CATALOGUE OF THE CRABS OF THE FAMILY PERICERID I IN THE U. S. NATIONAL MUSEUM.

BY

Mary J. Rathbun, Department of Marine Invertebrates.

## (With Plates Xxvir-xL.)

The classification arlopted in the following catalogue is that established by Mr. E. J. Miers, in the Journal of the Linnean Society of London, V1 I. YIV, pp. 662 to 667,1879 , and modified by him in the Challenger lu, ,ort, Zoölogy, Vol. xVII, 1886. His descriptions of Li binis and Pericera have been amended to receive new species which do not appear to be generically distinct.

In the key are inclurled all the genera supposed to belong to the family. The characters distinguishing those genera which have not been seen by the writer are inclosed in parentheses. In the key to species only those represented in the National Museum are enmmerated. At the end of the catalogue a list is given of the species of l'ericeridie not in the Museum, for the benefit of futmre students of the group, and also to call atteution to the deficiencies of the collection in the hope that it may be enriched in this direction through gifts and exchange.

Of the fo- ty-eight species of Periceridse contained in the National Musemm, one is European, two are East Indian, and the remainder American. Of the latter, eleven are found on the I'acific coast, from the Gulf of California to the Galapagos Islands, and thirty-four on the Atlantic coast. Of the Atlantic forms, two only range from Massachusetts southward. The remainder inhabit the southern Atlantic States and the West Indies, in many cases extending to Brazil. Fifteen species are described as new, of which six are from the Gulf of California, and, with two exceptions, represented by a single specimen each.

In aldition to the specimens in the National Museum, the writer was enabled to examine also the Periceridet in the Musem of Union College, Schenectady, N. Y., and those contained in a collection made in the Bahama Islands by Mr. Frederick Stearns, of Detroit, Mich., in 1888, and kindly lent by him for study. The latter collection yielded an additional species, which is here described. The writer is indebted
to Mr. James E. Benedict for valuable aid in the preparation of this paper.
In the synonymy, quotations not verified are inclosed in parentheses. Numbers in parentheses after localities are taken from the catalogue books of the museum.
The drawings were made by Mr. A. H. Baldwin, excepting those of Libinia emarginata and dubia, which are republished from "The Fisheries and Fishery Industries of the United States," through the courtesy of the U. S. Fish Commissioner.
In an appendix are given descriptions of Periceride collected by the North Pacific Exploring Expedition, preliminary notices of which were published by Dr. William Stimpson, in the Proceedings of the Philadelphia Academy of Natural Sciences, 1857. The specimens were destroyed in the Chicago fire. The figures have been copied and enlarged by Mr. Baldwin from the drawings accompanying the original mamseript.

## PERICERIDA.

Maioid brachyurans with eyes retractile in complete and well-defined orbits. Basal antennal joint well developed and forming the greater portion of the inferior wall of the orbit.

## KEY TO SUBFAMILIES.

$A^{\prime}$ Carapace more or lesi subtriangular. Rostrum well developed. Second joint of antenne not dilated. Fingers aeute at tips.

Pericerinc.
A." Carapace suboblong; interorlital space very broad. Rostrum very small. Seeond joint of antenne enlarged. Fingers excavated at tips....... Othomiine.
$A^{\prime \prime \prime}$ Carapace broadly triangular, sometimes transverse. Rostrum usually short. Second joint of antenne not dilated. Fingers exeavated at tips. . Mithracine.
key to genera.
Periceriur.
$A^{\prime}$ Rostrum not divided to the base.
$B^{\prime}$ Preoeular spine distinct
Libinia.
B $^{\prime \prime}$ Preocular spine absent
Prionorhynchus.
A $^{\prime \prime}$ Rostrum composed of two distinct spines.
$B^{\prime}$ Basal joint of antenna without spine at distal extremity.
$\mathrm{C}^{\prime}$ (Horns of rostrum lamellate)
$C^{\prime \prime}$ Horns of rostrum flattened, contignous, produeed at their extremities in a lateral lobe Lissa.
C ${ }^{\prime \prime \prime}$ Horns of rostrum slender and divergent Picroceroides.
$C^{\prime \prime \prime \prime}$ (Horns of rostrum very slender and contiguous) .................... Leptopisa.
$\mathrm{C}^{\prime \prime \prime \prime \prime}$ (Horns of rostrum small, parallel to each other)...................... Sisyphus.*
$B^{\prime \prime}$ Basal joint of antenne with one or more spines at distal extremity.
C' Carapace narrow and elongated, suboval.
$\mathrm{D}^{\prime}$ (Nearly vertically deflexed in front of gastric region) Cyphocarcinus.
$\mathrm{D}^{\prime \prime}$ (Not deflexed in front of gastrie region) Podohucnia.

[^0]C/" Carapace snbtriangular.
I) Carapace with a series of lateral spines or teeth.
$\mathrm{E}^{\prime}$ Lateral margins with sharp spines...................................... Pericera.
$\mathrm{E}^{\prime \prime}$ (Lateral margins laminate and dentate) .................... . . . Anaptychus.
$D^{\prime \prime}$ Carapace withont a series of lateral spines or teeth.
$\mathrm{E}^{\prime}$ Spines of rostrm very slender and contignons
Tiariaia.
$\mathrm{E}^{\prime \prime}$ Spines of rostrmu slender and more or less divergent.
$F^{\prime}$ (Spine at anteroextomal angle of antenmal joint very short and not visible from above) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . Tyloravcinns.
$F^{/ \prime}$ Spine at antero-external angle of antemal joint very long and visihe from above

Microphrys.
$\mathbf{E}^{\prime /}$ Spines of rostrum parallel or nearly so. Orbits tubular.. Macrocoloma.
$\mathbf{E}^{\prime \prime \prime \prime}$ (Spines of rostrmm short, divergent, obliquely deflexed).. Entomonyx.
Ohmouiarre.
$A^{\prime}$ Carapace with margins regularly dentated...................................... Othonia.

## Mithracime.

A' Ambulatory legs dilated and compressed. Rostrmm minnte................... Thoe. A $^{\prime \prime}$ Ambulatory legs not slilated and compressed.

B $^{\prime}$ (Basal antemal joint withont spiness at distal end) . ....................... . . . . . $13^{\prime \prime}$ Pasal antennal joint with one or more spines at distal end.
$\mathrm{C}^{\prime}$ Lateral margins with tuhereles or spines...........................................................
$C^{\prime \prime}$ (Lateral margins withont tubercles or spines)......................... I'aramaya.*

## KEY TO SPECIES EXAMINED.

Libinia.
$A^{\prime}$ Carapace with margin evenly rounded behind the front.
$\mathbf{B}^{\prime}$ Orbital fissures open ; carapace narrowly pyriform
mexicana.
$13^{\prime \prime}$ Orbital fissures closed; earapace broadly ovate.
$\mathrm{C}^{\prime}$ Rostrum deflexed.
D' Median spines six ....... ..... ............ . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . dubia.
$\mathrm{D}^{\prime \prime}$ Median spines nime.............. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . emarginata.
C" Rostrum pointing obliquely ирward. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . setosa.
$A^{\prime \prime}$ Carapace distemled at the hepatic regions.
$B^{\prime}$ Legs spinons. spinimana.
B/ Legs nnarmerl. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . macdonaldi.

## Priomorhyuchus.

Praoenlar spine absent
eduardsii.
Lissu.
Gastric region divided ly deep grooves from the earliae and branchial regions chiragra.
Picroceroides.
Horus of rostrum slender and divergent
tubularis.

[^1]
## Pericera.

$\mathrm{A}^{\prime}$ Carapace with strong median spines.$B^{\prime}$ Carapace oblong-ovateatlantica.
$B^{\prime \prime}$ Carapace triangulate riangulata.
$A^{\prime \prime}$ Carapace without strong mediau spines.
$\mathrm{B}^{\prime}$ Rostral horns divergent from the base cornuta.$B^{\prime \prime}$ Rostral horns divergent at tips onlycontigua.
Tiarinia
Carapace covered with prominent warty tubereles corniyera.
Microphrys.
$A^{\prime}$ Rostral horns short, flattened Microphrys, sp.
$A^{\prime \prime}$ Rostral horns long, thickened bicornutus.
Macrocerloma.
$\mathrm{A}^{\prime}$ Carapace with dorsal spines hesides the epibramehial and posterior spines. $1^{\prime}$ Carapace subtriangnlar.
(1) Rostrmon strongly deftexed septemspinosa.
D" Rostrum almost horizontal camptocera.
("/ Carapace with spiny ridge het ween epibranchial spines. subperrallela.
C $^{\prime \prime \prime}$ Carapace with two spines on the intestinal region temiirostra.
$B^{\prime \prime}$ Carapace subtrapezoidal ..... eutheca.
$A^{\prime \prime}$ Carapace without dorsal spines except the epibranchial and posterior spines.
$B^{\prime}$ Epibranchial spine two-lobed diplacantha.
$B^{\prime \prime}$ Epibranchial spine not lohed trispinosa.
Ohtomia.
A Antero-lateral teeth romed aculeata.
$A^{\prime \prime}$ Antero-lateral teeth acnte.
$B^{\prime}$ Carapace smooth, pmbescent ..... Therminieri.
$B^{\prime \prime}$ Carapace densely granulous. ..... rotunda.
1"" Carapare tuberenlous.
(" Carapace hroadest at fomrth pair of teeth ..... nicholsi.
$\mathrm{C}^{\prime \prime}$ Carapace bromest at thid pair of tee th. ..... carolinensis.
Thoe.
Antero-lateral margin straight or a little encave . ${ }^{\text {muella. }}$
Mitherex.
$A^{\prime}$ Carapace with dorsal sulci.
$1^{\prime}$ Antero-lateral margins with spines only.$\mathrm{C}^{\prime}$ Carapace longer than broad
$C^{\prime \prime}$ Carapace broader than long. forecps.
$\mathbf{B}^{\prime \prime}$ Antero-lateral margins with lobes, or lobes and spines.
$C^{\prime}$ Carapace much hoader than long; lateral margins angnlar.
$\mathrm{D}^{\prime}$ Lateral angle formed by a spine hooked forwart Alenticulatus.$\mathrm{D}^{\prime \prime}$ Lateral angle formed by a lobecoronatus.
("/ C'arapace slightly broader than long; lateral margin romded.

1) Lateral margin with three large lohes followed hy a spine ..... nodosus.
$\mathrm{D}^{\prime \prime}$ Lateral margin with fonr small lobes sculptus.
$A^{\prime \prime}$ Carapace without dorsal sulei.
$B^{\prime}$ Manus with spines.*

C/ Carapace punctate and spiny . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . .
C ${ }^{\prime \prime \prime}$ Carapace densely hairy
-pilosus.
B $^{\prime \prime}$ Manns without spines.
C' Rostrum tuberenliform.
$\mathrm{D}^{\prime}$ Ambulatory legs with a thin lamellate crest ............ Mithrax, sp., Miers.
$D^{\prime \prime}$ Ambnlatory legs withont a thin lamellate crest.
$\mathrm{E}^{\prime}$ Carpus with inner margin armed with two or thren blunt spines. rerrucosus. $\mathrm{E}^{\prime \prime}$ Carpus with surface tubereulous.
$F^{/}$Basal antemal joint with aspine at its antero-lateral angle.... simensis.
$F^{\prime \prime}$ Basal antemal joint with a lobr at its antero-lateral angle ...cristulipes.
$F^{\prime \prime \prime}$ Basal antennal joint with a truncate tooth at its antero-lateral angle
. braziliensis.
E"" Carpus with smrface unevяn . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . hispidus.
$\mathrm{C}^{\prime \prime}$ Rostrum short and sharp.
D ${ }^{\prime}$ Carapace strongly tubereulous. Lateral margins heavily armed. . hemphilli.
b" Carapace pmbescent. Lateral margins almost marmed........ bahamensis. (1"/ Rostrum long and sharp.

