Abstract—*Solanum* section *Aculeigerum* (the *Solanum wendlandii* group, Solanaceae) comprises eight species ranging from Mexico and Central America to Ecuador and Peru with one species in southeastern Brazil, Paraguay and northern Argentina. One species, *Solanum wendlandii*, is commonly cultivated worldwide in tropical and subtropical regions, and one new species from southern Mexico, *Solanum triunfense*, is described here. Members of *Solanum* section *Aculeigerum* are differentiated from other sections of *Solanum* by a combination of plurifoliate sympodial units, branched inflorescences, presence of prickles coupled with absence of stellate trichomes, and a vine-like habit. Unlike most other prickly species of *Solanum*, which are placed into *Solanum* subgenus *Leptostemonum*, they lack stellate hairs, and phylogenetic studies suggest that the section is one of several potential sister groups for the spiny solanums. A key, descriptions, habitat and distribution data, preliminary conservation assessments, specimens examined and illustrations are provided for all species in *Solanum* section *Aculeigerum*. Lectotypes are designated for the following five names: *S. aculeolatum* M. Martens & Galeotti, *S. mazatlanense* Coulter & Donn. Sm., *S. molinarum* J. L. Gentry, *S. pachyandrum* Bitter, and *S. sagranum* A. Rich., and neotypes are designated for *S. glaucescens* Zucc. and *S. wendlandii* Hook. f.

Keywords—Central America, heterandry, lianas, South America, vines.

INTRODUCTION

Solanum L. is one of the ten most species-rich genera of flowering plants (Frodin 2004) and has approximately 1,400 species (Särkinen et al. 2013) occurring on all temperate and tropical continents. The highest diversity of both groups and species is in tropical South America, concentrated in circum-Amazonia (Knapp 2002). Species of *Solanum* have usually five-merous flowers with fused sepals and petals, stellate to pentagonal corollas, stamens with short filaments, and anthers opening by terminal pores. The genus was one of Linnaeus's (1753) larger, with 23 species mostly described from European or African material. The last time *Solanum* was monographed in its entirety was in De Candolle's *Prodromus* (Dunal 1852), which included 901 species (with an additional 19 listed at the end of the treatment as incompletely or poorly known). Until the 21st century, the taxonomy of *Solanum* was largely limited to rearrangements of infrageneric taxa, species-level treatments of smaller groups within the genus, and floristic works. The large size of *Solanum* and its poorly understood infrageneric structure has meant that *Solanum* taxonomy has proceeded in a piecemeal fashion until relatively recently, and the genus has acquired a reputation of being intractable. A project funded by the United States National Science Foundation's Planetary Biodiversity Inventory (PBI) program begun in 2004 has sought to accelerate species-level taxonomic work across the genus as a whole. Ongoing work by participants of the PBI *Solanum* project is resulting in a modern monographic treatment of the entire genus available online in the electronic resource Solanaceae Source (<http://www.solanaceaesource.org>). This treatment is part of that collaborative effort.

Taxonomy of *Solanum* section *Aculeigerum*—One of the principal divisions in *Solanum* is that between spiny (technically prickly) and non-spiny species. Early authors distinguished all spiny solanums as members of *Solanum* subgenus *Leptostemonum* Bitter (Dunal 1852; Bitter 1911) due to their

tapered anthers, prickles, and pubescence of stellate trichomes. Phylogenetic studies using DNA sequences confirmed the monophyly of the spiny solanums with stellate pubescence (*Solanum* subgenus *Leptostemonum* or the *Leptostemonum* clade), but the species with prickles and lacking stellate pubescence did not resolve as members of this strongly supported group (Bohs 2005; Levin et al. 2006; Weese and Bohs 2007).

Solanum section *Aculeigerum* Seithe was broadly circumscribed by Seithe (1962) and included all *Solanum* species with prickles but lacking stellate trichomes. Child (1983) segregated *Solanum* section *Nemorensis* A. Child from Seithe's *Solanum* section *Aculeigerum* and included two of her *Aculeigerum* species (*S. barbeyanum* Huber and *S. hoehnei* C. V. Morton; see Table 1) within it along with *S. coriaceum* Dunal, *S. nemorensis* Dunal, and *S. reptans* Bumby. Child defined *Solanum* section *Nemorensis* as those species with difoliate sympodial units, scorpioid cyme inflorescences, and deeply stellate corollas up to 2 cm in diameter; he differentiated *Solanum* section *Aculeigerum* by its plurifoliate sympodial units, paniculate inflorescences, and rotate to stellate corollas up to 4 cm in diameter. Child did not consider *Solanum* section *Nemorensis* to be part of *Solanum* subgenus *Leptostemonum*, but was otherwise vague in assigning it to be closely related or affiliated with any specific section other than his large *Solanum* subgenus *Solanum*; he later included both *Solanum* sections *Nemorensis* and *Aculeigerum* in his *Solanum* subgenus *Potatoe* (G. Don) D'Arcy as "Anomalous prickly taxa" (Child 1990). Whalen (1984) recognized *Solanum* sections *Nemorensis* and *Aculeigerum* as distinct groups, the *Solanum nemorensis* and *Solanum wendlandii* species groups respectively. In contrast to Child (1983), Whalen (1984) included both these groups in *Solanum* subgenus *Leptostemonum*, but as a "phylogenetically isolated line" (Whalen 1984: 210). Nee (1999) treated these species with prickles but no stellate trichomes in *Solanum* subgenus *Leptostemonum*, with *Solanum* section

TABLE 1. Taxonomic position of species of *Solanum* section *Aculeigerum* (and other species previously considered related to them). Species treated in this revision are in bold face type.

Aculeigerum as “Series 2” of *Solanum* section *Herposolanium* Bitter and *S. nemorensis* Dunal + *S. barbeyanum* Huber as “Subsect. 2” of *Solanum* section *Micracantha* Dunal. He suggested the two groups were closely related, and that the lack of stellate pubescence was the result of reduction of stellate trichome complexity. See Table 1 for previous infrageneric classifications of all species treated as related to the taxa included in our current circumscription of *Solanum* section *Aculeigerum*.

Phylogenetic studies using DNA sequence data have shown that both *Solanum* sections *Aculeigerum* and *Nomorensis* do not belong to the strongly supported monophyletic *Leptostemonum* clade (*Solanum* subgenus *Leptostemonum*; Bohs 2005; Weese and Bohs 2007; Levin et al. 2006; Stern et al. 2011; Särkinen

et al. 2013). Three species of *Solanum* section *Aculeigerum* have been included in molecular phylogenetic analyses (*S. alternatopinnatum*, *S. bicone*, and *S. wendlandii*; note that *S. bicone* is determined as *S. refractum* in some of these publications, but all sequence data included in GenBank to date under *S. bicone* and *S. refractum* are from Iltis et al. 29694, identified here as *S. bicone*). In all of these analyses, the species of *Solanum* section *Aculeigerum* form a strongly supported clade, distinct from *Solanum* section *Nomorensis*. Within *Solanum* section *Aculeigerum* Stern et al. (2011) found *S. alternatopinnatum* resolved as sister to *S. bicone* (as *S. refractum*) + *S. wendlandii*. In the trees resulting from some phylogenetic analyses *S. allophyllum* (Miers) Standl. is sister to *Solanum* section *Aculeigerum*, but this relationship

is poorly supported and unexpected on the basis of morphology. Resolution and support is poor in the tree backbone so that relationships among *Solanum* sections *Aculeigerum* and *Nemorensis* and the *Geminata*, *Brevantherum*, *Cyphomandra*, and *Leptostemonum* clades are unclear (see Fig. 1 in Särkinen et al. 2013), but no analysis places *Solanum* section *Aculeigerum* within the well-supported *Leptostemonum* clade. Prickles are only found in *Solanum* sections *Aculeigerum*, *Nemorensis*, and the *Leptostemonum* clade, while stellate hairs are found in the *Leptostemonum* and *Brevantherum* clades (see Stern et al. 2013). Thus, both prickles and stellate hairs are of ambiguous origin, depending on the sister relationships of the various groups involved. Further analyses of *Solanum* using more markers will be helpful in resolving this. It is clear, however, that the species of *Solanum* section *Aculeigerum* are not part of the core spiny solanums and their relationship to the species of *Solanum* section *Nemorensis* is not well-resolved.

MATERIALS AND METHODS

The taxonomic conclusions presented here are a result of field and herbarium work and are supported by molecular phylogenetic results (Weese and Bohs 2007; Stern et al. 2011). We examined approximately 1,200 specimens representing more than 700 collections from the following herbaria (herbarium acronyms follow *Index Herbariorum*, found online at <http://sciweb.nybg.org/science2/IndexHerbariorum.asp>): AD, BH, BHC, BM, BR, C, CAS, CEPEC, CIQ, CM, CORD, CR, CUZ, DS, DUKE, E, G, GH, INB, JBSD, K, L, LE, M, MCNS, MEDEL, MEXU, MJG, MO, NY, P, PH, PMA, R, RB, SI, SP, TEX, U, UC, UPR, US, USM, WIS, XAL, and W. Images of type specimens from the web resource Global Plants (<http://plants.jstor.org>) were also used to establish the distribution of isotypes and to aid in lectotypification choices. Type specimens with sheet numbers are cited with the herbarium acronym followed by a dash and the sheet number (i.e. MO-1781232); barcodes are written as a continuous string (i.e. G00104280). We have cited geographically representative specimens for taxa where more than 100 collections are known. Identities of all numbered collections seen for this study are in the Index to numbered collections (Exsiccatae; <http://dx.doi.org/10.5519/0039503>) and full specimen details are available on the Solanaceae Source website (www.solanaceaesource.org).

Citation of literature follows BPH-2 (Bridson 2004) with alterations as implemented in IPNI (International Plant Names Index, <http://www.ipni.org>) and Harvard University Index of Botanical Publications (http://kiki.huh.harvard.edu/databases/publication_index.html). Following Knapp (2013) we have used the square bracket convention for publications in which a species is described by one author in a publication edited or compiled by another, the traditional "in" attributions such as Dunal in DC. for those taxa described by Dunal in Candolle's *Prodromus Systematis Naturalis Regni Vegetabilis*. This work is cited here as Prodr. [A. P. de Candolle] and the names are thus attributed only to Dunal. For "ex" attributions we cite only the publishing author, as suggested in the *Code* (McNeill et al. 2012). Standard forms of author names are according to IPNI (International Plant Names Index, <http://www.ipni.org>).

We cite page numbers for all previous lectotypifications. Where specific herbaria have not been cited in protologues we have followed McNeill (2014) and designated lectotypes rather than assuming holotypes exist.

We have followed the morphological species concept or "morphological cluster" concept (Mallet 1995) in delimiting species of *Solanum* section *Aculeigerum*. Taxa are recognized as distinct if they possess a unique suite of characters and are separated from similar entities by morphological gaps. In nearly all cases, taxa also occupy geographically circumscribed ranges. Molecular evidence corroborates the delimitation of taxa using morphological methods (Stern et al. 2011).

Measurements were made from dried herbarium material supplemented by measurements from living material. Colors of corollas, fruits, etc., are described from living material or from herbarium label data. Specimens with latitude and longitude data on the labels were mapped directly. Some species had few or no georeferenced collections; in these cases we retroactively georeferenced the collections using available locality data. Maps were constructed with the points in the centers of degree squares in a 1° square grid. Conservation threat status was assessed following the IUCN red list categories and criteria (IUCN 2014) using the

GIS-based method of Moat (2007) as implemented in the online assessment tools in GeoCat (<http://geocat.kew.org>). The extent of occurrence (EOO) measures the range of the species, and the area of occupancy (AOO) represents the number of occupied points within that range based on the default grid size of 2 km².

RESULTS

Morphology—HABIT AND STEMS—Members of *Solanum* section *Aculeigerum* are all woody or semi-woody vines with small, broad-based recurved prickles (Figs. 1A, 1B, 1D, 2C). These prickles are morphologically similar to those of the *S. lanceifolium* species group of Whalen (1984) (Micracantha clade of Stern et al. 2011) and almost certainly help the plants to clamber over and ascend vegetation. In general the prickles of *Solanum* section *Aculeigerum* are relatively widely spaced along the stems, averaging 1–5 prickles per cm of stem length, and are sometimes absent from the uppermost stems. Prickles in the spiny solanums are interpreted as being derived from stellate trichomes (Whalen 1984), and so their occurrence in members of *Solanum* section *Aculeigerum* is either convergent and follows a different developmental pathway, or stellate trichomes have been completely lost in *Solanum* section *Aculeigerum*.

Most species in *Solanum* section *Aculeigerum* can begin to flower when quite small and then they are recorded as shrubs on herbarium labels, but all species apparently grow to canopy height with long woody stems.

LEAVES—Leaves of members of *Solanum* section *Aculeigerum* vary from simple to pinnatifid, often on the same plant (e.g. *S. wendlandii*). The only species with what could be termed pinnately compound leaves with petiolulate leaflets is *S. alternatopinnatum*; others are merely very deeply pinnatifid with laminar tissue along the midrib. In common with many members of *Solanum* subgenus *Leptostemonum*, prickles can be borne on the midrib abaxially and occasionally also adaxially. The leaves of most of the species are glabrous, or occasionally with a few papillate trichomes when young; only *S. bicine* and *S. triunfense* have multicellular trichomes on the leaf lamina. The leaves of members of *Solanum* section *Aculeigerum* often have copious crystal sand – isolated idioblasts of calcium oxalate that appear as white dots in dry specimens.

PUBESCENCE—Despite bearing prickles, members of section *Aculeigerum* do not possess the distinctive stellate trichomes of *Solanum* subgenus *Leptostemonum*. Trichomes, if present, are generally simple and uniseriate, usually composed of only a few cells. *Solanum triunfense* has a few furcate trichomes mixed with the simple uniseriate pubescence of young stems and inflorescences; these hairs have a single small branch and are not dendritic as found elsewhere in the genus (e.g. *S. aureum* Dunal, a member of the Dulcamaroid clade, see Knapp 2013). It has been suggested (Nee 1999) that the simple trichomes of *Solanum* section *Aculeigerum* are similar to those found in members of *Solanum* section *Acanthophora* Dunal or *S. leucopogon* Huber (of the Micracantha clade sensu Stern et al. 2011) and are simply stellate trichomes that have lost the lateral rays. This loss occurs in *Solanum* section *Gonatotrichum* Bitter (Stern et al. 2013) in which *S. lignescens* Fernald is stellate-pubescent and other members of the section have distinctive geniculate trichomes with one short and one long cell. The few-celled trichomes of *S. bicine* are similar to those of *Solanum*

FIG. 1. Morphology of *Solanum* section *Aculeigerum*. A. *S. alternatopinnatum* inflorescence in bud (Giacomin et al. 1692). B. *S. alternatopinnatum* immature fruits; note the armed inflorescence rachis (Giacomin et al. 1692). C. Flower of *S. cobanense*; note fleshy petals and ellipsoid anthers (Christenhusz et al. 5584). D. *S. cobanense* inflorescence on young shoot (Christenhusz et al. 5584), note absence of prickles on the inflorescence rachis. Credits: A–B: L. L. Giacomin; C–D: K. Watson).

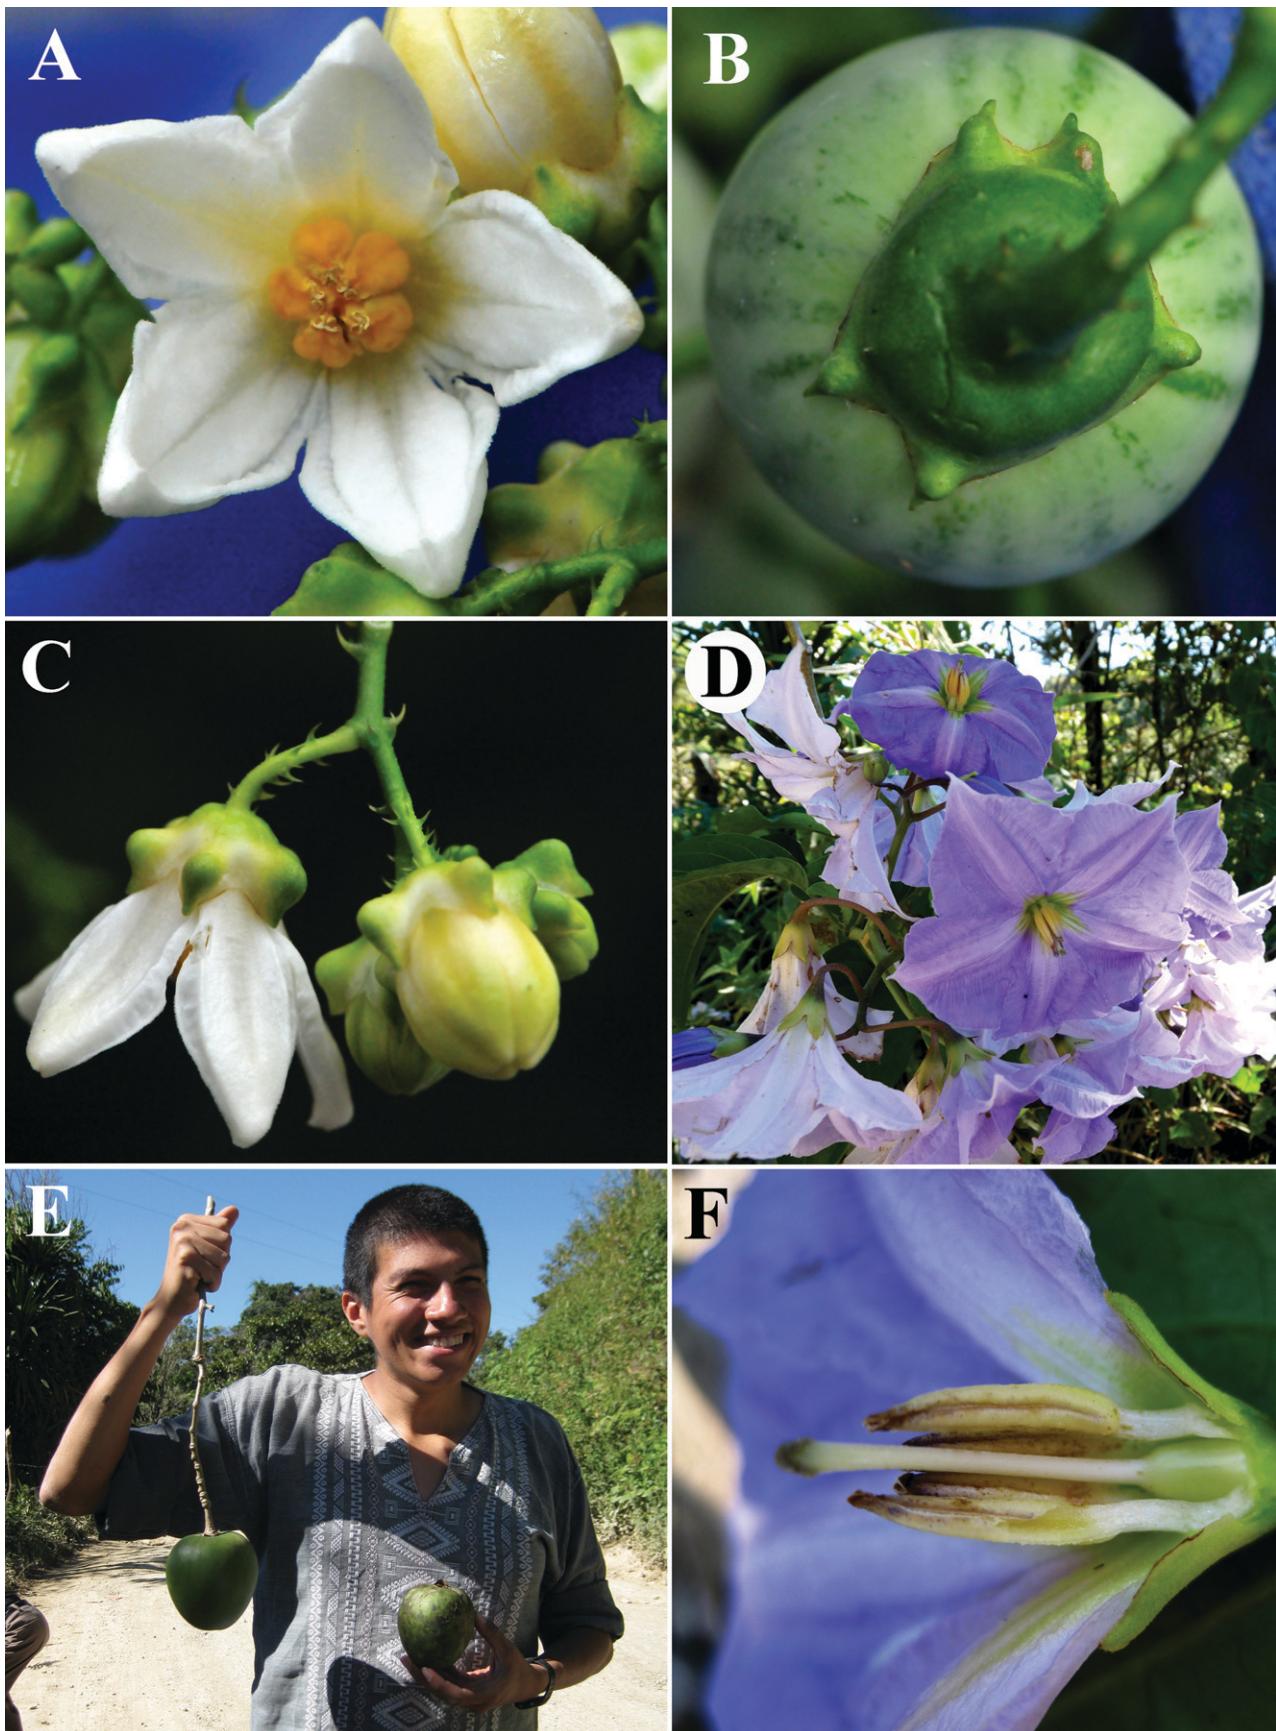

FIG. 2. Morphology of *Solanum* section *Aculeigerum*. A. *S. pachyandrum* flower; note ellipsoid anthers (Särkinen et al. 4546). B. *S. pachyandrum* immature fruit (Särkinen et al. 4546). C. *S. pachyandrum* inflorescence with buds; note the keeled calyx lobes and prickly pedicels (Särkinen et al. 4546). D. Inflorescence of *S. wendlandii* pistillate plant (Christenhusz et al. 5372). E. Immature fruit (seeds still very small and not at all well-developed) of *S. wendlandii* (Christenhusz et al. 5372). F. *S. wendlandii* pistillate flower (Christenhusz et al. 5372). Credits: A–C: T. Särkinen; D–F: M. Vorontsova.

section *Gonatotrichum*, with a long apical cell and a shorter (pustulate) basal cell (but are not geniculate). Those of *S. triunfense* are not of this morphology; they are typical simple, multicellular uniseriate trichomes like those found in major groups of non-spiny solanums (e.g. the Geminata Clade, see Knapp 2008a).

