foot and Ankle Outcome Score –Activities of Daily Living subscale (FAOS-ADL, 0 – 100 [extreme - no limitation]), 5 timed chair stands (unable and quartiles of completion time in seconds [s]), 8-foot walk (unable and quartiles of time in s), and standing balance (unable to stand without assistance, <10 s semi-tandem, semi-tandem 10 s but unable full tandem >2 s, full tandem 3–9 s, and full tandem 10 s). Foot pressure scans were used to determine foot structure (modified arch index) during standing and foot function (center of pressure excursion index) while walking. Based on population data, foot structure was categorized as high arch, low arch, and referent; foot function was categorized as over-pronated, over-supinated, and referent. The most extreme foot structure and function for each participant were used in analyses. Separate linear (continuous outcomes) and logistic (categorical outcomes) regression models were used to estimate the associations between foot types and physical function measures, adjusting for age, body mass index [BMI], sex, and race.

Results: 1571 participants had foot structure data and 1490 had foot function data (mean age 69 years, mean BMI 32 kg/m^2, 68% women, 30% African American). In standing, 22% had a low arch and 39% had high arch; during walking, 22% had an over-pronated foot and 31% had an over-supinated foot. Compared to the referent foot structure, higher FAOS-ADL scores (better physical function) were associated with a high arch in adjusted models, while a low arch was associated with worse physical performance on the chair stand and 8-foot walk tasks and with poorer balance (Table); these results were attenuated after controlling for age, BMI, sex, and race. Compared to the referent foot function, an over-supinated foot was associated with a faster 8-foot walk speed.

Conclusion: A high arch and an over-supinated foot were related to better lower extremity physical function. Longitudinal studies are needed to examine the effect of foot structure and function on changes in physical function and to assess interventions for modifying foot type (e.g., shoe orthotics) to limit physical decline in populations.

Table. Associations of Foot Structure and Foot Function with Physical Function

Physical Function		Foot Structure			Foot Function		
		Referent	Low Arch	High Arch	Referent	Over-Pronated	Over-Supinated

The Association Between Accelerometer Monitored Sedentary Behavior and Observed Physical Function Loss. Pamela Semanik[1], Rowland W. Chang[2], Jing Song[2], Jungwha Lee[2] and Dorothy D. Dunlop[2]. [1]Rush University College of Nursing, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL.

Background/Purpose: Preservation of function in older adults is critical to maintaining independence. Physical activity interventions often focus on increasing activity while giving limited attention to reducing sedentary behaviors. This study examined whether time spent in objectively measured sedentary behaviors is related to subsequent physical function loss among independent community-dwelling adults with or at high risk for knee osteoarthritis (OA).

Methods: Longitudinal data (2008–2012) from 1659 Osteoarthritis Initiative participants ages 49–83 years were used to evaluate the relationship of baseline time spent in sedentary behaviors (percentage of awake hours and average daily hours) to functional loss (gait speed and chair stand testing) after 2 years of follow-up. Average daily hours of sedentary- and moderate-vigorous intensity physical activity were objectively assessed at baseline by ActiGraph accelerometer monitoring. The relationship of sedentary hours to functional loss was examined by multiple linear regression.

Results: This cohort spent almost 2/3 of their waking hours (average 9.8 hours) in sedentary behaviors. Sedentary time was significantly associated with subsequent functional loss in both gait speed (−1.66 feet/minute decrease per 10% increment increase in percentage sedentary waking hours, 95% confidence interval (CI): −3.15, −0.18) and chair stand rate (−0.75 repetitions/minute decrease, 95% CI: −1.30, −0.20) after controlling for baseline function, socioeconomic (age, sex, race/ethnicity, income, education), health factors (obesity, depression, comorbidities, knee symptoms, knee osteoarthritis severity), and time spent in moderate-vigorous activity. These findings were consistent across subgroups defined by gender and weight, and age among older adults (>65). (Figure)

Conclusion: Being more sedentary was related to more future decline in physical function. Importantly, this finding is independent of time spent in moderate-vigorous activity. This independent relationship supports a dual strategy for designing physical activity interventions. Both limiting sedentary activities and promoting physical activity in adults with knee osteoarthritis may be important in maintaining function.

Adenosine a_{2A} Receptor As a Potential New Therapeutic Target for the Prevention/Treatment of Osteoarthritis. Carmen Corciulo[1], Aranzazu Mediero[1], Tuere Wilder[1] and Bruce N. Cronstein[2]. [1]NYU School of Medicine, New York, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Osteoarthritis results from trauma, mechanical factors or metabolic changes in bone and cartilage. Adenosine, acting via the $A_{2A}R$, inhibits inflammation and plays a critical role in regulating bone metabolism. Aging $A_{2A}KO$ mice experience difficulty in movement, taking food and walking. We determined whether changes in their bone or joint structure or function could explain these changes.

Methods: 8, 12 and 16 weeks old C57Bl/6 wild type (WT) and $A_{2A}KO$ mice (n=5) were sacrificed and knee joints were prepared for microCT and histology. PAS (Periodic Acid Staining), Safranin-O and Trichrome staining were carried out. MicroCT analysis of knees was performed on the distal femur below the growth plate. Immunostaining for MMP-13 and Collagen-X were performed. Human immortalized chondrocytes (TC28a2) and primary osteoarthritic chondrocytes were treated with $A_{2A}R$ agonist CGS21680 1μM in the presence/absence of the $A_{2A}R$ antagonist ZM241385 1μM. Collagen-X, MMP-13 and b-catenin were analyzed by Western Blot and ELISA.

Results: microCT analysis of $A_{2A}KO$ mice knees showed osteophyte formation together with mild remodeling and subchondral sclerosis when compared to WT starting at 8 weeks of age. Bone volume/total volume was significantly decreased in $A_{2A}KO$ mice when compared to WT (33.324±0.56 vs 35.782±0.78, respectively, $p<0.01$). Trabecular thickness was also decreased (0.0685±0.0035 vs 0.081±0.002, $p<0.05$) together with bone mineral density (0.3795±0.003 vs 0.4265±0.01 respectively, $p<0.5$). Trichrome, Safranin-O and PAS staining of $A_{2A}KO$ articular cartilage showed chondrocyte hyperthrophy with a reduction of collagen and proteoglycans. Immunostaining for MMP-13 and Collagen-X showed an increase in these biomarkers in $A_{2A}KO$ mice. In both TC28a2 and primary human chondrocytes, activation of $A_{2A}R$ by CGS21680 induced a significant decrease in Collagen-X and MMP-13 expression and release, with an increase in b-catenin expression. These effects are reversed by the $A_{2A}R$ antagonist ZM241385.

Conclusion: Deficiency in adenosine $A_{2A}R$ leads to spontaneous osteoarthritis and stimulation of $A_{2A}Rs$ on chondrocytes diminishes changes associated with osteoarthritis, findings that suggest that $A_{2A}R$ may be novel targets for development of therapies to ameliorate or prevent osteoarthritis.

S100 Proteins Induce Canonical Wnt Signaling, Which Causes Increased Expression of MMPs in the Synovium. Martijn H. van den Bosch[1], Arjen B. Blom[1], R. Pelle Hoek[1], Rik F. Schelbergen[1], Sylvia W. Suen[1], Anke E. van Erp[1], Wim B. van den Berg[1], Peter M. van der Kraan[1] and Peter L. van Lent[2]. [1]Radboud university medical center, Nijmegen, Netherlands, [2]Experimental Rheumatology, Radboud University, Nijmegen, Netherlands.

Background/Purpose: Many osteoarthritis (OA) patients show synovial activation, which is thought to be involved in joint destruction. Previously, we found that the alarmins S100A8 and A9, and various members of the Wnt signaling pathway, including Wnt16, were highly increased in the synovium of knee joints during experimental OA. WISP1, a downstream protein of β-catenin-dependent canonical Wnt signaling, was increased in both synovium and cartilage. S100A9KO mice showed strongly reduced pathology in experimental OA. Wnt signaling has been linked to OA through activation of β-catenin, but the role of the synovium in OA pathology under the influence of Wnt signaling is unclear. In this study we investigated whether S100 proteins induce Wnt signaling and determined the potency of Wnts to increase expression of cartilage-degrading enzymes in the synovium.

Methods: Pathway analysis of microarray data from synovium of a collagenase-induced OA was done using DAVID. Activation of Wnt signaling was determined with β-catenin immunostaining of whole knee joint sections. Gene expression was analyzed by qPCR. Human OA synovial specimens were collected from joint replacement surgery and stimulated with S100 or members of the Wnt signaling pathway or blocked with the Wnt inhibitors FrzB and DKK-1.

Results: Pathway analysis showed enrichment of Wnt signaling in the synovium during experimental OA. Because upregulation of both S100 and Wnt proteins during experimental OA showed comparable kinetics, we determined if S100 proteins could induce Wnt signaling. We found that injections of S100A8 into mouse knee joints led to increased expression of Wnt16 and WISP1 in the synovium and β-catenin accumulation in the joint. Underlining an interrelationship between Wnt signaling and S100A8/9, we found less β-catenin accumulation during experimental OA in S100A9KO mice. To determine the effects of canonical Wnt signaling in the synovium, we overexpressed Wnt16 and WISP1 in the synovium with adenoviral vectors. This resulted in increased expression of various MMPs in the synovium. To translate these finding to a human situation, we stimulated human OA synovial tissues with Wnt3a, as a model for a canonical Wnt, and WISP1. This led to significantly increased expression of MMP3, MMP9 and MMP13, whereas the expression of the MMP inhibitors TIMP1 and 3 was not altered. Next, we hypothesized that if Wnt signaling was increased in OA synovium and that stimulation of synovium with members of the Wnt signaling pathway led to increased expression of various MMPs, that we should be able to decrease the expression of MMPs by blocking the Wnt signaling pathway. Inhibition of Wnt signaling by both FrzB, a general Wnt inhibitor, and DKK-1, selectively blocking canonical Wnt signaling, led to significantly decreased expression of MMPs.

Conclusion: S100 proteins are able to increase Wnt signaling. Canonical Wnts produced in the synovium may play an important role in OA pathology. Stimulation of human OA synovium with Wnts and WISP1 increases the expression of MMPs, whereas blocking Wnt signaling results in decreased expression of MMPs. This underlines synovial Wnt/WISP1 expression to be a potential target for OA therapy.

Activation of AMP-Activated Protein Kinase (AMPK) By Berberine Limits Both Surgical Knee Instability-Induced and Aging-Related Osteoarthritis in Mice. Ru Bryan[1], Xianling Zhao[2], Yun Wang[3], Han Sol Lee[2], Hyunje Kim[4], Alifah Akasdi[2] and Robert Terkeltaub[5]. [1]VA Medical Center/University of California San Diego, San Diego, CA, [2]VAMC, San Diego, CA, [3]VA Medical Ctr/UCSD, San Diego, CA, [4]Yeungnam University, Daegu, South Korea, [5]VA Medical Ctr/University of California San Diego, San Diego, CA.

Background/Purpose: Human knee OA articular cartilage chondrocytes and aged mouse knee cartilage chondrocytes demonstrate decreased activation of master cellular energy bio-sensor AMPK. Moreover, inflammatory stimuli and biomechanical injury induce decreased chondrocyte AMPK activity, which transduces chondrocyte matrix pro-catabolic responses prevented by AMPK pharmacological activators *in vitro*. Therefore, we tested the hypothesis that activation of AMPK by berberine, an indirect AMPK activator that is employed in traditional medicine and as a dietary supplement, has chondroprotective effect in mice *in vivo*.

Methods: Two groups of male C57BL/6 mice (n=10 for each group), at age 3 months, were subjected to right knee destabilization of media meniscus (DMM) surgery, and left knee sham procedure. After surgery, 1 group was given berberine chloride (10 mg/kg body weight/day) via drinking water, with a no berberine treatment group serving as the control. Mice were sacrificed at 12 weeks after surgery. To study aging-related OA, 2 groups of five 6 month-old male mice were given berberine chloride as above, and 5 age-matched male mice for each group without berberine treatment were used as controls. Mice were sacrificed at age of 18 and 24 months. All mouse joints were fixed, decalcified, embedded in paraffin, and coronally sectioned (5 micron). We harvested 10–12 slides at ~75 micron intervals, and

stained with safranin-O and fast green for histologic scoring of the entire articular surface, using the OARSI grading system. Some knee sections also were analyzed by immunohistochemistry (IHC) for expression and -phosphorylation of AMPKα and appearance of NITEGE neoeitope of aggrecanase activity.

Results: After DMM surgery, non-treated mice developed OA in the knee medial compartment, with a mean score of 3.72, indicated by loss of safranin-O staining, fibrillation, and partial clefts/erosion down to the calcified cartilage of the articular surface. In comparison, mice receiving berberine treatment after surgery had a marked decrease in OA phenotype in the medial compartment with a mean score of 1.03 ($p<0.0001$, 95% CI of difference: 1.79 to 3.59). Our aging studies showed aging-related spontaneous OA development in non-treated mice, with mean total joint scores 1.5 and 6.6 ($p=0.002$, 95% CI of difference: -8.65 to -1.51) for 18 and 24 months-old mice, respectively. In contrast, berberine significantly reduced spontaneous OA development, and particularly so in 24 months-old mice. The mean total joint scores for the berberine treated mice were 0.38 and 2.2 ($p=0.008$, compared to non-treated mice at 24 months, 95% CI of difference: 0.84 to 7.97) at 18 and 24 months, respectively. Moreover, IHC analysis demonstrated that berberine inhibited both loss of phosphorylation of AMPKa and the appearance of NITEGE neoeitope in articular cartilage.

Conclusion: Maintenance of articular chondrocyte AMPK activity by berberine is therapeutically chondroprotective *in vivo* in mouse knee biomechanical injury and aging models. Targeted activation of AMPK by pharmacologic means, studied here using berberine, provides a novel approach to limiting OA development and progression in mice *in vivo*, and merits investigation in human OA.

Synovial Macrophages Promote TGF-β Activation after Intra-Articular Injections of Oxidized LDL in Naïve Murine Knee Joints, Preventing Production of Pro-Inflammatory Factors S100A8/9, Chemokines and Aggrecanase-Induced Neo-Epitopes. Wouter de Munter, Peter M. van der Kraan, Wim B. van den Berg and Peter L. van Lent. Radboud university medical center, Nijmegen, Netherlands.

Background/Purpose: In previous studies we found that synovial macrophages regulate joint pathology during experimental osteoarthritis (OA). Recently, we found that high systemic levels of LDL aggravate joint pathology during experimental OA with synovitis. LDL in inflamed synovium is oxidized and taken-up by macrophages via scavenger receptor A and CD36, leading to an activated macrophage phenotype. In this study, we investigate whether direct injection of oxLDL into a normal murine knee joint induces joint pathology and elucidate the role of synovial macrophages in that process.

Methods: Knee joints of C57BL/6 mice were injected at five consecutive days with 1.2 mg/mL oxLDL, LDL, or an equal volume of vehicle (PBS). This same procedure was done in mice which were depleted of synovial macrophages by intra-articular injection of clodronate liposomes seven days prior to the (ox)LDL or vehicle injections. Joint pathology was investigated by immunohistochemistry and RNA expression and protein production by synovium were determined using RT-PCR and luminex, respectively. Active TGF-β was measured using a functional CAGA-luciferase assay. Data are depicted as mean $\pm$ standard deviation.

Results: LDL and oxLDL injection in naïve knee joints did not increase synovial thickening, or production of pro-inflammatory factors (IL-1β, IL-6 and S100A8/9) compared to vehicle injection. Levels of active TGF-β in synovial wash-outs was, however, significantly increased by 33% (from 84.7 ng/mL/g synovium $\pm$ 14.4 to 113.0 ng/mL/g synovium $\pm$ 33.3; $p<0.05$). Immunohistochemistry of total knee joints showed that oxLDL injection decreased formation of aggrecanase-induced neo-epitopes (NITEGE) compared with vehicle injections, especially in areas along the bone margins that are prone to develop osteophytes (from arbitrary score 1.19 $\pm$ 0.57 to 0.33 $\pm$ 0.30; $p<0.05$).

In contrast, repeated injections of oxLDL in macrophage-depleted knee joints led to a 3.1 fold increase of synovial thickening (due to cell influx), compared with injection of vehicle ($p<0.01$), while LDL injections did not alter synovial thickening. Protein levels of S100A8/A9, markers for inflammation, were significantly increased in synovial wash-outs of oxLDL injected joints, compared with LDL (fold increase 5.6; $p<0.05$) or vehicle (fold increase 8.3; $p<0.01$) injection. RNA levels of chemokines CCL2 (Mcp-1) and CCL3 (Mip-1α) were also significantly upregulated after oxLDL injections (6.7 fold and 4.6 fold, respectively; $p<0.01$). No raise in active TGF-β was measured in macrophage-depleted joints. NITEGE expression was markedly increased (fold increase 1.92) in the synovial-cartilage contact areas after oxLDL injection ($p<0.05$).

Conclusion: Synovial macrophages promote anabolic effects after oxLDL injections in knee joints, supporting earlier studies which show increased ectopic bone formation during LDL-rich conditions in experimental osteoarthritis. In absence of synovial macrophages, however, oxLDL induces cell influx, production of pro-inflammatory mediators and aggrecanase activity.

Syndecan-4 Regulates Chondrocyte Phenotype and Cartilage Homeostasis Via the WNT Signaling Pathway. Charlotte Kimberley Clarke[1], Annelena Held[1], Richard Stange[2], Uwe Hansen[2], Lars Godmann[2], Jessica Bertrand[2], Thomas Pap[3], Giovanna Nalesso[4], Frank Echtermeyer[5], Francesco Dell'Accio[6] and Joanna Sherwood[4]. [1]Institute of Experimental Musculoskeletal Medicine (IEMM), Muenster, 48149, Germany, [2]University Hospital Münster, Münster, Germany, [3]University Hospital Muenster, Muenster, Germany, [4]Queen Mary University London, London, United Kingdom, [5]University Hospital Hannover, Hanover, Germany, [6]William Harvey Research Institute, Barts and the London Queen Mary's School of Medicine and Dentistry, Centre for Experimental Medicine and Rheumatology, London, United Kingdom.

Background/Purpose: Syndecan-4 (Sdc4), family member of type I transmembrane heparan sulfate proteoglycans (HSPGs), is a regulator of various cartilage-related processes including osteoarthritis (OA). Blockade of Sdc4 signaling protects mice from cartilage degradation in experimentally induced OA. OA is characterized by hypertrophic differentiation of chondrocytes and matrix remodeling. Various signaling pathways including the WNT signaling pathway may trigger this induction of chondrocyte differentiation. Experiments investigating the effect of different WNT3a concentrations on WT and Sdc4 deficient chondrocytes have emphasized a complex dialogue between canonical and non-canonical WNT pathways. We hypothesize that Sdc4 controls the chondrocyte phenotype by specific modulation of WNT signaling pathways.

Methods: *In vitro* analyses were performed using neonatal wild type (wt) and Sdc4$-/-$ chondrocytes, or blocking antibodies against Sdc4. The influence of WNT3a on glycosaminoglycan (GAG) production was analyzed using alcian blue staining of micromass cultures. Expression of marker genes (e.g. aggrecan, collagen2, MMP13) was measured by quantitative RT-PCR. Effects of WNT3a on canonical and noncanonical WNT signaling were analyzed using Western Blot and luciferase reporter assay (AP-1, NFAT, TCF/Lef). The influence of WNT3a on the remodeling of the ECM was investigated by electron microscopy. Basal calcium concentrations without and upon WNT3a stimulation were examined using the Fura-2 method. *In vivo* relevance was investigated upon induction of OA using the DMM model.

Results: Micromass cultures revealed a higher basal GAG production by Sdc4$-/-$ chondrocytes. WNT3a stimulation led to a decrease in GAG production in wt cells, which was absent in Sdc4$-/-$ chondrocytes. qRT-PCR showed a 10$\times$ higher basal production of aggrecan and collagen2 in Sdc4$-/-$ chondrocytes. WNT3a increased the expression of both genes in Sdc-4 $-/-$, whereas it decreased the expression in wt chondrocytes. MMP13 was significantly less expressed in Sdc4$-/-$ chondrocytes and, unlike in wt cells, was not upregulated upon WNT3a stimulation. Western blot showed that β-catenin is strongly reduced and not upregulated upon stimulation with WNT3a in Sdc4$-/-$ chondrocytes. LRP6 was less phosphorylated and TCF/Lef promotor was less activated upon WNT3a stimulation in Sdc4$-/-$ chondrocytes. pCamKII was increased under basal conditions, but decreased upon WNT3a stimulation in Sdc4$-/-$. The same effects on canonical and noncanonical WNT signaling upon WNT stimulation were obtained by using a blocking anti-Sdc-4 antibody. Upon WNT3a stimulation, Sdc4$-/-$ cells displayed a finer, more condensed and disorganized ECM structure compared

to wt. Sdc4−/− chondrocytes had increased intracellular Ca^{2+} levels, which were reduced after 24h incubation with WNT3a. *In vivo* stainings confirmed *in vitro* results.

Conclusion: Sdc4 is a major regulator of the chondrocyte cellular response to WNT signalling through facilitating the induction of the canonical WNT signaling pathway. The blockade of Sdc4 protects from OA induced changes in chondrocyte phenotype by inhibiting WNT induced differentiation of chondrocytes.

S100A9 Inhibitor Paquinimod (ABR-215757) reduces Joint Destruction in Experimental Osteoarthritis and Blocks Activating Effects of S100A9 in OA Synovium. Peter L. van Lent[1], Rik Schelbergen[1], Arjen B. Blom[1], Tomas Leanderson[2], Helena Eriksson[3] and Wim B. van den Berg[1]. [1]Radboud university medical center, Nijmegen, Netherlands, [2]Lund University, Lund, Sweden, [3]Active Biotech AB, Lund, Sweden.

Background/Purpose: Synovial activation is present in more than 50% of osteoarthritis (OA) patients and it is thought to be involved in the development of OA pathology. Previously, we found that alarmins S100A8 and S100A9 are elevated in synovium of OA patients and that high S100A8/A9 serum levels correlate with 2-year progression of the disease. Furthermore, in experimental OA, S100A8/A9 proteins regulate cartilage degradation and synovial activation. Paquinimod is a quinoline-3-carboxamide compound with immune modulatory properties that is currently in clinical development for treatment of systemic sclerosis. It targets the S100A9 protein and blocks the binding of S100A9 to RAGE and TLR-4. In the current study we investigated the effect of paquinimod in two experimental osteoarthritis models differing in synovial activation and its effect on S100A9 stimulated OA synovium.

Methods: Collagenase induced OA (CIOA) was induced by two times intra-articular injection of 1U collagenase and DMM was induced by transsection of the medial anterior meniscotibial ligament leading to destabilization of the medial meniscus (DMM), both in C57Bl6 mice. Paquinimod (3,75 mg/kg) was administered in the drinking water which was refreshed twice a week. Treatment started 4 days before induction of OA in both CIOA and DMM. Synovial thickening and cellularity was measured using an arbitrary score from 0–3. OA-like cartilage pathology was scored using a modified Pritzker OARSI score. Osteophyte size was assessed by a blinded observer using imaging software. Human OA synovium was anonymously obtained from patients undergoing arthroplasty and stimulated with S100A9 and/or paquinimod. Proteins released by synovium were measured with Luminex.

Results: Paquinimod treatment of CIOA expressing high synovial activation resulted in significantly reduced synovial thickening (57%), osteophyte size at the medial femur (66%) and cruciate ligament formation (67%). Moreover, cartilage damage was reduced by paquinimod in CIOA at the medial tibia (47%) and femur (75%). In contrast, paquinimod did not reduce cartilage damage and reduced osteophyte size only slightly (only at the medial femur) in DMM, in which synovial activation is scant. In addition, human OA synovium comprising lining macrophages, was incubated with human S100A9 and /or paquinimod. S100A9 significantly upregulated pro-inflammatory IL-6, IL-8 and TNFα (9-fold, 12-fold and 20 fold increase respectively) and catabolic factors MMP-1 and 3 (up to 2,5 fold). Adding paquinimod significantly inhibited S100A9-induced levels of IL-6 (35% reduction) and IL-8 (38% reduction) but not TNFα whereas MMP1 and MMP3 were reduced by 39% and 64% respectively.

Conclusion: Paquinimod reduces synovial activation, osteophyte formation and OA-like cartilage pathology in experimental OA with high synovial activation and ex vivo blocks pathological effects of S100A9 in OA synovium. Paquinimod could prove a very promising treatment for osteoarthritis patients expressing high synovial activation.

Background/Purpose: The idiopathic inflammatory myopathies (IIM) are a heterogeneous group of rare autoimmune diseases characterised by muscle weakness and extramuscular manifestations such as skin rashes and interstitial lung disease and with increased association with malignancy. Recent candidate gene studies in IIM and a genome-wide association study in dermatomyositis suggest a shared genetic architecture with other autoimmune diseases. We therefore conducted a genetic association study using the Immunochip; a custom Illumina array containing coverage of 186 established autoimmune susceptibility loci.

Methods: We genotyped 2,740 IIM cases of Caucasian descent comprising of dermatomyositis, juvenile dermatomyositis and polymyositis fulfilling Bohan and Peter classification criteria, and inclusion body myositis fulfilling Griggs/ENMC/Hilton-Jones criteria. Samples have been collected from 14 countries through the Myositis Genetics Consortium (MYOGEN). Data from all cases and 15,754 matched Caucasian control samples were combined for clustering, and SNPs were called using GenCall. SNP QC was based on a call rate >98% and/or cluster separation score >0.4. Sample QC was based on a call rate >98%. Samples with extreme heterozygosity, related individuals and ancestral outliers were also removed. Analysis was performed in PLINK v1.07 using logistic regression adjusting for the top 10 principal components.

Results: Initial analysis of 113,272 SNPs confirmed the MHC as the most strongly associated region. *PTPN22* was the only non-HLA region to reach genome-wide significance of $p=5\times10^{-8}$, previously associated in a candidate gene study. Using a second suggestive tier of significance at $p=5\times10^{-5}$, there was evidence for association at additional loci, including *STAT4, UBE2L3, SH2B3/ATXN2* and *RPL31P10*.

Conclusion: This is the largest genetic association study to date in IIM. The data confirm that *HLA* and *PTPN22* are associated at genome-wide significance, and identification of further novel loci at a suggestive level of significance indicates genetic overlap with other autoimmune diseases. These loci may differ from previously reported dermatomyositis specific associations. The IIMs are a heterogeneous set of diseases; additional clinical subgroup specific analyses are thus planned.

The Amino Acid Positions 11, 13 and 26 of HLA-DR Beta Chain 1 Explain the Majority of the Association Between Systemic Lupus Erythematosus and the Major Histocompatibility Complex Locus. Kwangwoo Kim[1], So-Young Bang[2], Hye-Soon Lee[2], Yukinori Okada[3], Woei-Yuh Saw[4], Paul IW. de Bakker[5], Yik-Ying Teo[6], Soumya Raychaudhuri[7] and Sang-Cheol Bae[2]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [3]Broad Institute, Cambridge, MA, [4]National University of Singapore, Singapore, Singapore, [5]University Medical Center Utrecht, Utrecht, Netherlands, [6]Genome Institute of Singapore, Agency for Science, Technology and Research, Singapore, Singapore, [7]Broad Institute of MIT and Harvard, Cambridge, MA.

Background/Purpose: Genetic association of the major histocompatibility complex (MHC) locus is well-established in systemic lupus erythematosus (SLE), but the causal functional variants in this region remain yet to be identified. This study aimed to examine the contribution of amino acid variants in major HLA genes (HLA-A, -B, -C, -DPA1, -DPB1, -DQA1, -DQB1 and -DRB1) to SLE susceptibility and dissect the association signals within the extended MHC locus.

Methods: We inferred HLA classical alleles, amino acid residues and MHC SNPs from the genotyped data of 5,342 unrelated Korean subjects including 849 SLE cases and 4,493 controls. For accurate imputation for the Korean population, we newly constructed an Asian HLA reference panel from two recent HLA reference panels from Korean (n=413; unpublished) and Southeast Asian (n=441) for use with the SNP2HLA software. The dosage effect of binary markers on SLE risk was assessed by a logistic regression and the overall difference of amino acid residues at each amino acid position between case and control groups was examined by a log-likelihood ratio test comparing the fit between null model and full model with amino acids effects.

Results: The new Asian reference panel demonstrated a reliable imputation accuracy, showing high concordance rates between genotyped and imputed alleles of 61 East Asian HapMap3 individuals (98.5% at 2-digit resolution and 93.2% at 4-digit resolution) and a subset of the study subjects (n=1306; 97.9% at 2-digit resolution and 94.1% at 4-digit resolution at HLA-DRB1). We found the primary association signal within HLA-DRB1. When adjusted with all classical alleles of HLA-DRB1, no signal passed a genome-wide significance threshold in our study. At the amino acid level, the most significant association with SLE susceptibility was mapped to the amino acid position 13 of HLA-DR beta chain 1 (HLA-DRβ1; $P = 2.48\times10^{-17}$). The amino acid position 13 explained the SLE risk better than any single HLA allele or SNP. Among six possible residues at the position 13, Arg/Tyr and Ser/His conferred the risk and protective effects on SLE susceptibility, respectively (OR=1.63, $P=1.15\times10^{-15}$ for Arg+Tyr and OR=0.65, $P=4.15\times10^{-14}$ for Ser+His). We validated the association and residue effects at the position 13 using an independent Korean population including 105 SLE cases and 391 controls who were genotyped for HLA-DRB1. In a conditional analysis, the position 26 was remained to be significantly associated with SLE ($P=2.42\times10^{-9}$) after conditioning on the amino acid positions 13 and its tightly correlated position 11. We observed 10 common haplotypes defined by the amino acid position 11-13-26. The reported SLE-risk *HLA-DRB1* alleles *15:01 and *03:01 belong to the SLE-risk haplotypes Pro-Arg-Phe and Ser- Ser-Tyr, respectively.

