General introduction to this factsheet

The Barcoding Facility for Organisms and Tissues of Policy Concern (BopCo) aims at developing an expertise forum to facilitate the identification of biological samples of policy concern in Belgium and Europe. The project represents part of the Belgian federal contribution to the European Research Infrastructure Consortium LifeWatch.

Non-native species which are being introduced into Europe, whether by accident or deliberately, can be of policy concern since some of them can reproduce and disperse rapidly in a new territory, establish viable populations and even outcompete native species. As a consequence of their presence, natural and managed ecosystems can be disrupted, crops and livestock affected, and vector-borne diseases or parasites might be introduced, impacting human health and socio-economic activities. Non-native species causing such adverse effects are called Invasive Alien Species (IAS). In order to protect native biodiversity and ecosystems, and to mitigate the potential impact on human health and socio-economic activities, the issue of IAS is tackled in Europe by EU Regulation 1143/2014 of the European Parliament and Council. The IAS Regulation provides for a set of measures to be taken across all member states. The list of Invasive Alien Species of Union Concern is regularly updated. In order to implement the proposed actions, however, methods for accurate species identification are required when suspicious biological material is encountered.

Because morphology-based species identifications are not always possible (e.g. cryptic species, trace material, early life-stages), the purpose of the present work is to investigate and evaluate the usefulness of DNA sequence data to identify each of the IAS included in the EU Regulation. The results are presented as factsheets (one per IAS) compiled using publicly available DNA sequence data and information aggregated from various sources. Each factsheet consists of two major parts; (i) a short introduction to the specific IAS compiling information on its taxonomy and current occurrence/distribution in Europe; (ii) an investigation with respect to the usefulness of publicly available DNA sequences to identify this IAS to the taxonomic level stated in the EU list using DNA barcoding. For further information about the reasoning behind the applied approach and details on the materials and methods utilised, please see below and Smitz *et al.* [1].

More info about BopCo on <http://bopco.myspecies.info/> or contact us via bopco@naturalsciences.be.

More info on the EU Regulation on http://ec.europa.eu/environment/nature/invasivealien/index_en.htm.

Impatiens glandulifera

Royle, 1835

Common names:

English: Himalayan balsam, Indian balsam, ornamental jewelweed, policeman's helmet, touch-me-not

French: balsamine de l'Himalaya, balsamine glanduleuse, balsamine géante

German: drüsiges Springkraut, Indisches Springkraut, Riesenspringkraut

Dutch: reuzenbalsemien

Last update: August 2020

General information on *Impatiens glandulifera*

Classification

Kingdom	Phylum	Clade	Order	Family	Genus
Plantae	Magnoliophyta	Eudicots	Ericales	Balsaminaceae	<i>Impatiens</i>

Species in the same genus: N = ca. 1047 [2, 3]

Note: We follow the classification of WCVP.

Impatiens and the genus *Hydrocera* (with one species) make up the whole family.

Infra-species level: N = 2 [2]

Note: Two forms are accepted: *I.g. forma albida* and *I.g. forma pallidiflora*.

Native range: [4, 5]

Western Himalayas; northern India, Nepal, northern Pakistan.

Invasive range: [4, 5]

Europe (geographical):

Austria, Belarus, Belgium, Croatia, Czech Republic, Denmark, Estonia, Finland, France, Germany, Hungary, Ireland, Italy, Latvia, Lithuania, Netherlands, Norway, Poland, Serbia, Slovakia, Spain, Sweden, Switzerland, Ukraine, United Kingdom.

For more detailed locality information and the most recent distribution updates, please visit:

www.gbif.org/species/2891770

<https://gd.eppo.int/taxon/IPAGL/distribution>

<http://alien.jrc.ec.europa.eu/SpeciesMapper>

Outside Europe (geographical):

Canada, Japan, New Zealand, Russia, United States of America.

Morphology, biology, invasion, negative effects and remedies

For more information on *Impatiens glandulifera* please see the references and online information listed at the end of this document.

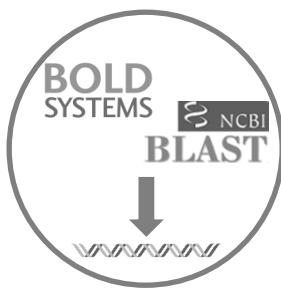

Species identification based on DNA barcodes

Introduction

DNA barcoding is a species identification method that uses a short genetic sequence (DNA barcode) to compare an unknown sample to a database of reference sequences with known species affiliations. The underlying rationale is that the divergence of nucleotide sequences among different species is larger than the nucleotide divergence between sequences within a species. DNA barcoding can facilitate the identification of IAS samples, especially when morphological characteristics are absent or useless. To assure correct species identifications, however, reference libraries need to include a sufficiently large number of sequences of (i) the IAS under investigation, in order to assess the intraspecific genetic divergence; (ii) the closely related species, in order to evaluate the interspecific genetic divergence; (iii) the different geographical areas covering the distribution range (native and invasive) of the IAS in order to detect potential population structure or local hybrids.