INFLORESCENCES—Members of *Solanum* section *Aculeigerum* usually have branched inflorescences; those of *S. wendlandii* can be many times branched and very large (Fig. 2D). Inflorescence branches are highly divaricate, usually spreading at ca. 90 degree angles so the structure is very open. Flowers are often clustered near the tips of the branches, but are usually evenly spaced along the inflorescence branches (0.5–1 cm apart). The rachis can be armed or unarmed; all of the pinnatifid-leaved species (*S. alternatopinnatum*, *S. pachyandrum*, *S. refractum*) have densely prickly inflorescences (Fig. 1B, 2C), while the rest of the taxa (Fig. 1D) only rarely have inflorescence prickles (*S. wendlandii* is variable in this regard).

FLOWERS—Flowers of members of *Solanum* section *Aculeigerum* are pentamerous and sympetalous, like all of *Solanum*. Flower buds are ellipsoid to tapering (turbinate), depending on the shape of the anthers (see below; Fig. 1A, C). The calyx is usually campanulate and openly spreading and the buds are usually exserted from the calyx tube when very young, long before anthesis. Most species have thickened lobes with scarious sinuses that tear early on in bud growth to leave broadly deltate regular calyx lobes. *Solanum triunfense*, however, has a calyx that completely encloses the buds until much later in growth and irregularly tears into deep uneven lobes. The calyx lobes of *S. pachyandrum* are markedly keeled (Fig. 2C). All species have copious crystal sand in the more robust tissue of the calyx lobes.

Members of *Solanum* section *Aculeigerum* have relatively large flowers; in *S. wendlandii* they can reach 6 cm in diameter (long-styled flowers, e.g. Christenhusz et al. 5372, see Fig. 18). Corolla shape varies from deeply stellate (*S. cobanense*; Fig. 1C, D) to almost rotate (*S. wendlandii*; Fig. 2D, F), and color varies from deep purple (*S. cobanense*, Fig. 1C) to white or greenish white (*S. alternatopinnatum*, Fig. 1A). Species that commonly have white or greenish white flowers (e.g. *S. alternatopinnatum*, *S. bicorne*, *S. refractum*) have also been recorded as having purple or lilac corollas, so it clear that polymorphism exists in corolla color as is common in other groups of solanums (e.g. Knapp 2013). Corolla color in *S. wendlandii* changes throughout anthesis (Fig. 2D); when flowers first open they are deep purple and with age they fade to pale violet (sometimes described on labels as blue) or white with a concomitant increase in size (SK, pers. obs.); this has been observed in other Solanaceae such as *Lycianthes* (Dean 2001), in some members of the Dulcamaroid clade of *Solanum* (Knapp 2013), and in *Solanum* section *Crinitum* (Whalen) A. Child in the spiny solanums (SK, pers. obs.).

ANDROECIUM—Like all species of *Solanum*, members of *Solanum* section *Aculeigerum* have poricidal anthers; the pores are directed distally and in these species usually split with age along the margins so that the anthers appear to be longitudinally dehiscent. *Solanum cobanense*, *S. pachyandrum* and *S. triunfense* have ellipsoid anthers (Figs. 1C, 2A), while the rest of the species have variously tapering anthers, from strongly tapering in *S. refractum* to only slightly tapering in *S. wendlandii* (Fig. 2F).

Many species of *Solanum* have dimorphic stamens (Anderson et al. 2006; Bohs et al. 2007; Vorontsova et al. 2013) and stamen

dimorphism occurs in almost half of the 13 major clades of the genus. It is especially diverse in *Solanum* subgenus *Leptostemonum*, with both anther (e.g. *S. rostratum* Dunal from the southwestern USA) and filament (e.g. *S. coagulans* Forsk. from Africa) dimorphism present. The dimorphic stamens of *Solanum* section *Aculeigerum* are due to differences in filament length. Four species of the group (*S. alternatopinnatum*, *S. bicorne*, *S. glaucescens*, and *S. wendlandii*) have one anther on a markedly elongate filament, while *S. cobanense*, *S. pachyandrum*, *S. refractum* and *S. triunfense* have filaments of equal size. Occasionally the anther borne on the long filament is slightly larger than the rest, but all anthers are usually of equal sizes, as are the remaining four filaments in any given flower.

Anther color in the group varies from cream to yellow or orange (*S. refractum*) to pale purplish blue (*S. wendlandii*). Label data often describes the anthers of *S. wendlandii* as yellowish at the base and blue or purple more distally (see Fig. 2F).

GYNOCIUM—The ovary and style of members of *Solanum* section *Aculeigerum* are glabrous, and the stigma is minutely papillate. Style length varies among flowers in an inflorescence, and section *Aculeigerum* has been interpreted as comprising andromonoecious plants (Whalen 1984). Short-styled flowers have styles that are included in the anther tube, while those of long-styled flowers are exserted (Fig. 2F). In *S. cobanense*, however, the stigma is held at the level of the tips of the anthers (Fig. 1C), suggesting that the expression of andromonoecy in this group may be more complex than previously described. *Solanum wendlandii* appears to have all long-styled or all short-styled flowers on any given plant; it may be dioecious, a breeding system that occurs several times in different clades of *Solanum* (Knapp et al. 1998; Martine et al. 2009), or sequentially monoecious with younger plants producing flowers with exclusively male function (see description of *S. wendlandii*). This needs further investigation of living plants in the field and greenhouse.

FRUITS AND SEEDS—Fruits of members of *Solanum* section *Aculeigerum* are bilocular berries with fleshy pulp (eaten by local people in some species; e.g. *S. pachyandrum*) and thick, leathery pericarp. The fruit surface appears rugose in dried specimens, but is smooth, glabrous and matte in fresh material (Fig. 2E). Immature fruits are often pale green or greenish white with darker markings (see Figs. 1B, 2B); mature fruit colour is quite variable. The pedicel and calyx lobes are thickened and woody in fruit, and the calyx lobes often break off in herbarium specimens. Fruiting specimens are rarely collected. Seeds are flattened-reniform, very large and many (usually > 100) per berry. The surfaces are minutely pitted with rectangular or pentagonal cells, and at least in *S. glaucescens*, the lateral testal cells walls are elongate, giving the seed a hairy appearance.

TAXONOMIC TREATMENT

SOLANUM SECTION ACULEIGERUM Seithe, Bot. Jahrb. Syst. 81: 291. 1962.—**TYPE SPECIES:** *S. wendlandii* Hook. f.

Solanum section *Micracantha* Dunal subsection *Juciri* Bitter ex Marzell, in Hegi, Flora von Mittel-Europa 5: 2548. 1927.—**TYPE SPECIES:** *S. wendlandii* Hook.f.

Perennial woody vines to canopy lianas, usually armed with recurved prickles on stems, petioles, and midveins of abaxial leaf surfaces. Stems subwoody to woody, sometimes

herbaceous, usually glabrous or puberulent with simple hairs, the prickles to 8 mm long, recurved, stout. Sympodial units usually plurifoliate, rarely difoliate, not geminate. Leaves simple and entire or pinnately lobed to compound, usually petiolate, occasionally decurrent to base. Inflorescence terminal, often appearing lateral, usually branched, with 5–35 flowers, the axes with or without prickles. Flowers 5-merous, usually long- or short-styled, the plants probably andromonoecious or in one case (*S. wendlandii*) dioecious. Calyx spreading with rounded lobes, the lobes usually equal in size but occasionally tearing and markedly unequal in size. Corolla rotate-pentagonal to stellate, purple, violet (blue), white, or greenish white. Stamens all equal or dimorphic with four filaments equal in length and one filament 2–6 times longer than the rest; anthers variously tapering, usually somewhat attenuate, ellipsoid in some species. Style cylindrical, glabrous, usually straight but sometimes slightly curved; stigma truncate or bilobed. Fruit a globose berry, ca. 2–10(–20 fide Christenhusz et al. 5372) cm in diameter, the surface glabrous (sometimes

rugose when dry), yellow or light green, less commonly red or orange, the mesocarp orange-red, green, or white. Seeds many per berry, strongly flattened-reniform, light brown, the surface minutely pitted, the testal cells pentagonal to rectangular in outline, the lateral testal cell walls elongate or not.

Solanum section *Aculeigerum* includes eight species: six in Mexico and Central America, one in southern Ecuador and northern Peru, and one in southeastern Brazil, northern Argentina and Paraguay (see maps of individual species). Section *Aculeigerum* is differentiated from other clades of *Solanum* by a combination of plurifoliate sympodial units, branched inflorescences, prickles with an accompanying lack of stellate trichomes, and a woody vine-like habit.

Section *Aculeigerum* is best known for the commonly cultivated species *S. wendlandii* (Figs. 2D–F). It is grown in the Americas and has also been introduced to tropical and subtropical regions of the Old World. It is also widely cultivated in greenhouses in the northern hemisphere (see description of *S. wendlandii* for more details).

KEY TO THE SPECIES OF *SOLANUM* SECTION *ACULEIGERUM*

1. Leaves simple, usually shallowly lobed, only deeply lobed on vigorous young shoots 2
2. Stem prickles all or mostly paired at base of petioles. 4. *S. glaucescens*
2. Stem prickles more or less evenly scattered, not paired at base of petioles
 3. Leaves chartaceous, mostly clustered on short shoots, pubescent with stiff simple trichomes with long basal cells; corolla creamy white (occasionally tinged with violet). 2. *S. bicorne*
 3. Leaves coriaceous, evenly distributed along the branches, glabrous or pubescent with simple uniseriate trichomes with 2–4 cells, the basal cell not markedly longer than the rest; corolla purple, blue or violet. 4
 4. Flowers rotate to pentagonal; filaments unequal; usually some pinnatifid leaves present on plant 8. *S. wendlandii*
 4. Flowers stellate; filaments equal; leaves never pinnatifid.
 5. Leaves and stems glabrous; leaf bases truncate to acute; inflorescence axes glabrous; buds exserted from the calyx 3. *S. cobanense*
 5. Leaves and stems with scattered simple uniseriate trichomes; leaf bases attenuate; inflorescence axes densely pubescent with simple 2–4-celled uniseriate trichomes; calyx completely enclosing the buds 7. *S. triunfense*
1. Leaves compound or deeply lobed with the lobe sinuses more than half the distance to the midrib, the uppermost leaves near the inflorescence sometimes only shallowly lobed or entire. 6
6. Flowers heterandrous, with one filament markedly longer than the other four.
 7. Corolla light blue to purple, rotate to pentagonal; leaves highly variable in shape on the same plant, often entire near the inflorescence, generally ranging from deeply lobed to pinnately compound. 8. *S. wendlandii*
 7. Corolla white or cream, stellate, lobed nearly to the base; leaves compound or deeply pinnatifid.
 8. Inflorescence axis and pedicels prickly; inflorescence borne on main branches, not borne on short shoots; leaves compound with the leaflets with distinct petiolules; southern South America 1. *S. alternatopinnatum*
 8. Inflorescence axis unarmed; inflorescence borne on short shoots; leaves deeply pinnatifid, the lobes with distinct wings of tissue decurrent along the main rachis, distinct petiolules absent; Mexico and Central America 2. *S. bicorne*
6. Flowers with all filaments equal in length within a flower.
 7. Anthers ca. 3 mm wide; flowers white; pedicels armed with stout prickles; southwestern Ecuador and northwestern Peru. 5. *S. pachyandrum*
 7. Anthers 1–1.5 mm wide; flowers greenish white; pedicels unarmed; Pacific slope, southern Mexico, Guatemala and Honduras. 6. *S. refractum*

1. *SOLANUM ALTERNATOPINNATUM* Steud., Nomencl. Bot. ed. 2: 600. 1841. Nom. nov. for *Solanum oleraceum* Vell. (1829), non *Solanum oleraceum* Dunal (1813). *Solanum oleraceum* Vell., Fl. Flumin. 89. 1829. — TYPE: BRAZIL. Rio de Janeiro (no specimens are known to exist; lectotype, designated by Knapp et al. 2015, pg. 832: original parchment plate held in Biblioteca Nacional. Rio de Janeiro [mss1198651_128]; incorrectly lectotypified by Matesevach Becerra 2013, pg. 290 on the published plate in Vellozo, Fl. Flumin. Icon. 2: Table 125. 1831).

Solanum viridipes Dunal, Prodri. [A. P. de Candolle] 13(1): 234. 1852 — TYPE: BRAZIL: Bahia, J. Guillot s. n. (holotype: P [P00384877, F neg. 39219]).

Solanum juciri Sendtn. var. *inermis* Glaz., Bull. Soc. Bot. France 58 (Mem. 3f): 497. 1911. —TYPE: BRAZIL. Rio de Janeiro: Fazenda de Boa Esperança, Chez M. Bellieni, dans les cafféiers, 22 Oct 1886, A. F. M. Glaziou 16294 (lectotype, designated here: P [P00319401]; isolectotypes: C, K [K000788574]).

Solanum juciri Sendtn. forma *paraguaricense* Hassl., Repert. Spec. Nov. Regni Veg. 9: 118. 1911. *Solanum viridipes* Dunal var. *intermedium* Hassl., Repert. Spec. Nov. Regni Veg. 15: 239. 1918. —TYPE: PARAGUAY. Caaguazú [Depto. Caaguazú], Amambay [Depto. Amambay] and Paraná regions, Mar 1905, É. Hassler 9365 (lectotype, designated by Matesevach Becerra 2013, pg. 290: BM [BM000087604];

isolectotypes: G [G00443009, Morton neg. 8558; G00443010], GH [no barcode or sheet number], K [K000788653], NY [NY00172245], P [P000384878, Morton neg. 8362], W [W-1906-0001280].

Woody or subwoody vines to 3 + m long or scandent shrubs, the stems 0.2–0.4 cm in diameter, prickly; internodes 1–5 cm long, glabrescent; prickles to 2 mm long, stout, recurved. Sympodial units usually plurifoliate, rarely difoliate, not geminate. Leaves pinnately compound, the blades in outline (5–)15–20 × (4–)6–12 cm, with 5–7 pairs of opposite to subopposite petiolulate leaflets, chartaceous, glabrous adaxially and abaxially, with calcium oxalate crystals commonly present, often armed on rachis with recurved prickles; major lateral veins 5–7 on each side, corresponding to the leaflets; petioles (1–)3–5 cm, glabrous, often armed with recurved prickles; leaflets 3–10 × 1–3 cm, oblong to elliptic, widest at the base; base cuneate and oblique; margin entire; apex acuminate; petiolules 0.3–1 cm. Inflorescences (10–)20–30 cm long and wide, terminal or appearing lateral, several times branched, with 20–35 flowers, the axes glabrous, densely prickly; peduncle (2–)5–15 cm; rachis 4–10 cm; pedicels 10–15 mm, slender at anthesis, articulated at the base; fruiting pedicels to ca. 20 × 3 mm and becoming subwoody. Flower buds ellipsoid to somewhat pointed, the corolla soon exserted from the calyx tube. Calyx campanulate, spreading, the tube 2–4 mm, the lobes ca. 3 × 2 mm, rounded, apiculate at tips, glabrous, reflexed at anthesis. Corolla 2.5–4 cm in diameter, spreading at anthesis, uniformly white or greenish white, sometimes tinged with violet (Nee 54960, plant cultivated in Bolivia), membranous to slightly fleshy, stellate, lobed ca. 3/4 way to the base, the lobes 1–2 × 0.3–0.5 cm, narrowly triangular, acute to acuminate at apices, glabrous abaxially and adaxially, the tips densely papillate. Stamens 5–10 mm long; filaments unequal, with four 1–1.5 mm long, the fifth 3–4 mm long, glabrous; anthers nearly equal, 5–7 × 1.5–2 mm, the one on the longer filament slightly larger, tapering at the tips, connivent, yellow or orange, poricidal at the tips, the pores lengthening to slits with age. Ovary glabrous; style in long-styled flowers ca. 10 mm long, straight, glabrous, in short-styled flowers ca. 4 mm long; stigma truncate. Fruit a globose berry, 3–4 cm in diameter, green with light green streaks when immature, yellow with white streaks when ripe, the pericarp glabrous, rugose when dry. Seeds > 20 per berry, ca. 3 × 3 mm, strongly flattened-reniform, light brown, the surface foveolate. Figs. 1A–B, 3.

Distribution and Habitat—*Solanum alternatopinnatum* (Fig. 4) occurs in Argentina (Province of Misiones), Brazil (States of Bahia, Distrito Federal, Espírito Santo, Mato Grosso, Minas Gerais, Paraná, Rio de Janeiro, São Paulo) and Paraguay (Provinces of Alto Paraná, Canindeyú, San Pedro) in the wet forests of “mata atlântica” or “Selva Paranense” at elevations from 100–950 m.

Phenology—*Solanum alternatopinnatum* is most commonly collected in flower from November to April, and fruiting collections are most common from June to August.

Common Names—Brazil: “juciri” (*Martius s. n.*); “jiquiri” (*Warming s. n.*). Paraguay: “yuá-pará” (*Woolston 826*).

Preliminary Conservation Status (IUCN 2014)—Least Concern (LC); EOO 2,998,232 km² (LC); AOO 240 km² (EN); 75 localities. Although the AOO suggests that *S. alternatopinnatum* is of some conservation concern, the large number of localities and wide habitat preferences of this species lead us to give it the assessment of LC.

Solanum alternatopinnatum differs from other species of *Solanum* section *Aculeigerum* in its compound leaves with clearly petiolulate leaflets, heterandrous flowers, and nearly herbaceous stems. *Solanum pachyandrum* and *S. refractum* have deeply pinnatifid leaves but do not have clearly petiolulate leaflets and *S. refractum* occasionally has leaves that are very shallowly lobed. We have only seen a single specimen of *S. alternatopinnatum* (Glaziou 16294, one of the type collections of *S. juciri* var. *inermis*) with simple leaves. The stems of *S. alternatopinnatum* are herbaceous or rarely subwoody in contrast to the subwoody stems of *S. refractum*. These species are also completely allopatric, with *S. refractum* restricted to southern Mexico, *S. pachyandrum* found in the Huancabamba depression of northern Peru and southern Ecuador and *S. alternatopinnatum* ranging from Brazil and Paraguay to northern Argentina.

Leaves of *S. alternatopinnatum* are eaten as a vegetable in Brazil (as jiciri or juciri; Mentz and Oliveira 2004); apparently the prickles soften with cooking.

This species was known for a long time as *S. juciri* Sendtn., a name coined as a replacement for *S. oleraceum* Vell. (Vellozo 1829), a later homonym of *S. oleraceum* Dunal (Dunal 1813; a synonym of *S. americanum* Mill. of the Morellloid clade). *Solanum juciri* is an illegitimate name (McNeill et al. 2012) as *S. alternatopinnatum* was cited in synonymy, with the comment “nomen ineptissimum plantae ab auctore non visae pinni tam alternantibus quam oppositis instructe datum” (this is a silly name given to this plant by the author who did not see alternate but opposite leaflets); Sendtner (1846) recognized the existence of the name but considered it inappropriate.