Conclusion: Our study identified the three amino acid positions 11, 13 and 26 at the antigen-binding groove of HLA-DRβ1 were responsible for most of the association between SLE and MHC.

The Impact of Northern European Ancestry and Susceptibility Loci on the Risk of Lupus Nephritis. Sarah French[1], Kimberly E. Taylor[1], Sharon A. Chung[1], Joanne Nitiham[1], Michelle Petri[2], Peter K. Gregersen[3], Ward Ortmann[4], Annette T. Lee[3], Timothy W. Behrens[4], Susan Manzi[5], F. Yesim Demirci[6], M. Ilyas Kamboh[6], Robert R. Graham[4], Michael F. Seldin[7] and Lindsey A. Criswell[1]. [1]University of California, San Francisco, Rosalind Russell / Ephraim P. Engleman Rheumatology Research Center, San Francisco, CA, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Feinstein Institute for Medical Research, Manhasset, NY, [4]Genentech, Inc., South San Francisco, CA, [5]Division of Rheumatology, University of Pittsburgh School of Medicine, Pittsburgh, PA, [6]University of Pittsburgh, Pittsburgh, PA, [7]University of California, Davis, Davis, CA.

Table 1.

Model	OR (95% CI) for 25% increase in N. European ancestry	P-value	BIC*
Model 1 (N. European ancestry + disease duration, gender)	0.84 (0.72, 0.99)	0.04	1305.6
Model 1 + European PCs	0.83 (0.70, 0.98)	0.03	1317.3
Model 1 + susceptibility loci (2 SLE risk alleles, 7 renal GWAS SNPs)	0.85 (0.72, 1.01)	0.07	1291.9
Model 1 + renal GRS	0.83 (0.70, 0.99)	0.03	1243.9

Multivariate logistic regression with odds ratios (OR) for LN associated with a 25% increase in proportion of northern European ancestry. Successive models incorporated other measures of genetic variance including European PCs (EIGENSTRAT), susceptibility loci, and a renal genetic risk score (GRS) = sum of number of risk alleles. * BIC = Bayesian information criterion, with lower BIC scores indicating a better fitting model.

Background/Purpose: Lupus nephritis (LN) has a higher prevalence among African Americans, Hispanics, and Asians compared to Caucasians. Significant differences in SLE severity also exist within continental groups, with northern European genetic ancestry conferring protection against autoantibody production and renal disease, which we have previously shown to be independent of socioeconomic status (SES). The goal of our study was to test whether the effect of northern European ancestry is mediated by known SLE risk alleles or recently identified LN susceptibility loci.

Methods: We studied 1142 SLE patients from four independent case collections with genotype data obtained from a previous genome-wide association study (GWAS). A set of continental and intra-European ancestry informative markers (AIMs) was analyzed using the program STRUCTURE to define percent European and northern European ancestry. Subjects with <90% European ancestry were excluded. Multivariate logistic regression of LN risk was performed including percent northern European and other covariates (Table 1). Susceptibility loci were incorporated as potential mediators of the effect of genetic ancestry on the risk of LN. Forty-nine established SLE susceptibility loci and 12 single nucleotide polymorphisms (SNPs) with the strongest association with LN in a recent renal GWAS of SLE subjects were tested for association with LN. A $p<0.05$ was required for SNPs in multivariate logistic regression with other putative risk SNPs to be included in the model of LN risk. A polygenic risk score (PRS), a statistical method for calculating the effect of many common variants in aggregate, was generated from a random 2/3 of individuals using the program PLINK to select 12,935 SNPs with evidence of cumulative association with LN ($p<0.05$).

Results: The overall rate of LN in the study population was 27.3%. A 25% increase in the proportion of northern European ancestry was associated with a 16% reduction in the odds of having renal disease, after adjustment for disease duration and gender (OR 0.84, 95% CI 0.72–0.99, p=0.04). Two previously reported SLE susceptibility loci (BANK1, HLA-DR3) and 7 of 12 LN risk SNPs were significantly associated with LN in our dataset. Adjustment for all 9 putative LN susceptibility loci did not substantially alter the association between northern European ancestry and LN (Table 1). Exploratory analyses incorporating the PRS were underpowered in our study but suggested that a more comprehensive set of genetic variants, as captured by the PRS, may explain more of the effect of Northern European ancestry on the risk of LN.

Conclusion: Northern European ancestry has a significant protective effect for renal disease among SLE patients of European ancestry; this

appears to be independent of currently known SLE risk alleles and LN susceptibility loci, but may be partially explained by a PRS.

Identification of Autoimmune Functional Variants Under Positive Selection in the Gullah African American Population of South Carolina. Paula S. Ramos[1], Satria Sajuthi[2], Jasmin Divers[2], Yiqi Huang[3], Uma Nayak[3], Wei-Min Chen[3], Kelly J. Hunt[1], Diane L. Kamen[1], Gary S. Gilkeson[1], Jyotika K. Fernandes[1], Ida J. Spruill[1], W. Timothy Garvey[4], Michèle M. Sale[3] and Carl D. Langefeld[2]. [1]Medical University of South Carolina, Charleston, SC, [2]Wake Forest School of Medicine, Winston-Salem, NC, [3]University of Virginia, Charlottesville, VA, [4]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: The reasons for the ethnic disparities in rheumatologic and autoimmune diseases (ADs) are largely unknown. We posit that population-specific selection influencing the allele frequencies at some loci contribute to ethnic disparities. Relative to other African-Americans (AA), the Gullah population has lower European admixture and higher ancestral homogeneity from the Sierra Leone (SL) area in Far-West Africa. The shorter genetic distance between the Gullahs and SL suggests that population genetic signals, such as regions under recent selection, may be more easily detected in the Gullahs than in other AA populations. Since both protein-coding and regulatory variation have important roles in recent human adaptation, our goal was to integrate evidence for natural selection with functional annotation for the identification of biologically relevant signals that may harbor risk loci for ADs.

Methods: We computed the cross population extended haplotype homozygosity test (XP-EHH) to identify alleles with higher than expected frequency relative to their haplotype length in Gullah population controls (n=277) relative to SL population controls (n=400), to HapMap Phase II Africans (YRI, n=203), and Caucasians (CEU; n=165). In total 679,513 SNPs met standard GWAS quality control criteria. Variants that met suggestive significance ($|$XP-EHH$|>4$, P<E-04) were annotated and prioritized based on the potential impact of amino acid changes and regulatory functions using RegulomeDB and HaploReg, as well as overlap with immune/autoimmune-related genes and regions associated with ADs.

Results: Nearly the same number of loci showed suggestive evidence for selection between the Gullah and YRI (0.15% of all SNPs), and Gullah and SL (0.14%), although only 106 SNPs in 12 regions showed evidence for selection in both comparisons. Fewer loci showed evidence for selection between Gullah and CEU (0.06%). This is reflected in the enrichment of different pathways in each comparison. Enhancer enrichment analysis of all suggestive SNPs revealed a significant enrichment of strongest enhancers in H1 human embryonic stem cells. Several regions showing evidence of selection between the Gullah and the YRI harbor missense SNPs in AD-relevant genes (*CENPO, IKBKA, USP31*). Other autoimmune-related genes harbor multiple SNPs with high regulatory scores based on the simultaneous presence of eQTLs, transcription factor binding and DNase sites, including those showing evidence of selection between Gullah and YRI (*CCR2, ADCY2, HLA, CD36, CAV1*, GLG1, FXR2), Gullah and SL (*CCR2, ADCY2*), and Gullah and CEU (*TET3*).

Conclusion: These results reveal several autoimmune-related genes with evidence for selection and concomitant high functional potential in the Gullah AA population. Given the increased prevalence of several ADs in AAs and the homogeneity of the Gullah, identification of functional regions under selection in the Gullah has the potential to elucidate AD risks in AA and help explain the ethnic disparity.

The Rheumatoid Arthritis -Risk Locus CCR6 and Its SNP-Dependent Response to Estrogen: A Possible Genomic Link Between Sex Hormones and the IL-17 Inflammatory Pathway. Ming-Fen Ho, Richard M. Weinshilboum, Liewei Wang and Tim Bongartz. Mayo Clinic, Rochester, MN.

Background/Purpose: The CCR6-CCL20–mediated migration of Th17 cells to inflamed tissues may represent an important mechanism in the etiology of rheumatoid arthritis (RA). The CCR6 SNP rs3093023 is associated with RA disease risk. Variation in the *CCR6* locus has been found to affect CCR6 expression and influence the IL17 serum concentration in RA patients (1). Importantly, an analysis of disease risk stratified by gender revealed opposing effects in Asian subjects: Specifically a *CCR6*SNP (rs3093024), which is in almost complete linkage disequilibrium with rs3093023, was associated with an increased risk of RA in women, but appeared to have a protective effect in men (2). We set out to determine whether variation in estrogen levels might influence the expression of CCR6 and other IL-17 pathway related genes. Furthermore, we aimed to clarify if such estrogen dependent regulation might be influenced by the presence of the variant *CCR6*genotype that is associated with RA disease risk in Europeans.

Methods: We genome-wide genotyped human lymphoblastoid cells using the Illumina 550K and 510S SNP BeadChip and the Affymetrix SNP array 6.0. We then cultured eight LCLs homozygous for the wild-type (WT) SNP rs3093023 sequence and eight LCLs homozygous for the variant (V) allele with increasing concentrations of estradiol (E2). Expression of CCR6, CCL20, IL17A and IL17RA mRNA was measured by qPCR. We then performed siRNA knockdown experiments for CCR6 to explore the downstream effects. To predict putative estrogen receptor binding sites in the *CCR6*gene, we queried the TRANSFEC database. The functional relevance of putative binding sites was confirmed using ChIP assays.

Results: The basal expression levels of CCR6, CCL20, IL17A and IL17RA showed no differences when comparing cell lines with *CCR6* WT versus V genotypes. Knockdown of CCR6 resulted in upregulation of CCL20 and IL-17A, but downregulation of IL-17RA expression. Treatment with E2 for 24 hours resulted in a significant increase in CCR6 expression in a dose-dependent manner, but only in cells with the V allele. CCL20, IL-17A and IL17 RA expression was also SNP-dependent: in cells with the variant genotype, E2 treatment resulted in higher IL-17RA expression. Conversely, CCL20 and IL-17A expression decreased with estrogen treatment only in cells homozygous for the V allele. The TRANSFEC database predicted the presence of two estrogen response elements in the *CCR6*intronic region flanking the rs3093023 SNP. Chip essays demonstrated increased binding of estrogen receptor alpha when the V allele was present.

Conclusion: Our results indicate that a *CCR6*variant, which is associated with RA disease risk, can modulate the CCR6/CCL20/IL-17 axis in an estrogen-dependent manner. Enhanced binding of estrogen receptor alpha to the variant CCR6 genotype may contribute to the mechanism underlying this observation. Such a genomic link between variation in sex hormone levels and variation in cytokine/chemokine expression may provide new insights into the gender differences in RA prevalence and prognosis.

Polygenic Analysis of Transport, Metabolism and Immune Related Genomic Compartments in Serum Urate and Gout. Eli A. Stahl[1], Tony R. Merriman[2], Amanda Dobbyn[3], David B. Mount[4], Peter Kraft[5] and Hyon Choi[6]. [1]Mt Sinai School of Medicine, New York City, NY, [2]University of Otago, Dunedin, New Zealand, [3]Icahn School of Medicine at Mount Sinai, New York, NY, [4]Brigham and Women's Hospital, Boston, MA, [5]Program in Molecular and Genetic Epidemiology, Harvard School of Public Health, Boston, MA, [6]Harvard Medical School, Boston, MA.

Background/Purpose: Genome wide association studies (GWAS) have identified loci associated with complex traits, and the current challenge is to glean biological insights from these findings. A GWAS in 110,347 samples discovered ~30 loci associated with serum urate; however, only two loci were associated with gout in 2,115 cases (*SLC2A9, ABCG2*)[1]. The strongest effects lie in renal urate transporter loci, with additional loci thought to include metabolic genes. Here we systematically assess polygenic effects of urate transport, metabolic and immune-related genes, excluding known associated loci, in both serum urate and gout.

Methods: GWAS results (2.2M HapMap2-imputed SNPs) for serum urate (110,347 individuals) and for gout case/control status (2,115 cases in 14 studies), were utilized to construct polygenic scores. After removal of the 31 significant urate GWAS loci (1Mb each), non-overlapping genomic compart-

ments were defined by SNPs in proximity (+− 50Kb) to genes involved in 1. Urate transport: ABCG and SLC family members of urate-associated transporters and their direct connections in Inweb and String network databases[2] (348 genes), 2. Urate metabolism: purine metabolism and glycolysis KEGG pathways (256 genes), 3. Immune-related: genes targeted by the Immunochip array (184 genes), 4. All other genic regions, and 5. Intergenic regions. Polygenic scores based on GWAS P-value thresholds[3] were calculated in Nurses Health Study (NHS) and the Health Professionals Follow-up Study (HPFS) samples, with incident gout cases having met ACR criteria for diagnosis, and were tested in multivariate analysis with sex, age, BMI and a 31 SNP urate genetic risk score as covariates.

Results: Polygenic scores were significantly associated with gout in metabolic genes (n=797 SNPs with $P_{GWAS}<10^{-2}$; P=0.005) and other genic regions (n=570,599 SNPs with $P_{GWAS}<0.5$; P=0.001), with similar results for association with serum urate (P=0.0025 and P=0.007 for metabolic and other genes respectively). The immune gene compartment was not significant in gout (P>0.12). The urate transporter compartment (excluding known significantly associated urate transporter loci) was not significant in gout or urate (P>0.13 and P=0.20, respectively).

Conclusion: Our results demonstrate an important role for metabolism in both serum urate and risk of gout, with genes outside of the defined compartments also contributing. Excluding known loci, we find no additional evidence for polygenic variation in urate transport or immune-related functions contributing to serum urate or gout. Genomic compartments defined on function can provide additional discoveries and further biological insights into the etiologies of urate and gout.

ACR Concurrent Abstract Session

Metabolic and Crystal Arthropathies II: Mechanisms of Disease

Wednesday, November 19, 2014, 9:00 AM–10:30 AM

2959

Twenty-Eight Loci That Influence Serum Urate Levels: Analysis of Association with Gout. Tony R. Merriman[1], Marilyn E. Merriman[1], Ruth Topless[1], Sara Altaf[1], Grant Montgomery[2], Christopher Franklin[3], Gregory T. Jones[1], Andre M. van Rij[1], Douglas HN White[4], Lisa K. Stamp[5], Nicola Dalbeth[3] and Amanda Phipps-Green[1]. [1]University of Otago, Dunedin, New Zealand, [2]Queensland Institute of Medical Research, Brisbane, Australia, [3]University of Auckland, Auckland, New Zealand, [4]Waikato Clinical School, Waikato Hospital, Hamilton, New Zealand, [5]University of Otago, Christchurch, New Zealand.

Background/Purpose: Twenty-eight genetic loci are associated with serum urate levels in Europeans. Ten are established, with a further 18 of weaker effect more recently detected. *SLC2A9*, *ABCG2*, *SLC17A1* and *GCKR*, with stronger effect sizes, have been consistently associated with gout. Evidence for association with gout at the other 24 loci is absent, equivocal or not replicated, with one explanation likely to be non-clinical ascertainment of gout. Our aim was to test the loci with prevalent gout meeting the ACR gout classification criteria in Aotearoa New Zealand (NZ) European and Polynesian case-control sample sets.

Methods: 648 NZ European cases and 1550 controls, and 888 Polynesian (Māori and Pacific) cases and 1095 controls were genotyped. Association with gout was tested by logistic regression adjusting for age and sex, and ancestry estimate for Polynesians. Power was adequate (>0.7) to detect effects of OR>1.3.

Results: We focused on the 24 loci without consistent evidence for association with gout. Association was detected at seven loci in Europeans, one of which was the first report of association with gout (*IGFR1*) (Figure). In combined Polynesians association with gout was detected at three loci (*SLC22A12, SFMBT1, VEGFA*). Meta-analysis of Europeans and Polynesians revealed association at nine loci, two which had not previously been associated with gout (*PDZK1* and *MAF*). In participants with higher Polynesian ancestry, there was association in an opposing direction to Europeans at *PRKAG2* and *HLF* (Figure). In Europeans there was obvious inconsistency of gout association at four loci (*GCKR, INHBC, SLC22A11, SLC16A9*) that display very similar effects on urate levels.

Conclusion: We provide the first evidence for association with gout at four (*IGRF1, PDZK1, MAF, HLF*) serum urate loci not previously associated with gout. Understanding reasons for lack of correlation between urate and gout effect sizes will be important in understanding the etiology of urate control and risk of gout.

Background: Gout is the most common inflammatory arthritis and is caused by hyperuricemia. The Global Urate Genetics Consortium (GUGC) has recently validated 28 SNP associations in serum urate. However, most corresponding data for the risk of gout have been based on suboptimal definitions (e.g., self-report, by the presence of hyperuricemia, or by anti-gout drug use) and prevalent cases (thus potentially selecting survivors given the risk of premature death associated with gout). To address these issues, we examined two large prospective cohorts and estimated the impact of the

GUGC urate genetic loci on the risk of incident gout, which was ascertained by a widely-used standard definition.

Methods: The Health Professionals Follow-up Study (HPFS) and Nurses' Health Study (NHS) have systematically collected a wide range of exposures and health outcome data, including incident cases of gout, regularly for several decades. We ascertained incident gout cases using the American College of Rheumatology survey criteria. Using GWAS data from the two cohorts (4223 men from the HPFS and 6850 women from the NHS), we calculated a weighted genetic risk score (GRS) based on GUGC urate loci (possible range 0 to 58). Cox proportional hazards models were used to examine the association of GRS as well as individual urate loci with the risk of incident gout in these cohorts separately and together.

Results: Over a total of 262,805 person years, we documented 1081 confirmed cases of incident gout (727 in the HPFS and 354 in the NHS). The GRS ranged from 12.2 to 44.5 among our study participants. Increasing GRS scores were associated with an increasing risk of incident gout in both cohorts (P for heterogeneity > 0.17), and the pooled relative risks (RRs) for incident gout according to increasing GRS categories were 0.34, 0.66, 1.00 (referent), 1.37, 2.01, and 3.48 (P for trend < 0.001) (**Table 1**). Our analyses for individual loci (**Table 2**) showed that *SLC2A9, ABCG2,* and *GCKR* were significantly associated with the risk of incident gout in each cohort as well as in the pooled cohort. *TMEM171, SLC17A1, INHBC, VEGFA,* and *UBE2Q2* were modestly associated only in men (HPFS), and *PRKAG2, B4GALT1, MAF,* and *HLF* were modestly associated only in women (NHS). Heterogeneity between the sexes of these loci was significant for *INHBC, PRKAG2, B4GALT1,* and *HLF*.

Conclusion: These two large prospective cohort studies confirm that the urate GRS scores are strongly associated with the risk of incident cases of confirmed gout among men as well as among women. *SLC2A9, ABCG2,* and *GCKR* were most strongly associated with the risk of incident gout, and nine additional urate loci are more modestly associated with the risk as well.

Conditional Analysis of 30 Serum Urate Loci Identifies 25 Additional Independent Effects. Eli Stahl[1], Hyon Choi[2], Murray Cadzow[3], Tanya Flynn[3], Ruth Topless[3] and Tony R. Merriman[3]. [1]Mt Sinai School of Medicine, New York City, NY, [2]Harvard Medical School, Boston, MA, [3]University of Otago, Dunedin, New Zealand.

Background/Purpose: Single variants in 30 genetic loci have been associated with serum urate levels in Europeans by meta-analysis of summary statistics of 48 individual genome-wide association study (GWAS) data sets.[1] Identifying independent effects can help fine map causal genes and reveal functional mechanisms of genetic variation, and has been successful in other complex phenotypes. Our aim was to test for the presence of independent effects at the 30 urate loci.

Methods: Summary level statistics from the Kottgen et al. GWAS[1] were used in collaboration with the Global Urate Genetics Consortium. The Genome-Wide Complex Trait Analysis (GCTA) package[2] was used to test for association conditional on the lead single nucleotide polymorphism (SNP). A total of 9713 HapMap2 genome-wide imputed genotypes from European participants of the Atherosclerosis Risk in Communities study were used as a reference. An independent effect at each locus was defined as an association signal, after conditional analysis, of $P<0.05$ divided by the number of SNPs analyzed. Further rounds of analysis were conducted if SNPs remained significant after conditioning. The percent variance explained for each SNP was calculated by the formula b^2*(var(X)/var(Y)).

Results: Twenty-five additional independent effects were detected at 14 of the 30 urate loci (Table). The percent variance explained by the 30 lead SNPs was calculated to be 4.83%, with the additional SNPs explaining a further 0.81% of variance (total 5.64%).

Conclusion: The independent effects provide evidence for multiple etiological variants at the serum urate loci in Europeans, emphasizing the complex genetic control of serum urate levels. These results are an important initial step in fine-mapping the causal variants. For example, one of the independent effects at *SLC2A9* (*rs3775948*) was the lead SNP in a urate GWAS in East Asian individuals,[3] indicating both shared and unique genetic effects between East Asians and Europeans. The use of multiple ancestral groups will be important in fine-mapping.

Background/Purpose: Gout results from innate immune response to monosodium urate (MSU) crystals that form in the context of supersaturation of urate. Identification of genetic risk factors for hyperuricemia and the MSU immune response is therefore important for insight into the etiology of gout. Genome-wide association studies have provided significant insights into the causes of hyperuricemia, however there are no confirmed loci for non-serum urate pathways in gout. Association of *rs2149356* in the TLR4 locus with gout was reported in a Chinese sample set (odds ratio TT genotype = 1.88)[1]. TLR4 triggers innate immune response to endogenous ligands, including MSU crystals. To replicate, we tested *rs2149356* for association with gout in 2,501 European and Polynesian cases and 9,105 controls.

Methods: All gout cases were clinically ascertained according to the American Rheumatism Association criteria. European cases (n=1614) were recruited from New Zealand (n=647), by the Eurogout consortium within the European Crystal Network (n=779) and by the Arthritis Genomics Recruitment Initiative in Australasia (AGRIA; n=188). European non-gouty controls (n=8017) were recruited from NZ (n=875) and sourced from the Atherosclerosis Risk in Communities (n=4143) and Framingham Heart (n=2999) studies. There were 872 New Zealand Māori and Pacific Island (Polynesian) cases and 1088 controls.

Genotyping of *rs2149356* was done by Taqman in the New Zealand samples and imputed in ARIC and FHS from Affymetrix genome-wide data. Association analysis was done by STATA and adjusted by age, sex and (as appropriate) estimate of Polynesian ancestry.

Results: Using controls unstratified for urate status, there was no evidence for allelic or genotypic association in the European sample sets (Table). However the TT genotype was associated with gout in Polynesians ($OR_{TTgenotype}$=0.68, P=0.012). Comparison of cases to hyperuricemic controls revealed evidence for association with gout in Europeans ($OR_{Tallele}$=1.26, P=0.005; $OR_{TTgenotype}$=1.63, P=0.009), but weakened evidence for association in Polynesians ($OR_{Tallele}$= 0.88, P=0.25; $OR_{TTgenotype}$=0.77, P=0.21).

Conclusion: The previous report of association of *TLR4* with gout in Chinese[1] was replicated in Europeans with the T allele of *rs2149356* conferring risk in both populations. Evidence for association was weaker in Polynesians, with the G-allele conferring risk. The strengthening of association in Europeans using hyperuricemic controls is consistent with a role for this locus in gouty inflammation in the presence of hyperuricemia. Subject to further replication, *TLR4* represents the first replicated non-serum urate genetic risk locus identified in gout, and provides support for a role of TLR4 in the etiology of gout.

The URAT1 Uric Acid Transporter Is Important in Uric Acid Homeostasis and Its Activity May be Altered in Gout Patients and in Drug-Induced Hyperuricemia. Philip K. Tan, Sha Liu and Jeffrey N. Miner. Ardea Biosciences, Inc., San Diego, CA.

Background/Purpose: Gout results from chronic hyperuricemia. Most gout patients exhibit an increased renal reabsorption of uric acid which leads to elevated levels of serum uric acid (SUA). SUA levels are controlled in part through URAT1, a transporter that is essential for the renal reabsorption of uric acid. Our current research suggests that the renal uric acid reabsorption system is more completely saturated in normal healthy individuals but not in gout patients. We hypothesize that this difference may be due to differences in URAT1 activity, and present evidence that in gout patients as well as in hyperuricemia induced by certain drugs, the activity of uric acid transport by URAT1 is altered by the presence of other URAT1 substrates.

Methods: An analysis based on data from 4 Phase I/Ib studies, in which xanthine oxidase inhibitors (XOI) were given to either normal healthy volunteers (NHV) or gout patients, was conducted. The relationship between change in reabsorption of uric acid versus baseline reabsorption, as well as reabsorption of uric acid versus SUA, was examined. Uric acid transport activity of URAT1 was measured in HEK-293T cells transiently transfected with URAT1 in the absence or presence of salicylate, nicotinate, and other URAT1 substrates.

Results: From the SUA lowering effect of XOI treatment, gout patients experienced a greater change in reabsorption compared to NHV. This indicates that in gout patients the reabsorption of uric acid may be more responsive to changes in SUA levels, and that in NHV the reabsorption of uric acid is less responsive and hence more saturated. URAT1 transported uric acid with an affinity (equilibrium dissociation constant or K_d) of 154 μM. At 500 μM uric acid, the uric acid transport activity of URAT1 was greater than 90% of the maximal activity, approaching saturation for total transport activity. Therefore, URAT1 is highly saturated for transport of uric acid at levels present in NHV (at or below 6.8 mg/dL or 408 μM), and the total transport activity of uric acid by URAT1 is reduced slightly upon physiologically-relevant reductions of uric acid, similar to the highly saturated renal reabsorption of uric acid observed in NHV. However, in the presence of other URAT1 substrates such as salicylate, URAT1 transported uric acid with a 2- to 4-fold lower affinity ($K_d$was increased), and at 500 μM uric acid, the uric acid transport activity of URAT1 was around 60% of the maximal activity.

Conclusion: The presence of other substrates leads to greater reductions in total uric acid transport by URAT1 as uric acid levels are reduced, as seen with the less saturated and more responsive renal reabsorption of uric acid in gout patients. The reabsorption profiles before and after XOI treatment in NHV or gout patients can be mimicked by the activity of the uric acid reabsorption transporter URAT1 *in vitro*, in the absence or presence of other URAT1 substrates, respectively. The results suggest the the possibility that the enhanced reabsorption of uric acid in gout patients and in drug-induced hyperuricemia may be due to the presence of other URAT1 substrates that alter the uric acid transport kinetics of URAT1, which may lead to, or sustain, hyperuricemia.

Association Analysis of Apolipoprotein B and Very Low-Density Lipoprotein with Hyperuricemia and Gout. Humaira Rasheed[1], Angela Hsu[1], Nicola Dalbeth[2], Lisa K. Stamp[3], Sally McCormick[1] and Tony R. Merriman[1]. [1]University of Otago, Dunedin, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]University of Otago, Christchurch, New Zealand.

Background/Purpose: Gout results from an innate immune response to monosodium urate (MSU) crystals deposited in joints. Increased very low-density lipoprotein (VLDL) has been associated with gout. Apolipoprotein B (apoB), present on VLDL, regulates neutrophil response to MSU crystals. ApoB has been positively associated with gout and the *APOB* mRNA-editing gene, *A1CF*, is associated with urate levels. However the relationship of ApoB and VLDL with gout in the presence of hyperuricemia has not previously been tested. Therefore we tested the association of VLDL and apoB with gout in the presence of hyperuricemia (HU).

Methods: New Zealand European (n=90) and Māori and Pacific Island (Polynesian) (n=90) male gout case and control sample sets were divided into normouricemia (NU: serum urate <0.41mmol/L), asymptomatic hyperuricemia (HU: serum urate ≥0.41mmol/L) and gout groups. Gout was classified using the 1997 American Rheumatism Association criteria. Size exclusion chromatography and enzyme-linked immunosorbant assay were used to measure VLDL and apoB. Multivariate linear regression was used to assess the risk of gout and HU per unit change in VLDL and apoB.

Results: Increased levels of VLDL triglycerides (Tg) were observed in the gout sample set compared to NU and HU in European ($P=1\times10^{-4}$ and 2×10^{-3}, respectively) and Polynesian subjects (P=0.042 and 0.019, respectively). This increase was driven by overproduction of VLDL particles in the European subjects and by the Tg-enrichment of existing VLDL particles in the Polynesian subjects. Each mmol/L increase in VLDL Tg was significantly associated with gout in the presence of HU in Europeans, with a similar trend

in Polynesians (OR=6.82, P=0.017 and 2.85, P=0.066, respectively). Each μmol/L increase in apoB was associated with a decreased risk of HU (OR=0.47; P=0.046) and, conversely, with increased risk of gout in the presence of HU (OR=4.79; P=0.005: Table 1) in combined sample set.

Conclusion: Increased VLDL Tg is associated with the risk of gout in the presence of HU. If genetic approaches indicate evidence for causality of VLDL in gout, this would provide further justification for clinical trials examining the effects of fibrates as a treatment option in gout.