D" Carapace with scatered tubercles spinipes.

## Snbfimily Pericerine.

## Libinia Learlh (amembled.)

Leach, Zoül. Misc., II, 1. 129, 1815. Say, Jour. Acad. Nat. Sci. Phila., I, p. 76, 1817. Latreille, Kège Anim., III, p. 21, 1817 (2nl. ed., N‘, p. 61); translation, III, p. 46, 1831. (Desmarest, Consid. sur les Crust., p. 161, 1825.) Milue Edwards, Hist. Nat. des Crust., 1, p. 298, 1834. De Haan, Fama Japonica, Crust., p. 86. De Kay, Crust. of N. Y., p. 1, 1844. Dana, C'rust. U. S. Ex. Ex., I, 1. 80, 1852. A. Milne Edwards, Miss. Sci. au Mexique, pt. 5, I, j. 127, 1875. Miers, Jour. Limn. Suc. Lomelon, xiv̌, p. 6ifi, 1879; Challenger Rept., Zoül., xvir, f. 72, 1886.
Carapace convex ; tubermlons or spinons; triangnlar-orbiculate and evenly rounded behind the frontal region, or oblong-orbiculate and ronstricted behind the hepatie regions which are dilated laterally. Preeocular spine usually distinet. Rostrmm emarginate or bifid at the apex. Orbits small, nearly cironlar, sometimes with an open fissure in the upper and lower margins. Basal antenal joint moderately eularged. Merus of exterior maxillipeds truneaterl at the distal emf. Cheliperls well developer; palm elongated; fingers evenly dentionlated on imner margins. Ambulatory legs well developed, sometimes elongated; joints subeylindrical, usually marmed.

## Libinia emarginata Le:tch.

Plate xxxi, fig. 2.

A variety from Charlotte Harbor, Florida, collected by the U. S. Fish Commission schooner Grampus, approaches somewhat the dubia type. It has the rostrum of emargimata, as well as the hepatic, the two intestinal, and the fom median gastrie spines; but the three branchial spines and those of the lateral margin, as well as some of the median spines, are long and strong as in dubiu.

One speeimen from St. Augustine, Florida, has a rostrum with three spines instead of two. one median, the others regularly diverging on either side.

Occasionally this species oceurs in such numbers on the oyster grounds of Lomg Island Somnd, and so interferes with the operations of the steam oyster dredgers that work is abandoned until the crabs (which are known to the oystermen as "spiders") have passed over.

## IRECORD OF SPECIMENS FNAMINED.

Massachmsetts; U. S. Fish Commission:
Wellfleet and Provinectown (2978) ; Provincetown (3898, 5875) ; Cape Cod (2025); sonth of Caje Cod, 27 fathoms ( 12852 ) ; east of Martha's Vineyarl, 3 to 7 fiathoms (9376) ; Vincyarl Summd, shore to 9 fathoms; Wood's Holl (6704); Menemsha Bight (6710); IBzzarls Bay, $5 \frac{1}{4}$ fathoms ( 4054 ) ; Mattapoisett Harbor (5825).

Rhode Island; U. S. Fish Commission:
Narragamsett Bay, slore to 15 fathoms.
Comnecticut; U.S. Fish Commission:
Noank (5874) ; New Haven (3843) ; Savin Rock (4102) ; oyster beds of H. C. Rowe, month of New Haven Harbor (3042) ; oyster gromils ofi Milford, Stratford, liridgeport, aml Norwalk (16023).
Long Island:
Fort Pond Bay, U. S. Fish Commission (14582); Fire Islami heach, Dr. T. H. Bean (8916).
Virginia; U. S. Fish Commission:
Chesapeake Bay (5870); IJampton Roads, 11 to 12 fathoms (12452).
North Carolina:
lBeanfort (Union College Coll.); Middle Somm, near Wihnington, lT. S. Fish Commission (3375).
Sontl Carolina; U. S. Fish Commission:
Bull Creek (16074); Charlenton Harbor (3911); west end of Sknll Creek (16075); Caliboghe somml (16073).

Florida:
St. Angustine, J. G. Hewitt (2018) ; Suuthern Florida, Silas Stearns (3147) ; Florida Reefs, Lient. J. F. Muser, U. S. Navy, U. S. C. S. S. Bache (14998); 4 miles east of Cape Romano, 18 feet, Lieut. J. F. Moser (13059) ; Marco, H. Hemphill (15122); Charlotte Harbor, U. S. Fish Commission (15203); W. H. Dall (15125) ; Sarasota l3ay, H. Hemphall (15124), (Union College Coll.).

This suecies is foumd as fim north as Casco Bay.

Libinia dubia Milue Eelwards.

## Plate NxXi, fig. 1.

Libinia dubia Milne Edwards, Hist. Nat. Ies Crust., I, p. 300, pl. 14 his, fig. 2, 1834. Gibles, op. cit., 1. 169. Strects, op. cit., 1. 10t. Smith, loc. cit. A. Milne Edwards, op. cit., p. 129, pl. xvifl, fig. 5. Kingsley, op. cit., p. 316, 1878; xxxi, ए. 386, 1879. R. Rathbm, op. cit., p. 778, pl. 269, fig. 5, 1884. Miers, loc. cit. Kentall, loc, cit. lves, Proc. Acad. Nat. Sci. Phila., 11. 178, 1891. Aurivillins, K. Sv. Vet.-Akad. Hand., Bıl. 23, 1, p. 53, 1889.

Libinia canaliculata De Kay, loc. cit. (partim).
Libinia distincta Gnérin, La Sigra's Hist. of C'nbar, vir, p. xir, 18.56. Capello, Jor. Sci. Lisbon, uI, 1. 263, pl. 3, tig. 2, 1871. Martens, Archiv. für Natur., xxivir, 1. 79 , pl. IV, figs. $1 a, 1 b, 1872$.

Libiniu rhomboidca Streets, op. cit., p. 106. A. Milne Edwards, op. cit., p. 131. Miers, loc. cit.
? Libinia inflata Streets, loc. cit.
Among five specimens from near Cedar Keys, Fla., there is one in which the upper orbital fissures are open as in the species of the second section of Libinia emmerated by Miers, op. cit., p.73. The lower margin of one orbit has a very narrow open fissure; in the other orbit, however, the fissure is closed, as in typical specimens.

A specimen from Merida, Yucatan, presents most of the characters of Streets's rhomboider. A. Mihe Edwards is probably right in considering this a variety of dubia. The specimen las the depressed median spines; the irregular transverse row on the gastric region; the strong spine on the hepatic region, forming with the lateral spines almost a semicirele; and the four strong spines arranged in a rhomboid on the branelial region, a character possessed by many of our specimens of dubia. On one side there is an additional smaller spine placed a little in front of the posterior spine of the rhomboid and nearer the median line. The preocular spine is prominent. The rostral spines are slightly divergent as in the typical rlubia, from which this specimen does not differ essentially except in the strong hepatic spine.

This species is not uncommonly covered with foreign matter, such as worm tubes, oysters, hydroids, and algat. A female from Barnegat, N. J., about 3 inches long, is enerusted with tubes of Serpula, which conceal the carapace with the exception of the posterior margin, the intestinal spine, and the orbits, rendering the identification doubtful. The rostrum is broken. The mass of tubes is about 3 inches high and of greater width. Another female from Great South Bay, Long Island, has an oyster growing vertically on the froutal region, the hinge being
attached to the hepatic region. Still another female, from Barnegat, has an oyster attached to the subhepatic region and extending liorizontally forward.

## RECORI) OF SPECLMENS EXAMINED.

Massaehusetts; U. S. Fish Commission:
Woods Holl (4905, 5839); Buzzards Bay, 7 fathoms (4551); Mattapoisett Harbor (15121).
Long Island; Dr. 'T. H. Bean:
Fire Island (8920) ; Patchogne (8915).
New Jersey:
Barnegat, William Calverly (5491, 5497); Ocean City, Dr. T. H. Bean (13012); Great Egg Harbor, Dr. William Stimpson (2066); Beesleys Point (2149).

## Plate xxini.

Libinia setosa Loekington, Proc. Cal. Acad. Sci., l'. 68, 1876. Streets and Kingsley, Bnll. Essex Inst., 9, p. 108, 1877. Miers, Challenger Rept. Zoül., xvir, p. 73, 1886.

Libinia semizonale Streets, Bull. U. S. Nat. Mus., No. 7, p. 103, 1877.
Lower Califoruia ( 2300 ). Type of Streets's semizonale.
Libinia macdonaldi, spl. nov.

## Plate xxix.

Entire surface, except the fingers and the tips of the ambulatory legs, densely eovered with short, soft hairs, which in alcohol are brown, the surfice being much lighter when the hairs are removed. Carapace broadly ovate, somewhat contracted behind the hepatic region, which is distended ontwardly, a character not common to any of the species
deseribed hitherto. A conspienous groove defining the inner angle of the branchial region ends anteriorly in a romd pit and is interrupted posteriorly at the widest part of the cardiae region, behind which point it is continued almost to the posterior margin and mites with a broad irregular depression occupying the posterior portion of the branchial region; another short groove on the bramehial region noar the inner angle. There is a pit at the imer angle of the hepatie region, and another further back, between the gastric and branchial regions.

The spines of the carapace are stout and blunt pointed. There are nine on the median line: four on the gastric, one on the genital, two on the cardiac, and two on the intestinal region. There is a spine on the frontal region on either side of the median line from which a ridge extends forward to the rostrum, which is either tuberenlous or amed with a small spine. Between these ridges there is a broad, shallow depression. On earh gastric region there is a spine which forms a T with those on the median line. There is a line of seven spines loginning at the summit of the hepatie region and terminating with the last antero-lateral spine. There two other strong antero-lateral spines, one at the prominent angle of the hepatic region, and one on the branchial. region midway between the other two. There are fome anditional spines on the branchial region: one between the first and second lateral spines, but a little higher up and smaller; one, small, near the anterior border; two larger, of which one is near the inner angle, and one at some distance posterior, and nearer the margin; a filth, nen the cardiac region, is sometimes wanting, and in one sperimen is irrompanied by another at a little distance. On the anterior margin of the hepatic region at the base of the lateral spine are one or two small irregular spines directed forward. In some specimens there is a small spine on the nostero-lateral margin just back of the last antero-lateral spine.

Rostrim depressed, flattened vertically, composed of two hroad spines coalesced for from one-third to more than one-half their length, their onter margins slightly converging.

Orbits with a single closed fissure above and below and prominent preocular and postocular spines. Orbital opening very small in proportion to the size of the carapace. Basal antennal joint broad, with a spine at the hase of the second joint, directed downward and forward, and a little smaller spine on the anterior margin near the onter angle.

Merus of external maxilliperl strongly notehed at its antero internal angle, slightly rounded at its antero-external angle. Tooth near the distal extremity of the inner margin of the exognath large, acute.

There are several tubercles on the pterygostomian region, and sometimes a small spine on the subbranchial above the base of the first ambulatory leg. Abdomen with a longitudinal carina which is broarler in the female than in the male; a spine or spiny tubercle o!n the first segment, and a tubercle on the second,

Chelipeds slenter, not so long is the first pair of ambulatory legs. Merus subcylindrical, with a row above of four spines and a few tubercles; inner, outer, and inferior surfaces, each with a longitudinal row of tubercles. Carpus obscurely tuberculatr, with a erest of fom tubereles above. Hands compressed, upper and lower margins parallel in the male, tapering in the female. Fingers meeting alung their inner edges, eveuly dentate.

