New therapeutic strategies aimed at minimizing damage caused by hepatic fibrogenesis in chronic liver diseases are of great interest. Adult bone marrow contains pluripotent stem cells with the ability to differentiate into diverse cell types, including hepatocytes, in situations under tissue stress in mice and human.

Innovations and breakthroughs

A number of reports have demonstrated that transplantation of bone marrow cells (BMCs) improves liver function, decreases fibrosis and contributes to parenchyma regeneration. In this report, described for the first time, are the effects of BMC therapy in a model of chronic liver disease caused by a parasitic infection.

Applications

Fibrosis is a common feature of chronic liver diseases. The increased deposition of extracellular matrix causes structural alterations in the liver and causes portal hypertension due to the obstruction of vessels and focal ischemic lesions. Therefore, means to decrease liver fibrosis are extremely relevant to improve liver function and to decrease complications related to chronic hepatopathies. In this study, the authors observed a significant decrease in liver fibrosis, an increase in precursor cells, and the generation of new hepatocytes after therapy with BMCs.

Peer review

Authors investigated the putative role in hepatic regenerative medicine by bone marrow mononuclear cells (BM-MC) in the experimental model of *S.mansoni* chronic infection. The experimental animal model used is appropriate and the study is in principle of interest.

Abstract

AIM: To investigate the effects of FR167653 on the development of dextran sulfate sodium (DSS)-induced colitis in mice.

METHODS: BALB/c mice were fed rodent chow containing 3.5% (wt/wt) DSS. The recipient mice underwent intra-peritoneal injection of vehicles or FR167653 (30 mg/kg per day). The mice were sacrificed on day 14, and the degree of colitis was assessed. Immunohistochemical analyses for $CD4^+$ T cell and $F4/80^+$ macrophage infiltration were also performed. Mucosal cytokine expression was analyzed by RT-PCR.

RESULTS: The body weight loss was more apparent in the FR167653-treated DSS mice than in the vehicle-treated DSS mice. The colon length was shorter in the FR167653-treated DSS mice than in the vehicle-treated DSS mice. Disease activity index and histological colitis score were significantly higher in FR167653- than in vehicle-treated DSS animals. Microscopically, mucosal edema, cellular infiltration (CD4 T cells and F4/80 macrophages), and the disruption of the epithelium were much more severe in FR167653-treated mice than in controls. Mucosal mRNA expression for interleukin-1β (IL-1β) and tumor necrosis factor-α (TNF-α) were found to be markedly reduced in FR167653-treated DSS mice.

CONCLUSION: Treatment with FR167653 aggravated DSS colitis in mice. This effect was accompanied by a reduction of mucosal IL-1β and TNF-α expression, suggesting a role of p38 mitogen-activated protein kinase (MAPK)-mediated proinflammatory cytokine induction in host defense mechanisms.

INTRODUCTION

Inflammatory bowel diseases (IBD), such as ulcerative colitis (UC) and Crohn's disease (CD), are associated with chronic relapsing inflammation of the intestinal tract of unknown etiology. The most widely held hypothesis on the pathogenesis of IBD is that the mucosal immune system shows an aberrant response towards luminal antigens such as dietary factors and/or commensal bacteria in genetically susceptible individuals[1-3]. Histologically, mucosal accumulation of leukocytes is a characteristic feature of IBD, and the activation of T cells and monocytes/macrophages has been regarded as a crucial factor in its pathogenesis[1,2].

Previous studies have clearly demonstrated that bacterial lipopolysaccharides (LPS) and pro-inflammatory cytokines, such as interleukin-1β (IL-1β) and tumor necrosis factor-α (TNF-α), activate the p38 mitogen-activated protein kinase (MAPK) pathway[4-6] and suggested that the p38 MAPK family play important roles in pathophysiology of IBD[1,7-9]. The p38 is a member of the MAPK family, which is ubiquitously expressed. Serine-threonine kinases are playing important roles in various signal transduction pathways in mammalian cells[4]. It has been demonstrated that p38 mediates phosphorylation of transcription factors, thereby regulating gene expression and the induction of cytokine production[6]. p38 is activated by dual phosphorylation on Thr180 and Tyr182 by the upstream MAPKs MKK3 and MKK6. MKK3 is especially

important for TNF-α-induced p38 activation[10] and for the p38-mediated synthesis of IL-12 and IFN-γ[11]. Thus, p38 is a promising candidate for targeted inhibition in acute and chronic inflammation.

FR167653 is a well-characterized inhibitor of p38 MAPK[12-16]. FR167653 specifically inhibits p38 *via* its ability to compete with adenosine triphosphate at adenosine triphosphate binding sites on p38 kinase[17,18], and such pharmacological actions resemble those of pyridinyl imidazole inhibitors of p38 MAPK such as SB 203580 and RWJ6. This compound dramatically and selectively attenuates the activity of p38, but does not significantly modulate JNK and ERK-1/2 activity[19]. FR167653 has been demonstrated to specifically inhibit p38 function and eventual IL-1β and TNF-α protein translation[13,20], but the expression of IL-6 and transforming growth factor (TGF)-β does not appear to be affected[21]. At present, FR167653 has not been studied in any animal models for IBD, and our knowledge of its action in chronic intestinal injury models is limited. In this study, we investigated the effects of FR167653 on the development of dextran sulfate sodium (DSS)-induced colitis in mice.

MATERIALS AND METHODS

Induction of colitis

Six- to eight-week-old male BALB/c mice were purchased from Charles River Japan (Kanagawa, Japan). They were acclimatized for 1 wk before the experiment, and were housed individually in a room maintained at 22℃ under a 12-h day/night cycle throughout the experiments. Mice were fed 3.5% (wt/wt) DSS (molecular weight 5000; Wako Pure Chemical Industries, Ltd, Osaka, Japan) mixed with normal chow (MF; Oriental Yeast Co., Ltd, Tokyo, Japan) and water *ad libitum*. The study protocol was approved by the Animal Care and Use Committee of the Shiga University of Medical Science (Otsu, Japan).

FR167653 was kindly provided by Fujisawa Pharmaceutical (Osaka, Japan). The recipient mice underwent intra-peritoneal injection of vehicles or FR167653 at a dose of 30 mg/kg per day dissolved in 200 μL phosphate-buffered saline (PBS) every day, starting on the first day of DSS administration. The dose of FR167653 was chosen with reference to publications showing *in vivo* effects of the drug[12,19].

Assessment of inflammation in DSS-induced colitis

Daily clinical assessment of DSS-induced colitis was performed, including measurements of food intake and body weight, an evaluation of stool consistency, and the presence of blood in the stools by a guaiac paper test. A validated clinical disease activity index ranging from 0 to 4 was calculated using the following parameters: stool consistency, presence of fecal blood, and changes in body weight[22]. The mice were sacrificed at day 14, and the length and weight of the colons were measured.

Histology

A histological examination was performed on three samples of the distal colon from each animal. The samples were fixed in 10% buffered formalin, dehydrated in ethanol, and then embedded in paraffin. Four micron-thick sections were then prepared and stained with hematoxylin and eosin. All histologic evaluation was performed in a blinded fashion using a validated scoring system[23].

For immunohistochemical staining, freshly isolated tissue from the distal portion of the colon was frozen in dry ice using OCT compound (Sakura Finetek, Tokyo, Japan). Acetone-fixed frozen sections (6 μm) were blocked with DAKO blocking reagent (#X0909, DAKO Japan, Kyoto, Japan) followed by incubation with the primary antibodies [anti-mouse CD4 (Santa Cruz Biotechnology, Inc., Santa Cruz, CA) and anti-mouse F4/80 (BD Pharmingen, San Diego, CA)], diluted 1:100 in PBS containing 5% skim milk overnight at 4℃ in a humidified chamber. After incubation with the primary antibody, the sections were reacted with 0.1% H_2O_2 in 0.1 mol/L PBS, and treated with biotin-conjugated second antibodies (diluted 1:50 in PBS containing 1% skim milk; Vector, Burlingame, CA) for 60 min at room temperature and followed by avidin-biotin-peroxidase complexes (ABC, Vector). The peroxidase activity was visualized using diaminobenzidine.

Reverse transcription (RT-) PCR

Cytokine mRNA expression in the mucosa was evaluated by RT-PCR. Total cellular RNA was isolated by the acid guanidium thiocyanate-phenol-chloroform (AGPC) method[24]. For each sample, the first-strand cDNA was synthesized using 0.5 μg of total cellular RNA with oligo (dT) primer and Superscript reverse transcriptase (GIBCO BRL, Rockville, MD). One μL of the cDNA sample was amplified in a 25 μL reaction containing 10 × Taq buffer (Perkin Elmer Cetus Corp., Norwalk, CT), 1.5 mmol/L $MgCl_2$, 0.1 μmol/L of each 5' and 3' primers, and 1 U of *TaqGold* polymerase (Perkin-Elmer Cetus). The PCR was performed in a thermal cycler (GeneAmp Model 2400; Perkin-Elmer Cetus) for 25 cycles (94℃ for 30 s, 55℃ for 30 s, and 72℃ for 40 s), followed by a 8 min extension at 72℃. Five μL of the PCR products were subjected to electrophoresis on 1.5% agarose gels and stained with 0.5 μg/mL ethidium bromide. A 100-bp DNA ladder (GIBCO BRL) was used as marker. Primers specific for the mouse IL-1β were purchased from BioSorce International, Inc. (Camarillo, CA). Specific primers for mouse TNF-α were constructed according to published sequence data[25] (5'-GCGACGTGGAACTGGCAGAAG-3', and 5'-GGTACAACCCATCGGCTGGCA-3').

Statistical analysis

Statistical analysis was performed using one-way ANOVA with Scheffe's post hoc test or the Kruskal-Wallis test when appropriate. Two-way ANOVA for

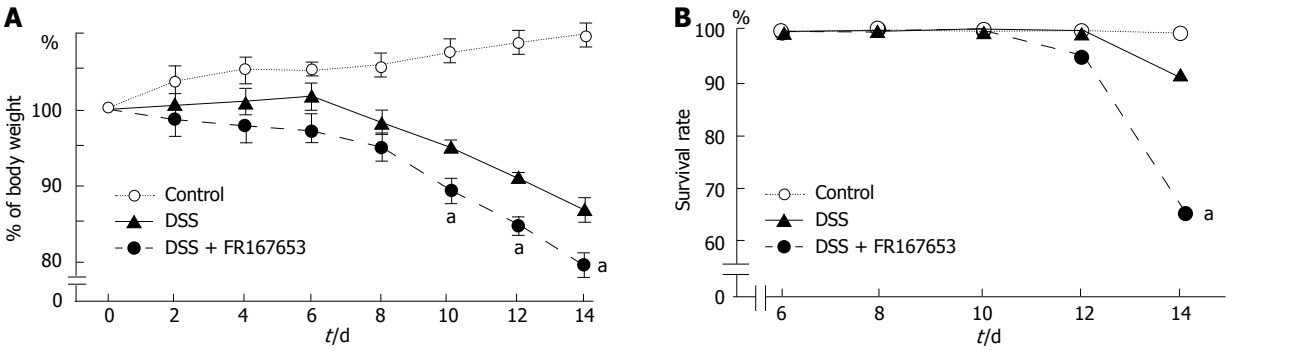

Figure 1 Changes in body weight (**A**) and survival rate (**B**). Mice were fed DSS and injected intraperitoneally with vehicle (PBS) or FR167653 (30 mg/kg per day) daily starting at d 0. The weight of individual mice was followed daily. Data represent mean ± SE (n = 8 mice/group). [a]$P < 0.05$, FR167653 *vs* vehicle (PBS).

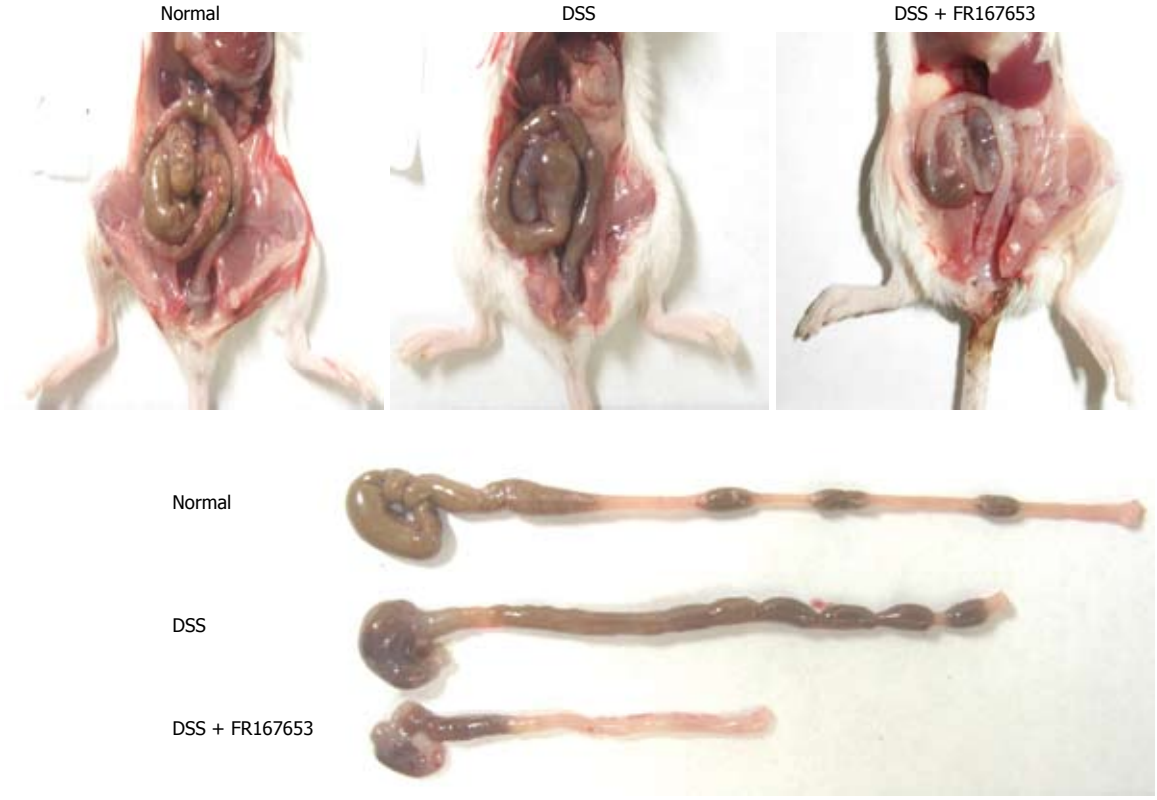

Figure 2 Pictures of laparotomy (upper part) and resected colon (lower part). On day 14, in the FR167653-treated DSS mice stool softening and colon shortening were remarkable, as compared to the vehicle (PBS)-treated DSS mice.

repeated measures was used to test for group and time effects on clinical data (*e.g.* disease activity index) over 7 successive days of clinical observation. $P < 0.05$ was considered to be statistically significant.

RESULTS

To evaluate the effect of FR167653 on DSS colitis, the administration of FR167653 was started at the time of DSS exposure. The administration of FR167653 and vehicle (PBS) was repeated every 24 h. As shown in Figure 1A, on day 10, day 12, and day 14 after the initiation of DSS-induced colitis, the body weight was significantly lower in the FR167653-treated than in the PBS-treated mice. On day 14, survival rate was significantly lower in FR167653- than in the PBS-treated DSS animals (Figure 1B). As shown in Figure 2, colon shortening and stool softening were apparent in the FR167653-treated DSS mice (Figure 2). The total colon length was significantly smaller in the FR167653-treated than in the PBS-treated DSS mice (Figure 3A).

A macroscopic examination of the colon revealed that hyperemia, erosions, and occasional tiny blood coagula occurred mainly in the rectum in both DSS-treated groups. Disease parameters such as the fecal blood score, diarrhea score, and disease activity index were significantly higher in the FR167653-treated than the PBS-treated DSS mice (Figure 3B).

DSS colitis is characterized by histological findings such as edema, infiltration of inflammatory cells into the mucosa and submucosa, ulceration, and mucosal thickening. Our histological analysis indicated that

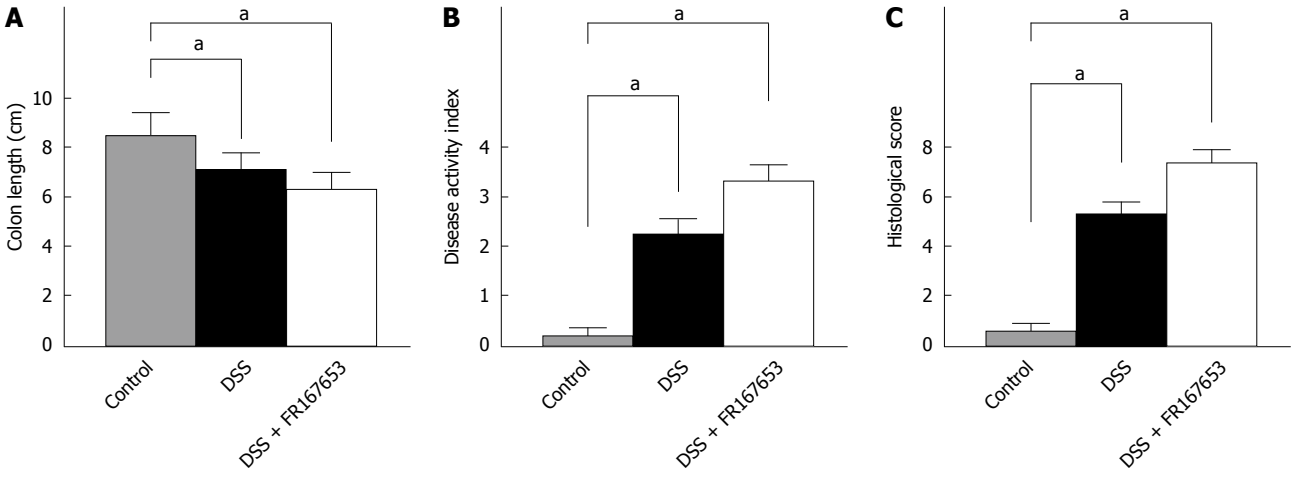

Figure 3 Effects of FR167653 on colon length (**A**), disease activity index (**B**), and histological score (**C**) at day 14. The criteria of scoring are described in Materials and Methods. Data represent mean ± SE (n = 8 mice/group), $^aP < 0.05$.

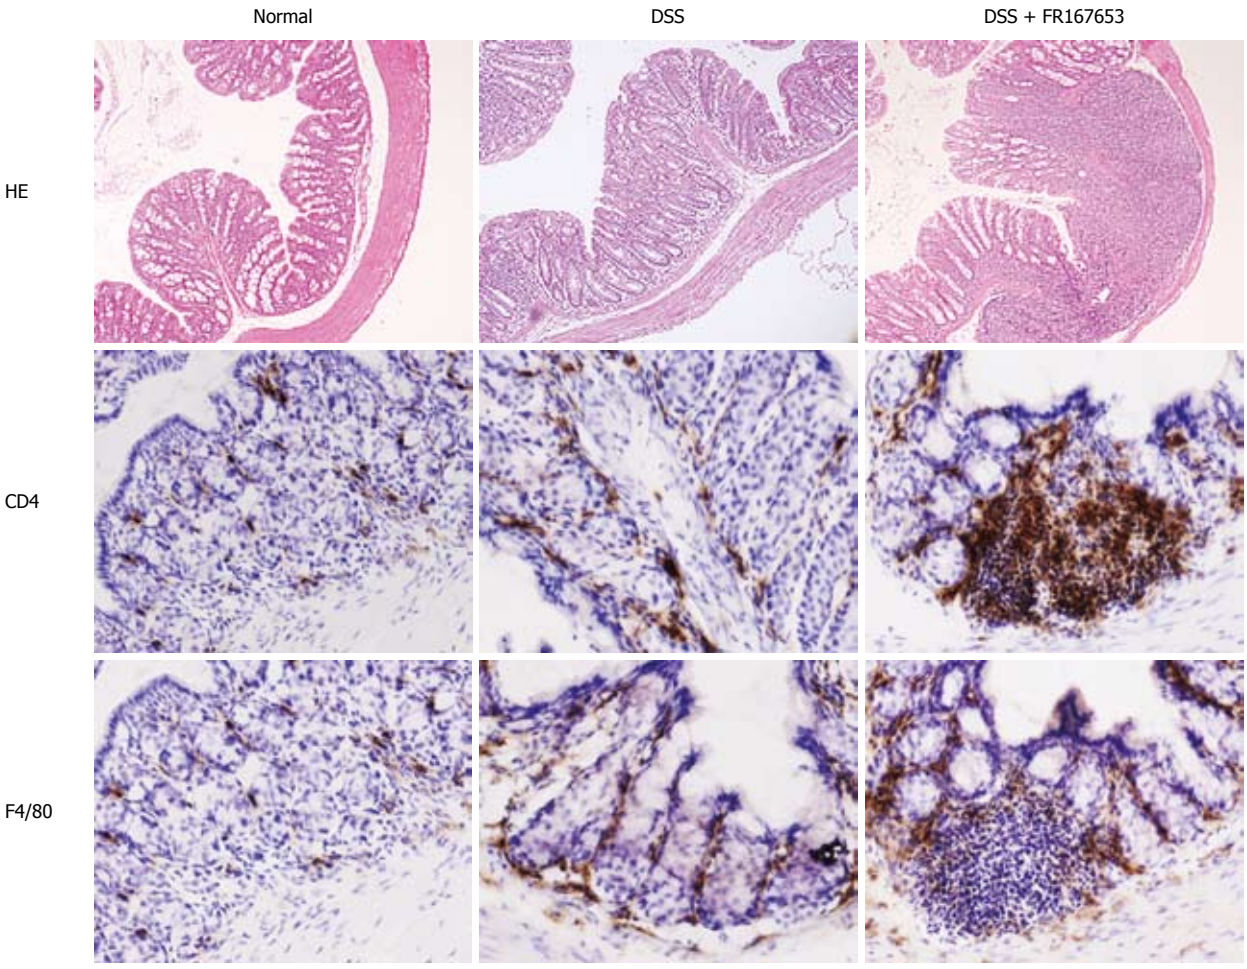

Figure 4 Histological analyses for FR167653 effects on DSS colitis. Colons were excised after 14 d of DSS treatment and stained with HE, anti-CD4 antibody, and anti-F4/80 antibody.

administration of FR167653 markedly enhanced the severity of the colitis as compared to the PBS-treated mice (Figure 3C).

An increase in the number of infiltrating cells and an enhancement of mucosal injury were observed in the PBS-treated DSS mice (Figure 4 upper part). These changes were enhanced in the FR167653-treated DSS mice. The immunohistochemical analysis indicated that the mucosal infiltration of CD4-positive T cells and F4/80-positive monocytes/macrophages was increased in the FR167643-treated DSS mice, compared to the PBS-treated DSS mice (Figure 4 middle and lower parts).

Inhibitory effects of FR167653 on IL-1β and TNF-α expression have been reported[26,27]. To confirm these

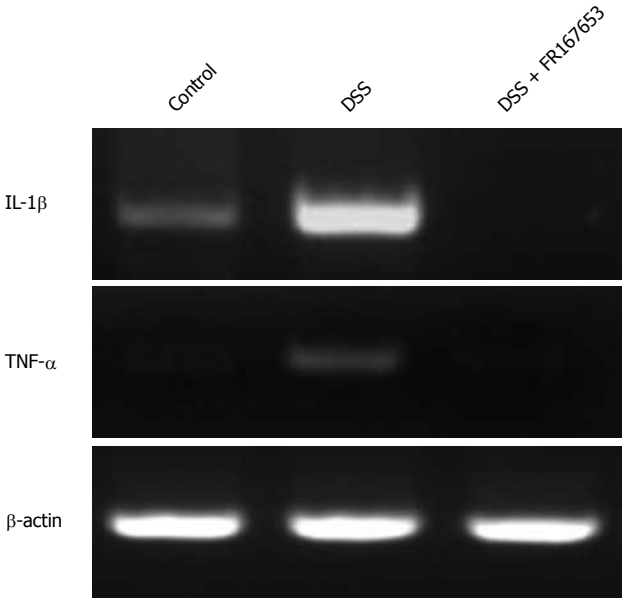

Figure 5 RT-PCR analysis of mucosal cytokine expression in DSS colitis. Representative results of 5 independent experiments are presented.

responses in our model, mucosal IL-1β and TNF-α mRNA expression was evaluated by semi-quantitative RT-PCR. Representative results are shown in Figure 5. DSS mice showed increased expression of IL-1β and TNF-α. The administration of FR167653 markedly reduced the expression of IL-1β and TNF-α mRNAs, although severity of colitis was enhanced. Similar results were observed in 5 different experiments.

DISCUSSION

The aim of this study was to analyze the impact of FR167653 upon inflammation in a mouse model of IBD. DSS-induced colitis in BALB/c mice is used as a model system for the respective human IBD. FR167653 was first discovered to be a potent inhibitor of IL-1 and TNF-α production in LPS-stimulated human monocytes and activated lymphocytes[17]. Recent studies suggest that FR167653 inhibits IL-1β and TNF-α production *via* specific inhibition of p38 MAPK activity[14,19,21]. While we initially expected that inhibition of p38 by FR167653 would block the development of DSS colitis, administration of FR167653 aggravated DSS colitis. Because mucosal IL-1β and TNF-α expression was markedly reduced in the FR167653-treated mice, aggravation of colitis might not be mediated by enhanced proinflammatory responses.

Previous findings of p38 activation in the pathophysiology of IBD are controversial. Waetzig *et al*[7] demonstrated that p38 and JNK1/2 were significantly activated in the inflamed colonic mucosa of IBD patients while the protein and mRNA expression of p38 and JNK were not significantly different between patients and controls. They suggested the role of p38 in the TNF-α signaling regulation loop in active CD patients. Hommes *et al*[8] showed an enhancement of phospho-p38 and phospho-JNK expression in neutrophils, epithelial cells, and lamina propria mononuclear cells in six patients with active CD compared to healthy controls. In contrast, Malamut *et al*[28] could not confirm p38 activation in patients with IBD, by measuring the protein levels and activity of p38. Moreover, a significant decrease in p38 activity and phosphorylated p38 levels was actually observed in the trinitrobenzene sulphonic acid (TNBS) colitis model.

There are two controversial reports of p38-inhibitor effects on experimental colitis. Ten Hove *et al*[29] observed a dichotomous effect of a specific p38 MAPK inhibitor, SB 203580, in TNBS-induced colitis in mice. In SB 203580-treated TNBS mice, weight loss was significantly worse and colon weight was significantly increased. However, activated lymph node cells of SB 203580 treated mice showed decreased IFN-γ but an increased TNF-α production. On the other hand, Hollenbach *et al*[30] showed that SB 203580 improved DSS colitis as reflected in the disease activity and histological disease score. Improvement of colitis was associated with down-regulation of NF-κB signaling and cytokine production.

The precise mechanisms underlying FR167653-induced aggravation of DSS colitis are unclear. Despite of aggravation of proinflammatory cell infiltration, FR167653 strongly reduced mucosal IL-1β and TNF-α expression. It may be that activation of p38 MAPK occurs downstream of the disease perpetuating signal transduction elements and that blockade at this level does not affect disease severity. Alternatively, cells playing roles in mucosal repair or anti-inflammatory process may be dependent on p38 MAPK. For example, it has been reported that p38 MAPK play an important role in epithelial restitution, a process aimed at re-epithelializing the wounded areas[31]. A recent study showed that production of IL-10, a representative anti-inflammatory cytokine, is dependent on p38 MAPK activation[32]. However, observed effects may be specific for models used in this study, and further experiments with other colitis models are needed.

In conclusion, treatment with the p38 MAPK inhibitor FR167653 induced an aggravation of DSS colitis although it reduced mucosal IL-1β and TNF-α production. This indicates that p38 MAPK is not only responsible for the production of proinflammatory cytokines but may also be involved in critical responses in host defense.

COMMENTS

Background

FR167653 is a well-characterized inhibitor of p38 mitogen-activated protein kinase (MAPK). At present, FR167653 has not been studied in any animal models for inflammatory bowel disease (IBD), and knowledge of its action in chronic colitis models is limited.

Research frontiers

Demonstration of the effects of a novel p38 MAPK inhibitor on dextran sulfate sodium (DSS) colitis.

Innovations and breakthroughs

Previous studies suggested that p38 MAPK acts as an enhancer of experimental colitis. Our study demonstrated that FR167653, a p38 MAPK inhibitor, aggravated DSS colitis, suggesting a protective role of p38 MAPK.

Applications
Clinical application of FR167653 to IBD may be possible.

Terminology
FR167653 is a well-characterized inhibitor of p38 MAPK. p38 MAPK mediates a major signal transduction pathway in pro- and anti-inflammatory responses.

Peer review
This is a carefully performed study detailing the effect of co-administration of a parenteral p38 MAPK inhibitor (FR167653) on the induction of DSS colitis in BALB/c mice. The use of this agent in various inflammatory conditions is not novel, nor is targeting p38 in IBD. What is novel is the finding that inhibiting p38 results in more severe DSS colitis.

Abstract

AIM: To study the role of mitochondrial energy disorder in the pathogenesis of ethanol-induced gastric mucosa injury.

METHODS: Wistar rats were used in this study. A gastric mucosal injury model was established by giving the rats alcohol. Gross and microscopic appearance of gastric mucosa and ultrastructure of mitochondria were evaluated. Malondiadehyde (MDA) in gastric mucosa was measured with thiobarbituric acid. Expression of ATP synthase (ATPase) subunits 6 and 8 in mitochondrial DNA (mtDNA) was determined by reverse transcription polymerase chain reaction (RT-PCR).

RESULTS: The gastric mucosal lesion index was correlated with the MDA content in gastric mucosa. As the concentration of ethanol was elevated and the exposure time to ethanol was extended, the content of MDA in gastric mucosa increased and the extent of damage aggravated. The ultrastructure of mitochondria was positively related to the ethanol concentration and exposure time. The expression of mtDNA ATPase subunits 6 and 8 mRNA declined with the increasing MDA content in gastric mucosa after gavage with ethanol.

CONCLUSION: Ethanol-induced gastric mucosa injury is related to oxidative stress, which disturbs energy metabolism of mitochondria and plays a critical role in the pathogenesis of ethanol-induced gastric mucosa injury.

Key words: Animal model; Ethanol; Gastric mucosa; Oxygen free radical; Energy metabolism

INTRODUCTION

Many people all over the world indulge themselves in drinking, which is correlated to a wide spectrum of medical, psychological, behavioral, and social problems. Ethanol is the major component of drinkable wine and alcoholic beverages. After drinking, alcohol is absorbed rapidly into the blood stream from the stomach and intestinal tract. High-concentration ethanol erodes directly the gastric mucosa and causes acute gastritis, leading to hyperemia, edema, hemorrhage, ulcer, *etc*. It is well known that chronic alcohol abuse may induce gastrointestinal dysfunction, chronic atrophic gastritis and is closely related with gastric carcinoma. However, the detailed mechanism by which ethanol affects the gastrointestinal mucosa remains to be elucidated.

Thorough research on how ethanol affects gastric mucosa will benefit the protection of gastric mucosa.

The effect of ethanol on gastric mucosa is a complicated and multifaceted process. It may be associated with disturbance of the balance between gastric mucosal defense and offensive factors. Gastric mucosa contains gastric acid, pepsin, stimulant, *etc*, while the offensive factors contain gastric slime layer, mucosal blood flow, HCO_3^-, prostaglandins (PGs), epidermal growth factor (EGF) and epithelial cell renewing. Ethanol induces vascular endothelium injury of gastric mucosa, disorder of microcirculation and ischemia as a result of more production of oxygen free radicals (OFR). *In vivo*, ethanol metabolism also produces OFR. Alarcon *et al*[1] found that perfusion of OFR induces gastric mucosal injury in rats. However, perfusion of superoxide dismutase (SOD) reduces gastric mucosal injury. Itoh and Guth[2] reported that SOD and catalase (CAT) significantly diminish gastric mucosal injury after ischemia reperfusion. OFR play an crucial role in acute gastric mucosal injury. Similar to other tissue inflammation, numerous inflammatory factors which cause infiltration of neutrophils are released when gastric mucosa is attacked by various insult factors. These neutrophils produce a lot of OFR by respiratory burst. OFR, mostly the superoxide radical anion ($O_2^{\cdot-}$), are metabolized through two endocellular pathways. One is peroxidation of cytomembrane lipid which produces lipoperoxide, malondiadehyde (MDA) and 4-hydroxynonena (4-HNE) after β-oxidation. MDA, a reaction product between OFR and cells, indicates the intracellular OFR. In the other path, OFR reacting with OFR scavengers (*e.g.* SOD) generate hydrogen peroxide (H_2O_2), which will be further oxidized by glutathione peroxidase (GPx) or CAT to H_2O and CO_2. Both of which are closely related to enzyme complexes of respiratory chain locating on the mitochondrial membrane.

Gastric parietal cells are rich in mitochondria[3-5]. Mitochondria provide energy for cells by oxidative phosphorylation (OXPHOS), which is critical to maintain the proper morphology and function of gastric mucosa. F_0F_1-ATP synthase, also known as cytochrome C oxidase (complex Ⅳ), is critical to oxidative phosphorylation and mediates generation of ATP[6]. The complex Ⅳ phosphorylates ADP to ATP at the advantage of transmembrane electrochemical proton gradient generated by respiratory electron-transport chain[7]. Mitochondrial ATP synthase (ATPase) subunits 6 and 8, the components of the F_0 part of this enzyme, which is encoded by mitochondrial DNA (mtDNA) independently, control the synthesis of ATP by mediating the proton transfer. Mitochondrion is an easily injured organelle and mtDNA is the major target of intracellular oxidative stress associated with ethanol[8]. However, the relation between OFR and alternation of mitochondrial ultra microstructure as well as how OFR interferes with gastric mucosal energy metabolism are obscure. This study was focused on the ultra microstructure alteration of mitochondria in response to the injury induced by and the role of disturbance of mitochondrial energy metabolism in ethanol-related gastropathy.

In this research, we established an acute and chronic animal model of gastric mucosa injury by ethanol gavage. The related parameters include index of gastric mucosa injury, pathological damage, alteration of mitochondria ultra microstructure, content of MDA and expression of mtDNA of ATPase subunits 6 and 8 in rat gastric mucosa. According to the above parameters, we aimed to find the relation between OFR and mediating factors of energy metabolism as well as the role of ethanol in ethanol-induced gastric mucosal injury.

MATERIALS AND METHODS

Rats

Healthy male Wistar rats of clean grade, purchased from Shanghai Slac Laboratory Animal Company, were bred in Anticancer Research Center of Xiamen University. All animal experiments were performed under the animal experimental rules of PRC.

Reagents

Medical anhydrous ethanol, purchased from the Shanghai Chemical Reagent Corporation, was diluted to the desired concentration with distilled water before experiment. Ten percents (W/W) formaldehyde fixatives were provided by Pathology Department of Zhongshan Hospital, Xiamen University. MDA kits were purchased from the General Hospital of People's Liberation Army. TRIzol reagent (Cat No. 15596-026) came from Invitrogen Corporation. RT-PCR kits (Cat No. A3500), Taq DNA polymerase, and 100 bp DNA ladder were bought from the Promega Corporation.

Equipments

Gavage needles and a set of animal anatomic equipments were provided by Anticancer Research Center and Zhongshan Hospital of Xiamen University, respectively. PCR was performed on Gene Amp2700 (Applied Biosystems, USA). Gel analysis was performed by GAS7100X (USA), and transmission electron microscope was made in Japan (Hitachi-Hu-12A, Hitachi, Japan).

Establishing animal model of ethanol-induced acute gastric mucosal injury

Thirty-two healthy male Wistar rats of clean grade, weighing 200-220 g, were randomly divided into normal control group (n = 8) and experimental group (n = 24). The rats were abstained from any food but water 24 h before experiment with free movement. Two hours before experiment, the rats were deprived of water. Rats in the control group were gavaged with 1 mL normal saline. Rats in the experimental group were divided into three subgroups (n = 8). Rats in each subgroup were gavaged respectively with 1 mL of anhydrous ethanol, 70% (W/W) ethanol and 40% (W/W) ethanol, respectively. Two hours later, all the animals were

anesthetized with ether, and their abdominal cavity was dissected along the inferior border of xiphoid and their stomach was mobilized, then the gastric cavity was dissected along the greater curvature and the gastric mucosa was spread. After the mucosa was poached three times with physiologic saline, degree of the gastric mucosal injury was determined according to the Guth law and biopsy was performed.

Establishing animal model of ethanol-induced chronic gastric mucosal injury

Ninety healthy male Wistar rats of clean grade, weighing 160-180 g, were randomly divided into 3 normal control groups and 6 experimental groups (n = 10) after feeding for a week. The 3 normal control groups were gavaged with normal saline, while the 6 experimental groups were gavaged two times with 25% (W/W) ethanol and 45% (W/W) ethanol daily. The volume of gavage solution was calculated according to 9 mL/kg per day. Rats in the control and experimental groups were sacrificed on days 3, 6, and 9, respectively, and dissected in the same way as described in establishing animal model of ethanol-induced acute gastric mucosal injury.

Determination of gross injury index for gastric mucosa

Gastric mucosal injury indices were calculated according to the Guth standard[9]: 1 point for the punctate hemorrhage, 2 points for the injury focus with its length shorter than 1 mm, 3 points for the injury focus with its length ranging 1-2 mm, 4 points for the injury focus with its length ranging 2-4 mm, 5 points for the injury focus with its length longer than 4 mm, respectively, for the streak-like hemorrhage. The score was doubled if the streak was wider than 2 mm. Injury index of the whole gastric mucosa for each rat was the summation of injury indices for each lesion.

Determination of pathological injury integral for gastric mucosa

A 0.5 cm × 1.0 cm tissue was taken from gastric gland, fixed with a 10% (W/W) formaldehyde solution and made into a paraffin block. The tissue was cut into 5-μm thick sections which were stained with hematoxylin and eosin. Pathological changes in the gastric mucosa were observed under optical microscope. Integrals were calculated according to the scoring standard reported by Masuda *et al*[10], namely, 0 point for normal tissue, 1 point for epithelial damage of surface layer, 2 points for hyperemia or edema of the upper stratum, 3 points for hyperemia, edema or even hemorrhage of stratum medium or under layer. Upper mucosal glands with structural disorders or necrosis had a score of 4 points, and the tissue with deep ulcer or necrosis had a score of 5 points. Integral of each section should not exceed 15 points.

Preparation of specimens for transmission electron microscopy (TEM)

All specimens were fixed with 3% (W/W) glutaraldehyde and 1.5% (W/W) paraformaldehyde at 4℃ for several days or hours, then postfixed for 1.5 h in 1% (W/W) osmium tetroxide and 1.5% (W/W) potassium ferrocyanide, and finally rinsed with PBS. The paraffin tissue block was stained in a solution buffer containing 70% (W/W) ethnal and uranyl acetate, then gradually dehydrated with alcohol-acetone and embedded in Epon 618. The tissue block was cut into ultra-thin (80 nm) sections, which were double stained with uranyl acetate and lead citrate for 5 min and examined under a Hitachi Hu-12A electron microscope.

Determination of MDA content in gastric mucosa with thiobarbituric acid (TBA) method

Mucosal specimens were taken from gastric glands and weighed, then immersed into 0.02 mmol/L Tris-HCl (pH 7.4) at the ratio of 1:10 (mg/μL). Tissue homogenate was centrifuged at 13000 r/min for 15 min at 4℃ and precipitates were discarded. Supernatant (0.15 mL) was transferred to a testing tube. A standard solution (0.15 mL) was added to each standard testing tube, and 0.15 mL of distilled water was added to another blank testing tube, 2.5 mL thiobarbituric acid (TBA) was added into each of these two tubes, which were agitated several times, and then incubated at 100℃ for 1 h. After that, each specimen was cooled to room temperature and centrifuged at 3000 r/min for 15 min. Finally, supernatant in each tube underwent colorimetric assay at 532 nm. MDA content (nmol/mL) was calculated according to the following formula: (absorbance of testing tube/absorbance of standard tube) × 2.5.

Detection of mRNA expression in mtDNA ATPase subunits 6 and 8 by RT-PCR

Stomach of each rat was split completely and washed at least three times with 0.1% (W/W) diethyl-pyrocarbonate (DEPC). Gastric mucosa was peeled carefully, and put into a frozen-storage pipe. Finally, each specimen was kept in liquid nitrogen. The anatomic equipments were degermed at a high-pressure and toasted at 200℃ for no less than 5 h beforehand. Meanwhile, frozen pipes were soaked in 0.1% DEPC water overnight and degermed at a high-pressure to remove all vestigial DEPC. Total RNA was extracted with TrizolTM (Invitrogen) according to its manufacturer's instructions. Reverse transcription (RT) of mRNA was performed with an AMV reverse transcription kit (Promega), following the manufacturer's instructions. RT reaction conditions were as follows: at 42℃ for 60 min, at 95℃ for 5 min, at 4℃ for 5 min. Reacting systems are listed in Table 1. Four uL of RT products (cDNA) was used as the template for PCR amplification. Primers were designed according to the sequences of mitochondrial ATPase subunits 6 and 8 for amplifying. For comparison, negative and positive controls were set up. *β-actin* gene was taken as a positive control. PCR primers were synthesized by Invitrogen Corporation. PCR products were assayed by 1.35% (W/W) agarose gel electrophoresis and stained with ethidium bromide to confirm the expected product size. Expression of ATPase subunits 6 and 8 was normalized to that of the corresponding *β-actin*. Analysis

of PCR products was performed on GAS7100X. PCR reacting system, information about primers, amplifying conditions were listed in Tables 2-4.

Statistical analysis

Statistical analysis was performed using SPSS 13.0 for Windows. $P < 0.05$ was considered statistically significant.

RESULTS

Changes in morphology of gastric mucosa with ethanol-induced acute injury

Gastric mucosa was injured in all experimental groups. A positive correlation was observed between injury and ethanol concentrations. Gastric mucosa from rats in the control group that received saline was smooth, complete, and pink, without congestion, edema, and erosion or bleeding. The mucosa was normal under microscope. With the increasing ethanol concentration, edema and congestion became obvious. In the rats that administrated 40% (W/W) ethanol, gastric mucosa became edematous and congestive. Furthermore, point and scattered bleeding lesions, focal hemorrhage, necrosis occurred. The necrosis was limited to the superficial 1/3 layer of mucosa. In the rats that administrated 70% (W/W) ethanol, congestion and edema aggravated. Superficial vessels of gastric mucosa became obviously dilated. Linear ulcer and bleeding lesions occurred. The common length of lesions was more than 4 mm, and there was significant infiltration of neutrophils and eosinophile granulocytes. Mucosa necrosis expanded to more than half of the whole layer. Rare normal mucosa was observed in the rats that administrated 100% (W/W) ethanol. Giant and deep ulcers were visible (Figures 1 and 2).

Table 4 PCR amplification conditions (mean ± SD)

Target sequence	Amplification conditions
β-actin	94.0℃ 30 s, 59.0℃ 30 s, 72.0℃ 30 s, 35cycles
ATPase subunit 6	94.0℃ 30 s, 53.0℃ 30 s, 72.0℃ 30 s, 33cycles
ATPase subunit 8	94.0℃ 30 s, 52.0℃ 30 s, 72.0℃ 30 s, 32cycles

Table 5 LI and MDA content in acute gastric mucosa injury treated with different concentrations of ethanol (mean ± SD)

Group	LI	MDA (nmol/mL)
Control	0.000 ± 0.000	0.968 ± 0.136
40% (W/W) ethanol	38.375 ± 6.368[a]	1.363 ± 0.152[a]
70% (W/W) ethanol	70.000 ± 8.018[a,b]	1.703 ± 0.124[a,b]
100% (W/W) ethanol	118.750 ± 14.820[a,b,c]	2.083 ± 0.153[a,b,c]

[a]$P < 0.01$ *vs* control group; [b]$P < 0.01$ *vs* 40% (W/W) ethanol group; [c]$P < 0.01$ *vs* 70% (W/W) ethanol group.

Integral index of acute injury in gastric mucosa

After administration of different concentrations of ethanol, the integral index was different for rats in different groups. The injury index was positively correlated with the ethanol concentration ($P < 0.01$, Table 5).

Changes in morphology of gastric mucosa with ethanol-induced chronic injury

Gastric mucosa from the control group was smooth and intact. In the rats that administrated with 25% (W/W) or 45% (W/W) ethanol, injuries exacerbated with the increasing gavage time. No significant change was observed in gastric mucosa of rats that received 25% (W/W) ethanol after three weeks. Occasionally, congestion and edema could be observed under microscope. After six weeks, congestion and edema became obvious but no obvious bleeding was found. After nine weeks, congestion and edema exaggerated and some superficial bleeding lesions were noted. Disorder of glands could be observed under microscope. Gastric mucosa of rats that received 45% (W/W) ethanol became dark red after three weeks. Congestion, edema and even point erosion

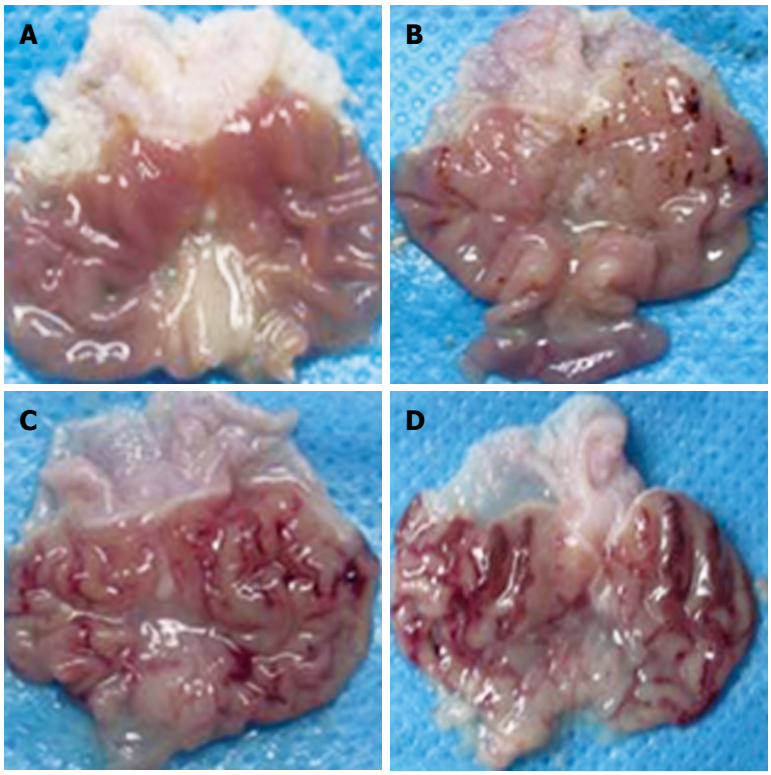

Figure 1 Gross appearance of gastric mucosa in rats with ethanol-induced acute gastric mucosa injury 2 h after administration of normal sodium (**A**), 40% (W/W) ethanol (**B**), 70% (W/W) ethanol (**C**), and 100% (W/W) ethanol (**D**), respectively.

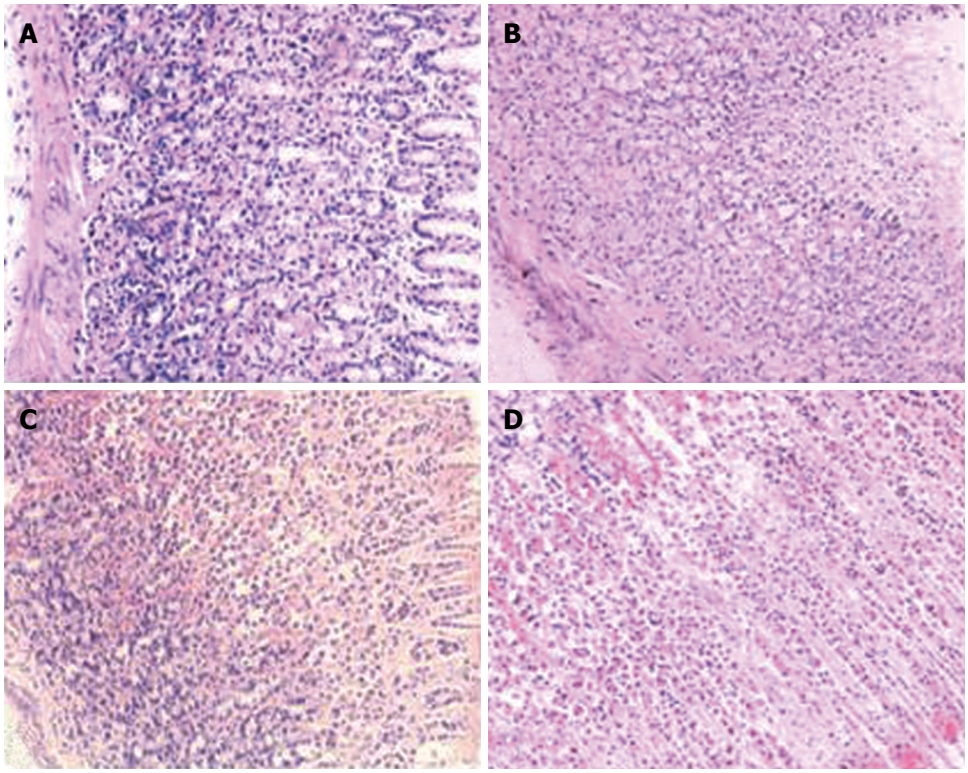

Figure 2 Histological changes in gastric mucosa of rats with ethanol-induced acute gastric mucosa injury (x 100) 2 h after administration of normal sodium (**A**), 40% (W/W) ethanol (**B**), 70% (W/W) ethanol (**C**), and 100% (W/W) ethanol (**D**), respectively.

could be observed. There was infiltration of neutrophils and eosinophile granulocytes but no disturbed glandular structure. After six weeks, the number of scattered hemorrhage lesions increased. There was infiltration of neutrophils, lymphocytes and eosinophile granulocytes. Principal cells and parietal cells became swollen. The upper structure of glandular mucosa was damaged. After nine weeks, gastric mucosa mainly displayed a dark red or red and white performance. Congestion and edema became obviously. Infiltration of neutrophils, lymphocytes and eosinophile granulocytes exacerbated. Principal cells and parietal cells became swollen and diminished. The upper glandular structure was disturbed and the nuclei of glandular epithelium in the lower part were deeply stained. Atypical hyperplasia occurred (Figures 3 and 4).

Integral index of chronic injury in gastric mucosa

Integral indices were different for all groups and

Table 6 Integral indices and pathological integrals for chronic gastric mucosa injury (mean ± SD)

Group	3 wk		6 wk		9 wk	
	Integral indices	Pathological integrals	Integral indices	Pathological integrals	Integral indices	Pathological integrals

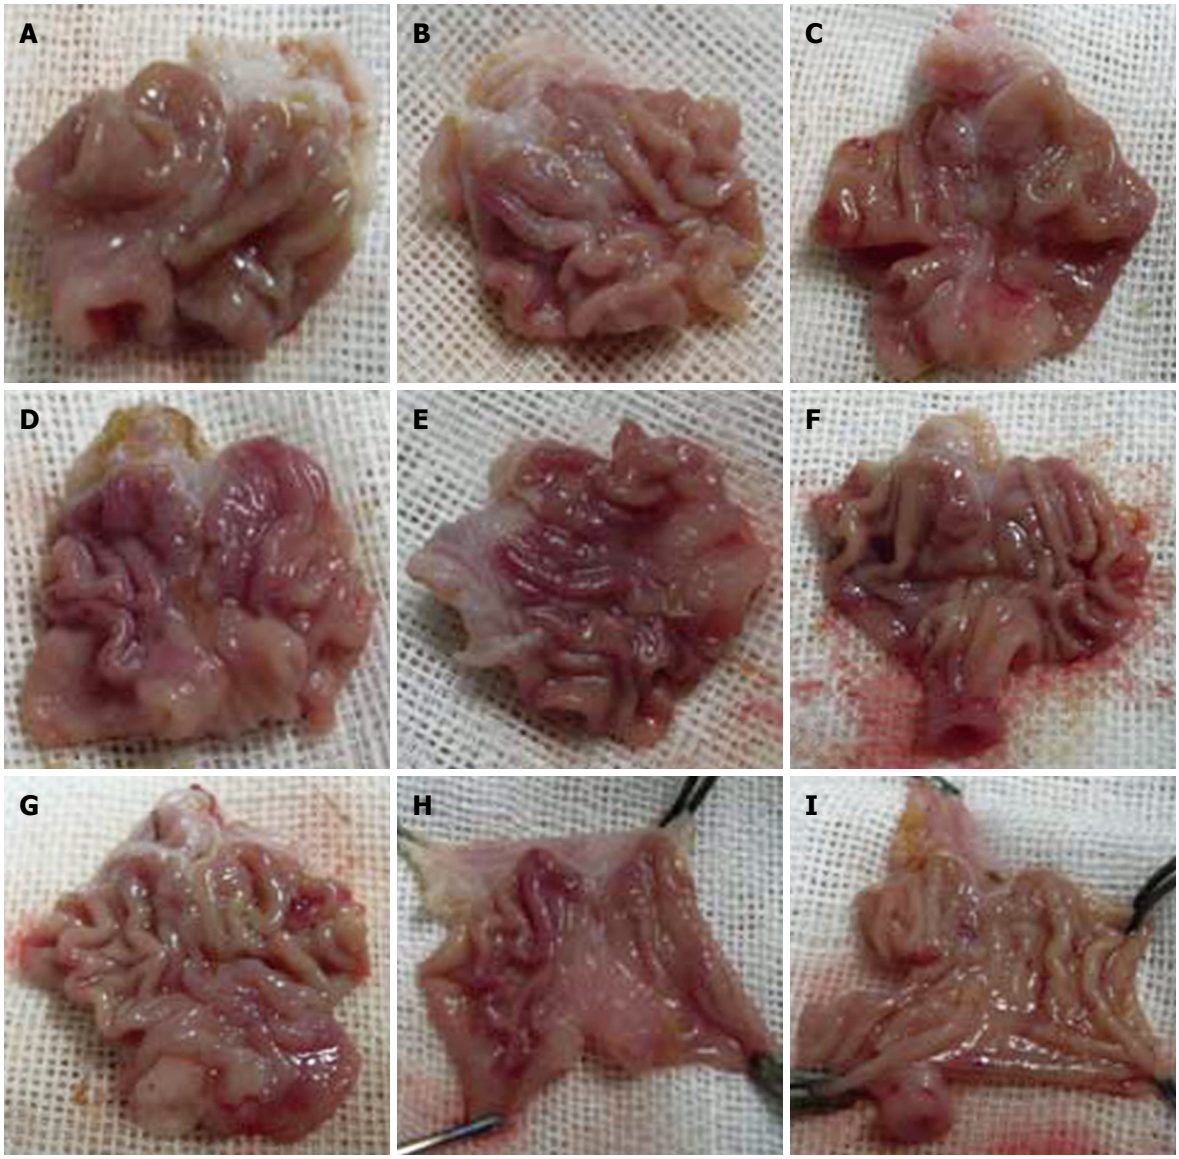

Figure 3 Gross changes in gastric mucosa of rats with ethanol-induced chronic gastric mucosa injury 3 wk after administration of normal sodium (**A**), 25% (W/W) ethanol (**B**), and 45% (W/W) ethanol (**C**), respectively; 6 wk after administration of normal sodium (**D**), 25% (W/W) ethanol (**E**), and 45% (W/W) ethanol (**F**), respectively; 9 wk after administration of normal sodium (**G**), 25% (W/W) ethanol (**H**), and 45% (W/W) ethanol (**I**), respectively.

increased with the increasing ethanol concentration ($P < 0.01$) and the gavage time ($P < 0.05$, Table 6).

Pathological integral of severity in chronic injury of gastric mucosa

Pathological integrals of all groups were different. Integral index increased with the increasing ethanol concentration ($P < 0.01$) and the gavage time ($P < 0.01$, Table 6).

Ultrastructure of mitochondria

Swollen mitochondria were observed in parietal cells under transmission electron microscope and collapsed 2 h after 100% (W/W) ethanol gavage. Mitochondria became homogeneous and vacuolar. Mitochondrial cristae diminished. However, no significant change occurred in mitochondria 2 h after 40% (W/W) ethanol or 70% (W/W) ethanol gavage. The structure of mitochondria was intact and mitochondrial cristae were clear. The number of mitochondria decreased with the increasing ethanol concentration. This was especially true in rats that received 100% (W/W) ethanol. In chronic alcohol damage experiment, abnormal

the increasing ethanol concentration. Compared with the control group, the expression of mtDNA ATPase subunits 6 and 8 mRNA increased in rats that received 40% (W/W) ethanol. However, the expression of mtDNA ATPase subunits 6 and 8 mRNA decreased in rats that received 100% (W/W) ethanol compared with rats in the control group. A same tendency was observed in rats that received 70% (W/W) ethanol (Table 7, Figure 7).

Expression of mtDNA ATPase subunits 6 and 8 mRNA in gastric mucosa with ethanol-induced chronic injury

The expression of mtDNA ATPase subunits 6 and 8 mRNA was significantly different in rats with alcohol-induced chronic injury ($P < 0.01$). However, it was negatively related with both of ethanol concentration and gavage time (Table 9, Figures 8 and 9).

Correlation analysis of mucosal injury, MDA, ATPase subunits 6 and 8

MDA and LI were positively correlated with ethanol-induced acute and chronic injury. However, ATPase subunits 6 and 8 were negatively correlated with L1 and MDA.

DISCUSSION

We successfully established an acute and chronic gastric mucosa injury model by oral administration of ethanol. MDA, a product of interaction between OFR and cell membrane, indirectly represents the OFR content in

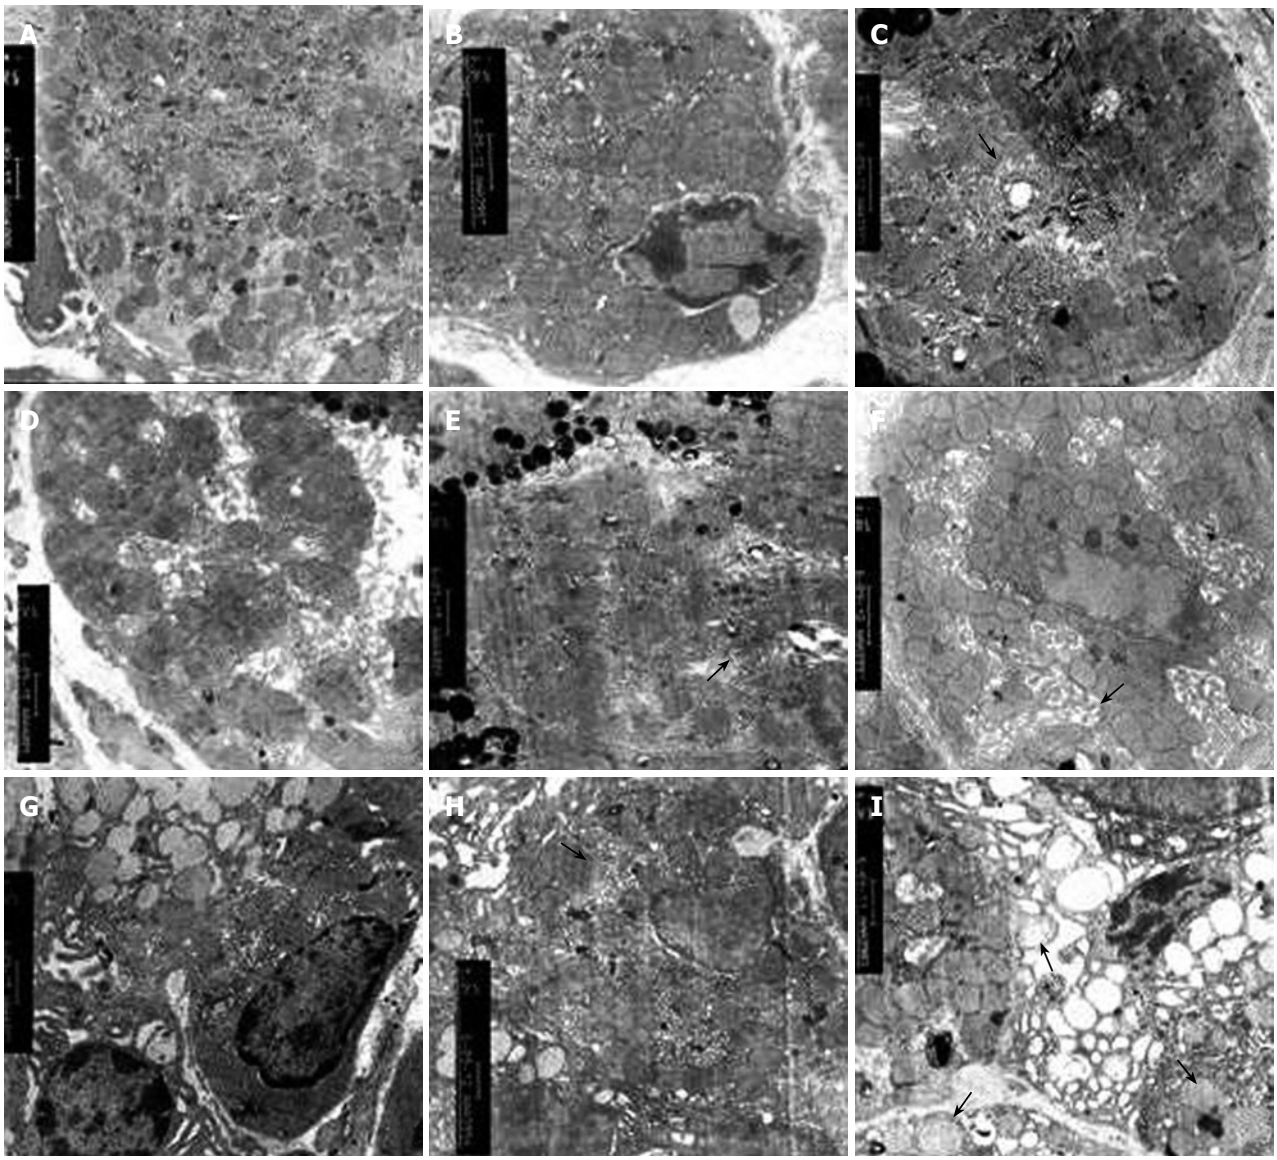

Figure 6 Changes in mitochondrial ultra-structure of rats with ethanol-induced chronic gastric mucosa injury 3 wk after administration of normal sodium (**A**), 25% (W/W) ethanol (**B**), and 45% (W/W) ethanol (**C**), respectively; 6 wk after administration of normal sodium (**D**), 25% (W/W) ethanol (**E**), and 45% (W/W) ethanol (**F**), respectively; 9 wk after administration normal sodium (**G**), 25% (W/W) ethanol (**H**), and 45% (W/W) ethanol (**I**), respectively.

cells. The MDA content was significantly higher in rats with ethanol-induced acute and chronic injury than in those of the normal control group. Furthermore, MDA increased with the increasing ethanol concentrations indicating that MDA is positively correlated with ethanol concentration and that ethanol metabolism in the stomach produces a large quantity of OFR in a dose-dependent manner. In the acute and chronic gastric mucosa injury model, the gastric mucosal damage aggravated with the increasing content of gastric MDA. OFR tended to react with unsaturated fatty acids in cell membrane, indicating that lipid peroxidation chain reaction decreases unsaturated fatty acid content and finally affects the fluidity and permeability of cell membrane[11,12]. Gastric mucosa is rich in protein sulfhydryl groups, which may be the target of OFR. Oxidized protein sulfhydryl groups lead to protein denaturation or enzyme inactivation, and receptor damage or modification on cell membrane, thus contributing to mucosal injury[13,14]. Gastric parietal cells are abundant in mitochondria, which are critical for maintaining the normal morphology and function of gastric mucosa since they afford usable energy through oxidative phosphorylation. Two hours after administration of 100% (W/W) ethanol, mitochondrial structure was significantly damaged in the acute gastric mucosal injury model, mitochondria became swollen and disaggregated, and mitochondrial cristae were dissolved and disappeared. Nine weeks after administration of 45% (W/W) ethanol, obscuring mitochondrial structure and swollen mitochondrial cristae were found in the chronic gastric mucosal injury model. However, no significant changes occurred in other experimental groups, which may be due to the following factors, such as a small sample size. The number of mitochondria in the gastric parietal cells reduced with the increasing ethanol concentration and time, and the number of mitochondria was negatively correlated with MDA in

the acute and chronic gastric mucosal injury model, suggesting that OFR can damage mitochondria.

mtDNA and expression of encoding genes have direct effects on mitochondrial respiration and ATP synthesis. mtDNA ATPase subunits 6 and 8, which are independently encoded by mtDNA, are critical parts of F_0 in the respiratory enzyme, F_0F_1-ATPase and involved in cellular energy metabolism, acting as a proton channel in the synthesis of ATP and controlling ATP synthesis by regulating the proton transfer. mtDNA is susceptible to the attack of OFR[15], which leads to the alteration of gene expression[16]. The following characteristics of mtDNA are believed to be the main cause of this phenomenon[17-19]. mtDNA lacks the protection of histone and effective repair systems against DNA damage and is near to the inner mitochondrial membrane where OFR, a highly mutagenic product of oxidative phosphorylation, generates. mtDNA has tightly aligned genes containing few intron sequences so that random mutation may significantly change the encoding sequence of mtDNA. In the field of ethanol-induced gastric injury, few reports are available on whether OFR affects the expression of mtDNA ATPase. In the present study, the mRNA expression of mtDNA ATPase subunits 6 and 8 in acute and chronic gastric injury model decreased with the increasing ethanol concentration and was negatively correlated with the increasing MDA content, showing that OFR is negatively related with the expression of ATPase subunits 6 and 8 and that ethanol-induced gastric mucosa injury may be achieved through the detrimental effect of OFR on cellular energy metabolism. Decreasing the mRNA expression of ATPase subunits 6 and 8 can reduce the synthesis of ATPase subunit 6 and 8, the encumbrance of proton channel F_0 and the activity of ATPase. Thus, the synthesis of ATP may be hindered and bring about the scarcity of provided energy. However, injured cells have an urgent demand of energy to fulfill the repair process. The contradiction between energy supply and demand eventually aggravates gastric mucosa injury, falling into a vicious cycle. The reduction in or lack of ATP synthesis may damage the gastric mucosa by inducing apoptosis and hampering the reconstruction of gastric epithelial injury. One important reaction to the epithelial damage is the rapid repair or epithelia rebuilding to recover the continuity and barrier function of mucosal epithelia. As reconstruction of gastric epithelial injury is a highly ATP-dependent process, lack of ATP may hinder this process and oxidative phosphorylation[20,21]. Lack of ATP may lead to metabolic acidosis, cellular edema, intracellular calcium overload, and further damage to gastric mucosa cells[22]. Therefore, it sounds reasonable that OFR plays an important role in ethanol-induced gastric mucosa injury. Damage may eventually affect, at least in part, cellular energy metabolism. The expression of ATPase subunits 6 and 8 in rats that received 40% (W/W) ethanol

was higher than that in those of the control group, suggesting that injured gastric mucosa can protect itself against a certain extent of oxidative stress.

Our study systematically described gastric mucosa injury from three levels, namely gross, microscopic appearance and ultrastructure. We also discussed the relationship between disturbed mitochondrial structure and oxidative stress caused by ethanol. We conclude that disorder of mitochondrial energy metabolism may play an important, role in the pathogenesis of ethanol-related gastropathy. However, changes in ATPase subunits 6 and 8 at protein level and alteration of mitochondrial membrane potential remain to be elucidated.

Abstract

AIM: To investigate the tight junction protein expressions of intestinal mucosa in an experimental model of cardiopulmonary bypass (CPB) in rats.

METHODS: Thirty anesthetized rats were randomly divided into two groups: Group S (n = 10) served as sham operation and group C (n = 20) served as CPB which underwent CPB for 1 h. Expression of occludin and zonula occludens-1 (ZO-1) were determined by Western blotting and immunocytochemistry, respectively. Plasma levels of diamine oxidase (DAO) and d-lactate were determined using an enzymatic spectrophotometry.

RESULTS: Immunohistochemical localization of occludin and ZO-1 showed disruption of the tight junctions in enterocytes lining villi at the end of CPB and 2 h after CPB. The intensities of the occludin and ZO-1 at the end of CPB were lower than those of control group (76.4% ± 22.5% *vs* 96.5% ± 28.5% and 62.4% ± 10.1% *vs* 85.5% ± 25.6%, $P < 0.05$) and were further lower at 2 h after CPB (50.5% ± 10.5% and 45.3% ± 9.5%, $P < 0.05$). Plasma d-lactate and DAO levels increased significantly (8.688 ± 0.704 *vs* 5.745 ± 0.364 and 0.898 ± 0.062 *vs* 0.562 ± 0.035, $P < 0.05$) at the end of CPB compared with control group and were significantly higher at 2 h after CPB than those at the end of CPB (9.377 ± 0.769 and 1.038 ± 0.252, $P < 0.05$). There were significant negative correlations between occludin or ZO-1 expression and DAO ($r^2 = 0.5629$, $r^2 = 0.5424$, $P < 0.05$) or d-lactate levels ($r^2 = 0.6512$, $r^2 = 0.7073$, $P < 0.05$) both at the end of CPB and 2 h after CPB.

CONCLUSION: CPB markedly down-regulates the expression of occludin and ZO-1 proteins in intestinal mucosa of rats. The close correlation between expression of tight junctions (TJs) and plasma levels of DAO or d-lactate supports the hypothesis that intestinal permeability increases during and after CPB because of decreases in the expressions of TJs.

Key words: Cardiopulmonary bypass; Occludin; ZO-1; Tight junction; Diamine oxidase; d-lactate

INTRODUCTION

Intestinal mucosa serves as a major anatomic and functional barrier separating potentially harmful intraluminal elements such as bacteria and endotoxins from extraintestinal tissues and the systemic circulation[1]. Some studies have shown that cardiopulmonary bypass (CPB) predisposes the intestines to inadequate perfusion, hypoxic injury, and increases in gut permeability[2,3]. During CPB, endotoxin which may originate from the gut has been found to rise in the circulation and may contribute to the cytokine and complement activation caused by the exposure of blood to artificial surfaces of the oxygenator. The resulting proinflammatory reaction can cause fever and high oxygen consumption in the direct postoperative period, *i.e.*, the so-called post-perfusion (or "post-pump") syndrome[4-6].

Tight junctions (TJs) are located at the apical part

of lateral membranes of polar epithelial cells, forming a barrier that regulates the permeability of ions, macromolecules, and cells through the paracellular pathway[7,8]. Three groups of macromolecules are considered as bona fide integral components of the TJ: occludin(s), claudins and junction adhesion molecule[9]. Zonula occludens (ZO)-1, -2 and -3 are the major TJ-plaque proteins that bind to the intracellular domain of occludins. The interaction between occludin and ZO-1 plays a crucial role in maintaining the structure of TJ and epithelial barrier function[10]. TJ structure and function present a highly dynamic nature, subjected to regulation by a variety of intracellular and extracellular signals, both in normal and pathologic conditions[7,8]. Intracellular events that may influence TJs' stability are related to energy depletion and extracellular events include cytokine activation, oxidative stress, attachment of enteropathogens on epithelial surface and neutrophil transmigration[7,11-14]. Most of these events have been demonstrated to play an important role during CPB[15-17].

According to our knowledge, there are no previous studies investigating whether cardiopulmonary bypass disrupts intestinal mucosal barrier by altering TJs' formation and function. The present study was initiated to address two important questions in the field of CPB-induced gut barrier dysfunction and the molecular mechanisms involved: first, to determine any change in occludin and ZO-1 expressions in the intestinal epithelium and, second, to determine if there is any correlation between occludin or ZO-1 expressions and intestinal mucosal damage during CPB, as reflected by plasma levels of diamine oxidase (DAO) and *d*-lactate[18,19].

MATERIALS AND METHODS

Materials

Adult male Sprague-Dawley (SD) rats (provided by the department of experimental animals, China Medical University) weighing 300-400 g were used in the present study. They were housed in stainless steel cages, three rats per cage, under controlled temperature (23℃) and humidity conditions, with 12-h dark/light cycles, and maintained on standard laboratory diet with tap water ad libitum throughout the experiment, except for an overnight fast before surgery.

The experiments were carried out according to the guidelines set forth by the Ethics Committee of China Medical University, Shenyang, China.

Methods

Experimental protocol: Thirty rats were randomly divided into two groups: Group S (n = 10) served as sham-operation and group C (n = 20) served as CPB. The rats of group C underwent 60 min of CPB and were sacrificed at the end of CPB (n = 10) or at 2 h after CPB (n = 10) randomly.

Surgical procedure for CPB[20-22]: Rats were anaesthetized with intraperitoneal administration of chloral hydrate (350 mg/kg). Once the anesthesia was achieved for the surgical level, the rats were placed in supine position. A 14G catheter was inserted into the trachea and the lungs were mechanically ventilated with a small animal ventilator (DH2800, Zhejiang University Medical Apparatus Co, China). The tidal volume was approximately 10 mL/kg, the respiratory rate was 60/min, peak airway pressure was 20-30 mmH_2O and the respiration concentration of O_2 was 100%. Anesthesia was maintained throughout the experiment with additional doses of chloral hydrate (100-150 mg/kg). All subsequent procedures were performed under aseptic conditions.

The left femoral artery was cannulated with a 24-gauge catheter to monitor systemic arterial pressure (SAP) and to collect arterial blood (0.2 mL) for arterial blood gas analysis before CPB, 30 min, 1 h and 2 h after CPB (blood gasanalyzer, GEM Premier 3000, USA). The homolateral femoral vein was cannulated with a 20-gauge catheter for fluid replacement (0.9% NS 0.5-1.0 mL/h). Following administration of heparin (300 U/kg), a 16-gauge catheter, modified to a multiside-orifices cannula in the forepart, was inserted into the right jugular vein and advanced to the right atrium for blood drained. A 22-gauge catheter was cannulated to the right carotid artery which served as the arterial infusion line for the CPB circuit. The electrocardiogram (ECG) was performed and rectal temperature (RT) was monitored.

The minute CPB circuit comprised a venous reservoir, a specially designed membrane oxygenator (Ke Wei Co. Ltd, Guandong, China), a roller pump(Longer Precision Pump Co. Ltd, Baoding, China), and sterile tubing with an inner diameter of 4 mm for the venous line and of 1.6 mm for the arterial line. The main priming fluid of the circuit constituted Hespander (synthetic colloid, 7 mL), Ringer's lactate solution (7 mL), 15% mannitol (1 mL) and 8% sodium bicarbonate (1 mL). After careful check, the clamps were released and the bypass was started. With an inspired oxygen fraction of 100%, 50 mL/min gas flow was sufficient to achieve adequate oxygenation and to maintain the $PaCO_2$ within 35-45 mmHg. At the initiation of perfusion, the flow-rate was gradually adjusted to a level that would sustain the arterial pressure near 60 mmHg. At this point, mechanical ventilation was terminated and CPB was stably performed at 90-100 mL/kg per min throughout the experiment. Body central temperature was monitored with a rectal probe and kept at about 33℃. After 60 min, the bypass was terminated when the temperature gradually elevated to 37℃ by a heat lamp placed above the animal and the infusion warmer (BIGGER, CBW68, USA). The mechanical ventilation was resumed until the rats gained steady active breath. The remaining priming solution was infused gradually after the termination of CPB and dopamine (3 μg/kg per min) was infused when the main arterial pressure was less than 60 mmHg.

The anesthetic and surgical procedure performed in the sham-group (n = 10) were the same as in the CPB group. Stable Mbp was maintained, but without CPB, for the same duration of surgery and anesthesia as in the CPB 1 h or 2 h group.

Sample collection: The rats from each group were sacrificed by decapitation. The arterial blood (0.2 mL) was sampled before CPB, at the end of CPB and 2 h after CPB for determination of serum DAO and *d*-lactate levels. At end of CPB and 2 h after CPB, intestinal (ileum) tissue samples were collected for immunohisto-chemical and Western blotting analysis. The animals in the sham-group were sacrificed at the end of the time period equivalent to the CPB-2 h group. All samples were determined in a blinded fashion; results were not available until completion of the study.

Plasma *d*-lactate measurement: Plasma *d*-lactate levels were measured by an enzymatic spectrophotometric assay using a centrifugal analyzer at 30℃ (Hoffmann-LaRoche, Basle, Switzerland) as described earlier[23]. *d*-lactate, *d*-lactate dehydro-genase and NAD^+ were purchased from Sigma Chemical Company (Milan, Italy).

Plasma DAO measurement: Plasma DAO activities were determined using an enzymatic spectrophotometry as described earlier[24]. O-dianisidine, Gadaverine Dihydrochloride and DAO were purchased from Sigma Chemical Company (Milan, Italy).

Immunohistochemistry for occludin and ZO-1: Four to 5 μm thick histologic sections, mounted on gelatinized glass slides, were dewaxed in xylene and hydrated through a series of graded concentrations of alcohol. Endogenous peroxidase activity was blocked with 1% hydrogen peroxide in methanol for 15 min. Sections were then processed in a microwave oven twice, 5 min each time at high power for antigen retrieval. Subsequently, a standard streptavidin-biotin-peroxidase technique was applied to detect occludin and ZO-1. After incubation with 1% bovine serum albumin to block nonspecific binding, sections were incubated with rabbit polyclonal antioccludin or antiZO-1 antibody (1:100, Zymed Laboratories, San Francisco, CA) for 1 h, and with biotinylated antirabbit immunoglobulin-G for 30 min. Color was developed with diaminobenzidine (Sigma Fast DAB tablets, D-4293) and counterstained with Harris hematoxylin. All procedures took place at room temperature and sections were washed in tris-buffered saline. The specimens were examined under microscope (Olympus BX51, Japan). The integrated optical density of ZO-1 or occludin in intestinal sections was analyzed using an image analysis system (UIC, MetaMorph, USA).

Western blotting analysis: After rats were killed as described above, terminal ileums were isolated, excised, flushed with ice-cold PBS to remove the fecal debris, and then opened longitudinally. Intestinal mucosa was harvested with a razor blade. Tissues were homogenized by mechanical disruption in lysis buffer (50 mmol/L Tris-Cl, pH 8.0, 150 mmmol/L NaCl, 0.1% dodecyl sodium sulfate, 1% Nonidet P-40, 0.5% sodium deoxycholate, 100 mg/mL phenylmethylsulfonyl fluoride, 1 mg/mL Aprotinin) and incubated on ice for 30 min. Homogenate was then pelleted at 6000 *g* for 10 min and supernatant was collected. Using Lowry method, the quantity of total protein was determined in the supernatant. The protein extracts were incubated with primary antisera (rabbit anti-occludin and anti-ZO-1, 1:500; Zymed Laboratories, San Francisco, CA) at 4℃ overnight and then the mixture was incubated with secondary antibody (horseradish peroxidase conjugated goat anti-rabbit IgG, 1:1000; Beijing Zhongshan Biotech,Co.) at 4℃ for 6-8 h. Immunoprecipitates were subjected to SDS-PAGE and electrotransferred to nitrocellulose membrane. After a final wash in TBST, using the enhanced chemiluminescence (ECL) kit (Shang hai Pufei Biotech, Co.), chemluminescent signals were collected on autoradiographic film. The quantity of band intensity was carried out using electrophoresis Gel Imaging Analysis System (ChemiImager 5500, ALPHA INNOTECH, USA). Results were expressed as ratio of relative intensity of target protein to that of the internal standard, β-actin.

Electron microscopy: Samples were immediately fixed in 2.5% glutaraldehyde in 0.1 mol/L sodium cacodylate buffer (pH 7.4) for 2 h at 22℃, rinsed for 18 h (4℃) with 0.05 Tris buffer (pH 7.6), and washed three times, for 5 min each time. An H-2000 transmission electron microscope was used for the examination.

Statistical analysis

Data were analyzed using a sigma stat statistical software (SPSS, Chicago, IL) and expressed as mean ± SD. Statistical significance of differences between groups were determined using one way analysis of variance (ANOVA) followed by LDS (for multiple comparisons. Linear regression analysis was used to assess associations between TJ protein relative expression levels and DAO or *d*-lactate levels at each period. $P < 0.05$ was considered as significant in difference.

RESULTS

Rat profile

All experiments progressed without incident and all animals survived from the operative process. Table 1 displays the physiologic data from the CPB and Sham rats over the study period. In the CPB group, CPB and post-CPB MAP, PaO_2 values were significantly lower than baseline ($P < 0.05$), whereas $PaCO_2$ remained stable. In the Sham group, there were no changes in MAP, PaO_2 and $PaCO_2$during the whole experiment. Hematocrit (HCT) had a significant decrease in the CPB group ($P < 0.05$) during the perfusion process but had no change in the Sham group. The pH values in the CPB group decreased and this group showed a tendency to develop a metabolic acidosis.

DAO activity (U/L)

There were no significantly differences between CPB

Table 1 Physiological data over the study period

Variables	Groups	Pre-CPB	30 min after CPB	60 min after CPB	2 h after CPB

(mg/L)	Sham	5.745 ± 0.364	5.983 ± 0.632	6.136 ± 0.847

[a]$P < 0.05$ *vs* baseline; [c]$P < 0.05$ *vs* Sham group; [e]$P < 0.05$ *vs* CPB 60 min.

groups and Sham group at baseline ($P > 0.05$, Table 2). In the CPB group, CPB and post-CPB DAO activity was significantly higher than baseline ($P < 0.05$), and DAO activity at 2 h after CPB was significantly higher than that at the end of CPB ($P < 0.05$). In the Sham group, there were no changes in plasma DAO activity during the whole experiment.

d-lactate evels (mg/L)

There were no significantly differences between CPB groups and Sham group at baseline ($P > 0.05$, Table 2). Plasma *d*-lactate levels increased significantly ($P < 0.05$) at the end of CPB compared with baseline or control group and remained higher at 2 h after CPB. In the Sham group, there were no changes in plasma *d*-lactate levels during the experiment.

Evaluation of ZO-1 and occludin immunostaining

All of the epithelial cells lining villi exhibited positive immunostaining for ZO-1 and occludin in control group (Figures 1-2A). In group C, there was loss of occludin and ZO-1 expressions in about 50% enterocytes lining villi (Figures 1-2B); this effect was more profound at 2 h after CPB and loss was about 80% (Figures 1 and 2).

Western blot analysis

Western blot analyses demonstrated alterations in expression of tight junctional proteins after CPB. Figure 3A shows the integral protein occludin with dual bands at 65-kDa .The 65-kDa band showed a significant ($P < 0.05$) decrease in group C compared with control(76.4% ± 22.5% *vs* 96.5% ± 28.5%) and reached lower value at 2 h after CPB (50.5% ± 10.5%). Figure 3B shows that ZO-1 expression significantly ($P < 0.05$) decreased after CPB compared with control (62.4% ± 10.1% *vs* 85.5% ± 25.6%) and became lower at 2 h after CPB (45.3% ± 9.5%).

Relationship between occludin or ZO-1 expression and DAO or d-lactate levels

To assess the relationship between changes of occludin

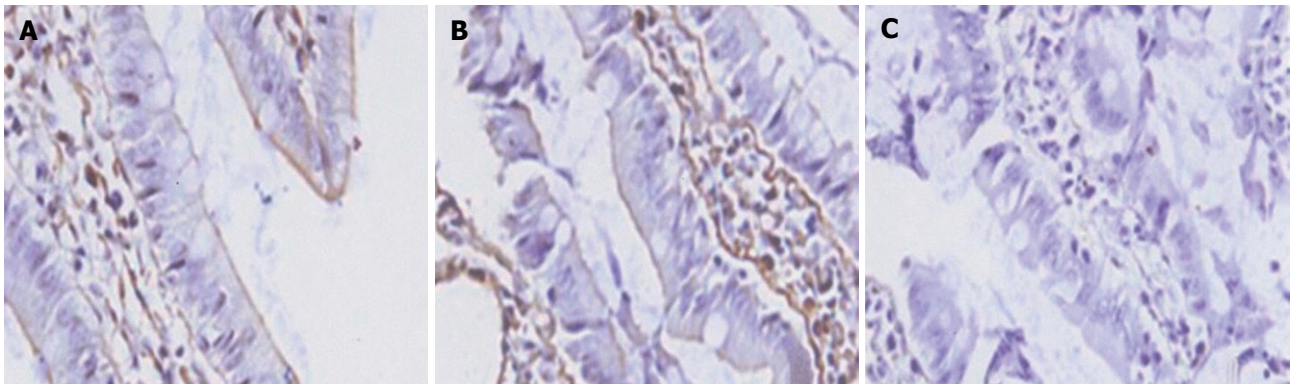

Figure 2 Immunohistochemical expression of ZO-1 in the rat terminal ileum (x 40). **A**: Control, shame-operated: the total of epithelia cell lining villi express ZO-1; **B**: End of CPB: loss of ZO-1 expression in about 50% enterocytes at the villi; **C**: 2 h after CPB: loss of ZO-1 expression in about 80% enterocytes at the villi.

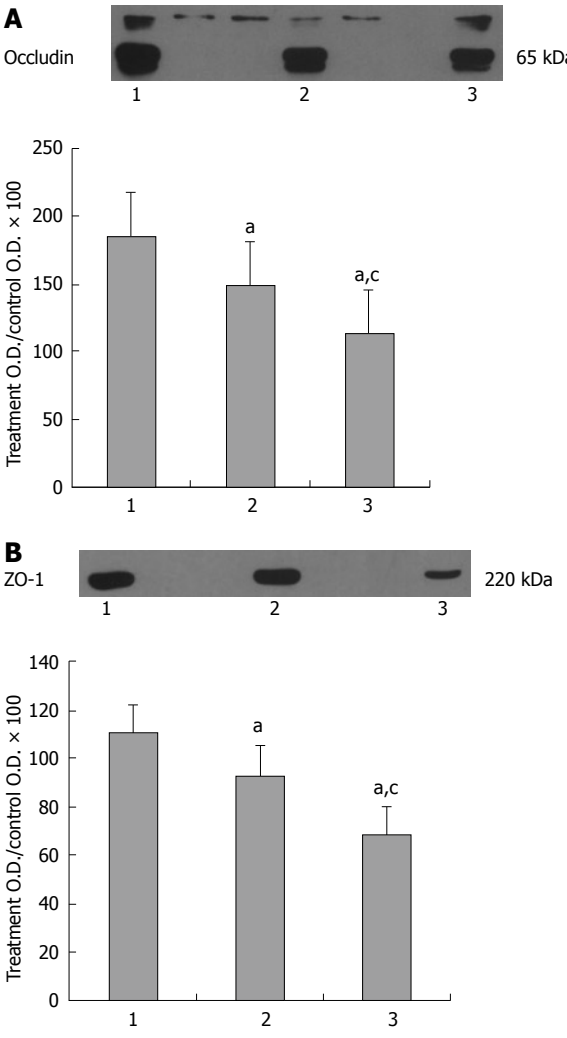

Figure 3 Western blot analysis of occludin and ZO-1 in terminal ileums. Lane 1: Control group; Lane 2: End of CPB; Lane 3: 2 h after CPB. **A**: Oclludin protein expression; **B**: ZO-1 protein expression. Total protein was extracted from rat terminal ileums. Band densities were normalized to the mean density of saline bands and expressed as % relative content. Gel staining was used as a loading control. Bars are mean % relative content ± SE, n = 10 for each group.

and ZO-1 expressions and the damages of intestinal mucosa after CPB, we used regression analysis to assess associations between TJ protein relative expression levels, DAO and *d*-lactate levels at each period. Significant negative correlations were observed between occludin or ZO-1 expression and DAO (r^2 = 0.5629, r^2 = 0.5424, $P < 0.05$) or *d*-lactate levels (r^2 = 0.6512, r^2 = 0.7073, $P < 0.05$) both at the end of CPB and at 2 h after CPB.

Ultrastructural examination of intestinal mucosa

To assess the relationship between changes of occludin and ZO-1 expressions and alterations of intestinal mucosal ultrastructure after CPB, we performed a morphological analysis of TJ (Figure 4), as occludin is an important component in TJ. In control group, regularly-aligned microvilli in intestinal epithelium, integral mitochondria and rough endoplasmic reticulum (RER) and distinct junction complex were observed. In experimental group, the amounts of microvilli were decreased with irregular length and arrangement. The mitochondria were swollen with cracked and vacuolated cristae. Some structures of the RER were destroyed. Intercellular space between epithelial cells was widened. The structure of TJ became short, and the dotted crystal structures were obscured or disappeared; other structures were disrupted and even disappeared. The damage was more severe at 2 h after CPB.

DISCUSSION

Although CPB is essential for some procedures in cardiovascular surgery, it causes peripheral hypoperfusion because of nonpulsatile flow, low blood pressure, hemodilution, and other nonphysiologic conditions. Furthermore, an increase in intestinal permeability and bacterial translocation (BT) has been demonstrated not only in animal models but also in patients during CPB[3,25,26]. Therefore, gastrointestinal integrity during the perioperative period is now recognized as an important factor for outcome of cardiac surgical procedures. In general, changes in mucosal permeability and morphology during CPB are used to reflect the degree of damage of the barrier. But studies on the molecular mechanism of the increased permeability of intestinal mucosa during CPB are rare.

The purpose of this study was to investigate the

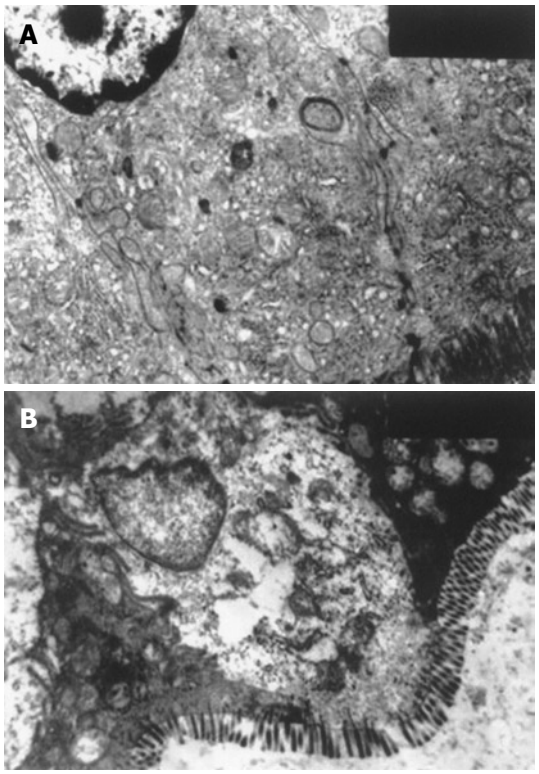

Figure 4 Effect of CPB on the ileum epithelia cells (x 7200). **A**: CPB group, epithelia damage was demonstrated by swollen mitochondria and loss of cristae, tight junction was disrupted; **B**: Control group, regularly-aligned microvilli in intestinal epithelium, integral mitochondria and RER and distinct junction complex were observed.

TJ protein expressions of intestinal mucosa in an experimental model of CPB. We chose the rat model because of the anatomical and physiologic similarity of the digestive tract and cardiovascular systems in rats and humans[27]. Using immunoblotting and immunohistochemistry, we found that CPB markedly down-regulated the expression of occludin and ZO-1 proteins in intestinal mucosa. The result demonstrated that all of epithelial cells lining villi exhibited positive immunostaining for ZO-1 and occludin in control group. In group C there was loss of occludin and ZO-1 expressions in about 50% enterocytes lining villi; this effect was more profound at 2 h after CPB. The intensity of occludin and ZO-1 at the end of CPB was weakened, and more weakened 2 h after CPB. These changes of TJs' proteins are positively associated with alterations of intestinal mucosal ultrastructure. After CPB, the mitochondria was swollen with cracked and vacuolated cristae. The structure of TJ became short, and the dotted crystal structures were obscured or disappeared; other structures were disrupted and even disappeared.

The TJ of epithelial cells forms the most apical component of the junction component of the junction complex, and appears to be a network of continuous and anastomosing filaments between adjacent epithelial cells, which consists of a continuous permeability barrier. It prevents both bacteria and toxin in the intestinal lumen from the paracellular space getting into deep tissues.

To elucidate the relationships between occludin or ZO-1 expression and intestinal mucosal damage during CPB, we measured the plasma levels of DAO and *d*-lactate used as indices of intestinal mucosal injury. DAO is localized mainly in the small intestine and reported to be elevated in intestinal ischemia[18]. Tsunooka demonstrated simultaneous increases in serum DAO activity and peptidoglycan concentration during clinical CPB, suggesting occurrence of small intestinal mucosal ischemia and BT[28,29]. In the present study, we got a similar result. During CPB, plasma DAO activity increased significantly and remained high at 2 h after CPB.

d-lactate is the dextrorotatory form of lactate commonly tested in the intensive care unit. Mammals only have one type of enzyme: *l*-lactate dehydrogenase. *l*-Lactate is a marker of cell hypoxemia, and its level correlates with survival of patients with septic shock[30-32]. Microorganisms, particularly bacteria, are equipped with *d*-lactate dehydrogenase and produce *d*-lactate during fermentation. *d*-lactate is therefore a marker of bacterial infection. *d*-lactate has also recently been proposed as a sensitive, specific, and early marker for translocation in gut ischemia[19]. In our rat model of CPB, plasma *d*-lactate levels increased significantly at the end of CPB compared with control group. It was significantly higher at 2 h after CPB.

We found significant negative correlations between occludin or ZO-1 expression and the plasma levels of DAO or *d*-lactate. These data support the hypothesis that CPB decreases occludin and ZO-1 expressions and then disruptes the intestinal integrity. Therefore, the plasma DAO activity and *d*-lactate level of the rats significantly increased. This further showed an increase of the intestinal permeability during CPB and remained higher 2 h after CPB. But the strong correlation obviously does not prove the cause and effect on intestinal permeability.

There are limitations to this complex model using rats subjected to CPB. The most important limitation of our study is that the CPB groups of animals (as compared with the Sham/control group) were exposed to severe hemodilution with much lower hematocrit, moderate hypotension, lower PaO_2, and probably lower systemic perfusion, and that these differences (*i.e.*, reduced oxygen delivery and tissue perfusion) may have caused or explained the abnormalities we observed in the CPB groups. Another limitation of the current study is that the model was non-transthoracic CPB not followed by deep hypothermic circulatory arrest. An additional limitation for this study may be the limited time that the animals were monitored after CPB. Although the postoperative period was only 2 h, numerous studies indicate that cytokine changes and neutrophil infiltration occur shortly after CPB in animals[33] and children[34].

CONCLUSION

To the best of our knowledge, this is the first study directly assessing CPB disrupts intestinal mucosal barrier by altering occludin and formation and function of

ZO-1 in rat model of CPB. Our data imply that CPB markedly down-regulates the expression of occludin and ZO-1 proteins in intestinal mucosa, indicating a possible mechanism for the increased intestinal permeability and BT during CPB. Thus, further studies are required to elucidate the regulation of the TJ of intestinal epithelium.

ACKNOWLEDGMENTS

We thank Professor Davy Cheng for his technical assistance and critically reading the manuscript. This work has been presented in a poster form at the 14th World Congress of Anesthesiologists in Cape Town, South Africa, March 5, 2008.

COMMENTS

Background

Some studies have shown that cardiopulmonary bypass (CPB) predisposes the intestines to inadequate perfusion, hypoxic injury, and increases in gut permeability. Tight junctions (TJs) are located at the apical part of lateral membranes of polar epithelial cells, forming a barrier that regulates the permeability of ions, macromolecules, and cells through the paracellular pathway. There are no previous studies investigating whether CPB disrupts intestinal mucosal barrier by altering the formation and function of TJs.

Research frontiers

In general, changes in mucosal permeability and morphology during CPB are used to reflect the degree of damage of the barrier function. But studies on the molecular mechanism of the increased permeability of intestinal mucosa during CPB are rare.

Innovations and breakthroughs

In this study, the effects of CPB on occludin and ZO-1 expressions in the intestinal epithelium of rats were investigated. Authors chose the rat model because of the anatomical and physiologic similarity of the digestive tract and cardiovascular systems in rats and humans.

Applications

The results show for the first time that CPB induced gut barrier dysfunction is associated, at the cellular level, with regional loss of occludin and ZO-1 expressions in the intestinal epithelium. These findings offer further insight in the pathophysiology of gut barrier failure during and after CPB. Understanding the pathophysiology of barrier alterations during CPB at the molecular level will help find novel and more effective treatment approaches.

Peer review

This is an interesting paper and it deals with a relevant clinical problem. The study appears well performed and the hypothesis is clear.

Abstract

AIM: To investigate the prevalence of the *ATP7B* gene mutation in patients with hepatic presentation of Wilson's disease (WD) in Lithuania.

METHODS: Eleven unrelated Lithuanian families, including 13 WD patients were tested. Clinically WD diagnosis was established in accordance to the Leipzig scoring system. Genomic DNA was extracted from whole venous blood using a salt precipitation method. Firstly, the semi-nested polymerase chain reaction (PCR) technique was used to detect the c.3207C>A (p.H1069Q) mutation. Patients not homozygous for the c.3207C>A (p.H1069Q) mutation were further analyzed. The 21 exons of the WD gene were amplified in a thermal cycler (Biometra T3 Thermocycler, Göttingen, Germany). Direct sequencing of the amplified PCR products was performed by cycle sequencing using fluorescent dye terminators in an automatic sequencer (Applied Biosystems, Darmstadt, Germany).

RESULTS: Total of 13 WD patients (mean age 26.4 years; range 17-40; male/female 3/10) presented with hepatic disorders and 16 their first degree relatives (including 12 siblings) were studied. Some of WD patients, in addition to hepatic symptoms, have had extrahepatic disorders (hemolytic anemia 3; Fanconi syndrome 1; neuropsychiatric and behavioural disorder 2). Liver biopsy specimens were available in all of 13 WD patients (8 had cirrhosis; 1-chronic hepatitis; 3-acute liver failure, 1-liver steatosis). Twelve of 13 (92.3%) WD patients had the c.3207C>A (p.H1069Q) mutation, 6 of them in both chromosomes, 6 were presented as compound heterozygotes with additional c.3472-82delGGTTTAACCAT, c.3402delC, c.3121C>T (p.R1041W) or unknown mutations. For one patient with liver cirrhosis and psychiatric disorder (Leipzig score 6), no mutations were found. Out of 16 first degree WD relatives, 11 (68.7%) were heterozygous for the c.3207C>A (p.H1069Q) mutation. Two patients with fulminant WD died from acute liver failure and 11 are in full remission under penicillamine or zinc acetate treatment. Three women with WD successfully delivered healthy babies.

CONCLUSION: The c.3207C>A (p.H1069Q) missense mutation is the most characteristic mutation for Lithuanian patients with WD. Even 92.3% of WD patients with hepatic presentation of the disease are homozygous or compound heterozygotes for the p.H1069Q mutation.

Key words: Wilson disease; *ATP7B* gene; c.3207C>A (p.H1069Q) mutation; Cirrhosis; Urine copper; Copper in liver biopsies

INTRODUCTION

Wilson's disease (WD) is a rare autosomal recessive disorder of copper metabolism with prevalence of 1/30 000 and a carrier frequency of 1/90[1,2]. The prevalence is as high as one in 10 000 in China, Japan, and Sardinia[3,4]. The disease is characterized by hepatic, neurological or psychiatric disturbances and decreasing biliary copper excretion with consequent copper accumulation in the liver and extrahepatic tissue[5]. The gene currently known to be associated with WD is the *ATP7B* gene, which was identified in 1993[6,7]. The *ATP7B* gene has 21 exons and encodes a copper-transporting *P*-type adenosine triphosphatase. A copper-transporting *P*-type ATPase incorporates copper into the serum ferroxidase, ceruloplasmin, and excretes by biliary tree. More than 360 mutations in the *ATP7B* gene have been identified as summarised in the human gene mutation database of the institute of medical genetics in Cardiff (accession date May 2008; http://www.hgmd.cf.ac.uk/ac/gene.php?gene=ATP7B). *ATP7B* gene mutations are rare and the majority of patients are compound heterozygotes. Consequently, identification of mutations in WD patients often requires sequencing of a significant proportion of the *ATP7B* gene. It is important to know regional distribution of mutations of the *ATP7B* gene to design appropriate diagnostic strategies for the disease[8]. As no data exist about WD genetic characteristics in the Lithuanian population, the purpose of the current study was to carry out a mutation analysis of Lithuanian WD patients.

MATERIALS AND METHODS

Patients

Lithuanian cohort, drawn from 11 unrelated families, consisted of 29 individuals and was comprised of 13 WD patients (mean age at onset of symptoms 26.4 years; range 17-40; male/female 3/10) and 16 of their first degree relatives. Patients were admitted at the Department of Gastroenterology, Hospital of Kaunas University of Medicine, Lithuania. The diagnosis of WD was established using the scoring system developed at the 8th International Meeting on WD, Leipzig/Germany, 2001. The diagnosis was accepted if the WD Leipzig score was $\geqslant 4$[9].

ATP7B gene mutation analysis

Genomic DNA was extracted from whole venous blood using a salt precipitation method[10]. Firstly, rapid, semi-nested PCR technique was used to detect the c.3207C>A (p.H1069Q) mutation as described previously[11]. Patients not homozygous for c.3207C>A (p.H1069Q) mutation were further analyzed. The 21 exons of the WD gene were amplified in a thermal cycler (Biometra T3 Thermocycler, Göttingen, Germany) as described elsewhere[12]. Direct sequencing of the amplified polymerase chain reaction (PCR) products was performed by cycle sequencing using fluorescent dye terminators in an automatic sequencer (Applied Biosystems, Darmstadt, Germany). Mutations were quoted according to the guidelines from http://www.HGVS.org/mutnomen/, using the reference sequence with the GenBank accession number NM_00053.1.

RESULTS

Total of 13 WD patients presented with hepatic disorders and 16 their first degree relatives (including 12 siblings) were studied. All WD patients and their relatives were consulted in Department of Gastroenterology of Kaunas University of Medicine during 1999-2008. WD patient's clinical, laboratory data, and mutation type are summarized in Table 1.

Some of WD patients, in addition to hepatic symptoms, have had extrahepatic disorders (hemolytic anemia 3; Fanconi syndrome 1; neuropsychiatric and behavioural disorder 2). Specimens of liver biopsy (either percutaneous or transjugular) were available in all of 13 WD patients (8 case of cirrhosis; chronic hepatitis-1; fulminant hepatitis-3; steatosis-1). Kayser-Fleischer ring was present in 6 out of 13 patients (46%). Hepatic copper content was measured in 7 WD patients and was above 250 μg/g dry weight in 4 cases.

Twelve of 13 (92.3%) WD patients had the c.3207C>A (p.H1069Q) mutation, 6 of them in both chromosomes, and 6 were presented as compound heterozygotes with additional c.3472-82delGGTTTAACCAT, c.3402delC, c.3121C>T (p.R1041W) or unknown mutation. For 1 patient with liver cirrhosis only mutation (p.H1069Q) in one allele was revealed, and for another patient with cirrhosis and psychiatric disorder, (Leipzig score 6) no mutations were found (Table 1). Out of 16 first degree WD relatives, 11 (68.7%) were heterozygous for the c.3207C>A (p.H1069Q) mutation. Two patients with fulminant WD died from acute liver failure (ALF), and 11 are in full remission under penicillamine or zinc acetate treatment. Three women with WD successfully delivered healthy baby.

DISCUSSION

WD might be a potentially life threatening disorder; however, with early diagnosis and consequent treatment the prognosis of WD is excellent and usually the need for liver transplantation can be prevented[13]. None of

Table 1 Clinical and genetic characteristics of Lithuanian WD patients

Patient	Gender	Age (yr) at disease diagnosis	Clinical presentation	Kayser-Fleischer ring	Ceruloplasmin lower than 0.2 g/L	Urine cooper (μg/24 h)	Cooper in liver biopsy (μg/g)	Mutation	Outcome
1	F	27	Cirrhosis	Yes	Yes	120	264	[p.His1069Gln] + [p.His1069Gln]	Alive
2	F	18	ALF	No	Yes	144	ND	[p.His1069Gln] + [p.His1069Gln]	Alive
3	M	35	Cirrhosis	Yes	Yes	84	ND	[p.His1069Gln] + [p.His1069Gln]	Alive
4	F	34	ALF, HA	No	No	280	536	[p.His1069Gln] + [p.Arg1041Trp]	Death
5	F	26	Asymptomatic CH	No	Yes	38	35	[p.His1069Gln] + [p.Arg1041Trp]	Alive
6	F	19	ALF, HA	No	No	324	326	[p.His1069Gln] + [c.3472-82 del-GGTTTAACCAT]	Death
7	F	17	Cirrhosis	No	Yes	120	126	[p.His1069Gln] + [c.3472-82 del-GGTTTAACCAT]	Alive
8	F	18	Cirrhosis, FS, HA	No	Yes	182	258	[p.His1069Gln] + [c.3402delC]	Alive
9	M	24	Cirrhosis, NPD	Yes	Yes	116	188	NK/NK	Alive
10	F	23	Cirrhosis	Yes	Yes	130	ND	[p.His1069Gln] + [p.His1069Gln]	Alive
11	F	27	Cirrhosis	Yes	Yes	145	ND	[p.His1069Gln] + [p.His1069Gln]	Alive
12	M	40	Liver steatosis, NPD	Yes	Yes	350	ND	[p.His1069Gln] + [p.His1069Gln]	Alive
13	F	36	Cirrhosis	No	Yes	126	ND	[p.His1069Gln] + NK	Alive

Mutational analysis was performed only for presence of p.H1069Q. 4th and 5th patients were siblings; 6th and 7th patients were siblings. ALF: Acute liver failure; CH: Chronic hepatitis; HA: Hemolytic anaemia (Coombs-negative); FS: Fancony syndrome; NPD: Neuropsychiatric disorder; ND: Not determined; NK: Not known.

the commonly used parameters alone allows a certain diagnosis of WD[14]. In our study, only in 6 (46%) of our patients was Kayser-Fleischer ring present and serum ceruloplasmin levels were even higher than 0.3 g/L in 2 patients with ALF. Urine cooper excretion exceeded 100 μg/24 h in 11 (84.6%) of 13 patients and in one asymptomatic sibling with WD it was even lower than 40 μg/24 h. Therefore, urinary cooper excretion and hepatic copper concentration, because of potential errors in evaluation, should always be assessed in the context of other diagnostic criteria[9,15].

WD is found worldwide with different geographical distribution of *ATP7B* gene mutations. The c.3207C>A (p.His1069Gln) missense mutation is the most frequent in Northern, Eastern and Central Europe[2,8,16], the c3400delC mutation is the most common in Brazil[17], and c.2333G>T (p.Arg778Leu) in Asia countries[18-21].

Knowledge of the regional distribution of mutations in the WD gene is important to design appropriate screening strategies[8]. In Central and Eastern Europe, the frequency of the c.3207C>A (p.H1069Q) mutation in exon 14 previously has been reported as the highest in Poland and Eastern Germany and decreases in Western and Southern European countries[8,22]. In Poland 72% of WD patients carry at least one allele with the c.3207C>A (p.H1069Q) mutation[23]. Caca *et al*[2] revealed that in East Germany 39% of WD patients were homozygous and 48% heterozygous for the c.3207C>A (p.H1069Q) mutation. Our study was the first to analyze genetic mutations of WD patients in Lithuania, a country in Baltic Sea area with 3.4 million inhabitants. The prevalence of the c.3207C>A (p.H1069Q) mutation in the *ATP7B* gene in WD patients in Lithuania was 92.3% (with 46.2% homozygotes and 46.2% compound heterozygotes). These findings were even higher than in Poland, a neighbour state, and were considerable higher than in Russia (49%) or Sweden (38%)[24]. In compound heterozygotes Lithuanian WD patients additional c.3472-82delGGTTTAACCAT, c.3402delC, and never mentioned new c.3121C>T (p.R1041W) mutations were detected. Only patients with hepatic or hepatic-neuropsychiatric presentation of WD were included in our study; however, other authors[25] have shown that the c.3207C>A (p.H1069Q) mutation is also associated with a late and neurological presentation of the disease.

In conclusion, the results of our study showed that the c.3207C>A (p.H1069Q) missense mutation is characteristic for Lithuania patients of WD. Even 92.3% of WD patients with hepatic presentation of the disease are homozygous or compound heterozygote for this mutation. Therefore, limited genetic testing of c.3207C>A (p.H1069Q) mutation might be of high value both to confirm WD disease diagnosis and for familial genetic screening in Lithuanian population.

ACKNOWLEDGMENTS

We are grateful to the head Dr. Olegas Abdrachmanovas and all personnel of the Laboratory for Environmental Health Research of the Institute for Biomedical Research for the copper analysis and Birute Sabaniene from Laboratory of Immunology and Genetics of Kaunas University of Medicine for excellent technical support.

COMMENTS

Background

Wilson disease (WD) is a life threatening autosomal recessive genetic disorder with impaired cooper metabolism and associated with hepatic, neurological and psychiatric symptoms. The diagnosis of WD is usually established using clinical signs and biochemical (hepatic copper concentration, ceruloplasmin concentration, copper urine excretion) tests; however, the most sensitive and

specific test is the detection of *ATP7B* gene mutations. The genetic testing is becoming the most important for confirmation of diagnosis and presymptomatic diagnostics in WD patients.

Research frontiers

The research was done to obtain data about the frequency and type of *ATP7B* gene mutations in WD patients in Lithuania.

Innovations and breakthroughs

It is important to know regional distribution of mutations of the *ATP7B* gene to design appropriate diagnostic strategies of WD. We have found an extremely high percentage of Lithuanian WD patients having the c.3207C>A (p.H1069Q) mutation. This is a new and interesting finding, showing that this mutation is typical for Lithuania WD patients, similar as was reported in some other Middle-Eastern European countries.

Applications

The present study indicates that due to high frequency of the c.3207C>A (p.H1069Q) mutation in Lithuania, even limited genetic testing of this mutation might be of high value both to confirm WD diagnosis and for familial genetic screening in Lithuanian population.

Terminology

ATP7B encodes a Cu-transporting P-type ATPase protein common to P-type ATPases. p.H1069Q missense mutations causes an amino acid substitution and disrupts ATP binding.

Peer review

This short report investigates the frequency and type of *ATP7B* gene mutations in Lithuanian patients with WD. The detected frequency (92.3%) of the c.3207C>A (p.H1069Q) mutation is one of the highest reported from Middle-Eastern European countries. This study is interesting.

Abstract

AIM: To investigate the cumulative development incidence and predictive factors for idiopathic pulmonary fibrosis in hepatitis C virus (HCV) positive patients.

METHODS: We studied 6150 HCV infected patients who were between 40-70 years old (HCV-group). Another 2050 patients with hepatitis B virus (HBV) were selected as control (HBV-group). The mean observation period was 8.0 ± 5.9 years in HCV-group and 6.3 ± 5.5 years in HBV-group. The primary goal is the development of idiopathic pulmonary fibrosis (IPF) in both groups. The cumulative appearance rate of IPF and independent factors associated with the incidence rate of IPF were calculated using the Kaplan-Meier method and the Cox proportional hazard model. All of the studies were performed retrospectively by collecting and analyzing data from the patient records in our hospital.

RESULTS: Fifteen patients in HCV-group developed IPF. On the other hand, none of the patients developed IPF in HBV-group. In HCV-group, the cumulative rates of IPF development were 0.3% at 10th year and 0.9% at 20th year. The IPF development rate in HCV-group was higher than that in HBV-group (P = 0.021). The IPF development rate in patients with HCV or HBV was high with statistical significance in the following cases: (1) patients ⩾ 55 years (P < 0.001); (2) patients who had smoking index (package per day × year) of ⩾ 20 (P = 0.002); (3) patients with liver cirrhosis (P = 0.042).

CONCLUSION: Our results indicate that age, smoking and liver cirrhosis enhance the development of IPF in HCV positive patients.

Hepatitis C virus enhances incidence of idiopathic pulmonary fibrosis. *World J Gastroenterol* 2008; 14(38): 5880-5886 Available from: URL: http://www.wjgnet.com/1007-9327/14/5880.asp DOI: http://dx.doi.org/10.3748/wjg.14.5880

INTRODUCTION

Hepatitis C virus (HCV) is one of the more common causes of chronic liver disease in world. Chronic hepatitis C is an insidiously progressive form of liver disease that relentlessly but silently progresses to cirrhosis in 20%-50% of cases over a period of 10-30 years[1-3]. In addition, HCV is a major risk for hepatocellular carcinoma (HCC)[4-8]. Yearly incidence of HCC in patients with HCV-related cirrhosis is estimated at 5%-10%, and it is one of the major causes of death, especially in Japan.

Chronic HCV infection has been associated with a variety of extrahepatic complications such as essential mixed cryoglobulinemia[9-11], porphyria

cutanea tarda[9], membranoproliferative glomerulonep hritis[12,13], autoimmune thyroiditis[14-16], sialadenitis[17], and cardiomyopathy[18]. A few previous studies have presented conflicting results, with some suggesting that an incidence of anti-HCV antibody positivity in patients with idiopathic pulmonary fibrosis (IPF) is significantly higher than that in patients without IPF both in Italy and Japan[19,20]. Others found that incidence of anti-HCV antibody positivity is not high compared to controlled patients[21]. These discrepancies might depend on factors such as geographical differences of race and/or ethnicity or differences in the false positive rate of anti-HCV testing.

In any case, there is little or no information on the yearly cumulative incidence and risk factors on the development rate of IPF in patients with HCV. In our hospital, we evaluate a large number of patients with HCV-related hepatitis, and often find HCC among our patients. Interestingly, we also find a small proportion of patients with HCV-related hepatitis who develop IPF.

With this background in mind, the present retrospective cohort study was initiated to investigate the cumulative incidence and risk factors of IPF among HCV-infected patients.

MATERIALS AND METHODS

Patients

The number of patients who were diagnosed with chronic HCV infection between April 1975 and March 2006 in the Department of Hepatology, Toranomon Hospital, Tokyo, Japan was 11 500. Of these, 6150 patients met the following criteria: (1) age of 40-70 years; (2) features of chronic hepatitis or cirrhosis diagnosed by laparoscopy, liver biopsy, ultrasonography clinical features, and/or laboratory tests; (3) positive for anti-HCV antibody and HCV-RNA; (4) no history of treatment with antiviral agents; (5) negative for hepatitis B surface antigens (HBsAg), antinuclear antibodies, or antimitochondrial antibodies in serum, as determined by radioimmunoassay or spot hybridization; (6) no evidence of HCC nodules as shown by ultrasonography and/or computed tomography; (7) no underlying systemic disease, such as systemic lupus erythmatosus, rheumatic arthritis; (8) no cough or dyspnea after exercising; (9) no history of chronic lung disease. Patients with any of the following criteria were excluded from the study: (1) alpha-fetoprotein of 400 ng/mL or higher; (2) advanced and decompensated stage of cirrhosis with encephalopathy, icterus, or refractory ascites; (3) a short follow-up period of 6 mo or less; (4) development of HCC within 6 mo after the initiation of follow-up. These 6150 patients were regarded as in HCV-group. The 2050 patients that did not have the HCV marker and have the HBsAg marker were selected as a control and they comprised the hepatitis B virus (HBV)-group. The patients in HBV-group meet all of the above criteria but 3. Control patients were matched 1:3 with HCV positive patients for age and sex. We compared the differences of the cumulative development rate of IPF in both the HC-group and the HBV-group. Next, we assessed predictive factors for IPF in patients with hepatitis C. All of the studies were performed retrospectively by collecting and analyzing data from the patient records.

Table 1 Diagnostic criteria of IPF

Number	Criteria
Major criteria 1	Exclusion of other known caused of interstitial lung disease, such as certain drug toxicities, environmental exposures, and connective tissue diseases
Major criteria 2	Abnormal pulmonary function studies that include evidence of restriction (reduced breathing vital capacity) and impaired gas exchange (increased $AaPO_2$ with rest or after exercising or decreased diffusion lung capacity)
Major criteria 3	Bibasilar reticular abnormalities with minimal ground glass opacities on conventional chest radiographs or high-resolution computed tomography scans
Major criteria 4	Histological lung examination or bronchoalveolar lavage showing no features to support an alternative diagnosis
Minor criteria 1	Age > 50 yr
Minor criteria 2	Insidious onset of otherwise unexplained dyspnea on exertion
Minor criteria 3	Duration of illness ⩾ 3 mo
Minor criteria 4	Bibasilar, inspiratory crackles (dry or "Velcro" type in quality)

Definition of IPF

IPF was diagnosed by respiratory specialist based on the presence of at the least three of the following four diagnostic major criteria, as well as all of the following four minor criteria, as shown in Table 1. Diagnostic criteria of IPF were recommended by American Thoracic Society/European Respiratory Society[22]. We excluded hepatopulmonary syndrome by conventional chest radiographs or high-resolution computed tomography scans, electrocardiogram, and/or ultrasonic cardiography.

Viral markers of HCV and HBV

Anti-HCV was detected using a second-generation enzyme-linked immunosorbent assay (ELISA Ⅱ) (Abbott Laboratories, North Chicago, IL). HCV-RNA was determined by the Amplicor method (Cobas Amplicor HCV Monitor Test, v2.0, Roche Molecular Systems, Inc., NJ). HBsAg was tested by radioimmunoassay (Abbott Laboratories, Detroit, MI). The used serum samples were stored -80℃ at the first consultation. Diagnosis of HCV infection was based on detection of serum HCV antibody and positive RNA. The study started in April 1975. At that time, HCV testing was not available. Thus, the patients diagnosed as HCV-infected were tested after HCV testing became available.

Evaluation of liver cirrhosis

Status of liver cirrhosis was mainly determined on the basis of peritoneoscopy and/or liver biopsy. Six thousand eight hundred and twenty six out of 8200 were diagnosed by peritoneoscopy and/or liver biopsy. Liver biopsy specimens were obtained using a modified Vim Silverman

Table 2 Clinical characteristics[1]

	Total	HBV-group	HCV-group	*P*
Number (*n*)	8200	2050	6150	
Age (yr)	51.8 ± 9.0	51.7 ± 8.7	51.8 ± 9.1	1
Sex (male, %)	77.8% (6380)	77.8% (1595)	77.8% (4785)	1
Liver cirrhosis[2]	20.2% (1659)	18.5% (379)	20.8% (1280)	< 0.001
Total alcohol intake of > 200 kg[3]	23.0% (1490/6465)	17.4% (253/1450)	24.7% (1237/5015)	< 0.001
Smoking index of > 20[3]	27.9% (1680/6032)	23.5% (293/1246)	29.0% (1387/4786)	< 0.001

Total bilirubin (mg/dL)	0.83 ± 0.94	0.98 ± 0.85	0.81 ± 0.77	< 0.001
γGTP (IU/L)	74.0 ± 106.2	77.1 ± 128.7	73.2 ± 99.8	0.951
Platelet count (x 10^4/mm^3)	19.3 ± 18.7	19.1 ± 14.4	19.4 ± 19.7	0.725

[1]Data are percent (number of patients) or mean ± SD; [2]The 1594 (77.8%) out of 2050 in HBV-group and 5232 (85.1%) of 6150 in HCV-group were diagnosed by laparoscopy and/or liver biopsy. The breakdown of histological staging in HCV-group was as follows: stage 1, 2707; stage 2, 1188; stage 3, 300; stage 4 (liver cirrhosis), 1037. The outbreak of histological staging in HBV-group was as follows: stage 1, 705; stage 2, 439; stage 3, 157; stage 4 (liver cirrhosis), 293; [3]Smoking index = (package/d) × yr; Total alcohol intake and smoking index indicate the sum of before and after first consultation.

needle with an internal diameter of 2 mm (Tohoku University style, Kakinuma Factory, Tokyo, Japan), fixed in 10% formalin, and stained with hematoxylin-eosin, Masson's trichrome, silver impregnation, and periodic acid-Schiff after diastase digestion. The size of specimens for examination was more than six portal areas. Baseline liver histology of chronic hepatitis was classified according to the extent of fibrosis, into four stages in progression order: stage 1, periportal expansion; stage 2, portoportal septa; stage 3, portocentral linkage or bridging fibrosis; stage 4, liver cirrhosis[23]. Remaining patients were diagnosed by clinical features, laboratory tests, and ultrasonographic findings. Ultrasonography was performed with a high-resolution, real-time scanner (model SSD-2000; Aloka Co., Ltd, Tokyo Japan. Logic 700 MR; GE-Yokokawa Medical Systems, Tokyo, Japan). The diagnosis of liver cirrhosis was defined as having a score of > 8 in ultrasonographical scoring system based on liver surface, liver parenchyma, hepatic vessel and spleen size as reported by Lin *et al*[24].

Follow-up

Patients were followed-up monthly to tri-monthly after the first medical examination in our hospital. Physical examination and biochemical tests were conducted at each examination together with regular check up using abdominal CT or US imaging in each patient. When a patient had any symptoms in relation to IPF (dry cough, dyspnea), we further explored the possibility of that patient having IPF. Three hundred thirty-four patients were lost to follow-up. Because the appearance of IPF and death was not identified in these 334 patients, they were considered as censored data in statistical analysis[25]. Moreover, patients treated with anti-viral agents were regarded as withdrawals at the time of starting antiviral agents.

Statistical analysis

Nonparametric procedures were employed for the analysis of background features of the patients, including the Mann-Whitney *U* test and χ^2 method. The cumulative appearance rate of IPF was calculated from the period of the first medical examination at our hospital to the appearance of IPF, using the Kaplan-Meier method. Differences in the development of IPF were tested using the log rank test. Independent factors associated with the incidence rate of IPF were analyzed by the Cox proportional hazard model. The following nine variables were analyzed for potential covariates for incidence of IPF at the time of first medical examination at our hospital: age, sex, state of liver disease (chronic hepatitis or liver cirrhosis), smoking index, total alcohol intake, platelet count, aspartate aminotransferase (AST), alanine aminotransferase (ALT), γ-glutamyl transpeptidase. $P < 0.05$ in two-tailed test was considered significant. Data analysis was performed using the SPSS computer program package (SPSS 11.5 for Windows, SPSS, Chicago, IL).