In describing *S. viridipes*, Dunal (1852) cited two elements: an herbarium specimen *Guillot s.n.* from Paris, and a living plant “v.v. in hort. Monsp.” cultivated in Montpellier. Since he only cited a single herbarium specimen, this is the holotype (McNeill 2014). He also further specified and annotated material as “*S. laxiflorum* Dunal mss. in herb. Schad. nec Sendtn.” The holotype specimen in P (P00384877) has a number of annotations on it, including “*S. laxiflorum* Dun. 1842 nec Sendtn. 1848.” We suspect “in herb. Schad.” is a misprint for “in herb. Sched.” and refers to an annotation on a herbarium specimen and not to a particular herbarium.

Names coined by Glaziou (1911) in his list of plants from Central Brazil are sometimes indicated as not validly published. Here we are treating the varietal name *S. juciri* var. *inermis* as validly published as it is accompanied by a (very short) description that distinguishes it from the species. Glaziou (1911) cited only his collection number 16294 in the protologue, but a compound locality (“Fazenda de Boa Esperança, près Cantagallo et Serra da Estrella RIO-JAN”). In Paris there are two sheets of this number that are clearly collected in two places — one in Serra da Estrella (P00319400, Feb 1880, Glaziou 16294a) and the other from Fazenda de Boa Esperança (P00319401, 22 Oct 1886, Glaziou 16294). The ‘a’ has been added to the number in Glaziou’s handwriting. Glaziou 16294a has typical pinnately compound leaves, while the other sheet has unusual simple leaves (see above). We select P00319401 as the lectotype of this varietal name as there is a clear duplicate at Kew as evidenced by the simple leaves on the K sheet.

Hassler described *S. juciri* forma *paraguariense* using his collection Hassler 9365 and seven years later used the same collection (together with Fiebrig 6157) to describe *S. viridipes* var. *intermedium* as a new name for his forma *paraguariense*

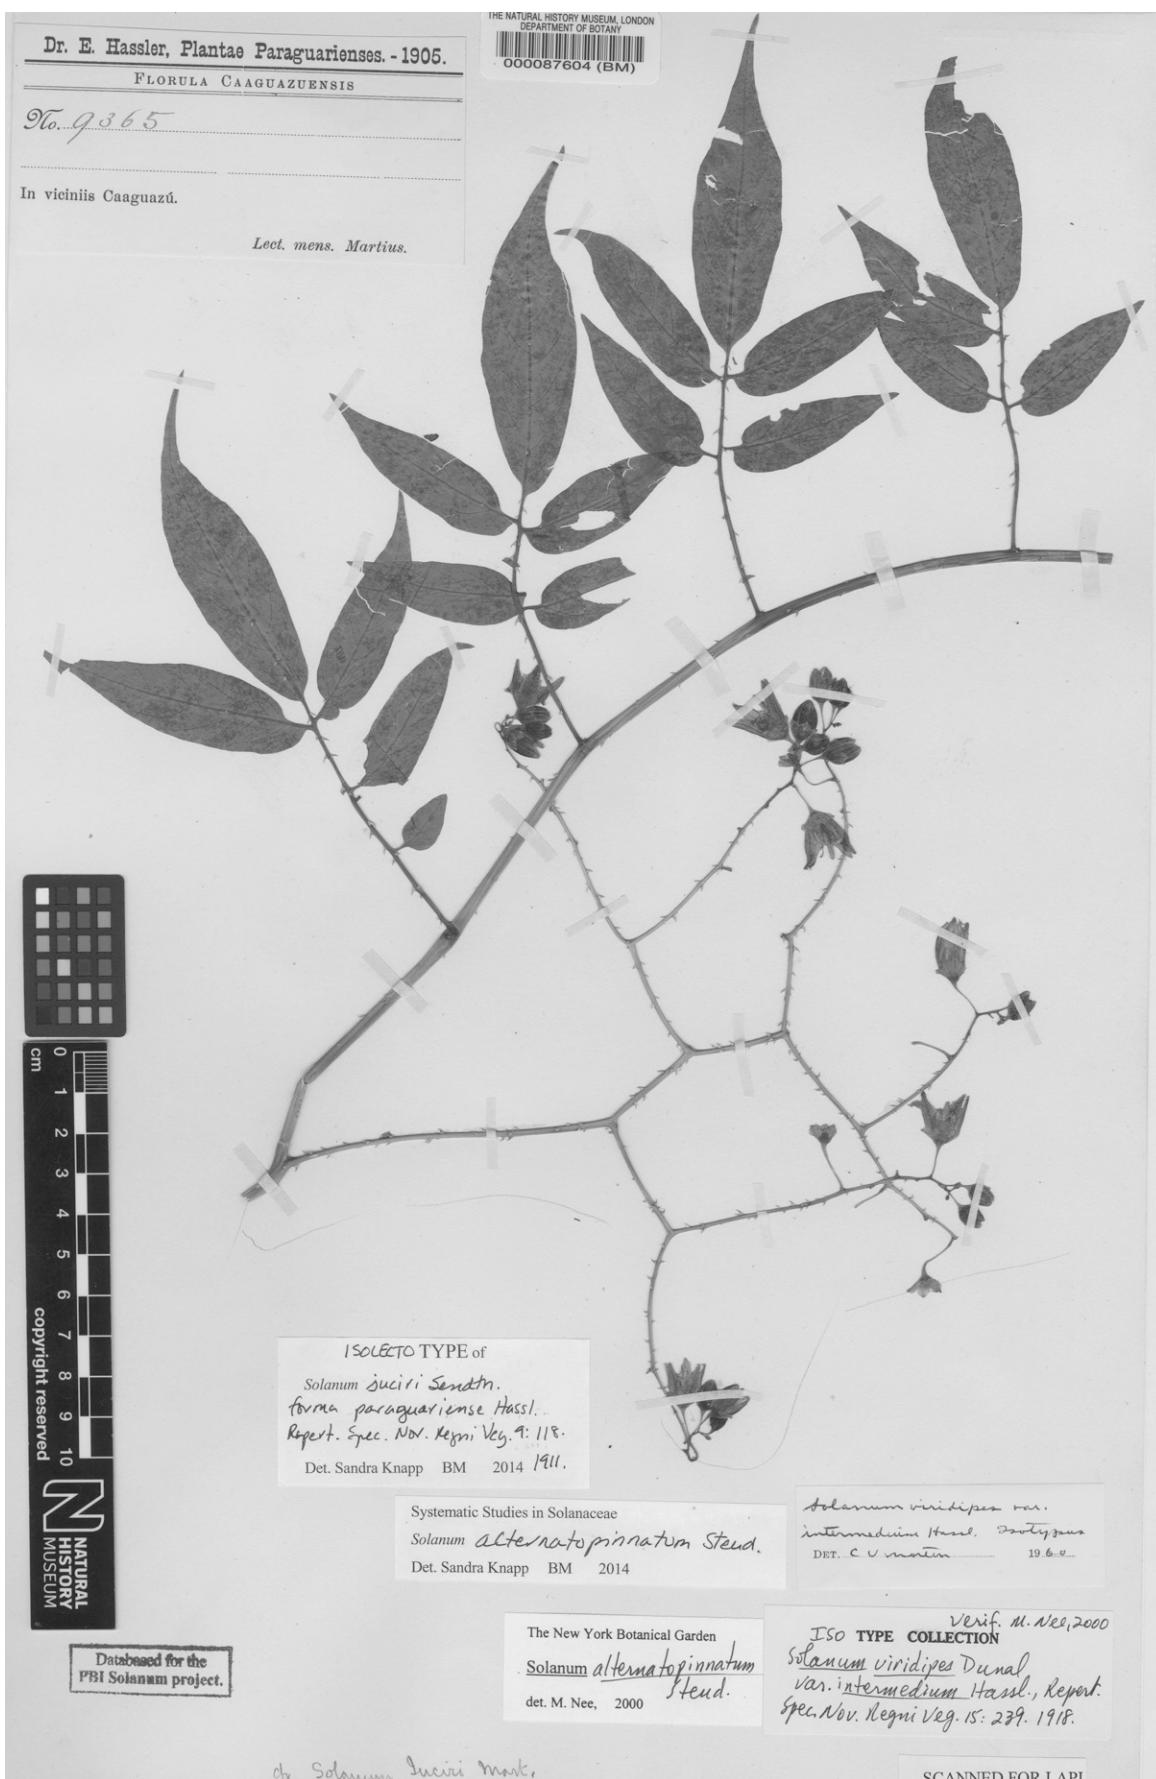

FIG. 3. *Solanum alternatopinnatum* from Paraguay (É. Hassler 9365, lectotype of *Solanum juciri* Sendtn. forma *paraguarieense* Hassl., BM [incorrectly labelled isolectotype in image]). Reproduced with permission of the Natural History Museum, London.

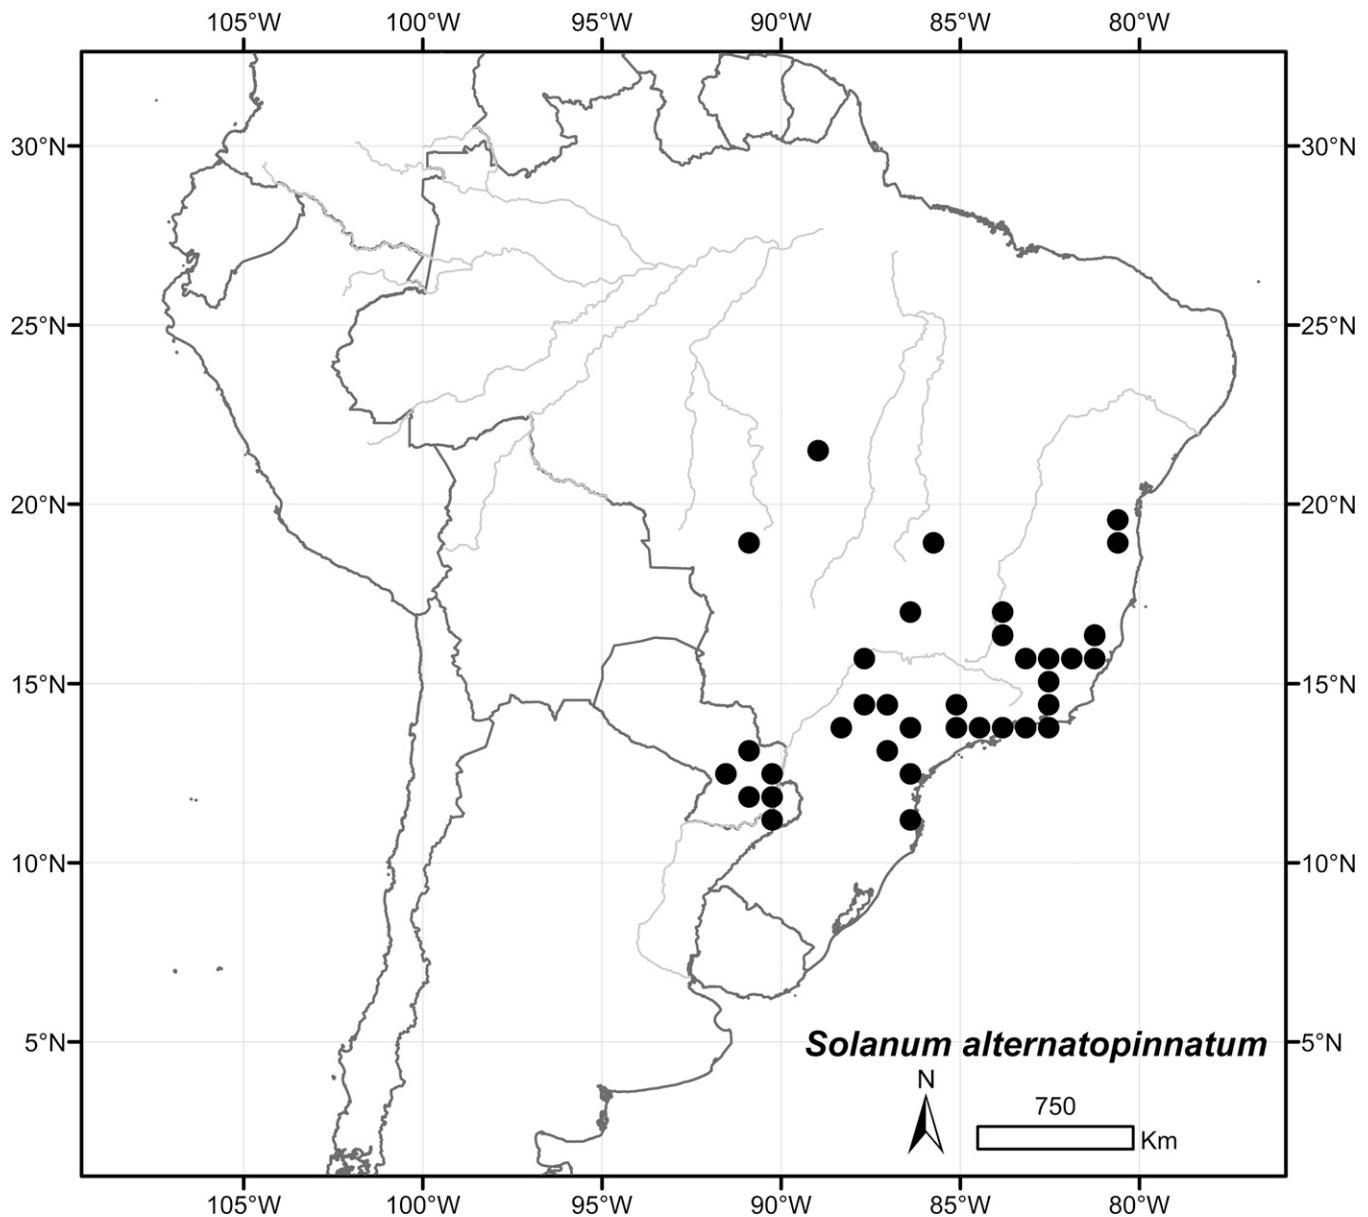

FIG. 4. Distribution of *Solanum alternatopinnatum*.

(Hassler 1911, 1918). He described var. *intermedium* in terms of his forma *paraguarieense* ("Caule foliis ut in Fedde Rep. l. c. pro forma *paraguarieensi* nob. indicatus" [stem and leaves from Fedde Rep. description of the new forma *paraguarieense*]: Hassler 1918: 239). We consider that he was explicitly coining a new name using the same material to replace forma *paraguarieense*, and therefore treat these two names as homotypic as did Matesevach Becerra (2013). It is unfortunate that Matesevach Becerra (2013) did not use material at G annotated by Hassler, but her lectotypification is correctly made and stands.

Representative Specimens Examined—BRAZIL. Bahia: Mun. Jussari, Palmira, entrada ca. 7.5 km de Jussari, Faz. Teimoso, RPPN Serra do Teimoso, 21 Apr 1999 (fl), Amorim et al. 2915 (CEPEC, MO, NY); Jucari, 27 May 1966 (fl), Belém & Pinheiro 2329 (US); Mun. Almadina, Faz. 2. **SOLANUM BICORNE** Dunal, Prodr. [A. P. de Candolle] 13: 232. 1852.—TYPE: MEXICO, “Pavón s. n.” [a collection made by M. Sessé and J. Mociño and distributed from Pavón’s herbarium, see Knapp 2008b] (holotype: G [G000343458, F neg. 34109]).

Solanum bincorne Dunal var. *angustifolium* Dunal, Prodr. [A. P. de Candolle] 13(1): 233. 1852.—TYPE: MEXICO, “Pavón s. n.” [a collection made by M. Sessé and J. Mociño and distributed from Pavón’s herbarium, see Knapp 2008b] (holotype: G [G000343452, F neg. 34110]; isotype: F [F-846743]).

Solanum dichotomum Sessé & Moc., Pl. Nov. Hisp. 35. 1888.—TYPE: MEXICO. Guerrero: Mazatlán, M. Sessé & J. Mociño 5348 (lectotype, designated by Knapp 2008b, pg. 11; MA [MA-604601, F neg. 48342]; isolectotypes: F [F-845066, fragment], MA [MA-604599, F neg. 48341; MA-604600]).

Solanum guamuchilense Cast.-Campos, Acta Bot. Mex. 27: 34, Fig. 1. 1994.—TYPE: MEXICO. Nayarit: Mpio. Bahía de Banderas, El Guamúchil, between Bucerías and Sayulita, ejido of Punta Mita, 300 m, 10 Oct 1990, G. Castillo Campos 6103 (holotype: XAL [XAL0106656]; isotype: XAL [XAL0106655]).

Woody vine to 15 + m long, the stems 0.25–0.9 cm in diameter; internodes 5–10 cm long on main stems, 0.5–1 cm long on short shoots, glabrous or puberulent with simple hairs to 0.5 mm long with enlarged pustulate bases; prickles

2–5 mm long, stout, recurved, occasionally very sparse on long internodes. Sympodial units plurifoliate, not geminate, the leaves clustered on short shoots to 5 cm long. Leaves usually simple (one specimen seen with deeply pinnatifid juvenile leaves on vigorous shoots), the blades 10–28 × 5–10 cm, oblanceolate to lance-elliptic, chartaceous, puberulent adaxially and abaxially with simple 2–4-celled hairs 1–1.5 mm long with an elongate basal cell, often armed abaxially on midrib with recurved prickles; major lateral veins 3–5 on each side; base long-attenuate; margin usually entire, occasionally sinuate with 2–3 pairs of shallow lobes ca. 3 × 2.5 cm (leaves on very young shoots possibly more deeply lobed); apex acute to acuminate; petioles broadly winged to base and nearly sessile. Inflorescences ca. 30 × 20 cm, terminal or lateral on young growth of short shoots, many times branched, with 20–55 flowers, the axes glabrous or occasionally minutely puberulent with simple 1–2-celled trichomes to 0.5 mm long, not prickly, or sometimes with a few prickles at the base (*Soto N.* 10188); peduncle 6–15 cm; rachis (5)–15–20 cm; pedicels 10–15 mm and slender at anthesis, elongating in fruit to 2–2.5 × ca. 1 cm and becoming subwoody, terminally clustered, articulated at the base. Flower buds narrowly ellipsoid to pointed, the corolla early exserted from the calyx tube. Calyx campanulate, spreading, the tube 2–4 mm, the lobes ca. 1.5 × 2 mm, rounded, apiculate at tips, glabrous. Corolla 2.5–4 cm in diameter, spreading at anthesis, creamy white, membranous, deeply stellate, lobed nearly to the base, the lobes 1–2 × 0.3–0.5 cm, narrowly deltate to triangular, acute to acuminate, glabrous abaxially and adaxially, densely short white pubescent at the hooked cucullate tips. Stamens 5–10 mm long; filaments unequal, with four ca. 1 mm long, and one ca. 5–6 mm long (at approximately the same height as the tips of the other four anthers), glabrous; anthers nearly equal, 4–6 × 1.5–2 mm, the one on the longer filament slightly larger, usually somewhat tapering, connivent, yellow or orange, poricidal at the tips, the pores lengthening to slits with age. Ovary glabrous; style in long-styled flowers ca. 10 mm long, approximately equal in height to the long stamen, straight, glabrous, in short-styled flowers ca. 5 mm long; stigma capitate. Fruit a globose berry, ca. 5.5 cm in diameter, globose, red or orange, the pericarp glabrous, rugose when dry. Seeds > 50 per berry, ca. 5 × 5.5 mm, strongly flattened-reniform, brown, the surfaces minutely pitted. Fig. 5.

Distribution and Habitat (Fig. 6)—*Solanum bincorne* is endemic to Mexico (States of Colima, Durango, Guanajuato, Guerrero, Jalisco, Michoacán, Morelos, Nayarit, Sinaloa, and Zacatecas), in deciduous forests, grasslands, and humid montane forests at elevations from sea level to 2,000 m.

Phenology—*Solanum bincorne* appears to flower and fruit throughout the year, but more fruiting specimens have been collected from November to April (e.g. *Gentry* 5248).

Uses—Mexico: “The fruits are red when ripe in March and April and eaten by birds” (*Gentry* 5248).

Common Names—Mexico. Guerrero: “chilacayote” (*Halbinger* s.n.); “tomate de chichalaca” (*Halbinger* s.n.); Sinaloa: “toronjo” (*Montes & Salazar* 591 and *Ortega* 4021).

Preliminary Conservation Status (IUCN 2014)—Least Concern (LC); EOO 545,195 km² (LC); AOO 404 km² (EN); 126 localities. *Solanum bincorne* is a commonly collected and apparently relatively common species where it occurs.

This species is easily differentiated from others in section *Aculeigerum* by the presence of clustered leaves on short shoots

FIG. 5. Representative specimen of *Solanum bicine* from Mexico (C. Pringle 6396, BM). Reproduced with permission of the Natural History Museum, London.