Ambulatory legs slender, decreasingsuccessively in length. Dactyls slightly arehed, shorter than the pemultimate joints.

Dimensions of a male in millimeters: Length, including rostrum, ss; width, withont spines, 70 ; length of cheliped, $1: 2$; length of first ambulatory leg, 14t; length of fourth ambulatory leg, 81 .

This species is named after the Hon. Marshall McDonald, U. S. Commissioner of Fish and Fisheries.

Libinia spinimana, sp. nov.
Plate xxx.
Carapace the same general shape as the preceding, studded with numerons sharp spines and covered, excepting on the distal half of the spines, with a dense pubescence, the hairs being lighter and shorter than in macelomidi. The depressions and grooves are placed similarly to those of mucdonuldi, but are more shallow. There are about twelve prominentspineson themedian line; five on the gastric region, twoon the genital, two on the cardiac, two on the intestinal, and one on the posterior margin. On the frontal region thereare two or threesmall spines placed longitudinally on either side of a broad shallow groove. On each gastric region there is a spine which forms a transrerse line with the second median spine. There is no continnons line of lateral spines, but near the margin there are prominent spines arranged as follows: Three on the hepatic region, the longest at the external angle, the other two on the anterior border and directed forwarl; two near the anterior portion of the lnanchial region, and two farther back. There is an irregular row of small spines near the posterior margin. The entire carapace is covered with spines of different sizes, varying with the specimen.

Rostrum but slightly deflexed, flattened vertically, composed of two sharp divergent spines coalesced for about one-thirel their length.

Orbits as in macdonaldi; prieocular and postocular spines more prominent than in that species. Basal antemal joint shaped as in macdon-
aldi, and bearing besides the two spines of that species a third on the outer margin behind the anterior angle.

Maxillipeds much as in machonaldi. P'terygostomian region armed with a few spines. Abdomen carinated, with a median spine on the first two segments in both sexes. On each side of the second, third, and fourth segments in the female, there is one prominent tubercle, and in some cases one or two smaller ones. In the male there are inconspicuous tubercles on either side of the first three segments.

Chelipeds shorter than the first mair of ambulatory legs; pubeseent, except the fingers and distal half of the hand, which are smooth. Ischimm with a few short spines. Merus with four longitudinal, equidistant rows of irregular spines, those of the upper margin being the longer. Between these rows are seattered a few small spines. Garpus spiny. Hands and fingerw shaped as in menclomuldi. Hand with small spines on the proximal half of the upper margin, more prominent in the male than in the female, and sometimes aranged in two rows, which become more divergent toward the distal end, the spines decreasing to small tubereles; immer and lower surfaces finely tuberenlate or granmate, with a few stomt tubercles in the male at the proximal end of the lower margin.

Ambulatory legs resembling those of macdonuldi; pubescent, exrept the distal two-thirds of the dactyls. Merns of the first pair with a longitudinal row of four or five shan spines on the mper surface, two on the outer side of the anterior margin, and six or eight smaller seattreed spines. Meral jointe of the remaining legs with a sharp spine on the outer side of the anterior margin, and one or more minnte spines on the anterior portion. ('arpal joints of first pair with a few small spines; of remaining pairs sometimes with faint tubercles. Other joints muarmed.

Dimensions of male in millimeters, as follows: Length, including rostrum, 86 ; width, withont spines, 69 ; length of cheliped, 114; length of first ambulatory leg, 147; length of fourth ambulatory leg, 98.

There is a small male trom the Gulf of Mexico, measuring 52 millimeters long and 36 wide, which differs from the three large specimens collected off Cape Looknout, North Carolina, in the following particulars: The dorsal spines are fewer and longer; there is only one spine on the genital region, and one on the anterior margin of the hepatic. The rostral spines are proportionally longer and more divergent. In other respects, however, this specimen agrees with the types.

RECORI ()F SPECLMENS EXAMINED.

Prot. N. M. 92-16

This species and the preceding differ from all other species of Libinia in the prominent hepatie regions, and in the sharp postocular spine durected ontward, characters which hardly seem to justify the formation of a new gemus. Excepting L. rostrata liell, they are the only speeies having long rostral horns in comention with closed orbital tissures. Id spinimana is peemliar in having spines on the hands.

Libinia mexicana, sp. nov.
Plate xxxi, fig. 3.
Carapace pyriform, covered with a short pubescence and bearing twelve long spines besides the prencular. Median spines four: two on the gastric region (the posterior the longer), one on the eardiac, and one on the intestinal. There is a small spine on each side of the anterior median gastric spine, a tubercle on the genital, and one on the cardiac behind the spine. There are two long spines on each branchial region, one on each side of the genital region, pointing outward and a little forward, the others further from the median line and nearly in line with the cardiae spine, but pointing backward and outward. Lateral spines two: one on the hepatic region, one on the anterior part of each branchial; further back on the margin there is an inconspicnons spiny tubercle.

Rostrum rather long, nearly straight, the distal half bifurcated. Horns tapering; outer margins slightly divergent; interspace $V$-shaped.

Orbits with an open fissure above and below; preocular spine prominent; postocular well developed, obtuse.

Basal antennal joint rather narrow, with a triangular acute spine at its distal extremity, pointing downward and forward. Second and third joints rather stont. Remaining portion wanting. There is a short spine and two or three tubereles on the pterygostomian region.

Legs short, covered with a close pubescence; joints unarmed. Chelipeds, in a young male, weak, almost as long as the first pair of ambulatory legs. Palms compressed, not dilated. Fingers uarrowly gaping, their distal half finely toothed.

Length, without rostrum, $10^{\mathrm{mm}}$; breadth, $7.5^{\mathrm{mm}}$; length of rostrum about $3.5^{\mathrm{mm}}$; length of cheliped abont $8.5^{\text {mm }}$.

Collected in the Gulf of California, oft Shoal Point, Mexico, near the mouth of the Colorado River, lat. $31^{\circ} 33^{\prime}$ N., long. $114^{\circ} 20^{\prime} 30^{\prime \prime}$ W., $10 \frac{1}{2}$ fath., fine gray sand, broken shells, station :30:99, U. S. Fish Commission, 188!) (16072).

This species is nearest to L. smithii Miers, but differs in the narrower carapace, the less divergent rostral horis, the shorter ambulatory legs. The lateral branchial spine is also farther forward in mexicann, and the twelve long spines are nearly equal in length, while in smithii the cardiac, intestinal, and second lateral spines are longer than the others. The marginal spine of the basal antemal joint is wanting in mexicanu.

Libinm mexictum belongs to that section of the gemns having opeen whital fissures, a section which shomld perhaps form a new gems and be transferred to the Maidare.

## Prionorhynchus edwardsii Jaçuinot and Lne:as.

Upper surface coansely and domsely gramons and rlosely set with short, coarse hairs. Dimensions in millimeters: Langth, 107; wioth, including teeth, 97 .

Anckland Island; Otago Vniversity Museum, Iunedin, New Zealand; one male (16297).

## Lissa chiragra (Filmicius).

Japan; Hl. Loomis; one female (162こ1).
This speries is distribnted thronghont the East Indies and the Indian Oce:m.

## Pericera Latreille (imended).

Latreille, Regne Anim. ( 2 l ed., IV, 1 . $5 \times$, 1829) ; tramslation m, p. 43, 1831. Milue Edwards, Hist. Nat. des Crust., I, p. 334, 1834. Dana, Crust U. N. Ex. Ex., I, p. 83, 18:2. Sanssure, Mém Sor. Phys. te Genève, Niv, p. 426, 1857 (partimı). A. Milne Edwards, Miss. Sci. au Mexique, pt. 5, I, p. 49, 1873. Mieris, Jour. Linn. Soc. London, XIV, p. 664. 1879; Challenger Rept., Zool., Xvir, 1. $76,1886$.
Carapace subpyriform, tuberrulated or spinose, with at series of lateral spines. Prieocular spine well developed. Spines of rostrum long and more or less divergent. Interorbital space broad. Basal joint of antemae very much enlarged, usmally with two small distant spimes at its distal end, not visible from above; sometimes, however,
the spine at the antero-external angle is long and visible from above. Anterior legs long, palm slender and elongated, fingers slightly or not at all gaping.

## Pericera cormuta (Herbst).

Cancer cormudo Herbst, Natur. der Krabhen m. Kirehse, nif, pt. 4, p. 6, p1. L1x, fig. 6, 1804. Maít turres Lamarek, Hist des Anim. sans Vert, r', p. 242, 1818.

## A. Milne Edwards records this species as far sonth as Bahia. <br> Pericera cornuta cælata (A. Milne Edwards).

Pericera calutu A. Milne Edwards (Bull. Soc. Philom., Jme, 1878, p. 5) ; Miss. Sci. au Mexique, pt. 5, ı, p. 200, pl. xv A, fig. 3, 1879; Bull. Mıs. Comp. Zoul., vin, p. 1, 1880. Mirrs, Challenger Rept., Zool., Xvir, p. 76, 1886.
Periccra corunta (?) and Pericera, sp., Kenlall, Bull. U. S. Fish Coumission, w, p. 303, 1889 (1891).
A comparison of a series of specimens from different localities seems to indicate that Pericere celate $A$. Milne Edwards is only a variety of $P$. cormutu (Herbst), as Miers has suggested (loc. cit.). A: Milne Edwards says of cormeta that the rostral horns are shorter, the interorbital space narrower and the carapace smoother than in crelutu. In this collection there are specimens of typical comutu, and a large series of specimens with prominent tnbercles on the carapace, in many cases more spiny than in A . Milne Edwards's creluta. In a specimen from the Gulf of Mexico (?), the carapace is smooth, and the rostral horns longer than in any specimen with tuberculons carapace; distally the horns are somewhat convergent. In another smooth specimen, from St. Thomas, the rostral homs are shorter than in many tuberenlons specimens,
and do not converge. The comparative length of the rostrim in the two forms is, therefore, mot constant. Most of the tuberculons finms have more divergent horns and greater interorbital breadth, but a specimen from Pensacola offers an exception to this rule, having horns no more divergent and a frontal breadth no greater than in the typical cormuta. There is then no additional character by which the tubereulous forms can be separated from the smooth. A. Milne Edwards's specimen was 36 millimeters long, including the rostrum. We have specimens of the same size which agree well with his description and figure; but larger specimens differ in having a number of the tubercles spiny; in all cases, however, the tubereles are disposed as in the typical cornuta.
In the collection of the museum, $P$. cornuth cerlatn ranges from 21 to 30 fathoms in the Gulf of Mexico and Caribbean Seal (A. Milne Edwards records it from 175 fathoms); while cormuta is found in shallower water.
The young specimens of both varicties it is almost impossible to separate, and moder the supposition that the variation in the adults is the result of the different range in depth, I propose to make the deep water form a subspecies of cormuta as the best arrangement that can be made with our present knowledge.
Length of largest specimen, from tip of rostrum to tip of posterior spine, 91 ; width, including spines, abont 65 ; width, without spines, 47.5 ; length of rost:um, abont 30 ; length of cheliped, 87 millimeters.