RESULTS

Patients' characteristics

Table 2 shows the characteristics of the 8200 patients with HCV or HBV. There were no significant differences between the two groups with regard to sex ratio or age. However, there were significant differences in histopathological stage of the liver, AST, ALT, total bilirubin, total intake of alcohol, and smoking index. The 1594 (77.8%) out of 2050 in HBV-group and 5232 (85.1%) of 6150 in HCV-group were diagnosed by laparoscopy and/or liver biopsy. The breakdown of histological staging in HCV-group was as follows: stage 1, 2707; stage 2, 1188; stage 3, 300; stage 4 (liver cirrhosis), 1037. The outbreak of histological staging in HBV-group was as follows: stage 1, 705; stage 2, 439; stage 3, 157; stage 4 (liver cirrhosis), 293.

On relationship between liver histology and IPF, liver biopsies were done in ten of 15 patients with IPF before diagnosis of IPF. The period before diagnosis of IPF was 10.2 ± 4.1 years. There was no evidence of plasma cells to indicate possible autoimmune hepatitis, which as a systemic disease could be associated with IPF.

Incidence of IPF in patients with HCV or HBV

In the HCV-group, 15 patients developed IPF during a

Table 3 Predictive factors for IPF development[1]

Factor	Univariate analysis				Multivariate analysis[1]			
	Category	Hazard ratio	95% CI	*P*	Category	Hazard ratio	95% CI	*P*

ALT (IU/L)	< 100/≥ 100	1/1.05	0.29-3.74	0.946				

Data are number of patients or mean ± SD. [1]Smoking index = (package/d) × year. Total alcohol intake and smoking index indicate the sum of before and after first consultation

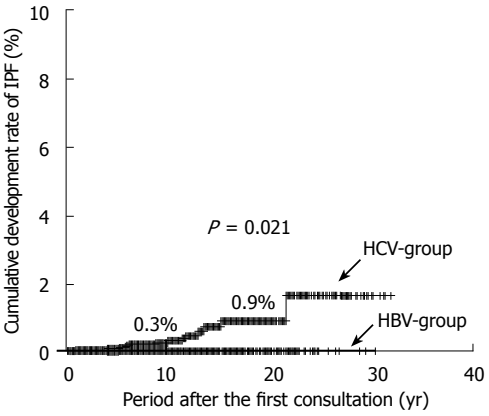

Figure 1 Cumulative rate of the incidence of IPF from the first medical examination at our hospital in patients with HCV or HBV.

mean observation period of 8 years. The cumulative rate of newly diagnosed IPF was 0.3% at the end of the 10th year, and 0.9% at the 20th year (Figure 1). On the other hand, none of the patients developed IPF during a mean observation period of 6.3 years in the HBV-group. The cumulative rate of newly diagnosed IPF in the HCV-group was higher than that in the HBV-group ($P = 0.021$).

Determinants of incidence of IPF

We then investigated the factors, except for virus marker, associated with the incidence of IPF in all the 8200 patients with HBV or HCV (Table 3). Univariate analysis identified the following three factors that influenced incidence of IPF: age ($P < 0.001$), state of liver disease ($P = 0.007$), and smoking index ($P = 0.015$). These three parameters were entered into multivariate Cox proportional hazard analysis. The IPF development rate of HCV positive patients was high with statistical significance in the following cases: (1) patients ≥ 55 years ($P < 0.001$); (2) patients who had smoking index (package per day × year) of ≥ 20 ($P = 0.002$), (3) patients who had liver cirrhosis ($P = 0.042$).

Next, we examined the factors associated with the incidence of IPF in all the 6150 patients with HCV multivariate Cox proportional hazard analysis. The IPF development rate of HCV positive patients was high with statistical significance in the following cases: (1) patients ≥ 55 years (OR: 14.24; 95% CI = 3.39-59.74, $P < 0.001$); (2) patients who had smoking index (package per day × year) of ≥ 20 (OR: 5.43; 95% CI = 1.74-16.88, $P = 0.003$); (3) patients who had liver cirrhosis (OR: 3.82; 95% CI = 1.23-11.86, $P = 0.02$).

Mortality and causes of death

Table 4 summarizes the characteristics of 15 patients who developed IPF in the HCV-group. Thirteen patients (12 men and 3 women; median age at the time of onset of IPF = 70 years, range = 57 to 79 years) with IPF were diagnosed by well-trained respiratory specialists.

During the observation period, 12 of the 15 patients with IPF in the HCV-group died. Seven patients died of liver-related disease (HCC, decompensated liver cirrhosis, rupture of esophageal varices) and five patients died of IPF. Liver-related death accounted for 58% (7/12) of all deaths and HCC was the major cause of liver-related deaths. IPF-related death accounted for 42% (5/12) of all deaths. On the other hand, of 6002 HCV positive patients without IPF, 1905 died of various diseases during the observation period. Of 1905 patients who died, 44 patients died of lung-related disease, such as acute pneumonitis or pulmonary tuberculosis. The incidence of death based on lung-related disease in patients with IPF was significantly higher than that in patients without IPF ($P < 0.001$).

DISCUSSION

We have described the development incidence of IPF in patients with HCV in the present study. The present study was limited by a retrospective cohort trial and age in patients. We selected patients with ages of 40-70 years at the first consultation. The reason is as follows: (1) onset of IPF is rare in young people with < 40 years; (2) the number of patients with > 70 years at the first consultation is few. Another limitation of the study was that HBsAg positive patients were selected as controlled group. Though there were no significant differences between the two groups with regard to sex ratio and age, there were significant differences in stage of the liver, AST, ALT, total bilirubin, total intake of alcohol, and smoking index. In Japan, HBV infection is usually

Table 4 Characteristics of patients with IPF in the HCV-group

Case	Age (yr)[1]	Sex	Liver disease[1]	Smoking index[2]	Age at the time of IPF onset	Period after IPF development[2]	Alive or death[2]	Cause of death

15	70	M	LC	42	76	4.1	Death	HCC

CH: Chronic hepatitis; d-LC: Decompensated liver cirrhosis; HCC: Hepatocellular carcinoma; IPF: Idiopathic pulmonary fibrosis; LC: Liver cirrhosis. [1]Characteristics of patients at the first consultation; [2]Smoking index = (package/d) × year, Smoking index indicates the sum of before and after first consultation; Period after IPF development, period (yr) between onset of IPF and final consultation; Alive or death, alive or death at the final consultation

acquired perinatally or in early childhood. Moreover, patients infected with HBV often have family history of HBV infection. Thus, patients infected with HBV might tend to avoid drinking alcohol or smoking on the merits of family advice. Next, AST, ALT, and total bilirubin levels were significantly high in HBV-group. These results may show that patients with HBV tend to have acute exacerbation of the liver. Another limitation is that we further explored the possibility that patient having IPF when a patient had any symptoms in relation to IPF (dry cough, dyspnea). However, Toranomon hospital was opened for attending patients who were officers or officials. Therefore, most of enrolled patients are officers, officials, or office workers. They have generally undergone chest checkup by the use of X-ray every year during incumbency and after retirement. This means that onset of IPF was checked constantly by respiratory specialists. Therefore, even if the diagnosis of IPF was late in cases in which hepatologists had no experience in the Department of Respiratory Disease, chest checkup by the use of X ray every year could assist on diagnosing IPF.

Among features of the present study are prolonged observation study and large number of the study population. The attending patients were followed closely base on the following reasons: (1) our hospital was opened for attending patients who were officers or officials; therefore, most of enrolled patients are officers, officials, or office workers; (2) our hospital is located in the center of the Tokyo metropolitan area in Japan, so it is convenient for patients to go to the our hospital. The present study shows several findings with regard to IPF in HCV positive patients. First, the IPF development rate in HC-group was higher than that in HB-group. Our retrospective study is the first to determine the annual incidence of IPF among patients with HCV at 0.03%-0.04%. The morbidity for IPF was estimated to be 0.003% to 0.004% in the general population in Japan[26]. Little is known about the relationship between the incidence of IPF and HCV. Conflicting studies on the incidence of HCV infection in patients with IPF have been published. Ueda *et al*[19] and Meliconi *et al*[20] reported a higher prevalence of HCV-antibody in patients with IPF compared with the general population. However, Irving *et al*[21] could not confirm the hypothesis that HCV may be a cause of IPF. The controversial results of the different research groups may be explained by the geographical differences of race and other factors. An accurate assessment of the exact risk could only come from a large cohort study. Thus, the present cohort study shows that prevalence of IPF tends to be slightly higher in the HC group compared to those in HB group in Japan. We believe this epidemiological study first elucidates the annual incidence of IPF among patients with HCV; the annual appearance rate was 0.03%-0.04%.

Second, the IPF development rate of HCV positive patients was high with statistical significance in the following cases: (1) patients $\geqslant$ 55 years; (2) patients who had smoking index of $\geqslant$ 20; (3) patients who had liver cirrhosis. Our results indicate that aging, liver cirrhosis and smoking enhance the development of IPF in patients with chronic hepatitis C infection. Idilman *et al*[27] have reported that HCV infection might be associated with an occult pulmonary inflammatory reaction manifested by an increased number of polymorphonuclear neutrophils in bronchoalveolar lavage fluid. Aging, liver cirrhosis, and smoking might enhance an occult pulmonary inflammatory reaction.

Third, the incidence rate of lung-related death of HCV positive patients with IPF was higher than that without IPF. IPF-related death corresponded to one-third of all deaths in patients with IPF. It can progress rapidly after such exacerbation and often proves fatal, despite treatment with oral corticosteroids and intravenous high-dose corticosteroid therapy. The fact that patients with IPF have high possibility dying from acute exacerbation due to IPF during the follow-

up shows the need to provide a high level of care to patients with IPF. In general, hepatologist regard the daily management of patients with HCV. When HCV patients complain dry cough and dyspnea, hepatologists should check the complication of IPF.

In the present study, hepatopulmonary syndrome was excluded by conventional chest radiographs or high-resolution computed tomography scans, electrocardiogram, and/or ultrasonic cardiography. However, hepatopulmonary syndrome tends to complicate in advanced liver disease. Therefore, it is still possible that some of these patients with IPF had complication of hepatopulmonary syndrome.

Despite extensive research, IPF remains a disease of unknown etiology with a poor prognosis after acute exacerbation. Idilman *et al*[27] have reported that an increased bronchoalveolar lavage neutrophil count in individuals with HCV induced chronic active hepatitis was identified. This finding suggests that HCV may have the potential to induce an alveolitis leading to fibrotic changes in the lung. In the formation of IPF in HCV positive patients, there are other mechanisms such as accumulation to lung tissue of immunoglobulin and/or immune complex or direct involvement of HCV-RNA. These mechanisms may be mutually related.

First mechanism could be explained by the following. Gut-derived antigens and antibodies from the bowel *via* portal circulation or other antigens and antibodies were not segregated in sufficient amounts in patients with severe liver dysfunction. Immune complexes formed by these antigens and antibodies were passed into the systemic circulation and finally, these immune complexes are accumulated in the glomeruli or lung. Owing to this mechanism, there could be a high prevalence of immunoglobulin deposition in glomeruli of patients with mesangial proliferative glomerulonephritis and membranoproliferative glomerulonephritis[28]. We also examined the lung in a few patients using immunofluorescence microscopy. However, we did not detect immunoglobulin in formalin-fixed lung tissue. These results might indicate that serum immunoglobulin play a minor role in IPF. However, there might be possibility of showing low sensitivities due to use the formalin-fixed tissue. On the other hand, Koike *et al*[29] reported that transgenic mice carrying the HCV envelope gene revealed an exocrinopathy resembling Sjogren syndrome. Similar to this, HCV might directly cause IPF. More studies are needed to confirm the mechanism producing IPF in HCV positive patients.

In conclusion, our retrospective study is the first to determine the annual incidence of IPF among patients with HCV at 0.03%-0.04%. Our results indicate that age, liver cirrhosis and smoking enhance the development of IPF in patients with chronic hepatitis C infection.

ACKNOWLEDGMENT

The authors are grateful to Drs. M Hara, Y Endo, K Ohashi (pathologist), S Tanimura, and K Nakada (respiratory specialist) for diagnosis of IPF. Moreover, the authors greatly acknowledged the editorial assistance of Thomas Hughes.

COMMENTS

Background

Idiopathic pulmonary fibrosis (IPF) is present in patients with chronic hepatitis C virus (HCV) infection. In any case, there is little or no information on the yearly cumulative incidence and risk factors on the development rate of IPF in patients with HCV.

Research frontiers

A few previous studies have presented conflicting results with some suggesting that an incidence of anti-HCV antibody positivity in patients with IPF is significantly higher than that in patients without IPF both in Italy and Japan, whereas others found that an incidence of anti-HCV antibody positivity is not high compared to controlled patients.

Innovations and breakthroughs

The morbidity for IPF was estimated to be 0.003% to 0.004% in the general population in Japan. This retrospective study is the first to determine the annual incidence of IPF among patients with HCV at 0.03%-0.04%. The results indicate that age, liver cirrhosis and smoking enhance the development of IPF in patients with chronic hepatitis C infection.

Applications

The fact that patients with IPF have a high possibility of dying from acute exacerbation due to IPF during the follow-up shows the need to provide a high level of care to patients with IPF. In general, hepatologists regard the daily management of patients with HCV. When HCV patients complain dry cough and dyspnea, hepatologists should check the complication of IPF.

Terminology

IPF was diagnosed by respiratory specialist based on the diagnostic criteria recommended by American Thoracic Society/European Respiratory Society. Smoking index was defined as (package/d) × year, indicating the sum of before and after first consultation; period after IPF development, period (year) between onset of IPF and final consultation.

Peer review

The manuscript is well written and the study is well designed. Authors investigated the cumulative development incidence and predictive factors for idiopathic pulmonary fibrosis in HCV positive patients.

Abstract

AIM: To explore the expression of differential gene expression profiles of target cell between non-invasive submucosal and invasive advanced tumor in colon carcinoma using laser microdissection (LMD) in combination with polypeptide analysis.

METHODS: Normal colon tissue samples from 20 healthy individuals and 30 cancer tissue samples from early non-invasive colon cancer cells were obtained. The cells from these samples were used LMD independently after P27-based amplification. aRNA from advanced colon cancer cells and metastatic cancer cells of 40 cases were applied to LMD and polypeptide analysis, semiquantitative reverse transcribed polymerase chain reaction (RT-PCR) and immunohistochemical assays were used to verify the results of microarray and further identify differentially expressed genes in non-invasive early stages of colon cancer.

RESULTS: Five gene expressions were changed in colon carcinoma cells compared with that of controls. Of the five genes, three genes were downregulated and two were upregulated in invasive submucosal colon carcinoma compared with non-invasive cases. The results were confirmed at the level of aRNA and gene expression. Five genes were further identified as differentially expressed genes in the majority of cases (> 50%, 25/40) in progression of colon cancer, and their expression patterns of which were similar to tumor suppressor genes or oncogenes.

CONCLUSION: This study suggested that combined use of polypeptide analysis might identify early expression profiles of five differential genes associated with the invasion of colon cancer. These results reveal that this gene may be a marker of submucosal invasion in early colon cancer.

Key words: Colon cancer; Laser microdissection; Polypeptide analysis

INTRODUCTION

Colon cancer ranks second of all gastrointestinal malignant tumors, it is one of the leading causes of cancer-related deaths worldwide. In the past five years, the incidence of colon cancer is reported to be especially high in Asia. Its clinical behavior depends on the potential metastasis of the tumor; its prognosis of advanced colon cancers remains very poor. Until now, several molecules have been reported to play an important role in gastroenterological tumorigenesis and tumor metastasis, but the molecular mechanisms involved tumor development and progression still remain unclear in colon cancer[1-3].

In this research, by using the combined methods of laser microdissection (LMD), P27-based RNA amplification, and polypeptide, we evaluated differentially expressed genes between early carcinoma and lymph node metastatic patients. Moreover, we further identified four differentially expressed genes in the progression of colon cancer in another group of 15 patients by means of semiquantitative reverse transcribed polymerase chain

reaction (RT-PCR), and the expression patterns of these four genes were similar to tumor suppressor genes or oncogenes.

It is now widely accepted that many malignant tumors contain heterogeneous subpopulations of cells. This heterogeneity is exhibited in a wide range of genetic, biochemical and immunologic characteristics. It is likely that specific tumor cells or colonies within the larger heterogeneous tumor specimen are the forerunners of distant metastases[4]. Therefore, many biologic differences exist between tumor cells in early carcinoma and those in metastatic lesions. Furthermore, the interaction of tumor cells within their living environment may add more differences between these two groups of cells[5]. As a result, tumor metastasis related genes can be identified by comparing the gene expression profiles between them.

LMD and polypeptide analysis are two new emerging technologies in the post-genomic era. LMD allows a specific area of tissue or group of cells to be obtained, and in this particular system, intracellular macromolecules remain intact. Since there is no heating of the sample or direct mechanical contact with the section, there is a reduced risk of contamination, sample loss or alteration of the protein sample[6,7].

The large-scale analysis of gene expression with a polypeptide allows us to evaluate the gene-expression profiles of hundreds to tens of thousands of genes in a single experiment[8]. This technology is a powerful tool for analyzing gene expression of which can be correlated with pathological phenotypes of various diseases. However, the expression profile of a specific cell type may be primarily masked or even lost because of the bulk of surrounding cells. Therefore, combined use of LMD and polypeptide analysis can provide a unique opportunity to study gene expression of subpopulations of cells in their native (*in vivo*) tissue environment.

MATERIAL AND METHODS

Patients with colon cancer and their pathological samples

Forty cases of advanced colon adenocarcinoma (TNM stage Ⅲ to Ⅳ) patients with lymph node metastasis were investigated in this study. There was 21 male and 19 female patients, with an average age of 58.7 ± 3.46 years old. Histologically, 22 cases had differentiated adenocarcinoma and 18 had poorly undifferentiated adenocarcinoma. Thirty cases of non-invasive submucosal colon adenocarcinoma patients (TNM stage I A) were obtained that included 19 male and 11 female patients. Histologically, 16 cases had differentiated adenocarcinoma and 14 had poorly undifferentiated adenocarcinoma, whose ages ranged from 45 to 80 years with an average age of 57.9 ± 3.24 years old (Table 1). All patients underwent gastrectomy with regional lymph nodes dissection and informed consent was obtained from each patient. Tissue blocks of normal colon epithelium from 20 healthy individuals, early tumors, advanced colon adenocarcinoma tissue and corresponding metastatic lymph nodes were obtained within 30 min after removal from the patient. Each block was cut into 2 pieces, one for routine pathologic diagnosis, and the other for molecular analysis. The latter samples were frozen in liquid nitrogen immediately and stored at -260℃ until use.

Table 1 Baseline clinical and pathological characteristics of the patients

Characteristic	Non-invasive tumor (*n*)	Invasive tumor (*n*)
Gender		
Male	19	19
Female	11	21
Age		
Median yr	57.9 ± 3.24	58.7 ± 3.46
Ranger yr	45-80	43-80
Cancer TNM stage		
IA	30	0
Ⅲ-Ⅳ	0	40
Histological type		
Differentiated	16	22
Undifferentiated	14	18

Laser microdissection and RNA extraction

Before sectioning, tissue blocks were embedded in Tissue Tek OCT compound medium (VWR Scientific Products, San Diego, CA, USA) in a cryostat. Then serial 8-micron-thick slices were prepared and mounted onto a foiled slide and stored at -70℃ until use.

Frozen section slides were stained just before LMD and the staining process was performed on ice. Briefly, the slides were fixed in 70% ethanol for 30 s and stained with 0.1% toluidine blue (TBO) for 15 s, followed by a 5-s dehydration step in each of 75%, 95% and 100% ethanol and a final 5-min dehydration step in xylene. Once air-dried, the sections were laser microdissected with a LMD system (Leica Microsystems, Wetzlar, Germany) and the target cells were selectively collected. Next, total RNA from the interest cells was extracted independently with the RNA-lyase Micro Kit (Qiagen, Hilden, Germany), according to the manufacturer's instructions. The integrity of the total RNA was measured by Lab-on-chip (Agilent, Palo Alto, USA).

Polypeptide

We carried out polypeptide analysis in 30 cases with early carcinoma, 40 cases with metastatic lymph node and 20 healthy individuals. All technical services were provided by Shanghai Biochip Corporation (Shanghai, China). Among the extracted total RNA, 200 ng was amplified for array analysis, while the other 100 ng was kept unamplified for later certification. After P27-based RNA amplification, aliquots (2.5 mg) of aRNA from early carcinoma tissues and the corresponding metastatic lymph node were labeled with Cy3-dCTP and Cy5-dCTP, respectively. The labeled probes were hybridized with Human cDNA Chip version 2.0 (SBC-R-HC-100-20, Shanghai, China) which contained 13 824 genes (including 10 positive controls and 6 negative ones), and the signals were detected by Agilent Scanner

(Agilent, Palo Alto, USA). We set the cutoff values for signal intensities, i.e., the signal to noise ratios of Cy3 or Cy5 must be greater than 2. Genes with Cy3:Cy5 ratios > 4 or < 0.25 in both cases were defined as commonly up- or down-regulated genes respectively.

Semiquantitative RT-PCR

Nonamplified total RNA (100 ng) was reverse transcribed into cDNA using Superscript Ⅱ reverse transcriptase (Invitrogen, USA) for 60 min at 42℃ and 15 min at 70℃. Each single-stranded cDNA was diluted for subsequent PCR amplification and the content of cDNA were semiquantitatively normalized by housekeeping gene *β-actin*. PCR conditions of different genes included an initial denaturation at 94℃ for 3 min, and 30-35 cycles of denaturation at 94℃ for 30 s, annealing for 30 s, and elongation at 72℃ for 1 min. The primer sequences, annealing temperatures and cycle numbers of each gene are available on request. Amplified PCR products were visualized by electrophoresis in 1% agarose gel containing ethidium bromide.

LMD

The target cells were successfully laser microdissected in every sample. Consequently, about 6-8 × 10^6 cells were collected for the total RNA extraction and near 200-400 ng total RNA was obtained. The integrity of every sample was proved by Lab-on-chip.

RESULTS

After P27-based amplification, we evaluated the expression profiles of the carcinoma cells from early colon cancer (ⅠA) in 30 cases in comparison with advanced colon adenocarcinoma and corresponding metastatic lymph node (TNM stage Ⅲ to Ⅳ) in 40 cases, scatter plots of polypeptide analysis showed in Figure 1. Amplified aRNA from early colon carcinoma cells (Cy-3) and metastatic carcinoma cells (Cy-5) were labeled and hybridized to the polypeptide.

The analysis of the polypeptide data showed that 49 genes (including 31 of unknown function) were commonly overexpressed (Cy3:Cy5 > 4) in 22 of 30 patients (TNM ⅠA) in early colon carcinoma, another 37 genes (including 9 of unknown function) were significantly suppressed (Cy3:Cy5 < 0.25) in the early carcinoma cells. The up-regulated genes were related to cell division, cell adhesion, cytoskeleton, and cell defense and cell metabolism. Meanwhile, the down-regulated genes included those associated with cell development, cell cycle, signal transduction, adhesion, cell defense, gene expression and cell metabolism (Table 2).

Expression of differential genes in the progression of colon cancer

By means of semiquantitative RT-PCR, we further evaluated the expression levels of 25 selected genes, which included 10 up-regulated and 15 down-regulated genes, in microdissected colon epithelium, early colon cancer cells and metastatic cells in lymph node from other 22 cases. First, we investigated the expression levels of these genes in early colon cancer and metastatic lymph node. The results showed that 12 genes were expressed in the same pattern in > 50% (8/15) cases as revealed by polypeptide analysis.

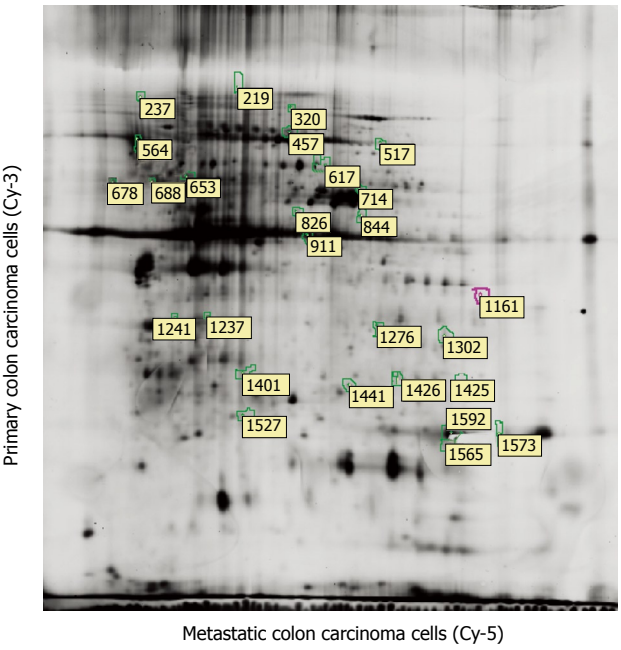

Figure 1 Scatter plots of polypeptide analysis. Amplified aRNA from early colon cancer cells (Cy-3) and metastatic cancer cells (Cy-5) are labeled and hybridized to the polypeptide.

We further measured the expression levels of these 12 genes in paired normal colon epithelium from healthy individuals and early carcinoma from the same 22 patients. We found that the expression pattern of 3 genes (*OPCML*, *RNASE1* and *YES1*) was similar to tumor suppressor genes in > 50% (8/15) cases, *e.g.* the expression level of these genes were highest in normal colon epithelium, decreased in early carcinoma, and further decreased in metastatic lymph node. Meanwhile, the expression level of ACK1 demonstrated the opposite tendency, the pattern of which was similar to oncogene in > 50% (8/15) cases (Figure 2). The expression pattern of OPCML was also confirmed at the gene level by immunohistochemical staining.

Confirmation of microarry finding

To examine the reliability of microarray data, we confirmed our data at the level of aRNA and gene expression. First, we selected three up-regulated genes (*SLC9A1*, *OPCML* and *UBAP*) and three down-regulated genes (*COX6C*, *SERPINB1* and *CCL22*) to measure their expression levels by semiquantitative RT-PCR. To obtain truly comparable results, we used the nonamplified total RNA (from the same batch that was used for the array hybridizations) as the template. The results were very similar to the microarray data for these genes.

Table 2 Representative list of differentially expressed genes detected by MALDI-TOF

GeneBank	Description	Cy3:Cy5[2]

[1]Confirmed by semiquantitative RT-PCR in another group of 15 cases; [2]aRNA from primary colon carcinoma tissues and the corresponding metastatic lymph node were labeled with Cy3-dCTP and Cy5-dCTP, respectively.

As an additional means to confirm our data at the gene level, the results paralleled the differential expression pattern observed with polypeptide and RT-PCR.

Overall, the above results demonstrated that the samples obtained by means of P27-based amplification reflected the status of the original RNA in a proportional manner, and supported the reliability of our previous data[9].

DISCUSSION

Polypeptides allow an effective investigation of functional genomics. However, the existence of of the amount of surrounding cells can produce a lot of useless, noisy information because of the high sensitivity[9]. Therefore, the selection of cancer cells using LMD is of indispensable value in combination with polypeptide analysis. The LMD system used in this study integrated a UV laser of 337 nm wavelength with an upright microscope. The ultraviolet laser microbeam causes dissection by local photolysis of the supporter membrane and tissue section due to the high photon density of the microbeam rather than by local heating or coagulation. The cut sample falls down into PCR tubes placed underneath by gravity without any mechanical contact or further destruction of energy, and the integrity of the extracted aRNA is maximally kept.

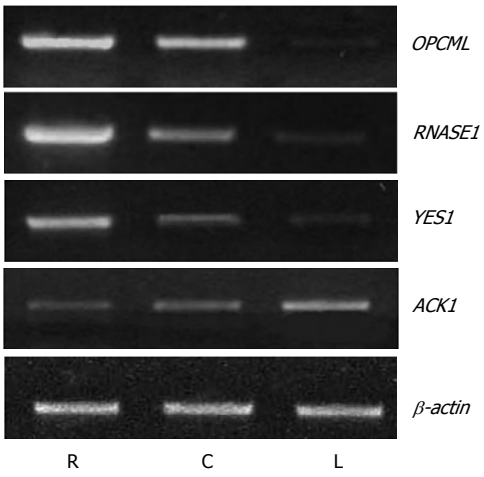

Figure 2 Identification of differentially expressed genes in progression of colon cancer by means of semiquantitative RT-PCR. R signifies a sample from normal colon epithelium, C signifies a sample from the colon carcinoma cells, and L signifies a sample from the metastatic carcinoma cells.

Metastasis of cancer is a highly selective sequential step, which favors the survival of a subpopulation of metastatic cells preexisting within the early tumor mass to produce clinically relevant metastases, the successfully metastatic cells must exhibit a complex phenotype that is regulated by transient or permanent changes in different genes at the DNA and/or aRNA level(s). This was also proved in colon cancer by work of other researchers[10].

Previously, our former study had discovered differential gene expression profiles between primary tumor and metastatic lesions in gastric cancer patients using LMD and cDNA microarray[11]. The results clearly demonstrated that an analysis of the gene-expression profile could be performed by using LMD, P27-based RNA amplification and polypeptide. Moreover, it was confirmed at the level of aRNA and gene. Although the majority of these genes have been implicated in various aspects of tumor biology, few have been demonstrated to be associated with colon cancer.

Among the above genes, some may be differentially expressed because of different living environments[12-15]. Therefore, to further confirm and screen the results of polypeptide analysis, we measured the expression levels of 25 selected genes in another group using semiquantitative RT-PCR. These target cells were collected by LMD, and the normal colon epithelium were included. As a result, we identified four genes, the expression level of were not only different between early carcinoma and metastatic lymph node (same as the results of polypeptide), but also different between normal mucosa and early tumor. These results suggested that these four genes could play a role in

the tumorigenesis and metastasis of colon cancer .The expression pattern of three genes (*OPCML*, *RNASE1* and *YES1*) was similar to tumor suppressor genes[16], *e.g.* the expression level of these genes were highest in normal colon epithelium, decreased in early carcinoma, and further decreased in metastatic lymph node. *OPCML* (opioid binding gene/cell adhesion molecule-like) encodes a member of the IgLON subfamily in the immunoglobulin gene superfamily and acted as a GPI-anchored gene[17,18]. Sellar *et al* had found that *OPCML* has tumor-suppressor function in epithelial ovarian cancer, which was in accordance with our findings in gastric cancer[19-22]. Interestingly, *YES1* is the cellular homolog of a virus oncogene and was considered to be associated with esophageal tumorigenesis[23-25], which was on the contrary to our results. In respect to the gene *RNASE1*, it encoded a member of the pancreatic-type of secretory ribonucleases, a subset of the ribonuclease A superfamily, and it had not been shown to have any relationship with human cancers previously[26].

On the contrary, the expression pattern of gene *ACK1* demonstrated the opposite tendency to the genes mentioned above, which was similar to oncogene[27]. *ACK1* encodes a tyrosine kinase that binds Cdc42Hs in its GTP-bound form and inhibited both the intrinsic and GTPase-activating gene (*GAP*)-stimulated GTPase activity of Cdc42Hs[28]. It was directly linked to a tyrosine phosphorylation signal transduction pathway. Up to now, its effect on tumor progression had not been reported.

Tumor suppressor genes and oncogenes were important target molecules in the clinical diagnosis and therapy of tumors. We reported the different expression of these four genes during the progression of colon cancer. In conclusion, using carefully controlled conditions, analysis of gene expression profile by means of LMD, P^{27}-based amplification, and polypeptide has been provided.

Useful information for clarifying the mechanism underlying development and metastasis of colon cancers[29,30]. These results not only reveal the differentially expressed genes in progression of colon cancer, but also provide information that may prove useful for identifying novel diagnostic and therapeutic targets.

COMMENTS

Background

Colon cancer is the second leading cause of cancer death in the worldwide. Its clinical behavior depends on the potential metastasis of the tumor. However, up to now, the difference of genes had rarely been reported between early colon adenocarcinoma (TNM stage Ⅰ) patients and advanced adenocarcinoma (TNM stage Ⅲ-Ⅳ) cases with lymph node metastasis.

Research frontiers

In this study, the authors revealed the gene profiles in non-invasive and invasive colon cancer using laser microdissection (LMD) and polypeptide analysis. Using these techniques they have identified early expression profiles of five differential genes associated with invasive colon cancer.

Innovations and breakthroughs

These studies have shown that certain genes are involved in the development of colon cancer and that the gene expression of non-invasive early colon adenocarcinoma was obviously different from that of invasive cases. This offers a new potential molecular mechanism of invasive colon cancer using LMD and polypeptide analysis. Our major finding in the study is that five genes are consequently differently expressed between early and advanced colorectal cancer (CRC) cases. Three of these resembled the expression pattern of tumor suppression genes (*OPCML*, *RNASE1* and *YES1*).

Applications

These results revealed that expression profiles of differential genes were associated with the progression of colon cancer, and these insights might play a role in identifying novel diagnostic and therapeutic markers in colon cancer.

Peer review

This is an interesting manuscript investigating the expression profile differences of early and advanced CRC at aRNA level using laser microdissection and polypeptide analysis. The major finding of the study was that five genes were consequently differently expressed between early and advanced CRC cases. Three of these resembled the expression pattern of tumor suppression genes (*OPCML*, *RNASE1* and *YES1*) while one further gene showed an expression pattern similar to oncogenes.

Abstract

AIM: To explore the diffusion gradient b-factor that optimizes both apparent diffusion coefficient (ADC) measurement and contrast-to-noise (CNR) for assessing tumor response to transarterial chemoembolization (TACE) in a rabbit model.

METHODS: Twelve New Zealand white rabbits bearing VX2 tumors in the liver were treated with TACE. Diffusion-weighted imaging (DWI) with various b values was performed using the same protocol before and 3 d after treatment with TACE. ADC values and CNR of each tumor pre- and post-treatment with different b factors were analyzed. Correlation between ADC values and extent of necrosis in histological specimens was analyzed by a Pearson's correlation test.

RESULTS: The quality of diffusion-weighted images diminished as the b value increased. A substantial decrease in the mean lesion-to-liver CNR was observed on both pre- and post-treatment DW images, the largest difference in CNR pre- and post-treatment was manifested at a b value of 1000 s/mm^2 (P = 0.036). The effect of therapy on diffusion early after treatment was shown by a significant increase in ADCs (P = 0.007), especially with large b factors ($\geqslant$ 600 s/mm^2). The mean percentage of necrotic cells present within the tumor was 76.3%-97.5%. A significant positive correlation was found between ADC values and the extent of necrosis with all b values except for b200, a higher relative coefficient between ADC values and percentage of necrosis was found on DWI with b1000 and b2000 (P = 0.002 and 0.006, respectively).

CONCLUSION: An increasing b value of up to 600 s/mm^2 would increase ADC contrast pre- and post-treatment, but decrease image quality. Taking into account both CNR and ADC measurement, diffusion-weighted imaging obtained with a b value of 1000 s/mm^2 is recommended for monitoring early hepatic tumor response to TACE.

INTRODUCTION

Transcatheter hepatic arterial chemoembolization (TACE) remains the initial treatment for unresectable hepatocellular carcinoma (HCC)[1]. Evaluating the therapeutic response of HCC to TACE is critical

in assessing the success of treatment and deciding therapeutic plan. Diffusion-weighted imaging (DWI) enables noninvasive characterization of biologic tissues based on their water diffusion properties. It is theoretically possible to quantify the combined effects of capillary perfusion and water diffusion *in vivo* by an apparent diffusion coefficient (ADC)[2], and its value is equal to the true diffusion coefficient *D* when diffusion is the only type of motion. Diffusion-weighted images are obtained by acquiring T2-weighted images with the addition of diffusion weighting gradient known as the "b value". Generally, the larger the b values used, the lower the ADC values owing to the contribution of perfusion. Large b factors should be chosen for more precise evaluation of ADC values of the tumor. However, image quality will be greatly diminished if large b factors are used. Thus, it is very important to select a suitable b value to evaluate the tumor response accurately. Diffusion-weighted imaging has recently been used to monitor tumor response after therapy. However, there are considerable discrepancies in the selection of b values in previous reports[3-7]. In our study, we compared different b-value DWI in evaluation of hepatic tumor necrosis after TACE in rabbits to explore the optimal b value.

MATERIALS AND METHODS

Animal model and study design

Fifteen male adult New Zealand white rabbits including three carrier rabbits (Animal Laboratory, Fudan University) with an average weight of 2.5 kg, were used in this experiment. The Animal Care and Use Subcommittee at Fudan University approved this experimental procedure. VX2 carcinoma strain was maintained by successive transplantation into the hind limb of a carrier rabbit. Tumor cell suspension was implanted with one subcutaneous injection into the hind leg of each carrier rabbit and grown for 2 wk. All animals were intramuscularly anesthetized with a mixture of ketamine hydrochloride (0.1 g/kg) and diazepam (5 mg/kg). The tumor was surgically excised from the carrier rabbit and placed in normal saline. Tumor tissue was dissociated into approximately 1-2 mm^3 fragments and suspended in 5 mL normal saline, then aspirated into a 1 mL injector. A midline laparotomy was performed to expose the liver of the recipient rabbit, and tumor suspension (0.1-0.2 mL) was implanted in the left lobe of liver *via* an 18-gauge needle. The abdomen was closed in two layers. The tumors were allowed to grow to 1-2 cm in diameter, which typically required 2 wk.

Conventional and diffusion-weighted imaging was performed before and 3 d after therapy using the same protocol.

TACE

TACE was performed under the guide of digital subtraction angiography (Infinix Vc-i, Toshiba, Japan). Animals were intramuscularly anesthetized with a mixture of ketamine hydrochloride (0.1 g/kg) and diazepam (5 mg/kg). Vascular access was achieved in the femoral artery through surgical cut down. Celiac angiography was performed to identify the hepatic arterial anatomy and the feeder artery of the tumor using a 3-F catheter (Cook, Bloomington, India). The left hepatic artery, which exclusively supplies blood flow to the tumor, was catheterized selectively. When the catheter was adequately positioned in the left hepatic artery after celiac arteriography was performed, a chemoembolization mixture consisting of 5 mg doxorubicin (adriamycin; Farmitalia Carlo Erba, Italy) and 1 mL ethiodized oil (lipiodol; Andre Guerbet, France) was injected carefully into the artery. Digital spot images were obtained after chemoembolization. The catheter was then removed, and the femoral artery was ligated.

MR imaging protocol

MR scanning was performed on a 1.5 T superconducting magnet (Signa Twinspeed excite, GE Medical Systems, USA) equipped with a maximum gradient strength of 40 mT/m. All images were acquired using a phased array knee coil. In all rabbits, unenhanced and contrast-enhanced T1-, T2-, and diffusion-weighted images were obtained in the axial, and/or coronal, sagittal plane, respectively. Diffusion-weighted images were obtained before contrast medium injection. The rabbits were anesthetized with a combination of ketamine hydrochloride and diazepam as described above. Each animal was placed in the knee coil at supine position with its abdomen fastened using a belt to control the motion artifacts caused by breathing.

T2-weighted fast spin-echo images (TR/TE, 2800/72.4; matrix, 512 × 512), and T1-weighted spin-echo images (TR/TE, 350/9.0; matrix, 256 × 256) were obtained. DWI was performed in the axial plane using a single-shot echo planar imaging (EPI) sequence with the following parameters: TR/TE = 3000-4000 /50.9-70.2 ms, FOV = 12 cm × 12 cm, pixel matrix = 256 × 256, section thickness = 3 mm, intersection gap= 0.5 mm. Different values of b factor (0, 200, 400, 600 or 1000, 2000 s/mm^2) were used. Then, 0.05 mmol/kg gadopentetate dimeglumine (Magnevist; Schering, Germany) was administered intravenously, and fat-saturated spoiled gradient-echo T1W sequences were obtained. Therefore, the overall scan time was approximately 15 min.

Image analysis

ADC maps were automatically generated on the post processing workstation (ADW4.0, GE Medical Systems, USA). One experienced radiologist established ROIs in the tumors, lesion-free liver parenchyma, and background on all series of diffusion-weighted images. For heterogeneous tumors, regions of interest (ROIs) covered the entire tumor at the maximum section consisting of at least 100 pixels, and then were copied to the corresponding ADC maps, from which the ADC value with different b factors for each ROI was calculated. Each of the signal intensities (SI) and ADCs was measured three times, and the measurements

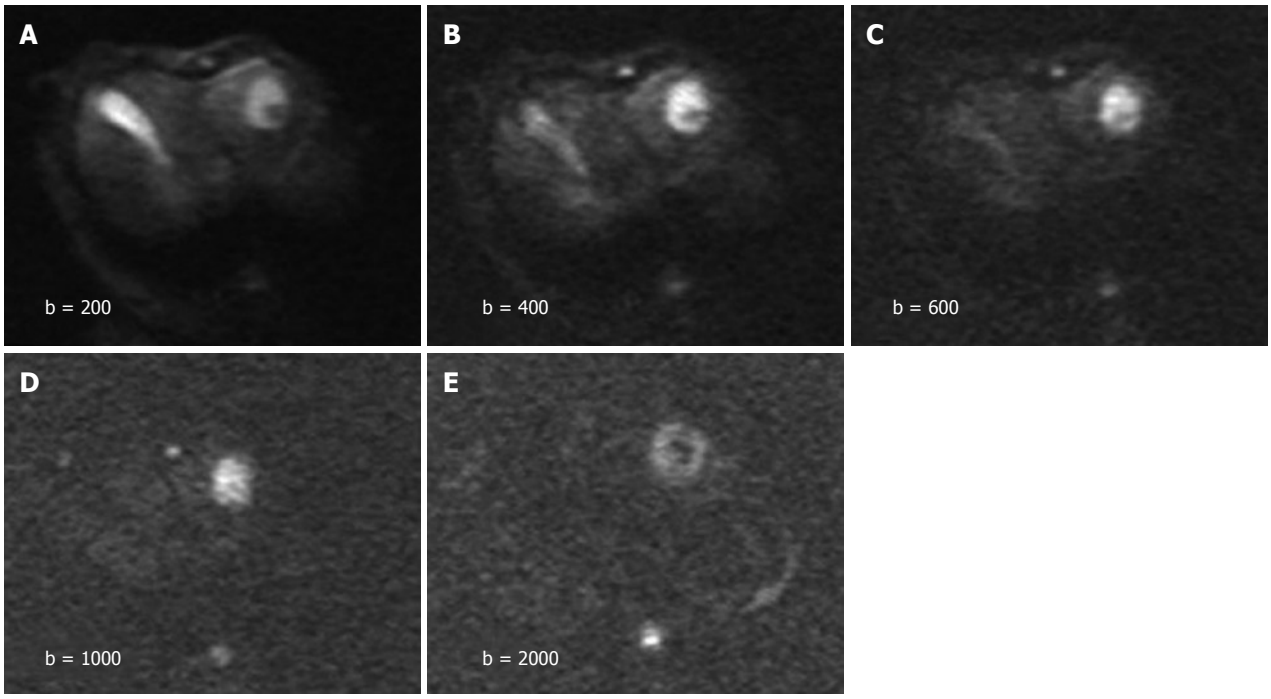

Figure 1 Diffusion-weighted images obtained with different b-values. **A** and **B**: High signal intensity in tumors and hyperintense gallbladder on b200 and b400 DWI; **C**-**E**: Hyperintensive tumors and invisible gallbladder on b600, b1000 and b2000 DWI. The image qualities degrade with increasing b values.

were averaged. CNR performed on all DWI series was calculated using the following formula: CNR = $(SI_{lesion}-SI_{liver})/SD_{noise}$, where SI_{lesion} and SI_{liver} are the signal intensity of the tumor and liver, respectively, and SD is the standard deviation from the background noise.

Histological analysis and comparison with MR images

All animals were sacrificed by giving an intravenous pentobarbital overdose immediately after the completion of MR imaging. The tumors were surgically removed and fixed in a 10% formaldehyde solution. From each tumor three 5 μm thick sections corresponding to the image planes were cut and stained with hematoxylin and eosin (H&E) and analyzed under a light microscope. Viable tumor and tumor necrosis were identified on these sections and correlated to the corresponding spin-echo images and the ADC maps. The percentage of necrotic area in each tumor was then calculated by an experienced pathologist.

Statistical analysis

Statistical analysis was performed using SPSS 13.0. ADC values were presented as mean ± standard deviation (SD). Pearson's correlation test was used to test for the relationship between ADC values and extent of necrosis. Differences in the ADCs pre- and post-treatment were assessed with the paired Student's *t*-test. The correlation between ADC, CNR and b factors was analyzed. $P < 0.05$ was considered statistically significant.

RESULTS

Chemoembolization

TACE was performed successfully in all animals, and no animals died within 3 d after the procedure. The left hepatic artery exclusively supplied blood flow to the tumor. A region of hypervascular blush was noted on the left side of the upper abdomen. Selective accumulation of deposits of iodized oil was observed in the hepatic tumors at digital spot images performed immediately after TACE.

MR imaging

The tumors were slightly inhomogeneous hyperintense on T2-weighted images, hypointense on T1-weighted images. A marked peripheral enhancement pattern was noted on contrast-enhanced T1WI before and after TACE, with centrally non-enhancing regions corresponding to the necrotic area. However, the margin between the viable tumor and its surrounding liver parenchyma was inconspicuous. On DWI obtained before treatment with a b value of 200 or 400 s/mm^2, both the tumor and gallbladder presented with hyperintense signals (Figure 1). On DWI with a b value equal to or larger than 600 s/mm^2, the gallbladder was depicted as a region of hypointense signal attenuation, whereas the tumor remained hyperintense (Figure 1). On DWI obtained after treatment, the viable tumor presented with hyperintense signals indicating a restricted diffusion capacity, whereas a necrotic area was depicted as hypointense indicating free diffusion. The image quality diminished greatly with increasing b value especially on b2000 DWI (Figure 1). A substantial decrease in the mean lesion-to-liver CNR was observed on both pre- and post-treatment DW images. On these series of DW images, the largest difference in CNR pre- and post-treatment was manifested at a b value of 1000 s/mm^2 ($P = 0.036$, Figure 2).

Table 1 ADCs obtained with different b-values on DWI before and after therapy

B value(s/mm^2)	ADC(10^{-3} mm^2/s) pre-treatment	ADC(10^{-3} mm^2/s) post-treatment
200	2.32 ± 0.53	2.41 ± 0.62
400	1.88 ± 0.45	1.99 ± 0.60
600	1.49 ± 0.26	1.79 ± 0.43
1000	1.19 ± 0.32	1.52 ± 0.42
2000	0.81 ± 0.29	1.22 ± 0.36

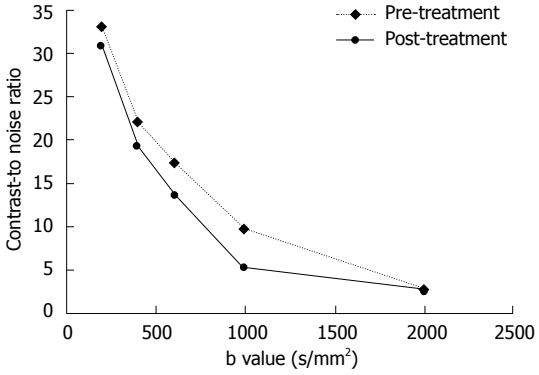

Figure 2 Contrast-to-noise ratio (CNR) of the diffusion-weighted images *vs* different sets of b-values of hepatic tumors pre- and post-treatment. CNR decreases with increasing b values after TACE, especially at b1000 on DWI.

The early effect of TACE on diffusion was shown by a substantial increase in ADC (P = 0.007), especially with large b factors (≥ 600 s/mm^2, Figure 3). These data are summarized in Table 1.

Histopathologic analysis

At microscopic examination, tumors treated with TACE revealed massive necrosis involving both the peripheral and central regions of the tumor. The mean percentage of necrotic cells present within the tumor was 76.3%-97.5% (mean 89.1%). A significant positive correlation was found between ADC values and extent of necrosis with all b values except for b200. A higher relative coefficient between ADC values and percentage of necrosis was found on DWI with b1000 and b2000 (P = 0.002 and 0.006, Figure 4).

DISCUSSION

Total necrosis after TACE has been reported to be as low as 10%-20%[8,9], and the presence of residual or recurrent tumor is inevitable. Precise evaluation with imaging modalities at an early stage is important to determine whether the tumor needs further treatment. The tumor volume has generally been used as an indicator of therapeutic response. However, necrotic tumors do not shrink until 1-2 mo after chemoembolization[10]. Besides, the apparent post-treatment increase may be due to the visualization of surrounding edematous changes. Thus, changes in tumor volume fail to predict the histological tumor response.

Diffusion-weighted imaging provides insights into tumor behavior for monitoring treatment response,

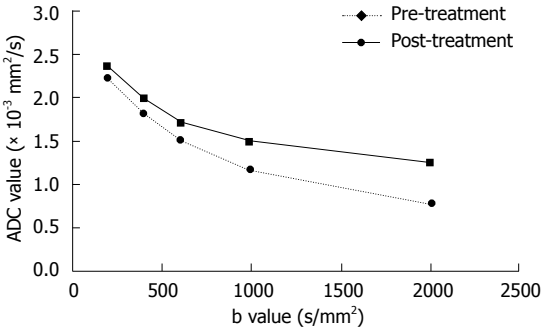

Figure 3 Plots of averaged ADC values for all 12 tumors vs different sets of b-values of hepatic tumors pre- and post-treatment. ADC values present as a function of b factors. The early effect of therapy on diffusion is shown by a substantial increase in ADCs, especially at a large b factor (≥ 600 s/mm^2).

thus enabling noninvasive depiction of molecular diffusion which is the Brownian motion of water protons in biologic tissues. Calculation of the ADC allows quantification of that motion[11-16]. The sensitivity of diffusion-weighted imaging to water motion can be varied by changing b value, which is a function of diffusion gradient strength, duration of the gradient, and interval between diffusion gradients. Diffusion-weighted imaging has been used to predict and monitor the effect of several treatment options and to differentiate between viable and necrotic tumor tissues[3-7]. In these studies, a variety of b values ranging from 0 s/mm^2 to 4000 s/mm^2 were used[3-7]. To our knowledge, however, comparison between DW images obtained with different b values on evaluation of the efficacy of TACE has not been reported.

In this study, we treated rabbits bearing VX2 tumors with TACE, whose vascularization is similar to that of human liver tumors[17-19]. Subsequently, the early tumor response to TACE was assessed *via* different b values on DWI to determine which b value is most suitable for evaluation.

In the present study, the tumor and gallbladder presented with hyperintense signals on DWI obtained with a low b value of 200 or 400 s/mm^2. When the b value increased to 600 s/mm^2, the gallbladder was depicted as a region of hypointense signal attenuation whereas the tumor remained hyperintense (Figure 1). Visual assessment of signal attenuation on DWI has been applied in tumor detection and characterization, however, signal intensity observed on DWI depends on both water diffusion and T2 relaxation time[20]. The relative contribution of T2 signal intensity to DWI, namely "T2 shine-through" effect, is a source of error in image interpretation. Tissues of organs with a long T2 relaxation time, such as gallbladder or cystic lesions, may appear hyperintense on DWI because of the T2 shine-through effect. This effect can be reduced by increasing the b value, but cannot be easily avoided. The ADC value is independent of magnetic field strength and can overcome the effects of T2 shine-through, thus allowing a more meaningful evaluation of tumor response to therapy.

In our study, the ADC values corresponded to the

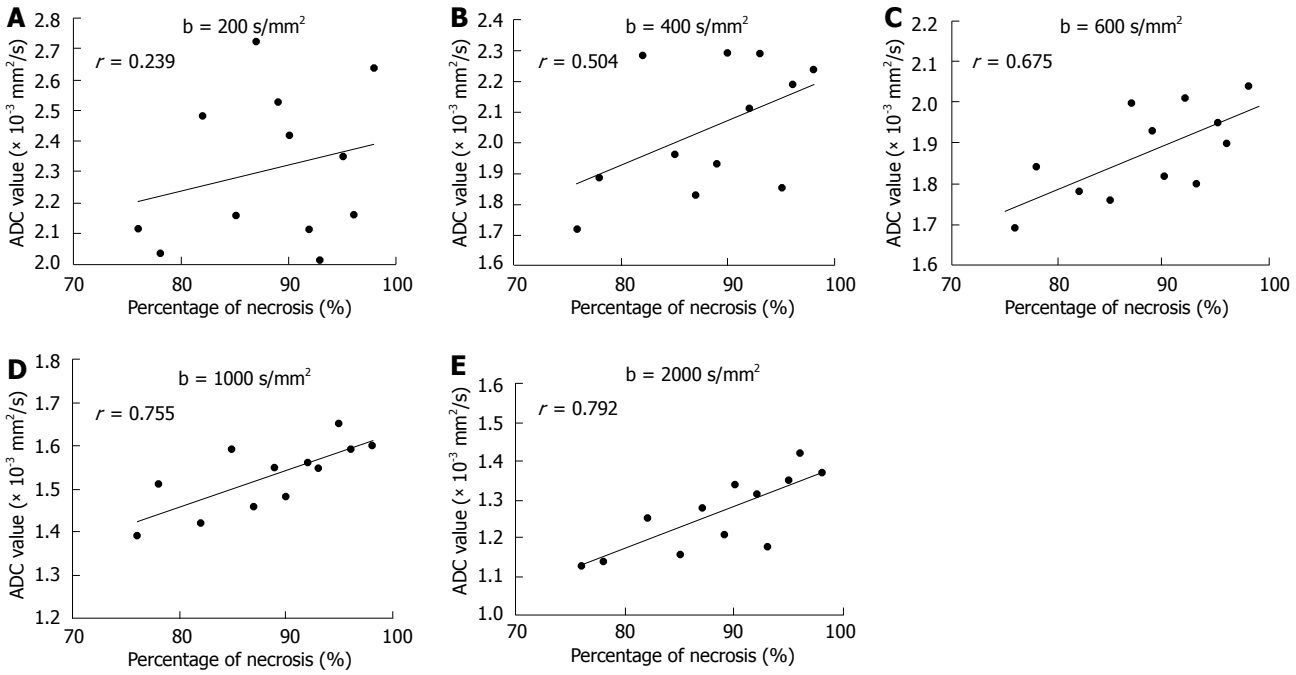

Figure 4 Plots of post-treatment ADC values as a percentage of necrosis measured on the sections of tumors. The r values of 0.239, 0.504, and 0.675 found at b200, b400 and b600 (**A**-**C**), and a higher *r* value at b1000 and b2000 are found on DWI (**D** and **E**).

histopathologic rate of necrosis within the tumors, suggesting that diffusion-weighted imaging has a potential for early detection of tumor necrosis after TACE, which is in agreement with the findings in theoretical diffusion models and *in vitro* and *in vivo* studies[3,5-7,11]. DWI can differentiate viable and necrotic tissues by calculating ADC values because in the former, cell and intracellular membranes are intact, restricting molecular diffusion into viable tumors. Conversely, necrotic tumors are characterized by a breakdown of these membranes, thereby allowing free diffusion and an increase of diffusing molecules, resulting in an increased ADC value[11,14].

Comparison between different b-values on DWI revealed that the ADC values decreased with the increasing b value, and the difference in ADC values pre- and post-treatment was significant. A higher relative coefficient between ADC values and percentage of necrosis was found on DWI with b1000 and b2000, indicating that a high b-value on DWI is more sensitive in early detection of tumor necrosis. The signal intensity on diffusion-weighted images is a mixture of diffusion and perfusion. On DWI obtained with a low b-value, perfusion effects usually cause larger signal attenuation than diffusion effects[21,22]. In the presence of perfusion, the ADC value calculated from images with a low b value would be overestimated due to this additional cause of signal attenuation. At a high b value, ADC measurement will be relatively perfusion insensitive and theoretically more reflective of tissue cellularity and the integrity of cellular membranes[23,24]. A few studies on evaluation of tumor response to therapy with high b values on DWI have recently been reported[25,26]. Mardor *et al*[25] reported that a high-b-value on DWI is highly correlated to radiotherapy-treated human brain tumors. Roth *et al*[26] demonstrated that high-b-value diffusion-weighted MR imaging can be potentially used in early detection of response to chemotherapy.

However, in the present study, the image quality diminished with the increasing b value especially at b2000 on DWI, CNR measurements showed that b1000 on DWI increased the contrast pre- and post-treatment, suggesting that higher b values may increase the diffusion sensitivity by diminishing the T2 shine-through effect. High b values may also decrease the absolute difference in signal intensity between tumor and liver parenchyma. The results of our study suggest that an intermediate b value (i.e., 1000 s/mm^2) may provide optimal visualization. In terms of the accuracy of ADC measurement, because the single-shot echo planar pulse sequence is very sensitive to magnetic susceptibility, resulting in geometric distortion artifacts that tend to be more severe when the b value is 2000 s/mm^2, image distortion may cause significant errors in the measurement of ADC values.

In abdominal diffusion-weighted imaging, the most challenging technical difficulty is to overcome the effects of breathing motion, while retaining the sensitivity to the microscopic motion. To reduce the artifact caused by breathing, several attempts were made in our study. First, fast imaging acquisition was applied. The most common form of data acquisition is a single-shot read out, in particular single-shot echo planar imaging[27-30], since the acquired phase error due to bulk motion is equal in each phase encoding step and therefore does not affect the image reconstruction. With EPI, the fastest MR imaging technique, an image can be acquired within 50 ms and physiologic motion can be literally frozen-out, so it has been widely applied in DW imaging.

Second, respiratory rate should be controlled

efficiently. To minimize the potential confounding artifacts caused by motion, Geschwind *et al*[13] acquired images shortly after the death of animals. We modified our protocol by fastening the abdomen of rabbits with a belt and using combined deep anesthesia. By this means, we obtained high quality images without virtually visible motion artifacts. The whole acquisition time was 15 min, and no animals died during the MR scanning procedure.

Our study had two major limitations. First, we placed the ROI covering the entire tumor. The ADC values of viable and necrotic area were not calculated. Second, due to the small population of animals, the results were not analyzed according to the tumor response or disease progress.

In summary, DWI can be used to assess the degree of tumor necrosis based on significant differences in ADC values. Based on the maximal contrast and changes in ADC values pre- and post-treatment, b values above 600 s/mm^2 are recommended. We hold that the optimal b value should be 1000 s/mm^2.

COMMENTS

Background

Necrotic tumor remnants or inflammatory fibrosis may not be accurately differentiated from residual tumor by conventional MR imaging early after therapy. DWI enables noninvasive characterization of biologic tissues based on their water diffusion properties and could provide information that is not readily available from conventional MR imaging. The sensitivity of diffusion-weighted imaging to water motion can be varied by changing the b value, which is a function of diffusion gradient strength. Thus, it is very important to select a suitable b value to evaluate the tumor response accurately.

Research frontiers

Diffusion-weighted imaging has been used to predict and monitor the effect of several treatment options and to differentiate between viable and necrotic tumor tissues. A few studies on evaluation of tumor response to therapy using at high b values on diffusion-weighted imaging (DWI) have recently been reported. Mardor *et al* reported that a high-b-value on DWI has a higher correlation to radiotherapy-treated human brain tumors. Roth et al demonstrated that a high-b-value on diffusion-weighted MR imaging can be potentially used in detecting early response of tumors to chemotherapy in an animal model.

Innovations and breakthroughs

A major limitation of previous studies is the lack of comparison between DW images obtained with different b values. In this study, we treated rabbits bearing VX2 tumors with transarterial chemoembolization (TACE). Subsequently, the early response of tumor to TACE was assessed *via* different b values on DWI to determine which b value is most suitable for evaluation.

Applications

DWI can be used to assess the degree of tumor necrosis based on significant differences in the apparent diffusion coefficient (ADC) values. With regard to maximal contrast, changes in ADC values pre- and post-treatment, b values above 600 s/mm^2 are recommended. Physicians should be aware of the trade-off between increased image distortion and ADC difference at higher b values, the optimal b value should be 1000 s/mm^2.

Terminology

DWI exploits the random, translational motion of water protons in biologic tissues, which causes phase dispersion of the spins resulting in signal loss. This signal loss can be quantified by calculating the ADC value, which refers to the specific diffusion capacity of a biologic tissue. The sensitivity of diffusion-weighted imaging to water motion can be varied by changing the b value, which is a function of diffusion gradient strength.

Peer review

In the study, the authors tried to find the diffusion gradient b-factor that optimizes ADC measurement and contrast-to-noise (CNR) for assessing tumor response to TACE in a rabbit model. The image modalities and technique they used in this study were advanced both at home and abroad. The study design is perfect. The conclusion about the optimal b value for monitoring early hepatic tumor response to TACE is of clinical importance.

Abstract

AIM: To evaluate the effect of different approaches in the treatment of achalasia in China.

METHODS: We performed a systematic review and meta-analysis of Chinese literature by searching the Chinese Biomedical Database and Chinese scientific Journals database (up to March 2008). All cohort studies (controlled or uncontrolled) in which the patients were observed for more than a year were reviewed in detail. Dichotomous outcomes were reported as relative risks (RR) with 95% confidence interval (CI) for controlled trials. The efficacy in uncontrolled trials was assessed by a pooled estimate of response rate with individual studies weighted in proportion to the sample size.

RESULTS: Seven controlled trials compared the effect of botulinum toxin injection (BoTx) with pneumatic dilation (PD). PD was superior to BoTx [65.2% *vs* 45.3%; RR 1.47 (95% CI 1.23-1.77), $P < 0.0001$], and had a lower clinical relapse rate (BoTx 30.2% *vs* PD 10%, RR 0.32 (0.16-0.65), $P = 0.001$). Heller myotomy (HM) had superior remission rate compared to PD [HM 94.0% *vs* PD 64.1%, RR 1.48 (1.15-1.99), $P = 0.002$]. In uncontrolled trials, the effectiveness of PD was 86.6% (23.9%) *vs* 94.8% (10.6%) for HM. The main complications of PD were perforation and gastroesophageal reflux disease.

CONCLUSION: HM is the most effective long-term treatment for patients with achalasia in China. In the future, controlled clinical trials on the treatment of achalasia should focus on comparing laparoscopic myotomy with or without antireflux procedure, including different partial and total fundoplication techniques.

Key words: Meta-analysis; Achalasia; Esophageal; Treatment; Pneumatic dilation; Botulinum toxin injection; Laparoscopic myotomy

INTRODUCTION

Achalasia is an idiopathic primary motility disorder, characterized manometrically by poor relaxation of the lower esophageal sphincter (LES) and complete loss of primary peristalsis, which leads to a compromise in the primary function of the esophagus[1]. The cause of achalasia is not known. Untreated, it leads to an extremely poor quality of life because of progressive dysphagia, esophageal dilation, and stasis[2]. Botulinum toxin (BoTx) injection of the LES, pneumatic dilation (PD) and Heller myotomy (HM) are the most commonly used techniques for the treatment of achalasia[3].

BoTx prompted a great deal of enthusiasm because it is safe, simple to use and can be easily repeated[4]. There are no reports of any serious complications after BoTx injection. However, symptoms often recur after the first injection and serial injections are required, with the efficacy waning over time due to the production of antibodies[5]. Currently, newly diagnosed achalasia patients are offered serial PDs, followed by surgical intervention if the dilatations fail[6]. With the introduction of HM, there has been a change in the initial management approach to the treatment of achalasia. However, there is much controversy as to which treatment provides the best efficacy, sustained symptom relief and low complication rate[7], especially in China[8]. Therefore, the aim of the present study was to

evaluate the effects of different treatment modalities by reviewing the published trials in China.

MATERIALS AND METHODS

Study design

All controlled and uncontrolled studies were included in the analysis if the patients underwent clinical, manometric, radiographic and endoscopic evaluation to confirm the diagnosis of primary achalasia. The presence of symptoms and esophageal function were reassessed at 6 mo and 1 year after therapy. Treatment efficacy was determined by the improvement rate (%) in the symptom score, 1 year after therapy. Treatment failure was defined as the lack of any reduction in the symptom grade of > 1, or a recurrence of symptoms 1 year after therapy.

Search strategy and data extraction

Two investigators independently searched the Chinese literature published in the Chinese Biomedical Database and Chinese scientific Journals database (up to March 2008). All controlled or uncontrolled trials involving patients with achalasia who were given any form of treatment were included in the analysis. The search terms used were "esophageal" or "oesophagus", "achalasia", and "therapy" or "treatment". Data was extracted by the same investigators using standardized forms. The date obtained included the number of patients, the exact methods of therapy, the outcome variables listed above, and any reported adverse effects of therapy. The quality of all selected articles was ranked in accordance with the Jadad composite scale. According to this scale, low quality studies had a score of $\leqslant 2$ and high quality studies had a score of $\geqslant 3$.

Statistical analysis

We performed the meta-analysis using the RevMan 4.2.10 software (provided by the Cochrane Collaboration, Oxford, UK) for the controlled studies. The relative risk (RR) was calculated with 95% confidence intervals (CI). We used χ^2 to assess statistical heterogeneity and the Higgins I^2 statistic to determine the percentage of total variations across studies due to heterogeneity. If the I^2 statistic was $\leqslant$ 50%, the fixed effect model was used to pool studies, otherwise, the random effects model was used. The efficacy in uncontrolled trials was assessed by a pooled estimate of the response rate with individual studies weighted proportionally to the sample size[9]. In calculating the weighted mean response for each treatment modality ($\hat{p}$), the studies were characterized by the number of subjects included (n) and the response rate in those subjects (p). Ellipses represents scant data.

$$\hat{p} = (n_1 p_1 + n_2 p_2 + n_x p_x)/(n_1 + n_2 + n_3)$$

$$SE(\hat{p}) = \text{Sqrt}\{[p_1(1-p_1)/n_1] + [p_2(1-p_2)/n_2] + [p_x(1-p_x)/n_x]\}$$

RESULTS

Study characteristics

The search strategy generated 612 studies. From these, we identified 43 studies (12 controlled studies and 31 uncontrolled studies) that met the inclusion criteria. Only studies that included more than 10 patients, and had a follow-up of at least 12 mo were tabulated (Table 1). Sample sizes in the trials ranged from 10 to 125 participants (total 1791); 46.9% of the participants were male. Ten controlled studies were considered to be of low quality, and two controlled trials were graded as high quality (Table 2).

Effects of the treatment of achalasia

Control studies: There were five controlled studies[10-14], while two studies[15,16] compared the clinical effect of BoTx with that of PD. Our meta-analysis showed that BoTx was significantly more effective than PD in the incidence of symptom remission [PD 65.2% *vs* BoTx 45.3%, *RR* 1.47 (95% CI 1.23-1.77), $P < 0.0001$, Figure 1A], whereas PD had a lower relapse rate than BoTx [PD 10% *vs* BoTx 30.2%, *RR* 0.32 (0.16-0.65), $P = 0.001$, Figure 1B]. The main adverse effect of BoTx injection was chest pain which was controlled by medical therapy. Complications with PD consisted of perforation and gastroesophageal reflux disease (GERD). Some patients were referred for Heller myotomy. We believe that PD is the preferred medical treatment for achalasia, if performed by a skillful expert.

One trial[17] compared PD with BoTX-PD. The one year remission rate in the BoTX-PD group was 61% compared with 28% in the PD group ($P < 0.05$). It was suggested that BoTx injection before PD improved the efficacy of PD. However, some studies have shown that primary BoTx treatment increased the risk for PD[53]. Therefore, more randomized controlled studies are required to evaluate whether combined therapy is superior to single treatment in achalasia.

Two controlled studies[18,19] compared the effect of PD with HM. Our meta-analysis showed that HM had superior remission rate compared to PD [HM 94.0% *vs* PD 64.1%, *RR* 1.48 (1.15-1.99), $P = 0.002$), (Figure 1C]. There was no difference in the complication rate between HM and PD. These findings suggest that HM offers better long-term clinical results than PD. Two trials[20,21] assessed the efficacy of laparoscopic myotomy (LM) with thoracoscopic myotomy (TM). The results showed that good or excellent relief of symptoms was obtained in 93.8% after TM and 98% after LM, with no difference in the remission rate [RR 1.48 (0.91-1.05, $P = 0.58$), Figure 1D]. These findings need further confirmation and validation.

Uncontrolled trials: There were 31 uncontrolled trials on different treatment methods for achalasia. Table 3 summarizes the results obtained with endoscopic and surgical treatment. Some studies were conducted prospectively[22-26], while others[27-31] were retrospective reviews. These studies evaluated the clinical effect

Table 3 Pooled estimate of response rate of non-controlled trials for achalasia treatments across referenced trials

Therapy and references	Total No. of patients	Weighted response of treatment methods for achalasia (1 yr after treatment)		
		Remission rate (þ) mean ± SE, %	Relapse rate (þ) mean ± SE, %	Weighted follow-up mean (range), mo
PD	667	86.6 ± 23.9	10.7 ± 21.0	26 (4-102)
HM	354	94.8 ± 10.6	1.5 ± 6.3	46 (1-178)
TM	64	92.0 ± 10.0	4.91 ± 9.0	30 (1-80)

PD: Pneumatic dilation; BoTx-PD: Botulinum toxin plus Pneumatic dilation; HM: Heller myotomy. In calculating the weighted mean response for each treatment modality (þ), included studies were characterized by the number of subjects included (*n*) and the response rate for those subjects (p). Ellipses represent scant data.

reported the efficacy of large diameter balloon dilation. Three trials[24,51-52] evaluated the efficacy of TM. The results were combined (shown in Table 3) because the findings were identical. In calculating the response rate of each study, we extracted the number of individuals with a good-to-excellent response that was sustained until the end of the observation period, without further therapy. Thus, if a patient required a second dilation or a second injection, or if a laparoscopic operation was converted to an open procedure, these were considered as failures of initial treatment. The results show that PD and HM are the most popular treatment methods for achalasia in China; the effectiveness of PD [weighted mean (SD)] was 86.6% (23.9%) *vs* 94.8% (10.6%) for HM. Only 3 of the 31 uncontrolled trials evaluated the clinical effect of TM [weighted mean (SD)] [92.0% (10.0%)], while one study evaluated the effect of LM (96.3%). However, in most western countries, the majority of patients undergo LM, with excellent results[54]. Some workers regard LM as the gold standard treatment for achalasia[55]. More randomized controlled trials should be carried out in China to evaluate the effect of LM. There was a significant difference in the effect of PD between controlled trials and uncontrolled trials (controlled 65.2% *vs* uncontrolled 86.6%). Therefore, a uniform standard for evaluating the effect of achalasia treatment should be developed.

DISCUSSION

The present review indicates that HM is the best choice for the treatment of achalasia in China. HM has gained widespread popularity for its excellent results and the advantage of a 1-shot therapy. There was no significant difference in the complication rate between LM and PD. PD was also a popular therapy in Chinese patients. Although side effects, such as perforation and bleeding occur with PD, the remission rate was higher with PD compared to BoTx. Moreover, the recurrence rate was higher with BoTx compared to PD.

However, Bassotti *et al*[56] using a different BoTx regimen, consisting of two injections within a 4-wk period, reported a success rate 80% at 12 mo. These findings may encourage new interest in this therapy. Moreover, BoTx treatment is less expensive, is virtually risk-free, is easy to administer by any endoscopist, and the results are reproducible. Therefore, there is an urgent need for high quality studies to evaluate the efficacy of repeated injections of BoTx, and BoTx combined with other treatment methods.

HM is an invasive and risky treatment modality for achalasia, and requires surgical skills that are not always available (the results obtained with HM depend largely on the surgeon's expertise). To reduce the complications and risks of HM, several modifications have been developed[57], including HM with partial fundoplication, and minimally invasive myotomy, using different endoscopic techniques. In the past, both laparoscopy and thoracoscopy were used to perform HM. However, it soon became clear that laparoscopy offers several inherent advantages, including superior visualization of the gastroesophageal junction, a single

lumen endotracheal intubation, the ability to add an anti-reflux procedure, and a shorter hospital stay. In addition, laparoscopy provided better symptomatic outcome and lower incidence of postoperative gastroesophageal reflux (GER)[58]. Our meta-analysis showed that there was no significant difference in the remission rate between LM and TM within 12 mo of the initial intervention. However, LM has a relatively higher response rate in uncontrolled studies (LM 96.3% *vs* TM 91.95%). Patients experienced greater relief of dysphagia after LM compared to TM. Moreover, GER is the most common complication after HM, and fundoplication cannot be performed at the same time with TM. Therefore, more studies are required to determine whether LM is superior to TM in the treatment of achalasia.

The number of trials included in the present meta-analysis, and the number of patients randomized to receive the different treatment modalities was relatively small. This was compounded by stratification of the subjects into smaller subgroups. Moreover, poor randomization techniques and inadequate follow-up further limited the interpretation of the findings. Few studies provided proper definitions of the postoperative events. Future trials should include standard measures to allow objective and comparable assessment of the outcomes. Standardization was lacking in the reporting of treatment outcomes, length of trial, and the proportion of recruited sample that was kept under follow-up. Several trials failed to accurately present such information. Disease recurrence may also be underestimated, since some studies used telephone contact or questionnaire-based follow-up. Therefore it is possible that a small number of patients with macroscopic but asymptomatic recurrence may not be detected using such assessment techniques.

Our results indicate that in China, HM is the most effective treatment for achalasia and can safely and durably relieve the symptoms of dysphagia. BoTx injection is recommended if multiple injections are given or is combined with other treatment modalities. PD provides better dysphagia control, but is associated with the risk of perforation. It is important that more randomized controlled clinical trials are carried out in China to compare LM, with and without an antireflux procedure, and with partial or total fundoplication.

ACKNOWLEDGMENTS

We are grateful to Dr. Yinglong Tao for his excellent assistance in the statistical analysis.

COMMENTS

Background

Botulinum toxin injection (BoTx), pneumatic dilatation and Heller myotomy (HM) are the most commonly used techniques for the treatment of achalasia in China. However, it unclear as to which is the best treatment modality for achalasia.

Research frontiers

The aim of the present study was to evaluate the outcome of different approaches for the treatment of achalasia in Chinese patients.

Innovations and breakthroughs

Previous studies in China suggest that pneumatic dilatation is as effective as HM. It remains unclear whether pneumatic dilatation can achieve sustained symptom remission. In the present study, HM was found to provide better results compared with other treatment modalities in China.

Applications

Our results helped to identify the best treatment method for Chinese patients. They also offer directions for randomized controlled trials in the future.

Terminology

Achalasia is a primary motor disorder, characterized by incomplete relaxation of the lower esophageal sphincter and aperistalsis of the esophageal body, secondary to the loss of the inhibitory ganglion cells in the myenteric plexus. The etiology of achalasia is unknown; genetic, autoimmune, infectious, and environmental factors have been implicated.

Peer review

This is a systematic review and meta-analysis of the current treatments options for achalasia, namely BoTx, pneumatic dilation, and Heller myotomy. The authors concluded that Heller myotomy is superior to endoscopic approaches. This is a very interesting study.

Abstract

AIM: To assess the effects of H_2-receptor blocking pharmacon, protease inhibitor, and gastro kinetic agents on the human Sphincter of Oddi (SO) motility by choledochoscope manometry.

METHODS: One hundred and seventy-five patients with T tube installed after cholecystectomy and choledochotomy were assessed by choledochoscope manometry. They were randomly assigned into groups of H_2-receptor blocking pharmacon, protease inhibitor, and gastro kinetic agents. The Sphincter of Oddi basal pressure (SOBP), amplitude (SOCA), frequency of contractions (SOF), duodenal pressure (DP), and common bile duct pressure (CBDP) were scored and analyzed.

RESULTS: SOBP and SOCA were significantly decreased after Cimetidine administration, and no statistical difference was seen in the Famotidine group. In the Gabexate mesilate group, SOBP had decreased significantly. In the Ulinastatin group, SOCA decreased when Ulinastatin was given at the rate of 2500 U/min; when Ulinastatin administration was raised to 5000 U/min, SOBP, SOF and SOCA all experienced a fall. SOBP and SOCA for Domperidone and SOCA for Mosapride groups all decreased distinctly after administration.

CONCLUSION: The regular dosage of Cimetidine showed an inhibitory effect on the motility of SO, while Famotidine had no obvious effects otherwise. Gabnexata mesilate, Ulinastatin and gastro kinetic agents also showed inhibitory effects on the SO motility.

Key words: Sphincter of Oddi; Medicamentum; Choledochoscope manometry

INTRODUCTION

The Sphincter of Oddi (SO) plays a vital role in maintaining the normal bile duct pressure, promoting gallbladder excretion and preventing from reflux. When Sphincter of Oddi dysfunction (SOD) occurs, the incidence rate for bile duct infection and cholelithiasis will greatly increase. The Sphincter of Oddi Manometry (SOM) is the gold standard for examining the SOD- in which the SO pressure is well accommodated by the abundance of nerves and hormone receptors on the SO. This study assessed the effects of H_2-receptor blocking pharmacon, protease inhibitor and gastro kinetic agents on the human SO pressure measured by choledochoscope manometry, and reveals the effects of different drugs on the SO pressure, which in turn provides the theoretical basis for clinical medication.

MATERIALS AND METHODS

Patients

Between the years 2002 and 2006, 175 individuals (59 men and 116 women, with a mean age of 56

years old, ranging from 21 to 80 years old) were subject to choledochofiberscope examination from the Department of the First Minimally-Invasive and Biliary Surgery of Shengjing hospital affiliated to the China Medical University were chosen. According to the random number table, adult subjects were further randomized into groups of H_2-receptor blocking pharmacon, protease inhibitor, and gastro kinetic agents. Every patient in each group has had cholecystectomy, biliary exploration, and T tube drainage troubled by biliary calculi. Choledochoscope examination was conducted two months after the procedures prior to manometry measurement. All the patients can close their T tube at 15 days post-operation continuously. The common bile duct diameter varied from 0.8 cm to 1.2 cm. Before the manometry was performed, all the patients were informed in detail of the procedure aims and probable dangers, with informed consent form signed.

Manometry system

The apparatus used were PC polygram HR (CTD-Synectics Medical Company, Sweden), triple lumen polyethylene manometry catheter (Wilson-Cook Medical Company, America), low compliance water perfusion system, nitrogen pump and PENTEX LX-750 Fiber Choledochoscope (PENTEX Company, Japan). A triple lumen polyethylene manometry catheter was 200 cm in length with an outer diameter of 1.7 mm. The three sided holes in the distal end were 2 mm apart facing different directions.

Method

Every patient was fasted overnight and kept drug-free to avoid biliary passage pressure changes before the examination. The computer manometry parameter was set at nitrogen pressure 40 kPa and the water velocity at 0.5 mL/min. After the manometry tubes were connected and the T tube removed, choledochoscope was inserted through the T tube sinus tract to observe the papilla vermicular movements at the end of the common bile duct to see whether if there was stenosis, fibrosis or calculus present. All the tested patients had never had EST, balloon dilation of the papilla or papilla plastic repair. During the operation we often used mollis urinary canal of F8 as an alternative to the metallic probe to pass the papilla avoiding the damage of papilla. The papilla moved properly, no parenchyma diseases were found and the regular lockage movements were found. For those patients who had stones in the common bile duct, the stones were removed first. Thirty minutes after the removal, the manometry catheter was introduced *via* the side-pore of choledochoscope, through the papilla into the duodenum under the euthyphoria, and 30 s later the manometry was performed. The catheter is then dragged to the SO; its position in the SO could be confirmed by direct observation through choledochoscope and by the phase waves displayed on the monitor. The SO contractions were recorded in one continuous act by the manometry. Following the SO, the catheter then moved into the common bile duct where the pressure was measured. Lastly, the drugs were then administered. The entire procedure described runs in repetition for every 10 min. The manometry was repeated and the curves were recorded. The administration program is shown in Table 1. The Medication dosage abides by clinic. Ulinastatin was given in different dosage due to clinical application.

Parameter observation

The Sphincter of Oddi basal pressure (SOBP), amplitude (SOCA), frequency of contractions (SOF), duodenal pressure (DP), and common bile duct pressure (CBDP) were scored and analyzed. The pressure of duodenum was used as null point.

Statistical analysis

SPSS 11.5 statistical package was adopted for analysis. The statistical data of our research were all measurement data in a normal distribution. DP was used as null point, and the relative magnitude of the remaining indexes were computed. The results were expressed by mean ± SD. The means of the sample before and after the administration were compared, and we also conducted the matched-pairs interclass *t*-test.

RESULTS

Effects of H_2-receptor blocking pharmacon on SO pressure (Table 2)

SOBP and SOCA were decreased after Famotidine administration, but there was no statistical difference. SOBP and SOCA decreased noticeably after Cimetidine administration, which indicated that Cimetidine had negative inotropic effects on the SO.

Effects of protease inhibitor on SO pressure (Table 3)

In the Gabexate mesilate group, SOBP decreased apparently with the rate of 2500 U/min, which had a statistical significance. SOCA and SOF experienced a tendency to drop but it was insignificant statistically. In the Ulinastatin group, SOCA decreased evidently with Ulinastatin when given at 2500 U/min. SOBP, SOF and SOCA all decreased obviously with Ulinastatin at 5000 U/min, and 20 min later such decrease became more apparent.

Effects of gastro kinetic agents on SO pressure (Table 4)

SOBP and SOCA decreased markedly 20 min after oral administration of Domperidone, which had a statistical significance. SOCA decreased markedly 10 min after administration of Mosapride. There was no obvious change in the indexes after oral administration of Tegaserod.

DISCUSSION

The focus of biliary tract kinetic research is the SO, and

Table 1 Single administration program

Group	Cases	Medication name	Medication dosage	Medication channel
H_2-receptor blocking pharmacon	20	Famotidine	40 mg	intravenous injection
	20	Cimetidine	200 mg	intravenous injection
Protease inhibitor	25	Gabexate mesilate	2.5 mg/min	intravenous injection with micro pump continuing
	25	Ulinastatin	2500 U/min	intravenous injection with micro pump continuing
	25	Ulinastatin	5000 U/min	intravenous injection with micro pump continuing
Gastro kinetic agents	20	Domperidone	10 mg	Take orally
	20	Mosapride	5 mg	Take orally
	20	Tegaserod	12 mg	Take orally

the SO pressure is recognized as the index reflecting the SO motor function. SO manometry plays an important role in illustrating the disease etiology, pathogenesis, and turnover.

Thus far, the direct manometry is the gold standard to evaluate the SO motor function. At present, the most

common and recognized method is the endoscopic retrograde cholangiopancreatography (ERCP) simultaneous manometry. Although the endoscope manometry is widely used, its shortcomings do exist, such as the profuse endoscopic technique experience needed, the short manometry time and the pancreatitic risk[1]. Choledochoscope manometry adopts the same manometry theorem, manometry system and software with ERCP but uses different ways of catheterization manometry. Before the T tube is removed after a bile duct operation, the regular choledochoscopy is needed to avoid residual stones. When manometry is performed through choledochoscope, the measuring tube can reach the biliary tract directly and transit the SO. It is easy to operate, and no medication is required for the operation. Long term manometry research can be conducted with rare complications. In addition, the position of the measuring tube can be defined under the orthophoria in choledochoscope manometry, which makes the result more precise. The effects of the drugs on SO can be observed in choledochoscope manometry. However the shortcomings of choledochoscope manometry do exist, the subjects are all the patients with bile duct stone and post-operation, it is difficult to obtain the relative normal values. In this experiment, all the patients had clear pressure graphs, and no complications occurred. The effects of H_2-receptor blocking pharmacon, protease inhibitor, and gastro kinetic agents had on the SO composed to a pleasant result.

The confirmed SO activity rhythm increasing drugs at present are opium, Anticholinesterase drug, α-adrena receptor blocking pharmacon and H_1-receptor blocking pharmacon. While the SO activity rhythm decreasing drugs are M cholinergic receptor blocker, nitroester drugs, Ca-ion channel blocker, gastro kinetic agents and ®- receptor blocking pharmacon. We studied many different drugs according to the clinical practical medication.

Nitroester drugs can relax vascular smooth muscle, gastrointestinal tract smooth muscle and the SO. M cholinergic receptor has blocking function by inhibiting the cholinergic receptor on the smooth muscle. Our previous research had shown that Nitroester drugs and M cholinergic receptor have inhibitory effect on the SO[2,3]. It is commonly believed that morphine functions through the μ acceptor. It was found in the former research that morphine had excitatory effects on the SO motility[4-6]. Our experiment had shown that morphine had excitatory effect and tramadol had inhibitory effect on the SO, while pethidine had no apparent effect[7]. The effects of somatostatin and its analogue octreotide on the SO are distinct in different genera, and the mechanism of somatostatin accommodation on the SO motility has not been known yet[8]. Our previous research showed that administration density of somatostatin and its analogues should be paid special attention in clinical application, because small dose can excite the SO, which may increase the basic pressure, restrain biliary and pancreatic fluid, exacerbate the obstruction factors and finally affect the curative effect[9].

Histamine, H_2-receptor blocking pharmacon, Famotidine and Cimetidine are often clinically used for the treatment of gastric acid related diseases such as peptic ulcer, gastrinoma and gastroesophageal reflux. Recently their effects on gastrointestinal motility have been given more and more attention, but the inhibitory mechanism hasn't been known. In the experiment regarding the effects of histamine on the SO of opossum, Toouli *et al*[10] found that histamine' inhibitory effect on the SO was aroused by stimulating the H_1 receptor mediated inhibitory nerve, and the inhibitory nerve was non-adrenergic and non-cholinergic nerve having nothing to do with H_2 receptor. Sand *et al*[11] also found that histamine' inhibitory effect on the SO was mediated by H_1 receptor. While the research of Maples *et al*[12] showed that H_2 receptor agonist betazole could increase CDBP and was correlated to duodenum myoelectricity activity. After the antagonistic effect of Cimetidine, the duodenum myoelectricity activity and CDBP decreased to the baseline level, which showed that H_2-receptor blocking pharmacon had inhibitory effect on the biliary tract. The effect of Cimetidine on gastrointestinal motility might vary in different species and sites of action, but the mechanism was controversial. Some people believed that Cimetidine had the anti-effect on acetylcholine, so the effect on gastrointestinal motility was related to M receptor. Others believed that the inhibitory effect of Cimetidine occurred *via* the endogenous prostaglandin receptor. In our research, we found that SOBP and SOCA had the decreasing tendency after the administration of Famotidine, but there was no statistical difference. SOD, SOF and CDBP showed no difference, which indicated that they had no obvious effect on the SO. The experiment also showed that common dose of Cimetidine had inhibitory effect on the SO. Famotidine and Cimetidine were both H_2-receptor blocking pharmacon and mainly inhibited gastric acid secretion, however Famotidine was more effective. However, there was no identical display in the effect on the SO motility, so it might be concluded that their effect on the SO had nothing to do with the effect of H_2 receptor.

Gabexate mesilate and Ulinastatin are the common clinical protease inhibitor; proteinase inhibitor, and the common drugs for pancreatitis treatment. They have been reported to be effective on the prevention of post-ERCP pancreatitis[13,14]. However, at present, there are few studies on the effect of Gabexate mesilate on the SO. Research by Kobayashi *et al*[15] on Gabexate mesilate's inhibitory effect on the SO in dogs was realized by non-adrenergic and non-cholinergic passageway. Di Francesco *et al*[16] adopted the endoscope manometry to study Gabexate mesilate's effect on the SO. SOCA and SOF decreased after the administration, while SOBP showed no apparent

change. The pertinent literatures and reports on Ulinastatin's effect on the SO have not been seen yet. We found that SOBP decreased with the intravenous injection of Ulinastatin 2.5 mg/min, and SOCA and SOF showed no apparent change. SOBP, SOCA, and SOF decreased obviously 20 min after the administration of Ulinastatin at 2500 U/min. SOBP and SOF decreased obviously 10 min after the administration of Ulinastatin at 5000 U/min, and 20 min later the decrease became more apparent and SOCA also decreased apparently. Therefore, it could be supposed that Ulinastatin's effect on the SO was related to the medication time and drug concentration. Our results of manometry indicate that Gabexate mesilate and Ulinastatin had some influence on the SO. The administration of these agents could reduce the incidence of post-ERCP pancreatitis.

Domperidone is the peripheral dopamine receptor blocker, and has strong affinity with D2 receptor especially the gastrointestinal dopamine receptor. It has no cholinergic activity and it is free of atropine inhibition[17]. The results of the studies on Domperidone's effect on the SO are different. Tankurt *et al*[18] found in the experiment that in the Domperidone group Gallbladder contraction increased apparently after administration. He believed that Domperidone's effect on the Gallbladder was nonspecific, and might not depend on dopamine receptor. However, its effect on the SO has not been reported. We found in the experiment that SOBP and SOCA decreased after the administration of Domperidone, and it might have non-adrenergic and non-cholinergic mechanisms. Mosapride stimulates the release of acetylcholine by exciting the 5-HT_4 of the myenteric nerve plexus, and strengthens the movement of the gaster and duodenum[19]. No reports on Mosapride's effect on the SO have been known yet. However, for the homoplastic cisapride there are studies and reports on its inhibitory effect on the SO, and it can be inferred that the effect is regulated by non-adrenergic and non-cholinergic nerves[20]. Our study results showed that Mosapride had an inhibitory effect on the SO, and its' mechanism of action might be similar to or the same as cisapride. Tegaserod is 5-HT_4 receptor partial agonist[21]. In the Tegaserod group, we didn't find the similar inhibitory effect on the SO, which might be related to Tegaserod's high selectivity towards the receptor. In addition, the result might also be influenced by the short administration time we spent on manometry.

Above all, we adopted simple but effective choledochoscope manometry to study the SO motility, and explored the effect of many kinds of drugs on the SO rhythm, which profited our clinical practice. However, their mechanisms of action are not the same, and they may function in different aspects such as nerves, hormone etc. Their influence on different species may be also different. Their mechanisms of action warrant further study.

Abstract

There is a strong association between porphyria cutanea tarda (PCT) and chronic viral hepatitis C. Therapy for chronic viral hepatitis C may improve PCT. However, there are only a few reports of the *de novo* development of PCT during therapy for chronic viral hepatitis C. We describe the development of PCT in a 56-year-old patient with chronic viral hepatitis C after 12 wk of peginterferon/ribavirin therapy. In addition, the patient was homozygous for the H63D hereditary hemochromatosis gene (*HFE*) mutation. The association of PCT with chronic viral hepatitis C and the possible role of hepatic iron overload and ribavirin-induced hemolytic anemia in the development of PCT during therapy for chronic viral hepatitis C are discussed.

Key words: Porphyria; Hepatitis C virus; Ribavirin; Pegylated interferon; Hemochromatosis

INTRODUCTION

Porphyria cutanea tarda (PCT), the most common of the porphyrias, results from reduced activity of uroporphyrinogen decarboxylase (UROD), an enzyme in the heme biosynthetic pathway[1]. Clinical signs of PCT include photodistributed erythema, skin fragility, bullae, erosions and hypertrichosis. A strong association between PCT and hepatitis C virus (HCV) infection is well established[2]. Improvement of PCT during HCV treatment with interferon has been frequently described[3-6]. On the other hand, *de novo* occurrence of PCT during interferon plus ribavirin therapy for chronic viral hepatitis C has previously been described in only four patients[7-9]. Herein we describe the *de novo* development of PCT in a patient with chronic HCV infection undergoing combined peginterferon/ribavirin therapy, who was also found to be homozygous for the H63D mutation of the *HFE* gene.

CASE REPORT

Chronic hepatitis C (genotype 1a) was diagnosed in a 56-year-old man with a history of blood transfusions while serving in Vietnam. Past medical history included alcohol and cocaine dependency, as well as a history of treatment for rheumatoid arthritis, which was later characterized as osteoarthritis. He denied alcohol use for more than four years prior to initiation of ribavirin/interferon therapy. Prior tests for hepatitis B and HIV were negative. He did not smoke. Family history was noncontributory. At presentation, liver biopsy showed mildly active chronic hepatitis C with portal fibrosis (Batts and Ludwig grade 2 inflammation and stage 1 fibrosis). Hepatic iron deposition was not commented on. HCV-RNA PCR showed 102 500 copies and serum transaminases were mildly elevated (AST 53 IU/L and ALT 100 IU/L). The patient was treated with peginterferon-α2b (150 μg/wk) and ribavirin (1200 mg/day) for 44 weeks of a planned 48-week course. Treatment ceased early secondary to anemia and neutropenia. Viral clearance was achieved after 16 wk of treatment and HCV-RNA PCR remained negative at the

end of and 6 mo following treatment.

After 12 wk of therapy, the patient presented with multiple hand blisters and erosions in various stages of healing, consistent with PCT. Diagnosis of PCT was confirmed by detection of elevated urinary uroporphyrin (599 μg/24 h, N < 44) and heptacarboxyl-porphyrin (799 μg/24 h, N < 12) levels. Because of the patient's anemia (hemoglobin dropped from 15.7 g/dL pretreatment to 10.4 g/dL at onset of PCT), treatment of PCT with phlebotomy was deferred until completion of his peginterferon/ribavirin treatment. Clinical resolution of PCT occurred thereafter with repeated phlebotomy. Prior to initiation of phlebotomy, ferritin was markedly elevated (2920 ng/mL, N < 464) and the transferrin saturation was 81%. The patient was found to be homozygous for the H63D *HFE* gene mutation.

DISCUSSION

PCT arises from decreased activity of hepatic uroporphyrinogen decarboxylase (UROD), an enzyme in the heme synthetic pathway[1,10]. Although about 20% of cases involve mutations in the UROD gene (type Ⅱ PCT), nearly all other occurrences (approximately 80%) are considered to arise sporadically (type Ⅰ PCT)[1]. The genetic defects in type Ⅱ PCT alone are not sufficient to cause phenotypic PCT, for they reduce UROD activity by no more than 50%[10]. Other contributing factors, including those that may be associated with type I PCT, must be present for phenotypic expression. Whether sporadic or familial, the clinical manifestations of PCT are the same, including skin fragility, erythema, bullae, erosions, hypertrichosis and milia in sun-exposed areas of the skin[11]. These lesions result from the photosensitizing effects of porphyrins that accumulate in the skin or dermal blood vessels[12]. The pathogenesis of the enzymatic defect in sporadic PCT is unclear, but is postulated to involve increased oxidative stress in the liver, modulated by multiple exogenous and endogenous factors[12,13].

Well-recognized risk factors for PCT include HCV infection, hereditary hemochromatosis and other iron overload syndromes, as determined by mutations in the *HFE* gene, excessive alcohol use, HIV infection, and exposure to estrogen (including pregnancy) and polyhalogenated aromatic compounds[10]. The association of PCT with chronic HCV infection is particularly strong. The prevalence of HCV infection in patients with PCT was found to be about 50% in a recent systematic review and meta-analysis, though there was marked regional variation[2]. The underlying mechanism is unclear, despite this strong association of PCT with chronic HCV infection[11].

Mainstays of PCT management include phlebotomy, chloroquine and avoidance of sun exposure[12]. HCV-associated PCT has, similarly, been reported to improve following initiation of interferon monotherapy[3-6], though improvement with interferon administration is not universally described[14]. Likewise, we found a single report describing the onset of HCV-associated PCT 2 years following initiation of interferon monotherapy in a patient who also had non-Hodgkins lymphoma and dermatomyositis[15]. The skin lesions resolved with chemotherapy and the authors hypothesized that the lymphoma had triggered PCT.

In addition to the case we report here, *de novo* occurrence of PCT during interferon and ribavirin therapy for chronic HCV infection has been described in only 4 other cases[7-9]. Jessner *et al*[7] reported what they considered to be *de novo* occurrence of PCT after 4 months of therapy in a woman who had noticed occasional self-resolving small blisters prior to HCV therapy. A liver biopsy showed moderate iron deposition. She was found to have both type Ⅰ ("familial") PCT and heterozygosity for the C282Y HFE gene defect. Thevenot *et al*[8] described two patients without HFE gene defects who had onset of PCT one and two months, respectively, after initiating ribavirin and interferon therapy. One patient was noted to have a ferritin of 2408 ng/mL and the other patients' liver biopsy showed mild iron deposition in Kupffer cells. Mutation analysis of the UROD gene was not reported in either case. Finally, Frider *et al*[9] reported a 47-year-old patient who developed PCT after 44 weeks of ribavirin and interferon therapy. HFE genotyping revealed C282Y/H63D compound heterozygosity.

In all 5 reported cases of *de novo* PCT during ribavirin/interferon therapy, including that we describe here, the patients had clinical evidence of systemic or hepatic iron overload. Although the mechanism is unclear, iron overload is believed to play a significant role in the pathogenesis of PCT[16,17], possibly modulated by an iron-dependent reversible inactivation of hepatic UROD[16]. Supporting this are the oft-noted observations that the majority of patients with PCT exhibit some iron overload, iron depletion improves PCT, and iron administration produces relapse[13,16,17].

Possibly contributing to hepatic iron loading in the reported *de novo* occurrences of PCT was the administration of ribavirin. A well-recognized major side effect of ribavirin is dose-dependent reversible hemolytic anemia[18]. Although Thevenot *et al*[8] did not comment on anemia, Jessner *et al*[7] noted onset of anemia concomitant with diagnosis of PCT. In addition to anemia, hepatic iron stores have been found to increase following prolonged ribavirin administration[19,20], with a relatively greater concentration of iron demonstrated in hepatocytes *versus* Kupffer cells[20]. The additional hepatic iron loading attributable to ribavirin administration may reduce the level of UROD activity sufficiently for PCT to become manifest in otherwise susceptible individuals. Consequently, screening for treatable PCT-associated conditions, such as hemochromatosis, should be considered prior to initiation of peginterferon/ribavirin therapy for chronic HCV.

Abstract

Jejunal diverticulosis (JD) is a rare clinical entity. The potential complications of this condition are discussed here through a series of cases presented to our centre. A retrospective analysis of four cases, which were diagnosed and treated, was performed. These included two cases of gastrointestinal haemorrhage, one case of perforation and one case of enterolith obstruction. All of these cases were secondary to jejunal diverticulosis and treated surgically. This was accompanied by a literature search to identify the different modalities for diagnosis and treatment of this condition. JD is rare and may lead to a diagnostic delay. Awareness of the wide spectrum of potential complications can prevent this delay.

INTRODUCTION

The majority of patients with jejunal diverticula are asymptomatic[1]. Jejunal diverticula are the rarest of all small bowel diverticula. An incidence of 0.5%-2.3% of small bowel contrast studies and 0.3%-4.5% of autopsies have been reported in the literature[2,3]. Chronic abdominal symptoms like abdominal pain/nausea and vomiting/flatulence/diarrhoea and malabsorption have been described in some reports. However, jejunal diverticulosis (JD) may present more acutely. Major complications include diverticulitis, gastrointestinal (GI) haemorrhage, intestinal obstruction and acute perforation[4,5]. We discuss four patients who presented with complications of JD.

CASE REPORT

Case 1: Gastrointestinal haemorrhage

A 71-year-old male was admitted as an emergency with a day history of lower abdominal pain associated with five episodes of passing altered blood per rectum (PR) and vomiting. He had no recent history of change in bowel habit. Past medical history included a laparotomy for a perforated appendix, duodenal ulcer and deep vein thrombosis. He was haemodynamically stable with a soft, non-tender abdomen. Rectal examination revealed dark blood with no masses. His Hb was 12.0 g/dL, white cell count was 12.0 cells/mm^3 and a raised urea of 12.9 mmol/L.

The following day he passed approximately 750 mL of blood PR with associated hypotension and a drop in his Hb to 5.5 g/dL. He was resuscitated and an upper gastrointestinal endoscopy was performed, which revealed a hiatus hernia. A flexible sigmoidoscopy showed dark blood but no identifiable bleeding source. An urgent mesenteric angiogram demonstrated extravasation of contrast into the proximal jejunum from the 2nd jejunal branch of the superior mesenteric artery.

He then underwent a laparotomy which revealed a 1.5 cm solitary jejunal diverticulum 25 cm from the duodeno-jejunal flexure. An enteroscopy *via* jejunal access showed a pulsating vessel at the neck of the diverticulum. A local jejunal resection was carried out with a functional end-to-end stapled anastomosis. The postoperative period was unremarkable and he was discharged home on day 9. His out patient review at 6 wk showed a good recovery with no further bleeding.

Case 2: Gastrointestinal haemorrhage

A 62-year-old Indian male presented with a day history of altered PR bleeding. He had a similar episode of this per rectal bleeding four years prior to this episode with no apparent cause established. He had an episode of loss of consciousness and his blood pressure dropped to 93/54 mmHg with 6.8 g/dL haemoglobin. After fluid resuscitation and 3 unit blood transfusion, he had a normal upper gastrointestinal endoscopy. He was discharged with an out-patient colonoscopy requested and had no further bleeding.

He re-presented on the 4th day with further PR bleeding with a blood pressure of 60/40 mmHg and 5.8 g/dL haemoglobin. Despite resuscitation with blood transfusion, his bleeding continued with a further drop of his haemoglobin to 3.9 g/dL. As he was haemodynamically unstable, he underwent an emergency laparotomy, which revealed blood in the proximal small bowel extending to the transverse colon with multiple jejunal diverticula. These first appeared 15 cm distal to the duodeno-jejunal flexure. Following cross clamping of this jejunal segment containing diverticula, no further bleeding was evident. This segment was resected and a side to side anastomosis was performed.

This gentleman spent a further 6 d in the Intensive Care Unit where he required ventilatory and inotropic support. The remainder of his in patient stay was unremarkable and he was discharged on day 12. His out patient follow-up has revealed a large, symptomatic incisional hernia for which he is currently awaiting repair.

Case 3: Perforation with abscess formation

A 66-year-old female presented with a 5-d history of right sided abdominal pain and watery mucoid diarrhoea. She was reviewed two days ago in the emergency department and diagnosed with exacerbation of irritable bowel syndrome. Her past medical history included angina/Sjorgen's syndrome and a previous appendicectomy. On examination she was haemodynamically stable and tender in both iliac fossae, being more prominent on the right side. Her initial white cell count was 11.3 g/dL with an abnormal renal function-urea of 11.4 and a creatinine of 156. An initial ultrasound scan of the abdomen and pelvis was normal. A computed tomography scan, the following day, revealed a modest amount of free fluid in the abdominal cavity. Free air was shown in the retroperitoneum anterior to the 2nd, 3rd, and 4th parts of the duodenum. A perforation was also noted in a thickened small bowel loop.

A laparotomy demonstrated multiple jejunal diverticular, one of which was perforated locally. This formed an abscess, the wall of which was formed by the mesentery corresponding to the perforated jejunal loop. A segmental resection of the jejunum was performed with a side to side stapled anastomosis. Post operative recovery was unremarkable initially and she was discharged home 8 d post operation. A small subcutaneous abscess was noted on follow-up, which was incised and drained. There were no other post operative problems subsequently.

Case 4: Small bowel obstruction

This 80-year-old gentleman presented with a 2-d history of left iliac fossa pain associated with bilious vomiting. He had not passed a bowel motion since the day before but had had intermittent diarrhoea for the preceding 3 wk. He was known to have sigmoid diverticula, confirmed on colonoscopy. His other medical history included a coronary artery bypass graft, non-insulin dependent diabetes mellitus and an appendicectomy. On examination he was mildly distended with tenderness in his lower abdomen with no associated peritonism. His white cell count was 15.5 cells/mm^3 and his abdominal radiograph showed no obvious abnormality. Computed tomography scan showed dilated small bowel loops with extensive jejunal diverticula.

Due to failure of conservative management, a laparotomy was performed, which revealed dilated proximal bowel with a transition point at the diverticular segment of the jejunum. Multiple large and medium sized inflamed jejunal diverticula were noted. An enterotomy was performed and an obstructing enterolith was removed. One of the inflamed jejunal diverticula was perforated but sealed by omental adhesions. This perforation was subsequently sutured. Post operatively, this patient made a full recovery and was discharged 8 d later. This gentleman's follow- up has been uneventful.

DISCUSSION

Jejunal diverticulosis was first described by Somerling in 1794 and by Sir Astley Cooper in 1807[6]. These false diverticula are acquired outpouchings of mucosa commonly found on the mesenteric border of the jejunum. Jejunal diverticula share similarities with colonic diverticula in that the mucosal herniations occur through gaps in the muscle layers along pathways of the visceral vessels. The sizes of these diverticula vary between a few millimetres to greater than ten centimetres. Jejunal diverticula may be the only site in the gastrointestinal tract. Of these diverticula, 35% are associated with colonic diverticula, 26% with duodenal diverticula and 2% with oesophageal diverticula, respectively[7,8].

Small bowel diverticula are frequently encountered in the elderly and have a slight male predominance[9]. Their presentation is variable from asymptomatic to chronic abdominal symptoms and the complications described in our case series. Their relative clinical rarity and varied presentation may make diagnosis both delayed and difficult. This is exemplified in our third patient whose symptoms were initially attributable to her previous diagnosis of irritable bowel syndrome. The discovery of jejunal diverticula may be incidental in imaging studies or may be found at laparotomy as the cause of clinical deterioration. Radiographic studies, which may incidentally demonstrate jejunal diverticula, are contrast enhanced small bowel follow through studies or computed tomography scans.

Haemorrhage from jejunal diverticula predominantly presents as lower gastrointestinal bleeding although cases of haematemesis have been reported[10]. This bleeding may be acute or chronic with iron deficiency anaemia noted. Gastrointestinal haemorrhage from the jejunum has a similar aetiology to that seen in the large bowel diverticula in that the diverticulum erodes through a perforating artery. Previous literature has presented flow charts to direct the clinician in establishing the difficult diagnosis of local gastrointestinal haemorrhage[11]. If the patient is considered haemodynamically stable, then endoscopic techniques, such as oesophagogastr oduodenoscopy or colonoscopy, may be used. These techniques, however, cannot visualise the jejunum. Small bowel contrast studies and computed tomography scans are able to visualise such regions and thus establish the diagnosis. The most sensitive imaging studies are technetium red cell-tagged scan and/or mesenteric angiogram. In our first patient, the latter modality was the choice of imaging technique and it aided identifying the exact bleeding source. The technique also has the advantage of offering mesenteric embolization. Haemodynamic instability warrants emergency laparotomy, which occurred in both of our patients suffering from a gastrointestinal haemorrhage. In such cases, intense supportive therapy is required adjunct to acute surgical treatment with the purpose of finding the precise bleeding point and ensuring definitive treatment. The preferred approach to acute haemorrhage is intestinal resection of the bleeding jejunal segment with primary anastomoses[12].

Perforation may present as a localised perforation with or without generalized peritonitis. Alternatively, the presentation may be that of a perforation with formation of a walled off abscess[12-14]. Perforation is rare, which may be related to the low intraluminal pressures within the small bowel. Instigating factors for perforation have been shown to be related to a necrotizing inflammatory reaction in 82% of cases, followed by blunt trauma in 12% of cases and foreign body impaction in 6% of cases[15]. Computed tomography is the most useful diagnostic imaging tool in such cases[16]. It has proved to be superior to barium studies in demonstrating the mural, serosal and mesenteric extent of disease[17-19]. The management is surgical with resection of the diseased segment advocated followed by primary jejuno-jejunal or jejuno-ileal anastomoses. Previous studies have shown that a laparoscopic approach is successful[20]. Extensive resection should be avoided as this has the potential to lead to short bowel syndrome. Novak *et al*[21] have demonstrated a few cases where a localised perforation of jejunal diverticula could be treated non-surgically with either intravenous antibiotic therapy or computed tomography-assisted percutaneous drainage of the abscess.

Acute intestinal obstruction is another complication of jejunal diverticula. Obstruction may be related to extrinsic compression from a nearby loop of jejunum containing a large diverticulum or from intussusception[12,22] or may be non-mechanical such as dyskinesia[23]. Obstruction may also be secondary to enterolith formation or gallstone migration. Enteroliths may form inside the diverticulum and consist of choleic acid, either de novo or around a bezoar. The acidic environment within diverticula is ideal for aiding the metabolism of bile salts to choleic acid, hence enterolith obstruction[24]. There are various diagnostic modalities which can be useful in such presentations. Abdominal radiographs may provide evidence of stones in the abdomen external to sites such as the gallbladder or renal tracts. Ultrasound examination may confirm or exclude gallstones. The diagnosis may be confirmed with either barium imaging or computed tomography scanning. Management may be either conservative or surgical. In our case, a trial of conservative treatment was unsuccessful and thus resulted in operative intervention. Strategies, which may be used in laparotomy, are crushing of the enteroliths and milking their fragments into the colon[22,24-28]. If this is unsuccessful, an enterostomy can be performed proximal or distal to the site of obstruction with the enterolith removed. If these two steps are unsuccessful, resection of the involved jejunal segment may have to be considered[27-29].

Though JD is rare, awareness of the wide spectrum of associated complications may be useful in preventing delay in treatment.

Abstract

We report an unusual pathological entity of a pseudoaneurysm of the right hepatic artery, which developed two years after the resection of a type Ⅱ hilar cholangiocarcinoma and secondary to an excessive skeletonization for regional lymphadenectomy and neoadjuvant external-beam radiotherapy. After a sudden and massive hematemesis, a multidetector computed tomographic angiography (MDCTA) showed a hepatic artery pseudoaneurysm. Angiography with embolization of the pseudoaneurysm was attempted using microcoils with adequate patency of the hepatic artery and the occlusion of the pseudoaneurysm. A new episode of hematemesis 3 wk later revealed a partial revascularization of the pseudoaneurysm. A definitive interventional radiological treatment consisting of transarterial embolization (TAE) of the right hepatic artery with stainless steel coils and polyvinyl alcohol particles was effective and well-tolerated with normal liver function tests and without signs of liver infarction.

Key words: Hepatic artery pseudoaneurysm; Hilar cholangiocarcinoma; Pseudoaneurysm embolization; Transarterial embolization; Chemoradiotherapy

INTRODUCTION

Bleeding from a pseudoaneurysm of major visceral arteries as a result of an adjacent septic condition or an intraoperative injury may lead to a troublesome emergency. Hepatic artery pseudoaneurysm can result in hemorrhage into the biliary tract when an abnormal communication is established between the vessel and the bile duct. Degeneration and weakness of hepatic arterial wall can be secondary to a trauma (accidental or iatrogenic) or an inflammation of the biliary tract [1,2]. A mechanical injury of the artery during operation, mainly due to lymph node dissection for malignancy, may be a clear predisposing factor for delayed arterial bleeding after hepatobiliary surgery.

We report an unusual pathological entity of a pseudoaneurysm of the right hepatic artery, which developed two years after the resection of a type Ⅱ hilar cholangiocarcinoma. This resulted in catastrophic upper gastrointestinal bleeding, which was ultimately treated by an aggressive combination of interventional radiological procedures.

CASE REPORT

A 78-year-old man with cholangiocarcinoma involving the proximal bile ducts (hilar cholangiocarcinoma or Klatskin tumor) was referred for surgical treatment in July 2005. Abdominal pain, discomfort, anorexia, weight loss, pruritus and jaundice with bilirubin of 18 mg/dL

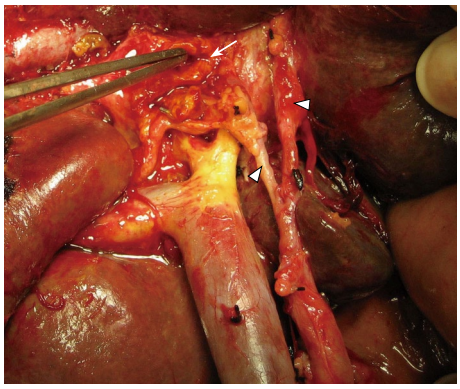

Figure 1 Skeletonization for regional lymphadenectomy with removal of neural and lymphoid tissues from hepatoduodenal ligament and liver hilus in a type Ⅱ hilar cholangiocarcinoma. A too-tight dissection around the right and left hepatic arteries (arrow heads) is shown. Left hepatic duct (arrow) is being prepared for bilio-enteric anastomosis.

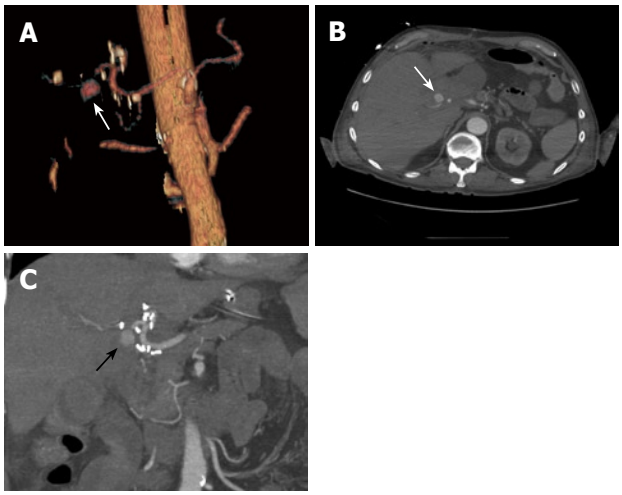

Figure 2 MDCTA. **A**: Arterial phase image precisely depicts a large pseudoaneurysm originating from the right hepatic artery (arrow). **B** and **C**: Jejunum Y-limb did not show a demonstrable communication with the arterial sac in cross-sectional and coronal views, respectively.

were the main symptoms. After a magnetic resonance imaging cholangiography, the patient was diagnosed as having a type Ⅱ cholangiocarcinoma (Bismuth-Corlette modified classification) without invasion of main portal vein, the proper hepatic artery or its branches[3] and a preoperative stage IB, according to AJCC staging system (T2N0M0). Percutaneous transhepatic biliary drainage and subsequent placement of a temporary endoprosthesis were performed prior to resection. A standard extrahepatic biliary tract excision associated with segment I resection was performed through an inverted T-incision. Skeletonization for regional lymphadenectomy with removal of neural and lymphoid tissues from hepatoduodenal ligament and liver hilus was also added (R0 resection) (Figure 1). Bilio-enteric continuity was restored by hepatojejunostomy to a Roux-en-Y loop of jejunum. Three duct orifices (right, left and segment I bile ducts) were anastomosed. The pathological result of the lymphadenectomy revealed metastases to two perihilar lymph nodes (N1). The postoperative stage was IIB (T2N1M0). The patient was discharged 11 d later without complications. Adjuvant therapy consisted of a gemcitabine-based regimen (1000 mg/m^2 as a 30-min infusion every 2 wk until achieving 6 treatment cycles) combined with conventional external-beam radiotherapy (5000 cGy given with an equivalent total dose in a 200 cGy/25 fractions). The time interval between operation and before starting chemo-radiotherapy was 6 wk.

In October 2007, the patient developed a transient minor gastrointestinal bleeding without hemodynamic repercussion and an upper digestive endoscopy disclosed no evidence of gastroduodenal bleeding. Ten days later, the patient was readmitted because of a sudden and massive hematemesis, causing hypovolemia and shock. After an initial resuscitation in ICU, hemodynamic stability was achieved. An upper digestive endoscopy only revealed an hemorrhage from the Y-limb jejunum. A multidetector computed tomographic angiography (MDCTA) was performed with a multidetector 16-row computed tomography scanner. Arterial phase images were obtained after intravenous injection of 150 mL of contrast material at a rate of 4 mL/s using the bolus triggering technique (Figure 2)[4]. This technique precisely detected a large pseudoaneurysm originating from the right hepatic artery. Angiography was carried out immediately with a 4 Fr. catheter. Contrast was seen jetting into the aneurysm, but no communication with the intestine could be proven. Embolization of the pseudoaneurysm was attempted using microcoils to stop the inflow into the pseudoaneurysmal lumen. Patency of the hepatic artery and its branches, and the occlusion of the pseudoaneurysm were confirmed (Figure 3). The patient was discharged in acceptable clinical condition with an uneventfully outcome.

Three weeks later, the patient suffered from a new episode of hematemesis, requiring readmission and supportive treatment. A new angiography displayed a partial revascularization of the pseudoaneurysm (Figure 4A). A definitive interventional radiological treatment was decided, consisting of transarterial embolization (TAE) of the right hepatic artery with stainless steel coils and polyvinyl alcohol particles (Figure 4B). Liver function tests were normal, with a transient elevation of transaminases. Embolization of the complete right hepatic artery was well-tolerated, without signs of liver infarction. The patient is in good clinical condition 5 mo after this last procedure.

DISCUSSION

Three major predisposing factors for delayed arterial bleeding after hepatobiliary surgery have been suggested[1]: (1) digestion of hepatic arterial wall due to infectious bile from anastomotic leakage; (2) arterial irritation by localized abscess in the inferior hepatic space; and (3) a mechanical injury of the artery during operation, mainly due to lymph node dissection for malignancy. The result is the formation of an arterial sac with a possible rupture into the biliary tract, and

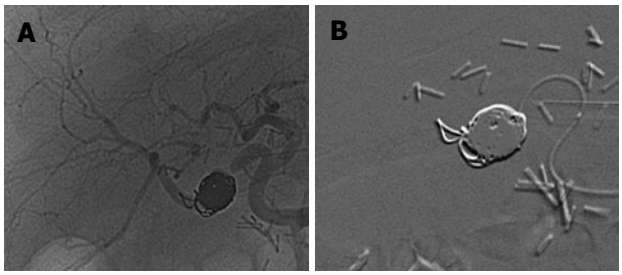

Figure 3 Patency of the hepatic artery and its branches, and the occlusion of the pseudoaneurysm. **A**: Embolization of the pseudoaneurysm using microcoils to stop the inflow into the pseudoaneurysmal lumen with patency of the hepatic artery and its branches. **B**: Subtracted angiogram after right hepatic artery pseudoaneurysm occlusion with stainless steel coils.

Figure 4 Partial revascularization of the pseudoaneurysm and TAE of the right hepatic artery. **A**: Angiography 3 wk after the embolization of the right hepatic artery pseudoaneurysm with a partial revascularization of the arterial sac (arrow) and a distal migration of coils (arrow head). A partial enteric migration of microcoils after the first and selective embolization suggests an arterio-enteric fistula origin. **B**: TAE of the right hepatic artery with stainless steel coils and polyvinyl alcohol particles. No distal arterial flow can be shown.

consequently, hemobilia. Surgery of the biliary tract may damage the hepatic artery by the dissection or suture, which may result in an arteriobiliary fistula or in a false aneurysm eroding into the extrahepatic bile ducts[5]. When a patient develops bleeding 1 or 2 wk after surgery for hilar cholangiocarcinoma, especially when the event is sudden in onset with hemobilia, arterial injury should be suspected. However, a late catastrophic bleeding requiring life-supporting treatment is unusual after surgery for Klatskin tumor. To our knowledge, there is only one case reported by Siablis *et al*[6] in which a hemobilia secondary to hepatic artery pseudoaneurysm after a resected IIIb Klatskin tumor appeared two years later due to a nearby biloma. In the absence of previous biliary leakage, we propose different explanations for the etiology of artery pseudoaneurysm in the present case report: (1) an excessive skeletonization for regional lymphadenectomy with removal of neural and lymphoid tissues; and (2) postoperative external-beam radiotherapy. Usually, the vasculature is injured by skeletonization for lymphadenectomy during radical surgery and too-tight ligation around the arterial conduit[7,8]. External radiotherapy may cause a degeneration of the arterial media. These two factors, alone or associated, can cause an iatrogenic trauma of the hepatic artery wall and, subsequently, the development of a false arterial sac. Another factor may be the short time interval between operation and before starting chemo-radiotherapy (6 wk), which probably contributed to the pre-existing vessel trauma and affecting optimal wound healing. However, the presence of positive lymph nodes suggested a more advanced disease than planned preoperatively and, consequently; chemo-radiotherapy was administered promptly after surgery in this patient.

MDCTA is a non-invasive modality to select patients who must be treated with angiographic intervention or surgery[4]. This technique is better than conventional contrasted-tomography and shows a good correlation with digital subtraction angiography. A sentinel bleeding as a precursor of vessel erosion after biliary surgery for hilar cholangiocarcinoma may lead to a prompt diagnosis preferentially with MDCTA. We cannot ascertain whether the GI bleeding was coming from an arterio-enteric or an arterio-bilial fistula. However, as shown in Figure 4A, a partial enteric migration of microcoils after the first and selective embolization suggests an arterio-enteric fistula origin.

In the setting of a prior complex bilio-enteric surgery, a new open surgical approach is not recommended because re-entering the previous scarred operative field for repair and hemostasis by suturing hepatic artery or placing a new conduit graft to restore circulation is too difficult and dangerous. Interventional radiology with selective embolization of pseudoanerysm is a safe and a definitive treatment in most of the cases. Angiographic embolization should be performed proximal and distal to the origin of the pseudoaneurysm rather than proceeding with embolization into the pseudoaneurysm cavity[7,9]. Newer technology detachable coils developed for neurovascular procedures may play a role in occluding pseudoaneurysms. These coils are placed into the pseudoaneurysm through microcatheters. Once they are placed in position adequately filling the space needed and stable, they can be released by a low voltage electric charge through the attachment wire. If the radiologist is not satisfied with coil placement or if the distal flow is compromised it can simply be withdrawn without detachment[10].

The best procedure after microcoil-embolization failure is not clear. Some authors suggest good results by placing covered grafts to secure hepatic arterial flow, guiding the blood flow into the proper direction out of the pseudoaneurysmal lumen, avoiding the possibility of interfering with arterial flow to the liver[11-15]. Nonetheless, the dual blood supply to the liver makes it extremely tolerant of arterial occlusion for haemostasis. Indeed, the compensatory arterial circulation to the liver after arterial ligation for the treatment of ruptured hepatic artery has been recognized by Michels *et al*[16]. At least 26 possible routes of collateral arterial blood supply to the liver from the common hepatic trunk were described. The main collateral pathways to the liver after TAE included the right inferior phrenic artery, the aberrant left hepatic artery and the intrahepatic communicating branches. The main vascular collateral pathways in the liver may be reliable in an "undisturbed or virgin liver". In post-resection, where the liver may have undergone extensive

mobilization, these collaterals may have been disrupted and may be unreliable. However, we performed the procedure without this extensive mobilization of the liver, maintaining the native ligaments of the liver and only mobilizing perihilar and hilar tissues. Phrenic arteries and intrahepatic communicating branches were well preserved. In any case, complete hepatic occlusion cannot be a standard approach, and it has only place as an extreme solution for an extremely urgent patient with selective embolization failure and/or a high-risky surgical intervention. In this setting, TAE on the hepatic artery has generally been considered to be relatively safe if the portal blood flow is preserved.

Abstract

Stapled hemorrhoidopexy is a surgical procedure used worldwide for the treatment of grade Ⅲ and Ⅳ hemorrhoids in all age groups. However, life-threatening complications occur occasionally. The following case report describes the development of pelvic sepsis after stapled hemorrhoidopexy. A literature review of techniques used to manage major septic complications after stapled hemorrhoidopexy was performed. There is no standardized treatment currently available. Stapled hemorrhoidopexy is a safe, effective and time-efficient procedure in the hands of experienced colorectal surgeons.