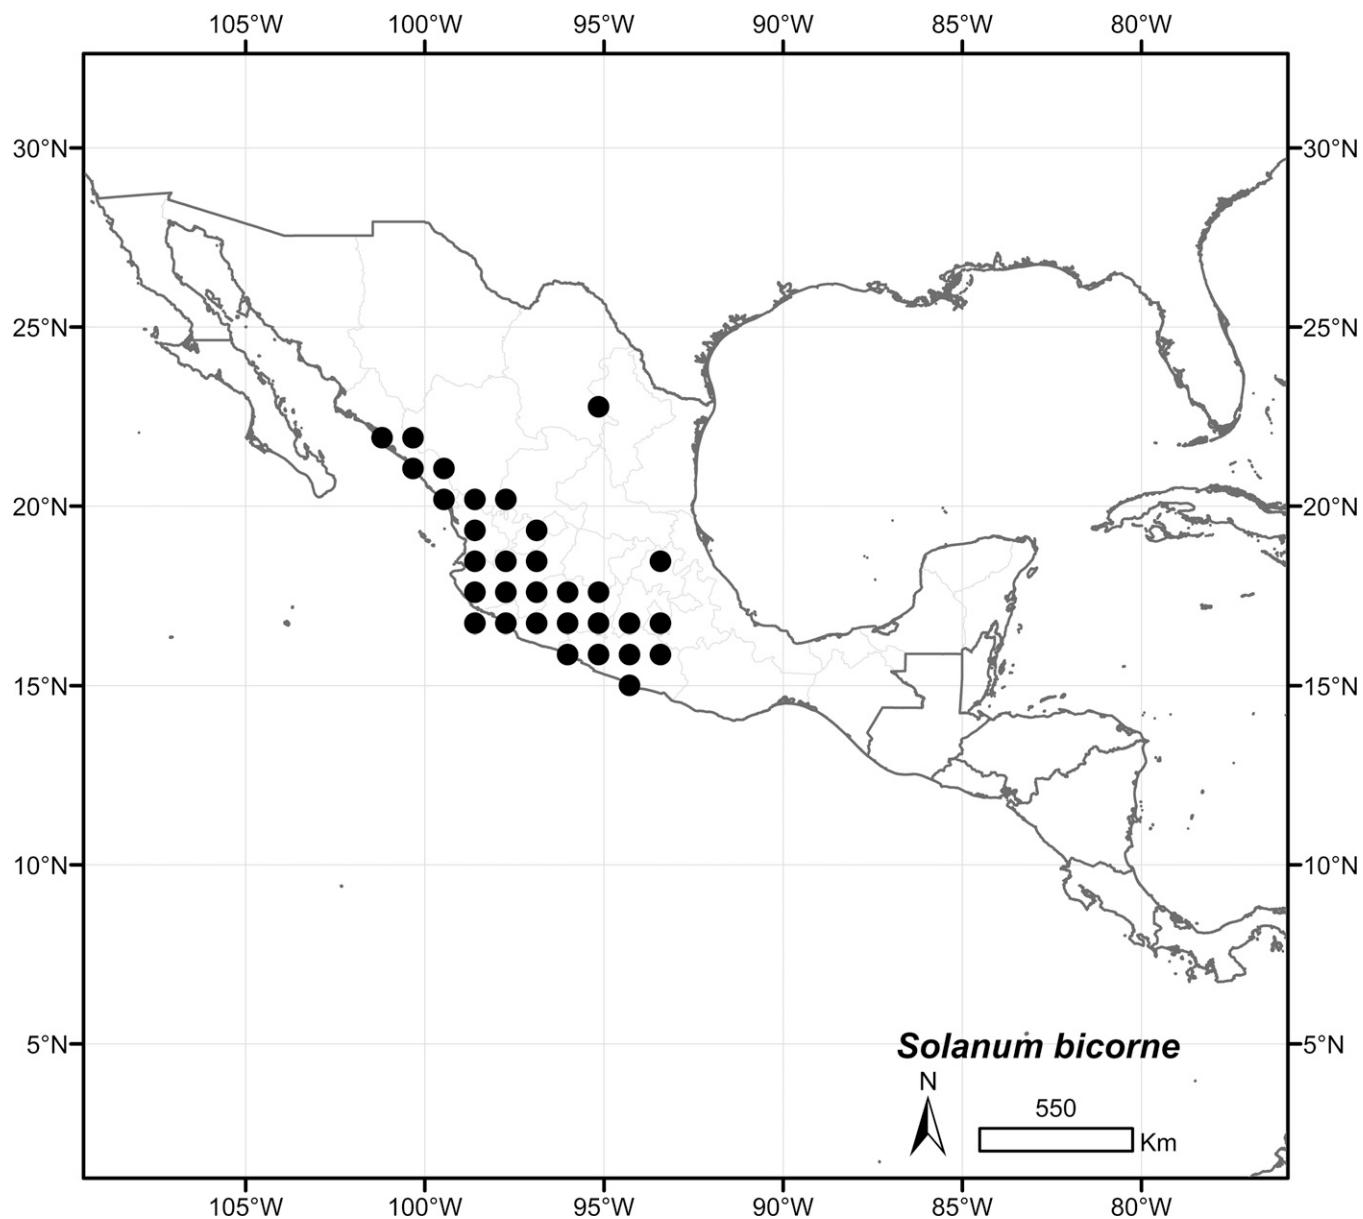

FIG. 6. Distribution of *Solanum bicorne*.

(Fig. 5). Dunal, in describing *Solanum bicorne*, mistook the clustered stem leaves as being the rosette of a possibly acaulescent herb (Dunal 1852: 232) when in fact the plant is a high-climbing, robust, woody vine. This species is similar to *S. glaucescens*, especially with respect to the white, stellate flowers with dimorphic stamens, but differs by its leaves that are narrowed to the base with definite wings on the petiole and short shoots with densely crowded leaves. A pair of prickles at the base of the petiole is present in *S. glaucescens* but absent in *S. bicorne*.

A single specimen identified here as *S. bicorne* from Sinaloa (Sanders *et al.* 4576, MO-3279500) has quite deeply lobed leaves that resemble those of *S. refractum*, but these seem to be from a very young shoot and have fewer lobes than typical specimens of *S. refractum*. The non-prickly inflorescence rachis arising from a short shoot and distribution suggest this specimen is *S. bicorne* with juvenile foliage. Other *Solanum* species have pinnatifid juvenile foliage (e.g. members of the Dulcamaroid clade such as *S. dulcamaroides* Poir., see Knapp

2013) that is rarely collected; this needs further investigation in the case of *S. bicorne* and other members of this group of woody vines.

In his description of *S. bicorne* Dunal (1852) cited a specimen from "Nova Hispania (Pavon in hb. Boiss. sub nom. *S. bicorne*)"; he used the name on the specimen that almost certainly came from the original collection made in Mexico by Martin Sessé and José Mociño. A single specimen from the Boissier herbarium (now part of the general collections at G) is therefore the holotype for this name. The complex typification of names for this species based on the Mexican and Central American collections of Martin Sessé and José Mociño is discussed in detail in Knapp (2008b).

Representative specimens examined—MEXICO. Colima: 14 mi WNW of Santiago, road to Cihuatlán, Jalisco, 5 m, 25 Jul 1957 (fl), McVaugh 15741 (MEXU); Mpio. 3. *SOLANUM COBANENSE* J. L. Gentry, Phytologia 26(4): 276. 1973.—TYPE: Nom. nov. for *Cyphomandra aculeata* Donn. Sm. (1914), non *Solanum aculeatum* (Jacq.) O. E. Schulz.

Cyphomandra aculeata Donn. Sm., Bot. Gaz. 57: 423. 1914.—TYPE: GUATEMALA. Alta Verapaz: Cobán, Apr 1882, F. Lehmann 1334 (holotype: US [US-1324994, barcode US00036715]; isotypes: BM [BM000514914], G [G00442620]).

Robust woody vine or canopy liana to 18 m long, the stems 0.3–0.8 cm in diameter, prickly, sometimes densely so; internodes 3–10 cm long, completely glabrous; prickles to 3 mm long, stout, recurved. Sympodial units plurifoliate, not geminate. Leaves simple, the blades (6–)12–17 × 3–5(–9) cm, ca. 3 times as long as wide, oblong or elliptic to narrowly elliptic, widest at the middle, coriaceous, glabrous on both surfaces, armed abaxially on midrib with recurved prickles; major lateral veins 6–9 on each side; base truncate to acute; margin entire; apex acuminate to acute; petioles (1–)3–7 cm, glabrous, armed with recurved prickles. Inflorescences 10–15 cm long and wide, terminal, few-branched, the axes glabrous, not prickly; peduncle 3–5 cm; rachis (3–)5–10 cm; pedicels (10–)25–50 mm and slender at anthesis, elongating in fruit to ca. 50 × 6 mm and becoming woody, articulated at the base. Flower buds ellipsoid, the corolla strongly exserted from the calyx when very young. Calyx campanulate, spreading, the tube 5–7 mm, the lobes ca. 2 × 4 mm, rounded, the tips apiculate, minutely papillate on the thickened margins. Corolla 4–6 cm in diameter, spreading at anthesis, thick and fleshy, blue to violet, deeply stellate, lobed ca. 3/4 of the way to the base, the lobes 1.2–2 × 0.3–0.6 cm, deltate to triangular, glabrous adaxially, mostly glabrous abaxially, the tips deeply cucullate, minutely papillate at the tips and margins. Stamens equal, to 12 mm long; filaments ca. 2 mm long, glabrous; anthers ca. 10 × 1 mm, ellipsoid, yellow, poricidal at the tips, the pores lengthening to slits with age. Ovary glabrous;

FIG. 7. Representative specimen of *Solanum cobanense* from Guatemala (Förther et al. 10950, BM). Reproduced with permission of the Natural History Museum, London.

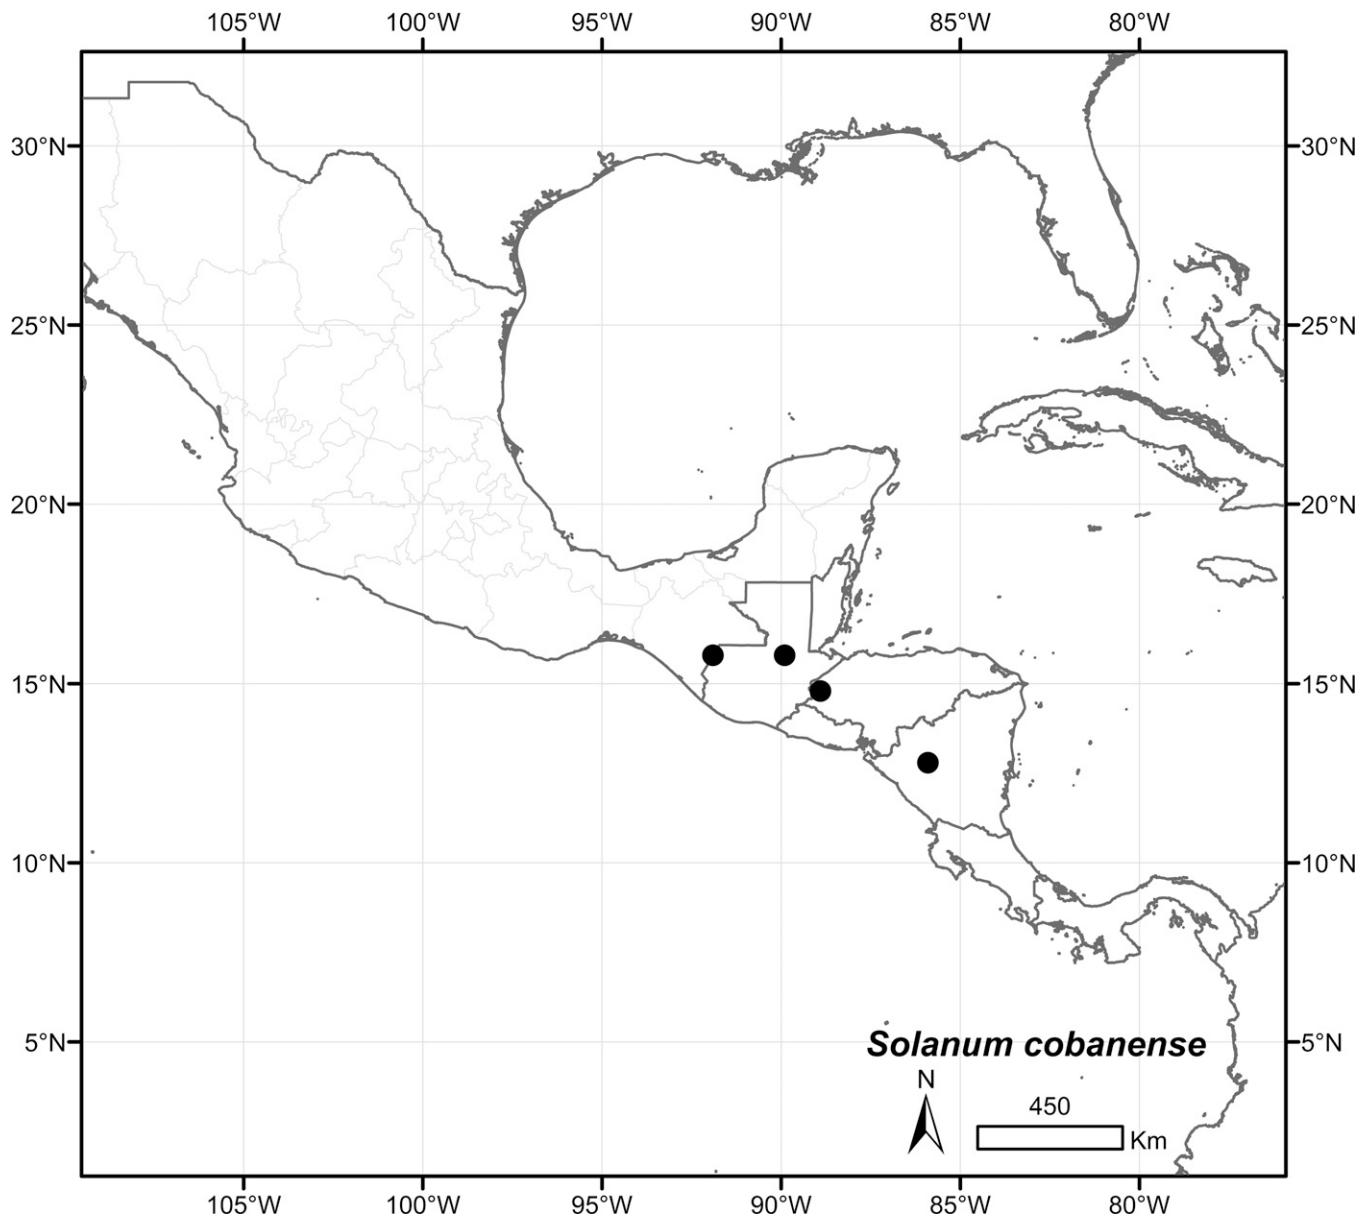

FIG. 8. Distribution of *Solanum cobanense*.

style in long-styled (?) flowers ca. 6 mm long; stigma clavate and somewhat bilobed. Fruit a globose or apically pointed ("turnip-shaped" fide Steyermark 42873) berry ca. 3.5 × 4 cm, green, glabrous with rugose surface when dry, the flesh white. Seeds < 30 per berry, ca. 4 × 5 mm, strongly flattened, light brown, the surface foveolate. Figs. 1C–D, 7.

Distribution and Habitat—*Solanum cobanense* (Fig. 8) occurs in the cloud forests of Honduras (Dept. of Lempira, Comayagua), Nicaragua (Dept. of Estelí), and Guatemala (Dept. of Alta Verapaz, Huehuetenango) at elevations from 900–2,550 m.

Phenology—*Solanum cobanense* is most commonly collected in flower from March to May, and fruiting specimens have been collected from October to January.

Preliminary Conservation Status (IUCN 2014)—Vulnerable (VU); EOO 6,668 km² (LC); AOO 28 km² (EN); 8 localities. *Solanum cobanense* would merit a status of endangered based on the AOO, but given that it is a canopy liana, it is likely that it is overlooked by many general collectors.

Solanum cobanense differs from all species of *Solanum* section *Aculeigerum* except *S. triunfense* by its woody canopy liana habit, coriaceous leaves, and large, fleshy flowers (4–6 cm in diameter) with stamens and anthers of equal size (Fig. 1C). Some specimens of *S. wendlandii* have simple leaves and might be confused with *S. cobanense*, but the rotate flowers of *S. wendlandii* with unequal anthers are distinctive.

Solanum cobanense differs from *S. triunfense*, with which it is nearly sympatric, in its regular calyx lobes that do not completely enclose the bud at late stages, the completely glabrous stems and new growth, and the acute, rather than attenuate, leaf bases. The flowers of *S. cobanense* are more deeply stellate than those of *S. triunfense*, but this character can be difficult to assess in herbarium sheets where flowers are collected at different stages of development.

Specimens examined—GUATEMALA. Alta Verapaz: Sierra de Chamá, Montaña Yalijux, Finca Chelem-há, Aufsteig vom Tal des Riachuelo Yalijux [15°23'09"N - 90°03'45"W] zum nördlichen Bergkamm [15°23'32"N - 90°04'12"W], ca. 15 km Luftlinie NE von Tucurú, 27 Mar 2001 (fl), Förther

et al. 10950 (BM); Pansamala, May 1887 (fl), *von Türkheim* 746 (US). Huehuetenango: Nentón, Nuevo San José Frontera, along trail to Laguna Yolnojal (=Laguna Brava), 16°03'N, 91°33'W, 900–1,100 m, 6 Mar 2009 (fl), Christenhusz *et al.* 5584 (BM, NY). Zacapa: Sierra de Las Minas, between Cerro de Monos and upper slopes of Monte Virgen, 6,562–8530 ft., 17 Jan 1932 (fr), Steyermark 42873 (F, NY).

HONDURAS. Comayagua: Campo Naranja, trail from Gracias “El Mahon,” 10 km SW of Gracias, 13°32'N, 88°39'W, 2,550 m, 13 May 1992 (fl), D’Arcy 17923 (MO). Lempira: Quebrada Naranjo, W of Campo Don Tomás, 10 km SW of Gracias, Parque Nacional de Celaque, 14°33'N, 88°40'W, 1,950 m, 29 Jan 1992 (fr), Hawkins *et al.* 140 (MO); Río Naranjo, Parque Nacional de Celaque, 14°33'N, 88°40'W, 2,100 m, 24 May 1991 (fl), House & Andino 968 (MO); W of Campo Don Tomás, 10 km SW of Gracias, Parque Nacional de Celaque, 14°32'N, 88°40'W, 2,200 m, 11 Feb 1993 (fr), Mejía 252 (MO).

NICARAGUA. Estelí: Salto de Estancuela, Río Estancuela, ca. 6 km S of Estelí, 13°01' N, 86°20'W, 920–1,020 m, 1 Oct 1979 (fr), Stevens *et al.* 14381 (MO).

4. *SOLANUM GLAUCESCENS* Zucc., Abh. Math.-Phys. Cl. Königl. Bayer. Akad. Wiss. 2: 325. 1837.—TYPE: Grown in the Munich Botanical Garden by Zuccarini from seeds collected in Mexico by Karwinsky [Wilhelm Friedrich Karwinsky von Karwin], 1835, *Anonymous s.n.* (neotype, designated here: M [M0124264, Morton neg. 8691]; isoneotype: BR [BR0000008366221]).

Solanum hamatile Brandegee, Univ. Calif. Publ. Bot. 6: 192. 1915.—TYPE: MEXICO. Oaxaca: Río San Gerónimo, Jul 1914, C. Purpus 7164 [“6164” in the protologue] (holotype: UC [UC175042]; isotypes: BM [BM000514922], F [F-424575], MO [MO-555119], NY [NY00138991], US [US-467485]).

Solanum oaxacanum Dunal, Prodr. [A. P. de Candolle] 13(1): 204. 1852.—TYPE: MEXICO. Oaxaca: Tehuántepēc, Aug, G. Andrieux 189 (holotype: G-DC [G00154874, F neg. 6832, IDC microfiche 800–61.2078:I.6]; isotypes: K [K000063703, K000195650], W [W0003308]).

Solanum sagranum A. Rich., Hist. Fis. Cuba 11: 124. 1850, as “*sagraeanum*”. *Solanum lanceifolium* Jacq. var. *sagranum* (A. Rich.) M. Gómez, Anal. Hist. Nat. Madrid 23: 268. 1894, as “*sagraeanum*”—TYPE: CUBA. Sin. loc., R. De la Sagra *s.n.* (lectotype: designated here: P [P00370903]; isolectotypes: F, K [K000449492], P[P00371124, P00371122, P00371123, P00445150], W).