## Plate xxxir, fig. 1.

Carapace triangular-ovate, covered with a short, close pubescence. Median spines nine; form on the gastric region, of which the one next the posterior is the longest; our, tubermlons, on the genital region; two on the cardiac, the anterior one the longest of the median spines; and two on the intestinal, the last one projectiug almost horizontally over the posterior margin. There are two long spines arranget lengthwise through the center of each branchial region, the anterior one being much nearer the median line. A little farther forward on the branchial region, and in a transverse line with the posterior gastric spine, there is a tubertle. On the branchial there is also a tubercle just above the margin midway between the first and serond lateral spines; and a line of three faint tubercles, almost parallel with the antero-lateral margin and between the margin and the dorsal bramchial spines. There is a small tubercle on the hepatic region, and a spiny tubercle on the anterion part of each gastric region, almost in line with the first median spine.

Rostral horns straight, widely divergent, with fine hairs on the margins. Preorular spine long, acuminate, strongly upturned; postocular sharp; sinhs wide.

Antero-lateral magin slightly convex, amed with three triangular acute spines: one on the hepatic region; one at the lateral angle of the carapare pointing outward and harkward; the other half way between, almost parallel with the hepatic spine. From the last lateral spine to the last median spine the margin is marked by an almost straight rirlge.

Basal joint of the external antemna with a short tooth at its anteroexternal angle, and a tubrele at the insertion of the next joint. Remaining joints with a few long marginal ciliar. Antenna a little longer than the rostrmm and inserter molerueath it.

Ablomen of immature female with an uneven carina throngh the renter, cansed by a tuberele on each segment.

Chelipeds no longer than first pair of ambulatory legs, slender. Merus tuberculons above; ham long, slender, somewhat compressed, slightly tapering. The chelipeds, with the exerption of the hames ant fingers, and the ambulatory legs, are clothed with a sott, thitk pubescence.

Entire length, 18.7 ; width, inclurling second lateral spines, 13.2 ; width withont spines, 10.2 ; width between tips of postocular spines, 8.3 . millimeters.

A single sperimen was dredged in the (iulf of ('alifornia, lat. $23^{\circ} 28^{\prime}$ N., long. $11 \because 004^{\prime} 30^{\prime \prime} W^{+} .29$ fathoms, gray sand, temperature $62.9^{\circ}$, station 3014, 1859 (160166).

## Pericera atlantica, sp. мov.

Ievicert, sp.. Smith. Rept. U: S. Commr: of Fisheries for 188: (1887), p. 627:
Carapred oblong-ovate; spines of the dorsal surface and margin in number and position corresponding to those of triangulutu; but the spines are shorter and weaker, the two dorsal branchial spines are arranged more longitudinally, and there is no tubercle on the hepatic region and none on the branchial region above the margin. Width of front greater than in trianguluta. In addition to the close pubeseence of the surface, the carapace is eovered with long' "urved hairs. Color in alcohol very light, while trinntulaten is a reddish brown. In other respects this species agrees with trimgulate, of which it appears to be the Atlantic analogne. It resembles in form speeimens of $P$. comute of equal size, but the series of dorsal spines, the wider orbital fissures and shorter rostrum separate it from that species.

Entire length, 17; width, including second-lateral spines, 12.3; width without spines, 10.3 : width between tips of postornlar spines, 9 millimeters.

The above description is made from a young female collected off Key West, Florida, lat. $24025^{\prime} 45^{\prime \prime}$ N., long. $81046^{\prime}$ W., 45 fath., coral, temperature $75^{\circ}$, station 2318, by the U. S. Fish Commission in 1885 (15142). A smaller female was eolleeted in lat. $35^{\circ} 10^{\prime} 40^{\prime \prime}$ N., long. $75^{\circ}$ $06^{\prime} 10^{\prime \prime}$ W., 68 fath., gray mud, temperature 71.30, station 2268, 1884 (7220).

Two very small specimens from the Gulf of Mexico, lat. $29027^{\prime \prime} 30^{\prime \prime}$ N., long. $87^{\circ} 48^{\prime} 30^{\prime \prime} \mathrm{W}$., 30 fath., coarse sand, blark specks, shells, station 2390 , U. S. Fish Commission, 1885 (16044) have been doubtfully referred to this species. They have the form and orbits of atlunticu, but are too small for exart iletermination.

Pericera contigua, sp. nor.
Plate xxmit fig. 2.
Carapace oblong-ovate, narrower at the orbits than posteriorly; pribescent; armed with three lateral spines: one on the hepatic, one a little above the margin at the postero-lateral angle of the carapace, and the other, the longest, situated halfway between the two.

Protuberances of the dorsal surface arranged as follows: Three spiny tuberces in a triangle on the gastrie, the posterior one on the median line most prominent. On each branchial region a spine in a transverse line with the posterior border of the gastric; another spine midway between this and the lateral epibranchial spine; a spiny tubercle close to the posterior-lateral border of the cardiae region; behind the last a rounded tubercle near the posterior margin; and a spiny tubercle on the anterior portion. On the intestinal region, a spiny tubercle, and
behind it another directed mpard just over the posterior margin. The cardiac region has a spine at its summit.

Rostrum slightly deflexed, abont one-fifth of the entire length of the carapace. Horns somewhat scythe-shaped, thick, regularly tapering, acuminate; convex to each other, separated at base by a slight cavity, then curving inward and in contact for abont two-fifths of their length, finally diverging. Præocular spine prominent, long pointed; postocular acute. Basal joint of antenna broad, armed with one long triangular spine, parallel with the pracocular spine and visible in a dorsal view.

Pterygostomian regions pubescent, with a few tubercles. Abdomen carinated.

Chelipeds sleuder, pubescent, a little longer than the first pair of ambulatory legs; merus with an irregular spiny ridge above; hands tapering; fingers slender, in contact for nearly their whole length. Ambulatory legs stout, very pubescent.

In spite of the long spine of the basal antennal joint, I have placed this species in the genus Pericern, because it has the orbits of Pericera and the lateral row of spines. The prominence of the antemnal spine can hardly be said to be a character sufficient to distinguish Pericera and Macrocoloma, as there is at least one species of Macrocoloma in which it is not visible from above, M. diplucuntlu Stimpson. Besides this character, contigua can readily be separated from the other known speries of I'ericera by the peculiar rostrum.

Length including rostrum, 2 Z ; widith withont spines, 16.3 ; width with spines, 21 ; width between tips of postocular spines, 14 millimeters.

One female from the Gulf of Califormia, lat. $25^{\circ} 02^{\prime} 45^{\prime \prime}$ N., long. $110^{\circ}$ $43^{\prime} 30^{\prime \prime}$ W., 21 fathoms, saud, shells, coralline, station 3005, U. S. Fish Comm., 1889 (16067), ant two males from lat. $31^{\circ} 21^{\prime} \mathrm{N} .$, long. $113^{\circ} 49^{\prime}$ W., 11 fathoms, sand, broken shells, gravel, temperature $67 \circ$, station $30 \simeq 4$ (16975).

## Picroceroides tubularis Miers.

$$
\text { (hallenger Rept., Zool., xvif, l. 77, 11. x, fig. 1, } 1886 .
$$

In one male the rostral horns and proocular spines are longer than in the specimen figured by Miers. The largest specimen, a female, measures 20.5 millimeters in length from the base of the horns and 13.5 millimeters in width at the branchial regions. Collected off Havana, Cuba, lat. $23^{\circ} 10^{\prime} 25^{\prime \prime}$ N., long. $82020^{\prime} 24^{\prime \prime}$ W., 33 fathoms, station 2324, coral, temperature $79.1^{\circ}$; by the U. S. Fish Commission steamer Albutross, 1885 (9495); also at station 2138, 1884, lat. $16044^{\prime}(0 .)^{\prime \prime} \mathrm{N}$. , long. $75^{\circ} 39^{\prime}$ W., 23 fathoms, coral, broken shells (6928).

This species was collected on the coast of Brazil by the Chullenger.

## Macrocoeloma trispinosa (Latreille).

Pisa trispinosa (Latreille, Eucycl. Méth. Hist. Nat., x, p. 142, 1825).
Pericera trispinoxa Guérin, Icon. des Crust., pl. 8, fig. 3. Milne Ellwards, Hist. Nat. des Crust., 1, p. 336, 1834. Saussure, Mém. Soc. Phys. de Genìve, xrr, p. t26, 1857. Martens, Arehiv. fiir Natur., Xxxyii, p. 84, pl. iv, figs. ta, H1, 1872. A. M. Edwards, Miss. Sci. au Mexique, pt. 5, i, p. $\mathrm{n}^{2}$, pl. x', fig. 2, 1873, and synonymy; Bull. Mus. Comp. Zool., viri, p. 1, 1880. Aurivillins, K. Sv. Vet.-Akad. Hand., Bıl. 23, 1, p. 55, pl. 2, tig. 2, 1889. Ives, Proc. Acad. Nat. Sci. Plilit.. p. 178, 1891.

Macrocceloma trispinosa Miers, Jour. Linn. Soc. London, xiv, p. 665̈, 1879; Challenger Rept., Zool., xvir, pp. 79, 80, 1886.
In most of our specimens of this variable speeies the rostral horns are parallel and deflexed for two-thirds of their length, and then become divergent and upturned. In an individnal from Fermandode Noronha, the four lobes at the summit of the carapace are very distinct aud defined by deep depressions.

IEECORD OF SPECLMENS EXAMINED.

## Plate xxxir, fir. 2.

Pericera cumptocera stimpson, Bull. Mus. Comp. Zool., n, p. 112, 1870. A. M. Edwards, Miss. S'i. au Mexique, pt. 5, t, p. 57, 1873.
Macrocalomat camptocera Miers, Challenger Rept., Zool., xvit, pp. 79, 80, 1886.
This species is distinct from trispinosu, as in a series from eight localities most of the differeuses pointed out by Stimpson hold good. The rostrim, however, though nsually longer than in the specimens of trispinost examined, varies in length, being from more than one-half to less than one-third the length of the post-frontal pertion of the carapace.

The difference in the size of the antemie, noted by Stimpson, is not constant, but varies with the specimen. The four spines of the dorsal surface are situated on the cardiac, gastric, and at the inner angle of the branchial region. In addition to the close pubescence of the carapace, the front, the gastric region and the lateral portions of the branchial region are clothed with long hairs eurved at the extremities. The lateral and posterior spines are longer, more slender and upturned than in trispinosa.
Total length of large male, 37 millimeters; total width, 29.5 millimeters.

Macrocœeloma eutheca (Stimpson).
Pericera eutheca Stimpson, Bull. Mus. Comp. Zool., if, p. 112, 1870. A. Milne Edwards, Miss. Sci. an Mexique, pt. 5, 1, pp. 58, 200, pl. xv A, lig. 1, 1873. Anrivillius, K. Sv. Vet.-Akad. Hand.. Bıl. 23, 1. p. 55, pl. 2, fig. 1, 1889.
Macrocoloma cutheca Miers. Challenger Rept., Zool., xvir, pp, 80, 82, 1886.
To this species I have referred an adult male from off Havana, lat. 230 $10^{\prime} 51^{\prime \prime}$ N., long. se $s^{\circ} 199^{\prime} 03^{\prime \prime}$ W., 163 fath., white and brown corat, station 2323, U. S. Fish Commission, 1885 (942); akso a young male from near Aspinwall, lat. $903 y^{\prime}$ N., long. 790 o4' $30^{\prime \prime}$ W., 34 fath., broken shells, station 2144,1884 ( 7780 ) ; and a young femate from lat. $23^{\circ} 10^{\prime} 36^{\prime \prime}$

The adult male differs from Stimpson's description in its slightly narrower carapace, longer rostrun with divergent horns, and in the presence of tubercles insteal of spines on the gastric region. A. Milue Edwards figmes, without remark, a specimen which he calks enthecu, although it is much narrower than the one in fuestion, the posterior half of the carapace is moch rommed, and the rostral homs are separated by a trianguar interspace.