Key words: Hemorrhoids; Hemorrhoids/treatment; Sepsis; Stapled hemorrhoidopexy; Circular mucosectomy

INTRODUCTION

Stapled hemorrhoidopexy is used worldwide for the treatment of grade Ⅲ and Ⅳ hemorrhoids, because it is a safe, effective and time-efficient procedure for all age groups[1,2]. However, life-threatening complications occur occasionally[3,4]. We carried out a literature search to review the treatment options for managing major septic complications after stapled hemorrhoidopexy. Since there is no standardized treatment, we propose diagnostic and therapeutic guidelines for this complication.

CASE REPORT

A 26-year-old female patient was referred to our hospital with grade Ⅲ-Ⅳ hemorrhoids. She underwent a circular mucosectomy by a stapling device (PPH03, 33 mm, Ethicon EndoSurgery, Cincinnati, OH, USA). Clinical examination showed fully intact doughnuts. The patient recovered well, and left the hospital without any complaints.

After 4 d, she was readmitted with fever and pain over the lower abdomen, without any rebound tenderness. Laboratory tests showed leucocytes count of 16.9×10^9/L (reference 4.0-10 $\times 10^9$/L) and a C-reactive protein of 298 mg/L (reference CRP < 6 mg/L). Computer tomography (CT) scan with rectal contrast showed a presacral fluid collection with gas extending to the retroperitoneal space (Figures 1 and 2). A rectal perforation with a presacral abscess was diagnosed. Laparotomy showed the presence of hematomas in the sigmoid mesentery and in the retroperitoneum. A loop ileostomy was performed. Rectal examination showed a perforation at the right dorsolateral side of the rectum. A Foley catheter was inserted into the presacral space. Postoperatively, the patient received antibiotics, and she was discharged after 19 d.

DISCUSSION

During the last decade, stapled hemorrhoidopexy has become increasingly popular for the treatment of symptomatic grade Ⅲ and Ⅳ hemorrhoids. Stapled hemorrhoidopexy does not remove the hemorrhoids, but rather a strip of mucosa and submucosa at the top of the hemorrhoids is removed. An anastomosis of the proximal and distal mucosa and submucosa is made through the staple line, approximately 4 cm above the dentate line[4,5].

Figure 1 Axial image CT scan: Free air near the staple line.

Figure 2 Sagital reconstruction CT scan with rectal contrast: presacral abscess.

Septic complications after stapled hemorrhoidopexy such as in the present case are rare. Brusciano *et al*[5] evaluated the causes of reintervention in patients with complicated or failed stapled hemorrhoidopexy. The reoperation rate was 5.1%. Anorectal sepsis was the indication for reintervention in 16.9% of patients, which is 0.9% of all patients, whereas retro-rectal hematoma occurred in 1.5% patients. An survey of 224 departments of surgery in Germany, involving a total of 4635 stapled hemorrhoidopexies, revealed three cases of rectal perforation, one case of a large retro-rectal hematoma and one patient with lethal sepsis from Fournier's gangrene[6]. The cause of severe sepsis and retroperitoneal sepsis associated with both surgical and non-surgical treatment of hemorrhoids remains uncertain. It has been postulated that stapling itself may allow bacterial entry into the perirectal region. Full-thickness wall stapling may also allow organism to reach the perirectal space. By contrast, the presence of muscle tissue in the excised specimens is not uncommon. Several studies have observed muscle tissue in the doughnuts in 100% of patients[7,8].

There is no standard treatment for sepsis after stapled hemorrhoidopexy, and several different approaches have been used. Molloy and Kingsmore[3] reported a case of retroperitoneal sepsis, which required exploratory laparotomy and an end colostomy. The presacral space was drained. The staple line appeared to be normal and no rectal perforation was identified. Maw *et al*[9] reported a case of retroperitoneal sepsis, which was treated with intravenous antibiotics alone, without any surgical intervention. The staple line appeared to be intact on rectal examination. Wong *et al*[10] described a patient who had an interrupted line and a rectal perforation just above the peritoneal reflection resulting in a fecal peritonitis. The patient was treated with an end colostomy. Pessaux *et al*[11] reported a patient with an incomplete staple line, resulting in pelvic sepsis, that was treated with debridement and a temporary end colostomy.

When the staple line is intact, a conservative approach appears to be sufficient. However, surgery is mandatory when a rectal tear is diagnosed or the staple line is not intact. In our opinion, the latter situation compares with rectal perforation. Several different treatment approaches have been employed for the management of rectal perforations. In a recent review, de Feiter *et al*[12] noted that surgery is not always indicated for rectal perforation occurring after a barium enema. Intramural or a small retroperitoneal perforation can be treated with conservative measures such as bowel rest, total parenteral feeding, intravenous fluids and broad-spectrum antibiotics. Surgical debridement is only required in patients not responding to conservative treatment, and in patients with intramural abscesses. Perirectal abscesses always require drainage. By contrast, conservative treatment has been used even for major rectal perforation occurring after barium enema. This approach can be employed if the perforation was restricted to the retroperitoneum, the patient's general condition was good, the bowel was clean and the rectal tear was minor[13].

Di Venere *et al*[14] have attempted to standardize the treatment of rectal perforation. These workers argued that intraperitoneal rectal perforation should be considered as colonic or sigmoid perforation. Such patients should undergo surgical treatment depending upon the size of the bowel injury, the duration of intestinal spillage, comorbid conditions, and the surgeon's experience. Hartmann procedure was considered as the most appropriate technique if the wound exceeded 50% of the bowel circumference, with extended bowel wall loss and severe peritoneal contamination. Smaller lesions with less peritoneal contamination were considered more suitable for primary closure of the rectal wound followed by a diverting colostomy. A loop colostomy was proposed as the only possible treatment in severely ill and older patients with extraperitoneal rectal perforation. In all other cases of extraperitoneal rectal perforations, these workers recommended primary closure of the rectal wound with a diverting colostomy.

We prefer not to perform a primary closure of such perforations. In patients with intraperitoneal perforation, we recommend resection of the injured rectum, with anastomosis, and with or without a diverting (loop) colostomy or ileostomy. If severe peritonitis is present, we employ the Hartmann procedure. In patients with extraperitoneal perforation, the treatment is based on the extent of the perforation. Antibiotics and bowel rest as sole therapy is used for small perforations. For large perforations and/or severe sepsis, a diverting (loop)

colostomy or ileostomy is performed. Closure of the rectal perforation is not an option, because adequate drainage is the treatment of choice for (presacral) abscesses.

In conclusion, stapled hemorrhoidopexy is a safe, effective and time-efficient procedure. However, life-threatening complications can occur. There is no standard treatment for the management of pelvic sepsis. We recommend that only experienced colorectal surgeons, who are familiar with the technique and its complications, should perform such procedures. Further studies are needed to investigate and classify the best treatment for pelvic sepsis after stapled hemorrhoidopexy.

Abstract

Dedifferentiated liposarcoma is a variant of liposarcoma with a more aggressive course. Mutations of the *p53* gene have been found in different types of soft tissue sarcoma. It is generally accepted that *p53* mutations in human malignant tumors are often related to a poor prognosis. In our case, analysis of *p53* gene mutation in tumor samples was performed. *p53* gene mutation was observed in dedifferentiated tumor tissue samples but not in well-differentiated tumor tissue samples. It has been reported that *p53* gene mutation occurs most commonly in the retroperitoneum and rarely in other anatomic locations. Herein we report a case of dedifferentiated liposarcoma located at intraperitoneum.

Key words: Dedifferentiated liposarcoma; *p53* gene; Mutation; Intraperitoneum

INTRODUCTION

Liposarcoma is one of the most frequent malignant soft tissue tumors and currently classified into five main subgroups: well-differentiated, myxoid, round cell, pleomorphic, and dedifferentiated[1]. It is generally accepted that *p53* mutations in human malignant tumors are often related to a poor prognosis[2,3]. Taubert *et al*[4] reported that patients with nonframeshift mutations have a rather poor prognosis. Moreover, *p53* overexpression alone is associated with a poor clinical outcome[5,6]. Mutations of the *p53* gene have been found in different types of soft tissue sarcoma[7]. Well-differentiated liposarcoma is the most common variant. Dedifferentiated liposarcoma, a variant of liposarcoma with a worse prognosis, has a less frequency and occurs most commonly in retroperitoneum[8,9].

CASE REPORT

A 62-year-old man presented with a 3-mo history of constant right flank discomfort, fatigue, recent weight loss, loss of appetite and abdominal fullness. Physical examination revealed an abdominal mass in the right lower quadrant. T1-weighted magnetic resonance image (MRI) of the abdomen demonstrated a high-intensity mass. The tumor, located at intraperitoneum, was in the inferio-lateral to the cecum (Figure 1). Laboratory tests including tumor markers showed no abnormality. Surgery was performed to expose the tumor through a right lower abdominal incision. Gross examination revealed a 10 cm yellow, fleshy mass. Pathological examination revealed a dedifferentiated liposarcoma (Figure 2). Immunolabeling for S-100 was positive, while CD117 (C-KIT) and CD34 were negative in the well-differentiated tumor tissue samples, thus ruling out a gastrointestinal stromal tumor. Based on the histology and immunoprofile, a diagnosis of dedifferentiated liposarcoma was established. Furthermore, we investigated the occurrence of *p53* gene mutations in the tumor samples.

DNA extraction

Tissue samples were incubated for 15 min at 65℃,

Figure 1 T1-weighted magnetic resonance image (MRI) demonstrating a high-intensity mass.

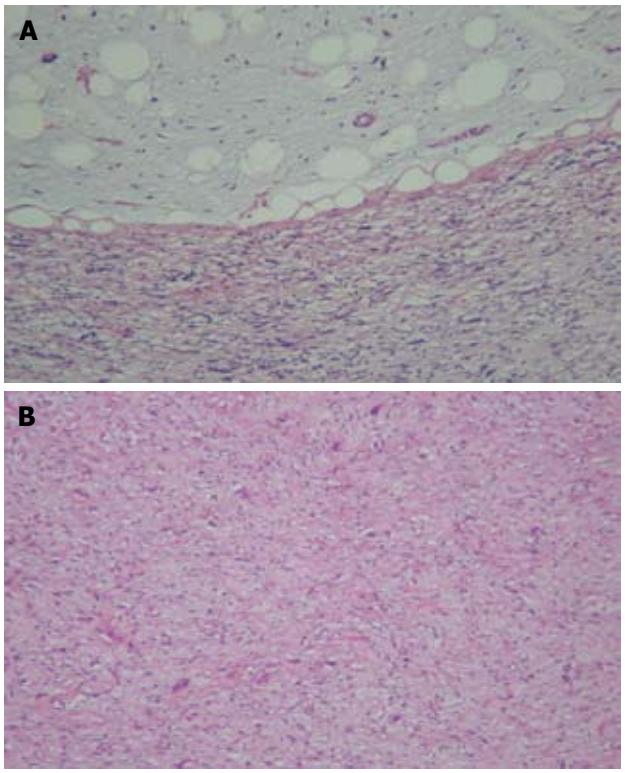

Figure 2 Well-differentiated tumor shows numerous lipoblasts and the dedifferentiated tumor resembles pleomorphic, spindle cells with hyperchromatic nuclei (HE, x 100) in the area revealing an abrupt transition from the well-differentiated to the dedifferentiated tumor (**A**), and dedifferentiated tumor shows low cellularity, fusiform cells with small hyperchromatic nuclei, and abundant collogen in the low grade fibrosarcoma area (**B**) (HE, x 100).

then overnight at 37℃ in a lytic solution containing 1 mg/mL proteinase K, 10 mmol/L Tris/HCl, 10 mmol/L ethylene diamine tetraacetic acid, 150 mmol/L NaCl, 0.4% sodium dodecyl sulfate. DNA was extracted twice with an equal volume of 1:1 SS-phenol/chloroform, and precipitated for 2 h at -20 ℃ after addition of 0.1 volume of 3 mol/L sodium acetate, 20 μg of glycogen as a carrier, and 2.5 volume of 100% ethanol. After centrifugation, the precipitate was washed with 2 mL of 80% ethanol, dried with a Speed Vac concentrator, and reconstituted with 50 μL of TE buffer.

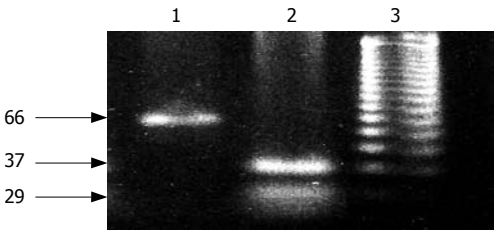

Figure 3 Amplification of the BstU1 within exon 4 produces a 66 bp long segment while cleavage results in 37 bp and 29 bp long fragments. Lane 1: No mutation of *p53* gene in well-differentiated tumor; lane 2: Mutation of *p53* gene in dedifferentiated tumor; lane 3: DNA marker.

PCR analysis

PCR was performed using a thermal cycle (PE 9700) with 50 ng of genomic DNA extracted from biopsy samples, 20 pmol of each primer, four deoxynucleotide triphosphates (dNTPs), reaction buffer and 1 μL (5 units) of fermentase Taq polymerase in a reaction volume of 100 μL. The PCR conditions consisted of an initial cycle at 95℃ for 10 min, at 57℃ for 1 min, and at 72℃ for 10 s followed by 34 cycles at 95℃ for 1 min, at 57℃ for 30 s, and at 72℃ for 10 s. The sequences of primer used are sense: 5'-CAGATGAAGCTCCCAGAA-3' (upstream) and anti-sense: 5'-GTGTAGGAGCTGCTGGTG-3' (downstream). An amplicon of 66 bp was produced, which was cleaved into 29 bp and 37 bp fragments with the enzyme BstU1, if its recognition site (CGCG) was present. The primer amplified a region containing codon 72 in exon 4 of *p53*[10,11]. Mutation of the *p53* gene was only observed in dedifferentiated tumor tissue samples but not in well-differentiated tumor tissue samples (Figure 3).

DISCUSSION

Mutation or allelic deletion of *p53* gene appears to play an important role in the development of human carcinoma[12]. It has been established that accumulation of wild type *p53* protein results in two pathways: cell cycle arrest and programmed cell death, both of which are involved in tumor suppressor functions[13]. Therefore, mutation of *p53* leads to disruption of these pathways, a selective growth advantage for tumor cells, and loss of function may increase proliferation activity and development of tumor[14].

Liposarcoma arising in extremities or retroperitoneum affects middle-aged and old patients, and tend to follow a relatively indolent clinical course with local recurrences after resection and occasional distant metastasis, mainly to the lungs[1]. Dedifferentiated liposarcoma is defined histologically by a transition from well-differentiated liposarcoma to a non-lipogenic sarcoma with variable histological grade[1]. The dedifferentiated tumor can resemble any sarcoma, but often mimics a malignant fibrous histiocytoma (MFH)[9].

Dedifferentiated liposarcoma, despite its high-grade histology, has a less aggressive clinical course than other

types of high grade sarcoma, although the underlying mechanism is unclear[1]. Compared to well-differentiated liposarcoma, dedifferentiated liposarcoma has similar genetic changes, ring or giant marker chromosomes, but a worse prognosis[1]. Approximately 40% of dedifferentiated liposarcomas will recur locally, 17% will metastasize, and 28% of the patients will ultimately die as a result of tumor[1].

It was reported that dedifferentiated liposarcoma occurs most commonly in retroperitoneum but rarely in other anatomic locations[9]. Five cases of dedifferentiated liposarcoma in small bowel mesentery have been described[15]. In addition, a case of dedifferentiated liposarcoma has been documented in the sigmoid mesocolon[16]. The present tumor, located at intraperitoneum.

Immunohistochemically, dedifferentiated liposarcoma is usually negative for CD117 and CD34 in dedifferentiated tissue and positive for S100 protein in well-differentiated tissue. Dedifferentiated liposarcoma needs to be distinguished from other high-grade sarcomas such as MFH because these high-grade sarcomas have a much worse prognosis[17].

We investigated the exon 4 of *p53* gene in adipose tissue tumor by PCR observed mutation of *p53* gene in dedifferentiated liposarcoma samples. Similarly, Taubert *et al*[4] detected mutations of *p53* gene in 5/32 of liposarcomas. It was reported that wild type p53 protein can induce cell apoptosis, whereas intracellular accumulation of mutant p53 protein can inhibit cell apoptosis, promote cell transformation and proliferation, resulting in carcinogenesis[5,14].

The patient underwent adjuvant radiation therapy and was asymptomatic during the 15-mo follow-up period. However, because the recurrence rate of dedifferentiated liposarcoma is very high, it is necessary to follow up carefully for a long term.

Abstract

Gastric lipomas are rare tumors, accounting for 2%-3% of all benign gastric tumors. They are of submucosal or extremely rare subserosal origin. Although most gastric lipomas are usually detected incidentally, they can cause abdominal pain, dyspeptic disorders, obstruction, invagination, and hemorrhages. Subserosal gastric lipomas are rarely symptomatic. There is no report on treatment of subserosal gastric lipomas in the English literature. We present a case of a 50-year-old male with symptomatic subserosal gastric lipoma which was successfully managed with removal, enucleation of lipoma, explorative gastrotomy and edge resection for histology check of gastric wall. The incidence of gastric lipoma, advanced diagnostic possibilities and their role in treatment modalities are discussed.

Key words: Stomach neoplasm; Subserosal gastric lipoma; Dyspeptic disorders; Surgical treatment/ enucleation

INTRODUCTION

Gastrointestinal lipomas are uncommon, slowly growing benign tumors composed of mature adipose tissue that can occur anywhere along the gut. Mostly are located in the colon, ileum and jejunum[1]. Lipomas found in the stomach are even more unusual, accounting for 2%-3% of all benign gastric tumors[2,3]. They are of submucosal or extremely rare subserosal origin, most frequently localized to the antrum[4-7]. Although it is reported that 5%-10% of gastric lipomas are located at subserosal layer[1], so far, there is no report on treatment of subserosal gastric lipomas in the English medical literature. Karadeniz *et al*[8] in 2007 described an exceptional case of subserosal lipoma within an inverted Meckel's diverticulum. In the past, preoperative accurate diagnosis was very difficult even for symptomatic gastric lipomas[9]. The treatment of large symptomatic gastric lipomas has not yet been established[10]. Actual imaging technologies and endoscopy have become new approaches to the management of gastric lipomas[9-12]. We present a case of a large symptomatic subserosal gastric lipoma which was successfully managed with removal, enucleation of lipoma, explorative gastrotomy and edge resection for histology check of gastric wall.

CASE REPORT

A 50 year-old male patient was admitted to the Division of Abdominal Surgery with a 6-mo history of upper abdominal pain, dyspeptic disorders, vomiting mainly after the meal, and tachycardia, without significant weight loss. He was previously medically treated for bronchial asthma and chronic gastritis with pronison, aminophylline, spalmotil, omeprazol, and surgically underwent appendectomy, repair of limb fracture and nose deviation. He stopped smoking twelve years ago.

On admission, physical examination was unremarkable. Abdomen was soft and flat with mild tenderness in epigastrium and no palpable masses. Laboratory examinations including tumor markers, CEA, CA19-9 and AFP, showed no abnormalities. Barium meal study showed

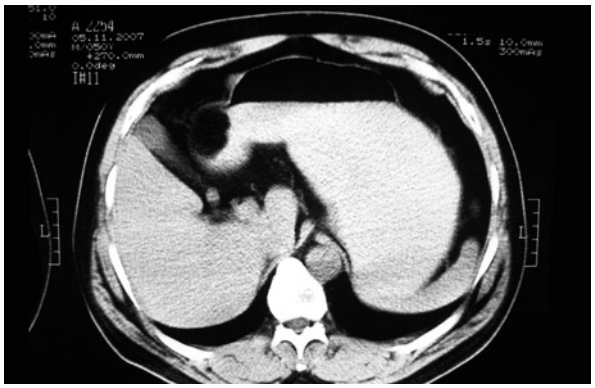

Figure 1 CT scan image showing a well-defined oval mass on the antro-pyloric part of stomach.

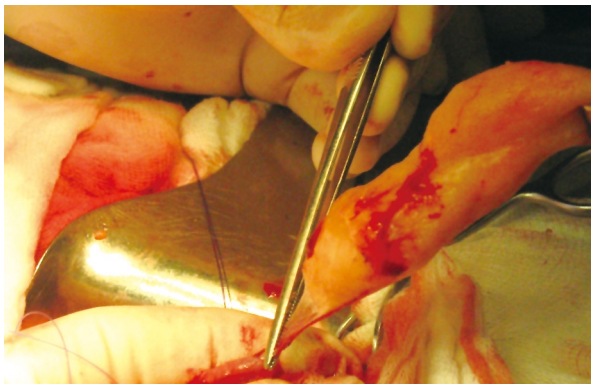

Figure 2 Intraoperative view showing a yellowish subserosal neoplasm on the anterior wall of gastric antrum during extirpation.

a normally shaped stomach without signs of filling defects and motility abnormalities, except for an axial hiatus hernia. Upper gastrointestinal endoscopy which was done two times, revealed a soft submucosal oval-shaped mass with an approximate diameter of 5 cm in gastric antrum. Overlying mucosa had a normal appearance with slight local hyperemia. Multiple gastric mucosa biopsies showed normal epithelium and rare stromal infiltrate with regular mucosa built up by regular tubular glands. Abdominal CT scan showed on the antro-pyloric part of the stomach a homogeneous well-defined oval mass around 6 cm in diameter with negative densitometry values (-50 and -60 Hounsfield units) that corresponds to fatty tissue (Figure 1). The patient underwent midline supraumbilical laparotomy. Intraoperatively, a yellowish, soft surface subserosal, well-defined tumor with a longitudinal diameter of around 5-6 cm, was found in the anterior wall of gastric antrum. The tumor was dissected and totally removed, enucleated, through an incision of gastric serosa without any technical difficulties (Figure 2). Explorative gastrotomy, endoluminal check of mucosa, and edge resection of underlying layers of gastric wall were performed. Gastrotomy was closed with PDS 3.0 using one layer Gambee sutures. Macroscopically, the specimen was capsulated by fatty content in a size of 5.5 cm. Histologicaly, the diagnosis of lipoma containing mature well-differentiated adipocytes (Figure 3), and no pathological lession in resected gastric edges were confirmed. Postoperative course was uneventful and the patient was discharged on the seventh postoperative day. Clinical and endoscopy follow-up 1 and 4 mo later showed that the tumor and clinical symptoms disappeared completely.

DISCUSSION

Lipomas of the stomach are very rare, accounting for less than 3% of all benign tumors of stomach[10,13]. Although generally single, they can be multiple as well[14]. Subserosal gastric lipomas are extremely rarely symptomatic. Probably because of this, there is no report on treatment of subserosal gastric lipomas in the English medical literature. In our case, subserosal lipoma localized in the antrum caused symptoms such as upper

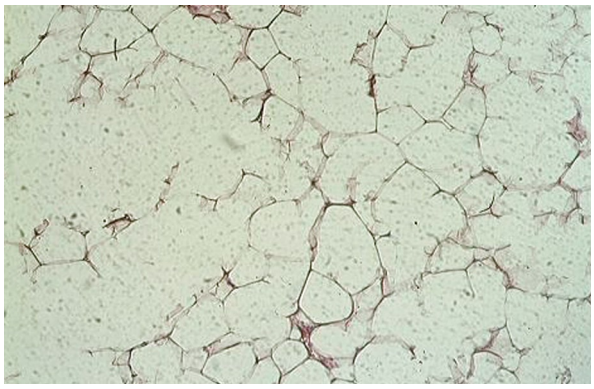

Figure 3 Histopathology confirming the diagnosis of lipoma containing mature fat cells with slight variation in size and shape (HE, x 100).

abdominal pain, dyspeptic disorders, and vomiting. This location is mainly responsible for dyspeptic and obstructive symptomatology[15,16]. The size of the lesion is correlated with the onset of abdominal disorders[7,10].

Diagnosis of gastric lipoma, in the past, before the era of modern diagnostic technology, was generally made after surgery[9,15]. Usually, on barium studies, extra mucosal tumors including lipomas reveal a smooth filling defect with a "bull's eye" appearance that is indistinguishable from other mesenchymal tumors[3]. Computerized tomography is a highly specific imaging diagnostic tool for lipoma[1,3,7,17]. In our case, barium studies did not show any filling defect, whereas abdominal CT scan showed a homogeneous well-defined oval mass with negative densitometry values of -50 and -60 Hounsfield units that corresponds to lipoma (Figure 1). However, CT scan is not accurate in determining the layer of location in the gastric wall. Although endoscopic sonography (EUS) provides more accurate findings of submucosal tumors regarding their shape, size and location inside gastric walls[18], because of limited resources in our hospital, this technique is not available. Upper GI tract endoscopy and biopsies were performed twice for our case. However, they played a complementary role in offering a description of a soft submucosal oval-shaped mass in gastric antrum, normal overlying mucosa and histopathology findings. A clear-cut endoscopic differentiation between gastric lipomas and other submucosal neoplasm is not

feasible, because routine endoscopic gastric biopsies do not reach the submucosal layer[16]. Furthermore, in the subserosal location, it was impossible to reach the neoplasm endoscopically. Despite the fact that CT scan is highly pathognomonic, there are reports suggesting the necessity of verifying specificity and sensibility of non-radiation based imaging systems, such as high resolution transabdominal ultrasound (TAUS)[19] and abdominal magnetic resonance imaging (MRI)[16].

The treatment modalities for gastric lipomas have been changed in parallel with the advances in endoscopic and imaging techniques. The choice of treatment for gastric lipomas is still controversial[16]. It was reported that different surgical and endoscopic procedures have been used in treatment of submucosal lipomas, but more accurate diagnosis preoperatively enable the replacement of previously used resection methods[6,9] by limited procedures such as tumor enucleation, partial resection or other endoscopic and minimally invasive procedures[4,7,10,11,20]. Although there are no malignant transformations of a gastric lipoma, coincidental separated malignant lesions have been reported[18]. As it was discussed by Yamamoto *et al*[18] in 2004, submucosal lipomas that have extended into the gastric lumen may provoke repeat erosions or local inflammation of gastric epithelium, which is thought to promote gastric cancer. Therefore, complete pretreatment diagnostic evaluation is needed. In our patient, preoperative evaluation did not find any morphologic and histological pathology in the gastric epithelium. Since his lipoma was symptomatic and its location in the gastric wall was not diagnosed preoperatively, the patient was treated with open laparotomy. Intraoperatively, a subserosal lipoma was found and enucleated through an incision of gastric serosa. To rule out the underlying concomitant pathology, explorative gastrotomy and edge resection of the gastric wall were carried out.

In summary, we report here a very rare case of subserosal symptomatic gastric lipoma successfully treated with enucleation. Subserosal gastric lipoma, although extremely rare, can be the cause of abdominal pain and dyspeptic disorders that need surgical treatment. Accurate diagnosis of gastric lipoma, which can be reached with a combination of endoscopic and imaging diagnostic techniques, is a very useful precondition in choosing the appropriate, less mutilating procedures of treatment.

Abstract

A 71-year-old Japanese man with acute cholecystitis and an incarcerated gallbladder (GB) stone was admitted. Plain ultrasonography (US) incidentally detected a mass-like lesion in the fundus. Doppler US revealed that this elevated lesion had no blood flow. Computed tomography showed a relatively low-density mass, measuring 5 cm x 4 cm in diameter, with no positive enhancement. Magnetic resonance imaging showed a mass in the fundus with a slightly low intensity on T1-weighted images and a slightly high intensity on T2-weighted images. We were agonized in making the qualitative diagnosis of mass-like lesions of the fundus, such as a benign tumor, cancer, or debris. We performed laparoscopic cholecystectomy, because the incarcerated GB stone clearly caused acute cholecystitis. Intra-operative cholangiography clearly revealed pancreaticobiliary maljunction. Amylase levels in the common bile duct and gallbladder were quite high. The elevated lesion in the fundus clearly showed severe necrosis. Although this necrotic nodule included non-viable adenocarcinoma cells, viable cancer cell nests were located in the muscularis propria and subcutaneous layer. Histopathological examination confirmed a solid adenocarcinoma. Thus, we diagnosed it as a gallbladder cancer, based on histopathological analysis of the resected specimen. We therefore undertook radical surgery, including wedge resection of the liver, radical dissection of regional lymph nodes, and resection of the extrahepatic bile duct. Histopathological findings revealed no cancer, hyperplasia or dysplasia in the additionally resected specimens. The patient was finally staged as T2, N0, H0, P0, M(-), stage Ⅱ. We present the first case of spontaneous necrosis of solid gallbladder adenocarcinoma, with a review of previous studies.

Key words: Gallbladder carcinoma; Pancreaticobiliary maljunction; Spontaneous necrosis

INTRODUCTION

Traditionally, gallbladder (GB) cancer had a poor prognosis because of the lack of recognized symptoms at early stages. Early-stage GB cancer is often detected in resected specimens after cholecystectomy for benign diseases[1,2]. Moreover, GB cancer is sometimes detected in association with pancreaticobiliary maljunction (PBM), which is the union of the pancreatic and biliary ducts at a site outside the duodenal wall[3].

Some previous studies have described spontaneous necrosis of parathyroid and adrenal gland tumors[4-7]. However, spontaneous necrosis of GB tumors is quite rare. Only one case of spontaneous necrosis of papillary GB adenocarcinoma has been reported[8]. We present

here the first case of spontaneous necrosis of solid GB carcinoma accompanied with PBM, and the etiology of spontaneous necrosis was discussed with a review of previous studies. In the present case, histopathological findings were described, based on the general rules for surgical and pathological studies of cancer of the biliary tract of the Japanese Society of Biliary Surgery[9], according to the TNM classification[10].

CASE REPORT

Clinical course after admission

A 71-year-old Japanese man was referred to Takayama Red Cross Hospital (Gifu, Japan) due to severe right upper quadrant pain and frequent episodes of spiking fever and shivering chills. He had a history of hypertension and atherosclerosis. Ultrasonography (US) showed acute cholecystitis due to an incarcerated GB stone. He underwent drug treatment including sulbactam/cefoperazone (SBT/CPZ) in the first instance, and his symptoms were well controlled, without percutaneous transhepatic bile drainage. Although serum biochemistry showed elevated levels of aspartate aminotransferase, alanine aminotransferase, lactate dehydrogenase, γ-glutamyltransferase, alkaline phosphatase and C-reactive protein at admission, peripheral blood examination was normal after administration of SBT/CPZ. Thereafter, we performed detailed investigations.

Image studies and tumor markers

Plain US of the GB showed wall thickening of the neck and body (consistent with cholecystitis), a strong echo with acoustic shadow at the neck (consistent with GB stones), and a mass-like lesion of the fundus (Figure 1A). In addition, this mass-like lesion moved according to the patient's position. Doppler US revealed that the elevated lesion of the fundus had no feeding arteries and drainage veins (Figure 1B). Plain computed tomography (CT) showed a relatively low-density mass in the fundus, measuring 5 cm × 4 cm in diameter (Figure 2A). Contrast-enhanced CT revealed that this mass-like lesion had no positive enhancement in the early (Figure 2B) or late (Figure 2C) phase. Magnetic resonance imaging (MRI) showed a mass in the fundus with a slightly low intensity on T1-weighted images (Figure 2D) and a slightly high intensity on T2-weighted images (Figure 2E). Magnetic resonance cholangiography (MRC) showed a round defect due to an incarcerated stone in the neck and irregular defects due to the elevated lesion in the fundus (Figure 3A). Serum carbohydrate antigen (CA) 19-9 level was elevated, although other tumor markers including carcinoembryonic antigen, alpha-fetoprotein, squamous cell carcinoma antigen, CA125 and CA15-3 were all normal. Upper gastrointestinal and colorectal endoscopy did not reveal any abnormal findings. Positron emission tomography with fluorine-18-labeled fluoro-deoxyglucose (FDG-PET) showed no FDG uptake in the GB.

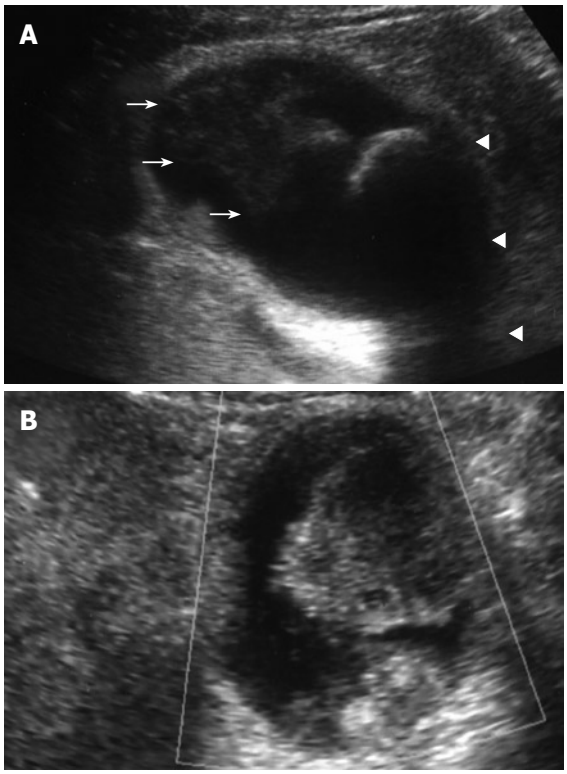

Figure 1 Plain US. (**A**) of the GB showing wall thickening of the neck and body (consistent with cholecystitis), a strong echoic level with acoustic shadow at the neck (consistent with stones), and a mass-like lesion of the fundus, and Doppler US (**B**) revealing no blood flow in the mass-like lesion.

Preoperative diagnosis and surgical treatment

We were agonized in making the qualitative diagnosis of mass-like lesions of the fundus, such as benign tumor, cancer, debris or bile sludge. However, the incarcerated GB stone clearly caused acute cholecystitis. We performed elective surgery (three-port laparoscopic cholecystectomy), with informed consent required for an additional surgery based on histopathological diagnosis. Intraoperative cholangiography clearly revealed PBM (Figure 3B). In addition, amylase levels in the common bile duct (CBD) (bile obtained during cannulation of the CBD) and GB (bile obtained from the resected specimen) were quite high (82 752 IU/L and 69 442 IU/L, respectively). Postoperative course was uneventful, and CA19-9 levels normalized immediately after surgery.

Histopathological diagnosis

Microscopic examination revealed chronic cholecystitis with infiltration of inflammatory cells. In addition, histopathological examinations showed no necrotic changes in walls of the GB neck and body and gangrenous cholecystitis. Moreover, the elevated lesion of the fundus obviously developed necrosis (Figure 4A). This necrotic nodule included non-viable adenocarcinoma cells and remnants of glandular structures and vessel fragments (Figure 4B). Viable cancer cell nests were located in the muscularis propria and the subcutaneous layer beneath the necrotic nodule (Figure 4C). Histopathological examination confirmed a T2 solid

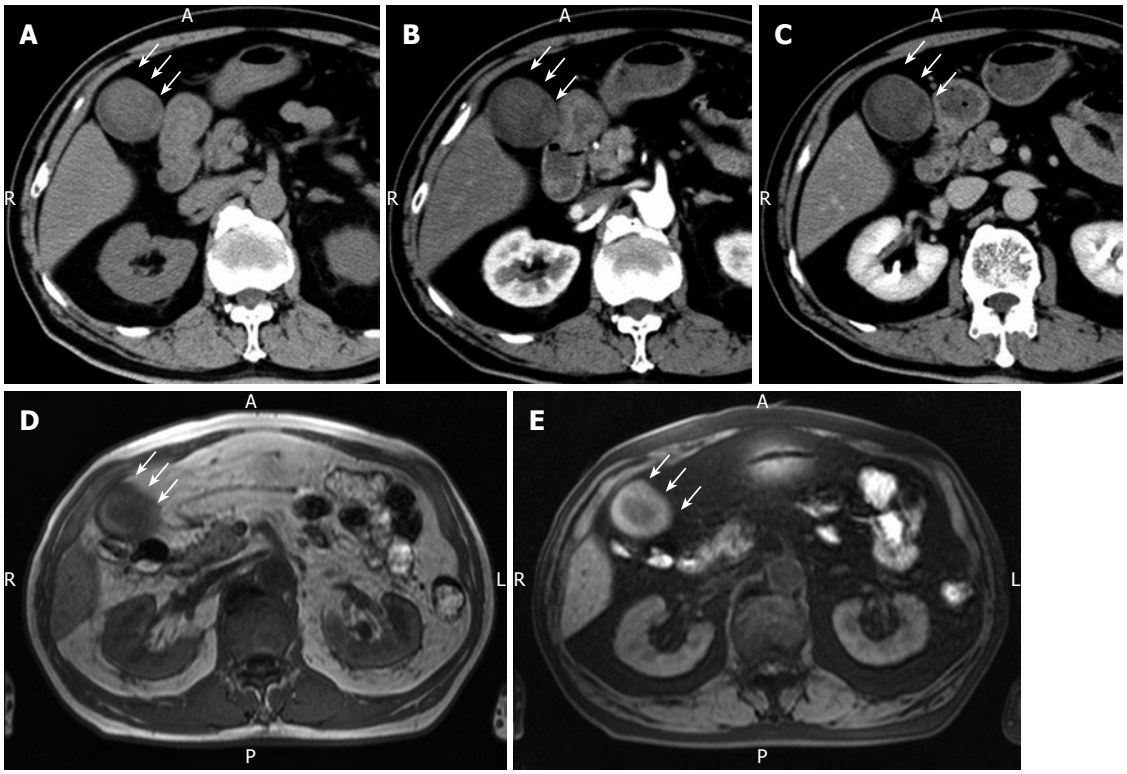

Figure 2 Plain CT. (**A**) showing a relatively low-density mass of the fundus measuring 5 cm x 4 cm in diameter, contrast-enhanced CT revealing no positive enhancement of this mass-like lesion in its early (**B**) and late (**C**) phases, MRI showing a mass in the fundus with a slightly low intensity on T1-weighted images (**D**) and a slightly high intensity on T2-weighted images (**E**). White arrow represents the mass-like lesion of the fundus.

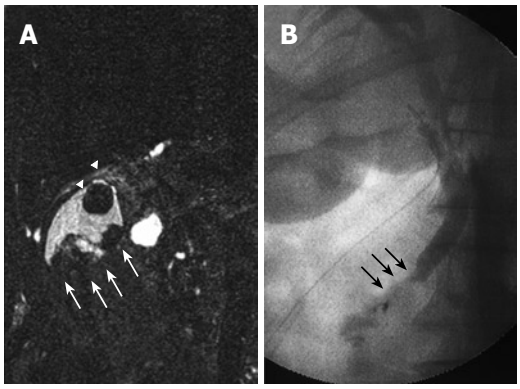

Figure 3 MRC. (**A**) showing irregular defects due to the elevated lesion of the fundus (white arrow) and a round defect due to stone incarceration in the neck (white arrow head), intra-operative cholangiography (**B**) revealing PBM and a 15 mm long common channel (black arrow).

adenocarcinoma [solid adenocarcinoma, ss, INFα, ly0, v0, pn0, hinf0, binf0, pvx, ax, St (+)] (Figure 4D). Regional lymph nodes (LNs) of the cystic duct (LN #12c) were noted without macroscopic metastasis. Thus, we diagnosed it as a GB cancer, based on histopathological analysis of the resected specimen.

Additional radical operation with radical dissection of regional LNs

The viable cells invaded perimuscular connective tissue, but did not penetrate the serosa. We were concerned about the safety margin, regional LN metastasis, and malignant potential of the CBD due to PBM. We therefore performed radical surgery, including wedge resection of the liver, including the GB bed to achieve negative margins, and radical dissection of regional LNs, including para-aortic LNs. Intraoperative histopathological examination of the induration of the mesocolon and peritoneum revealed no cancer dissemination. Furthermore, resection of the bile duct, including intrapancreatic and hilar bile ducts, was carried out. The intrahepatic bile ducts were reconstructed using hepaticojejunostomy in an end-to-side fashion. In addition, we resected the right hepatic artery by *en-bloc* resection with a safety margin, because an elastic, hard induration of the Calot's triangle involved the right hepatic artery showing back flow from the remnant liver, and we did not reconstruct the hepatic artery. Histopathological findings and imaging studies finally staged the patient as T2, N0, H0, P0, M(-), stage Ⅱ. No cancer, hyperplasia or dysplasia was found in the additionally resected specimens, and no regional LNs revealed metastasis (LNs #8a, 8p, 12a, 12b, 12p, 13a, 16a2, 16b1). In addition, no cancer or any precancerous lesions were seen in the extrahepatic bile duct microscopically. Until postoperative day 18, he had a good postoperative course except for gastric ulcer and pneumonitis. However, celiac artery rupture occurred suddenly on postoperative day 19, and he finally died of disseminated intravascular coagulation on postoperative day 20, despite intensive treatments.

DISCUSSION

Occult GB cancer has been incidentally found after

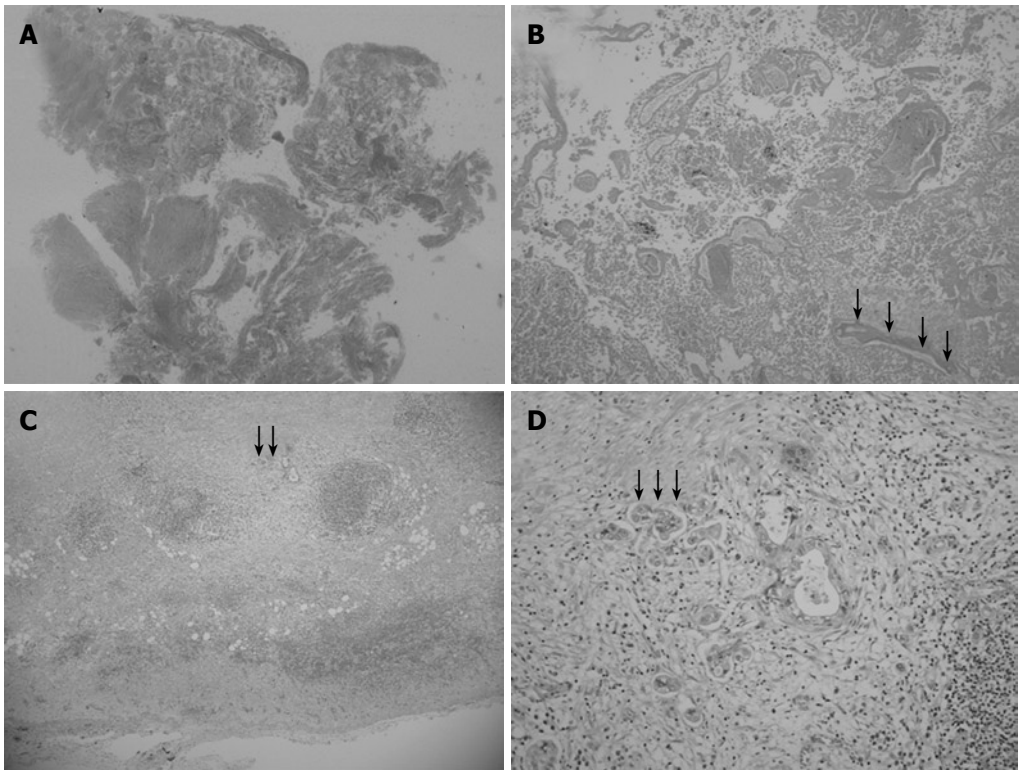

Figure 4 Low magnification view of the elevated lesion of the fundus showing obvious nodule necrosis. (**A**, HE, loupe) including non-viable adenocarcinoma cells and remnants of glandular structures and vessel fragments (**B**, black arrow) (HE, × 40), viable cancer cell nests invading perimuscular connective tissue but not penetrating the serosa in the muscularis propria and subcutaneous layer beneath the necrotic nodule (**C**, black arrow) (HE, × 20), and a solid adenocarcinoma (**D**, black arrow) (HE, × 100).

cholecystectomy (approximate 1%)[1,2]. However, we sometimes have difficulty in making a precise diagnosis of necrotic tumor based on imaging studies[11,12]. In this case, we did not make the qualitative diagnosis before laparoscopic cholecystectomy, although we did not deny the possibility of the existence of cancer. Since cholecystectomy for occult GB cancer may increase the risk of intraperitoneal dissemination and port recurrence[13,14], further precise diagnosis is required before surgery. In this case, we were in a dilemma as to whether we should perform radical surgery in a suspicious case with a risk of postoperative mortality and morbidity. Regional LNs of the cystic duct (LN #12c) are sometimes obtained from resected specimens after cholecystectomy. It was reported that LN #12c may be predictive of metastasis from occult GB cancer after cholecystectomy[15]. In the present case, LNs had no metastasis and the additional resected specimens showed no metastasis microscopically, indicating that this case supports the importance of LN #12c as an indication for additional surgery in cases of occult GB cancer after cholecystectomy. Even if radical resection for inapparent carcinoma after cholecystectomy is warranted, based on the excellent prognosis after additional radical surgery[1,2,13,15,16], it is still controversial about the optimal radical surgery for T2 GB cancer of the fundus[1,2,13-17]. Some investigators have recommended several surgical methods for T2 GB cancer, such as extended right hepatectomy, segmental resection of 4a/5 or 4b/5, and radical cholecystectomy with a 2-cm margin of liver around the GB bed[17-21]. Especially in cases of T2 carcinoma of the fundus after cholecystectomy, we still have some concerns about the determination of optimal surgical treatment. The establishment of optimal surgical treatment for occult T2 cancer after cholecystectomy is necessary.

Sakurai *et al*[8] reported a rare case of spontaneous necrosis of GB papillary adenocarcinoma of the fundus with PBM and suggested that the causes of spontaneous necrosis are disturbance of blood flow, gangrenous cholecystitis, necrotic debris, initial wall thickening due to cancer itself, PBM and increased intraluminal pressure in the GB. We could not clearly explain the cause of spontaneous necrosis, even after reviewing the literature. Although some of our findings are consistent with previously reported findings, such as cancer in the fundus with cholecystitis and PBM[8], some factors such as initial wall thickening due to cancer itself, intravascular thrombosis, gangrenous cholecystitis and necrotic debris were not seen in our case. We speculate that the cause of spontaneous necrosis of GB cancer is the increased intraluminal pressure in GB due to stone incarceration or the activated pancreatic enzymes consequently stimulating mutagenicity due to PBM[22,23]. In particular, our case clearly demonstrated a significantly elevated level of amylase in GB, suggesting that PBM participates in the process of necrosis. The case presented may show that overlapping of increased intraluminal pressure and activated pancreatic enzyme causes spontaneous necrosis.

Bile duct carcinoma including GB cancer is one of the malignant gastroenterological tumors which are most difficult to be cured and curative resection is essential for the long-term survival of such patients. In the surgical treatment for these cancers, systematic extended lymph node dissection is frequently required for curative resection. However, even with margin-negative resection, its prognosis after curative resection remains poor. The possible reason for the poor outcome is existence of occult lymph node metastasis that cannot be detected by conventional hematoxylin and eosin staining at surgical resection[24,25]. Recently, immunohistochemical and molecular techniques have made it possible to identify lymph node micrometastasis missed by traditional methods, and Taniguchi *et al*[24,25] clearly demonstrated that occult lymph node metastasis is crucial for the prognosis of bile duct carcinomas including GB cancer. At present, we are still troubled about the additional treatment for occult T2 GB carcinoma after cholecystectomy. For the time being, we will recommend the radical surgery including systematic lymph node dissection for this cancer, because of the excellent prognosis after additional radical surgery[1,2,13,15,16] and the possibility of lymph node micrometastasis[24,25].

This is the first case of spontaneous necrosis of solid GB adenocarcinoma. As GB carcinoma is rarely accompanied with spontaneous necrosis, more cases should be studied in order to analyze the mechanism of spontaneous necrosis, to make a precise preoperative diagnosis, and to perform optimal radical surgery based on the adequate indication.

Abstract

Acute pancreatitis is one of the most common diseases in the everyday's practise of gastroenterologists and surgeons. However, the physicians' therapeutic armamentarium is very limited. The present letter to the editor briefly describes the recent evidence from the literature with the aim to optimize a conservative management of patients with acute pancreatitis.

Key words: Acute pancreatitis; Conservative treatment; Enteral nutrition

Peer reviewer: Marko Duvnjak, MD, Department of Gastroenterology and Hepatology, Sestre Milosrdnice University Hospital, Vinogradska Cesta 29, 10000 Zagreb, Croatia

TO THE EDITOR

In a recent issue of the Journal, I read with interest the article by Bang and co-authors[1], who reviewed the current possibilities of pharmacological prevention and treatment of patients with acute pancreatitis. Obviously, the chosen topic is of contemporary interest from both scientific and practical points of view, as the therapeutic armamentarium for this disease is fairly scarce. Herewith, I would like to make a brief comment on the list of options considered in the referred review.

A substantial part of the article by Bang *et al*[1] is devoted to the pharmacological prevention of post-endoscopic retrograde cholangiopancreatography (ERCP) acute pancreatitis. Unfortunately, the promising potential of many drugs in the experimental studies has never been confirmed in the clinical trials and the data from many reports are inconsistent. At the same time, as a recent meta-analysis of randomised controlled trials[2] revealed no difference in outcomes between patients with acute pancreatitis but without coexisting acute cholangitis who received either early ERCP or conservative care, I would argue that the best preventive strategy for post-ERCP acute pancreatitis is to obviate the unnecessary ERCP, i.e. to use it only as a therapeutic but not as a diagnostic modality. Thus, it should be mainly reserved for patients with acute cholangitis, the incidence of which is marginal. In contrast, the majority of patients without cholangitis should be diagnosed noninvasively by endoscopic ultrasonography or by magnetic resonance tomography, which are virtually riskless. Adherence to this strategy may drastically diminish the need for pharmacological prevention of post-ERCP acute pancreatitis.

Another matter of concern is that Bang *et al*[1] did not consider a favorable effect of enteral nutrition in patients with (severe) acute pancreatitis. Probably, this is because enteral nutrition has been viewed as a supportive care for years. Indeed, in the majority of clinical settings, it should be considered so, because it is possible to demonstrate a beneficial effect of enteral nutrition only on nutritional parameters (body weight, nitrogen balance *etc*), which are essentially surrogate endpoints. However, the use of enteral nutrition in acute pancreatitis, unlike many other pathologies, is associated with a significant reduction in the incidence of clinically meaningful outcomes (infectious complications, need for surgery, mortality) coherently derived from nearly a dozen of randomized controlled trials. The findings from only high quality of these studies have been statistically aggregated in a recent meta-analysis[3], showing a significantly reduced risk of total infectious complications [relative risk (RR) = 0.47, 95% confidence interval (CI) = 0.28-0.77, $P < 0.001$], pancreatic infectious complications (RR = 0.48, 95% CI = 0.26-0.91; $P = 0.02$), need for surgery (RR = 0.37, 95% CI = 0.21-0.65, $P = 0.001$), and mortality (RR = 0.32, 95% CI = 0.11-0.98, $P = 0.03$) with the use of enteral nutrition in patients with severe acute pancreatitis.

Furthermore, as Dorland's medical dictionary[4] defines a drug as "any chemical compound that may be used in or administered to humans or animals as an aid in the diagnosis, treatment, or prevention of diseases or other abnormal conditions, for the relief of pain or suffering, or to control or improve any physiologic or pathologic condition", it seems to me that it is time now to consider enteral nutrition as a full-fledged drug in patients with acute pancreatitis.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

World Journal of Gastroenterology ISSN 1007-9327

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903
Ocean International Center, Building D
No. 62 Dongsihuan Zhonglu
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

The striking gender disparity observed in the incidence of hepatocellular carcinoma (HCC) suggests an important role of sex hormones in HCC pathogenesis. Though the studies began as early as in 1980s, the precise role of sex hormones and the significance of their receptors in HCC still remain poorly understood and perhaps contribute to current controversies about the potential use of hormonal therapy in HCC. A comprehensive review of the existing literature revealed several shortcomings associated with the studies on estrogen receptor (ER) and androgen receptor (AR) in normal liver and HCC. These shortcomings include the use of less sensitive receptor ligand binding assays and immunohistochemistry studies for ERα alone until 1996 when ERβ isoform was identified. The animal models of HCC utilized for studies were primarily based on chemical-induced hepatocarcinogenesis with less similarity to virus-induced HCC pathogenesis. However, recent *in vitro* studies in hepatoma cells provide newer insights for hormonal regulation of key cellular processes including interaction of ER and AR with viral proteins. In light of the above facts, there is an urgent need for a detailed investigation of sex hormones and their receptors in normal liver and HCC. In this review, we systematically present the information currently available on androgens, estrogens and their receptors in normal liver and HCC obtained from *in vitro*, *in vivo* experimental models and clinical studies. This information will direct future basic and clinical research to bridge the gap in knowledge to explore the therapeutic potential of hormonal therapy in HCC.

Key words: Sex hormones; Estrogen receptor; Androgen receptor; Hepatocellular carcinoma; Hepatocarcinogenesis

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most lethal malignancies with limited treatment options. The major risk factors for HCC are chronic liver diseases with cirrhosis that include hepatitis B, hepatitis C, alcoholic liver disease and non-alcoholic steatohepatitis. Epidemiological reports indicate that regardless of etiologies, the incidence of HCC is higher in males than in females with the male: female ratio usually averaging between 2:1 and 4:1[1]. This male predominance is further supported by the clinical observations that chronic liver disease progresses more rapidly to cirrhosis in males than females and therefore cirrhosis that leads to HCC development is largely considered to be the disease of men and postmenopausal women[2]. In view of this remarkable gender disparity, various *in vitro* as well as *in vivo* studies have been initiated from time to time to explore the importance of sex hormones in HCC. However, the precise role of male and female sex hormones and their receptors in HCC remains still poorly understood. Androgens have been suggested to induce and promote HCC[3] and altered androgen metabolism has been reported to be associated with HCC[4]. In contrast, the role of estrogen in HCC has been controversial with evidence suggesting both carcinogenic and protective effects in the liver[3,5-9]. Very limited information is currently available regarding the mechanism of estrogen and androgen action in normal liver as well as in HCC.

It is well known that estrogen and androgen mediate their biological functions by binding with a high affinity to specific receptors, the estrogen receptor (ER) and the androgen receptor (AR). Both ER and AR belong to the family of nuclear receptors that act as transcription factors and regulate the expression of several genes. Our present day knowledge of structure and function of these receptors is primarily attributed to the extensive research on ER and AR in cancer of reproductive organs. However, recent advances in molecular research reveal that sex hormones do play a significant role in normal physiology of various organs other than the organs of the reproductive system. Both androgens and estrogens regulate transcriptional activation of various molecules involved in key cellular processes such as generation of immune responses, cell proliferation and apoptosis through functional receptors localized in various sub-cellular organelles[10-12].

The expression and functional status of AR and ER appear to play a significant role in the carcinogenesis of all hormone sensitive organs. However, liver has remained a less studied organ in the context of sex hormones and their receptors. Differential expression of wild type and variant forms of ER and AR has been reported in normal liver and HCC, indicating a strong link between sex hormones and pathogenesis of HCC[13-19]. Recent *in vitro* studies also provide further evidence in support of AR and ER involvement in various cellular events as well as interaction with viral proteins in hepatitis B virus (HBV) and hepatitis C virus (HCV)-induced HCC[20-25]. This review is focused on the compilation of the information so far available on the significance of AR and ERs in HCC and brings forth wide gaps in the existing knowledge to the notice of scientific world for future research.

SEX HORMONE RECEPTORS IN NORMAL HUMAN LIVER AND HCC

Estrogen receptor

The role of estrogen in modulating morphological and physiological features of liver became evident in early 1970s when a possible correlation between occurrence of hepatic neoplasms and use of oral contraceptives was suggested[26,27]. In the reproductive system, estrogen is known to act by binding to specific cytoplasmic and nuclear receptors. Hence, search began to identify such a receptor in the liver. In 1978, Duffy and Duffy first reported the presence of ER in normal human liver[28]. Subsequently, the presence of ERs in human HCC was demonstrated by Molteni *et al*[29] followed by Friedman *et al*[30] and Iqbal *et al*[31]. Since then, a number of studies have been reported addressing the expression of ERs in normal as well as neoplastic liver tissues. The early studies used indirect methods of receptor detection based on ligand binding assays. Table 1 gives the details of these studies[13,15,17,30-37]. These assays were quantitative and measured the amount of receptor in the samples as well as its affinity for the ligand in terms of dissociation constants. The percentage positivity for ER expression varied significantly among different studies. These variations may be attributed to the differences in sample size, methodologies, ethnicity of the population studied, stage of the disease and underlying etiologies. Earlier studies by Friedman *et al*[30] and Iqbal *et al*[31] showed that ER content is similar in HCC and normal liver. In contrast, later studies consistently showed that the expression of ER is decreased in HCC tissue specimens as compared to normal liver tissue specimens or the non-tumor part of the liver[17,32,38]. However, Eagon *et al*[33] documented elevated levels of cytosolic ER in 3 of the 9 tumors as compared to non-cancerous tissues. Nuclear ER expression was found to be suppressed in all HCC samples as compared to normal samples[33]. The major drawback of these studies was the use of binding assays for detection that do not provide any information on the subtype of ER, i.e. ERα and ERβ as known today. It is important to study the relative expression of both isoforms of ER since ERα and ERβ are known to have overlapping but quite distinct functions. There are few reports on direct detection of ER using specific antibodies. Table 1 gives the details of these studies[32,39-47]. However, all these studies have employed either immunohistochemistry (IHC) or enzyme-immuno assays (EIA) using antibodies specific for only ERα isoform. The ERβ isoform was identified later in 1996[48] and information on the expression of ERβ protein in HCC is lacking though few studies at mRNA levels have been documented.

Since the molecular characterization and cloning of ERα in the mid 1980s[49,50], attempts have been made to determine the expression of ER in liver tumors at mRNA level. Table 2 gives the details of these studies[18,19,40,45,51,52]. *In situ* hybridization using ER specific oligonucleotide sequence probe revealed that 11 out of 15 HCC tissue samples expressed ER mRNA[40]. Interestingly, the same samples were found to be negative for ER protein by IHC, suggesting the use of more sensitive methods and more specific antibodies for detecting ER at protein level. Subsequently, the mRNA expression of ER in HCC tissues was studied in different populations by a highly sensitive method of reverse transcriptase-polymerase chain reaction (RT-PCR). Villa *et al*[51] were the first to demonstrate the presence of wild type ERα in peritumoral and tumoral tissue of HCC patients using this technique. The use of RT-PCR further enabled the authors to detect a splice variant of ERα lacking exon 5 in the hormone binding domain[18,51]. A similar splice variant has been described in breast cancer tissues to be associated with tumor pathogenesis[53]. The significance of the variant ERα (vERα) in pathology, prognosis and treatment of HCC has also been studied. The presence of vER receptor is able to influence the natural history of patients with HCC by regulating tumor growth as well as patient survival. The presence of the liver vERα transcript in the tumor has been described to be the strongest negative predictor of survival in operable HCC patients[54,55]. Furthermore, the presence of vERα was found to correlate with a higher

clinical aggressiveness of the tumor in comparison with the tumors characterized by wild-type ERα transcript. These tumors were responsive to megestrol and unresponsive to anti estrogen tamoxifen. High rates of vERα expression have been shown to be present in men at high risk of HCC development[56,57]. In patients with chronic hepatitis and cirrhosis, the expression of vERα has been associated with higher oxidative stress-induced DNA damage and c-myc mRNA expression, a factor indicating increased genomic instability, augmented cytoproliferation and carcinogenesis[5].

Using RT-PCR, in addition to ERα, the expression of the lately identified isoform of ER, i.e. ERβ, has also been studied in HCC patients. Iavarone *et al*[19] report that both ERβ and ERα wild type receptors either alone or together with vER are co-expressed more frequently in patients with chronic liver disease than in those with HCC. However, both ERs are similarly expressed in tumoral and extratumoral tissues of HCC patients[19]. In this study, HBV-related tumors either expressed wild type ERα and ERβ or expressed variant ER and ER delta 5 more often than HCV-related tumor, and HBV-related tumors showed a tendency towards loss of ERβ expression as the disease progressed from chronic inflammatory liver disease to HCC[19].

Breast cancer studies suggest that ERα:ERβ expression ratio changes during carcinogenesis and is believed to play a role in tumor development[58]. Recently, Wang *et al*[52] studied the expression of ERα and ERβ in HCC tissues of Korean population using RT-PCR, and assessed 32 tumoral and peritumoral tissues from HCC patients with underlying chronic HBV or HCV

Table 3 Estrogen receptor and androgen receptor expression in normal and non-cancerous liver tissue samples

infection and observed that wild type and variant ERα are expressed in all the samples. However, the expression of vERα is stronger in tumor than in peritumor tissues. Interestingly, ERβ was found to be significantly over-expressed in HCV-infected HCC tissues as compared to HBV-infected HCC tissues. The differences in ER expression in HCV-infected HCC tissues compared to HBV-infected HCC tissues suggest different pathogenetic mechanisms. Overall from these studies there appears to be a change in co-expression pattern of ERα and ERβ from cirrhosis to HCC development in both HBV- and HCV- related tumors. Thus, these studies provide further evidence in support of importance of wild type and variant ERs in HCC, suggesting detailed investigations in this area.

Androgen receptor

Like estrogens, androgens have also been reported to play an important role in liver carcinogenesis. Iqbal *et al*[31] showed the presence of androgen receptors (AR) in HCC in 1983. However, it was not until 1985 that normal human liver was believed to express AR. In 1985, Nagasue and colleagues[14] demonstrated the presence of AR in normal human liver as well as in tumor and non-tumor parts of HCC tissues. Since then, several reports showing protein and mRNA expression of AR in liver have been published. Table 3[13,15,17,28,30-33,35,40,41,52,59-64] and Table 4[14-17,31,33-36,39,41,47,52,65-71] give the details of these studies. In general, AR is found to be over expressed in liver tumor compared to the adjacent normal tissue[15,17,33,36,38]. However, like ER expression studies, majority of the early studies employed indirect binding assays to detect AR in the liver tissues. More precise quantitative methods of direct detection of AR protein are needed. Reports using antibody-based detection of AR in liver tissues are very sparse.

The mRNA levels of AR have been assessed in the non-cancerous and HCC tissues primarily by RT-PCR (Tables 3 and 4). In 1994, Negro and colleagues[16] developed a non-radioisotopic *in situ* hybridization assay specific for human AR mRNA and found that 73% of HCC tissues could express variable amount of AR mRNA. However, normal hepatocytes were stained weakly in 42% of the non-neoplastic tissues. Though initial binding studies demonstrated higher AR levels in tumor tissues than in respective peri-tumoral part[15,17,33,36,38], more recent observations based on mRNA expression do not reveal any significant differences in tumor and peri-tumor tissues. Tavian *et al*[71] found higher AR mRNA levels in tumor than in the corresponding peri-tumoral tissue in a relatively small percentage of HCC samples, suggesting that AR mRNA levels are associated with the histological tumor differentiation showing a lower AR expression in poorly-differentiated HCC than in well-differentiated tumors. In contrast, AR levels in Korean population with HCC do not show differences between tumor and peri-tumor tissues using RT-PCR[52]. Due to these conflicting reports on AR expression in HCC, there is a need for detailed investigation of AR mRNA as well as protein levels using more sensitive and accurate detecting quantitative methods.

Table 4 Androgen receptor protein and mRNA expression in liver tissue samples from HCC patients

CLINICAL AND PATHOLOGICAL SIGNIFICANCE OF ESTROGEN AND ANDROGEN RECEPTORS IN HCC

Despite a wide variability observed in studies of ER and AR expression in HCC, attempts have been made to determine the significance of these receptors by correlating their levels with clinical and pathological parameters. Table 5[13,15,34,42,55,69,70,72] and Table 6[30,54,73-77] present the salient findings of such clinical studies.

In few earlier studies using binding assays, no correlation was found between ER protein expression and sex, age, alcohol abuse, serum alpha-feto protein, carcinoembryonic antigen, HBV markers or tumor histology[15,34]. However, in subsequent reports, ER mRNA levels were shown to be associated with sex and viral etiology[19,51,52]. Increased vERα expression has been demonstrated more often in males than in females with HCC in Italian population, suggesting a strong link of ER with a higher incidence of HCC in males[19,51]. On the other hand, in Korean subjects no correlation has been found between the expression of vERα and HCC prevalence in males[52]. Interestingly, a distinct difference in ER expression pattern was observed in HBV- and HCV-infected HCC patients. Delta 5 deletion variants of ERα (vERα) and ERβ were found to be more often expressed in HBV-related tumors than in HCV-related tumors (67% *vs* 15%, $P < 0.0007$)[19]. In contrast, Wang *et al*[52] showed no remarkable difference in vERα levels in HCV- and HBV-infected HCC tissues (91.3% *vs* 100%). Nevertheless, a predominant expression of ERβ has been reported in HCV-infected than in HBV-infected patients with HCC (95.7% *vs* 44.4%, $P < 0.05$), suggesting that ERβ may play an important role in HCV-induced liver disease[52].

In addition to gender and etiological factors, tumor size, histopathology, operative mortality, tumor recurrence and survival after curative resection have also been studied in relation to ER expression in HCC[34,42,55]. Nagasue *et al*[34] showed that the large tumors are more commonly found in ER negative HCC patients and therefore the incidence of major hepatic resection is significantly higher in this group than in ER positive HCC patients. However, they did not report significant differences in histopathology of ER positive and ER negative tumors. Rates of mortality, tumor recurrence and long-term survival were also found to be similar in the two groups. In contrast to these observations, Jonas *et al*[42] showed that in patients undergoing curative resection, the 1- and 2-year survival rates in ER positive group are substantially lower than in ER negative group[42], suggesting that ER positive status has a negative effect on patient survival after curative resection of advanced HCC. Further, significantly longer survival rates have been reported in HCC patients with wild type ERs than in those expressing variant ERs[55].

In contrast with ER expression, AR levels are strongly associated with intra hepatic recurrence of tumors. The 5-year survival of recurrence free HCC patients was shown to be 55% for AR negative, 24% for ER negative, 10% for ER positive and 0% for AR positive tumors[67]. Similar findings have been reported by other researchers, suggesting a negative impact of AR positivity on tumor recurrence[69]. It was reported that AR negative patients show significantly better survival than AR positive patients[70]. Considering the tumor size, variable results have been documented in relation with AR expression. Boix *et al*[69] showed that AR expression is significantly related to smaller tumor size while Zhang *et al*[70] found that AR levels are positively correlated to tumor size.

Table 5 Studies on correlation of estrogen receptor and androgen receptor expression with clinical and pathological parameters in HCC patients

Receptor protein/ mRNA expression	Clinical parameter	*n*	Country	Salient findings	Yr	Reference
ER protein	Serum alpha-fetoprotein, carcinoembryonic antigen, HBV profile, tumor histology	30	Japan	No correlation with any parameter	1986	[13]
ER and AR protein	Serum alpha fetoprotein, HBV markers, histopathology	19	Japan	No correlation	1989	[15]
ER protein	Sex, age, alcohol abuse, underlying liver disease, hepatic functions	66	Japan	No correlation	1990	[34]
	Tumor size, hepatic resection Histopathology			Large tumor size and higher rate of resection in ER- No differences in ER+ and ER-		
	Operative mortality, tumor recurrence, long-term survival rate			Similar in ER+ and ER-		
ER and AR protein	Intrahepatic recurrence	78	Japan	AR expression strongly associated with intrahepatic recurrence. Weak association with ER expression	1995	[72]
ER protein	Survival after curative resection	28	Germany	Negative effect of an ER+ tumor on patient survival after curative resection	1997	[42]
Wild type and variant ER mRNA	Survival	96	Italy	Significantly long survival in patients with wild type ERs than variant ERs	2000	[55]
AR protein	Recurrence rate	45	Japan	Significantly higher recurrence rates in AR+ group than AR-	1989	[15]
	Survival rate			Significantly better survival rates in AR- patients than in AR+		
AR protein	Tumor size	43	Spain	AR expression was significantly related to smaller tumor size	1995	[69]
	Tumor recurrence			Higher tumor recurrence rates in surrounding tissues of AR+ than AR-		
AR protein	Tumor size and survival time	32	China	Survival rate correlated inversely with the levels of AR expression	1998	[70]
				AR levels had positive correlation with the tumor size		

CURRENT STATUS OF HORMONAL TREATMENT IN HCC

The association of estrogens and androgens in HCC observed in basic and clinical studies has led to initiation of various clinical trials on hormonal treatment of HCC. Differential clinical outcome was reported in these trials that have resulted in continued debate about the use of hormonal therapy in HCC. Table 6 presents a list of few clinical studies that utilized hormonal therapy in HCC patients. A systematic review of these clinical trials on therapeutic evaluation of anti-estrogen and anti-androgen agents in liver cancer has been recently compiled by Di Maio *et al*[78]. The authors conclude that hormonal treatment should not be a part of the current management of HCC patients[78,79]. However, in most of these clinical studies, various inherent factors may have contributed to the observed inconclusive results. Few of these may include faulty patient subset selection criteria, no monitoring of tumor ER and AR expression at the time of recruitment and also during treatment of these patients and lastly the type of hormonal treatment given to the patient. Therefore, the debatable potential of hormone therapy in HCC may finally be attributed to the lack of complete understanding of ER and AR expression and hormonal responsiveness in the liver and their involvement in development of HCC.

Currently, limited information is available on the functional significance of ER and AR in HCC. In the following sections, we review the *in vivo* animal studies on liver carcinogenesis and *in vitro* studies on cell lines that have been conducted to understand the role of ER and AR in the liver.

ESTROGEN RECEPTOR AND ANDROGEN RECEPTOR STUDIES IN ANIMAL MODELS OF EXPERIMENTAL LIVER CARCINOGENESIS

Estrogen receptor studies

Several attempts have been made to establish the role of estrogen and its receptors in hepatocarcinogenesis using animal models. Rat is the most extensively used model to study liver carcinogenesis. Rat hepatocytes are known to express ERs. ERα is the predominant isoform expressed in rat hepatocytes while cholangiocytes express both ERα and ERβ[80]. However, Inoue *et al*[81] showed that the levels of ERβ are higher than those of ER in cultured rat hepatocytes[81]. Hepatic stellate cells from rats appear to contain mainly ERβ[82]. Due to the lack of information about the existence of various ER isoforms, in most of the earlier studies, hepatic stellate cells did not differentiate ER into ERα and ERβ. In addition, majority of the *in vivo* studies have been conducted in animal models of chemical carcinogenesis. Diethylnitrosamine (DEN) is the most commonly used carcinogen in rat and mouse models of HCC. The pathogenesis of HCC in DEN-induced carcinogenesis in

Table 6 Clinical outcome of hormonal therapeutic trials in HCC patients

Receptor protein/ mRNA expression	Clinical parameter	Treatment	*n*	Country	Salient Findings	Yr	Reference
ER protein	Tumor growth	Progestin	5	United States	Tumor regression in 2	1982	[30]
NA	Anti-tumor response	Tamoxifen 20 mg twice daily	33	United States	No complete or partial antitumor response	1990	[73]
	Survival time				Long term survival (18+ to 39+ mo) in 4 patients		
NA	Anti-tumoral effect	Tamoxifen 20 mg daily	120 (placebo = 62)	Spain	No-antitumor effect	1995	[74]
	Survival time				No significant differences in survival rate of placebo and treated groups		
Wild type and variant ER mRNA	Tumor size and growth rate	Tamoxifen 80 mg daily or Megestrol 160 mg daily	8	Italy	Growth rate 4 times higher in tumors expression variant ER than wild type ERs. Tumor regression to half size in patients with wild type ER following tamoxifen treatment. Megestrol slowed down tumor growth in tumors with variant ERs	1996	[54]
ER protein	Mortality rates	Tamoxifen	119 (placebo = 58)	China	No difference in 1 mo mortality rates and median survival in treated and control groups	2000	[75]
	Survival				No effect of ER expression on survival		
Variant ER mRNA	Tumor growth, survival	Megestrol 160 mg daily	24 placebo, 21 treated	Italy	Significantly slowed down tumor growth and improved survival in treated patients than placebo group	2001	[76]
NA	Survival rates	Tamoxifen 120 mg daily or 60 mg daily	329	Singapore	No positive effect on survival and increasingly negative impact with increasing doses	2005	[77]

NA: Information not available.

animal models differs from that in humans and therefore may not be directly comparable to human HCC[83]. Nevertheless, the histology and genetic signatures are similar to human HCC and a striking gender disparity with male predominance is also observed in these animal models as seen in humans[84]. In addition to DEN, acetylaminofluorene (AAF), di(2-ethylhexyl) phthalate (DEHP), peroxisome proliferator, arsenic and carbon tetrachloride have been used to induce HCC in various animal models[85-90].

Use of oral contraceptives and synthetic estrogens in women is reported to be a major risk factor for the development of hepatocellular adenoma, a benign liver tumor with malignant potential[26,27]. Shimomura *et al*[91] studied the role of ethinyl estradiol (EE) in inducing HCC in female rats, following EE treatment for 12 mo, 8% of rats developed HCC, revealing that EE causes mutations in hepatocytes leading to DNA adduct formation and induces HCC development in affected cells. The initial events in HCC, i.e. DNA adduct formation by EE, appear to be carried out in an ER independent manner since tamoxifen, a known selective estrogen receptor modulator (SERM), inhibited ER expression and suppressed HCC, but did not affect DNA adduct formation. Exogenous estrogens have also been shown to promote hepatocarcinogenesis induced by other agents[92,93]. Campen *et al*[92] documented that administration of 17-alpha ethinylestradiol in ovariectomized rats promotes DEN-induced carcinogenesis in a dose dependent manner. Further, it was reported that synthetic female hormones act synergistically with ethanol to increase HCC incidence[93]. Alcohol could affect HCC development due to EE by promoting changes in ER kinetics and expression as well as in DNA adduct formation.

Liver is the major site of estrogen metabolism[94]. Alterations in sex hormone metabolism are also considered a critical factor determining the significance of sex hormones in the process of liver carcinogenesis. Eagon *et al*[86,87] reported that the activity of male estrogen-metabolizing enzyme, estrogen 2-hydroxylase and male specific estrogen sequestering protein is reduced in liver, which explains the raised serum estradiol levels but the decreased hepatic activity of cytosolic and nuclear ER observed in DEHP-induced HCC in male Fischer 344 rats. The expression of cytochrome P450 enzymes that play an important role in estrogen metabolism have also been shown to be affected during hepatocarcinogenesis. Waalkes and colleagues[88] have described the feminized pattern of P450 genes in male mice with HCC induced by exposure to arsenic in utero. The expression of female dominant CYP2A4 and CYP2B9 is increased whereas levels of male dominant CYP7B1 gene gets reduced in arsenic treated animals. Recent findings suggest that cytochrome P450 (CYP) is regulated by estrogen itself through the involvement of estrogen receptors[94]. Nonetheless, elucidation of the exact mechanism of regulation of CYP isoforms by estrogen in liver needs further investigation.

In contrast with earlier animal studies that support

estrogens in promoting and inducing carcinogenesis, recent studies highlighted the protective role of estrogens in HCC development. Shimizu *et al*[8] showed that estrogen can suppress chemical hepatocarcinogenesis induced by dimethylnitrosamine (DEN)-2-acetylaminofluorene (AAF) in partial hepatectomy (PH) model of hepatocarcinogenesis. In addition, estrogen has been shown to prevent the progression of liver disease to HCC. Estradiol treatment could reduce hepatic steatosis and restore the impairment in mitochondrial and peroxisomal fatty acid β-oxidation in aromatase-deficient mice which lack intrinsic ability to produce estrogen[95]. Furthermore, estradiol treatment was also shown to result in a dose dependent suppression of hepatic fibrosis in hepatic fibrosis models of male rats[96,97]. The mechanism of protective action of estrogens against progression of chronic liver disease has been recently reviewed by Shimizu and Ito[7].

Recently, using a mouse model of DEN-induced hepatic carcinogenesis, Naugler *et al*[83] described a molecular mechanism explaining the lower HCC susceptibility in females and the anti-inflammatory role of estrogen in preventing HCC development. The authors investigated the relationship between HCC development and gender dependent expression of interleukin-6 (IL-6). IL-6 is a proinflammatory cytokine that plays an important role in chronic hepatitis, the prerequisite for progression to cirrhosis and HCC. The serum IL-6 levels were higher in male mice than in female mice after administration of DEN, leading to a higher rate of liver cell proliferation in male mice. This effect can be further mediated by ERα, suggesting that ERβ plays a little role in modulating the expression of IL-6.

Androgen receptor studies

The role of AR has also been studied in animal models of chemical induced carcinogenesis[87,98-100]. In DEN treated Wistar rats, a 20-fold increase in hepatic AR concentration was reported in females, suggesting that increased hepatic AR concentration is correlated with accelerated tumor development in these animals, in which male rats showed a slower tumor development with no change in AR concentrations[98]. Subsequent studies in the same model revealed that removal of ovary increases AR levels in the liver of female rats but testosterone treatment does not further enhance AR levels[99]. On the other hand, normal adult males with intact testis or testosterone treatment maintain high levels of AR but in castrated rats estrogen treatment reduces AR expression[99]. Animal studies demonstrated that the expression of both AR and ER increases during preneoplastic stages and that progression towards cancer development can suppress ER and maintain AR expression levels[94,100].

Interestingly, anti-androgen treatment has been shown to reduce AR levels in liver as well as the size and number of tumors in male Spargue Dawley rat model of hepatocarcinogenesis[101]. It has been shown that inhibition of AR positive HCC with anti-androgen cypertone acetate in male mice involves cell cycle arrest and to some extent induction of apoptosis due to increased synthesis of transforming growth factor-β 1 (TGF-β1)[102]. In another model of chemical-induced liver carcinogenesis, inhibition of androgens using 5-alpha reductase inhibitors significantly suppressed HCC development in rats[103]. Recent studies in a xenograft model of hepatocarcinogenesis in nude mice suggested that AR expression remains elevated until development of tumor and starts declining as the size of tumor increases[104]. It is therefore proposed that androgen therapy may be ineffective after establishment of the tumor. Nevertheless, for better understanding and rationale design of hormone-based therapies, it is mandatory to study the role of ERs and AR in animal models mimicking the natural course of disease progression to HCC development as in humans. Currently available HBV and HCV transgenic mice depicting features close to human HCC pathogenesis, appear to be promising models for future *in vivo* studies.

SEX HORMONE RECEPTORS: GENOMIC AND NON-GENOMIC ACTIONS IN LIVER CELLS MEDIATING HEPATOCARCINOGENESIS

Estrogen receptor

Estrogen action and the role of ERs in carcinogenesis have been well documented in mammary carcinoma and the studies have revealed the involvement of estrogens in key cellular processes such as apoptosis, cell cycle, proliferation, oxidative stress and inflammation. The progress in understanding the role of estrogen in regulating various cellular events in liver carcinogenesis has been rather slow. However, the research conducted over recent years provides key insights in this direction.

The classical mode of estrogen action is the genomic mechanism in which ERs function as ligand-activated transcription factors[105]. Activated ERs translocate to the nuclei and regulate the expression of specific target genes. These transcriptional regulations are achieved through interaction with estrogen responsive element (ERE) sequences located in the promoter region of the target gene[106]. However, one third of the genes regulated by ERs in humans do not contain ERE-like sequences[107]. ERs can also regulate the transcription of such genes without binding to DNA through protein-protein interactions with other transcription factors, such as AP-1 and Sp-1 in the nuclei[108]. In addition, this transcriptional control at alternate response elements is also facilitated by non-genomic actions of estrogen. The non-genomic functions of estrogen are initiated by membrane-localized ERs and are associated with activation of various signaling pathways especially protein kinases[109]. The functions of many transcription factors are regulated through protein kinase-mediated phosphorylation including CREB, NF-κB and AP-1 and these transcription factors may thus be targets

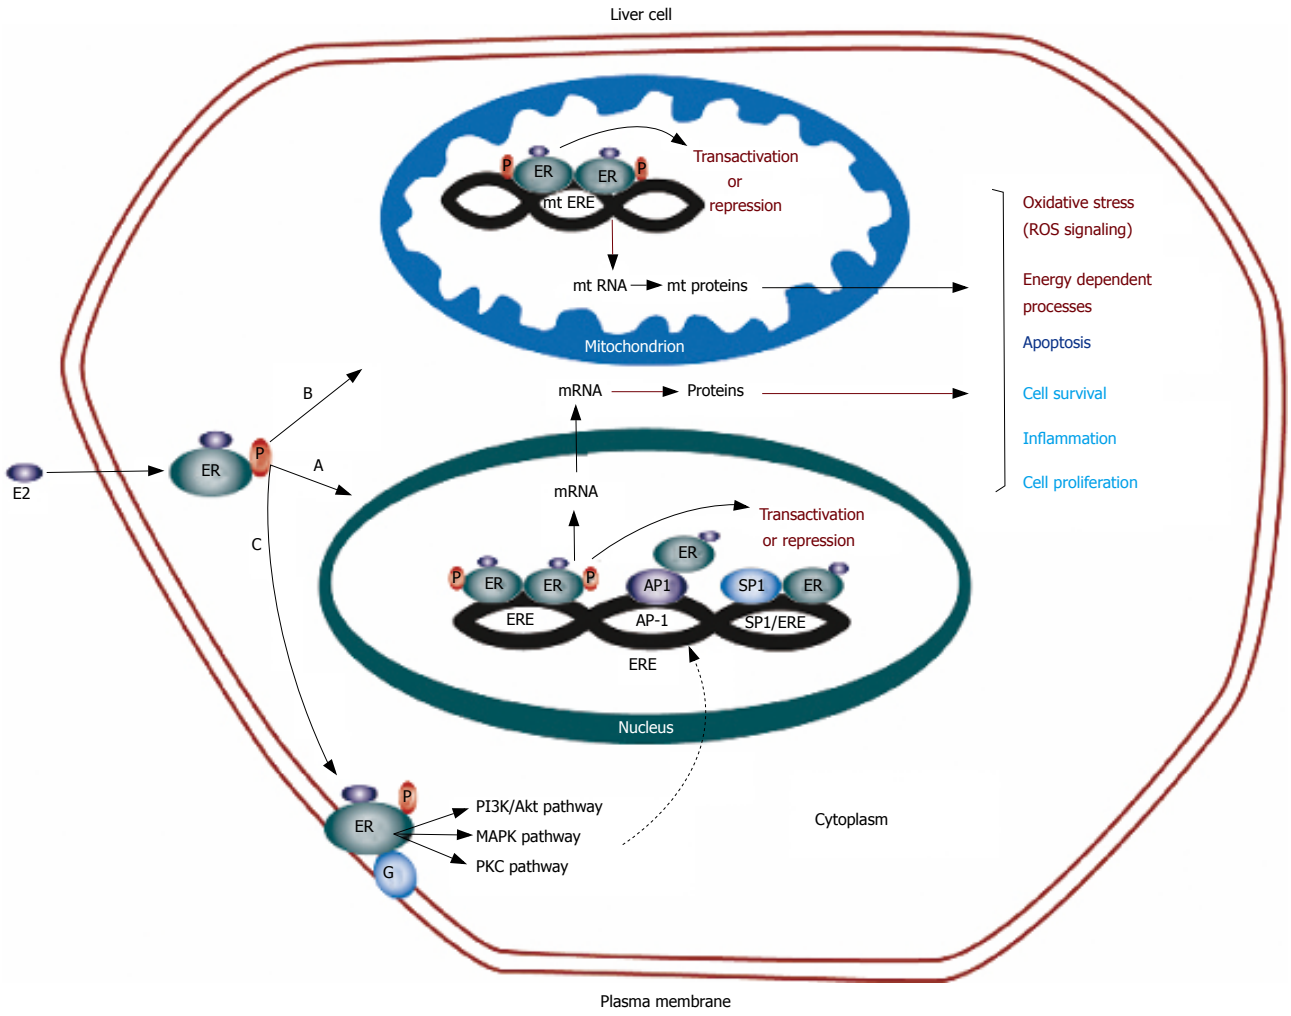

Figure 1 Genomic and non-genomic functions of estrogen mediated by estrogen receptors (ERs) localized in different sub-cellular organelles of a liver cell. A: Genomic actions include translocation of ligand-activated ERs to the nuclei for regulating gene transcription. This transcriptional control is carried out by binding to DNA at a sequence containing either full estrogen response element (ERE) site or an ERE half site adjacent to the binding site for another transcription factor like Sp1. An additional mechanism involves gene regulation at alternate response element through protein-protein interactions with other transcription factors (AP-1, CREB, NF-κB); B: Activated ERs control mitochondrial gene transcription by binding to ERE like sequences (mt ERE) leading to modulation of mitochondrial functions including metabolism, oxidative stress and apoptosis; C: Membrane localized ERs are G-protein coupled receptors that activate various protein kinase pathways. These signal transduction cascades in turn regulate functions of many transcription factors resulting in modulation of expression of a number of genes involved in cell proliferation, survival, apoptosis and inflammation. Genomic and non-genomic actions of estrogen converge to exhibit a fine degree of control for the regulation of transcription by ERs in a liver cell. Modified from: Chen *et al*[110] 2005.

for non-genomic actions of estrogens. This possible convergence of genomic and non-genomic actions at multiple response elements provides an extremely fine degree of control for the regulation of transcription for ERs (Figure 1)[105,110]. In the following section, we discuss the findings of recent *in vitro* studies highlighting the significance of ER in mediating genomic and non-genomic actions of estrogen in liver cells to modulate the expression of a number of genes involved in cellular processes central to carcinogenesis.

Telomerase activation has been implicated in hepatocarcinogenesis and the expression of human telomerase reverse transcriptase (hTERT) that encodes for the catalytic subunit of the multicomponent enzyme telomerase hTERT is the prerequisite for telomerase activation[111,112]. Several studies indicated that estrogen regulates transactivation of the hTERT gene by direct interaction of activated ER with an imperfect ERE sequence in the hTERT promoter[113]. Estrogen treatment has been shown to up-regulate the expression of hTERT mRNA and protein in three normal human hepatic cell lines (hc-cells, hNheps and WRL-68) expressing ERα to varying degrees[90]. Furthermore, estrogen exposure prevents shortening of telomeres and decreases the number of cells undergoing senescence, indicating that estradiol acts as a positive modulator of the hTERT gene in the liver[90]. However, the mechanism of ER-mediated transactivation of hTERT in the liver is not well understood. In contrast, in HepG2 cells, estrogen modulation of telomerase activity has been found to be regulated post-transcriptionally *via* the IP3/PKC pathway[114,115]. IP3 production has been shown to be up-regulated by estrogens in HepG2 cells[114]. Furthermore, estradiol-induced IP3/PKC-alpha production is dependent on either ERα or ERβ expression in both HepG2 and Hela cells[114]. It is

hypothesized that membrane ER-mediated IP3/PKC-alpha pathway represents an alternative signaling pathway utilized by cells when low ER levels are unable to activate classic ER-mediated genomic mechanisms as in HepG2 cells[114].

A similar regulatory mechanism has been observed in case of estrogen modulation of expression of cyclin D1 gene in hepatoma cells. Cyclin D1, important for progression of cells through G1 phase of cell cycle, is a well defined target for estrogen action in mammary carcinoma[116,117], although no detectable estrogen responsive element like sequence in the cyclin D1 gene promoter has been reported in these cells[118]. The cyclin D1 mechanism identified in mammary carcinoma cells involves direct interaction of ERα and Sp1 or ERα and Ap-1[119]. Interestingly, Marino *et al*[23] demonstrated that in HepG2 cells, estrogen-induced activation of cyclin D1 transcription can occur independently of the transcriptional activity of ER. They further showed that the effect of 17-beta estradiol on HepG2 cells is mediated by activation of the MAPK/ERK pathway by membrane-localized ER that increases the expression of cyclin D1 gene through activation of AP-1 transcription factor[23], suggesting that non-genomic signaling pathways play an the pivotal role in estrogen-mediated regulation of gene expression at multiple response elements.

Besides, modulating the molecules involved in cell cycle control and cell proliferation, estrogen has also been shown to regulate the expression of genes crucial for apoptosis of hepatocytes and dysregulation of apoptosis in hepatic cells is reported to be a significant factor in accelerating hepatocarcinogenesis or tumor progression in HCC[120]. The Bcl-2 family of proteins regulates one of the key steps in the conserved apoptotic pathway. Among the members of this family, Bcl-2 and Bcl-xL act as inhibitors of apoptosis where as Bax and Bak promote apoptosis[121,122]. Ethinyl estradiol is known to increase the levels of Bcl-2 protein in cultured female rat hepatocytes[123]. Estradiol and idoxifene, two selective estrogen receptor modulators, are known to induce the expression of Bcl-2 protein in male rat liver tissues[124]. Omoya *et al*[9] and Inoue *et al*[81] also demonstrated that estradiol is able to stimulate the expression of Bcl-2 and Bcl-xL and to suppress Bad expression in oxidative stress-induced early apoptotic rat hepatocytes. Similar findings have been recently documented in response to estradiol treatment of Huh-7 human hepatoma cells describing a dose dependent increase in expression of Bcl-2 and Bcl-xL and a reduction in Bad levels[22]. No change was observed in expression of pro-apoptotic protein Bax. The regulation of Bcl-2 gene expression by estrogen in mammary carcinoma cells has been shown to be mediated indirectly through activation of Sp-1 transcription factor[125]. However, the precise mechanism of Bcl-2 transactivation in hepatocytes has not been clearly understood.

One of the most interesting mechanisms of transcriptional regulation at alternate response elements by estrogen is through inhibition of transcription factor NF-κB. Studies demonstrating a mutually antagonistic cross-talk between these families of transcription factors have been recently reviewed[126]. The ER has been shown to mediate opposition of NF-κB functions at various levels by inhibiting the activation of signaling pathways, preventing nuclear translocation, blocking DNA binding or inhibiting recruitment of co-activators for transcription[126]. Estrogen has been shown to bring about its anti-inflammatory and anti-oxidant effects on liver cells by suppressing the NF-κB activity as evident from the following studies. It was reported that 17 beta-estradiol-bound ERα interferes with cytokine-induced activation of a NF-κB reporter in HepG2 cells, suggesting that estrogen exerts its anti-inflammatory and protective effects on human liver cells[127]. Moreover, in an *in vivo* model, estrogen treatment has been shown to block the induction of hepatic expression of inflammatory vascular cell adhesion molecule-1 (VCAM-1), tumor necrosis factor-α (TNF-α), and regulate normal T-cell expression and secretion upon activation[128]. In a mouse model of DEN-induced HCC, ERα was suggested to suppress IL-6 production, a pro-inflammatory molecule, through the involvement of the NF-κB pathway[83]. Estrogen has also been reported to suppress oxidative stress-induced reactive oxygen species (ROS) generation, lipid peroxidation, activation of AP-1 and NF-κB as well as loss of Cu-Zn SOD activity in cultured rat hepatocytes[2,9].

In addition to genomic and non-genomic actions of estrogen mediated by nuclear and membrane ER, mitochondria have also recently been identified as important targets of estrogen and ERs[110]. Early binding studies on sub-cellular fractions indicated that ER is present in rat liver mitochondria[129]. Both ERα and ERβ have been reported to be present in the mitochondria of human HepG2 cells[130-132]. The mitochondrial genome has been shown to contain sequences that have partial homology to the estrogen responsive elements[132-134]. Both ERα and ERβ bind to mitochondrial DNA and the binding can be increased by estradiol using mobility shift assays and surface plasmon resonance[135]. These results suggest that estradiol is directly involved in the regulation of mitochondrial DNA transcription (Figure 1). Regulation of apoptosis and oxidative metabolism by estrogens in mitochondria may be important in the normal liver and in the development of HCC.

Ethinyl estradiol treatment has been shown to elevate the expression levels of mitochondrial DNA-encoded cytochrome C oxidase subunit Ⅲ (CO Ⅲ) and ATP synthase 6 *in vivo* as well as in HepG2 cells[136]. This increased expression of mitochondrial transcripts is accompanied by increased mitochondrial superoxide production and respiratory chain activity that require cytochrome P450-mediated biotransformation of ethinyl estradiol and 17-beta estradiol to catechol metabolites[136,137]. In addition to CO Ⅲ, the levels of CO Ⅰ and CO Ⅱ encoded by mitochondrial DNA have also been found to be elevated in ethinyl estradiol treated female rat hepatocytes. This effect is accompanied

by increased mitochondrial superoxide production, high ATP levels and increased Bcl2 production, and is suggested to play a role in ethinyl estradiol-mediated inhibition of apoptosis[123]. In contrast, 17-beta estradiol and 17-beta estradiol like compounds, diethylstilbestrol (DES), tamoxifen and genistein, have been found to induce apoptotic effects in human hepatoma Hep3B cell line[138]. These compounds cause the leaking of cytochrome C from mitochondria and activation of caspase-3 in an ER dependent manner. In another study, the two isoforms, ERα and ERβ, showed their opposing actions on apoptosis in a poorly differentiated HCC cell line HA22T[139]. Over-expressed ERβ but not ERα induces the expression of caspase-8 and TNF-α in HA22T cells in response to estradiol treatment, indicating that the death receptor-mediated apoptotic pathway is activated[139].

Differential roles of ERα and ERβ have also been observed in non-genomic actions of estrogen in the liver[21,23]. There is indirect evidence that membrane ER may exist in human liver as the binding of gold tagged estrogen-BSA conjugate on the surface of clathrin-coated pits in HepG2 cells has been demonstrated by electron microscopic visualization[140]. The non-genomic mechanism of action of sex steroids on the plasma membrane involves the activation of protein kinase cascades (Figure 1). Two major cascades, protein kinase C, and mitogen-activated protein (MAP) kinase are active and important in carcinogenic liver cells. Protein kinase C cascade and its second messenger IP3 are important in cell proliferation and have been discussed in this review in context of transcriptional regulation of hTERT expression by estrogen. The mitogen-activated protein (MAP) kinase cascade is another pathway that is regulated by the action of sex steroids at the plasma membrane. This complex signaling cascade involves three major pathways: ERK, p38, and JNK[141]. In HepG2 cells, estradiol has been found to rapidly increase the phosphorylation of ERK[21,23]. Naringenin, an anti-estrogenic flavonone, induces the activation of p38 in ERα containing HepG2 cells or in ERβ containing human colon adenocarcinoma DLD-1 cells[142], suggesting that naringenin has an antiestrogenic effect only on the ERα expressing cells, whereas it mimicks the estradiol effects on ERβ expressing cells. The role of ERα and ERβ in the regulation of MAP kinase cascade has been further studied in cell lines expressing either ERα or ERβ[21]. It was found that estrogen-bound ERα can rapidly activate the ERK and AKT signal transduction pathways leading to cell cycle progression and inhibition of apoptosis, whereas estrogen-complexed ERβ can induce rapid phosphorylation of p38 leading the cells to the apoptotic cycle and cell death. These studies further support the functional antagonism between ERα and ERβ with respect to estrogen-induced cell proliferation and emphasize the need to study the independent and interactive role of both isoforms in hepatocarcinogenesis.

Androgen receptor

In comparison with ER, there is limited information about genomic and non-genomic functions of AR in the liver. Like ER, AR has also been shown to regulate gene transcription by binding to androgen responsive sequences (ARE)[143,144]. Yoon *et al*[145] demonstrated that androgen can directly regulate the expression of transformation growth factor-beta 1 (TGF-β1) through binding of AR to ARE in TGF-β1 promoter, suggesting that such activation might regulate the progression of HCC in both human and animal models[145]. Furthermore, AR has been shown to interact with a newly identified transcription factor, paternally expressed gene 10 (PEG 10) in hepatoma cell line[146]. PEG 10 has growth promoting properties and is implicated in hepatocarcinogenesis[147,148]. Dihydrotestosterone (DHT) promotes hepatoma formation in nude mice through PEG 10 activation. In addition, DHT treatment is shown to up-regulate hTERT expression in hepatoma cell lines in a PEG-10 dependent manner[146]. These studies indicate that PEG-10-mediated transactivation of target genes by AR has an essential role in hepatocarcinogenesis.

To the best of our knowledge, AR has not been detected in the liver mitochondria. The information about the membrane localization of AR in human liver cells is also lacking. However, AR has been reported to occur in the plasma membranes of male rat liver[149]. Androgens are also involved in the regulation of the MAP kinase signaling pathways as orchiectomy of H-ras 12V transgenic mice decreases phospho-MEK and phospho-ERK in liver tissues. In addition, orchiectomy reduces hepatotumorigenesis in male mice while ovariectomy increases phospho-MEK and phospho-ERK in liver tissue from female mice, but ovariectomy does not affect the incidence of tumorigenesis[150]. Detailed investigations are urgently needed to confirm the existence of non-genomic signaling actions of androgens in liver and the role of AR in mediating these functions.

INTERACTION OF ER AND AR WITH VIRAL PROTEINS IN HBV AND HCV PATHOGENESIS

Chronic infection with HBV and HCV is the major cause of increasing incidence of HCC worldwide. Several reports support the role of HBV and HCV proteins in disturbing cellular homeostasis and causing malignant transformation of hepatocytes[151,152]. Recent studies in hepatoma cell lines suggest the interactive role of ERs and AR with HBV and HCV proteins in viral pathogenesis.

Estrogen receptor and viral proteins

Han *et al*[24] recently reported that HBV protein (HBx) interacts with ERα. HBx is a multifunctional protein involved in neoplastic transformation in cultured cells and can induce HCC in transgenic mice. HBx associates with both ERα and delta 5 deletion variant of ERα (vERα) and inhibits ERα transcriptional activity by recruiting histone deacetylase enzyme, HDAC-1[24].

HDAC-1 belongs to the family of enzymes involved in deacetylation of hyperacetylated histone tails, leading to compaction of chromatin and transcritptional repression[153]. Both HBx and vERα have additive effects on suppression of ERα transactivation[24].

ERα has also been shown to interact with nonstructural (NS) 5B protein of HCV[25]. NS5B is a RNA-dependent RNA polymerase, which plays a central role in viral genome replication[154]. HCV replication takes place in a replication complex consisting of viral RNA and non structural proteins including NS5B[155]. The replication complex forms on the surface of intracellular membranes including endoplasmic reticulum membrane and is associated with lipid rafts rich in caveolin 2 (CAV 2) on these membranes[156-158]. Using chemical biology approach, Watashi *et al*[25] demonstrated that ERα facilitates the interaction of NS5B with CAV 2 in lipid rafts and hence promotes the participation of NS5B in HCV replication complex. However, they did not find that ERβ affects HCV replication in the same study[25]. An important observation of the study is that tamoxifen inhibits ERα actions and suppresses HCV genome replication, further supporting the potential for anti-ER drugs in developing new anti-HCV strategies.

Androgen receptor and viral proteins

Like ER, HBx protein has also been shown to interact with AR. HBx functions as a positive transcriptional co-regulator to increase AR-mediated transcriptional activity. This transcription enhancement is increased in the presence of androgen in a concentration-responsive manner. However, HBx does not physically associate with ligand-bound AR in the nuclei, suggesting that HBx augments AR activity by increasing the phosphorylation of AR through HBx-mediated activation of the c-Src kinase signaling pathway[159]. In contrast, Zheng *et al*[160] demonstrated that HBx can physically bind to AR in the liver and alter the subcellular localization of AR both in the presence and absence of dihydrotestosterone (DHT). Further studies indicated that HBx can enhance the gene transactivation activity of AR by enhancing its DNA binding activity in a DHT-dependent manner.

CONCLUSION

Taken together, studies on hepatoma cell lines, HCC tissues and animal models of hepatocarcinogenesis, highlight the importance of sex hormones and their receptors in HCC pathogenesis. Further investigations are urgently needed to elucidate the precise mechanism of action of estrogens, androgens and their receptors in regulating normal liver physiology and pathophysiology of chronic liver diseases resulting in HCC.

A thorough re-examination of studies conducted so far to detect the expression of ER and AR in liver tissues is needed using newer specific, sensitive and quantitative methods. With the emerging significance of ERβ and the availability of isoform specific antibodies, the relative levels of both ERα and ERβ can be determined. The studies on mRNA expression in liver tissues have demonstrated the presence of deletion mutants (variant forms) that need to be further validated at protein levels for establishing their significance in diagnosis and prognosis of HCC. Considering the male predominance of HCC and the wide gap in the information available on AR in liver, detailed mechanistic studies need to be conducted to reveal the mechanism of androgen function in normal liver and HCC. In addition, evaluation of ER and AR status at premalignant stages of chronic liver disease due to different etiological factors is required for critical understanding of their role in HCC pathogenesis.

Recent *in vitro* studies focusing on molecular interaction of hormonal receptors with viral proteins need to be further confirmed in *in vivo* animal models. Currently available HBV and HCV transgenic mouse models as well as human hepatocyte xenograft models can serve as a valuable preclinical tools to validate the importance of sex hormone receptors in chronic liver disease development and progression to HCC. Thus, with the availability of state of the art technologies, the time is ripe to embark on to move this important field forward. Well designed, systematic studies employing adequate tools to study ERs and ARs in chronic liver disease and HCC may contribute to the development of novel therapeutics or prognostic markers. These studies may also be further helpful in resolving controversies about the use of hormonal therapy for HCC.

Abstract

MYC is an oncogene involved in cell cycle regulation, cell growth arrest, cell adhesion, metabolism, ribosome biogenesis, protein synthesis, and mitochondrial function. It has been described as a key element of several carcinogenesis processes in humans. Many studies have shown an association between *MYC* deregulation and gastric cancer. *MYC* deregulation is also seen in gastric preneoplastic lesions and thus it may have a role in early gastric carcinogenesis. Several studies have suggested that amplification is the main mechanism of *MYC* deregulation in gastric cancer. In the present review, we focus on the deregulation of the *MYC* oncogene in gastric adenocarcinoma carcinogenesis, including its association with *Helicobacter pylori* (*H pylori*) and clinical applications.

Key words: *MYC*; Gastric adenocarcinoma; Gastric preneoplastic lesions; Gastric carcinogenesis; *Helicobacter pylori*

INTRODUCTION

A temporal decline in gastric cancer (GC) incidence has been seen in several countries, including Brazil[1,2]. However, this cancer causes nearly one million deaths a year worldwide and is still a serious public health cancer[3], especially in the Pará State, Northern Brazil, where mortality rates are higher than the national average rate[2]. GC is usually diagnosed at advanced stages and the single curative therapy available requires surgical resection[4].

Over 95% of gastric malignancies are adenocarcinomas[5]. They are subdivided into two main histological types: well-differentiated or intestinal-type, and undifferentiated or diffuse-type[6]. Intestinal-type gastric tumors predominate in high-risk geographic areas whereas diffuse-type tumors are more common in low-risk areas[7].

The identification of peculiar genetic characteristics of gastric tumors may help predict prognosis of GC patients and allow more accurate therapeutic approaches. Genetic analyses of GC suggest that there occur structural and functional alterations of several oncogenes and tumor suppressor genes, as well as genetic instability[8]. Additionally, GC has been an interesting carcinogenesis model. Evidence suggests that intestinal- and diffuse-type gastric carcinomas develop through distinct genetic pathways due to different genetic alterations identified in these histological types[9,10].

MYC (*C-MYC*) oncogene has been described as a key element of several carcinogenesis processes in humans[11]. In the present review, we focus on the deregulation of the *MYC* oncogene in gastric carcinogenesis.

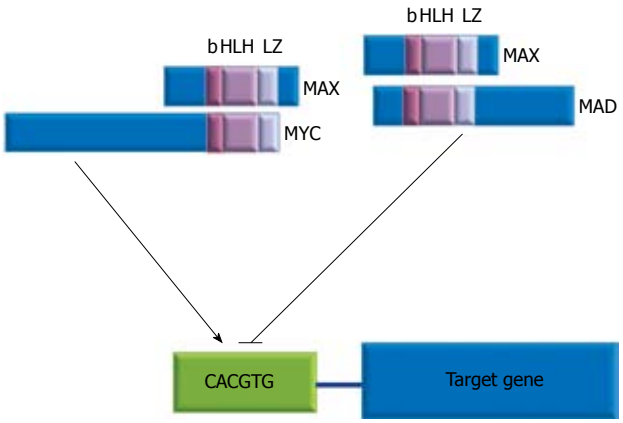

Figure 1 Activation of MYC target genes by the interaction between MYC:MAX or their repression by MAX:MAD. Domains that are common to each protein and are involved in heterodimerization are shown; b: Basic region; HLH: Helix-loop-helix; LZ: Leucine zipper. E-box sequence is shown in green.

MYC AND CANCER

MYC gene was found to be the cellular homolog of retroviral v-myc oncogene about 30 years ago[12-14]. It is located on chromosomal region 8q24.1, has 3 exons[15,16] and encodes a nuclear phosphoprotein[17].

MYC has to heteromerize with MAX, a protein expressed constitutively, to acquire DNA-binding activity. MYC/MAX dimmers are made viable by a basic region helix-loop-helix leucine-zipper motif (bHLH-Zip), conserved sequences in the carboxyl terminus of both proteins. MYC/MAX dimmers bind to E-box sequence CACGTG in the promoters of specific target genes and stimulate their transcription[18].

MYC has an effect on up to about 15% of genes in genomes of many organisms, from flies to humans[19]. Groups of genes involved in cell cycle regulation, metabolism, ribosome biogenesis, protein synthesis, and mitochondrial function are over-represented in the Myc target gene network.

MYC also consistently represses genes involved in cell growth arrest and cell adhesion[20]. Dominguez-Sola *et al*[21] recently showed that Myc interacts with the pre-replicative complex and localizes to early sites of DNA synthesis. Thus, it also has a direct role in the control of DNA replication.

MYC regulates transcription from its targets through several mechanisms, including recruitment of histone acetylases, chromatin modulating proteins, basal transcription factors and DNA methyltransferase[22-26].

Protein products of *MYC* target genes go on to mediate the downstream effects of *MYC* on cell biology. MYC is then rapidly degraded, and the pathway switches to a transcriptionally repressive state when MAX dimerizes with a group of related bHLH-Zip proteins, the MAD family, that act as MYC antagonists[27] (Figure 1).

MYC expression might be regulated transcriptionally (initiation and elongation), post-transcriptionally (mRNA stability and translation) or post-translationally (protein stability)[28].

MYC is generally recognized as an important regulator of proliferation, growth, differentiation and apoptosis[29,30]. Therefore, it is also accepted that the deregulation of *MYC* expression is a major event in cancer pathogenesis or progression. Deregulated expression of a wild-type MYC protein is sufficient to lead to cellular transformation *in vitro* and tumorigenesis *in vivo*[31].

Recent studies have also found that MYC oncoprotein, in addition to its directly transforming role, can mediate genomic instability *via* the induction of reactive oxygen species and by promoting whole chromosome instability leading to tetraploidy and aneuploidy. MYC's ability to promote chromosomal instability is closely linked to its function as a transcriptional regulator[32]. Our research group reported higher frequency of tetraploid clones in GC cell line[33] and aneuploid cells in primary gastric tumor[34,35].

Oncogenic alterations of *MYC* are commonly induced by events such as point mutations, gene amplification, chromosomal translocation, viral insertion at the *MYC* locus, and resistance of MYC protein to ubiquitin-mediated proteolysis and enhanced transcription or translation by other oncogenic signaling pathways[30].

MYC AND GASTRIC CARCINOGENESIS

MYC overexpression has been described in over 40% of GC[36]. We found that MYC protein was expressed in all cases of both intestinal- and diffuse-type gastric adenocarcinoma samples of individuals from Northern Brazil[37]. Table 1[38-59] shows the proportion of cases with *MYC* aberration in several GC studies.

Several studies have shown the association between MYC expression and histopathologic characteristics. Xu *et al*[51] and Yang *et al*[54] described a significantly higher expression of MYC in intestinal-type than in diffuse-type GC.

Kozma *et al*[50] and Yang *et al*[54] reported that higher MYC expression was associated with the presence of metastasis. Onoda *et al*[41] also found *MYC* mRNA levels were higher in metastatic than in primary lesions. Han *et al*[45] described that patients with high levels of MYC expression had poor disease-free survival. Therefore, MYC expression may represent an aggressive phenotype of GC.

MYC overexpression has also been seen in early GC when tumor invasion is confined to the mucosa or submucosa regardless of the presence of lymph node metastasis[40,41,45,46,52,54,59]. Yang *et al*[54] found a significantly higher expression of MYC in advanced GC than in early stage GC. However, Onoda *et al*[41] reported that MYC expression was found to be more frequent and stronger in early than in advanced lesions. Other studies have not found this same difference.

Several studies demonstrated an increased MYC expression in pre-cancerous gastric lesions and its increased expression also has been associated with *Helicobacter pylori* (*H pylori*) infection. *H pylori* is defined as a carcinogen factor to gastric carcinoma infection by the International Agency for Research on Cancer (IARC)[60].

Table 1 Several MYC studies in gastric cancer

Reference	Cause of MYC deregulation	Increased MYC	Number of cases	Rate (%) of cases with MYC deregulation
[38]	Overexpression	Protein	88	55

[59]	Amplification/Overexpression	DNA/Protein	5 early	100

Chronic gastritis caused by *H pylori* infection may progress to intestinal metaplasia and even to GC[61,62].

Tatsuta *et al*[63] evaluated *MYC* mRNA expression by in situ hybridization in 31 elevated gastric lesions. Patients who had borderline lesions with and without *MYC* overexpression were followed up with repeated endoscopic examinations and gastric biopsies. The authors reported that well-differentiated elevated-type adenocarcinomas were detected in 46% of patients with elevated lesions that presented *MYC* overexpression during a follow-up period of about 15 mo (range, 2-32 mo) and that no cancers were found in patients with elevated lesions without *MYC* overexpression. These sample groups were significantly different. Therefore, *MYC* overexpression may provide a valuable tool for distinguishing between adenomas and well-differentiated elevated-type adenocarcinomas.

Xu *et al*[51] noticed that MYC protein expression increased progressively as follows: chronic active gastritis, gastric ulcer, mild nonclassic proliferation, severe non-classic proliferation, early GC, and progressive GC.

Lan *et al*[53] found that MYC expression was higher in GC than in chronic gastritis, intestinal metaplasia and dysplasia. MYC expression was higher in type Ⅲ intestinal metaplasia with *H pylori* compared to the same metaplasia without infection and the positive rate in dysplasia with *H pylori* was higher than that without infection. Zhang *et al*[55] also reported that MYC expression was higher in chronic atrophic gastritis with severe intestinal metaplasia than that with mild intestinal metaplasia. In chronic atrophic gastritis with severe intestinal metaplasia, MYC expression was higher in cases with *H pylori* infection than in those without infection. Higher MYC expression was also found in GC with *H pylori* infection than in that without infection. Thus, MYC expression was coordinately up-regulated in *H pylori* infected GC and chronic atrophic gastritis with severe intestinal metaplasia. Authors have suggested that *H pylori* infection may affect MYC expression in gastric diseases, especially in chronic atrophic gastritis.

Several studies have shown that patients with preneoplastic and neoplastic gastric epithelial lesions are more likely to be infected by cagA positive strains. *H pylori* cagA is one of the most virulent strains of *H pylori*. Increased cancer risk is described in individuals infected by cagA-positive *H pylori* strains compared with those infected by cagA-negative *H pylori* strains and, in general, in those living in areas with a high rate of cagA-positive *H pylori* strains[64]. Yang *et al*[54] compared MYC expression in gastric tissues (intestinal metaplasia, dysplasia and GC) with and without *H pylori* cagA. These authors found that MYC expression was significantly higher in those lesions of type Ⅲ intestinal metaplasia and dysplasia Ⅱ-Ⅲ with cagA than in those without cagA. Nardone *et al*[64] also suggested that the increased prevalence of MYC expression was in agreement with the high prevalence of cagA positivity seen in the population studied.

Kim *et al*[65] investigated the expression of MYC protein and mRNA in 22 patients with chronic gastritis who had been successfully treated for *H pylori*. Two endoscopic antral biopsies were taken before and 2 mo after *H pylori* eradication. The proportion of gastric antral epithelial cells expressing MYC protein was significantly lower after *H pylori* eradication. *MYC* mRNA expression was not changed by *H pylori* eradication. *H pylori* may affect cell cycle progression and carcinogenesis through post-translational effects on specific gene expression. Nardone *et al*[64] also found that MYC expression disappeared after *H pylori* eradication.

In vitro studies have also confirmed that *H pylori* can

affect *MYC* expression. Yang *et al*[66] described that *H pylori* induces apoptosis in human gastric adenocarcinoma cells mediated by an increased expression of *MYC* mRNA.

Epstein-Barr virus (EBV) is another infectious agent thought to contribute to cancerous transformation of human host cells. EBV infection is seen in about 10% of gastric adenocarcinoma cases[49,58,67]. Ishii *et al*[49] found MYC expression in early stages of EBV-positive GC was higher than that of EBV-negative GC, while MYC expression in advanced stages of EBV-positive GC was lower than that of EBV-negative tumors. It was inferred that EBV might cause the host cell to induce MYC expression in early cancer development, but then negatively affect MYC expression in advanced stages of cancers, making them less likely to have a natural regression *via* apoptosis. Lima *et al*[58] also reported MYC low expression in EBV-positive GC samples. However, Luo *et al*[67] have not found any correlation between EBV and MYC expression in GC, suggesting that EBV does not inhibit MYC expression in advanced stages of EBV-positive gastric cancer.

MECHANISMS OF MYC DEREGULATION IN GASTRIC CANCER

Copy number gains are frequently detected along chromosome 8 in gastric tumors[43,48,56,68-73]. Suzuki *et al*[43] described that chromosome 8 copy number was significantly higher in differentiated than undifferentiated types of GC. Our research group found 8q24.1 gain, where *MYC* is located, exclusively in intestinal subtype with metastasis by comparative genome hybridization (CGH)[72]. However, Koo *et al*[48] reported that amplifications in 8q region were more common in diffuse-type cancer.

Some studies have showed an association between MYC amplification and GC[42-44,48]. We have also previously seen *MYC* amplification in intestinal adenocarcinoma by dual-color fluorescence in situ hybridization (FISH), such as homogeneously staining chromosomal regions and double minutes, supporting our CGH results[56]. Our findings support that these two histological GC types follow different genetic pathways.

Our research group also found that all five early GC cases with MYC overexpression also had three signal to MYC gene by FISH assay, varying between 13% and 26% of cells/case[59]. Suzuki *et al*[43] found *MYC* amplification in all 6 early GC cases studied, varying between 19% and 89% of cells/case, and this rate was not significantly difference from that found in advanced GC samples. These findings suggest that *MYC* amplification can be a critical event to gastric carcinogenesis.

MYC translocation is frequently described in Burkitt's lymphoma. Few studies have also found translocation of the *MYC* locus associated with gastric carcinogenesis. Yamashita *et al*[74] identified chromosomal translocations involved in 8q24 breakpoint by spectral karyotyping (SKY) analysis of established GC cell lines and cancerous ascitic fluids. In a previous study, our findings suggested that translocations can be related to diffuse-type GC using FISH assay[37,56].

Epigenetic events play a significant role in cancer development and progression. DNA methylation is the most studied epigenetic alteration. Some studies also have demonstrated that *MYC* hypomethylation, which leads to its activation, is significantly more common in GC samples than non-cancerous tissues[75,76]. Fang *et al*[77] and Weng *et al*[78] suggest that folate level reduction is associated with upregulation of *MYC* expression and its promoter hypomethylation in GC.

FUTURE PERSPECTIVES

Proto-oncogenes have a major role not only in cancer development, but also in cancer therapies[79]. *MYC* alteration is seen in the early gastric carcinogenesis progress. The detection of *MYC* locus amplification may be used as an auxiliary tool to GC diagnosis and as a predictor of GC aggressiveness.

MYC also could be used as a therapeutical target. Several experimental studies showed that *MYC* inactivation suppresses tumors in animal models, suggesting *MYC* as a molecular target in cancer treatment[80-83].

Chen *et al*[84] evaluated the effect of MYC expression inhibition by recombinant antisense *MYC* adenovirus (Ad-ASc-myc) infected SGC7901 human gastric carcinoma cells, which have *MYC* gene amplification, in the proliferation, apoptosis and growth processes of human gastric tumors in nude mice. It was found that MYC expression inhibition may strongly inhibit cell growth and induce apoptosis in SGC7901 cells. Proliferation of Ad-ASc-myc-infected SGC7901 cells was reduced by 44.1%. Studies involving tumorigenicity in nude mice and experimental therapy in nude mice model using Ad-ASc-myc also support these findings. These studies also suggest that Ad-ASc-myc overexpression may result in the elimination of tumor cells *via* apoptosis and proliferation inhibition, and therefore reduce tumor burden.

Inhibiting MYC expression can be a potential tool for GC treatment in tumors with MYC overexpression. MYC's therapy target may help identifying more specific and less toxic therapeutic agents[30].

Abstract

Congenital absence of portal vein (CAPV) was a rare event in the past. However, the number of detected CAPV cases has increased in recent years because of advances in imaging techniques. Patients with CAPV present with portal hypertension (PH) or porto-systemic encephalopathy (PSE), but these conditions rarely occur until the patients grow up or become old. The patients usually visit doctors for the complications of venous shunts, hepatic or cardiac abnormalities detected by ultrasonography (US), computed tomography (CT) and magnetic resonance imaging (MRI). The etiology of this disease is not clear, but most investigators consider that it is associated with abnormal embryologic development of the portal vein. Usually, surgical intervention can relieve the symptoms and prevent occurrence of complications in CAPV patients. Moreover, its management should be stressed on a case-by-case basis, depending on the type or anatomy of the disease, as well as the symptoms and clinical conditions of the patient.

Key words: Congenital absence of portal vein; Abernethy malformation; Focal nodular hyperplasia

INTRODUCTION

The first account of congenital absence of the portal vein (CAPV) was given by John Abernethy in 1793[1], based on a postmortem examination of a 10-mo-old female, which revealed the termination of portal vein in the inferior vena cava at the insertion level of the renal veins and multiple congenital abnormalities other than CAPV. It was reported that complete portosystemic shunts not perfusing the liver *via* portal vein are defined as type Ⅰ, whereas partial shunts with a remaining degree of portal perfusion to the liver are defined as type Ⅱ[2]. Furthermore, type Ⅰ is sub-classified into types Ⅰa and Ⅰb depending on the anatomy of portal vein. In type Ⅰa, the splenic vein (SV) and superior mesenteric vein (SMV) drain separately in type Ⅰa, while both drain together in type Ⅰb after uniting to form a common trunk[3]. Howard and Davenport[4] suggested that the congenital diversion of portal blood away from the liver, by either an end-to-side or a side-to-side shunt, is known as the Abernethy malformation. Thus, CAPV associated with extra hepatic portocaval shunts can be referred to as an Abernethy type Ⅰ malformation (Figure 1).

ANATOMY AND EMBRYOLOGY

The portal vein returns blood from the intraperitoneal section of the gastrointestinal tract and the spleen, pancreas, and biliary apparatus, while SV and SMV return blood form the portal vein. At the porta hepatis, the portal vein is subdivided into right and left branches (besides providing the quadrate lobe with an additional branch). These branches ramify to form small vessels that drain into the sinusoids[5]. CAPV with an extrahepatic porto-caval shunt means that the mesenteric vasculature where splanchnic blood bypasses the liver through a congenital shunt vessel, completely drains into the systemic circulations, such as inferior vena cava, left renal vein, right atrium, iliac vein, left hepatic vein (HV), and azygos vein[6-8]. Strictly speaking, CAPV is also characterized by complete absence of venules within the portal areas, which has been confirmed by liver biopsy[9,10]. The case seems to be a complete portal vein agenesis[10]. Similarly, complete absence of the portal

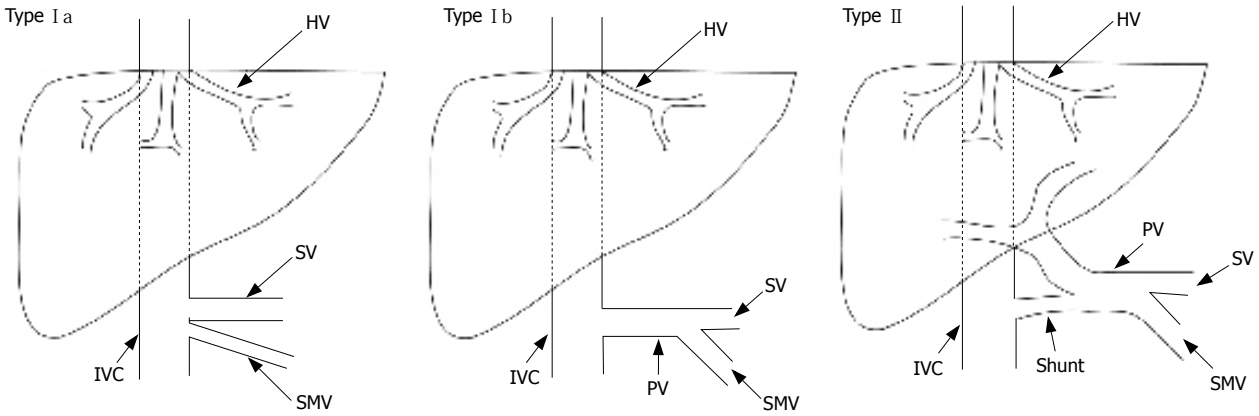

Figure 1 Schematic demonstration of different types of Abernethy abnormality[2]. SMV: Superior mesenteric vein; HV: Hepatic vein; SV: Splenic vein; PV: Portal vein; IVC: Inferior vena cava.

vein with intrahepatic portal venules can be named portal vein atresia.

The portal vein develops embryologically between the 4th and 10th weeks[10,11]. In the 4th week embryo, three paired venous systems are present: umbilical veins of chorionic origin, vitelline veins from the yolk sac and cardinal veins from the body of the embryo. Towards the end of the 4th week, three cross links are formed between the right and left vitelline veins[12]. The intrahepatic portal veins develop from the superior link, while the extrahepatic portal vein forms during the selective involution of the caudal part of the right and left vitelline veins. Selective involution of these communications generates the fully developed portal vein[11]. Primary failure to form this critical anastomosis will lead to complete or partial absence of the portal system. As a result, mesenteric and splenic venous flow cannot but drain into renal veins, HVs, or directly into the inferior vena cava (IVC)[6-8,13], with relatively poor perfusion of the liver[14].

