## Key words

Gobiidae  
Sicydiinae  
*Lentipes caroline*  
Micronesia  
Freshwater  
New species

During the past 35 years many freshwater gobies, including those of the subfamily Sicydiinae Gill, 1860 (Gobioidei), have been collected and identified from freshwater streams throughout the tropical Indo-Pacific. Indeed, approximately 50 new species of Sicydiinae have been described from the Pacific region since 1979 (Watson *et al.*, 2007; Keith *et al.*, 2010).

Pohnpei is a tropical island ( $355 \text{ km}^2$ ) in the western Pacific Ocean. It is the largest island in the Federated States of Micronesia (FSM). The interior is mountainous with much of the native rainforest still intact. According to Merlin *et al.* (1992), Pohnpei is characterized by heavy annual rainfall with estimates of the mountainous interior of the island receiving more than 1,000 cm annually. Maciolek and Ford (1987) conducted the first comprehensive surveys of river macrofauna in Pohnpei. This initial work led to descriptions of four endemic species (in three genera) of sicydiines (Parenti and Maciolek, 1993). Only later (Buden *et al.*, 2001) was the presence of an unknown *Lentipes* species confirmed,

**Abstract.** – *Lentipes caroline* n. sp., a freshwater goby, is described on the basis of 21 specimens (12 males, 9 females) collected from high gradient streams on the island of Pohnpei, Federated States of Micronesia. It differs from other species of the genus by a combination of characters including a urogenital papilla lacking lateral lobes and being not retractable into a sheath-like groove, 16 pectoral fin rays, pore O generally lacking, a small head (head length 18–24% of SL), many tricuspid teeth in the upper jaw in females (23–39), and a greyish body colour in both sexes, with only hints of brighter colours including occasional blue anal fin margining and gold blotching across the dorsum of many individuals.

**Résumé.** – Une nouvelle espèce de gobie d'eau douce de Micronésie (Gobioidei : Sicydiinae).

*Lentipes caroline* n. sp., un gobe dulçaquicole, est décrit à partir de 21 exemplaires (12 mâles, 9 femelles) collectés dans les rivières de l'île de Pohnpei (Micronésie). Il diffère des autres espèces du genre par plusieurs caractères dont une papille urogénitale non rétractable dans une cavité et sans lobes latéraux, 16 rayons aux nageoires pectorales, le pore O généralement absent, une tête courte (longueur de la tête 18–24% de la LS), de nombreuses dents tricuspides sur la mâchoire supérieure des femelles (23–39) et une coloration générale grise chez les mâles et les femelles avec parfois une marge bleue sur la nageoire anale et des taches dorées le long du dos.

the first record of this genus from Micronesia.

Compared with other sicydiine genera, *Lentipes* Günther, 1861, is unique in having tricuspid premaxillary teeth in both males and females, but with generally 0–6 canine teeth at the posterior tip of the premaxilla in males. The ascending process on the premaxilla is narrow at the dorsal tip. The tongue is fused to the floor of mouth. The pelvic disc is adherent to the belly between all five rays and scales are never present on the nape and the belly in adults (Keith and Lord, 2011). *Lentipes* also exhibits considerable morphological variation in the form of the urogenital papilla.

*Lentipes* is currently known by 13 species, and is distributed in the Pacific Ocean from Indonesia and Papua New Guinea, and from southern Japan to Hawaii and the Marquesas islands (Watson *et al.*, 2002; Keith *et al.*, 2006, 2011). The purpose of this paper is to provide a description of *Lentipes caroline* n. sp., a freshwater goby known only from Pohnpei, FSM and the only species of *Lentipes* known to Micronesia.

## METHODS

Methods follow Watson *et al.* (2002) and Keith and Marquet (2005). Measurements were taken with a dial calliper to the nearest tenth of a millimetre. All counts were taken from the right side. The size is given in standard length (SL). Teeth were counted to the right of the premaxillary symphysis. Abbreviations for institutions and collections cited follow Leviton *et al.* (1985). Abbreviations for the cephalic sensory pore system follow Akihito (1986).

Counts of scales and fin rays are reported as: A, anal fin elements (includes flexible spine and segmented rays); D, dorsal fins (D1, first dorsal fin spines; D2, second dorsal fin elements); P, pectoral fin rays; C, caudal fin rays (only branched rays are reported); LS, scales in lateral series counted from upper pectoral fin base, or anteriormost scale along lateral midline, to central hypural base; PD, predorsal midline scales counted from scale directly anterior to first dorsal fin insertion to the anteriormost scale; TRB, transverse series backward, refers to scales counted from the first scale anterior to second dorsal fin origin, in a diagonal manner, posteriorly and ventrally to the anal fin base or ventralmost scale; TRF, transverse series forward, refers to scales counted from the first scale anterior to second dorsal fin origin, in a diagonal manner, anteriorly and ventrally to the centre of abdomen or ventralmost scale; ZZ, zigzag series, refers to scales on the narrowest region of the caudal peduncle counted from the dorsalmost scale to the ventralmost scale in a zigzag (alternating) manner.