The specimen moder examination has the carapace very much marrower posteriorly than in II. comcara Miars (Op. cit., p. S1, pl. x, fig. 2),
from which it differs also in the protuberances of fhe carapace. In its proportion it approaches nearer the figme wiven ly Amrivillius (loc. cit.). A datailed description of the individual is given below, as a series may in the futme connect these two species. The two small specimens in the collertion offer no essential differences.

Carapace with a scattered pubescence, subtrapezoidal. concave at the hepatic region; outline of branchial region rombled. The protuberances of the carapace are as follows: three tubereles forming a triangle on the gastric region, the posterior one large and on the median line, the other two inconspicuous; a spiny tubercle on the cardiac region; another longer on the intestinal; on the branchial regiou, a prominent slender spine just above the margin aud behind the broadest part of the carapace; above this spine another very small; on the lateral margin an irregular row of suall spines and spiny tubereles, one on the hepatic and about five on the branchial, the one next to the last being the longest, but only two-thirds as long as the epibranchial spine: a branch of this marginal row is rontinued on the pterygostomian region, which is covered with small tubereles.

Rostrum thin, almost straight; horns separated by a triangulate space; their distal half slemer, acmminate; proximal half broad, subtriangular, with convex onter margin.

Orbital sheaths long, prominent. Distance between the tips of the postocular spines a little greater than the width of the carapace at the branchial regions axchnsive of spines. On the mper orbital margin there is a tooth above the postocular; aud a small spine on the lower margin. Basal joint of external antenne armed with two sharp spines.

Chelipeds morlerate. Merus tuberenlous, with a row of four small spines above. Hands long, compressed, fincly julsescent. Finger's arehed, partially gaping ; distal thim brown. First pair of ambulatory legs barely rearding the manns.

Entire length, ex ; length of rostrum, 6 ; width at the branchial regions, withont spines, 15.6 ; length of cheliped, 28 ; length of first ambulatory leg, 20 millimeters.

1I. ruthece has been collected at the 'Tortugas, Florida Straits, 1: to 115 fathoms, siuta ('ru\%, besides other localities.

Macrocœloma tenuirostra. sp. nor.
Plate xximit, fig. I.
Car:apace much lomger than broad, subrectangular, slightly convex; finely pubescent. . Epibranchial spine short, slender; posterior margin with a slender upturned spine. Dorsal surface with a blunt median spine above the posterior margin; a tuberele oceupying the cardiac region; another far bark on the gastric region; remainder of the surface with small depressed tubereles, which on the antero-lateral margin form an indistinct row.

Rostrm very slender, more than half as long as the remainder of the carapace. Horms subcylindrical, tapering to a fine point; onter margin spinulose for its posterior half; a narrow interspace at hase; horms contignous for the middle third; slightly divergent at tips.

Orbits slightly projecting. Preocular and postocular teeth distinct, acute. Basal antemal joint with a short sipine at the antero-external angle, visible from above. There is a tooth at the insertion of the second joint, pointing downwarl; and an olotuse tooth on the onter margin. Remaining jonts very slender.
('helipeds long, slenter, pubescent except on the fingers. Merns and carpus tuberculate. Hand long, compressed, not dilaterl, gramlate. Fingers in male gaping at base; tips brown; a short broal tooth on the dactyl. Ambulatory legs very slender, pubescent. First pair much longer than the others. Dactyls spinulose beneath.

Length of carapace, including rostrum and posterior spine, 22 ; length of rostrum, 7.5 ; branchial width, ineluding spines, 10 ; withont spines, 8.5; width between tips of maocular teeth, 6 millimeters.

One individual, a male, was taken in the tangles, betwedn Jamaica and Hayti, lat. $17^{\circ} 44^{\prime} 05^{\prime \prime}$ N., long. $75039^{\prime}$ W., 23 fathoms, coral, broken shells, station 2138, 1884, U. S. Fish Commission (6929).

This species can not be confommerl with any other deseribed species of the genus, on arrount of its narrow, elongater carapace and slenter rostrum.

## Microphrys, sp.

Carapace broadly triangulate. Regions well defined, tuberculous. There is one sharp spine at the lateral angle of the carapace; a little nearer the median line are two spiny tubereles. Anterior portion of branchial region much swollen in an oblong tuberenlous lobe. There are small tubercles on the margin of the hepatic region and on the subbrauchial region.

Rostrim depressed, short, reaching to the middle of the thind joint of antemne. Horns narowly triangular, acute, separated by a narrow V-shaped notell. Præocular angle distinct.

Basal antennal joint with two marginal teeth separated by a narrow sims; the anterior tooth long, flat, procmed, subacute.

Cheliperls in young female weak, not mueh longer than first pair of ambulatory legs. Merus with four tubereles on upper margin; carpus tuberculous on outer surface; margins of hand subparallel; fingers evenly dentate, gaping at base.

Ambulatory legs with meral joints spinous above and tuberenlous on onter face; carpal joints with one spine above; propodal joints with a broad, rounded, lamelliform process for the articulation of the dactyl, as in platysoma.

Length, including rostrum, 12 millimeters; width, without spines, 9 millimeters.

Gulf of California, lat. $25^{\circ} 16^{\prime}$ N., long. $111^{\circ} .4^{\prime}$ W., 22 fathoms, fine gray sand, temperature $63^{\circ}$, station 3012, U. S. Fish Commission, 1889 (16374).

This species appears to be nearest to bicormutus. The species desoribed from the Paufic coast are so mmerous and the literature so inad-
equate that the writer, with only one immature specimen at hand, hesitates to give a name to a species perhaps already overburdened.

Othonia Therminieri (Schramm, Cmist. de la Cnadeloupe, pr, 20, 1867). A. Mihe Edwards, Miss Sci. au Mexique, pt. 5, 1, p. 116, pl. xxif, tig. 5, 1875.
Othonia aculeata Stimpson, Bull. Mns. Comp. Zool., i1, p. 116, 1870 (partim). Kingsley, Proc. Acad. Nat. Sci. Phila., xxxr, ]. 388, 1879 (partim).
Othonia anisodon Martens, Archiv. fiir Natur., p. 83, pl. 1v, fig. 3, 1872.
An examination of numerons lots of this species proves it to be very distinct fiom $O$. aculentu (Gibbes), with which it has been confonnded by some anthors.

The front is much narrower than in aculeatu, rostrmu more advanced and less deflexed. In aculcutu a groove runs from the tip of the inner upper angle of the orbit along the margin of the front to the base of the rostrum. This groove is very slight in therminieri. Orbital angles less produced and less conspicnons in herminieri. In both species the basal article of the external antenna has the anterior margin more or less dentate. Second article, in lherminieri, with an external lobe which is shorter than in cuculeutu and directed forward rather than ontward. Antero-lateral teeth sharp, while in aculeuta they are obtuse.

Appendages of the male abdomen with the distal third of a light brown color, and gradually tapering; and arranged in the form of a lyre, widely spreading at the tips (l'l. xxxiv, fig. 4). In aculente, the appendages are bown for ahont the distal half, the brown parts in con-
tact for one-half their length, diverging at the extremities in slight curves convex to each other, each appendage terminating in a rightangled hook, the point of which is directed toward the median line of the carapace (Pl. xxxiv, fig. 2).
The chelipeds are variable, in full grown males usnally slender, shorter than the first pair of ambulatory legs and not much stronger than in the female; but in five out of fifteen large males the chelipeds are from one and a half times to nearly twice as long as the carapace, and are of the same character as in aculeata. The palms are, however, longer and narrower, and the merns more cylindrical and less angled than in Iculenta, in which species the merus has three depressel tubercles on the upper margin. The two species agree in the widely gaping fingers of the male, with a tooth near the base of the dactyl, and in the short, weak chelipeds of the female, with fingers evenly dentate and in contact.

The carpal joints of the ambulatory legs are longer and more slender than in aculeata, and have a shallow groove on the outer surface which in aculeata is broad and deep, leaving a conspicuons ridge on either side.

The carapace of therminieri is smoother and more pubescent; that of aculeata more tuberculous; a character most noticeable in very young specimens.

On the west coast of Florida where lherminieri is abmondant, aculenta rarely oceurs, but one suall specimen in the Union College collection representing that region.
O. Therminieri has been recorded from Guadalonpe and Cuba.

Othonia carolinensis, sp. nov.
Plate xxxy, figs. 1 and 2.
The following description is based on two imperfect male specimens collected off Charleston, S. C., by Mr. R. E. Earll, U. S. Fish Commission, 1880:
Garapace nearly as broad as long, tapering posteriorly, broadest at the third antero-lateral tooth; regions well defined. Width of front intermediate between that of aculentu and lherminieri. Carapace with
scattered tubercles, six or eight on the branchial region, four or tive on the mesogastrie, two or three on the gastric, and a row near the posterior margin. The rostrim and the inner and onter orbital angles are about equally advanced. Orbital angles acute.

Antero-lateral teeth five, the first three prominent, acnte, the fourth smaller, the fifth almost obsolete. Sinns between the second and third not so deep as between the first and serond, making a partial roalescence of the second and third teeth, which, however, is very slight as compared with the coalescence of the same teeth in renleata and therminieri, where the seroud troth is much more feebie than the first and third.

Basal article of the antemat with a shallow emargination on its anterior border outside the insartion of the second article, which is narrower than in therminieri, the onter lobe prodnced forward but little beyond the inner lobe. Remaining artirles wanting in our specimens.

Appendages of the male abdomen in contact at abont three-fitths of the distance from the distal end, then separating slightly in faint curves concave to each other, and again converging before they finally spread out at the tips. Distal three-fifths yellow, very slender, tapering gradnally to a fine point (pl. xxxy, fig. 2).
('helipeds small, longer than the first pair of ambulatory legs. Merus somewhat angled, unamed. P'alms abont ome and a half times as long' as broar, tapering slightly toward the distal end. Fingers with distal half minutely dentate and in contact; proximal ends gaping, a slight tooth at the base of the dactyl. Ambulatorv legs short, sparsely hairy, a longitudinal depression on the carpal joints as in aculeata.

Length, 14.2 millimeters; width, 14 millimeters; width of front, s .7 millimeters.

Near C'harleston Harbor, 1 to 12 fathoms (3158).
Blackfish l3ank, off Charleston, 12 fathoms, from stomach of fish (5755).
An egg-bearing female from Jamaica, T. H. Morgan, 1891, has been doubtfully referred to this species. The carapace is wider posteriorly and narrower in the center, sparsely pubescent. The basal intennal joint is dentate on its anterior margin.

Othonia nicholsi, sle nov
Plate xxxv, fig. 3.
Carapace oblong, outline of anterior portion much as in aculeata, broader posteriorly. Carapace with strongly marked tubereles of which the larger are arranged as follows: Two on the median line of the mesogastric, the anterior one the smaller; two transversely on the anterior part of the carrlar: region; three or fomr on each branchial region, where they have a tendency to become spiny. Oi smaller tubercles, there is one on mach gastris lobe, two transversely at the Proc. N. M. $92-17$
posterior end of the mesogastric, one on the anterior edge of the cardiac. There is a loug line of stout granules a little above the posterior margin; a shorter line of granules behind this; a curved liue of four granules just back of the middle of the cardiae region, arranged concave to the posterior margin; and two lines of granules on the posterior half of the branchial region, one following the general direction of the posterior margin, the other shorter, along the inner boundary of the branchial region and meeting the first line at an acute angle. There are other granules scattered on the carapace, but no conspicnous protuberances on the hepatic region.