CLINICAL MANIFESTATIONS

CAPV can cause a broad spectrum of clinical manifestations, which can be divided into two groups: concomitant congenital abnormalities and sequent syndromes. The former can be referred to as a congenital hepatopathy and a congenital cardiopathy, which can be explained by its close relation to the development of cardiovascular system.

Systemic shunting of the visceral venous return can lead to abnormal hepatic development, function and regeneration secondary to the absence of portal hepatotrophic factor, resulting in the development of focal nodular hyperplasia (FNH) and hepatic tumors[15-17]. Other than CAPV, many cases are presented with liver abnormalities, including FNH[7,15,18-30] or nodular regenerative hyperplasia (NRH)[8,31-35]. Several patients have been found to have combined hepatocellular adenoma[31,36,37]. These are generally considered benign parenchymatous lesions, and also have the potential to deteriorate into hepatoblastoma[26,28] and hepatocellular carcinoma (HCC)[12,20,38,39]. CAPV, though rare, could be found along with chronic hepatitis[20] and liver cirrhosis[17]. Gocmen *et al*[40] reported a 7-year-old boy with congenital hepatic fibrosis (CHF). Intrahepatic calcification was detected during prenatal diagnosis in a fetus. The liver volume is often larger than normal because of the regenerative or hyperplasia nodular change and sometime hepatomegaly might be observed[15]. Moreover, the mass can cause a series of mechanical pressure symptomes, such as mild intermittent jaundice and pruritus[35]. Nevertheless, the liver size may be small due to insufficient portal vein supply or lobular hypoplasia[41,42]. Abnormal hepatic development, with aberrant lobation, absence of ligamentum teres and falciform ligament, has been noted in Hellwegg's patients[43]. Liver dysfunction (LD), frequently found in liver tumors, also occurs in patients without liver mass.

CAPV may result from a embryologic insult which causes defect of the cardiovascular system and complicated cardiogenesis could be affected by the insult or the systemic diversion of portal venous flow[11]. Congenital cardiac diseases including atrial septal defect (ASD)[2, 21,26,28,37,44,45] or patent foramen ovale[43], ventricular septal defect (VSD)[16,17,21,26,31,40], and patent ductus arterious (PDA)[12,23,43,44] are frequently observed along with CAPV. Bellah *et al*[45] have also detected a fatal congenital hypertrophic cardiomyopathy with ultrasound in an infant. Dextrocardia[1] and Mesocardia[44] that reported congenital cardiac abnormalities are rarely found in CAPV cases. Congenital stenosis of aortic valve[11] and pulmonary artery valve[45], found in a few CAPV cases, can cause tricuspid regurgitation[44]. Even stenosis[11] or coarctation[12] has been observed in aorta. Most frequently encountered Cardiovascular lesions, most frequently encountered in CAPV patients with Goldenhar syndrome, are tetralogy of Fallot and VSD[46]. Cardiomegaly has been noted in CAPV patients[41,47], which may result from congenital insult or increased blood flow into the heart with a certain degree of congestive heart failure. A large number of non-heart abnormalities are found in all the cases reviewed[3,9,14,27,34-36,39,48,49].

Besides CAPV, visceral or cutaneous vascular

malformations have been reported, such as double SV[1], double inferior vena cava[40], left sided IVC[2,17,26], hepatic artery originating from superior mesenteric artery[8,50], intrapulmonary shunting[7], azygos and hemiazygos continuation[1,17,43,48], and skin hemangioma[14,43]. Obvious compensatory changes may be found in blood vessels, especially in veins returning visceral blood or ramus anastomoticus, such as the SV[51], inferior mesenteric vein[33,52], left renal vein[44,53], azygos system[30,51], IVC[14,44,53], and right atrium[14]. Hepatic artery is enlarged and hypertrophied[1,19] due to the same reason.

Polysplenia[1,2,4,17,26,54], megalosplenia[14,24,51] and hypersplenism[51] are the frequently encountered splanchnic abnormalities other than hepatic and cardiac abnormalities, which may be due to the embryonic impairment or portal hypertension (PH). The latter is a fault because CAPV accompanying PH has merely been observed in several cases[9,16,55], which is inconsistent with our general deduction. One reasonable explanation is out of the congenital adaptation.

It was reported that CAPV patients could also have congenital biliary atresia (CBA)[2,4,17,21], congenital choledochal cyst[29], and intrahepatic gallbladder[43]. The urinogenital system including cystic dysplasia of the kidneys[22,24], bilateral ureteropelvic obstruction of the kidneys[45], vesicoureteral reflux[33], crossed fuses renal ectopia[33,40], and hypospadias[56], is also involved. Nonfunctioning pancreatic tumor[25], ulcerative colitis(UC)[33], juvenile polyposis[21], inguinal hernia[23,37], and even situs inversus viscerum[2,4], are sporadically observed in CAPV patients.

The skeletal systematic abnormalities, such as radial hypoplasia[33] and congenital absence of the first metacarpophalangeal complex of the right hand[33], are noted in Grazioli's patients. Vertebral abnormalities or hemivertebra scoliolosis[15,40,57], and oculoauriculovertebral dysplasia or Goldenhar's syndrome[16,26,28,58] exhibit thoracic hemivertebrae, right maxillary hypoplasia, mild micrognathia, and short fifth fingers, are not uncommon in CAPV patients.

Sequent syndromes, which can result in poor prognosis[27], are mainly related to LD or liver abnormalities besides CAPV malformation. Although most cases do not possess any liver abnormalities[1,3,9,27,43-45,47-49,54,57], CAPV patients suffer from different levels of LD[2-4,9,15,16,20,23,24,26-29,34,37,38,44,47,55,56] possibly due to the lack of portal flow. Hepatic encephalopathy, hepatopulmonary syndrome (HPS), and hepatorenal syndrome are closely related to metabolic disorder because of liver lesions, including hyperammonemia[3,27,41,59] and galactosemia[20,27]. Toxic compounds produced in the digestion process only bypass the liver into the systemic circulation in CAPV patients, and are prone to cause hepatic encephalopathy[23,26,27,34,40,49,56]. Mild CAPV patients present with cognitive retardation[33] or mental retardation[27], and their symptoms are merely drowsiness or delirium[56]. Wakamoto *et al*[23] reported the first case of sub-clinical porto-systemic encephalopathy (PSE) with CAPV. When it becomes worse, tremor or orthostatic disturbance[56], abscess in the brain[60], even epilepsy[38] and cerebellar meningioma[55] may occur. If the porto-systematic shunt ratio is high enough, HPS[27,30,60-63] may occur, including cyanosis[30] of the hands, feet, and lips, digital clubbing and pectus excavatum[60], bronchial asthma[8,23] or hypoxemia-induced bronchial stenosis[56], pulmonary hypertension[56,64]. When the shunt ratio is over 90%, CAPV patients would have hematuria and proteinuria, namely hydropigenous nephritis[65]. CAPV patients also could have chronic renal failure[33,34]. Gonadal hormonal disorder[33,47,66] can result in hypergalactocemia[66-68], primary amenorrhoea and signs of virilization[33]. Satoh's patients present with hyperandrogenism, insulin resistant hyperinsulinaemia, and hyperglycaemia[47]. A few cases of PH[9,16,55], rectal bleeding[9,21,33,42], anaemia[31,33] and peripheral edema[21] have also been reported. All the metabolic disorders described above can lead to growth retardation[21,40,56], small head or microcephaly[14,38].

Routine clinical examination can find the above or other diseases in CAPV patients, suggesting that there are a large number of asymptomatic CAPV patients.

ETIOLOGY

Cardiovascular system

Embryologically, paired vitelline veins enter the embryo with yolk stalk, anastomose with each other around the developing duodenum forming a loop, and pass through the septum transversum to the sinus venosus. Portal venous system development occurs depending on selective apoptosis of the bilaterial vitelline veins and their median links before entering the septum transversum[33]. The whole process is complex and coinciding, any insult may affect the development resulting in a preduodenal portal vein, CAPV and duplications, as well as communications between the portal and pulmonary veins[10,12,16,28]. The pathogenesis of CAPV may be attributed to excessive involution of the peri-intestinal vitelline venous loop[10,13,22,69], or to total failure of the vitelline veins to establish the critical anastomosis with hepatic sinusoids[4]. Behind the abnormalities, the initiative event may be referred to genetic mutation or chromatosome variation as CAPV has been sometimes reported in conjunction with chromosomal disorders[70], such as translocation (2,10)[21] and turner syndrome (45, XO)[6,71]. The associated extrahepatic portosystemic shunts may occur due to the persistent subcardinohepatic anastomosis with the vitelline veins. The subcardinohepatic anastomosis connects the vitelline vein that develops into the portal system and the right subcardinal vein that develops into the renal segment of the IVC, as well as forms the hepatic segment of the IVC, thus accounting for the high incidence of draining points at the suprarenal IVC[3].

Cardiac malformations are frequently observed in patients with CAPV[11,72], the close relationship between the development of vitelline veins and the heart in embryonic life may be responsible for the association

between cardiovascular malformations and CAPV[12,40,45]. The cardiac abnormalities may result from a some embryogenic insults and compensate for the congestive effect of portal vein absence and shunting[37], indicating that prenatal insult occurs during the concurrent development of the heart and gastrointestinal tract. However, it was also supposed that systemic shunt of the portal venous flow could adversely affect the hepatic and cardiac development and function[11]. It was reported that concomitant atrial and ventricular septal defects related to CAPV may be attributed to a congenital adaptive change occurring during the development from the embryonic stage, which tends to compensate for the congestive effects of portal venous aplasia[10]. CAPV can result in cardiomegaly or even congestive heart failure due to the shunts of blood flow[10].

Liver

The importance of intact portal vein flow following liver resection or transplantation has been recognized both in experiments and in clinical practice[46,73]. The lack of portal flow can affect the development, function and regenerative pability of the liver. The importance of certain substances, such as insulin and glucagon, is underscored because of CAPV[73], and these substances are no longer supplied to the liver through the mesenteric blood flow and lead to hepatic hypoplasia because they help maintain the hepatic structure and function[74-77]. The hepatic volume is extremely small compared with the standard one as detected by computed tomography (CT) volumetry[56]. However, as far as the regenerative ability of the liver is concerned, such an assumption is questionable. In fact, in cases of CAPV, the regenerative ability appears to be normal after liver lobectomy and trisegmentectomy[16,37].

CAPV is frequently observed with hepatic tumors and tumor-like conditions, such as FNH and NRH[40], suggesting that intrahepatic changes due to hemodynamic imbalance participate in the development of liver tumors[8]. In CAPV patients, liver is supplied only by the hepatic artery in the absence of the portal vein[18]. Many CAPV patients have an enlarged and hypertrophied hepatic artery with a high flow[1,19,50,54] as well as the absence of portal vein, or the presence of hypervascular liver tumor[28]. Such conditions affect the development, function and regenerative capacity of liver, thus predisposing to the development of nodular dysplasia, hepatocarcinoma, or other benign and malignant hepatic tumors[38]. It was reported that abnormal hepatic circulation is one of the etiological factors for hepatocellular hyperplastic nodular lesions[78-80]. Both CAPV and other situations, such as Budd-Chiari syndrome, cause abnormal hepatic flow or peripheral portal venous thrombosis[81,82]. HCC can occur in patients with chronic Budd-Chiari syndrome[82]. Cells in the hyperplastic nodules contain fat deposits[8,83,84], which can be differentiated from other masses.

Marois *et al*[16] demonstrated that abnormal thin-walled vessels filled in a retrograde fashion from hepatic arteries, may be too weak to burden the changed flow. FNH is an uncommon benign tumor-like lesion of well-circumscribed hyperplastic liver parenchyma, often with central stellate scars. These lesions are hypervascular and can be supplied exclusively with arterial blood[79,85]. FNH, derived from acquired thrombosis, has been reported as well[85]. NRH is due to obstruction or narrowing of portal branches caused by thrombosis or atrophy of areas with severely impaired blood flow, and hypertrophy of areas with a relatively mild impairment of blood flow, leading to nodular formation[80].

Yoshidome *et al*[86] observed morphological alterations in the liver parenchyma of patients with congenital portocaval shunts, and proposed that morphological changes in the liver of patients with cirrhosis and acquired portocaval shunts as well as HCC may be explained by a common mechanism, namely reduced portal flow. However, circulatory disturbance alone cannot explain the pathogenesis and the underlying unknown mechanism[25]. Simple occlusion of the portal vein and a compensatory increase in arterial blood flow have been proved insufficient for nodule formation[82]. Although rare, fibrosis may develop due to hemodynamic imbalance[20], because flow disturbance only affects hyperplastic hepatic cells but not mesenchymal cells. CAPV occasionally involves HCC, and 40% of HCC patients have no cirrhosis or chronic liver disease[87,88], suggesting that HCC is related to genetic alterations[38]. Indeed, early genetic alterations or the common genetic pathways of hepatic tumors and CAPV would allow accurate comprehension of the commensalisms.

Intrahepatic bile ductules develop from the primitive ductal plate. It was reported that the portal vein plays a crucial role in the formation and remodelling of the ductal plate[89]. Lack of remodeling of the ductal plates results in persistence of an excess of embryonic bile duct structures. This is why biliary atresia and choledochal cysts concur in CAPV patients.

PSE

When the portal vein is absent, toxic metabolites such as ammonia and bile acids collected from the gastrointestinal tract have to bypass the liver directly drainage into the systemic circulation, thus may initiate hepatic encephalopathy. Interestingly, PSE is rarely observed in CAPV patients with mild hyperammonemia and CAPV patients show no clinical manifestations of hepatic encephalopathy until they become obvious[41]. Only a small number of CAPV cases present with subclinical PSE[23,90-92]. Although PSE is not usually observed in CAPV patients, the serum ammonia level in such patients is not always highly elevated. In fact, a significantly low blood ammonia level in SMV is discovered in patients with CAPV[36,37], suggesting that this low level might indicate the presence of a homeostatic control mechanism[37]. The presence of compensatory alterations in intestinal bacterial flora has been suggested as an explanation[9,15,16]. Kamiya[36] analyzed intestinal flora in faeces of CAPV patients and healthy persons before operation, and did not isolate any microorganisms with a strong urease activity. However,

intestinal microorganisms isolated from the faeces of patients after operation produced as much urease *in vitro* as from healthy volunteers[36], indicating that some inhibitory factors for urease-positive microorganisms may exist in the intestinal tract. It was reported that *lactulose* is effective on hyperammonemia of hepatic encephalopathy by inducing a remarkable growth of *Lactobacillus* to produce lactic acids which interfere with urease-producing microorganisms[93,94]. It is also possible that proteolysis might be inhibited in the intestine of patients, causing decreased production of ammonia[36]. Kavukcu *et al*[95] hold the opposite opinion as among the varieties of bacteria displaying urease activity, only three species have been detected: *Klebsiella pneumonia*, *Enterococcus avium*, and *Peptostreptococcus productus*. Moreover, the number of these bacteria is extremely small with no significant differences observed in the flora in fecal specimens obtained before, during, and after surgery[95]. Another likely explanation is that PSE might be due to the increased sensitivity of an aging brain to ammonia and other toxic materials[23] or that homeostatic control may gradually become disordered with increasing age[52]. The brain sensitivity to ammonia or other toxic metabolites may increase with aging[96]. Healthy brain may tolerate to high ammonia levels, while aging brain may not cope with high ammonia and other metabolites and develop symptoms[96-98]. Such mechanisms may contribute to the delayed presentation with hyperammonemia-related encephalopathy[99]. Moreover, another plausible one is that the thin anastomoses at birth slowly become large as the patient ages. The shunt ratio may play a certain role in the occurrence of symptoms[100]. Certain special unknown mechanisms underlying CAPV lead to the delayed PSE.

Others

Bile acids are synthesized in the liver, secreted into bile ducts, and expelled into the intestinal lumen where they are reabsorbed into the systemic circulation *via* the lymphatic system followed by hepatic uptake from the portal vein, and then metabolized in the liver. However, when the portal vein is absent, these fatty acids, after absorption by the intestinal tract, assume the form of chylomicrons that are transported into the vena cava. Before arriving at the liver, blood from the vena cava reaches the capillaries of peripheral tissues, including adipose and muscular tissue where fat is accumulated, and this presumably constitutes the cause of obesity in such cases[37]. Gitzelmann *et al*[67] detected patients with hypergalactosaemia along with congenital portosystemic shunts[66-68], and proposed that high blood galactose found in newborns is useful for detecting this abnormality. Hypergalactosaemia might also result from insulin resistance (IR) which is correlated to LD[47]. Imbalance between vasodilator and vasoconstrictor substances has been reported in CAPV patients with HPS[27,30,60-63], and decrease in metabolism or synthesis of these substances in the liver is responsible for the imbalance[60]. Mehrotra *et al*[101] observed extrahepatic portal vein obstruction in children with high serum levels of growth hormone and somatostatin (IGF- I), and showed that there is some resistance to the action of growth hormones[101]. Chronic anemia (secondary to loss of blood caused by bleeding and/or hypersplenism), and intestinal venous congestion with secondary malabsorption may interfere with the growth rate[31]. Liver dysfunction causing hepatotrophic hormone deprivation also results in growth retardation[40,59,102]. Takeichi[34] reported a CAPV case of patient with chronic renal failure in a vicious circle of toxic materials, leading to severe encephalopathy with coma, waiting for liver transplantation (LT).

However, since CAPV cases have individual series of presentations, more or less, subtle or obvious, the pathology of these manifestations seems to be complicated and covered. Further study is needed to confirm its etiology by analyzing more entities.

IMAGEOLOGY

Imaging abnormality is often coincidentally discovered in children with portal vein disorder. Routine liver examination can reveal the extraordinary mass in majority of these children, triggering further imaging exploration. Portosystemic shunt diagnosis is usually based on clinicopathologic and portographic findings[103]. Portography, ultrasonography, scintigraphy, CT and magnetic imagining are used in diagnosis of this portal vein disorder.

Doppler ultrasonography has been extensively used in evaluating vessels of the abdomen. It is most useful for determining flow direction and pattern besides liver tumor. However, the most important advantage of this technique is its noninvasiveness and no requirement for anesthesia. It yields much useful information about the detailed vascular anatomy as well as hemodynamics[104]. Prenatal screening and intraoperative ultrasonography is especially superior to other techniques[104]. Although color Doppler sonography first depicted the image of the absent portal vein in most cases, ultrasonography (US) may fail to accurately detect the associated extrahepatic shunts because of its subtle US features[31]. Experience and good ultrasound system, knowledge of the examination protocol, and familiarity about the ultrasound anatomy of abdominal vessels and portal vein abnormalities, contribute to the accurate diagnosis of CAPV.

Accurate depiction of intra and extrahepatic vascular anatomy will undoubtedly guide management decisions and surgical or angiographic approaches[21]. Cross-sectional imaging (CT and MR) is very helpful in depicting the course of portosystemic shunt and in identifying absent vessels and type of malformations[42,50]. Currently, 3D-computed tomography angiography (3D-CTA) and magnetic resonance angiography (MRA) can confirm CAPV and visualize the portosystemic shunt[50]. It was reported that multi-slice CTA displays even small vascular branches and has superior spatial resolution to MRA[105]. The posterior or short gastric veins cannot be visualized

in patients with portal vein disorders by conventional angiographic portography, but can be clearly revealed by 3D-CT portography[106]. However, a breath-holding technique has been recommended to prevent motion artifacts during scanning by Tsuji *et al*[8] who assumed that if a patient is able to hold the breath, 3D-CTA can easily capture the entire abnormal vasculature during one breath holding. Unfortunately, CAPV predominately occurs in children difficult to hold breath that urges us to search the substitute. MRA is also a reliable and noninvasive diagnostic modality for the portal venous system[49]. MR imaging can be used both in diagnosis of CAPV and in evaluation of focal hepatic lesions[41]. In addition, previous reports indicate that the presence of a portosystemic shunt may cause lesions of middle cerebellar peduncles, which are responsible for cerebellar symptoms[91]. MR imaging can be used to find cerebral lesions. It was recently reported that conventional high-resolution MR angiography seems unnecessary[41], as the spatial resolution time of MR angiography is almost equivalent. Since 3D-MRA obtained from quality multiplanar reformatted images and volume-rendered images has the advantage of high temporal resolution, contamination from overlapping vascular structures can be avoided, flow dynamics can be assessed, and quality feature is obtainable even in young children with free breaths because the technique is relatively insensitive to motion artefacts[41]. Perhaps, it will be widespread in the diagnosis of CAPV several years later.

Although cross-sectional imaging in most cases can approximately suggest the diagnosis of portal vein disorder, the definitive diagnosis can be made only with catheter angiography[15] and by additional histological analysis of the hepatic parenchyma that demonstrates the absence of hepatic portal venules within the portal triad[35]. Mesenteric portovenography, a usually indirect technique depicting the portal system anatomy, can clarify CAPV abnormality and extrahepatic shunts. In recent years, CO_2-wedged venography is considered a good and safe technique for demonstrating the portal circulation[107]. It has such advantages over indirect portography obtained during visceral arteriography[108] as only a venous puncture is required, free and wedged pressure measurements can be obtained with no iodinated contrast medium injected, and transvenous liver biopsy can be made at the same time. However, opacification of portal vein branches could not be obtained[35].

Portovenography can facilitate measurement of the pressure gradient indicating vein blood flow and selected embolism shunts as a therapy. In dogs, transvenous retrograde portography[109] is less invasive than operative mesenteric portography and allows measurement of portal pressures before and after temporary shunt ligation. It also helps differentiate rich-vessel tumor and confirm parenchymal magnetic resonance imaging (MRI) findings. Conventional angiography is not good for children, although it is fairly safe[49,110].

Rectal portal scintigraphy plays an important part in suspected abnormalities of portal circulation and is precise to quantitate portosystemic shunts and valuable for clinical diagnosis[111]. During performing this kind of examination, shunt indexes (SI) are calculated, relative portal hemodynamics can be observed noninvasively, and portal collateral circulation can be detected as well[112]. This technique is hopeful to be extensively applied in detecting CAPV if not expensive.

DIFFERENTIAL DIAGNOSIS

Definitive diagnosis of CAPV should exclude many seemingly resemble cases. For example, histologically confirmed absence of portal vein in the liver is mandatory in the diagnosis. Abernethy type Ⅱ was previously misclassified as CAPV[21]. Kerlan *et al*[96] reported a case similar to CAPV, but surgery for closing the fistula between portal vein and inferior cava, revealed an intrahepatic portal vein. Absence of stigmata in patients with portal venous hypertension is an important clue to the final diagnosis[40]. Radiologically, absence of the portal vein must be distinguished from portal vein thrombosis[15,28], based on the absence of venous collaterals or other secondary signs of PH, such as splenomegaly or ascites. Compensatory hypertrophy of the hepatic artery may be present[19]. Appel *et al*[51] assumed that it is a secondary phenomenon, most properly due to thrombotic occlusion of the extrahepatic portal vein. However, gradual thrombosis of the portal vein stem may allow the development of collaterals without acute dramatic episodes, similar to CAPV. The term of portal vein "aplasia" or "agenesis" in such cases is inadequate since intrahepatic bile ducts are normal[51,113]. Extrinsic compression of tumors, such as HCC and extrahepatic malignant tumor, especially pancreatic adenocarcinoma[5], is another reason. If the portal flow is ceased, initial thrombus arises asymptomatically, the only sign may be the formation of new vessels, which on Doppler US is known as "portal cavernoma" or "cavernomatous transformation" due to the blood volume at the site[102]. It is not easy to differentiate this condition from Abernethy. It was reported that hepatic nodules with rich artery blood flow may prevent influx of portal blood resulting in increased sinusoidal pressure, the portal vein will not be visualized at portography[82]. Owing to the progressive growth of tumor in the omentum and mesentery, increased portal flow would produce extrahepatic portosystemic venous shunts[114].

During fetal life, ductus venosus is the continuation of umbilical vein, which directly inflows into the inferior vena cava, allowing blood returning through the umbilical vein to bypass the portal venous system[115,116]. Failure to close patent ductus venosus within 2 wk after birth would lead to portosystemic encephalopathy or malformations, including congenital heart disease and minor abnormalities[117]. Hepatic nodular lesions, such as FNH, and PSE, have been reported in patients with patent ductus venosus[117,118]. Although the clinical manifestations of patent ductus venosus and CAPV are similar, the mechanism is different. The treatment of

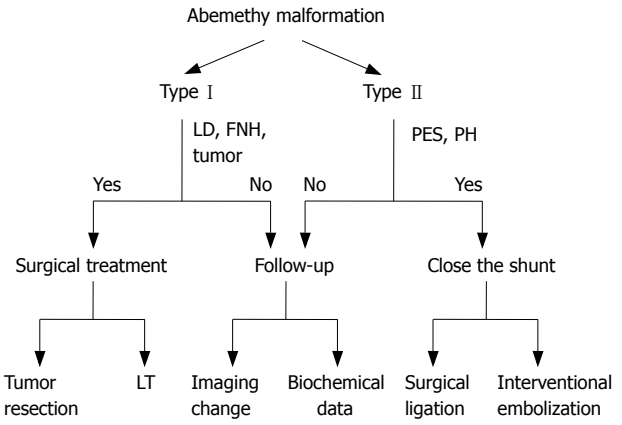

Figure 2 Schematic demonstration of decision-making advices for treatment of Abernethy malformation. LD: Liver dysfunction; FNH: Focal nodular hyperplasia; PSE: Porto-systemic encephalopathy; PH: Portal hypertension; LT: Liver transplantation.

CAPV needs liver transplantation and surgical ligation of the patent ductus venosus[18].

It is difficult to differentiate hepatic benign lesions (FNH, FNH-like lesions, and NRH) from malignant lesions (HCC or hepatoblastoma) by imaging except in cases of such abnormal hepatic circulation while transvenous liver biopsy is a valuable alternative diagnostic tool[35,119]. Intrahepatic portal vasculature abnormalities should be differentiated from congenital diseases, such as idiopathic non-cirrhotic PH, portal venous hypoplasia, or hepatic microvascular dysplasia. Histologic findings of these liver diseases are similar to those seen in congenital liver diseases. Thus, it is not possible to differentiate these diseases from congenital shunts[120]. CAPV with PSE should be differentiated from mental disorder involving hyperammonemia or galactosemia due to metabolic deficiencies[121].

Potential etiologies of extrahepatic shunts include shunt formation in association with PH and mesenteric adhesion due to prior abdominal surgery, abdominal trauma, and congenital shunts[97,98,122]. As a result, congenital extrahepatic portosystemic shunts in CAPV patients must be confirmed by excluding the existence of the three liver diseases.

TREATMENT

Treatment options for extrahepatic portosystemic venous shunts strongly depend on the type of Abernethy abnormalities (Figure 2). Balloon-occluded retrograde transvenous obliteration (BRTO), embolization with metallic coils and surgical correction of the shunts are available[97]. In type Ⅱ patients previously diagnosed with CAPV, occlusion of the shunt is indicated in case of serious symptoms such as hepatic encephalopathy[4] or lateral bleeding. The occlusion techniques include surgical ligation[56,96,123] and interventional embolization[124-126]. Otake *et al*[99] used coils as embolic materials, because they can progressively occlude the shunt, avoiding acute overload of the portal venous system, and confirmed that there is no evidence that the shunt vessels were recanalized after a two-year follow-up period. The treatment for venous shunts in type I patients without severe symptoms other than liver tumors and LDs is inactive, indicating that close clinical, biochemical, and imaging follow-up should be performed.

The treatment for such patients depends on the conditions of liver neoplasm, such as size and histology[20,50]. It involves LT for hepatoblastoma[26] and chemotherapy for hepatoblastoma after resection of the right hepatic lobe[16]. The choice of treatment for liver tumor in CAPV patients is radical resection of the tumor[39], although mostly it is benign, because the mass becomes larger and then progresses to malignancy[8,26]. Morse *et al*[28] reported a patient with CAPV who finally underwent LT for hepatoblastoma initially diagnosed as FNH 2 years ago[26,28], suggesting that long-term follow-up and monitoring for malignancy are mandatory, even for benign tumors.

After tumor resection, liver regeneration is said to be dependent on hepatotropic factors in the portal venous blood[37,73]. However, in the patients resected for liver tumor reported[12,15,16,24,37], the resection was uncomplicated and the postoperative course uneventful, despite the absence of gut-derived hepatotropic factors to stimulate liver regeneration. Stimuli other than those transported with the portal blood stream must thus be sufficient to ensure an adequate postoperative liver regeneration in these patients[39].

Some authors hold that increased blood flow comes mainly from the SV in patients with PH and hypersplenism or megalosplenia, indicating that partial splenic embolization can decrease the blood flow and pressure of the main portal vein, similar to the conjoint effects of splenectomy and devascularization[127]. Surgical decompression is also recommended for selected children in order to promote their growth[128].

CAPV has been thought to be asymptomatic and has no indication for LT, and only a few cases having been reported[2,17,27,56,129]. More and more surgeons hold that LT is necessary when medical therapy cannot relieve CAPV-associated abnormalities, such as CAPV-associated cirrhosis caused by biliary atresia[4,17], diffuse hepatoblastoma involving both lobes of the liver[26], and severe portosystemic encephalopathy[56]. No surgical method is available for reconstructing the portal structures of the native liver[56,59]. Shinkai *et al*[56] reported that LT is an effective surgical treatment for symptomatic CAPV patients when the disease is unresponsive to medical treatment, and believe that prophylactic LT is justified for patients with CAPV before the development of fatal pulmonary complications, such as pulmonary hypertension or HPS, which might complicate or preclude LT[56]. Woodle *et al*[17] successfully transplanted liver for a biliary atresia patient, and assumed that CAPV is not a contraindication for LT. Taoube *et al*[130] performed the first paediatric liver transplant for a patient with portal venous agenesia, using the de piggy-back technique.

Recently, auxiliary partial orthotopic liver

transplantation (APOLT) was developed in order to reverse fulminant hepatic failure (FHF), which is advantageous over the orthotopic liver transplantation (OLT) and avoids eliminating regeneration of the native liver and a life-long immune suppression[131]. It also has been utilized as an aid in small-for-size grafts to larger recipients during living donor liver transplantation (LDLT)[131]. Soejima *et al*[27] performed LT for a male patient using a left lateral segment graft from his mother to preserve his native right lobe. Configuration of the donor PV, hepatic artery, HV and bile duct was normal. The results indicate that APOLT is an ideal procedure for patients with CAPV[27]. However, APOLT has certain drawbacks, such as portal steal phenomenon and potential risk of developing tumors in the remnant native liver.

Both the anatomy of portal vein and the function of liver can be restored, and other liver dysfunctions-associated complications may be relieved after LT, such as disappearance of high-intensity lesions in the brain[59].

In conclusion, the prognosis of CAPV patients depends on congenital heart disease, liver disease, and the site of portosystemic shunts. The outcome of CAPV patients with no other abnormalities is different. A long-term follow-up including laboratory tests and image screening is recommended for CAPV patients[20,35,50,126].

Abstract

AIM: To examine the role of Fibrinogen-like protein 2 (fgl2)/fibroleukin in tumor development. Fgl2 has been reported to play a vital role in the pathogenesis in MHV-3 (mouse hepatitis virus) induced fulminant and severe hepatitis, spontaneous abortion, allo- and xeno-graft rejection by mediating "immune coagulation".

METHODS: Tumor tissues from 133 patients with six types of distinct cancers and the animal tumor tissues from human hepatocellular carcinoma (HCC) model on nude mice (established from high metastasis HCC cell line MHCC97LM6) were obtained.

RESULTS: Hfgl2 was detected in tumor tissues from 127 out of 133 patients as well as tumor tissues collected from human HCC nude mice. Hfgl2 was highly expressed both in cancer cells and interstitial inflammatory cells including macrophages, NK cells, and $CD8^+$ T lymphocytes and vascular endothelial cells. Hfgl2 mRNA was localized in cells that expressed hfgl2 protein. Fibrin (nogen) co-localization with hfgl2 expression was determined by dual immunohistochemical staining. *In vitro*, IL-2 and IFN-γ increased hfgl2 mRNA by 10-100 folds and protein expression in both THP-1 and HUVEC cell lines. One-stage clotting assays demonstrated that THP-1 and HUVEC cells expressing hfgl2 had increased procoagulant activity following cytokines stimulation.

CONCLUSION: The hfg12 contributes to the hypercoagulability in cancer and may induce tumor angiogenesis and metastasis *via* cytokine induction.

Su K, Chen F, Yan WM, Zeng QL, Xu L, Xi D, Pi B, Luo XP, Ning Q. Fibrinogen-like protein 2/fibroleukin prothrombinase contributes to tumor hypercoagulability *via* IL-2 and IFN-γ. *World J Gastroenterol* 2008; 14(39): 5980-5989 Available from: URL: http://www.wjgnet.com/1007-9327/14/5980.asp DOI: http://dx.doi.org/10.3748/wjg.14.5980

INTRODUCTION

Fibrinogen-like protein 2 (fgl2)/fibroleukin, also called fg12 prothrombinase, has recently been identified as a new member of fibrinogen-related protein superfamily, with the serine protease activity. Mouse fgl2 (mfgl2) and human fgl2 (hfgl2) are localized in chromosomes 5 and 7, respectively. The biological activity of fgl2 prothrombinase, similar to coagulating factor Xa, can directly catalyze prothrombinase into activated thrombinase, thereby, initiating a cascade coagulating reaction[1]. Several studies indicate that fgl2 is involved in MHV-3 induced fulminant hepatitis and severe or fulminant viral hepatitis in human, spontaneous abortion and xenograft rejection by mediating pathological changes such as immune coagulation, fibrin deposition, and micro-thrombus[2-5]. In addition to its primary role in homeostasis and blood coagulation, thrombin is a potent mitogen that dramatically increases the growth and metastasis potential of tumor cells. Both tissue factor (TF) and thrombin exert their influence on tumor angiogenesis and metastasis through clotting-dependent

and clotting-independent pathways[6,7]. Fgl2 functions as a novel immune coagulant with the ability to generate thrombin directly. Therefore, we propose that fgl2 may contribute to tumor angiogenesis and metastasis through a clotting-dependent pathway.

In the present study, the authors investigated the expression and histological localization of hfgl2, co-localization of fgl2 with fibrin in cancer and the gene regulation of fgl2 upon cytokine induction, in the hope of providing a new point of view on the characteristic hypercoagulability of cancer and a novel anticoagulant target, the fgl2 gene.

MATERIALS AND METHODS

Patients' tumor tissues

Informed consent was obtained from all the participants, and the research protocol was reviewed and approved by the Institutional Review Board of Tongji Hospital, Wuhan, China. Patients were recruited at Tongji Hospital, and 133 tumor samples and their paired adjacent normal tissues were collected. The patients' characteristics are shown in Table 1. The specimens for RNA extraction were frozen in liquid nitrogen until studied. Specimens for immunohistochemical and *in situ* hybridization were fixed in 4% paraform.

Table 1 General data and pathologic diagnosis of hfgl2 positive samples

Diagnosis	Case	Gender		Age (yr)	Subtype	Metastasis
		F	M			
Colon carcinoma	21	12	9	58.27 ± 10.27	AC 21	17
Breast cancer	20	0	20	49.70 ± 11.06	IDC 20	16
Lung cancer	20	17	3	55.17 ± 12.53	SCC 5 SqC 5 AC 7 AdCa 3	19
Gastric cancer	26	13	13	55.8 ± 15.88	AC 26	20
Esophageal carcinoma	18	15	3	56.44 ± 8.63	SqC 15 AC 3	13
Cervix cancer	22	0	22	39.14 ± 6.48	SqC 16 AC 6	22

AC: Adenocarcinoma; IDC: Infiltrating ductal carcinoma; SCC: Small cell carcinoma; SqC: Squamous carcinoma; AdCa: Adenosquamous carcinoma.

Mice

Male BALB/c-nu/nu mice (Shanghai Shilaike Animal Seed Center), 4-6 wk of age, with a body weight of 15.0-18.7 g, were kept in micro-isolated cages housed in Tongji Hospital and fed a standard lab chow diet and water ad libitum. Animals were divided into two groups: tumor-bearing mice (experimental group) and tumor-free mice (control group).

Cell and culture conditions

THP1 and HUVEC cell lines were purchased from Biology Treasure Center of Wuhan University. Human hepatocellular carcinoma (HCC) cell line MHCC97LM6 with high tendency of metastasis were purchased from Liver Cancer Institute, Fudan University, Shanghai. The HUVEC and MHCC97LM6 cell lines were cultured in Dulbecco modified Eagle medium (DMEM), and THP-1 cell lines were maintained in RPMI 1640 supplemented with 10% heat inactivated fetal calf serum (FCS, Gibco Life Technologies), 100 U/mL penicillin, and 100 mg/mL streptomycin and cultured at 37℃, 50 mL/L CO_2, and 95% humidity.

Tumor cell inoculation and quantification of pulmonary metastatic foci

MHCC97LM6 cell lines were cultured *in vitro* by sub-confluent passage in DMEM. Sub-confluent tumor cells were washed with phosphate-buffered saline (PBS), detached by a brief exposure to a 0.125% trypsin and 0.02% EDTA solution, washed in serum-containing media, and then resuspended in cold serum-free medium to get the single cell suspension. The 95% viability of the tumor cells was determined by trypan blue exclusion. The cells were kept in an ice bath until transplanted into mice. A single cell suspension of 9×10^6 cells in 100 μL serum-free media was injected subcutaneously into the dorsal scapular skin of nude mice using a 27-gauge needle. Injection with the same volume of serum-free media served as the negative control. Once a tumor was clearly visible, it was measured daily and the volume estimated by the formula $V = ab^2/2$, where a = longest diameter, b = shortest diameter. After 36 d, the nude mice were sacrificed and the tumors and other organs including brain, heart, lung, liver, kidney, spleen, and small intestine were removed and rinsed in PBS. Aliquot of the tissue specimens were frozen in liquid nitrogen for RNA extraction. Other aliquots were fixed in 4% paraform and prepared for immunohistochemical studies. The lungs were separated into individual lobes and the number of metastatic foci was counted under a microscope with HE stain.

Immunohistochemical staining of fgl2 prothrombinase

Immunohistochemical staining was used to assess fgl2 expression in tumor tissue and HUVEC and THP-1 cell lines. Tissues were fixed with 4% paraform, processed into paraffin, and sectioned. Then they were rehydrated with 0.1 mol/L PBS (pH 7.4) and endogenous peroxidase. Nonspecific binding was blocked by sequential incubation of the sections in 10% hydrogen peroxidase solution for 10 min followed by 10% normal goat serum in PBS at room temperature for 30 min. Thereafter tissue or cultured cell slices were incubated with a polyclonal antibody against fgl2 at a dilution of 1/300 in PBS at 4℃ for 16 h. Subsequently, sections were incubated with immunoperoxidase-conjugated goat IgG fraction to rabbit IgG Fc (Zhongshan Company) at room temperature for 15 min, followed by three washes in PBS. The secondary antibody, an anti-rabbit IgG linked to peroxidase, was incubated with 3,3' -diaminobenzidine chromagen and counterstained with hematoxylin.

Fibrin in human malignant tumor tissues

Fibrin was detected with the use of a rabbit-anti-fibrinogen antibody (Dako Cytomation). This reagent is known to react with fibrinogen and fibrin in mouse and human tissues. The technique used for detection of fibrin was the standard avidin-biotin complex (ABC) method. The biotinylated secondary antibody was an anti-rabbit IgG linked to peroxidase incubated with 3,3'-diaminobenzidine chromagen, followed by counterstaining with hematoxylin.

Dual immunohistochemical staining of hfgl2 and fibrin

Dual staining for hfgl2 and fibrin on the same tissue was performed using a Vectastain ABC kit (Vector Laboratories), with second Abs labeled with AP or HRP, respectively.

Immunohistochemical *staining of macrophages, T lymphocytes, NK cells, and* vascular endothelial cells

Antibodies against CD68,CD57, CD4, CD8 and a monoclonal antibody against von Wille brand factor antigen (NeoMarkers) were individually used at a dilution of 1:50-1:100 in PBS to detect macrophages (Kupffer cells), NK cells, T lymphocytes, and vascular endothelial cells using immunoperoxidase staining *via* similar methodology described above.

Western blot analysis

Cells were solubilized in lysis buffer containing 10 mmol/L Tris-HCl, pH 7.4, 150 mmol/L NaCl, 1 mmol/L EDTA, 1% TritonX-100, at 4℃ for 30 min. The cell lysates were subjected to centrifugation at 10000 × *g* at 4℃ for 1 min. The supernatants were saved and their protein contents were measured. Thirty mg lysate protein was loaded onto 12% SDS-polyacrylamide gels. After the proteins were separated, they were transferred to a NC membrane. The membrane was blocked and probed with a polyclonal antibody against fgl2 at a dilution of 1:200 in 5% milk in TBS. After washing with TBS and 0.5% Tween-20, the blot was incubated with secondary antibodies conjugated to horseradish-peroxidase. Immunoreactive bands were detected with the enhanced chemiluminescence (ECL) reagent (Pierce).

In situ hybridization

A digoxigenin-11-UTP (Dig-UTP) (Roche)-labeled cDNA probe was cut by EcoRI following subcloning of a 169-bp fragment of mfgl2 cDNA, representing nt 756 (ACTGTGACA …) to 924 (… GAGTAAGGA), into pCR2.1 vector (Invitrogen Life Technologies). The Dig-UTP-labeled probe concentration was determined by immunoenzymatic reaction with chemiluminescent detection, and the probes were stored at -80℃. Tissue sections were deparaffinized in 100% xylene and 100% alcohol, followed by prehybridization in 50% formamide and 2 × SSC at room temperature for 1 h. The hybridization mixture consisted of 50% deionized formamide, 5% dextran sulfate, 250 μg salmon sperm DNA per milliliter, and 2 μg Dig-labeled cDNA probe per milliliter in 2 × SSC. The hybridization mixture with the probe was denatured by heating in an 85℃ water bath for 5 min, chilled on ice for 1 min, and added to tissue sections for hybridization at 42℃ overnight. Post-hybridization washing in a series of dilutions of SSC was followed by application of 3% blocking reagent at room temperature for 30 min. After a brief wash in Tris-HCl buffer (pH 7.5), sections were incubated with polyclonal anti-Dig Fab, conjugated to alkaline phosphatase (AP; Boehringer Manheim), and diluted 1/500 in Tris-HCl buffer. Unbound antibody was removed by two 5-min washes with Tris-HCl buffer. A purple reaction product was developed using AP substrate, 5-bromo-4-chloro-3-indolyl-phosphate, and NBT to sections at room temperature for 120 min. Sections were counterstained with methylene green and mounted with Per mount for viewing.

RNA preparation and quantitative real-time PCR

Total RNA was isolated from tumor specimens and cell lines using TRIZOL reagent (Invitrogen) according to the manufacturer's instructions. The concentration and purity of RNA were determined by measuring the absorbance at 260 nm and 280 nm. Subsequently, the cDNAs were synthesized. The nucleotide sequences of the primers for PCR amplification of 169 bp fragment of fgl2 were the following: sense primer, 5'-ACTGTG ACATGGAGACCATG-3', and antisense primer, 5'-T CCTTACTCTTGGTCAGAAG-3'. The amplified 571 bp fragment of GAPDH cDNA was used as an internal control to ensure equal loading and first strand synthesis with forward primer, 5'-ATCACCATCTTCCAGGAG-3' and reverse primer, 5'-TGCTTCACCACCTTCTT G-3'. In the PCR reaction the DNA was amplified over 36 cycles, denatured at 94℃ for 40 s, annealed at 60℃ for 45 s, and extended at 72℃ for 60 s. The real-time PCR reactions were performed using a SYBR green PCR kit (Biotium) in Roche Sequence Detection System. Specificity of the PCR reaction was verified by dissociation-curve analysis and agarose gel electrophoresis. Fgl2 mRNA relative quantification was assigned by reference to standard curve analysis.

Cytokine treatment

THP-1 and HUVEC cell lines were maintained in medium containing 10% FBS in six well plate for 72 h until they reached sub-confluence. Then they were incubated with IL-2 (100 U/mL) or IFN-γ (200 U/mL) in medium for 4 h, 8 h, 12 h and 24 h before they were collected for immunohistochemical staining and real-time PCR studies.

Prothrombinase assays (PCA)

Samples to be assayed for PCA were washed three times with unsupplemented RPMI 1640 and resuspended at a concentration of 10^6/mL. The cells were then subjected to three cycles of freeze-thawing to obtain maximal total cellular procoagulant activity. Milliunits of PCA were determined from a standard curve generated by serial log dilutions of a standard rabbit brain thromboplastin

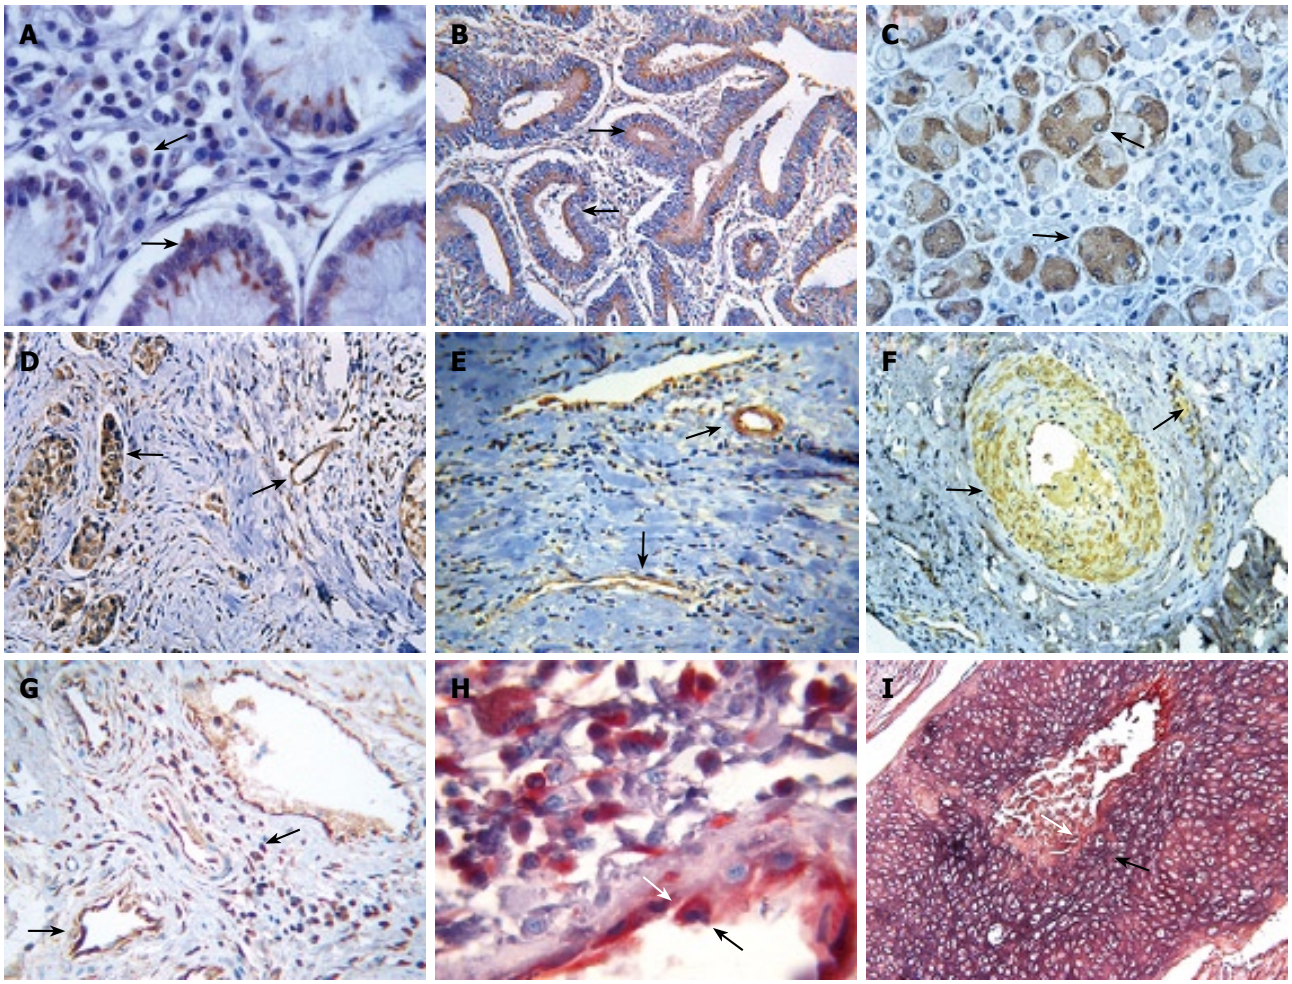

Figure 1 Immunohistochemical analysis of hfgl2 prothrombinase and fibrin in tumor tissues. Fgl2 was verified by immunohistochemistry in colon cancer (**A**, x 400), esophageal cancer (**B**, x 200), gastric cancer (**C**, x 400), breast cancer (**D**, x 200), lung cancer (**E**, × 200) and cervix cancer (**F**, x 100). Fibrin deposition was stained for colon cancer (**G**, x 200). Dual staining of hfgl2 (indigo) and fibrin in colon cancer (**H**, x 1000) and cervix cancer (**I**, x 400) displayed the co-localization of hfgl2 (indigo) and fibrin (scarlet) expression. Cells expressed fgl2 protein and fibrin were detected with antibodies specific for fgl2 (black arrows) and fibrin (white arrow), respectively.

(Sigma) to determine functional shorting of the spontaneous clotting time of normal citrated human platelet-poor plasma. After addition of cellular sample, 0.1 mL of normal plasma and 0.1 mL of 25 mmol/L $CaCl_2$ were added and clotting time was visually determined by the appearance of white precipitate after incubation at 37℃. Human plasmas deficient in specific clotting factors such as factor Ⅱ or factor X (ADI/DELLWIN) were also used as substrate in the clotting assay in place of normal human plasma.

Statistical analysis

Quantitative data were expressed as mean ± SD. Statistical analysis was performed by one-way analysis of variance with $P < 0.05$ considered statistically significant.

RESULTS

Fgl2 expression in tumor tissues from patients

The study population was composed of 133 patients, of whom 107 patients were noted clinically to have metastasis (Table 1). Tumor tissues of the patients were examined for fgl2 expression at both the mRNA and protein levels by *in situ* hybridization and immunohistochemical staining respectively. The normal tissue surrounding the tumor tissue was used as control. Fgl2 was present in cancer cells as well as interstitial infiltrated and vascular endothelium cells of the microvasculature (Figure 1A-F). There was significantly upregulated hfgl2 expression with cancers when compared with those in no magnificent tumor tissues which showed little or no fgl2 expression (data not shown). Dual staining of hfgl2 and fibrin displayed the co-localization of these two molecules, indicating the contribution of highly expressed hfgl2 protein to the hypercoagulability (Figure 1G-I). *In situ* hybridization showed a similar pattern of hfgl2 staining in tumor tissues of the patients (Figure 2).

Cellular source of fgl2 and fibrin deposition in tumor tissues

As shown with staining of serial tumor sections, the majority of CD68+, CD57+, CD8+, and vascular endothelial cells displayed increased expression of fgl2 protein in tumor tissues of the patients (Table 2 and Figure 3).

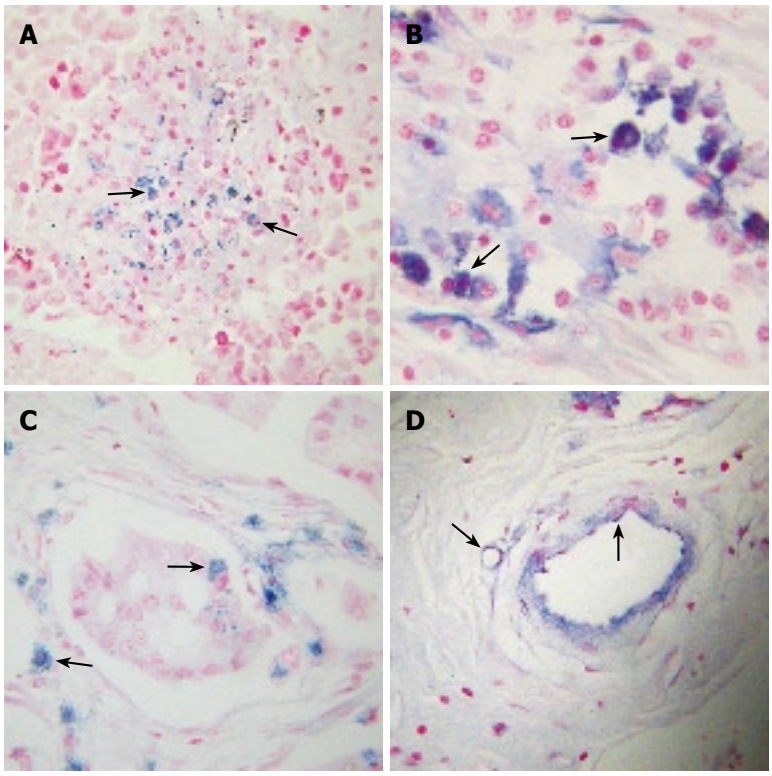

Figure 2 Hfgl2 mRNA detection in human tumor tissues by in situ hybridization. **A**: Hfgl2 mRNA was stained purple in lung small cell carcinoma, hfgl2 mRNA present in the nests of tumor cells, some tumor cells secreted melanin (x 400); **B**: Submucosa of colon descendens tubular adenocarcinoma, hfgl2 mRNA present in the infiltrated cells and single migrating tumor cells (x 400); **C**: Invasive ductal breast carcinoma, hfgl2 mRNA localized to nest tumor cells, exfoliated tumor cells and infiltrated cells around the duct (x 400); **D**: Submucosa of gastric adenocarcinoma, hfgl2 mRNA localized to tumor blood vessel endothelium (x 400). Arrows indicate hfgl2 mRNA locations.

Hfgl2 expression in tumor tissue from HCC nude mouse model

In the HCC nude mouse model, no evidence of histoincompatibility or tumor rejection was observed based on the rapid development of visible tumors after injection (100% of mice within 3 d). The steady growth of the tumors was found in MHCC97LM6 mice (Figure 4 Ⅰ A and B) whereas tumors were not observed in the control group. Almost all MHCC97LM6 mice developed on site palpable tumors and metastatic foci in lung tissues within 7 d of injection (Figure 4 Ⅰ C). Further studies showed that mfgl2 (mouse fgl2) expression

Table 2 Histological localization and involved cell type in hfgl2 positive samples

in interstitial inflammatory cells and vascular endothelial cells (Figure 4 I D-H). Furthermore the fgl2 was detected at mRNA level in the tumor tissue (Figure 4 Ⅱ).

Increased hfgl2 expression and PCA in IL-2 or IFN-γ stimulated HUVEC and THP-1 cell lines

Endothelium original HUVEC and mononuclear original THP-1 cells were used to investigate the regulatory expression of fgl2 in response to various tumor cytokines involved in tumor development *in vitro*. RT-PCR analysis demonstrated minimal constitutive fgl2 mRNA levels in both cell lines, but increased in response to stimulation with IL-2 or IFN-γ (data not shown). This primary observation was further demonstrated by real-time PCR, which showed a 10-100 fold increase of fgl2 mRNA copies following stimulation of IFN-γ or IL-2 (Figure 5Ⅲ). Immunohistochemical staining and Western-blotting also detected upregulated hfgl2 protein expression upon stimulation of cytokines (Figure 5 I and Ⅱ). The functional measurement of fgl2 protein was carried out by one-stage clotting assay expressed as PCA. Both HUVEC and THP-1 cells displayed basal levels of PCA with a significant increase following IL-2 or IFN-γ stimulation in parallel with fgl2 protein expression (Figure 6A). The induced PCA was independent of factor X, but closely associated with factor Ⅱ, thus demonstrating the PCA was induced by increased expression of fgl2 protein (Figure 6B).

DISCUSSION

The association between thrombosis and cancer was observed by Professor Armand Trousseau in 1865, who noted that patients who present with idiopathic venous thromboembolism (VTE) frequently harbor an occult cancer. We now believe that there are two key mediators of this link: one being the thrombin[6] whose broad substrate specificity supports a variety of cellular effects relevant to tumor growth and metastasis; and the other being the tissue factor (TF)[7], the primary initiator of the coagulation cascade, whose rather ubiquitous presence as a transmembrane receptor on a variety of nucleated cells confers responsibility for the generation of cell-surface thrombin in many pathologic situations *via* both clotting-dependent and clotting-independent mechanisms. TF and thrombin are capable of inducing angiogenesis, the process of generating new blood vessels from preexisting vessels, which is essential for tumor growth and metastasis.

We and many others have described a new procoagulant other than tissue factor and thrombin: fgl2 prothrombinase, a member of the fibrinogen superfamily, which was primarily reported to be produced by activated macrophages, T cells, and endothelial cells. Mouse fgl2 (mfgl2) and human fgl2 (hfgl2), were localized in chromosomes 5 and 7, respectively[1,3,8]. Fgl2 is a 64-70 kDa, type 2 transmembrane protein containing a C-terminal FRED (fibrinogen related extracellular domain). The fgl2 amino acid sequence is 36% homologous to the β and γ fibrinogen chains[9]. There is 78% homology between human and mouse fgl2 with 90% homology in their C-terminal domains containing FRED[3]. Fgl2 functions as a strong prothrombinase which directly cleaves prothrombin to thrombin leading to fibrin deposition in the absence of factor Ⅶ or factor X[10]. The direct prothrombinase activity of fgl2 is implicated in the pathogenesis of several inflammatory disorders including fulminant hepatitis and severe hepatitis, allo- and xeno-graft rejection[4,11,12]. Furthermore, its role is also evidenced in murine and human cytokine induced fetal loss[5,13-15] and neonatal death from contractile dysfunction and rhythm abnormalities during embryonic and postnatal development[16]. The observations that neutralizing Abs to mfgl2 prevent both fibrin deposition and death from MHV-3 infection support its role as a coagulant[17]. Recent studies have shown that inhibition of reticuloendothelial cell mfgl2 expression through the use of gene-targeted fgl2-deficient (fgl2-/-) mice or targeted fgl2 gene with antisense mfgl2 results in the prevention of MHV-3-induced fibrin deposition, liver injury, and death[2,18].

Our study shows that fgl2 prothrombinase was expressed in malignant tumor tissues including colon, breast, lung, gastric, esophageal, and cervical tissues from patients and in HCC nude mouse models. Up-regulation of fgl2 gene expression is evident not only in cancer cells, but also in interstitial infiltrated cells including macrophages, NK cells, $CD8^+$ T lymphocytes, and vascular endothelial cells. Dual staining shows that fibrin (nogen) uniformly co-localized with fgl2 protein. In breast cancer, fgl2 is present predominantly in the same cellular types in which TF was expressed[19]. Other studies have further shown fibrin (nogen) co-localization with TF expression. Cross-linked fibrin (XLF) was found within the endothelium of angiogenic vessels of invasive breast cancer specimens, but not within the vessels of benign breast tumors in histological specimens from the patients[20]. The similar expression patterns of TF and fgl2 have led us to hypothesize that both fgl2 and TF may be responsible for the coagulation cascade in cancer. Fgl2 and TF cleavage of prothrombin to thrombin results in fibrin deposition in the tumor microenvironment (TME). Thrombin-catalyzed, XLF formation is a characteristic histopathological finding in many human and experimental tumors[21].

Fgl2 induces angiogenesis by generating thrombin. Thrombin dramatically increases the growth and metastatic potential of tumor cells *via* clotting dependent and independent mechanisms. The fibrin matrix that develops around tumors provides a provisional proangiogenic scaffold that supports vessel formation and stimulates endothelial cell proliferation and migration through clotting dependent mechanisms. Clotting independent mechanisms are thought to be mediated *via* proteolytic cleavage of the PARs and subsequent activation of G-protein-coupled signal transduction cascades, leading to the upregulation of many angiogenesis-related genes, including VEGF,

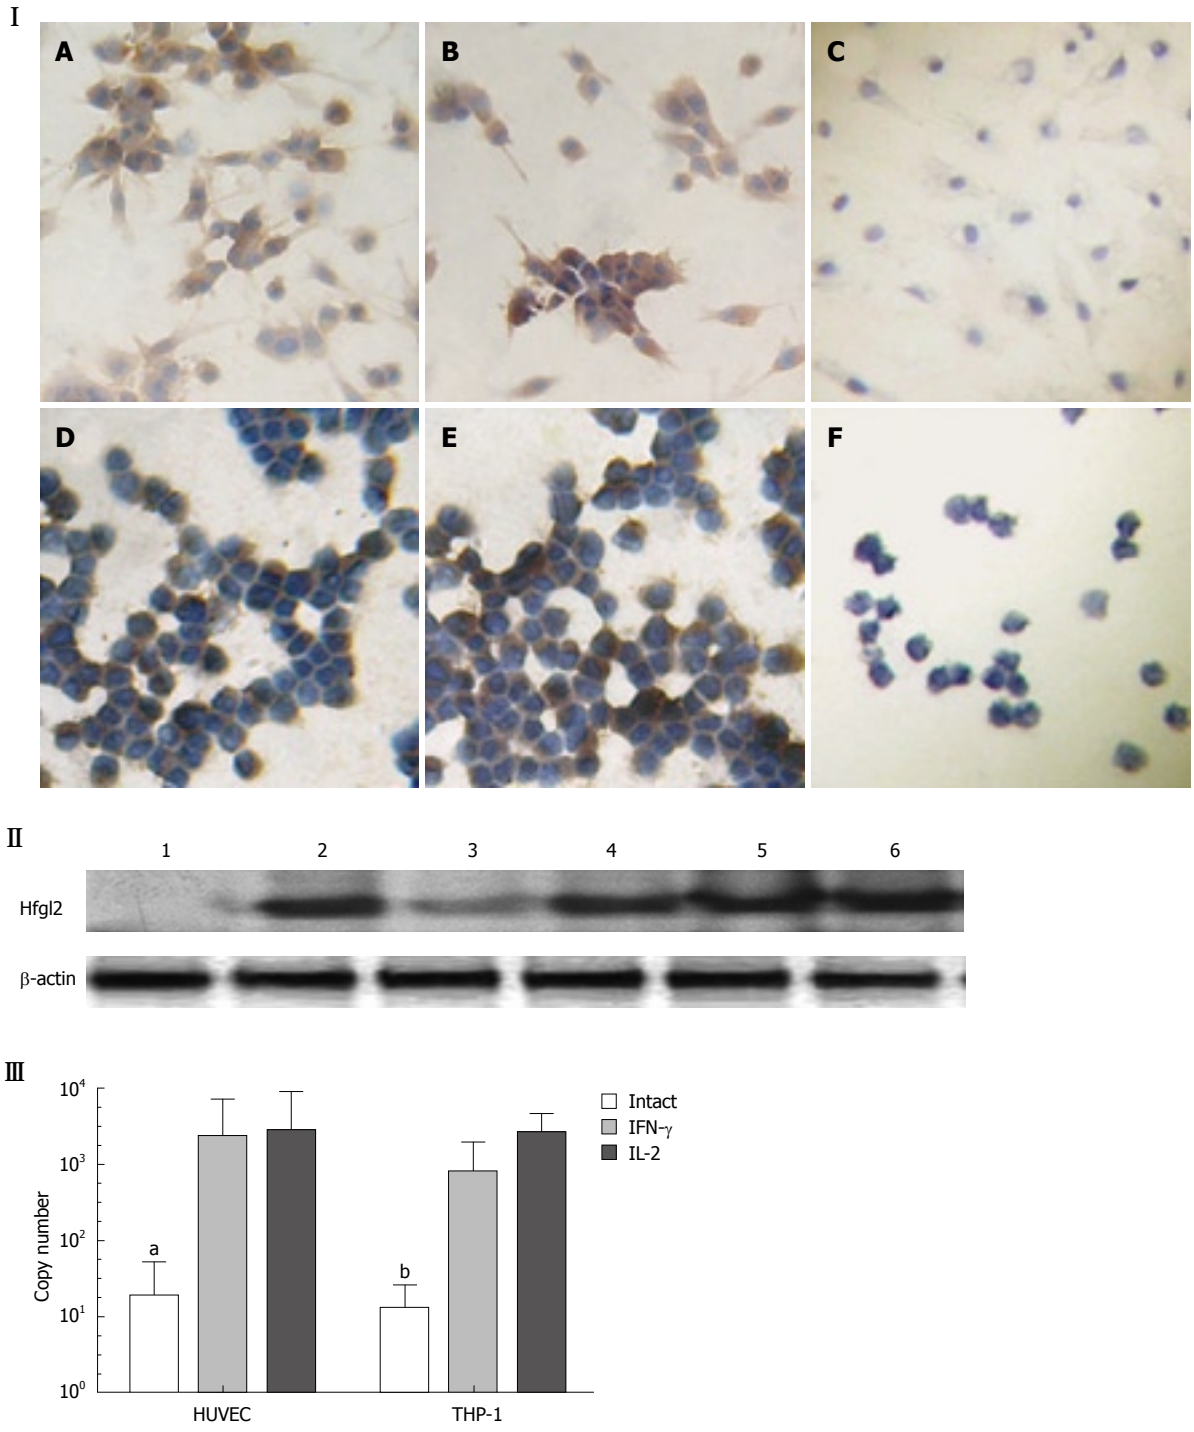

Figure 5 Increased expression of fgl2 after IFN-γ or IL-2 stimulation. Ⅰ: HUVEC and THP-1 cells were treated with IFN-γ (200 U/mL) and IL-2 (100 U/mL) and stained with antibodies specific for hfgl2. **A**: IFN-γ (200 U/mL, 12 h) + HUVEC (SP, x 200); **B**: IL-2 (100 U/mL, 8 h) + HUVEC (SP, x 200); **C**: NS +HUVEC (SP, x 200); **D**: IFN-γ (200 U/mL, 12 h) + THP-1 (SP, x 200); **E**: IL-2 (100 U/mL, 8 h) + THP-1(SP, x 200); **F**: NS + THP-1 (SP, x 200). Ⅱ: Western blotting analysis of hfgl2 expression after IFN-γ (200 U/mL) and IL-2 (100 U/mL) stimulation for 12 h and 8 h on HUVEC and THP-1 cells. 1: Intact HUVEC; 2: IFN-γ + HUVEC; 3: Intact THP-1; 4: IFN-γ + THP-1; 5: IL-2 + HUVEC; 6: IL-2 +THP-1. Ⅲ: Real-time PCR analysis of inducible hfgl2 mRNA after stimulation for 4 h. $^aP = 0.0329$, *vs* HUVEC alone; $^bP = 0.0059$, *vs* THP-1 alone.

VEGF receptors, TF, bFGF, and MMP-2[22-24]. These genes can create a number of pleiotropic responses, such as change in endothelial cell shape, increased vascular permeability, increased endothelial cell proliferation, and increased proteolysis, all of which contribute to increased tumor angiogenesis.

The pathogenic role of fgl2 is not entirely understood as only one pathway of fgl2 activation has been studied so far. In murine hepatitis viral infection, nucleocapsid protein induces transcription of fgl2 through the transcription factor hepatic nuclear factor 4α and its cognate receptor[25,26]. HBV X and core protein was shown to induce hfgl2 expression through a host factor c-Ets-2 and MAPK signal pathway[27]. In transplantation, fgl2 transcription appears to be regulated by cytokines. Macrophage induction of fgl2 is

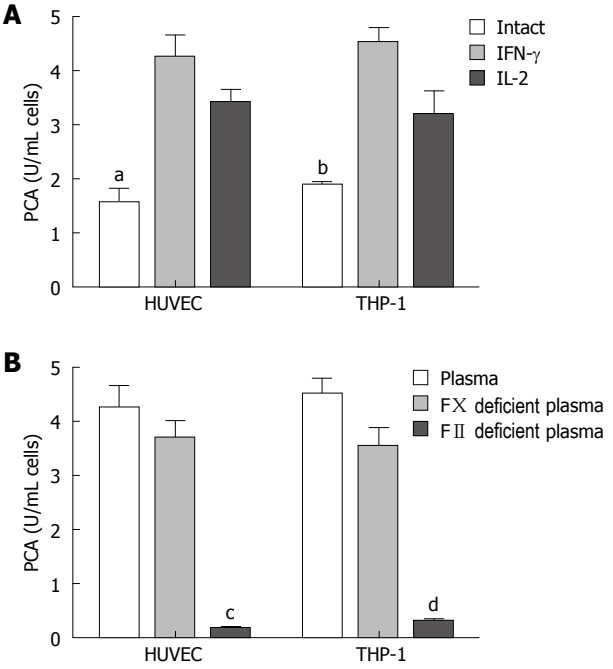

Figure 6 Increase of procoagulant activity (PCA) in HUVEC and THP-1 cells after IFN-γ and IL-2 stimulation dependent on FⅡ but not FX. HUVEC and THP-1 cells received IFN-γ (200 U/mL) and IL-2 (100 U/mL) for 12 h and the PCA was assayed. IFN-γ and IL-2 increased PCA and this effect is preserved in FX poor plasma whereas is absent in FⅡ poor plasma. [a]*P* = 0.0026, *vs* HUVEC alone; [b]*P* = 0.0037, *vs* THP-1 alone; [c]*P* = 0.0002, FⅡ deficient plasma group *vs* normal plasma group or FX deficient plasma group; [d]*P* = 0.0001, FⅡ deficient plasma group *vs* normal plasma group or FX deficient plasma group.

induced by IFN-γ, whereas preliminary data suggest that fgl2 transcription in endothelial cells occurs in response to TNF-α but not IFN-γ[28].

Our study has also shown that cultured HUVEC and THP-1 cells activated by IFN-γ or IL-2 demonstrated induction of hgl2 expression and enhanced activation of human prothrombin. The induced PCA activity was independent of factor X, but closely associated with factor Ⅱ. These results suggest that macrophages are attracted to invading tumors and subsequently release cytokines that later induce fgl2 expression in cancer. Increased fgl2 expression may activate thrombin, to exert its effect on tumor angiogenesis and metastasis through clotting-dependent and independent mechanisms. Additional studies in molecular pathways for induction of fgl2 in cancer are presently underway in our laboratory.

The fgl2 protein described here is a membrane bound prothrombinase. The recent discovery of a secreted form of fgl2 (sfgl2) produced by T regulatory cells has potent immune modulatory effects on the adaptive immune system. Sfgl2 was reported to prevent maturation of dendritic cells (DC) by inhibiting NF-κB nuclear translocation, expression of CD80 and MHCII, by inhibiting T cell proliferation in response to CD3/CD28, Concanavalin A, and allo-antigens. These observations have provided a potential explanation for many of the biological functions influenced by fgl2 protein[29-31] in our laboratory. fgl2 was also found in the extracellular matrix in malignant tumor tissue samples. This suggests the involvement of sfgl2 protein. Further studies are necessary to solve this conundrum.

In this study, we first reported the highly expressed fgl2 prothrombinase in a variety of tumor tissues both from patients and an animal model. Tumor related cytokines IFN-γ and IL-2 lead to the induction of hfgl2 expression and enhanced activation of human prothrombin. These observations suggest that fgl2 prothrombinase, in conjunction with thrombin and tissue factor, may contribute to tumor hypercoagulability and possibly to angiogenesis and metastasis. In turn, fgl2 may serve as a novel target for intervention of tumor development.

ACKNOWLEDGMENTS

The authors express their deepest appreciation to Dr. Gary Levy in University of Toronto for offering the reagents and critical comments for this study.

COMMENTS

Background

Fibrinogen-like protein 2 (fgl2)/fibroleukin, also called fg12 prothrombinase, has been found recently and belongs to fibrinogen-related protein superfamily. Fgl2 prothrombinase has serine protease activity. Human fgl2 gene is mapped at chromosome 7q11,23. Biological activity of the product of fgl2 prothrombinase, similar to coagulating factor Xa, can directly catalyze prothrombinase into activated thrombinase, initiating cascade coagulating reaction. Several studies abroad indicate that mouse fgl2 has been involved in MHV-3 induced fulminant hepatitis, spontaneous abortion and xenograft rejection by mediating "immune coagulation", fibrin deposition and microthrombus leading to the pathological changes.

Research frontiers

In addition to its primary role in hemostasis and blood coagulation, thrombin is a potent mitogen capable of inducing cellular functions. Thrombin can dramatically increase the growth and metastatic potential of tumor cells, thus it should be of great importance in the behavior of cancer. Both tissue factor (TF) and thrombin exert their influence on tumor angiogenesis and metastasis through clotting-dependent and clotting-independent mechanisms. Fgl2 functions as a novel immune coagulant with the ability to generate thrombin directly.

Innovations and breakthroughs

Fgl2 highly expressed in tumor cells and activated interstitial infiltrated cells, which may contribute to the characteristics of hypercoagulability and in turn induces tumor angiogenesis and metastasis.

Applications

In present study, the authors investigated hfgl2 expression and its histological localization in cancer, which will provide a new point of view on the characteristic hypercoagulability of cancer and efficacious anticoagulant therapy in cancer treatment.

Peer review

It has been proved that fgl2 functions as an immune coagulant with the ability to cleave prothrombin to thrombin directly and there are relationships between thrombosis and cancer. The aim of this study was to investigate the role of fgl2 in tumor development. They found that Hfgl2 was detected in tumor tissues from 127 out of 133 patients as well as tumor tissues collected from human HCC nude mice and IL-2 and IFN-γ could increase hfgl2 mRNA *in vitro*. It is an interesting subject and results were clearly described.

Abstract

AIM: To investigate the anti-oxidant and anti-neutrophil recruitment effects of rectal d-alpha (d-α) tocopherol administration on mild and moderately active ulcerative colitis (UC).

METHODS: Fifteen patients with mild and moderately active ulcerative colitis were enrolled in an open-label study of d-α tocopherol enema (8000 U/d) for 12 wk. All patients were receiving concomitant therapy with 5-aminosalicylic acid derivatives (5-ASA) and/or immunomodulator medications. Endoscopic evaluation was performed at baseline and after 4th and 12th weeks. Disease activity was measured with the Mayo disease activity index (DAI) and remission was defined as DAI of $\leqslant 2$ with no blood in stool. Clinical response was defined as a DAI reduction of $\geqslant 2$.

RESULTS: At the end of 12th week, the average DAI score significantly decreased compared to the beginning of the study (2.3 ± 0.37 *vs* 8 ± 0.48, $P < 0.0001$). One patient was withdrawn after 3 wk for being unavailable to follow-up. On the 4th week of therapy, 12 patients showed clinical response, 3 of whom (21.4%) achieving remission. After 12 wk, all 14 patients responded clinically to the therapy and remission was induced in 9 of them (64%). No patient reported adverse events or was hospitalized due to worsened disease activity.

CONCLUSION: This preliminary report suggests that rectal d-α tocopherol may represent a novel therapy for mild and moderately active UC. The observed results might be due to the anti-inflammatory and anti-oxidative properties of vitamin E.

Key words: Vitamin E; Ulcerative colitis; Inflammatory bowel disease; Enema; Activity index

INTRODUCTION

Inflammatory bowel disease (IBD) comprises a group of chronic, lifelong, immuno-inflammatory disorders, characterized by flare-ups due to increased inflammatory activity of the intestinal mucosa, interspersed with asymptomatic periods of remission[1]. Although the etiology of IBD remains unknown, it is believed that the generation of an exaggerated intestinal immune response to otherwise innocuous stimuli plays a key role in the pathophysiology of this intestinal disorder[2]. IBD is mainly characterized by upregulation of synthesis and release of different proinflammatory mediators, including reactive oxygen and nitrogen metabolites, eicosanoids, platelet-activating factor and cytokines. All of these mediators actively contribute to the pathogenic cascade that initiates and perpetuates the inflammatory response of the gut. Thus, the treatment strategy for IBD focuses on eliminating these causal inflammatory triggers and mediators.

Unfortunately no disease-specific treatment for IBD has yet emerged, and the best strategy to effectively downregulate the exacerbated immune response is likely

to interfere with multiple stages of the inflammatory cascade[3]. In fact, the drugs currently used for the management of human IBD, i.e. 5-aminosalicylic acid derivatives, immunosuppressives and systemic or local glucocorticoids, exert their beneficial effects through a combination of different mechanisms[4]. On the other hand, even the most effective drugs used in inflammatory bowel disease are only successful in about two-thirds of patients[5,6], while these drugs are not devoid of potentially serious side effects that limit their use in a further substantial proportion of patients[7,8].

It is now well established that vitamin E is a major lipophilic antioxidant in cellular membranes with excellent antioxidant activities[9,10] which protects membrane lipids from peroxidation[11,12] by scavenging not only chain carrying peroxyl radicals but also singlet oxygen and superoxide anion radicals[13]. This is especially interesting in the case of ulcerative colitis (UC), considering the pivotal role of oxygen free radicals in the genesis of mucosal damage. Additionally, the production of reactive oxygen species increases by the colonic mucosa in patients with UC[14-16]; and inhibition of lipid peroxidation or scavenging of oxygen free radicals produces valuable preventive and therapeutic strategies for IBD[12].

Thus, given the recent evidence suggesting anti-inflammatory properties for vitamin E[17,18], d-alpha (d-α) tocopherol, as the dominant vitamin E isomer in plasma with the highest biopotency, may be expected to reduce the development of tissue injury in IBD. In support of this hypothesis, we report the preliminary results of an ongoing open-label case series study on clinical and endoscopic changes of disease severity in patients with active UC who received daily rectal doses of d-α tocopherol for at least 12 wk.

MATERIALS AND METHODS

Inclusion and exclusion criteria

We recruited 15 volunteer UC patients (5 males, 10 females) between February 2006 and February 2008, seen in our university-based gastroenterology practice. The study protocol was submitted to the university ethics committee and written informed consent was obtained from all participating patients. All enrolled patients had active disease, limited to sigmoid at the beginning of the study. In order to minimize observation errors, all diagnoses were made on the basis of a combination of clinical, endoscopic and histological criteria by a single faculty member gastroenterologist. Only patients with mild and moderately active UC despite a minimum of 4 wk of therapy with at least 3 g/d of an oral 5-ASA compound were eligible for inclusion to whom we permitted concomitant therapy with azathioprine or 6-mercaptopurine as long as the patient had been receiving the medication for a minimum of 24 wk and was on a stable dose for a minimum of 12 wk before enrolment. No patient received concomitant therapy with corticosteroids or rectally administered therapies of any kind. Use of anti-diarrheal medications was not permitted and no patient had taken additional non-steroidal anti-inflammatory drugs (NSAIDs) and/or antibiotics during the 3 mo preceding their enrolment.

Patients were excluded if they had evidence of infectious colitis, history of an active malignancy, previous surgical procedure except for cholecystectomy or appendicitis, and contraindication to flexible sigmoidoscopy or biopsy. Further exclusion criteria included present or recent pregnancy, and concomitant serious illness such as history of diabetes mellitus, hypertension, severe liver disease and cardiac failure.

Study design

Disease activity was assessed using Mayo Disease Activity Index (DAI)[19]. This index is calculated by summing the scores of four factors, each of which are graded on a scale from 0 to 3. The four features of disease activity are stool frequency, bleeding, physician's assessment of disease activity, and mucosal appearance. The maximum potential score is 12 points, with mild and moderate disease activity defined as a score below 10. Only patients with mild or moderate active UC based on DAI score were selected.

A primary clinical and colonoscopic evaluation was performed in all cases. Patients were then assessed clinically every 2 wk, and the following endoscopic evaluations were performed after 4th and 12th weeks. Therefore, it was not possible to calculate a DAI score at each time point. However, we computed a modified DAI (mDAI) score that includes all components of the full DAI score except the endoscopic appearance of the bowel. The maximum potential score in the mDAI is 9.

Meticulous laboratory evaluations were conducted for all participants at the time of recruitment, including determination of the hematocrit value, white blood cell and platelet count, liver function tests, ERS, stool exam and culture, and serum level of vitamin E. Serum samples were stored at -80℃ until analysis. Vitamin E was measured, after extraction with methanol, by HPLC, with UV detection at 294 nm. Methanol, deionized water and butanol (90:4:6) were used as mobile phase and the column was Eurospher 100 C_8 (4.6 mm × 25 cm). Re-evaluation of these tests was done each month until completion of study[20].

All patients were trained to rectally apply the sufficient amount of liquid vitamin E (0912, NOW Foods, IL, USA) equivalent to 8000 IU (15 mL) using specific instrument for enema (Enema irrigator disposable, Model: D-201, Taiwan Snatch Co., Taiwan; Figure 1) every night at home and were advised to lie for at least 15 min in left supine position after administration. During the first 12 wk all patients were given diary sheets containing multiple choice questions on stool characteristics including the number of defecation per day, stool consistency and type of blood excretion at each defecation episode. Patients were asked to complete each sheet on its day and bring them back at next visit (every 2 wk). After the first 12 wk we stopped obtaining diary sheets from patients and continued the follow-up by monthly visits only and endoscopic

Figure 1 Specific instrument for enema (Enema irrigator disposable). Fifteen mL of the liquid vitamin E was rectally administered in our patients using this disposable enema irrigator.

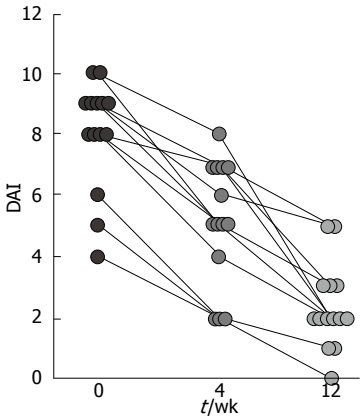

Figure 2 Individual changes in disease activity from week 0 to 12, assessed by the Mayo Disease Activity Index, in subjects who received d-α Tocopherol enema. One patient who was withdrawn early from the study is not included. There was a significant decrease in the mean DAI score for patients after 4th and 12th weeks of therapy ($P < 0.0001$).

studies every 3 mo. This second phase of study is still in progress.

Definition of outcomes

Patients with a final DAI score of $\leqslant 2$ points were considered to have achieved remission. A clinical response was defined as a reduction in the DAI of $\geqslant 2$ points. Clinical relapse was defined as the occurrence or worsening of symptoms, accompanied by an increase in the DAI score to 4, necessitating a change in therapy (addition of rectal therapies such corticosteroids or 5-ASA, surgery, *etc*). Refractory patients were those who had no significant improvement from their baseline, despite 12 wk of drug application.

Statistical analysis

Descriptive data are reported as percentages and medians and ranges. For statistical analysis, the 1-way analysis of variance (ANOVA) followed by Tukey post hoc was used. When appropriate, The Student *t* distribution was employed to compare 2 groups. Average DAI and mDAI scores at different time points were compared using the Mann-Whitney *U* test. All analyses used two sided tests of statistical significance with a significance level of 0.05.

RESULTS

Fifteen patients (5 males) were enrolled in the study

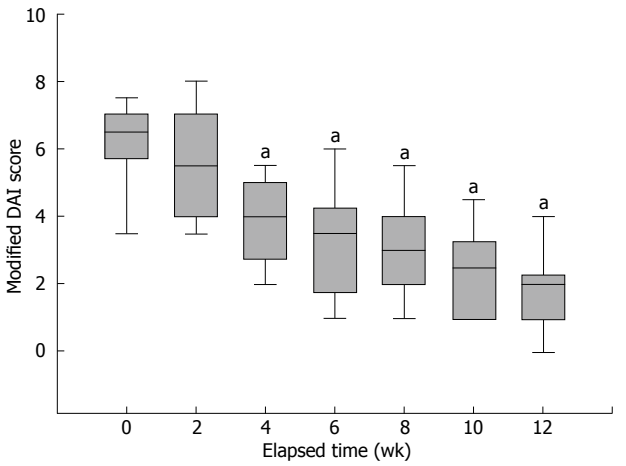

Figure 3 Change in the modified DAI. A modified DAI score, including all components of the complete DAI other than the endoscopic appearance is calculated at each observation point. By week 4 the mean modified DAI score significantly decreased compared to baseline (week 0) scores. [a]$P < 0.0001$ *vs* baseline.

and one patient left the study due to permanent change of his city of residence. Therefore the analysis was performed on 14 patients. The age of patients was 33 ± 9.6 years (mean ± SE) ranging from 21 to 55 years old, and the duration of UC was 4.7 ± 1.6 years. At enrolment, all patients had active disease with mild and moderate disease activity restricted to sigmoid (30 cm maximum involvement). All patients were receiving treatment at the time of entry into the study, consisting of sulphasalazine in 4 cases and mesalazine in the others. Two patients were also receiving azathioprine. No patient was on corticosteroids, antimicrobials or NSAIDS. At enrollment, the median Mayo DAI score was 8 (range, 4 to 10). Only 3 patients had mild disease activity, while the other 11 patients had moderate UC. On the 12th week, 9 patients had disease of mild severity and 5 had moderately active disease (Figure 2).

As summarized in Figure 2, clinical response was observed in 12 patients on the 4th week while clinical remission was induced only in 3 patients. After 12 wk, all patients responded clinically to therapy, with 9 of them going to clinical remission. In a secondary analysis, we examined the change in the DAI and mDAI scores over time (Figures 2 and 3). The mean DAI score before and on the 4th and 12th week of therapy were 8 ± 0.48, 5.1 ± 0.54 and 2.3 ± 0.37, respectively. Mann-Whitney *U* test revealed significant decrease in the mean DAI scores on 4th and 12th week of therapy comparing to the baseline ($P = 0.01$ and $P < 0.0001$, respectively) as shown in Figure 2. The average mDAI score started to decrease significantly on second week (Figure 3). As shown in Figure 4, mDAI score was significantly lower than at baseline for patients by week 4 and remained significantly lower for the remainder of the study ($P < 0.0001$ at weeks 4, 6, 8, 10 and 12, respectively). During the course of study there was no case of worsening disease activity or report of serious adverse event.

At the end of 12 wk, 12 patients elected to continue to receive d-α tocopherol, while 2 patients left the

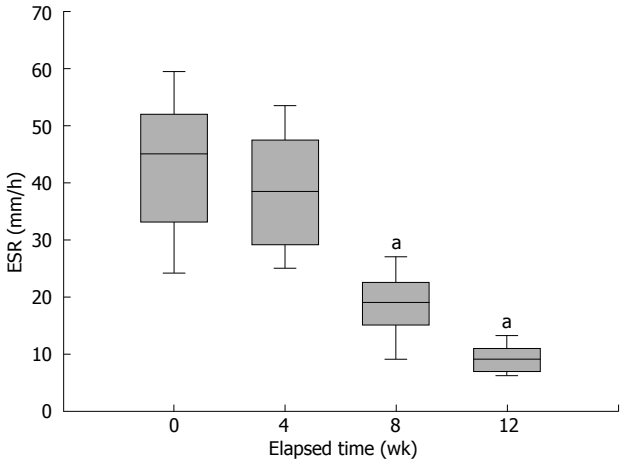

Figure 4 Individual changes in ESR from week 0 to 12, in our patients. There was a significant decrease in the mean ESR on the 8th and the 12th week of therapy compared to the beginning of the study. $^{a}P < 0.0001$ *vs* baseline (0 wk).

survey due to personal reasons despite achieving a desirable response and satisfaction with therapy. All patients are assessed monthly for symptoms of disease activity and undergo endoscopic studies every 3 mo. The overall follow-up of patients in our study is approaching its mean of 8 mo by the time of composing this article. Interestingly, there have been no recurrences in patients who remained on therapy, while 2 flare-ups occurred in patients who left the study, after 4 wk and 7 wk.

As shown in Figure 4 the mean value of baseline ESR was 42.26 ± 11.7 while it was 9.33 mm/h on 12th week, showing a significant decrease ($P < 0.0001$). Eleven patients had moderate anemia at baseline (defined as haematocrit < 35 in men and < 40 in women) for which supplemental iron and folic acids were prescribed. At the end of the 12 wk, a low haematocrit was detected in only 3 patients, and it increased from 35.3 ± 6 to 43.9 ± 6 after 12 wk. The serum level of α-tocopherol did not change significantly after 12 wk compared to that of baseline (7.2 ± 4.2 and 6.7 ± 1.1, respectively), and all patients had serum levels less than or within the normal range (5-12 μg/dL).

DISCUSSION

This case series provides evidence suggesting that local administration of d-α tocopherol might exert protective effects against UC in patients with mild and moderately active disease. In our study, rectal administration of d-α tocopherol significantly reduced the clinical disease activity indices and eliminated further need to corticosteroid therapy in otherwise non-responsive UC patients.

Recent studies demonstrated that plasma levels of α-tocopherol decrease after infection, trauma, burns, and inflammatory reactions, indicating that this antioxidant is exhausted during acute tissue injury[21,22]. Similar concept exists for inflammatory bowel disease, indicating that anti-oxidants are intimately involved in the process of active IBD, for example ingested high doses of vitamin E as an anti-oxidant along with other anti-oxidants reduce the extent of tissue damage in IBD, and tissue antioxidant levels are shown to be decreased in UC patients[23-25]. Systemic α-tocopherol in conjunction with selenium is also shown to reduce the severity of IBD in chemically induced colitis in rats[26]. Therefore, it is tempting to hypothesize that increasing the exposure of affected intestinal mucosa to this anti-oxidant might strengthen the defense capacity of the affected gut.

Vitamin E, particularly α-tocopherol, exerts a number of non-anti-oxidant functions, some associated with inhibition of protein kinase C (PKC) such as inhibition of platelet aggregation, and others independent of PKC such as the expression of intercellular adhesion molecule-1 (ICAM-1, CD54), integrins and CD36[27,28]. α-tocopherol also inhibits respiratory burst in human macrophages via a mechanism involving PKC inhibition, followed by attenuation of p47 (phox) phosphorylation and membrane translocation[29].

Increased NF-κB activity is found in inflamed intestinal mucosa; and factors implicated in IBD, such as TNF-α, LPS, and IL-1, are potent activators of NF-κB[30]. On the other hand, reactive oxygen species, the hypothetical mediators of IBD flare-ups, have been implicated in the stimulation of the signal transduction pathway involving NF-κB. Many current therapies for IBD act at least in part through the inhibition of NF-κB or through inhibition of signals that activate NF-κB. Interestingly, α-tocopherol is proved to inhibit NF-κB activation in rat Kupffer cells and a human monocytic cell line[31,32].

One of the proinflammatory genes regulated by NF-κB is ICAM-1 (cell surface glycoprotein, playing a critical role in mediating leukocyte-endothelial and a marker of active inflammation). Gulubova *et al*[33] demonstrated a marked upregulation of endothelial E-selectin, ICAM-1, and VCAM-1 expression in the inflamed colonic mucosa and submucosa in active UC. Infiltration of neutrophils into colonic mucosa is a central event in the acute phase of UC for which cell adhesion molecules are necessary[34]. Accordingly, by blocking the activity of NF-κB, which leads to decreased production of proinflammatory cytokines, anti-inflammatory properties of α-tocopherol might be explained. Therefore, α-tocopherol in high local doses might also affect the binding affinity between the neutrophil and the endothelial cell by decreasing the expression of adhesion molecules on the endothelial cells.

Systemic markers of inflammation, such as ESR, CRP, platelet count and white blood cell count are commonly used in clinical practice, but correlation to ongoing intestinal inflammation is poor[35]. Therefore, we monitored the consecutive changes in ESR (Figure 4) and complete blood count (CBC) of our patients. These results show a significant conversion of ESR and quantitative increase in haematocrit.

To the best of our knowledge, this is the first data on remission inducing properties of vitamin E. This study also confirms the feasibility and acceptability of rectal administration of vitamin E in patients with IBD. Except for one patient who left the study due to difficulty for

follow-up, all patients completed the three month course of study required for primary assessments. Furthermore, 12 patients are still taking medication and participate in the regular evaluations. By the time of composing this article, the average course of treatment is approaching 8 mo. Disease activity was rated as inactive (clinical remission) in 64%. Comparing these results with the beginning of study demonstrates a significant reduction in disease severity of UC patients ($P < 0.0001$) starting after the 4th week of therapy. As shown in Figure 3, symptoms started to improve after 3 wk. This result is comparable with conventional therapies for IBD such as mesalazine or sulfasalazine. Overall satisfaction of patients despite the uncomfortable method of nightly rectal administration of d-α tocopherol reflects that the desirable outcomes outweigh its difficulty in application.

Elevated and toxic levels of plasma vitamin E were a concern in our study, since there was no previous study measuring the systemic absorption of vitamin E when applied intrarectally. Thus, plasma levels of vitamin E were measured to eliminate concerns about vitamin E overdosage and results revealed that the mean vitamin E level was not significantly different from that of before the study. This shows that despite the high doses of rectal vitamin E administered every night, little is absorbed and no concern remains about the overdosage of vitamin E in patients.

In the setting of a case series study we only recruited UC patients with strictly defined criteria. Our hypothesis was the increased local effects of vitamin E in UC, in which the pathology is mainly restricted to mucosal layer. In addition to the substantial physical and financial burden of IBD on patients, it is often difficult to continue treatment due to decreased therapeutic effects or adverse reactions over time[7,8]. In this regard, use of vitamin E may expand the choices available for treatment of IBD, simplifying prescription or therapeutic technique.

The nature of our study casts limitations to implicate definite clinical results from this report, since case series cannot measure and do not eliminate the placebo effect. However, the best expected placebo effect is reported to be 16%-52% in rectal therapies of IBD which is still far lower than our results[36]. Best UC therapies only have 60% to 80% success rates, while we gained 100% clinical response with over 60% remission induction in our patients on the 12th week. This is especially important considering that these results are achieved without prescribing any synthetic agent, and we eliminated the need to corticosteroids in patients otherwise resistance to therapy.

Taken together, case series like this study are best used as a source of hypotheses for investigation by stronger study designs. Thus, future researchs should aim at testing the efficacy of natural vitamin E enema in a well controlled study to measure its exact effect on reducing risk of flare-ups with the minimum confounding factors. This evidence suggests that vitamin E reduced the development of colon inflammation. The observed effect seems to be due to antioxidative and anti-inflammatory effects of vitamin E which is potently taking effect by local administration. Based on our preliminary results vitamin E might show considerable promise as a new therapeutic modality for IBD.

COMMENTS

Background

The exact etiology of inflammatory bowel disease (IBD) is not yet understood, however it is believed that the generation of an exaggerated intestinal immune response to otherwise innocuous stimuli plays a key role in the pathophysiology of this intestinal disorder. IBD is mainly characterized by upregulation of synthesis and release of different pro-inflammatory mediators all of which actively contribute to the pathogenic cascade that initiates and perpetuates the inflammatory response of the gut. Thus, the current treatment strategy for IBD focuses on eliminating these causal inflammatory triggers and mediators.

Research frontiers

Vitamin E is a major lipophilic antioxidant in cellular membranes with excellent antioxidant activities which protects membrane lipids from peroxidation by scavenging not only chain carrying peroxyl radicals but also singlet oxygen and superoxide anion radicals. This is especially interesting in case of ulcerative colitis (UC), considering the pivotal role of oxygen free radicals in the genesis of mucosal damage. Given the recent evidence suggesting anti-inflammatory properties for Vitamin E, d-alpha (d-α) tocopherol, as the dominant vitamin E isomer in plasma with the highest biopotency, may be expected to reduce the development of tissue injury in UC.

Innovations and breakthroughs

This case series provides evidence for the first time that local administration of d-α tocopherol might exert protective effects against UC. The authors have carefully followed the serial alterations of patients' disease activity index, along with few other markers of disease severity and have shown that rectal administration of d-α tocopherol significantly reduces the clinical disease activity indices which eliminated further need to corticosteroid therapy in otherwise non-responsive UC patients with mild and moderately active disease. The observed effect seems to be due to antioxidant and anti-inflammatory effects of vitamin E which is potently taking effect by local administration.

Applications

The results of this interesting study suggests that natural antioxidants like d-α tocopherol might show considerable promise as new therapeutic modalities for IBD, with apparently lower side effects and complications compared to the current therapies.

Peer review

This is the first study to address the immunoregulatory effects of d-α tocopherol in a dominant Th1 response disease. The outstanding results demonstrate that natural isomer of vitamin E, reduces the extent of macroscopic mucosal damage and clinical severity of related syndromes in UC patients, when applied intra-rectally for as short as 4 wk.

Abstract

AIM: To investigate the effects of (dietary) glycine against oxidant-induced injury caused by bile duct ligation (BDL).

METHODS: Either a diet containing 5% glycine or a standard diet was fed to male Sprague-Dawley (SD) rats. Three days later, BDL or sham-operation was performed. Rats were sacrificed 1 to 3 d after BDL. The influence of deoxycholic acid (DCA) in the presence or absence of glycine on liver cells was determined by measurement of calcium and chloride influx in cultivated Kupffer cells and lactate dehydrogenase (LDH) activity was determined in the supernatant of cultivated hepatocytes.

RESULTS: Serum alanine transaminase levels increased to about 600 U/L 1 d after BDL. However, enzyme release was blunted by about two third in rats receiving glycine. Release of the alkaline phosphatase and aspartate aminotransferase was also blocked significantly in the group fed glycine. Focal necrosis was observed 2 d after BDL. Glycine partially blocked the histopathological changes. Incubation of Kupffer cells with DCA led to increased intracellular calcium that could be blocked by incubation with glycine. However, systemic blockage of Kupffer cells with gadolinium chloride had no effects on transaminase release. Incubation of isolated hepatocytes with DCA led to a significant release of LDH after 4 h. This release was largely blocked when incubation with glycine was performed.

CONCLUSION: These data indicate that glycine significantly decreased liver injury, most likely by a direct effect on hepatocytes. Kupffer cells do not appear to play an important role in the pathological changes caused by cholestasis.

Key words: Glycine; Bile duct ligation; Cholestasis; Kupffer cells; Serum alanine transaminase; Deoxycholic acid

INTRODUCTION

Chronic cholestasis liver diseases lead to liver injury and ultimately progress to portal fibrosis, cirrhosis, and end-stage liver disease requiring liver transplantation. They include primary sclerosing cholangitis, primary biliary cirrhosis, extrahepatic biliary atresia, idiopathic adulthood ductopenia, idiopathic neonatal hepatitis, Byler's disease, and arteriohepatic dysplasia[1-4]. Various drugs, total parenteral nutrition, sarcoidosis, chronic liver transplant rejection, and graft-versus-host disease may also cause chronic cholestasis[5-7]. Currently the most promising therapy for chronic cholestatic liver diseases is ursodeoxycholic acid[8], that may delay liver disease progression, but cannot prevent liver injury or fibrosis[9].

The pathophysiology of cholestasis induced liver injury and fibrosis remains unclear. One possible mechanism is that hepatic accumulation of hydrophobic bile acids causes oxidative stress in the liver[10]. Previous studies showed that hepatic mitochondria generate reactive oxygen species when isolated hepatocytes are exposed to hydrophobic bile acids[10,11]. This mitochondrial free radical production may be an important mechanism of cholestatic liver injury. However, the major source of free radicals remains unclear. One possible cell type responsible for the generation of free radicals could be the Kupffer cells, the resident macrophages of the liver. They are involved in disease states, such as endotoxin shock[12], alcoholic liver diseases[13], and other toxicant-induced liver injury by releasing eicosanoids, inflammatory cytokines (IL-1, IL-6, TNF-α), and free radical species[14].

Glycine, a simple nonessential amino acid, is a well-known inhibitory neurotransmitter in the central nervous system that acts *via* a glycine-gated chloride channel and has been shown to be protective against hypoxia, ischemia, and various cytotoxic substances[15-17]. Furthermore, it was demonstrated that dietary glycine protected both, the lung and the liver against lethal doses of endotoxin in the rat[18] and improved graft survival after liver transplantation[19].

Based on pharmacological data[15-17], a glycine-gated chloride channel was detected in Kupffer cells and other macrophages[20] that influenced the activation process of these cells. Glycine binds to and opens a chloride channel at the cell membrane, causing cell hyperpolarization that subsequently blocks calcium influx[20]. Thus it prevents the activation of intracellular signaling cascades.

Accordingly, we hypothesized in this study that dietary glycine has a protective effect in liver injury after bile duct ligation (BDL) by preventing activation of Kupffer cells.

MATERIALS AND METHODS

Animal husbandry and diet treatment

Adult male Sprague-Dawley (SD) rats (200-250 g) were housed four to a cage in a facility approved by the Association for the Accreditation and Assessment of Laboratory Animal Care International. Three days before surgery, rats were randomly assigned to two experimental groups and fed either a semisynthetic powdered diet (Teklad test diets, Madison, WI, USA) containing 5% glycine and 15% casein (glycine group) or 20% casein (control group). After surgery, each rat continued to receive its assigned diet throughout the entire experimental period. All animals received humane care in compliance with guidelines approved by the Institutional Animal Care and Use Committee of the University of North Carolina at Chapel Hill.

BDL

Rats underwent BDL and transection or sham operation under ether anesthesia, as described elsewhere[21]. Briefly, the common bile duct was located through a midline abdominal incision, double ligated near the liver, and transected between ligatures. Control rats received sham operation underwent the same procedure except that the bile duct was only gently manipulated, but not ligated or sectioned. Some rats were given gadolinium chloride ($GdCl_3$; 20 mg/kg body weight iv 24 h before BDL) to selectively deplete Kupffer cells. Rats were sacrificed 1 to 3 d after BDL or sham operation for further investigations (n = 5-6 per group).

Clinical chemistry and histology

Blood samples were collected from the tail veins at times indicated. Serum alkaline phosphatase (ALP), alanine aminotransaminase (ALT), aspartate aminotransaminase (AST), and bilirubin were measured using analytic kits from Sigma (St. Louis, MO, USA). On the day of death, each rat was anesthetized with pentobarbital sodium (75 mg/kg ip), the abdomen was opened, and the portal vein was cannulated with a 20-gauge cannula. The liver was rinsed using a syringe containing 10 mL physiological saline, followed by slow infusion of 5 mL 10% buffered formaldehyde (VWR International, West Chester, PA, USA). After 48 h in fixative, paraffin sections were prepared and stained with hematoxylin-eosin. Liver pathology was scored in a blinded manner based on a scoring system described by Nanji *et al*[22] (inflammation and necrosis: 1 focus per low-power field: 1+; 2 or more foci: 2+).

Preparation and culture of Kupffer cells and hepatocytes

Kupffer cells were isolated by collagenase digestion and differential centrifugation using Percoll (Sigma, Taufkirchen, Germany) as described elsewhere[23] with slight modifications[24]. Briefly, the liver was perfused through the portal vein with Ca^{2+}- and Mg^{2+}-free HBSS at 37℃ for 10 min at a flow rate of 20 mL/min. Subsequently, perfusion was with HBSS containing 0.02% collagenase Ⅳ (Sigma) at 37℃ for 10 min. After the liver was digested, it was excised and cut into small pieces in collagenase buffer. The suspension was filtered through nylon gauze and the filtrate was centrifuged two times at 70 *g* for 3 min at 4℃ to remove parenchymal cells. The nonparenchymal cell fraction (mostly Kupffer cells) in the supernatant was washed with buffer and centrifuged at 650 *g* for 7 min at 4℃. Cell pellets were suspended in buffer and centrifuged on a density cushion of Percoll (25% and 50%) at 1800 *g* for 15 min at 4℃. The Kupffer cell fraction was collected, centrifuged at 650 *g* for 7 min and suspended again in buffer. Viability of cells was determined by Trypan blue exclusion. Purity (> 90%) of Kupffer cell cultures was evaluated by morphological observation and by phagocytic uptake of FITC-labeled 1 μm latex-beads. Kupffer cells were cultured in RPMI-1640 medium (Sigma) supplemented with 10% FCS and antibiotics/antimycotics (100 U/mL of penicillin G, 100 μg/mL of streptomycin sulfate, and 0.25 μg/mL amphotericin B; Sigma) at 37℃ in a 10% CO_2-containing atmosphere. Nonadherent cells were removed after 30 min by replacing the culture medium.

The parenchymal cell fraction (mostly hepatocytes) was also isolated by Percoll (50%) centrifugation as described previously[25] and cultured at 1×10^6 cells/well in RPMI 1640 medium (Sigma) containing 10% heat-inactivated fetal bovine serum and antibiotics as described above. Cells were cultured for 24 h before used for further experiments.

Measurement of intracellular Ca^{2+} concentration in Kupffer cells

Intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) was measured fluorometrically using the fluorescent calcium indicator dye fura-2. KC (1×10^6 cells/plate) were incubated in modified HBSS (mHBSS; in mmol/L): 110 NaCl, 5 KCl, 0.3 Na_2HPO_4, 0.4 KH_2PO_4, 5.6 glucose, 0.8 $MgSO_4 \cdot 7H_2O$, 4 $NaHCO_3$, 1.26 $CaCl_2$, 15 HEPES, pH 7.4 containing 5 μmol/L fura-2 AM (Molecular Probes, Eugene, OR, USA) at room temperature for 45 min. Coverslips plated with Kupffer cells were rinsed and placed in chambers with mHBSS at room temperature. Changes in fluorescence intensity of fura-2 at excitation wavelengths of 340 and 380 nm and emission at 510 nm were monitored in individual Kupffer cells. A Nikon inverted fluorescent microscope interfaced with dual-wavelength fluorescent photometer (Intracellular Imaging, Cincinnati, OH, USA) was used to ratiometrically determine $[Ca^{2+}]_i$. Data were collected and analyzed using InCyt software (Intracellular Imaging).

Determination of lactate dehydrogenase (LDH) release in hepatocytes

Twenty-four hours after isolation, hepatocytes were stimulated with deoxycholic acid (DCA; 0.1 mmol/L; Sigma) or normal saline in the presence or absence of glycine (1 mmol/L; Sigma). After 4 h of culture, supernatant was collected and LDH assays were performed *via* standard enzymatic techniques as described elsewhere[26].

Measurement of radiolabelled chloride influx by Kupffer cells

Assays for uptake of ^{36}Cl used an adaptation of a method described for neurons by Schwartz *et al*[27] and modified by Morrow and Paul[28]. Briefly, 2×10^6 Kupffer cells were plated on coverslips in 60 mm^2 culture dishes and incubated as described above. After 24 h, media was replaced with HEPES buffer (20 mmol/L HEPES, 118 mmol/L NaCl, 4.7 mmol/L KCl, 1.2 mmol/L $MgSO_4$, and 2.5 mmol/L $CaCl_2$, pH 7.4) and allowed to equilibrate for 10 min at room temperature. Coverslips were gently blotted dry and incubated in a petri dish with 2 mL of buffer containing 2 mCi/mL ^{36}Cl in the presence of glycine (1 mmol/L) and/or DCA (0.01 and 0.1 mmol/L) for 5 s. Chloride influx was linear between 2-10 s; thus, a 5 s incubation time was chosen for all experiments. Chloride influx was terminated by washing the coverslip with ice-cold buffer for 3 s followed by a second wash for 7 s[28]. Coverslips were placed in scintillation vials, and protein was solubilized by adding 1.6 mL NaOH (0.2 mol/L) for 2 h. An aliquot (0.16 mL) was collected for determination of protein by the method of Lowry *et al*[29]. Ecolume (10 mL) was added and radioactivity was determined by standard scintillation spectroscopy.

Statistical analysis

Data are presented as mean ± SD. ANOVA and the Student-Newman-Keuls post hoc tests were used for the determination of statistical significance between treatment groups, and $P < 0.05$ was selected before the study as the level of significance.

Boxplots illustrate median values and interquartile distance. The error bars represent the 5th and 95th percentiles.

RESULTS

Effects of dietary glycine on serum enzymes and histology after BDL

In untreated rats fed a standard chow diet, serum alanine transaminase (ALT) levels average 40 U/L and were not significantly altered by sham operation (data not shown). One day after BDL, ALT increased to 541 U/L (Figure 1A), and remained elevated at day 2 and 3 after BDL with 599 U/L and 543 U/L, respectively. When rats were treated with dietary glycine, ALT levels increased to 248 U/L one day after BDL (Figure 1A). On day 2 and 3, ALT levels were also significantly decreased compared to bile duct-ligated rats fed a control diet (232 U/L on day 2 and 161 U/L on day 3). Serum aspartate aminotransferase (AST) and alkaline phosphatase (AP) levels, which were also measured at day 1, 2, and 3 after BDL, revealed similar results as ALT (Figure 1B and C).

Normal liver architecture was observed in rats on a control and a glycine diet after sham operation (Figure 2A). Two days after BDL focal necrosis and white blood cell infiltration were detected in livers of rats receiving a standard diet (Figure 2B). These pathological changes were partially blocked in rats receiving dietary glycine (Figure 2C).

Influence of DCA on calcium and chloride influx in cultivated Kupffer cells in the presence or absence of glycine

Intracellular calcium concentration ($[Ca^{2+}]_i$) in cultured Kupffer cells was determined fluorometrically with the calcium indicator fura-2 as described in MATERIALS AND METHODS. After the addition of 0.01 or 0.1 nmol/L DCA, $[Ca^{2+}]_i$ levels increased as expected over the investigated time period of 10 min (Figure 3). Glycine (1 mmol/L) added 3 min before DCA inhibited this increase/induction in $[Ca^{2+}]_i$. Glycine alone had no detectable effect on $[Ca^{2+}]_i$ (data not shown).

The glycine-gated chloride channel mediates the influx of chloride and hyperpolarizes the cells[30] thereby preventing DCA-induced increases of $[Ca^{2+}]_i$ (Figure 3). Indeed, glycine (1 mmol/L) caused a significant, about 4-fold influx of radiolabeled chloride in the presence of DCA (0.01 or 0.1 nmol/L) (Figure 4).

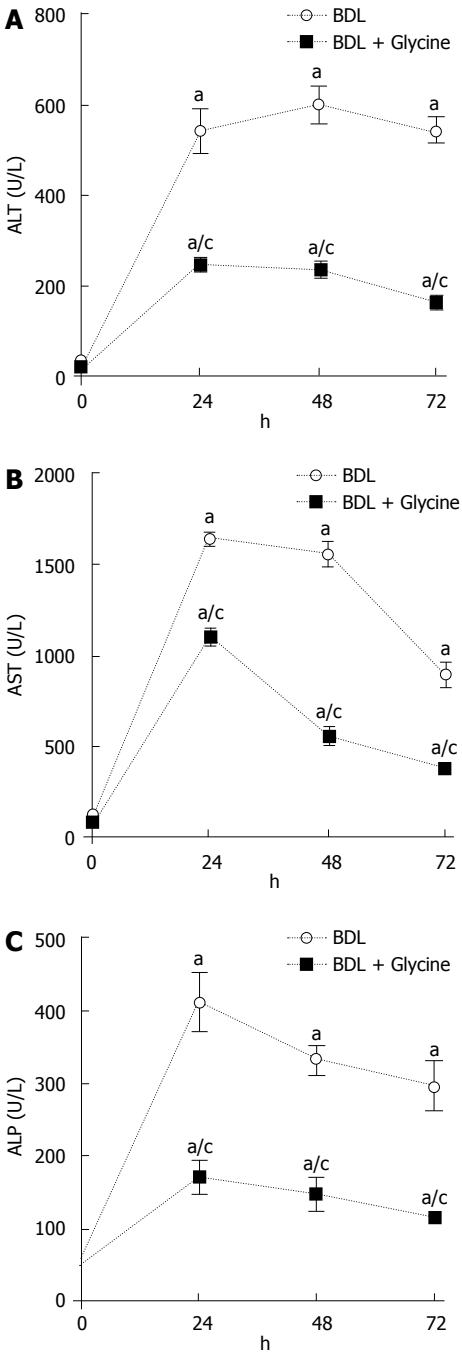

Figure 1 Dietary glycine blunts increased liver enzyme release after BDL. Blood was collected at the time points indicated. Serum alanine aminotransferase (**A**), aspartate aminotransferase (**B**), and alkaline phosphatase (**C**) activity was determined using commercial kits. Values are mean ± SD (n = 5-6 in each group). $^{a}P < 0.05$ *vs* sham operation; $^{c}P < 0.05$ *vs* bile duct-ligated rats fed control diet.

This effect of glycine was significantly reduced by the classical glycine-gated chloride channel antagonist strychnine (data not shown).

Effects of Kupffer cell elimination on serum enzymes after BDL

To investigate whether Kupffer cells play an important role in cholestatic liver injury, rats were treated with $GdCl_3$ that selectively depletes Kupffer cells, before BDL. Suppression of Kupffer cells with $GdCl_3$ neither

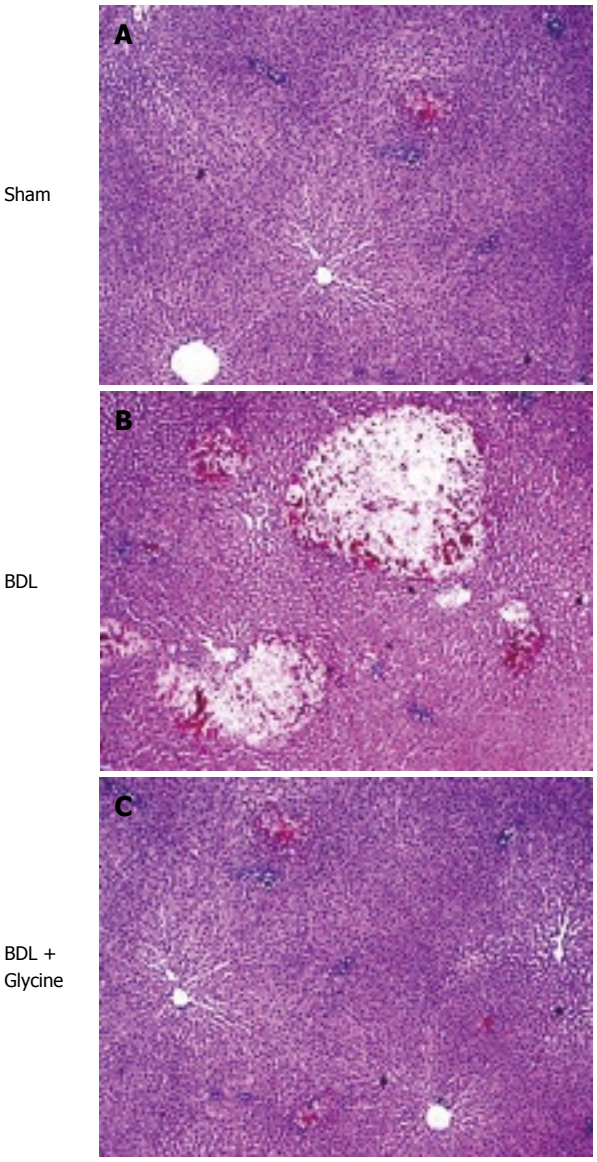

Figure 2 BDL induced focal necrosis that was blunted by dietary glycine. Shown are representative images (× 75). **A**: Sham operation with control diet; **B**: BDL with control diet; **C**: BDL with dietary glycine.

blunted ALT release (Figure 5) nor attenuated focal necrosis after BDL (data not shown), confirming our previously published data[31]. In detail, ALT levels increased up to 779 U/L (± 53) 24 h after BDL. Pretreatment with $GdCl_3$ one day before BDL had no effect on this transaminase release after BDL (870 ± 78 U/L).

Influence of DCA on LDH release in isolated hepatocytes in the presence or absence of glycine

Incubation of isolated hepatocytes with DCA (0.1 mmol/L) led to a specific release of LDH (Figure 6) over the investigated time period (1 h incubation time: 101 ± 8 U/L; 2 h incubation time: 112 ± 7 U/L; 3 h incubation time: 119 ± 8 U/L; 4 h incubation time: 149 ± 18 U/L). This release was significantly blocked when glycine was simultaneously added (1 h incubation time: 42 ± 7 U/L; 2 h incubation time: 77 ± 7 U/L; 3 h incubation time: 92 ± 8 U/L; 4 h incubation time:

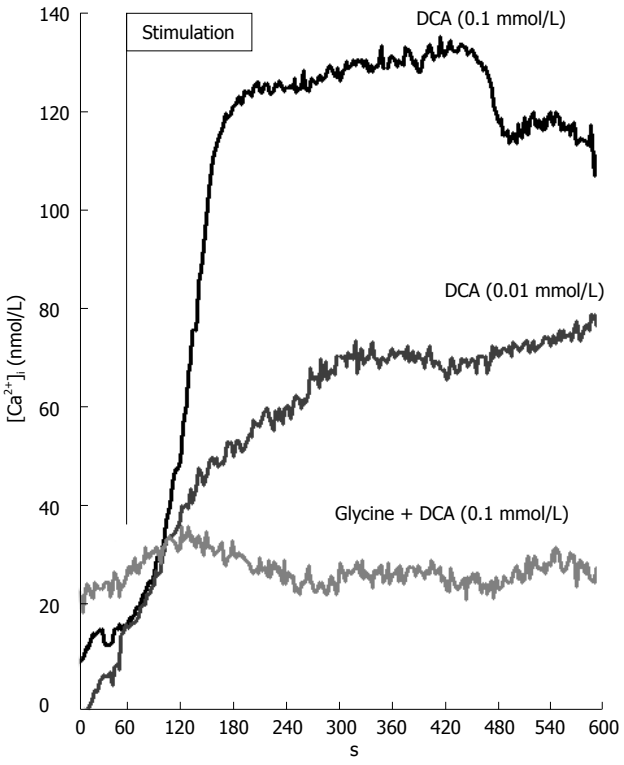

Figure 3 Glycine prevents DCA-induced rise of intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) in Kupffer cells. $[Ca^{2+}]_i$ was measured fluorometrically. Data are representative of 6 independent experiments.

79 ± 6 U/L). Incubation with glycine or saline alone had almost no effect on the release of LDH (Figure 6).

DISCUSSION

Chronic cholestatic liver diseases are one of the leading indications for liver transplantation in children and adults[1,2]. Therefore, new strategies to reduce the pathological changes caused by (chronic) cholestasis are needed, because current therapies, such as ursodeoxycholic acid[9], do not prevent liver injury. Oxidative stress and activation of Kupffer cells are probably involved in the pathogenesis of liver injury caused by cholestasis. Glycine has been shown to be an anti-inflammatory amino acid acting *via* inhibitory effects on several white blood cells, including Kupffer cells[15-19]. Glycine activates a chloride channel, leading to cell hyperpolarization and a concomitant blocking of calcium influx *via* a voltage dependent calcium channel[20]. Accordingly, we hypothesized that the activation of Kupffer cells and the associated free radical formation after BDL could be blocked by glycine, thus leading to a decreased liver injury.

Dietary glycine blunts liver injury due to BDL

In confirmation of previous work from our and several other laboratories[21,31-35], BDL caused hepatic enzyme release (Figure 1) and focal cell necrosis (Figure 2), as expected. However, hepatic enzyme release (ALT, AST, AP) was significantly blunted and histopathological changes were partially blocked in the group receiving

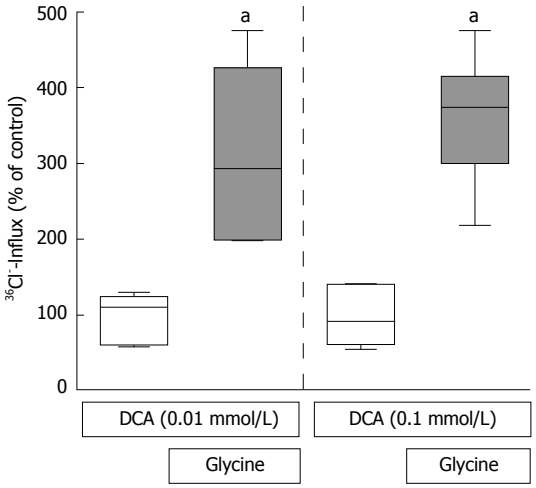

Figure 4 Glycine stimulates influx of radiolabeled chloride in Kupffer cells. Data are expressed as % of control. Values are mean ± SD and are representative of at least 6 individual experiments. $^aP < 0.05$ *vs* DCA (= control) group.

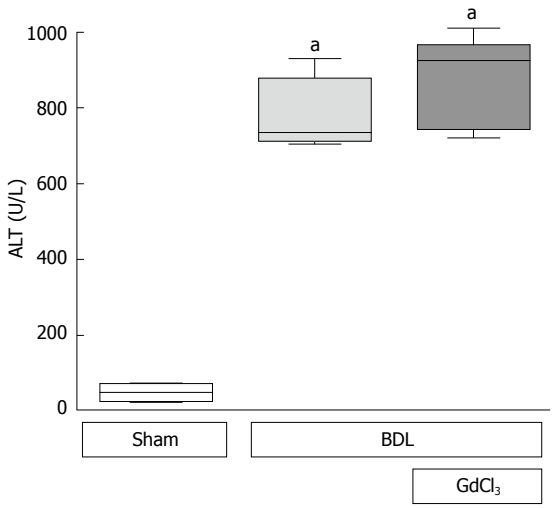

Figure 5 Elimination of Kupffer cells does not prevent elevated ALT release after BDL. Rats were given gadolinium chloride ($GdCl_2$; 20 mg/kg body weight) or saline 24 h before BDL or sham opration was performed. Values are mean ± SD (n = 5-6 in each group). $^aP < 0.05$ *vs* sham-operated group.

dietary glycine. Incubation of Kupffer cells with DCA led to increased intracellular calcium that was inhibited by incubation with glycine (Figure 3), most likely thru a glycine stimulated influx of chloride (Figure 4). However, systemic blockage of Kupffer cells with gadolinium chloride had no effect on transaminase release (Figure 5), indicating a minor, if any role of Kupffer cells in the pathophysiology of experimental cholestasis. Incubation of hepatocytes with DCA *in vitro* led to a significant release of LDH that was reduced by glycine (Figure 6).

How does dietary glycine decrease cholestasis-induced liver injury?

The protective effects of glycine are probably due to its direct effect on target cells or mediated by inhibition of inflammatory cell activation. Glycine appears to exert several protective effects, including anti-inflammatory, immunomodulatory and direct cytoprotective actions.

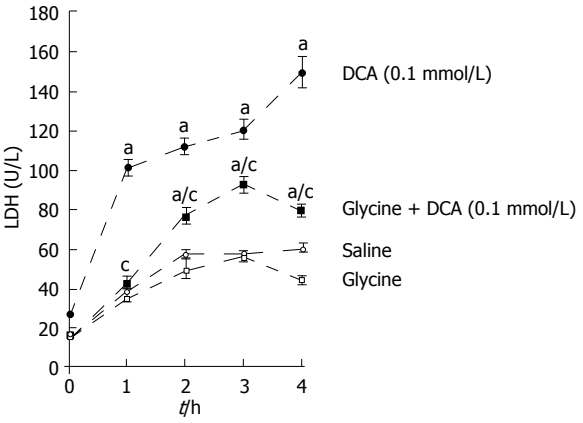

Figure 6 Glycine reduces DCA-induced release of LDH in isolated hepatocytes. Cells were isolated and stimulated with DCA (0.1 mmol/L) or saline in the presence or absence of glycine (1 mmol/L). Values are mean ± SD (n = 5-6 in each group). $^{a}P < 0.05$ *vs* saline or glycine group; $^{c}P < 0.05$ *vs* DCA treated hepatocytes.