Table 1: Analysis of association of VLDL Tg and apo B associated traits with gout and hyperuricemia

All associations are adjusted for age, BMI, type 2 diabetes, SSB intake (drinks/day), alcohol intake (drinks/week), estimated glomerular filtration rate (eGFR) and prescription of lipid-lowering medication. The Polynesian data are also adjusted by number of self-reported Polynesian grandparents. Combined sample sets are additionally adjusted for ethnic class. VLDL Tg and total FPLC Tg are measured in mmol/L. Apo B is measured in μmol/L.

Effects of Anti-NGF Strategies in Two Animal Models of Osteoarthritis (OA). Lilian Ngozi Nwosu[1], Paul Mapp[1], Karyn Bouhana[2], Steven Andrews[2], Victoria Chapman[1] and David Walsh[1]. [1]Arthritis Research UK Pain Centre, University of Nottingham, Nottingham, United Kingdom, [2]Array BioPharma, Boulder, CO.

Background/Purpose: Levels of endogenous nerve growth factor (NGF) are increased in osteoarthritic (OA) joints in patients and animal models and may be an important cause of pain associated with OA. NGF binds to the high-affinity tropomyosin kinase A (Trk A) and low affinity p75 receptors. Analgesic benefits of the humanized antibody tanezumab in clinical trials have encouraged development of NGF blockade as a novel analgesic strategy for OA, although rare and currently unexplained adverse effects on joint structure have been a concern. Blocking antibodies against NGF inhibit signalling through both Trk A and p75. The ability of selective inhibitors of Trk A tyrosine kinase activity to inhibit OA pain has not previously been reported. We investigated the effect of a selective Trk A inhibitor on pain behaviour, synovial inflammation and joint structure in a chemically induced monosodium iodoacetate (MIA) model and a surgically induced medial meniscal transection (MNX) model of OA.

Methods: Male Sprague Dawley rats (n=10/group, 200–300g) were briefly anaesthetised and given a single intra-articular injection of (1mg/50μl) MIA or saline or underwent MNX or SHAM surgery. The development of pain behaviour was assessed using weight bearing asymmetry (difference in hind limb weight bearing (%)). Two weeks after OA induction, rats were stratified according to their pain responses and received a selective Trk A inhibitor (AR00475786) or vehicle for the remainder of the study. Alterations in knee structure and inflammation were examined by macroscopic visualisation of articular surfaces (Guingamp classification) and histology. Differences between groups were analysed using Kruskal Wallis test followed by post hoc Dunn's test and presented as mean (95% confidence interval).

Results: Rats receiving intra-articular injection of MIA or that underwent MNX surgery developed significant increases in %weight-bearing asymmetry (saline v MIA; day 3 = 2.9 [−4.7 – 11] v 36 [22–51], day 7 = 3.3 [−3 – 9.6] v 24 [14–35] *p<0.05, SHAM v MNX; day 3 = 11.5 [−0.78 – 3.9] v 20 [9.3–31], day 7 = 1.4 [−0.83 – 3.7] v 18 [9.4–26] *p<0.05) with significant increases in synovial inflammation (saline v MIA; 0.78 [0.14–1.4] v 2.3 [2–2.6] **p<0.01). Following drug treatment with AR00475786, there was a significant reversal of %weight-bearing asymmetry (MIA + Vehicle v MIA + drug; day 21 = 27 [21–23] v 3.7 [−1.4 – 8.8] **p<0.01, MNX + Vehicle v MNX + drug; day 21 = 27 [21–32] v 4.8 [1.1–8.6] **p<0.01) and reduced synovial inflammation (MIA + Vehicle v MIA + drug; day21 = 2.3 [2–2.6] v 1.2 [0.32–2.1] *p<0.05). Administration of the Trk A inhibitor did not significantly affect macroscopic chondropathy.

Conclusion: NGF may mediate pain behaviour in rats with MIA or MNX-induced OA through diverse mechanisms. Reductions in weight bearing asymmetry suggest effects of blockade of endogenous NGF activity through Trk A inhibition on peripheral pain processing. Reductions in synovitis suggest additional analgesic mechanisms of NGF inhibition. Trk A inhibition has therapeutic potential in the treatment of OA. Better understanding of the contributions of NGF to OA pathology may help realise the potential of NGF inhibition for OA treatment.

Genome-Wide Association Analysis of Pain Reduction in Rheumatoid Arthritis Patients Treated with TNF Inhibitors. Marieke J. H. Coenen[1], Maša Umicevic-Mirkov[1], Sophine B. Krintel[2], Julia Johansen[3], Corinne Miceli-Richard[4], Henrik Kallberg[5], Hans Scheffer[1], Wietske Kievit[1], Mart A. van de Laar[6], Piet L. C. M. van Riel[1], X. Mariette[7], Saedis Saevarsdottir[8], Merete Lund Hetland[9], Sita Vermeulen[1] and Cornelis A. Albers[1]. [1]Radboud university medical center, Nijmegen, Netherlands, [2]Copenhagen University Hospital at Glostrup, Glostrup, Denmark, [3]University of Copenhagen, Frederiksberg, Denmark, [4]Université Paris-Sud 11, Bicêtre Hospital,, Kremlin Bicêtre, France, [5]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [6]University Twente & Medisch Spectrum Twente, Enschede, Netherlands, [7]Paris-Sud University, Paris, France, [8]Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [9]DANBIO, Center for Rheumatology and Spine Diseases, Glostrup Univ Hospital, Glostrup, Denmark.

Background/Purpose: Pain is the dominant and prevailing symptom of rheumatoid arthritis (RA). Tumor necrosis factor inihibitors (TNFi) have proven very successful in pain reduction. Interestingly, improvement of pain, is notable rapidly after administration of TNFi agents, and well before anti-inflammatory effects of treatment can be observed. The vast majority of pharmacogenetic studies of response to TNFi utilized the clinical outcome measure, disease activity score 28 (DAS28). This measure is very useful for clinical practice, however it might be less heritable as compared to individual, potentially more homogeneous, disease measures. Usage of less complex phenotypes, such as pain (heritability 28–71%), might significantly aid the identification of genetic markers predicting differential response to TNFi. We aimed to identify and replicate genetic factors predicting pain reduction upon TNFi treatment in patients with RA using genome-wide association approach.

Methods: We included 508 TNFi treated RA patients. Association analysis of change of visual analogue scale of pain (VAS-pain) after 14 weeks of treatment was performed on imputed genome-wide genotyping data under additive genetic model with adjustment for baseline VAS-pain. We also conducted a meta-analysis including 1287 RA patients. Gene-based analysis was performed using VEGAS.

Results: No findings reached the threshold for genome-wide significance (P-value≤1×10-8) in the discovery cohort. Meta-analysis revealed 213 SNPs suggestively associated (P<10-4) with change in VAS-pain after fourteen weeks of TNFi treatment. The most significant SNP rs2295739 (p=2.21×10-6), located ~50kb upstream from the *KCNK10* gene. Which belongs to a family of genes involved in sensory perception. The top hit in the gene-based analysis was RET, known to regulate ion channels and receptors participating in detection and transduction of sensory stimuli. Besides Ret-deficient mice show elevated pain responses.

Conclusion: We have identified several suggestive genomic regions, further studies are required to validate if these regions play a role in pain reduction upon TNFi treatment.

Patient Reported Pain By the Paindetect Questionnaire Reveals Multimodal Elements to Pain Perception in Rheumatoid Arthritis. Saqa Ahmed[1], Tejal Magan[1], Mario Vargas[1], Abiola Harrison[1] and Nidhi Sofat[2]. [1]St George's, University of London, London, United Kingdom, [2]St. George's University of London, London, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) is an inflammatory autoimmune condition typified by systemic inflammation targeted towards synovial joints. Inhibition of pro-inflammatory networks by disease-modifying anti-rheumatic drugs e.g. methotrexate and biologic therapies including TNFα inhibitors, often leads to suppression of disease activity. However, despite the era of widespread use of disease-modifying treatments, there remain significant groups of patients who continue to experience pain.

Methods: Our study formulated a pain assessment tool to be used in the arthritis clinic to assess feasibility of measurements including the visual analogue scale (VAS) for pain (range 0–100 mm) and painDETECT questionnaires (range 0–38) to evaluate neuropathic features of pain in people with established RA (n=100). Clinical measures of disease activity (DAS28), disease-modifying medication use, body mass index (BMI) and worst pain ever were also recorded. Continuous data was described and analysed using parametric statistics, with ANOVA and Chi-squared tests for groups with 3 or more categories.

Results: We found that participants with RA reported relatively high pain levels, despite widespread use of disease-modifying drugs (Table 1). The majority, 54%, reported 'severe pain' on the visual analogue scale (VAS), which identifies people with a VAS of 54–100 mm as having the highest severity of pain. The mean DAS28 in the group was 2.09 $\pm$ 0.96. The majority of subjects had duration of diagnosis greater than or equal to 5 years (84%), suggesting that pain was a persisting symptom despite sustained use of disease-modifying agents and a DAS28 score suggesting clinical remission. All participants evaluated had been stable on DMARD therapy for at least 3 months prior to completing the study and had not required a change in their treatment, or addition of corticosteroid therapy during that time. The majority of participants were being treated with disease-modifying drugs, including the commonest agent, methotrexate (82%). Using the painDETECT questionnaire, 67% of patients had unlikely neuropathic pain. A significantly high proportion of 28% subjects had possible neuropathic pain and 5% had features of likely neuropathic pain by painDETECT scoring. We found a positive correlation between VAS and painDETECT (r^2=0.757). Of note, the group who had likely or probable neuropathic pain also showed significantly increased pain reporting by VAS ($p < 0.01$). Subjects who were clinically obese (BMI > 30) had statistically higher proportions of pain reporting (VAS 89.0 $\pm$ 0.7) compared with subjects who had a normal BMI (VAS 45.2 $\pm$ 21.8), p<0.05.

Conclusion: Our findings suggest that multimodal features of pain perception exist in RA, including neuropathic and sensitisation elements, perhaps explaining why a subgroup of people with RA continue to experience ongoing pain, despite their apparent suppression of inflammation.

Improvement Following Total Knee Replacement (TKR) Surgery: Exploring Preoperative Symptoms and Change in Preoperative Symptoms. Ernest R. Vina[1], Michael J. Hannon[2] and C. Kent Kwoh[3]. [1]University of Pittsburgh and VA Healthcare System, Pittsburgh, PA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, [3]University of Arizona, Tucson, AZ.

Background/Purpose: Few have examined the trajectories of preoperative health-related quality of life (HRQL) measures in osteoarthritis (OA) patients who undergo TKR. Yet, the type and rate of preoperative decline may predict the outcomes of TKR. The objectives of the study are to determine whether changes in preoperative HRQL measures are associated with improvement after TKR and to identify important predictors of clinically significant improvement.

Methods: Data from people who underwent TKR were obtained from the Osteoarthritis Initiative (OAI), a study which annually assessed participants. T0 was the assessment prior to TKR while T-1 was the assessment prior to that. T+2 was the second assessment after TKR. We compiled data on OA-related symptoms (i.e. pain/aching/stiffness most days of the month in the last year), the WOMAC, activities, and radiographic severity (i.e. Kellgren-Lawrence grade, KLG). We defined clinically significant improvement as improvement in WOMAC total score $\geq$ to the minimal important difference (0.5 standard deviation of mean change in the study data) between T0 and T+2. After conducting bivariate tests for differences, logistic regression models were performed to evaluate the relationship between improvement and preoperative measures. Only variables associated with improvement at $p \leq 0.2$ in a series of stepwise regressions were included.

Results: Our sample consists of 211 improved & 58 unimproved patients. Improved, compared to unimproved, patients had higher preoperative (T0) WOMAC pain (39.31 $\pm$ 17.86 vs. 22.73 $\pm$ 17.92, p<0.001), disability (39.17 $\pm$ 15.08 vs. 18.23 $\pm$ 16.86, p<0.001) and stiffness (46.45 $\pm$ 20.21 vs. 27.37 $\pm$ 20.47, p<0.001) scores in the index knee (i.e. TKR knee). Those who had improvement were more likely to report OA-related symptoms in the index knee (96.68% vs. 77.59%, p<0.001). They also had greater worsening of their WOMAC pain (9.65 $\pm$ 19.53 vs. 2.48 $\pm$ 13.19, p=0.002), disability (9.87 $\pm$ 17.22 vs. $-$0.16 $\pm$ 13.38, p<0.001) and stiffness (9.11 $\pm$ 23.23 vs. $-$0.24 $\pm$ 20.34, p=0.009) scores from T-1 to T0 in the index knee.

Preoperative measures as predictors of improvement in our multivariate model included: Higher WOMAC disability (OR 1.09, 95% CI [1.05–1.13], p<0.001), presence of OA-related symptoms in the index (OR 7.13, 95% CI [1.77–28.67], p=0.006) but absence in the contralateral (OR 8.07, 95% CI [2.75–23.74], p<0.001) knee, exposure to frequent knee bending (OR 3.01, 95% CI [1.02–8.87], p=0.045), having a KLG of 4 (vs. 0, 1, 2 or 3) in the contralateral (OR 4.40, 95% CI [1.24–15.56], p=0.022) and index (p=0.124) knee, and worse SF-12 Mental Health score (p=0.209).

Conclusion: More than 75% of OAI patients had clinically significant improvement after TKR. Improved patients had more self-reported pain and disability prior to surgery and were more likely to have escalation of these symptoms than unimproved patients. Worse OA-related disability prior to surgery, presence of OA symptoms in the surgical knee, prior exposure to frequent knee bending, and having marked radiographic features of OA but without OA-related symptoms in the contralateral knee all increase the likelihood of achieving clinically significant improvement after TKR.

Mortality after Knee Replacement Surgery for Osteoarthritis in a Population-Based Propensity-Score Matched Cohort. Devyani Misra[1], Tuhina Neogi[1], Na Lu[1], David T. Felson[1], Thomas Einhorn[1], Hyon Choi[2], Jessica Maxwell[3] and Yuqing Zhang[1]. [1]Boston University School of Medicine, Boston, MA, [2]Harvard Medical School, Boston, MA, [3]Boston University, Boston, MA.

Background/Purpose: Knee replacement (KR) surgery for osteoarthritis (OA) provides improvement in symptoms and function. Whether these improvements translate into survival benefit has been unclear, likely related to selection of healthier patients for surgery, exclusion of the post-operative immortal time, and inadequate length of follow-up in prior studies. The purpose of this study was to determine risk of mortality related to KR by comprehensive adjustment for confounders using a propensity-score (PS) matched cohort approach and long follow-up.

Methods: Participants ages 50–89 years with a diagnosis of knee OA (from Read Codes) were included from The Health Improvement Network

(THIN), an electronic medical records database representative of the UK general population. High risk subjects who are less likely to be surgical candidates (BMI>40, history of joint infection, high risk cancers (pancreatic, esophageal, gastric or other metastatic), end-stage renal disease on dialysis, use of nasal cannula oxygen, or DMARD therapy) were excluded. PS for KR was calculated using logistic regression with KR as the dependent variable and the confounders listed in the table as independent variables, that reflect indications for KR and risk for poor outcomes. One year cohort-accrual blocks were created, and each KR subject was matched 1:1 by PS with a non-KR subject. Follow-up started from the index date, which was the date of surgery for KR subjects and a random date within the cohort accrual block for non-KR subjects, and continued until death or censoring. We examined the association of KR with mortality by calculating crude incidence rates (IR) and Hazard ratios (HR) using Cox proportional hazard regression. We also examined the association stratified by age category (<70 years, ≥70years) as well as within percentile categories of the PS.

Results: There were 14,675 pairs of subjects with knee OA (mean age 71yrs; 57% women; mean BMI 29kg/m^2) in the PS-matched cohort. The follow-up years were 63769 and 60582 for matched KR and non-KR subjects, respectively. Overall there was 31% lower risk of mortality among subjects with KR (HR 0.69, 95% CI 0.64–0.75). The lower risk remained in subjects ≥70 years but no such relation was noted in subjects <70 years (table). The crude IR for mortality among KR subjects decreased as PS percentile category increased, while no such trend was noted for the non-KR subjects. Mortality risk was lowest (HR 0.29, 95% CI 0.13–0.63) in the highest PS percentile (>98%) category (table).

Conclusion: We found KR to be protective for mortality risk among subjects ≥70 years and among those with the highest propensity for KR. Although a protective effect of KR cannot be ruled out, there likely remains confounding by indication despite comprehensive adjustment of covariates. Patients, physicians, and surgeons consider additional factors in performing KRs that are not adequately captured within administrative databases.

Psoriatic Arthritis is Associated with Heterotopic Ossification after Total Hip Arthroplasty.

Mario Cedillo[1], Arielle Fein[2], Susan M. Goodman[2], Rebecca Zhu[2], Mark P. Figgie[2], Michael Alexiades[2], Jayme C. Burket[2] and Lisa A. Mandl[2]. [1]Weill Cornell Medical College, New York, NY, [2]Hospital for Special Surgery, New York, NY.

Background/Purpose: Heterotopic ossification (HO), the pathologic deposition of ectopic bone in soft tissues, is a feared complication of total hip arthroplasty (THA). HO is strongly associated with ankylosing spondylitis. However, whether rates of HO are also increased in psoriatic arthritis (PsA), another seronegative spondyloarthopathy with a predisposition to build bone, is unknown.

Methods: We performed a case–control study of validated PsA THA cases, each matched 2:1 on age and date of surgery with osteoarthritis (OA) controls. All THA were performed between May 2007 and June 2012. Radiographs taken ≥ 6 months after surgery were reviewed to detect evidence of HO, based on Brooker classification criteria. Chart review was conducted to identify potential known risk factors for HO, which were evaluated in univariate models. A logistic regression model was constructed to evaluate independent predictors of HO. Risk factors considered for inclusion in the model were those with p-values < 0.20 from the univariate models, which were then removed in a step-wise fashion until only terms with p < 0.1 remained.

Results: 242 PsA THA were identified and matched to 484 OA controls. No PsA THA received prophylactic radiation to prevent HO. 94.2% of PsA surgeries were primary THA and 5.8% were revisions while 93.8% of OA surgeries were primary THA and 6.2% were revisions. Average age was 62.3 for PsA ± 11.7 years and 62.8 for OA ± 11.5. 55.2% of PsA were male while 44.4% of OA were male. More PsA THA than OA THA developed HO (42.2% vs. 29.6%; p-value = 0.012). In univariate models, PsA diagnosis, primary vs. revision surgery, inpatient NSAID use, ASA use, blood transfusions, sex, age, BMI, and length of stay were associated with HO. In the final logistic regression model, HO was significantly associated with PsA (OR: 1.62; 95% CI 1.16–2.27; p-value = 0.005), age (OR for each 10-year increase in age 1.15; 95% CI 1.00–1.3; p-value = 0.047), and being discharged on Coumadin for DVT prophylaxis (OR: 1.86; 95% CI 1.23–2.65; p-value = 0.0007). Inpatient Lovenox was associated with an over 4-fold increase in the odds of having HO (OR: 4.16; 95% CI 1.05–16.6; p-value = 0.043). Female gender was protective against HO (OR: 0.44: 95% CI 0.32– 0.62; p-value < 0.001).

Conclusion: To our knowledge, this is the first study to show that psoriatic arthritis is associated with increased odds of HO following THA. Being older, receiving inpatient Lovenox, or being discharged on Coumadin also increased the risk of HO. Being female decreased the risk of developing HO. This is important information to convey to THA surgeons and patients with PsA contemplating THA.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Clinical Aspects VII: New Aspects of Monitoring Disease
Wednesday, November 19, 2014, 9:00 AM–10:30 AM

2971

Patient's Self-Monitoring Via Smartphone: The Compass Study Correlation Between Patient Self-Assessment of Rheumatoid Arthritis Disease Activity Via Smartphone Technology and Physicians' Validated Scores.

Ruediger Mueller[1], Ulrich Walker[2], Diego Kyburz[3], Robert Theiler[4], Adrian Forster[5], Fabiana Ganz[6] and Patrick Dufner[6]. [1]Kantonspital St. Gallen, St. Gallen, Switzerland, [2]Department of Rheumatology, Basel University, basel, Switzerland, [3]University Hospital, Basel, Switzerland, [4]Triemli spital, Zurich, Switzerland, [5]Spital Thurgau AG, Diessenhofen, Switzerland, [6]Abbvie AG, Baar, Switzerland.

Background/Purpose: In clinical practice, patients with RA are usually seen every 3 to 6 months[1]. Although desirable, monthly visits with assessments of disease activity are often not possible due to limited physician resources[2]. However, patients increasingly wish to be actively involved in treatment decisions. Therefore, the development of an internet-based tool for disease activity score assessments by patients could represent an innovative solution. The COmPASS study aims to demonstrate a correlation between the patient assessments of RA disease activity via smartphone and the disease activity done by the physician using traditional scores.

Methods: Adult RA patients under current non-intravenous DMARD treatment were included in the prospective, single-arm, multicentre study. Patients were equipped with smartphones and educated to use a web application (WebApp) for self-assessment. Patients were assessed clinically by the treating physician at baseline. The assessment included joint counts, global assessment, laboratory values, along with simultaneous WebApp questionnaires (RAPID3/4) that were filled in by the patient. During the subsequent 3 months, patients were asked to fill in the WebApp questionnaires at least once a week. Descriptive statistics for RA disease activity according to the WebApp and rheumatologist evaluation at the baseline visit were analysed with the Pearson Correlation. Sensitivity analysis was performed. The correlation between RAPID3/4 scores and DAS44 as well as CDAI and SDAI was evaluated.

Results: Ninety patients were recruited in five Swiss clinics [mean (SD): RA duration: 7.1 years (8.6); age: 54.7 years (13.5); 60% male]. The data showed a strong correlation between patient and rheumatologist assessment of disease activity when comparing RAPID3 with DAS44 at baseline (Fig 1, R=0.60; 95% CI 0.43 – 0.73), CDAI (R=0.53; 95% CI 0.34 – 0.68) and SDAI (R=0.49; 95% CI 0.28 – 0.65). The sensitivity analysis demonstrated that this correlation was independent of disease characteristics, treatment type, demographics, and centre effects, as well as unaffected by a delay of the smartphone data entries up to 7 days after baseline assessment by the rheumatologist. A similar correlation was seen for RAPID4 and DAS44 (R=0.61; 95% CI 0.45 – 0.74), CDAI (R=0.55; 95% CI 0.37 – 0.70) and SDAI (R=0.50; 95% CI 0.30 – 0.66).

Conclusion: In this multicentre study patients' self-assessment of disease activity (RAPID3 and 4) correlated strongly with that of rheumatologists (DAS44, CDAI, SDAI), indicating that patients are able to self-assess their disease activity. This provides a rationale to further explore the use of smartphone technology for tight disease monitoring in order to help the rheumatologist to optimize RA management. Whether or not the use of a WebApp for self-assessment will lead to better treatment outcomes will have to be shown in future studies.

Figure 1: Pearson Correlation at Baseline – RAPID3 and DAS44 at baseline as primary endpoint.

Elevations of Certain Memory-Effector T Cell and Inflammatory Monocyte Subpopulations in Rheumatoid Arthritis Are Associated with the Presence of Subclinical Coronary Artery Atherosclerosis. Robert Winchester[1], Jon T. Giles[1], Simona Nativ[2], Hui-Zhu Zhang[1], Kendall Downer[1] and Joan Bathon[1]. [1]Columbia University, New York, NY, [2]Morristown Medical Center, Morristown, NJ.

Background/Purpose: Factors that identify cardiovascular disease (CVD) fully in RA are lacking. Peripheral blood mononuclear cell (PBMC) subsets in RA patients differ markedly, on average, from non-RA controls in T-cell activation/differentiation to memory effector status and in the degree monocytes exhibit an intermediate 'inflammatory' phenotype. We hypothesized that elevations in these subpopulations would distinguish those with subclinical atherosclerosis.

Methods: Patients with RA and no clinical CVD underwent cardiac computed tomography (CT). Coronary arterial calcium (CAC) was quantified by the Agatston method. PBMC subsets were assessed by multiparameter flow cytometry. Multivariable linear and logistic regression were used to assess the associations between PBMC subpopulations and CAC, adjusting for relevant confounders associated both with PBMC subsets of interest and CAC. The area under the receiver operator curve (AUC) was used to estimate the contribution of covariates on the prediction of any CAC.

Results: 72 RA patients [mean age 54±14 years; 84% female; shared epitope positive=64%, median RA duration=6.6 years; median DAS28=3.9; current biologic use in 31%] were studied. Any CAC [CAC>0] was observed in 34%. In univariate analyses, compared with patients with no CAC, those with CAC had significantly higher percentages of circulating CD4 T cell subsets denoting activation ($CD4^+HLA\text{-}DR^+$, $CD4^+CD28^-HLA\text{-}DR^+$), differentiation to memory effector ($CD4^+CD28^-HLA\text{-}DR^+$, $CD4^+CD56^+CD57^+$), and acquisition of NK receptors ($CD4^+CD56^+CD57^+$) and similar increases of analogous CD8 T cell subsets, along with increases in the proportion of intermediate $CD14^{++}CD16^+$monocytes. The CD4 and CD8 subsets were highly correlated, while the $CD14^{++}CD16^+$monocyte subset was independent of the CD4 and CD8 subsets. In multivariable models including all non-collinear PBMC subsets of interest, only levels of $CD4^+CD56^+CD57^+$ T cells and $CD14^{hi}CD16^+$monocytes remained significantly associated with the presence of CAC after adjusting for relevant RA and CVD risk factors (Figure). CRP, serum IL-6 and DAS28 were not associated with CAC. The AUC for any CAC for the model containing only the two PBMC subsets of interest was 0.76 (95%CI=0.64–0.87), this increased to 0.89 (95%CI 0.82–0.96) with the addition of age and systolic blood pressure to the model. Neither PBMC subset of interest was associated with the extent of CAC within those with a positive CAC score.

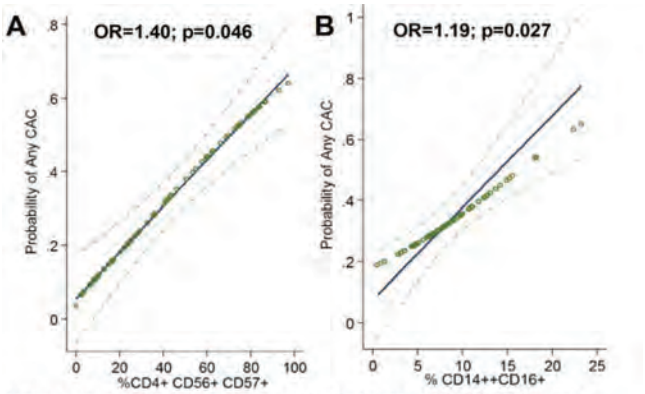

Figure. Crude and Adjusted Associations of the Proportions of $CD4^+CD56^+CD57^+$ and $CD14^{++}CD16^+$ Cells with the Probability of Any CAC. Crude associaitons are depicted by open circles. Adjusted associations are depicted with the solid least squares indicator and 95% confidence interval (light dashed line). Each unit increase in the square root of $\%CD4^+CD56^+CD57^+$ was associated with a 40% higher adjusted odds of any CAC (Panel a; p=0.046) while each unit increase in $\%CD14^{++}CD16^+$ was associated with a 19% higher adjusted odds of any CAC (Panel b.; p=0.027). Adjustments for age, systolic blood pressure, and the other PBMC subset. Other RA and CVD risk factors were not retained in adjusted models as they were not associated with both the PBMC subsets of interest and the presence of CAC.

Conclusion: Subclinical atherosclerosis was robustly associated with levels of circulating PBMCs reflecting differentiation to memory effector status/acquisition of NK receptors and higher levels of intermediate (inflammatory) monocytes, independent of demographics, CVD risk factors, and, importantly, RA disease activity and severity. These factors may account for a portion of the unexplained contributors to enhanced atherogenesis in RA.

The Multi-Biomarker Disease Activity Score As a Predictor of Radiographic Progression in a Registry of Patients with Rheumatoid Arthritis. Eric H. Sasso[1], George Wu[1], CC Hwang[1], Michael E. Weinblatt[2], Nancy A. Shadick[2], Claire Alexander[1] and Oscar Segurado[1]. [1]Crescendo Bioscience Inc., South San Francisco, CA, [2]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: This study evaluated the association between baseline disease activity, as assessed with the multi-biomarker disease activity (MBDA) blood test, CRP or clinical measures, and the rate of radiographic progression over 2 years for patients with rheumatoid arthritis (RA) receiving stable therapy in the Brigham and Women's Hospital Rheumatoid Arthritis Sequential Study (BRASS) Registry.

Methods: MBDA scores, CRP, DAS28-CRP, CDAI, RAPID3, and radiographic progression were analyzed at baseline (defined as the initial visit in the BRASS registry), for 143 patients with RA who had received a stable treatment, i.e., with no addition or removal of DMARDs and irrespective of dosing, over 2 years. Radiographs of hands and wrists only, taken within 3 months of baseline in BRASS and 2 years later, were evaluated to determine the change per year in total Sharp score (ΔTSS). Radiographic progression (RP) was defined as ΔTSS >3 per year over 2 years. Predictive performance was assessed using AUROC. Associations with RP were evaluated using univariate and multivariate logistic regression adjusted for potential confounders.