Lobes of the rostrum acute, emarginate on their imer margins near the tips. Orbital angles sharp, the inner one produced in a line with the tip of the rostrum, the onter angle less produced.

Antero-lateral teeth five, irregular, the second small and somewhat coalesced with the third at its base. Carapace broadest at the fourth tooth. Fifth tooth small.

Basal joint of antema with its anterior margin cut into three inregular teeth. Second joint with the lobe at its outer angle projecting laterally, but not so long as in uculeata.

Meral joint of outer maxillipeds longer than broad; antero-external angle produced; no perceptible noteh at internal angle.

Chelipeds in the young female slender, no longer than the first pair of ambulatory legs. Merus somewhat angled; carpus compressed; upper and lower margins of hand subparallel; fiugers finely dentate, with a narrow hiatus at their base.

Ambnlatory legs with a fine scattered pubescence. Carpal joints distended as in aculeata with an meven ridge above and a longitndinal depression on the onter face.

Length from tip of rostrum, 9 millimeters; greatest width, 8.5 millimeters.

Collected in the Gulf of California, lat. $29^{\circ} 30^{\prime}$ N., long. $112^{\circ} 40^{\prime} \mathrm{W} .$, 45 fath., by Lieut. Commander H. E. Nichols, U. S. Navy, 1880-1882 (15822) ; specimen imperfect, dried.

This species (an hardly be identical with $O$. picteti Saussure (Rev. et Mag. de Zoül. (2), v, p. 3.57, pl. 13, fig. 2, 1S53) as the carapace is broader posteriorly, the tubercles are differently disposed, the front is broader, and the orbital angles more prodnced than in Saussure's figure.

Othonia rotunda, sp. now.
Plate xixim, tig. 1.
Carapace as broad as long, widest at the fourth antero-lateral teeth, much swollen in both dircetions, transversely rising abruptly from the bases of the antero-lateral teeth, longitudinally rising in almost an equal curve from behind the front and from the posterior margin. Regions tantly indicated. Gamabe covered with gramules which are more thickly set on the posterior half. Long the hairs proreed from
the top of the granules. Along the outer margins of the gastric lobes, bunches of granules beset with coarse hairs form a broad line which is continued to the rostrum. Rostral teeth sharp, produced beyond the orbital angles. Preorbital angle obtuse, less produced thau the postorbital, which is subacute.

Antero-lateral teeth usually five in number (in one specincu four), acute, separated to their bases, the first the largest, the others as a rule decreasing regularly in size to the posterior, the tips of the five teeth making a single curve. In the largest specimen, however, the third twoth on one side is mnch smaller than the fourth; the third tooth on the other side is broken, but, judging from the base, it was intermediate in size between the second and formth. Anterior margins of teeth thickened. Antero-lateral margin marked by inconspicnous grames irregularly placed, giving the teeth the appearance of being themselve's minutely dentate.

Basal article of the antenna with a sharp longitudinal groove through the middle. Tooth at distal extremity slightly more prooluced than the superior inner angle of the orbit, and visible in a dorsal view. Second article broad, with the outer lobe directed forvard, and slightly thickened on the outer and anterior margins. Third article as broad as long.
Surface of the abdomen and the sternum minutely pubesceat. Appendages of male abdomen diverging slightly at the distal ends, hooked at the tips.

Chelipeds in both sexes, slender, longer than the ambulatory legs, covered with fine punctures, upper margin with thinly seattered hairs. Merus angled, a few small tubercles on the upper margin. Mamis very slightly tapering toward the distal end. Fingers in the male gaping for the proximal third, with a tooth on the dactyl; in the female, evenly dentate and in contact for nearly their whole length, a slight gape at the proximal end. Ambulatory legs very hairy above, first pair reaching to about the middle of the manns.

Length aul width of "large female, 17.5 millimeters; width of front, 9.8 millimeters. Length and width of largest male, 14 millimeters; width of front, 8.5 millimeters.
Teu specimens were collected at Key West, Fla., by Henry Hemphill, 1885 (15807), and one female at the same locality, by the U.S. Fish Commissiou in 1884 (16298).

## Subfamily Mithracine.

## Mithrax (Nemausa) spinipes (Bell).

Pisa spinipes Bell, Trans. Zoïl. Sor., London, If, 1. 50, pl. ix, tig. 6, 1833 .
Nemaust spinipes A. Milne Elwards, Miss. Sci. an Mexique, pit. 5, i, p. 8", 1875.
Miers, Jour. Limn. Soe., London, xiv. J. 666, 1879.
Mithras (Nemanst) spinipes Miers, ('hallenger Rept. Zoïl., x'it, p. אi.t, 18*it.
A single male from the Gulf of California, has been refered to this species. It is a smaller specimen than the one figmed by Bell (loc. cit.)
and differs in some respects. The original description says that there are seven or eight lateral spines (A. Mihe Edwards says six or seven), and in the figure there are six besides the postorbital. In our speecimen there are fire besides the postorbital, the fourth being the longest and defining the lateral angle of the carapace, the fifth shorter than the others and elevated a little on the branchial region.
The gramules of the anterior two-thirds of the carapace are very inconspicuous. There are two large grannles on the median line of the cardiac region, five or six granules on the posterior half of the branchial region, and a conspicnons row of four spiny gramules on the intestinal region, making a curve concave to the posterior margin. The two teeth on the upper margin of the orbit are minutely serrate. The orbital simuses are deeper than in other species of Mithrox.
Spine at antero-external angle of basal antennal joint about half as long as the rostrum; remaining tooth spiniform.

Chelipeds in our specimens shorter than the first pair of ambulatory legs. Merus spiny, bearing on the anterior part of its npper margin one or two spineslongerand more slender than the rest. Carpus tubercinlons, some of the tubercles spiny. Hands slender, smooth. Fingers spoon-shaped, finely dentate, when closed showing but a faint hiatus.

Ambulatory legs pubescent, third and fourth joints with long spines above, third joint with small spines below.

Length from hase of rostral horns, 11 millimeters; width, without spines, 8.2 millimeters.
Lat. $24^{\circ} 55^{\prime} 15^{\prime \prime}$ N., long. $110^{\circ} 39^{\prime} \mathrm{W}$., 33 fathoms, fine gray sand, broken shells, temperature 64.50, station 3001, U. S. Fish Commission, 1889 (16064).

Bell records this species from the Galapagos Islands, 16 fathoms, and St. Elena, ${ }^{6}$ fathoms.

## Mithrax (Nemausa) acuticormis (Stimpsou).

Plate xaxiil, fig. 1.
Mithrax acuticornis stimpson, Bull. Mus. Comp. Zö̈l., If, p. 116, 1870. A. Milne Edwards, Miss. Sci. an Mexirne, pt. 5, 1, p. 98, 187.. Miers, Challenger Rept., Zö̈l., x'11, pp, 86, 88, 1886.
Mithrax (?) sp., Kendall, Bull. U. S. Fish Commission, IX, 1. 303, 1889 (1891).
Stimpsol says, "The margin of the orbit is armed with six spiniform teeth, not including those of the antemal joint." In some of the specimens examined the tooth on the inferior margin of the orbit next to the basal antennal joint is obliterated, leaving only five orbital teeth; three on the superior margin, one at the external angle, and one on the inferior margin.

The fothowing are the dimensions of three sperinens, the length measured from the base of the rostrum, and the wilth, not including thespines. No. 1 . Length 13; width 10 millimeters; ratio $1: .7$. No. 2.

Length 11 ; width 9 millimeters; ratio 1 :.S. No. N. Sength 10.r): width 9 millimeters; ratio 1 :. . 86.

The color in alcohol is a cimanom brown; fingers of a pinkish tinge.
I think this species is not the yomg form of $M$. cornutus. Sanssme.
In large specimens of cormutus, according to A. Milne Edwards, the length is only a trifle greater than the width; while in our series of ucuticomis, the larger the specimen the narower the carapace. In acuticornis the preocular spine is proportionally shorter and the antennal spine longer than in Milne Edwards's figure of cormutus. In the twenty-two specimens examined there is no trace of spines on the manns.

The young Mi.hrox enumerated by Mr. W. C. Kendall (loc. cit.) in his list of Brachyura collected by the schooner Grampus: on the fishing grounds off the west coast of Florida, undonbtedly belongs to this speries.

Mithrax pilosus, sp. nov.

## Plate xxin.

Carapare ovate-orbicular; width, without spines, less than the length. Postero-lateral margin rather long for the genus. Entire upper surface of the crab except the fingers, the proximal half of the manns, and the horny tips of the dactyls of the ambulatory legs closely covered with velvety hairs, which are present also on all the spines. Carapace furnished with spinose tubercles as follows: Three, small, arranged longitudinally each side of the median line just behind the rostrum; four transversely on the gastrie region in two distant pairs; one further back on the median line of the gastric; three forming a triangle on the cardiac; nine or ten scattered on each loranchal region; four in an areuate row above the posterior margin.

Rostrmm composed of two spines strongly incurved at the tips; interspace U-shaped. Preocular spine distinct, upturned.

Lateral spines five, stont, triangular, tipsliooked forward. The fifth of the series is on the postero-lateral margin. Farther back is a very small spine. There is also a small spine between the first and second lateral and the secoud and third lateral. There are three small tubercles on the posterior margin.

Basal antemal joint hoad. Spine at the antero-external angle about as long as the rostrum, hut not so much advanced, directed ontward; tip turned inward. Farther back on the outer margin there is a sharp triangular tooth, and another at the insertion of the second joint. Flagellum rather long. There is a triangular tooth on the lower orbital border next the postocular tooth. Lower surface of the crab eovered with a short pubescence.

Cheliperls a little shorter than the next pair of legs, not enlarged. Merus and carpus spiny above, the merus widening at the proximal end, the spines forming a crest on the distal half. Hand compressed, tapering sliglitly towards the fingers, spinose on the upper surface near the base, a character mesent in both sexes. Fingers slightly gaping at base. Ambulatory legs very stout. Heral and earpal joints with two rows of spines above; earpal joints with one or two additional spines. I'ropodal joints short, broadly cylindrical; those of the first three pairs of legs with one or more spinose tubercles. Dactyls broad at the articulation, tapering abruptly to the curved horny tip.

When the hairs are removen, the surface is iperkled with small pmeple spots.

Length of carapace, with rostrum, 28 ; width, with spines, 30 ; without spines, 24 ; length of "helipel, about 26 millimeters.
Three males and one young female were collecterl at Abaco, Bahamas, by the U. S. Fish Commission steamer Albatross, 1886 (16299).

This species is very distinct from any hitherto described. Like spinosissimus, uculeatus, and cormutus, it has spines on the manns, but it is realily distinguished from these speries by the stont lateral spines, the dense prbescence, and the short legs.

Mithrax hemphilli, sp. now.
Plate xxxtif, fig. 2.
Carapace oblong-trimgular, covered with strong tubereles and granules. Regions distinct. The largest tubereles are arranged as follows: One on either side of the median line on the fiontal region; a transverse row of fom on the gastric; two on the median line of the mesogastric, the posterion one being the larger; one on the genital region; a line of three arross the cardiac forming a transverse curve concave to the front; behind these, one on the median line; about seren strong tubercles on the lymelial region, those most posterion being spinons; fow spinous tulberes on the intestinal region forming a transrerse cmive concalve to the posterior margin. The two tubercles at the extremities of this curve are contimuons with a line of granules which border the posteriour margin. The two central protuberances of the marginal line are small tubercles. Besides the strong tubereles of the earapace, there are numerons smaller tubercles and granules, seattered or elustered abont the larger tubercles. There is a row of granules just within and parallel to the posterior margin of the mesogastric region.
Rostrum rather long for the grnus, but not so long as in ceuticornis, divided by a $U$-shaped sinns, each horn bearing two or three minute denticles on its outer margin near the tip. Prepocular tooth long, acuminate. The two simuses of the npper orbital margin small, V-shaped.