The underlying mechanisms are not completely understood. Glycine decreases oxidative stress[15-19] by different and partly indirect mechanisms that prevent reactive oxygen species formation. Furthermore, glycine protects renal tubular cells, hepatocytes and endothelial cells against injury from hypoxia, ischemia-reperfusion and ATP depletion[16,36-39]. Most studies show that glycine protects plasma membrane integrity, but does not restore ATP levels or affect intracellular pH[16,38-40].

Activation of the glycine-gated chloride channel is another widely postulated mechanism for the effects of glycine. The glycine receptor exists in a wide variety of cells, beside its typical occurrence at the postsynaptic neuronal membranes of the spinal cord. Besides endothelial cells and renal proximal tubular cells[17,41], cells involved in inflammatory and immune responses, such as macrophages, monocytes, neutrophils, and T lymphocytes, express a glycine receptor[18,20,42-44]. Glycine acts thru its receptor on inflammatory cells, such as Kupffer cells, to suppress activation of transcription factors and the formation of free radicals and inflammatory cytokines. In the plasma membrane, glycine appears to activate a chloride channel[20,30] that stabilizes or hyperpolarizes the plasma membrane potential (Figure 4). As a consequence, agonist-induced opening of L-type voltage dependent calcium channels and the resulting increases in intracellular calcium ions are suppressed (Figure 3), which may account for the immunomodulatory and anti-inflammatory effects of glycine. By preventing Kupffer cell activation, a decreased formation of inflammatory and fibrogenic mediators may be achieved. However, the role of Kupffer cells in fibrosis is controversial. Destruction of Kupffer cells attenuated liver fibrosis caused by carbon tetrachloride[45]. By contrast, in a rat model of reversible biliary obstruction, inactivation of Kupffer cells impaired collagen metabolism and inhibited the resolution of fibrosis[46]. Kupffer cells release many mediators, like TNF-α, TGF-β, human growth factor, PDGF, and reactive oxygen species[47,48] that activate stellate cells leading to fibrosis. TNF-α production and NF-κB activation increase during cholestasis[49,50]. Activation of NF-κB, probably due to oxidative stress, could lead to expression of TNF-α. However, suppression of Kupffer cell function with $GdCl_3$, a treatment that blocks carbon tetrachloride-induced fibrosis, did not attenuate injury caused by cholestasis (Figure 5) confirming previous work from our laboratory[31]. This finding indicates that Kupffer cells most likely do not play a prominent role in cholestasis-induced fibrosis *in vivo* and that glycine does not work exclusively by inhibiting Kupffer cell activation.

Recent work suggested that liver parenchymal cells at least contain a glycine dependent receptor. In isolated hepatocytes, glycine blocks the increase in intracellular calcium due to PGE2 and phenylephrine, an a1-type adrenergic receptor agonist[51]. Low-dose strychnine partially reverses the inhibition by glycine. When extracellular chloride is omitted, glycine is much less effective in preventing increases in intracellular calcium due to PGE2. These data suggested that hepatoprotection by glycine is, in part, due to its direct effect on hepatocytes *via* regulating of intracellular calcium[51]. Consistent with these earlier findings, a direct effect of glycine on LDH release in isolated hepatocytes was observed in the present study after DCA challenge (Figure 6). Nevertheless, the effect of the conjugation of glycine and the used "secondary bile acid" DCA on the ability to lyse cells directly and solubilize cellular and membrane components should be also considered.

In conclusion, we demonstrated that hepatic injury, due to BDL, is significantly reduced by dietary glycine. Moreover, the data indicate that glycine decreases liver injury under the conditions of experimental cholestasis thru a direct effect on hepatocytes. Surprisingly, Kupffer cells do not appear to play a major role in the pathological changes caused by cholestasis.

COMMENTS

Background

Chronic cholestasis leads to liver injury and will ultimately progress to portal fibrosis, cirrhosis and end-stage liver disease requiring liver transplantation. Oxidative stress and activation of Kupffer cells are probably involved in liver injury caused by cholestasis. The nonessential amino acid glycine has been shown to be anti-inflammatory in several injury models, acting *via* inhibitory effects on several white blood cells, including Kupffer cells. Additionally, it activates a chloride channel, leading to cell hyperpolarization and a concomitant blocking of calcium influx into the cell *via* a voltage dependent calcium channel.

Research frontiers

Ursodeoxycholic acid is currently the most promising therapy for chronic cholestatic liver diseases; however, it cannot prevent fibrosis. How cholestasis induces liver injury and fibrosis remains unclear. One possible mechanism is that accumulation of hydrophobic bile acids causes oxidative stress in the liver, leading to tissue injury, fibrosis and finally liver cirrhosis. One possible cell type responsible for the generation of free radicals could be the Kupffer cells, the resident macrophages of the liver. It is known that destruction of Kupffer cells by gadolinium chloride or transduction of Kupffer cells by recombinant adenovirus can protect the liver against injury. However, the role of Kupffer cells in fibrosis is controversial. Destruction of Kupffer cells attenuated liver fibrosis caused by carbon tetrachloride. By contrast, in a rat model of reversible biliary obstruction, inactivation of Kupffer cells impaired collagen metabolism and inhibited the resolution of fibrosis.

Innovations and breakthroughs

Recent studies demonstrated that dietary glycine protected both the lung and

liver against lethal doses of endotoxin in the rat and improved graft survival after liver transplantation. Based on pharmacological data a glycine-gated chloride channel could be detected in Kupffer cells and other macrophages that influence the activation process of these cells by preventing the activation of intracellular signaling cascades.

Applications

The aim of this study was to investigate the effects of (dietary) glycine against oxidant-induced injury caused by bile duct ligation (BDL). The findings suggested that glycine significantly decreased liver injury, most likely by a direct effect on hepatocytes. Kupffer cells do not appear to play an important role in the pathological changes caused by cholestasis.

Terminology

Glycine, a simple nonessential amino acid, is a well-known inhibitory neurotransmitter in the central nervous system that acts *via* a glycine-gated chloride channel and has been shown to be protective against hypoxia, ischemia, and various cytotoxic substances. Kupffer cells, which are derived from monocyte/macrophage cell lineage, are the resident macrophages of the liver. Although they represent about 80% of the total fixed macrophage population, they are less than 5% of the total hepatic cell population. Kupffer cells play a critical role in the pathogenesis of several disease states, including endotoxin shock and alcoholic liver disease, because they release physiologically active substances such as eicosanoids, inflammatory cytokines, and many free radical species leading to localized tissue injury.

Peer review

This is an interesting study. It investigated the effects of (dietary) glycine against oxidant-induced injury caused by BDL.

Abstract

AIM: To observe the effect of berberine on insulin secretion in rat pancreatic islets and to explore its possible molecular mechanism.

METHODS: Primary rat islets were isolated from male Sprague-Dawley rats by collagenase digestion and treated with different concentrations (1, 3, 10 and 30 μmol/L) of berberine or 1 μmol/L Glibenclamide (GB) for 24 h. Glucose-stimulated insulin secretion (GSIS) assay was conducted and insulin was determined by radioimmunoassay. 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay was performed to evaluate cytotoxicity. The mRNA level of hepatic nuclear factor 4 alpha (*HNF4α*) was determined by reverse transcription polymerase chain reaction (RT-PCR). Indirect immunofluorescence staining and Western blot analysis were employed to detect protein expression of HNF4α in the islets. Glucokinase (GK) activity was measured by spectrophotometric method.

RESULTS: Berberine enhanced GSIS rather than basal insulin secretion dose-dependently in rat islets and showed no significant cytotoxicity on islet cells at the concentration of 10 μmol/L. Both mRNA and protein expressions of HNF4α were up-regulated by berberine in a dose-dependent manner, and GK activity was also increased accordingly. However, GB demonstrated no regulatory effects on HNF4α expression or GK activity.

CONCLUSION: Berberine can enhance GSIS in rat islets, and probably exerts the insulinotropic effect *via* a pathway involving HNF4α and GK, which is distinct from sulphonylureas (SUs).

Key words: Berberine; Sulphonylureas; Hepatocyte nuclear factor 4 alpha; Glucokinase; Pancreatic islet

INTRODUCTION

Type 2 diabetes mellitus is a complex and heterogeneous disorder caused by the interaction of hereditary and environmental factors, pathophysiologically characterized by insulin resistance and functional defects in insulin release from pancreatic β cells.

Sulphonylureas (SUs) are the most commonly prescribed insulin secretagogues. These drugs act *via* augmentation of insulin secretion from pancreatic β cells. The SU receptor-1 on the ATP-sensitive potassium channels (K_{ATP} channels) is occupied by SU leading to closure of the potassium channels and subsequent opening of calcium channels, resulting in exocytosis of insulin granules[1]. Yet, the maintenance of satisfactory long-term glycaemic control in patients undergoing SU therapy is usually restricted by increased risk of

hypoglycemia coupled with declined insulinotropic activity due to desensitized β cells to the agents[2,3]. Therefore, new types of insulinotropic substances with an alternative action profile are in demand.

Berberine, the major active constituent of Chinese herb *Rhizoma Coptidis*, is being used to treat diabetes for decades, showing obvious therapeutic actions with few reported side effects. Previous studies have demonstrated that berberine modulates cholesterol through increasing low-density lipoprotein receptor mRNA stability[4], reduces body adiposity and increases insulin sensitivity partly through activating AMP-activated protein kinase[5], and improves glucose metabolism *via* induction of glycolysis[6], implying a promising future for berberine in the therapy of diabetes. Moreover, a new research further revealed that berberine also possessed insulinotropic property in isolated pancreatic islets[7]. However, the underlying mechanism is not fully understood.

Recently, the hepatocyte nuclear factors (HNFs) transcriptional regulatory networks were identified in pancreatic islet tissue, providing insight into the molecular basis of abnormal β cell function. It was deemed that three members of HNFs family, HNF4α, HNF1α and HNF6, were at the center of the connected network, operating cooperatively to regulate numerous developmental and metabolic functions in human pancreatic islets. It was also revealed that HNF4α was bound to about 11% of the genes represented on the DNA microarray in pancreatic islets[8,9]. The occupancy by HNF4α of a substantial fraction of expressed genes suggests that HNF4α is a widely acting transcription factor and crucial for development and proper secretary function of pancreatic β cells. Furthermore, Bartoov-Shifman *et al*[10] found that HNF4α could activate insulin gene directly, through a previously unrecognized cis element. Clinical researches have indicated that mutations in gene encoding HNF4α result in maturity-onset diabetes of the young type 1, characterized by autosomal dominant inheritance, early onset and impairment of glucose-stimulated insulin secretion (GSIS)[11]. And two independent laboratory studies demonstrated that β-cell-specific HNF4α knock-out mice exhibited impaired GSIS and deficient intracellular calcium response to glucose or SU[12,13].

Increasing evidences suggest an essential role for HNF4α in the maintenance of proper secretary function of pancreatic β cell and glucose metabolism. In this study, we hypothesize that berberine facilitates insulin secretion through a pathway involving HNF4α in pancreatic islets. We introduce Glibenclamide (GB) as a control to compare the action profile of berberine with SUs, and to explore the possible molecular mechanism.

MATERIALS AND METHODS

Animals

Adult male Sprague-Dawley rats weighing 250-300 g [Grade SPF, Certificate No. SCXK (E2004-0007)] were purchased from the Experimental Animal Center, Tongji Medical College, Huazhong University of Science and Technology. The rats were housed at 22℃, and 60%-70% relative humidity, with 12 h light/dark cycle. The rats were given free access to food and tap water. All rats received humane care in compliance with the institutional animal care guidelines approved by the Experimental Animal Ethical Committee of Tongji Medical College, Huazhong University of Science and Technology.

Drug preparation

Berberine hydrochloride (Sigma, St Louis, MO, USA) and GB (Alexis CO, San Diego, CA, USA) were dissolved in dimethyl sulfoxide (DMSO, Amresco, TX, USA), with a final concentration of DMSO 0.01% (v/v) in the culture medium.

Islet isolation and culture conditions

Primary pancreatic islets were isolated as previously reported[14,15]. In brief, rats were anesthetized with intramuscular pentobarbital injection, 8-10 mL ice-cold Hanks' balanced salt solution (HBSS) containing 0.75 mg/mL type V collagenase (Sigma, St Louis, MO, USA) was injected *via* pancreatic duct, extended pancreas was removed and digested in a 38℃ water bath for 8-10 min. Then digestion was terminated by 30 mL ice-cold HBSS with 10% fetal bovine serum (Gibco, USA), and the suspension was filtered through a 600 μm screen to discard the undigested tissue. After twice washes with HBSS, islets were purified by Ficoll-400 (Amersham Pharmacia Biotech, Uppsala, Sweden) discontinuous gradient centrifugation at 800 × *g* for 20 min at 4℃, and hand-picked under dissecting microscope. About 250-400 islets were yielded from each pancreas. The purity of islets was evaluated by dithizone (DTZ, Sigma, St Louis, MO, USA) staining[16], and the viability was assessed according to the acridine orange/propidium iodide (AO/PI, Sigma, St Louis, MO, USA) fluorescent staining method[17]. Freshly isolated islets were first cultured overnight at 37℃ in a 50 mL/L CO_2-950 mL/L air atmosphere in serum-free RPMI 1640 (Hyclone, Gaithersburg, MD, USA) containing 2% (w/v) bovine serum albumin fraction V (BSA, Amresco, TX, USA), 11.1 mmol/L glucose, 5 mmol/L glutamine, 1 mmol/L sodium pyruvate, 100 IU/mL pennicillin, 100 μg/mL streptomycin and 15 mmol/L HEPES. Then islets were cultured for 24 h in various experimental media containing 1, 3, 10 and 30 μmol/L berberine or 1 μmol/L GB. Normal control was also set by incubating islets with medium in the absence of berberine or GB.

GSIS assay

For evaluation of insulin secretion, islets were washed twice with Krebs-Ringers Bicarbonated HEPES [KRBH, containing 120 mmol/L NaCl, 4.8 mmol/L KCl, 2.5 mmol/L $CaCl_2$, 1.2 mmol/L $MgSO_4$, 1.2 mmol/L KH_2PO_4, 25 mmol/L $NaHCO_3$, 10 mmol/L HEPES, 2.8 mmol/L glucose, 0.5% BSA (w/v), pH 7.4] at the end of the incubation. Batches of 10 size-matched islets (six replicas per condition) were transferred into

1.5 mL Eppendorf tubes, and pre-incubated for 30 min at 37℃ in KRBH with 2.8 mmol/L glucose. Subsequently, islets were incubated in KRBH supplemented with either 2.8 mmol/L or 16.7 mmol/L glucose for 1 h at 37℃. Aliquots of supernatant were collected after gentle centrifugation and stored at -20℃ for insulin determination by radioimmunoassay kit (Beijing Institute of Atomic Energy, China).

3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide (MTT) cytotoxicity assay

Cytotoxicity of berberine and GB on islet cells was tested by a colorimetric assay that detected the conversion of MTT (Sigma, St Louis, MO, USA) into the formazan by the mitochondrial enzyme succinate dehydrogenase in viable cells[18]. After *in vitro* treatment, islets were dissociated into single cells by incubation in Ca^{2+}/Mg^{2+}-free KRBH containing 5 mmol/L EDTA and 0.25 mg/mL trypsin for 10 min at 37℃ with gentle shaking, and then resuspended in RPMI 1640. Islet cells were cultured in a 96-well plate supplemented with 0.5 mg/mL MTT. After 4 h incubation, the insoluble formazan crystals within islet cells were extracted by DMSO, and absorbance was measured by ELX800 Universal Microplated Reader (BioTek Instruments Inc, USA) at wavelength of 630 nm.

Semi-quantitative reverse transcription polymerase chain reaction (RT-PCR) analysis

Semi-quantitative RT-PCR was performed to determine the mRNA level of HNF4α in the islets. Total RNA was extracted from about 300 islets by the Trizol Reagent Kit (Gibco, USA) according to the manufacturer's instructions. Two μg of RNA from each sample was then reverse-transcribed into first-strand cDNA in 25 μL solution using Oligo (dT) Primers and MMLV reverse transcriptase (Promega, Madison, WI, USA). PCR reaction was performed in a standard 25 μL reaction solution contained 3 μL cDNA, 0.5 μL each of sense and anti-sense primers. Sequence-specific primers for cDNA amplification were as follows: *HNF4α* (product 464 bp, sense 5'-GCAGTGCGTGGTAGACAAAGA TA-3'; anti-sense 5'-AGTGCCGAGGGACGATGTA G-3') and the housekeeping gene *β-actin* (product 213 bp, sense 5'-AGATCTGGCACCACACCTTCTAC-3'; anti-sense 5'-TCAGGATCTTCATGAGGTAGTCT-3'). Reaction conditions for *HNF4α* were as follows: predenaturing at 95℃ for 5 min , denaturing at 95℃ for 1 min, annealing at 60℃ for 50 s, extending at 72℃ for 1 min, 35 cycles, with final extending at 72℃ for 10 min. Amplification of *β-actin* was performed by predenaturing at 94℃ for 5 min, denaturing at 94℃ for 1 min, annealing at 55℃ for 50 s, extending at 72℃ for 50 s, 30 cycles and final extending at 72℃ for 10 min. PCR products were electrophoresed through 1.5% agarose gel, stained with ethidium bromide and visualized under ultraviolet illumination. Band intensity was calculated densitometrically using the SensiAnsys software (Shanghai PeiQing Science & Technology, China).

Immunofluorescence

Indirect immunofluorescence assay was performed as previously described with a few modifications[19,20]. In brief, islets were placed into 1.5 mL Eppendorf tubes, fixed in 4% paraformaldehyde/10 mmol/L PBS for 30 min, followed by a 3 h permeabilization with 0.3% Triton-X100/10 mmol/L PBS. Subsequently, islets were blocked with 5% fetal bovine serum/0.2 Triton-X100/10 mmol/L PBS overnight at 4℃ and then equilibrated in antibody dilution buffer (1% BSA/0.2% Triton X-100/10 mmol/L PBS) twice for 20 min at room temperature. Primary antibodies used were as follows: goat anti-rat HNF4α IgG (1:300, Santa Cruz, San Diego, CA, USA), Guinea pig anti-insulin antibody (1:300, Sigma, St Louis, MO, USA), and the incubation was carried out for 16 h at 4℃. The secondary antibodies were Cy3 conjugated rabbit anti-goat IgG (1:400, Sigma, St Louis, MO, USA) and FITC conjugated rabbit anti-guinea pig IgG (1:250, Sigma, St Louis, MO, USA), incubation was performed for 1 h at room temperature. Finally, islets were mounted with 50% glycerol/10 mmol/L PBS, smeared onto glass slides and subjected to Confocal Laser Scanning Microscope (Olympus FV500, Japan). The excitation wavelengths for Cy3 and FITC were 552 nm and 488 nm, and the emission wavelengths were 565 nm and 525 nm, respectively. To avoid variability in fluorescent intensity caused by depth-related changes and wide range of islet diameters, a single section image was taken at the depth 1/3 the distance between the upper islet surface and its maximum diameter. Ten areas from each cover slip were randomly selected and analyzed by the HMIAS-2000 Imaging System (Champion Medical Imaging Co., Wuhan, China).

Western blot analysis

Primary pancreatic islets treated with the various experimental conditions were lysated in buffer containing 25 mmol/L Tris, 1% SDS, 5% β-mercaptoethanol, 10 mmol/L EDTA, 20 mmol/L PMSF, 10 mg/L aprotinin, 10 mg/L leupeptin, 10 mg/L antipain, 8 mol/L urea. Homogenates were centrifuged at 12 000 × *g* for 15 min at 4℃, supernatants were harvested. Protein concentrations were measured by the method of Bradford[21], with Coomassie brilliant blue staining kit (Jiancheng Biology Institute, Nanjing, China). And 50 μg total protein for each group was boiled for 5 min in sample buffer [50 mmol/L Tris·Cl (pH 6.8), 100 mmol/L DTT, 2% SDS, 0.1% bromchlorphenol blue, 10% glycerol] and separated by 12% SDS-PAGE. Thereafter, proteins were transferred electrophoretically onto a polyvinylidine fluoride membrane. Before immunostaining, the membranes were blocked with 5% non-fat milk in Tris-buffered saline and 0.1% Tween (TBST) overnight at 4℃, followed by incubation with appropriate dilutions of the primary specific antibody goat anti-rat HNF4α IgG (1:500, Santa Cruz Biotechnology Inc, CA, USA) in 5%BSA/TBST at 4℃ for 16 h. The secondary antibody was horseradish

peroxidase (HRP) conjugated rabbit anti-goat IgG (1:2000, Sigma, St Louis, MO, USA), incubation was carried out at room temperature for 2 h. GAPDH was probed with anti-GAPDH IgG as a loading control. Immunodetection was performed using an enhanced chemiluminescence detection kit (Pierce, Rockford, IL). Protein bands on films (Eastman Kodak, Rochester, NY, USA) were analyzed by densitometry (Bio-Rad, Hercules, USA) using "Quantity One" quantitation analysis software program.

Glucokinase (GK) activity assay

GK activity was measured by spectrophotometric assay as previously described[22]. Briefly, islet were washed twice with PBS, approximately 150 islets from each group were homogenized (30 strokes) in 200 μL lysis buffer containing 20 mmol/L K_2HPO_4, 5 mmol/L dithiothreitol, 1 mmol/L EDTA, and 110 mmol/L KCl, followed by sonication (20 KHz, 60 W) for 3 × 10 s on ice. The homogenate was then centrifuged at 12000 × *g* for 10 min, and the supernatant fraction was used for GK determination. Then 10 μL of the supernatant was added to 100 μL reaction buffer, containing 50 mmol/L HEPES/HCl (pH 7.6), 100 mmol/L KCl, 7.4 mmol/L $MgCl_2$, 15 mmol/L β-mercaptoethanol, 0.5 mmol/L NAD^+, 0.05% BSA (w/v), 2 IU/mL glucose-6-phosphate dehydrogenase, and 5 mmol/L ATP. The assay was conducted for 1 h at 30℃, and reaction was stopped by adding 1 mL of 500 mmol/L $NaHCO_3$ buffer (pH 9.4). In each assay, blanks were obtained by incubating 0.5 or 100 mmol/L glucose in the absence of ATP. Absorbance was measured at 340 nm, correction for hexokinase activity was applied by substracting the activity measured at 0.5 mmol/L glucose from the activity measured at 100 mmol/L glucose. Protein concentrations were determined by the Bradford assay.

Statistical analysis

All the data were expressed as mean ± SD, and analyzed with SPSS 13.0 software by one-way analysis of variance (ANOVA) LSD-*t* and SNK-*q*. $P < 0.05$ was considered statistically significant.

RESULTS

Purity and viability of freshly isolated islets

The purity of the freshly isolated islets was estimated by the percentage of DTZ-positive islets (crimson red) in the preparation. According to the method, an approximate 95% purity was assessed. For viability evaluation, islets were exposed to AO/PI, and subjected to fluorescent microscopy (Nikon ECLIPSE TE2000-U, Japan) with viable cells stained green while nonviable cells bright red. The viability exceeded 90% as assessed by the method (Figure 1).

Effects of berberine and GB on insulin secretion

In the experiment, we employed static incubation assay to further examine the facilitative effect of berberine on islet insulin secretion. Islets were first incubated with 2.8 mmol/L glucose, and then challenged with 16.7 mmol/L glucose. All samples were determined by immunoradioassay. As Figure 2A depicted, islets in control group exhibited a normal response to glucose stimulation, with insulin secretion of 7.21 ± 1.43 *vs* 30.50 ± 5.17 (mIU/L per hour per 10 islets). Treatment of islets with 1 μmol/L GB potently elevated basal insulin secretion ($P < 0.01$), while inhibited GSIS by about 3 folds relative to normal control ($P < 0.05$). In contrast, although none of the four berberine groups showed any promoting effects on basal insulin secretion, treatment with 1, 3, 10 μmol/L berberine resulted in dose-dependently increased GSIS ($P < 0.05$ or $P < 0.01$), still no enhancement was observed in islets of 30 μmol/L berberine group.

Cytotoxicity of berberine and GB on islet cells

We used MTT assay to analyze cytotoxicity caused by berberine and GB. Results were expressed as percentage of formazan absorbance relative to control value. It was observed that, 30 μmol/L berberine inhibited formazan absorbance by about 2 folds compared to the control, indicating significant cytotoxicity on islet cells ($P < 0.01$). None of the other groups demonstrated significantly diminished absorbance (Figure 2B).

Effects of berberine and GB on HNF4α gene expression

In RT-PCR experiment, it was observed that at concentrations lower than 10 μmol/L, berberine

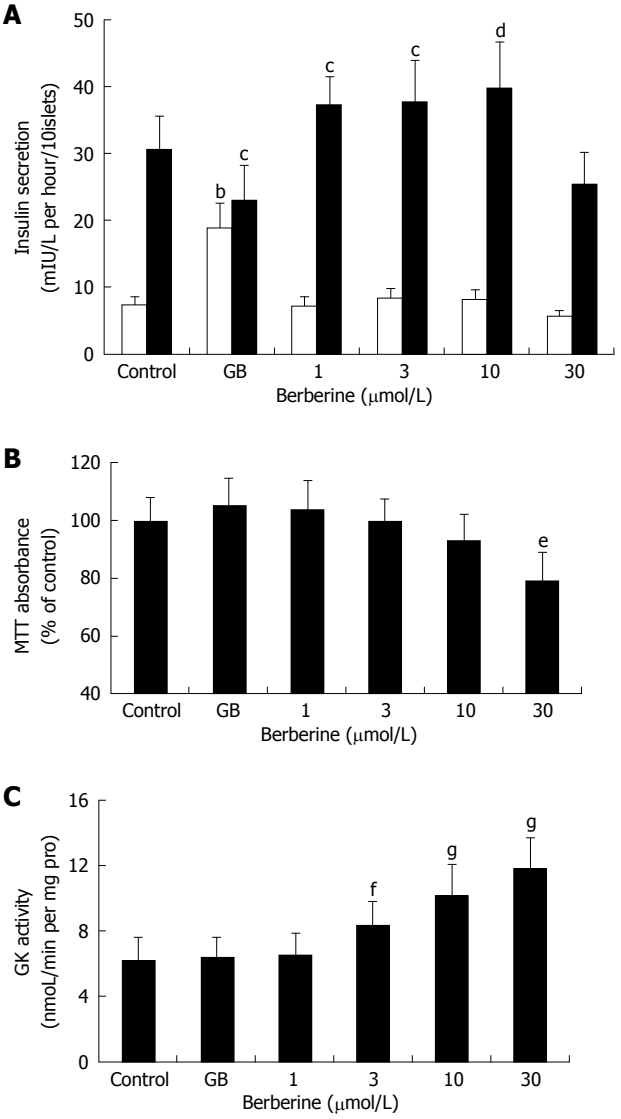

Figure 2 Pharmacological effects of berberine and GB on pancreatic islets. **A**: Effects of berberine and GB on basal (2.8 mmol/L Glucose) and GSIS (16.7 mmol/L Glucose) by pancreatic islets. Control and GB represent islets of untreated and 1 μmol/L GB treated groups, while 1, 3, 10 and 30 represent berberine groups of indicated concentrations. $^{b}P < 0.01$ *vs* control at 2.8 mmol/L glucose; $^{c}P < 0.05$, $^{e}P < 0.01$ *vs* control at 16.7 mmol/L glucose; **B**: Cytotoxicity of berberine and GB on islet cells assessed by MTT assay. Results were expressed as the percentage of absorbance to the control value. Data are presented as mean ± SD ($n = 6$). $^{e}P < 0.01$ *vs* control. **C**: Effects of berberine and GB on islet GK activity. $^{f}P < 0.05$, $^{g}P < 0.01$ *vs* control.

treatment induced a general dose-dependent increase relative to control in *HNF4α* mRNA expression ($P < 0.05$ or $P < 0.01$). However, no significant difference was observed in islets incubated with either 30 μmol/L berberine or 1 μmol/L GB compared with the control (Figure 3).

Immunofluorescence and confocal microscopy

Confocal images showed apparent co-localization of insulin (green) and HNF4α (red) in the islets. As Figure 4 depicts, islets exhibited a normal architecture, featuring predominant distribution of insulin throughout the entire β cell cytoplasm as well as typical nuclear localization of HNF4α in both β cell and peripheral

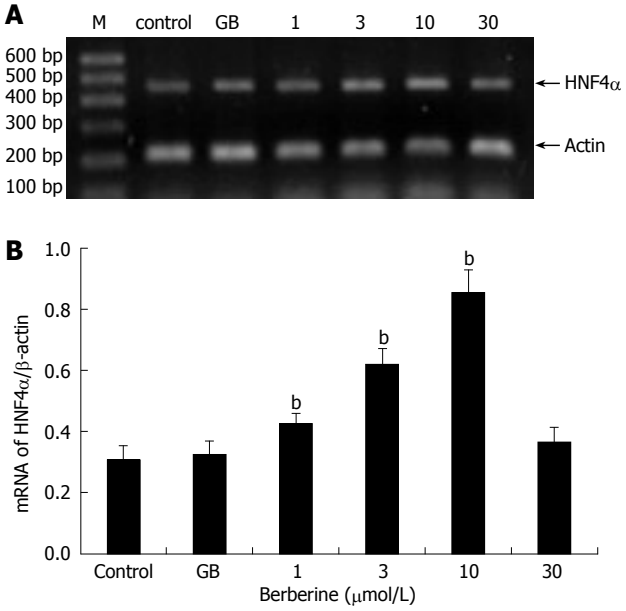

Figure 3 Effects of berberine and GB on HNF4α mRNA expression. **A**: A representative gel electrophresis profile of DNA fragment; **B**: Semi-quantitative mRNA determination, results were normalized to β-actin and expressed as arbitrary unit. M: DNA Marker, control and GB represent islets of untreated and 1 μmol/L GB treated groups; 1, 3, 10 and 30 represent berberine groups of indicated concentrations. Data are presented as mean ± SD ($n = 6$), $^{b}P < 0.01$ *vs* control.

α cell. It was noteworthy that islets of berberine treated groups demonstrated more intense and distinct fluorescence of HNF4α than control group, with the strongest red fluorescence emitted from the 10 μmol/L berberine treated group. However, no distinguishable change of HNF4α staining was observed in GB group compared with control group.

Effects of berberine and GB on HNF4α protein expression

To further clarify the correlation of berberine's insulinotropic effect with HNF4α expression, we quantified the protein level of HNF4α by Western blot. Similar to the result of immunofluorescence, protein expression of HNF4α also demonstrated a dose-dependent increase in the berberine treated islets ($P < 0.05$ or $P < 0.01$), with maximum expression in 10 μmol/L berberine group. Still no significant difference was found between GB group and control group (Figure 5).

Effects of berberine and GB on islet GK activity

In the experiment, GK activity was determined in the islet homogenates. As shown in Figure 2C, compared to the control, treatment with 3, 10 and 30 μm/L berberine significantly activated islet GK activity ($P < 0.05$ or $P < 0.01$) in a dose-dependent manner, while no enhancement of GK activity was observed in the islets incubated with 1 μmol/L berberine or 1 μmol/L GB.

DISCUSSION

The SUs are a family of oral hypoglycemic agents used

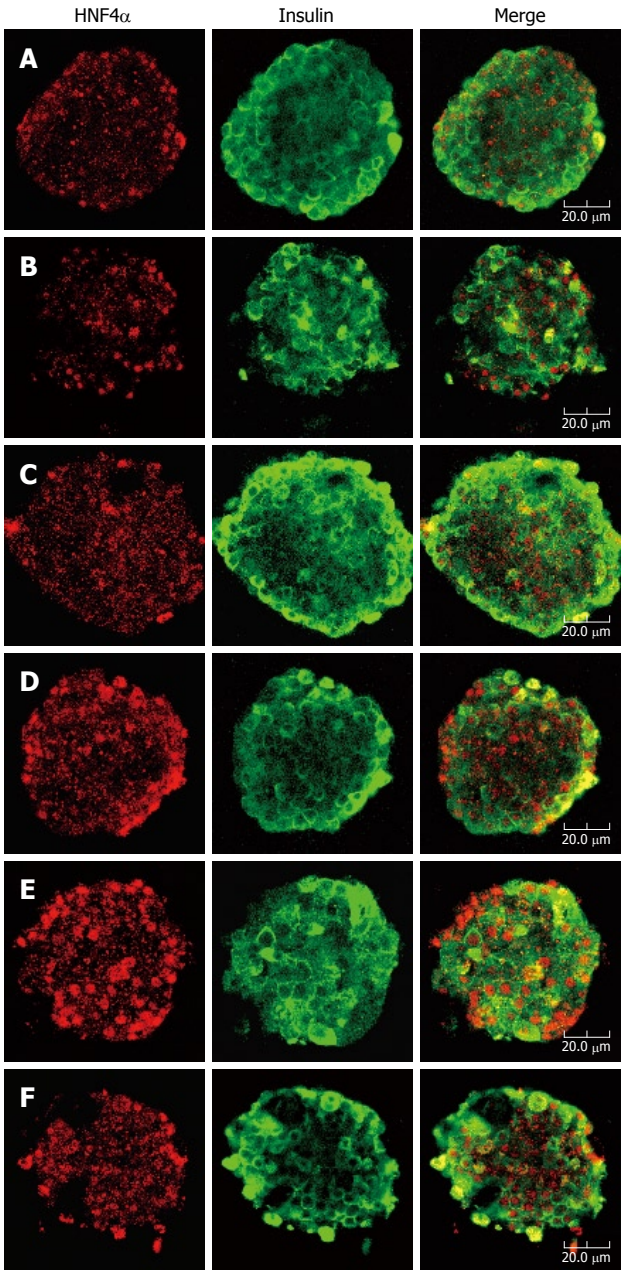

Figure 4 Double immunofluorescence staining for HNF4α (red) and insulin (green) of rat pancreatic islets. After treatment with indicated concentrations of berberine or GB for 24 h, islets were fixed and stained with anti-HNF4α and anti-insulin antibodies. Images of islets were taken at the corresponding depth by confocal laser microscopy (x 40). **A**: Control, **B**: 1 μmol/L GB; **C** to **F**: Represent 1, 3, 10 and 30 μmol/L berberine. Bar in the figure indicates 20 μm. Apparent nuclear localization of HNF4α could be observed in all groups of islets, while insulin fluorescence was diffusely distributed in cytoplasma of β cells. In the islets treated with various concentrations of berberine, the red fluorescence emitted was comparatively intense, suggesting up-regulated expression of HNF4α, while no obvious difference of HNF4α staining was found between control and GB treated islets.

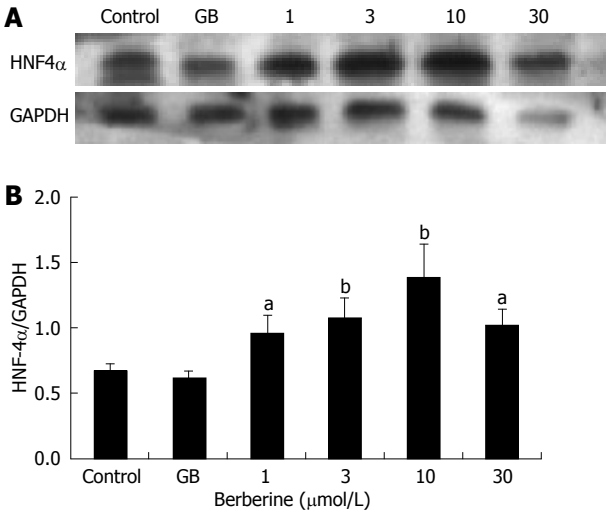

Figure 5 Effects of berberine and GB on protein expression of HNF4α. **A**: A representative Western blot of HNF4α; **B**: Quantification of HNF4α protein, results were adjusted to GAPDH and expressed as relative density units. Control and GB represent islets of untreated and 1 μmol/L GB treated groups, 1, 3, 10 and 30 represent berberine groups of indicated concentrations. Data are presented as mean ± SD (n = 3). $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* control.

extensively for the treatment of type 2 diabetes. They mediate the insulinotropic effect *via* blocking β cell K_{ATP} channels and depolarizing the membrane. Nonetheless, because the potent insulin stimulating property is independent of glucose challenge, they enhance insulin secretion even at basal glucose levels. Therefore, patients receiving SUs therapy are at high risk of hypoglycemia. Moreover, chronic SUs therapy may lead to a selective desensitization of pancreatic β cells to SUs[1,2].

In the present study, the insulinotropic effect of berberine on rat islets was compared with GB, a classical SU derivative. It was demonstrated that 1 μmol/L GB acutely promoted basal insulin secretion by approximately 250% in isolated islets, while markedly reduced GSIS in the presence of 16.7 mmol/L glucose. This observation is in good agreement with previous reports[2,23]. The suppressed GSIS might partly result from the reduction of K_{ATP} channel activity induced by chronic exposure to GB and/or the depletion of insulin stores, reflecting the controversy of β-cell desensitization *vs* β-cell exhaustion[3,24]. In contrast to the action profile of GB, berberine induced no significant changes in basal insulin secretion but increased GSIS dose-dependently at the concentrations of 1-10 μmol/L. This result is consistent with a previous research by Ko *et al*[25], which showed that berberine exerted no stimulatory effect on basal insulin secretion (2 mmol/L glucose), but increased GSIS at the concentration of 5 and 50 μmol/L in MIN6 cells.

To define the underlying mechanism for the completely different action profile of GB and berberine, we first examined the cytotoxicity caused by the drugs. Our results indicated that only 30 μmol/L berberine demonstrated statistically significant toxicity on islet cell. Hence, it could not be the distinctions of cell metabolism that account for the different action modalities of the two agents. Accordingly, we concluded berberine probably stimulated insulin secretion *via* a mechanism distinct from SUs! In the following experiments, we determined the gene and protein expressions of HNF4α, a transcription factor confirmed to play an essential role in GSIS, attempting to explore if HNF4α a potential target underling the facilitating effect of berberine on GSIS. Our data conspicuously showed

that both the mRNA and protein expressions increased in a dose-dependent manner, reaching their maximum at 10 μmol/L berberine then declining to the levels parallel those of control. No significant changes were observed in the islets treated with 1 μmol/L GB compared with the control. These results strongly suggest the potential involvement of HNF4α in berberine's insulinotropic action but not GB-induced insulin secretion. The significant cytotoxicity caused by 30 μmol/L berberine might offer a plausible explanation for the reduction of HNF4α expression.

The question remains as to how HNF4α mediate the stimulatory effects of berberine on GSIS in pancreatic islets, as few evidences to date substantiate that HNF4α regulates GSIS directly in pancreatic islets. For elucidating this, we further investigated the effect of berberine on GK activity in rat islets. It is generally acknowledged that GK plays the crucial role of "glucose sensor" in pancreatic β-cell, due to its specific kinetic properties that include low affinity and positive cooperativity for glucose and a lack of inhibition by its product glucose-6-phosphate. GK regulates GSIS by modulation of the glycolytic pathway and controlling the rate of its subsequent metabolism[26,27]. It is also deemed that GK is one of the downstream targets of the HNFs transcription regulatory circuit in pancreatic islets[9]. Therefore, there is a good possibility that berberine exerts the facilitating effect on GSIS through direct action of GK! As expected, our results showed that berberine also elevated GK activity dose-dependently in islets, exhibiting the strongest effect at the concentration of 30 μmol/L. Yet, still no significant difference was observed between islets treated with 1 μmol/L GB and the control, which agrees with a previous report indicating that GB exerted no regulatory effect on GK activity in isolated islets[28]. Thus, our data further support the hypothesis that GK plays a role in the stimulatory effect of berberine on GSIS.

It appears puzzling that discrepancies also existed despite the conspicuous correlation among insulin secretion and HNF4α expression and GK activity in general. It was demonstrated that 1 μmol/L berberine significantly increased insulin secretion, HNF4α gene and protein expressions, however, no enhancement of GK activity was observed. In contrast, 30 μmol/L berberine significantly increased GK activity, while both insulin secretion and HNF4α gene expression were at a normal level. As mentioned above, HNFs form a network, function solely or cooperatively to regulate the expression of multiple target genes that are important in the maintenance of metabolism homeostasis. It is conceivable, therefore, that not only HNF4α but also other HNFs such as HNF1α or HNF6 might participate in the modulation of GK activity. However, these need to be clarified further.

Taken together, our results suggest that berberine might exert its insulinotropic effect in isolated rat islets by up-regulating the expression of HNF4α, which probably acts solely or together with other HNFs to modulate GK activity, rendering β cell more sensitive to glucose fluctuation and response more effectively to glucose challenge. Interestingly, Ko *et al*[25] revealed that berberine facilitated GSIS in MIN6 cells partly *via* an enhanced insulin/insulin-like growth factor-1 (IGF-1) signaling cascade, which seems discrepant from the pathway we proposed. However, it is speculated that insulin signaling could interact with HNF-regulated transcription in beta cells, and insulin or IGF-1 act as potential upstream inductive signals regulating the HNFs and their target genes[9]. This might at least in part provide plausible explanation for the controversy.

In conclusion, our findings indicate that berberine enhances GSIS, rather than basal insulin secretion dose-dependently in isolated rat islets. This might partly be attributable to the up-regulation of HNF4α expression and GK activity by berberine. It is also suggested that HNF4α and GK might not participate in GB-induced insulin secretion. Berberine would be a promising insulin secretagogue which works through a mechanism distinct from SUs.

COMMENTS

Background

Berberine, a main constituent isolated from Chinese herb *Rhizoma coptidis*, is gaining increasing attention, especially for its anti-diabetic properties, including improving insulin resistance, lowing blood glucose and modulating lipid metabolism. Recent researches further reveal that berberine also possesses insulinotropic action, yet, the molecular mechanism remains unclear.

Research frontiers

The transcriptional regulatory circuit of hepatic nuclear factors (HNFs) has recently been identified in pancreatic islets. And numerous evidences suggest an essential role for hepatic nuclear factor 4 alpha (HNF4α) in the proper secretary function of β cells. This study aims to elucidate if HNF4α underlies the mechanism of berberine's facilitating effect on insulin secretion.

Innovations and breakthroughs

In this study, the authors found that berberine could promote glucose-stimulated insulin secretion (GSIS) rather than basal insulin secretion in primary rat islets. Furthermore, they revealed that berberine might exert the insulinotropic effect through a mechanism involving HNF4α and glucokinase (GK), which is absolutely distinct from that of the widely used sulphonylureas (SUs).

Applications

The data suggest that berberine might be a promising insulin secretagogue which works *via* a unique mechanism in diabetes treatment.

Terminology

HNF4α is a transcriptional factor belonging to the hepatocyte nuclear factor family. It has been demonstrated that HNF4α is expressed mainly in liver and pancreatic islet tissue, regulating the transcription of multiple target genes implicated in glucose metabolism and insulin secretion. GK is known as "glucose sensor", modulating insulin secretion by controlling the rate of glycolysis in pancreatic β cells.

Peer review

It is a simple and elegant study. Authors observed the effect of berberine on insulin secretion by rat pancreatic islets and explored its possible molecular mechanism.

Abstract

AIM: To investigate the effects of lubiprostone and Polyethylene Glycol 3350 (PEG) on mucosal barrier repair in ischemic-injured porcine intestine.

METHODS: Ileum from 6 piglets (approximately 15 kg body weight) was subjected to ischemic conditions by occluding the local mesenteric circulation for 45 min *in vivo*. Ileal tissues from each pig were then harvested and mounted in Ussing chambers and bathed in oxygenated Ringer's solution *in vitro*. Intestinal barrier function was assessed by measuring transepithelial electrical resistance (TER) and mucosal-to-serosal fluxes of ^{3}H-mannitol and ^{14}C-inulin. Statistical analyses of data collected over a 120-min time course included 2-way ANOVA for the effects of time and treatment on indices of barrier function.

RESULTS: Application of 1 μmol/L lubiprostone to the mucosal surface of ischemic-injured ileum *in vitro* induced significant elevations in TER compared to non-treated tissue. Lubiprostone also reduced mucosal-to-serosal fluxes of ^{3}H-mannitol and ^{14}C-inulin. Alternatively, application of a polyethylene laxative (PEG, 20 mmol/L) to the mucosal surface of ischemic tissues significantly increased flux of ^{3}H-mannitol and ^{14}C-inulin.

CONCLUSION: This experiment demonstrates that lubiprostone stimulates recovery of barrier function in ischemic intestinal tissues whereas the PEG laxative had deleterious effects on mucosal repair. These results suggest that, unlike osmotic laxatives, lubiprostone stimulates repair of the injured intestinal barrier.

Key words: Intestinal ischemia; Barrier function; Permeability; Laxative; Polyethylene Glycol

INTRODUCTION

Ischemic intestinal disorders including intestinal volvulus, thromboembolic disease, and low flow states associated with shock, have a high mortality rate due to the rapid onset of sepsis and multiple organ failure[1-3]. Intestinal ischemic lesions are characterized by sloughing of the apical villus epithelium and rapid breakdown of mucosal barrier function[2,4,5], accompanied by increased intestinal permeability and subsequent bacterial translocation, sepsis, and multiple organ dysfunction syndrome (MODS)[6-8]. Rapid restoration of the compromised intestinal barrier is critical for patient survival. However, limited treatment options are available that target mucosal barrier repair[9].

Lubiprostone, an FDA-approved laxative (Amitiza, Sucampo Pharmaceuticals, Inc.) was previously shown to stimulate rapid repair of intestinal barrier function in ischemic-injured porcine ileum[10]. Lubiprostone activates ClC-2 Cl^- channels resulting in luminal Cl^- secretion and water movement responsible for its laxative properties[11-15]. ClC-2 Cl^- channel activation

by lubiprostone is also the predominant mechanism by which this compound stimulates repair of the tight junctions and mucosal barrier repair in ischemic tissues[10]. The mechanism for this action may relate to co-localization of ClC-2 with tight junction proteins such as occludin[16,17]. Other commercially available laxative agents such as high molecular weight Polyethylene Glycol (PEG 3350) also induce fluid movement into the lumen *via* different mechanisms. Polyethylene laxatives are composed of high molecular weight PEG which triggers an osmotic gradient in the lumen serving to draw ions and water from the paracellular space. In addition to its laxative effects, PEG agents have been shown to confer mucosal protective effects in various gastrointestinal injury animal models including 2, 4, 6-trinitrobenzene sulphonic acid (TNBS)-induced colitis[18] and bacterial translocation and sepsis induced by surgical stress[19].

Given the potential alternative beneficial roles of these two oral laxatives in intestinal injury and repair, the objective of this study was to compare the effects of lubiprostone and PEG 3350 on repair of mucosal barrier function in ischemic-injured intestine.

MATERIALS AND METHODS

Compounds

Lubiprostone was obtained from R-Tech Ueno (Sanda, Japan). PEG 3350 (Miralax, Schering-Plough Health Care Products, Inc. Kenilworth NJ) was obtained from the North Carolina State University, College of Veterinary Medicine pharmacy. ^{3}H-mannitol and ^{14}C-inulin were obtained from Sigma Chemical (St. Louis, MO).

Experimental animal surgeries

All studies were approved by the North Carolina State University Institutional Animal Care and Use Committee. Six to eight-week-old Yorkshire crossbred pigs of either sex were housed individually, and maintained on a commercial pelleted feed. Pigs were fasted for 24 h prior to experimental surgery. General anesthesia was induced with xylazine (1.5 mg/kg, IM), ketamine (11 mg/kg, IM), and 5% isoflurane vaporized in 1000 mL/L O_2 and was maintained with 2% isoflurane delivered *via* an endotracheal tube. Pigs were placed on a heating pad and ventilated with 1000 mL/L O_2 using a volume-limited, time-cycled ventilator (Hallowell, Pittsfield, MA). Lactated Ringers solution was administered iv at a maintenance rate of 15 mL/kg per hour. The ileum was approached *via* a ventral midline incision. Ileal segments were delineated by ligating the intestine at 10-cm intervals, and subjected to ischemia by occluding the local mesenteric blood supply for 45 min.

Using chamber studies

Following the 45-min ischemic period, tissues were harvested from the pig and the mucosa was stripped from the seromuscular layer in oxygenated (950 mL/L O_2/50 mL/L CO_2) Ringer's solution (mmol/L: Na^+, 154; K^+, 6.3; Cl^-, 137; HCO_3^-, 24; pH 7.4) containing 5 μmol/L indomethacin to prevent endogenous prostaglandin production during the stripping procedure. Tissues were then mounted in 1.14 cm^2 aperture Ussing chambers, as described in previous studies. For Ussing chamber experiments, ileal tissues from one pig were mounted on multiple Ussing chambers and subjected to different *in vitro* treatments. Data means are representative of 6 Ussing chamber experiments (n = 6 animals). Tissues were bathed on the serosal and mucosal sides with 10 mL Ringer's solution. The serosal bathing solution contained 10 mmol/L glucose, and was osmotically balanced on the mucosal side with 10 mmol/L mannitol. Bathing solutions were oxygenated (950 mL/L O_2/50 mL/L CO_2) and circulated in water-jacketed reservoirs. The spontaneous potential difference (PD) was measured using Ringer-agar bridges connected to calomel electrodes, and the PD was short-circuited through Ag-AgCl electrodes using a voltage clamp that corrected for fluid resistance. Transepithelial electrical resistance (TER) ($\Omega.cm^2$) was calculated from the spontaneous PD and short-circuit current (I_{sc}). If the spontaneous PD was between -1.0 and 1.0 mV, tissues were current-clamped at ± 100 μA for 5 s and the PD recorded. I_{sc} and PD were recorded at 15-min intervals over a 120-min experiment.

Experimental treatments

After tissues were mounted on Ussing chambers, tissues were allowed to acclimate for 30 min to achieve stable baseline measurements after which experimental treatments were added. Lubiprostone (1 μmol/L) or PEG 3350 (20 mmol/L) were added to the mucosal side of tissues and TER and I_{sc} were measured at 15-min intervals over a 120-min recovery period. The PEG 3350 dose was selected as it is the recommended oral dosage for laxative properties and thus would approximate the luminal concentrations attained *in vivo*.

Mucosal-to-serosal fluxes of radiolabeled paracellular probes

To assess mucosal permeability after experimental treatments, 0.2 μCi/mL ^{3}H-labeled mannitol (180 kDa) and 0.2 μCi/mL, ^{14}C-labeled inulin (5000 kDa) were added to the mucosal side of tissues mounted in Ussing chambers. After a 15-min equilibration period, standards were taken from the mucosal side of each chamber and a 60-min flux period was established by taking 0.5 mL samples from the serosal compartment. The presence of ^{3}H and ^{14}C was established by measuring β-emission in a liquid-scintillation counter (LKB Wallac, Model 1219 Rack Beta, Perkin Elmer Life and Analytical Sciences, Inc., Boston, MA). Unidirectional mannitol fluxes from mucosa-to-serosa were determined using standard equations.

Histological examination

Tissues were taken at 0 and 120 min for routine histological evaluation. Tissues were sectioned (5 μm)

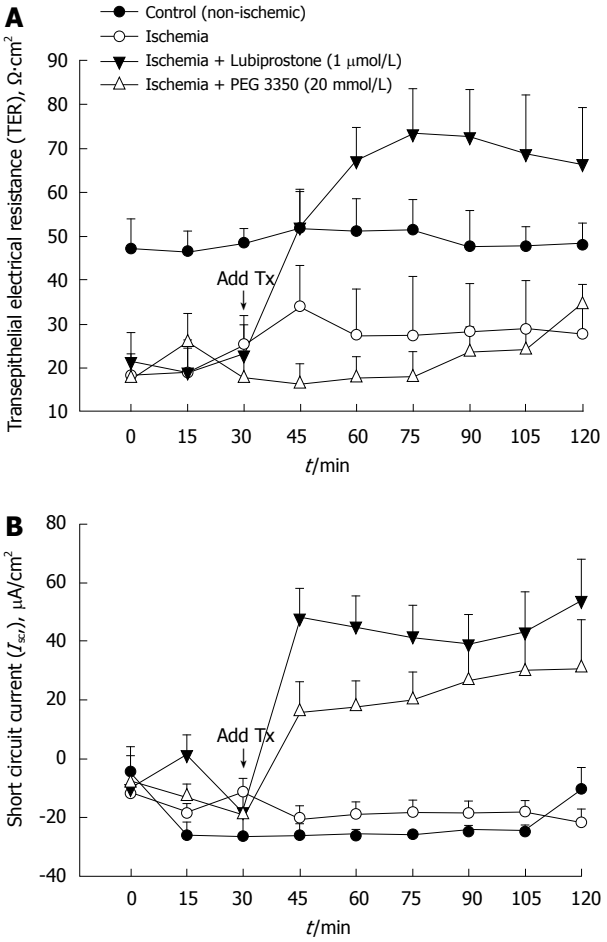

Figure 1 TER (**A**) and short circuit current (I_{sc}) (**B**) in ischemic porcine ileum treated with lubiprostone and PEG 3350.

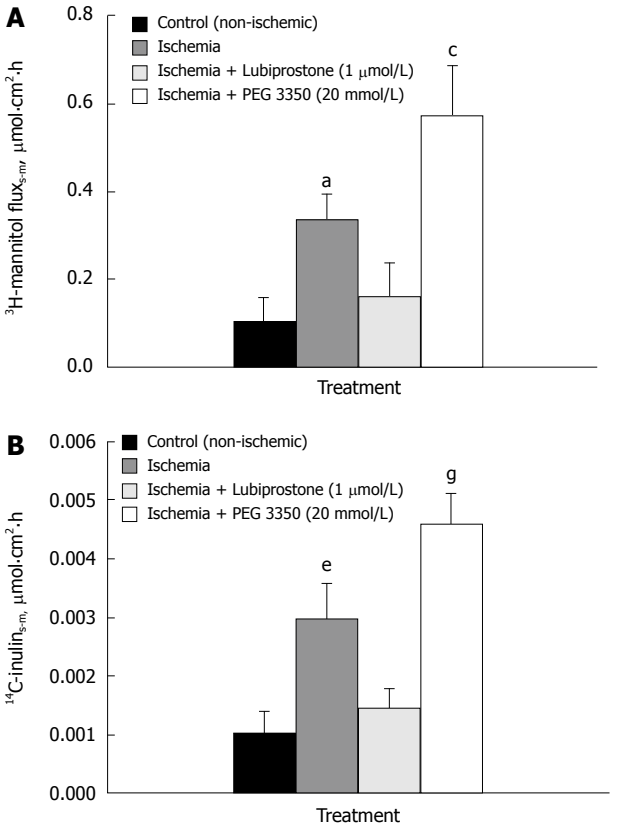

Figure 2 **A**: Mucosal-to-serosal flux of ^{3}H-mannitol in porcine ileum. $^aP < 0.05$ ischemia *vs* control, ischemia/lubiprostone; $^cP < 0.05$ ischemia + PEG3350 *vs* control, ischemia, ischemia + lubiprostone; **B**: Mucosal-to-serosal flux of ^{14}C-inulin in porcine ileum. $^eP < 0.05$ ischemia *vs* control, ischemia/lubiprostone; $^gP < 0.05$ ischemia + PEG3350 *vs* control, ischemia, ischemia/lubiprostone.

and stained with hematoxylin and eosin. For each tissue, 3 sections were evaluated. Four well-oriented villi and crypts were identified in each section. Villus length was obtained using a micrometer in the eye piece of a light microscope.

Statistical analysis

All data were reported as mean ± SE. TER and I_{sc} data were analyzed by using an ANOVA for repeated measures. Radiolabeled flux data was analyzed by using a standard one-way ANOVA (Sigmastat, Jandel Scientific, San Rafael, CA). A Tukey's test was used to determine differences between treatments following ANOVA.

RESULTS

TER and I_{sc} in ischemia-injured porcine ileal mucosa treated with lubiprostone or PEG 3350

Porcine ileum was subjected to 45 min of acute mesenteric ischemia and mounted on Ussing chambers for measurement of TER and I_{sc} over a 120-min recovery period. Ischemic-injured mucosa had significantly lower starting TER values (by approximately 40%) compared with non-ischemic control tissue (Figure 1), indicating significant impairment of intestinal barrier function induced by ischemia. Application of 1 μmol/L lubiprostone to the mucosal side of ischemic-injured mucosa induced rapid elevations in TER that attained non-ischemic control tissues within 15 min of its addition and TER continued to increase 45 min post-treatment. Lubiprostone stimulated rapid elevations in I_{sc} (an index of electrogenic ion transport) that peaked at 15 min post-treatment (peak ΔI_{sc} = 66 μA/cm^2) and remained elevated throughout the remainder of the experiment. Mucosal addition of 20 mmol/L PEG 3350 stimulated a transient increase in TER measured 15 min after treatment; however, TER returned to ischemic control levels within 30 min post-treatment. PEG 3350 stimulated significant elevations in I_{sc} (peak ΔI_{sc} = 35 μA/cm^2) compared with ischemic control tissues. In non-ischemic ileal tissues, lubiprostone and PEG 3350 induced similar elevations in TER (ΔTER = 30% ± 7% and 36% ± 8% in lubiprostone and PEG 3350-treated tissues) (data not shown).

Mucosal-to-serosal flux of paracellular probes

Mucosal-to-serosal flux of both medium molecular weight (^{3}H-mannitol, 180 kDa) and large molecular weight (^{14}C-Inulin, 5000 kDa) paracellular probes in ileal tissues mounted in Ussing chambers were conducted as an alternative measurement of mucosal permeability. In line with TER responses, ischemic tissues had greater (P < 0.01) serosal-to-mucosal fluxes of both ^{3}H-mannitol and ^{14}C-inulin (Figure 2). Lubiprostone treatment significantly

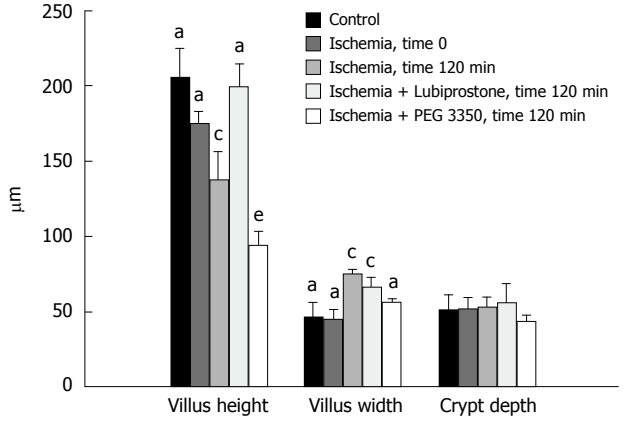

Figure 4 Morphometric evaluations of ischemic intestinal tissues. Villus height: $^{a}P < 0.05$ control, ischemia time 0 min, lubiprostone *vs* ischemia time 120 min, PEG 3350; $^{c}P < 0.05$ ischemia time 120 min *vs* all other groups; $^{e}P < 0.05$ PEG 3350 *vs* all other groups; Villus width: $^{a}P < 0.05$ control, ischemia time 0 min *vs* ischemia time 120 min, lubiprostone; $^{c}P < 0.05$ ischemia time 120 min, lubiprostone *vs* all other groups.

decreased the fluxes of ^{3}H-mannitol and ^{14}C-inulin ($P < 0.05$). Alternatively, ischemic tissues treated with PEG 3350 displayed significantly increased fluxes of permeability markers compared with all other treatments ($P < 0.05$).

Histological evaluation of ischemic-injured tissues

Control (non-ischemic) tissues treated with lubiprostone or PEG 3350 had no identifiable histopathological findings compared with non-treated control tissues (not shown). Ileal tissues subjected to ischemia displayed classic histological ischemic lesions characterized by sloughing of the surface epithelium of the apical villus (Figure 3). The epithelial layer was completely restituted after 60 min of mounting tissues on Ussing chambers (not shown); this effect has been demonstrated in our previous studies[4,5]. At 120 min post-ischemia on Ussing chambers, villus contraction was evident demonstrated by villi that were reduced in height and increased in width compared with non-ischemic control tissues (Figure 4). Laxative agents had a significant effect on intestinal villous length in ischemic-injured tissues in this study. Lubiprostone-treated tissues had greater villous lengths compared with ischemic-injured controls when measured at 120 min post-ischemia. In contrast, PEG 3350-treated ischemic tissues had significantly reduced villous height compared with ischemic-injured control tissues.

DISCUSSION

Results from the present study demonstrate marked differences in the ability of two oral laxatives, lubiprostone and PEG 3350, to stimulate repair of intestinal barrier function in ischemic-injured porcine ileum. Lubiprostone stimulated rapid repair of mucosal barrier function in ischemic ileal mucosa as defined by rapid elevations in TER and reductions in the mucosal-to-serosal flux of ^{3}H-mannitol and ^{14}C-inulin. PEG 3350 failed to induce significant changes in TER and had a detrimental influence on mucosal barrier repair evidenced by enhanced mucosal permeability to ^{3}H-mannitol and ^{14}C-inulin in ischemic-injured tissues treated with PEG 3350.

Oral lubiprostone and PEG 3350 both have laxative properties *via* different mechanisms. Lubiprostone activates ClC-2 Cl^- secretion promoting Na^+ and water movement into the lumen[20,21], whereas PEG 3350 induces luminal osmotic effects drawing electrolytes and water into the lumen. This is the reason that both compounds induced significant increases in short circuit current in the Ussing chambers, an indirect measure of ionic movement across the mucosa. Alternatively, there was no change in short circuit current in untreated tissues. Lubiprostone also stimulated rapid repair of mucosal barrier function in ischemic ileal tissues. Previous studies showed that lubiprostone's influence on intestinal permeability is due to its ability to activate ClC-2 channels[10]. Although exact signaling events triggered by ClC-2 activation that lead to intestinal repair are not well understood, lubiprostone treatment was shown to trigger rapid recruitment of the tight junction protein occludin to the apical intercellular space, an event critical for the re-establishment of mucosal electrical resistance. In the present study, lubiprostone increased baseline TER in non-injured control tissues, suggesting that lubiprostone's effect is not restricted to injured mucosa.

To our knowledge, the influence of PEG 3350 on intestinal mucosal repair has not been directly investigated. However, PEG compounds have been shown to be protective against different forms of intestinal injury. Videla *et al*[18] demonstrated that oral PEG 4000 was protective against TNBS-induced colitis in rats. In a study by Wu *et al*[19], luminal administration of a high molecular weight PEG prevented increases in intestinal permeability induced by *P. aerugenosa* in Caco-2 monolayers and prevented lethal sepsis *in vivo*

induced by *P. aerugenosa* following surgical stress. In the latter study, PEG 4000 treatment resulted in increased mucosal hydrophobicity and reductions in baseline mucosal permeability. The reduction in permeability seen with PEG is likely attributable to its osmotic effects which may draw water from the paracellular space resulting in collapse of the tight junctions. Madara JL demonstrated that mucosal osmotic loads of 600 mosM induced rapid elevations in TER in guinea pig jejunum in Ussing chambers, an effect mediated by decreased cation selectivity of the tight junctions and alterations in the cytoskeleton[22]. In the present study, PEG 3350 induced increases in TER (by 36% ± 8%) in control (non-injured) ileal tissues. However, in the present study PEG 3350 was ineffective in improving TER in ischemic tissues and further increased mucosal permeability in ischemic-injured tissues. This suggests intact barrier function is required for PEG to stimulate increases in TER. In ischemic tissues, it is likely that PEG 3350 would freely traverse the damaged epithelium and equilibrate with the serosal compartment failing to produce an osmotic gradient in tissues.

Villous contraction in response to ischemic injury is a protective mechanism that aids in reducing the surface area of the denuded basement membrane, allowing epithelial cells adjacent to the injury to migrate and cover the epithelial defect and restore epithelial continuity[23-26]. In the present study, lubiprostone-treated ischemic ileal tissues had significantly greater villous lengths compared with other ischemic tissues. It is unclear whether this response was due to lubiprostone' s ability to inhibit villous contraction or stimulate villous lengthening during repair. Lubiprostone could have had a direct action on the principal contractile cells within the villus: myofibroblasts. These cells are arranged in linked chains of cells adjacent to the central lacteal and subjacent to the epithelial basement membrane. More studies, including a detailed time course of lubiprostone's effects on villous architecture during recovery of ischemic injury, are required to determine this and lubiprostone's overall relevance to intestinal barrier repair. In contrast to lubiprostone, PEG 3350-treated ileal tissues had significantly shorter villi compared with ischemic controls measured 120 min post-ischemic injury. This may represent ongoing injury in these tissues supported by increased paracellular permeability induced by PEG 3350.

Overall, this study demonstrates that lubiprostone stimulates recovery of mucosal barrier function in ischemic intestinal tissues, whereas the PEG laxative enhanced intestinal permeability. These results suggest that, unlike osmotic laxatives, lubiprostone stimulates repair of the injured intestinal barrier.

COMMENTS

Background

A number of important intestinal diseases, including ischemia/reperfusion injury, are characterized by damage to the epithelium lining the gut. Mechanisms are in place to rapidly repair epithelial defects, including epithelial migration (restitution). More recently, studies have shown the importance of the interepithelial tight junctions in recovery of the epithelial barrier. Studies have shown that prostaglandins and prostones increase the rate of epithelial recovery *via* re-assembly of tight junctions.

Research frontiers

The prostone lubiprostone, a new medication on the market indicated for treatment of chronic constipation and irritable bowel syndrome has its effect on chloride channels (ClC-2) within tight junctions. These channels are involved in secretion of chloride in the intestine, but to a far lesser extent than the chloride channel that is genetically disrupted in patients with cystic fibrosis (CFTR). Recent studies have shown that ClC-2, when activated by prostaglandins or prostones such as lubiprostone, also play an important role in re-assembly of tight junctions, resulting in increases in the speed of epithelial repair.

Innovations and breakthroughs

Stimulation of one of the minor chloride channels, ClC-2, is an innovative way to induce low level secretion into the gut, thereby serving as a laxative. This is in contrast to traditional laxatives such as Polyethylene Glycol 3350 (PEG), which result in increased fluid in the intestinal lumen because of its osmotic properties. Other effects of ClC-2 activation by lubiprostone have recently been discovered, particularly the ability to increase mucosal repair. A comparison of lubiprostone and PEG showed that only lubiprostone facilitated the repair of the mucosa. This increased repair could not be seen at the histological level. This is consistent with prior studies showing that enhanced repair is noted at the level of tight junctions.

Applications

When treating constipation, the choice of medication includes laxatives such as PEG and the ClC-2 activator lubiprostone. The present study suggests that use of lubiprostone will also hasten the recovery of injured gut mucosa in patients with more severe intestinal disease. Further basic science research followed by clinical trials will be needed to determine the validity of these findings.

Terminology

The term ClC-2 is used to describe a chloride channel in the gut epithelium that is localized to interepithelial tight junctions. The term prostone refers to a new group of compounds which are distinct from prostaglandins and specifically activate ClC-2.

Peer review

The present study was performed using porcine tissues; it demonstrates that lubiprostone stimulates recovery of barrier function in ischemic intestinal tissues whereas the PEG laxative had deleterious effects on mucosal repair. This is an interesting study and well written manuscript.

Abstract

AIM: To analyze, retrospectively in a population-based study, the management and survival of patients with recurrent rectal cancer initially treated with a macroscopically radical resection obtained with total mesorectal excision (TME).

METHODS: All rectal carcinomas diagnosed during 1998 to 2000 and initially treated with a macroscopically radical resection (632 patients) were selected from the Amsterdam Cancer Registry. For patients with recurrent disease, information on treatment of the recurrence was collected from the medical records.

RESULTS: Local recurrence with or without clinically apparent distant dissemination occurred in 62 patients (10%). Thirty-two patients had an isolated local recurrence. Ten of these 32 patients (31%) underwent radical re-resection and experienced the highest survival (three quarters survived for at least 3 years). Eight patients (25%) underwent non-radical surgery (median survival 24 mo), seven patients (22%) were treated with radio- and/or chemotherapy without surgery (median survival 15 mo) and seven patients (22%) only received best supportive care (median survival 5 mo). Distant dissemination occurred in 124 patients (20%) of whom 30 patients also had a local recurrence. The majority (54%) of these patients were treated with radio- and/or chemotherapy without surgery (median survival 15 mo). Twenty-seven percent of these patients only received best supportive care (median survival 6 mo), while 16% underwent surgery for their recurrence. Survival was best in the latter group (median survival 32 mo).

CONCLUSION: Although treatment options and survival are limited in case of recurrent rectal cancer after radical local resection obtained with TME, patients can benefit from additional treatment, especially if a radical resection is feasible.

Key words: Rectal cancer; Total mesorectal excision; Local recurrence; Relative survival

INTRODUCTION

Colorectal cancer is the second most common cancer in the Western world and approximately one third of these tumours are located in the rectum or rectosigmoid[1]. Annually, over 3000 patients are registered with a newly diagnosed rectal or rectosigmoid carcinoma in the Netherlands[2,3]. In these patients, locally recurrent disease is a major concern and is often accompanied with intractable pain and severely disabling complications which are difficult to treat[4-6]. It has a tremendous impact on quality of life[7] and frequently induces an awful last period of a patient's life. Therefore, the focus in rectal cancer research has been on the prevention of locally recurrent disease, which resulted in the introduction of preoperative radiotherapy and total mesorectal excision (TME)[8-12].

There are many reports on the treatment of

recurrent rectal cancer[4,6,13-16]. However, these reports present mainly results from randomised clinical trials or specialised institutes, which are known to be biased[17]. There are only a few population-based reports on the treatment of locally recurrent rectal cancer disease[13,18], although they are probably the best reflection of daily practice.

In 1996, TME was introduced in Greater Amsterdam, the region of the Comprehensive Cancer Centre Amsterdam (CCCA). Its introduction was facilitated by the CCCA. Surgeons were supervised by teacher-surgeons in order to qualify as TME-surgeon and a documentation project was started to investigate the influence of TME-surgery on the incidence of local recurrences and survival[19]. From 1998 on, all patients in Greater Amsterdam are treated with TME in case of rectal resection.

The aim of the present study was to analyze, retrospectively in a population-based setting, the management and survival of patients with recurrent rectal cancer, initially treated with macroscopically radical local resection obtained with TME.

MATERIALS AND METHODS

Cancer registry data

All primary rectal carcinomas (rectosigmoid excluded) diagnosed in patients with residence in Greater Amsterdam, the region of the CCCA, between January 1, 1998 and December 31, 2000, and who underwent a macroscopically radical resection obtained with TME in the absence of distant dissemination, were selected from the Amsterdam Cancer Registry of the CCCA. The Amsterdam Cancer Registry is a regional, population-based cancer registry with complete regional coverage. Non-epithelial cancers, carcinoids and cases with preceding invasive cancers were excluded. The population of the region amounted to 2.8 million inhabitants on December 31, 2000, approximately 17% of the total population of the Netherlands.

The information for the cancer registry is routinely extracted from detailed hospital and outpatient clinic records by registration clerks. Apart from demographic data, data are collected on morphological classification, stage of the tumour and primary treatment of the patients. The TNM system for classification of malignant tumours is prospectively registered to classify all rectal carcinomas. Stage grouping in this study was performed according to the 6th edition of the TNM-classification[20], based on the available information after surgery (pTNM).

Of the selected cases, a supplementary data set was extracted from the medical records. This data set included the occurrence and the date of local recurrence or distant dissemination. Local recurrence was defined as cancer recurrence within the lower pelvis. Additional treatment of recurrence, the presence of microscopic or macroscopic residual disease after salvage surgery for recurrent disease, the date of salvage surgery and the cause of death were also collected. Cases were generally followed for five, but at least three years after the date of initial surgery.

Table 1 Initially applied radiotherapy in surgically treated, primary rectal carcinoma patients according to pTNM-stage in Greater Amsterdam, the Netherlands, 1998 to 2000

Stage of disease	Number of cases (% of total)	Radiotherapy, number of patients (%)

Unknown	6 (1)	2 (33)	-	4 (67)
Total	632	238 (38)	99 (16)	295 (47)

RT: Radiotherapy.

Vital status

The vital status was updated by active follow-up in the hospitals, by linking files with deceased persons to the cancer registry and by linkage to the electronic death registry of the Central Office for Genealogy in September, 2003 and February, 2005, as described earlier[21]. Completeness of follow-up of the vital status is estimated to be over 99.5%.

Statistical analysis

$P < 0.05$ was considered statistically significant. All statistical analyses were performed using a two-sided 5% level of significance.

Survival probabilities were estimated using the Kaplan-Meier method[22]. Multivariate analyses using the Cox proportional-hazard method were performed to calculate the hazard ratio (HR) for death after recurrent disease[23]. Cox regression and Kaplan-Meier survival curves were calculated with STATA (Stata Corporation, College Station, TX, USA).

RESULTS

Initial treatment and incidence of local recurrence

A total of 632 patients diagnosed with primary rectal carcinoma in the absence of clinically manifest distant dissemination between 1998 and 2000 underwent a macroscopically radical local resection obtained with TME. Characteristics of the initial treatment of the primary tumour in these patients are given in Table 1. Local recurrence within five years after diagnosis occurred in 62 patients (10%), including 30 cases with distant dissemination (6%). Of these 30 patients, 24 patients had synchronous local and distant recurrence, while 6 patients developed distant dissemination after the local recurrence.

Treatment of local recurrence

There were 32 out of 62 patients (52%) without signs

Table 2 Secondary treatment of local recurrence (in the absence of distant dissemination) according to treatment with radiotherapy and stage at initial diagnosis (after a macroscopically radical resection obtained with TME)

Non-radical surgery	10	0.5 (0.2-1.3)

HR > 1: Worse prognosis; HR < 1: Better prognosis.

of distant dissemination at the time of diagnosis of recurrent disease. Median survival after recurrence in the absence of distant dissemination was 25 mo. Ten of these 32 patients underwent a microscopically radical resection of their recurrence (Table 2). As is depicted in Figure 1, radical surgery resulted in a significantly better survival than non-radical surgery, radio- and/or chemotherapy without surgery or best supportive care (log-rank test radical surgery *vs* other treatments: $P < 0.001$). About three quarters of the patients who underwent a radical resection survived for at least three years. Median survival after non-radical surgery (8 patients) was 24 mo, 7 mo after radio- and/or chemotherapy without surgery (7 patients) and was 5 mo in case of best supportive care only (7 patients).

In 30 patients (48%), distant dissemination was present at the time of diagnosis of local recurrent disease. Median survival after local recurrence in the presence of distant dissemination was 10 mo. None of these patients underwent curative surgery, two patients underwent non-radical surgical resection, 14 patients were treated with radio- and/or chemotherapy without surgery (median survival 14 mo) and 14 patients received best supportive care only (median survival 9 mo).

Prognostic factors for survival after recurrence

Several factors were analysed to identify prognostic factors for improved survival after local recurrence. The results of the multivariate analysis are shown in Table 3. Surgery for recurrent disease (radical and non-radical) was a prognostic factor for improved survival, while radiotherapy applied during the initial treatment did not influence survival after local recurrence (Figure 2).

Distant dissemination

Distant dissemination within five years after diagnosis occurred in 124 patients (20%). The majority of patients (54%) with distant dissemination were treated with radio- and/or chemotherapy (Table 4). The median survival after distant dissemination was 15 mo.

Twenty patients (16%) underwent surgery for their recurrence, including liver resections in eight patients, lung resections in five patients, and other surgical procedures in seven patients. Median survival after surgery was 32 mo, while median survival after radiotherapy and/or chemotherapy without surgery was 15 mo and 6 mo if best supportive care was applied (Figure 3). Patients with distant dissemination who were treated surgically experienced the highest survival (log-rank test surgery *vs* other treatments: $P < 0.001$).

DISCUSSION

This is the first population-based study concerning

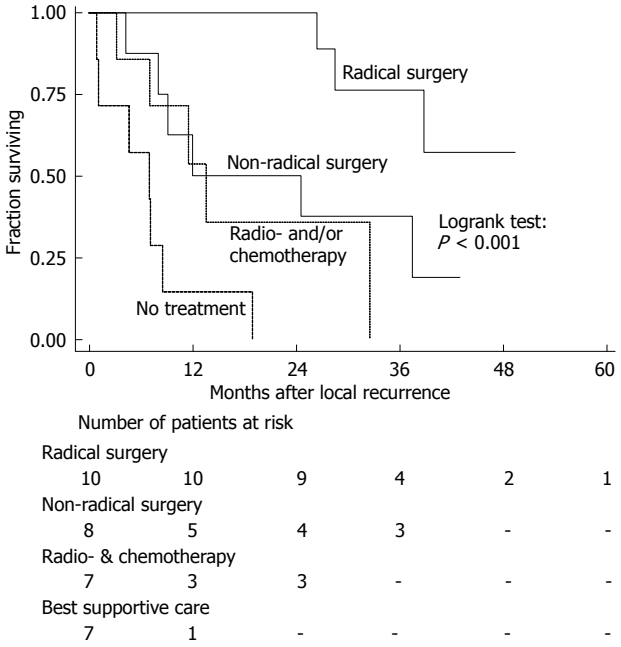

Figure 1 Crude survival after isolated local recurrence in rectal cancer patients initially treated with a macroscopically radical local resection obtained with TME in Greater Amsterdam according to treatment for recurrence. Radical surgery is defined as surgery without macroscopically or microscopically residual disease. Non-radical surgery is defined as surgery with macroscopically or microscopically residual disease.

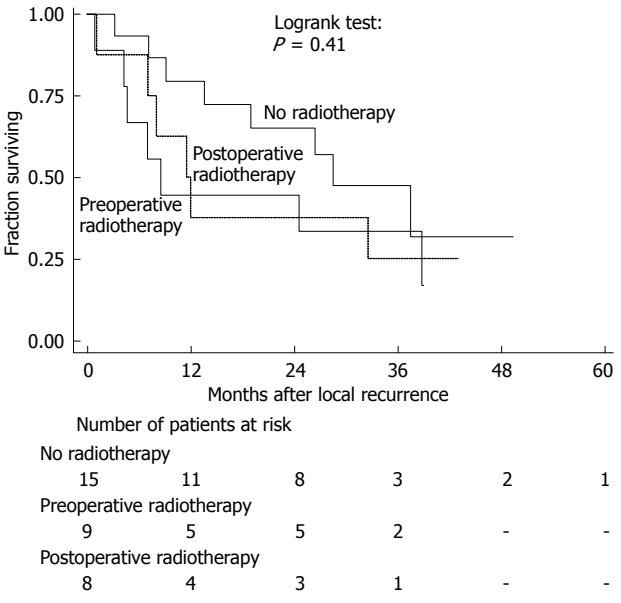

Figure 2 Crude survival after isolated local recurrence in rectal cancer patients initially treated with a macroscopically radical local resection obtained with TME in Greater Amsterdam according to radiotherapeutic treatment of the primary tumour.

recurrent rectal cancer treatment after the introduction of TME. All patients in this study were initially diagnosed between 1998 and 2000 in Greater Amsterdam and treated by macroscopically radical local resection obtained with TME. A local recurrence occurred in 62 of the 632 patients (10%), while distant dissemination was found in 124 patients (20%).

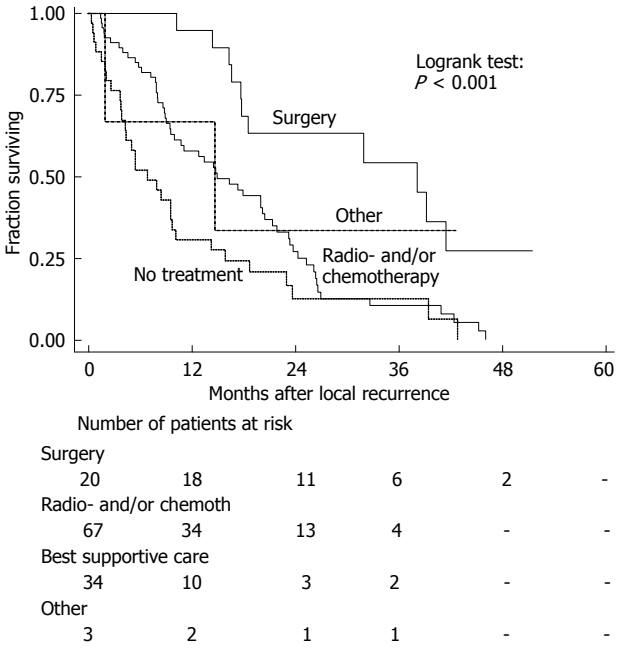

Figure 3 Crude survival after distant dissemination in rectal cancer patients initially treated with a macroscopically radical local resection obtained with TME in Greater Amsterdam according to treatment for distant dissemination.

Treatment of patients with isolated recurrent disease

Of the 32 patients with an isolated local recurrence, 31% were treated by a radical resection. These patients experienced a significantly better survival compared to patients who underwent a non-radical resection for their recurrence. As has been shown previously, radical resection of locally recurrent disease can achieve long-term survival[4,13-15,24] and should, therefore, be aimed at, even if extended resection (*e.g.* abdominosacral resection or exenteration)[16,25,26] or flap-reconstruction[27] is required.

Survival in patients treated with non-radical surgery and patients treated with radiotherapy and/or chemotherapy without surgery was comparable, but was significantly worse in patients not treated with surgery, radiotherapy or chemotherapy. Although no information concerning the extent of recurrent disease was available in this study, treatment has probably been more aggressive in case of limited disease and, therefore, selection bias may have played an important role in the outcome of the various treatment modalities.

Treatment of patients with distant dissemination

The median survival after distant dissemination was 15 mo for patients diagnosed between 1998 to 2000. In a previous study, we have described that patients diagnosed in 1988 between 1991 in Greater Amsterdam only survived 9 mo after distant dissemination (log-rank test: $P = 0.004$)[19]. The majority of patients diagnosed between 1998-2000 (54%) with distant dissemination were treated with radiotherapy and/or chemotherapy without surgery, while 16% were treated with surgical resection and 27% received only best supportive care. Survival was significantly better in the group of patients

treated with surgery compared to other groups. This is probably due to the limited spread of disease in these patients (selection bias). As no treatment data were available for the patients diagnosed between 1988 to 1991 in Greater Amsterdam, it is unclear which treatment modality has contributed to the increase in the median survival.

CONCLUSION

In this population-based study, treatment options and survival were limited in patients with recurrent rectal cancer after macroscopically radical local resection obtained with TME. Approximately one third of the patients only received best supportive care with a subsequent poor survival. On the other hand, in one third of the patients with an isolated local recurrence, radical resection was feasible with a favourable survival. We conclude that a locally recurrent rectal cancer without distant dissemination does not automatically lead to a hopeless situation[28]. However, survival after local recurrence in combination with distant dissemination remains extremely poor.

ACKNOWLEDGMENTS

The surgeons in the 20 participating hospitals (Academic Medical Centre, Free University Medical Centre, Sint Lucas Andreas Hospital, Netherlands Cancer Institute, BovenIJ Hospital, Onze Lieve Vrouwe Hospital, Slotervaart Hospital, Waterland Hospital, Amstelland Hospital, Zaans Medical Centre, Flevo Hospital, IJsselmeer Hospitals, Gooi-Noord Hospital, Hilversum Hospital, Kennemer Hospital, Red Cross Hospital, Spaarne Hospital, Gemini Hospital, Westfries Hospital, Medical Centre Alkmaar) are greatly acknowledged.

COMMENTS

Background

Colorectal cancer is a common cancer in the Western world and rectal cancer has been subject to significant treatment changes over the last decade. Despite this change, recurrent rectal cancer treatment remains a frustrating and ongoing process.

Research frontiers

In the recent decade, the main changes in rectal cancer treatment have been the application of preoperative radiotherapy and the introduction of total mesorectal excision (TME) which led to a significant decrease in local recurrence percentages. In the current article, the influence the introduction of TME on recurrent rectal cancer treatment is evaluated in a population based cohort.

Applications

The current results show that recurrent rectal cancer treatment is in some cases worthwhile, especially if a radical resection is feasible. However, avoiding a local recurrence remains an important aspect in future rectal cancer treatment.

Terminology

TME is a surgical technique initiated by B. Heald during which the entire mesorectum is excised using the so-called "holy" plane. This provides the opportunity to remove the entire rectum with possibly infiltrated lymph nodes.

Peer review

This is an interesting study which was well organized. It demonstrated that although treatment options and survival are limited in case of recurrent rectal cancer after radical local resection obtained with TME, patients can benefit from additional treatment, especially if a radical resection is feasible.

Abstract

AIM: To evaluate and present our experience with laparoscopic Roux en Y gastric bypass (RYGB) in a selected patient population.

METHODS: A cohort of 130 patients with a body mass index (BMI) between 35 and 50 kg/m^2 were evaluated in relation to postoperative morbidity, weight loss and resolution of co-morbidities for a period of 4 years following laparoscopic RYGB.

RESULTS: Early morbidity was 10.0%, including 1 patient with peritonitis who was admitted to Intensive Care Unit (ICU) and 1 conversion to open RYGB early in the series. There was no early or late mortality. Maximum weight loss was achieved at 12 mo postoperatively, with mean BMI 30 kg/m^2, mean percentage of excess weight loss (EWL%) 66.4% and mean percentage of initial weight loss (IWL%) 34.3% throughout the follow-up period. The majority of preexisting comorbidities were resolved after weight loss and no major metabolic disturbances or nutritional deficiencies were observed.

CONCLUSION: Laparoscopic RYGB appears to be a safe and effective procedure for patients with BMI 35-50 kg/m^2 with results that are comparable to previously published data mostly from the USA but from Europe as well.

INTRODUCTION

Obesity has reached epidemic proportions in society today[1] and it is associated with high rates of morbidity and mortality due to the presence of severe comorbidities, many of which show complete resolution after weight loss[2]. According to published data, surgery is the only reliable way of achieving both adequate and long-term weight loss in the morbidly obese population[3]. Roux en Y gastric bypass (RYGB), which was first described by Mason and Ito at the University of Iowa in 1967, is now considered the gold standard of bariatric procedures[4]. In 1994, Wittgrove *et al*[5] first introduced a totally laparoscopic approach to this procedure, which is now a routine practice for the majority of bariatric centers in United States and this trend seems to be spreading throughout Europe as well. However, there are few published studies to date regarding the implementation of this procedure in Europe[6].

The aim of this study, therefore, is to report the experience of a single centre in Greece with the laparoscopic RYGB.

MATERIALS AND METHODS

Since 1994, 1095 surgical procedures for clinically severe obesity have been performed at our institution. The type of procedure performed is based on specific selection criteria according to an algorithm developed

Hypertriglyceridemia	36 (27.9)

COPD: Chronic obstructive pulmonary disease.

by our center, whereby patients with body mass index (BMI) over 50 kg/m^2 undergo biliopancreatic diversion with RYGB (BPD-RYGB), as modified in our center[7], while patients with BMI < 50 kg/m^2 undergo RYGB with long limb (RYGB-LL) or sleeve gastrectomy (SG) depending on comorbidities and eating habits. Sweet consumers and patients with diabetes mellitus undergo RYGB-LL whereas volume consumers may undergo SG. Since October 2003 in patients with BMI < 50 kg/m^2 all procedures have been performed laparoscopically, and the present study refers to 130 of these patients who underwent RYGB-LL as their primary procedure.

All patients participated in a multistage educational and informational program to accomplish full disclosure preoperatively and to engage them in compliance with bariatric management postoperatively.

A multidisciplinary team including the surgeon, an endocrinologist, a cardiologist, a pneumonologist, a psychiatrist and a nutritionist-dietitian evaluate all patients preoperatively and postoperatively to assess and optimize their physical condition. Table 1 shows the patients' preoperative characteristics and Table 2 shows the patients' preoperative comorbidities.

At the operating room, during induction in anesthesia, a single dose of antibiotics (cephalosporin second generation 1.5 g and metronidazole 500 mg) was given and continued for 48 h postoperatively. Thromboembolic prophylaxis using low molecular weight heparin at a dose adapted to patients' weight was started the day before operation and continued till the discharge. Complementary measures consisting of air compression boots and specially designed mattress were used.

Surgical technique

The main characteristics of the RYGB-LL are a gastric pouch of 15 ± 5 mL, a biliopancreatic limb of 50 cm, an alimentary limb of 150 cm and the remainder of small intestine as the common limb. We prefer to pass the alimentary limb antecolic and antegastric and to create a gastrojejunostomy using a 25 mm circular stapler performing a circular end to end anastomosis (CEEA) by passing the anvil transorally. The gastrojejunostomy is reinforced with interrupted non-absorbable sutures. The proximal end of Roux limb is closed with application of linear stapler. A side to side jejunojejunostomy is performed using a linear stapler and the mesenteric defects are closed with non-absorbable running sutures.

Cholecystectomy is always added to the main procedure. Furthermore, because fatty liver and non-alcoholic steatohepatitis are common, liver biopsy is routinely performed to assess preoperatively liver histopathology and will be used as a baseline for comparison if a problem in hepatic function arises in the future.

Postoperative management

Patients were mobilized in the evening of surgery. Pain management consisted of parecoxib 40 mg intravenously every 12 h and meperidine 50 mg intramuscularly as needed for 3 d.

On the fourth postoperative day, after an uneventful upper gastrointestinal evaluation, a clear liquid diet was begun with gradual progression to full liquids and blenderized food. High protein supplements were administered to all patients until 4 wk postoperatively when per os feeding was advanced by the nutritionist.

All patients received a daily multivitamin and mineral supplement and 1000 mg of calcium. An iron supplement was also prescribed for premenopausal women at a dose of 80 mg/d. After the 6th postoperative month, vitamin B_{12} supplementation was given intramuscularly at a dose of 1000-3000 μg depending upon the measured values.

Follow-up visits were scheduled at 1, 3, 6 and 12 mo postoperatively and annually thereafter. Each follow-up visit included complete medical and nutritional evaluation, with laboratory workup and evaluation by other specialists as needed.

Statistical analysis

The data presented are expressed as mean ± SD, unless otherwise stated. During the study comparisons of the observed values at various time periods were performed using ANOVA (one way analysis of variance). If there were any statistic significant differences, the Tukey post-test was used to determine the time points that contribute to this significance.

RESULTS

From October 2003 to June 2008, 130 patients with BMI 35-50 kg/m^2 underwent laparoscopic RYGB-LL as their primary bariatric operation. In addition,

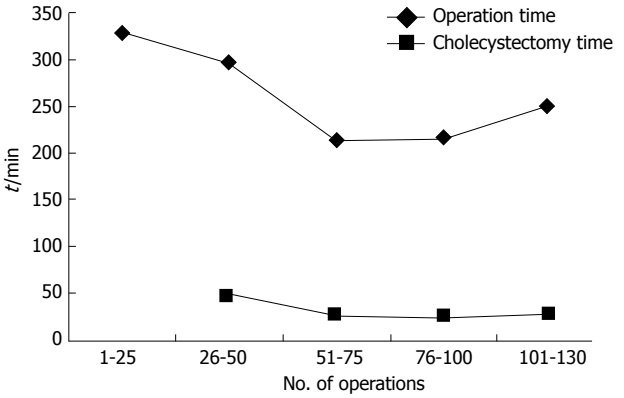

Figure 1 Operation time for the first 130 patients. Values in graph lines are mean values.

cholecystectomy was performed in all but nine patients who had previously undergone this procedure elsewhere and other abdominal procedures were performed in five patients. The mean total operative time was 260 ± 87.4 min (range 120-270) and the mean operative time for cholecystectomy was 18 ± 17.2 min (range 15-70). The operative time decreased significantly over time, especially after the first 50 cases ($P < 0.05$) (Figure 1). Conversion to open RYGB was necessary in one patient (0.8%) early in the series.

The mean length of hospital stay was 9 d (range 8-29) primarily due to standard hospital protocol in Greece. The mean follow-up time was 24.3 mo (range 1-48). The number of patients who successfully completed follow-up was 110 of 112 patients (98.2%) at 12 mo, 85 of 90 patients (94.4%) at 24 mo, 51 of 55 patients (92.7%) at 36 mo and 16 of 18 patients (88.9%) at 48 mo. Four patients were lost to follow-up. Thus far there has been no need for revision surgery.

Mortality

There was no early or late mortality.

Complications

Intraoperative period: One conversion to open RYGB was necessary early in the series, due to inability to construct the jejuno-jejuno anastomosis.

Early postoperative period (< 30 d): In the early postoperative period, as shown in Table 3, there were three gastrointestinal haemorrhages, one of which was intraluminal, probably from the jejunojejunal anastomosis, presenting as small obstruction and requiring reoperation, while the others were intrabdominal and treated conservatively. In addition, there were two enterocutaneous fistulas, caused by attachment of small intestine loop to mesh after simultaneous repair of incisional hernias, one episode of ileus due to volvulus and one case of peritonitis, all of which required surgical intervention. The last patient required admission to the Intensive Care Unit (ICU) after reoperation for peritonitis caused by leakage of the alimentary limb stump on the 6th postoperative day. The latter was caused by herniation of a small bowel limb to port site. The patient was finally discharged 168 d after surgery following a complicated and difficult postoperative course, including acute compartment syndrome requiring reoperation and development of acute renal insufficiency requiring dialysis. There was also one episode of portal vein thrombosis treated with anticoagulant medication, one wound infection of port site treated with antibiotics, one lung atelectasis, two orthopaedic injuries due to inappropriate patient positioning and securing intraoperatively. Finally, there was one anastomotic leakage from gastrojejunal anastomosis, which presented on the 6th postoperative day with severe sepsis without hemodynamic instability and was treated successfully conservatively with drainage under computer tomography (CT) guidance and total parenteral nutrition. The total early postoperative morbidity was 10.0% (13 patients).

Table 3 Incidence of postoperative complications and management

Time	Complications	Treatment	% of patients
Early < 30 d			
	3 gastrointestinal hemorrhages	Conservative (2) Operation (1)	2.4
	2 enterocutaneous fistulas	Operation	1.6
	1 peritonitis	Operation, ICU admission	0.8
	1 ileus due to volvulus	Operation	0.8
	1 portal vein thrombosis	Anticoagulants	0.8
	1 wound infection of port site	Antibiotics	0.8
	2 orthopedic injuries	Immobilization	1.6
	1 atelectasis	Antibiotics peros	0.8
	No incisional hernia		0.0
	1 anastomotic leak	Conservative	0.8
Intermediate 30-90 d			
	1 incisional hernia	No operation	0.8
Late > 90 d			
	5 incisional hernias	Operation (4)	3.9
	4 episodes of ileus	Operation (1) Conservative (3)	3.1
	1 suicide attempt		0.8
	1 gastrojejunal anastomosis stenosis	Endoscopic dilatation	0.8

Intermediate postoperative period (30-90 d): During the intermediate postoperative period there was one incisional hernia with no other major complications.

Late postoperative period (> 90 d): During the late postoperative period there were 5 incisional hernias, 4 of which were treated surgically, 4 episodes of small bowel obstruction, one of which was due to adhesions requiring surgical intervention, one episode of gastrojejunal anastomosal stenosis, which was treated with endoscopic dilation and one suicide attempt 5 mo after surgery due to undetected severe pre-existing depression.

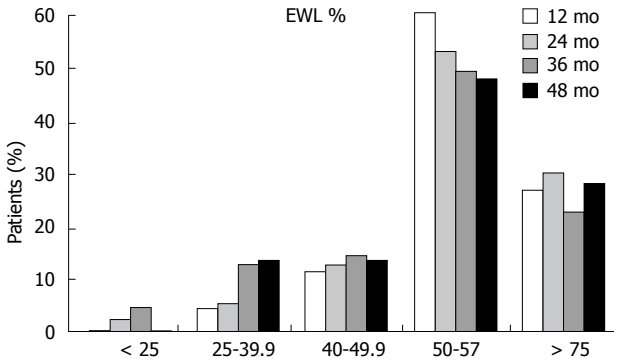

Figure 2 Percentage of EWL during follow-up.

Weight loss

The results of weight loss expressed as actual weight, BMI, percentage of excess weight loss (EWL%) and percentage of initial weight loss (IWL%) at 12, 24, 36 and 48 mo, respectively, are shown in Table 4. Maximum weight loss was observed at 12 mo, with mean BMI 30 kg/m^2, mean EWL 66.4% and mean IWL 34.3% which remained stable throughout the follow-up period. Ninety-two (83.6%) of 110 patients achieved an EWL of at least 50% at 12 mo which was maintained throughout the follow-up period (Figure 2). An EWL of 50% is considered successful.

Comorbidities

Comorbidities were present in 117 (90.7%) patients preoperatively with an average of 3 ± 2.6 (range 0-10) per patient. The majority of these showed significant improvement during the 48 mo follow-up. Table 5 presents the postoperative results of relevant comorbidities.

Hypertension was present in 21 patients (16.3%) preoperatively, 16 of whom (76.2%) were on medication. After the 2nd postoperative year, only one patient (4.8%) remained on antihypertensive medication.

Preoperatively 24 patients had diabetes mellitus (blood glucose > 125 mg/dL), 14 of whom were on oral hypoglycemic agents while 2 were being treated with insulin. An additional 8 patients had impaired oral glucose tolerance test (OGTT) preoperatively. Postoperatively, diabetes mellitus was completely resolved in 22 patients (91.7%) by the 12 mo follow-up. Only one patient remained on insulin therapy throughout the study period.

Hypercholesterolemia (blood cholesterol > 200 mg/dL) was present in 64 patients preoperatively. Mean cholesterol levels were 230 ± 28.8 mg/dL preoperatively and had decreased to 179 ± 42 mg/dL by the 12 mo follow-up and remained at these levels for the rest of the follow-up period. Among the 52 of 64 patients who completed the 12 mo follow-up, 14 (26.9%) still had elevated blood cholesterol levels > 200 mg/dL. By the 36th month following surgery, only 6 of the 24 patients (25.0%) still had cholesterol levels > 200 mg/dL.

There were 34 patients with hypertriglyceridemia (TGs > 160 mg/dL) preoperatively, with mean levels 225 ± 64.8 mg/dL. Postoperatively, mean TGs levels dropped to 96 ± 33.2 mg/dL and 96 ± 37.7 mg/dL at 12 and 24 mo respectively and none of the patients had hypertriglyceridemia.

Table 4 Weight loss during follow-up

	0 mo	12 mo	24 mo	36 mo	48 mo
Patients	130	110	85	51	16
Weight (kg)	125	81.6	81.4	84.1	79.2
BMI	46	30	31	32	31
IWL %		34.2	34.3	32.2	31.4
EWL %		66.2	65.9	61.5	61.1
Pts > 50% EWL		92	68	35	12

Values for weight, BMI, EWL, IWL are mean values.

Table 5 Postoperative resolution of comorbidities

Comorbidities	No. of patients	Follow-up period (mo)	Resolved (%)	Improved (%)	Without change (%)
Hypertension	21	24	84		16
COPD	22	12		100	
Sleep apnea	13	12		100	
Osteoarthritis	21	12		100	
Depression	11	24		89	11
Diabetes Mellitus	24	12	91.7		8.3
OGTT	8	12	100		
Hypercholesterolemia	64	36	94.4		5.6
Hypertriglyceridemia	36	12	100		

Metabolic complications

Anaemia: Anaemia, as defined by haemoglobin level < 13.5 mg/dL in men and < 12.5 mg/dL in women, was observed at mean rate of 20.1%. More specifically, a low haemoglobin level was seen in 14.8%, 20.2%, 22% and 26.7% of patients at 12, 24, 36 and 48 mo, respectively. Regarding other parameters associated with anaemia including iron (< 35 μg/dL), vitamin B12 (< 200 pg/mL) and ferritin (< 9 ng/mL), the mean rates of postoperative deficiency were 6.1%, 18.7% and 10.0%, respectively. No deficiency of folic acid was observed following surgery and none of the above deficiencies were clinically severe. All patients were treated successfully with oral supplementation.

Hypoalbuminemia: Hypoalbuminemia did not occur at any time during the postoperative follow-up. The mean levels of albumin were > 4 g/dL at all follow-up evaluation and no patient presented with albumin levels below the minimum normal level.

DISCUSSION

In this study, 130 patients underwent laparoscopic RYGB-LL with an acceptable total early complication rate (minor and major) 10.0%, a low conversion rate (0.8%) and no mortality.

The mean hospital stay was quite high (9 d) but this is due to the existing health care system in Greece, which

lacks the services of early postoperative care for patients from distant places.

Maximum weight loss in our series was achieved at 12 mo, with a mean EWL of 66.4%, which was maintained through out the study period. However, 14% of patients did not achieve adequate weight loss (EWL < 50%) and the reason for these failures has not been clarified yet causing problems for the surgeons and the patients.

In addition to adequate weight loss, improvement of pre-existing comorbidities is one of the most important criteria for evaluating success of a bariatric procedure. In our study, as in others[1,2,6,8-10], that was achieved, as shown in Table 2. Diabetes mellitus was completely resolved in the majority of the patients, finding supported by other reports, which also proposed mechanisms that this can be achieved[11,12]. Hypercholesterolemia was resolved in the majority of patients and hypertriglyceridemia in all patients, results similar to those described for malabsorptive procedures[13,14]. Regarding metabolic complications the most significant were vitamin B_{12} and iron deficiency. However there was no clinical impact and all the patients were treated conservatively with intramuscular injections of vitamin B_{12} and oral iron supplements as necessary.

The surgical complications rate in our series was comparable to that described by others[6,15-20] and included primarily gastrointestinal haemorrhages, enterocutaneous fistulas and obstructive ileus. We had no internal hernias, which was probably due to the antecolic position of the Roux limb[21]. Furthermore, the low incidence of anastomotic gastrointestinal stricture (0.8%) may be attributed to the use of 25 mm circular stapler. The prevalence of wound infection and anastomotic leakage was similar to that reported by others[15,17,18].

The laparoscopic approach to bariatric surgery is technically challenging, but with experience it can be mastered. The learning curve is steep and long operating times are required[22]. As shown in Figure 2, our operating time decreased significantly as our experience accumulated, which was supported by Wittgrove *et al*[5]. Since practice makes perfection, we could also manage to improve our port-site closure technique and after the first 5 unfortunate incisional hernias there was no new case recorded. Furthermore, our 2 cases of enterocutaneous fistulas were attributed to simultaneous mesh placement and eventually this approach was abandoned.

Our results suggest that laparoscopic RYGB-LL as performed at our institution provides adequate weight loss and resolution or improvement of comorbidities up to 4 years. Recently, it has been increasingly recognised that RYGB may have an effect on appetite and eating behaviour, which, in turn, may improve long-term results. These effects may be related to changes in the circulating levels of the gastrointestinal hormones known to influence appetite including PYY[7,23-28], and this may play a role in the overall success of the procedure.

CONCLUSION

In our experience laparoscopic Roux-en-Y gastric bypass appears to be a safe and effective surgical procedure for patients with BMI 35-50 kg/m^2 with results which are comparable to previously published data primarily from the USA, but some from Europe as well. It is associated with minor postoperative pain, early patient mobilization, low incidence of perioperative complications, improvement or complete resolution of preexisting comorbidities and weight loss results that are comparable to those seen following the open procedure. For all these reasons we consider laparoscopic RYGB-LL to be a procedure of choice for the treatment of clinically severe obesity in properly selected patients.

COMMENTS

Background

Obesity, has reached epidemic proportions in society today and it is associated with high rates of morbidity and mortality due to the presence of severe comorbidities. Surgery is the only reliable way of achieving adequate and long-term weight loss in the morbidly obese population. Nowadays, Roux en Y gastric bypass (RYGB) is considered as the gold standard of bariatric procedures. In the present study, the experience of a single centre in Greece with the laparoscopic RYGB is reported.

Research frontiers

Laparoscopic RYGB-LL as performed at authors' institution provides adequate weight loss and resolution or improvement of comorbidities up to 4 years. Apparently, RYGB seems to have an effect on appetite and eating behaviour, which, in turn, may improve long term results. These effects are related to changes in the circulating levels of the gastrointestinal hormones known to influence appetite including ghrelin, PYY and GLP-1. Further in depth research upon this topic is required in order to elucidate the precise mechanisms involved in weight loss.

Innovations and breakthroughs

According to authors' experience, laparoscopic Roux-en-Y gastric bypass appears to be a safe and effective surgical procedure for patients with BMI 35-50 kg/m^2. The vast majority of their complications occurred early at the learning curve. The authors were able to minimize their complication rate and further improve operation and shorten hospitalization.

Applications

Laparoscopic RYGB-LL is a safe and efficious bariatric procedure as it is associated with minor postoperative pain, early patient mobilization, low incidence of perioperative complications, improvement or complete resolution of preexisting comorbidities and durable weight loss. For these reasons, it should be a procedure of choice for the treatment of clinically severe obesity in properly selected patients.

Peer review

A single institutional series of 130 patients with laparoscopic gastric bypass is presented. Although not a huge series the results are excellent and the series is from a European country where lap gastric bypass is less common. The manuscript is likely of interest.

Abstract

AIM: To evaluate the association between ineffective esophageal motility (IEM) and gastropharyngeal reflux disease (GPRD) in patients who underwent ambulatory 24-h dual-probe pH monitoring for the evaluation of supraesophageal symptoms.

METHODS: A total of 632 patients who underwent endoscopy, esophageal manometry and ambulatory 24-h dual-pH monitoring due to supraesophageal symptoms (*e.g.* globus, hoarseness, or cough) were enrolled. Of them, we selected the patients who had normal esophageal motility and IEM. The endoscopy and ambulatory pH monitoring findings were compared between the two groups.

RESULTS: A total of 264 patients with normal esophageal motility and 195 patients with the diagnosis of IEM were included in this study. There was no difference in the frequency of reflux esophagitis and hiatal hernia between the two groups. All the variables showing gastroesophageal reflux and gastropharyngeal reflux were not different between the two groups. The frequency of GERD and GPRD, as defined by ambulatory pH monitoring, was not different between the two groups.

CONCLUSION: There was no association between IEM and GPRD as well as between IEM and GERD. IEM alone cannot be considered as a definitive marker for reflux disease.

Key words: Ineffective esophageal motility; Gastroesophageal reflux disease; Gastropharyngeal reflux disease

INTRODUCTION

Gastroesophageal reflux disease (GERD) is characterized by increased exposure of the esophageal mucosa to the gastric contents. This is mainly due to a various combinations of an increased number of gastroesophageal reflux episodes and abnormally prolonged clearance of the refluxed material[1,2]. The mechanisms for efficient clearance are effective peristalsis, the volume of saliva and gravity.

Ineffective esophageal motility (IEM) is the most recently described esophageal motility abnormality. IEM is defined as contractions with an amplitude of less than 30 mmHg and/or with a rate of nontransmission to the distal esophagus in number of 30% or more of water swallows[3,4]. IEM is associated with an increased acid clearance times in the distal esophagus[3]. Increased acid exposure in these patients is associated with the development of erosive esophagitis and GERD-

associated respiratory symptoms[5,6].

Gastropharyngeal reflux, also called laryngopharyngeal reflux, is a term used to describe esophageal acid reflux into the laryngeal and pharyngeal areas. It causes supraesophageal manifestations (*e.g.* globus, chronic cough, hoarseness, asthma, chronic sinusitis, or other pulmonary or otorhinolaryngologic diseases). Currently, the best way to demonstrate gastropharyngeal reflux is ambulatory 24-h dual probe pH monitoring[7].

It might be hypothesized that patients with IEM would be unable to clear refluxed acid; this would lead to a prolonged esophageal dwell time of the refluxed acid and then the refluxed acid would reach to a higher level. As a result, it would be presumed that patients with IEM have more gastropharyngeal reflux than those patients with normal esophageal motility.

Therefore, the aim of this study was to evaluate the association between IEM and gastropharyngeal reflux in a large series of patients who underwent ambulatory 24-h dual-probe pH monitoring for the evaluation of supraesophageal symptoms.

MATERIALS AND METHODS

Study population

We retrospectively analyzed the medical records and the findings from endoscopy, esophageal manometry and ambulatory 24-h pH monitoring of an unselected group of consecutive patients who were referred to our motility laboratory from July, 2003 to December, 2006. A total of 632 patients received all three examinations due to supraesophageal symptoms (*e.g.* globus, hoarseness or cough). Of them, we selected the patients who had normal esophageal motility and a diagnosis of IEM. We did not enroll those patients who had a history of gastric surgery, a diagnosis of scleroderma or those who were on anti-reflux medications at the time of the study.

This study was reviewed and approved by the Institutional Review Board of Pusan National University Hospital.

Assessment by endoscopy

The presence or absence of reflux esophagitis, hiatal hernia and endoscopically suspected esophageal metaplasia (ESEM) were determined by two endoscopists (G.H. Kim, G.A. Song).

Reflux esophagitis: If esophagitis was present, it was graded according to the Los Angeles classification[8].

Hiatal hernia: Hiatal hernia was defined as a circular extension of the gastric mucosa above the diaphragmatic hiatus greater than 2 cm in the axial length.

Endoscopically suspected esophageal metaplasia: The presence or absence of endoscopically suspected esophageal metaplasia (ESEM) was examined in the lower portion of the esophagus, including the esophagogastric junction, during inflation of the esophagus before inserting the endoscope into the stomach. The esophagogastric junction was defined as the oral side end of the fold, which exists continuously from the gastric lumen[9], as well as the end of the anal side of the fine longitudinal vessel, because the veins in the lower part of the esophagus were distributed uniformly, running parallel and longitudinally in the lamina propria[10,11]. The squamo-columnar junction was defined by a clear change in the color of the mucosa. ESEM was defined as the area between the squamo-columnar junction and the esophagogastric junction.

Esophageal manometry

All antisecretory and prokinetic medications were discontinued at least 7 d before testing. Esophageal manometry was performed, after an overnight fast, with using an eight-lumen catheter (Synetics Medical Co., Stockholm, Sweden) with side holes 3 cm, 4 cm, 5 cm, 6 cm, 8 cm, 13 cm, 18 cm, and 23 cm from the catheter tip and a water-perfused, low-compliance perfusion system (Synetics Medical Co., Stockholm, Sweden), according to a standard protocol. Briefly, the manometry protocol included the following: First, a station pull-through was performed through the lower esophageal sphincter (LES) to determine the end-expiratory resting pressure, the LES length and the location relative to the nares. The catheter was then positioned with the most distal side-hole 2 cm below the upper margin of the LES. Ten 5-mL water swallows were given to evaluate peristalsis; only the esophageal body contractions, measured at 3 cm, 8 cm and 13 cm above the LES, were recorded for data analysis. The catheter was then pulled through the upper esophageal sphincter (UES) in the same manner (station pull-through) to determine the resting UES pressure, the length and the location relative to the nares. Patients were identified as having IEM when the total sum of the low amplitude peristaltic contractions (the distal amplitude measured at 3 or 8 cm above the LES was < 30 mmHg) and the nontransmitted peristaltic contractions (dropouts at either 3 cm or 8 cm above the LES) was equal or greater than 30% of the total number of swallows used for the esophageal body study[4].

Ambulatory 24-h dual-probe pH monitoring

Ambulatory 24-h dual-probe pH monitoring was performed immediately after esophageal manometry with using a single-use monocrystalline antimony dual-site pH probe (Zinetics 24, Medtronic Inc., Minneapolis, USA) with the electrodes placed at the tip and 15 cm proximal to the tip. A cutaneous reference electrode placed on the upper chest was also used. All the electrodes were calibrated in buffer solutions of pH 7 initially and then pH 1. The pH catheter was introduced transnasally into the stomach and it was withdrawn back into the esophagus until the electrodes were 5 cm above the proximal margin of the LES. The subjects were encouraged to eat regular meals with restriction for the intake of drink or food with a pH below 4. All the subjects recorded their meal times (start and end), body position (supine and upright) and any symptoms

in a diary. The data were collected using a portable data logger (Digitrapper Mark Ⅲ, Synetics Medical Co., Stockholm, Sweden) with a sampling rate of 4 seconds, and the data was then transferred to a computer for analysis using "Polygram for Windows®" (Release 2.04, Synetics Medical Co., Stockholm, Sweden). For both sites, a decrease in pH below 4, which was not induced by eating or drinking, was considered the beginning of a reflux episode, and the following rise to pH above 4 was considered the end of such an episode. To be accepted as a gastropharyngeal reflux event, the decrease at the proximal probe had to be abrupt and simultaneous with the decrease at the distal probe, or it was preceded by a decrease in pH of a similar or larger magnitude at the distal probe. Thus, acid episodes induced by oral intake, aero-digestive tract residue and secretions, proximal probe movement or loss of mucosal contact in which the proximal pH decline may precede the esophageal pH drop were not included as gastropharyngeal reflux episodes.

The variables assessed for gastroesophageal reflux at the distal probe were the total percentage of time the pH was < 4, the percentage of time the pH was < 4 in the supine and upright positions, the number of episodes the pH was < 4, the number of episodes the pH was < 4 for ⩾ 5 min, the duration of the longest episode the pH was < 4 and the DeMeester composite score[12].

The variables assessed for gastropharyngeal reflux at the proximal probe were the total percentage of time the pH was < 4, the percentage of time the pH was < 4 in the supine and upright positions, and the number of episodes the pH was < 4.

For the diagnosis of GERD at the distal probe, two different aspects were analyzed[13,14]; (1) the total reflux time: the total proportion of the recorded time with pH < 4; a value of > 4% was considered abnormal; (2) the number of reflux episodes: the total number of pH episodes with pH< 4 during the recording; a value of > 35 episodes was considered abnormal.

For the diagnosis of gastropharyngeal reflux disease (GPRD) at the proximal probe, we considered more than 0.1% for the total time, 0.2% for the upright time and 0% for the supine time of pH < 4 to be pathological. For the number of reflux episodes, more than 4 reflux episodes were considered pathological[15,16].

Statistical analysis

The data are expressed as mean ± SE unless otherwise noted. The student *t*-test was used to assess the statistical significance of age, the body mass index, the pressure and length of the LES and the parameters of ambulatory pH monitoring between the two groups. The differences in gender, alcohol intake, smoking, typical reflux symptoms, indications for pH monitoring, reflux esophagitis, hiatal hernia, ESEM, GERD and GPRD, as defined by the ambulatory pH monitoring between the two groups were assessed using the χ^2 test. A $P < 0.05$ was considered statistically significant. Statistical calculations were performed using the SPSS version 12.0 for Windows software (SPSS Inc., Chicago, IL, USA).

[1]More than 2 d per wk; [2]Other indications were halitosis, throat clearing and laryngeal pathology such as vocal polyp; [3]Los Angeles classification grade. IEM: Ineffective esophageal motility.

RESULTS

A total of 264 patients with normal esophageal motility and 195 patients with the diagnosis of IEM were included in this study. Age, gender, the body mass index, typical reflux symptoms and indications for pH monitoring were not different between the two groups. There was no difference in the frequency of reflux esophagitis and hiatal hernia between the two groups (Table1).

The LES pressure was lower in the patients with IEM than in those patients with normal esophageal motility. All the variables showing gastroesophageal reflux at the distal probe were not different between the two groups. There was no difference in all the variables showing gastropharyngeal reflux at the proximal probe between the two groups (Table 2).

The frequency of GERD and GPRD, as defined by ambulatory pH monitoring was not different between the two groups (Table 3, Figure 1).

DISCUSSION

Esophageal acid clearance consists of two processes, first is rapid removal of most of the intraluminal refluxate, which is achieved by gravity and primary or secondary peristalsis (volume clearance), and this is followed by a slow neutralization of the acidified mucosa by the swallowed saliva (chemical clearance). Previous analysis of the relationship between peristaltic dysfunction and the efficacy of esophageal emptying, with using concurrent manometry and fluoroscopy, illustrated that absent or incomplete peristaltic contractions invariably

Table 2 Results of the lower esophageal sphincter and ambulatory 24-h dual probe pH monitoring in the patients with normal esophageal motility and ineffective esophageal motility

	Normal (n = 264)	IEM (n = 195)	P value

GERD: Gastroesophageal reflux disease; GPRD: **G**astropharyngeal reflux disease; IEM: Ineffective esophageal motility.

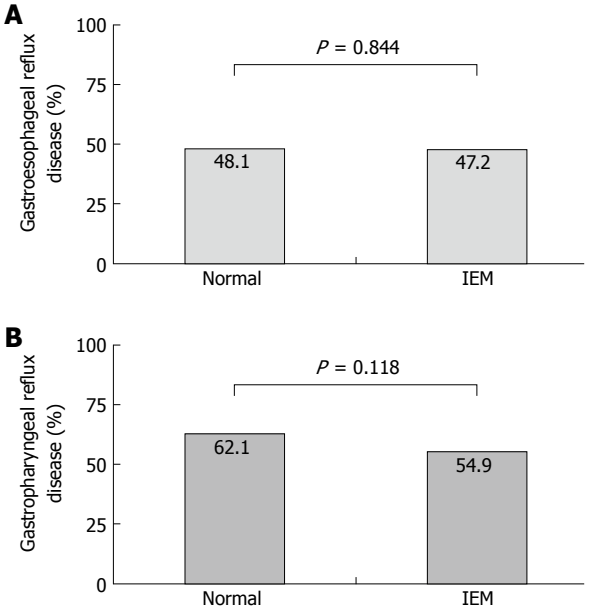

Figure 1 Frequency of gastroesophageal reflux disease (**A**) and gastropharyngeal reflux disease (**B**), as defined by ambulatory pH monitoring, in the patients with normal esophageal motility and ineffective esophageal motility (IEM).

resulted in little or no volume clearance and ineffective esophageal propulsion of a bolus occurs when the amplitude of the peristaltic waves is below 30 mmHg[17]. Thus, peristaltic dysfunction could potentially prolong esophageal acid clearance by delaying the first phase, that of esophageal emptying.

GERD motility abnormalities are part of the nonspecific motor disorders that have been described many years ago[18], and IEM has been found in 20%-50% of the patients with GERD[19]. In addition, there have been some studies suggesting a link between IEM and delayed esophageal acid clearance[3,5,20]. When GERD patients underwent pH monitoring, there were significantly more recumbent and upright reflux episodes and delayed acid clearance in the patients with IEM than in those patients without IEM[3,20]. A greater frequency of IEM was found in patients with respiratory presentations of GERD (chronic cough, asthma and laryngitis) and identification of IEM was particularly useful for patients with supraesophageal GERD[5].

In present study, we selected the patients who had normal esophageal motility and IEM among the patients who received the endoscopy, esophageal manometry and ambulatory pH monitoring due to supraesophageal symptoms. We then analyzed the degree of gastroesophageal and gastropharyngeal reflux in both group. Our results indicated that IEM was not associated with GPRD as well as GERD, as defined by ambulatory pH monitoring. In addition, all the variables for gastropharyngeal reflux and gastroesophageal reflux were not higher in the patients with IEM than those with normal esophageal motility. These findings are consistent with the previous studies[21,22] showing that there was no association between esophageal dysmotility and abnormal acid reflux in patients with supraesophageal GERD symptoms. We also examined the degree of gastroesophageal and gastropharyngeal reflux according to the severity of IEM, but there was no association (data not shown), which was similar to the previous report[23] showing that the severity of IEM was not different in erosive and in nonerosive GERD patients. These results suggest that IEM alone is unlikely to be the major determinant of abnormal esophageal acid exposure.

Although many studies have assessed the link between IEM and esophagitis, this issue remains controversial. Most of the previous studies restricted the enrolled subjects to the GERD patients. IEM was associated with reflux esophagitis in some studies of patients with confirmed GERD[6,24]. However, other studies showed that the presence of reflux esophagitis was similar between the patients with IEM and those patients with normal esophageal peristalsis[20] and there was no difference in the severity of IEM when comparing the erosive and non-erosive GERD patients[23]. In our present study, we included the patients who had normal esophageal motility and IEM over a defined period, providing that the ambulatory study had been done in the absence of anti-secretory therapy, thereby insuring the presence of a control group with normal esophageal acid exposure. Our result showed that reflux esophagitis was not associated with IEM.

There were some merits of this study when

comparing it with the previous studies. First, in contrast to previous reports[5,21,22] that focused on an association between IEM and supraesophageal reflux disease, our study limited the enrolled subjects to patients with normal esophageal motility and those with IEM to maximize the effect of IEM on GPRD. Second, in the current analysis, we defined GERD and GPRD according to the strict criteria of ambulatory 24-h dual-probe pH monitoring, which is the best available test for diagnosing GPRD, as well as GERD[7]. Third, because all the patients in the current study underwent upper endoscopy, we were able to classify them according to the presence or absence of esophagitis and hiatal hernia.

There were some limitations in this study. First, the ambulatory pH monitoring is not 100% accurate and it has a sensitivity as low as 70% in patients with esophagitis, and the sensitivity is substantially lower in patients with nonerosive disease[25], so that some of our patients may have been misclassified. Yet, we included a large number of cases (459 cases), so this limitation was probably lessened. Second, a great deal of controversy exists about the location of the proximal probe. Recording the pH in the hypopharynx is technically difficult. Acid exposure in the hypopharynx can easily be missed because of the relatively large space within the hypopharynx[15]. On the contrary, placement of the proximal probe in or below the upper esophageal sphincter allows for more permanent contact with the mucosa during the 24-h period and this results in fewer artifacts[15,16]. We used a dual-site pH probe with electrodes placed at the tip and 15 cm proximal to the tip, and we could not choose the exact location of the proximal probe. Yet in most cases (75.4%, 346/459), the proximal probe was located in the UES. So, for the diagnosis of GPRD, we used the criteria proposed by Smit *et al*[15,16].

Why is IEM not associated with GPRD as well as GERD? Conventional manometry may be unable to evaluate the "true effectiveness" of esophageal peristalsis[26,27]. In addition, the refluxed acid is neutralized by both the esophageal submucosal secretions and the swallowed salivary secretions, so it becomes non-acid reflux material. Therefore, even though this non-acid refluxate in the upper level actually increased in the patients with IEM, the proximal pH probe cannot detect it. To solve this problem, a prospective study using a combined multichannel intraluminal impedance and pH measurement, which are able to detect both acid and non-acid reflux, as well as the proximal extent of the refluxate, will be needed.

In conclusion, by analyzing a large cohort of patients who had normal esophageal motility and IEM, we demonstrated that there was no correlation between IEM and GPRD, as well as between IEM and GERD, as defined by ambulatory pH monitoring. Although we do not completely exclude that such an association may be possible, IEM alone cannot be considered a definitive marker for reflux (gastroesophageal or gastropharyngeal).