Woody vine or scandent shrub 2–5 m long, the stems 0.25–0.6 cm in diameter, usually very sparsely prickly; internodes 1–5 cm long, glabrous, with paired prickles at base of each petiole, these 2–8 mm long, stout, recurved. Sympodial units plurifoliate, not geminate. Leaves deciduous in the dry season, simple, the blades 3.5–9 × 1.5–5.5 cm, 1.6–2.3 times as long as wide, narrowly oblong to ovate, chartaceous, glabrous adaxially and abaxially, often armed abaxially on midrib with recurved prickles; major lateral veins 3–6 on each side; base cuneate to decurrent; margin entire; apex acuminate; petioles 1–4 cm, glabrous, often prickly. Inflorescences 7–10 × 15–20 cm, terminal or lateral, unbranched or few-branched, with 5–12 flowers, the axes glabrous, not prickly; peduncle 1–2 cm; rachis 2–7 cm; pedicels 5–10 mm and slender at anthesis, articulated at the base; fruiting pedicels elongating to 3–4 cm and becoming woody. Flower buds ellipsoid, the corolla exserted from the calyx tube long before anthesis. Calyx campanulate, spreading, the tube 2–4 mm, nearly entire with five shallowly subcaudate, broadly deltate, acuminate lobes, glabrous except for the

puberulent tips. Corolla 2–4 cm in diameter, spreading at anthesis, pale yellow to yellow-green, membranous, deeply stellate, lobed nearly to the base, the lobes ca. 1.5 × 0.5 cm, lanceolate to broadly deltate, acute at apices, glabrous abaxially, glabrous adaxially except puberulent at tips. Stamens 10–15 mm long; filaments unequal, with four 1.5–2 mm long, the fifth 3.5–4.5 mm long, glabrous; anthers nearly equal, 6–9 × 1.5–2 mm, the one on the longer filament slightly larger, slightly tapering, connivent, white to yellowish-orange, poricidal at the tips, the pores lengthening to slits with age. Ovary glabrous; style in long-styled flowers ca. 15 mm long, straight, glabrous in short-styled flowers ca. 2 mm long; stigma truncate. Fruit a globose berry, ca. 3.5 cm in diameter, mottled dark green and light green when immature, turning orange when mature with orange-red pulp, the pericarp glabrous, rugose when dry. Seeds > 50 per berry, 4–5 × 3–5 mm, flattened-reniform to somewhat ovoid, light brown, the surfaces minutely pitted, the testal cells pentagonal in shape, the lateral cell walls elongate and the seed appearing hairy when outer testal walls break down. Fig. 9.

Distribution and Habitat (Fig. 10)—Endemic to southern Mexico (States of Chiapas, Guerrero, Oaxaca, and Puebla) in deciduous and semi-deciduous forests; 10–1,400 m.

Phenology—*Solanum glaucescens* appears to flower and fruit at the same time; flowering specimens are most commonly collected from April to July and fruiting specimens from July to January.

Common names—Mexico. Puebla: “cuatomate” (*Huerta Z. & Huerta Z. 1*); Oaxaca: “zarza” (*Elorsa 301*).

Preliminary Conservation Status (IUCN 2014)—Least Concern (LC); EOO 221,062 km² (LC); AOO 324 km² (EN); 95 localities. *Solanum glaucescens* is known from a large range, and is relatively commonly collected within it.

Solanum glaucescens differs from other members of section *Aculeigerum* by the presence of paired recurved prickles flanking the petiole base (Fig. 9). These appear stipular, but stipules are absent in the Solanaceae, and these are prickles like those found on the rest of the plant. The similar situation occurs in the unrelated spiny solanum species *S. microphyllum* (Lam.) Dunal of the West Indies (Knapp 2009). *Solanum glaucescens* differs from *S. bincorne*, with which it is partly sympatric, in its widely spaced leaves (not clustered as in *S. bincorne*), smaller yellowish green rather than white flowers, and in its glabrous leaf undersides. *Solanum glaucescens* is usually a more delicate plant than *S. bincorne*. Trichomes, if present, on all parts of *S. glaucescens* are small and unicellular, not the uniseriate trichomes with elongate basal cells of *S. bincorne*.

Zuccarini (1837) mentions no herbarium specimens in the protologue of *S. glaucescens*, and states only “Crescit in imperio mexicano, unde semina misit clar. de Karwinski. Floret nobis caldariis Augusto, Septembri (v.v.)”, although the herbarium of the Munich garden is mentioned in the title of his article. The indication “(v.v.)” indicates he saw a living plant, from which the extant herbarium specimens were presumably made. We therefore designate the sheet in the Munich herbarium (M0124264) taken from plants cultivated there in 1835 as the neotype of *S. glaucescens*; the sheet in BR labelled as coming from “h. Mon.” (garden [hort.] or herbarium [herb.] of Munich) with no date is a probably an isoneotype.

The epithet *sagranum* honoring Ramón De la Sagra was originally spelled *sagraeanum*, a correctable orthographic error following Art. 60 Rec. 60C.1 of the *Code* (McNeill *et al.* 2012).

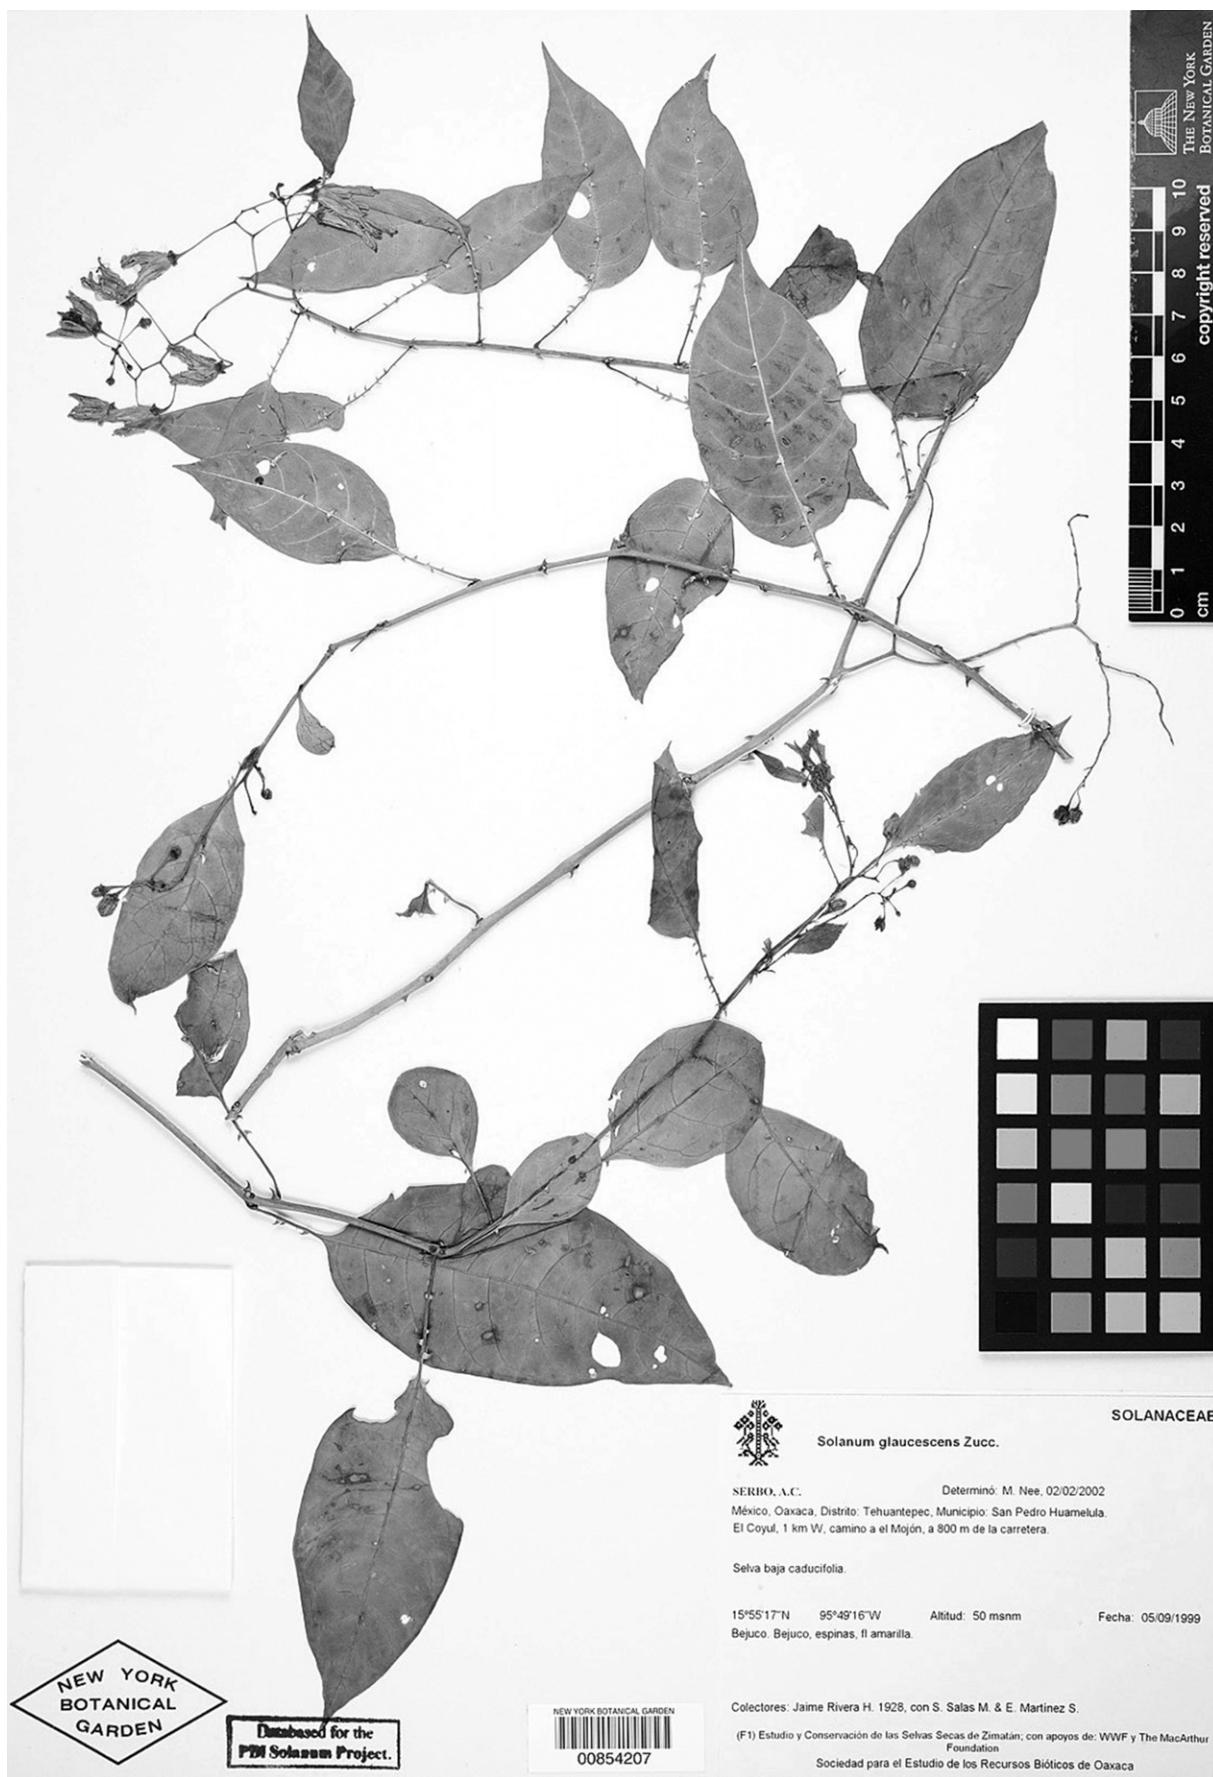

FIG. 9. Representative specimen of *Solanum glaucescens* from Mexico (J. Rivera H. et al. 1928, NY). Reproduced with permission of the New York Botanical Garden, Bronx, NY.

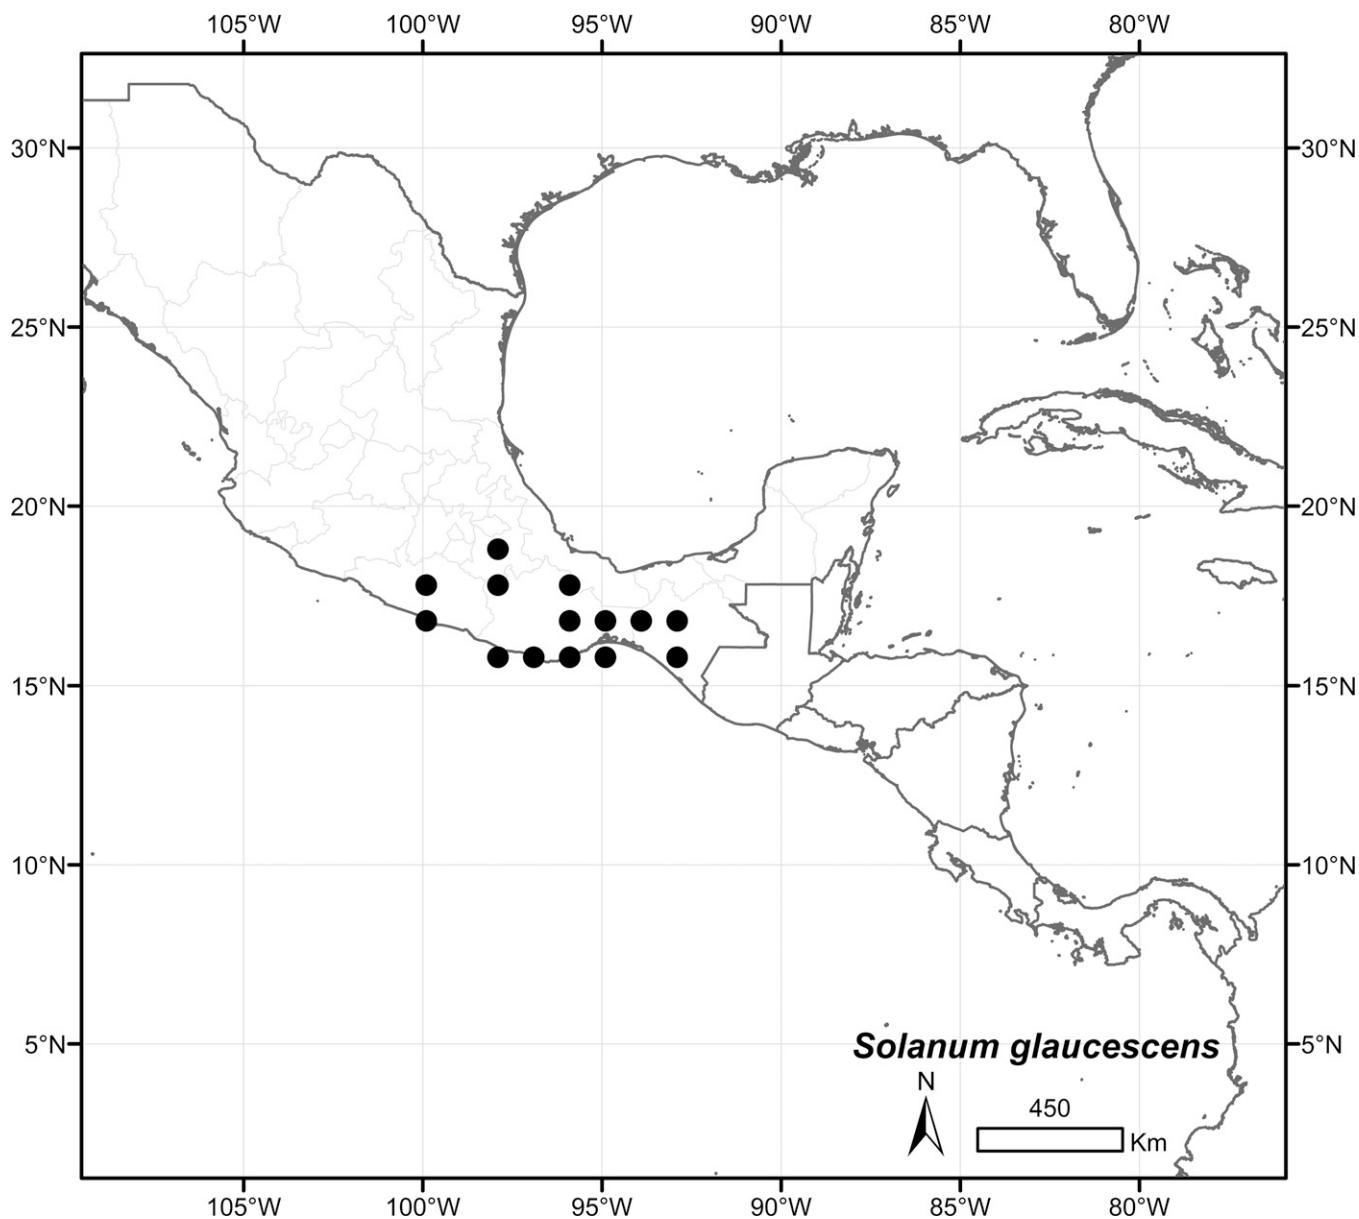

FIG. 10. Distribution of *Solanum glaucescens*.

The illustration of *Solanum sagranum* in the plates (De la Sagra 1855: pl. 62) accompanying the botany volumes of De la Sagra's *Historia física, política y natural de la isla de Cuba* published five years after the protologue (Richard 1850) is clearly *S. glaucescens*. The paired recurved prickles at the base of the petioles are distinctly shown, but the heterandrous flowers clearly described in the protologue ("Uno de sus estambres es constantemente mayor que los otros cuatro." [One of the stamens is always longer than the other four]; Richard 1850: 124) are not; specimens at P and K collected by De la Sagra (see below) have heterandrous flowers and paired prickles. No other collections of *S. glaucescens* from Cuba have been seen, and its occurrence on Cuba has not been reconfirmed. The type of *Solanum sagranum* may represent a cultivated collection and/or a mis-labeling of the collecting locality. Several duplicates of a collection attributed to Ramón De la Sagra exist in the Paris herbarium. We have selected that labeled as "Herbarium Richard" and "*Solanum punctulatum* nob.

Sagrænum nob." (P00370903) as the lectotype as it was clearly part of A. Richard's herbarium and is indicated as a new species on the sheet [*Solanum punctulatum* new *Sagrænum* new]; Richard clearly changed his mind about the name for this taxon and crossed his original epithet, *punctulatum*, out). Other sheets attributed to De la Sagra (see synonymy) appear to be duplicates and are here recognized as isolectotypes.

Representative Specimens Examined—MEXICO. Chiapas: Mpio. Jiquipilas, 8 miles E of Cintalapa, along hwy. 190, 2,200 ft, 12 Jun 1965 (fl), Breedlove 10304 (F, US), 10317 (F, TEX, US); Mpio. 5. SOLANUM PACHYANDRUM Bitter, Repert. Spec. Nov. Regni Veg. 13: 88. 1914.—TYPE: ECUADOR. Manabí: El Recreo ["El Keereo"], 200 m, 6 Mar 1897, *H. von Eggers* 15730 (lectotype, designated here: US [US-1324689, barcode US00027720]; isolectotypes: B, †destroyed [F neg. 2672], F [F-143295], K [K000788525], L [L-897313-55], LE, M [M0124267], P [P00367219]).

Woody vine to 5 + m long, the stems 0.4–0.7 cm in diameter, densely prickly; internodes (2–)4–9 cm long, glabrous; prickles 0.5–1.2 mm long, stout, recurved. Sympodial units plurifoliate, not geminate. Leaves pinnatifid to deeply pinnatifid with 4–6 pairs of lobes, the blades in outline 12–19(–27) × 5–10(–17) cm, oblong, chartaceous, glabrous on both surfaces, the midrib with recurved prickles abaxially; major lateral veins 4–6 on each side, corresponding to the lobes; petioles 2–3 cm, glabrous, often armed with recurved prickles; leaflets 2–4 × ca. 1 cm, widest at the middle or in the basal third, basally decurrent on the midrib and with a wing of tissue to 3 mm wide connecting all leaflets to some degree, not petiolulate; base rounded to acute; margins deeply pinnatifid, entire, the terminal leaflet confluent with lateral leaflets; apex acuminate to rounded. Inflorescences 12–20 cm long and wide, lateral or terminal, several times branched, with 5–20 flowers, the axes glabrous or minutely papillate, densely prickly; peduncle 5–8 cm; rachis 4–8 cm; pedicels 4–5 mm, prickly, slender at anthesis, elongating in fruit to ca. 2.5 × 0.2 cm and becoming subwoody, articulated at the base. Flower buds ellipsoid to oblong, the corolla soon exserted from the calyx tube. Calyx campanulate, spreading, the tube 1–2 mm, the lobes ca. 3 × 2 mm, deltate, glabrous, the central part a protruding green knob, this more prominent in fresh plants. Corolla to 3.5 cm in diameter, spreading at anthesis, white, fleshy, stellate, lobed 1/2–2/3 of the way to the base, the lobes 1–1.2 × 0.5–0.6 cm, narrowly triangular, acute to acuminate at apices, glabrous on both surfaces, minutely papillate at the tips. Stamens equal in size, 6–8 mm long; filaments ca. 2 mm long, glabrous; anthers 5–6 × 2.5–3 mm, ellipsoid, connivent, yellow, poricidal at the tips, the pores lengthening to slits with age. Ovary glabrous; style in long-styled flowers ca. 10 mm long, straight, glabrous, in short-styled flowers ca. 5 mm long; stigma truncate. Fruit a globose berry, 3–5 cm in diameter, purple when immature and yellow when mature (*Rodríguez et al.* 1607), the pericarp glabrous. Seeds ca. 100 per berry, ca. 2 × 4 mm, strongly flattened, light brown, the surfaces minutely pitted, the testal cells rectangular. Figs. 2A–C, 11.