Antero-lateral teetl four, stont, conical, pointed, and so embossed with granules about their sides that their margins have more or less the appearance of being denticulate. There is a spiny tubercle in the simus between the second and third teeth, also a spine near the margin of the branchial region just back of the last anterolateral tooth, which forms the angle of the carapace.
The basal joint of the antenea is armed with form spines and teeth. There is a long slender spine at the anterior outer angle, and farther back a broad triangular tooth which forms part of the orbital margin. At the base of the movable joint is a prominent spiniform tooth, visibe in a dorsal view. Just below the simus between the two marginal teeth is another small tonth, whieh, with the one at the base of the
movable joint, forms part of a row of six teeth ending at the subhepatic region. There are several irregular rows of tubercles leneath the lateral teeth of the carapace.

Chelipeds slightly longer than the first pair of ambulatory legs. Merus with spinous margins, a ridge of strong spines above, and tubercles on the inner and outer faces. Carpus covered with tubereles, some of which are spiny. Hands smooth, upper and lower margins nearly parallel. Fingers finely dentate, showing when closed only a slight hiatus at the base.

A mbulatory legs pubescent, with the meral and carpal joints flattened above, both margins of the upper faces with strong spines. Lower margins with a few small spines. Propodal joints with a few weak spines above.
Length, from base of horns, 15.5 millimeters: width, exclusive of spines, 13.5 millimeters; proportion, 1: . 871 .

Indian Key, Fla.; H. Hemphill, 1885 (15823); one immature female.
A somewhat worn specimen of a male not differing essentially from the above description was collected at Rio Formoso, Pernambuco. Brazil, by R. Rathbun, 1875-1877.

## Mithrax aculeatus (Herbst).

Cancer aculeatus Herbst, Natur. der Krahhen und Krebse, 1, p. 248, pl. xix, fig. 104, 1782.

Mithrax aculeatus Milne Edwards, Mag. de Zonl., ir, $18: 32$; Hist. Nat. des Crust., I, p. 321, 1834 ; (Atlas du Règne Animal de Cuvier, pl. 27, fig. 1). White, Cat. Brit. Mus. Crust., p. 6, 1847. Stimpson, Amer. Jour. Sci., NXIX, p. 132, 1860; Ann. Lye, Nat. Hist. N. Y., VII, p. 188, 1860. (Desbome amd Schramm, Crust. de la Guadelouje, p. 5, 1867.) Martens, Arch. fiir Natur., xxxvir, p. 81, 1872. A. Milne Edwards, Miss. Sci. an Mexigue, pt. 5, I, p. 102, 1875. Miers, Challenger Rept., Zool. Xvir, 1. 86, 1886. Aurivillins, K. Sr. Vet.-Akad. Hand.. Bd. 23. 1, p. 56, 1889 .

There are no specimens of large size in the collection. In individuals one and a half inches long the rostrum is no longer than in specimens of verrucosus of the same size.

Mithrax pleuracouthus Stimpson, loc. cit. A. Milne Edwards, op. cit., p. 95, pl. xx, fig. 3. Kingsley, loc. cit. Aurivillins, K. Sv. Tet.-Akad. Hand., Bd. 23, 1, 1. 58, 1889.

Mithrax hispidns var. plewacauthus Miers, op. cit., p. 88.
A comparison of a number of small specimens from many different localities leads me to believe that the pleuracunthus of Stimpson is not eveu a variety, but merely the youmg form of hispidus. As a rule, the smaller the specimen the more tuberenlons the carapace, the sharper the teeth or spines of the orbit and basal joint of the antemna, and the less evident are the punctures of the carapace. The specimens of medinm size show characters intermediate between these and the large or typical hispidus, so that there seems to be no line where a separation can be made into two distinct varieties. In many young specimens all the antero-lateral teeth except the last have a tendency to
become bhut, amd cach thoth comsists of a central spine or tooth with a cluster of tubereles surmuding it. One female, however, measuring 20 millimeters wide between the tips of the spines, has teeth even more slenter than in large specimens. The carpus in small specimens is more or less tubereulous.
Length of largest specimen from tip of rostrim, s6,in millimeters; width, including spines, 114 millimeters.

Bom Fim, Bahia, on stone reef.
Plataforma, Bahia.
Mithrax sinensis, sp . nov.
Plate xxxini, fig. .2.
Carapace ovate, a little longer than broad, covered with tubereles. A deep sulens divides the hepatic and branehial from the gastric and cardiac regions.

Front shaped much as in hispidus; rostrum consisting of two taberculiform and gramulate teeth separated by a romuded simus. Preocular angle obtnse; margin denticulate. Orbit with six teeth besides those of the antennal joint: three on the superior margin, one at the external angle, and two on the inferior margin.

Antero-lateral spines fone, tuberenliform, irregnlar in shape; the first most distinct aud suromuded by the tubereles of the hepatic region; the second and thirl each having on its anteriow margin a spiny tubercle almost as large as the tooth itself. Last tonth single.
Basal joint of the antenna with a spiniform tonth at the anteroextermal augle visible from above, and another farther back almost as large; also a smaller tooth at the insertion of the movable joint.

Chelipeds moderate. Merus tuberculons, armed with six spines on the outer margin, a row of smaller spines ou either side of the outer margin, and three spines on the inner margin. Carpus strongly tuberculons. Hand slightly compressed, smooth, marmed, showing seattered punctures under the lens. Fingers stont, prehensile edges cremulate, with a slight hiatus at the base. Ambulatory legs with fine seattered hairs; meral joints having two longitudinal rows of spines above; earpal and propodal joints with short spines above; dactyls spiny below.
Color in alcohol reddish; hands of a deeper hue.
Entire length, 9.2 millimeters; width, including tubercles, 8.9 millimeters.
Gulf of California, lat. $25^{\circ} 02^{\prime} 15^{\prime \prime}$ N., long. $110^{\circ} 43^{\prime} 30^{\prime \prime}$ W., 17 fathoms, sand, shells, station 3002, U. S. Fish Commission, 1889 (16065).
In general appearance this species most nearly resembles hispidus; the prominences of the dorsal surface, the shape of the front and preorbital tooth, are very much as in specimens of hispidus of the same size. In sinensis, however, the last antero-lateral tooth is not loug and conspicuous as in hispidus, and the lateral angle of the carapace is nct well defined.

## Mithrax bahamensis, sp. nov.

Plate xxxyin, fig. 1.
Carapace longer than broad, oblong-ovate, covered with a close, tough pubescence. There is a tuft of hair near the imer angle of the branchial region; another behind each gastric lobe; and a line of hair exteuding from the rostrum back upon the gastric. Gastric region elevated. Tubercles of the surface not prominent. There are two on the frontal region, one on each gastric lobe, five or six on each branchial region besides the marginal tubereles, and four in a curve concave to the posterior margin.

Front deflexed, composed of two sharp incurved homs; interspace broadly U-shaperd.

Antero-lateral margin with fom protuberances: one on the hepatic region, a spiny tubercle; three on the branchial region of which the first two are tubercles, the last a small spine.

Preocular spine annte, conspicuons; postocular subacute; two intervening teeth, small. There is a small suborbital tooth besides those of the basal joint.

Merns joint of exterior maxillipents deeply ant at the antero-internal angle.

Basal joint of antemna with a small tooth at the base of the movable joint. Spine at external angle, long, more advanced than the preocnlar spine, incurved. There is a smaller spine farther bark on the margin. Remaining joints long with long hairs on the margins.

There are two subhepatic tubercles, and an irregular longitudinal line of fom granules on the vertical face of the subbranchial region.

Chelipeds a little longer that the first pair of ambulatory legs, pubescent like the carapace. Upper margin of merns tuberenlons. Carpus with one or two faint tubercles on the posterior end of the upper surface. Manns in the male with upper and lower margins almost parallel, slightly contracted near the fingers. There is a small tooth at the base of the dactyl. Fingers gaping at base. Ambulatory legs with the joints flattened above; margins beset with long hairs.

Color in alcohol, reddish brown; chelipeds lighter. Fingers pinkish red for their proximal half; tips white.

Length of largest specimen 18.8 ; greatest width, 16.5 ; width at postocular teeth, 11.2 millimeters.

Found with Mithrax cinctimanus in sponges at Andros Island, Bahamas, by Mr. Frederick Stearns, 1888.

This species in its shape and antero-lateral teeth most nearly resembles cinctimamus, but it is more oblong, more convex, and is also readily distinguished by the absence of sulci on the branchial regions, and hy the flattened joints of the ambulatory legs.

## Mithrax cinctimanus (Stimpson).

Mithraculus cinctimanus Stimpson, Amer. Jour Sci., xxix, p. 132, 1860; Ann. Jy̧. Nat. Hist. N. Y., Vif, 1. 186, 1860. A. Milne Edwards, Miss. Sci. an Mexique, pt. 5, 1, 〕. 112, pl. xxirı, fig. 3, 1875. Kingsley, Proc. Acad. Nat. Sci. Phila., XXXi, p. 389, 1879. Aurivillins, K. Sv. Vet.-Akad. Hand., Bd. 23, 1, p. 5!. 1889. Found also in the Gulf Mexico.
Mithrax braziliensis, sp. nov.

## l'late xxxvi, fig. 2.

Carapace a little broader than long, ovate, slightly convex, without sulei. Regions faintly defined. There is a short line of indistinct flattened tubercles extending back from each rostral lobe, and two or three
tubercles and a few gramles near the lateral border of each branchial region. The surface above the posterior margin is covered with seattered granules.

Rostral lobes very short, truncate, minutely "remulate; interspace hroadly $V$-shaped. Upper orbital border with two small teeth.

Antero-lateral spines fomer the hepatic spine is subacnte, with tubercles on its anterior borler; branchial spines sharp, procurved, with a small spine anterior to the first and second. On the postero-lateral border just back of the lateral angle is a minute depressed spine.

Basal antennal joint with three teeth visible from above; the tooth at the insertion of the next joint subacnte; the one at the external angle, truncate; posterior tooth acute. Two additional teeth on the suborbital border; that next the postocular tooth acute; the other rounded, serrulate. Subhepatic and subbranchial regions tuberculate.

Chelipets longer and larger than the next pair of legs. Merns with a row of five sharp spines above, two tubercles on the lower inner border, a triangle of three spines on the inner face, two spines on the upper anterior margin, and two on the onter surface near the anterior border. Carpus with two or three tubercles near the merus and two on the imer margin. Hand smooth, marmed, with seattered punctures. Fingers slightly gaping at base with a tooth on the dartyl in both sexes. Ambulatory legs with meral aud carpal joints spinose above; propodal joints and dactyls marmed.

Carapace and ambulatory legs finely pubescent. In the largest specimen from Pernambuen the carapace is demuded, probably aceidentally, and the surface under the lens presents a cellular structure with seattered punctures. Alcoholic specimens show traces of crimson.

Length of carapace, 15 millimeters; width without spines, 15.5 millimeters.

Mar Grande, Bay of Bahia, one specimen; Rio Formoso, Pernambuco, five specimens; collected by R. Rathbun, 1875-1877.

This species, in the characters of the front, lateral spines, and legs, is very much like forceps, from which it is at once separated by the comparative smoothess of the carapace. The sharp tooth on the basal antennal joint, forming part of the suborbital border, is conspicuous in this species. The praorbital angle is not advanced as in forceps, and the legs are less hairy.