Results: For 143 patients, mean age and disease duration were 59 and 18 years, respectively, with 84% female, 80% seropositive (RF+ and/or anti-CCP+), and 52% receiving MTX/non-biologic DMARD monotherapy, 19% a TNF inhibitor alone, 27% both in combination, and 2% not on any DMARD therapy. Mean baseline values were MBDA score=39, CRP=0.86 mg/dL,

DAS28-CRP=4.1, CDAI=24.8, RAPID3=8.1 and TSS=68. RP was observed in 18% (26/143) of patients. Better predictive accuracy for RP was observed for baseline MBDA score (AUROC=0.75), compared with baseline clinical CRP (AUROC=0.71), DAS28-CRP (AUROC=0.62), CDAI (AUROC=0.59) or RAPID3 (AUROC=0.50). Adjusting for BMI and baseline TSS, the significant independent predictors for RP were MBDA score (OR_{1SD}=2.90, 95% CI=1.69–4.97), CRP (OR_{1SD}=2.36, 95% CI=1.46–3.82), and DAS28-CRP (OR_{1SD}=1.74, 95% CI=1.04–2.93), but not CDAI (OR_{1SD}=1.46, 95% CI=0.89–2.41) and RAPID3 (OR_{1SD}=0.97, 95% CI=0.61–1.55). For patients with low CRP (≤1 mg/dL) at baseline, RP was observed in 34.8% (8/23) with high MBDA score (>44) versus 8.1% (7/86) with low/moderate MBDA score (≤44) (p=0.003).

Conclusion: Baseline MBDA score was a better predictor of radiographic progression over 2 years than CRP, DAS28-CRP, CDAI or RAPID3 in patients with RA on stable therapy from the BRASS registry.

2974

Multi-Biomarker Disease Activity Score Is Associated with Power Doppler Ultrasound in Patients with Rheumatoid Arthritis in Low Disease Activity State. Margaret H. Ma[1], Toby Garrood[2], Wanying Li[3], Nadine A. Defranoux[3], Gabrielle H. Kingsley[4], Andrew P. Cope[5] and David L. Scott[6]. [1]King's College Hospital, London, United Kingdom, [2]Guy's and St. Thomas' Foundation Hospital NHS Trust, London, United Kingdom, [3]Crescendo Bioscience Inc., South San Francisco, CA, [4]Kings College London, London, United Kingdom, [5]King's College London, London, United Kingdom, [6]King's College London, Department of Rheumatology, London, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) patients increasingly achieve clinical remission with intensive treatment regimens. However, ultrasound (US) subclinical synovitis has been reported in remission states. The multi-biomarker disease activity (MBDA) blood test assesses overall RA disease activity.

The purpose of this study was to evaluate associations between US signals, MBDA score and its component biomarkers in the REMIRA cohort, a 1 year prospective observational study of patients with RA in low disease activity.

Methods: We studied 95 patients with RA on stable therapy for ≥6 months with DAS28 ≤3.2 for ≥1 month. Clinical measurements and serum samples were collected every 3 months for 1 year and US were conducted at baseline (BL) and 1 year. MBDA scores (range 1–100) were calculated from the serum concentrations of VCAM-1, EGF, VEGF-A, IL-6, TNF-RI, YKL-40, MMP-1, MMP-3, leptin, resistin, SAA and CRP using the validated Vectra® DA algorithm. MBDA disease activity thresholds have been defined as remission (<26), low (26–29), moderate (30–44), and high (>44). Power doppler (PD) and synovial hypertrophy (SH) of bilateral MCP joints and wrists were assessed by the same sonographer on the same machine and scored 0–3 for each joint and summed to provide total PD and SH scores (range 0–36). More stringent modified PD (mPD) and SH (mSH) scores were derived, based on MCP joint measures only, using signal thresholds determined from the distributions of BL PD and SH signals measured in a subset of patients who maintained no swollen joints (SJC28=0) without intensification of therapy over 1-year follow-up. Correlations between PD or SH and DAS28, MBDA scores or their components were evaluated by Spearman's rank correlation.

Results: Mean (±SD) BL disease activity measures were: DAS28 2.1 (±1.0), MBDA score 30 (±13), PD score 3.7 (±5.1), mPD 1.1 (±2.7), SH score 12.1 (±4.7), and mSH 0.4 (±1.1). At BL, 67% of patients were in DAS28 remission, 43% were in MBDA remission, 91% had PD>0 (31% had mPD>0) and 100% had SH>0 (21% had mSH>0). Statistically significant correlations (p<0.05) with PD and mPD were observed at both time points for MBDA scores (correlations ranged from 0.22–0.36), DAS28 (r=0.22–0.30), SJC28 (r=0.28–0.39), and four MBDA biomarker components: CRP (r=0.21–0.31), SAA (r=0.21–0.35), IL-6 (r= 0.26–0.39) and MMP-3 (r=0.24–0.36). The frequency of having MBDA score <26 was significantly greater in patients with mPD=0 than those with mPD>0 (52% vs. 24% at BL; 36% vs. 9% at 1 year). Correlations at BL or 1 year between SH or mSH and DAS28, MBDA score or components were weak or non-significant.

Conclusion: Ultrasound PD and SH signals could be detected in most RA patients of the REMIRA cohort. After applying a modified, more stringent, scoring system, 21% to 31% had detectable US signals. We have shown, for the first time, significant correlations with PD and mPD scores for MBDA scores and some of its component biomarkers. Correlations were also found with DAS28 and SJC28. Remission by MBDA score was significantly associated with mPD=0. These results suggest that MBDA score detect low grade inflammation and subclinical synovitis in patients with RA in clinical remission or low disease activity.

2975

Residual Large Joint Synovitis By Power Doppler Ultrasonography Is Associated with Higher Disease Activity and Significant Impact of Disease in Multi-Ethnic Asian Patients with Established Rheumatoid Arthritis. Yu Xiao Guo[1], Manjari Lahiri[2] and Peter Cheung[2]. [1]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, [2]Division of Rheumatology, National University Hospital, Singapore, Singapore.

Background/Purpose: Regular monitoring of disease activity with appropriate modification of disease-modifying anti-rheumatic drug (DMARD) therapy results in improved radiographic and functional outcomes in patients with rheumatoid arthritis (RA). Large joint involvement has been shown to impact significantly on both disease activity and disability. Power Doppler ultrasound (PDUS) can effectively detect subclinical active synovitis not appreciated by clinical examination. The objective is to evaluate the presence of residual large joint disease in established RA patients in a multi-ethnic Asian cohort using PDUS as the reference standard, and whether there is increased impact and disability.

Methods: Patients with established RA (ACR 1987 criteria) and stable disease were recruited as part of a randomized controlled single centre study, evaluating the use of ultrasonography feedback as training tool for patient self-assessment of synovitis. At baseline, 28 joints (2 shoulders, 2 elbows, 2 wrists, 10 MCP, 10 PIP, 2 knees) of each patient were assessed for synovitis in B-mode (from 0=absence of synovial thickening to 3=marked synovial thickening) and PDUS (from 0=absence of signal, no intra-articular flow to 3=marked signal in more than half of the synovial area). Semiquantitative grade ≥1 on PDUS was considered as active synovitis. Patients with residual large joint disease (shoulders, elbows, knees) on PDUS were evaluated for differences in baseline demographics, disease activity, physical function (modified Health Assessment Questionnaire, mHAQ and SF12-physical component score) and impact of disease (Rheumatoid Arthritis Impact of Disease Score, RAID) with patients that did not have large joint involvement. Measures of association were evaluated using logistic regression.

Results: Of the 101 patients included, median (IQR) age was 54 (48, 63) years old, Chinese (73%), female (81%), non-smokers (85%), and 77% were positive for either rheumatoid factor or anti citrullinated peptide antibody. Median disease duration was 5 (2, 9) years with PDUS-DAS28 of 3.2 (2.6, 4.2). PDUS indicated a large proportion of patients with residual large joint involvement (44%) – 21% of shoulders, 20% of elbows and 6% of knees involved. The most common small joint involvement was the wrist (27%) with MCP and PIP joints rarely involved (both 2% respectively). A higher proportion of Chinese patients had large joint involvement (p=0.03). No significant differences in other baseline patient characteristics such as age, sex and seropositivity were seen. Patients with large joint disease had higher PDUS-DAS28 (p<0.001), ESR (p=0.002) and were more likely to receive combination triple therapy (DMARDs) (p=0.008). Residual large joint involvement was significantly associated with mHAQ>0.5 (p=0.03), lower SF12 physical component scores (p=0.02) and higher RAID score (p<0.001).

Conclusion: Multi-ethnic Asian RA patients with relatively stable established disease have a high proportion of residual PDUS large joint activity that significantly impacts on patients. Physicians should aggressively treat this subset of patients with either systemic/local therapies to prevent further disability.

2976

Lung Ultrasound Screening for Interstitial Lung Disease in Rheumatoid Arthritis. Comparison with Usual Detection Algorithms in Clinical Practice. Marco Antivalle, Michel Chevallard, Michele Battellino, Maria-Chiara Ditto, Valentina Varisco, Federica Rigamonti, Alessandra Mutti, Fabiola Atzeni, Alberto Batticciotto and Piercarlo Sarzi-Puttini. L. Sacco University Hospital, Milano, Italy.

Background/Purpose: Interstitial lung disease (RA-ILD) is one of the most serious extraarticular complications of rheumatoid arthritis (RA). Presently, it is not clear which is the best strategy for the detection of RA-ILD. We have previously reported on the feasibility and accuracy of lung ultrasound (LUS) in the detection of RA-ILD (1). Aim of the present study was to assess the performance of LUS in the detection of RA-ILD in clinical practice, and to compare its accuracy with the detection algorithms usually adopted.

Methods: 147 unselected RA patients (114 F and 33 M) were studied. In all patients, LUS was performed as previously described (1) by an expert physician (MC), blinded to clinical and HRCT data, using a standard commercially available US equipment (Esaote MyLabFive) with a 7.5–12 MHz probe. By LUS, RA-ILD was defined by a B-lines score >10. The results of the LUS study were compared to clinical, pulmonary function tests, chest X-ray, and lung CT (HRCT) data, as available from clinical records. Four clinical algorithms (ALG) were identified: ALG 1: presence of dyspnea (NYHA class >=2) and/or bibasilar crackles; ALG 2: as ALG 1 + FVC < 80%; ALG 3 as ALG 1 + DLCO<80%; ALG 4 as ALG 1 + evidence of ILD at chest X-ray. Sensitivity, specificity, and predictive values of LUS and clinical algorithms with reference to HRCT were calculated, and compared by McNemar test.

Results: RA-ILD was detected by LUS in 41/146 (28.1%) patients. Clinical data, FVC, DLCO, X-ray, and CT were available in 146(100%), 63(43%), 61(42%), 102(70%), and 67(46%) cases respectively. LUS showed a significantly higher accuracy in the detection of RA-ILD than clinical algorithms (Table 1). 33/64(52%) asymptomatic patients, and 31/82(38%) patients with clinical suspicion of RA-ILD, were not further evaluated by neither PFTs nor by HRCT. Overall, LUS detected unsuspected signs of RA-ILD in 9/146(6%) patients (Fig 1).

Conclusion: LUS is more accurate than usual clinical algorithms in the evaluation of RA-ILD, and allows the detection of a substantial number of unsuspected cases.

Tab. 1 – Sensitivity, specificity, and predictive power of LUS and clinical algorithms in the detection of RA-ILD. HRCT is the gold standard.

		LUS	ALG 1 (crackles a/o dyspnea)	ALG 2 (ALG 1 +FVC < 80%)	ALG 3 (ALG 1 + DLCO < 80%)	ALG 4 (ALG 1 + X-ray +)
Sensitivity % (IC 95%)		87.0 (76.0–93.6)	78.3 (66.2–87.0)	9.5 (3.3–22.7)	47.6 (32.9–62.7)	41.7 (26.7–58.2)
Specificity, % (IC 95%)		72.7 (60.3–82.6)	43.2 (31.3–55.8)	96.0 (84.4–99.4)	52.0 (37.0–66.7)	89.3 (74.5–96.3)
PPV % (IC 95%)		62.5 (49.8–73.8)	41.9 (30.1–4.5)	66.7 (51.1–79.4)	45.5 (31.0–60.7)	62.5 (45.8–76.8)
PPN% (IC 95%)		91.4 (81.4–96.5)	79.2 (67.2–87.8)	55.8 (40.5–70.1)	54.2 (39.0–68.7)	78.1 (61.8–89.1)
p*	total	–	0.02	0.005	0.05	0.05

Distinct Serum Protein Signature and Novel Biomarkers of primary Sjogren's Syndrome Revealed by comprehensive High-Throughput Proteomic Analysis. Ayumi Nishikawa[1], Katsuya Suzuki[1], Yoshiaki Kassai[2], Yuumi Gotou[3], Takahiro Miyazaki[2], Maiko Takiguchi[4], Masaru Takeshita[1], Atsuko Murota[1], Rimpei Morita[5], Akihiko Yoshimura[5] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Takeda Pharmaceutical Company Limited, Kanagawa, Japan, [3]Takeda Pharmaceutical Company Limited, Tokyo, Tokyo, Japan, [4]Takeda Pharmaceutical Company Limited, Tokyo, Japan, [5]Department of Microbiology and Immunology, Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: The EULAR SS Disease Activity Index (ESSDAI) is currently used as an objective evaluation method of clinical disease activity in clinical research into primary Sjogren's syndrome (pSS). This comprehensive indicator reflects patient signs and symptoms and organ involvement. However, a useful substitute serum biomarker of disease activity has not been established. Although several proteomic investigations of small and large salivary and lachrymal glands have been recently reported, information on serum protein is insufficient. Here, we aimed to reveal a distinct serum protein signature of pSS and identify novel biomarkers of disease activity.

Methods: We studied 90 serum samples from 30 pSS patients, 30 untreated rheumatoid arthritis (RA) patients as non-SS autoimmune disease controls, and 30 healthy control (HC) subjects. 1128 serum proteins, including inflammatory cytokines and chemokines, were quantitatively measured by comprehensive high-throughput proteomics assay using nucleic acid aptamers (SOMAscan™ Assay; Somalogic Inc., CO, USA). Associations between serum protein concentrations, clinical indicators and laboratory test results were statistically analyzed.

Results: After exclusion of 28 proteins for statistical reasons, 1100 of 1128 proteins in 90 subjects were analyzed. We first screened differentially up- and down-regulated proteins among the three groups, by which 195 proteins, including some overlap (85; pSS vs HC, 124; RA vs HC, 81; pSS vs RA), were statistically extracted ($p<0.05$ in the t-test and U-test, and fold change ≥ 1.2 or ≤ 0.83). Sixty proteins were up-regulated in pSS compared with HC, including BAFF (pSS patients/healthy control subjects: 9.4-fold), I-Tac (1.82-fold), vWF (1.57-fold), β2-microglobulin (1.47-fold), while 25 were down-regulated, including Immunoglobulin (Ig) D (0.21-fold), CTAP-III (0.79-fold), and GPIIbIIIa (0.83-fold). Enrichment analysis for characterization of up-regulated genes identified these as cytokines and chemokines including TNF-associated molecules and coagulation factors, indicating a serum protein signature in pSS. Multivariate analysis of these 60 proteins and ESSDAI identified 15 proteins with a statistically positive correlation, including TNF-associated molecules (BAFF, sCD163, TRAIL1-R4 and others), LAG-3, β2-microglobulin, and others.

Conclusion: This comprehensive proteomics analysis highlighted a dysregulated immunity and coagulation signature in patients with pSS. Fifteen up-regulated proteins were found to be correlated with disease activity. These proteins are candidate serum biomarkers for use in the clinical prediction of disease activity of pSS.

Characterization of the Sjögren's Syndrome Intergenic Non-Coding RNA 1 (SSINCR1). John A. Ice[1], He Li[1], Indra Adrianto[1], Mikhail G. Dozmorov[1], Astrid Rasmussen[1], Graham B. Wiley[1], Jennifer A. Kelly[1], Kimberly S. Hefner[2], Donald U. Stone[3], Raj Gopalakrishnan[4], David M. Lewis[3], Stephen Young[3], Michael D. Rohrer[4], Juan-Manuel Anaya[5], Swamy Venuturupalli[6], Barbara M. Segal[7], Nelson L. Rhodus[4], Lida Radfar[3], Michael H. Weisman[8], Judith A. James[1], Courtney G. Montgomery[1], R. Hal Scofield[9], Patrick M. Gaffney[1], Linda F. Thompson[1], A. Darise Farris[10], Susan Kovats[1], Jonathan D. Wren[1], Kathy L. Sivils[3] and Christopher J. Lessard[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Hefner Eye Care and Optical Center, Oklahoma City, OK, [3]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [4]University of Minnesota, Minneapolis, MN, [5]Center for Autoimmune Diseases Research (CREA), Universidad del Rosario., Bogota, Colombia, [6]Cedars-Sinai Medical Center, West Hollywood, CA, [7]Hennepin County Medical Center, Minneapolis, MN, [8]Cedars-Sinai Medical Center, Los Angeles, CA, [9]US Department of Veterans Affairs Medical Center, Oklahoma City, OK, [10]Oklahoma Medical Research Foun, Oklahoma City, OK.

Background/Purpose: Sjögren's syndrome (SS) is a common autoimmune disorder characterized by immune-mediated exocrine gland destruction and systemic inflammatory responses that contribute to clinical heterogeneity. Widespread dysregulation of transcribed RNAs in SS, including coding and non-coding elements, has been identified, but the complex regulatory mechanisms governing these responses are poorly understood. We performed an RNA-sequencing (RNA-seq) study that identified over 2,600 differentially expressed (DE) transcripts associated with SS, including 969 long non-coding RNAs (lncRNAs). This study sought to validate, replicate, and functionally characterize one upregulated lncRNA mapped to chromosome 2p25.1, SSINCR1, to better understand its role in SS pathogenesis.

Methods: Whole blood RNA from 27 healthy controls and 57 SS patients was sequenced, and 2,632 statistically significant DE transcripts were identified. Technical validation and replication of SSINCR1 upregulation was assessed by qRT-PCR in an independent set of 36 SS patients and 21 controls. Bioinformatic analyses using GAMMA-seq and the lncRNAtor database were performed to identify co-expression patterns of SSINCR1 with other coding and non-coding transcripts and to identify candidate protein binding partners. To determine cellular expression patterns of SSINCR1, we employed fluorescence-assisted cell sorting (FACS) staining for 10 distinct immune cell subsets in a healthy control followed by RNA isolation and assessed SSINCR1 expression by qRT-PCR. Statistical comparisons were made using t-tests and Pearson correlations.

Results: RNA-seq showed significant upregulation of SSINCR1 when comparing healthy controls and SS patients ($P_{adj}=3.69\times10^{-5}$; Fold Change=2.4). Technical validation by qRT-PCR using the RNA-seq cDNA library confirmed this finding ($P=0.0096$), and correlation with RNA-seq results was observed ($r=0.869$). Transcript expression in an independent sample set replicated and confirmed SSINCR1 upregulation ($P=0.0183$). Co-expression patterns by GAMMA-seq showed T, NK, and dendritic cell activation, development, and proliferation, and assessment of SSINCR1 using lncRNAtor suggested protein binding with cyclin T1 and FIP1L1. FACS analysis showed that SSINCR1 expression levels were highest in the $CD3^+CD56^+$ compartment (containing NKT cells; relative units [RU]= 8.25), followed by $CD8^+$ T cells (RU=3.34), CD56int NK cells (RU=2.08), CD56hi NK cells (RU=0.83), and $CD4^+$ T cells (RU=0.81). Expression was not detected in $CD141^+$ and $CD1c^+CD11c^+$ myeloid DCs, monocytes, B cells, or pDCs.

Conclusion: We have identified, technically validated, and independently replicated the upregulation of a novel SS lncRNA, SSINCR1. We show that transcript expression is highly enriched in CD4+ and CD8+ T cells, NKT cells, and NK cells. Ongoing studies are assessing potential protein binding partners and SSINCR1 expression in refined T and NK subsets and in expanded groups of affected and healthy individuals to determine subset-specific DE. This study establishes SSINCR1 as the first lncRNA associated with SS and lays the groundwork for further functional characterization in the pathogenesis of this complex disorder.

Nucleic Acid Sensing Receptors TLR7, RIG-I and MDA5 Collaborate in Driving the Systemic IFN Signature and Amplify the Pathogenic Loop: Potential New Targets for Therapy in Primary Sjogrens Syndrome. Naomi I Maria[1], Cornelia G. van Helden-Meeuwsen[1], Eline C. Steenwijk[1], Arne S. IJpma[2], Wouter Beumer[1], Zana Brkic[1], Virgil A. Dalm[1], Paul L. van Daele[1], P. Martin van Hagen[1], Peter J. van der Spek[2], Hemmo A. Drexhage[1] and Marjan A. Versnel[1]. [1]Erasmus Medical Center, Immunology, Rotterdam, Netherlands, [2]Erasmus Medical Center, Bioinformatics, Rotterdam, Netherlands.

Background/Purpose: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by autoantibodies targeting RNA-associated antigens, anti-SSA/SSB. The IFN-signature is present in over half of pSS patients, and is associated with higher disease-activity and autoantibody presence. Endosomal Toll-like receptors, TLR7 and TLR9, are crucial for both the generation of auto-antibodies by B-cells and immunecomplex-mediated IFN production by plasmacytoid Dendritic Cells (pDCs) in autoimmunity. Recently opposing effects were described for TLR7 and TLR9 in murine lupus-models, where TLR7-deletion limited autoimmunity and TLR9-deletion paradoxically exacerbated disease. Interestingly, we recently found the TLR7-pathway upregulated in IFNpositive pDCs of pSS patients, whereas TLR9 was not. Here we set out to further investigate this imbalanced endosomal TLR-signaling in IFN-driven pSS.

Methods: Blood samples were obtained from 33 Healthy controls (HC) and 58 pSS patients, diagnosed according to the 2002 American-European criteria, and stratified according to their IFNsignature. Fluorescence-activated cell sorting was used to isolate CD123+BDCA4+ pDCs, CD14+ monocytes, CD3+ T-cells and CD19+ B-cells >98% purity, from peripheral blood mononuclear cells (PBMCs). Genome-wide Microarray analysis conducted on sorted pDCs and monocytes revealed increased expression of cytoplasmic and endosomal pattern recognition receptors: TLR7, retinoic acid inducible gene-I (RIG-I/*DDX58*), melanoma differentiation associated gene-5 (MDA-5/*IFIH1*), and further downstream MyD88-dependent signaling, confined to IFNpositive patients. mRNA expression of the resulting differentially expressed genes (DEGs), as assessed by Ingenuity pathway analysis (IPA), was validated in sorted cell-suspensions and whole blood (Paxgene) using real-time quantitative PCR. To further clarify the possible TLR7-driven activation of the IFN signature, PBMCs of HC were stimulated *in vitro*with imiquimod, a TLR7 agonist, and inhibited with the TLR7 antagonist IRS661.

Results: Confirming our microarray results, we found an upregulation of TLR7 ($p<0.05$), *but not TLR9*, in IFNpositive pDCs, monocytes, B-cells and in whole blood ($p<0.0001$) as well as further downstream MyD88, RSAD2 and IRF7 ($p<0.001$). We also observed the upregulation of intracellular RNA-sensing receptors RIG-I and MDA-5 ($p<0.01$), recently described to collectively initiate effective IFN signaling. This widespread upregulation of TLR7 and its downstream signaling pathway is confined to IFNpositive pSS patients. *In vitro*studies with HC-PBMCs reveal that triggering of the TLR7-pathway by Imiquimod causes further upregulation of the other RNA-sensing receptors RIG-I and MDA5, inflammatory cytokines, IFN-inducible genes and also BAFF. Specific TLR7-inhibition subsequently showed a dose-dependent decrease.

Conclusion: Taken together, these RNA-sensing receptors — TLR7, RIG-I and MDA5 — seem to collaborate in amplifying the pathogenic IFN-driven loop in pSS. A better understanding of this unrestrained and potentially autoreactive loop reveals novel targets for therapeutic interventions in pSS.

Genome-Wide DNA Methylation Analysis of CD19+ B Cells in Primary Sjögren's Syndrome. Gunnel Nordmark[1], Juliana Imgenberg-Kreuz[2], Jonas Carlsson Almlöf[2], Jessica Nordlund[2], Roald Omdal[3], Katrine B. Norheim[3], Maija-Leena Eloranta[4], Lars Rönnblom[4] and Johanna K. Sandling[2]. [1]Rheumatology, Department of Medical Sciences, Uppsala University, Uppsala, Sweden, [2]Molecular Medicine and Science for Life Laboratory, Department of Medical Sciences, Uppsala University, Uppsala, Sweden, [3]Clinical Immunology Unit, Department of Internal Medicine, Stavanger University Hospital, Stavanger, Norway, [4]Department of Medical Sciences, SciLife Lab, Rheumatology, Uppsala University, Uppsala, Sweden, Uppsala, Sweden.

Background/Purpose: Increasing evidence suggests an epigenetic contribution to the pathogenesis of autoimmune diseases, including primary Sjögren's Syndrome (pSS) (1). A genome-wide DNA methylation study in T cells from patients with pSS and controls identified a large number of differentially methylated genes (2). B cells play an important role in pSS with production of autoantibodies and the potential development of B cell lymphomas. The aim of this study was to investigate DNA methylation profiles in purified CD19+ B cells from patients with pSS and healthy controls.

Methods: Seventeen female patients with pSS, mean age 53.2 years and 28 healthy blood donors, 11 females/17 males, mean age 46.7 years were included. All patients fulfilled the AECG criteria for pSS, 94.1 % were anti-SSA and/or -SSB positive and none of the patients had lymphoma. DNA was prepared from CD19+ B cells positively selected from fresh blood samples. Genome wide DNA methylation profiles were generated on the Illumina HumanMethylation450 BeadChip array. After quality control and normalization, 383 258 CpG sites remained. A threshold of 10% difference between cases and controls in average methylation level per CpG site was applied. Age and sex were included as covariates and a Bonferroni corrected p-value of $<1\times10^{-7}$ was considered significant.

Results: We identified 482 differentially methylated CpG sites, 91 hypomethylated annotated to 63 genes and 391 hypermethylated annotated to 316 genes. Pathway analysis of genes with hypomethylated sites showed over-representation in Interferon signalling genes, and for genes with hypermethylated sites Syndecan-1-mediated signalling events and the EGF receptor signalling pathway. Disease association of genes with differentially methylated sites showed enrichment for genes implicated in cancer, viral infections and B cell and follicular lymphomas. The most distinct difference in average methylation was observed in the interferon-induced gene *IFI44L* with 31 % decreased methylation in pSS CD19+ B cells compared to control B cells.

Conclusion: Our results demonstrate that DNA methylation is altered in CD19+ B cells from patients with pSS, which underscores the importance of these cells in the pathogenesis of the disease. The significance of genes in the interferon system is highlighted and the enrichment of genes involved in B cell lymphoma is intriguing and warrants further investigation.

Prognostic Value of the Complex P2X7 Receptor-Inflammasome in Patients with Primary Sjögren's Syndrome at Lymphoma Risk. Chiara Baldini[1], Eleonora Santini[2], Chiara Rossi[2], Francesca Sernissi[1], Daniela Martini[1], Alessia Gallo[3], Valentina Donati[2], Nicoletta Luciano[1], Francesco Ferro[1], Illias Alevizos[3], Anna Solini[2] and Stefano Bombardieri[2]. [1]Rheumatology Unit, Pisa, Italy, [2]Rheumatology Unit, University of Pisa, Pisa, Italy, [3]NIDCR, Bethesda, MD.

Background/Purpose: Pro-inflammatory P2X7-receptor has been recently implicated in the pathogenesis of primary Sjögren's syndrome (pSS), suggesting that it may be involved in the initiation and amplification of the innate immune response in salivary glands. In particular, previous studies have shown that the expression of P2X7R message in minor salivary glands was significantly higher in patients with positive anti-Ro-SSA and that it correlated with the minor salivary gland biopsy focus score. To date, however, no data are available on the role of the complex P2X7 receptor-inflammasome in the prognostic stratification of patients with pSS, specifically concerning their risk for lymphoma. The aim of this study was, therefore, to explore any eventual association or correlation between P2x7 mRNA levels in pSS minor salivary glands and in blood peripheral lymphocytes and traditional histological and serological risk factors for lymphoma in pSS.

Methods: Consecutive, unselected patients with a diagnosis of pSS made according to the AECG 2002 were enrolled in this study. All subjects had a standardized evaluation for pSS which included oral and ophthalmologic examinations, laboratory testing and a rheumatologic evaluation. Mononuclear cells were isolated from fresh blood by density gradient centrifugation. Total RNA was extracted from the frozen salivary gland tissue and from the frozen pellet of lymphocytes and expression of the P2X7R mRNA was determined by real-time PCR. Minor salivary gland biopsies were re-evaluated by light microscopy in order to identify GC-like structures. For statistical comparisons, non parametric Mann-Whitney test and Spearman's rank correlation coefficient were employed.

Results: Twenty pSS subjects were enrolled in the study. At diagnosis, 20% of pSS patients had GC-like structures in their salivary glands. P2X7R mRNA expression was significantly higher in the salivary glands of pSS with GC-like structures than in those without GC-like structures and correlated significantly with minor salivary gland focus score ($r=0.688$, $p=0.000$), beta-2 microglobulin levels ($r=0.538$, $p=0.02$) and IgG levels ($r=0.452$, $p=0.02$). Moreover, P2X7R mRNA salivary expression levels were significantly higher in patients with clinically evident major salivary glands enlargement and/or disease specific parenchyma dyshomogeneity documented by salivary gland ultrasonography. No significative correlations were found between P2X7R expression in peripheral lymphomonocytes and all the histological and laboratory risk factors for lymphoma examined in the study.

Conclusion: The results of this proof of concept study reinforce the potential involvement of the salivary P2X7R in pSS chronic salivary inflammation which have consistently been associated with an increased risk of malignant lymphomas. Further investigation are mandatory to clarify whether salivary P2X7R expression might be useful to identify pSS patients at lymphoma risk.