Distribution and Habitat (Fig. 12)—*Solanum pachyandrum* occurs on the western slopes of the Andes and in the Huancabamba Depression of Ecuador (Prov. Manabí) and Peru (Dept. of Cajamarca, La Libertad, and Tumbes) in moist forests on slopes; 200–1,000 m. The Ecuadorian type collection is somewhat disjunct from the rest of the species distribution.

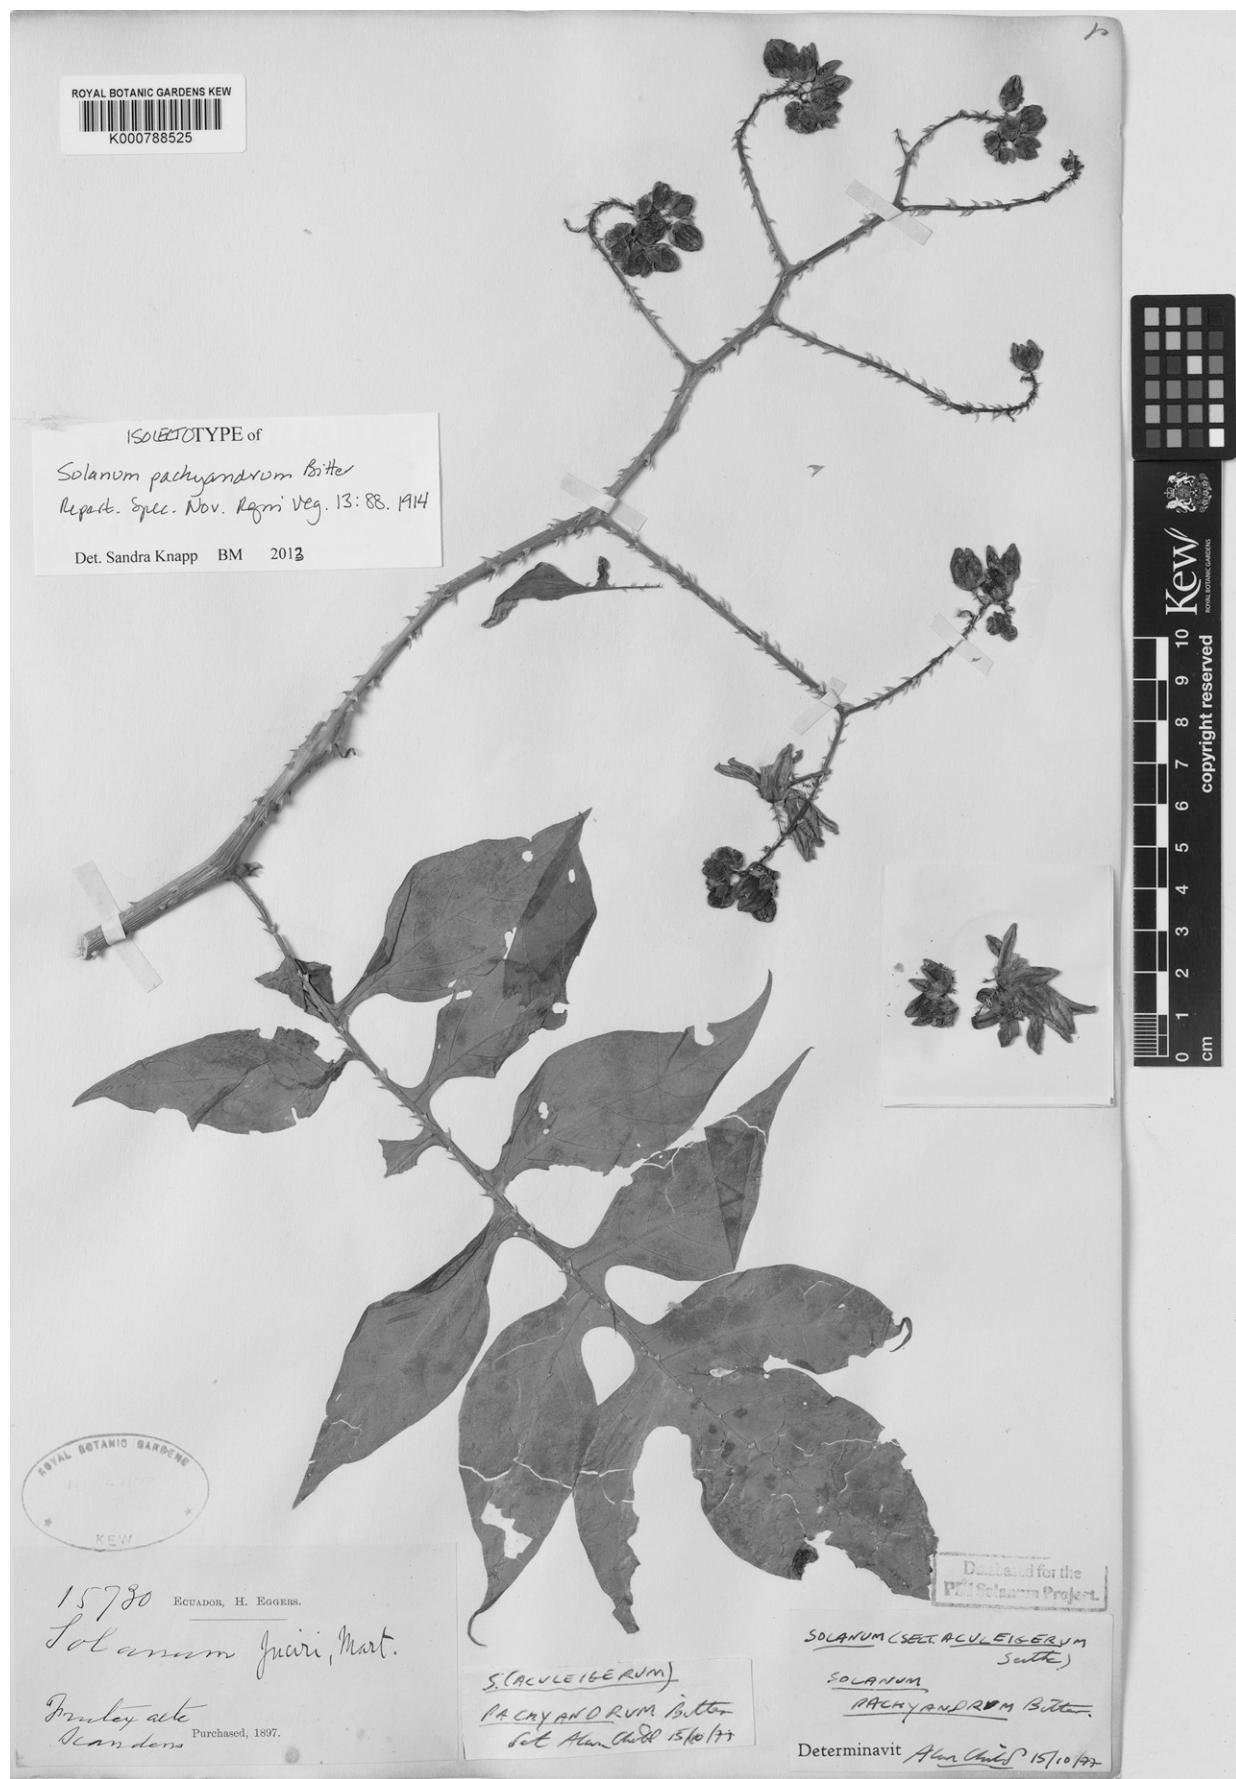

FIG. 11. Isolectotype specimen of *Solanum pachyandrum* from Ecuador (H. Eggers 15730, K). © Trustees of the Royal Botanic Gardens, Kew. Reproduced with permission of the Royal Botanic Gardens, Kew.

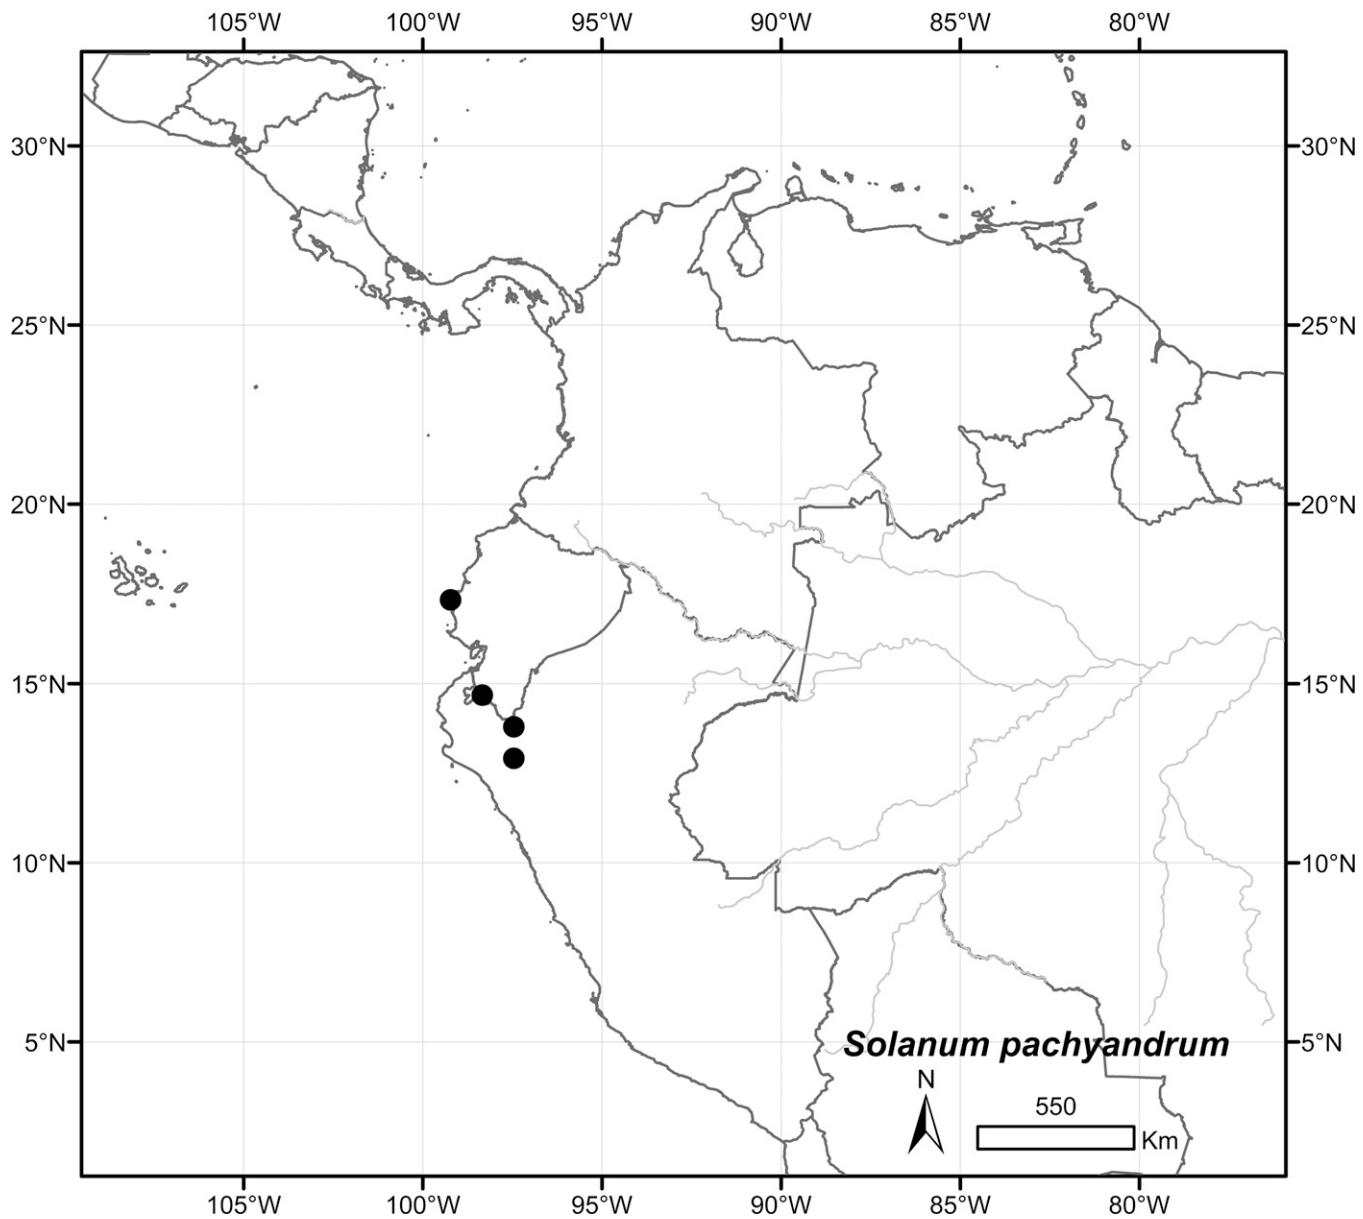

FIG. 12. Distribution of *Solanum pachyandrum*.

Phenology—*Solanum pachyandrum* appears to flower and fruit at the same time; flowering and fruting specimens have been collected from April to September.

Common Names—Peru. Cajamarca: “bombona” (Rodríguez et al. 1607).

Preliminary Conservation Status (IUCN 2014)—Near Threatened (NT); EOO 30,173 km² (LC); AOO 24 km² (EN); 7 localities. Although the EOO would not place *S. pachyandrum* into one of the threatened categories (CR, EN or VU) the single point that expands the range is derived from the type collection. *Solanum pachyandrum* has not been collected again in coastal Ecuador since. If that point is removed from the analysis the threat status is EN. Searches for *S. pachyandrum* in southern Ecuador are a priority.

Solanum pachyandrum differs from all other species in section *Aculeigerum* by the presence of stout armed prickles on its pedicels and non-tapering (ellipsoid) anthers. Additionally, *S. pachyandrum* is restricted to the western lowlands of

Ecuador and northwestern Peru. This species is geographically isolated from all other members of the section. The large juicy fruits are eaten by local people and are considered a great treat by children (J. Campos, pers. comm.).

No herbarium was cited in the protologue of *S. pachyandrum*. We have therefore chosen the best preserved of the duplicates of Eggers 15730 as the lectotype (US00027720). It is often assumed that when Bitter cited no herbarium he was citing a specimen in Berlin; no internal evidence to that effect is to be found in the publication, so we are including a reference to the B sheet photographed by MacBride among the isolectotypes.

Specimens Examined—PERU. Cajamarca: Prov. San Ignacio, Distrito Huarango, San Martín, 5°16's, 78°43'W, 900 m, 18 May 1996 (fl,fr), Campos et al. 2806 (MO, MOL, NY, USM); Prov. San Ignacio, San Martín del Chinchipe, 5°19'16"S, 78°41'05"W, 1,000 m, 15 Sep 1999 (fr), Flores et al. 160 (BM, NY, USM-2 sheets); Prov. Jaén, Huayhuaya-Peña Blanca (Tamborapa-Tabaconas), 890 m, 1 Aug 1994 (fr), Leiva G. et al. 1231 (HAO†[destroyed], NY); Prov. San Ignacio, distrito Namballe, Namballe, arriba del margen derecho del Río Namballe, 4°58's, 79°10'W, 760–800 m, 6 Jul 1997 (fl,fr), Rodríguez et al. 1607 (HAO†[destroyed], HUT, MO, NY,

USM); Prov. Cutervo, on road from La Capilla to Jaen, in Laguna, km 1575, 1,126 m, 9°09'57.77"S, 78°51'14"W, 14 Apr 2013 (fl, fr), Särkinen et al. 4546 (BM, E, USM). Tumbes: Prov. Zarumilla, entre puesto de vigilancia El Caucho–Campoverde, 700 m, 9 Jul 1992 (fr), Díaz et al. 4739 (HUT, MO, USM).

6. *SOLANUM REFRACTUM* Hook. & Arn., Bot. Beechey Voy. 304. 1838.—TYPE: MEXICO. Nayarit: Tepic, F. Beechey s.n. (holotype: K [K000195651, MICH neg. 751]).

Solanum aculeolatum M. Martens & Galeotti, Bull. Acad. Roy. Sci. Bruxelles 12: 143. 1845.—TYPE: MEXICO. Oaxaca: "Près la Mer Pacifique", 1840, H. G. Galeotti 1170 (lectotype, designated here: BR [BR0000005538768, BH neg. 2394]; isolectotype: P [P00445058]).

Solanum molinarum J. L. Gentry, Phytologia 26: 276. 1973.—TYPE: HONDURAS. Comayagua: edge of Humuya River bank, vicinity El Edén, Comayagua Valley, 500 m, 28 Sep 1969, A. Molina R. & A. R. Molina 24532 (lectotype, designated here: F [F-1724479]; isolectotypes: EAP [EAP70442], F [F-1964597, F-1724480, F-1964595], NY [NY00139010]).

Woody or subwoody vine to 15 m long, the stems 0.2–0.3 cm in diameter, prickly; internodes (2–)4–10 cm long, glabrous or puberulent with simple hairs ca. 0.2 mm long; prickles 0.5–1.5 mm long, stout, recurved. Sympodial units plurifoliate, not geminate. Leaves pinnatifid to deeply pinnatifid, the blades in outline 6–12(–16) × 3–10(–16) cm usually ovate (rarely elliptic), widest at the base, chartaceous, glabrous adaxially and abaxially, or rarely both surfaces puberulent with minute simple papillae, often armed abaxially on midrib with recurved prickles; major lateral veins 3–5 on each side, corresponding to lobes; petioles 1–2.5(–5) cm, glabrous, often armed with recurved prickles; lobes (1.5–)3–6 × (1–)1.5–3 cm, widest at the middle of in the basal 1/3, confluent with the midrib and with a wing of tissue to 1 cm wide connecting all leaflets; base acute; margin deeply pinnatifid with 3–4 pairs of lobes, the terminal and adjacent lateral lobes broadly confluent; apex acuminate to rounded; petiolules absent, the lobes confluent with the midrib. Inflorescences 10–15 cm long and wide, terminal, several times branched, with 20–40 flowers, the axes glabrous or puberulent with minute papillae, moderately to densely prickly, occasionally with very few prickles only at the base (type specimen); peduncle 3–5(–10) cm; rachis 3–10 cm; pedicels 3–5 mm and slender at anthesis, articulated at the base; fruiting pedicels elongating to ca. 2.5 × 0.4 cm and becoming woody. Flower buds sharply pointed (turbinate), the corolla strongly exserted from the calyx tube before anthesis. Calyx campanulate, spreading, the tube 1–3 mm, the lobes ca. 1 × 1.5 mm, broadly rounded and the calyx almost truncate, glabrous, the lobe tips somewhat rounded and swollen. Corolla to 2.5 cm in diameter, spreading at anthesis, green or yellowish green, sometimes tinged with purple (Hinton 10967 "flowers purple and yellow"), membranous, stellate, lobed to the base, the lobes 0.9–1.5 × 0.2–0.3 cm, narrowly triangular to lanceolate, acute to acuminate at apices, glabrous abaxially and adaxially. Stamens equal in size, 7–9 mm long; filaments ca. 0.5 mm long, glabrous; anthers 6–8 × 0.75–1 mm, strongly tapering, connivent, yellow, poricidal at the tips, the pores only somewhat lengthening to slits with age. Ovary glabrous; style in long-styled flowers 12–13 mm long, straight, glabrous, in short-styled flowers ca. 6 mm long; stigma truncate. Fruit a globose berry, ca. 3–5 cm in diameter, light green, the pericarp glabrous, rugose surface dry. Seeds 20–50 per

berry, ca. 3 × 5 mm, strongly flattened-reniform, light brown, the surfaces minutely pitted. Fig. 13.

Distribution and Habitat (Fig. 14)—*Solanum refractum* occurs in Mexico (States of Chiapas, Guerrero, Oaxaca), Guatemala (Depts. of Chiquimula, Zacapa, Jalapa), and Honduras (Depts. of Comayagua, La Paz) in deciduous and semi-deciduous forests at elevations from sea level to 1,100 m.

Phenology—*Solanum refractum* appears to flower and fruit at the same time throughout the year, with a small peak in flowering specimens from June to August (but this is possibly a collecting artefact) and in fruiting specimens from September to November.

Preliminary Conservation Status (IUCN 2014)—Least Concern (LC); EOO 133,321 km² (LC); AOO 112 km² (EN); 31 localities. *Solanum refractum* is widespread in the habitats where it occurs.

Solanum refractum is similar to *S. alternatopinnatum* of southeastern Brazil, Paraguay, and northern Argentina but the terminal leaflets in the latter are usually petiolulate and not broadly confluent with the uppermost pair of lateral leaflets. The leaves of *S. refractum* are occasionally puberulent with unbranched papillae on both surfaces in contrast to the consistently glabrous leaves of *S. alternatopinnatum*. The inflorescence structure, flowers, and fruits, are very similar in *S. alternatopinnatum* and *S. refractum*. *Solanum pachyandrum* of Ecuador and Peru shares consistently pinnatifid or deeply pinnatifid leaves with *S. refractum*, but differs from it in its white flowers with ellipsoid anthers; the yellow-green flowers of *S. refractum* are more delicate than those of *S. pachyandrum* and have strongly tapered rather than ellipsoid anthers. *Solanum alternatopinnatum*, *S. pachyandrum* and *S. refractum* all share a prickly inflorescence rachis, a character that can be used to differentiate these species from cultivated *S. wendlandii* with pinnately compound leaves.