Against this background, BopCo evaluated the inclusion of the IAS and their close relatives in both publicly available reference libraries BOLD (www.boldsystems.org/) and GenBank (www.ncbi.nlm.nih.gov/nuccore/) to estimate the reliability with which a species identification can be obtained using DNA barcoding.

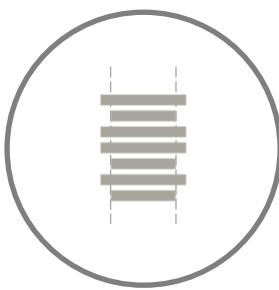

Material and Methods [1]

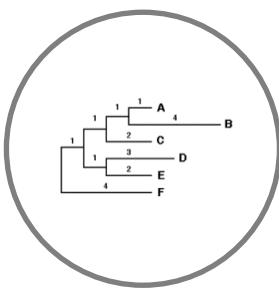

Download all sequence data available for the genus

Filtering the data and selecting 'promising' markers

Aligning and trimming of the sequences

Building Neighbour-Joining tree with Bootstrap support

Conclusion

Based on the present evaluation of the available sequence data, the ITS regions are the most reliable DNA markers for the identification of *Impatiens glandulifera*.

Discussion

DNA markers for which *Impatiens* sequences were available, were downloaded from GenBank and BOLD for all represented species of the genus *Impatiens*. Seven DNA markers were evaluated (Table 1).

The full ITS region and the component ITS1 and ITS2 regions, have similar datasets including by far the highest number of represented species of all evaluated DNA markers (Table 2). In each dataset *I. glandulifera* is represented by sequences from both native and invasive regions which are found to form a single, well-supported cluster. For the component ITS1 and ITS2 datasets a single *I. glandulifera* sequence does not cluster with all others (GenBank accession number KC905488), yet this might involve a misidentification. If so, the full ITS as well as the individual components ITS1 and ITS2 represent DNA marker regions which can be used to differentiate *I. glandulifera* from other *Impatiens* species.

Using the universal barcode marker matK, results in a supported clustering of the available *I. glandulifera* sequences. However, the latter all originate from Canadian populations and there is a very low overall species representation (Table 2). Notwithstanding the lack of data, the marker seems valuable to distinguish *I. glandulifera* from the similar looking species *I. capensis*, *I. noni-tangere* and *I. parviflora*. Additional sequences for *I. glandulifera* (from the native regions) and the missing congeners would allow to better evaluate the performance of the marker for species identification.

The dataset for the universal barcode marker rbcL is also very limited and additionally shows little genetic variation. In the current state of the online reference libraries it is therefore not advisable to apply this marker for species identification.

Although bigger datasets are available for the markers DEF1 and DEF2, few sequences are available for *I. glandulifera*. It is currently impossible to assess the usefulness of these markers. However, since many *Impatiens* species are already represented, it might be interesting to further investigate these markers once additional *I. glandulifera* sequences become available.

For the atpB-rbcL, trnH-psbA and trnL-trnF intergenic spacer and the trnL gene fewer sequences are available, the species *I. glandulifera* is not or poorly represented and/or the marker shows little genetic variation for among the different species. Therefore, it is currently impossible to assess the ability of these markers to identify *I. glandulifera*.

Table 1: Overview of the encountered issues concerning the DNA-based identification of the IAS [1]: (1) Insufficient publicly available DNA sequences of the IAS to capture the intra-species divergence; (2) Poor geographical coverage of the IAS sequences (native or invasive range missing); (3) The IAS sequences do not form supported clusters; (4) Potential misidentification of a specimen which influences the clustering of the IAS sequences; and (5) Not all congeneric species are represented in the final NJ-tree. An 'X' indicates that the issue was encountered, a '1' indicates only one unique *I. glandulifera* sequence was available.

Markers analysed	1	2	3	4	5
rbcL	X	X	X		X
matK	X	X			X
Full ITS			X	X	X
ITS1			X	X	X
ITS2			X	X	X
DEF1	1	X	1		X
DEF2	X	X	X		X

Table 2: Publicly available sequences downloaded (March 2019) from BOLD and GenBank (including sequences extracted from plastid genomes) which were withheld as reliable and informative in the final alignment that was used for building the NJ-trees. The species names follow [2]. The list of species is limited to those members of *Impatiens* for which at least one sequence was used in any of the NJ-trees. Species names with * are not accepted in [2] but used on GenBank. An 'X' indicates that at least one sequence was used in the final alignment, an '(X)^{1 or 2}' indicates only ITS region 1 or 2 was available for analysis.