ACNOWLEDGEMENTS

We wish to thank Jin Seon Kim (Gastrointestinal Motility Laboratory, Pusan National University Hospital) for her assistance with this study.

COMMENTS

Background

Ineffective esophageal motility (IEM) is associated with an increased acid clearance times in the distal esophagus. Gastropharyngeal reflux causes supraesophageal manifestations such as globus, chronic cough, hoarseness, asthma, chronic sinusitis, or other otorhinolaryngologic diseases. It might be hypothesized that patients with IEM would be unable to clear refluxed acid; this would lead to a prolonged esophageal dwell time of the refluxed acid and then the refluxed acid would reach to a higher level. As a result, it would be presumed that patients with IEM have more gastropharyngeal reflux than those patients with normal esophageal motility.

Research frontiers

The research front in this area is focused on evaluating the association of IEM and gastropharyngeal reflux disease (GPRD), as well as gastroesophageal reflux disease (GERD). Although many studies have assessed the link between IEM and esophagitis, this issue remains controversial. Most of the previous studies restricted the enrolled subjects to GERD patients. IEM was associated with reflux esophagitis in some studies of patients with confirmed GERD. However, other studies showed that the presence of reflux esophagitis was similar between the patients with IEM and those patients with normal esophageal peristalsis. This study showed no association between IEM and GPRD, as well as between IEM and GERD in a large series of patients who underwent ambulatory 24-hour dual-probe pH monitoring, for the evaluation of supraesophageal symptoms.

Innovations and breakthroughs

There are few reports on the association between IEM and GPRD. Most previous studies are symptom-based and lack objective tests such as ambulatory 24-h dual-probe pH monitoring. This study is the largest study to evaluate the association of IEM and GPRD in patients who underwent ambulatory 24-h dual-probe pH monitoring for the evaluation of supraesophageal symptoms.

Applications

IEM is not associated with GPRD, as well as GERD. Further studies using a combined multichannel intraluminal impedance and pH measurement, which are able to detect both acid and non-acid reflux, as well as the proximal extent of the refluxate, will be needed.

Terminology

Ineffective esophageal motility (IEM) is defined as contractions with an amplitude of less than 30 mmHg and/or with a rate of nontransmission to the distal esophagus in number of 30% or more of water swallows. Esophageal acid reflux into the laryngeal and pharyngeal areas causes extraesophageal manifestations such as chronic cough, hoarseness, asthma, globus sensation, chronic sinusitis, or other otorhinolaryngologic diseases. This condition is called as gastropharyngeal reflux disease (GPRD).

Peer review

This is an interesting study since physicians who perform esophageal manometry frequently find IEM. This study is well structured and definitions of esophagitis, GERD and GPRD are adequate since they were based on endoscopy and 24-h dual esophageal pH monitoring.

Abstract

AIM: To investigate Kupffer cell dynamics and phagocytic activity, using a rat nonalcoholic steatohepatitis (NASH) model.

METHODS: Male F344 rats were fed either a control diet or a choline-deficient L-amino acid-defined (CDAA) diet, followed by contrast enhanced ultrasonography (CEUS) using Levovist®. The uptake of latex beads by the Kupffer cells was determined by fluorescent microscopy. The status of the Kupffer cells was compared between the two groups, using the immunohistochemical staining technique.

RESULTS: After 4 or more wk of the CDAA diet, CEUS examination revealed a decrease in the signal intensity, 20 min after intravenous Levovist®. Fluorescent microscopic examination showed that the uptake of latex beads by the Kupffer cells was reduced at week 1 and 2 in the study group, compared with the controls, with no further reduction after 3 wk. Immunohistochemical staining revealed no significant difference in the Kupffer cell counts between the control group and the CDAA group.

CONCLUSION: CEUS examination using Levovist® demonstrated reduced contrast effect and phagocytic activity in the liver parenchymal phase, although the Kupffer cell numbers were unchanged, indicating reduced phagocytic function of the Kupffer cells in the rat NASH model. We believe that CEUS examination using Levovist® is a useful screening modality, which can detect NASH in fatty liver patients.

INTRODUCTION

Nonalcoholic steatohepatitis (NASH) is characterized by hepatic steatosis, inflammation and fibrosis, with increased risk of developing cirrhosis and hepatocellular carcinoma (HCC)[1-3]. The progression from simple steatosis to cirrhosis has been attributed to inflammatory cytokines such as tumor necrosis factor alpha (TNF-α), oxidative stress and endotoxins, in combination with fatty degeneration due to insulin resistance[4]. At present, histopathological examination of liver biopsy tissue is the only way to definitively diagnose NASH[5-8].

The diagnosis of NASH is important in clinical practice, since this condition can progress to cirrhosis and HCC. When patients with NASH undergo contrast enhanced ultrasonography (CEUS) using Levovist

® (galactose-palmitic acid ultrasound contrast agent), a reduced contrast effect is seen in the liver parenchymal phase[9]. The activity of Kupffer cells and hepatic sinusoids can be evaluated using the contrast effect in the liver parenchymal phase during CEUS examination with Levovist®. The findings strongly implicate Kupffer cells in the pathogenesis of NASH. Reduced function or uneven distribution of Kupffer cells in the liver may play a part in the development of NASH, although this hypothesis remains conjectural at the present time.

In this study, we investigated the contrast effect in the liver parenchymal phase of CEUS using Levovist®, and assessed the Kupffer cell dynamics and phagocytic activity.

MATERIALS AND METHODS

Animals, NASH model induction

Six-week-old male F344 rats weighing 180-200 g were purchased from Japan SLC Inc. (Hamamatsu, Shizuoka, Japan). The animals were housed in stainless steel mesh cages under controlled conditions of temperature (23 ± 3℃) and relative humidity (50% ± 20%), with 10 to 15 air changes per hour, and light illumination for 12 h a day. The animals were allowed access to tap water ad libitum throughout the duration of the study. A choline-deficient L-amino acid-defined (CDAA), and a choline-supplemented L-amino acid-defined (CSAA) diet were purchased from CLEA Japan Inc. (Tokyo, Japan). The details of both diets are described elsewhere[10]. The study group was fed a CDAA diet for 8 wk in order to produce NASH. All procedures were approved by the institutional animal care committee and conducted in accordance with Nara Medical University Guidelines for the Care and Use of Laboratory Animals.

Serum alanine aminotransferase (ALT)

Serum samples from CSAA-fed rats and CDAA-fed rats, killed at 1, 4 and 8 wk were used to measure the serum ALT levels. The levels of serum ALT were determined using a 7170 Clinical Analyzer (Hitachi High-Technologies, Tokyo, Japan).

Histological examination

The liver tissues were fixed in 10% formalin, and the first section was stained with hematoxylin and eosin for histological examination. Another section was stained with Azan and Sirius red to detect fibrosis. Histological grading and staging were performed using a modified scoring system based on the classification of either Matteoni *et al*[5] or Brunt *et al*[6]. Matteoni *et al*[5] proposed NAFLD types 1-4 based on long-term outcome studies; Brunt *et al*[6] proposed a system of grading and staging for NASH that follows methods of separate assessment of necroinflammatory lesions (grading) and fibrosis (staging), accepted in other forms of non-biliary chronic liver diseases.

Levovist® CEUS studies

We compared the contrast effects in the CEUS liver parenchymal phase before administering the CDAA diet (control group, n = 5), and after 1, 4, and 8 wk of the CDAA diet (1-, 4-, and 8-wk groups, n = 5 for each group). The studies were performed with the Logiq 7 ultrasonographic system (GE Healthcare, Tokyo, Japan), using a 7L probe (3-7 MHz), and employing the Coded Harmonic Angio mode. Levovist® (Schering AG, Berlin, Germany) was diluted to 300 mg/mL, and injected into the animal's tail vein at a dose of 0.1 mL/100 g body weight. Following confirmation that the contrast had entered the right kidney, we scanned the liver, using 1-s intermittent transmission scans at 5, 10, 15, and 20 min, with a different section for each scan. The fluorescent intensity in the region of interest (ROI) in each image was calculated by the equipment software using the time intensity curve (TIC).

Observation of FITC-latex beads phagocytosis by Kupffer cells in vivo

An injection of 2×10^{10}/kg 1 μm fluorescent latex beads (Polyscience, Warrington, PA, USA) was given into the animal's tail vein before CDAA (control group, n = 5), and after 1, 2, 3, 4, and 8 wk of CDAA (1-, 2-, 3-, 4- and 8-wk groups, n = 5 for each group). Two hours after the injection, the animals were killed and 4% paraformaldehyde and 0.5% glutaraldehyde in phosphate buffer saline (PBS) was perfused into the portal vein. After fixation with the same fixative for 60 min, the liver specimens were sliced into 5-μm-thick sections with a cryostat microtome CM 1510 (Leica Microsystems, Wetzlar, Germany). The uptake of latex beads by the Kupffer cells was determined using fluorescent microscopy Leica DM IRB (Leica Microsystems), and the fluorescent intensities were analyzed and compared using IP LabTM software (BD Biosciences, Rockville, MD, USA).

Isolation and culture of Kupffer cells

The Kupffer cells were harvested from the liver using the isolation buffers described by Seglen[11]. The liver was perfused in situ with Ca^{2+}-free minimum essential medium (Sigma, St. Louis, MI, USA) followed by 0.3% pronase (Roche Diagnostics Corp., Indianapolis, IN, USA), and 0.05% type IV collagenase (Sigma) in Dulbecco's modified eagle's medium/F-12 (Sigma) at a rate of 10 mL/min through the portal vein. The liver was carefully removed and minced with scissors. The minced liver was incubated in a shaker water bath with 0.035% pronase and 62.5 U/mL DNase (Sigma) in Dulbecco's modified eagle's medium/F-12 at 37℃ for 20 min, and was then filtered through gauze; the parenchymal cells were removed by low-speed centrifugation. The resultant supernatant was laid on top of 4 separate densities (1.035, 1.045, 1.058, and 1.085) of arabinogalactan solution (Sigma) in one test tube and centrifuged at 400 r/min for 45 min at 37℃ using a Beckman SW41-Ti rotor (Beckman Instruments, Fullerton, CA, USA). The third and fourth layers from the top were recovered and washed twice with Ca^{2+}-free Hanks balanced salt solution (Sigma). The final cell pallet was subsequently suspended in RPMI 1640 medium,

and cultured in a culture flask at 37℃ in humidified atmosphere containing 50 mL/L CO_2 and air for 2 h.

The purity of the isolated Kupffer cells was over 98%, as determined by the uptake of 1 μm latex beads[12], and the viability was over 95% in the trypan-blue-dye exclusion test.

The Kupffer cells were seeded in 12-well plastic plates and incubated in RPMI 1640 medium at a concentration of 5×10^5 cells/mL. The dishes were washed with Hanks balanced salt solution to remove the unattached cells. The Kupffer cells were cultured in RPMI 1640 supplemented with 50 μg/mL streptomycin and 50 μg/mL ampicillin (Nakalai tesque, Kyoto, Japan).

Observation of FITC-latex beads phagocytosis by Kupffer cells in vitro

Fluorescent latex beads (1×10^7 1 μm) were placed in each well, and culture was performed at 37℃ for 2 h under 50 mL/L CO_2 on plastic dishes that were washed three times with Hanks balanced salt solution to remove un-phagocytosed latex beads. The uptake of latex beads by the Kupffer cells was determined using fluorescent microscopy, and the fluorescent intensities were analyzed and compared using IP Lab™ software.

Kupffer cells immunohistochemical staining

The Kupffer cell dynamics were analyzed by comparing the cell counts of each group, using immuno-histochemical staining with anti-rat macrophage/dendritic cell monoclonal antibody (RM-4: Trans Genic Inc., Kobe, Japan), a Vectastain ABC Elite Kit (Vector Laboratories, Burlingame, CA, USA), and DAB peroxidase substrate solution (Vector Laboratories), with counterstaining by Hematoxylin Mayer. The stained areas were analyzed and compared using NIH-image software (Version 1.61; U. S. National Institute of Health, Bethesda, MD, USA).

Statistical analysis

P-values were calculated, assuming equal sample variance, using the paired *t*-test, and Statview software (version 5.0; SAS Institute, Cary, NC, USA), considering $P < 0.05$ as statistically significant. The values are mentioned as mean ± SD.

RESULTS

Serum ALT

The mean serum ALT level in the control rats was 41.7 ± 7.4 IU/L, compared to 524.6 ± 101.7 IU/L, 267.9 ± 47.5 IU/L and 251.4 ± 81.6 IU/L in the 1-, 4-, and 8-wk, respectively in the CDAA-fed rats. All NASH groups showed statistically significant elevations, compared with the control animals ($P < 0.01$) (Figure 1).

Changes in liver histology

Histological examination of the liver of 1-wk CDAA-fed rats revealed inflammation and fat deposits, but no fibrosis, and was considered as Matteoni's type 2.

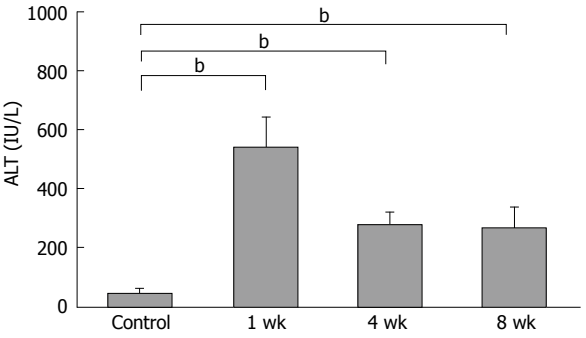

Figure 1 Serum ALT levels were elevated significantly in 1-wk CDAA-fed rats, and decreased gradually in the 4 and 8-wk CDAA-fed rats, although, both were elevated significantly compared with the control animals ($n = 5$), $^bP < 0.01$.

The 4-wk CDAA-fed rats had more inflammation, fat deposits, and fibrosis, which was equivalent to Matteoni's type 3 and Brunt's NASH classification of grade 2/stage 2. The histological findings in the 8-wk CDAA-fed rats were equivalent to Matteoni's type 4 and Brunt's grade 2/stage 3. In the 4- and 8-wk groups, Sirius red staining revealed abundant collagen (Figure 2).

Levovist® CEUS examination

Assessment of changes in fluorescent intensity up to 20 min (-25.5 ± 6.4 dB, -37.5 ± 7.5 dB, -55.2 ± 3.9 dB, -59.3 ± 5.6 dB in the control, 1-, 4-, and 8-wk CDAA-fed rats) after administration of Levovist®, with the values at 5 min (-30.2 ± 4.4 dB, -31.8 ± 1.8 dB, -38.8 ± 4.1 dB, -39.7 ± 6.2 dB in the control, 1-, 4-, and 8-wk CDAA-fed rats, respectively) considered as the standard, showed that the fluorescent intensity in the control group tended to rise from 10 min onwards, and remained elevated. In the 1-wk group, the contrast effect remained fairly constant from 5 min to 20 min. In the 4- and 8-wk groups, the contrast effect was decreased significantly at 20 min (Figure 3A). When the fluorescent intensity was quantified using TIC, the fluorescent intensity at 20 min tended to be lower in the 1-wk group and significantly lower in the 4- and 8-wk groups compared with the control group (Figure 3B).

Phagocytosis of FITC-latex beads by Kupffer cells in vivo

Fluorescent microscopic examination showed that the latex bead uptake per Kupffer cell *in vivo* was lower in the 1-wk group compared to the controls, with no further reduction after 4 and 8 wk (Figure 4A and B). To avoid the influence of Kupffer cell cross-sections, and to count the Kupffer cells more accurately, we observed the images again at lower magnification. In comparison with the control group, the uptake was reduced to approximately 50% in the 1-wk group, and to 30% in the 2-wk group, with no further decrease after 3 wk (Figure 4C).

Phagocytosis of FITC-latex beads by Kupffer cells in vitro

Similar to the *in vivo* findings, the fluorescent microscopic examination showed that the *in vitro* latex bead uptake

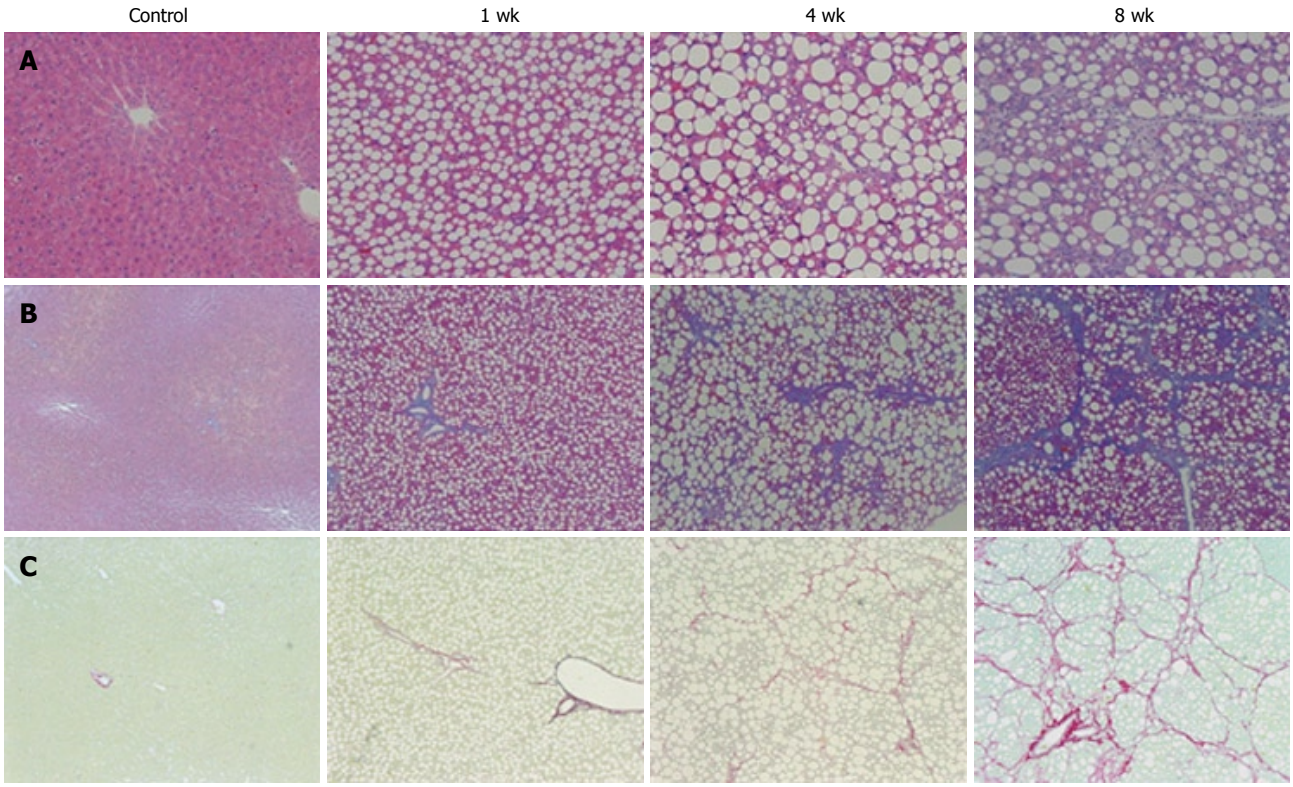

Figure 2 Histological analysis of the liver sections. **A**: Hematoxylin and eosin stain (x 200); **B**: Azan stain (x 100); **C**: Sirius red stain (x 100). Histological examination of the liver tissue of 1-wk CDAA-fed rats showed inflammation and fat deposits, but no fibrosis, corresponding to Matteoni's type 2. The 4-wk CDAA-fed rats had more inflammation, fat deposits, and fibrosis, which was equivalent to Matteoni's type 3 and grade 2/stage 2 of Brunt's NASH classification. The histological findings in the 8-wk CDAA-fed rats were equivalent to Matteoni's type 4 and Brunt's grade 2/stage 3. In the 4 and 8-wk groups, Sirius red staining revealed abundant collagen (n = 5).

per Kupffer cell was lower in the 1-wk group than in the controls, with no further reduction after 4 and 8 wk. To avoid the influence of Kupffer cell cross-sections, and to count the Kupffer cells more accurately, we observed the images again at lower magnification. In comparison with the control group, the uptakes were reduced to approximately 60% in the 1-wk group, and to 30% in the 2-wk group, with no further decrease after 3 wk (Figure 5).

Kupffer cells immunohistochemical staining

Immunohistochemical staining showed no significant difference in the number of stained cells per field between the control group and any of the CDAA groups. Quantitative analysis using NIH Image™ also showed no significant difference between the groups (Figure 6).

Relationship of Kupffer cell phagocytic activity with Kupffer cell count and liver histology

There was no correlation between the changes in the contrast effect, and the Kupffer cell count or the degree of fat deposition.

DISCUSSION

Ultrasonographic examinations have been performed to assist in the diagnosis of abdominal diseases since the 1970s, and continue to be widely used in clinical practice because of the ease of use and low level of invasiveness[13]. Until recently, ultrasonography enhanced by CO_2 microbubbles, delivered through an intra-arterial catheter (developed in the 1980s), was the only CEUS technique available[14,15]. The intravenous ultrasonographic contrast agent Levovist®, available for clinical use in Japan since September 1999, facilitates the hepatic blood flow imaging with an inherently low level of invasiveness[16-19]. Levovist® CEUS provides information on both the blood flow and the parenchyma through the characteristics of the contrast agent[20,21]. Microbubbles injected *via* the intravenous route travel through the blood vessels, producing vascular images, and the gas is finally eliminated through the lungs[22]. However, some kinds of microbubbles accumulate in the organs such as the liver[23] and the spleen[24], which allows delayed phase imaging[25]. Recently, Levovist® CEUS has been reported to be a useful screening modality for NASH[9]. The reduced contrast effect in the liver parenchyma has been attributed to sinusoidal or Kupffer cell dysfunction, although this finding remains to be established[26].

In the present study, we performed Levovist® CEUS examination using a rat NASH model induced by the CDAA diet. We also assessed Kupffer cell dynamics and phagocytic activity, and confirmed that the contrast effect is reduced in the hepatic parenchymal phase. The liver histology progressed from steatosis and inflammation to marked fibrosis during 8 wk of CDAA

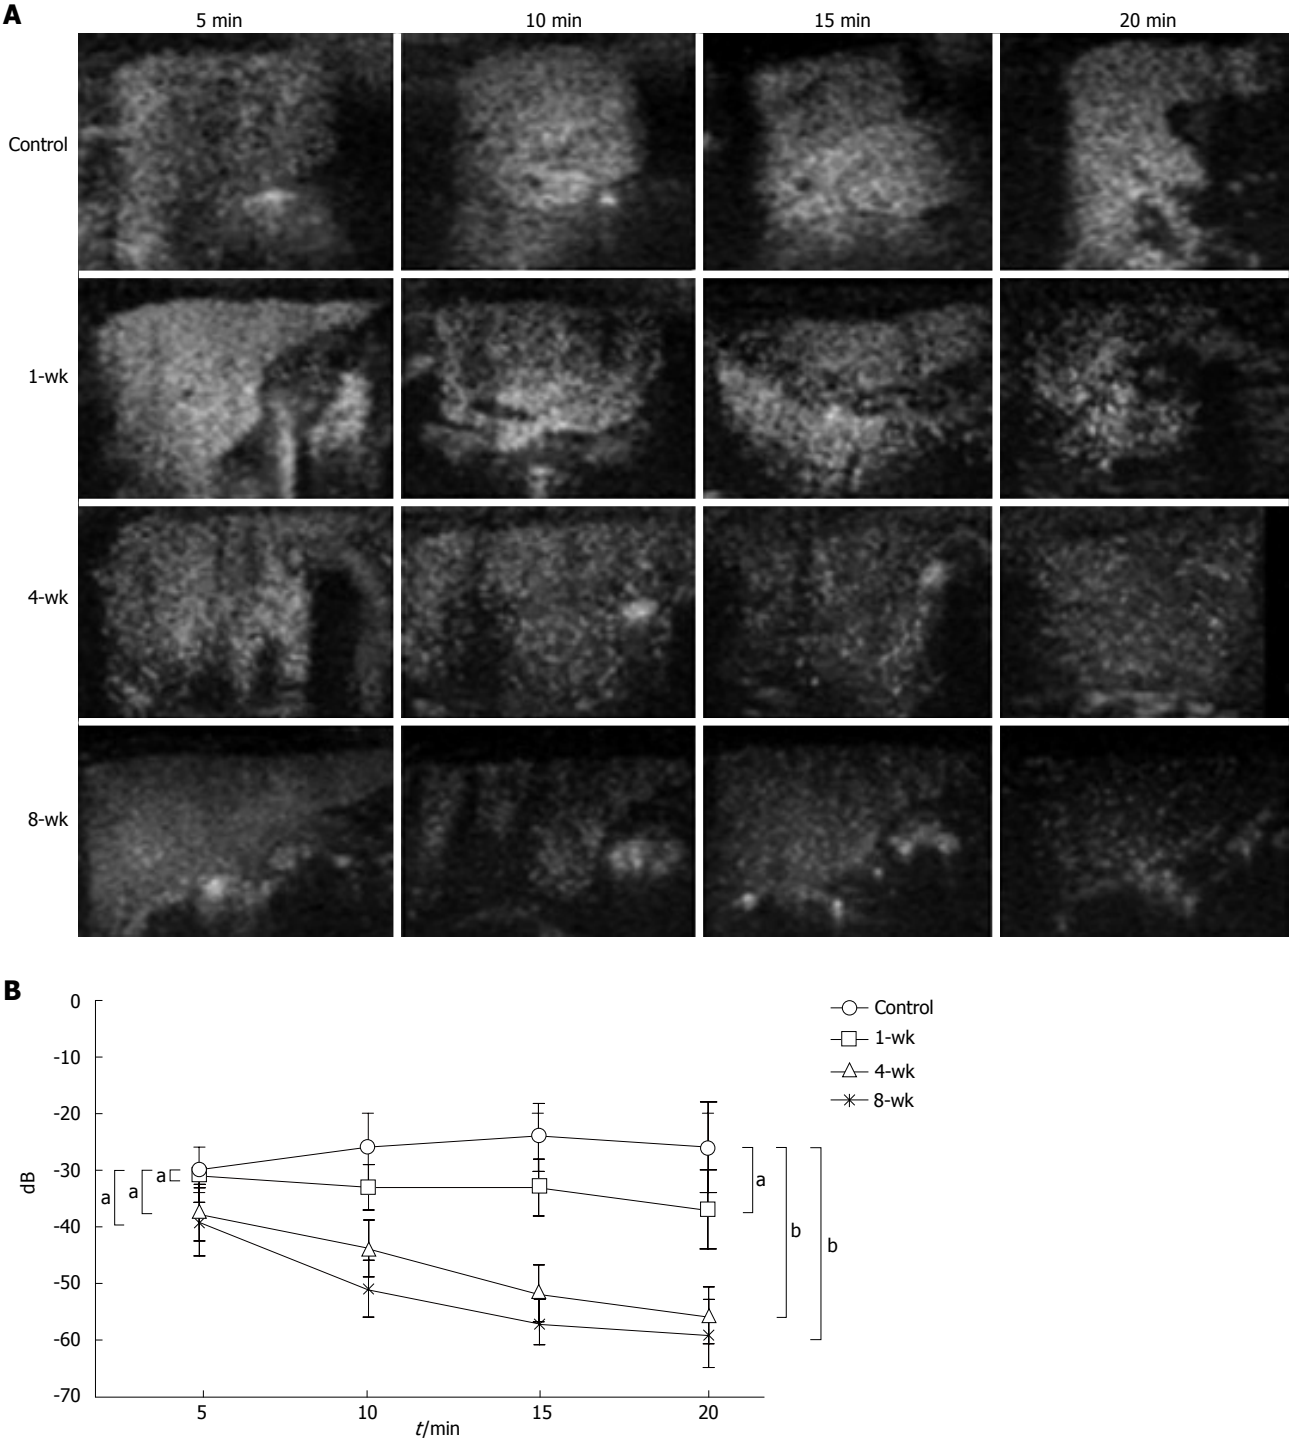

Figure 3 Results of Levovist® CEUS in each group. **A**: Examination of changes in the fluorescent intensity up to 20 min after administration of Levovist®, with the values at 5 min considered as the standard, showed that the fluorescent intensity in the control group tended to rise from 10 min onwards, and remained elevated. In the 1-wk group, the contrast effect remained fairly constant from 5 min to 20 min. After 4 or more wk of the CDAA diet, CEUS examination revealed a decrease in the signal intensity, 20 min after intravenous Levovist®; **B**: Changes in the fluorescent intensity in Levovist® contrast enhanced ultrasonograms in each group. In the control group, the fluorescent intensity increased significantly at 20 min compared with the findings at 5 min, whereas a significant chronological decrease was seen in the NASH groups ($n = 5$). $^{a}P > 0.05$, $^{b}P < 0.01$.

feeding. The changes in fluorescent intensity up to 20 min after the administration of Levovist® revealed distinct differences depending on the duration of the CDAA diet. In the early phase, the effect of Levovist® in the hepatic sinusoids and the blood stream was strong, whereas at 20 min the effect of the contrast taken up by the Kupffer cells was apparent. When the values obtained at 5 min were taken as the standard, the contrast effect at 20 min was low even in the 1-wk CDAA-fed group. The contrast effect at 20 min was significantly lower in the 4-wk and 8-wk CDAA-fed groups compared with the findings in the control group. The decrease in the phagocytic activity of Kupffer cells in the early phase of rat steatohepatitis was further

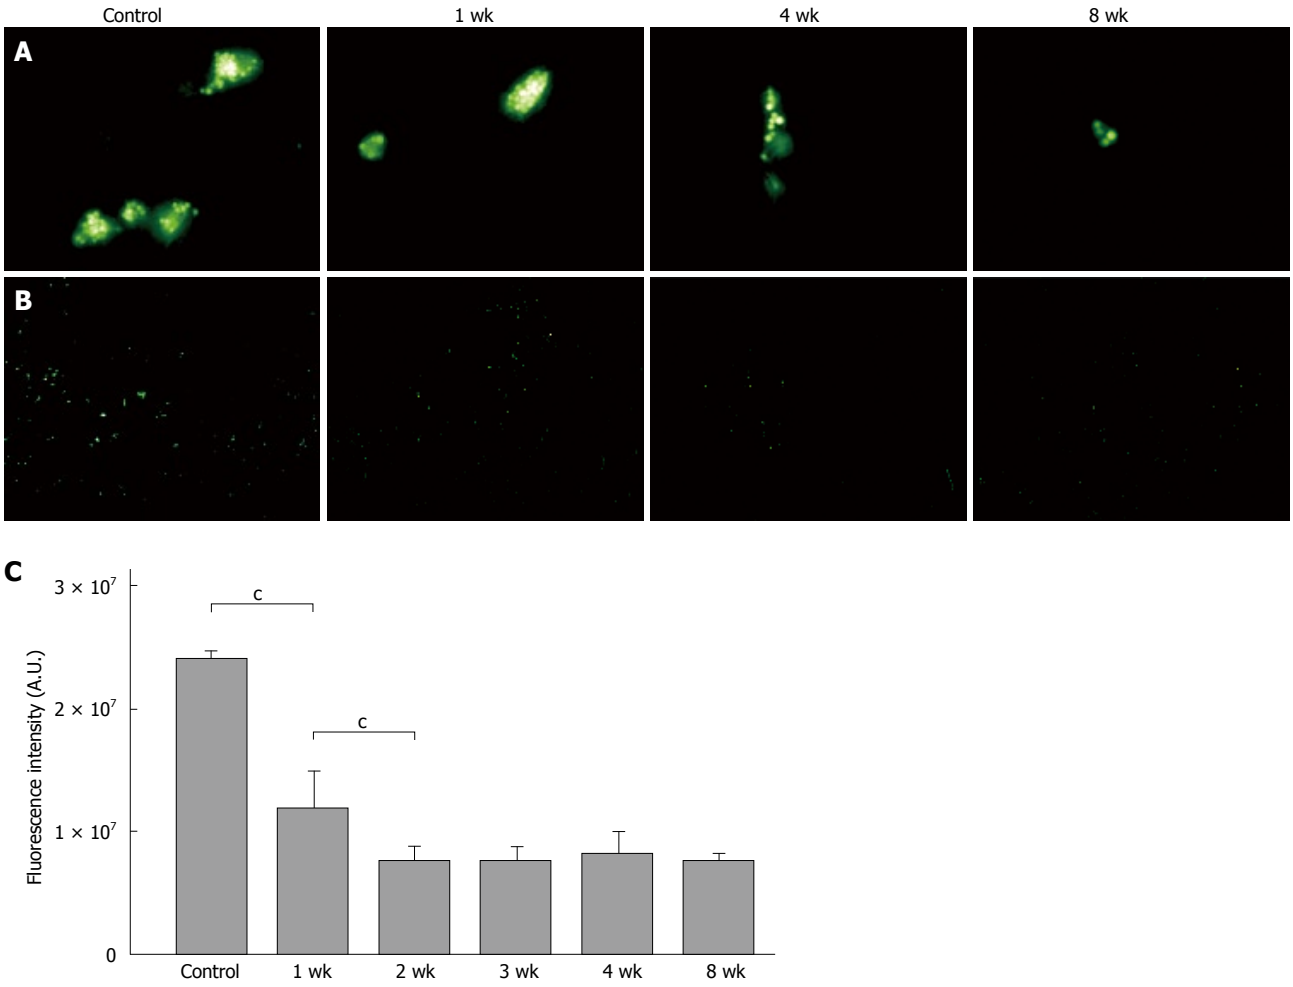

Figure 4 **A**: Fluorescence micrographs (x 1000). In the control group, there was no uptake of multiple latex beads (phagocytic activity) by the triangular shaped Kupffer cells, whereas the latex bead uptake was reduced in the NASH groups; **B**: Phagocytosis of FITC-latex beads by Kupffer cells *in vivo* (x 100). Decreased latex bead uptake was seen in the NASH groups compared with the control group; **C**: When compared with the control group, fluorescence was reduced to approximately 50% in the 1-wk group, and to 30% in the 2-wk group, but there was no further decrease after 3 wk (n = 5). $^{c}P < 0.001$.

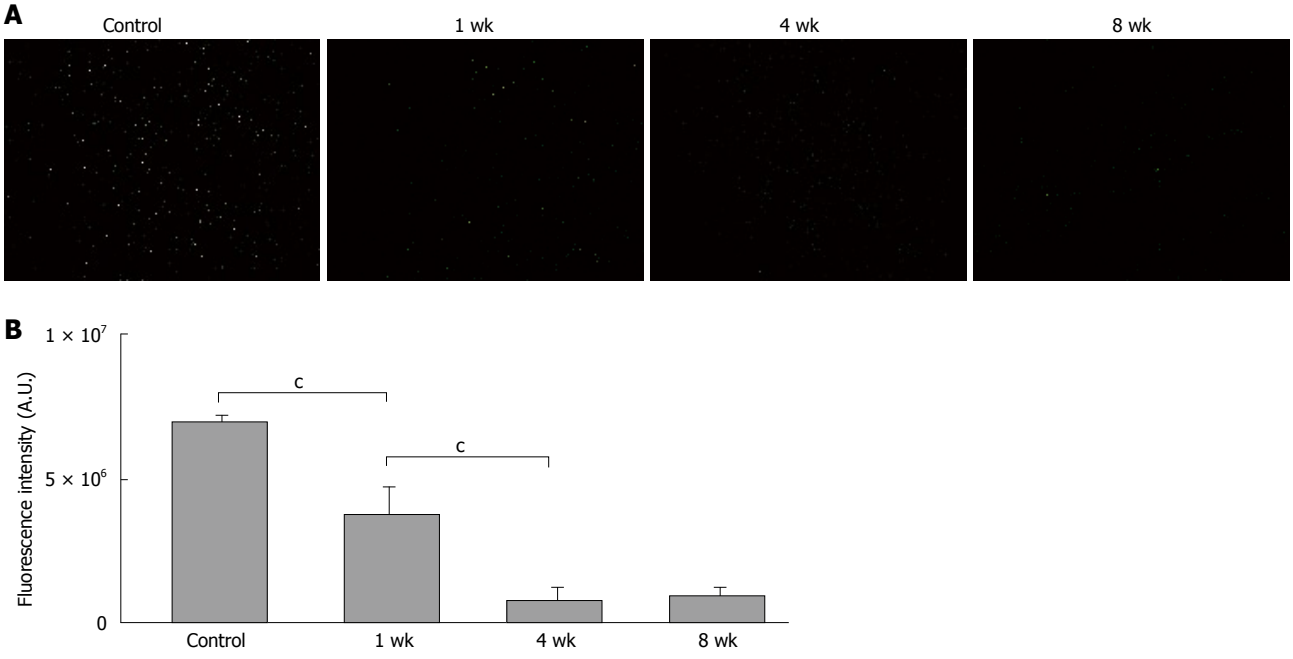

Figure 5 **A**: Phagocytosis of FITC-latex beads by the Kupffer cells *in vitro* (x 100). There was reduced latex bead uptake in the NASH groups compared with the control group; **B**: When compared with the control group, fluorescence was reduced to approximately 60% in the 1-wk group, and to 30% in the 2-wk group, but no further decrease was observed after 4 wk (n = 5). $^{c}P < 0.001$.

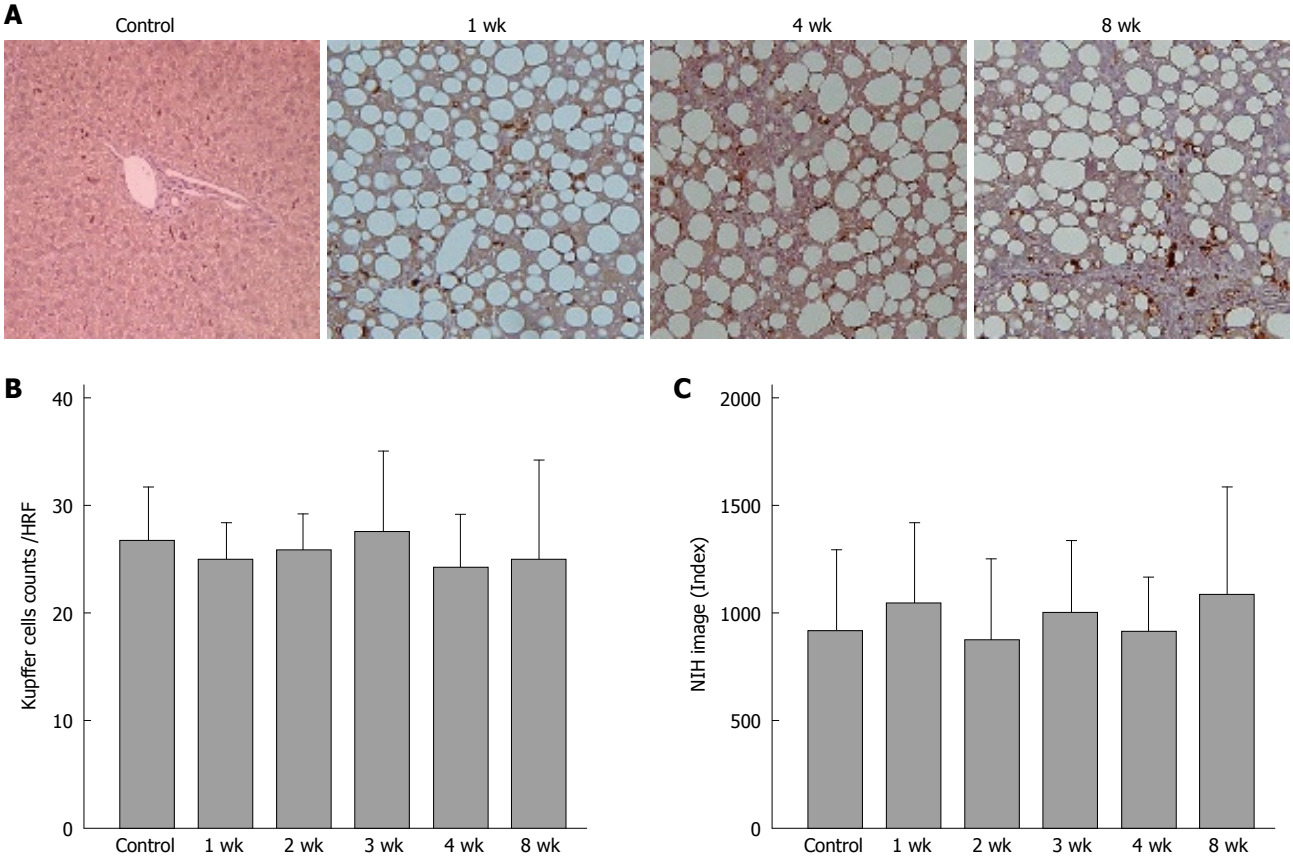

Figure 6 **A**: Kupffer cell immunohistochemical staining (x 200). Brown-stained cells are positive; **B**: There were no significant differences between the different groups in the number of stained cell per field; **C**: No significant differences were found between the groups in the quantitative analyses (n = 5).

confirmed by the latex bead uptake test. In the present *in vitro* study, we demonstrated that isolated Kupffer cells from CDAA-fed rats had reduced phagocytic activity. The marked decrease in the phagocytic activity in the presence of normal Kupffer cell counts suggests the presence of Kupffer cell functional abnormalities in our NASH model. We propose that persistent inflammation leads to reduced phagocytic activity of the Kupffer cells. Although the cause of the marked decrease in the phagocytic activity is unclear[27], it may be attributable to intestinal bacterial endotoxins, which are believed to play a key role in the choline deficiency model of liver injury[28]. Further studies are necessary to exclude the possibility of hypoperfusion of the sinusoids, and to confirm Kupffer cell abnormality in steatohepatitis.

In the present study, we used the CDAA model, because the changes induced in the liver are reproducible and similar to those observed in NASH. The development of NASH in patients receiving total parenteral nutrition has been attributed to choline deficiency[29]. Furthermore, alcoholic liver disease may be associated with hepatic choline deficiency and hepatic steatosis, abnormalities that are also observed in rats fed a CDAA diet[27]. Although, our steatohepatitis model lacks obesity and insulin resistance, two major characteristics of human NASH, a possible association between Kupffer cells, with inflammation and fibrosis may resemble the findings in humans. Further studies on cytokine production by the Kupffer cells in the present NASH model may reveal Kupffer cell dysfunction and add new insight to the hepatic consequences of human NASH.

In conclusion, ultrasound examination by Levovist® confirmed the presence of a reduced contrast effect in the liver parenchymal phase in the rat NASH model. We believe that CEUS examination using Levovist® is a useful screening modality which can detect NASH in patients with fatty liver.

COMMENTS

Background

The diagnosis of nonalcoholic steatohepatitis (NASH) is important in clinical practice since this condition can progress to hepatic cirrhosis and hepatocellular carcinoma (HCC). At present, histopathological examination of liver biopsy tissue is the only way to definitively diagnose NASH. When NASH patients undergo contrast enhanced ultrasonography (CEUS) using Levovist®, reduced contrast effect is seen in the liver parenchymal phase.

Research frontiers

Levovist® CEUS provides useful information on both the blood flow and the liver parenchyma, based on the characteristics of the contrast agent. Recently, Levovist® CEUS is being increasingly used as a screening modality for NASH. The reduced contrast effect in the liver parenchyma has been attributed to sinusoidal or Kupffer cell dysfunction, but this finding remains to be established. Therefore, the present workers performed Levovist® CEUS in a rat NASH model, induced by a choline-deficient L-amino acid-defined (CDAA) diet, and examined the Kupffer cell dynamics and phagocytic activity. The results obtained confirmed that the contrast effect is reduced in the liver parenchymal phase in the rat NASH model.

Innovations and breakthroughs

The present study demonstrated the contrast effect in the liver parenchymal

phase of CEUS using Levovist®. In addition, Kupffer cell dynamics and phagocytic activity were assessed in the rat NASH model. The results confirmed the effectiveness of CEUS in diagnosing NASH.

Applications

The authors believe that the CEUS with Levovist® is a useful screening modality, which can detect NASH in patients with fatty liver.

Terminology

Levovist (Schering AG, Berlin, Germany) is a galactose-palmitic acid ultrasound contrast agent, currently in use in European and Asian countries.

Peer review

The manuscript includes well designed figures, and the results clearly show a reduction in KC function, which was not attributed to changes in KC number, during the course of CDAA feeding. The hypothesis is simple and clear.

Abstract

AIM: To investigate the prevalence and genotype distribution of Torque teno virus (TTV) in patients with different liver diseases and chronic renal failure treated at a referral hospital in North India.

METHODS: Whereas prevalence of TTV was based on amplification of conserved region of ORF2 of TTV genome, the genotyping of TTV was carried out using restriction fragment length polymorphism (RFLP) procedure on the N22 region of ORF1.

RESULTS: TTV-DNA was detected in 137 of 513 (26.7%) patients with liver diseases and 38 of 65 (58.5%) patients with chronic renal failure. TTV was also detected in 27% of healthy controls. The sequence analysis of the PCR product from 10 randomly selected cases failed to show a significant sequence divergence when compared with that of the TRM1 isolate of TTV genotype 1. The results of genotyping in 55 randomly selected patients showed the presence of genotype 1 (G1) in 53 (96.4%) and genotype 2 (G2) in 2 cases (3.6%), respectively. Other genotypes were not identified in this patient subgroup, suggesting that G1 is predominant in this area. The results of genotyping by RFLP were also supported by phylogenetic tree analysis, where G1 was found to be the major genotype.

CONCLUSION: These results indicate that TTV is moderately present in Indian patients, with G1 to be the major genotype in North India. The pathogenicity and etiological role of TTV in different diseases is still a question mark and warrant further studies.

Key words: Torque teno virus; Genotype; Restriction fragment length polymorphism; Torque teno; Hepatocellular carcinoma

INTRODUCTION

Torque teno virus (TTV), formerly known as transfusion-transmitted virus, is a small, non-enveloped, icosahedral, single-stranded, circular-DNA virus[1] approximately 30 nm in diameter. TTV contains a 3.6-3.9 kb DNA genome of minus polarity[2-4] and belongs to a novel virus family, *Circoviridae*[3]. At least 40 TTV genotypes from 5 major phylogenetic groups have been identified[5]. They display over 30% nucleotide diversity[6]. TTVs are ubiquitous in nature and have been demonstrated in high proportion of serum samples from healthy individuals where they persist overtime[3,7-9]. A tissue culture system that supports efficient replication of TTV is not available[10], and this has delayed the study of both TTV genome replication and TTV gene expression. Antibodies reacting with two proteins encoded by the 2.8-kb mRNA have been detected in TTV-infected individuals[11,12]. The first is the large protein encoded by TTV ORF1 (the ORF1 protein), which is predicted to be 736 amino acids in length and initiates from a methionine at nucleotide (nt) 581 (O1AUG). The second protein is encoded by the 2.8-kb mRNA in ORF2, initiating at a methionine in the position of nt 354 (O2AUG) and extending for 117 amino acids[13].

TTV belongs to the group of *Anelloviruses* that are widely diverse. Indeed, based on their heterogeneity,

Anelloviruses are currently classified into two species, each subdivided into numerous genotypes. Thus, TTV, the first anellovirus species identified[1], is currently subdivided into approximately 40 genotypes, which cluster in five clearly distinct phylogenetic groups designated from 1 to 5[1,6,10,14]. TTV is transmitted parenterally through transfusion with blood or blood products, but the natural route of its transmission is still unknown[15,16].

TTV is found in the plasma of > 80% of the human population worldwide. Co-infection of single individuals with multiple TTV isolates is frequent[17]. The epidemiology and pathogenic potential of TTV is poorly understood. In several studies, however, the viral genome has been detected at comparable prevalence rates in the blood of healthy persons and patients and this led to the hypothesis that TTV might be essentially non-pathogenic in nature[18].

TTV can be transmitted by parenteral route, although its role in causing post-transfusion hepatitis has not been established. The majority of individuals who become TTV-DNA-positive after blood transfusion usually have normal ALT and do not develop chronic hepatitis, although TTV viremia frequently persists for several years. Patients who develop chronic hepatitis are invariably coinfected with HBV or HCV and chronic hepatitis is closely correlated with HBV or HCV infection. This raises the possibility that TTV is merely an innocent bystander rather than a primary hepatitis virus[19].

Although TTV appears to be widespread in the general population of several geographical regions, its prevalence in many areas is still unknown. The reports on status of TTV available from India are very preliminary and therefore there is a need of extensive studies to understand the endemicity, epidemiology and etiological potential of TTV infection in various diseases. Also, very little is known about the genotyping of TTV strains circulating in this country. Thus, the present study was undertaken to elucidate the prevalence and detect genotypes distribution of TTV in patients with liver and renal diseases in North India.

MATERIALS AND METHODS

Patients and blood samples

Five hundred and seventy eight adult patients of both sexes were included. There were 126 patients with acute viral hepatitis (AVH, age range: 21-48 years), 111 patients with chronic viral hepatitis (CVH, age range: 19-48 years), 132 patients with liver cirrhosis (CIR, age range: 34-57 years), 51 patients with fulminant hepatic failure (FHF, age range: 28-46 years), 93 patients with hepatocellular carcinoma (HCC, age range: 24-71 years) and 65 patients with chronic renal failure (CRF, age range: 20-74 years)[19]. All these patients attended either the Outpatient Department or were admitted to the Liver and Renal Units of All India Institute of Medical Sciences, New Delhi, from June 2001 to March 2008. They were evaluated clinically and biochemically and their sera were tested for various markers and parameters. The diagnosis of different types of diseases was based on accepted clinical, biochemical and histological criteria as outlined elsewhere[20].

AVH was diagnosed when patients exhibited overt jaundice and/or increased alanine aminotransferase levels (at least 3 times above the normal value) documented at least twice at a 1-wk interval without any history of pre-existing liver disease. None of the patients had a past history of alcohol intake or were using any drug or had clinical or serological evidence of autoimmune diseases or biliary infection. The patients with CVH and liver cirrhosis were diagnosed based on histopathological criteria established by the International Study Group on Chronic Hepatitis[21]: All of them had persistent elevation of transaminases (at least twice the upper limit of the normal range) for more than six months and histologic evidence of chronic hepatitis on liver biopsy at the beginning of follow-up. FHF was diagnosed if the patients developed hepatic encephalopathy within 4 wk from the onset of acute hepatitis, as outlined elsewhere[20]. The diagnosis of HCC was based on histological criteria. CRF was diagnosed using criteria as detailed elsewhere[22]. One hundred age- and sex-matched healthy subjects were used as controls.

From each of the above patients, 6-10 mL of venous blood was drawn and aliquoted in plain tubes without anticoagulant. Serum was separated after centrifugation and then stored at -70℃ until further analysis. Repeated freezing and thawing of serum was avoided as far as possible. These serum samples were used to analyze liver function tests and routine hematogram.

Detection of TTV-DNA by PCR

Viral DNA was extracted from 200 μL of sera stored at -20℃ using QiAmp Mini Elute viral spin kit (Qiagen, Germany) and following the manufacturer's instructions. The DNA was eluted in 50 μL of elution buffer supplied with the kit. TTV-DNA (conserved region of ORF2) was detected by nested PCR using primers NS1 (sense) 5'-GGGTGCCGAAGGTGAGTTTAC-3' (175-195), NS2 (anti-sense) 5'-GCGGGGCACGAA-GCACAGAAG-3' (474-494), NS3 (sense) 5'-AGTTTA-CACACCGAAGTCAAG-3' (189-209) and NS4 (anti-sense) 5'-AGCACAGAAGCAAGATGATTA-3' (463-483) as described by Biagini *et al*[23], 1999 (Accession No. AB008394). Briefly, 10 μL of DNA was used for the amplification in a 50 μL reaction mixture containing 10 × PCR buffer, 25 pmol/μL of each primer, 10 mmol/L of each dNTPs, and 1.5 U Taq polymerase (Qiagen). Each of the 35 cycles of the 1st round and 25 cycles for the 2nd round of amplification consisted in an initial denaturation step at 95℃ for 5 min and a cycling denaturation at 94℃ for 30 s, annealing at 60℃ for 45 s, extension at 74℃ for 45 s, with a final extension for 3 min at 74℃.

Genotyping of TTV was done by amplifying the N22 region using specific primers as described by Okamoto *et al*[4], 1999. Briefly, a first round of amplification was performed with sense primer NG059 5'-ACAGAC-

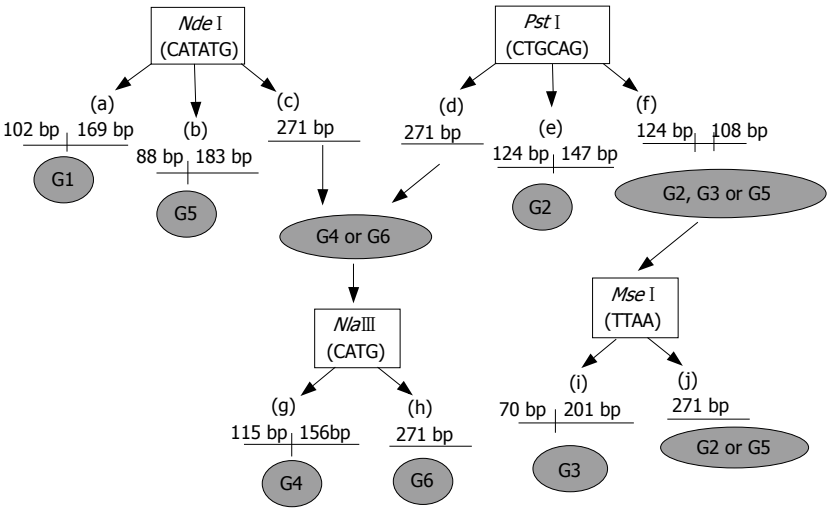

Figure 1 Strategy for RFLP analysis (Tanaka *et al*[24], 1998).

AGAGGAGAAGGCAACATG-3' and anti-sense primer NG063 5'-CTGGCATTTTACCATTTCCAAAGTT-3' for 10 min at 95℃ (initial denaturation) followed by 35 cycles of denaturation at 95℃ for 30 s, annealing at 55℃ for 1 min, and extension at 74℃ for 1 min with a final extension at 74℃ for 5 min. The second round of PCR was performed using sense primer NG061 5'-GGCAACATGYTRTGGATAGACTGG-3' and anti-sense primer NG063 5'-CTGGCATTTT-ACCATTTCCAAAGTT-3' following same conditions as used for first round amplification. Three microliters of the PCR product were electrophoresed on 2% agarose gel and stained by ethidium bromide to observe as 295 bp product of ORF2 region and 271 bp product of N22 region.

Sequence analysis

PCR products of ORF2 were recovered from 2% agarose gels after staining with ethidium bromide and visualized under UV and were purified with QIAquick Gel Extraction Kit, Qiagen, Germany. They were sequenced in both directions using an automated DNA sequencer at M/s Lab India. The same set of primers was used for both sequencing and amplification by PCR.

Restriction fragment length polymorphism (RFLP)

Restriction digestion was carried out overnight using 10 μL of the second round PCR product of the N22 region and 10 × enzyme buffer according to the manufacturer's instructions. Reactions were carried out with 20 U each of *Nde* I , *Pst* I (New England Biolabs, MA, USA), *Nla* Ⅲ (MBI Fermantas, Canada) at 37℃. Similarly, 20 U of *Mse* I (MBI Fermantas, Canada) were used for digestion at 65℃. The digested PCR products were electrophoresed on 2% agarose gel and stained with ethidium bromide. The RFLP pattern was then evaluated under UV light[24]. The procedure using restriction digestion enzymes for genotyping by RFLP is shown schematically in Figure 1. Briefly, restriction digestion pattern with *Nde* I producing two fragments of 102 bp and 169 bp shows the presence of genotype 1 (G1). Production of fragments of 88 bp and 183 bp with *Nde* I shows the presence of genotype 5 (G5). Similarly, a digestion pattern with *Pst* I producing two fragments of 124 bp and 147 bp size shows the presence of genotype 2 (G2). Restriction digestion with *Nla* Ⅲ produces two fragments of 115 bp and 156 bp if genotype 4 (G4) is present. Digestion pattern of *Mse* I , producing two fragments of 70 bp and 201 bp length, shows the presence of genotype 3 (G3). Genotype 6 (G6) does not contain site of any of the above restriction enzymes.

Phylogenetic analysis

DNA sequences derived from TTV ORF2 positive samples were compared to an online database for the best possible match using the BLAST (Basic Local Alignment Search Tool) program of National Center for Biotechnology Information (www.ncbi.nlm.nic.gov) and CLUSTALX program[25]. Phylogenetic tree was constructed using the neighbor-joining method in CLUSTALX program and PHYLIP version 3.5[26]. The data set was bootstrap re-sampled 1000 times to ascertain support for major branches of the tree.

RESULTS

Presence of TTV in sera samples from healthy persons and patients with different liver and renal diseases was detected using PCR amplifying the conserved region of ORF2 (107 to 715 nt) (Accession No. AB008394)[23]. TTV-DNA was detected in 175 of 578 patients, giving an overall prevalence of 30.3% (Table 1). Similarly, it was detected in 27 of 100 healthy persons (prevalence of 27%). Typical TTV amplicons of 295 bp are shown in Figure 2. The break-up of TTV prevalence in different disease groups shown its presence in 29 of the 126 (23.0%) patients with AVH, 26 of 111 (23.4%) with CVH, 46 of 132 (34.8%) with CIR, 15 of 51 (29.4%) with FHF, 21 of 93 (22.6%) with HCC and 38 of 65

Table 1 Prevalence of TTV-DNA in different liver & renal disease groups

Disease group	Number of samples	TTV-DNA positivity *n* (%)
Acute viral hepatitis (AVH)	126	29 (23.0)
Chronic viral hepatitis (CVH)	111	26 (23.4)
Cirrhosis (CIR)	132	46 (34.8)
Fulminant hepatic failure (FHF)	51	15 (29.4)
Hepatocellular carcinoma (HCC)	93	21 (22.6)
Chronic renal failure (CRF)	65	38 (58.5)
Healthy controls	100	27 (27.0)

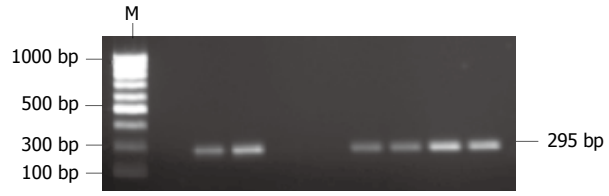

Figure 2 TTV detection by PCR (ORF2: nt 107-712). Amplifiction of ORF-2 region of TTV-DNA using NS1, NS2, NS3 and NS4 primers. (Biagini *et al*[23], 1999. Accession No.: AB008394)

Table 2 Relation between TTV infection & ALT level in different liver disease groups *n* (%)

Diseases group	TTV-DNA+ samples	ALT level (IU/L)			
		50-200	201-400	401-600	> 600
AVH	29	17 (59)	8 (28)	0	4 (14)
CVH	26	18 (69)	6 (23)	0	2 (8)
CIR	46	35 (76)	19 (41)	0	2 (4)
FHF	15	2 (13)	6 (40)	1 (7)	6 (40)
HCC	21	8 (38)	5 (24)	3 (14)	5 (24)

Percent value was computed in comparison to total number positive for TTV-DNA.

Table 3 TTV genotype analysis by RFLP *n* (%)

Restriction enzymes used	Number of cases treated	Digestion noticed	Possible TTV genotypes	Genotypes prevalence
Nde Ⅰ	55	53	G1	53 (96.4)
Pst Ⅰ	55	2	G2	2 (3.6)
Mse Ⅰ	55	0	-	0
Nla Ⅲ	55	0	-	0

Each sample was treated with four restriction enzymes (*Nde* Ⅰ, *Pst* Ⅰ, *Mse* Ⅰ, *Nla* Ⅲ) to determine genotyping of TTV following criteria mentioned in material and methods
The DNA remaining undigested with REs indicated absence of corresponding genotypes
There was no effect of *Mse* Ⅰ and *Nla* Ⅲ on TTV-DNA on digestion with these enzymes

(58.5%) with CRF.

The relation of TTV-DNA with ALT level in sera in these disease groups is shown in Table 2. The majority of cases with liver diseases had low levels of ALT, suggesting a very benign role of TTV in causing liver cell necrosis. The raised level of ALT up to the level of more than 600 IU was detected only in FHF cases, where TTV infection may not be the major cause.

The PCR products from 10 sera were processed for DNA sequencing. The sequence of TTV-DNA from each case was compared to the corresponding region of ORF2 from the TRM1 isolate of genotype 1 (Accession No. AB026345), gathered from the published literature. The full length sequence of amplicons compared to the published sequence of this same region is shown in Figure 3. The results of sequencing indicate the substitution of C by T or Y at nt position 632, A by C at 640 position, substitution of A by G at position 643, T by C at position 696 and at 770 C is being substituted by T or Y. Significant sequence divergence involving more than 2 bp was not observed. Sequencing of additional cases is underway.

Characterization of the TTV genotypes prevalent in the current study population was conducted in 55 cases by RFLP analysis of N22 nucleotide sequence belonging to ORF1. Digestion of the N22 amplicon with *Nde* Ⅰ produced fragments of 169 and 102 bp, corresponding to genotype 1, in 53 of 55 cases. Digestion with *Pst* Ⅰ produced fragments of 124 and 147 bp, corresponding to genotype 2, in 2 of 55 cases. The digestion with other restriction enzymes, *Nla*Ⅲ and *Mse* Ⅰ, could not produce any fragments, thus indicating the the absence of other genotypes. The results of genotype distribution are shown in Table 3 and Figure 4.

Genotypes of TTV in these cases were also confirmed by phylogenetic analysis of DNA sequences obtained from above. The results are shown in Figure 5. This analysis shows the maximum alignment of the sample sequence with TRM1 isolate of genotype 1 indicating a major presence of TRM1 isolate genotypes 1 and supporting the results of RFLP analysis. From these results, it is clear that genotype 1 is predominantly prevalent in all these cases with TTV infection.

DISCUSSION

TTV was assumed to be one of the possible agents

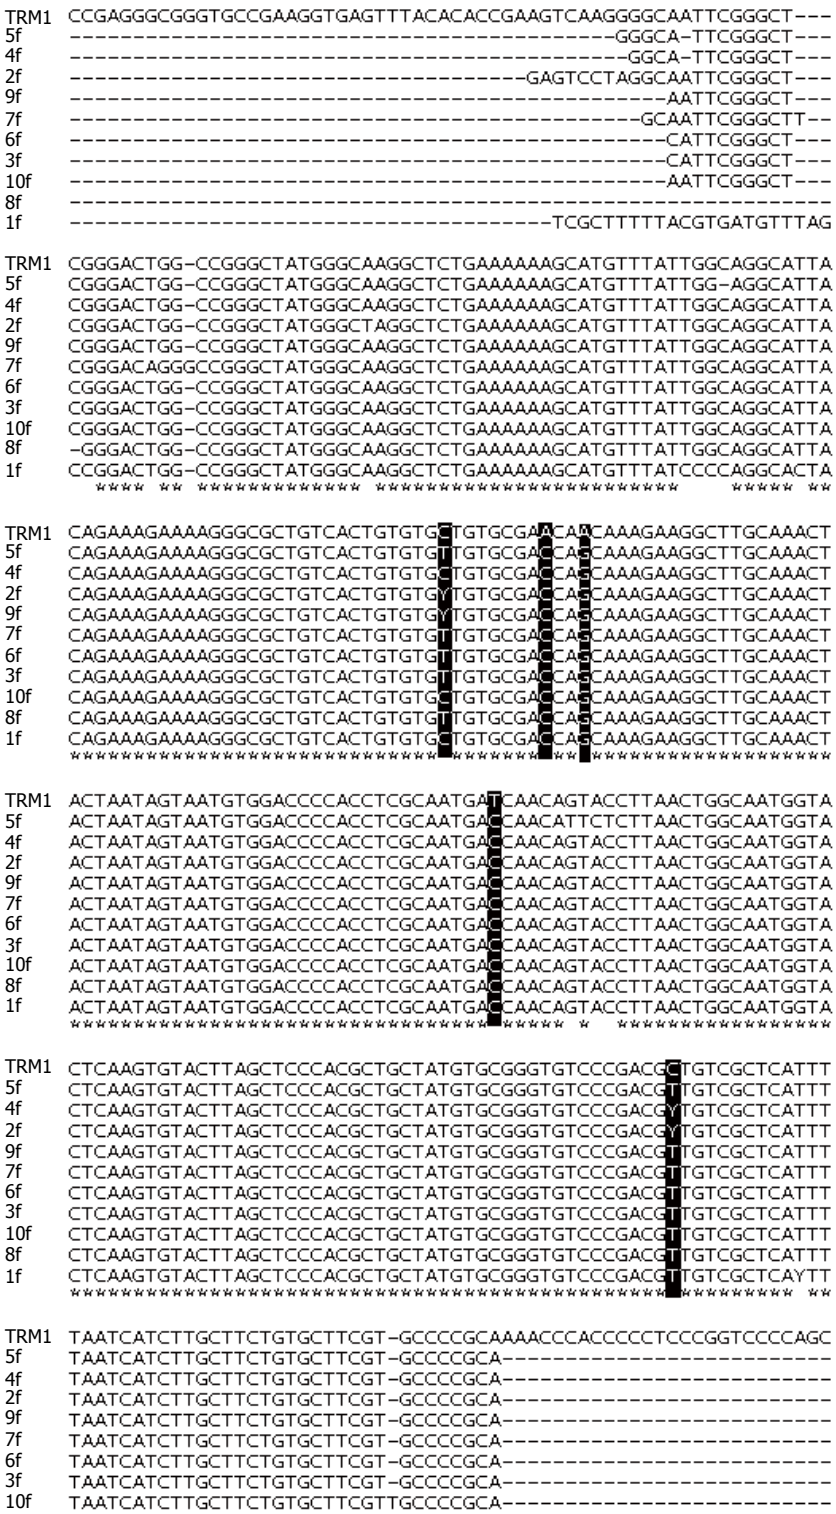

Figure 3 Sequence analysis of amplicons and their comparison with TRM1 isolates of Genotype 1 (ORF2: nt 107-712).

causing non A-G hepatitis. Its characterization and significance in causing hepatitis became more interesting with the findings by Okamoto *et al*[27], showing level of TTV-DNA in liver tissue to be 10-100 times higher than those in serum. A similar report by Nishizawa *et al*[1], who reported the appearance of TTV-DNA in the sera of patients with post-transfusion hepatitis of unknown etiology and displayed a close correlation with ALT levels, triggered an additional interest in this virus for its potential relationship with hepatitis. In India, viral hepatitis is a common disease in all parts of the country, with an established endemicity of all known hepatitis viruses. Previous studies from India have reported the existence of a group of viruses other than A-G hepatitis viruses, causing liver diseases[28]. This remains an enigma to investigate and characterize the responsible agent for non A-G hepatitis in this country. TTV attracted our attention to study this virus for its prevalence and

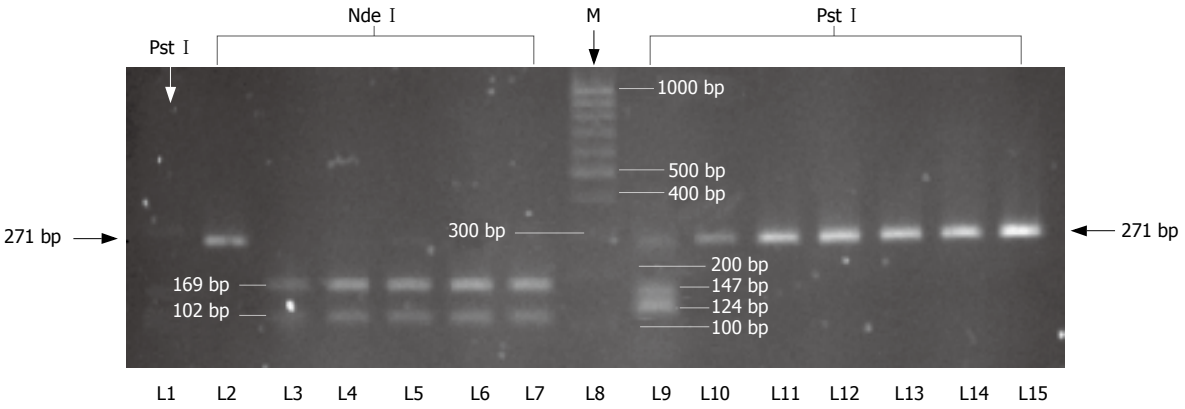

Figure 4 RFLP pattern of N22 region of TTV-DNA. L1-15: Lane 1 to lane 15. L1 is Pst I undigested product (271 bp), L2 is Nde I undigested product (271 bp), L3-7 is Nde I degested product resulting in 102 bp & 169 bp fragments, L8 is marker, L9 is Pst I digested product resulting in fragments of 124 bp & 147 bp size, L10-15 is Pst I undigested product (271 bp).

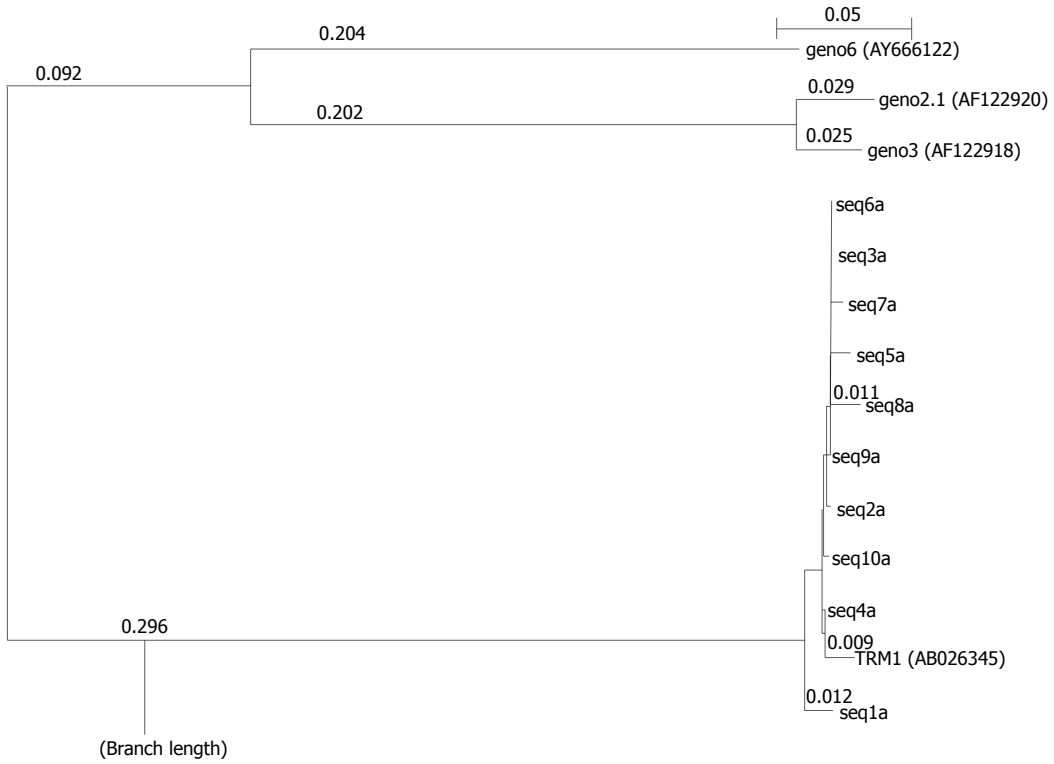

Figure 5 Phylogenetic tree analysis of amplicons with known TTV genotypes.

molecular form in Indian populations to understand its possible role in causing hepatitis as well as other blood transmitted diseases.

The prevalence of TTV infections in India has not been well documented. Only a few reports are available[19,29] that demonstrate the presence of TTV in patients population randomly selected from various studies. In this study, we found the presence of TTV-DNA in 22 to 35% of patients with different liver diseases. In CRF, on the contrary, its prevalence was relatively higher, reaching the level of 58.5%. A low prevalence of TTV in liver diseases, comparable to that reported in healthy persons (27%) supports our earlier preliminary report demonstrating a little role of TTV in liver diseases[19]. TTV infection has been found to be common in humans with prevalence which may exceed 90%. Its prevalence in healthy populations in India is lower than those previously reported for Turkish (51.6%), Japanish (92.0%) and Polish (78%) blood donors[30].

Our findings indicate that TTV prevalence in all tested groups was comparable to that among healthy controls, with the exception of a higher value in chronic renal failure patients, thus indicating that TTV infection in both the healthy population and liver disease patients is not very frequent in the northern part of India. Moreover, presence of TTV in liver diseases does not necessarily indicate its role in the etiology of liver damage. This is supported by the low level of ALT detected in all liver disease groups carrying TTV infection. Several other studies have similarly suggested that TTV does not seem to cause disease, simply acting as a by-stander virus. High prevalence in CRF patients

may be attributed to repeated blood transfusion or procedural transmission in these patients, due to the fact that TTV is frequently transmitted *via* parenteral routes.

The results of the sequence analysis in these cases has shown a point mutation at a fixed position of TTV genome, corresponding to ORF2. A nucleotide sequence heterogeneity is not very frequent, but is premature to conclude from these data about the impact of the genomic variation on its pathogenicity or change in etiological potency. It was interesting to find here that the heterogeneity in nucleotide sequence was at the same position in all amplicons studied. This suggests the likelihood of a single isotype circulating in all of the patients studied.

In this study, the genotyping of TTV was based on a RFLP procedure involving a set of four restriction enzymes targeting the N22 nucleotide region. The results indicate that most isolates assessed in our study belong to genotype 1, with only a minor contribution of genotype 2. Since there are very few reports available from our country, it is not possible to support or contradict other observations and therefore this report should be taken as accepted at this stage. While comparing TTV genotypes circulating in India with those reported from other countries, there are reports available showing evidence for the existence of 4 major genotypes, G1, G2, G3 and G4 with most belonging to G1 and G2. There are three major genotypes, i.e. G1, G2, G3, that are prevalent worldwide. Different countries have reported different genotypes in their population. G2 was reported from Western Anatolia, where appears to be very common[31]. Similarly, G3 & G4 genotypes were reported from Turkey, whereas G3 is detected primarily from Europe[32]. Asian countries have reported predominantly G4 genotype[24]. All these findings indicate diversity in the prevalence of TTV genotypes in different countries of the world. The reason(s) why G1 is predominant in India is difficult to explain and needs further investigations. The predominance of G1 was also supported by phylogenetic tree analysis of the amplicons studied in our patients' population.

In conclusion, our results indicate a low prevalence of TTV infections in North India. This also demonstrates that the prevailing genotype in North India is G1 with minor prevalence of G2 genotype. The presence of strains belonging to G1 reveals the limited genetic diversity in TTV genome circulating in this country.

ACKNOWLEDGMENTS

The authors thank and appreciate the financial aid provided by ICMR, New Delhi, India to conduct this study. Authors are also thankful to Mrs. Suman Rawat for preparing this manuscript and Mr. Surendra Singh to help in test performance.

COMMENTS

Background

Our results indicate that Torque teno virus (TTV) infection is moderately present in North India. Analysis of different genotypes of TTV demonstrate that G1 is the predominant genotype prevailing in North India. The presence of strains belonging mostly to G1 reveals that there is a limited genetic diversity in the TTV genome circulating in this part of country.

Research frontiers

There are only preliminary informations available on the status of TTV in India. There is a need to study and understand the endemicity, epidemiology and etiological potential of TTV infection in various diseases. The present study was planned to determine the prevalence of TTV in North India and which was the prevailing genotype(s).

Innovations breakthrough

The prevalence of TTV infection was observed in various categories of liver and renal diseases. In particular, the rate of TTV infection in liver diseases was comparable to that of a normal healthy populations, although it was significantly higher in chronic renal failure patients. In all these cases genotype 1 (G1) was the predominant genotype with a minor contribution of genotype 2 (G2).

Applications

The results of prevalence and genotyping of TTV infection in Indian patients' will be helpful in understanding the role of TTV in causing various diseases.

Peer review

Authors have studied TTV infection and found that TTV infection has minor role in causation of liver diseases. Its significant prevalence in renal diseases needs further investigations.

Abstract

AIM: To examine the expression of *beta-catenin* in colorectal cancer and look for association with other clinico-pathological parameters.

METHODS: Tumor samples from 163 cases of colorectal cancer (CRC) who had undergone primary colectomy between May, 1998 and November, 2002 with complete follow-up data for either 5 years or until death were recruited for a beta-catenin immunohistochemical study. The percentage of immunoreacted tumor cells was defined as overall staining density (OSD) and percentage of cells having nuclear localization was counted as nuclear staining density (NSD). Univariate exploration used log-rank test and multivariate survival analysis used Cox's hazard regression model.

RESULTS: Beta-catenin immunoreactivity was detected in 161 samples (98.8%), of which 131 cases had nuclear staining. High OSD (≥ 75%), detected in 123 cases (75.5%), was significantly associated with earlier clinical staging ($P < 0.01$), lower nodal status ($P = 0.02$), non-metastatic status ($P < 0.01$) and better differentiation ($P = 0.02$). Multivariate analysis found that high OSD was independently associated with better survival [Cox's hazard ratio 0.51, 95% confidence interval (CI) 0.31-0.83]. Although high NSD (≥ 75%) was correlated with high pre-operative serum CEA ($P = 0.03$), well differentiation ($P < 0.01$), and increased staining intensity ($P < 0.01$), the parameter was not significantly associated with survival.

CONCLUSION: Unlike previous reports, the study did not find a predictive value of nuclear beta-catenin in CRC. Instead, the overall expression of beta-catenin in CRC showed an association with better differentiation and earlier staging. Moreover, the parameter also independently predicted superior survival.

Key words: Colorectal carcinoma; *beta-catenin*; *CTNNB1*; Wnt-signaling pathway; Prognosis

INTRODUCTION

According to the recent World Cancer Report[1], colorectal cancer (CRC) ranks as the third most common malignancy, following breast and lung cancers. The incidence of CRC in developing countries, including Thailand, has been increasing in recent years[2]. The increasing adoption of Western life style habits in these countries is believed to be responsible for the growing magnitude of the CRC problem. Although surgical therapy is the mainstay treatment for early stage CRC, there is an expanding role for multidisciplinary treatment. As adjuvant treatments are considered based on an individual patient risk, prognosticating factors

are essential for risk stratification. Well accepted factors influencing outcome in CRC patients are tumor invasion, nodal status, lymphovascular invasion and serum carcinoembryonic antigen level[3,4]. Various histological parameters and molecular markers have been investigated and some have shown promising results in CRC, such as microvascular density[5] and microsatellite instability[6]. However, none of those biological factors have yet been integrated into the treatment algorithm.

Beta-catenin, a central molecule of the Wnt-signaling system, expresses in epithelial cells as two main forms; membrane localization and nuclear accumulation. Membrane localization can be detected in normal cells and tumor lineage, whereas nuclear beta-catenin is exclusively detected in immature cells and tumor cells[7]. Evidence of somatic mutations and nuclear accumulation of beta-catenin in various pediatric cancers signifies a role of the Wnt-signaling pathway in their tumorigenesis[8,9]. Accumulation of beta-catenin is a result of defects in its degradation process, which usually takes place in the cytoplasm by an interaction between *beta-catenin* and a complex of *APC*, *AXIN* and *GSK-3-beta*. Stabilized beta-catenin translocates into the nucleus where the protein acts as a transactivation factor and promotes tumor growth. In CRC, the molecular pathology involving members of the pathway has been elucidated[10]. Inactivation of APC, the tumor suppressor gene which regulates intracellular level of beta-catenin, is one of the earliest events observed in CRC development. Loss of APC function leads to pathologically increased cytoplasmic beta-catenin, which can be translocated into the nucleus or to the cell membranes[11]. At cell membranes, beta-catenin forms a complex with E-cadherin which plays a role as an adhesion molecule. Furthermore, Wnt-signaling may contribute to the process of colonic epithelial cells differentiation[12].

Recent studies have focused on the clinical meaning of nuclear beta-catenin accumulation in CRC and demonstrated its diagnostic as well as prognostic significance[13-19]. A high density of beta-catenin nuclear accumulation was associated with higher mortality in selected groups of CRC patients[14,18,19]. However, data from different series have been inconsistent. We conducted a study of beta-catenin immunohistochemistry in our clinical CRC series. With awareness that beta-catenin does not have only a growth promoting role, we did not limit our analysis to nuclear accumulation only, but also examined overall staining density against outcomes. The study failed to find evidence that nuclear beta-catenin accumulation could be a risk factor for unfavorable outcome in CRC. However, the study found a strong correlation between overall beta-catenin expression and better survival probability.

MATERIALS AND METHODS

CRC patients

Archival tumor samples from 163 non-consecutive patients with histologically proven colonic adenocarcinoma who underwent primary resection at Songklanagarind Hospital, a tertiary teaching hospital in southern Thailand, between May, 1998 and November, 2002, were examined for this immunohistochemical study. CRC patients who were treated elsewhere, received a non-curative excision so that accurate pathological staging could not be determined, or were lost to follow-up after surgical treatment were not included in this study. All patients were evaluated for at least 5 years after surgery or until death. Survival status was evaluated by the institutional Tumor Registry Unit on December, 2007.

Before the surgical treatment, all patients had routine pre-operative investigations, including chest-X-rays, blood chemistry including serum albumin and carcinoembryonic antigen (CEA), and an evaluation for liver metastasis by ultrasonography and/or computerized tomography. Primary tumor staging followed the sixth edition of TNM staging system of the American Joint Committee on Cancer (AJCC)[20]. Adjuvant chemotherapy was given to stage Ⅲ, colonic cancer patients, and adjuvant chemo-radiation was reserved for stages Ⅱ and Ⅲ rectal cancer cases. In stage Ⅳ CRC patients, chemoradiation therapy for advanced disease was considered for patients who were in status 0-2, according to the Eastern Cooperative Oncology Group. Follow-up visits were scheduled at 1-mo intervals during the first year after surgery, every 3-mo period during the second year, and every 6 mo, thereafter. Access to pathological samples and clinical records was approved by the institutional research ethics committee.

For analysis, age of the patients was stratified to less than 65 years and 65 years or more. Pre-operative serum CEA level was stratified at 5 ng/mL.

Beta-catenin immunohistochemistry

Hematoxylin and eosin stained slides were re-examined by a gastrointestinal pathologist and selected for the beta-catenin immunohistochemical study. From formalin-fixed paraffin embedded tissue, sections of 3 micrometer thickness were cut, deparaffinized, and rehydrated. Beta-catenin monoclonal antibody (1:500, Abcam Plc., UK) was used as the primary antibody. The staining protocol followed the manufacturers' instructions of Dako EnVision + System (Dako). Briefly, antigen retrieval was performed in a microwave oven using Tris-EDTA buffer. Endogenous peroxidase activity was blocked with 0.03% hydrogen peroxide containing sodium azide. Slides were incubated with non-immune serum for 30 minutes and were then incubated with the primary antibody for 120 minutes in a moist chamber, followed by a 30 minute incubation with peroxidase labeled polymer conjugated to goat anti-mouse immunoglobulins. Color was then developed by the liquid 3,3'-diaminobenzidine chromogen solution. Light counterstaining was done with hematoxylin. All immunohistological staining in this study was performed by one technician.

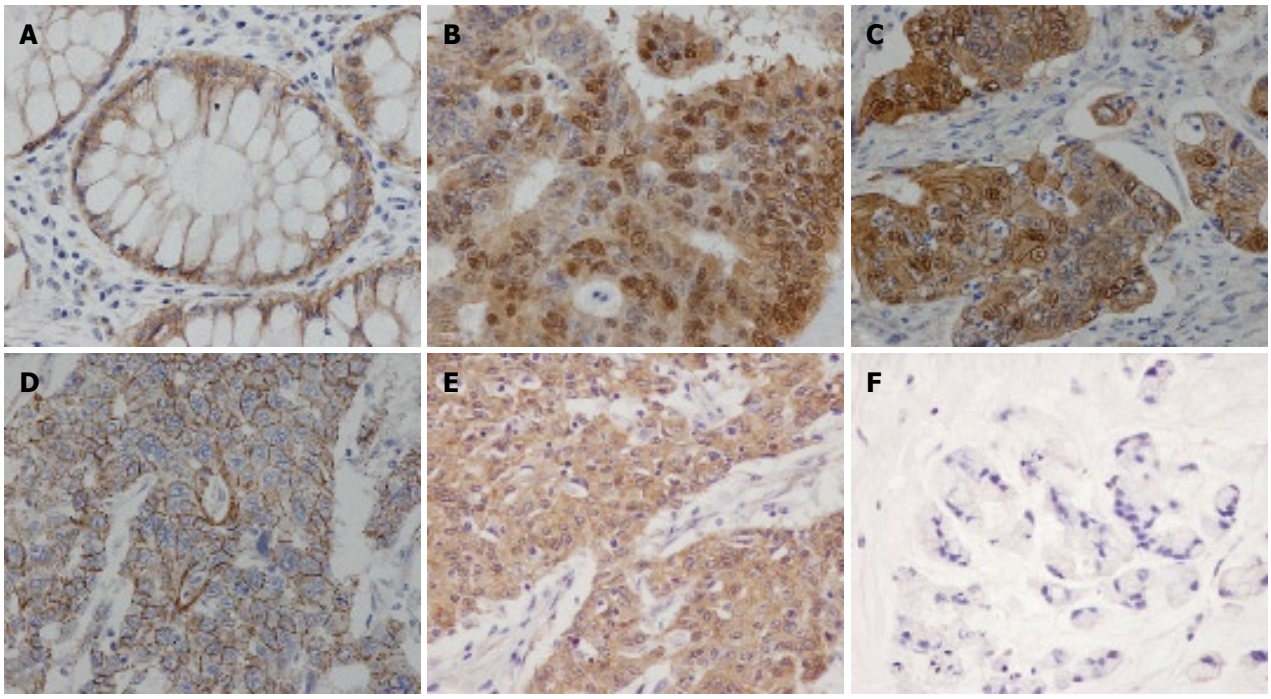

Figure 1 Immunohistochemistry study of beta-catenin in CRC. **A**: Membranous staining pattern in normal colonic mucosa; **B**: Nuclear staining pattern and high OSD in a case with well differentiation histology; **C**: Nuclear and membranous staining pattern; **D** Membranous staining pattern; **E** Cytoplasmic staining pattern; **F**: Very weak staining intensity in a case of poorly differentiated CRC. (40 × magnification).

Staining intensity of beta-catenin was graded as weak, moderate, strong and very strong intensity. Intracellular localization patterns of beta-catenin were categorized according to the dominant pattern as nuclear staining, nuclear together with membrane staining, cytoplasm staining and membrane staining.

Beta-catenin nuclear staining density (NSD) was defined as the number of tumor cells with nuclear staining per 100 cells examined. Overall staining density (OSD) meant number of beta-catenin immunoreacted cell per 100 tumor cells examined. Tumors were defined as having high NSD when NSD was 75% or more, and OSD at 75% or more indicated high OSD. The pathologists responsible for histological slide examination were blinded to the clinical outcomes before data analysis.

Statistical analysis

Death from cancer was assigned as failure in the overall survival analysis. Local recurrence and distant metastasis were counted as failure in disease-free survival, which were analyzed only for cases in AJCC stage Ⅰ-Ⅲ. Univariate analysis used Chi-square test to evaluate any association between parameters and Log rank test for survival analysis. Multivariate survival analysis used a multiple Cox's regression model. Parameters with *P*-value less than 0.3 from the Log rank test were included for analysis. Those with a *P*-value $\geqslant$ 0.05 in Cox's regression were excluded until every parameter in the model was independently associated with survival. A *P*-value of less than 0.05 was considered statistically significant.

Calculations used the R-program (Foundation for Statistical Computing, Vienna, Austria).

RESULTS

The clinical characteristics and pathological descriptions of the 163 patients are shown in Table 1. The mean age of the patients was 61.6 years (range 20-88 years). Median pre-operative serum CEA was 4 ng/mL (range 0.5-1215 ng/mL). Eleven of the primary tumors (6.7%) were at the cecum, 13 (8.0%) at the ascending colon, 5 (3.0%) at the hepatic flexure colon, 11 (6.7%) at the transverse colon, 2 (1.2%) at the splenic flexure colon, 3 (1.8%) at the descending colon, 37 (22.7%) at the sigmoid colon and 81 (49.7%) at the rectum.

Staining characteristics of beta-catenin

Beta-catenin immunoreactivity was detected in 161 cases (98.8%). Among these, 131 cases (80.3% of all cases) were positive for nuclear beta-catenin staining while the remaining cases showed limited immunoreactivity within the cell membranes and/or cytoplasm. Among cases with positive nuclear beta-catenin, 40 (30.5%) were also positive for membrane immunoreactivity. Concerning staining intensity, 74 cases (45.4%) displayed very strong immunoreactivity, 35 (21.5%) showed strong intensity, 27 (16.6%) had moderate intensity, and 25 (15.5%) cases exhibited weak staining (Figure 1). Interestingly, nuclear beta-catenin was detected in a significantly higher proportion in cases with strong or very strong intensity (99.1%), compared to cases with moderate or weak immunoreactivity (44.23%). Cases with positive nuclear staining had a higher incidence of lymph node metastasis (50.3%) when compared to cases with only membranes or cytoplasm staining (33.3%), however, the difference was not statistically significant (Chi-square *P*-value = 0.09).

High (⩾ 75%)	62 (52.8)	7 (17.5)	9 (64.2)	

Overall staining density ranged from 5% to 100% with an average value of 86%. One hundred and twenty-three cases (75.5%) were rated as high OSD. On univariate analysis, high OSD was significantly associated with earlier AJCC staging, lower nodal status, non-metastatic status and better differentiation status (Table 1).

Among the 131 cases in which the nuclear staining appeared positive, nuclear accumulation density ranged from 1% to 99 % with an average value of 65.6%. Eighty-six cases (52.8%) had nuclear accumulation density at 75% or more and were counted as high NSD. High NSD had significantly positive correlation with pre-operative serum CEA ($P = 0.03$), well differentiation ($P < 0.001$), and staining intensity ($P < 0.001$). In addition, cases with NSD at 25% or more had significantly higher incidence of nodal metastasis at the operation ($P = 0.01$).

Survival analysis

There were no missing data in this study. The mean follow-up period was 56.2 mo. Overall survival and disease-free survival at 5-years were 57.7% and 54.0%, respectively. Univariate analysis found that AJCC staging, nodal status, metastatic status and tumor location were among the clinical parameters that had significant association with both overall survival and disease-free survival. Tumor differentiation was correlated with disease-free survival and the overall survival only at borderline significance (Log rank *P*-values 0.05 and 0.06, respectively) (Table 2). CEA at 5 ng/mL or more predicted significantly poorer outcome only in the AJCC stage I subgroup (Log rank *P*-value 0.045).

Five-year overall survival in patients with high NSD (59.3%) was not different from cases with low density (55.8%) when compared by Log-rank analysis ($P = 0.59$).

Parameter	Intensity-adjusted 5-yr survival	
	5-yr DFS (%)	5-yr OS (%)
OSD		
Low (< 75%)	34.9	38.2
High (⩾ 75%)	73.2	77.8
NSD		
Low (< 75%)	55.3	58.4
High (⩾ 75%)	68.7	75.7

OS: Overall survival; DFS: Disease free survival; OSD: Overall staining density; NSD: Nuclear staining density.

On the other hand, OSD showed a significant influence on both overall ($P < 0.001$) and disease-free survival probability ($P < 0.001$) (Figure 2). Two and five-year overall survival rates in cases with high OSD (84.6% and 60.5%, respectively) were obviously higher than low OSD (50.0% and 34.7%, respectively). Adjusting for the staining intensity resulted in a greater difference of 5-year overall survival probability between the high OSD (77.8%) and low OSD group (38.2%) (Table 3).

With Cox's hazard multivariate analysis, the final model demonstrated that perioperative parameters that were independently associated with survival probability in colorectal cancer were nodal status, metastatic status, and OSD (Table 4). When subgroup analysis was performed for cases without metastasis at the time of diagnosis, nodal status (hazard ratio 2.0, $P < 0.001$), OSD (hazard ratio 0.36, $P < 0.001$), serum CEA at 5 ng/mL or more (hazard ratio 1.8, $P < 0.001$) and differentiation status (hazard ratio 1.4, $P < 0.02$) were significantly

Table 4 Final Cox's regression model (*P*-value of the model < 0.001), Log likelihood = -347.75

Parameter	Hazard ratio	95% CI	*P*
Nodal status	1.87	1.43-2.44	< 0.001
Metastatic status	7.50	3.89-14.43	< 0.001
OSD	0.51	0.31-0.83	0.007

OSD: Overall staining density.

associated with disease-free survival. Within the same non-metastatic subgroup, factors that significantly fit the final regression model analyzing overall survival were nodal status (hazard ratio 2.3, $P < 0.001$), OSD (hazard ratio 0.4, $P < 0.001$), and age more than 65 years (hazard ratio 1.6, $P < 0.04$).

Excluding OSD from the model, the Cox's hazard analysis showed that high NSD had a hazard ratio of 2.04 [95% confidence interval (CI) 1.0-4.2], compared with NSD less than 50, when adjusted for tumor stage, differentiation, nodal and metastatic status.

DISCUSSION

An outcome prognosticating factor is an essential component for risk categorization in utilizing the risk-based therapy concept. Defining an individual at-risk of unfavorable prognosis helps in selecting patients who are most likely to benefit from intensive adjuvant treatment. Earlier successful examples of risk-based therapy in biological factors have been integrated into the management scheme are neuroblastoma[21], breast cancer[22] and gastrointestinal stromal tumors[23]. In CRC, although various biological outcome predictors have been discovered, those parameters have not yet been adopted into a standard treatment protocol of CRC.

The Wnt-signaling pathway plays several roles in humans; a physiological role in normal development and a pathological role in tumorigenesis[7]. A common denominator of the pathway activation is the intracellular amount and localization of beta-catenin, the central molecule. The carcinogenic process of CRC could be linked to the Wnt-signaling cascade through the loss of APC function, which has been attributed to up to 60% of sporadic tumors[24]. Because APC is essential for clearance of excessive intracellular beta-catenin, accumulation of beta-catenin occurs as a result of APC down-regulation. Positive nuclear accumulation has been reported between 21%-100% in sporadic CRC[15-17,19], depending on the characteristics of the patients in the series, the staining protocol and their histological parameter. In our study, tumor cells with nuclear staining was detected in at least 80% of the cases, however, only 66% of these cases had high NSD. In a series of 136 patients with CRC, Cheah and colleagues identified a negative survival influence of nuclear beta-catenin[15]. In their study, the nuclear beta-catenin was covariate with tumor stage; however, it could be a strong prognosticator when combined with another factor p27b12. Two publications by Wong and colleagues reported that progression of nuclear beta-catenin immunohistochemistry scores was correlated with advances in the malignant potential of colonic neoplasms[13,14]. The studies also showed survival differences between cases with high and low expression density of nuclear beta-catenin. Outcome prognosticating ability of non-membranous beta-catenin was also supported by another two other separate works from Europe[16,17]. Lines of epidemiological evidence suggested that nuclear accumulation of beta-catenin could be employed as a factor identifying cases at risk of treatment failure. However, consensus histological criteria had not been established at the time of there studies and most of them focused only on nuclear localization.

Our study aimed to evaluate the roles of beta-catenin in our clinical series of CRC patients in whom the therapeutic process was homogenously performed by the same multidisciplinary team and the follow-up period was long enough to give reliable data. Apart from nodal status, pre-operative CEA and chronological age predicted disease-free survival and overall survival non-metastatic CRC in the series. Although NSD showed no significant survival function, hazard analysis demonstrated that the factor was associated with mortality risk when other factors were adjusted. Moreover, high NSD was linked to lymph node metastasis and high serum CEA, a finding consistent with previous reports which found that nuclear-accumulated beta-catenin predicted an unfavorable outcome. However, in our series, the influence of nuclear beta-catenin was not independent from other major prognosticators. On the other hand, when we analyzed the overall expression of beta-catenin in term of OSD, it was found that the factor was strongly associated with survival advantage. This conflicting data could not be simply explained by using the mainstream theory of the Wnt-signaling cascade. A positive correlation between NSD, OSD and staining intensity was one of the interesting findings in our study. If NSD is regarded as a localization parameter of beta-catenin and OSD represents an overall expression level of the protein, it appears that the two parameters are co-variant and OSD has much stronger influence on survival.

Besides the growth promoting function, alternative roles of beta-catenin should not be overlooked. Beta-catenin performs necessary physiologic tasks in cellular differentiation and cell-to-cell adhesion[25]. Our study detected a significant correlation between beta-catenin expression and tumor differentiation. Poorly differentiated tumors harbored a significantly smaller proportion of high NSD and OSD. This association was also shown in previous series, although the survival correlation appeared in an opposite direction[15]. A recent study from our group demonstrated that beta-catenin promotes differentiation in another malignancy, neuroblastoma[26]. If these things are taken together, it might be hypothesized that beta-catenin plays a role in

maintaining a good differentiation status in cancer cells. Furthermore, the physiologic function of beta-catenin at the cell membranes is related to cell-to-cell adhesion, which possibly prevents metastasis. A study by Lugli[18] and colleagues found that membranous beta-catenin co-localized with E-cadherin and loss of membranous or cytoplasmic beta-catenin characterized a higher stage disease. In our series, loss of OSD was evident in advanced stage CRC, and there was also a significantly higher OSD proportion in early nodal status. The physiologic functions of beta-catenin in tumor cell differentiation and adhesion may explain our findings. However, to conclude that beta-catenin expression provides a protective role in CRC, further functional genetics research needs to be performed.

In summary, expression and localization of beta-catenin immunohistochemistry in a series of CRC were analyzed. The study did not find a prognosticating role of the nuclear localization; however, overall expression of beta-catenin was found as a strong and independent predictor of favorable outcome.

ACKNOWLEDGEMENT

This work was partially supported by the Faculty of Medicine, Prince of Songkla University. The authors thank Kanda Tongmitr for her assistance in pathological techniques. Arinda Ma-a-lee contributed greatly to the statistical analysis. English language in the manuscript was kindly edited by Dave Patterson.

COMMENTS

Background

The authors examined the expression of beta-catenin in colorectal cancer and looked for association with other clinicopathological parameters, and outcomes.

Research frontiers

Beta-catenin immunohistochemistry was performed in 163 cases of colorectal cancer in whom the outcome data was clearly available.

Innovations and breakthroughs

The study found certain data that was not in-line with previous reports. Instead of nuclear beta-catenin that was associated with survival, the overall staining density of this protein showed strong and independent correlation with overall survival and disease-free survival. Moreover, the parameter (overall staining density) also had positive association with tumor differentiation.

Applications

The data suggested that beta-catenin may have an alternative role in colorectal cancer that was associated with differentiation of tumor cells.

Terminology

Beta-catenin nuclear staining density (NSD) was defined as the number of tumor cells with nuclear staining per 100 cells examined. Overall staining density (OSD) meant number of beta-catenin immunoreacted cell per 100 tumor cells examined. Tumors were defined as having high NSD when NSD was 75% or more, and OSD at 75% or more indicated high OSD.

Peer review

This is a well analyzed paper and provides a new insight into the importance of beta catenin staining as a prognostic marker in colorectal cancer.

Abstract

AIM: To observe the therapeutic effects of new traditional Chinese medicine (TCM) therapy on coagulation disorder and accompanying intractable jaundice in HBV-related liver cirrhosis patients.

METHODS: Using stratified random sampling according to fibrinogen (Fib) levels, 145 liver cirrhosis patients due to hepatitis B complicated by coagulation disorder were treated. Of them, 70 in research group were treated with TCM by "nourishing yin, cooling blood and invigorating blood circulation" and Western medicine, 75 in control group were treated with conventional Western medicine. The indexes of liver function, coagulation function and bleeding events were observed and compared.

RESULTS: The prothrombin time (PT) was shorter and the fibrinogen (Fib) level was higher in the research group than in the control group (Fib = 1.6-2.0 g/L, 1.1-1.5 g/L, and ≤ 1.0 g/L). The total bilirubin (TBIL) level was significantly lower in the research group than in the control group, except for the subgroup of FIB ≤ 1.0 g/L.

CONCLUSION: TCM therapy can improve coagulation function and decrease TBIL.

Key words: Combination of traditional Chinese and Western medicine; Liver cirrhosis; Coagulation disorder; Nourishing yin; Cooling blood and invigorating blood circulation

INTRODUCTION

About 25% of hepatitis B virus (HBV)-infected patients would die of severe chronic liver diseases such as liver cirrhosis and liver failure[1]. Coagulation disorder is prevalent in patients with chronic liver disease which is usually detected in laboratory tests and characterized by prolonged prothrombin time (PT), decreased fibrinogen (Fib, coagulation factor Ⅰ) level and thrombocytopenia[2]. For the lack of blood products (plasma and coagulation factor) and high medical expenditure, economical and effective treatment modalities for coagulation disorder are demanded. Moreover, intractable jaundice accompanying coagulation disorder in HBV-related liver cirrhosis patients is also a puzzle and there is no effective treatment for it. We have proved in our prophase researches that coagulation function indexes are significantly related to total bilirubin (TBIL). Therefore, this study was to observe the therapeutic effects of traditional Chinese medicine (TCM) on coagulation disorder and accompanying intractable jaundice in HBV-related liver cirrhosis patients.

MATERIALS AND METHODS

Inclusion criteria

Patients with HBV-related liver cirrhosis[3,4], patients with

coagulation disorder (PT > 14.5 s, fib < 2.0 g/L with or without platelets < 100×10^9/L before admission), patients with no bleeding events (such as epistaxis, gum bleeding, hematemesis and hematochezia before admission), and those at the age of 20-75 years, were included in the study.

Exclusion criteria

Patients with coagulation disorders accompanying liver cirrhosis due to different reasons (such as parasitic infection, autoimmune liver disease, intrahepatic cholestasis, alcoholic liver disease, drug-induced liver disease, fatty liver disease, liver hereditary diseases and liver vascular diseases), patients with other hepatovirus superinfection, haemolysis, disseminated intravascular coagulation (DIC), complications of severe diseases (such as cardio-cerebrovascular disease, hematological disease, respiratory disease, urinary disease and psychosis), and those with pregnancy and lactation, patients with poor compliance, incomplete clinical data, hospitalization time < 14 d, were excluded from the study.

All patients were given their informed consent before therapy.

Information about patients

All the 145 patients with HBV-related liver cirrhosis accompanying coagulation disorder were randomly chosen according to their Fib levels from the Third Affiliated Hospital of Sun Yat-Sen University from January 2002 to February 2008. The data were collected and analyzed retrospectively. The 145 patients were assigned to three subgroups

Subgroup A: Sixty patients (Fib = 1.6-2.0 g/L) were divided into in research group and control group (n = 30). There were 20 males and 10 females in the research group, their average age was 49.83 ± 12.32 years and the average hospitalization time was 35.73 ± 24.20 d. There were 21 males and 9 females in the control group, their average age was 44.67 ± 10.34 years and the average hospitalization time was 36.83 ± 18.15 d.

Subgroup B: Sixty patients (Fib = 1.1-1.5 g/L) were divided into research group and control group (n = 30). There were 20 males and 10 females in the research group, their average age was 50.27 ± 11.71 years and the average hospitalization time was 37.10 ± 19.94 d. There were 21 males and 9 females in the control group, their average age was 49.60 ± 10.45 years and the average hospitalization time was 30.37 ± 16.81 d.

Subgroup C: Twenty-five patients (Fib ⩽ 1.0 g/L) were divided into research group (n = 10) and control group (n = 15). There were 7 males and 3 females in the research group, their average age was 40.80 ± 8.92 years and the average hospitalization time was 41.70 ± 27.57 d. There were 10 males and 5 females in the control group, their average age was 43.20 ± 10.17 years and the average hospitalization time was 54.93 ± 37.10 d.

Methods

Control group: Patients in the control group were treated with conventional Western medicine supplemented with coagulation factors and platelets. Artificial liver system therapy and liver transplantation were not performed.

Research group: Patients in the research group were treated with TCM by nourishing yin, cooling blood and invigorating blood circulation (basic prescription: Yiwei Decoction and Dahuang Zhechong Pills: shashen 15 g, maidong 15 g, shengdi 30 g, yuzhu 15 g, dahuang 6-30 g, huangqin 12 g, gancao 6 g, taoren 9 g, xingren 12 g, shaoyao 12 g, shuizhi 6 g, tubiechong 6 g), in combination with conventional Western medicine. The prescription was modified if symptoms changed.

The herbal decoction was taken half an hour after each meal, one dose a day for 2-3 wk according to the severity of liver cirrhosis.

Observation indexes

Observations included serological index, coagulation function (PT, Fib and PLT), liver function [alanine aminotransferase (ALT), aspartate aminotransferase (AST), albumin (ALB) and TBIL], bleeding events and other complications, death rate and side effects during the treatment.

Statistic analysis

Statistical analysis was performed using Spss11.5. Data were expressed as mean ± SD and analyzed by t-test. Numeration data were analyzed by chi square test. $P < 0.05$ (two-sided test) was considered statistically significant.

RESULTS

Analysis of comparability

Fib level was used as the standard for all the patients who were divided into three subgroups. Chi square test and t-test showed that the general conditions of patients in the research and control groups were similar (Table 1). The serological indexes of coagulation function, liver function and the severity of liver cirrhosis were similar in the two groups before treatment (Tables 2-4). Improvement in coagulation function of the three subgroups was comparable.

Analysis of data

PT, Fib and TBIL levels were significantly higher in subgroups (Fib = 1.6-2.0 g/L and Fib = 1.1-1.5 g/L) of the research group than those in subgroup of the control group after treatment. There was no significant difference in ALB and PLT between the groups (Tables 5 and 6).

PT and Fib levels were significantly higher in subgroups (Fib ⩽ 1.0 g/L) of the research group were significantly higher than those in subgroups of the control group after treatment. There was no significant difference in ALB, PLT and TBIL between the two groups (Table 7).

Bleeding events occurred in 3 patients of the

Table 1 Balance test for general information

		Cases (*n*)	Sex (male/female)	Age (mean ± SD)	Days of hospitalization (mean ± SD)

	After treatment	0.90 ± 0.36	39.08 ± 22.78	70.93 ± 54.06	173.47 ± 149.30	35.86 ± 5.71
P value		0.013	0.043	0.421	0.061	0.807

PT and Fib were significantly higher in the research group than in the control group after treatment.

research group and in 19 patients of the control group ($P < 0.0001$).

DISCUSSION

Fib, which has coagulation function, is a kind of protein that is synthesized in the liver. Fib, the most important coagulation factor in human body, is transformed into fibrin in the coagulation process. Fib decrease is a sensitive change in chronic hepatitis patients, which means that the biological enzyme is declined and the coagulation function is abnormal[5]. Fib can also be used to diagnose DIC caused by liver diseases. It was reported that Fib contents are closely related with the damage degree of hepatocytes, the severity and prognosis of liver cirrhosis[6-10]. Therefore, Fib was chosen as a criterion in this research.

TCM believes that the original etiological factor for HBV infection is "damp-heat", which belongs to the category of warm pathogens. By analyzing and differentiating the development of an epidemic febrile disease and by studying conditions of the four systems (Wei, Qi, Ying, Xue) of patients with coagulation disorder, Yingfen syndrome and Xuefen syndrome are diagnosed. As one of the febrile disease characteristics, warm pathogen can injure yin easily, meanwhile "cooling the blood and invigorating blood circulation" is the traditional therapeutic method for Xuefen syndrome. Therefore, we chose TCM to treat liver cirrhosis accompanying coagulation disorder by nourishing yin, cooling the blood and invigorating blood circulation.

This study showed that TCM therapy for liver cirrhosis could improve PT and Fib, and reduce occurrence of bleeding events by improving microcirculation, increasing blood and oxygen supply to the liver, thus promoting regeneration and restoration of hepatocytes. It was reported that this new TCM therapy has anti-thrombosis effects by relieving the microangium spasm and hypercoagulable state in the liver[11-15]. Heat-clearing and blood-cooling drugs can stimulate pituitary-adrenal axis, enhance stress capability, dredge microcirculation, protect vessel wall, and maintain the balance between coagulation and anti-substance[14], suggesting that such drugs can promote cell proliferation and speed up cell cycle progression. This new TCM therapy can alleviate hepatocellular immune injury caused by HBV infection and degenerative necrosis of hepatocytes. It was reported that blood circulation promoting therapy can inhibit cellular and humoral immunity. Herbal medicine for cooling the blood and invigorating blood circulation can alleviate immune injury by inhibiting autoimmune effect and γ-globulin[12,14,15], and damaged hepatocytes and vascular endothelial cells caused by endotoxmia and inflammatory factors. Studies showed that nourishing yin, cooling the blood and invigorating blood circulation can antagonize apoptosis of vascular endothelial cells

induced by endotoxin[16-18]. The reason why PLT does not ameliorate is that coagulation disorder in patients with HBV-related liver cirrhosis is usually accompanied with hypersplenia and PLT is severely destroyed and phagocytosed by the spleen. In addition, PLT does not come from liver but from bone marrow megakaryocytes.

This study also showed that the new TCM therapy could significantly decrease TBIL. TCM believes that jaundice would not regress easily if only the blood circulation is fluent. Since the pathogenesis of jaundice is blood stasis which is one of the pathogenic factors for coagulation disorder in liver cirrhosis patients, the new TCM therapy can achieve the purpose of treating different diseases with the same method. On the one hand, it can improve hepatocyte function by exerting its anti-thrombosis microcirculation effect and by improving the blood circulation of liver. On the other hand, it can promote biliary excretion by inhibiting immunologic reaction, alleviating inflammation of intrahepatic bile ducts, which can improve the coagulation disorder in liver cirrhosis patients and decrease jaundice. The reason why TBIL can be decreased only when Fib > 1.0 g/L, may be due to the impaired liver function, a short course of treatment and a relative small sample.

In conclusion, this new TCM therapy can improve coagulation function indexes, such as PT and Fib in patients with HBV-related liver cirrhosis and reduce bleeding events which can also decrease TBIL.

COMMENTS

Background

Hepatitis B virus (HBV) infection is prevalent all over the world and 2000 million people have been infected with HBV, 350 million of them are chronic HBV carriers and 25% of HBV-infected individuals will die of chronic severe liver diseases. Coagulation disorder is an important clinical feature of chronic liver disease characterized by prolonged PT, decreased Fib and thrombocytopenia. HBV infection usually leads to bleeding, anaemia, decreased granulocytes, thrombosis and even multiple organ failure,*etc*. Plasma infusion can improve coagulation disorder. We performed this study to find a new traditional Chinese medicine (TCM) therapy for coagulation disorder in patients with HBV-related liver cirrhosis.

Research frontiers

Conventional treatment modalities for coagulation disorders in Western medicine are to improve liver function, avoid using drugs which can affect platelet function and aggravate coagulation disorder, and supply vitamin K, coagulation factors and platelets. Due to the disadvantages of blood products, such as limited supply, allergic reaction and virus infection during infusion, the third generation recombinant coagulation factor VIIa (rhVIa) is a highlight and has been used in clinical practice. In the field of TCM, promoting blood circulation to remove blood stasis for coagulation disorder can increase fibrinogen (Fib), improve prothrombin time (PT) and eliminate complications.

Innovations and breakthroughs

Fib level was used as a criterion to observe the new TCM therapeutic effects on coagulation disorder in patients with HBV-related liver cirrhosis. Early treatment of coagulation disorder by nourishing yin, cooling the blood and invigorating blood circulation before occurrence of bleeding events can reduce bleeding events and prevent disseminated intravascular coagulation (DIC). Meanwhile, this TCM therapy could improve coagulation function and decrease total bilirubin (TBIL).

Applications

The present study confirmed that the TCM therapy by nourishing yin, cooling the blood and invigorating blood circulation focusing on the pathogenic factors and pathogenesis of coagulation disorders in patients with HBV-related liver cirrhosis, could improve coagulation function, decrease TBIL. Therefore, it can be used in the treatment of chronic liver diseases.

Peer review

Deterioration of coagulation function is a serious problem in liver cirrhosis patients. This new TCM therapy is encouraging and interesting with satisfactory therapeutic effects on serum prothrombin, fibrinogen and TBil in patients with HBV-related liver cirrhosis.

Abstract

AIM: To evaluate the patterns of use of clarithromycin for gastrointestinal disease treatment and promote its rational use.

METHODS: Using a structured pro forma, we conducted a two-month survey of the electronic prescriptions containing immediate-release (IR) or sustained-release (SR) product of clarithromycin for outpatients with gastrointestinal diseases in a 2200-bed general hospital. Suitability of the prescription was audited retrospectively.

RESULTS: One hundred and sixty-four prescriptions of SR product and 110 prescriptions of IR product were prescribed for gastrointestinal disease treatment. Among prescriptions for anti-*Helicobacter pylori* (*H pylori*) therapy, triple therapy take the dominant position (91.8%), followed by quadruple therapy (4.3%) and dual therapy (3.9%). Amoxicillin was the most frequently co-prescribed antibiotic. Furazolidone and levofloxacin are used more widely than metronidazole or tinidazole. Clarithromycin SR was administered at inappropriate time points in all prescriptions. Fifty percent of all prescriptions of clarithromycin SR, and 6.4% of prescriptions of clarithromycin IR, were prescribed at inappropriate dosing intervals. Surprisingly, disconcordance between diagnoses and indications was observed in all prescriptions of clarithromycin SR which has not been approved for treating *H pylori* infection although off-label use for this purpose was reported in literature. On the contrary, only one prescription (0.9%) of clarithromycin IR was prescribed for unapproved indication (i.e. gastro-oesophageal reflux disease). 1.4% of prescriptions for chronic gastritis or peptic ulcer treatment were irrational in that clarithromycin was not co-prescribed with gastric acid inhibitors. Clinical significant CYP3A based drug interactions with clarithromycin were identified.

CONCLUSION: There is a great scope to improve the quality of clarithromycin prescribing in patients with gastrointestinal disease, especially with regard to administration schedule, concordance between indications and diagnoses and management of drug interactions.

INTRODUCTION

Clarithromycin is a semi-synthetic macrolide antibiotic

that inhibits bacterial protein synthesis. It is more acid-stable, better absorbed, and is widely used as a component of anti-*Helicobacter pylori* (*H pylori*) regimens[1,2]. The oral clarithromycin formulations available on the market include immediate-release (IR) clarithromycin and sustained-release (SR) clarithromycin. The two formulations have different administration schedule, clinical indications and therapeutic cost. The SR clarithromycin has obvious advantages over the IR product when they are prescribed for the same indications. These advantages are as follows: (1) higher antimicrobial activity in that clarithromycin is a time-dependent antibiotic; (2) better tolerability, fewer gastrointestinal adverse reactions and reports of abnormal taste[3,4]; (3) bioequivalence between the SR (1000 mg *qd*) and IR (500 mg *bid*)[4]; and (4) enhanced medication compliance due to its convenience.

The patterns of combination use of clarithromycin for *H pylori* infection have not been reported in literature. Meanwhile, many patients with *H pylori* infection also suffer from other diseases and hence may receive polytherapy regimens, which may exert complex, significant drug interactions[5]. Up to now, drug utilization of clarithromycin for gastrointestinal disease treatment has not been available. Targeting inappropriate prescribing is one means of trying to reduce drug costs and promote rational use of drug. The aim of this two-month drug utilization study was to assess the extent and appropriateness of clarithromycin by examining prescribing practice for outpatients in a general hospital.

MATERIALS AND METHODS

The setting of this study is a 2200-bed general hospital in Zhejiang Province, China. The pharmacy has two products of clarithromycin [Klaci® (clarithromycin IR tablets, Abbott S.P.A.) and Nuobang® (clarithromycin SR tablets, Jiangsu Hengrui Medicine Co., Ltd, China)]. Each tablet of BIAXIN® contains 250 mg of clarithromycin. Each tablet of Nuobang® contains 500 mg of clarithromycin. Prescribing information for these products along with BIAXIN® XL Filmtab® (clarithromycin SR tablets, Abbott S.P.A.) were referenced[6]. Relevant literature was identified by performing Pubmed searches until the end of 2007. A structured pro forma was used to perform a survey of electronic prescriptions containing IR or SR product for outpatients with alimentary disease covering the period from December 2007 to January 2008. The pro forma included details of the patient's age and sex, indication for clarithromycin therapy, the type of clarithromycin product prescribed, the dose and duration of therapy and details of other prescribed medications. Suitability of the prescription was audited retrospectively.

Differences between patient groups were tested for statistical significance using χ^2 analysis. A P-value < 0.05 was considered significant.

RESULTS

Over a two-month period clarithromycin SR was prescribed for 949 patients whereas clarithromycin IR product was prescribed for 197 patients (Table1). With respect to use for alimentary disease treatment by gastroenterologists, 164 patients (17.3%) were on SR product compared to 110 patients (55.8%) on IR product ($P < 0.05$). The mean age of these patients was 45.9 years (range: 18-82 years). The number of male patients was equal to that of female patients. Among prescriptions for anti-*H pylori* therapy, triple therapy take the dominant position (91.8%), followed by quadruple therapy (4.3%) and dual therapy (3.9%).

Table 1 Details of prescriptions of the two clarithromycin products

	Clarithromycin	
	Sustained-release	Immediate release
Total number of prescriptions	949	197
Number of prescriptions for alimentary disease	164	110
Mean age (range) yr	45.9 (18-82)	
Male:Female	137:137	
Number of prescriptions for anti-*H pylori* therapy	159	96
Triple therapy	151	83
PPI/Clarithromycin/Amoxicillin	43	58
PPI/Clarithromycin/Furazolidone	44	21
PPI/Clarithromycin/Levofloxacin	63	1
PPI/Clarithromycin/Metronidazole	1	1
PPI/Clarithromycin/Tinidazole	0	2
Quadruple therapy	5	6
PPI/Bismuth/Amoxicillin/Clarithromycin	0	2
PPI/Bismuth/ Furazolidone/Clarithromycin	1	3
PPI/Bismuth/Levofloxacin/Clarithromycin	4	1
Dual therapy	3	7
Clarithromycin/PPI	2	7
Clarithromycin/Ranitidine bismuth citrate	1	0

PPI: Proton pump inhibitor.

Administration schedule

Post-meal dosing of clarithromycin was specified in all investigated electronic prescriptions. According to the prescribing information, Nuobang® should be taken with food whereas Klaci® may be given irrespective of food intake. Thus, Nuobang® in all prescriptions was administered at inappropriate time.

Eighty-two prescriptions of Nuobang® (50%) were prescribed twice daily, which was inconsistent with the once-daily dosing method according to its prescribing information. Klaci® was given twice daily according to all prescriptions, which met the requirements for triple therapy. However, dual therapy requires clarithromycin IR 500 mg to be given three times daily[6]. Thus, 7 prescriptions of dual therapy containing clarithromycin IR tablet (500 mg *bid*) and PPI were identified as irrational.

Diagnoses of patients on clarithromycin-based therapy

For patients with alimentary disease receiving clarithromycin-based therapy, diagnoses were summarized in Table 2. The diagnoses were various. Combining the results of upper gastrointestinal

Prednisone		1	[16]

SR: Sustained-release; IR: Immediate release.

endoscopy or ^{13}C-urea breath test, concordance between diagnoses and indications were examined. Except for patients with mesenteric lymphadenitis or abdominal pain of unknown origin, 90.6% of other patients test positive for *H pylori* infection prior to initiation of anti-*H pylori* regimen. Surprisingly, disconcordance between diagnoses and indications was observed in all prescriptions of clarithromycin SR. On the contrary, only one prescription (0.9%) of clarithromycin IR was prescribed for unapproved indication (i.e. gastro-oesophageal reflux disease).

Drug interactions

Concomitant PPIs and anti-*H pylori* agents used in clarithromycin-based triple therapy were listed in Table 3. The PPIs included omeprazole, lansoprazole, pantoprazole, esomeprazole magnesium and rebeprazole. The antibiotics co-presribed with clarithromycin included amoxicillin, furazolidone, levofloxacin, metronidazole, tinidazole and amoxicillin/clavulanate potassium. Amoxicillin was the most frequently co-prescribed antibiotic. Furazolidone and levofloxacin were used more widely than metronidazole or tinidazole. The CYP3A dependent clinical significant drug interactions with clarithromycin in this survey were summarized in Table 4.

Clarithromycin plays its role of anti-*H pylori* only under the circumstance of pH more than 4.0 and thus it usually needs concomitant use of anti-gastric-secretion drugs. However, 4 prescriptions for chronic gastritis or peptic ulcer treatment did not contain gastric acid inhibitors, and thus were judged as irrational.

DISCUSSION

Administration schedule

Food has no significant effects on pharmacokinetics of IR clarithromycin and thus the product may be given irrespective of food intake. With regard to Nuobang®, administration under fasting conditions is associated with approximately 30% lower area under the plasma concentration-time curve (*AUC*) for clarithromycin relative to administration with food. Therefore, it should be taken with food to maximize bioavailability. Physicians and pharmacists should pay attention to this biopharmaceutical requirement and strengthen patient education.

Compared to the triple therapy, the dual therapy has a lower eradication rate of *H pylori*. Moreover, regimens which contain clarithromycin as the single antibiotic are more likely to be associated with the development of clarithromycin resistance among patients who fail therapy. When the IR clarithromycin tablet is combined with PPI as dual therapy, the dose needs to be tailored to 500 mg three times daily[6].

The SR clarithromycin has obvious advantages over the IR product when they are prescribed for the same indications[3,4]. However, the novelty of the SR product and its administration of only once a day would decrease the benefit for patients and their compliance if given twice daily as detected in most prescriptions.

Concordance between indications and diagnoses

Chronic gastritis is an inflammation of the lining of the stomach that occurs gradually and persists for a prolonged time. It can be classified based on the underlying etiologic agent (e.g. *H pylori*, bile reflux,

nonsteroidal anti-inflammatory drugs, autoimmunity, allergic response) and the histopathological pattern. Diagnosis of chronic gastritis is broad and disconcordant with indications described in the package insert of clarithromycin. It should be further specified if patients test positive for *H pylori* (i.e. *H pylori*-associated chronic gastritis instead of chronic gastritis) and the rationale also applies to diagnoses of gastric ulcer, peptic ulcer and duodenal ulcer.