## Mithrax forceps (A. Milne Edwards).

Mithraculus forepps A. Milne Edwards, Miss. Sci. an Mexiчue, pt. 5, 1, p, 109, pl. xxir, fig. 1, 1875.
Mithracnlus hirsutipes Kingsley, Proc. Boston Soc. Nat. Hist., Nx, p. 147, 1879; Proc. Acad. Nat. Sci. Phila., xxxi, p. 389, pl. xiv, fig. 1, 1879. Heilprin, op. cit., p. 318, 1888.

Mithoux hirsutipes Miers, op. cit., p. 87.
A large series of specimens from nine teen different localities shows this species to be extremely variable. The small specimens show marked
variations from those described by A. Milne Eiwards, and some of them are identical with Kingsley's Mithraculus hirsutipes. The specimens intermediate in size present every gradation in character between the large and small and prove the two extremes to br variations of one species.

Carapace subtriangular, comparatively smonth, the large specimens with scattered punctures, the small ones deeply semp,tured. In large specimens three grooves run diagonally backward from near the first, second, and fourth sinuses of the antero-lateral margin to the cardiac: region. There are six or seven depressed tubercles along the margin and on the posterior part of the lranchial region, two or three along the onter margin of the hepatic region, and two pairs on the frontal region directly behind the lobes of the rostrum. In small specimens the grooves are deeper and the tubercles more prominent; the ontline of the mesogastric region is well defined; and there are depressed tubercles on the anterior part of the gastric region.

Lobes of rostrum short, broad; median noteh broadly V-shaped. Orbital angles acute, internal angle prominent.
Antero-lateral teeth four, acute, slender, separated by broad rommled simuses, the tirst the shortest and in large specimens subacntr, the remainder shary and directed forward, the second one nsually the longest and largest. In some sperimens there is a small tifth tooth on the postero-lateral margin just bark of the fourth tooth.
In large specimens, chelipeds proportionately larger, strong and smooth. Merus with five spines or spiniform tubereles on the mper margin, two on the imer face just below the margin. On the inmer margin are two proninent teeth, the anterior one often more or less flattened, broad and obtuse, the posterior one sometimes with a lobe on its posterior margin. Carpus rounded, smooth, sometimes mamed, often with a short spine or tubercle on the inner margin, anterior to the inner angle, which is often produced in a less conspicuous prominence, giving the carpus the appearance of being double-toothed.

Hands from the articulation to the tips of the fingers much longer than the carapace, broat, compressed; mper and lower margins nearly parallel. Dactyl loug, arched, with a tooth one-third the distance from the proximal end. Fingers widely gaping when closed. The fingers are exreedingly variable. Sometimes there are from one to three small irregular teeth or tubereles on the pollex half way to the end. Sometimes there are a few mimute teeth on the dactyl instead of one large one. In some of the females and smaller males the dactyl is little arched and the gape is slight.

Ambulatory legs spiny and hairy above, propodal joints slightly hairy below, dactyls equally hairy above and below.

It is the rule that the smaller the specimen the more prominent the protuberances, the shanper the teeth and spines. Small sperimens have the meral mines acmonate and ocasionally two tubereles on the carpus near its posterior magin.

This species approaches most nearly to senlptus, but the anterolateral teeth are sharp instead of tuberculous, the carapace is invariably wider, the ambulatory legs are less hary, the color is cimamon, while in sculptus it is sage green or bluish green. While the contiguration of the earapace is very variable, in no case is the posterior half deeply seulptured and the anterior half smooth, as is often the case in sculptus. Of the three ridges running from the antero-lateral margin to the cardiae region, the two anterior ones are continnous and not broken up by transvarse grooves as in sculptus.

Length of largest specmen, measming between the rostral lobes, 30.5 ; width, without spines, 35 millimeters. Length of three large males, 25 ; width, 29 millimeters.

## Mithrax cristulipes (Stimpsom).

Telcophirys cristulipes Nimpsem, Am, Lye. Nit. Hist. N. Y., V11, p. 1!0, pl. n, fig. 2,

 Pocock, op, cil., xx, p. 51s, 18:90.

Two specimens, in ald and femalr, wre eollected at Rio Fommose, Permambuco, Bazil, by R. Rathbm dming the Hartt explarations of 1875-77. The types from Cape St. Lacas, said to be in the Smithsonian Institntion, are not extant. Califomia and the Bay of Panama are also given as localities for.this species. Mr. R. I. Pocoek, lor. cit. gives a detailed deseription of a specimen fomm at Fernando de Norouha, which he donltfully refers to this species.

The male from Permmburo agres with his speemen in mearly every detail. The thbercles of the antero-iateral margin are vary small. The merus of the eheliperl is fumished below with there small teeth. There is one mimate tooth on the miditle of the pollex. The teeth of all the legs are mueh smatler and less conspicmous than in the figures of cristhlipes. The female has smaller cheliperds, fimgers less gaping, two small teeth on the pollex in the salpe, and mo teeth on the lower margin of the merus.

As this Musem possesses no specimens from the west coast af Ameriea, and as the individuals at hamd are more or less imperfect, the writer is umilling to designate them as a distinct species.

> Mithrax sp., Miers.
(ip. cil., p. S! , pl. x, lig. 3.

 mission, 1 ssis ( 160 ois), apmatently belongs to the same species as the fonms sperimens deseribed by Miers from Fermando Noronha, 7 to 20 fathoms. As our specimen is no larger than those collected by the Chellenger, amblats only one cheliped and one of the first pair of amber latory legs, I prefer not to give it a name, hoping that at some future time morr perfert specimens may bo obtained.

$$
\text { Pror. N. M. } 1 \text { O- } 18
$$

It, agrees with the specimens deseribed in all essential particulars. The tubercles of the frontal region are, however, not apparent. The tooth at the antero-external angle of the basal joint is sharp and emed. The ambulatory leg is bordered above and helow by a thin lamellate erest rut into teeth, which are arranged almost as in the figure cited. This rrest is most moticeable on the meral joint. The teeth of the merus of the cheliped are allso thin, and partake of the same character.

## Thoe puella Stimpson.

Thoe puella Stimpson, Am. Lyc. Nat. llist. N. Y., vif, p. 178, 1860. A. Milne Edwards, Miss. Sci. an Mexirpue, pt. 5, i, p. 122, pl. xix, fig. 3, 1873.
Pisa latipes (Deshonne and Schramm, Crust. de la Gnadelonpe, 1. 19, 1867.)
The length of the largest specimen, a female, is $\mathbf{1 1 . 7}$ millimeters; width, 10 millimeters. The merus of the last pair of ambulatory legs is dilated outwardly, but to a less extent than in the first three pairs.

FAST INDIAN REGIGN.

Paramaya dehaamii White.

EXTRACT FROM THE UNPLBLISHED RETORT OF DR. WILLIAM STIMPSON, ON THE CRUSTACEA OF THE NORTH PACHFIC EXPLORING EXPEDIT1ON, 1853 TO 1856.

Tiarinia cornigera : latreille).
Our specimens differ from thase dessribed and figured by Dana in having, at the smmit of the intestinal region, one very large and two ineonspicuous tubercles, instead of three of equal size. They are also much larger, some being nearly 2 inches in length.
They are found on the reefs at low-water mark, and were collected at the Amakirima Lslands by the officers of the steamer John Hancoek, and by myself at Loo Choo and Ousima.

Tiarinia depressa stimpsom.
(Plate xl, lif. 1.)
Carapax in shape mull like that of T. cornigera: proportion of bradth to length, $1: 1.5$; form depressed; mper surface with tuberes less mumerons and more flattened than in the rormiger. There is a small marginal sipine on each side at the branchial region, above which an are of foum depressed warts extends aromel the side; the first (posterior") one largest and placed a little behind the level of the trituberenlated cardiae protuberance; the forth and smallest is near the anterior extremity of the branchial region, with a still smaller one before it. A submarginal chamel of some depth passes aromed behind, above the intestinal region. Posteriorly, at the mper or intestinal inargin, there is a subtriangular median tuberele, with as smaller tribobate one on either side of it; on the lower margin there are fom small tubercles.

On the stomathal region there are three warts in the median line, the anterior one smallest and placed some little distance before the others, with a wart on either side of it ; behind the posterion one there are two warts placed close together. The ambulatory feet are depressed, smooth above, their edges not spinulosi, but sparsely fringed with stont clavate setar. Only one specimen of this species was taken, a sterile female, the dimensions of which are: length, 0.77; breadth, 0.52; length of a foot of secomd pair, 0.67 inch.

In the characters of the rostrmm, orbits, ete., our species mull resembles T. corniger". The towth at the extemal angle of the basal joint of the extomal antrmar is, howerer, less prominent than in that speceies, and the rostron "uves mpand at its shemder tip, where the horns are slighty divergent. It is more depressed than T. tiaruta; the forks of the rostrum ine less divergent; the preorbital spine less prominent, and is wanting in the wooly hairs characteristic of that species.

The specimell was taken at the Island of Ousima, which forms one of the chain comecting sunthern Japan with Loo Choo.

Tiarinia spinigera N'mpson.
(I'late xi, lig. ㄹ.)
Carapax somewhat elongated, the greatest breadth, exoluding spines, being considerably less than the postorbital length. Upper surface not very convex except at the well-developed gastric region; cardiac region, with three tubereles at the smmmit, placed as usual in the gemm; on either side of this on the branchial regions there are three sharp, ereot spines, the ontar one being lateral a little larger than the others, aud sommehat inclined ontward. There is a single longish clavate seta at the smmmit of each spine. Upper posterior margin with seven small spines, the middle one largest at the summit of the intestinal region; lower posterior margin also with seveu spines, but of much smaller size. The sides of the carapax, including the hepatic regions, and the posterior half of the upper sufface are covered with small, sharp tubercles ocenpying the interspaces between the spines and larger warts; while the gastric region and parts adjacent on either side, although irregularly protuberant, are nemy smooth. Rostrum sharp and very slemder, in length equaling two-thinds of the interorbital width; horns contignons throughont their length. Preorbital tooth prominently salient, very slemrer and sharp, couved upward; a single closed fissure separates it from the somewhat prominent postorbital tooth. The hasal artirle of the extermal antemme is broater than long; its suteroexterior tooth lies mose beneath the preorbital tooth and helps to form the deep tubulas orbit, which incloses the eye as in a sheath. The edges of the rostrom and of the external intenne are, as usual, ciliated; and there are some few rispate seta on the prominent parts of the carapax anteriorly and at the sides.

In the feet of the anterior pair the eappos and meros are sparingly spinulose above. The ambulatory feet are almost smooth; those of the first pair in the femald are swarely as long as the campax. The abdomen in the temate is tomentose. Two sperimens only of this species were fomm, both females. The dimensions of the largest are: length of the carapax, 0.79 ; brealth, including spines, 0.57 inch.

This speries oreured at the islands Ousima and 'Tanegasima, of the southerin Japanese chain.

## Perinea tumida * Dana.

Crust. U. ふ. Expl. Exped., I, p. 114, ,1. iv, fig. 1, 1852.
Onf specimens agree well with those of Dana, except that in the male the pincers are math smaller and less gaping, while the sizeof the carapax is the same; this may, however, result from a difference of age and development.

Taken from hamehes of Madrepora fomd below low-water mark near Hilat, Island of Hawaii.

[^3]
[^0]:    *May belong to the Maiida.

[^1]:    * This genus is clonbtfully referred to the Iericeride.

[^2]:    * In young specimens and fimales, the spines are not always evident.

[^3]:    *Now inclumed in the genus Microphrys.