2982

Identification of Whole Blood Gene Expression Signature in Primary Sjögren's Syndrome Associated Lymphoma. Shereen Al-Ali[1], Simon Cockell[2], Andrew Skelton[3], Katherine James[2], Jessica Tarn[2], David Young[3], Bridget Griffiths[4], Simon Bowman[5], James Locke[2] and Wan-Fai Ng[2]. [1]University of Basrah, Basrah, Iraq, [2]Newcastle University, Newcastle upon Tyne, United Kingdom, [3]Newcastle University, Newcastle Upon Tyne, United Kingdom, [4]Freeman Hospital, Newcastle Upon Tyne, United Kingdom, [5]University Hospital Birmingham, Birmingham, United Kingdom.

Background/Purpose: Primary Sjögren's syndrome (pSS) is associated with a substantially increased risk of lymphoma development. The aim of our study is to identify a whole blood gene expression signature of pSS-associated lymphoma and to explore the potential biological significance of such signature using pathway and network analysis.

Methods: Whole blood RNA samples (n=144) from pSS patients and healthy controls taken part in the UK primary Sjögren's syndrome registry (UKPSSR). All patients fulfilled the AECG criteria and were stratified into five clinical subsets (pSS = 61, pSS with lymphoma = 16, pSS with other cancers=21, pSS with paraproteinemia = 23 and healthy controls = 23). RNA was extracted and globin mRNA were removed using GLOBINClear kit. Whole genome microarray (illumina, HumanHT-12 v4 BeadChips) was used for gene expression profiling. Microarray data were analyzed by R Bioconductor. The differentially expressed genes between the pSS-associated lymphoma group and pSS patients without lymphoma were validated using RT-PCR.

Results: Distinct gene expression profiles and similar differentially expressed genes were observed when comparing each clinical subset with healthy controls. Comparison between the "Lymphoma" group and those without lymphoma revealed 25 upregulated genes and 43 downregulated genes. When compared with pSS patients with other cancers, only one gene was differentially expressed and it was

downregulated in the "lymphoma" group. No differentially expressed gene were found when comparisons were made between other clinical subsets. Go terms and KEGG pathway analysis revealed 14 biological processes and 23 different biological pathways that might be important which included (e.g. mismatch Repair, T-cell receptor signaling pathway and pathways in cancer).

Conclusion: A potential gene expression signature for pSS-associated lymphoma was identified. Further experiments to validate the biosignature with another cohort and to evaluate the sensitivity and specificity of such signature are in progress.

Infliximab Added to Naproxen Does Not Increase Frequency of New Fatty Lesions on MRI of the Sacroiliac Joints and of the Spine As Compared to Naproxen Alone in Early Axial Spondyloarthritis. Denis Poddubnyy and Joachim Sieper. Charité Universitätsmedizin Berlin, Berlin, Germany.

Background/Purpose: Fatty lesions of the bone marrow in the axial skeleton (sacroiliac joints – SIJ, and spine) on magnetic resonance imaging (MRI) are considered nowadays as earliest post-inflammatory changes preceding new bone formation in axial spondyloarthritis (axSpA). It has been shown in several trials with tumour necrosis factor (TNF) α inhibitors that resolution of inflammation under anti-TNF therapy is associated with an increase of a fatty lesion score. This raised concerns that TNF blockers might therefore promote the process of new bone formation in axSpA. The aim of the current analysis was to investigate the difference in fatty lesions formation rates in patients treated with the TNF inhibitor infliximab (IFX) added to naproxen (NPX) as compared to NPX alone given over 28 weeks in patients with early axSpA.

Methods: Part I of the INFAST study was a double-blind, randomized controlled trial of IFX in biologic-naïve patients 18–48 years of age with early (<3 years symptom duration), active axSpA with signs of active sacroiliitis on MRI. A total of 158 patients were randomized (2:1) to receive 28 weeks of treatment with either intravenous IFX 5 mg/kg (weeks 0, 2, 6, 12, 18, and 24) + NPX 1000 mg/d (n=106) or intravenous PBO+NPX 1000 mg/d (n=52). MRIs of the SIJ and of the spine were performed at baseline and week 28 and were scored according to the Berlin scoring system for active inflammation and for fatty lesions, including a detailed fatty degeneration score for the SIJ by a reader who was blinded for clinical data including treatment allocation.

Results: Complete MRI sets (baseline and week 28, both STIR and T1-weighted sequences) were available in 147 patients for the spine (n=99 IFX+NPX, n=48 NPX alone) and in 143 patients for the SIJ (n=97 IFX+NPX, n=46 NPX alone). At baseline there were no meaningful differences between treatment group neither in osteitis nor in fatty lesion scores. In both treatment groups there was a significant reduction of inflammation in the spine and in the SIJ at week 28 as compared to baseline – ***table***, which was however more prominent in the combined treatment group since after 28 weeks patients in the IFX+NPX group had significantly lower osteitis scores in the SIJ ($p=0.001$) and in the spine ($p<0.001$). Similarly, in both groups there was a significant and comparable increase in the fatty lesion score (***table***) in the spine and in the SIJ at week 28 as compared to baseline, but no statistically significant difference between treatment groups was observed in the fatty lesion status score at week 28.

Conclusion: Effective anti-inflammatory treatment of axSpA in this study was associated with an increase in the fatty lesion score in the SIJ and in the spine that was independent of the treatment arm. The results suggest that fatty lesion formation after resolution of inflammation is possibly a universal pathogenetic mechanism in axSpA and not a direct effect of anti-TNF therapy.

Table. Changes in MRI scores over 28 weeks in patients with active axSpA in the INFAST study.

	IFX+NPX			NPX		
Parameter	**Baseline**	**Week 28**	**p-value***	**Baseline**	**Week 28**	**p-value***
Spine osteitis score (0–69)	3.7 ± 5.4	0.8 ± 1.9	<0.001	4.7 ± 5.7	2.7 ± 4.0	0.001
Spine fatty lesion score (0–69)	4.9 ± 7.4	5.7 ± 8.2	<0.001	6.2 ± 8.0	7.2 ± 8.9	<0.001
SIJ osteitis score (0–24)	5.3 ± 5.3	1.0 ± 1.9	<0.001	6.1 ± 4.0	2.2 ± 2.6	<0.001
SIJ fatty lesion score (0–24)	9.2 ± 7.6	10.8 ± 7.3	<0.001	11.2 ± 8.6	12.5 ± 8.1	<0.001

Degenerative Changes of the Spine on MRI in Patients with Inflammatory Back Pain from the DESIR Cohort. F. de Bruin[1], Marc Olivier Treyvaud[2], Antoine Feydy[2], Maxime Dougados[3], Laure Gossec[4], J.L Bloem[1], Désirée van der Heijde[1] and Monique Reijnierse[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Paris Descartes University, Radiology B department, Cochin Hospital, Paris, France, [3]Descartes University, Cochin Hospital, Paris, France, [4]UPMC Paris 06 University, GRC 08, Paris France and Pitié Salpétrière Hospital Paris France, Paris, France.

Background/Purpose: MRI is a sensitive method to detect early signs of axial spondyloarthritis (axSpA). A positive MRI of the sacroiliac joints is part of the imaging arm of the ASAS criteria. However, the exact role of MRI of the spine in screening for axSpA needs to be determined. Degenerative changes (DCs) are a common finding in the spine of adults; they might be an alternative explanation for complaints and might interfere with diagnostic decision making. Purpose of this study was to describe the prevalence of DCs on spine MRI in axSpA and no axSpA patients in the DESIR cohort

Methods: The DESIR cohort is a prospective longitudinal cohort study of adults aged 18–50 with inflammatory back pain (IBP) ≥3 months, ≤3 years. Patients (pts) were categorized as axSpA or no axSpA, based on the ASAS criteria for axial spondyloarthritis. Baseline 1.5T MRI (sagittal T1TSE and STIR) of the spine were scored independently by two blinded readers, for: degree of disc degeneration (DD) (Pfirrmann 5 point scale, class ≤2 considered normal), endplate changes (Modic 3 point scale) and presence of a high intensity zone (HIZ), disc protrusion or extrusion, canal stenosis, spondylolisthesis, facet joint osteoarthritis (FJOA) and Schmorls nodes (±edema). In case of disagreement, a third reader acted as adjudicator. AxSpA and no axSpA pts were compared using chi2 test, regression analysis was used for association between age and DCs

Results: 648 pts (303 male, 47%) with mean age 34 (±9) had a MRI spine available and were evaluated. Of these, 454 (70%) had axSpA. 456 pts (70%) showed one or more DCs (range 1–39). In 366 (57%) pts, DCs were observed in the lumbar spine and in 292 (45%) pts in L4-S1 (fig 1). Less pts had DCs in the cervical spine (119, 18%), and thoracic spine (253, 39%). DD and Schmorls nodes were most prevalent (table 1, fig 1). Modic type 3 was not observed. Table 1 lists the number of pts with none, one or multiple changes.

192(30%) pts with no DCs were evenly distributed between the axSpA and no axSpA groups (56/194, 29% and 136/456, 30%) (P=.854). With increasing age, the total number of DCs increased (b=0.11; P<.001) and this was also for canal stenosis, extrusion, HIZ, FJOA, Modic I and Pfirrmann (b=.002 to. 058; *P*=.047 to <.001).

Conclusion: Prevalence of DCs is high in pts with IBP in the DESIR cohort and in accordance with literature. Most DCs are found in the (lower) lumbar spine. With age, the prevalence of DCs increased. No difference was found between axSpA and no axSpA pts.

Table 1

	Number of changes					
	0 (%)		1 (%)		≥2 (%)	
	No axSpA (n=194)	AxSpA (n=454)	No axSpA (n=194)	AxSpA (n=454)	No axSpA (n=194)	AxSpA (n=454)

Autoantibodies to 14-3-3η Are Novel Biomarkers Associated with Inflammation and Radiographic Progression in Ankylosing Spondylitis. WP Maksymowych[1], Stephanie Wichuk[1], RG Lambert[1], Mairead Murphy[2] and Anthony Marotta[2]. [1]University of Alberta, Edmonton, AB, [2]Augurex Life Sciences Corp., North Vancouver, BC.

Background/Purpose: 14-3-3η is a ubiquitous intracellular chaperone protein that is expressed extracellularly in rheumatoid arthritis and mediates inflammatory cascades that result in expression of inflammatory factors and metalloproteinases. An autoantibody response (AAb) is elicited to a range of epitopes on the native protein both within and outside the ligand-binding groove. We aimed to determine whether autoantibodies to the native protein were generated in AS and which specific autoantibody might be associated with inflammation and have diagnostic and prognostic properties.

Methods: Sera from 116 patients with AS followed prospectively and 106 healthy controls were screened against ten 14-3-3η peptides (Pan 1–10) using an electrochemiluminescent multiplex assay platform. Inflammation was assessed by CRP and MRI of the sacroiliac joint (SIJ) and spine, which was performed by two central readers and an adjudicator using the Spondyloarthritis Research Consortium of Canada (SPARCC) score. Radiographic progression over 2 years was assessed by two central readers and an adjudicator using the modified Stoke AS Spine Score (mSASSS). Patients had mean age of 39.7 years, 73% male, mean symptom duration 16.9 years, and 51 (44%) received TNF blocker therapy. Mean (SD) baseline mSASSS was 13.8 (17.6), mean change in mSASSS was 1.8 (2.7), and 52.5% had mSASSS change $>$ 0. Mann-Whitney U-test was used to determine group differences and ROC analysis (AUC) was used to assess diagnostic utility. Potential associations were assessed by Pearson correlation. Multivariate regression analyses were used to examine associations significant in univariate analyses.

Results: Discrimination by AUC ranged from 0.81–0.89 for all 10 autoantibodies ($p<0.0001$ for all). For example, median (SD) expression of the Pan-1 14-3-3η autoantibody was significantly higher in SpA than in healthy controls (838 U/ml (605–1287) vs. 456 U/ml (346–568), $p=0.0001$) and area under the ROC curve was 0.86, 95%CI (0.82–0.91). A cut-off of 803 U/ml delivered 95% specificity and 53% sensitivity (LR+ 11.2, LR- 0.5). For inflammation parameters, Pan-1 and Pan-5 correlated significantly with CRP ($r=0.23, p=0.02$; $r=0.27, p=0.005$) and Pan-1 correlated with SPARCC SIJ MRI score ($r=0.21, p=0.04$). For radiographic progression measured by change in mSASSS, significant correlations were observed with all 10 Pan specificities, notably, Pan-2 ($r=0.39, p<0.0001$), Pan-3 ($r=0.34, p=0.0004$), and Pan-10 ($r=0.35, p=0.0003$). Independent predictors of MRI inflammation were sex ($p=0.006$) and Pan 1 autoantibody ($p=0.008$) (adjusted for age, sex, symptom duration, CRP). Controlling for baseline mSASSS CRP, age, sex, symptom duration, and treatment, Pan antibodies were the only significant predictors of the change in mSASSS at 2 years in multivariate regression analysis: Pan composite score ($p=0.001$), Pan-1 ($p=0.0008$), Pan-2 ($p=0.0001$), Pan-3 (0.0005), Pan-10 ($p=0.0003$).

Conclusion: 14-3-3η autoantibodies are novel serum markers that are differentially expressed in AS versus healthy controls. They are significantly associated with MRI inflammation and baseline expression of several autoantibody specificities predicts radiographic progression.

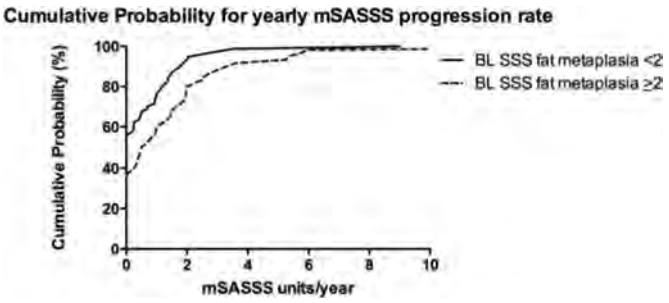
Fat Metaplasia on MRI of the Sacroiliac Joints Is a Lead Indicator of Radiographic Progression in the Spine of Patients with Ankylosing Spondylitis. WP Maksymowych[1], S Wichuk[1], P Chiowchanwisawakit[2], RG Lambert[1] and Sj Pedersen[3]. [1]University of Alberta, Edmonton, AB, [2]Mahidol University, Bangkok, Thailand, [3]Copenhagen Center for Arthritis Research, Copenhagen, Denmark.

Background/Purpose: Fat metaplasia in the SIJ on MRI is an early feature of sacroiliitis and occurs both in subchondral bone marrow and also in the excavated area caused by erosion, when it is called backfill. Recent data has shown that these lesions are key intermediaries in the development of SIJ ankylosis. We aimed to test the hypothesis that these lesions may also be lead indicators of new bone formation in the spine of patients with axial SpA. This could provide an important target for therapeutic intervention.

Methods: Bone marrow fat metaplasia and backfill were scored using the SPARCC MRI SIJ structural score (SSS) by two readers and an adjudicator using pre-specified rules for adjudication. 137 pairs of MRI scans blinded to time point (baseline, 2 years) were assessed from a prospective cohort of AS patients (mean age 40.5years, mean symptom duration16.9 years, 53% on anti-TNF) followed for mean 2.3 years. Two readers and an adjudicator independently scored pairs of radiographs (baseline, 2 years) from the same patients using the mSASSS. Radiographic progression was compared in patients with and without positive SIJ MRI for fat metaplasia (SSS score ≥ 2 or <2) and the degree of SIJ fat metaplasia at baseline (absolute SSS score) was compared in patients with and without radiographic progression (mSASSS >0 or $=0$) using Mann-Whitney and cumulative probability. Multivariate regression analyses included variables significant in univariate analyses (age, sex, symptom duration, CRP, baseline mSASSS) and treatment.

Results: Radiographic progression was significantly greater in those with positive SIJ fat metaplasia ($p=0.015$) (figure), and especially in patients who only received non-biologic therapy ($p=0.023$). Baseline SSS SIJ fat metaplasia scores were significantly higher in those who developed radiographic progression compared to those without (1.58 vs 0.65, $p=0.008$). Both positive SIJ MRI for fat metaplasia and the degree of fat metaplasia were significantly associated with radiographic progression in multivariate analyses ($\beta=0.38$ ($p=0.005$) and $\beta=0.06$ ($p<0.0001$) respectively). SSS score for backfill was also significantly associated with radiographic progression in multivariate analysis ($\beta=0.04$ ($p=0.019$)).



Conclusion: The appearance of fat metaplasia in SIJ subchondral bone marrow and/or at sites of erosion in the SIJ may identify AS patients at increased risk of radiographic progression in the spine.

2987

Value of Color Doppler Ultrasound Assessment of Sacroiliac Joints in Patients with Inflammatory Chronic Low Back Pain. Maximiliano Bravo[1], Leandro Ferreyra Garrott[1], David A. Navarta[1], Emmanuel Bertiller[1], Ricardo Garcia-Monaco[2], Santiago Ruta[1], Javier Rosa[3] and Enrique Soriano[1]. [1]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Radiology and Imagenology Department, Hospital italiano de Buenos Aires, Buenos Aires, Argentina, [3]Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.

Background/Purpose: The utility of ultrasound in the evaluation of sacroiliitishas not been extensively studied yet. To evaluate the diagnostic value of color Doppler ultrasound (US) for the detection of sacroiliac (SI) active inflammatory lesions in patients with inflammatory chronic low back pain (LBP).

Methods: Consecutive patients older than 18 years, with chronic inflammatory low back pain, defined as LBP with more than 3 months of continuous duration, of insidious onset, with improvement with exercise, no improvement with rest, and pain at night (with improvement upon getting up), without a definitive diagnosis (patients at risk of having undetected spondyloarthritis (SpA)), referred from orthopedics or general practitioners clinics for an axial magnetic resonance imaging (MRI), were included. Patients with Ankylosing spondylitis (AS) according to modified New York criteria, were included as control group.Clinical assessment included BASDAI, BASFI, and HAQ. Ultrasound evaluation was performed by a blinded rheumatologist experienced in this technique with a My lab 70 machine (Esaote) with a multi-frequency convex array transducer (1–8 MHz). Standardized scanning method was used to investigate increased local perfusion with color Doppler US. When color Doppler signal was found in or around the SI joints, spectral Doppler was used and the resistive index (RI) was measured. Color Doppler US sacroiliitis was defined as a positive color Doppler signal with a RI <0.75 at any of the SI joints.

The following sequences were used on the MRI assessment: T1-weighted spinecho (SE) and short-tau inversion recovery (STIR). MRI sacroiliitis was defined according to ASAS definition of active sacroiliac inflammatory lesions.

Sensitivity, specificity, positive and negative predictive values for the diagnosis of sacroiliitisbycolor Doppler US features was calculated, using MRI as the gold standard.

Results: Forty-four patients were included. Twenty-four (54%) were males. Mean age was: 40 years (SD: 11 yrs). Median disease duration was 2 years (IQR: 0.5–10 yrs). Mean BASDAI was 4.8 (SD: 2.4), mean BASFI: 3.6 (SD: 2.7), and mean HAQ was 0.6 (SD: 0.5).Ten patients had AS. Among all patients, 21 (48%) had active sacroiliitis by MRI. Active sacroiliitis by MRI was present in 4 (40%) of AS patients, and in 17 (50%) of patients with inflammatory LBP, respectively.

Color Doppler US sensitivity for the diagnosis of sacroiliitis among all patients was 62 % (95% CI: 48–76%) and specificity was 91%. (95% CI: 83–99.6%). Positive predictive value (PPV) was 87% (95% CI: 77–97%) and negative predictive value (NPV) was: 72% (95% CI: 59–86%). Among AS patients observed values were: sensitivity 75% (95% CI:48–100%), specificity 83% (95% CI: 60–99), PPV: 75% (95% CI:48–100%) and NPV: 83% (95% CI: 60–99%) and among inflammatory LBP patients diagnostic test values were: sensitivity 59 % (95% CI:42–75%), specificity: 94% (95% CI:86–100%), PPV: 91% (95% CI;81–100%) and NPV: 70% (95% CI: 54–89%).

Conclusion: color Doppler US seems to be a practical and useful tool for the diagnosis of active sacroiliitis. Larger studies would be needed to confirm these results.

2988

Calgranulin Levels Are Elevated in Spondyloarthritis and Reflect the Presence of Acute Microscopic Gut Inflammation. Heleen Cypers[1], Gaëlle Varkas[1], Liesbet Van Praet[1], Johannes Roth[2], Thomas Vogl[2], Claude Cuvelier[3], Dirk Föll[4], Miha Lavric[4], Filip van Den Bosch[1] and Dirk Elewaut[1]. [1]Department of Rheumatology Ghent University Hospital, Ghent, Belgium, [2]Institute of Immunology University of Muenster, Muenster, Germany, [3]Department of Pathology Ghent University Hospital, Ghent, Belgium, [4]University Children's Hospital Muenster, Muenster, Germany.

Background/Purpose: Microscopic gut inflammation is present in about 50% of spondyloarthritis (SpA) patients. Two types can be distinguished: an acute type resembling infectious enterocolitis, and a chronic type similar to early Crohn's disease. Although subclinical, microscopic gut inflammation appears to be a prognostic factor in SpA, linked with more extensive disease and a less favorable outcome. At this moment, however, reliable biomarkers are missing. The calgranulins S100A8/S100A9 and S100A12 are very sensitive markers of innate immune activation. They are released from monocytes and granulocytes in the early phase of the immune response and exert important pro-inflammatory effects via Toll-like receptor 4 dependent mechanisms. Calgranulins can be measured in serum and stool. Moreover, the S100A8/S100A9 heterodimer, also called calprotectin, has been established for a long time as a fecal marker of disease activity in inflammatory bowel disease. Our aim was to assess whether calgranulins can be used as biomarkers for microscopic gut inflammation in SpA.

Methods: Serum levels of calgranulins were measured in 103 newly diagnosed SpA patients and 24 healthy controls. Ninety seven SpA patients underwent an ileocolonoscopy to assess the presence of microscopic gut inflammation. Ileal and colonic biopsies were histologically scored and subsequently immuno-stained for S100A8 and S100A9.

Results and Conclusion: Serum levels of S100A8/S100A9 and S100A12 were significantly higher in SpA patients versus healthy controls ($p= 0,035$ and $p = 0,024$). Levels correlated moderately with CRP, but not with ASDAS, BASDAI or swollen joint count. SpA patients with the acute type of microscopic gut inflammation ($N= 17$) had significantly higher calgranulin levels compared to those with normal gut histology ($N= 56$) ($p = 0,021$ for S100A8/S100A9 and $p = 0,05$ for S100A12). Furthermore, immunohistology showed high staining of S100A8 and S100A9 on acutely inflamed gut biopsies, compared to absent/minimal staining on normal biopsies. Chronically inflamed biopsies ($N=24$) stained positive only when they had high inflammatory activity (in $\sim$ 50% of cases). Importantly, NSAID intake had neither influence on immunohistology stainings nor on serum levels of calgranulins. To conclude, we found that calgranulin levels, both systemically and locally, marked the presence of acute microscopic gut inflammation in SpA. These results illustrate their high sensitivity as they reflected inflammation present only on a subclinical level. Therefore we anticipate that they may be of particular value in detecting (or excluding) latent (systemic) disease.

ACR Concurrent Abstract Session
Systemic Lupus Erythematosus - Clinical Aspects and Treatment: Central Nervous System and Other Clinical Aspects
Wednesday, November 19, 2014, 9:00 AM–10:30 AM

2989

Lupus Impact Tracker Is Responsive to Changes in Disease Activity in Lupus. David Giangreco[1], Hervé Devilliers[2], Narender Annapureddy[1], Joel A. Block[1] and Meenakshi Jolly[1]. [1]Rush University Medical Center, Chicago, IL, [2]Department of internal medicine and systemic diseases, Dijon, France.

Background/Purpose: Patient reported outcomes (PRO) are important to understand, educate, manage and follow patients with systemic lupus erythematosus (SLE). Lupus Impact Tracker (LIT) is a ten-item tool developed to facilitate patient-physician communication. Herein, we present its responsiveness to physician and patient assessed changes in disease status from data obtained during routine SLE patient care visits.

Methods: Longitudinal data on LupusPRO, physician assessed disease activity assessment, and patient reported changes in SLE health status was collected during 182 SLE patient routine clinical care visits. LIT score was derived from PRO data. Disease activity assessments used as anchors for testing responsiveness were the SLEDAI physician global assessment (PGA), Total SELENA-SLEDAI score, SELENA-Flare Index (SFI), and Patient reported changes in SLE health status. Cut-offs used to determine change in disease activity were as follows: PGA (change of 0.3), Total SELENA-SLEDAI (change of 4), SFI (remitting, stable, and flaring) and Patient reported changed in SLE health status (−7 to 7). For patient reported change in SLE health status, we categorized −2 to 2 as unchanged, −3 to −7 as worsening and 3 to 7 as improvement. Mixed model regression analysis was used to compare changes in LIT against disease activity and patient reported changes in SLE health status anchors.

Results: There were 658 visit data available for 182 SLE patients. Consecutive visits were 2–5 months apart with a median number of visits per patient of 7. PGA was available for 630 visits; Total SLEDAI was available for 249 visits; SFI was available for 610 visits; Patient reported change in SLE health status was available for 449 visits. Mean (SD) age and SELENA-SLEDAI were 43.5 (13.2) years and 6.4 (7.3), respectively. PGA changed significantly for 269 visit data (increased in 125, decreased in 144) while 361 visit data had unchanged PGA. Total SELENA-SLEDAI changed significantly among 66 visits (29 increased, 37 decreased) and remained stable among 183 visits. Significant changes in SFI were observed in 149 visit data (80 remitting, 69 flaring) while 461 visit data was unchanged. Patient reported change in SLE health status changed significantly for 221 (150 improved, 71 worsened) and remained stable for 228 visits. LIT scores responded significantly and in the appropriate direction for changes in PGA ($p<0.05$), Total SLEDAI ($p=0.01$), and SFI ($p<0.05$) and patient reported changes in SLE health status ($p=0.001$).

Conclusion: LIT is responsive to physician- and patient-assessed changes in disease status in SLE. In addition to being used in clinical trials, LIT is an effective tool that may be used by patients and physicians in facilitating communication and tracking disease impact in SLE.

2990

Risk Factors for Posterior Reversible Encephalopathy Syndrome in Systemic Lupus Erythematosus Patients: A Single Center Study. Javier Merayo-Chalico[1], Elia Apodaca[2], Ana Barrera-Vargas[1], Jorge Alcocer-Varela[1] and Diana Gómez-Martín[1]. [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición, Mexico City, Mexico.

Background/Purpose: Posterior reversible encephalopathy syndrome (PRES) is a well-known but rare complication in systemic lupus erythematosus (SLE) patients (<1%). However, current epidemiologic data is quite scant. The aim of the present study was to describe potentially unrecognized risk factors.

Methods: We performed a single-center retrospective case-control study in a tertiary care center in Mexico City between 1999 and 2014. We included 48 patients (cases) with SLE diagnosis (≥4 ACR criteria) who presented with reversible neurological manifestations (seizures, visual abnormalities, acute confusional state, among others) associated with changes by magnetic resonance (MRI) (iso or hypointensity in T1 and hyperintensity in T2/FLAIR). Controls (n=96) were patients with SLE without evidence of PRES that were hospitalized during the same period as cases (± 3 months) and matched by gender. Association between variables was calculated by X^2 test and OR (95% CI). Multivariate analysis was performed by logistic regression.

Results: SLE patients with PRES were younger (27.9±1.05 vs 36.2±1.36 years, $p<0.001$). Ninety percent of the cases occurred in women. PRES occurred in 28/48 patients (40%) after 24 hours of admission (2–30 days). The vast majority (80.2%) of cases presented with seizures, and up to 18% showed "atypical" MRI images. Decrease or resolution of MRI images in the first 12 weeks after the event occurred in 88.8% of cases. Variables associated with the development of PRES, three months prior to hospitalization and at the time of the event are summarized in Table 1. After multivariate analysis, hypertension at admission [OR 16.3, 95% CI 4.03–65.85, $p<0.001$], renal replacement therapy at discharge [OR 6.65, 95% CI 1.24–35.64, $p=0.027$], persistent lymphopenia (<1,000 cells/uL in at least two consecutive measurement previous to the event) [OR 5.76, 95% CI 1.36–24.40, $p=0.017$], SLEDAI≥6 prior to admission [OR 1.11, 95% CI 1.01–1.22, $p=0.031$] and age [OR 0.863, 95% CI 0.81–0.91, $p<0.001$] were independent risk factors for the development of PRES in SLE. Length of hospital stay was similar between groups (17.2±2.07 vs 14.60±1.11 days, $p=0.26$) and none of the cases died during hospitalization.

Conclusion: Our data is in agreement with prior studies that link end-stage renal disease, hypertension and high SLEDAI scores to the development of PRES in SLE. Furthermore, we found that persistent lymphopenia is a novel independent risk factor for PRES in SLE, which could be related to endothelial dysfunction in these patients.