Confusion over the application of the names *S. refractum* and *S. bicorne* has resulted in many specimens of *S. bicorne* being annotated in herbaria as *S. refractum* (in these cases the name *S. aculeolatum* was used for the plants here recognized as *S. refractum*). Considerable care must be exercised in using pre-2005 annotations on specimens not re-annotated for this monograph.

The type locality for *Solanum refractum* is given by Hooker and Arnott (1838: 275) on the page at the beginning of their Mexico section in the account of the Beechey voyage as: "When no habitat is mentioned, the specimens are understood to have been collected at Tepic."

Martens and Galeotti (1845) mentioned no specific herbarium in the protologue of *S. aculeolatum*. We have selected the specimen at BR (BR0000005538768) as the lectotype because it has more copious inflorescence and leaf material than the duplicate of Galeotti 1170 at P (P00445058); both are relatively scrappy specimens.

We have selected F-1724479 from among the many duplicates of *Molina R. & Molina 24532* as the lectotype of *S. molinarum* because it is annotated as "holotype" in J. L. Gentry's hand, and the species name is also written by Gentry on the sheet. The other duplicate labelled "holotype" (F-1964595) has a typed species name on the label.

Representative Specimens Examined—MEXICO. Chiapas: Cintalapa de Figueroa, km 22 de la carretera Tapanatepec–Tuxtla Gutiérrez, 16°27'N, 94°05'W, 700 m, 4 Jun 1995 (fl), Panero et al. 5750 (NY). 7. *SOLANUM TRIUNFENSE* S. Knapp, sp. nov.—TYPE: MEXICO.

Chiapas: Mpio. Jaltenango/Mapastapec, Reserva El Triunfo (Campamento/HQ 15°39' N, 92°48' W), path to Palo Gordo, 1,900 m, May 1989 (fl), *M. Heath & A. Long MA129* (holotype: MEXU [MEXU-877597]; isotype: BM [BM001118119]).

Diagnosis—Like *S. cobanense* J. L. Gentry but differing in densely puberulent new growth and buds, long-attenuate leaf bases, calyces completely enclosing the buds until just before anthesis and tearing into irregular lobes at flowering.

Woody vine or scandent shrub to 3 + m long, the stems 0.2–0.7 cm in diameter; internodes (2–)4–10 cm long, puberulent with 0.2 mm long simple uniseriate few-celled trichomes, these occasionally furcate; prickles 0.5–1.5 mm long, stout, recurved, sometimes absent on young shoots near the inflorescence. Sympodial units plurifoliate, not geminate. Leaves simple, the blades 6–15 × 2.5–6.5 cm, elliptic, widest at the middle, chartaceous, both surfaces minutely puberulent with simple or occasionally furcate uniseriate 2–5-celled trichomes ca. 0.5 mm long, often armed abaxially on midrib with recurved prickles; major lateral veins 6–9 on each side; base acute; margin entire; apex acute; petioles 0.5–3 cm, minutely puberulent with simple uniseriate trichomes like those of the leaf surfaces, sometimes armed with recurved prickles. Inflorescences 5–10 cm long and wide, terminal, few-branched, with 10–15 flowers, the axes puberulent with simple or furcate uniseriate 2–7-celled trichomes, not prickly; peduncle 1–3 cm; rachis 1–3 cm; pedicels 17–35 mm, articulated at the base, evenly spaced 2–5 mm apart; fruiting pedicels not known. Flower buds ellipsoid, the corolla completely enclosed in the calyx until shortly before anthesis. Calyx campanulate, spreading, tearing into irregular lobes, the tube 1–3 mm, the lobes 5–8 × 4–6 mm, pubescent with simple or occasionally furcate uniseriate 2–4-celled trichomes; fruiting calyx not known. Corolla to 4.5 cm in diameter, spreading at anthesis, purple or violet, membranous or slightly fleshy, stellate, lobed 1/2 way to the base, the lobes 1–1.5 × 0.6–1 cm, broadly deltate, glabrous on both surfaces, the tips cucullate and minutely papillate abaxially. Stamens equal in size, 8–11 mm long; filaments 1–2 mm long, glabrous; anthers 7–10 × 1–1.5 mm, ellipsoid, connivent, yellow, poricidal at the tips, the pores lengthening to slits with age. Ovary glabrous; style in long-styled flowers ca. 13 mm long, straight, glabrous, in short-styled flowers ca. 3 mm long; stigma capitate. Fruit and seeds not known. Fig. 15.

Distribution and Habitat (Fig. 16)—*Solanum triunfense* is endemic to the Sierra Madre Occidental in the State of Chiapas, Mexico, in evergreen humid forests at elevations from 1,800–1,900 m. Most collections are from the El Triunfo Biosphere Reserve.

Phenology—*Solanum triunfense* has been collected in flower from February to June; fruiting specimens are not known.

Common Names—Mexico. Chiapas: “quistan” (Heath & Long MA129).

Preliminary Conservation Status (IUCN 2014)—Endangered (EN) B1,2a,b iii; EOO 493 km² (EN); AOO 16 km² (EN); 4 locations. *Solanum triunfense* is assessed as endangered based on the low extent of occurrence and area of occupancy and the threats to the habitat in the region where it occurs. It does occur in a protected area (Reserva El Triunfo, a UNESCO Biosphere Reserve) so is afforded some protection there.

Solanum triunfense is very similar to *S. cobanense*, and has also been identified in herbaria as *S. wendlandii*. It differs from *S. cobanense* in its buds that are completely enclosed in the calyx until just before anthesis (Fig. 15), the pubescence of simple uniseriate and sometimes furcate trichomes on the new growth, and in the attenuate leaf bases. The flowers of *S. triunfense* are stellate, as opposed to the rotate to pentagonal flowers of *S. wendlandii*. Plants of *S. wendlandii* collected at very early anthesis could be mistaken for *S. triunfense*, but lack the pubescence on the new growth that is characteristic of this new species.

Specimens Examined—MEXICO. Chiapas: SW side of Cerro Mozotal, 11 km NW of the junction of the road to Montozintla along the road to El Porvenir and Siltepec, 25 Jun 1972 (fl), Breedlove 25708 (DS, MEXU, MO); Mpio. La Concordia, El Triunfo Reserve, trail WSW from Palo Gordo towards Finca Catarina, 15°40'N, 92°51'W, 1850 m, 25 Feb 1990 (fl), Hampshire et al. 694 (BM); El Triunfo, S edge, 29 Apr–1 May 1960 (fl), MacDougall s.n. (MEXU); Mpio. Escuintla, Santa Rosa, Ojo de Agua, 2 Jun 1948 (fl), Matuda 17838 (DS, F).

8. *SOLANUM WENDLANDII* Hook. f., Bot. Mag. 113: pl. 6914. 1887.—TYPE: Cultivated at Kew in the Water Lily House, 28 Jul 1886, Anonymous s.n. (neotype, designated here: K [K000195647]; isoneotype: K [K000195646]).

Solanum mazatenangense Coulter & Donn. Sm., Bot. Gaz. 37: 421. 1904.—TYPE: GUATEMALA. Retalhuleu: San Felipe, 2050 ft, Apr 1892, J. Donnell Smith 2669 (lectotype, designated here: US [US-1324650, barcode US00840548]; isolectotypes: F [F-267128], GH [GH0077513], K [K000195648, K000195649], NY [NY00139006], US [US-1324649, US-258628]).

Solanum tlacotalpense Sessé & Moc., Fl. Mexic., ed. 2. 1894.—TYPE: MEXICO. Veracruz: “ad fluviorum Tuxtlanium” [on the banks of Río Tuxtla, presumably near San Andrés Tuxtla], M. Sessé & J. Mociño s.n. (lectotype, designated by Knapp 2008b, pg. 20: MA [MA-604681, F neg. 48334]; isolectotypes: MA [MA-604680, F neg. 483333, MA-604682, F neg. 48335]).

Solanum unguis-cati Standley, Publ. Field Columbian Mus., Bot. Ser. 4: 320. 1929.—TYPE: HONDURAS. Atlántida: Lancetilla Valley, near Tela, 50 m [“20–600” on label], 9 Mar 1928 [“Dec. 6, 1927–Mar. 20, 1928” on label], P. Standley 56726 (holotype: F [F-581029]).

Woody (sometimes herbaceous) vine or canopy liana to 20 + m long, the stems 0.25–0.8 cm in diameter, prickly, the prickles often lacking on herbarium collections of flowering material; internodes 1–10 cm long, glabrous; prickles to 1 mm long, stout, recurved, sometimes absent on terminal shoots near the inflorescence. Sympodial units plurifoliate, not geminate. Leaves highly variable in shape on the same plant, ranging from simple (usually near the inflorescences) to pinnately compound, the blades 10–20 × 8–15 cm, usually ovate (rarely elliptic), widest at the base, chartaceous, glabrous adaxially and abaxially, or occasionally the abaxial surface puberulent with unbranched hairs, often armed abaxially on midrib with curved prickles; major lateral veins 5–8 on each side; base rounded to acute; margin entire or pinnatifid or pinnate with 3–7 lobes or leaflets, the terminal and adjacent lateral leaflets broadly confluent; apex acuminate to rounded; petioles 1.5–7 cm, glabrous, often armed with curved prickles. Inflorescences 10–20 cm long and wide, terminal, many times branched (rarely unbranched), with 20–30 flowers, with either staminate or pistillate flowers on a single individual, glabrous, not prickly, or occasionally with a few prickles at the very base; peduncle 5–10 cm; rachis 5–20 cm; pedicels 15–20 mm and slender at anthesis, articulated at the base; fruiting pedicels elongating to 3–5 × 0.3 cm and becoming woody. Flower buds narrowly ellipsoid, the corolla long exserted from the calyx tube, the calyx tube in bud unlobed with deep papery sinuses regularly tearing before anthesis. Calyx campanulate, spreading, the tube 2–9 mm, the lobes ca. 3 × 2 mm, rounded or quadrate with a distinct apiculate tip, glabrous to puberulent on the tips. Corolla 2.5–6(–9) cm in diameter, spreading at anthesis, pale lavender to deep

FIG. 15. Isotype specimen of *Solanum triunfense* from Mexico (M. Heath & A. Long MA129, BM). Reproduced with permission of the Natural History Museum, London.

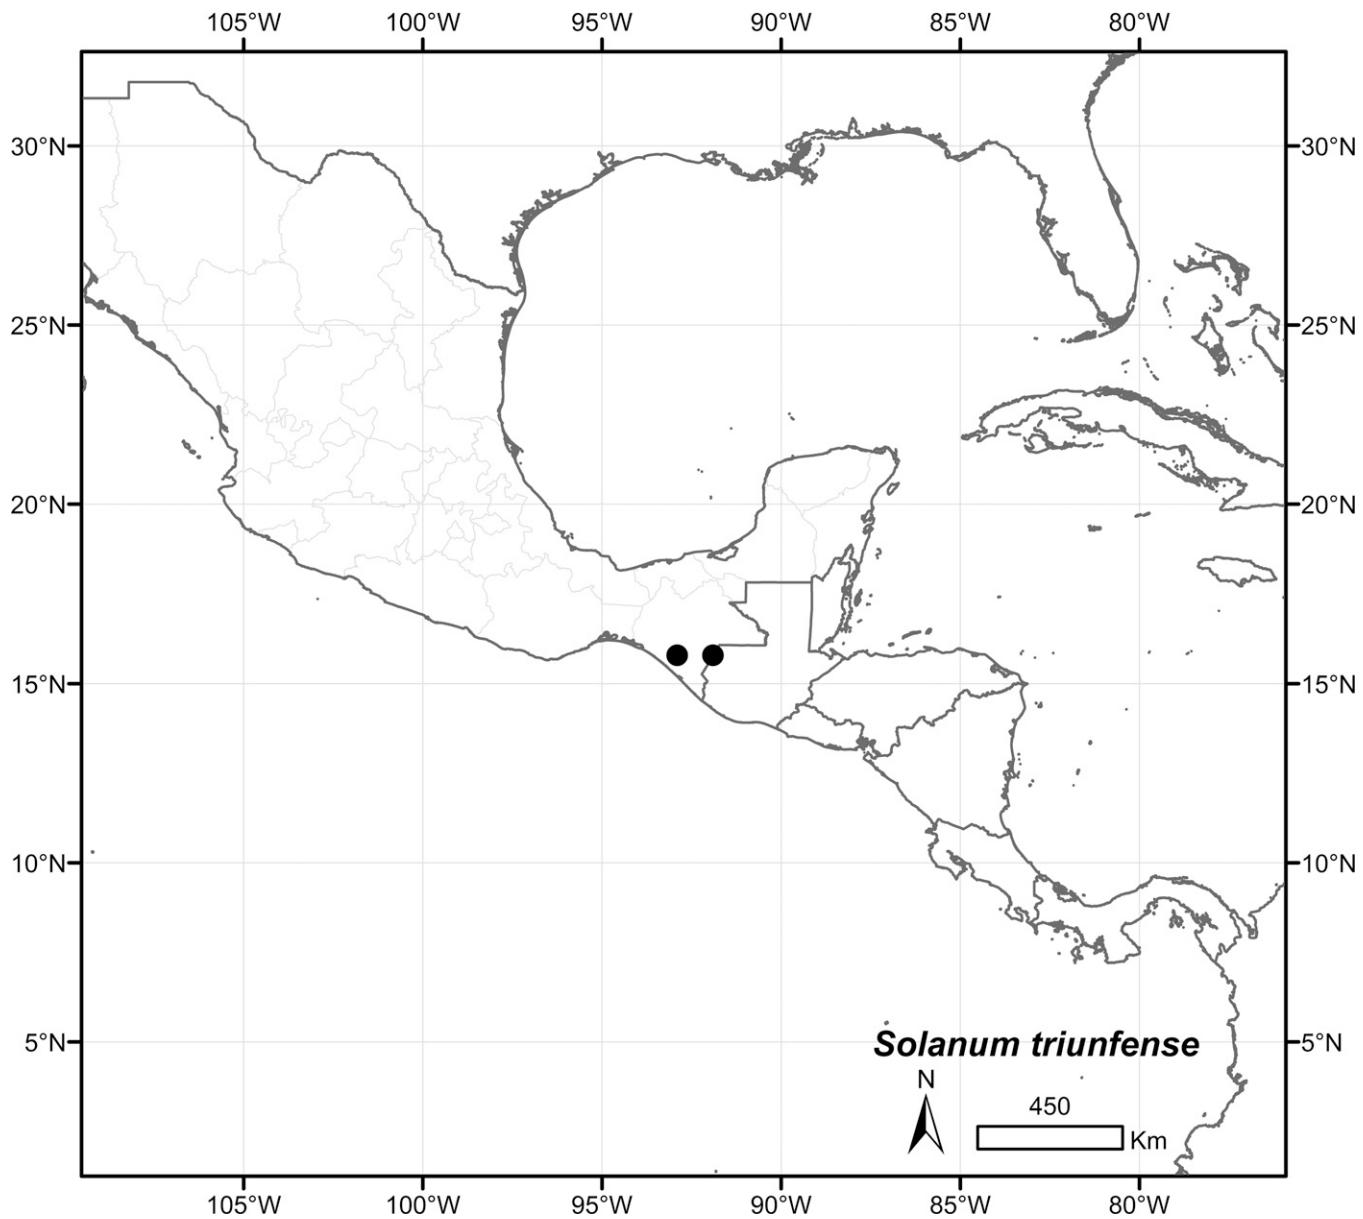

FIG. 16. Distribution of *Solanum triunfense*.

purple, membranous, rotate-pentagonal, lobed ca. 1/4–1/3 of the way to the base, the lobes 0.7–1.2 × 1.2–1.7 mm, broadly deltate, acuminate at the tips, glabrous abaxially and adaxially. Stamens 5–10 mm long; filaments unequal, with four 1–1.5 mm long, the fifth 2.5–4 mm long, glabrous; anthers nearly equal, 4–10 × 1.5–2 mm, the one on the longer filament slightly larger, somewhat to strongly tapering, connivent, cream or pale purplish blue, sometimes yellowish cream at base and pale purple distally, poricidal at the tips, the pores lengthening to slits with age. Ovary glabrous; style in long-styled flowers ca. 12 mm long, straight, glabrous, in short-styled flowers 2–4 mm long; stigma truncate. Fruit a globose berry, 4.5–10 cm (dry, to 20 cm in diameter when fresh fide Christenhusz et al. 5372) in diameter, globose, green with green to white pulp, the pericarp glabrous, rugose when dry. Seeds 50–100 per berry, 4–5 × 6–8 mm, strongly flattened-reniform, light reddish brown, the surfaces minutely pitted, the testal cells pentagonal. Chromosome number: $n = 12$ (Fedorov 1974). Figs. 2D–F, 17–19.

Distribution and Habitat—*Solanum wendlandii* is probably native from southern Mexico to Panama in wet and semi-deciduous forests at elevations from 400–2,200 m. It is a commonly cultivated and sometimes naturalized vine in tropical and subtropical areas worldwide. Most cultivated plants apparently never bear female-fertile (long-styled) flowers and are possibly clones of plants with only staminate flowers (see below).

Phenology—*Solanum wendlandii* flowers throughout the year; fruiting specimens have been collected in its putative native range in January and February.

Common Names—Mexico. Chiapas: “kishtan” (Matuda 17481); Tabasco: “cola de gato” (Rovirosa 885); Guatemala. Retalhuleu: “kishtan” (Cosminsky 112 and 128).

Preliminary Conservation Status (IUCN 2014)—Least Concern (LC). We have not evaluated *S. wendlandii* using GeoCat due to the large number of cultivated and/or naturalized specimens whose status is not clear from collecting information. We do consider it of some conservation