### *Lentipes caroline*, n. sp.

(Figs 1-3, Tabs I-IV)

#### Material examined

Twenty-one specimens from Pohnpei, Federated States of Micronesia, totalling 12 males, 9 females; size range 34-46 mm SL [40-55 mm, total length (TL)], largest male 46 mm SL, largest female 45 mm SL.

*Holotype*. - MNHN 2012-0213, male (34 mm SL), Nanpil River (Pahn-Pwet), elevation 236 m, Pohnpei, FSM, 13 Mar. 2012, Lynch, Keith, Taillebois, Marquet, Castelin, coll.

*Paratypes*. - MNHN 2012-0214, 1 male (38 mm SL), 6 females (38-44 mm SL), same data as holotype. AMNH 259433, male (45 mm SL), Nanpil River, elevation 280 m, Pohnpei, FSM, 20 Nov. 1999, B. Lynch, coll. AMNH 259434, female (45 mm SL), Nanpil River, elevation 219 m, Pohnpei, FSM, 28 Aug. 1999, B. Lynch, coll. CAS 235705, female (42 mm SL, C&S), Nanpil-Kiepw River, 2.3 km SSW of weir, Pohnpei, FSM, 16 Oct. 1999, D.B. Lynch, coll. CAS uncat., female (39 mm SL), Nanpil-Kiepw River, 2.3 km SSW of weir, Pohnpei, FSM, 16 Oct. 1999, D.B. Lynch, coll. USNM 410585, male (45 mm SL), Nanpil River, stn.

#### Comparative material

The new species is compared with *Lentipes* species having no enlarged lobes associated with the urogenital papillae in females or elongate finger like projections in males, having a urogenital papilla in both sexes that is not retractable into a sheath-like groove, and possessing 16-17 pectoral fin rays. These species are *Lentipes concolor* (Gill, 1860), *Lentipes watsoni* Allen, 1997 and *Lentipes mindanaoensis* Chen, 2004.

*Lentipes concolor* (Gill, 1860). - BPBM 35638, male (48 mm SL); **Molokai**: Waiakeakua Stream; 19 Aug. 1991, G. Hagashi. USNM 83078, female (68 mm SL); 1838-1842, Wilkes Exploring Expedition. ### Diagnosis

The new species has 16 pectoral rays. The urogenital papilla is not retractable into a sheath-like groove and is without lobes or other expanded tissue. The pore O is generally lacking. The cycloid scales are generally restricted to caudal peduncle but may extend to mid flank. The head is small (head length 18-24 % of SL) and there are many tricuspid teeth in the upper jaw in females (23-39). The general pattern of both males and females is greyish, with little bright coloration.

### Description

Number of pectoral rays in species of *Lentipes* are given in table I, number of upper jaw teeth in table II, zigzag scale counts in table III, and morphometrics expressed to the nearest whole percent of standard length in table IV.

Below, the holotype counts are given first, followed in brackets if different, by paratype counts.

First dorsal fin (D1) with six flexible spines, second dorsal fin (D2) with one flexible spine and ten segmented rays (D VI-I,10). Anal fin with one flexible spine and ten segmented rays (A I,10) and directly opposite to second dorsal fin. Membrane on first dorsal fin not reaching base of second dorsal fin origin in female, touching in male; spines not filamentous in females, slightly filamentous in males. Pelvic fins a strong adhesive disc adherent to abdomen between all five rays. Pectoral fin with 16 rays, ventral most 1 or 2 rays simple; posterior margin slightly pointed. Lateral scales (LS), 7-9 in males, 10-13 in females, lightly embed-

ded, thin cycloid, generally limited to caudal peduncle, few may extend anteriorly along midline between second dorsal and anal fins; one female with 27. Caudal fin (C) 13(13-15) branched rays. No scales in transverse backwards (TRB) and in transverse forward series (TRF) in most, including holotype, observed TRB scales in two females with rows of variable completion, a few TRF scales in partial row in one female. Zigzag scales (ZZ) 8(7-9). Head, breast, nape and belly without scales. Upper jaw teeth distinctly tricuspid anteriorly, males 6(5-6), females (23-39). Premaxilla in males with 3(3-9) recurved canines posterior to tricuspid teeth; females usually without teeth posterior to tricuspid teeth. Teeth in lower jaw recurved and canine in males 5(4-8), small and conical in females (0-3). Head small (22(18-24)% of SL); jaw short in males (9(9-10) % of SL). Cephalic sensory pore system A, B, C, D, F, H, K, L; pores N and O generally absent in females; few males with pore N, generally without pore O; pore D singular with all others paired (Fig. 2); oculoscapular canal divided into anterior and posterior canal between pores H and K. Some cutaneous sensory papillae present on head, but not well developed. Sensory papillae generally absent on infraorbital region, preopercle, opercle, trunk or caudal peduncle. Urogenital papilla in males slender and pointed distally without associated lobes or expanded tissue (Fig. 3A), urogenital papilla not retractable into a sheath-like groove; in females urogenital papilla rectangular in appearance (Fig. 3B) and also not retractable into a sheath-like groove.