Table 1. Variables associated with development of PRES in SLE patients (univariate analysis)

Three months prior to admission	OR	95% CI	p value
SLEDAI ≥6 points	4.41	1.87–10.40	<0.001
Hypertension	3.50	1.68–7.32	0.001
Lymphopenia	3.36	1.36–8.29	0.006
Low C3 levels	2.71	1.21–6.07	0.013
History of renal replacement therapy	2.66	1.15–6.12	0.019
At admission	**OR**	**95% CI**	**p value**
SLEDAI ≥6 points	33.80	4.43–257.54	<0.001
Hypertension	13.63	5.88–31.56	<0.001
GFR ≤60 mL/min/1.73 m^2	4.75	1.93–11.65	<0.001
Renal replacement therapy at discharge	4.27	1.97–9.24	<0.001
Low C3 levels	2.22	1.02–4.81	0.041

Anti-Ribosomal P Antibody Is a Key Autoantibody Associated with Complications of NP-SLE with High-Levels of CSF IL-8. Hidenaga Kawasumi[1], Takahisa Gono[1], Yasushi Kawaguchi[1], Yasuhiro Katsumata[1], Hisae Ichida[1], Akiko Tochimoto[1], Masanori Hanaoka[1], Yuko Okamoto[1], Sayuri Kataoka[1] and Hisashi Yamanaka[2]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Complications of neuropsychiatric systemic lupus erythematosus (NP-SLE) are associated with the morbidity and mortality of patients with SLE. Although the detailed pathophysiology of NP-SLE remains unknown, complements, autoantibodies, and cytokines are involved in the inflammation of the central nervous system (CNS) or the peripheral nervous system (PNS) in SLE. Previous studies have demonstrated that anti-phospholipid (PL), anti-ribosomal P, anti-*N*-methyl-D-aspartate receptor subunit 2 (NR2), and anti-U1-RNP antibodies are associated with the development of NP-SLE. In addition, cerebrospinal fluid (CSF) proinflammatory cytokines, such as IL-6, are increased in NP-SLE. In this study, we evaluated the associations between several serum autoantibodies and CSF proinflammatory cytokines in NP-SLE.

Methods: In the present study, seventy patients with SLE who had been admitted to our hospital from 2001 to 2013 were enrolled. SLE was diagnosed according to the 1997 ACR revised criteria for the classification of SLE. Disease activity was measured using the SLE disease activity index 2000 (SLEDAI-2k). NP-SLE manifestations were classified according to the 1999 ACR nomenclature and case definitions for NP-SLE syndromes. Serum and CSF samples were obtained from all enrolled patients with SLE. We measured serum autoantibodies, including anti-PL, anti-ribosomal P, anti-NR2, anti-U1-RNP and anti-Sm antibodies, and CSF cytokines (IL-6, IL-8, and IFN-α).

Results: Of the 70 patients with SLE, all patients were female, and their median age was 32 years. The median score on the SLEDAI-2k was 12. NP-SLE was diagnosed in 24 patients. Serum anti-PL, anti-ribosomal P, anti-NR2, anti-U1-RNP, and anti-Sm antibodies were detected in 15, 23, 23, 24, and 13 patients, respectively. The CSF levels of IL-8 were significantly higher in the NP-SLE subset compared with the non-NP-SLE subset ($p<0.05$). There were no significant differences in the CSF levels of IL-6, IFN-α, total protein, or IgG index between the two subsets. High levels of CSF IL-8 (>30 pg/ml) were significantly ($p<0.001$) associated with the complications of NP-SLE. No patient was diagnosed with NP-SLE when the CSF levels of IL-8 were less than 30 pg/ml. To identify the specific autoantibodies associated with high levels of CSF IL-8, a multivariate analysis was conducted. Anti-ribosomal P was the most significant autoantibody involved in the high levels of CSF IL-8.

Conclusion: High levels of CSF IL-8 are associated with the complications of NP-SLE. Anti-ribosomal P is a key autoantibody associated with NP-SLE with high levels of CSF IL-8.

Usefulness of Diagnostic Biomarker for Neuropsychiatric Systemic Lupus Erythematosus By Anti-Microtubule Associated Protein 2 Antibody in Cerebrospinal Fluid. Yusuke Yamada, Department of Internal Medicine and Rheumatology, Juntendo University Faculty of Medicine, Tokyo, Japan.

Background/Purpose: Microtubule associated protein-2 (MAP-2) is found exclusively in nerve cells. MAP-2 has been shown to stabilize microtubules by binding to the outer surface and participate in determining the structure of nerve cells. Interestingly, a previous report has shown that an autoantibody against MAP-2 has been reported to be found in sera with SLE patients especially having neuropsychiatric manifestations. However, there are no additional reports concerning anti-MAP-2 antibody. NPSLE involves a wide range of focal and diffuse central and peripheral nervous system disorders. The diagnosis of NPSLE is often clinically difficult because discrimination of secondary causes such as infection, medication side-effects, and metabolic abnormalities was required. The diagnostic inference of NPSLE can be made only after these secondary causes have been excluded. There is no one single diagnostic tool specific to NPSLE so far. Multiple diagnostic examinations such as IL-6 measurement in cerebrospinal fluid or Magnetic Resonance Imaging (MRI) have been used for diagnosis with NPSLE. However, the findings from these examinations are not specific for NPSLE. Therefore, novel diagnostic biomarkers have been expected to be established. Herein, we conducted this study to clarify that anti-MAP-2 antibody in cerebrospinal fluid can be used for a diagnostic biomarker of NPSLE.

Methods: Anti-MAP-2 antibody, anti-ribosomal P antibody, and IL-6 was measured by ELISA in cerebrospinal fluid from NPSLE patients (n=24) or non NPSLE controls (n=18). The diagnosis with NPSLE was made by the nomenclature system proposed by American College of Rheumatology (ACR, 1999). Non NPSLE controls consisted of SLE patients with CNS disorders caused by the secondary causes such as steroid psychosis, and other tissue connective diseases with CNS disorder.

Results: Titer of anti-MAP-2 antibody in cerebrospinal fluid was significantly higher in NPSLE patients compared to non NPSLE controls. When the cutoff value was designed as average + 3SD of the controls, the prevalence of anti-MAP-2 antibody in NPSLE patients was 33.3% (8/24), and none of patients with non NPSLE controls (0/18) had an anti-MAP-2 antibody. Furthermore, titer of anti-ribosomal P antibody and IL-6 concentration in cerebrospinal fluid, which are other diagnostic biomarker for NPSLE, were significantly higher in NPSLE patients with anti-MAP-2 antibody compared to NPSLE patients without anti MAP-2 antibody or non NPSLE controls.

Conclusion: Anti-MAP-2 antibody in cerebrospinal fluid was recognized in 33.3% patients with NPSLE and the appearance was highly specific for NPSLE. We propose that anti-MAP-2 antibody in cerebrospinal fluid is a novel diagnostic biomarker for NPSLE.

MRI in Neuropsychiatric Lupus: Correlations with the 1999 ACR Case Definitions. Minyoung Her[1], Dongyook Kim[1], Na young Park[1], Seong-Kyu Kim[2], Lee Sung Won[3] and Lee sang Yeob[3]. [1]Inje University, Pusan Paik Hospital, Busan, South Korea, Busan, South Korea, [2]Catholic University of Daegu, Daegu, South Korea, Daegu, South Korea, [3]Dong-A university, Busan, South Korea, Pusan, South Korea.

Background/Purpose: Neurological manifestations in SLE are diverse. Because of its varied manifestations and low prevalence, the ACR has developed nomenclature and case definitions for neuropsychiatric SLE (NPSLE) to facilitate clinical research. Brain MRI has been used for the evaluation of neurologic symptoms. The purpose of this study was to identify characteristic brain MRI findings in NPSLE and to investigate the association between brain MRI findings and NPSLE manifestations.

Methods: All brain MRI cases that received the diagnosis of SLE at three tertiary university-based hospitals from August 2002 to August 2013 were screened. 219 brain MRIs with diagnosis of SLE were screened. All clinical manifestations found by brain MRI were retrospectively assessed and were classified as NPSLE according to the 1999 NPSLE ACR nomenclature and case definitions. In total, 139 brain MRIs in 121 patients with NPSLE from 2002 to 2013 were retrospectively reviewed. The images were evaluated for the presence of white matter hyperintensity (WMH), gray matter hyperintensity(GMH), parenchymal defects, atrophy, enhancement, and the abnormalities in diffusion-weighted image (DWI). The number, size and location of WMH, GMH and parenchymal defects were evaluated. The NPSLE manifestations of each patient were classified according to the 1999 ACR case definitions for NPSLE syndromes. The associations between MRI findings and manifestations of NPSLE were examined.

Results: In total, 97 MRIs (69.8%) demonstrated abnormalities among the 139 brain MRIs reviewed. There were 164 NP events that encompassed 16 of 19 NP syndromes. The most common MRI abnormalities were WMHs. One or more WMHs were found in 78 MRIs (56.1 %) among the total 139 MRIs. GMHs were observed in 42 MRIs (32.0%). GMHs tended to involve much larger areas than WMHs. Patients with cerebrovascular disease or seizures were more likely to have GMHs than patients with other NP manifestations. 33 MRIs among 42 MRIs which had GMHs also exhibited WMHs. Parenchymal defects were found in 34 MRIs (24.5%). Atrophy was detected in 20 MRIs (14.4%). Brain MRIs were enhanced in 21 of the 122 cases that had undergone enhancement. Patients who had seizures were more likely to demonstrate MRI enhancement than patients with other NP manifestations. DWIs were obtained in 97 MRIs and abnormal DWIs were obtained in 17 MRIs cases. Patients with cerebrovascular disease were more likely to have GMH, parenchymal defects and abnormal DWI than patients with other NP manifestations.

°°	Number of MRIs (%)	Abnormalities of MRI	WMH	GMH	Parenchymal defect	Atrophy	Enhancement
Acute confusion	9 (6.5%)	6	3	3	3	1	3
Anxiety disorder	1 (0.7%)	0	0	0	0	0	0
Aseptic meningitis	6 (4.3%)	4	3	0	1	0	2
Cerebrovascular disease	32 (23.0%)	32	26	15	15	4	4
Cognitive dysfunction	4 (2.9%)	3	3	0	1	3	0
Demyelinating disease	2 (1.4%)	2	2	1	1	0	1
Headache	33 (23.7%)	17	12	6	2	4	2
Mood disorder	1 (0.7%)	0	0	0	0	0	0
Movement disorder	4 (2.9%)	3	3	0	0	0	0
Psychosis	4 (2.9%)	3	2	0	1	1	1
Seizure	23 (16.6%)	17	14	12	5	5	7
Autonomic disorder	3 (2.2%)	0	0	0	0	0	0
Cranial neuropathy	12 (8.6%)	7	7	2	2	0	0
Mononeuropathy	3 (2.2%)	1	1	1	1	0	0
Myasthenia gravis	0 (0%)	0	0	0	0	0	0
Polyneuropathy	2 (1.4%)	2	2	2	2	2	1
Total	139 (100%)°°	97	78	42	34	20	21

Conclusion: Diverse brain MRI abnormalities were observed in the brain MRI of patients with NPSLE. In addition to WMHs, which were previously known as SLE findings, we also noted the presence of GMHs, parenchymal defects and abnormal DWI in a substantial portion of SLE patients, particularly in those with cerebrovascular disease or seizure.

Blood Brain Barrier and Anti-NR2 Antibody in SLE Patients with Cognitive Impairment. Gaurav Gulati[1], Philip Iffland[2], Vikram Puvenna[2], Damir Janigro[2] and Michael Luggen[1]. [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]Cleveland Clinic Lerner College of Medicine, Cleveland, OH.

Background/Purpose: Cognitive Impairment (CI) is one of the most common manifestations of neuropsychiatric SLE (NPSLE) and one of the most devastating. The pathogenesis of CI in SLE is not known, but in animal models, antibody to the NR2 subunit of the N-methyl D-aspartate receptor (aNR2) can cause memory impairment. However, this effect can only be demonstrated if the blood brain barrier (BBB) has been disrupted or if the antibody is introduced intrathecally. Several studies in SLE patients have failed to find an association of aNR2 with CI. None, however, has assessed the integrity of the BBB as a potential pathogenic cofactor. S100B protein is an astrocyte specific protein that has been used as biomarker of BBB disruption in traumatic brain injury and some neurodegenerative disorders. And, antibodies to this protein may indicate previous exposure to this immunologically privileged protein and might be used as an indicator of preceding BBB disruption. We hypothesized that aNR2 antibody is pathogenic in SLE patients only if there evidence of previous or ongoing BBB disruption as indicated by increased levels of S100B or anti-S100B.

Methods: Patients who fulfilled the revised American College of Rheumatology (ACR) criteria for SLE and were stable for at least 4 weeks were recruited from three different settings. Basic demographic, clinical and laboratory data was collected. The Automated Neuropsychological Assessment Metrics (ANAM), a computerized and validated tool, was utilized to measure cognitive function. The Total Throughput Score (TTS = number of correct responses/time) was used as the primary outcome measure. CI was defined as a score of less than 1.5 SD below the age, sex, and race matched RA population mean. Patients also had assessment of fatigue, depression, SLE activity and SLE damage using the FACIT fatigue score, Becks Depression Inventory (BDI), SLEDAI 2K, and SLICC respectively. Serum was analyzed by established ELISA techniques for aNR2 antibody, anti-S100B antibody and intact serum S100B protein.

Results: A total of 57 patients were evaluated. Demographic and clinical data is summarized in TABLE 1. The age, ethnicity, and family income were significantly different between the two groups ($p<0.05$). In a multiple regression model using the above independent variables together with simple reaction time and opioid use, no significant effects of aNR2, S100b, or aS100b on decreasing TTS were found. However, aNR2 antibodies significantly decreased TTS at higher, but not lower, levels of S100b ($p<.01$, model R^2 of 0.657, $p<.0001$).

Conclusion: Antibody to NR2 may play a role in the pathogenesis of CI in SLE patients, but it does so only if there is disruption of the blood brain barrier as has been previously suggested. Confirmation of these findings and further investigation of the causes of BBB damage in these patients may improve our understanding of this important problem.

ACR Concurrent Abstract Session
Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics III: Updates in Predictors and Outcomes in Systemic Sclerosis

Wednesday, November 19, 2014, 9:00 AM–10:30 AM

2995

Surrogate Measures of Extent of Interstitial Lung Disease As Measured By Quantitative Radiographic Analysis in Patients with Systemic Sclerosis.

Elizabeth Volkmann[1], Donald Tashkin[2], Chi-hong Tseng[1], Kim Hyun[1], Jonathan Goldin[1], Philip J. Clements[3], Daniel E. Furst[1], Dinesh Khanna[4], Eric Kleerup[1], Michael Roth[1] and Robert Elashoff[5]. [1]University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, CA, [2]University of California at Los Angeles, Los Angeles, CA, [3]University of California, Los Angeles, Department of Medicine, Los Angeles, CA, [4]University of Michigan Health System, Ann Arbor, MI, [5]University of California, Los Angeles, Los Angeles, CA.

Background/Purpose: Extent of systemic sclerosis (SSc)-related interstitial lung disease (ILD) predicts disease course, mortality and treatment response. While quantitative analyses of total extent of ILD (QILD) are more sensitive and reproducible than visual assessments of SSc-ILD, these analyses are not widely available. This study evaluates the relationship between disease parameters and QILD scores to identify potential surrogate measures of QILD.

Methods: Using baseline data from the Scleroderma Lung Study I (SLS I) (N=158), multivariate regression analyses were performed using the best subset selection method to identify 1 to 5 variable-models that best predict QILD scores in both whole lung (WL) and the zone of maximal involvement (ZM). These models were subsequently validated using baseline data from SLS II (N=142). SLS I&II did not include patients with clinically significant pulmonary hypertension (PH).

Results: Diffusing capacity for carbon monoxide (DLCO) was the single best predictor of QILD in the WL and ZM in all of the best subset models (Tables 1, 2). Adding other disease parameters to the models did not substantially improve model performance. Forced vital capacity (FVC) did not predict QILD scores in any of the models.

Conclusion: In the absence of PH, DLCO provides the best overall estimate of HRCT-measured QILD in patients from 2 large SSc cohorts. FVC, which is commonly used to monitor disease course in SSc-ILD, may not be the best surrogate measure of extent of QILD.

Intestinal Pseudo-Obstruction in Patients with Systemic Sclerosis: An Analysis of the Nationwide Inpatient Sample. Antonia Valenzuela[1], Shufeng Li[1], Laren Becker[1], Nielsen Fernandez-Becker[1], Dinesh Khanna[2], Linda Nguyen[1] and Lorinda Chung[1]. [1]Stanford University School of Medicine, Palo Alto, CA, [2]University of Michigan Health System, Ann Arbor, MI.

Background/Purpose: Intestinal pseudo-obstruction accounted for 3.7% of hospitalizations of patients with systemic sclerosis (SSc), and led to death in 10% of patients in a previous dual-center study. We aimed to determine the prevalence of intestinal pseudo-obstruction in hospitalized patients with SSc in a large US national database and to compare outcomes between patients with intestinal pseudo-obstruction and SSc, patients with intestinal pseudo-obstruction secondary to other causes, and SSc patients without intestinal pseudo-obstruction.

Methods: This is a case-control study using the Healthcare Cost and Utilization Project Nationwide Inpatient Sample (NIS) for the period 2002–2011. We included patients using the previously validated International Classification of Diseases-Clinical Modification-9 code 710.1 for SSc in combination with codes for intestinal pseudo-obstruction. We used multivariate logistic and linear regression, adjusting for potential confounders and comorbidities using a modified Charlson comorbidity index, to determine the risks for surgical procedures (total or partial resection of small or large intestine), use of parenteral nutrition, and in-hospital mortality, and to estimate the length of stay in SSc patients compared with controls.

Results: A total of 193610 SSc hospitalizations occurred in the US between 2002 and 2011, of which 5.4% (n=10386) were associated with a concurrent intestinal pseudo-obstruction diagnosis (cases). The mean age of this group was 62.5±0.4 years, 81% were female, and 55% Caucasian. In-hospital mortality was 7.3%, mean length of stay was 9.3±0.3 days, 13.5% received parenteral nutrition, and 6% underwent surgical procedures (Table 1). In multivariate analyses, cases were more likely to die during the inpatient stay and to receive parenteral nutrition than patients with idiopathic intestinal pseudo-obstruction (control group 1), patients with intestinal pseudo-obstruction and diabetes (control group 2), and SSc patients without intestinal pseudo-obstruction (control group 3). Cases had longer in-hospital stay than control groups 2 and 3, and were less likely to undergo surgical procedures than control groups 1 and 2 (Table 2).

Conclusion: The prevalence of intestinal pseudo-obstruction in patients with SSc was 5.4% in this large US-based hospitalization database. SSc patients with intestinal pseudo-obstruction are more likely to die and to receive parenteral nutrition than patients with intestinal pseudo-obstruction secondary to other causes and SSc patients without intestinal pseudo-obstruction.

Table 1

	Cases n (%)	Controls 1 n (%)	Controls 2 n (%)	Controls 3 n (%)

Development and External Validation of a Five-Year Mortality Risk Stratification Tool for Early Diffuse Systemic Sclerosis Patients. Robyn T. Domsic[1], Svetlana I. Nihtyanova[2], Mary Lucas[1], Stephen R. Wisniewski[3], Michael J. Fine[4], C. Kent Kwoh[5], Christopher P. Denton[6] and Thomas A. Medsger Jr.[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Royal Free and University College Medical School, London, United Kingdom, [3]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, [4]University of Pittsburgh and Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare, Pittsburgh, PA, [5]The University of Arizona Arthritis Center, Tucson, AZ, [6]Centre for Rheumatology, Royal Free and University College Medical School, London, United Kingdom.

Background/Purpose: Knowledge of mortality risk and predictors is important in systemic sclerosis (SSc) patient care and clinical trial design. There is no validated 5-year mortality model in early diffuse SSc (dcSSc); a high risk population. The objective of this study was to derive and externally validate a 5-year mortality risk stratification tool in early dcSSc patients.

Methods: The derivation cohort was a prospectively enrolled inception cohort of adult early dcSSc patients first seen between 1980 and 2009 and enrolled in a US Scleroderma Center databank. Early dcSSc was defined as <2 years from the first SSc symptom and proximal skin thickening. Predefined candidate predictor variables at the first visit (demographic, history, exam, lab values, organ system objective tests) were placed into a stepwise multivariable logistic regression model. Regression diagnostics were performed. Beta-estimates were rounded to the nearest 1, and then summed for a total score, which was then classified into low, moderate and high risk morality categories. The external validation cohort was a large UK Scleroderma Center databank, with patients meeting identical inclusion criteria and an initial visit between 2000 and 2008. Area under the curve (AUC) was calculated to assess discrimination in the derivation and validation cohorts, and stratum-specific chi-square analysis performed.

Results: In the US derivation cohort, 760 early dcSSc patients were identified, of whom 388 were Caucasian and had all objective testing required to assess internal organ involvement at the first visit. The mean age was 50.4±13.3 years, 76% female and median disease duration 0.93 years (IQR 0.63, 1.33). The mean skin thickness score was 26.1 ± 11.7. After 5 years, 110 of the 388 (28.4%) had died. 144 patients composed the UK validation cohort, with no significant differences in age, gender or skin score from the US cohort. Median disease duration was longer at 1.02 (0.78,1.45) years (p=0.03). At 5 years 38/144 (26.4%) had died, which was not different (p=0.65) from the US cohort.

Table 1: Multivariable model and risk point assignment for 5-year mortality

Characteristics	β	Odds Ratio	95% Confidence Interval	p-value	Point Assigned
Age at first visit (years)	−0.66	0.56	0.20–1.53	<0.001	−1
<35	−0.38	0.69	0.31–1.54		0
35-44	–	1	–		0
45-54	0.76	1.96	0.94–4.10		1
55-64	1.4	4.12	1.92–8.85		1
>65					
Male gender	0.55	1.8	1.01–3.20	0.05	1
Tendon friction rubs	0.73	1.94	1.02–3.70	0.002	1
2-Jan	1.34	3.36	1.71–6.59		1
≥3					
GI involvement*	0.93	2.42	1.39–4.21	0.002	1
RNA polymerase III antibody†	−0.86	0.41	0.23–0.72	0.002	−1
Anemia (hemoglobin < 12 mg/dL)	0.62	2.17	1.25–3.76	0.0006	1
Total Sum Score					

*defined as any one of the following: heartburn *plus* dysphagia, abnormal esophagram or manometry, antibiotics for or documented small bowel bacterial overgrowth, small bowel dysmotility by radiographic imaging, pseudoobstruction, malabsorption or necessity for hyperalimentation.
†note that RNA polymerase III is protective.

Significant independent predictors of 5-year mortality at first visit were age, gender, tendon friction rubs, GI involvement, RNA polymerase III antibody and anemia (Table 1). The AUC in the US derivation cohort was 0.79 (95% CI 0.74–0.84) for the overall model and 0.74 (0.65–0.82) in the UK cohort. Using the total sum score, risk stratification was defined as low (≤0), moderate (1–2) and high (≥3) risk. The AUC for the 3-level risk stratification in the US derivation cohort was 0.76 (0.72–0.81) compared to 0.68 (0.60–0.76) in the UK validation cohort (p=0.24). There were no significant differences in mortality rate between each strata of the risk stratification model in the US and UK cohorts.

Conclusion: We have developed and externally validated an easy-to-use 3-level risk stratification tool for 5-year mortality in *early* dcSSc patients. This tool requires only history, exam and bloodwork.

Screening for Interstitial Lung Disease in Systemic Sclerosis: Performance of High-Resolution Computed Tomography with Limited Number of Slices – a Prospective Study. Thomas Frauenfelder[1], Anna Winklehner[1], Thi Dan Linh Nguyen[1], Rucsandra Dobrota[2], Stephan Baumüller[1], Britta Maurer[3] and Oliver Distler[3]. [1]Institute of Diagnostic and Interventional Radiology, University Hospital Zurich, Zurich, Switzerland, [2]Department of Internal Medicine and Rheumatology, Dr.I.Cantacuzino Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, [3]Division of Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: Early diagnosis of interstitial lung disease (ILD), currently the main cause of death in systemic sclerosis (SSc), is needed. The gold standard is high resolution computed tomography (HRCT) of the chest, but regular screening faces the risk of increased radiation exposure. We perform a prospective validation of a dedicated, 9-slice HRCT protocol with reduced radiation dose for the detection of ILD in patients with SSc.

Methods: We analysed 170/205 consecutive patients with SSc. Whole chest HRCT, serving as standard of reference, and the reduced HRCT with 9 slices allocated according to a basal-apical gradient were obtained. ILD presence, extent (>or<20%) and diagnostic confidence were assessed. The reduced CT was independently analysed by 2 blinded radiologists, who also evaluated image quality. The effective radiation doses and the test performance parameters of the reduced HRCT were calculated.

Results: The study cohort included early (n=66), limited cutaneous SSc (n=66) and diffuse cutaneous SSc (n=34) patients, with a median disease duration of 60 months (Q1;Q3 28,120). Standard chest HRCT showed ILD in 77/170 patients. With the reduced HRCT, 68/77 cases with ILD were identified (sensitivity 88.3%, both readers). The accuracy (91.8%-reader1, 94.7%-reader2), diagnostic confidence (98.8%-reader1, 95.3%-reader2) and image quality rates were high (Table 1). Missed cases were exclusively borderline to minimal ILD on standard CT. Minimal ILD was correctly quantified in 73.1% (reader1) /71.2% (reader2) and extensive ILD in 88% (reader 1) /100% (reader 2) (Table 2). Importantly, the reduced CT had a significantly lower radiation dose. The mean DLP (effective dose) was only 5.66±4.46 mGycm (0.08±0.06 mSv), compared with the standard protocol dose of 149.00±95.90 mGycm (2.09±1.34 mSv).

The presence of associated lung pathology was also assessed. In this cohort, 8/10 lung nodules were also detected on the reduced CT (all <6 mm diameter and stable at follow-up).

Table 1. Estimated accuracy and diagnostic certainty in detecting ILD on reduced CT scans

	Reader 1	Reader 2
Sensitivity (95% CI)	88.3% (78.5%–94.2%)	88.3% (78.5%–94.2%)
Specificity (95% CI)	94.6% (87.3%–98.0%)	100% (95.1%–100%)
Accuracy	91.8%	94.7%
NPV (95% CI)	90.7% (82.7%–95.4%)	91.2% (83.5%–95.6%)
High diagnostic confidence*	98.8%	95.3%

* degree of confidence score 1 or 2 (i.e. 1 = fully confident; 2 = probably confident); CI = Confidence interval (in parenthesis), NPV = Negative predictive value

Table 2. Estimated extent of ILD in standard CT and reduced CT scans

	Estimated extent in reduced CT			
Lung involvement in standard CT	**No ILD** Reader 1/2	**Minimal (<20%)** Reader 1/2	**Extensive (>20%)** Reader 1/2	**Indeterminate** Reader 1/2
Minimal (<20%) n = 52	n = 9/9	**n = 38/37***	n = 5/6	n = 0/0
Extensive (>20%) n = 25	n = 0/0	n = 3/0	**n = 22/25***	n = 0/0

ILD was present in 77 patients in standard CT. *Correctly estimated extent in reduced CT as compared to standard CT.

Conclusion: The above-described reduced chest HRCT protocol reliably detects even mild SSc-ILD in clinical practice, with the advantage of a much lower radiation dose compared to standard whole chest HRCT. This makes it an attractive protocol for periodical screening for ILD in SSc.

Background/Purpose: Diffuse systemic sclerosis (dcSSc) is a multisystem disease that involves skin and internal organs. Our objective was to develop a composite response index in dcSSc (CRISS) for use in clinical trials using expert consensus and data driven approaches.

Methods: Consensus was achieved on core set measures for a 1-year multicenter trial where 11 domains and 31 core items were proposed. Subsequently, a prospective NIH-funded observational cohort of 200 early dcSSc (disease duration < 5 years) was established to assess psychometric properties of the core measures. Using data from the cohort study and literature review, the steering committee assessed the feasibility, reliability, validity, and sensitivity to change for each core set measure. For endorsed core measures, paper patient profiles (n=150) were developed using cohorts from NIH and the Canadian Scleroderma Research Group. The literature was searched to assess the most prevalent/ bothersome issues faced by patients with SSc. 54 SSc experts were invited to participate in web-based evaluation to rate 20 patient profiles each on: 1. whether each patient had improved, worsened, or stabilized, and 2. rank the 3 most important variables that influenced their decision regarding change. Cluster analysis was conducted on the experts' answers to determine clusters that identified the most influential core items. We defined consensus as 75% agreement among the experts of a patient's status (improved, worsened or stabilized). Using only profiles where consensus was reached, we fit logistic regression models to the experts' ratings for patients being improved vs. not and the core items as covariates. For each model, sensitivity, specificity and AUC were computed and predicted probabilities of improvement were derived for each patient profile. CRISS algorithm was subsequently evaluated in a RCT of methotrexate vs. placebo of dcSSc (Pope A&R 2001).

Results: 16 of 31 variables were chosen to be included as part of the patient profiles after review of test characteristics and available literature by the Steering Committee. Literature review suggested pain and fatigue as important attributes in SSc and were also included. 40 experts rated patient profiles and consensus was achieved in 118 of 150 profiles. Patients were not considered improved if they developed: 1. New renal crisis; 2. New decline in FVC% predicted by 15% (relative) and confirmed after 1 month; and 3. New onset left ventricular failure (systolic ejection fraction <45%) or PAH. Ranking and cluster analysis indicated that the change in the modified Rodnan skin score, FVC% predicted, patient and physician global assessments, and HAQ-DI had an AUC of 0.986; sensitivity of 0.982 (95%CI 0.981–0.983) and specificity of 0.931 (95% CI 0.929–0.932). A cut-off at 0.6 in the predicted probability of being improved yielded the smallest misclassification error. In the patients with complete data in the MTX

trial, 58% of MTX group vs. 19% in placebo group were considered improved.

Conclusion: We've developed a feasible composite response index with strong ability to discriminate patients who have improved vs. those who have not. The CRISS is currently being validated in RCTs of dcSSc.