Gastro-oesophageal reflux disease (GERD) is an unapproved indication for IR or SR clarithromycin. Although a significant proportion of patients with GERD have *H pylori* infection, it is unclear whether or not *H pylori* should be treated. Eradication therapy is currently not recommended for most of GERD patients with *H pylori* infection[1,2]. Relief of abdominal pain of unknown origin was also an unapproved indication for clarithromycin-based therapy. Seven prescriptions for mesenteric lymphadenitis treatment included monotherapy with clarithromycin (n = 1), dual therapy with clarithromycin-levofloxacin (n = 3), clarithromycin-cefdinir (n = 1), clarithromycin-amoxicillin/clavulanate potassium (n = 2). Given the predominance of *Y. enterocolitica* in mesenteric lymphadenitis infection, initial oral antibiotic selection from third-generation cephalosporins, broad spectrum penicillins, fluoroquinolones and doxycycline may be considered. Recently, association of mesenteric lymphadenitis with mycoplasma was revealed by Tao *et al*[17]. Among 108 patients with mesenteric lymphadenitis in that study, 36 patients (33%) were Mycoplasma-IgM positive. The switch to macrolide azithromycin provided a benefit for patients with an unsatisfactory response to third-generation cephalosporins or broad spectrum penicillins. In our survey, follow-up indicated that the combination of macrolide clarithromycin with levofloxacin, amoxicillin/clavulanate potassium or cefdinir showed satisfactory results in patients suffering from mesenteric lymphadenitis.

Clarithromycin IR based triple therapy or dual therapy is indicated for the treatment of patients with *H pylori* infection. However, the efficacy and safety of clarithromycin SR treatment for *H pylori* infection have not been established, as indicated in the prescribing information for Biaxin Xl Filmtab®. There have been three studies on clinical efficacy of clarithromycin SR -based triple therapy to cure *H pylori* infection. Coelho *et al*[18] observed that the combination of lansoprazole 30 mg, clarithromycin SR 500 mg and furazolidone 400 mg, once daily for 7 d, was inexpensive, safe and an effective alternative for anti-*H pylori* therapy in family members of gastric cancer patients. Chu *et al*[19] proved that one-week once-daily course of lansoprazole 30 mg, clarithromycin SR 500 mg and metronidazole 800 mg was a safe, well-tolerated, easy to comply with, and efficacious treatment for *H pylori* infection. A randomized controlled trial study by Liou *et al*[20] provided the direct evidence that clarithromycin SR 1000 mg once daily can be used as an alternative to clarithromycin IR 500 mg twice daily for the treatment of *H pylori*-associated peptic ulcer disease. In that study, 161 patients with *H pylori*-associated peptic ulcer were randomized to receive one-week triple therapy with either clarithromycin SR 1000 mg once daily or clarithromycin IR 500 mg twice daily combination with amoxicillin 1000 mg twice daily and esomeprazole 40 mg once daily. The eradication rates were comparable in the two groups. Further clinical trials with a larger sample size are required to establish the efficacy and safety of clarithromycin SR. Effective communication between patients and gastroenterologists are rather necessary prior to initiation of off-label use of clarithromycin SR.

Drug interactions

The combination of clarithromycin with omeprazole has a synergic effect. The C_{max}, AUC0-24, and $T_{1/2}$ derived from omeprazole increased by 30%, 89%, and 34%, respectively by the concomitant administration. The mean 24-h gastric pH value was 5.2 when omeprazole was administered alone and 5.7 when co-administered with clarithromycin[6]. On the other hand, by concomitant administration of omeprazole, clarithromycin concentrations in the gastric tissue and mucus increased (e.g. clarithromycin mucus concentrations 2 h after application increased by about 9-fold)[21]. Simultaneous administration of lansoprazole, amoxicillin and clarithromycin increases the serum concentrations of lansoprazole and the active 14-OH-clarithromycin metabolite significantly[22]. Compared to treatment with esomeprazole alone, the mean steady state AUC and C_{max} of esomeprazole increased by 70% and 18%, respectively, during triple therapy (esomeprazole magnesium 40 mg *qd*, clarithromycin 500 mg *bid* and amoxicillin 1000 mg *bid* for 7 days)[23]. The AUC and C_{max} of rabeprazole and 14-hydroxyclarithromycin (active metabolite of clarithromycin) increased, although the AUC and C_{max} for clarithromycin were not different following combined administration consisting of rabeprazole, amoxicillin and clarithromycin compared to values following single administration[24]. Although there is no significant pharmacokinetic interaction between clarithromycin and pantoprazole, clarithromycin has a better effect in *H pylori* treatment when pantoprazole is used concomitantly[25].

Clarithromycin is a potent inhibitor of CYP3A4 and P-gp. Concomitant administration of clarithromycin and any of the following CYP3A4 substrates is contraindicated: cisapride, pimozide, astemizole, terfenadine, and ergotamine or dihydroergotamine, as described in standard information sources. In this survey, such prescriptions were not found. Coadministration of clarithromycin and a drug primarily metabolized by CYP3A may be associated with elevations in drug concentrations that could increase or prolong both the therapeutic and adverse effects of the concomitant drug. Dosage adjustments may be considered, and when possible, plasma concentrations of drugs primarily metabolized by CYP3A should be monitored closely in patients concurrently receiving clarithromycin.

Triazolobenziodidiazepines (e.g. triazolam

and alprazolam) and related benzodiazepines (e.g. midazolam) have been observed of CYP3A based drug interactions with erythromycin products and/or with clarithromycin in postmarketing experience. For example, intestinal and hepatic CYP3A inhibition by clarithromycin can significantly reduce the clearance of midazolam, resulting in an increase in the *AUC* of midazolam by 8-fold following oral dose in the elderly[8]. Zolpidem is extensively metabolized, mainly by CYP3A4[7]. Thus, a prescription containing alprazolam, zolpidem and clarithromycin has a high risk for excessive sedation (Table 4). Pharmacotherapy monitoring and dosage adjustment for these sedative drugs should be implemented accordingly.

Clarithromycin may increase the levels/effects of amlodipine[9]. Levoamlodipine is an eutomer of amlodipine and the first enantiomerically pure dihydropyridine calcium channel blockers. Levoamlodipine is also mainly metabolized by CYP3A4, so its levels/effects may also be affected by clarithromycin. A case of vasodilatory shock possibly resulting from a clarithromycin-nifedipine interaction was reported by Gerónimo-Pardo *et al*[10]. A potentially significant pharmacokinetic interaction between clarithromycin and carbamazepine was identified in two patients with long-standing epilepsy who were given omeprazole/clarithromycin therapy for *H pylori* gastritis[9]. Serum carbamazepine levels were augmented by clarithromycin and returned to the therapeutic range following cessation of clarithromycin therapy. Empirically in such cases carbamazepine dose need to be tailored by 30% to 50%.

Clarithromycin did have a significant effect on atorvastatin pharmacokinetic parameters. When coadministered, clarithromycin raised atorvastatin *AUC* by 82% and C_{max} by 56%. Hence, clarithromycin should be avoided in patients taking atorvastatin and similarly metabolized HMG-CoA inhibitors[12]. Sipe *et al*[13] reported a case of rhabdomyolysis causing AV blockade due to possible atorvastatin, esomeprazole, and clarithromycin interaction. The antiplatelet effects of the prodrug clopidogrel can be reduced by concomitant administration of erythromycin or troleandomycin. The proposed mechanism is inhibition of CYP3A4 activity, which is responsible for the conversion of clopidogrel to its active metabolite. Clarithromycin also inhibits CYP3A4 activity and is also expected to affect clopidogrel metabolism[14]. Until more information is available, monitoring for altered efficacy of clopidogrel may be advisable if clarithromycin is co-administered with clopidogrel.

In a combination of clarithromycin, nifedipine, clopidogrel and atorvastatin (Table 4), at least 4 clinical significant pharmacokinetic interactions are involved, e.g. clarithromycin-nifedipine, clarithromycin-clopidogrel, clarithromycin-atorvastatin and atorvastatin-clopidogrel[26]. Such a prescription with high risk of adverse drug interactions is irrational. Considering the short course of clarithromycin therapy, close monitoring and proper dose adjustment may be more practicable than to switch to alternatives not mainly metabolized by CYP3A4.

Clarithromycin may increase levels of ergoloid mesylate by inhibiting CYP3A4 metabolism, resulting in toxicity (ischemia, vasospasm) and the combined use is contraindicated[15]. So the combination therapy of clarithromycin with amlodipine and ergoloid mesylate at conventional dosage is irrational. A case of mania due to prednisone-clarithromycin interaction was reported by Finkenbine *et al*[16], suggesting that pharmacotherapy monitoring should be performed during the concurrent therapy.

Triple therapy with a PPI, clarithromycin and either amoxicillin or metronidazole is the first-line treatment regimen to eradicate *H pylori* infection[1,2,27]. Significant differences are observed in the prevalence of metronidazole resistance between developed and developing countries[28-30]. High levels of resistance to metronidazole mainly relates to the wide application in parasite infection, dental infection and gynecological diseases in developing countries. Antimicrobial susceptibility tests performed in Zhejiang Province of China indicated that the antibiotic resistance rate increased perceptibly during the period of 2003-2007[31,32]. Among six antibiotics (metronidazole, amoxicilin, gentamycin, levofloxacin, furazolidone and clarithromycin), the rate of resistance to metronidazole (99.32%) appeared to be the highest and the levofloxacin resistance rate (0.51%) was the lowest. Amoxicillin rarely induces resistance[33]. Fluoroquinolones are active against *H pylori* in vitro and have a synergistic effect with PPIs[34]. Strains resistant to furazolidone are rare. Furthermore, there is no cross-resistance to metronidazole and furazolidone is effective in populations with a high prevalence of metronidazole resistance[35]. The resistance status may explain the pattern of antibiotic use in this hospital, i.e. furazolidone and levofloxacin are used more widely than are metronidazole or tinidazole. Guo *et al*[28] reported that *H pylori* eradication rates were significantly different in patients receiving OAC (omeprazole/amoxicillin/clarithromycin) and OFC (omeprazole/furazolidone/clarithromycin) compared to those receiving OMC (omeprazole/metronidazole/clarithromycin). The eradication rate for *H pylori* infection was 90.3%, 90.9% and 70.9% in OAC, OFC and OMC groups, respectively. Based on these results, one-week of triple therapy with OAC or OFC were recommended for Chinese patients with duodenal ulcers and chronic gastritis. Since furazolidone is cheap and the *H pylori* eradication rate is high, OFC regimen is recommended to be one of choices for *H pylori* eradication.

PPI-based double combinations were clearly inferior to triple regimens, which is in accordance with the evidence-based data and they are not recommended in the first-line treatment. However, concurrent therapy of ranitidine bismuth citrate and clarithromycin have a similar efficacy compared to the triple regimens[36-38]. Thus, the prescription of a combination of clarithromycin and ranitidine bismuth citrate in our survey is rational. A 7 d

quadruple therapy based on PPI, bismuth, tetracycline and metronidazole is the more frequently accepted[1,2]. Our survey found that some patients received quadruple therapy regimens containing PPI, bismuth, clarithromycin, and one of antibiotics including amoxicillin, furazolidone or levofloxacin.

In conclusions, a retrospective utilization study of clarithromycin for gastrointestinal disease treatment was conducted. There is a great scope to improve the quality of clarithromycin prescribing, especially with regard to administration schedule, concordance between indications and diagnoses and management of drug interactions.

COMMENTS

Background

The oral clarithromycin formulations available on the market include immediate-release (IR) clarithromycin and sustained-release (SR) clarithromycin. Due to difference in pharmaceutical forms, the IR and SR formulations have different administration schedule, clinical indications and therapeutic cost. Meanwhile, the patterns of combination use of clarithromycin for *Helicobacter pylori* (*H pylori*) infection have not been reported in literature. Many patients with *H pylori* infection also suffer from other diseases and hence they may receive polytherapy regimens, which may exert complex, significant drug interactions if clarithromycin is used. In order to promote its rational use in gastrointestinal disease treatment, it is essential to assess the extent and appropriateness of clarithromycin by examining prescribing practice.

Research frontiers

Drug utilization studies can provide useful information to improve the appropriate and effective use of pharmaceuticals in populations. In recent years many such studies have been performed to monitor prescribing patterns and assess adherence to standard therapeutic guidelines in clinical practice.

Innovations and breakthroughs

This is the first drug utilization study of clarithromycin for gastrointestinal disease treatment and the article critically compares the prescribing patterns of clarithromycin with different pharmaceutical forms.

Applications

The significance of this article is: (1) it provides insights into the aspects of drug use and prescribing pattern; (2) it helps to improve the quality of clarithromycin prescribing, especially with regard to administration schedule, concordance between indications and diagnoses and management of drug interactions; (3) it helps doctors to attach equal importance to other medicines for gastrointestinal disease treatment and finally promote rational drug use in clinical practice.

Terminology

Drug utilization: The study to describe the extent, nature and determinants of drug exposure, consider clinical appropriateness and cost effectiveness, and facilitate rational use of drugs in populations. Drug administration schedule: time schedule for administration of a drug in order to achieve optimum effectiveness and convenience. Drug interactions: The action of a drug that may affect the activity, metabolism, or toxicity of another drug. Polypharmacy: The use of multiple drugs administered to the same patient, most commonly seen in elderly patients.

Peer review

This retrospective utilization study is well designed. It is of particular interest to the practical medicine and can improve the quality of clarithromycin prescribing in patients with gastrointestinal disease.

Abstract

AIM: To identify biomarkers indicating virus-specific hepatocarcinogenic process, differential mRNA expression in 32 patients with hepatitis B virus (HBV)-/hepatitis C virus (HCV)-associated hepatocellular carcinoma (HCC) were investigated by means of cDNA microarrays comprising of 886 genes.

METHODS: Thirty two HCC patients were divided into two groups based on viral markers: hepatitis B virus positive and HCV positive. The expression profiles of 32 pairs of specimens (tumorous and surrounding non-tumorous liver tissues), consisting of 886 genes were analyzed.

RESULTS: Seven up-regulated genes in HBV-associated HCC comprised genes involved in protein synthesis (*RPS5*), cytoskeletal organization (*KRT8*), apoptosis related genes (*CFLAR*), transport (*ATP5F1*), cell membrane receptor related genes (*IGFBP2*), signal transduction or transcription related genes (*MAP3K5*), and metastasis-related genes (*MMP9*). The up-regulated genes in HCV-infected group included 4 genes: *VIM* (cell structure), *ACTB* (cell structure), *GAPD* (glycolysis) and *CD58* (cell adhesion). The expression patterns of the 11 genes, identified by cDNA microarray, were confirmed by quantitative RT-PCR in 32 specimens.

CONCLUSION: The patterns of all identified genes were classified based on the viral factor involved in HBV- and HCV-associated HCC. Our results strongly suggest that the pattern of gene expression in HCC is closely associated with the etiologic factor. The present study indicates that HBV and HCV cause hepatocarcinogenesis by different mechanisms, and provide novel tools for the diagnosis and treatment of HBV- and HCV-associated HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common cancers worldwide[1]. The major risk factors for HCC are chronic hepatitis resulting from infection with HBV and HCV, and exposure to various exogenous carcinogens, including aflatoxin B1[2]. Several studies have shown that the incidence of HCC has increased substantially in East Asia, including China, Korea and Japan[3,4]. More than 350 million people worldwide are known to be chronic carriers of HBV[5]. Moreover, the incidence of HCC is increasing in many countries in

parallel with the increase in chronic HCV infection[1,2]. Therefore, clarification of the genetic portrait of hepatocarcinogenesis caused by HBV or HCV infection may provide clues to help reduce the incidence of HCC, and establish effective treatments for HCC. However, the molecular nature of this association is poorly understood.

The phenotypic diversity of cancer is accompanied with a corresponding diversity in the gene expression patterns[6-10]. Honda *et al*[11] showed the presence of different gene expression profiles in the liver lesions of chronic hepatitis caused by HBV and HCV, and suggested that the molecular mechanisms responsible for the pathogenesis of HCC differ between HBV and HCV infections. In the present study, we investigated the gene expression patterns of 32 HCC samples, using cDNA microarrays containing 886 clones in order to gain additional insight into hepatocarcinogenesis or cancer progression related to HBV and HCV infections. The aim of the present study was to characterize the gene expression associated with HCC, with a view to better understand the molecular pathophysiology, which may lead to better methods of detection, diagnosis, and classification of HCC.

MATERIALS AND METHODS

Patient material

The Institutional Review Board on Medical Ethics, Zhejiang Provincial People Hospital (China), approved the method of tissue collection. The present study was conducted in the department of surgery, Zhejiang Provincial People Hospital, on 32 patients who underwent hepatectomy for sporadic HCC without preoperative radio- or chemotherapy. All of tissue samples were immediately frozen in liquid nitrogen, and stored at -80℃ until use. A total of 32 HCC samples from 15 lymph node negative and 17 lymph node positive cases were used (Table 1).

Laser microdissection

Eight μm-thick sections of the frozen tissue were cut at -20℃ and stained with HE. Under microscopic observation, parts of cancer cells nests in the invasive and intraductal components were microdissected, using the LM100 laser capture microdissection system (Arcturus Engineering, Mountain View, CA, USA). A 15 μm-diameter beam was used to capture the tumor cells and the corresponding non-cancerous liver tissues. The cell nests were transferred to a LCM transfer film (CapSure TF-100S transfer film carrier, 5 mm-diameter optical-grade transparent plastic; Arcturus Engineering).

RNA preparation and T7-based RNA amplification

Total RNA was isolated from the dissected specimens using Trizol reagent (Gibco BRL) and a modified acidic guanidinium phenol-chloroform method, following the manufacturer's recommendations. Total RNA was treated with DNase I for removal of genomic DNA, and the mRNA was purified using a poly(A) purification kit (Oligotex, Qiagen), according to the manufacturer's instructions. The quality of mRNA was assessed by $A_{260/280}$ ratios and the contamination of genomic DNA was checked using the PCR method. cDNA was synthesized with T7-oligo (dT) primer (Ambion) and Superscript II enzyme (Gibco BRL), as described in the instruction manual. cDNA was purified by cDNA clean-up column (DNA clear™ kit, Ambion). cRNA was generated by T7 MEGAscript™ kit (MEGAscript *in vitro* Transcription Kit, Ambion, AUSTIN, Tex), per the manufacturer's recommendations. Column purification of cRNA was performed with RNeasy kit (Qiagen), according to the manufacturer's protocol. The concentration and quality of cRNA were analyzed by GeneQuant pro RNA/DNA Calculator (Amersharmacia biotech).

Microarray hybridization and scanning

Human Cancer Chip version 4.0 (IntelliGene, TaKaRa) was used for these studies. This array was spotted on a glass slide with 886 cDNA fragments of human genes, which are composed of 588 human identified genes related to cancer, and 298 cDNA fragments prescreened by differential display method between cancer tissue and normal tissue. Three μg of cRNA from the tumor and

the matched normal tissue were labeled with Cy3-dUTP and Cy5-dUTP respectively (Amersham Pharmacia Biotech, Buckinghamshire, England), using a labeling kit (RNA Fluorescence Labeling Core kit, TaKaRa), according to the manufacturer's instructions. The labeled probe was purified by centrifugation in a spin column (Centrisep, Princeton Separations, Adelphia, NJ). Two separate probes were combined, and 2 μL of 5 × competitor containing Cot I (Gibco BRL), poly dA (Amersham Pharmaca Biotech), and tRNA (TaKaRa) were added. After addition of 50 μL of 100% ethanol and 2 μL of 3 mol/L sodium acetate (pH 5.2), the mixture was cooled at -80℃ for 30 min, followed by centrifugation at 15 000 *g* for 10 min, and pelleted down. For final probe preparation, the pellet was washed in 500 μL of 70% ethanol twice, and eluted in 10 μL hybridization buffer (6 × SSC, 0.2% SDS, 5 × Denhardt's solution, 0.1 mg/mL salmon sperm solution). The probe were denatured by heating for 2 min at 95℃, cooled at room temperature, and centrifuged at 15 000 *g* for 10 min (20-26℃). Supernatants were placed on the array and covered with a 22-mm × 22-mm glass coverslip. The coverslip was sealed with a glue, and the probes were incubated overnight at 65℃ for 16 h in a custom-made slide chamber with humidity maintained by underlying moist papers. After hybridization, the slides were washed in 2 × SSC with 0.1% SDS, 1 × SSC, and 0.05 × SSC, sequentially for 1 min each, and then spin dried. Hybridized arrays were scanned using a confocal laser-scanning microscope (Affymetrix 428 array scanner, Santa Clara, CA). Image analysis and quantification were performed with ImaGene 4.2 software (BioDiscovery), according to the manufacture's instructions.

Data processing

Each spot was defined by manual positioning of a grid of circles over the array image. For each fluorescent image, the average pixel intensity within each circle was determined, and a local background, outside of 3 pixel buffer range from the circle was computed for each spot. Net signal was determined by subtraction of the local background from the average intensity of each spot. Signal intensities between the two fluorescent images were normalized by the intensities of the house-keeping genes provided on the arrays. The fluorescence intensities of Cy5 (non-tumor) and Cy3 (tumor) for each target spot were adjusted so that the mean Cy3:Cy5 ratios of 32 housekeeping gene spots were equal to one. Because data derived from low signal intensities are less reliable, we first determined the cutoff values for signal intensities on each slide so that all of the filtered genes had greater S:N (signal to noise) ratios of Cy3 or Cy5 than three, and we excluded genes for further analysis when both Cy3 and Cy5 dyes gave signal intensities lower than the cutoff. To estimate the range of expression ratio within which the expression change could be considered as fluctuation in non-cancerous cells, we compared expression profiles of non-cancerous cells from 6 patients. Because 90% of expression ratios in non-cancerous cells fell within the range of 1.726 and 0.503, we categorized genes into three groups according to their expression ratios (Cy3:Cy5): up-regulated (ratio, 2.0); down-regulated (ratio 0.5); and unchanged expression (ratios, between 0.5 and 2.0); provided that signal counts of T (Cy3) and R (Cy5) were > 500. Genes with Cy3:Cy5 ratios > 2.0 or < 0.5 in more than 75% of the cases examined were defined as commonly up- or down-regulated genes, respectively.

Real-time reverse transcription PCR

LightCycler (Roche Diagnostics) technology was applied to confirm the data obtained by cDNA microarray. The primer sequences of 11 genes were obtained from the GDB Human Genome Database (http://www.gdb.org/gdb/) (Table 2). We used the same RNA from the dissected cells for the microarray analysis. First-strand cDNA was obtained by reverse transcription using a commercially available kit (first strand synthesis kit, Amersham). For each PCR, 2 μL (20 ng) first strand cDNA template, 50 pmol of each primer, 2.4 μL (3 mmol) $MgCl_2$, and 2 μL 10 × SYBR Green I (Roche Laboratories)were mixed in 20 μL of PCR mixture. The running protocol was programmed as follows. In the first step, initial denaturation, reaction mixture was incubated for 10 min at 95℃. In the second step, DNA was amplified for 45 cycles at 95℃ for 10 s, specific annealing temperature (the primer sequences dependent) for 0-10 s, and elongation at 72℃ for some seconds [amplicon (bp)/25 s]. Finally, the temperature was raised gradually (0.2℃/s) from the annealing temperature to 95℃ for the melting curve analysis. Twelve μL of PCR product were visualized by electrophoresis on 2% agarose gel stained with ethidium bromide.

The amount of gene expression was normalized to the amount of glyceraldehyde-3-phosphate dehydrogenase (GAPDH) using Human GAPDH kit (GmbH Heidelberg, Heidelberg, Germany). The qRT-PCR analysis was carried out in triplicate for each cDNA sample, and the median values were used for the three experiments. Up- and down-regulation were defined as the median value > 2.0 and < 0.5, respectively.

Statistical analysis

Statistical analysis among mean values was performed on the association of lymph node metastasis with expression levels by applying non-parametric Kruskal-Wallis and Mann-Whitney *U* tests. Statistical significance was defined as a *P*-value of < 0.05. Differential expression between the groups of HBV-infected and HCV-infected HCC was considered significant, with $P < 0.05$.

RESULTS

Quality analysis of total RNA after LCM and cRNA after T7-based amplification

About 20 slides were prepared from each sample, and the target cells were captured with at least 1000 cells per slide. Consequently, we captured a total of approximately 25 000-30 000 tumor cells and normal cells for RNA extraction. The quality of total RNA extracted after LCM was assessed by A_{260}/A_{280} and electrophoresis. To be considered for microarray analysis, the RNA samples were required to pass quality control criteria, with integrity of 28S and 18S, and A_{260}/A_{280} greater than 2.0. Products of cDNA synthesis and cRNA were also checked by A_{260}/A_{280} and electrophoresis. The results showed that A_{260}/A_{280} of all the RNA samples met the quality control criteria for sample preparation. Clear image appearance of 28S and 18S of ribosomal RNA was seen under the electropherogram for each total RNA sample, which had to be intact and without degradation. RNA was subjected to two rounds of T7-based RNA amplification after removal of DNA contamination by RNase-free Dnase I treatment as described in the methods section. All RNA samples were successfully amplified by an estimated 250-fold, using T7 RNA polymerase. cDNA synthesis and cRNA showed satisfactory quality control criteria, with 1.5 kb < cDNA < 5.0 kb; 1.0 kb < cRNA < 4.5 kb); and A_{260}/A_{280} ratio of cDNA and cRNA greater than 2, respectively.

Identification of genes related to HBV-positive or HCV-positive status

After reverse transcription, each cDNA probe was labeled with Cy3- or Cy5-conjugated dyes and hybridized to microarray cDNAs with 886 genes. We compared the expression profiles of cancer cells and the corresponding normal cells in each case. A representative scatter plot of microarray analysis of carcinoma cells and non-cancerous tissue in case 20 (HCV-infected HCC) is shown in Figure 1. Up-regulated, down-regulated and unchanged genes are indicated by red, green and blue spots, respectively. We first arranged the relative expression of each gene (Cy3/Cy5 intensity ratio) into one of four categories: up-regulated (ratio > 2.0), down-regulated (ratio < 0.5), unchanged (ratio between 0.5 and 2.0), and not expressed (or slight expression but under the cutoff level for detection).

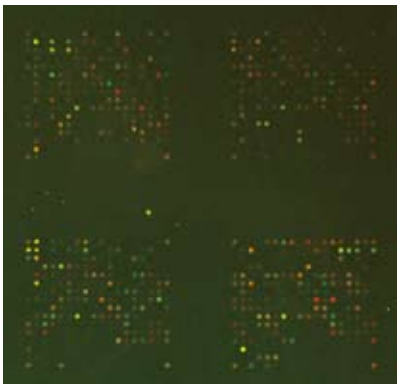

Figure 1 A representative of cDNA microarray expression pattern obtained from case 20. Up-, down-regulated and unchanged genes were indicated by red, green and blue spots, respectively.

To identify the genes related to HBV-positive and HCV-positive status, 32 patients were divided into two groups: HBV- associated HCC group in which HBV was positive in 17 patients, and HCV-associated HCC group in which HCV was positive in 15 patients (Table 1). When comparing gene expression profiles in the two groups, there were 7 genes that were commonly up-regulated, and expressed more than 2.09-fold in the HBV-infected group compared with in the HCV-infected group. On the other hand, 4 down-regulated genes in HBV-infected group correlated significantly with the HCV-infected group. Table 3 shows the list of differentially expressed genes and their respective category based on the GO (Gene Ontology) system and TreeView. The up-regulated genes in HBV-infected group were involved in protein synthesis (RPS5), cytoskeletal organization (KRT8), apoptosis related genes (CFLAR), transport (ATP5F1), cell membrane receptor related genes (IGFBP2), signal transduction or transcription related genes (MAP3K5), and metastasis-related genes (MMP9). The up-regulated genes in HCV-infected group included genes such as VIM (cell structure), ACTB (cell structure), GAPD (glycolysis) and CD58 (cell adhesion).

Verification of the genes related to HBV- and HCV-associated HCC using quantitative RT-PCR

To more quantitatively examine our data on hepatitis virus infection in HCC, we selected 7 up-regulated genes from the HBV-infected group, and 4 up-regulated genes from the HCV-infected group. The expression level of the selected genes was confirmed by quantitative RTPCR analysis in 32 patients. We used cDNA synthesized from 32 pair samples without amplification as template for real-time semiquantitative reverse transcription PCR. The results demonstrated that the samples obtained by means of T7-based amplification appropriately reflected the status of the original RNA in a proportional manner. The results of the DNA microarray were reproduced by reverse transcriptase PCR.

DISCUSSION

Genome-wide gene expression analysis of human cancer

Table 3 The 11 genes for which expression levels differed between HBV- and HCV-associated HCC

Gene name	Symbol[1]	Accession[2]	Fold change[3]	HBV:HCV[4]
7 genes up-regulated in HBV-associated HCC				
Ribosomal protein S5	RPS5	NM_001009	6.35	2.38
Keratin 8	KRT8	NM_002273	5.68	3.19
CASP8 and FADD-like apoptosis regulator	CFLAR	Y14039	2.86	2.09
ATP synthase, H+transporting, mitochondrial F0 complex, subunit b, isoform 1	ATP5F1	X60221	4.11	3.52
Insulin-like growth factor binding protein 2 (36 kDa)	IGFBP2	NM_000597	3.37	2.49

[1]Symbol in LocusLink database; [2]GeneBank accession number; [3]Fold change, ratio of mean expression values in HBV- or HCV-associated cases (cancer cells *vs* non-cancerous cells); [4]HBV:HCV ratio of mean expression values (HBV positive cases to HCV positive cases).

may provide important clues in understanding HCC oncogenesis and may lead to improvement in predicting its clinical behavior[12]. Using cDNA microarray, we examined the difference in gene expression profiles between normal liver tissues and HCC cells, as well as between HBV positive and HCV-associated HCC. The data from cDNA microarray are consistent with RT-PCR data from HCC tissues and the corresponding non-tumor tissues. These expression profiles may be useful in elucidating the molecular carcinogenesis of HCC, especially HBV- and HCV-associated HCC.

In the present study, we attempted to establish a link between gene expression and the viral status of HCC. Comparative analysis of HBV- and HCV-associated HCC revealed that 11 genes, for which the expression levels differed between HBV- and HCV-associated HCC. Ribosomal-related genes such as RPS5 (RPL family genes) were up-regulated in HBV-associated HCC compared to HCV-associated HCC, suggesting the activation of protein translation in HBV-infected HCC. This observation is consistent with a previous report that major classes of genes encoding ribosomal proteins were up-regulated by the HBX protein[13]. Cytoskeletal organization, such as KRT8 was shown to be up-regulated in HBV-associated HCC, as well as genes such as ACTB in HCV-associated HCC. Our results support the hypothesis that the deregulation of genes encoding proteins associated with cytoskeleton play a role in liver carcinogenesis[14]. These findings also indicate that the pathway for liver carcinogenesis in the cytoskeleton may be different in HBV- and HCV-associated HCC. Cell adhesion genes such as CD58 were found to be up-regulated in HCV-associated HCC, but have not been reported to be related with human HBV-associated HCC. Xu *et al*[15] showed that several signal transduction related genes, including MAPK family genes were up-regulated in HBV-associated HCC. Up-regulation of MAPK has also been suggested as a common pathway for hepatocarcinogenesis caused by HBV and HCV infections[16]. In the present study, MAP3K5 was up-regulated in HBV-associated HCC compared with the non-tumorous liver tissue. However, MAP3K5 was down-regulated in HCV-associated HCC compared with the non-tumorous liver. Thus, additional studies are necessary to clarify the contribution of the MAPK pathway to each type of HCC. MMP9, which may promote metastasis, was up-regulated in HBV-associated HCC compared with HCV-associated HCC. Other genes such as IGFBP2, ATP5F1, VIM and GAPD, which are expressed differently in HBV- and HCV-associated HCC, were newly identified, although the findings of up-regulation of genes such as IGFBP2 and ATP5F1 in the HBV-associated HCC, and the up-regulation of genes such as VIM and GAPD in the HCV-associated HCC, were in agreement with previous observations[17]. It has been suggested that liver carcinogenesis induced by HBV and HCV, in addition to common genetic and epigenetic alterations, may involve distinct pathways[18]. Our expression profiles suggest that hepatitis viruses affect the expression of dozens of genes in HCC in a type-specific manner, thus invoking slightly different mechanisms of carcinogenesis. We believe that the results obtained in the present study will help our understanding of the molecular mechanisms underlying the pathogenesis of HBV- and HCV-associated HCC. The identification of genes defining virus type-specific expression profiles may contribute to our ability to develop virus type-dependent treatment regimens.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is one of the most common fatal cancers worldwide. The major risk factors for HCC are chronic hepatitis resulting from infection with hepatitis B virus (HBV) and hepatocellular carcinoma (HCC), and exposure to various exogenous carcinogens, including aflatoxin B1. It has been reported that the incidence of HCC is increasing in several countries in parallel with the increase in chronic HBV and HCV infections. Therefore, clarification of the genetic portraits of hepatocarcinogenesis caused by HBV and HCV infection may provide clues to reducing the incidence of HCC, and establishing effective treatments for each type of HCC. However, the molecular nature of this association is poorly understood.

Research frontier

The aim of the present study was to identify any useful biomarkers indicating virus-specific hepatocarcinogenic process. The differential mRNA expression in 32 patients with HBV-/HCV-associated HCC was investigated by means of

cDNA microarrays comprising of 886 genes.

Innovations and breakthroughs

It has been suggested that liver carcinogenesis induced by HBV and HCV, in addition to common genetic and epigenetic alterations, may involve distinct pathways. The results of the present study suggest that hepatitis viruses affect the expression of dozens of genes in HCC in a type-specific manner, thus invoking slightly different mechanisms of carcinogenesis. Genome-wide gene expression analysis of human cancer may provide important clues to understanding HCC oncogenesis and lead to improvements in predicting its clinical behavior.

Applications

We believe that the results obtained in this study will provide greater understanding of the molecular mechanisms underlying the pathogenesis of HBV- and HCV-associated HCC. The identification of genes defining virus type-specific expression profiles may contribute to our ability to develop virus type-dependent treatment regimens.

Terminology

DNA microarray is a meticulous technology used in molecular biology and in the field of biomedicine. This technique involves an arrayed series of thousands of microscopic spots of DNA oligonucleotides. It may involve a short section of a gene or other DNA elements that are used as probes to hybridize cDNA or cRNA samples (called target) under high-stringency conditions. Probe-target hybridization is usually detected and quantified by fluorescence-based detection of fluorophore-labeled targets to determine relative abundance of nucleic acid sequences in the target.

Peer review

This is a nice study on the changes in the expression patterns in cancer liver tissue associated with two different hepatitis viruses involved in hepatocarcinogenesis. The paper is well written and contains valuable data. The authors, using microarray technology, have compared gene expression between cancerous and non-cancerous liver tissue in both HBV and HCV infected patients. Seven genes were up-regulated in HBV and 4 genes, which were different, were up-regulated in HCV infected patients.

Abstract

Endoscopic ultrasonography (EUS)-guided biliary drainage was performed for treatment of patients who have obstructive jaundice in cases of failed endoscopic retrograde cholangiopancreatography (ERCP). In the present study, we introduced the feasibility and outcome of EUS-guided choledochoduodenostomy in four patients who failed in ERCP. We performed the procedure in 2 papilla of Vater, including one resectable case, and 2 cases of cancer of the head of pancreas. Using a curved linear array echoendoscope, a 19 G needle or a needle knife was punctured transduodenally into the bile duct under EUS visualization. Using a biliary catheter for dilation, or papillary balloon dilator, a 7-Fr plastic stent was inserted through the choledochoduodenostomy site into the extrahepatic bile duct. In 3 (75%) of 4 cases, an indwelling plastic stent was placed, and in one case in which the stent could not be advanced into the bile duct, a naso-biliary drainage tube was placed instead. In all cases, the obstructive jaundice rapidly improved after the procedure. Focal peritonitis and bleeding not requiring blood transfusion was seen in one case. In this case, pancreatoduodenectomy was performed and the surgical findings revealed severe adhesion around the choledochoduodenostomy site. Although further studies and development of devices are mandatory, EUS-guided choledochoduodenostomy appears to be an effective alternative to ERCP in selected cases.

Key words: Endoscopic ultrasonography-guided fine needle aspiration; Biliary drainage; Endoscopic retrograde cholangiopancreatography

Endoscopic ultrasound-guided choledochoduodenostomy in patients with failed endoscopic retrograde cholangiopancreatography. *World J Gastroenterol* 2008; 14(39): 6078-6082 Available from: URL: http://www.wjgnet.com/1007-9327/14/6078.asp DOI: http://dx.doi.org/10.3748/wjg.14.6078

INTRODUCTION

Endoscopic transpapillary biliary stenting is the most common procedure for biliary drainage in patients with obstructive jaundice. However, there are patients who failed to achieve bile duct access because of failed biliary cannulation or an inaccessible papilla due to severe duodenal stenosis caused by tumor invasion. Percutaneous transhepatic biliary drainage (PTBD) or surgical intervention is required in such cases. Both methods have a higher morbidity and mortality than endoscopic methods[1-5]. Recently, endoscopic ultrasonography (EUS)-guided choledochoduodenostomy has been reported as an alternative biliary drainage technique[6-10]. The aim of the study is to evaluate the potential role of EUS-guided choledochoduodenostomy in the biliary drainage.

CASE REPORT

This series includes all procedures performed at our institution between June 2005 and January 2008. At first,

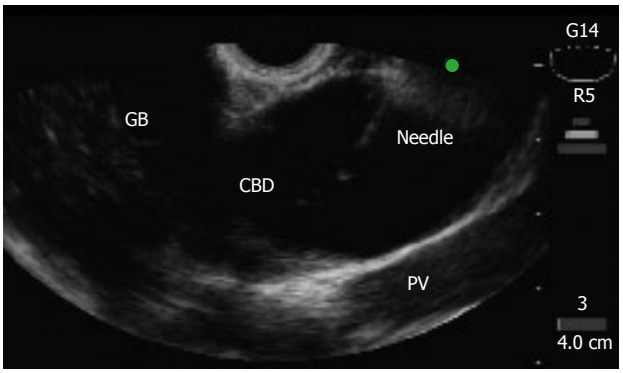

Figure 1 Convex echoendoscope clearly depicts the extrahepatic bile duct (green) (patient 3). GB: Gallbladder; CBD: Common bile duct; PV: Portal vein.

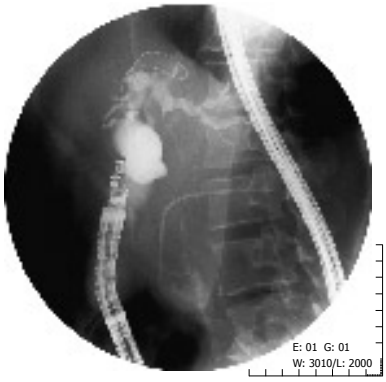

Figure 2 After EUS-guided puncture, contrast medium is injected into the bile duct for cholangiogram, a 0.035-inch guidewire was inserted into the outer sheath (patient 3).

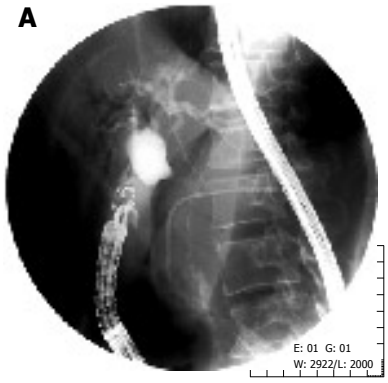

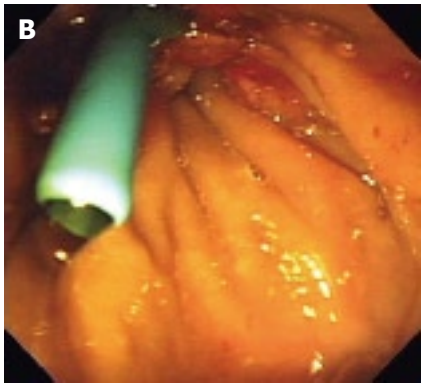

Figure 3 **A**: Choledochoduodenostomy was accomplished with a 7-Fr plastic stent in the apex of the duodenal bulb (patient 3); **B**: The stent was visible in the duodenal bulb (patient 3).

we attempted endoscopic retrograde cholangiography (ERCP) in all patients. If standard ERCP techniques failed, precut sphincterotomy was used for biliary cannulation. The EUS-guided choledochoduodenostomy was performed only in case of failed biliary cannulation or inaccessible papilla due to severe duodenal stenosis caused by tumor invasion. Using an echoendoscope with a curved linear array transducer, and a 3.7-mm accessory channel with an elevator (GF-UCT2000-OL5, Olympus Medical Systems Co. Ltd, Tokyo, Japan), the extrahepatic bile duct was visualized at the level of the duodenal bulb (Figure 1). A 19-gauge needle (EchoTip, Wilson-Cook, Winston-Salem, NC) without electrocoagulation, or a needle knife (Zimmon papillotomy knife, Wilson-Cook) with electrocoagulation (EndoCut ICC200, ERBE ELEKTROMEDIZIN GmbH, Tübingen, Germany) was inserted transduodenally into the bile duct under EUS visualization. After the central needle is removed, bile is aspirated and contrast medium is injected into the bile duct for cholangiography, and 450 cm long, a 0.035-inch guide wire is inserted into the outer sheath (Figure 2). If necessary, a biliary catheter for dilation, or papillary balloon dilator is used for dilation of duodenocholedochostomy site. Finally, a 7-Fr biliary plastic stent (FLEXIMA, Boston Scientific Japan, Tokyo, Japan) was inserted through the choledochoduodenostomy site into the extrahepatic bile duct (Figure 3).

After written informed consent was obtained from patients, all endoscopic procedures were performed with the patients under conscious sedation with intravenous flunitrazepam (5-10 mg). As for antibiotics, 1 g cefotiam hydrochloride was administered by intravenous drip infusion once on the test day and twice on the following day. This study was approved by the institutional review board of our institution.

Patient 1

An 80-year-old man was admitted for treatment of obstructive jaundice. Tumor invasion to the duodenal wall at the circumference of the major papilla was detected when the procedure was impossible. Biopsy specimens from the major duodenal papilla revealed adenocarcinoma of the papilla of Vater. Using a Zimmon needle knife, EUS-guide choledochoduodenostomy was performed. After dilation by a Soehendra dilator catheter (SBDC-7 and SBDC-9, Wilson-Cook), an indwelling 7-Fr plastic stent was placed across the choledochoduodenostomy site into the extrahepatic bile duct without any complications. The obstructive jaundice rapidly improved after insertion of the biliary stent. The stent did not occlude, and the patient died of pneumonia 3 mo after the procedure.

Patient 2

A 71-year-old man admitted for abdominal pain and obstructive jaundice. Computer tomography (CT)

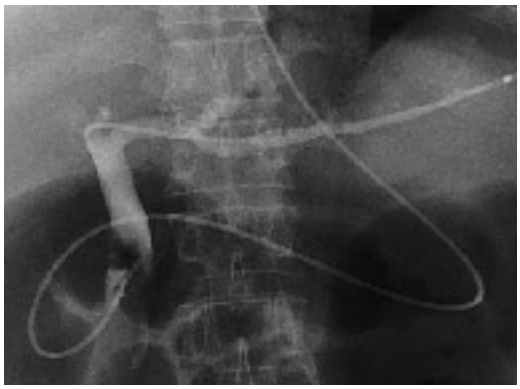

Figure 4 Choledochoduodenostomy was accomplished using a 5-Fr naso-biliary tube (patient 2).

showed a huge papilla of Vater tumor with a dilated bile duct and mild pancreatitis. Biopsy specimens from the major duodenal papilla revealed adenocarcinoma of the papilla of Vater. Imaging revealed that the tumor was resectable. However, since the biliary cannulation for biliary decompression was impossible because the tumor occupied the duodenal lumen, EUS-guided choledochoduodenostomy was performed. After puncture using a Zimmon needle knife, dilation of the choledochoduodenostomy site by a Soehendra dilator catheter was performed. Subsequently, we attempted to insert a 7-Fr plastic stent from the first portion of duodenum into the extrahepatic bile duct, but stent insertion was impossible because the tip of the stent became impacted in the bile duct site of choledochoduodenostomy. Although balloon dilation was performed across the choledochoduodenostomy site, a 7-Fr stent could not be inserted, therefore, a 5-Fr naso-biliary drainage tube was inserted into the left intrahepatic bile duct (Figure 4). Although the obstructive jaundice rapidly improved after the procedure, there was bleeding not requiring blood transfusion and smoldering focal peritonitis of choledochoduodenostomy site. No evidence of intra-abdominal bile leak was found by several cholangiography procedures via the naso-biliary drainage tube. Pancreatoduodenectomy 16 d after the procedure revealed severe adhesion around the choledochoduodenostomy site although choledochoduodenostomy was completed (Figure 5A). Histological examination revealed mild inflammatory cell infiltrate adjacent to the sinus tract in the duodenal and bile duct walls (Figure 5B-D). The patient is presently healthy 13 mo after surgery.

Patient 3

A 69-year-old man with a history of chronic pancreatitis and placement of pancreatic stent for the treatment of abdominal pain, was admitted with obstructive jaundice. ERCP was impossible because the duodenoscope could not pass through a severe stricture. EUS-FNA specimens from pancreas mass showed adenocarcinoma. Using a 19-gauge needle (EchoTip, Wilson-Cook), EUS-guided choledochoduodenostomy was performed. After dilation by a Soehendra dilator catheter, a 7-Fr plastic

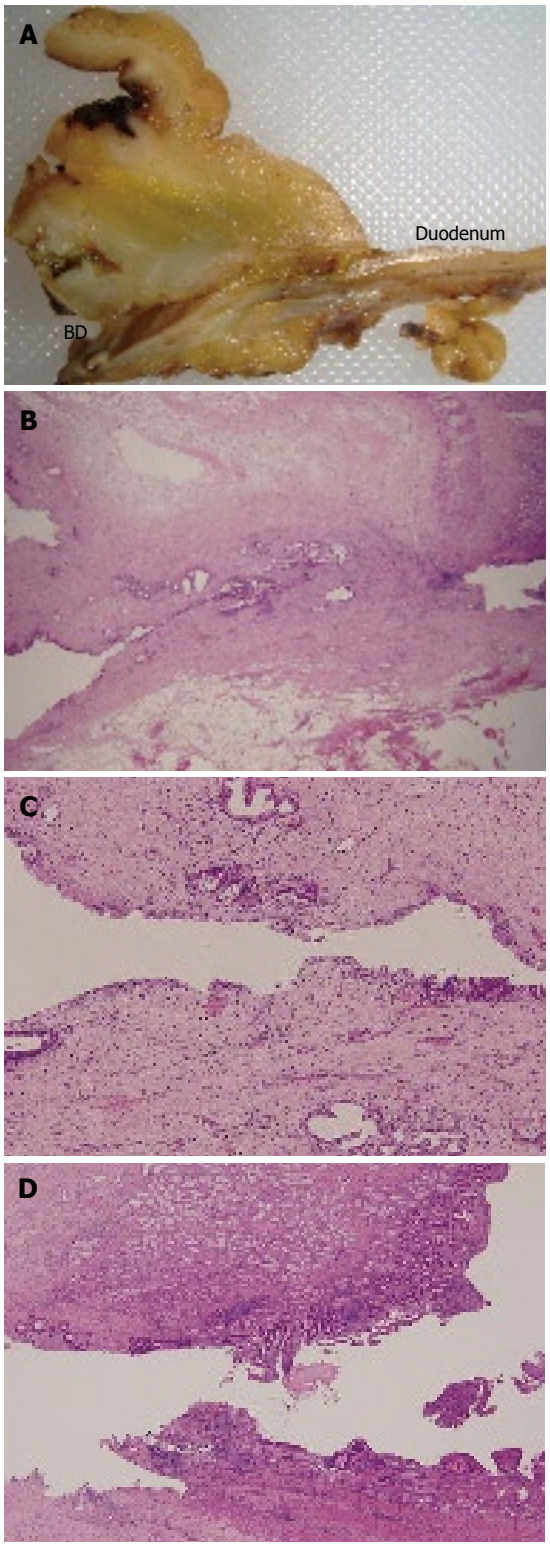

Figure 5 **A**: Macroscopic view of completed choledochoduodenostomy (patient 2); **B**: Surgical specimens showing the completed choledochoduodenostomy with mild inflammatory cell infiltrate adjacent to the sinus tract in the duodenal and bile duct walls (HE, × 20, patient 2); **C**: Magnification of bile duct site (HE, × 100, patient 2); **D**: Magnification of bile duct site (HE, × 100, patient 2). stent was placed into the extrahepatic bile duct without any complications. The obstructive jaundice rapidly improved after insertion of the biliary stent. Since acute cholangitis occurred 2 wk after the procedure due to stent clogging, we replaced the plastic stent

by a self-expandable metallic stent (SEMS) using a guide wire plus snare forceps technique because the choledochoduodenal fistula seemed to be incomplete. Actually, after placement of the first 10-Fr uncovered SEMS (Niti-S, Teung Medical Co. Ltd. Seoul, Korea), contrast medium flowed out of the bile duct to the intra-abdominal space. A second 10-Fr covered SEMS (Combi-S, Teung Medical Co. Ltd.), therefore, was placed in the first SEMS. No complications occurred and the patient had no symptoms 3 mo later at follow-up.

Patient 4

An 86-year-old woman with unresectable cancer of the head of the pancreas who had undergone biliary stenting 1 mo previously, was admitted with obstructive jaundice. At initial ERCP, an indwelling 10-Fr plastic stent (FLEXIMA, Boston Scientific Japan, Tokyo, Japan) was placed. ERCP was impossible because the duodenoscope could not pass through the tight stricture caused by cancer invasion. Then, EUS-guided choledochoduodenostomy was performed. Using a 19-gauge needle (EchoTip, Wilson-Cook), EUS-guided choledochoduodenostomy was performed. After dilation by a Soehendra dilator catheter, a 7-Fr plastic stent was placed into the extrahepatic bile duct without any complications. The obstructive jaundice rapidly improved after insertion of the biliary stent. No complications occurred and the patients had no related symptoms till she died 1 mo later.

DISCUSSION

Endoscopic biliary stent placement is the most well-established method for the treatment of obstructive jaundice[11]. When ERCP fails, usually, PTBD is chosen as an alternative method for treating biliary decompression[12]. Recently, EUS-guided biliary drainage using either direct access or a rendezvous technique, has attracted attention as an alternative procedure to ERCP or PTCS[6-10,13-17]. Until now, of these EUS-guided biliary drainage procedures, EUS-guided choledochoduodenostomy has been performed in 17 cases consisting of 11 pancreatic cancer, 4 papilla of Vater cancer, 1 bile duct cancer, and 1 bile duct stone[6-10].

The methodology and devices of EUS-guided choledochoduodenostomy are not yet fully established. Therefore, there are several important factors during the procedure to ensure technical success. First, as Yamao *et al*[9] mentioned, the scope position and puncture site are very important. Theoretically, the scope pushing position at which the tip of the convex transducer is directed at the hepatic hilum, is promising because the access route to the bile duct is shorter from the duodenal bulb to the bile duct and the echoendoscope is stable when several devices are advanced into the bile duct through the working channel[9]. However, when there is duodenal stenosis due to tumor invasion, anatomically abnormal situation after surgery, the same scope position may not be always possible. Second, the type of puncture needle also may be one of the most important factors. Several reports describe that various types of needle knife are used for puncture in all but two cases (88%, 15/17)[6-10]. Although a needle knife could make a larger hole compared to a fine-needle aspiration (FNA) needle which needs dilators or balloon dilation for the subsequent procedure, a larger hole may lead to possible intra-abdominal bile leak. In the present series, we used both a FNA needle and a needle knife with electrical coagulation. Unfortunately, one case using a needle knife failed in stent insertion despite making a comparatively large hole and also using a dilator and balloon. The main reason for this may be that the tip of the convex transducer was directed not at the hepatic hilum but the distal bile duct. In this case, the direction of the guidewire was changed from distal bile duct to hepatic hilum to enable technical success. Therefore, it may be possible that the choledochoduodenostomy site became kinked and the stent could not torque adequately because of the instabilization of the scope. These data suggest that technical success of EUS-guided choledochoduodenostomy may depend not on the choice of needle, but mainly the scope position and direction of puncture.

Several investigators used various diameter plastic stents[6,7,9,10,18] or a SEMS[8]. Although the stent diameter depends on the echoendoscope used, large bore plastic stent may be better for long patency, similar to the conventional transpapillary plastic stent. Recently, Yamao *et al*[19] has reported that the mean stent patency of 7- 8.5-Fr plastic stents for EUS-guided chodedocho-duodenostomy was 211.8 d. Since there are few data on SEMS in this procedure, the usefulness of SEMS should be evaluated from the aspect of cost effectiveness including the issue of the use of uncovered or covered SEMS.

Previous data revealed that the procedure was successful in all but 2 cases (a total success rate of 88%) and once stents were placed, all patients had successful resolution of biliary decompression. In the present study, in all patients, the obstructive jaundice rapidly improved after insertion of the biliary stent. These data suggest that this procedure may be as effective as conventional transpapillary biliary drainage once the indwelling stent is placed.

Surprisingly, no serious procedure-related complications were found in several reports although there was 1 case of mild focal bile peritonitis and 3 of pneumoperitoneum[6-10]. In the current study, we encountered 1 focal peritonitis with bleeding without severe complications. However, we must be cautious in evaluating the safety of the procedure because previous published data may be biased towards successful cases.

In conclusion, we report four cases of EUS-guided choledochoduodenostomy for the treatment of obstructive jaundice. This procedure was performed successfully, without severe complications and with highly effective biliary drainage. Although further studies and development of devices are necessary, EUS-guided choledochoduodenostomy can be an effective alternative to ERCP.

Abstract

A 76-year-old woman with a 5-mo history of recurrent diarrhea and generalized edema was admitted to our hospital. Colonoscopy revealed edematous mucosa, and histopathological examination was compatible with collagenous colitis. Protein leakage from the colon, particularly in the ascending portion, was identified on 99mTc-human serum albumin scintigraphy. Collagenous colitis associated with protein-losing enteropathy (PLE) without small bowel disease was diagnosed. Prednisolone treatment ameliorated diarrhea and hypoproteinemia. Collagenous colitis should be included in the differential diagnosis of chronic diarrhea with hypoproteinemia for appropriate management.

Key words: Collagenous colitis; Protein-losing enteropathy; Prednisolone; 99mTc-human serum albumin scintigraphy; chronic diarrhea

INTRODUCTION

Since the first report in 1976[1], collagenous colitis has been found to be associated with a variety of conditions, including use of non-steroidal anti-inflammatory drugs[2] and proton pump inhibitors[3]. This condition is characterized by chronic watery diarrhea and abnormal deposition of collagen beneath the colonic epithelium[4]. Severe hypoproteinemia due to enteric protein loss is rare unless accompanied by small bowel malabsorption syndrome, such as celiac sprue. To the best of our knowledge, only 1 case of collagenous colitis associated with protein-losing enteropathy (PLE) in the absence of small bowel disease has been reported[5]. We report herein another case of collagenous colitis associated with PLE without small bowel disease, in which PLE was diagnosed by 99mTc-human albumin (HSA) scintigraphy.

CASE REPORT

A 76-year-old woman with a 5-mo history of recurrent diarrhea and generalized edema was admitted to our hospital. Repeated colonoscopies and gastrointestinal scope at a previous hospital had shown no abnormal changes in the gastrointestinal mucosa. The patient had been taking 180 mg of loxoprofen sodium and 30 mg of lansoprazole every day for the past 3 years, for osteoarthritis of the knees, but had otherwise been healthy with no prior history of gastrointestinal disease. Family history was unremarkable.

On admission, weight was 53 kg and height was 144 cm. She was afebrile, with a blood pressure of 128/84 mmHg and a heart rate of 82 beats/min. The right lower abdominal quadrant was slightly painful on palpation, the face was swollen, and pretibial pitting edema was also present. No superficial lymph nodes

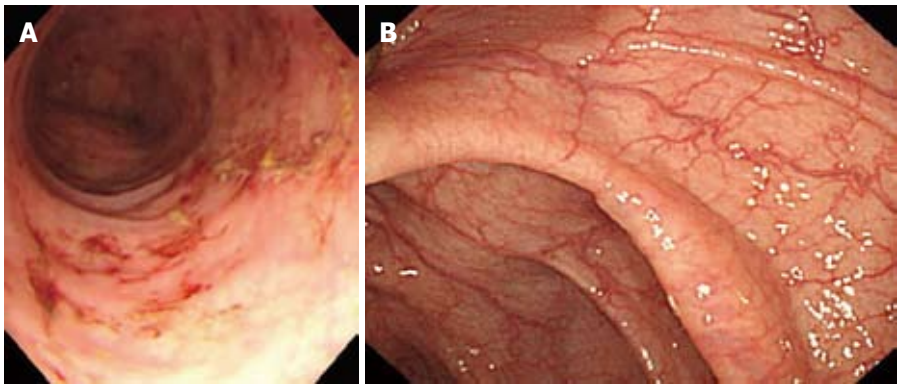

Figure 1 Colonoscopy shows an edematous mucosa, diminished vascular transparency throughout the colon on admission. Friability of mucosa and multiple erythema were observed (**A**). Endoscopic findings 1 mo after treatment showed normal mucosa (**B**).

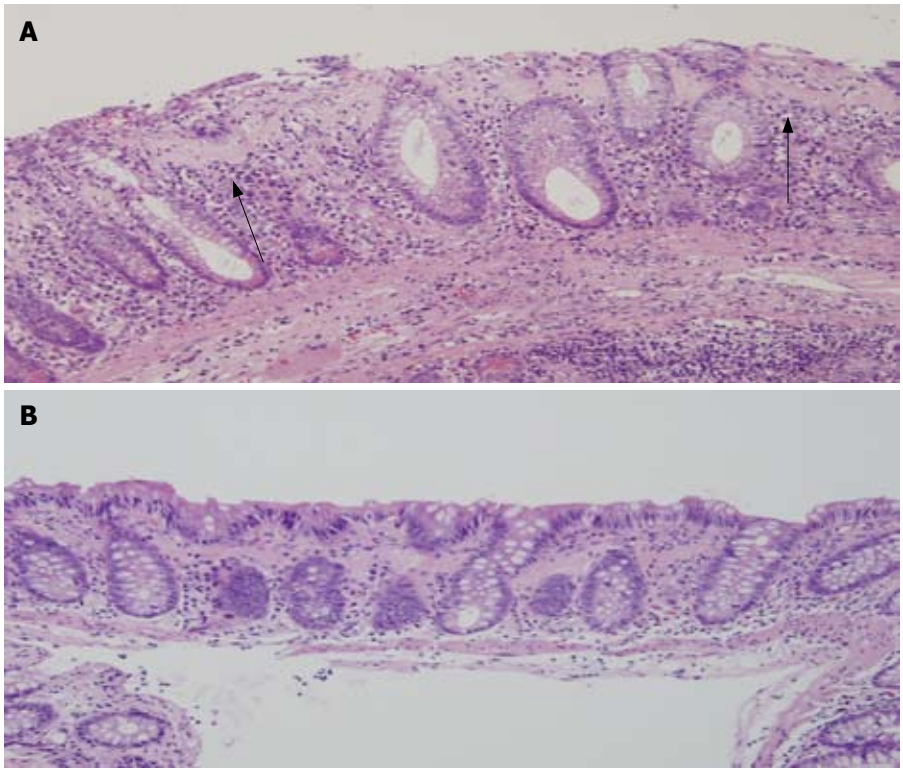

Figure 2 Histology of the biopsied specimen demonstrates subepithelial from eosinophilic band-like deposit (arrows), with increased lymphocytes and plasma cells. Sloughing of surface epithelium is also shown (**A**). Epithelial detachment and inflammatory cells decreased, although the collagen band beneath the mucosa was not reduced (**B**).

were palpable. Laboratory investigations revealed: white blood cells, 7960/mm^3; C-reactive protein, 0.31 mg/dL; total protein, 4.8 g/dL; plasma albumin, 2.8 mg/dL; no abnormalities in liver, renal, thyroid and adrenal function tests; negative serology for rheumatoid factor; normal results of urinalysis and no proteinuria. Moreover, no steatorrhea was identified, indicating that malabsorption syndrome was unlikely.

Endoscopic examination of the lower intestinal tracts showed edematous mucosa, diminished vascular transparency and multiple areas of erythema (Figure 1A). Multiple biopsies revealed changes consistent with collagenous colitis, showing prominent subepithelial eosinophilic band-like deposits with increased lymphocytes and plasma cells (Figure 2A). The distribution of the disease was whole colon and the findings were worse in the right compared to the left colon. The thickness of the collagen layer was 80-100 μm in the right and 40-50 μm in the left. There were no areas of cryptitis, crypt abscesses and no area of superimposed infection inflammatory bowel disease. Sloughing of surface epithelium was also identified. Endoscopic examination and biopsies of other portion of the gastrointestinal tract showed no obvious abnormalities in the stomach and the small intestine, and there was no evidence of celiac sprue. The duodenum showed normal villi and no obvious lymphocyte infiltration. Small bowel barium study showed no abnormalities. On 99mTc HSA scintigraphy, protein leakage was detected throughout the whole colon, particularly in the ascending portion (Figure 3A). No leakage was apparent from the stomach or small intestine. Neither chest/abdominal computed tomography (CT) nor ^{67}Ga scintigraphy showed any evidence of malignancy. On the basis of these findings, collagenous colitis associated with PLE was diagnosed.

After diagnosis, loxoprofen sodium and lansoprazole were discontinued. However, general condition remained unimproved. Administration of 1.8 g polycarbophil calcium, 2 g natural aluminum silicate, 2 g bifidobacterium, 20 mg scopolamine butylbromide, 4 mg loperamide hydrochloride and 2 g albumin tannate

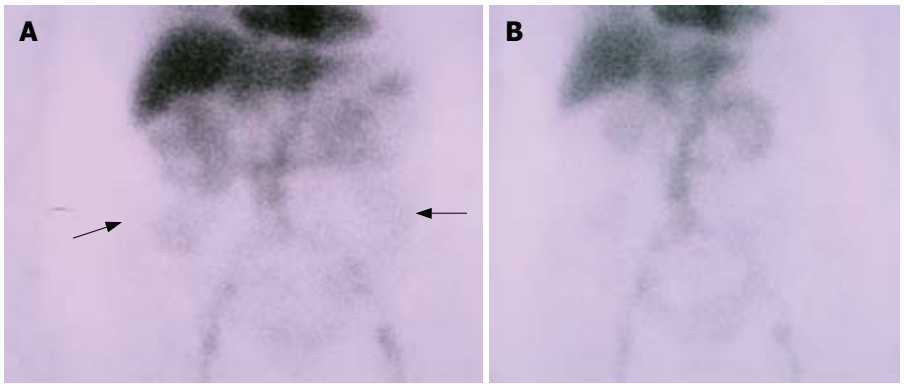

Figure 3 99mTc-human serum albumin scintigraphy shows leakage of the tracer in the large bowel (arrows) on admission (**A**) but no accumulation 1 mo after starting oral prednisolone (**B**).

likewise did not improve symptoms, and serum protein and albumin levels remained low despite administration of human serum albumin. Frequency of diarrhea increased and abdominal pain became extremely severe, and the condition of the patient deteriorated. We decided to start prednisolone therapy after hypovolemic shock developed. Soon after initiating prednisolone treatment at 30 mg/d, abdominal pain and diarrhea dramatically improved along with general condition. Total plasma protein and plasma albumin levels gradually increased to 5.4 g/dL and 3.4 g/dL, respectively, by 1 mo after starting prednisolone therapy. Follow-up endoscopy showed normal-appearing colonic mucosa (Figure 1B), and multiple biopsies showed decreased epithelial detachment and inflammatory cells, although the collagen band beneath the mucosa was not reduced (Figure 2B). Additional 99mTc HSA scintigraphy showed no accumulation of tracer in the large bowel, indicating remission of PLE (Figure 3B).

DISCUSSION

This patient presented with chronic diarrhea and anasarca with severe hypoproteinemia, and colonoscopic examination revealed collagenous colitis. We considered that hypoproteinemia was enteric in origin, as no proteinuria, liver disease, cardiac disease or other inflammatory disease was present. Severe enteric protein loss causing hypoproteinemia is reportedly rare in collagenous colitis unless accompanied by small bowel malabsorption syndrome. In the present case, coexistence of malabsorption syndrome was unlikely given the absence of steatorrhea, which is characteristic of malabsorption syndrome. Furthermore, histopathology of the duodenum revealed no evidence of celiac sprue.

The cause of hypoproteinemia was thus considered to be excessive enteric protein loss without malabsorption syndrome. Small bowel barium radiography showed no abnormality such as Crohn's disease or malignant lymphoma, or other diseases that could cause PLE. Furthermore, 99mTc HSA scintigraphy revealed no accumulation of tracer in the small bowel. Considering that no obvious small bowel disease was present, collagenous colitis itself might have been the cause of PLE and 99mTc HSA scintigraphy is useful in this case[6,7].

Although the mechanisms of enteric protein loss in patients with collagenous colitis have not been clarified, abnormalities of the surface epithelium[8], superficial capillaries[9] and pericryptal fibroblasts[10] have been hypothesized. Long-term use of loxoprofen sodium and lansoprazole may be associated in the pathogenesis of severity of collagenous colitis in this patient. In the present case, histological examination revealed marked reductions in epithelial detachment together with clinical improvement after prednisolone therapy, suggesting that abnormalities of surface epithelium play an important role in the development of PLE. The endoscopic findings of collagenous colitis are thought to be normal and nonspecific[11]. In the present case, however, endoscopic examination revealed edematous mucosa, diminished vascular transparency and multiple red spots, and histological examination revealed sloughing of surface epithelium, suggesting this was a severe case of collagenous colitis. This may be one reason why the patient developed PLE.

No established treatments have yet been defined for PLE associated with collagenous colitis[12]. Corticosteroids are occasionally used for the treatment of collagenous colitis and some studies have shown that prednisolone treatment is ineffective[13] and budesonide is effective for collagenous colitis without PLE[14,15]. As oral budesonide is unavailable in Japan, prednisolone treatment was selected because prednisolone has been reported to ameliorate PLE caused by other diseases through the reduction of submucosal edema and inflammation in the gastrointestinal tract. In the present case, oral prednisolone was effective for refractory diarrhea and exudative enteropathy. Corticosteroid was provided at a dose of 30 mg/d, and general status of the patient immediately improved in parallel with a decrease in the frequency of diarrhea and an increase in serum total protein.

Abnormal protein leakage on 99mTc HSA scintigraphy was diminished and biopsy specimens from the colon after treatment histopathologically reflected the efficacy of this therapy in terms of reduced epithelial sloughing and inflammatory cells, although the collagen band under the mucosa was largely unchanged. These results suggest that treatment with prednisolone may be effective for PLE associated with collagenous colitis.

In summary, we have reported a patient with collagenous colitis who presented with PLE. Prednisolone treatment ameliorated diarrhea and hypoproteinemia. Collagenous colitis should be included in the differential diagnosis of chronic diarrhea with hypoproteinemia to achieve appropriate management.

Abstract

A 69-year-old man was diagnosed as having myasthenia gravis (MG) in September 2004, and treated with thymectomy and prednisolone. He was then diagnosed as having steroid-induced diabetes mellitus, and received sulfonylurea (SU) therapy in May 2005. An alpha-glucosidase inhibitor (αGI) was added in March 2006, resulting in good glycemic control. He experienced symptoms of abdominal distention, increased flatus, and constipation in October 2007, and was admitted into our hospital in late November with hematochezia. Plain abdominal radiography revealed small linear radiolucent clusters in the wall of the colon. Computed tomography (CT) showed intramural air in the sigmoid colon. Colonoscopy revealed multiple smooth surfaced hemispherical protrusions in the sigmoid colon. The diagnosis of pneumatosis cystoides intestinalis (PCI) was made on the basis of these findings. As the αGI voglibose was suspected as the cause of this patient's PCI, treatment was conservative, ceasing voglibose, with fasting and fluid supplementation. The patient progressed well, and was discharged 2 wk later. Recently, several reports of PCI associated with αGI therapy have been published, predominantly in Japan where αGIs are commonly used. If the use of αGIs becomes more widespread, we can expect more reports of this condition on a global scale. The possibility of PCI should be considered in diabetic patients complaining of gastrointestinal symptoms, and the gastrointestinal tract should be thoroughly investigated in these patients.

INTRODUCTION

Pneumatosis cystoides intestinalis (PCI) is a rare condition in which multiple submucosal or subserosal pneumocystis develop in the submucosa or in subserosa of the colon[1,2]. The etiological mechanisms are unclear, although PCI has been reported to develop in association with raised intra-abdominal pressure due to ileus surgery[3-5], colonoscopy[6], pulmonary diseases such as chronic bronchitis and emphysema[7], trichloroethylene exposure[8], connective tissue disorders[9,10], the use of immunosuppressants[11], and ingestion of carbohydrates such as lactulose[12] and sorbitol[13]. Recently, the development of PCI during treatment with alpha-glucosidase inhibitors (αGIs), a new class of anti-diabetic agents, has been reported[14,15]. Our literature search yielded only 13 cases of PCI associated with αGI therapy[14-26]. Herein, we present a case depicting αGI as the probable cause of PCI, along with a review of the literature.

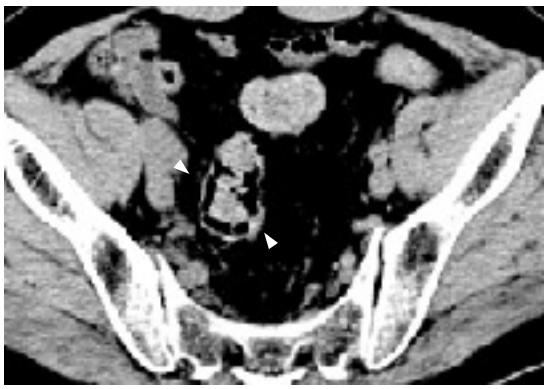

Figure 2 Computed tomography (CT) scanning of the abdomen on admission revealing intramural gas in the sigmoid colon (white arrows).

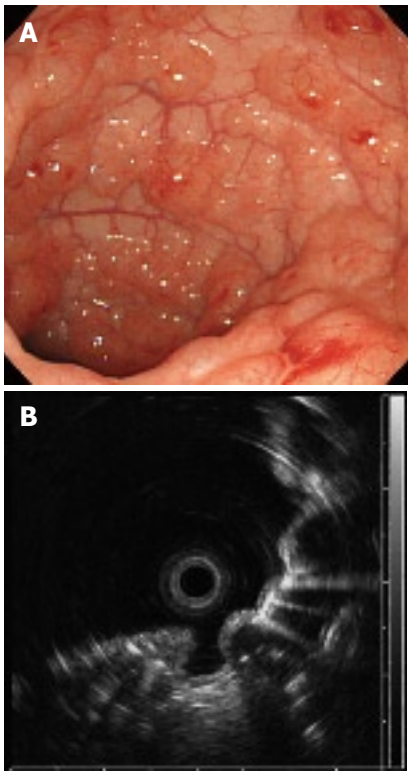

Figure 3 Colonoscopy on admission showing multiple round and smooth-surfaced elevated lesions like submucosal tumors in the sigmoid colon (**A**) and endoscopic ultrasonography (EUS) revealing hyperechoic lesions and acoustic shadows in the submucosal layer (**B**).

CASE REPORT

A 69-year-old man was diagnosed as having severe myasthenia gravis (MG) in September 2004, and treated with prednisolone (5 mg/d) from October of that year. He underwent thymectomy in March 2005. Hyperglycemia was detected in May 2005, leading to the diagnosis of steroid-induced diabetes mellitus, and sulfonylurea (SU) therapy was commenced immediately. As his blood sugar could not be controlled, αGI was prescribed in March 2006, resulting in good glycemic control. He claimed to have experienced abdominal distension, increased flatus and constipation, and noticed small amounts of bright rectal bleeding as early as mid-October 2007, but did nothing about it. The amount of rectal bleeding increased in late November that year, and he was referred to our hospital for investigation and treatment.

Laboratory investigations revealed no abnormalities in white blood cell (WBC) count, hemoglobin (Hb), or C-reactive protein, and HbA1c was slightly elevated to 6.0%. Plain abdominal radiography revealed small linear radiolucent gas collections along the wall of the colon (Figure 1). Unenhanced computed tomography (CT) of the abdomen showed intramural air in the sigmoid colon, and free gas in the peritoneal cavity around the sigmoid colon (Figure 2). Colonoscopy revealed multiple smooth surfaced small hemispherical protrusions in the sigmoid colon, and endoscopic ultrasonography (EUS) demonstrated highly echogenic submucosal lesions with acoustic shadows (Figure 3). The diagnosis of PCI was made on the basis of these findings.

As voglibose was suspected to be the cause of this patient's PCI, conservative treatment was administered, including ceasing the voglibose, along with fasting and fluid supplementation. The patient progressed well and plain abdominal radiography 2 wk later showed that the linear collections of gas along the wall of the colon were disappeared, and consequently the patient was discharged. Colonoscopy 3 mo later showed complete resorption of the pneumocystis throughout the sigmoid colon, leaving white scars. EUS confirmed disappearance of the submucosal acoustic shadows, indicating the resolution of PCI.

DISCUSSION

PCI, first reported by Du Vernoi[27] in 1730, is a rare condition in which multiple submucosal or subserosal pneumocystis develop in the submucosa or subserosa of the colon. It was previously thought to occur most frequently in the ileum, but with the recent increase in the number of barium enemas and colonoscopies performed, PCI now reportedly affects the colon more commonly.

There are some recent reports on PCI associated with αGI therapy[14-26]. The mechanism is thought to involve intestinal gas production through fermentation-by the intestinal flora-of carbohydrates whose absorption is inhibited by αGI. Along with peristaltic hypofunction

associated with diabetes mellitus, this leads to raised intraluminal pressure, allowing the gas-producing bacteria to invade the colonic mucosa through breaks in the mucosal integrity, forming pneumocystis[14,15].

Our review of the medical literature between 1983 and 2008 yielded 7 cases of PCI associated with αGI therapy in PubMed [English language; 14, 15, 18, 21, 22, 25, 26], and 6 in Japana Centra Revuo Medicina [Japanese language; 16, 17, 19, 20, 23, 24]. The details of these cases, totaling 14 with the addition of our present case, are shown in Tables 1 and 2. All but 1 of the 14 cases was reported in Japan. About 30% of

ND: Not done.

the Japanese diabetics are prescribed αGIs, which are rarely administered in Western countries where fats account for a larger proportion of the caloric intake than carbohydrates[28,29]. The preponderance of Japanese reports on αGI-associated PCI is not surprising as the Japanese market accounts for 98% of the total sales of voglibose, and 34% of those for acarbose.

The mean age of the 14 patients was 65.9 years, while 7 were male and 7 were female. The causative agent was voglibose in 9 cases and acarbose in 5, while none was caused by miglitol. The global market share in 2005 for voglibose and acarbose was in a ratio of

roughly 3:2. Miglitol was not released in Japan until 2006, and accordingly no reports are available on PCI associated with the newest agent. As future cases are reported, we expect that there will be no significant differences in the incidence of PCI between these agents. The mean prescribed dosages were 0.64 mg/d for voglibose and 200 mg/d for acarbose. The interval between commencement of αGI therapy and the onset of PCI varied greatly, ranging from 7 d to 11 years. The most common symptoms were abdominal distention (57%) and abdominal pain (36%), while only 2 cases had hematochezia (14%) as in the case described herein (Table 1).

Different radiological and endoscopic modalities are useful in the diagnosis of PCI. To summarize the imaging findings in the 14 reported cases (Table 2), linear or round radiolucent gas collections were seen along the wall of the colon in plain abdominal radiographs in most cases, and pneumatosis was seen within or along the wall of the colon on abdominal CT scanning. Subserous pneumocystis in particular are liable to rupture, releasing free gas into the peritoneal cavity, making it important to distinguish this condition from bowel perforation[30]. Multiple rounded protrusions are a common finding in barium enema examinations of patients with PCI. The colonoscopic findings may be similar to multiple polyposis or collections of submucosal tumors, but subserous pneumatosis may go undetected.

With cessation of αGI therapy, conservative treatment could lead to resolution of PCI within 28 d. In the 2 cases where αGI therapy was continued, resolution took more than 120 d. Therefore, ceasing the αGI therapy is the key to successful treatment of PCI. One case underwent emergency surgery due to the presence of free air in the peritoneal cavity, where bowel perforation could not be ruled out[19]. In our case, there were 2 possible causes, namely, the αGI voglibose and prednisolone. Since our patient claimed to have experienced abdominal distention, increased flatus and constipation prior to the onset of PCI, we considered voglibose the causative agent. We therefore ceased αGI and continued corticosteroid therapy, and kept our patient fasting with fluid supplementation, achieving resolution of PCI after 14 d (Table 1).

The symptoms of PCI include abdominal pain, diarrhea and abdominal distention, none of which is disease specific. Diabetic patients sometimes develop autonomic neuropathy, with gastrointestinal symptoms similar to those of PCI. As αGI therapy is commonly used in Japan, it is difficult to determine whether diabetic patients complaining of gastrointestinal symptoms are suffering only from diabetes mellitus or from PCI. If the clinical picture of diabetes mellitus is consistent with that of PCI, diabetes mellitus can be detected by plain abdominal radiography. The possibility of PCI should be considered in diabetic patients complaining of gastrointestinal symptoms, and appropriate investigations should be performed with this potential diagnosis in mind.

In this report, we presented a case of PCI associated with αGI therapy, and a review of the literature. Our patient recovered rapidly after conservative treatment, including ceasing of the voglibose, fasting, and fluid supplementation. Recently, several reports on PCI associated with αGI therapy have been published, predominantly from Japan where αGIs are commonly used[14-21,23,24]. If the use of αGIs becomes more widespread internationally, we can expect more reports of this condition globally. The possibility of PCI should be considered in diabetic patients complaining of gastrointestinal symptoms, and the gastrointestinal tract should be thoroughly investigated in these patients.

Abstract

Transgastric endoscopic necrosectomy has been recently introduced as the effective and alternative management of infected pancreatic necrosis and pancreatic abscess. However, up to 40% of patients who undergo endoscopic necrosectomy may need an additional percutaneous approach for subsequent peripancreatic fluid collection or non-resolution of pancreatic necrosis. This percutaneous approach may lead to persistent pancreatocutaneous fistula, which remains a serious problem and usually requires prolonged hospitalization, or even open-abdominal surgery. We describe the first case of pancreatocutaneous fistula and concomitant abdominal wall defect following transgastric endoscopic necrosectomy and percutaneous drainage, which were endoscopically closed with fibrin glue injection *via* the necrotic cavity.

Key words: Fibrin glue; Pancreatocutaneous fistula; Infected pancreatic necrosis; Pancreatic abscess; Endoscopic necrosectomy

INTRODUCTION

Infected pancreatic necrosis and pancreatic abscess are serious complications of acute pancreatitis, and open necrosectomy is the mainstay of management for these complications[1]. However, operation-related morbidity and mortality, and longer hospitalization are not uncommon complications[1,2]. Transgastric endoscopic necrosectomy has been recently introduced as the effective and alternative management for infected pancreatic necrosis and pancreatic abscess[3-7]. However, up to 40% of patients who undergo endoscopic necrosectomy may need an additional percutaneous approach for subsequent peripancreatic fluid collection or non-resolution of pancreatic necrosis[8]. This percutaneous approach may lead to persistent pancreatocutaneous fistula, which remains a serious problem and usually requires prolonged hospitalization, or even open-abdominal surgery[9-12]. We describe the first case of pancreatocutaneous fistula and concomitant abdominal wall defect following transgastric endoscopic necrosectomy and percutaneous drainage, which were endoscopically closed with fibrin glue injection *via* the necrotic cavity.

CASE REPORT

A 63-year-old woman with acute biliary pancreatitis was admitted to our hospital. A computer tomography (CT) scan showed pancreatitis, peripancreatic fluid collection and gallbladder (GB) wall thickening with polypoid lesions. Endoscopic retrograde cholangiopancreatography (ERCP) showed a GB cancer with combined anomalous union of the pancreaticobiliary duct. After interdisciplinary consultation, although the patient suffered from acute biliary pancreatitis with peripancreatic fluid collection,

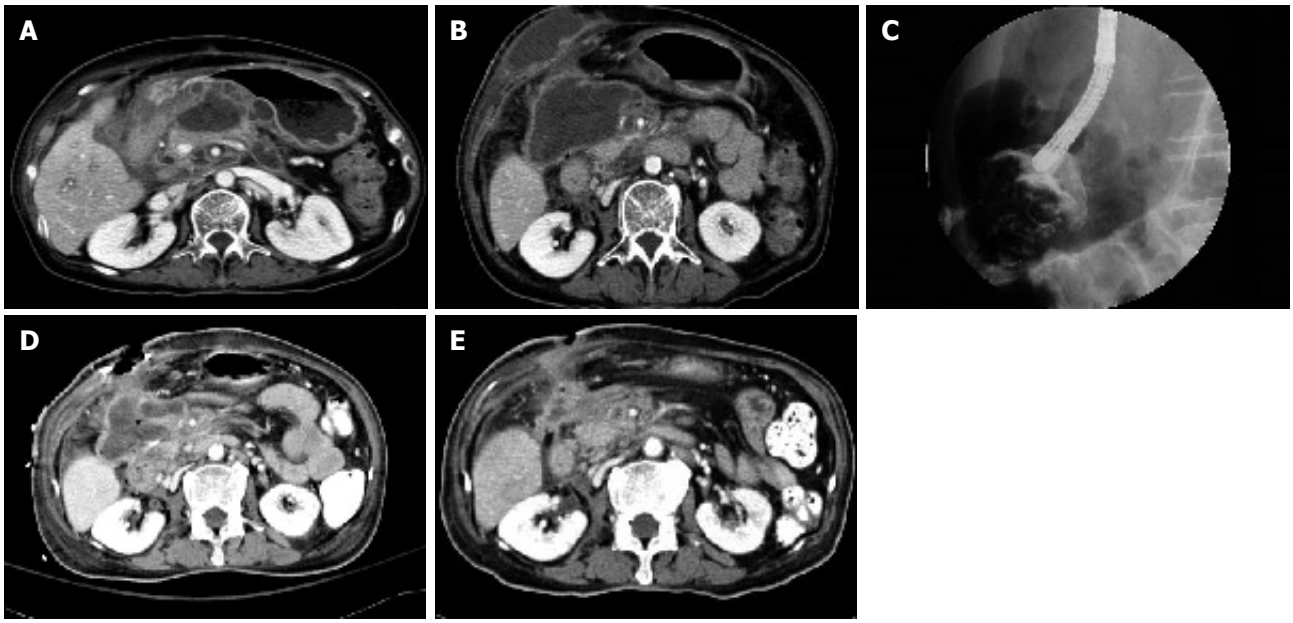

Figure 1 Multiple peripancreatic fluid collections on the body and head portions of the pancreas with a subcutaneous abscess on the right upper quadrant connected to theses peripancreatic fluid collections (**A**, **B**), fluoroscopy and follow-up CT showing a frank pancreatocutaneous fistula and abdominal wall defects alongside the percutaneous route (**C**, **D**), follow-up CT showing nearly resolved infected peripancreatic nerosis, pancreatocutaneous fistula, and abdominal wall defect after endoscopic necrosectomy and repair of the fistula with fibrin glue (**E**).

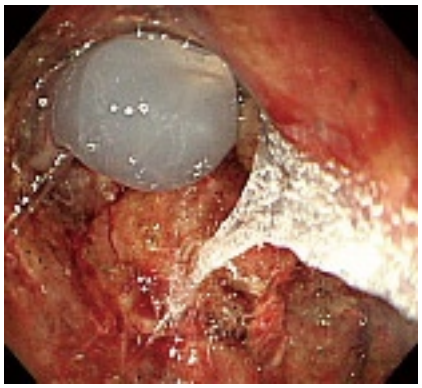

Figure 2 Complete obliteration of the fistula tract after injection of fibrin glue beyond and on the luminal side of the fistula.

we decided to perform an open cholecystectomy. Resected specimen revealed a stage Ⅱ GB cancer. The patient's postoperative recovery was uneventful.

Two months later, she was readmitted for fever and previous operation wound site bulging, redness, and heat. A CT scan revealed the aggravation of fluid collection in her abdominal wall's right upper quadrant, in addition to peripancreatic fluid collection bulging into the body portion of her stomach (Figure 1A and B). We inserted a percutaneous pig-tail catheter for subcutaneous fluid collection and performed an endoscopic transgastric necrosectomy because the patient refused a surgical intervention.

As our previous reports illustrate[13,14], a transgastric endoscopic necrosectomy was performed. During endoscopic necrosectomy and saline irrigation with a water-jet scope (GIF-Q 260J; Olympus Optical Co, Tokyo, Japan), skin wound dehiscence at the incision site of open cholecystectomy occurred alongside the percutaneous route (Figure 1C and D). The patient suffered from discharge (about 100 CC/d) of necrotic materials through the skin wound dehiscence, and extensive skin excoriation. During follow-up endoscopic examination, 50-100 CC of pus with a high concentration of amylase (23220 IU/L) was drained daily through the fistula tract and abdominal wall defect. Subsequent ERCP showed the long common channel of pancreatobiliary duct but no disruption of the main pancreatic duct. Because the surgeon recommended conservative management with additional insertion of a Penrose drain to resolve the wound dehiscence, rather than an operative wound revision, we decided to close the fistula endoscopically. On follow-up endoscopic evaluation, we identified a fistula tract between the necrotic cavity and skin connected to the subcutaneous abscess. The size of fistula was about 1 cm. We endoscopically injected fibrin glue as a sealing material *via* the necrotic cavity (Figure 2). A total of 8 mL of fibrin glue (Tisseel; Baxter, West-lake Village, Calif.) was injected into the fistula tract through a double lumen catheter. The patient showed no post-procedural complications, such as anaphylactic reaction. The day after endoscopic closure of the fistula with fibrin glue injection, no pus was discharged from the pancreatocutaneous fistula. On the fifth day after endoscopic closure of the fistula, the wound's dehiscence was also spontaneously closed, with no additional sutures. A follow-up CT scan also showed near resolution of the infected peripancreatic necrosis and sealing of the pancreatocutaneous fistula and abdominal wall defect (Figure 1E). During a 3-mo follow-up period, no relapse of the pancreatocutaneous fistula occurred.

DISCUSSION

During transgastric endoscoic necrosectomy with

a percutaneous approach, patients may develop a pancreatocutaneous fistula. Although small external fistulae with integrity of pancreatic duct can be spontaneously closed, management of large external fistulae or abdominal wall defects, as in our case, may be cumbersome[9-11]. During endoscopic necrosectomy, adequate endoscopic irrigation is essential for removal of necrotic tissue[7]. As in this case, however, saline irrigation with a water-jet scope during endoscopic necrosectomy may be a precipitating factor for frank pancreatocutaneous fistula and wound site dehiscence alongside the percutaneous catheter because the endoscope may block the outflow tract of the cavity during lavage and consequence pressure becomes too high and the wall is perforated[7]. For closure of this pancreatocutaneous fistula, we selected fibrin glue. Fibrin glue injection has been previously used during endoscopy for wound closure and fistula repair[15-18]. Fibrin glue is a biologic tissue adhesive based on a combination of fibrinogen and thrombin that forms a cell-free clot, and it has been shown to have tissue-healing properties and to be fully reabsorbed by macrophages and fibroblasts within 2 wk of application[15,16,19].

High-output (> 500 CC/d) external fistulae have a particularly poor prognosis, and are a potential cause of recurrence compared to low-output (< 200 CC/d) external fistulae[10,11]. Our patient showed a low-output external fistula and an intact main pancreatic duct on pancreatography. This is why endoscopic fibrin glue injection *via* the necrotic cavity alone is effective for rapid closure of fistula and abdominal wall defect, without further surgical management. Though there are few data about the fistula size, a small size of fistula might have contributed to our complete result and good prognosis. In addition, we did not consider using a hemoclip to close the fistula because its placement *via* the necrotic cavity would have been "in-body" and we were concerned with the difficulty of approximating, and bleeding of the friable necrotic cavity using a hemoclip. After the fistula was closed, no fluid recollection was observed, thus complete removal of necrotic tissue was achieved.

In summary, endoscopic fibrin glue injection *via* necrotic cavity is a safe, less invasive, rapid, and effective technique for closure of pancreatocutaneous fistulae and abdominal wall defects following transgastric necrosectomy with percutaneous drainage. We think that this procedure is proper for low-output (< 200 CC/d), small size (diameter < 1 cm) fistulae, and inner surface should be reached endoscopically. However, some established indications for selecting patients are lack as yet. Therefore, further studies are necessary.

Abstract

The molecular targets of sunitinib are receptor tyrosine kinases (RTKs), and this drug has also been known to exert blocking effects on the activation of KIT, which is similar to the mechanism of action of imatinib. Moreover, sunitinib has an additional anti-angiogenic effect through its inhibition of the vascular endothelial growth factor receptor activation. We report here a 70-year-old patient diagnosed with a recurrent gastrointestinal stromal tumor (GIST), which invaded the transverse colon and led to a perforation during sunitinib treatment. A computed tomography scan and 3-dimensional reconstruction showed necrosis of the recurrent hepatic mass and perforation of the invaded transverse colon. After percutaneous drainage of the intraperitoneal abscess, antibiotic treatment and restricted diet, the condition of the patient improved. The present case is the first to report that sunitinib, which is administered to treat GIST resistant to imatinib, can cause unexpected colon perforation and subsequent peritonitis.

INTRODUCTION

Sutent (Pfizer, New York, NY) is the malate salt of sunitinib, which is a small molecule that inhibits multiple receptor tyrosine kinases (RTKs)[1]. This molecular target is the basis for the application of sunitinib in the treatment of gastrointestinal stromal tumors (GISTs), which result from the molecular abnormalities of tyrosine kinases such as KIT[2]. In addition, the targets of sunitinib involve vascular endothelial growth factor receptors (VEGFR1, VEGFR2 and VEGFR3), platelet-derived growth factor receptors (PDGFRα and PDGFRβ) and the like. Although this drug has been approved by the US Food and Drug Administration (FDA) for treatment of GIST patients following progression or resistance to imatinib (Gleevec; Novartis, Switzerland), randomized phase Ⅲ clinical trials have shown some common adverse effects such as diarrhea, mucositis, abnormal heart function and myelosuppression of imatinib[3]. However, there has never been a report focused on the relationship between bowel perforation and sunitinib treatment. In the present paer, we describe, for the first time, a case of unexpected colon perforation during sunitinib treatment.

CASE REPORT

Here we report a 70-year-old patient who was initially treated with proximal gastrectomy, distal pancreatectomy, splenectomy and transverse colectomy for a GIST of the stomach that was categorized as high risk in 1993. Eight years later, the GIST relapsed on the gastrohepatic ligament, which led to left hepatectomy

and cholecystectomy to excise the mass curatively. A year later, the tumor recurred in the liver, when imatinib (400 mg/d) was started as the initial treatment. Three years later, a follow-up computed tomography (CT) showed the progression of the hepatic metastasis, which resulted in an escalation in the imatinib dose to 600 mg/d. Unfortunately, two years later in April 2007, the hepatic mass grew so large that it invaded the transverse colon as evaluated by CT and colonoscopy (Figure 1). Consequently, we changed the therapy to oral sunitinib at 50 mg/d with a 4-wk-on and 2-wk-off regimen. He had no combined diseases but a history of smoking with two to thirty packs/year.

In June 2007, the patient was on the second day of the second cycle of sunitinib treatment and complained of diffuse abdominal pain and general prostration upon visiting our emergency room. The patient presented with symptoms and signs of localized peritonitis on the right side of the abdomen. The systolic and diastolic blood pressures were 90 mmHg and 60 mmHg, respectively, pulse rate was 120 per min and respiratory rate was 25 per min. The body temperature was 37.3℃. Laboratory studies were conducted immediately after the patient's arrival at the emergency room. He had anemia (Hb 98 g/L) (normal range: 140-180) and thrombocytopenia (83×10^9/L) (normal range: 150-450), but a WBC count was normal (7.25×10^3/mm^3) with 84% neutrophils. Other laboratory findings were presented as high serum levels of CRP (293.07 mg/L) (normal range: < 5), ALP (416 IU/L) (normal range: 96-254), slightly increased BUN (34 μmol/L) (normal range: 8-23) and creatinine (1.53 μmol/L) (normal range: 0.5-1.2), low level of sodium (127 mEq/L) (normal range: 135-148), potassium (2.8 mEq/L) (normal range: 3.5-5.1) and serum albumin (2.17 g/dL) (normal range: 3.8-5.3), and normal range of GOT (15 IU/L) (normal range: 13-36), GPT (8 IU/L) (normal range: 5-33). A CT scan showed necrosis of the recurrent hepatic mass and perforation of the invaded transverse colon, which led to intraperitoneal air and pus collection (Figure 2A). Three-dimensional reconstruction also revealed colonic perforation (Figure 2B). We could not perform the operation for a correction of colon perforation owing to the poor patient's condition. With percutaneous drainage of the intraperitoneal abscess under guided ultrasonography, the patient's diet was restricted to parenteral nutrition, intravenous fluid administration for correction of dehydration, and both cefoperazone (4 g/d, intravenous) and metronidazole (1500 mg/d, intravenous) were injected for 2 wk. After drainage procedure and conservative treatments, the patient's condition was fortunately improved without operation and laboratory findings 2 wk after treatment were decreased serum CRP level (70.43 mg/L), normal range of platelets (413×10^9/L), BUN (11.3 μmol/L), creatinine (0.72 μmol/L), albumin (3.23 g/dL), sodium (139 mEq/L) and potassium (3.6 mEq/L) (Figure 3). The patient was discharged from the hospital after his condition improved. After completion of the second cycle, the disease was stable according to the response evaluation criteria in the solid tumor group (RECIST) with a 23% decrease in the diameter of the mass.

DISCUSSION

GIST is the most common mesenchymal neoplasm

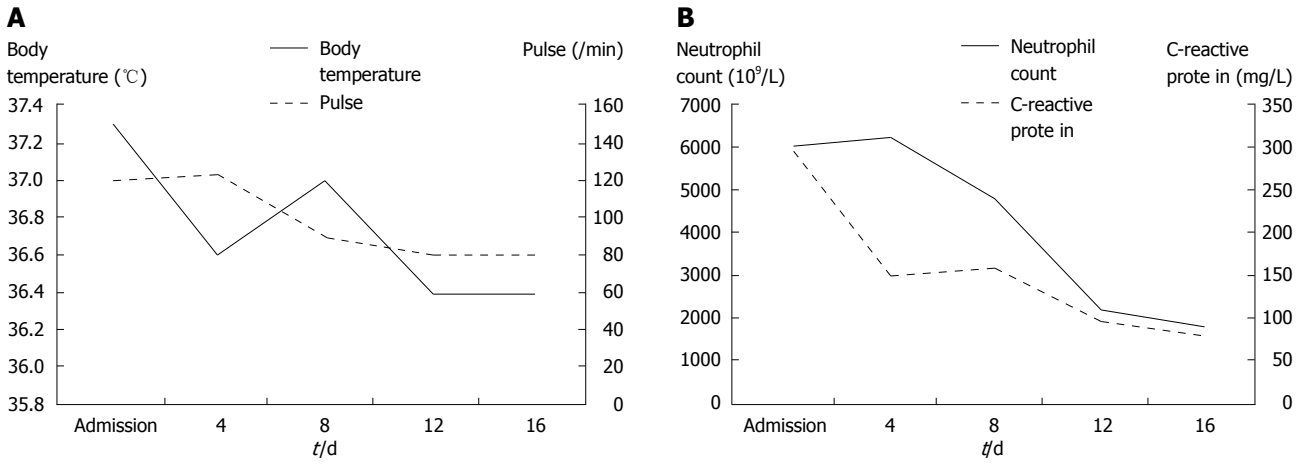

Figure 3 Changes in body temperature and pulse (**A**) and in neutrophil counts and C-reactive protein (**B**) of the patient.

of the gastrointestinal tract. Although this tumor has been known as a neoplasm that is highly resistant to conventional chemotherapy, several recent findings of molecular abnormalities could provide a rationale for treatment with targeted therapies[2]. Recently, applications of several molecularly targeted therapies like imatinib and sunitinib have been proven sufficient for systemic treatment of inoperable or metastatic GIST.

Imatinib is a small molecule tyrosine kinase inhibitor with actions on various transduction molecules such as ABL, BCR-ABL, and KIT[4]. Some clinical trials have shown that imatinib therapy affects prolonged disease-free survival of advanced GIST patients. Sunitinib has recently received approval from the FDA for patients with GIST who are resistant to imatinib[3]. In one randomized controlled trial, sunitinib resulted in a significantly longer time of tumor progression than placebo in patients with GIST after failure of imatinib treatment[5]. Thus, the drug has become a new treatment strategy for these patients, since there is no proven second-line therapy for GIST. The molecular targets of sunitinib are RTKs, and this drug has also been known to have blocking effects on the activation of KIT or PDGFR, which has a similar mechanism of action to imatinib[1]. Moreover, sunitinib exerts an additional anti-angiogenic effect by inhibiting the activation of VEGFR[6]. Because of this effect, sunitinib has been considered beneficial for GIST patients who are resistant to imatinib or cannot tolerate it as a second line treatment[7,8]. A series of clinical studies on sunitinib reported that sunitinib can result in various adverse events, including hypertension, abnormalities of the thyroid and adrenal function, gastrointestinal symptoms such as constipation or diarrhea, and dermatologic abnormalities such as hand-foot syndrome[5,9]. However, bowel perforation associated with the use of sunitinib has not been reported to date. In this case, physical examination of localized tenderness and 3-D reconstructed CT scan confirmed the colon perforation. Then, the perforation was completely treated by percutaneous drainage without operation. This treatment strategy was possible because there was a small amount of colon content localized in a particular area of the peritoneum due to the adhesions from previous operations.

Several cases of colon perforation related to anti-cancer therapy have been reported[10,11], particularly with the VEGFR inhibitor bevacizumab (Avastin; Genentech, South San Francisco, CA), which shares one of the mechanisms of action of sunitinib. A randomized controlled clinical trial showed that bevacizumab, a humanized monoclonal antibody that binds to and neutralizes VEGF, led to gastrointestinal perforation in six of 393 patients (1.5%) who had metastatic colon cancer[10]. Furthermore, another case of colon perforation was documented after treatment with bevacizumab in a patient with non-small cell lung cancer[11]. In addition, the mechanism by which bevacizumab causes bowel perforation is attributed, at least in part, to the increased risk of arterial thrombosis that is observed in the use of drugs targeting VEGF[12,13]. Therefore, this drug is likely to generate rapid tumor degeneration, which in turn leads to colon perforation in patients with bowel metastasis or invasion, due to this inhibitory effect. In addition, the patient's history of smoking might contribute to risk of colon perforation in our case. However, the mechanism of anti-angiogenic agents-induced colon perforation remains to be elucidated.

In conclusion, sunitinib, which is administered to treat GISTs resistant to imatinib, causes unexpected colon perforation and subsequent peritonitis. Hence, careful attention and appropriate clinical evaluation are required for patients presenting with gastrointestinal symptoms during sunitinib treatment.

Abstract

A gastric carcinoid tumor concomitant with gastrointestinal stromal tumor (GIST) is rarely encountered in clinical practice. We report a 65-year-old female who had a 0.8 cm gastric carcinoid tumor on the posterior wall of the upper gastric corpus detected during an esophagogastroduodenoscopy at a routine physical examination, and a concomitant 1.1 cm GIST on the anterior wall of the upper gastric corpus incidentally found during surgery of the gastric carcinoid tumor. Normal serum gastrin level and histological findings suggested that she had a type Ⅲ gastric carcinoid tumor and a GIST which were categorized a very low risk of malignancy, based on their small size and lack of mitosis. Both tumors were treated successfully by surgical excision. The patient had an uneventful recovery. Neither recurrence nor metastasis was found after a 28-mo follow-up.

INTRODUCTION

Gastrointestinal neuroendocrine tumors are derived from the diffuse neuroendocrine system of the gastrointestinal (GI) tract, composed of amine- and acid-producing cells with different hormonal profiles, depending on their site of origin[1]. Gastrointestinal stromal tumors (GISTs) are mesenchymal tumors arising from interstitial Cajal cells of the wall of the GI tract[2,3]. GISTs can be distinguished from other mesenchymal tumors by optimal immunostaining for CD117, and a prognostic classification is based on tumor size, mitotic score, and MIB-1 grade[4]. Gain-of-function mutation of the *c-kit* gene, and immunoreactivity of the c-kit protein (CD117) in many GIST support the idea that GIST is a biologically distinct entity. Both carcinoid tumors and GISTs are malignant or potentially malignant tumors, and are considered to have a specific molecular pathogenesis. Herein we report a gastric carcinoid tumor concomitant with a gastric GIST, and also provide a review of the literature.

CASE REPORT

In October 2005, a 65-year-old Asian female came to our hospital for a routine physical examination. She had no history of peptic ulcer, epigastralgia, abdominal pain, diarrhea, flushing, or palpitations. Esophagogastroduodenoscopy showed an approximately 0.8 cm sessile polypoid lesion, with superficial reddish striation, on the posterior wall of the upper gastric corpus (Figure 1). A biopsy sample was taken and eight specimens were acquired. Histological studies showed a gastric mucosa tumor. The tumor demonstrated uniform ovoid cells with cordal and small nestic patterns within the lamina propria. After immunohistochemical

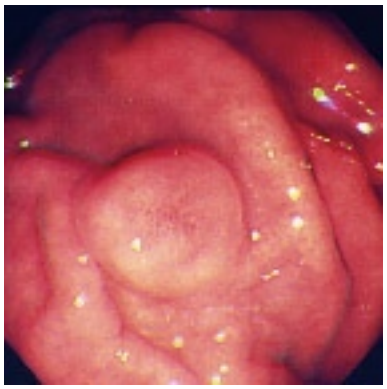

Figure 1 EGD endoscopy showing a protruding polypoid mass with superficial reddish striation on the posterior wall of the gastric upper corpus.

(IHC) staining, the tumor cells were positive for cytokeratin, synaptophysin, and chromogranin-A (Figure 2A-D). The Ki-67 index was < 1%. A gastric carcinoid tumor was diagnosed pathologically, and Helicobacter-like microorganisms were also found. A biopsy urease test (CLO test) for *Helicobacter pylori* (*H pylori*) infection also demonstrated a positive reaction. The serum gastrin level was 34.4 ng/L (normal range, 25-111 ng/L). Owing to the tumor's potentially malignant nature, surgery was performed one week later. During the surgical procedure, in addition to the 0.8 cm carcinoid tumor, a 1.1 cm tumor was found incidentally over the serosal side of the anterior wall of the upper gastric corpus. Both small tumors were locally resected simultaneously and separately. Grossly, a patch of gastric tissue, measuring 3.9 cm × 2.5 cm × 0.7 cm, from the posterior wall of the upper corpus disclosed a 0.8 cm × 0.6 cm × 0.3 cm carcinoid tumor. The other gastric tissue taken from the anterior wall of the upper gastric corpus, measuring 2.5 cm × 2.0 cm× 0.5 cm, demonstrated a 1.1 cm × 0.7 cm × 0.3 cm tumor within the muscularis propria of the gastric wall. Histologically, this 1.1 cm tumor displayed swirling bundles of spindle cells with focally palisading areas within the fibrotic stroma. Neither mitotic activity nor tumor necrosis was found. The spindle tumor cells were positive for CD117, CD34, neuron-specific enolase, and S-100 protein, but negative for actin-M851 and glial fibrillary acidic protein after IHC staining (Figure 2E-H). Finally, a gastric carcinoid tumor and a GIST were pathologically diagnosed. The patient had an uneventful recovery, and was discharged one week after surgery. After a 28-mo follow-up, there was no evidence of tumor recurrence or metastasis.

DISCUSSION

Gastric carcinoid tumor concomitant with gastric GIST is clinically rare. To the best of our knowledge, it has not been reported in the English literature. The pathogenesis of gastric carcinoid tumor concomitant with GIST is unclear. It was reported that *H pylori* are related to the pathogenesis of gastric carcinoma and mucosa-associated lymphoid tumor[5,6]. We previously reported a case of a 0.4-cm GIST concomitant with an early gastric cancer in 2005[7], and between 2003 and 2007, we intermittently detected one case of multiple 0.2-cm to 0.5-cm gastric neuroendocrine tumors and additional 5 cases of 0.4-15 cm gastric GISTs. All except for 2 of the cases yielded positive CLO tests. The present case also showed positive *H pylori* infection. However, this finding is more like an incidental event rather than a causal association. Whether the concomitant carcinoid tumor with GIST correlates to *H pylori* infection or not requires more collected cases and further studies.

Gastric carcinoids are classified into three subtypes, all of which originate from gastric enterochromaffin-like cells in the gastric mucosa. The first subtype is combined with chronic atrophic gastritis (type Ⅰ). The second subtype, Zollinger-Ellison syndrome, is nearly a part of the multiple endocrine neoplasia-1 (MEN-1) syndrome (type Ⅱ). Clinically, these two subtypes are linked to a hypergastrinemic state. The third sporadic subtype (type Ⅲ) occurs without hypergastrinemia but takes an aggressive course, with 54%-66% metastasis[1]. As stated by Shinohara and colleagues, even a 0.5-cm carcinoid tumor can present with metastasis[8]. On account of neither atrophic gastric mucosa nor elevated seral gastrin level in our case, a small type Ⅲ carcinoid tumor was favored. The potential for metastasis cannot be ignored and demands close follow-up.

Gastric carcinoids may have different clinical features in different locations of GI tract, including abdominal pain, vomiting, and anemia[9]. Carcinoid tumor associated with vascular malformation may cause massive gastric bleeding[10]. Carcinoid syndrome with symptoms of flushing, diarrhea, abdominal pain, cutaneous edema, and bronchoconstriction is uncommon. Due to a small nonfunctional carcinoid, our case never experienced any GI symptom or carcinoid syndrome.

Since 1999, GISTs have been considered to be a group of mesenchymal neoplasms arising from interstitial Cajal cells of the gastrointestinal walls[2,3]. GISTs are now preferentially defined as tumors with c-kit (CD117) positive mesenchymal spindle cells or epithelioid neoplasms, found primarily in the GI tract, omentum, and mesentery[11]. The most important manifestation of this tumor is its indolent, slow-growing nature. This tumor is generally found within the deeper stroma and the submucosa, and incidentally during an imaging study and surgery. In our case, a GIST protruding to the serosal side of the gastric wall was found incidentally during a surgical procedure. Histologically, it arose from the muscularis propria of the gastric wall.

Patients with GIST often present with nonspecific symptoms, such as nausea, vomiting, abdominal pain, GI bleeding, and may have metastatic disease. Bleeding is the most common symptom. The tumor size and mitotic score are considered important diagnostic criteria and prognostic predictive indicators[12]. Our case was asymptomatic and diagnosed as GIST with a very low risk of malignancy based on its small size and lack of mitosis and was positive for CD117 after IHC staining.

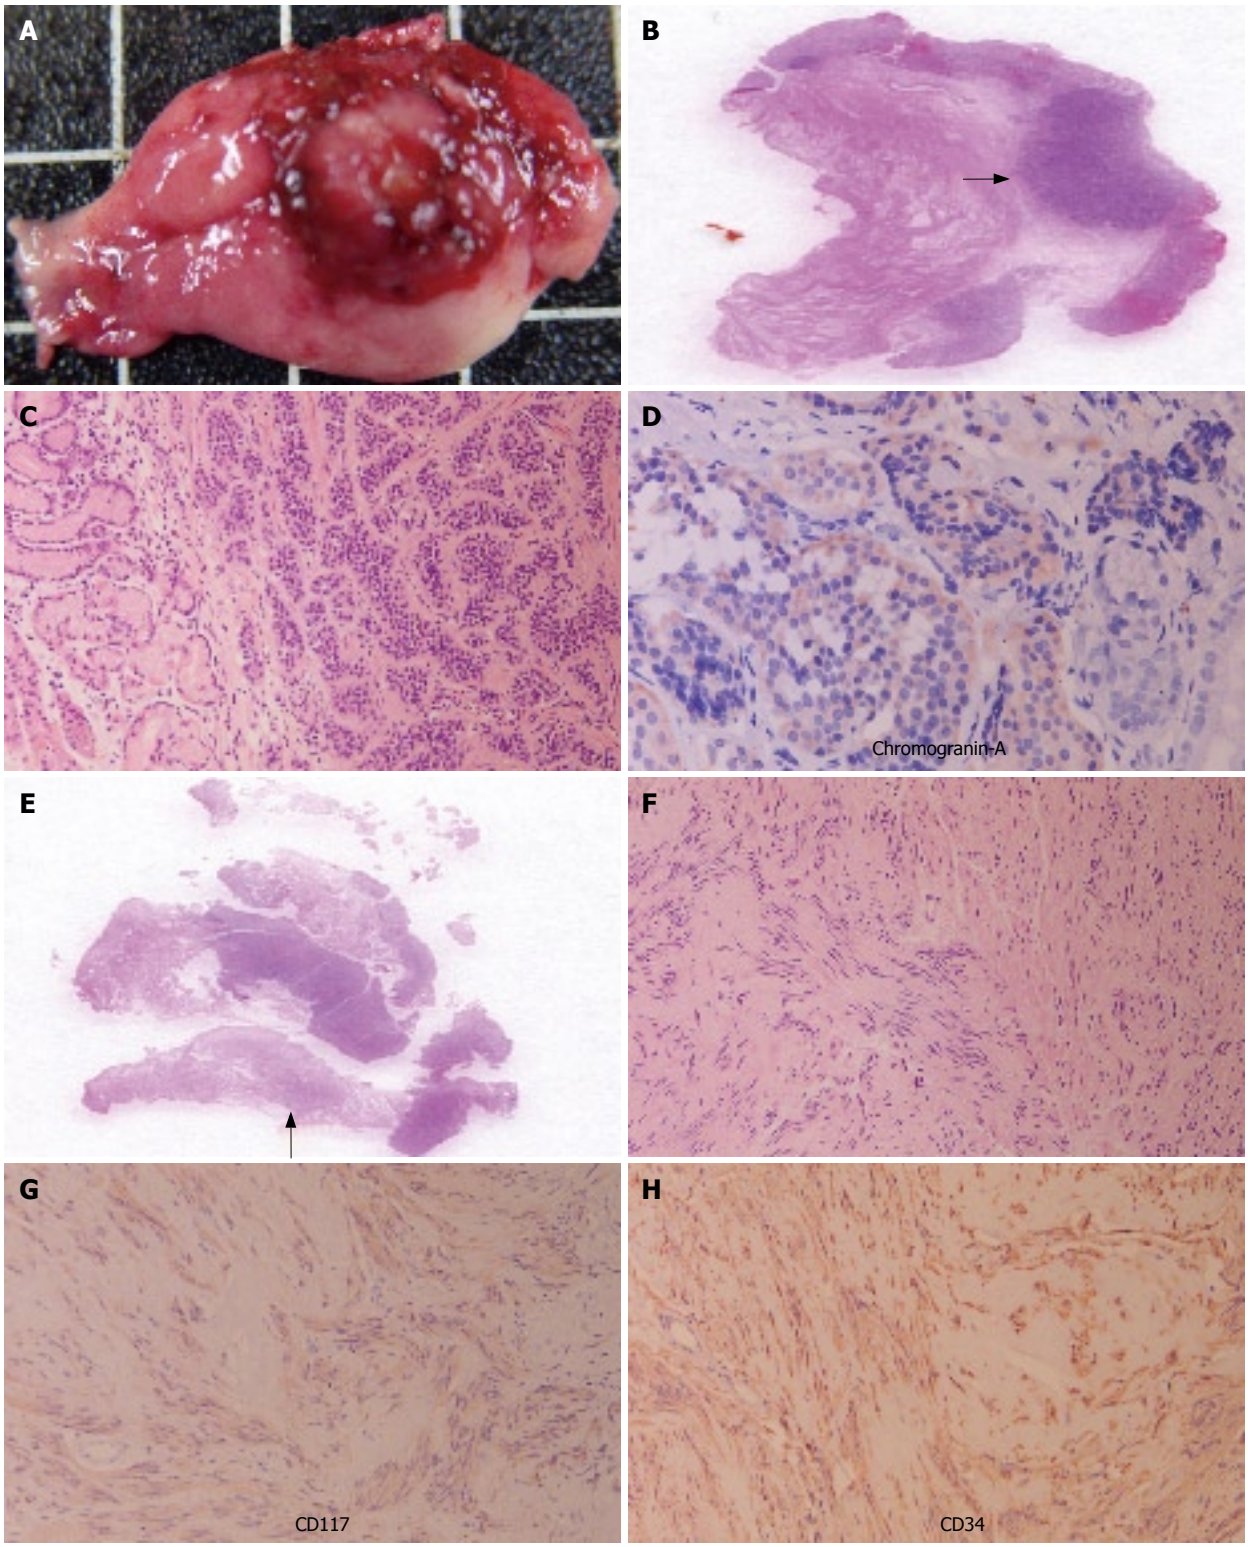

Figure 2 Postoperative wedge-shaped gastric tissue demonstrating a 0.8-cm centrally polypoid mass (**A**), scanning microscopic view disclosing a crescent ulcerative mass (arrow) involving gastric mucosa and submucosa (**B**), carcinoid tumor (right half) displaying uniform ovoid cells in chordal and small nestic patterns (hematoxylin and eosin stain, × 200) (**C**), chromogranin a positively stained tumor cells (IHC staining, × 400) (**D**), stromal tumor (arrow) within the gastric wall (scanning microscopic view) (**E**), tumor cells demonstrating whirling and palisading spindle cells interlaced with smooth muscle cells of gastric muscularis propria (hematoxylin and eosin stain, × 200) (**F**), CD117 (**G**) and CD34 (**H**) stained spindle tumor cells.

Treatment modalities for non-metastatic small carcinoid tumors include endoscopic mucosal resection, minimally invasive laparoscopic wedge resection, and surgery[13,14]. To date, surgery is the mainstay and the only potentially curative therapy for carcinoid tumors. Treatment modalities for metastatic carcinoid tumors include orthotopic liver transplant, hepatic artery embolization, and somatostatin analog, adjuvant indium-111 octreotide-receptor targeted therapy[9]. Therapeutic options for GISTs include surgery and

treatment with STI-571 (Gleevec). When inoperative, residual or recurrent tumor exists, STI-571 is the choice[15,16]. Owing to the treatment of two synchronized small gastric tumors in our case, local resections were performed simultaneously and separately. No evidence of tumor recurrence or metastasis was found after a 28-mo follow-up period.

In conclusion, we report a rare case of small gastric carcinoid tumor concomitant with a small gastric GIST with no clinical symptoms and positive *H pylori* infection. More studies are required for evaluating the relation between *H pylori* infections and tumorigenesis of concomitant gastric carcinoid and gastric GIST. A long term follow-up period of all carcinoids and GISTs is greatly needed, due to their potential for metastasis.

ACKNOWLEDGMENTS

The authors greatly appreciate the financial and technical support of Dalin Tzu Chi General Hospital, and the help of the President of Japan Jichi Medical University, Professor Fumimaro Takaku, who kindly revised the manuscript.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Patent (list all authors)

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903
Ocean International Center, Building D
No. 62 Dongsihuan Zhonglu
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

Cannabinoids are a group of compounds acting primarily *via* CB1 and CB2 receptors. The expression of cannabinoid receptors in normal liver is low or absent. However, many reports have proven up-regulation of the expression of CB1 and CB2 receptors in hepatic myofibroblasts and vascular endothelial cells, as well as increased concentration of endocannabinoids in liver in the course of chronic progressive liver diseases. It has been shown that CB1 receptor signalling exerts profibrogenic and proinflammatory effects in liver tissue, primarily due to the stimulation of hepatic stellate cells, whereas the activation of CB2 receptors inhibits or even reverses liver fibrogenesis. Similarly, CB1 receptor stimulation contributes to progression of liver steatosis. In end-stage liver disease, the endocannabinoid system has been shown to contribute to hepatic encephalopathy and vascular effects, such as portal hypertension, splanchnic vasodilatation, relative peripheral hypotension and probably cirrhotic cardiomyopathy. So far, available evidence is based on cellular cultures or animal models. Clinical data on the effects of cannabinoids in chronic liver diseases are limited. However, recent studies have shown the contribution of cannabis smoking to the progression of liver fibrosis and steatosis. Moreover, controlling CB1 or CB2 signalling appears to be an attractive target in managing liver diseases.

Key words: Hepatic fibrosis; Endocannabinoids; Endocannabinoid receptors; CB1; CB2

INTRODUCTION

Hepatic fibrosis is a dynamic process resulting from liver tissue injury. Previously, it was believed that hepatic fibrosis is irreversible. However, current knowledge allows us to consider fibrosis as an active, potentially reversible process originating from wound-healing responses to chronic liver injury of various etiology. The continuous influence of injuring stimuli leads to an imbalance between the accumulation and degradation of extracellular matrix (ECM) components, which include mainly deposits of fibrillar collagens, proteoglycans and glycoproteins. The major sources of ECM elements are hepatic stellate cells (HSCs), which physiologically constitute about 5%-8% of liver cells. In the course of chronic liver injury, HSCs are activated and transformed from fat-storing cells (Ito cells) to myofibroblast-like cells. Along with this transformation, they undergo morphological and functional changes into contractile, smooth muscle α-actin-positive cells expressing profibrogenic and proinflammatory properties[1,2]. Among mediators activating HSCs, transforming growth factor-β (TGF-β) and platelet-derived growth factor (PDGF) are of special concern. PDGF stimulates proliferation and migration of HSCs, whereas TGF-β, which is the most potent profibrogenic cytokine, acting through its receptor, induces downstream signalling involving Smad family mediators. Thus, it regulates transcription of TGF-β target genes. The results of the above-mentioned signalling are complex; these include increased synthesis of fibrillar collagens, especially collagen type 1, and other ECM components, reduced expression of matrix metalloproteinase, along with augmented production of tissue inhibitor of metalloproteinase-1 (TIMP-1). So far, the perfect non-invasive biomarkers of hepatic fibrosis are under investigation include TGF-β, ECM components and TIMPs[3-5]. The overproduction of ECM components and imbalanced processes of synthesis-degradation eventually lead to progressive liver fibrosis[2]. Thus, reduction of fibrosis

can be obtained by either reduced liver myofibroblast activity, resulting from inhibition of ECM components synthesis, or enhanced degradation of ECM. The clinical data demonstrated that even advanced liver fibrosis can be inhibited and reversed[6]. However, the compounds with antifibrotic activities, potentially useful in clinical practice, are still under investigation.

CANNABINOIDS AND ENDOCANNABINOID SYSTEM IN PHYSIOLOGY AND PATHOLOGY

Cannabinoids are a group of compounds acting primarily *via* CB1 and CB2 receptors. The first cannabinoid discovered, in 1964, was a plant-derived Δ^9-tetrahydrocannabinol (THC), the psychoactive component of *Cannabis sativa*[7]. Following this finding was the discovery and determination of receptors for cannabinoids in nervous tissue. The first results were obtained by Matsuda *et al*[8] and presented the effects of cloning cDNA of G protein-coupled receptor found in neural cells, recognized then as CB1 receptor. However, this receptor was shown to be responsible primarily for psychoactive and neuronal effects of cannabinoids, which did not explain the other effects exerted by THC. Hence, the research for other receptors led to the discovery of CB2 receptor, expressed in macrophages of the spleen[9]. The presence of cannabinoid receptors in mammalian tissues prompted the research for its endogenous ligands and resulted in isolation of anandamide (AEA) and 2-arachidonoyl-glycerol (2-AG)[10,11]. So far, among several endogenous discovered ligands for cannabinoid receptors, AEA and 2-AG are the best characterized. The interesting feature of endocannabinoid mediators is that they are not stored in cells, instead, they are synthesized from lipid precursors in cellular membranes and released in response to specific stimuli[12].

The endocannabinoid system is comprised of at least two types of receptors for THC (CB1 and CB2), endogenous lipid compounds acting as ligands, and molecules regulating the synthesis and degradation of endocannabinoids. The expression of CB1 receptors was initially associated with the nervous system, as they were shown to control perception, cognitive, motor and behavioral functions. Nevertheless, the CB1 receptors are present peripherally in endothelial cells, adipocytes, gut and liver cells[13-16]. It has been shown that cannabinoid CB1 signalling regulates intake of high-energy-containing food and alcohol, energy homeostasis and hepatic lipogenesis. As to CB2 receptors, they are largely expressed in several lines of peripheral blood immune cells, tonsils, spleen and testis[17]. Moreover, their presence at low levels has been confirmed in various other tissues and cells, like hepatic myofibroblasts[18].

The imbalance in endocannabinoid system signaling is observed in various pathological conditions, including nervous system disorders, metabolic disturbances, impaired immunological responses (both allergy and hypersensivity), cardiovascular and gastrointestinal diseases, and carcinogenesis[19].

CANNABINOIDS IN HEPATIC FIBROSIS

The expression of cannabinoid receptors in normal liver is very low, partially because they are not expressed in hepatocytes. However, many studies have demonstrated the up-regulation of the expression of CB1 and CB2 receptors in hepatic myofibroblasts and vascular endothelial cells, as well as increased concentration of endocannabinoids, especially AEA, in liver in the course of chronic progressive liver diseases[18,20,21]. Teixeira-Clerc *et al*[20] have provided evidence for the involvement of CB1 receptor in regulation of hepatic fibrosis and the profibrogenic effect of CB1 signaling. Increased expression of CB1 receptors has been observed in human cirrhotic liver samples, primarily in HSCs during their transformation into myofibroblasts during the course of chronic liver injury. Moreover, the effect of CB1 inactivation was demonstrated in three experimental models of liver injury induced by CCl_4, thioacetamide or biliary cholestasis. The favorable antifibrogenic results were obtained either by pharmacological inactivation with rimonabant (SR141716), a selective antagonist of CB1 receptor, and *via* genetic inactivation in homozygous CB1-deficient mice. Decreased progression of fibrosis was accompanied by reduced hepatic TGF-β expression, and growth inhibition and increased apoptosis of myofibroblasts. These effects seemed to result from reduced phosphorylation of protein kinase B (PKB/Akt) and extracellular signal-regulated kinase (ERK), thus affecting the pathways responsible for cell proliferation and survival.