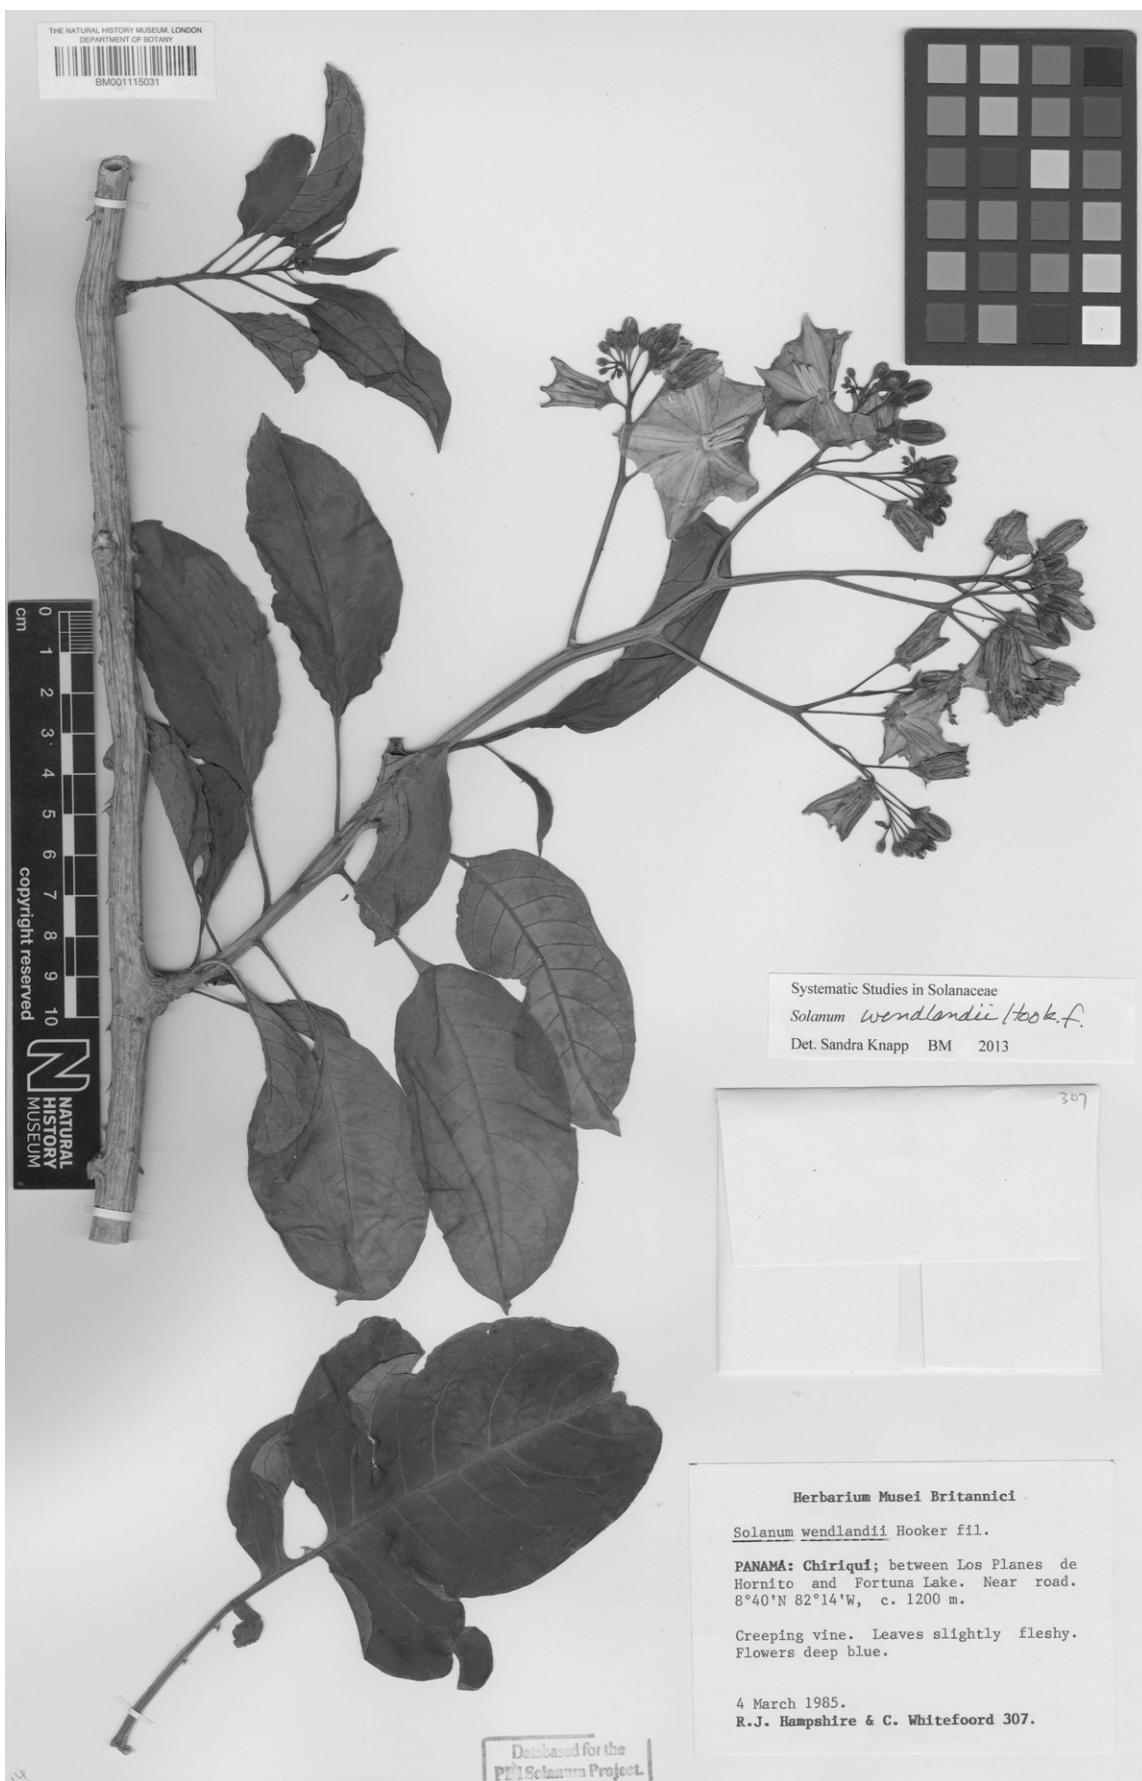

FIG. 17. Staminate-flowered specimen of *Solanum wendlandii* from Panama (R. Hampshire & C. Whitefoord 307, BM). Reproduced with permission of the Natural History Museum, London.

FIG. 18. Pistillate-flowered specimen of *Solanum wendlandii* from Guatemala (M.J.M. Christenhusz et al. 5372, BM). Reproduced with permission of the Natural History Museum, London.

FIG. 19. Lithograph of *Solanum wendlandii* illustrating the plant from which the neotype specimen was probably taken (*Curtis's Botanical Magazine* 113: pl. 6914. 1887). Reproduced with permission of the Library of the Natural History Museum, London.

concern, however, in its presumed area of native distribution, given the few fruiting specimens (and thus contributors to future native populations) we have seen.

Solanum wendlandii is quite variable in appearance. Most herbarium specimens, collected from flowering twigs, have only simple, entire leaves while much of the rest of the vine has pinnatifid to pinnate leaves. Simple-leaved collections of *S. wendlandii* can be confused with *S. cobanense*, but the leaves of the latter are more coriaceous and the flowers are stellate and very fleshy rather than pentagonal in outline with thin petal tissue like those of *S. wendlandii*. Non-flowering pinnately-leaved specimens of *S. wendlandii* can be very similar to *S. refractum*, but lack the densely prickly inflorescence of that species.

Flower size in *S. wendlandii* is extremely variable, but this is in part due to flower growth throughout anthesis. Flowers of this species last approximately three days (Shelly et al. 2000), and on the first day they are both darker purple and smaller than on subsequent flowering days (see Figs. 2D, 19). Plants with small-flowered inflorescences (young ones with flowers only one day old) can be confused with *S. triufense* and *S. bicorne*, but both of these species have stamens of equal size.

The breeding system of this species has not been closely investigated. Nearly, if not all, cultivated material seems to bear only staminate flowers with vestigial styles and fruit from cultivated collections is almost never seen (although immature fruits are described in the protologue; Hooker 1887). Fruiting material is seldom collected from the wild, perhaps because the plants only produce their large fruit upon reaching the canopy. The species is possibly dioecious, this may in part account for the paucity of fruiting collections.

Solanum wendlandii is apparently native from southern Mexico to western Panama in wet forests of the Atlantic Coast, but the exact range is difficult to discern since it is seldom collected in the wild, is widely planted for the showy panicles of large flowers, and label data usually do not specify whether the plants were cultivated or truly wild. Collections outside this range seem to be either escapes from cultivation or merely cultivated plants, although this is not always stated clearly on herbarium labels. We have not cited these numerous collections here, but full details can be found on the Solanaceae Source website (www.solanaceaesource.org). We have seen cultivated or perhaps naturalized material from the following countries outside its native range: Argentina, Australia, Bermuda, Brazil, Cameroon, China, Colombia, Cuba, Dominican Republic, Ecuador, Egypt, Haiti, India, Jamaica, Kenya, Malawi, Paraguay, Peru, Philippines, Puerto Rico, Singapore, Sri Lanka, Tanzania, United Kingdom, United States of America, Venezuela, and Zimbabwe.

Solanum wendlandii is reportedly used in cooking in Guatemala ("Leaves and flowers cooked" fide Cosminsky 112 and 128) and the plants are reported in the Flora of Guatemala to be edible (Gentry and Standley 1974). In at least one collection (Nee & Taylor 28770) from Veracruz, Mexico, however, it was noted that the fruits are not eaten. In this location, where the plants seem to be native, the green fruits were pecked open by birds, which remove the seeds and green pulp, leaving only an empty shell (Nee & Taylor 29770).

No herbarium specimens were cited in the protologue of *S. wendlandii* (Hooker 1887). The neotype collection was made by an unknown collector from a cultivated plant

grown in England at the Royal Botanic Gardens, Kew (see Fig. 19). The species was described from living plants by Hooker (1887) as "Living plants of this beautiful *Solanum* were sent to the Royal Gardens [Kew] in 1882 by Dr. Wendland, Director of the Royal Gardens at Herrenhausen, Hanover, with the information that it is a native of the cold regions of Costa Rica, where it climbs trees. This habit it has retained at Kew, where it ascends to the rafters of the Water Lily House, and flowers profusely."

Two specimens at Kew are labeled "Type specimen of Bot. Mag. t. 6914!" and dated 28 July 1886 in an unknown handwriting (not Joseph Dalton Hooker's); one (K000695647) has stem, leaves and one opened out flower, while the other (K000695646) has only stem and leaves. We select the more complete K000195647 as the neotype for *S. wendlandii*. Another specimen collected from the Water Lily House in 1892 (K000195646) may have come from the same plant, but is not type material. Edmonds (2012) incorrectly cited a Kew holotype for *S. wendlandii*, and did not effectively typify the name.

Six Guatemalan collections were cited in the protologue of *S. mazatenangense*: Shannon 618, Shannon 624, Heyde & Lux 4735, Heyde & Lux 3442, Donnell Smith 2263 and Donnell Smith 2669. We have chosen the US duplicate (US-1324650) of Donnell Smith 2669 as the lectotype of this species, as it is the best preserved and most widely distributed of the collections cited. It is likely that Donnell Smith used the US sheet in his description of the material annotated by Coulter as this species.

Representative Specimens Examined—(putative native range only; cultivated and naturalized specimens outside this range can be viewed in Solanaceae Source, <http://www.solanaceaesource.org>) — MEXICO. GUATEMALA. Alta Verapaz: near Tactic, above bridge across Río Frío, 1400–1500 m, 30 Mar 1941 (ster), Standley 90308 (F). Guatemala: Arrazola, 1600 m, May 1892 (fl), Heyde & Lux 3442 (F, US); Guatemala City, 1,530 m, 3 May 1970 (fl), Harmon 2280 (MO); Calderas, 5 Jul 1941 (fl), Johnston 1896 (F). Escuintla: Escuintla, 1,100 ft, Apr 1890 (fl), Donnell Smith 2263 (BM, US). Huehuetenango: Barillas, along the road between Barillas and Malpais, 1,554 m, 28 Feb 2009 (fl, fr), Christenhusz et al. 5372 (BM, NY); between Xoxlac and Nucapuxlac, Sierra de los Cuchumatanes, 1,650–2,500 m, 17 Jul 1942 (ster), Steyermark 48926 (F). Jutiapa: Cuesta de la Conora, between San José Acatempa and Río de los Esclavos, 900–1,200 m, 21 Dec 1938 (ster), Standley 60614 (F). Petén: Chichi, 9 Apr 1933 (fl), Lundell 2751 (F); La Libertad, 23 Apr 1933 (fl), Lundell 2984 (F, GH). Quetzaltenango: Fuentes Georginas, W slope of Volcán de Zunil, 2,850 m, 4 Mar 1939 (ster), Standley 67476 (F); Los Positos, SW of San Martín Chile Verde, 1,500 m, 8 Mar 1939 (ster), Standley 67932 (F); above Mujulia, between San Martín Chile Verde and Colombia, 1,800 m, 1 Feb 1941 (ster), Standley 85541 (F); Finca Pirineos, between Santa María de Jesus and Calahuache, 1,300 m, 20 Jan 1940 (fl), Steyermark 34499 (F). Quiché: Chichicastenango, 8 Apr 1949 (fl), Beer s.n. (CM). Retalhuleu: Finca San Luis, Dec 1974 (fl), Cosminsky 112 (F); Finca San Luis, San Sebastián, 1,000–1,500 ft, Jan 1976 (ster), Cosminsky 128 (F); Las Delicias, S of Retalhuleu, 200 m, 22 Feb 1941 (fl), Standley 88039 (F). Sacatepéquez: 5 km E of Antigua, 1700 m, 24 May 1970, Harmon 2358 (MO); Embaulada, 5,500 ft, Nov 1891 (fl), Heyde & Lux 4735 (F-2 sheets, US); Las Lajas, 1,200 m, 28 Nov 1938 (ster), Standley 58087 (F). San Marcos: between Canjula and La Unión Juárez, SE portion of Volcán Tacana, 2,000–3,000 m, 22 Feb 1940 (fl), Steyermark 36504 (F, US); between Tajumulco and Tecutla, 9 miles S and W of Tajumulco, NW slopes of Volcán Tajumulco, 1,800–2,500 m, 27 Feb 1940 (ster), Steyermark 36751 (F); Aldea Fraternidad, between San Rafael Pie de la Cuesta and Palo Gordo, 1,800–2,400 m, 10–18 Dec 1963 (fl), Williams et al. 25977 (F); Tajumulco Volcano, 8–10 km W of San Marcos, 2,300 m, 31 Dec 1964–1 Jan 1965 (fl), Williams 26935 (F). Santa Rosa: Cuilapa, 895 m, 20–27 Nov 1940 (fr), Standley 78130 (F). Sololá: Santa Bárbara, 410 m, Aug 1891, Shannon 618 (US). Suchitepéquez: Las Animas, 200 m, Sep 1891, Shannon 624 (US); SW slopes of Volcán Zunil, Finca Montecristo, SE of Santa María de Jesús, 1,200–1,300 m, 31 Jan 1940 (ster), Steyermark 35231 (F). Zacapa: Zacapa, 225 m, 23 Apr 1939 (ster), Standley 71996 (F); Quebrada Alejandria, summit of Sierra de las Minas, Finca Alejandria, 2,500 m, 13 Oct 1939 (ster), Steyermark 29864 (F).

HONDURAS. Atlántida: Lancetilla Valley, near Tela, 20–600 m, 6 Dec 1927–20 Mar 1928 (ster), Standley 53328 (F, GH, US). Comayagua: Comayagua Valley, 22 Sep 1973 (fl), Hazlett 853 (MO); Río Selguapa, El Taladro, 650 m, 27 Jun 1964 (fl), Molina R. 14320 (F, NY); Valle Comayagua entre Las Mercedes y Villa de Flores, 650 m, 28 Jun 1964 (fl), Molina R. 14367 (F, NY); Comayagua Valley between Comayagua and Villa San Antonio, 570 m, 1 May 1947 (fl), Williams & Molina R. 12610 (F). Morazán: drainage of the Río Yeguare, entre San Antonio del Mico y La Estancia, camino Río Cobre, 1,600 m, 29 Sep 1948 (fl), Molina R. 1152 (F); Suyapa, 1,100–1,200 m, 1 Aug 1950 (ster), Standley 22266 (F). Yoro: entre Yoro y Morazán, 700 m, 11 May 1956 (fl), Molina R. 6924 (F); Coyoles, 30 Jun 1938, Yuncker et al. 8160 (F, NY).

EL SALVADOR. Ahuachapán: P. N. El Imposible, camino al cerro Dávila, 13°49'N, 89°56'W, 26 Sep 1991 (fr), Morales et al. 1284 (MEXU). La Libertad: Mpio. Antiguo Cuscatlán, Laderas de la Laguna, 13°40'N, 89°15'W, 830 m, 18 May 1989 (fl), Cruz 195 (MEXU). San Salvador: San

Salvador, 650–850 m, 30 Mar–24 Apr 1922 (fl), Standley 22402 (GH, NY). Santa Ana: Cerro Las Mesas, 10 km NO de la ciudad de Santa Ana, 14°02'N, 89°36'W, 850 m, cult., Linares & Martínez 2623 (MEXU).

NICARAGUA. Estelí: road to Laguna de Miraflores, 8 Jun 1975 (fl), Atwood 320 (NY). Jinotega: Sierra W of Jinotega, along trail to Cerro de la Cruz, 1,050–1,350 m, 27 Jun 1947 (fl), Standley 10277 (F); La Montanita and Las Mesitas, W of Jinotega, 1,100–1,400 m, 29 Jun 1947 (fl), Standley 10416 (F). Madriz: Cerro Quisica, 13°31'N, 86°31'W, 1,100–1,250 m, Stevens & Montiel 17336 (MEXU). Managua: Reparto Belmonte, NO de la ciudad de Managua, 49 m, 10 Aug 1979 (fl), Araquistain 6 (MEXU); Casa Colorada near El Crucero, summit of Sierra de Managua, 800–900 m, 14–25 May 1947 (fl), Standley 8664 (F). Matagalpa: Finca La Castilla, 23 km NE de Matagalpa, carretera al Tuma, 6 May 1982 (fl), cult., Sandino 2810 (MEXU).

COSTA RICA. Alajuela: R.B. Monteverde, Río Peñas Blancas, 10°19'N, 84°43'W, 700 m, 27 Mar 1988 (fl), Haber & Bello 8350 (CR); Cantón de San Ramón, Cordillera de Tilarán, Monteverde, San Gerardo Biological Station, Sendero Congo, 1 km W of station, 10°22'0" N, 84°48'0" W, 1,200–1,300 m, 14 Mar 1995 (fl), Pennys 249 (CR, INB, MO); Arenal Volcano, S slope of Cerro Chato, trail to summit, 25 Feb 1989 (fl), Russell et al. 988 (CR, US). Guanacaste: El Dos de Tilarán, 54 km N, Cerro La Chirripa, Atlantic slope rain forest, 10°25'N, 84°50'W, 1,000 m, 12 Apr 1986 (fl), Haber et al. 4422 (MO); Río Chiquito de Tilarán, 10 km N Monteverde, 12 Nov 1986 (fl), Haber & Bello 6366 (CR). Heredia: Cantón de Santo Domingo, town of Santo Domingo, 9°59' N, 84°06'W, 1,150 m, 2 Sept 1990 (fl), Solomon 19142 (CR, INB, MO). Limón: near Rangalle, Telire River watershed, 400–900 m, 25–29 Mar 1983 (ster), Hazlett 5211 (MO); Telire, Talamanca, 24–28 Mar 1983 (ster), Ocampo 4011 (CR). Puntarenas: Zarcero de Álfaro Ruiz, 1,550 m, 21 Dec 1924 (fl), Brenes 4157 (F); Cantón de Coto Brus, P. I. La Amistad, Cordillera de Talamanca, Estación Pittier, 9°01'30"N, 82°57'40"W, 1,680 m, 28 Jan 1995 (fl), Donzo et al. 3 (CR, INB, MO); Zarcero, 5300 ft, 7 Sep 1937 (fl), Smith 319 (F). San José: Sabanilla de Montes de Oca, Residencias Palas Atena, S side of Rte. 202, ca. 0.5 km W of Cristo, 9°57'N, 84°02'W, 1,310 m, 16 Jan 1987 (fl), Grayum 7967 (CR, MO); San Ignacio de Acosta, Carretera 4, km 27–28, cult., 1100 m, 17 Jan 1984 (fl), Khan et al. 292 (BM, CR); Cerro Pico Blanco, 4 km S of Escazu, 2,000 m, 12 Dec 1976 (fr), Lent 3987 (CR, F, MO, NY); Cantón de Aserrí, Z. P. Cerros de Escazú, Cuenca del Río Poás, Mesón, en la cuenca media del Río Lajas, 4 km aguas arriba, 9°52'15"N, 84°05'50"W, 1,500 m, 30 Jan 1994 (fl), Morales et al. 2312 (INB, MO).

PANAMA. Bocas del Toro: Caribbean slopes of Cerro Fabrega at foot of 'Falso Fabrega' in Palo Seco Reserve, second N-most tributary (on map) of Río Culebre, Pavón Camp, 9°09'51"N, 82°39'41"W, 1,300 m, 20 Mar 2005 (fl), Monro & Cafferty 4802 (BM, INB, MEXU, MO, PMA). Chiriquí: Palo Santo, 3 miles N of Volcán, 14 Feb 1971 (fl), Croat 13547 (F, MO); between Los Planes de Hornito and Fortuna Lake, 8°40'N, 82°14'W, 1,200 m, 4 Mar 1985 (fl), Hampshire & Whitefoord 307 (BM, MEXU).

NAMES NOT VALIDLY PUBLISHED

Solanum dichotomum Pav. ex Dunal, Prodri. [A. P. de Candolle] 13(1): 233. 1852. Nom. nud. pro syn. *S. bicorne* Dunal var. *angustifolium* Dunal.

Solanum juciri Mart. ex Sendtn., Fl. Bras. [Martius] 10: 110. 1846. Nom. illegit. superfl. with *S. alternatopinnatum* Steud. (1841), in synonymy.

Solanum laxiflorum Dunal, Prodri. [A. P. de Candolle] 13(1): 234. 1852. Nom. nud. pro syn. *S. viridipes* Dunal.

Solanum shannoni Coul., nom. nud. in sched. (*Heyde & Lux* 4735). This collection is a syntype for *S. mazatenangense* Coul. & Donn. Sm. and the epithet also appeared as a name only in the original description of *S. unguis-cati* (Standley 1929), but with no description it does not meet the requirements for valid publication.

ACKNOWLEDGMENTS. We thank the herbaria cited in the text for making their material (as specimens and digital images) available; Nicholas Fumeaux and Lorenzo Ramella (G) for help finding and citing specimens; Frances Crawford (K), Leandro Giacomini (UFOP), Tiina Särkinen (E), Kim Watson (NY), and Maria Vorontsova (K) for photographs of

specimens and live plants; Patrick Meyer-Higgins and Paweł Ficinski (BM) for assistance in geo-referencing; Mindy Syfert (BM) for producing the maps; and Paloma Rojas (BM) for databasing much of the material cited here. This project was funded by the National Science Foundation, Planetary Biodiversity Inventory (PBI) *Solanum*: A worldwide treatment (DEB-0316614) to LB, SK and MN; SK travel to Madrid was funded by the SYNTHESYS Project <http://www.synthesys.info/> financed by European Community Research Infrastructure Action under the FP6 "Structuring the European Research Area" Programme. The Department of Botany at the Smithsonian Institution's National Museum of Natural History kindly hosted JLC during his postdoctoral work as part of the PBI *Solanum* project (2005–2006).