Comparison of Systemic Sclerosis Subsets As Predictors of Mortality and Morbidity. Hebah Alhajeri[1], Marie Hudson[1], Canadian Scleroderma Research Group CSRG[1] and Murray Baron[2]. [1]McGill University, Montreal, QC, [2]Lady David Institute for Medical Research and Jewish General Hospital, Montreal, QC.

Background/Purpose: Identifying systemic sclerosis (SSc) subsets that predict mortality and morbidity could provide useful prognostic information. We undertook this study to compare the predictive ability of different approaches to subsetting SSc.

Methods: SSc subjects from the Canadian Scleroderma Research Group cohort were studied. Three approaches to subsetting were used: Leroy subsets based on skin involvement (limited (lcSSc) and diffuse cutaneous (dcSSc) subsets), serological subsets (anti-centromere (ACA), anti-topoisomerase I (ATA) and anti-RNA polymerase III (RNAP)), and unsupervised cluster analysis based on the items in the ACR/EULAR 2013 classification criteria, of which 3 clusters were identified (cluster 1 (ACA negative subjects with digital ulcers (DU)), cluster 2 (ACA positive subjects), and cluster 3 (ACA negative subjects with no DU)). Morbidity was defined as forced vital capacity (FVC) $<$ 70% predicted, interstitial lung disease (ILD), pulmonary hypertension (PH) and impaired health-related quality of life (defined as SF-36 Physical Component Summary (PCS) score $<$ 40). Kaplan Meier curves were generated to compare the time to event between the various subsets. Log rank p values $<$ 0.05 were considered statistically significant.

Results: 805 subjects were included (86.1% (N=693) female, 49.8% (N=401) dcSSc, disease duration since onset of first non-Raynaud's disease manifestation 10.8±9.2 years). Subsetting based on autoantibodies and unsupervised clustering (but not Leroy classification) predicted mortality, with ACA having better survival than RNAP and cluster 1 having better survival than the 2 other clusters. All three approaches to subsetting predicted FVC $<$ 70% and development of ILD: dcSSc was worse than lcSSc, ACA was better than ATA and RNAP, and cluster 1 was better than the other clusters. None of the 3 approaches to subsetting predicted time to PH. Subsetting based on Leroy classification and autoantibodies, but not clusters, predicted time to SF-36 PCS $<$ 40, with dcSSc worse than lcSSc, and ATA worse than ACA.

Conclusion: Different approaches to subsetting provide different prognostic information. Subsetting based on clinical and serological profiles remains a challenge in SSc. In the future, subsetting based on molecular profiles may improve the predictive ability of SSc subsets.

Targeting IL-6 By Both Passive or Active Immunization Strategies Prevents Inflammation-Driven Skin Fibrosis. Jerome Avouac[1], Lucille Desallais[2], Maxime Fréchet[3], Muriel Elhai[3], Jean François Zagury[2] and Yannick Allanore[1]. [1]Paris Descartes University, Rheumatology A Department and INSERM U1016, Cochin Hospital, Paris, France, [2]Chaire de Bioinformatique, Laboratoire Génomique, Bioinformatique et Applications, EA 4627, Conservatoire National des Arts et Métiers, Paris, France, [3]INSERM U1016, Cochin Institute, Paris, France.

Background/Purpose: Interleukin 6 (IL-6) is a pleiotropic cytokine involved in inflammatory and autoimmune processes. Preliminary data have suggested that IL-6 might contribute to systemic sclerosis (SSc). Our aims were to investigate i) IL6 expression in SSc patients ii) the efficacy of both passive and active immunization against IL-6 to reduce skin fibrosis in complementary mouse models of SSc.

Methods: Human serum levels and skin expression of IL-6 were determined by ELISA and immunohistochemistry, respectively. We evaluated the monoclonal IL-6R antibody MR16-1 in the mouse model of bleomycin-induced dermal fibrosis, reflecting early and inflammatory stages of SSc. Six-week-old DBA/2 mice received in parallel subcutaneous injections bleomycin (0,5 mg/ml) and intraperitoneal (ip.) injection of MR16-1 or control antibody at a dose of 2 mg at day 0 followed by one ip. injection of 1 mg at day 7 and 14. Then, we assessed the merit of MR-16 in the tight skin (Tsk-1) mice, an inflammation-independent mouse model of skin fibrosis. Tsk-1 mice received a first ip. injection of 2 mg of MR16-1 or control antibody at the age of 5 weeks followed by one ip. injection of 1 mg once a week for 5 weeks. Thereafter, because of the drawbacks of anti-cytokine monoclonal antibodies, we developed an innovative strategy using active immunization against a small peptide derived from murine IL-6, which was performed in the mouse model of bleomycin-induced dermal fibrosis. Infiltrating leukocytes, T cells and B cells were quantified, and IL-6 levels were measured in the serum and lesional skin of mice after passive or active immunization.

Results: Serum and skin levels of IL-6 were significantly increased in patients with early SSc. Passive immunization with MR16-1 exerted antifibrotic effects in the mouse model of bleomycin-induced dermal fibrosis: dermal thickness, hydroxyproline content and myofibroblast counts were reduced by 25±4% (P=0.02), 30±6% (P=0.007) and 45±7% (P=0.005) respectively, compared to mice receiving control antibody. MR16-1 demonstrated no efficacy in Tsk-1 mice. Mice immunized against the mIS200 peptide derived from murine IL-6 exhibited in the bleomycin mouse model similar antifibrotic effects as passive immunization. We observed a significant reduction of dermal thickness by 20±3% (P=0.02), hydroxyproline content by 25±4% (P=0.005) and myofibroblast counts by 41±9% (P=0.01), compared to the group immunized against the carrier protein alone. Passive and active immunization led to decreased T cell infiltration in the lesional skin of mice challenged with bleomycin. Upon bleomycin injections, serum and skin IL-6 levels were increased after treatment with MR16-1, and were significantly reduced after the anti-IL-6 active immunization.

Conclusion: Our results support the relevance of targeting IL-6 in patients with early SSc since IL-6 is overexpressed in early stages of the disease. Targeting IL-6 by both passive or active immunization strategies prevented the development of bleomycin-induced dermal fibrosis in mice. Our results highlight the therapeutic potential of active immunization against IL-6, which is a seducing alternative to passive immunization.

Anti-Fibrotic Effects of a Newly Discovered HGF Receptor Carboxy-Terminal Fragment in Systemic Sclerosis. Yuichiro Shirai[1], Ilia Atanelishvili[2], Tanjina Akter[1], Richard Silver[3] and Galina Bogatkevich[1]. [1]Medical University of South Carolina, Charleston, SC, [2]Medical University of South Carolina, Charleston, USA, Charleston, SC, [3]Medical University of South Carolina, Charleston, SC.

Background/Purpose: Systemic sclerosis (SSc) is an irreversible fibrotic disorder with interstitial lung disease (ILD) being a major complication and leading cause of mortality. African American SSc patients exhibit higher prevalence of ILD and worse outcomes than those of other races. We previously reported that a cell-protective and antifibrotic factor, hepatocyte growth factor (HGF), is downregulated in bronchoalveolar lavage fluid and plasma from African American SSc-ILD patients compared with white SSc-ILD patients. Here we report a newly identified C-terminal fragment of the HGF receptor, designated as "M10", as a peptide with robust antifibrotic properties that is lacking in certain African American SSc-ILD patients.

Methods: Lung tissue was collected postmortem from SSc patients with ILD and RNA was extracted from lung fibroblasts. The coding exons of the HGF receptor, MET (mesenchymal-epithelial transition factor), were amplified by PCR, and sequences were analyzed. Adenoviruses carrying wild type MET gene or the D1398G mutant observed in African American patients were generated. Lung fibroblasts were infected by either type of adenovirus and treated with HGF, transforming growth factor-β (TGF-β), and the M10 peptide. MET phosphorylation, connective tissue growth factor (CTGF, CCN2) and collagen expression was examined by immunoblotting. Potential peptide-protein interactions were modulated *in-silico*.

Results: We have identified the D1398G mutation in African American SSc-ILD patients whose MET signaling is impaired. When we compared MET phosphorylation following HGF treatment between normal lung fibroblasts expressing wild type or the D1398G MET, we found that the D1398G mutant showed reduced MET phosphorylation. Additionally, normal fibroblasts expressing the D1398G mutant exhibited a diminished reduction in CTGF and collagen expression following HGF treatment compared with wild type. Sequence analysis revealed that the D1398G mutation is located at the terminal amino acid sequence of "DEVD" which is a Caspase-3 cleavage motif, suggesting that the D1398G MET mutant is incapable of generating the terminal 10-amino-acid-fragment of MET, M10. We found that synthetic M10 effectively reduces, in a dose-dependent manner, collagen and CTGF in SSc fibroblasts. Computational molecular modeling based on the peptide-binding sites from protein surfaces predicts that M10 may negatively regulate TGF-β signaling by an interaction with protein domains identified as 2KXQ and 1U7V (Protein Data Bank).

Conclusion: A D1398G mutation in MET is associated with impaired phosphorylation and reduced HGF signaling in African American SSc-ILD lung fibroblasts. On the other hand, the M10 peptide generated from wild type MET signaling demonstrates strong antifibrotic effects and should be considered as a potential therapeutic agent for SSc-ILD and other fibrosing diseases.

Am80 Ameliorates Bleomycin-Induced Dermal Fibrosis By Suppressing the Pro-Fibrotic Phenotype of Fibroblasts, Endothelial Cells, and Immune Cells. Tetsuo Toyama[1], Yoshihide Asano[1], Takehiro Takahashi[1], Ryosuke Saigusa[1], Yohei Ichimura[1], Takashi Taniguchi[1], Shinji Noda[1], Kaname Akamata[1], Shinichi Sato[1], Takafumi Kadono[1] and Koichi Shudo[2]. [1]University of Tokyo Graduate School of Medicine, Tokyo, Japan, [2]Reseach Foundation ITSUU Laboratory, Tokyo, Japan.

Background/Purpose: Am80 is a synthetic retinoid serving as an agonist for retinoic acid receptor α/β with chemical and pharmacological advantages over all-trans retinoic acid, such as higher chemical stability, a lower affinity for cellular retinoic acid-binding protein, and a lack of affinity for retinoic acid receptor-γ. Am80 has been shown to modulate the pathological processes of various autoimmune and inflammatory diseases and their animal models. The aim of this study was to investigate the effect of Am80 on dermal fibrosis of a bleomycin (BLM)-induced animal model of systemic sclerosis (SSc), normal dermal fibroblasts treated with TGF-β1 and SSc dermal fibroblasts.

Methods: A BLM-induced murine model of SSc was generated with wild type C57BL/6 mice in the presence or absence of oral administration of Am80. The mRNA and protein levels of target molecules were determined by quantitative reverse transcription-PCR, immunostaining, and immunoblotting in the skin and cultured cells. Th1/Th2/Th17 polarization of immune response and macrophages polarization were evaluated by flow cytometry.

Results: Am80 significantly decreased tissue fibrosis and mRNA levels of the *Tgfb* and *Ctgf* genes in the lesional skin of BLM-treated mice. In response to Am80, the expression levels of cytokines and chemokines, including IL-4, IL-10, IL-13, IL-17A, TNF-α, IFN-γ, and MCP-1, in the lesional skin were decreased and the differentiation of naïve $CD4^+$ T cells into cytokine producing effector T cells, such as Th1/Th2/Th17 cells, and regulatory T cells were suppressed in BLM-treated mice. In addition, the infiltration of macrophages, mast cells, and T cells was attenuated by Am80 in BLM-treated mice. Am80 also exerted on dermal microvascular endothelial cells through attenuating the induction of endothelial-to-mesenchymal transition and the expression of intercellular adhesion molecule-1, and shifted macrophages from M2 phenotype to M1 phenotype. Furthermore, Am80 directly reversed the pro-fibrotic phenotype of normal dermal fibroblasts treated with TGF-β1 and SSc dermal fibroblasts via suppressing the transcription and reducing the mRNA stability of *COL1A2* gene, increasing mRNA levels of *MMP-1* gene, and decreasing mRNA levels of *CTGF* gene.

Conclusion: These results suggest that Am80 inhibits the development of experimental dermal fibrosis via reversing the pro-fibrotic phenotype of fibroblasts, dermal microvascular endothelial cells, and immune cells and would be a candidate of new therapeutic drugs against dermal fibrosis of SSc.

Autoantibody-Mediated Raynaud's Phenomenon: Animal Model and Human Disease. Dana P. Ascherman[1], Yunjuan Zang[2], Laisel Martinez[1], Judith Pignac-Kobinger[2], Irina Fernandez[2] and Eric L. Greidinger[2]. [1]Miami VAMC, Miami, FL, [2]University of Miami, Miami, FL.

Background/Purpose: Raynaud's Phenomenon (RP) is frequently seen in autoimmune conditions, but an autoimmune basis for RP has not been established.

Methods: Sera derived from anti-RNP+ individuals were screened for antibodies associated with RP by immunoprecipitation, western blot, and ELISA. Autoantigen targets were then identified by mass spectrometry. Biological effects of antigen-specific monoclonal antibodies as well as human and murine antisera were assessed in in vitro endothelial cell culture and in vivo adoptive transfer experiments involving various wild type and knockout mice.

Results: Immunoprecipitation and mass spectrometric sequencing identified cytokeratin 10 (K10) as a putative antigen linked to RP in anti-RNP+ sera. Subsequent ELISA-based screening of 123 anti-RNP+ patients demonstrated that antibodies to K10 were strongly linked to the presence of RP (present in 92% of RP patients; Odds Ratio of RP in anti-K10+ patients = 4.6 (95% confidence interval 1.6–13.4). In vitro endothelial expression of K10 was confirmed at the mRNA and protein level by rtPCR and western blot, respectively. Fluorescence microscopy further demonstrated that anti-K10 antibodies bound to the surface of K10-expressing endothelial cells, with corresponding induction of endothelial cell apoptosis not observed with control antibodies. Endothelial cell K10 expression (but not other cytokeratins) was found to be dramatically upregulated by cold exposure in vitro. Consistent with these observations, in vivo passive transfer of anti-K10+ antisera or anti-K10 monoclonal antibodies to wild type recipient mice induced a high rate of ischemia and damage of thermoregulatory tissues (ears and tail) that was exacerbated by preconditioning with cold exposure. These effects were not observed in K10 knockout mice, which were resistant to tissue ischemia induced by either anti-K10 antisera or mAb.

Conclusion: Anti-K10 antibodies induce endothelial apoptosis, mediate a murine model of RP via their recognition of the K10 antigen, and are strongly linked with clinically evident RP in human anti-RNP autoimmunity. These findings suggest that RP may be driven by anti-K10 or other endothelial apoptosis-inducing antibodies, establishing the foundation for development of novel diagnostic and treatment modalities in this frequent complication of systemic autoimmune disease.

Essential Role for Alternately Spliced Tenascin C and TLR4 Signaling in Persistent Organ Fibrosis. Swati Bhattacharyya[1], Wenxia Wang[1], Luisa Morales-Nebreda[1], Katja Lakota[1], Robert Lafyatis[2], Monique E. Hinchcliff[1], GR Scott Budinger[1], Zenshiro Tamaki[1] and John Varga[3]. [1]Northwestern University, Feinberg School of Medicine, Chicago, IL, [2]Boston University School of Medicine, Boston, MA, [3]Northwestern University Feinberg School of Medicine, Chicago, IL.

Background/Purpose: Transforming growth factor-beta stimulates collagen synthesis and myofibroblast differentiation, and is implicated as a key initiating factor in pathological tissue remodeling in scleroderma. However, the mechanism responsible for the persistence fibrotic response associated with scleroderma is not well understood. Recent studies provide evidence for activated innate immunity in patients with scleroderma. Many alternately spliced factors that govern normal embryonic and fetal development are currently recognized as being central to postnatal repair and injury responses. We hypothesized that tissue injury in scleroderma leads to generation and accumulation of alternately spliced extracellular matrix molecules such as tenascin C that are recognized by, and serve as endogenous ligands for TLR4 to drive persistent fibrosis.

Methods: Tissue expression of tenascin C was investigated in scleroderma skin biopsies by microarray, immunofluorescence and real-time qPCR. Tenascin C was assayed in 3-D human skin equivalents reconstituted with scleroderma fibroblasts and in scleroderma serum. Cellular responses elicited by tenascin C in human and mouse skin fibroblasts and in 3-D organotypic human skin equivalents were examined. The role of tenascin C in scleroderma skin and lung fibrosis was investigated using tenascin C-null mouse.

Results: Levels of an alternately spliced full-length tenascin C isoform (TN-FL) were markedly elevated in scleroderma serum and skin biopsies, as well as in fibrotic skin and lung tissues from mice. TN-FL mRNA level correlated with the skin score. The splicing factor serine/arginine-rich (SR)-rich splicing factor SRSF6, implicated in alternate splicing of tenascin C, was elevated in scleroderma skin biopsies as well as in scleroderma fibroblasts populating skin equivalents. Treatment with TGF-β stimulated the expression of both SRSF6 and TN-FL. In vitro, TN-FL stimulated collagen synthesis and myofibroblasts differentiation, and induced dermal sclerosis in skin equivalents. All of these profibrotic responses were abolished by genetic or pharmacological disruption of TLR4 signaling. Importantly, tenascin C-null mice treated with bleomycin were protected from development of skin and lung fibrosis and loss of lung compliance.

Conclusion: Increased SRSF6-driven alternate splicing of tenascin C leads to aberrant TN-FL accumulation in scleroderma. TN-FL triggers TLR4-dependent fibroblasts activation, contributing to intractable skin and lung fibrogenesis. Disrupting the tenascin C-TLR4 signaling axis by preventing tenascin C accumulation through SRSF6 blockade, or by blocking TLR4 signaling using selective small molecule inhibitors, represent appealing novel strategies for attenuating progressive fibrosis as treatment for scleroderma.

Activation of the Thromboxane A2 Receptor By 8-Isoprostane Inhibits the Pro-Angiogenic Effect of Vascular Endothelial Growth Factor in Scleroderma. Pei-Suen Tsou[1], George Zakhem[2], Beatrix Balogh[2], M. Asif Amin[3], Phillip Campbell[3], Gautam Edhayan[3], Ray A. Ohara[3], Elena Schiopu[3], Dinesh Khanna[1], Alisa E. Koch[4] and David A. Fox[3]. [1]University of Michigan Scleroderma Program, Ann Arbor, MI, [2]University of Michigan Medical School, Ann Arbor, MI, [3]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI, [4]Department of Veteran's Affairs and University of Michigan, Ann Arbor, MI.

Background/Purpose: Scleroderma (SSc) is a complex disease characterized by inflammation, vasculopathy, and excessive deposition of extracellular matrix. Various studies have demonstrated a paradoxical increase in angiogenic mediators, such as vascular endothelial growth factor (VEGF), in both the skin and serum of patients with SSc. Despite this, angiogenesis does not occur normally. 8-isoprostane is an oxidized lipid created by excessive oxidative stress, and has been shown to be elevated in SSc. The thromboxane A2 receptor (TXAR) and ROCK pathway, which can be activated by 8-isoprostane (8-IP), inhibits VEGF-induced endothelial cell (EC) differentiation and migration. However, its role in SSc has not been examined. In this study we determined whether the TXAR pathway was activated by 8-IP in SSc ECs. Its effect on VEGF-induced angiogenesis was also determined.

Methods: Dermal ECs were isolated from punch biopsies from healthy subjects or patients with diffuse cutaneous SSc. Angiogenesis was assessed by chemotaxis and *in vitro*Matrigel tube formation assays. TXAR expression was determined by qPCR and Western blotting. Knockdown studies were performed using TXAR siRNAs.

Results: SSc patients had significantly higher 8-IP plasma levels (60.9 ± 8.4 pg/ml) compared to healthy subjects (24.9 ± 5.0 pg/ml, $p<0.05$). Increased oxidative stress was detected in SSc ECs as increased 8-IP in SSc EC conditioned media and excessive superoxide in SSc ECs were observed. In healthy ECs, 8-IP inhibited VEGF-induced EC migration, and the inactivation of TXAR or ROCK pathways restored VEGF-induced angiogenesis inhibited by 8-IP. In SSc ECs, VEGF did not induce EC migration, however, addition of the TXAR or ROCK inhibitors restored the pro-angiogenic effect of VEGF. This was further confirmed by TXAR siRNA experiments which showed that TXAR-knockdowned SSc ECs migrated towards VEGF while the SHAM-transfected ECs did not. We then measured ROCK activity in healthy and SSc ECs before and after VEGF or 8-IP stimulation. Basal ROCK activity was significantly higher in SSc ECs compared to healthy ECs. Moreover, 8-IP-induced ROCK activation was significantly higher in SSc ECs while VEGF induced significantly higher ROCK activation in healthy ECs. The expression of key players in this pathway was also examined. The protein expression of TXAR, RhoA, ROCK1/2 were all elevated in SSc ECs compared to healthy ECs.

Conclusion: We show that 8-IP inhibits VEGF-induced migration in healthy ECs through the TXAR/ROCK pathway. ECs not only produce high levels of 8-IP, but also show elevated expression of TXAR and RhoA/ROCK levels. This could explain the increased activation of the TXAR pathway in terms of ROCK activity in SSc ECs compared to healthy ECs. This hyper-activation leads to inhibition of VEGF-induced EC migration, as using the TXAR or ROCK inhibitor, as well as specific knockdown of TXAR, results in restoration of VEGF activity. These results suggest that the TXAR pathway plays a crucial role in angiogenesis and that 8-IP is not just a by-product as a result of oxidative stress, but instead plays a significant role in impaired angiogenesis that characterizes SSc.

Can Knee Pain be Prevented through Diet and Exercise Among Those at High Risk? the Look Ahead Study. Daniel White[1], Tuhina Neogi[2], W. Jack Rejeski[3], Michael Walkup[3], Cora E. Lewis[4], Michael Nevitt[5], Capri Foy[3] and David T. Felson[2]. [1]Boston Univ School of Med, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Wake Forest University, Winston-Salem, NC, [4]The University of Alabama at Birmingham, Birmingham, AL, [5]UCSF, San Francisco, CA.

Background/Purpose: Weight loss combined with exercise is effective for reducing pain and improving function in adults with knee pain. However, it is not known if this same approach prevents the development of knee pain among those at high risk. We examined whether an intensive weight loss and exercise intervention prevented the development of knee pain among overweight and obese adults with type II diabetes, a group at risk for knee pain due to excess weight.

Methods: We carried out a secondary analysis of the Look AHEAD study, a multi-center randomized intervention trial of an intensive lifestyle intervention (ILI) vs. diabetes support and education (DSE) comparison group in adults with a BMI > 25 kg/m^2 and type II diabetes. Participants in the ILI had goals of reducing weight by 7% and participating in > 175 minutes/week of physical activity by one year. We included subjects with no knee pain at baseline and examined to what extent the ILI

group protected against developing knee pain at year 1 and 4. Knee pain was assessed by asking "Have you had any pain or discomfort in your knees in the past month?" In a second separate analysis, we examined whether meeting treatment goals, i.e., weight loss only, physical activity only, or both weight loss and physical activity, reduced the risk of developing knee pain compared with those not meeting any goal at year 1 and 4. This second analysis was performed in a subset of 989 participants whose clinic sites provided an accelerometer.

Results: Of the 2998 participants with no knee pain at baseline (age 58.5±6.7, men 44.9%, BMI 35.1±5.6) 50.1% were assigned to the ILI group and the remainder to the DSE. Subject characteristics were similar between groups at baseline. At year 1, ILI participants were 15% less likely to develop knee pain compared with. At year 4, this decreased to 5% and was not statistically significant. In the second analysis, participants meeting both weight loss and physical activity goals had 47% less risk of developing knee pain at year 1. Only those meeting the weight loss goal at year 1 had less risk that met statistical significance of developing knee pain at year 4.

Conclusion: An intensive lifestyle intervention of diet and exercise prevented the development of knee pain among those at high risk in the short-term. Weight loss appears to have the most relevant for preventing the development of knee pain over four years.

Table: (A) Association of an Intensive Lifestyle Intervention vs. Diabetes Support and Education control with developing knee pain (n = 2998). (B) Association of meeting treatment goals at one year with the development of knee pain at one and four years among all participants who were an accelerometer (n = 989).

High Prevalence of Subclinical Ultrasonographic Enthesopathy and Synovitis in Patients with Inflammatory Bowel Disease without Clinical Signs or Symptoms of Spondyloarthritis. Esther Vicente[1], Silvia Pérez-Esteban[2], María Chaparro[1], Francisco Rodríguez-Salvanés[1], Lorena Vega[1], Santos Castañeda[1] and Javier P Gisbert[3]. [1]Hospital Universitario de La Princesa, IISP, Madrid, Spain, [2]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, [3]Hospital Universitario de La Princesa. IIS La Princesa, Madrid, Spain.

Background/Purpose: Musculoskeletal manifestations as peripheral arthritis, axial disease and enthesitis are present in 10–62% of Inflammatory Bowel Disease (IBD) patients. Ultrasonography is more sensitive than physical examination to detect enthesopathy and synovitis, so we believe it may be useful to identify subclinical involvement.

Our Purpose is to evaluate the presence of subclinical enthesitis and synovitis with power Doppler ultrasonography (PDUS) in IBD patients and to investigate its correlation with IBD variables.

Methods: Cross-sectional study that recruited prospectively IBD patients, without clinically overt musculoskeletal disease, attended by Gastroenterology during 2013. Gastroenterological, rheumatological and PDUS evaluation, blind to each other, were performed. Clinical assessment included demographics, comorbidities, IBD characteristics and musculoskeletal clinical examination. PDUS evaluation consisted of the detection of grey scale (GS) and power Doppler (PD) signs of enthesopathy and synovitis in 12 enthesis scored according to the Madrid Ankylosing Spondylitis Enthesitis Index (MASEI) and in 44 joints using a LOGIQ7 General Electric machine with a 12-MHz linear array transducer. Statistical analysis: continuous variables are expressed as mean±SD or range and categorical variables as number of cases (%). The associations between PDUS and clinical variables were evaluated by the Student's t test, Mann-Whitney test, $\chi 2$ test or Pearson and Spearman correlations as appropriate. The intra-reader agreement for US was estimated in all the images obtained. Statistical significance was set at $p<0.05$ (Stata 10).

Results: A number of 23 (56.5% male) IBD patients [9 Crohn's disease and 14 ulcerative colitis] have been included so far. Clinical variables: Age 42±12 years, evolution time 9 years (range: 0.1–33), CDAI 28±21, Mayo index 0.4±1, DMARD therapy in 91.3% for 5.5±5.3 years, ESR 12±8.8 mm/h and CRP 0.12±0.14 mg/dL. A positive MASEI was present in 95.7%, with a mean score of 35.2±9.5. GS enthesal abnormalities were found in at least 1 enthesis in 100% of patients: enthesophytes or calcifications (100%), altered echoestructure (100%), increased thickness (100%), erosion (13%) and bursitis (34.8%). GS joint effusion and synovial hypertrophy in at least 1 joint were present in 91.3% and 100%, respectively, with poliarticular (≥5 joints) involvement in 47.8% and 74%, respectively. Entheseal and joint PD signal was positive in 52.2% and 47.8% of patients, respectively. Joint effusion and synovial hypertrophy were more frequent in MTF, MCF and carpal joints and PD signal in carpal and knee joints. We found no association between PDUS variables and clinical or analytical IBD variables, probably due to the yet small sample size. The intra-reader agreement was high (0.8 intra-class correlation variability).

Conclusion: Subclinical joint and entheseal PDUS abnormalities are common in IBD patients, regardless of clinical subtype, evolution time and intestinal activity. Prospective longitudinal studies are needed to define its predictive value of clinically overt musculoskeletal disease and its association with structural deterioration.

Stem Cell Augmentation for Cardiovascular Risk in Rheumatoid Arthritis. Nidhi Garg[1], Ashit Syngle[2] and Pawan Krishan[1]. [1]Punjabi University Patiala, India, Patiala, India, [2]Healing Touch City Clinic, Fortis Multispeciality Hospital, Chandigarh, India.

Background/Purpose: Bone marrow derived stem cells, endothelial progenitor cells (EPCs), protect against atherosclerotic vascular damage by overcoming endothelial damage. However, EPCs are depleted in RA and contribute to the enhanced cardiovascular (CV) risk. Therapeutic potential of augmenting EPCs to treat the heightened CV risk of RA has not yet been exploited. We aimed to investigate the effect of rosuvastatin on EPCs population, endothelial dysfunction, nitrite, adhesion molecules and on markers of inflammation in RA.

Methods: 50 RA patients were randomized to receive 24 weeks of treatment with rosuvastatin (10mg/day, n=25) or placebo (n=25) as an adjunct to existing stable antirheumatic drugs. EPCs (CD34+/CD133+) were quantified by Flow Cytometry. Flow mediated dilatation (FMD) was assessed by AngiodefenderTM (Everest Genomic Ann Arbor, United States). Inflammatory measures included DAS28, CRP, ESR and Pro-inflammatory cytokines (TNF-α, IL-6 and IL-1) were measured at baseline and after treatment. Estimation of serum nitrite, Lipids, and adhesion molecules (ICAM-1 and VCAM-1) was done at baseline and after treatment.