#### Colour in preservation

*Male.* - Background of body greyish to blackish. Dorsal to midline light dusky. Background of head blackish. Snout dusky. Head ventrally with black pigment, except on isthmus. Lateral midline with a well-marked black subcutaneous band. All scales on caudal peduncle with brown blotches. Anterior half and dorsal margin of upper lip dusky. Brown band posterior to eye extending across preopercle onto opercle. Nape greyish. Caudal fin rays dusky. Dorsal and anal fins blackish. Pelvic disk without pigment. Pectoral rays greyish. Pectoral fin base with black medial band.

*Female.* - Background of body and head greyish. Snout

dusky. Head ventrally without pigment. Anterior half and dorsal margin of upper lip dusky. Lateral midline with a black subcutaneous band terminating as a brownish spot at caudal fin base. Most scales on caudal peduncle with greyish blotches. Brownish band posterior to eye extending across preopercle onto opercle. Nape with numerous tiny brownish blotches. Caudal fin rays slightly dusky, dorsal and ventral margins clear. Anal fin and pelvic disk without pigment. Pectoral fin rays greyish, brownish blotch on dorsal half of fin basally. Pectoral fin base with blackish medial band.

#### Colour in life (Fig. 1)

*Male.* - Colour somewhat variable, but generally appears bluish grey to darker grey, lighter on the belly with some rectangular lighter blotching across the dorsum and black spotting running laterally across the body from the caudal peduncle to mid-body, spotting fainter towards the anterior. Bright blue anal fin margin sometimes present.

*Female.* - Colour less variable in females. Body grey to olive, darker across the dorsum. Six to eight gold rectangular blotches are frequently present across the dorsal median evenly spaced starting at the tip of the snout. Lateral black spots on scales starting with the anterior of the anal and second dorsal fins running to the caudal peduncle. Black horizontal band running from operculum across the head below eye and around the snout above the mouth.

#### Distribution

Currently known only from the Nanpil and Lehn Mesi Rivers, Pohnpei, FSM.

#### Ecology

*Lentipes caroline* was collected in a swift, clear high gradient stream with a rocky and boulder-strewn bottom. It has been observed resting on the rocks between 120 and 236 m in altitude in the northern facing Nanpil River. It is presumed to be amphidromous as with other members of the subfamily (Radtke et al., 2001; Keith, 2003; McDowall, 2007). *Lentipes caroline* was frequently observed swimming in the upper water column of deep pools moving from one point to another. The species also tends to share the uppermost

elevations of streams in Pohnpei with *Sicyopus nigriradiatus* Parenti & Maciolek, 1993, though the range of the latter species extends further into lower elevations.

### Comparison

*Lentipes caroline* differs from all other *Lentipes* in generally lacking pore O. It differs from *L. kaaea*, *L. rubrofasciatus*, *L. solomonensis* and *L. whittenorum* in not having enlarged lobes associated with the urogenital papilla in males. It differs from *L. adelphizonus* in not having elongate finger like projections anterior to the urogenital papillae in males. From *L. armatus*, *L. multiradiatus*, *L. venustus* and *L. dimetrodon* it differs in having a non-retractable urogenital papilla in both sexes vs. a urogenital papilla that retracts into a sheath-like groove, and in having 15–16 pectoral fin rays vs. 18–19.

Furthermore, it differs in particular from *L. concolor* in having more tricuspid teeth in the upper jaw in females (23–39 vs. 11–21), fewer in males (5–6 vs. 6–13), and a shorter caudal peduncle length (12–16 vs. 15–21% SL); from *L. crittersius* in having 16 pectoral fin rays vs. 19. Finally, it differs from *L. watsoni* in having fewer tricuspid teeth in the upper jaw in males (5–6 vs. 20–25) and females (23–39 vs. 40–44), and a shorter jaw length in males (9–12 vs. 14–15% SL), and from *L. mindanaoensis* in having a shorter predorsal length (33–39 vs. 41% SL) and longer second dorsal (32–45 vs. 26% SL) and anal fin length (32–38 vs. 25% SL) in males.

### Etymology

The new species is named for both the first author's daughter and the beautiful islands of Micronesia for which she was named, the Caroline Islands. The name is a noun in apposition.

**Acknowledgements.** – We wish to thank Don Buden (Professor, College of Micronesia-FSM) and the Marine Science students of COM-FSM that have joined the various collection trips over the years. We also thank the following for help during Pohnpei Expeditions: P. Gerbeaux from the Department of Conservation of New Zealand, G. Marquet, L. Taillebois and M. Castelin from the National Museum of Natural History of Paris, and Relio Lengsi and the Conservation Society of Pohnpei for their interest and concerns for the conservation of flora and fauna native to Pohnpei. Some aspects of this research were funded by a National Science Foundation (NSFATE) grant to COM-FSM which supports Marine Science Program activities and NSF OISE grant 0553910 to FP.
