

Marine Birds – Storm Petrel Colonies

description

Storm Petrels are among the smaller marine birds. This feature includes two species of Storm Petrel: Fork-tailed Storm Petrels (*Oceanodroma furcata*) and Leach's Storm Petrels (*Oceanodroma leucorhoa*). Fork-tailed Storm Petrels are silver-grey with black rings around the eyes. Leach's Storm Petrels are a mix of black and brown with a white rump. Both species have a forked tail. Storm Petrels breed on islands along coastlines. They are colonial breeders, nesting in burrows they dig in soft soil or in crevices in rocks.

The atlas page depicts active and historic Storm Petrel colonies in terms of their relative importance, a value that corresponds to the number of "nest pairs" of both species estimated at any one site during the most recent survey year. This value was compared to the total BC population, which was determined by summing the estimated number of individuals at all colonies during the most recent survey year. Using these values, relative importance was determined as follows:

- High: colony has >5% of the species' total BC population.
- Moderate: colony has 1-5% of the species' total BC population.
- Low: colony has <1% of the species' total BC population.

These categories correspond with the 1% threshold that has been applied at global and national levels by Bird Studies Canada (and other groups around the world) to identify Important Bird Areas.

Sites have been included regardless of whether breeding had been previously confirmed at a particular site. Attributes for each site also include the date that breeding was last confirmed and the most recent survey results. Colony locations were buffered to represent some of the marine habitat used by these birds adjacent to each colony, based on the distances employed in the creation of the Canadian Wildlife Service's Marine Bird Areas of Interest dataset.

data sources

- Environment Canada (Canadian Wildlife Service) British Columbia Seabird Colony Inventory
- Parks Canada Nesting Seabird Colonies

data resolution

• 1:250,000 (some points have been adjusted to match the 1:20,000 TRIM coastline)

data collected

• 1977-1997 (years breeding was confirmed)

date compiled

• 2008

reviewers

- Harry Carter, Consultant
- Peter Davidson, Bird Studies Canada
- Representatives from Environment Canada, Canadian Wildlife Service

reviewer comments

• Relative importance classes were revised to address comments from the initial review.

caveats of use

- Gaps in the extent of this feature should not be inferred to be an absence of the species, but rather an absence in survey effort.
- Buffer distances do not represent the entire foraging area of the birds.
- Sites of low relative importance may include extirpated sites or sites where the most recent survey did not obtain a count for breeding birds. Not all colonies are surveyed each year and colonies that were active in the past may or may not still support breeding populations. Therefore, these sites are still deemed important by the experts.
- Possible breeding sites are sites where breeding is suspected but has not been confirmed or counted. This information is only available for the Parks Canada dataset for Haida Gwaii.
- Recommended date of expiry for use of these data in a marine planning context: None provided.