Results: At baseline, inflammatory measures, pro-inflammatory cytokines, adhesion molecules and nitrite levels were elevated and EPCs and endothelial function were impaired among both groups. At 24 wks: DAS28, ESR, CRP, TNF-α and IL-6 improved significantly ($p<0.05$) in rosuvastatin group. Concentration of serum nitrite ($p=0.02$) and ICAM-1 ($p=0.01$) was significantly lower in the rosuvastatin group compared with placebo. EPCs increased significantly from ($CD34^+/CD133^+$, 0.01 ± 0.001 to 0.035 ± 0.001, $p<0.01$) after treatment with rosuvastatin as compared with placebo and after 24 wks percentage change in EPCs was 71.4% and 22.2% in the rosuvastatin and placebo groups respectively (Fig.1). After treatment with rosuvastatin there was significant improvement in FMD ($p<0.01$) as compared to placebo. Rosuvastatin exerted positive effect on lipid spectrum by signicantly increasing HDL cholesterol levels ($p=0.01$) and decreasing LDL cholesterol ($p=0.02$). Significant inverse correlation was observed between EPCs and CRP ($r=-0.44$, $p=0.02$), TNF-α ($r=-0.42$, $p=0.03$), ICAM-1($r=-0.45$, $p=0.03$) and FMD($r=-0.47$, $p=0.01$) after treatment with rosuvastatin.

Conclusion: First study to show that rosuvastatin augments EPCs population in RA mediated by lowering the levels of cytokines, especially IL-6 and TNF-α, which downregulates adhesion molecule, CRP and nitric oxide production. This defines a novel mechanism of rosuvastatin treatment

in patients with RA: the augmentation of EPCs with improvement in inflammatory disease activity and endothelial dysfunction. The augmentation of EPCs by rosuvastatin represents a fascinating new approach for the management of RA.

3010

The Development and Evaluation of a Self-Monitoring and Patient-Initiated Follow-up Service for People with Rheumatoid or Psoriatic Arthritis on Methotrexate. Hayley McBain[1], Michael Shipley[2], Abigail Olaleye[2], Samantha Moore[3], Shashi Hirani[4] and Stanton Newman[4]. [1]East London Foundation Trust, London, United Kingdom, [2]University College Hospital London, London, United Kingdom, [3]University College London, London, United Kingdom, [4]City University London, London, United Kingdom.

Background/Purpose: Patient-initiated services in rheumatology have been found to be cost-saving without compromising the clinical or psychosocial well-being of patients with rheumatoid arthritis. Self-monitoring is a technique used in many other long-term conditions and is associated with reductions in healthcare utilisation and mortality and has been found to be satisfactory from the patient's perspective. The aim of this study was to evaluate the efficacy of a service which integrates self-monitoring into patient-initiated follow-ups for patients with RA or PsA on methotrexate; in terms of healthcare utilisation and clinical outcomes; using a mixed methods approach including a randomised controlled trial (RCT) and qualitative semi-structured interviews.

Methods: One hundred patients with RA or PsA (according to ACR/EULAR/CASPAR criteria)on methotrexate were randomised to either an intervention group or usual care. All participants were assessed over 6 blood tests. Those in the intervention group attended one training session where they were taught how to monitor their blood test results and which symptoms and side effects they should report. These participants had no scheduled appointments with their rheumatology nurse during the trial period, but continued with their consultant appointments as usual. Blood test results were sent to intervention participants and along with their assessment of symptoms and side effects; patients initiated a review with their nurse, when necessary. If these reviews were required an immediate outpatient appointment was made. Healthcare utilisation was monitored throughout the trial period. Poisson regressions and multi-level modelling were used to explore the impact of the intervention on healthcare usage and clinical outcomes.

Results: There were no significant differences in clinical or demographic variables between the two groups at baseline. Across the trial period 77% of decisions made by intervention participants were considered to be safe. At the end of the trial period participants in the intervention group had 54.55% fewer appointments with their rheumatology nurse specialist ($p<0.0001$). There were no significant differences in the number of appointments with the rheumatologist or GP. Levels of pain, fatigue, ESR, CRP and disease activity did not differ between groups ($p>0.05$). Intervention participants were positive about the new model of care, valuing its efficiency and tailored approach. The service allowed patients to gain new knowledge and use this information along with the skills they obtained to take control of their health and arthritis.

Conclusion: After brief training patients with RA and PsA can successfully understand and interpret their blood test results and use this information along with reports of their symptoms and side effects to initiate appropriate reviews with their rheumatology nurse. Participants in the intervention group had fewer hospital appointments with their nurse specialist with no detrimental effects to their clinical status and with no increase in visits to the rheumatologist or GP. This model of care offers a viable alternative for established RA and PsA patients on DMARD therapy.

Ambulatory Gait Analysis in Clinical Practice: Single or Dual Task Conditions? Bernard Auvinet[1], Claude Touzard[2] and Vincent Goëb[3]. [1]Polyclinic, LAVAL, France, [2]Hospital of Laval, LAVAL, France, [3]Amiens University Hospital, Amiens, France.

Background/Purpose: Interest in ambulatory gait analysis is increasing thanks to validated gait analysis apparatus dedicated to clinical practice. Such methodology has to be reproducible, sensitive, specific and pertinent. Traditionally gait analysis was carried out during a walking test with no additional tasks (called single task (ST)). Recently due to the fact that gait control involves the cognitive domain, gait analysis has additionally been carried out using the dual task paradigm, when a task demanding attention is performed during walking - this type of gait analysis is known as Dual Task (DT). We hypothesize that gait analysis under ST or DT conditions has to be chosen according to the objectives of the clinician, as well as that of the choice of gait variables.

Methods: Locometrix is a validated accelerometric device which allows the measurement of the following gait variables: walking speed (WS, m/s), stride frequency (SF, Hz), stride length (SL, m), step symmetry (SS, dimensionless), stride regularity, an index of similarity of successive strides (SR, dimensionless), cranio-caudal power (CCP, W/Kg), high frequency energy modulus at heel contact (HFEM,%: a measurement of shock wave (SW)).

ST gait analysis was performed in three pathological conditions: 1- knee osteoarthritis compared to a control group (41 patients, age: 65 ± 10y, BMI 28 ± 4 kg/m^2, mean Lequesne index: $9\pm4/24$); 2- newly diagnosed Parkinson patients with no treatment, compared to a control group (22 patients, age 69 ± 9y, BMI: 26 ± 3 kg/m^2, mean motor score: 23.5 ± 3.0); 3-Fibromyalgia patients (52 matched pairs of female patients and controls, age: 44 ± 7y, BMI: 24 ± 4 kg/m^2).

DT gait analysis was performed in 80 elderly patients (age 68 ± 14y, BMI 25 ± 5 kg/m^2). suffering from gait instability, memory impairment, recurrent falls.

Results: Study 1: In knee osteoarthritis two gait variables are highly significant and relevant: area under the ROC curve (SR: 0.79 ± 0.05), SW: 0.78 ± 0.06)

Study 2: In Parkinson's disease two gait variables are highly significant and correlated to motor score: SR ($r=0.59$, $p<0.01$); CCP ($r=-0.65$, $p<0.003$)

Study 3: Fibromyalgia patients

- ROC curves confirmed the utility of SF (0.74 ± 0.04), SR (0.68 ± 0.05) and CCP (0.69 ± 0.05) in the identification of fibromyalgia patients,
- SR is correlated to the Fibromyalgia Impact Questionnaire ($r=-0.33$, $p=0.01$)
- SR is correlated to cognitive dysfunction measured by the Coping Strategy Questionnaire ($r=0.31$, $p=0.003$)
- CCP is correlated to pain (weekly VAS: $r=-0.33$, $p=0.01$)

Study 4: Gait exhibited no abnormality under ST in 13 patients. Gait abnormalities occurred under DT in each patient, moreover the decrease of one or more of the following gait variables (WS, SR, SF) alerted the clinician to an underlying neurological pathology.

Conclusion: The Single Task Gait Analysis condition is well adapted to knee osteoarthritis (SR and SW: a measurement of shock wave), to Parkinson's disease (SR, CCP: a measurement of kinesia); to fibromyalgia patients (SR, SF, CCP: a method for the identification of homogenous subgroups). Gait Analysis Test under Dual Task conditions is of major interest in exploring the cognitive reserve and explaining gait instability in the elderly.

Needs Assessment Survey – Evaluation of Sexual Dysfunction Among Patients at a Tertiary Rheumatology Clinic. Sharon Nesher Peleg[1], Ori Elkayam[2], Bruria Yahini[1] and Jacob N. Ablin[1]. [1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Tel-Aviv Medical Center, Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel.

Background/Purpose: Sexual function is a major component of wellbeing and is adversely affected by many disease states. Previous studies have demonstrated various aspects of sexual dysfunction among rheumatological patients. These may include reduced libido, pain upon intercourse (dyspareunia) and erectile dysfunction; tenderness, limitations of range of motion and depression may have a compounding negative effect. In a previous study we have demonstrated aspects of sexual dysfunction found among fibromyalgia patients. The aim of the current preliminary study was to evaluate aspects of sexual dysfunction among rheumatological patients. We also wished to evaluate the needs of rheumatological patients vis-à-vis sexological counseling, in order to assess the need for establishing a reproductive health clinic at our rheumatology center and design future interventions in this field. A similar approach has been previously used for evaluation the needs of cancer patients.

Methods: Patients: patients were recruited among those attending the rheumatology clinic at the Tel Aviv Sourasky Medical Center from a broad range of rheumatological diagnoses. Participants filled out the following questionnaires:

1. A demographic questionnaire
2. Self-report Sexual questionnaire which was translated into Hebrew and adapted for the needs of the patients at the rheumatology institute-. This questionnaire included questions regarding common domains of sexual dysfunction, including decreased libido, difficulty achieving arousal, difficulty in achieving an erection (males) or vaginal dryness (females) pain during intercourse, difficulty in achieving an orgasm, and feeling unattractive sexually.

Results: Forty three patients were recruited, (8 males and 35 females). The most frequent age group of the patients was 41–50.

Diagnoses included Rheumatoid arthritis (50%), Osteoarthritis (3.2%), Fibromyalgia (13%), Systemic Lupus Erythematosus (3.2%) Psoriatic arthritis (13%), Other. 31% reported being currently active sexually.

41 % expressed interest in receiving attention for their sexual issues by the attending rheumatologist and 19% would be interested in receiving specialized sexual consultation with their partner, in the context of the rheumatology follow up.

Among female patients, 25.7% reported a decrease in libido. 17.1% reported pain during sexual intercourse and 17.1% reported difficulty achieving sexual arousal. 14.3% reported vaginal dryness and a decrease sense of attractiveness respectively. 11.4% reported difficulty in achieving an orgasm.

Conclusion: Sexual dysfunction is highly prevalent among rheumatology patients. While not routinely evaluated in clinical practice, this issue appears to be pertinent for many patients who also express interest in receiving specific advice and treatment, as part of their rheumatological follow up. Rheumatological health care providers should be aware of this important aspect of the quality of life of their patients and should feel comfortable about raising the topic during the course of follow up. Further research is warranted into the specific causes of sexual dysfunction in various rheumatological populations and regarding the optimal treatment of these problems.

The Reserve Capacity Model in Patients with Rheumatoid Arthritis: Understanding the Relationship of Socioeconomic Status, Psychosocial Resources, Mood, and Pain. Desiree Azizoddin[1], Taylor Draper[1], Sarah Ormseth[1], Perry M. Nicassio[1], Michael R. Irwin[1], Michael Weisman[2] and Hilary Wilson[1]. [1]University of California, Los Angeles, Los Angeles, CA, [2]Cedars-Sinai Medical Center, Los Angeles, CA.

The Reserve Capacity Model in Patients with Rheumatoid Arthritis: Understanding the Relationship of Socioeconomic Status, Psychosocial Resources, Mood, and Pain.

Background/Purpose: The reserve capacity model is a framework for understanding how low SES may affect health outcomes through both positive and negative emotions separately and the depletion of psychosocial resources. The purpose of this study was to explore the reserve capacity model in persons with rheumatoid arthritis, using structural equation modeling (SEM; see Figure 1). It was hypothesized that SES would be negatively related to self-reported pain directly and/or indirectly through the potential mediators of positively related psychosocial resources (reserve capacity) and negatively related negative mood.

Methods: Data of 106 participants were drawn from a randomized comparative efficacy trial of psychosocial interventions for RA. In the hypothesized model, SES (years of education and annual income) predicted pain (Pain VAS and Rapid Assessment of Disease Activity in Rheumatology total joint score) through reserve capacity (Personal Mastery Scale, Arthritis Helplessness Index, and Social Provisions Scale), and negative mood (Hamilton Depression Rating Scale, Perceived Stress Scale and the Positive and Negative Affect Schedule), using EQS 6.1 to evaluate the structural model.

Results: SEM revealed a confirmed the hypothesized relations among model constructs (see Figure 1). Higher SES was positively associated with reserve capacity, which predicted lower levels of negative mood and related directly and positively to pain severity. The indirect effect of SES on pain via reserve capacity and negative mood was significant ($\beta_{indirect} = -.10$, $p = .027$). Evidence supported a partial mediation of reserve capacity and negative mood between SES and pain, as the direct effect of SES on pain remained significant after controlling for the attenuating mediators of reserve capacity and negative mood.

Conclusion: These findings underscore the importance of a multidimensional framework in evaluating pain in RA using a structural-equation approach. The mediating variables of reserve capacity and negative mood may play major roles in explaining pain in RA, and represent modifiable factors for targeted interventions.

Does the Order or Amount of Risk-Benefit Information Presented Influence patients' Perceived Value of a Proposed New Medication? Liana Fraenkel[1], Richard Street[2], Harjinder Chowdhary[3], Sarah Swift[3] and Ellen Peters[4]. [1]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT, [2]Texas A&M University, College Station, TX, [3]Yale University, New Haven, CT, [4]Ohio State University, Columbus, OH.

Background/Purpose: The order and amount of information has been shown to influence risk perceptions related to hazards. In this study we sought to examine whether order and amount of risk and benefit information influences patients' perceived value of a proposed new medication.

Methods: We created 5 videos of a physician describing a new medication. The videos were identical except for the order and number of side effects (SEs) and benefits presented (see Table). Subjects with a systemic inflammatory rheumatic disease were randomly assigned to view one of the videos. Perceived medication value (PMV) was assessed by having subjects choose: the risks outweigh the benefits, the risks and benefits are equally balanced or the benefits outweigh the risks. We subsequently examined whether differences in the order and amount of information was associated with subjects' PMV. This outcome was chosen because one's overall impression more strongly predicts behavior than recall of verbatim information. We also examined the association of demographic characteristics (age, minority status, and difficulty paying for medications), attitudes towards illness and treatment (factor analysis of illness perceptions, patient activation and trust resulting in 4 factors: worry about illness, perceived treatment efficacy, impact of illness, patient activation), and current medications on PMV using bivariate analyses. Variables found to be significant ($p<0.05$) were included in a multinomial logistic regression model. Because of the known influence of numeracy on risk perception, all analyses were stratified by high versus low subjective numeracy (dichotomized at the median).

Results: 389 subjects participated: mean (SD) age= 55 (14), 75% female, 40% minority (African American and/or Hispanic). In bivariate analyses, the order and number of SEs and benefits, current use of prednisone, and minority status were associated with PMV in subjects with high numeracy (n=242). Presenting SEs first or between benefits were both associated with more negative PMV compared to the reference video (3 benefits followed by 6 SEs) (See Table). Among subjects with low numeracy (n=142), the order and

number of risk and benefits presented were not associated with PMV. In bivariate analyses, use of a biologic, difficulty paying for medications, perceived treatment efficacy, patient activation, and minority status, were associated with PMV in subjects with low numeracy. Except for current use of a biologic, all remained significant in the multivariate model (see Table).

Conclusion: Order and amount of information matter, but only in patients with high subjective numeracy. Minority patients have a much more negative PMV compared to Caucasian, non-Hispanic patients, regardless of their level of numeracy.

Table: Multinomial logistic regression model examining association of risk-benefit presentation and patients characteristics on perceived medication value.

Variable	Perceived Medication Value (Ref= Risks outweigh Benefits)	Adjusted Odd Ratio (95% CI)
High Numeracy		
Video (Ref= 3 benefits → 6 SEs)		
6 benefits → 6 SEs	Balanced	1.87 (0.59–5.98)
	Benefits outweigh Risks	0.45 (0.14–1.48)
6 benefits → 3 SEs	Balanced	0.79 (0.24–2.64)
	Benefits outweigh Risks	0.60 (0.19–1.83)
6 SEs → 3 benefits	Balanced	0.47 (0.16–1.40)
	Benefits outweigh Risks	**0.20 (0.07–0.58)**
3 benefits → 6 SEs → 3 benefits	Balanced	0.54 (0.18–1.66)
	Benefits outweigh Risks	**0.26 (0.09–0.78)**
Currently on prednisone	Balanced	0.75 (0.34–1.67)
	Benefits outweigh Risks	1.77 (0.82–3.80)
Minority vs Caucasian	Balanced	0.95 (0.48–1.89)
	Benefits outweigh Risks	**0.25 (0.11–0.58)**
Low Numeracy		
Perceived treatment efficacy	Balanced	1.46 (0.90–2.37)
	Benefits outweigh Risks	**2.22 (1.28–3.83)**
Patient activation	Balanced	**1.75 (1.09–2.81)**
	Benefits outweigh Risks	1.05 (0.62–1.78)
Currently on a biologic	Balanced	1.13 (0.35–3.66)
	Benefits outweigh Risks	2.64 (0.87–8.04)
Difficulty paying for medications	Balanced	**0.17 (0.07–0.44)**
	Benefits outweigh Risks	0.73 (0.27–2.00)
Minority vs Caucasian	Balanced	**0.23 (0.09–0.62)**
	Benefits outweigh Risks	**0.22 (0.08–0.63)**

Evaluation of the effuc Educational Needs Assessment Tool (ENAT) Focused Patient Education on Health Outcomes in Patients with Rheumatolid Arthritis - a Randomised Controlled Trial. Adewale O. Adebajo[1], Dawn Johnson[2], Hardware Bernadette[3], Claire Hale[4] and Mwidimi Ndosi[4]. [1]University of Sheffield, Sheffield, United Kingdom, [2]Barnsley Hospital NHS Foundation Trust, Barnsley, United Kingdom, [3]Barnsley Hospital NHS Foundation Trust, Baarnsley, United Kingdom, [4]University of Leeds, Leeds, United Kingdom.

Background/Purpose: The Educational Needs Assessment Tool (ENAT) is a quick and simple, self completed questionnaire that ensures that patient education is relevant, appropriate and timely for people with Rheumatoid Arthritis (RA). It has been validated for use in RA and six other rheumatic diseases and has been cross-culturally adapted into nine European languages. Our aims were (i) to evaluate the effectiveness of ENAT focused patient education on self-efficacy, patient knowledge and health outcomes (physical function, symptoms, role/work, social interaction and psychological status/affect) (ii) to evaluate the usability of the ENAT in clinical practice, from both a practitioner and patient perspective.

Methods: This was a mixed methods (quantitative and qualitative) study conducted in seven rheumatology centres across the United Kingdom. Patients were randomised to either the ENAT group (EG) where patients completed the ENAT which was then used as a template by the Nurse Practitioner (NP) to meet their educational needs; or usual care (UC) by NP without the ENAT. Patients were seen at baseline then at weeks 16 and 32. The outcomes were self-efficacy (ASES), health status (AIMS2-SF) and patient knowledge (PKQ). The primary outcome was self-efficacy (ASES) at week 32. The ASES has two subscales: ASES-Pain and ASES-Other symptoms.

Results: A total of 132 patients were entered into the study of which 70 received ENAT (53%) and 62 usual care (47%). At week 16, there were no significant between-group differences. By week 32, the ASES mean scores, were higher for the ENAT group than the usual care group; ASES-Pain, MD=4.36(95%CI: 1.17, 7.55), t=2.72, P=0.008; ASES-Other symptoms, MD=5.84(95%CI: 2.07,9.62), t=3.07, P=0.003). (Bonferroni-adjusted P-value = 0.025 for significance at the alpha level). While there were no significant changes in ASES scores in the usual care group over the whole follow-up period, the ENAT group saw significant improvements in ASES-pain and ASES-Other symptoms scores, suggesting that the ENAT helped improve patients' self-efficacy. Initially, patients were asked if they wanted any education about their arthritis (yes/no); at week 0, 33 patients (48%) said 'yes' and this dropped to 13 (21%) at week 16 and 9 (16%) by week 32 (Chi Sq.=18.76, $p < 0.001$). Trends over time reveal significant decrease in the overall ENAT score for all domains (managing pain, movement, arthritis process, self-help measures and support) except the feelings domain. The decrease in the total ENAT score by the end of the study, indicates that patients' educational needs were being met effectively.

Qualitative interviews were undertaken with patients and Nurse Practitioners. All found the ENAT to be a comprehensive and easy to use tool. For most patients, the process helped them to focus on what they needed to know from the NP and for some, it made them think of additional questions to ask and topics to think about. Both the EG and the CG perceived that they were getting a good and adequate education provision from their NP.

Conclusion: This is the first study to report the effects of ENAT-focused education in people with RA. The results of the primary outcome (ASES-Pain and ASES-Other symptoms) suggest that the ENAT could be a useful addition to usual care.

Measuring the Impact of an Early RA Support and Education Program Using a Program Evaluation with Patient Identified Outcomes. Adena Batterman[1], Kathryn Klingenstein[1], Roberta Horton[1], Linda Leff[1], Theodore R. Fields[2] and Vivian P. Bykerk[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery Weill Cornell Medical College, New York, NY.

Background/Purpose: The Early RA Support and Education Program addresses the unique psycho-educational needs of people recently diagnosed (<2yr) with RA. This free monthly program is co-facilitated by an MSW and RN and was developed based on a needs assessment with patient input; it features an RA- focused lecture followed by a support group, aimed at enhancing emotional coping and disease management. In order to measure program impact on concerns most relevant to new RA patients, we developed an evaluation tool incorporating patient identified outcomes (Hewlett, 2003), on which we previously reported. Since that time, we have piloted the evaluation and now report on the results.

Methods: Through a multi-level collection of data, we identified patient derived program outcomes and language most relevant to participants. This process yielded 3 key domains: Managing RA, Connecting with Others with RA and Coping with the Emotional Impact (Wolrich, 2011). From this data we created a 20-item evaluation, using a 6 point Likert scale and open-ended questions, which incorporates patient identified outcomes under each of the domains. This new tool was administered to participants after each of 12 monthly sessions.

Results: 127 evaluations were completed from 180 participants. Demographics: Gender: 93%F; Mean age: 49; Ethnicity: White 59%; African American 19%; Asian American 11%; Latino 11%; Education: College or higher: 92%. Results indicate % of participant agreement (either "completely" or "a great deal") with the following Likert scale question statements, which represent each of the 3 key domains. I. MANAGING RA: As a result of this session, I feel. . . *"more prepared to discuss my RA treatment with my doctor"* (84%); *"I can make informed choices about my RA"* (90%). II.CONNECTING WITH OTHERS: *"Speaking with other group members, I feel more hopeful about my RA"* (77%). *"Sharing information and feelings in the group helps me cope with RA"* (89%). III EMOTIONAL IMPACT: Participating in this program makes me feel. . ."*more confident in managing my RA"(79%); "my RA is less disruptive to my daily life than it was before"* (61%).

Responses to open ended questions re learning and impact supported the program's value within the 3 domains: Managing ("will follow up with MD

about what I learned"); Connecting ("I don't feel so alone"); Emotional Coping ("learned ways to deal with stress of RA").

Conclusion: Evaluation results indicate that in domains I and II, and in domain III, "more confident in managing my RA", the program is making a strong positive impact. In domain III, " RA is less disruptive to my daily life," results reflect positive impact, though not as marked as in other questions. Future work is needed to explore how patients define "disruptive" and develop targeted content to address this for future groups. Future research might also follow participants longitudinally, to determine how program participation over time, and other variables, impact this outcome. This tool was administered to measure how effectively the program meets patient identified needs. Our process can serve as a model for including the patient perspective in evaluating outcomes in other disease specific support and education programs.

Program Evaluation of 'the Joint Clinic': An Innovative Clinical Service for Patients with Hip or Knee Osteoarthritis. J. Haxby Abbott[1], Helen Harcombe[1], Chris Crane[2], Liam Hutton[2], Kirsten Stout[2], Cathy Chapple[1] and David Gwynne-Jones[1]. [1]University of Otago, Dunedin, New Zealand, [2]Southern District Health Board, Dunedin, New Zealand.

Background/Purpose: In socialized healthcare systems with free public access to healthcare, there are circumstances wherein patients referred by general medical practitioners (GPs) for specialist physician consultation may not be not offered a first specialist appointment (FSA), when demand exceeds supply. Thus, clinical prioritization is necessary. To address unmet need for FSA in patients with hip or knee osteoarthritis, we initiated and evaluated a physical therapist-led clinic offering non-surgical management of osteoarthritis and outpatient treatment.

Methods: We conducted a program evaluation comprising: a proof-of-concept evaluation, an implementation evaluation, a process evaluation, and an outcomes evaluation. Mixed-methods qualitative and quantitative methodology grounded in health services research were used. Patients, GPs, surgeons, and hospital clinical, management and administrative staff were interviewed and/or surveyed. Patient trajectories were analysed and patient-reported outcome measures were assessed.

Results: The concept model was supported by best-practice literature, and was implemented in close concordance with the model proposed. Qualitative interviews and survey data indicate the "Joint Clinic" has been well accepted by key stakeholders and end-users, is functioning well within the host organisation, is accessible and operating at close to intended capacity. In the 2-year evaluation period, the clinic served 358 new patients [53% female, mean(sd) age 66(10), BMI 29.9(7.5)] in 637 consultations. Unmet need was reduced by 80% compared with pre-implementation for hip/knee OA patients; 30% overall. 31% of patients experienced clinically significant (>20%) improvement on patient-reported outcome measures. 25% of patients were referred for FSA (mean wait 77 days) for fast-track access to joint replacement surgery. 70% of patients were satisfied to be seen by the "Joint Clinic" instead of an orthopaedic surgeon; 98% were satisfied with the knowledge and expertise of the "Joint Clinic" staff; 80% would recommend the clinic to others. Cost-per-patient was NZ$384 (year 2). The host organisation has accepted the service as value-for-money and sustainable.

Conclusion: These data indicate successful implementation and functioning of an innovative service. The service is achieving satisfactory outcomes benefiting patients through clinically significant improvement, monitoring on optimal non-surgical management, or fast-tracked referral for joint replacement surgery.

Testing of a Newly Developed Computerized Animated Activity Questionnaire for Assessing Activity Limitations in Patients with Hip and Knee Osteoarthritis. Wilfred FH Peter[1], Mick Loos[1], Henrica de Vet[1], Maarten Boers[1], Jaap Harlaar[1], Leo D. Roorda[2], Rudolf Poolman[3], Vanessa Scholtes[3], Jan Bogaard[1], Hilda Buitelaar[1], Martijn P.M. Steultjens[4], Ewa M. Roos[5], Anne-Christine Rat[6], Francis Guillemin[7], Maria Grazia Benedetti[8], Antonio Escobar Martinez[9], Nina Østerås[10] and Caroline Terwee[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Amsterdam Rehabilitation Research Center Reade, Amsterdam, the Netherlands, Amsterdam, Netherlands, [3]Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands, [4]Glasgow Caledonian University, Glasgow, Scotland, [5]University of Southern Denmark, Odense, Denmark, [6]University of Lorraine, Nancy, France, [7]INSERM, Centre d'Investigation Clinique - Epidémiologie Clinique (CIC-EC) CIE6, Nancy, France, [8]Istituto Ortopedico Rizzoli, Bologna, Italy, [9]Basurto University Hospital, Bilbao, Spain, [10]Diakonhjemmet Hospital, Oslo, Norway.

Background/Purpose: Self-report questionnaires and performance-based tests correlate moderately in measuring activity limitations, indicating that they measure different aspects. Self-reports measure mainly how patients think they perform an activity, and is influenced by pain, fatigue or situations they are referring to. This may lead to cross-cultural differences. Performance-based tests measure an artificial situation, is resource-intensive and burdensome for patients. To overcome these drawbacks we developed and tested a pilot version of an Animated Activity Questionnaire (AAQ), which demonstrated some promising features[1]. The aim of this study was to develop a computerized Animated Activity Questionnaire (AAQ) to assess activity limitations in patients with hip/ knee osteoarthritis and preliminary testing of its validity and reliability.

Methods: Based on the pilot version, International Classifications of Functioning core set for osteoarthritis, focus groups of patients, and existing measurement instruments, the AAQ was developed. In 482 patients correlations were calculated between the Animated Activity Questionnaire (AAQ) and self-reported Hip disability and Knee injury Osteoarthritis Outcome physical functioning score. In addition internal consistency was calculated. In 65/482 patients also correlations with performance based tests (Stair Climbing Test, Timed Up and Go test, and the 30 second Chair Stand Test) were calculated. Test-retest reliability was assessed by repeated scoring in 56/482 patients.

Results: The Animated Activity Questionnaire (AAQ) includes animated videos of 17 basic daily activities with four levels of increasing difficulty (check the following link for two examples: http://kmin-vumc.nl/_14_0.html). Patients were asked to select the video that best matched their own performance. Cronbach's alpha was 0.95. Correlation with self-reported physical functioning scores was high (0.72). The AAQ correlated moderately with the performance based tests (0.49, 0.44, and 0.57, respectively). Correlations of the AAQ score with pain was lower (0.51) than the correlation of the self-reported physical functioning score with pain (0.75). For test-retest reliability, a Intraclass Correlation Coefficient of 0.97 (95% Confidence Interval 0.93–0.98) was found.

Conclusion: A computerized Animated Activity Questionnaire (AAQ) was developed showing a high internal consistency and excellent test-retest reliability. Content validity was considered good, and construct validity is supported by high correlations with self-reported physical functioning and moderate correlations with performance-based tests. The AAQ seems to be less influenced by pain compared with self-reported physical functioning. Since the AAQ needs no reading ability or translation, it has potential for international use. Continuing research will focus on construct validity and cross-cultural validity.