Although CB1 receptor is believed to have profibrogenic effects, studies on the CB2 receptor have proven its antifibrogenic activity in liver, as CB2 knockout mice developed augmented cirrhosis when exposed to CCl_4, compared to wild type[18]. It has been demonstrated in human cirrhotic liver samples that the expression of CB2 receptor is limited primarily to the cells positive for smooth muscle α-actin located within fibrotic septa; however, it is also detected in non-parenchymal cells, inflammatory cells and bile duct epithelial cells adjacent to fibrotic septa. The supporting results were obtained in separate research on cultured human hepatic myofibroblasts and activated rat HSCs, which were shown to express CB2 receptor. The final effects of the stimulation of CB2 receptor with THC or selective agonist JWH-015 are dose-dependent and expressed as growth inhibition or apoptosis. Interestingly, these two endpoints result from two distinct pathways, the induction of cyclooxygenase-2 (COX-2) in growth inhibition and intracellular oxidative stress for apoptosis, as they are diminished by the selective COX-2 inhibitor and two potent antioxidants, respectively.

Additionally, apart from receptor-dependent mechanisms of endocannabinoid actions on HSCs, the direct mechanism exerted by AEA leading to cell death have been observed in the research of Siegmund *et al*[22]. Stimulation of cultured human HSCs with AEA induces cell death in the necrotic pathway. This event is preceded by reactive oxygen species (ROS) formation and an increase in intracellular Ca^{2+} in HSCs. The pharmacologi-

cal inactivation of CB1, CB2 and vanilloid receptor-1 (VR1) does not prevent AEA-triggered cell death, which appears to be mediated by membrane cholesterol. Furthermore, the distinction between cholesterol content in the cellular membrane of HSCs and hepatocytes results in selective elimination of HSCs that are richer in cholesterol[22]. The conclusion of their analysis is that AEA exerts a potential antifibrogenic effect by inhibition of HSC proliferation and induction of necrotic death. The elevated levels of circulating AEA in cirrhotic patients might reflect the regulatory antifibrotic response to progression of fibrosis[22,23]. However, due to disadvantageous properties, such as triggering a local inflammatory response to necrosis and tissue damage, as well as systemic vasodilatation, the usefulness of AEA in the treatment of liver fibrosis is limited.

CANNABINOIDS IN LIVER STEATOSIS

Metabolic syndrome, leading to liver steatosis, has emerged as an important and frequent cause of chronic liver injury, ranging from simple steatosis to steatohepatitis, which is accompanied by inflammatory reaction and progressive fibrosis of liver tissue. The involvement of the endocannabinoid system in the pathogenesis of fatty liver disease has been shown recently. Since endocannabinoids are essential in regulation of energy balance, food intake and lipogenesis, impairment of this homeostasis results in various metabolic disturbances. Apart from central control of energy homeostasis *via* CB1 receptors localized in the brain, endocannabinoids seem to exert, as well CB1-receptor-dependent, peripheral effects on lipid metabolism in adipocytes, liver tissue and skeletal muscle[14]. This could be partially explained by increased expression of lipogenic transcription factor and activation of downstream enzymes, which result in increased fatty acid synthesis. Moreover, fat-rich diet has been shown to contribute to enhanced hepatic expression of CB1 in liver tissue and increased levels of endocannabinoids, thus increasing the metabolic imbalance[15].

ROLE OF ENDOCANNABINOID SYSTEM IN CONDITIONS ACCOMPANYING END-STAGE LIVER DISEASE

The role of the endocannabinoid system in liver diseases is complex. It has been particularly examined in end-stage liver disease and shown to contribute to hepatic encephalopathy and vascular effects such as portal hypertension, splanchnic vasodilatation, relative peripheral hypotension and probably cirrhotic cardiomyopathy.

There is limited, but reliable data on the neuroprotective role of the endocannabinoid system in hepatic encephalopathy. It has been demonstrated in a murine model that during fulminant hepatic failure, the levels of 2-AG in the brain are elevated, probably as a response to liver damage. The administration of CB2 endogenous ligand 2-AG, an antagonist of CB1 receptor, SR141716A, or an agonist of CB2 receptor, HU308, accomplished a marked improvement in neurological score. Hence, influencing the endocannabinoid system with exogenous cannabinoid derivates specific for the CB2 or CB1 receptor might have a beneficial therapeutic effect on neurological dysfunction in liver diseases[24]. Further research has indicated the impact of CB2 signaling on the activity of cerebral AMP-activated protein kinase (AMPK) in conditions of liver failure. It has been shown in wild type mice that administration of THC leads to increased activity of AMPK in the brain and neurological improvement, possibly *via* stimulation of CB2 receptors, as this effect is absent in CB2 knock-out mice[25].

Numerous hemodynamic vascular effects contributing to the poor prognosis of disease outcome accompany end-stage liver disease. The cirrhotic rebuilding of hepatic tissue results in increased resistance in portal circulation and eventually in elevated portal pressure. Additionally, the arterial vasodilatation in splanchnic and systemic circulations contributes to hyperdynamic state, arterial hypotension and increased blood inflow from mesenteric arteries, which augments the unfavorable effect of portal hypertension. There are many reports linking these vascular effects with the improper activity of the endocannabinoid system, particularly with stimulation of CB1 receptor in vascular endothelial cells with endogenous cannabinoids. The cirrhotic state is often accompanied by the endotoxemia caused by release of bacterial lipopolysaccharide (LPS) synthesized by the intestinal flora into the systemic circulation, while its hepatic elimination is insufficient[26]. The effects of blood LPS on systemic circulation correspond to the hemodynamic changes observed in cirrhosis[27]. Batkai *et al*[21] have provided evidence that explains the association between the endocannabinoid system and its influence on circulatory changes in cirrhosis. It was demonstrated in an animal model of cirrhosis complicated by hemodynamic alterations, that treatment with CB1 receptor antagonist (SR141716A) sufficiently improved hemodynamic state, which manifested in elevation of arterial pressure and reduction of mesenteric blood flow and portal pressure. It was shown that the intravenous injection of the monocyte fraction isolated from the blood of both cirrhotic rats and a patient with cirrhosis, was able to induce hypotension. This was reversible by treatment with SR141716A, whereas the injection of monocytes from controls did not exert such an effect. Moreover, the examination of monocytes from cirrhotic and control individuals and animals demonstrated increased levels of AEA in the monocytes in cirrhotic state, which may have reflected the stimulation of endocannabinoid synthesis by bacterial LPS shown in previous studies[21]. Additionally, upregulation of CB1 receptors in hepatic arterial endothelial cells isolated from cirrhotic livers was observed, thus, indicating its increased sensitivity to vasodilatory stimuli, such as endocannabinoids secreted by the monocytes and platelets adhering to endothelium[21].

Vascular effects exerted by endocannabinoids are divergent and complex. It is postulated that endocannabinoids might contribute to potency disorders in cirrhosis, as was observed in animal models. AEA was shown to

augment the relaxation of samples of corpus cavernosum from biliary cirrhotic rats, probably through CB1 and VR1 signalling[28].

Recently, the role of endocannabinoid signaling in the development of cardiomyopathy during liver cirrhosis has been investigated. It is characterized by decreased β-adrenergic responsiveness, impaired cardiac conduction and insufficient heart muscle contraction to excitation stimuli, whereas cardiac output remains increased compared to baseline. Gaskari *et al*[29] have confirmed in an animal model the role of CB1 signaling in the pathogenesis of cirrhotic cardiomyopathy. It has been shown that, when the cardiac muscle probes from cirrhotic rats are pre-incubated with the CB1 antagonist, AM251, their contractility is similar to the controls[29]. The significance of CB1 signaling has been demonstrated *in vivo* in cirrhotic rats presenting late symptoms of decreased cardiac contractility, hypotension and tachycardia. These symptoms were ameliorated in cirrhotic rats, by the bolus injection of AM251, whereas its administration in controls had no effect. Hence, the authors concluded that the above-mentioned cardiac effects might have resulted from increased concentration of AEA in cardiac tissue in liver cirrhosis, as the cardiac expression of CB1 receptors was similar in cirrhotic and non-cirrhotic control rats[30]. These observations are consistent with the study of Bonz *et al*[31] assessed the influence of AEA on the contractility of human heart atrial muscle upon electrical stimulation. The inotropic negative effect exerted by AEA and other examined CB1 agonists was predictably abolished by pre-incubation with CB1 antagonist ation[31]. Thus, blocking the CB1 signaling might have advantageous therapeutic effects on various clinical aspects of cirrhotic cardiomyopathy and other related conditions.

CLINICAL ASPECTS

There are limited clinical data on the effects of cannabinoids in chronic liver diseases. According to clinical research of Hezode *et al*[32], daily cannabis smoking appears to be an independent factor of fibrosis progression in chronic hepatitis C (CHC) patients. The research was performed on a group of 270 CHC patients, divided into non-cannabis users (52.2%), occasional cannabis users (14.8%) and daily cannabis users (33.0%). The collected data on epidemiological, demographic, metabolic and virological aspects, and history of cannabis, alcohol and tobacco abuse, allowed them to specify the factors for fibrosis progression. This study confirmed the well-recognized independent fibrosis predictors such as necroinflammatory activity ⩾ A2 (METAVIR score), age > 40 years at the time of exposure, steatosis and serious alcohol abuse, but also rated the daily cannabis use as a distinct factor that influenced alone the progression of liver fibrosis. This could result from profibrogenic activity of CB1 signaling, thus implying the beneficial therapeutic potential of CB1 antagonists.

Moreover, it has been proven that regular daily cannabis use has a significant impact on the severity of steatosis, which may eventually contribute to fibrosis progression in the course of CHC[33]. It has been shown that high fat dietary supply increases the hepatic levels of AEA, expression of CB1 receptor and augments fatty acid synthesis, thus contributing to obesity and other metabolic disorders proceeding to liver steatosis[15,34]. The mechanisms, in which endocannabinoids lead to obesity-associated fatty liver, or even steatohepatitis, are CB1-receptor-dependent and include increase in fatty acids intake, induction of lipolysis in adipocytes, stimulation of hepatic lipogenesis and downregulation of adiponectin in adipose tissue. Interestingly, CB1-knockout mice are resistant to obesity induced by high-energy-containing food intake[35]. Similarly, the pharmacological inactivation of CB1 with rimonabant (SR141716) results in reduction of obesity and hepatic steatosis in rodents[36,37].

ENDOCANNABINOID SYSTEM AS A THERAPEUTIC TARGET

The beneficial effect of the regulation of endocannabinoid signaling is postulated in management of various pathological conditions, including obesity and metabolic syndrome; addiction to alcohol, tobacco and opiates; Alzheimer's disease, Parkinson's disease, schizophrenia, memory loss, chronic pain, liver fibrosis, and numerous inflammatory conditions and allergies[38].

Due to their regulatory functions in chronic hepatic disorders, especially fibrosis, influencing the endocannabinoid receptors seems to be an advantageous therapeutic target. It seems that treatment with CB1 antagonist, CB2 agonist or both, may offer clinical benefits, resulting in at least deceleration of disease progression. It has also been shown that blocking CB1 signaling is favorable in maintaining the proper blood pressure in hypotensive cirrhotic rats[21,39]. Moreover, in clinical studies, rimonabant has exerted additional beneficial actions influencing the profile of blood lipids and glycemia control in obesity, metabolic syndrome and type 2 diabetes mellitus. It also had an impact on lifestyle modification, for instance, cigarette smoking cessation rates were significantly higher during treatment with rimonabant[40]. Interestingly, Wang *et al*[41] have suggested a possible link between CB1 signaling and ethanol preference in immature mice, and this effect was diminished after administration of rimonabant. This observation might be particularly useful in patients with alcoholic liver disease who persist in drinking.

CONCLUSION

The role of the endocannabinoid system in hepatic physiology and pathologic conditions has been studied recently. Unquestionably, influencing endocannabinoid signaling may have a beneficial effect on delaying or even reversing hepatic fibrosis. It is particularly important due to the lack of antifibrotic drugs with established advantageous profiles of activity, despite years of investigations into this subject. Thus, further research may provide the valuable means of management in hepatic fibrosis in the future.

Abstract

Recently, inflammatory bowel disease (IBD) has been the subject of considerable research, with increasing attention being paid to the loss of intestinal epithelial cell barrier function as a mechanism of pathogenesis. Ste20-related proline/alanine-rich kinase (SPAK) is involved in regulating barrier function. SPAK is known to interact with inflammation-related kinases (such as p38, JNK, NKCC1, PKCθ, WNK and MLCK), and with transcription factor AP-1, resulting in diverse biological phenomena, including cell differentiation, cell transformation and proliferation, cytoskeleton rearrangement, and regulation of chloride transport. This review examines the involvement of Ste20-like kinases and downstream mitogen-activated protein kinases (MAPKs) pathways in the pathogenesis and control of intestinal inflammation. The primary focus will be on the molecular features of intestinal inflammation, with an emphasis on the interaction between SPAK and other molecules, and the effect of these interactions on homeostatic maintenance, cell volume regulation and increased cell permeability in intestinal inflammation.

Key words: Inflammatory bowel diseases; WNK; NKCC1; Barrier function; Ste20-related proline/alanine-rich kinase

INTRODUCTION

Inflammatory bowel diseases (IBD), primarily ulcerative colitis (UC) and Crohn's disease (CD), are chronic idiopathic inflammatory disorders of the gastrointestinal tract that are thought to arise as a result of an interplay of genetic and environmental factors. The mechanisms implicated in the pathogenesis of IBD (Figure 1) include: (1) inappropriate regulation of the innate immune response at the level of the intestinal mucosa; (2) deregulation of the adaptive immune system stemming from an imbalance between regulatory and effector-cell immune responses to luminal antigens; and (3) increased permeability across the mucosal epithelial barrier due to loss of structural integrity and/or abnormal transepithelial transport[1,2]. The loss of barrier function, in particular, has gained increasing support as an IBD pathogenic mechanism because the epithelium represents a potential intersection of both genetic and environmental influences. The intestinal mucosa is composed of a single layer of polarized intestinal epithelial cells (IECs) that protects against direct contact with enteric antigens, bacteria and other pathogens (Figure 1). The integrity of the epithelium is maintained primarily through a combination of intercellular adhesion structures and specialized junctions. In addition, other factors such as the presence of mucins, rapid turnover of epithelial cells, and peristaltic movement of the gastrointestinal tract, all help to protect against colonization and invasion of the intestinal mucosa by pathogens[3]. Moreover, epidemiological and genetic linkage studies have confirmed a strong link between modulation of the barrier function and IBD; these include, for example, the loci IBD1-9, corresponding to regions on chromosomes 16, 12, 6, 14, 5, 19, 1, 16 and 3, respectively[4-13], and a new IBD locus on chromosome 2[14].

MITOGEN-ACTIVATED PROTEIN KINASES (MAPKs) ARE INVOLVED IN INTESTINAL INFLAMMATION

Intracellular signaling cascades are the main route of communication between the plasma membrane and

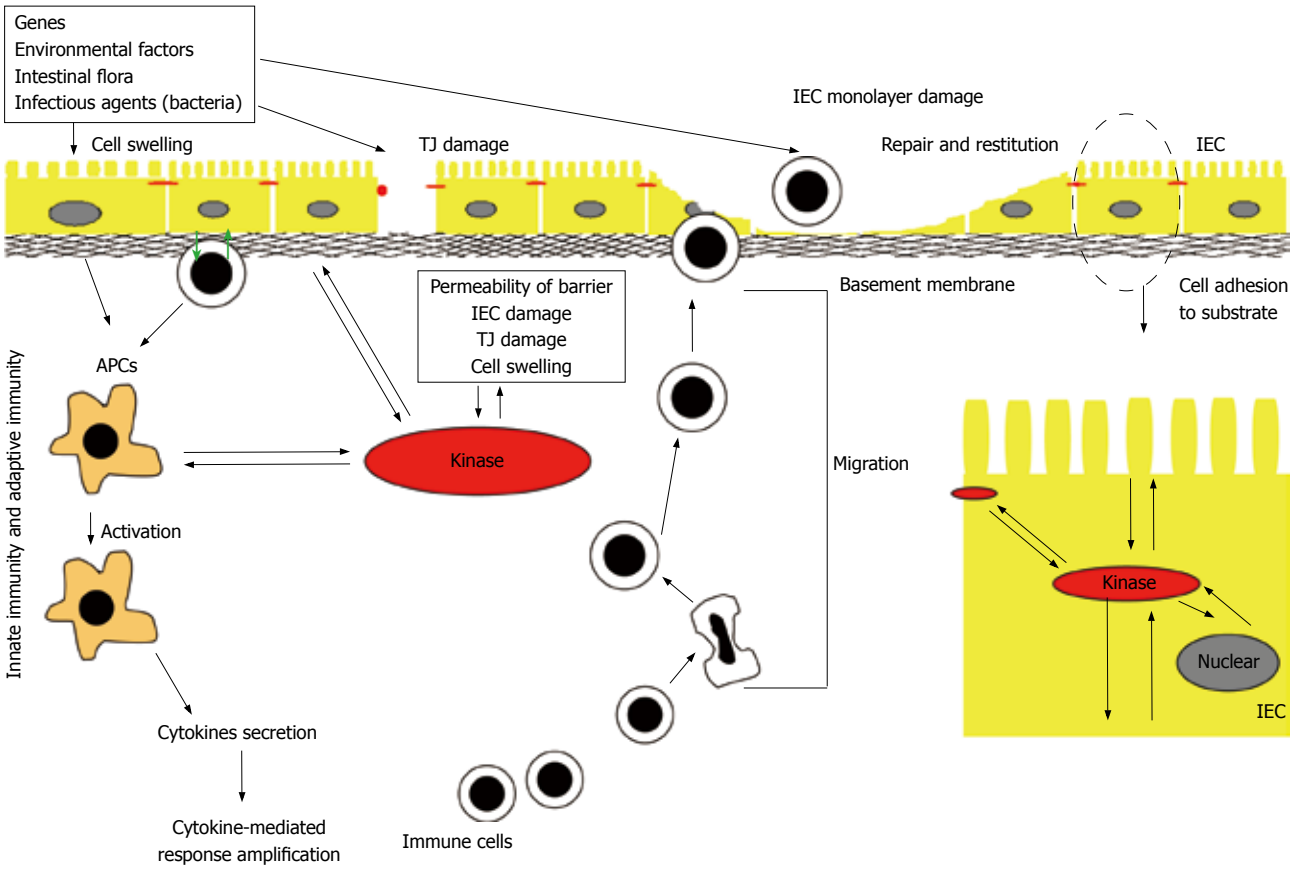

Figure 1 Pathogenesis of IBD. Many different factors, such as genetic factors, environmental factors, and intestinal non-pathogenic or pathogenic bacteria can damage the mucus, epithelium, or the tight junction, to initiate the inappropriate regulation or deregulation of the immune response, leading to the secretion of pro-inflammatory cytokines, decrease in epithelial barrier function and initiation of the inflammation-related signaling pathways. IEC: Intestinal epithelial cell; APC: Antigen presenting cell; TJ: Tight junction.

regulatory targets in various intracellular compartments. The evolutionarily conserved MAPK signaling pathway plays an important role in transducing signals from diverse extra-cellular stimuli (including growth factors, cytokines and environmental stresses) to the nucleus in order to affect a wide range of cellular processes, such as proliferation, differentiation, development, stress responses and apoptosis. MAPK signaling cascades, which comprise up to five levels of protein kinases that are sequentially activated by phosphorylation, are also involved in intestinal inflammation[15-17] (Figure 2).

MAPK signaling pathways are involved in regulating crucial inflammatory mediators and could thus serve as molecular targets for anti-inflammatory therapy. At least six distinct MAPK pathways have been identified in multicellular organisms, of which three, the extra-cellular signal-regulated kinase (ERK), Jun N-terminal kinase (JNK) and p38 cascades, are significantly activated and directly involved in inflammatory diseases such as IBD (Figure 2). In this context, cross-talk between these pathways and other inflammatory signaling pathways, including the NF-κB and Janus kinase/signal transducers, and activation of transcription (STAT) cascades[18-20], is also relevant to the action of MAPK pathways.

The involvement of some MAPK members in IBD is suggested by linkage studies. For example, the ERK1 gene is located in a major IBD susceptibility region on chromosome 16[4], and the p38α gene is located in a major IBD susceptibility region on chromosome 6[9]. Activation of p38 MAPK is also known to induce the production and secretion of pro-inflammatory cytokines, such as interleukin (IL)-1β and tumor necrosis factor-α (TNF-α)[21], and increased activity of p38 MAPK has been observed in patients with IBD[18,22]. Inhibition of p38 has been well documented to suppress IBD[17], and the guanylhydrazone compound, CNI-1493, which inhibits both JNK and p38, strongly reduces clinical disease activity in CD patients. In addition, inhibition of either ERK or p38 kinase pathway decreases lipopolysaccharide (LPS)-induced production of the cytokines, IL-6 and TNF-α[23]. The involvement of JNK pathways in intestinal inflammation has been intensively studied both in patients with IBD and in an experimental colitis model[18,24,25]. JNK inhibitors, which affect either JNK signaling pathway indirectly (e.g. CEP1347) or block the catalytic domain of JNK (e.g. SP 600125), have been tested for their potential value in treating IBD. Collectively, these observations demonstrate a very important role for MAPK pathways in the control and therapy of IBD.

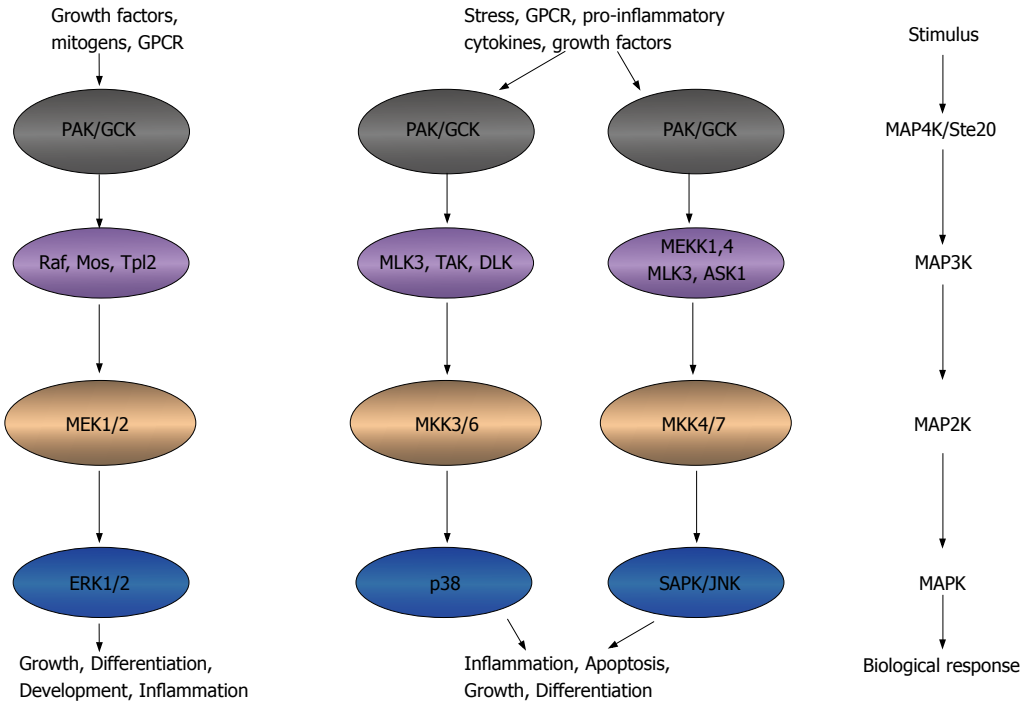

Figure 2 Ste20 kinases participate in inflammation. Ste20 kinases that function as an MAP4K can activate MAP3K, MAP2K and MAPK, leading to the inflammatory functions. This model adapted from the model presented in http://www.cellsignal.com/pathways/map-kinase.jsp. MAPK: Mitogen-activated protein kinase. GPCR: G-protein coupled receptor; PAK: p21 activated kinase; GCK: Germinal central kinase; MLK: Multiple lineage kinase; TAK: Tat-associated kinase; DLK: Dual leucine zipper-bearing kinase; MEK: MAPK/Erk kinase; MEKK: MEK kinase; ASK: Aspartate kinase; MKK: MAPK kinase; Erk: Extracellular signal-regulated kinase; SAPK: Stress-activated protein kinase; JNK: Jun-amino-terminal kinase.

STE20-LIKE KINASES ACT UPSTREAM OF MAPK PATHWAYS

The various MAPK pathways share a common family of upstream mediators: the Ste20 kinases. Ste20 was originally identified as a component of the pheromone-response pathway in budding yeast, and has also been shown to participate in the signaling pathways that regulate osmotic responses, including those to high osmolarity glycerol (HOG)[26]. Several mammalian Ste20 homologs have been identified. The Ste20 family includes two subfamilies that share basic structural and functional properties. The first subfamily includes the p21-activated kinases (PAKs), which are characterized by a C-terminal catalytic domain and an N-terminal binding site for the small G proteins, Rac1 and Cdc42. The second family comprises of the germinal center kinases (GCKs), which contain an N-terminal kinase domain and a C-terminal regulatory domain.

Ste20-like kinases function as MAP4Ks, triggering activation of MAPK cascade[27-29] and transmitting signals from extra-cellular stimuli that activate transcription factors (Figure 2). The resulting changes in gene expression, in turn, regulate cellular functions[27-31] that are important in the maintenance of epithelial barrier function, apoptosis, growth, morphogenesis, cell permeability, and rearrangements of the cytoskeleton that lead to changes in cell shape and motility. For example, members of the PAK subfamily of Ste20 kinases have been shown to increase endothelial permeability[32,33]. The pro-inflammatory cytokine, TNF-α, stimulates expression of the yeast Ste20 homolog, Map4k4, through TNF-α-receptor-1-mediated signaling to c-Jun[34], the chemokine CXCL12 and the complement factor C5a. The resulting increase in Map4k4 activity triggers cell migration *via* a PAK1/2-p38α MAPK-MAPKAP-K2-HSP27 pathway[35]. Other relevant examples include: (1) Ste20-like kinase (SLK)[36], Ste20-like oxidant stress-activated kinase (SOK)[37] and prostate-derived Ste20-like kinase 1-α (PSK1-α)[38], which induce apoptosis by activating the JNK pathway; (2) lymphocyte-oriented kinase (LOK)[39] and SLK[40], which regulate Rac1-mediated actin reorganization during cell adhesion and spreading; (3) mixed lineage kinase-3 (MLK-3)[41], which activates the SAPK/JNK and p38/RK pathways *via* SEK1 and MKK3/6; and (4) hematopoietic progenitor kinase 1 (HPK1), which is activated by prostaglandin E2 (PGE2) through a G-protein coupled receptor (GPCR) pathway, and negatively regulates transcription of the *fos* gene[42].

Ste20-like kinases has been reported to be activated by at least three pathogen-associated molecular patterns (PAMPs)-lipopolysaccharide, peptidoglycan, and flagellin-produced by invading microbial pathogens, and has been shown to initiate innate immune responses by binding to pattern recognition receptors (PRRs)[43]. PAMPs activate GCKs (Ste-20 family of kinases), which signal through MLK-2 and -3 to recruit JNK, p38 and their effectors[43]. These findings indicate an important role for GCKs and MLKs in PAMP-stimulated MAPK pathway activation, and therefore in stimulating the expression of pro-inflammatory genes involved in intestinal inflammation.

STE20-RELATED PROLINE/ALANINE-RICH KINASE (SPAK) IS A STE20-LIKE KINASES INVOLVED IN INTESTINAL INFLAMMATION

The GCKs may be divided into eight subfamilies based on homologies in their C-terminal domains (GCKI-VII). The Ste20-like kinase SPAK[44], PASK (the rat SPAK homolog)[45,46] and OSR1[47] share GCK Ⅵ homologies. Among these, SPAK and OSR1 are ubiquitously expressed. PASK is also expressed in most rat tissues, but its expression is particularly notable in cells with high ion-transport activity[45,48]. Both SPAK and PASK are highly expressed in epithelia and neurons[49]. On the other hand, PASK is found only in negligible levels in the liver and skeletal muscle[50]. SPAK, OSR1 and PASK contain a series of proline and alanine repeats (PAPA box) at the extreme N-terminus, followed by a serine/threonine kinase domain, a nuclear localization signal, a consensus caspase cleavage recognition motif, and a C-terminal regulatory region. However, the colonic SPAK isoform is unique in that it lacks the PAPA box and N-terminal F-alpha helix loop, due to the presence of a 5' splice junction-like sequence within exon-1[51]. Given its ubiquitous expression and diverse functional domains, the SPAK protein may be associated with diverse biological roles. It has been shown that under hyper-osmotic (but not hypo-osmotic) stress conditions, SPAK translocates from the cytosolic pool to a Triton X-100-insoluble fraction; although present in both fractions, SPAK associated with the Triton X-100-insoluble pool is dephosphorylated[52]. Our laboratory has observed that upon SPAK over-expression[51] or under TNF-α stress conditions (unpublished data), SPAK is cleaved and the N-terminal fragment is translocated to the nucleus.

The Na^+-K^+-$2Cl^-$ cotransporter 1 (NKCC1), a member of the Slc12 family of solute carriers and target of SPAK, plays a crucial role in cell volume regulation, cell proliferation and survival, and epithelial transport[53]. The activity and expression of NKCC1 can be regulated by cell volume[53] and intracellular chloride concentration[54], which act through NKCC1's N-terminal (R/K) FX (V/I) binding motif. The pro-inflammatory cytokines IL-1β, TNF-α[55] and IL-6[56] also regulate NKCC1 activity. In addition, NKCC1 can be activated by α- and β-adrenergic stimulation *via* the cAMP/PKA-dependent pathway[57-59] and can be stimulated by PKC in a cell-specific manner[60,61]. Notably, NKCC1 can be phosphorylated by hyperosmolarity and, *in vitro*, by JNK, which can also be activated by hyperosmolarity[62,63]. As an upstream kinase to NKCC1, SPAK can associate through its conserved C-terminal domain with the (R/K) FX (V/I) motif of NKCC1 and phosphorylate Thr203, Thr207, and Thr212 residues on NKCC1, thereby playing an important role in inflammation[45,64,65]. However, SPAK alone is unable to activate NKCC1. SPAK is a substrate of WNK1/4, which are serine threonine kinases lacking a lysine in subdomain I of the catalytic domain[66]. SPAK physically associates through its conserved C-terminal domain with the C-terminus of WNK, resulting in phosphorylation and activation of SPAK by WNK. WNK is also unable to activate NKCC1 in the absence of SPAK, indicating that this association of SPAK with WNK is required for SPAK-dependent phosphorylation and activation of NKCC1. A mutation of WNK1 is involved in the pathogenesis of pseudohypoaldosteronism type Ⅱ (PHA Ⅱ), characterized by hypertension and hyperkalemia[67].

SPAK can also activate p38 pathways in different cell types[51,68,69] to play a role in cell differentiation; an observation that may be relevant in the context of the known relationship between the p38 pathway and inflammation[17,70-74]. Interestingly, p38 activation has been noted in damaged corneal epithelial tissue and in an *in vitro* intestinal epithelial restitution model[75-78], suggesting that under some circumstances p38 may be involved in regulating cell motility and wound healing. Protein kinase C θ (PKCθ) is known to be an intestinal inflammation-related kinase[79]. By associating with Rho GTPases, PKCθ migrates from the cytosol to the membrane and the actin cytoskeleton[80], where SPAK may act as both a substrate and target of PKCθ in a TCR/CD28-induced signaling pathway that leads selectively to AP-1 activation, T-cell transformation and proliferation, and IL-2 production[81]. SPAK is also known to associate with F-actin under conditions of stress, which, along with the activation and phosphorylation of myosin light chain kinase (MLCK), leads to cytoskeleton rearrangement[47,52]. Fray, the Drosophila orthologue of mammalian SPAK, has been shown to participate in the activation of the JNK pathway by sorbitol[47]. Fray probably functions by activating MAP3K, leading to activation of MAP2K/MEK4 and MEK7, and ultimately, JNK activation.

Accumulating evidence points to the important role that SPAK plays in the physiology and pathogenesis of intestinal inflammation (Figure 3). First, by activating and phosphorylating p38, Ap-1, NKCC1, as well as p21-activated protein kinase 1 (PAK1, another Ste20 line kinase), SPAK induces the transcription of inflammation-related genes or modulates the function of inflammation-related proteins. Second, SPAK is activated and phosphorylated by WNK1/4, PKCθ and MLCK. In addition, SPAK has been reported to associate with the heat shock protein HSP105, the cytoskeleton protein gelsolin, and the apoptosis-associated tyrosine kinase AATYK. We have observed that SPAK can increase the permeability of Caco2-BBE cells (unpublished observations). Additional unpublished data indicate that colonic epithelial SPAK expression is increased in IBD patients and in mice with experimentally induced colitis. Importantly, we have also found that the pro-inflammatory cytokine, TNF-α, increases colonic SPAK expression, an observation that underscores the importance of SPAK in the pathogenesis of intestinal inflammation.

PERSPECTIVE

Increased permeability across the mucosal epithelial

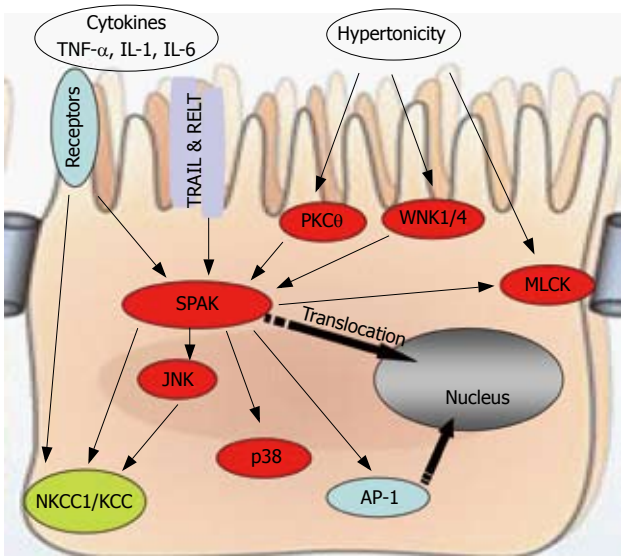

Figure 3 SPAK interacts with other molecules to maintain cellular homeostasis. SPAK can be a substrate, indirectly or directly, for pro-inflammatory cytokines, environmental stress including hypertonicity, some other kinases such as PKCθ, WNK1/4, or other receptors, for example TRAIL & RELT. Also SPAK can function as upstream kinase to JNK, p38, or ion transport NKCC1/KCC, transcription factor AP-1, as well as MLCK. WNK: With no lysine kinase 1/4; TRIL: TNF-related apoptosis-inducing ligand; RELT: Receptor expressed in lymphoid tissues; MLCK: Myosin Ⅱ regulatory light chain kinase; NKCC1: Sodium potassium chloride chloride transporter 1; KCC: Potassium chloride chloride transporter; AP-1: Activating protein 1.

barrier resulting from loss of structural integrity and/or abnormal transepithelial transport is thought to be one of the main functional changes that lead to IBD. Numerous studies have focused on epithelial barrier function, measuring transepithelial electrical resistance (TER), which is known to be decreased in intestinal epithelium by over-expression of SPAK[51]. Other studies have assessed cell adhesion and migration, providing a measure of wound healing. The pro-inflammatory cytokine TNF-α is both necessary and sufficient to trigger the onset of IBD. In fact, nearly half of the drugs used for the treatment of IBD target TNF-α. In *in vitro* studies, we have found that TNF-α increases SPAK expression in intestinal epithelial cells in a dose- and time- dependent manner (unpublished data). It is therefore reasonable to speculate that the regulation of SPAK by TNF-α could account for TNF-α-mediated alterations of barrier function and inflammation in intestinal epithelial cells. Additional studies on the role of SPAK in intestinal barrier function would likely substantially advance the field of IBD.

Intestinal inflammation is usually associated with hyper-osmotic status in the lumen. The WNK1/4-SPAK-NKCC1 pathway has been highlighted in this context as a molecular mechanism that may contribute to ion transport and cell volume changes. This pathway, together with its interactions with other related molecules, such as MLCK, claudin and zo-1, may play an important role in maintaining cell shape, since the epithelial cell tight junctions that play a dominant role in TER would collapse in IBD. In short, more attention should be paid to tight junction and cell volume regulation as important contributing factors in IBD.

It should be evident from this review that SPAK occupies an important intracellular position, integrating extra-cellular pro-inflammatory signals and converting them into pro-inflammatory cellular responses. Given its unique position at the crossroads of multiple pathways, SPAK appears to represent an attractive target for developing effective and efficient strategies to treat IBD. Continuing work along the lines suggested above could make important contributions to the effort to realize the potential of this therapeutic approach.

Abstract

Many physiological effects of natural antioxidants, their extracts or their major active components, have been reported in recent decades. Most of these compounds are characterized by a phenolic structure, similar to that of α-tocopherol, and present antioxidant properties that have been demonstrated both *in vitro* and *in vivo*. Polyphenols may increase the capacity of endogenous antioxidant defences and modulate the cellular redox state. Changes in the cellular redox state may have wide-ranging consequences for cellular growth and differentiation. The majority of *in vitro* and *in vivo* studies conducted so far have attributed the protective effect of bioactive polyphenols to their chemical reactivity toward free radicals and their capacity to prevent the oxidation of important intracellular components. However, in recent years a possible novel aspect in the mode of action of these compounds has been suggested; that is, the ultimate stimulation of the heme oxygenase-1 (HO-1) pathway is likely to account for the established and powerful antioxidant/anti-inflammatory properties of these polyphenols. The products of the HO-catalyzed reaction, particularly carbon monoxide (CO) and biliverdin/bilirubin have been shown to exert protective effects in several organs against oxidative and other noxious stimuli. In this context, it is interesting to note that induction of HO-1 expression by means of natural compounds contributes to protection against liver damage in various experimental models. The focus of this review is on the significance of targeted induction of HO-1 as a potential therapeutic strategy to protect the liver against various stressors in several pathological conditions.

Key words: Heme oxygenase; Hepatobiliary function; Natural inducers; Carbon monoxide; Oxidative stress

INTRODUCTION

Heme oxygenase (HO) is the first, and the rate limiting enzyme in the catabolism of heme[1], to yield equimolar amounts of biliverdin, carbon monoxide (CO) and free iron (Figure 1). To date, two isoforms of HO designated as HO-1 and HO-2 have been identified in mammals[2]. HO-1 is also known as heat shock protein 32. Its human form is composed of 288 amino acids with a molecular mass of 32800 Da and shares about 80% amino acid sequence identity with rat HO-1[3]. On the other hand, human HO-2 is a 36-kDa protein that consists of 316

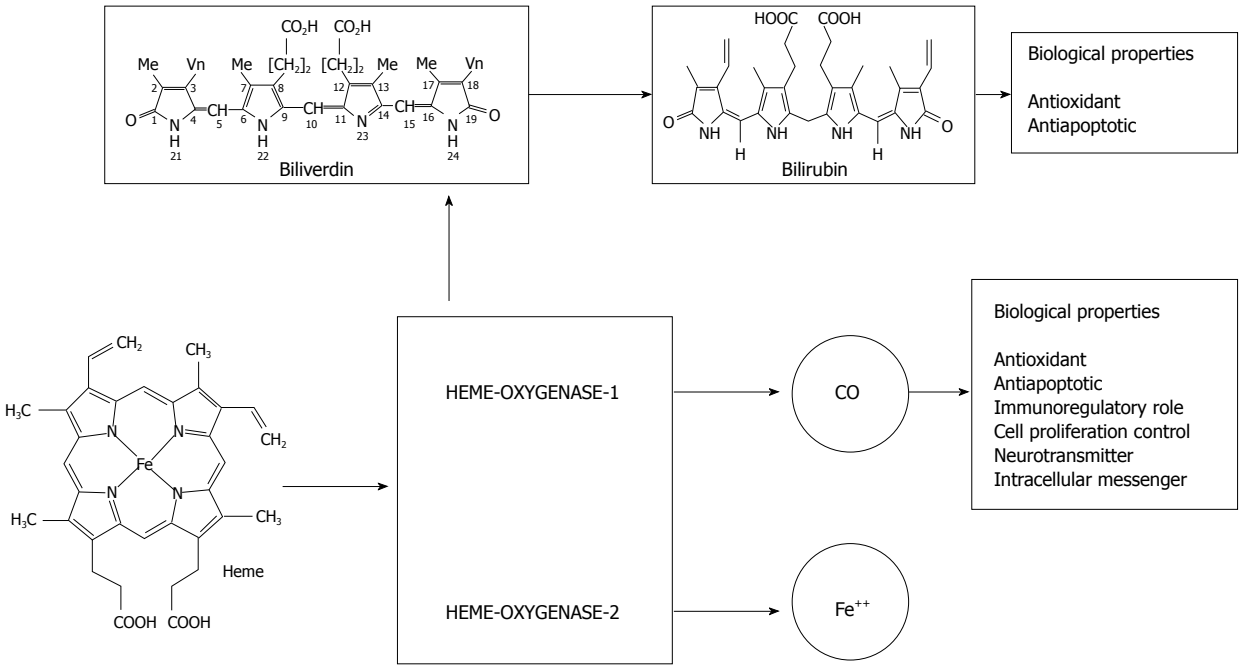

Figure 1 Schematic representation of heme degradation with biological properties of its byproducts.

amino acids with three cysteine residues[4]. HO-1 is highly inducible by hemin and other chemical and physical agents such as ultraviolet, hydrogen peroxide, heavy metals, hypoxia, and nitric oxide[5,6]. Immunohistochemical studies with specific monoclonal antibodies have revealed the distribution of HO-1 and HO-2 in rat liver with distinct topographical patterns[7]: HO-1 has been shown to be expressed principally in Kupffer cells, while HO-2 is expressed in parenchymal cells[8]. Trakshel *et al*[2] have demonstrated that under unstimulated conditions, the activity of HO-2 was two- to three-fold higher than that of HO-1, while the activity of HO-1 increased more than 100-fold in the presence of cadmium or cobalt. Under conditions of oxidative stress, hypoxia or hyperthermia, the induction of HO-1 accounts for the majority of heme breakdown, leading to the formation of bilirubin and CO. Since HO-1 is induced as a protective mechanism in response to various stimuli, targeted induction of this stress-response enzyme may be considered as an important therapeutic strategy for the protection against inflammatory processes and oxidative tissue damage (Figure 1). In this article, recent findings on the implications of HO-1 induction on the cellular adaptive cytoprotective response to various insults and inflammatory conditions are reviewed, with particular emphasis placed on targeted HO-1 induction by natural compounds for hepatoprotection.

NATURAL INDUCERS OF HO-1

A number of natural antioxidant compounds contained in foods and plants have been demonstrated to be effective non-stressful and non-cytotoxic inducers of the response protein HO-1 in hepatic cellular models. Most of these compounds are contained in plants that, besides being widely used as food, spices or flavoring, since ancient times, also represent locally traditional medicinal plants.

Curcumin

Curcumin (diferuloylmethane, Figure 2) is the most investigated natural HO-1 inducer. Curcumin is a yellow pigment obtained by populations living in Asian tropical regions by drying and powdering the rhizome of turmeric (*Curcuma longa Linn*). Widely used as food flavouring, it also plays an important role in traditional medicine because of its anti-inflammatory, anticarcinogenic and antioxidant properties. Curcumin has been demonstrated to be a potent HO-1 inducer in several cellular models (for a Review see Lin[9]). However, the ability of curcumin to induce HO-1 in human hepatocytes has been demonstrated only recently by McNally *et al*[10]. Interestingly, curcumin is able to confer, at non-toxic doses, a significant protective effect in two transplant-related models of cellular injury, such as cold preservation and warm reperfusion. In a successive study[11], these authors confirmed the HO-1 induction ability of curcumin and elucidated the possible biochemical mechanism. Indeed, at both non-toxic and toxic doses, curcumin treatment resulted in ROS generation, activation of Nrf2 and mitogen-activated protein kinases (MAPKs) and in the inhibition of phosphatase activity. They concluded that at non-toxic doses these multiple pathways converged to induce HO-1.

Flavonoids

Flavonoids are naturally occurring antioxidants belonging to the large family of polyphenols. They are widely distributed in plants used as food, as well as traditional medicines, because of their peculiar variety of clinically relevant properties, such as anti-tumor, antiplatelet, anti-ischemic, and anti-inflammatory activities. Antioxidants with strong free-radical scavenging properties contribute

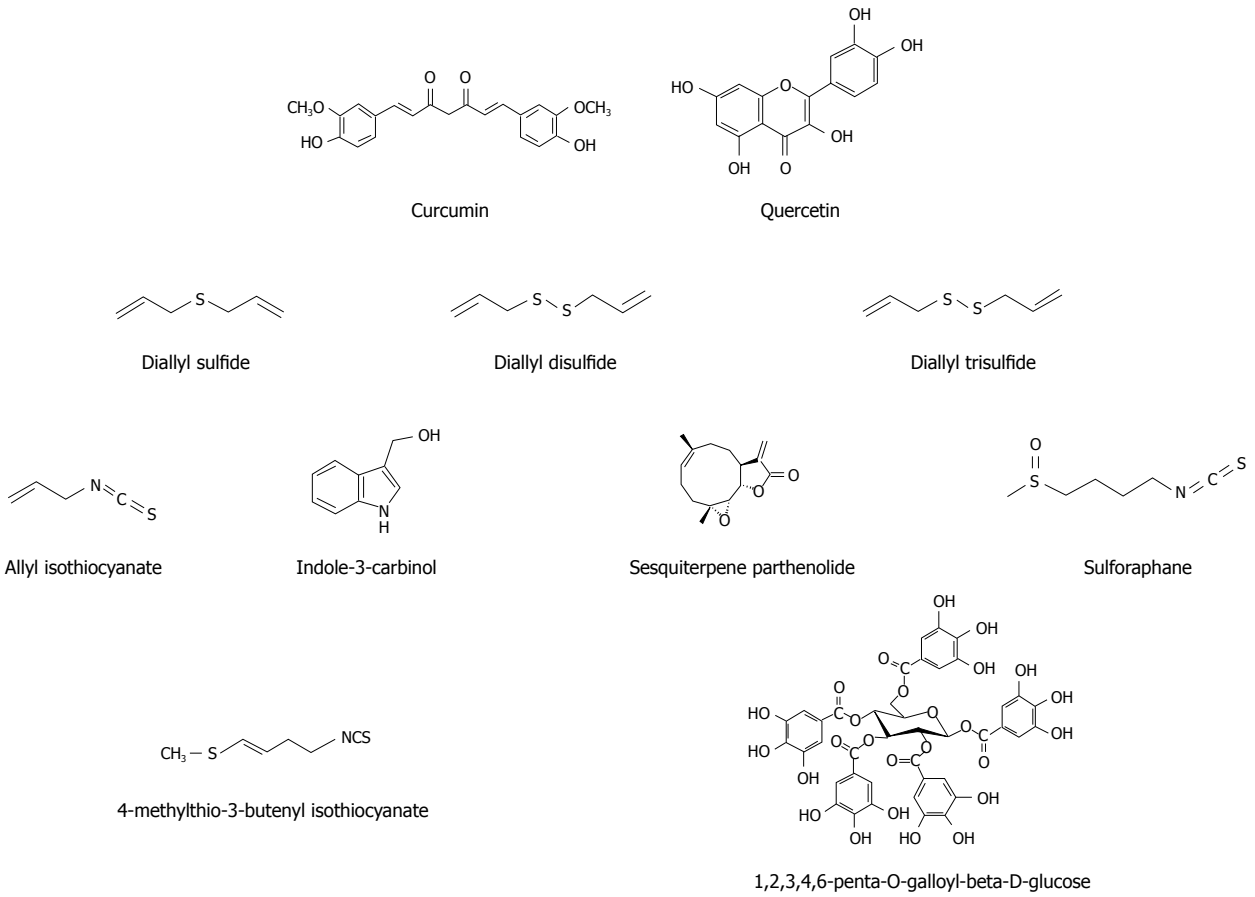

Figure 2 Chemical structures of various natural HO-1 inducers.

to their biological effects mainly by the Michael reaction acceptor function. However, recent studies[12] have demonstrated the ability of flavonoids to exert their protective properties also by influencing signaling pathways, thus indirectly interacting with the endogenous antioxidative defense system.

Quercetin (Figure 2) is one of the most common flavonoids and, probably, overall the most investigated. In human hepatocytes, quercetin is able to attenuate ethanol-induced oxidative damage by HO-1 induction *via* p38 and, especially, *via* ERK/Nrf2 transduction pathway[13,14]. Recently, in the same cellular model, Kluth *et al*[15] have confirmed that quercetin is able to activate the gene expression regulated by the EpRE of HO-1, although its ability was about 10 times less than that of thyme.

Garlic-derived organosulfur compounds

Diallyl sulfide (DAS), diallyl disulfide (DADS), and diallyl trisulfide (DATS) (Figure 2), the three major garlic (*Allium sativum*) organosulfur compounds, have been demonstrated to be HO-1 inducers in hepatic cellular models. In human hepatoma HepG2 cells, Chen *et al*[16] observed that garlic organosulfur compounds induced HO-1 as the result of Nrf2 activation. Gong *et al*[17] have confirmed the involvement of Nrf2 activation in the induction of HO-1 by garlic DAS in HepG2 cells. Additionally, in this latter study a different pathway of HO-1 induction has been revealed for DATS, leading the authors to argue that structural differences in terms of the number of sulfur moieties and the length of alkyl side chains can explain the differential effects of garlic-derived organosulfur compounds on the MAPK-mediated activation of Nrf2 and HO-1 induction.

Isothiocyanates

Cruciferous vegetables, particularly Brassica vegetables (i.e. broccoli, Brussels sprouts and cabbage), contain high concentrations of glucosinolates (β-thioglucoside *N*-hydroxysulfates) that are the precursor of isothiocyanates, potent inducers of cytoprotective enzymes and inhibitors of carcinogenesis. Noteworthy, the isothiocyanate sulforaphane, due to its peculiar ability to inhibit phase I enzymes and induce phase Ⅱ enzymes (i.e. HO-1), exerts valuable pleiotropic pharmacologic effects.

Jeong *et al*[18] have investigated the regulatory role of allyl isothiocyanate, indole-3-carbinol, the sesquiterpene parthenolide and sulforaphane (Figure 2) in the expression and degradation of Nrf2 and the induction of the antioxidant enzyme HO-1. Allyl isothiocyanate is an effective inducer of Nrf2 protein expression, ARE-reporter gene and HO-1, but had little effect on delaying the degradation of Nrf2 protein. Parthenolide and indole-3-carbinol also induced ARE-reporter gene expression and Nrf2, although to a lesser extent if compared to sulforaphane and allyl isothiocyanate. Nonetheless, parthenolide considerably induces the HO-1 expression at a level comparable to sulforaphane, while indole-

3-carbinol shows no effect. Of note, sulforaphane strongly induces Nrf2 protein expression and ARE-mediated transcription activation, retards degradation of Nrf2 through inhibiting Keap1, thereby activating the transcriptional expression of HO-1. In the same cellular model, Keum *et al*[19] have confirmed that transcriptional activation of Nrf2/ARE is critical in sulforaphane-mediated induction of HO-1. Further evidence of the ability of isothiocyanate to activate ARE-mediated HO-1 gene transcription through Nrf2/ARE signaling pathway has been provided by a study from Prawan *et al*[20] on HepG2-C8 cells.

Hanlon *et al*[21] have demonstrated that 4-methylthio-3-butenyl isothiocyanate (Figure 2), the isothiocyanate metabolite of glucoraphasatin, a glucosinolate uniquely contained at high concentrations in Spanish black radishes, significantly induces HO-1.

Other compounds and plant extracts

1,2,3,4,6-Penta-*O*-galloyl-beta-d-glucose (PGG), a bioactive tannin contained in many medicinal plants, is able to induce HO-1 in hepatic cells (Hep-G2)[22]. PGG confers hepatoprotection against oxidative injury by inducing HO-1 expression *via* stimulating NF-E2-related factor 2 nuclear translocation in an ERK-dependent manner.

In an *in vivo* study, Yao *et al*[14] have demonstrated that a standardized *Ginko biloba* extract, containing not identified terpenes and flavonol heterosides, is able to induce hepatic microsomal HO-1 on mRNA, protein expression and enzymatic activity, providing a hepato-protective effect in ethanol challenged animals.

Hep-G2 cells have been used as a cellular model to demonstrate that the α-methylene-γ-butyrolactone moiety in dehydrocostus lactone, one of the bioactive constituents of the medicinal plant *Saussurea lappa*, increases cellular resistance to oxidant injury in HepG2 cells, presumably through Nrf2/ARE-dependent HO-1 expression[18]. The same biochemical mechanism is supposed to explain the upregulation of HO-1 synthesis induced by inchinkoto, a Chinese/Japanese herbal medicine[23].

HEME OXYGENASE AS A REGULATOR OF HEPATOBILIARY FUNCTION

In rat liver, HO-1 is prominent in Kupffer cells, whereas HO-2 is most abundant in hepatocytes[7]. Upon stimulation with lipopolysaccharide (LPS), HO-1 not only occurs in tissue macrophages, but is also markedly induced in hepatocytes. On the other hand, HO-2 does not change. Sinusoidal endothelial cells and/or hepatic stellate cells have little if any HO-1, but in culture, appear to express HO-2[8]. HO mRNA levels are high in fetal rat liver during prenatal maturation (9 d before birth) and reach a maximum 24 h after birth, when levels decline but remain above adult levels for at least 1 mo. This correlates with a greater capacity of the liver for bilirubin production in fetuses compared with adults and such circumstances could render the fetus more susceptible to drug injuries because of a depressed heme-cytochrome P450 system[24]. However, Dennery *et al*[25] have found that serum bilirubin protects against oxidative damage in the first few days of life in neonatal Gunn rats exposed to hypoxia.

Another condition in which there is induction of HO-1 is liver regeneration following 2/3 hepatectomy[26]. In HO-1-deficient mice, there is an increased susceptibility of the liver to endotoxin and interruption of a major pathway of iron recycling[27]. Most importantly, the phenotype of the first human case of HO-1 deficiency includes endothelial cell damage, iron accumulation in the liver and kidney, and an increasing cell susceptibility to heme overloading *in vitro*[28].

The major source of CO in animals is the degradation of heme by HO; CO produced by HO may serve as an important cellular signal in the microenvironment. In 1994, Suematsu *et al*[29] have shown that CO is present at submicromolar levels in the liver effluent and that inhibition of HO with ZnPP increases perfusion pressure in the isolated perfused rat liver, an effect that can be reversed by adding CO or a cGMP analogue to the perfusate. CO serves as an endogenous factor that reduces sinusoidal tone involving, at least in part, hepatic stellate cells[30]. The importance of CO as an endogenous modulator of vascular portal perfusion has been confirmed by Pannen *et al*[31] who demonstrated how NO serves as a potent vasodilator in the hepatic arterial circulation, but exerts only a minor vasodilatory effect in the portal venous vascular bed, while CO does not regulate hepatic artery tone, but is able to maintain portal vascular tone in a relaxed state. Wakabayashi *et al*[32] have confirmed these results, by showing that the induction of HO-1 with hemin causes a decrease in baseline resistance and in the response to endothelin-1 through an increase in CO production in the extrasinusoidal compartment. We have also shown that overproduction of CO by induction of HO with $CoCl_2$, reduces the response to the vasoconstrictor endothelin-1, but not to phenylephrine, in the isolated perfused rat liver[33].

Elimination of constitutive CO generation through administration of ZnPP not only increases sinusoidal tone, but also stimulates bile-acid-dependent bile flow[34]. The choleretic action coincides with an increase in microvascular tone and oxygen consumption and may thus reflect a prolonged duration of bile acid uptake by hepatocytes. Exogenous CO at micromolar concentrations completely reverses these changes. The effect of ZnPP is mimicked by administration of methylene blue, a soluble guanylate cyclase inhibitor, but not fully reversed by membrane-permeable 8Br-cGMP, suggesting some involvement of cGMP-independent mechanisms. CO generated in hepatocytes may also affect bile excretion by altering the contractility of the bile canaliculus (BC)[34]. Inhibition of CO with ZnPP shortens intervals of contraction of BCs and increases intracellular Ca^{2+}, an effect that is reversed by CO at a micromolar level without increasing cGMP[35].

As to mechanisms of the CO effect, several lines of experimental evidence suggest that CO modulates BC functions through its action on cytochrome P450-mediated calcium mobilization[36].

Jaundice

Bilirubin production is two- to three-fold greater in newborns than in adults. This increase in plasma bilirubin levels is due in large part to the combination of the rapid degradation of fetal hemoglobin in the first few days of life and the immaturity of the hepatic bilirubin conjugating system, thus leading to an increase in unconjugated bilirubin. If the levels of unconjugated bilirubin become too high, the bilirubin may cross the blood-brain barrier, resulting in bilirubin encephalopathy or kernicterus. Phototherapy is the method of choice to lower serum bilirubin levels, but its safety and efficiency have been called into question and is still a matter of debate. The clinical use of HO inhibitors is an alternative therapy. Sn-PP produces a significant decrease in the levels of serum (mean decrease, 38%) and biliary bilirubin (mean decrease, 47%) in normal subjects. The decrease in these parameters lasts for a minimum of 4 d after administration of the metalloporphyrin[37]. The tin porphyrins have been used on newborns with ABO incompatibility[38], on patients with hereditary porphyria[39], liver disease[37], or Crigler-Najjar type I syndrome[40]. Results indicate that the use of SnMP within 24 h of birth in premature newborns substantially moderates the development of hyperbilirubinemia and reduces the requirement for phototherapy markedly (> 75%) in inhibitor-treated infants compared with control subjects[41]. When administered at the appropriate time to near-term and term newborns with hyperbilirubinemia, it can entirely eliminate the need for phototherapy. In patients with biliary cirrhosis and hemochromatosis, Sn-PP is able to reduce bilirubin levels for about 4 d. Biliary bilirubin concentrations decreased (mean decrease, 49%) in hemochromatosis patients after Sn-PP administration. No decrease in biliary bilirubin concentrations can be detected in primary biliary cirrhosis patients under the same conditions[37].

HEME OXYGENASE CONFERS PROTECTION VERSUS DIFFERENT TYPES OF INSULT

Hypoxia, ischemia/reperfusion (IR) and transplantation

Hemorrhagic shock (HS) causes severe hepatic dysfunction or acute failure related to decreased hepatic microcirculatory flow, and results in enhanced hepatic expression of HO-1[8]. Furthermore, the increase in portal resistance, upon blockade of the HO-CO pathway, is much more pronounced after HS compared with sham controls. After HS is endogenously generated, CO preserves sinusoidal perfusion, mitochondrial redox state, and secretory function in the isolated perfused rat liver[42]. This protective role of CO is mediated *via* a relaxing mechanism, in part, involving Ito cells. Similar results have been obtained by Kyokane *et al*[43] in endotoxemic rats overexpressing both inducible nitric oxide synthase (i-NOS) and HO-1. In this condition, inhibition of CO, but not of NO, causes marked vasoconstriction and cholestasis. Thus, CO may exert a protective function against hepatobiliary dysfunction after HS and endotoxemia.

Reperfusion injury has been defined as the conversion of reversibly injured cells (myocardial, endothelial, *etc.*) to irreversibly injured cells, and is mediated by a burst of free-radical generation as the previously hypoxic cells are flooded with oxygen. HO mRNA increases within 4 h of reperfusion of non-necrogenic ischemic rat liver[44]. Redaelli *et al*[45] have shown that the significant effects of heat preconditioning on liver transplantation after cold storage are prevented by inhibition of HO with tin protoporphyrin, and can be reproduced by administration of cobalt protoporphyrin, an inducer of HO. Thus, overexpression of HO-1 improves post-transplantation survival from 3 d to 3 wk and graft function after prolonged cold ischemia preservation. The mechanism underlying these beneficial effects does not appear to be the prevention of apoptosis. The same beneficial effects of induction of HO-1 with cobalt protoporphyrin (CoPP) or with adenoviral HO-1 (Ad-HO-1) transfection have been shown in steatotic livers[46]. Following cold ischemia/isotransplantation, HO-1 over-expression extended animal survival from 40% in untreated controls to about 80% after CoPP or Ad-HO-1 therapy. This effect is correlated with the preserved hepatic architecture, improves liver function, depresses infiltration by T cells and macrophages, causes suppression of local expression of i-NOS, and modulates the pro- and anti-apoptotic pathways[47]. More recent data have shown that HO-1 modulates pro-inflammatory responses that are triggered *via* TLR4 signaling, a putative HO-1 repressor[48].

The role of CO in protecting liver grafts from cold I/R injury associated with liver transplantation has been studied by Kaizu *et al*[49]. Inhalation of CO reduces hepatic injury and is associated with marked downregulation of early mRNA expression for tumor necrosis factor TNF-α, interleukin IL-6, and NOS. CO significantly inhibits phosphorylation of ERK1/2 MAPK and its upstream MEK1/2 and downstream transcriptional factor c-Myc. CO also significantly inhibits I/R injury-induced STAT1 and STAT3 activation. In contrast, CO does not inhibit p38 or JNK MAPK pathways during hepatic I/R injury. These results demonstrate that exogenous CO suppresses early pro-inflammatory and stress-response gene expression and efficiently improves hepatic I/R injury by downregulation of the MEK/ERK1/2 signaling pathway with CO. CO production, evaluated by CO-Hb, is associated with improved function in liver-transplanted patients[50]. Furthermore, an increase in HO-1 during transplantation is more protective than high HO-1 expression before transplantation[51].

Buis *et al*[52] have shown that donor HO-1 genetic polymorphism may influence the outcome of liver transplantation. Allele genotype is associated with increased graft survival. Graft survival at 1 year is significantly better for A-allele genotype compared to TT-genotype (84% *vs* 63%). Graft loss, due to primary dysfunction (PDF), occurs more frequently in TT-genotype compared to A-receivers ($P = 0.03$). Recipients of a liver with TT-genotype have significantly higher serum transaminases after transplantation and hepatic HO-1 mRNA levels are significantly lower compared to the A-allele livers. No differences are found for any outcome variable between class S and LL-variant of the (GT) (n) polymorphism. Haplotype analysis has confirmed dominance of the A (-413) T single nucleotide polymorphism over the (GT) (n) polymorphism. In conclusion, HO-1 genotype is associated with outcome after liver transplantation, suggesting that HO-1 mediates graft survival after liver transplantation. Excessive shear stress secondary to portal hypertension is probably involved in the augmented HO-1 expression in small-for-size graft liver[53]. In this model, recombinant Ad-HO-1 administered to donors 48 h before transplantation enhances HO-1 expression in both whole and small-for-size allografts, with a predominant augmentation in the small-for-size allografts, suggesting favorable conditions for the induction of HO-1 expression in small-for-size allografts. In close relation to the expression level of HO-1, Ad-HO-1 significantly prolongs both whole and small-for size allograft survivals, with a remarkable effect in the small-for-size allograft group. The prolongation of allograft survival is blocked by the HO-1 inhibitor (Zinc protoporphyrin Ⅸ). The non-treated small-for-size allografts demonstrate impaired liver function during the early period after reperfusion, which can be improved by over-expression of HO-1, but reversed by the HO-1 inhibitor. The markedly increased expression of HO-1 in small-for-size allografts is associated with lower levels of adhesion molecules and pro-inflammatory cytokines in the early phase after reperfusion[54]. Also, in aged liver, HO-1 overexpression can provide potent protection against cold I/R injury. This effect depends, at least in part, on HO-1-mediated inhibition of the anti-apoptotic mechanism, as an active form of pro-apoptotic caspase-3 (p20) protein, and was found to be 2.9-fold lower at 24 h in the hemin-pretreated group, as compared to saline liver transplant controls[55].

The other product of HO activity, biliverdin, also exerts protective effects against liver I/R injury[56]. Adjunctive biliverdin improves portal venous blood flow from the beginning of reperfusion and increases bile production as compared with the control group. I/R-induced hepatocellular damage, as measured by GOT/GPT release, is diminished by biliverdin. Improved liver function by biliverdin is accompanied by preservation of the histologic structure. Additionally[56], biliverdin adjuvant after orthotopic liver transplantation (OLT) decreases endothelial expression of cellular adhesion molecules (P-selectin and intracellular adhesion molecule 1), and decreases the extent of infiltration by neutrophils and inflammatory macrophages. Biliverdin also inhibits expression of i-NOS and pro-inflammatory cytokines (IL-1β, TNF-α, and IL-6) in OLTs. Finally, biliverdin therapy promotes an increased expression of anti-apoptotic molecules independently of HO-1 expression, consistent with biliverdin, being an important mediator through which HO-1 prevents cellular death.

Alcohol and non-alcoholic steatosis

Steato-hepatitis is a liver disease characterized by fat accumulation, inflammation, necrosis, and fibrosis. It can be caused by alcohol, or be independent from alcohol and defined as non-alcoholic steato-hepatitis (NASH). In hepatic NASH, Malaguarnera *et al*[57] have shown that HO-1 expression is significantly increased, and the increase reflects the severity of the disease. They observed a significant correlation between the increased levels of HO-1 and ferritin, and between the increased levels of HO-1 and lipid peroxidation. Moreover, NASH patients with lower levels of GSH exhibit higher expression of HO-1. Thus, the induction of HO-1 seems an adaptive response against oxidative damage elicited by lipid peroxidation, and it may be critical in the progression of the disease.

The only data on alcoholic steato-hepatitis are those of Yao *et al*[14] who have shown that the induction of HO-1 by *Ginkgo biloba* is associated with a decrease in liver damage caused by ethanol feeding for 90 d in rats. This is probably due to the enhanced anti-oxidative capacity against the ethanol-induced oxidative stress and the maintenance of cellular redox balance.

Liu *et al*[13] have shown that ethanol dose-dependently induces HO-1 and increases HO activity in human hepatocytes in culture, and that HO-1 mRNA increases after 30 min of exposure. Induction of HO-1 with CoPP prevents damage from ethanol. These results have been confirmed by Yao *et al*[43], who showed that quercetin prevents ethanol toxicity in human hepatocytes, an effect which is mediated by HO-1 induction. HO activity is also increased by chronic ethanol consumption in rats[58]. While 2.5-mo-old rats respond to acute ethanol intoxication by displaying increased expression of liver HO-1 mRNA, and 6-mo-old rats exhibit a mild response, 18-mo-old rats do not show any response, probably because of a decreased transcriptional ability to respond to stress in older animals[59].

Cirrhotic and pre-hepatic portal hypertension

In cirrhosis induced by bile duct ligation, Wei *et al*[60] have shown that HO-1 mRNA and protein expression is increased in hepatocytes and some Kupffer cells in the early phase of the disease, while HO-2 expression is unchanged. HO-1 induction is also related to iNOS induction.

In cirrhotic livers, mainly biliary cirrhosis, both HO-1 and HO-2 were found to be increased by Goh *et al*[61]. HO-1 was localized mainly in Kupffer cells, while HO-2 was localized in the cytoplasm of the

hepatocytes. Similar results were obtained in patients with post-hepatic cirrhosis by Makino *et al*[62]. They have shown that HO-1 is increased in the liver, being mainly distributed in Kupffer cells and hepatocytes. By contrast, in livers in which portal hypertension is idiopathic and due to increased perisinusoidal resistance, there is a decreased expression of HO-1 in Kupffer cells and an absence in hepatocytes. A study in cirrhotic patients undergoing liver transplantation has shown that HO-1 is up-regulated through heme-independent stimuli according to the development of portal hypertension and that induced HO-1 plays a pathophysiological role in portal hypertension through CO production[63].

In cirrhotic patients CO-Hb is increased, as demonstrated by Tran *et al*[64], but does not correlate with disease severity (MELD score, Child Turcotte Pugh score, or other biochemical or clinical measurements). In cirrhotic patients with spontaneous bacterial peritonitis, CO production, evaluated as CO concentration in the exhaled air and blood CO-Hb level, is further increased and may participate in circulatory alterations[65].

A clear role of the HO-CO system in the pathophysiology of hemodynamic alterations related to experimental cirrhotic portal hypertension in the rat is now established.

Decreased HO-2 expression in the liver is associated with increased portal resistance[33], while mesenteric artery dilatation and hypo-reactivity to vasoconstrictors, phenylephrine, KCl, endothelin-1, is associated with induction of HO-1 and increased HO-2. As a confirmation of these findings, transfection of normal rats with human HO-1 mimics mesenteric arterial alterations of portal hypertension[66]. Hyper-expression of HO-1 is particularly relevant in cirrhotic rats with ascites and its function is mediated by large-conductance calcium-activated potassium channels[67]. The alpha subunits of these channels, in particular, are increased in cirrhotic animals and their increase may be mediated by the increased HO-1[68].

In experimental pre-hepatic portal hypertension, obtained by partial portal vein ligation in rats, Fernandez *et al*[69] have shown that HO activity is increased in the liver. HO-1 expression is present in hepatocytes and Kupffer cells of portal hypertensive rats but not of normal animals, while HO-2 is similarly expressed in all liver cell types of normal and portal-vein ligated rats. They have also evaluated the role of CO in hyporeactivity of the mesenteric vascular beds of prehepatic portal hypertension in rat[69]. In this model, inhibition of HO with ZnMP does not modify the hypo-reactivity to KCl that is partially attenuated by NOS inhibition and completely corrected by simultaneous inhibition of HO and NOS. Also the hypo-reactivity to methoxamine is not affected by ZnMP, but it is completely overcome by L-NAME, without any increase in response after combined inhibition of NOS and HO. In cirrhotic patients with hepatopulmonary syndrome (HPS), characterized by decreased arterial pO_2 levels and increased alveolar-arterial oxygen gradient, CO-Hb levels are increased, compared to those without the syndrome, and are correlated with pO_2 ($P < 0.001$) and Aa pO_2 ($P < 0.001$) levels. Thus, CO may contribute to human HPS[70]. These data confirm what was experimentally found: in cirrhosis experimentally induced in the rat by bile duct ligation, NO-mediated up-regulation of HO-1 expression has been shown to participate in HPS[71]. In the same model, HO-1 mRNA transcription and protein expression are significantly increased in cirrhotic hearts compared with sham-operated controls, whereas there is no difference in HO-2 mRNA or protein levels. Total HO activity and cGMP levels are significantly increased in cirrhotic ventricles *vs* controls, and treatment with ZnPP significantly decreases cGMP production and improves the blunted papillary muscle contractility, whereas it has no effect on control muscles. CO perfusion inhibits papillary muscle contractility, an effect completely blocked by methylene blue and partially blocked by ZnPP. Thus, activation of the HO-CO-cGMP pathway is involved in the pathogenesis of cirrhotic cardiomyopathy[72].

Renal HO-1 expression is decreased in cirrhotic rats (bile ligation) in renal tubules and interlobular arterioles, while it is increased in the liver. The decreased HO-1 is related to renal dysfunction[73].

During HPS caused by liver cirrhosis, pulmonary endothelial NOS expression and NO production are increased. Increased NO contributes to the blunted hypoxic pressure response (HPR) during cirrhosis and may induce HO-1 expression and CO production, exacerbating the blunted HPR. We hypothesized that NO regulates the expression of HO-1 during cirrhosis, contributing to HPS. Cirrhosis was induced in rats by common bile duct ligation (CBDL). Rats were studied 2 wk and 5 wk after CBDL or sham surgery. Lung HO-1 expression was elevated 5 wk after CBDL. Liver HO-1 was increased at 2 wk and remained elevated at 5 wk. In catheterized rats, the blunted HPR was partially restored by HO inhibition. Rats treated with the NOS inhibitor *N*(G)-nitro-l-arginine methyl ester for the entire 2 wk or 5-wk duration had normalized HO-1 expression and HPR. These data provide *in vivo* evidence for the NO-mediated up-regulation of HO-1 expression and support the concept that HPS is multifactorial, involving not only NO, but also HO-1 and CO.

In kidneys from CBDL rats, Miyazono *et al*[73] have shown that HO-1 protein expression is increased slightly at 2 wk but is abolished at 5 wk. In addition, histologically, HO-1 expression was suppressed in renal tubules and interlobular arterioles in 5-wk-old CBDL rats. Conversely, HO-1 expression in liver was strongly increased. Consistent with the development of cirrhosis and renal dysfunction, mean arterial pressure (MAP), glomerular filtration rate (GFR), and renal blood flow (RBF) are decreased in CBDL rats, compared with sham-operated controls. In sham rats, treatment with the selective HO inhibitor ZnPP markedly decreases GFR and RBF to values similar to those measured in CBDL rats without decreasing MAP. In conclusion, decreased renal HO-1 expression contributes to deteriorated renal function and hemodynamics during cirrhosis. This finding provides a novel mechanism for the pathophysiology of renal dysfunction during cirrhosis.

Hepatitis

Interactions between hepatitis viruses B and C and HO have been described, both directly and through the effects on the immune response.

Hepatitis B

Protzer *et al*[74] have investigated the effects of HO-1 induction in models of human hepatitis B virus (HBV) infection. Adenoviral transfer of an HBV 1.3 genome into wild-type mice was used as a model for acute hepatitis B. HBV transgenic animals were used as a model for chronic HBV infection. To investigate HO-1 effects on HBV replication at a molecular level, stably HBV-transfected hepatoma cells were used. In the acute hepatitis B model, liver injury was reduced significantly after HO-1 induction. In addition, HO-1 showed a pronounced antiviral effect, which was confirmed in stably HBV-transfected hepatoma cells and in persistently HBV replicating transgenic mice. HO-1 induction repressed HBV replication directly in hepatocytes at a post-transcriptional step by reducing stability of HBV core protein and thus blocking refill of nuclear HBV covalently closed circular DNA. Small interfering RNA directed against HO-1 proved that this effect was dependent on the expression level of HO-1. The authors[74] concluded that, besides its hepato-protective effect, HO-1 showed a pronounced antiviral activity in HBV infection.

Hepatitis C

Conflicting data are available on HO-1 in hepatitis C. Ghaziani *et al*[75] have shown that human hepatoma cells expressing HCV have increased HO-1 and decreased Bach1 expression. Abdalla *et al*[76], on the contrary, have found a clear decrease in HO-1 and HO-1 mRNA in liver biopsies from HCV-infected patients. The expression of HO-1 was also reduced in cell lines that stably express HCV core protein, which suggests that core gene products are capable of regulating the expression of HO-1. These results are confirmed by Wen *et al*[77] have who shown that HCV core protein attenuates the induction of HO-1 by heme, heavy metals, and peroxides and contributes to hepatocellular damage by increasing both steady-state levels of pro-oxidants and the susceptibility of hepatocytes to damage by impairing their response to other sources of oxidative stress. Concerning the effects of HO-1 induction on hepatitis C, Shan *et al*[78] have shown a decrease in HCV replication, an effect similar to that described by Protzer *et al*[74] in HBV hepatitis.

CRITICAL CONSIDERATIONS AND FUTURE STUDIES

The amount of experimental data that demonstrate important properties of many ingredients and/or bioactive substances from plants and food plants is vast and continues to increase rapidly. The use of terms such as nutraceuticals, functional foods, herbal extracts, bioactive dietary constituents, phytochemicals and similar is becoming copious. In many cases marketing strategies abuse these terms and health properties are claimed although far from being scientifically demonstrated. Thus, researchers are requested to have scientific objectivity in evaluating health properties of food ingredients. It is possible to sustain those diverse bioactive substances from plants and food plants are promising candidates as natural HO-1 hepatic inducers. However, some critical evaluations on literature data are necessary. It is important to note that the majority of studies were conducted in cellular models, whereas only two studies were conducted on rats. Thus, the reproduction of natural HO-1 hepatic inducers in more relevant *in vivo* models is certainly necessary. With regards to the inductive mechanism of natural HO-1 hepatic inducers, although other pathways cannot be excluded, it seems quite clear that the prevalent mechanism is an ARE-mediated HO-1 gene transcription through the Nrf2/ARE signaling pathway.

Other uncertainties derive from the fact that the referred studies have reported data on natural HO-1 inducers considered both as single chemicals and food extracts. In some cases, scarce or no information has been provided about (1) the quantitative measurements of the proposed active compound; (2) methods of analysis and, (3) extraction procedures. Obviously, the above information is essential to enable other researchers to reproduce the experiments and to obtain comparable data.

When considering a possible therapeutic use of future natural HO-1-inducer-based drugs, the amount of work to perform is even more significant. Indeed, exhaustive information on absorption, distribution, metabolism and excretion by the main possible routes (oral, intraperitoneal, intravenous, intrathecal) are largely insufficient. A potential point of strength of natural HO-1 hepatic inducers is that, generally, they have no toxic effects, and it is presumed that they should not have side effects or teratogenic properties.

Abstract

The requirements of growth and organ development create a challenge in nutritional management of newborn infants, especially premature newborn and intestinal-failure infants. Since their feeding may increase the risk of necrotizing enterocolitis, some high-risk infants receive a small volume of feeding or parenteral nutrition (PN) without enteral feeding. This review summarizes the current research progress in the nutritional management of newborn infants. Searches of MEDLINE (1998-2007), Cochrane Central Register of Controlled Trials (The Cochrane Library, Issue 3, 2007), abstracts and conference proceedings, references from relevant publications in the English language were performed, showing that breast milk is the preferred source of nutrients for enteral feeding of newborn infants. The number of nutrients found in human milk was recommended as a guideline in establishing the minimum and maximum levels in infant formulas. The fear of necrotizing enterocolitis and feeding intolerance are the major factors limiting the use of the enteral route as the primary means of nourishing premature infants. PN may help to meet many of the nutritional needs of these infants, but has significant detrimental side effects. Trophic feedings (small volume of feeding given at the same rate for at least 5 d) during PN are a strategy to enhance the feeding tolerance and decrease the side effects of PN and the time to achieve full feeding. Human milk is a key component of any strategy for enteral nutrition of all infants. However, the amounts of calcium, phosphorus, zinc and other nutrients are inadequate to meet the needs of the very low birth weight (VLBW) infants during growth. Therefore, safe and effective means to fortify human milk are essential to the care of VLBW infants.

Key words: Breast milk; Infant formula; Trophic feeding; Parenteral nutrition

INTRODUCTION

The requirements of growth and organ development create a challenge in nutritional management of newborn infants. The stress of critical illness further complicates the delivery of adequate nutrients. Enteral feeding has several advantages over parenteral nutrition (PN), such as preservation of the gastrointestinal mucosa and decreasing the occurrence of sepsis related to bacterial translocation. Although feeding through the gastrointestinal tract is the preferred route for nutritional management, there are specific instances when PN as an adjunctive or sole therapy is necessary to meet nutritional needs. When meticulous attention is paid to the requirements of fluid, calory, protein, and fat along with monitoring the metabolic status of patients, it is possible to provide full nutritional support for critically ill newborn infants.

MACRO-NUTRIENTS OF BREAST MILK AND INFANT FORMULA

Breast milk is the preferred source of nutrients for newborn infants, and the number of nutrients found in human milk is recommended as a guideline in

establishing the minimum and maximum levels in infant formulas[1]. Following macronutrients (e.g. proteins, fatty acids and carbohydrates) for infant formulas based on scientific investigations of breast milk during the last decades were recommended by the American Academy of Pediatrics, Committee on Nutrition (AAP-CON) in 2003, and approved by Food Safety and Applied Nutrition, Food and Drug Administration (FDA)[2].

Proteins and amino acids

A minimum protein content of 1.7 g/100 kcal (i.e. total nitrogen × 6.25) and a maximum total protein content of 3.4 g/100 kcal in infant formulas have been recommended[2,3]. The current maximum protein content of 4.5 g/100 kcal is too high because there is no physiological reason to provide protein at this level. Milk contains two primary sources of protein: caseins and whey[2,3]. It has been reported that human breast milk contains whey/caseins at a ratio of 9/1 to 6/4 in different lactating periods. However, most of the marketing formulas for infants contain whey/caseins at a ratio of 6/4 to 4/6[2,3].

Whey, a protein complex derived from milk, is touted as a functional food with a number of health benefits. The biological components of whey, including lactoferrin, β-lactoglobulin, α-lactalbumin, glycomacropeptide, and immunoglobulins, demonstrate a variety of immune-enhancing properties[2,3]. In addition, whey, an antioxidant, can act as an antihypertensive, antitumor, hypolipidemic, antiviral, antibacterial, and chelating agent. The primary mechanism by which whey exerts its effects is by intracellular conversion of amino acid cysteine to glutathione, a potent intracellular antioxidant. A number of clinical trials have successfully been performed using whey in the treatment of cancer, human immunodeficiency virus (HIV) infection, hepatitis B, cardiovascular disease, osteoporosis, and as an antimicrobial agent[3].

Lactoferrin is an important protein in human milk (range 0.02-0.2 g/dL) at different lactating stages[2,3]. Although it is technically feasible to add bovine lactoferrin or transgenic human transferrin to infant formulas, bovine lactoferrin does not bind consistently to human lactoferrin receptors and whether it increases iron absorption remains unknown. The efficacy and safety of adding human lactoferrin to infant formulas have not been adequately evaluated. Given the emerging knowledge about the biological importance of human lactoferrin in infant nutrition, lactoferrin supplementation is worthy of consideration. However, clinical studies will be essential to demonstrate the efficacy and safety of such addition.

A minimum carnitine content of 1.2 mg/100 kcal (a level similar to that in human milk) and a maximum content of 2.0 mg/100 kcal in infant formulas (a value similar to the upper limit in human milk), have been recommended[2,3]. Although evidence that dietary carnitine is essential for infants, biochemical changes are noted when infants are fed with a carnitine-free diet. A few anecdotal reports are available on the abnormal clinical manifestations associated with diets low in carnitine[2]. Infants nourished with soy-protein-based formulas with a low carnitine content have lower plasma and urine carnitine levels and altered lipid metabolism, but no significant difference in rates of growth compared with those not nourished with soy-protein-based formulas with a low carnitine content.

Glutamine and taurine are free amino acids commonly detected in human breast milk[2-4]. The addition of glutamine to infant formulas is not recommended because no convincing evidence is available on glutamine requirement in diet. Also, no compelling evidence mandates the addition of taurine to formulas for infants. However, taurine has been used in some commercially available formulas. Currently, a minimum taurine content of zero and a maximum taurine content of 12 mg/100 kcal in infant formulas (a value similar to the limit in human milk) are recommended.

There are few compelling reasons for the addition of nucleotides to infant formulas[2,3,5]. The beneficial effects of nucleotide supplementation to infant formulas are intriguing, and further research in this area is strongly urged. When data from long-term, large-scale clinical trials are available, the question of adding nucleotides to infant formulas should be reconsidered. A maximum content with 16 mg/100 kcal of nucleotides and their precursors in infant formulas, a value similar to the upper limit in human milk, is recommended.

Fat and fatty acids

A minimum fat content of 4.4 g/100 kcal (40% of total energy) and a maximum fat content of 6.4 g/100 kcal (57.2% of total energy) in infant formulas have been recommended[2,3,5,6]. With the proposed minimum protein of 1.7 g/100 kcal (6.8 kcal/100 kcal) and minimum carbohydrate of 9 g/100 kcal (36 kcal/100 kcal), a maximum value for fat may not, therefore, exceed 57.2 kcal/100 kcal, which is equivalent to 6.4 g/100 kcal.

Medium-chain triglyceride (MCT) is not recommended to be supplemented in infant formulas, with the exception of certain exempt formulas for infants with impaired fat digestion or absorption.

Linoleic acid (LA) is recommended with a minimum content of 8% of total fatty acids in infant formulas. With a minimum fat content of 4.4 g/100 kcal, the minimum LA content is, therefore, 350 mg/100 kcal. Concentrations of LA in human milk vary widely as a reflection of maternal dietary intake, but values less than 8% of fatty acids are rarely reported. Currently, marketed infant formulas provide more than 8% of fatty acids as LA. A maximum LA content of 35% of total fatty acids in infant formulas is recommended. With a maximum fat content of 6.4 g/100 kcal, the maximum LA content is, therefore, 2 240 mg/100 kcal. The polyunsaturated vegetable oils (corn, safflower, and soybean oils) used in manufacture of infant formulas contain an abundant amount of LA (usually 45%-70% of total fatty acids). Historically, infant formulas, particularly corn-oil-based

formulas, contained LA exceeding 35% of fatty acids, with no adverse effects. Moreover, this value (35% of fatty acids) is within the limit reported for individual human milk samples[2,3].

α-Linolenic acid (ALA) is recommended with a minimum content of 1.75% of fatty acids in infant formulas, with the further stipulation that the ratio of LA:ALA should not exceed 16 to 1. With the minimum total fat content of 4.4 g/100 kcal, the minimum content of ALA is 77 mg/100 kcal, approximately 0.7% of energy. This recommendation is based on the essentiality of ALA as a precursor of the n-3 series of long-chain polyunsaturated fatty acids (LCPUFAs). Studies showed that formulas providing ALA at levels below this may be associated with delayed development of visual function and lower levels of docosahexaenoic acid (DHA) in the brain[6]. The recommended upper limit for the ratio of LA:ALA (16:1) is intended to prevent an inappropriate combination of high LA content with low ALA content, which might interfere with the formation of longer-chain fatty acids of the n-3 series. A maximum ALA content of 4% total fatty acids in formulas can be additionally stipulated that the ratio of LA:ALA is not less than 6 to 1. With a maximum fat content of 6.4 g/100 kcal, 4% of fatty acids from ALA amounts to 256 mg/100 kcal. The maximum is based on the long history of use of formulas containing soy oil (soybean oils typically contain 6%-9% ALA) as the source of unsaturated fatty acids. The recommended minimum ratio of 6 to 1 is intended to ensure that combination of the minimum LA content with the maximum ALA level does not interfere with the production of longer-chain fatty acids of the n-6 series[2,3].

LCPUFAs, including arachidonic acid (AA) and DHA, are not recommended in infant formulas. Breast milk contains adequate AA and DHA (range 5-20 mg/dL). However, whether AA + DHA should be added to infant-formula milk is uncertain. The results of studies on the growth and neurodevelopment in infants fed with milk formula supplemented with AA + DHA are inconsistent[6,7], suggesting that LCPUFAs are not essential in the diet of infants. Because of the uncertain efficacy and safety, LCPUFAs should not be added to infant formulas. The FDA expert panel plans to revisit this field in 5 years when more data from larger studies are available[2,3,6,7].

Carbohydrate and oligosaccharides

An energy density of 63-71 kcal/dL in infant formulas is recommended. Carbohydrate is the most important nutrient for energy. A minimum total carbohydrate content of 9 g/100 kcal in infant formula is recommended. This minimum is based on a theoretical calculation taking into account the amount of glucose needed for obligatory central nervous system oxidation. A maximum of 13 g/100 kcal is recommended for total carbohydrate in infant formulas. This value is obtained by subtracting from 100% of the total energy (63 to 71 kcal/dL), the minimum energy provided by protein (1.7 g protein/100 kcal = 6.8 kcal) and the minimum energy from fat (4.4 g fat/100 kcal = 39.6 kcal), resulting in a maximum of 53.6 kcal from carbohydrate, which is equivalent to 13.4 g/100 kcal[2,3].

The addition of glucose to infant formulas is not recommended, because inclusion of glucose in infant formulas offers no biological advantage over other carbohydrate sources and would unnecessarily increase the osmolality of formulas. Lactose is safe and appropriate for use in formulas by most healthy infants, and may be used as a sole carbohydrate source. However, it should not be used at a level higher than the recommended maximum value for total carbohydrate (i.e. 13 g/100 kcal). Also, addition of sucrose to infant formulas is safe and may be used for the palatability of some formulas (e.g. protein-hydrolysate-based formulas).

The concentration and composition of oligosaccharides in breast milk are increased in a dynamic process. The highest amount of oligosaccharides, 2 g/dL milk, is reached on the fourth day of life. On days 30 and 120 of lactation, it decreases to 20% and 40%, respectively, in comparison to that on day 4. Most studies have reported that oligosaccharide in human milk consists of approximately 70%-90% galacto-oligosaccharides (GOSs) and 10%-30% fructo-oligosaccharides (FOSs) in the first few months. The available data are insufficient at present to establish a minimum or a maximum level of these substances in infant formulas. However, some infant formulas supplemented with GOS 0.2-0.4 g/dL and FOS 0.05-0.1 g/dL are available on the market. Although glucose polymers are safe and appropriate for use in formulas by most healthy infants, either a minimum or a maximum level of such substances is not recommended. The amount of carbohydrate from glucose polymers in a formula should be within the lower and upper limits of total carbohydrate. Inclusion of modified food starches in infant formulas involves toxicologic concerns rather than nutritional concerns. Therefore, such food starches in infant formulas are not recommended[2,3,8].

TROPHIC AND ENTERAL FEEDING

The provision of adequate enteral nutrition for preterm infants is one of the major clinical challenges facing neonatologists throughout the world. Many preterm infants are too ill to receive substantial enteral feeds and require prolonged PN. It was reported that normal gastrointestinal structure and function are lost, villi become shorter, mucosal DNA is lost, protein content and enzymatic activity are reduced both in animal models and in children, although an anabolic state is maintained by PN[9]. In a rat model, atrophy occurred after only 3 d of no enteric intake, while gastrointestinal atrophy and dysfunction were reversed following enteral feeding[9].

Trophic feeding (synonyms include minimal enteral feeding or nutrition, gastrointestinal priming, gut priming, and early hypocaloric feeding) is a relatively recent concept that has been introduced into clinical practice in an attempt to counter the effects of enteral starvation[9,10]. It may be defined as the practice of feeding nutritionally insignificant volumes of enteral

Table 1 Evidence-based enteral nutrition in preterm newborns

	Evidence-based enteral nutrition
Human milk	Human milk from the preterm infant's own mother is the first choice. Human milk can be stored at room temperature for up to 24 h after expression in colostrum and up to 6 h for mature milk. Beyond that, it should be stored at 3-4℃ before use. If not used for more than 5 d, it should be frozen
Human milk fortifier	Human milk fortifier is indicated in preterm infants < 31 wk and/or < 1500 g. Human milk (100 mL/kg) is given per day and discontinued when the infant has established full breast-feeding
Formula milk	If human milk from the preterm infant's own mother is not available, the only acceptable alternative is a preterm formula. A concentration of about 60 kcal/100 mL or 20 kcal/oz is recommended, but should be increased to 80 kcal/100 mL or 24 kcal/oz when the infant has achieved full enteral feeds
Feeding methods	Gavage feeding is given via an indwelling nasogastric tube during mechanical ventilation. An indwelling orogastric tube is used after endotracheal extubation. Intermittent intragastric feeding is the first choice method, but continuous transpyloric feeding can be tried in selected preterm infants with extremely poor gastric emptying and symptomatic gastro-esophageal reflux
Commencement of feeds	Hourly feeds of 1 mL are generally used in infants weighing less than 1000 g, 2-h 2 mL for infants weighing 1000-1500 g, 3-h 3 mL for infants weighing 1500-2000 g, and 4-h 4 mL for infants weighing more than 2000 g, unless there is significant respiratory distress, when the infant remains on 1-2-h feeds. If this might not be tolerated, milk may be commenced at 1 mL every 2 h, even less than 1 mL every 4-6 h. Such trophic feeding should begin as soon as possible after birth, and definitely within the first 3-4 d
Progression of feeds	Daily increment in the range of 10-30 mL/kg of milk feeds is safe. Demand feeding is started after infants have established full milk feeds on a 4 h regimen. Non-nutritive sucking is beneficial without side effects
Supplements	Multivitamin supplement is started when the infant has established full enteral feeds, and iron is started when the infant has doubled their birth weight (usually at 2 mo). Medium-chain triglycerides can be used as an energy supplement for preterm infants who fail to thrive

substrate to sick neonates, to supply nutrients to, and directly stimulate, the developing gastrointestinal system without increasing disease severity. Typically, a milk volume of 10-20 mL/kg per day is given at the same rate for at least 5 d. Several studies have examined the clinical outcome after trophic feeding[9-11], showing that milk tolerance, liver function, metabolic bone disease, days to hospital discharge, and weight gain are improved after trophic feeding. Nosocomial infections due to PN (because of its interference with the immune system and translocation of enteric pathogenic microorganisms into the circulation) may be reduced either because of improved gastrointestinal mucosal barrier function or because of beneficial alteration of the enteric flora.

Since premature infants are unable to coordinate sucking, swallowing, and breathing, orogastric tube-feeding is necessary. The most common methods used are continuous milk infusion and intermittent (bolus) milk delivery (usually every 3 h). Recent studies have suggested that bolus feeding promotes more "normal" feed-fasting hormonal concentrations that potentially benefit intestinal development and nutrient partitioning, and marked differences are observed in feeding tolerance and growth between continuous *vs* bolus tube-feeding methods[9-13]. Since continuous feeding is associated with more significant feeding intolerance, more infants are switched to bolus feeding. Importantly, throughout hospitalization, the continuous feeding method is associated with slower growth compared with the bolus group. Thus, bolus feeding is more advantageous than continuous infusion for premature infants with relatively healthy gastrointestinal tracts.

Current data support the practice of starting GI priming early, which does not add complications of neonatal intensive care[9,10,12]. Further studies are needed to determine if early feeding can be advanced in volume so that the use of PN can be reduced. Bolus feeding results in better feeding tolerance and growth than continuous tube-feeding and also obviates the need for costly infusion pumps and support care. The use of human milk, however, may have the most profound effects because of its association with a decrease in morbidity. The evidence-based guidelines for enteral nutrition in preterm infants are listed in Table 1[14].

PN

PN can meet neonates' requirement for growth and development when their size or condition precludes enteral feeding. Although feeding through the gastrointestinal tract is the preferred route for nutritional management, there are specific conditions for which PN as an adjunctive or a sole therapy is necessary. In very low birth weight (VLBW) premature infants, enteral feeding cannot be established in the first few days of life, due to the immaturity of the gastrointestinal system. PN can successfully meet the nutritional demands in critically ill neonates, neonates with protracted diarrhea and neonates undergone a major gastrointestinal surgery. The evidence-based guidelines for PN in preterm infants are summarized in Table 2[14].

Fluids and energy requirements

PN is a fundamental part of neonatal intensive care[15,16]. Fluid intake volume varies from 60 to 150 mL/kg per day, depending on maturity of the infant and environmental conditions influencing insensible water loss from the skin. An energy intake of 50 kcal/kg per day is adequate to match ongoing expenditure but an additional energy intake of 70 kcal/kg per day is required to achieve optimal growth. The ideal distribution of calories should be 60% carbohydrate, 10%-15%

Table 2 Evidence-based PN in preterm newborns

	Evidence-based PN
Fluids	D 1: 60-80 mL/kg per day. Infants < 28 wk gestation are nursed in a maximally humidified environment (90% humidity) for at least 7 d. Postnatal weight loss of 5% per day to a maximum of 15% is acceptable, which is achieved by progressively increasing the fluid intake to 120-150 mL/kg per day at 1 wk of age
Energy	An intake of 50 kcal/kg per day is sufficient to match ongoing expenditure, but it does not meet additional requirements of growth. The goal energy intake is 120 kcal/kg per day, which is higher in infants with chronic lung diseases
Protein	Optimal parenteral amino acid intake is 3.5 g/kg per day. Parenteral amino acids can begin from day 1 at a dose of 1.75 g/kg per day
Carbohydrate	From day 1, 6-10 g/kg per day can be infused and adjusted to maintain blood glucose level of 2.6-10 mmol/L. Insulin is only used in infants whose blood glucose level is higher than 15 mmol/L and associated with glycosuria and osmotic diuresis, even after glucose intake has been decreased to 6 g/kg per day. Carbohydrate is given as a continuous infusion commencing at a rate of 0.05 U/kg per hour, and increased as required for persistent hyperglycemia
Fat	Intravenous fat, 1 g/kg per day, can be started from day 1, or when intravenous amino acids are started. The dose of intravenous fat is increased to 2 g/kg and 3 g/kg per day over the next 2 d. Twenty percent intravenous fat is delivered as a continuous infusion via a syringe pump, separated from the infusate containing amino acids and glucose. The syringe and infusion line should be shielded from ambient light
Minerals	Minerals should include sodium (3-5 mmol/kg per day), chloride (3-5 mmol/kg per day), potassium (1-2 mmol/kg per day), calcium (1.5-2.2 mmol/kg per day), phosphorus (1.5-2.2 mmol/kg per day), and magnesium (0.3-0.4 mmol/kg per day)
Trace elements	Trace elements should include zinc (6-8 μmol/kg per day), copper (0.3-0.6 μmol/kg per day), selenium (13-25 nmol/kg per day), manganese (18-180 nmol/kg per day), iodine (8 nmol/kg per day), chromium (4-8 nmol/kg per day), and molybdenum (2-10 nmol/kg per day)
Vitamins	Vitamins must be added to the fat emulsion to minimize loss of vitamins due to adherence to tubes and photodegradation

protein, and 30% fat. A 10% dextrose solution provides 0.34 kcal/mL, a 10% lipid solution provides 0.9 kcal/mL. Although protein is a potential energy substrate, it should be utilized only for tissue growth. Glucose and lipids can provide sufficient calories to avoid protein catabolism. A preterm neonate needs 100-150 kcal/kg per day, whereas a term neonate needs 100-120 kcal/kg per day.

Carbohydrate requirements

Glucose is the most widely used intravenous carbohydrate for neonates because it is readily available to the brain. A preterm infant has a higher glucose demand and hence early administration of glucose is vital. It is important to balance non-protein calories between carbohydrates and fats, and a 2:1 ratio is recommended. Excess use of glucose would result in lipogenesis, excess production of CO_2 and hyperglycemia leading to osmotic diuresis. Hyperglycaemia during PN can be minimized by starting glucose infusion at a rate of 4-6 mg/kg permin (6-8 g/kg per day) with progressive increase to 12-15 mg/kg per min (16-20 g/kg per day) for 2-3 wk after birth[15,16].

Treatment of hyperglycemia is initiated with insulin if blood glucose is > 200 mg/dL, although the dextrose infusion is below 5 mg/kg per min. Insulin can be started at a dose of 0.05-0.1 U/kg per hour. Insulin infusion rate should be adjusted to 0.05 U/kg per hour to keep the glucose level at 150-200 mg/dL. When the glucose level decreases to < 100 mg/dL, the glucose is monitored every 4 h once the target level is achieved[15,16]. Other causes of hyperglycemia like sepsis, intraventricular hemorrhage, and steroids should be ruled out before insulin is used.

Protein requirements

The goal of giving proteins is to limit catabolism, maintain endogenous protein stores, and provide sufficient energy and protein to support growth. It has been reported that early administration of PN is safe and efficacious with no metabolic derangements[17]. The concept put forth by the American Academy of Pediatrics that nutrition should support postnatal growth that approximates the in utero growth of a normal fetus should be accepted. Parenteral nitrogen requirement is 30-35 mmol/kg per day, which is equivalent to 3.0-3.5 mg/kg amino acids per day. These solutions contain nine essential amino acids and cysteine, tyrosine, taurine and arginine as the semi-essential amino acids. In the absence of an exogenous protein source, a preterm infant catabolizes 1 g/kg of its own body protein per day to meet its metabolic needs. Excess protein administration causes a rise in blood urea, ammonia and high levels of potentially toxic amino acids such as phenylalanine[18]. In our unit, we usually start amino acids (1 g/kg per day) on the second day of life for extremely low birth weight (ELBW) infants and increase to 3 g/kg per day with 1 g/kg daily increments per day. Protein with a maximum of 15% calories should be given.

Glutamine, one of the most abundant amino acids in both plasma and breast milk, is not included in amino acid preparations for PN. Glutamine, which is unstable in solution, is usually regarded as a non-essential amino acid. However, glutamine provides an important metabolic fuel for rapidly dividing cells of the gastrointestinal tract and immune system, and is an intermediate in a large number of metabolic pathways, and a precursor that donates nitrogen for the synthesis of purines, pyramidines, nucleotides and amino sugars. In addition, glutamine plays a key part in acid-base balance by acting as the most important substrate for renal ammonia production. It was reported that glutamine supplementation may decrease sepsis and mortality in critically ill adult patients[19]. In view of the

important metabolic roles of glutamine, further clinical evaluation is required in neonates.

Lipid requirements

Lipid is a major source of non-protein energy and has a nitrogen sparing effect. Serving as a source of essential fatty acids and LCPUFA, lipid is a major source of non-protein energy and has a nitrogen-sparing effect. The commercial intravenous lipid emulsions are aqueous suspensions containing neutral triglycerides derived from soybean, safflower oil and egg yolk to emulsify and adjust glycerin tonicity. Hydrolysis of triglycerides by hepatic and lipoprotein lipase results in formation of free fatty acids. Circulating free fatty acids can be used as an energy source or they enter adipose tissue where they are re-esterified to form triglycerides[15,16].

Parenteral fat is introduced at 1 g/kg per day, and gradually increased to 3 g/kg per day, given as a continuous infusion. In our unit, we usually start lipids on the third day of life in ELBW infants when the most acute phase of respiratory distress or other life-threatening events are controlled. We start 1 g/kg of lipids per day and increase it to 3 g/kg per day. At present, a 20% lipid emulsion is preferred over 10% emulsion, because the higher phospholipid content in 10% solution impedes plasma triglyceride clearance, resulting in higher concentrations of triglyceride and plasma cholesterol. Also, combined MCT/long-chain triglyceride (LCT) and lipid emulsion is preferred over LCT emulsion in preterm and critical neonates, because MCT/LCT is more easily metabolized. Advantages of lipid emulsions over concentrated glucose solutions include their isotonicity and greater energy density, the latter means that a low volume is required per calorie[15,16].

Minerals, trace elements and vitamins

Minerals and trace elements delivered with PN are calculated to meet in-utero accretion rates. Sodium, potassium, chloride, calcium, magnesium and phosphorus levels need to be closely monitored and the infusion needs to be prescribed accordingly. Neonates on long-term TPN may develop trace element deficiencies which should be checked regularly. TPN can provide the daily requirements for water and fat-soluble vitamins. The dose of water-soluble vitamins is 1 mL/kg per day, which should be added to the dextrose-electrolyte solution. The dose of fat-soluble vitamins is 1 mL/kg per day, which should be added to the lipid emulsions[14-16].

PN-associated cholestasis

In neonatal intensive care units where appropriate medical, nursing, pharmacy and laboratory experts are available, the potential benefits of PN outweigh its hazards. However, PN-associated cholestasis, onset of hyperbilirubinemia with direct bilirubin > 2 mg/dL within 2 wk after starting PN, are the common complications of PN, along with hepatomegaly, and mild elevation of conjugated bilirubin, alkaline phosphatase and transaminases[20,21]. Liver function generally becomes normal within 1-4 mo after stopping PN, but prolonged liver dysfunction and even fibrosis have been reported in certain cases[20,21]. The following factors may contribute to PN-associated liver diseases, including prolonged duration of PN therapy, sepsis, low serum albumin, excessive caloric load, enteral fasting, deficiency in nutritional taurine, carnitine, manganese, oxidative stress and hormonal factors such as elevated insulin/glucagon ratio, gut hormones and biliary stasis. Simple interventions such as minimizing the duration of therapy, early detection and treatment of sepsis, and choosing enteral nutrition rather than PN whenever possible, can minimize liver injury[20,21]. Ursodeoxycholic acid (UDCA) is used in the treatment of cholestasis[20], because it increases the hydrophilic non-hepatotoxic bile acid pool, decreases hepatocyte display of histocompatibility antigens and gives direct cytoprotection. The dose of UDCA is 20-30 mg/kg per day.

Abstract

Chronic hepatitis C is a leading cause of hepatocellular carcinoma (HCC) worldwide. Interferon (IFN) therapy decreases the incidence of HCC in patients with chronic hepatitis C. Prevention of chronic-hepatitis-C-related HCC is one of the most important issues in current hepatology. We have previously reported that male gender and high titer of hepatitis C virus (HCV) RNA are predictive factors for the development of HCC in HCV-related cirrhosis. Clinical efforts at eradicating or reducing the viral load may reduce the risk for HCC. Furthermore, because HCC often recurs after ablation therapy, we performed a trial of IFN in patients with chronic liver disease caused by HCV to see whether IFN therapy decreases recurrence after ablation therapy of HCV-related HCC. By using IFN therapy as a secondary prevention, patients with HCC who had received complete tumor ablation showed better survival, primarily as a result of the preservation of liver function and also probably prevention of recurrence. Postoperative IFN therapy appears to decrease recurrence after ablation therapy such as radiofrequency ablation (RFA) therapy of HCV-related HCC. We believe that there is a survival benefit in secondary prevention using IFN therapy. However, a controlled study is essential to obtain conclusive evidence of the efficacy of this strategy.

Key words: Hepatocellular carcinoma; Radiofrequency ablation; Interferon; Secondary prevention

INTRODUCTION

In Japan, the overwhelming majority of hepatocellular carcinoma (HCC) is caused by chronic hepatitis and liver cirrhosis due to persistent hepatitis C or B, mostly hepatitis C virus (HCV) infection. The onset of HCC can be roughly divided into intrahepatic metastasis and multicentric carcinogenesis. The latter can be further divided into synchronous multicentric carcinogenesis, in which HCC occurs in multiple locations simultaneously, and asynchronous multicentric carcinogenesis, in which HCC occurs some time after localized therapy such as partial hepatectomy, percutaneous ethanol injection therapy (PEIT), or percutaneous radiofrequency ablation (RFA). With asynchronous multicentric carcinogenesis, the prognosis of patients can be improved by preventing carcinogenesis in the remaining liver. HCC is treated by analyzing multiple factors, including: (1) decreased hepatic function due to chronic hepatitis and cirrhosis; (2) multicentric carcinogenesis (synchronous/asynchronous) due to persistent infection; and (3) early intrahepatic metastasis due to portal invasion, which is one of the characteristics of HCC. In other words, unlike other cancers, it is necessary to assess not only cancer progression, but also the hepatic reserve. The main objective of interferon (IFN) therapy for chronic hepatitis C infection is to end persistent infection and prevent the progression of liver disease. The present article discusses the significance of IFN therapy as secondary prevention after localized therapy for HCC, particularly IFN therapy combining pegylated IFN (PEG-IFN) and ribavirin.

ABLATION THERAPY FOR HCC

Unlike other cancers, the treatment of HCC involves not only the stage of the carcinoma itself, but also the stage of underlying chronic hepatitis. In patients with advanced HCC or extrahepatic metastasis, chemotherapy is mostly performed and its usefulness has been shown[1-5]. However, in patients with stage I or Ⅱ HCC, including early-stage HCC, percutaneous therapy is useful because its impact on normal hepatocytes is relatively small. Percutaneous therapy began with PEIT[6] and advanced to percutaneous microwave coagulation therapy (PMCT)[7], and today, RFA that combines the advantages associated with the previous two techniques is often performed[8-10]. In Japan, RFA was first performed in 1999, and it is still premature to discuss its long-term results, but regarding overseas results, Rossi *et al*[8-10] have reported that the survival rate for RFA was 94% at 1 year, 68% at 3 years, and 40% at 5 years, and that the rate of local recurrence was 5% with an average follow-up of 22.6 mo. At present, three RFA needles are available: Radionics Cooltip (single needle), RTC LeVeen probe (expandable needle), and RITA Model 90/70 (expandable needle). In our department, different RFA needles are used depending on tumor site and size, and according to our data, the extent of thermocoagulation per single ablation for RITA Model 90 is 43.2 mL, which is significantly greater when compared to the others. The rate of local recurrence within a range of 20 mm or 30 mm is significantly lower for RITA Model 90 (data not shown). Ablation therapy appears useful for the local control of HCC, but even if local control is sufficient, it is necessary to take into account background liver factors when suppressing recurrence. In other words, as in chronic hepatitis B [11], it is important to treat chronic hepatitis C using IFN.

CARCINOGENIC FACTORS IN HCV-RELATED CHRONIC HEPATITIS

While the onset mechanism of HCV HCC has not been elucidated, it has been suggested that persistent HCV-induced inflammation causes abnormally high levels of transaminase and results in excessive cellular turnover consisting of hepatocyte necrosis and regeneration, thus increasing the risk for genetic abnormalities leading to carcinogenesis. We examined carcinogenic factors in patients with HCV cirrhosis and advanced liver fibrosis; long-term follow-up examinations revealed that high viral titer, sex (male), and age (elderly) were significant onset factors (Tables 1 and 2)[12]. Hence, it is necessary to prevent HCC in patients with these risk factors.

PRIMARY PREVENTION OF HCV-RELATED CHRONIC HEPATITIS BY IFN THERAPY

Many studies have documented that IFN significantly suppresses the onset of HCC from chronic hepatitis and liver cirrhosis. Studies have found that IFN therapy for HCV infection is useful in suppressing carcinogenesis and improving liver function[13,14] and that IFN therapy eliminates HCV RNA and clearly suppresses the onset of HCC in patients with normalized transaminase levels[15]. Additionally, even if a complete response is not achieved, IFN therapy suppresses HCC when compared to untreated cases[16].

Furthermore, even in the presence of advanced chronic hepatitis, cirrhosis improves in about half of patients with a sustained response to IFN therapy[17], and IFN therapy lowers transaminase, maintains platelet counts, and reduces carcinogenesis[13]. This suggests

Shiratori[24]	49 *vs* 25	IFN-α	84	80 *vs* 92[1]	53 *vs* 23

[1]IFN therapy did not markedly lower the rate of recurrence the first time, it significantly lowered the rate of recurrence the second and third times.

that IFN suppresses persistent hepatitis in liver cirrhosis and carcinogenesis. Regarding the onset of HCC, it is not clear if it is important to maintain low transaminase levels or suppress liver fibrosis, but it is highly likely that blocking fibrosis is important in suppressing carcinogenesis. Therefore, IFN therapy appears to prevent liver fibrosis in liver cirrhosis.

Ever since the national health insurance system began covering IFN therapy in 1992, antiviral therapy for hepatitis C has steadily advanced and at present, therapy combining PEG-IFN and ribavirin is considered the most potent. The combination therapy was markedly effective in about 90% of patients with genotype-2 HCV when administered for 24 wk[18], and it was markedly effective in about 50% of patients with intractable hepatitis (genotype-1 HCV or high viral load) when administered for 48 wk[19]. In Japan, PEG-IFN and ribavirin combination therapy has improved the therapeutic results for intractable chronic hepatitis C.

IFN THERAPY AS SECONDARY PREVENTION FOR RECURRENT HCC

IFN therapy has been performed to prevent recurrent HCC (Table 3). One study retrospectively investigated recurrence after curative resection of HCV HCC, and found that alanine aminotransferase levels remained high[20]. In other words, hepatocyte necrosis and inflammation appear to be closely involved with recurrence. If IFN is successful in lowering HCV to an undetectable level, necrotic inflammation is naturally improved. At the same time, carcinogenesis is believed to be suppressed even in biochemical responders. Ikeda *et al*[21] have investigated the suppression of recurrent HCC by IFN-β following surgical resection or PEIT for HCC in patients with HCV cirrhosis. They have reported that intermittent IFN-β administration following surgical resection or PEIT for HCV HCC suppresses recurrence.

Kubo *et al*[22] have conducted a randomized controlled trial of postoperative IFN therapy in patients with HCV HCC and have reported that the rate of recurrence is significantly lower for patients with IFN therapy.

Suou *et al*[23] administered 6 MU of IFN-α for 24 wk and reported that the 3-year survival rate for patients without IFN-α was 18% and that of patients with IFN-α was 63%. Additionally, Shiratori *et al*[24] have reported that while IFN therapy does not markedly lower the rate of recurrence the first time, it significantly lowers the rate for the second and third times. Hence, IFN may initially act on tumors to suppress intrahepatic micrometastases following therapy for HCC, and then it may act on the virus to suppress recurrence 3-5 years later. Furthermore, it is reported to the contrary that although the cumulative recurrence rate in the IFN group was found to be lower than in the control group during the first 3 years after commencement of IFN administration, the recurrence rate in the IFN group increased with the lapse of time over 3 years. However, long-term, low-dose, intermittent IFN therapy successfully delayed clinical recurrence of HCC after radical RFA therapy[25]. In these studies, IFN therapy consisted of non-PEG-IFN monotherapy and the rate of sustained viral response was low, at 13%-33%. Therefore, if PEG-IFN and ribavirin combination therapy further improves antiviral effects[26], then recurrence may be suppressed even more. However, many patients with HCV HCC are elderly or have cirrhosis, and the dose and duration of PEG-IFN and ribavirin combination therapy have not been established in these patients. Further investigations are warranted.

IFN therapy following therapy for HCC is safe in selected patients. However, IFN therapy for the prevention of recurrent HCC is different from that for the treatment of primary HCC. Because prevention involves not only inflammation, fibrosis, and HCV, but also HCC-related factors, further investigations, including randomized controlled trials, are needed. Furthermore, antiviral therapy itself may improve liver reserve and expand the therapeutic options at the time of recurrence, thus improving the prognosis of HCC, and this issue also needs to be addressed by further studies including randomized controlled trials.

CONCLUSION

Secondary prevention of HCC is an important clinical issue because the recurrence rates of HCC are extremely high even after effective local treatment with hepatic resection or percutaneous ablation. This involves multicentric carcinogenesis in which new lesions are formed as a result of underlying hepatitis. Therefore, IFN therapy following the treatment for HCC is safe in selected patients and IFN therapy is an effective secondary prevention. In the future, PEG-IFN and ribavirin combination therapy may prove to be effective in preventing recurrence, and further investigations involving more cases are needed.

Abstract

AIM: To evaluate the protective effect of diallyl sulfide (DAS) against *N*-nitrosodiethylamine (NDEA)-induced liver carcinogenesis.

METHODS: Male Wistar rats received either NDEA or NDEA together with DAS as protection. Liver energy metabolism was assessed in terms of lactate, pyruvate, lactate/pyruvate, ATP levels, lactate dehydrogenase (LDH) and glucose-6-phosphate dehydrogenase (G6PD) activities. In addition, membrane disintegration of the liver cells was evaluated by measuring lipid-peroxidation products, measured as malondialdehyde (MDA); nitric oxide (NO) levels; glucose-6-phosphatase (G6Pase), catalase (CAT) and superoxide dismutase (SOD) activities. Liver DNA level, glutathione-S-transferase (GST) and cytochrome c oxidase activities were used as DNA fragmentation indices. Aldose reductase (AR) activity was measured as an index for cancer cells resistant to chemotherapy and histopathological examination was performed on liver sections from different groups.

RESULTS: NDEA significantly disturbed liver functions and most of the aforementioned indices. Treatment with DAS significantly restored liver functions and hepatocellular integrity; improved parameters of energy metabolism and suppressed free-radical generation.

CONCLUSION: We provide evidence that DAS exerts a protective role on liver functions and tissue integrity in face of enhanced tumorigenesis caused by NDEA, as well as improving cancer-cell sensitivity to chemotherapy. This is mediated through combating oxidative stress of free radicals, improving the energy metabolic state of the cell, and enhancing the activity of G6Pase, GST and AR enzymes.

Key words: *N*-nitrosodiethylamine; Diallyl sulfide; Liver cancer; Energy metabolism; Aldose reductase

INTRODUCTION

Primary liver cancer has been classified as the fifth most common cause of cancer and the fourth most common cause of cancer mortality in the world. One of the main pathological subtypes of liver cancer is hepatocellular carcinoma, which constitutes a major contributor to cancer incidence and mortality[1]. The population of Egypt has a heavy burden of liver disease, mostly due to chronic infection with hepatitis C virus. Since the liver offers a very important site for detoxification of xenobiotics, the use of synthetic chemoprotective agents offers potential risk factors[2,3]. Several reports have stressed the importance of many dietary habits in modifying the initiation, promotion and progression stages in carcinogenesis[4]. Garlic (*Allium sativum*), an important flavoring agent, exhibits medicinal properties that include immunomodulatory, hepatoprotective, antioxidant, antimutagenic, and anticarcinogenic effects[5,6]. The anticarcinogenic property of garlic has been documented from both epidemiological and experimental studies which suggests that the consumption of garlic can decrease the incidence of several cancers[2,7,8]. The ability of garlic to reduce the incidence of cancer has been attributed to its content of organosulfur compounds which reportedly suppress carcinogen-induced tumors in various organs of animals including the colorectum, breast and liver[9-11].

A major constituent of garlic, diallyl sulfide (DAS), has been shown to inhibit chemical toxicity and tumorigenesis in several animal models[12]. Nonetheless, the possibility that DAS may exert a protective role against *N*-nitrosodiethylamine (NDEA)-induced liver tumorigenesis cannot be ruled out. In this study, we investigated the cellular and molecular mechanisms of the protective effects of DAS against liver damage induced by NDEA, a potent inducer of liver cancer. We determined the histopathological effect of DAS on liver tissue, as well as on enzymatic and non-enzymatic liver functions. In addition, we investigated the possibility that DAS might act on maintaining liver tissue functions, which were assessed by investigating energy metabolism, membrane disintegration and DNA integrity indices.

MATERIALS AND METHODS

Animals

We used a total of 36 male albino rats of the Wistar strain, weighing 170-200 g, that were obtained from the central animal facility at the Faculty of Pharmacy, Cairo University, Cairo, Egypt. All rats were housed in a room with a controlled environment, at a constant temperature of 23 ± 1℃, humidity of 60% ± 10%, and a 12 h light/dark cycle. The animals were housed in groups and kept at constant nutritional conditions throughout the experimental period. The experimental protocols were approved by the Ethical Committee of Cairo University.

Drugs and chemicals

NDEA, DAS, enzymes and coenzymes were obtained from Sigma Chemical Co. (St. Louis, MO, USA). Other chemicals were of Analar grade. NDEA was prepared as 8 mg/mL saline, whereas DAS was prepared as 80 mg/mL corn oil.

Induction of liver cancer

Each rat received an oral dose of 20 mg/kg per day NDEA for 5 d per week for 9 wk, followed by 10 mg/kg per day for 5 d per week for another 6 wk.

Protocols and experimental groups

Animals were divided into three groups: Group Ⅰ was the NDEA-induced cancer group, and Group Ⅱ was the DAS-treated group. Cancer was induced in this group by the same protocol. In addition, DAS was co-administered at a daily oral dose of 200 mg/kg per day for 5 d per week for the total period of the experiment (i.e. 15 wk). Group Ⅲ consisted of normal rats that received an oral dose of vehicles (saline, corn oil) for the total period of the experiment.

Biochemical estimations

Blood analysis: At the end of the experimental period, all animals were killed by cervical dislocation. The separated plasma was analyzed for total protein[13] and albumin[14]. The separated serum was analyzed for aspartate aminotransferase (AST), using a kit provided by Bicon, Germany[15]; alkaline phosphatase (ALP) using a kit provided by Biolabo, France[16,17], and gamma glutamyltransferase (GGT) using a kinetic photometric method[18].

Tissue analysis: The liver was removed, rinsed with ice-cold saline and blotted dry. Accurately weighed pieces of liver tissue were treated differently for the separation and estimation of the studied parameters.

Measurement of liver malondialdehyde (MDA) content: A 10% homogenate was prepared in 1.15% KCl, centrifuged at 1000 × *g* at 4℃ for 20 min, and the resultant supernatant was used for the assay of liver MDA content[19].

Measurement of liver cytochrome c oxidase activity and nitric oxide (NO) content: Liver tissue was homogenized in Tris-sucrose buffer, pH 7.4 (5% homogenate), using Potter-Elvejhem glass homogenizer, and centrifuged at 2000 × *g* at 4℃ for 10 min. The resultant supernatant was used for the estimation of cytochrome c oxidase activity[20] and NO content[21].

Measurement of liver glutathione-S-transferase (GST), lactate dehydrogenase (LDH), glucose-6-phosphate dehydrogenase (G6PD), superoxide dismutase (SOD) and catalase (CAT) activities: A 10% homogenate was obtained in Tris-sucrose buffer, pH 7.4, and centrifuged at 105 000 × *g* at 4℃ for 30 min, using a Dupont Sorvall Ultracentrifuge (USA), to isolate the cytosolic fraction which was used for the assay of GST[22], SOD[23], LDH[24], G6PD[25] and CAT[26] activities.

Estimation of liver pyruvate and lactate concentrations: Liver tissue was homogenized in 5% meta-phosphoric acid, and centrifuged at 3000 × *g* at 4℃ for 15 min. The resultant supernatant was used for the estimation of pyruvate and lactate concentrations according to the method of Mohun and Cook[27] and David[28], respectively.

Estimation of liver ATP content: Liver tissue was homogenized with 3 mL ice-cold 3 mol/L perchloric acid, using Potter-Elvejhem glass homogenizer. Following that, 12.5 mL of 1 mmol/L EDTA was added and the mixture was centrifuged at 1000 × *g* at 4℃ for 1 h. The supernatant was further treated for the estimation of ATP[29].

Determination of liver glucose-6-phosphatase (G6Pase) activity: Liver tissue was homogenized in ice-cold solution containing 0.15mol/L KCl; 4 mmol/L $MgSO_4$; 4 mmol/L EDTA and 4 mmol/L N-acetylcysteine, pH 7, and centrifuged at 12000 × *g* at 4℃ for 10 min. The resultant supernatant was analyzed for G6Pase activity[30].

Estimation of liver DNA content: Liver tissue was homogenized in 0.25 mol/L sucrose/in TKM buffer (0.05 mol/L Tris-HCl, 0.025 mol/L KCl, 0.005 mol/L

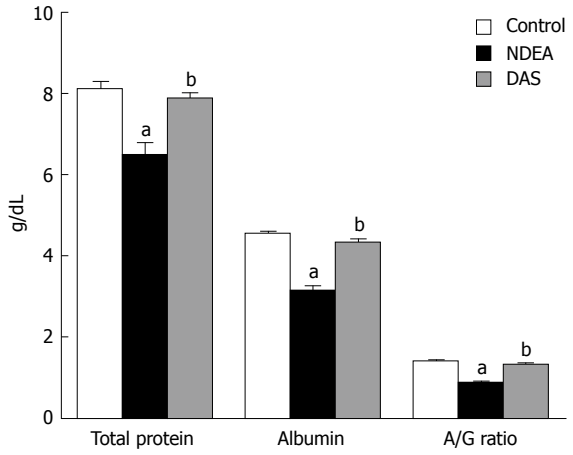

Figure 1 Non-enzymatic liver functions in rats treated with NDEA in absence or presence of DAS (mean ± SE) differed significantly compared to the control and NDEA-treated group ($^aP = 0.045$, $^bP = 0.042$, respectively).

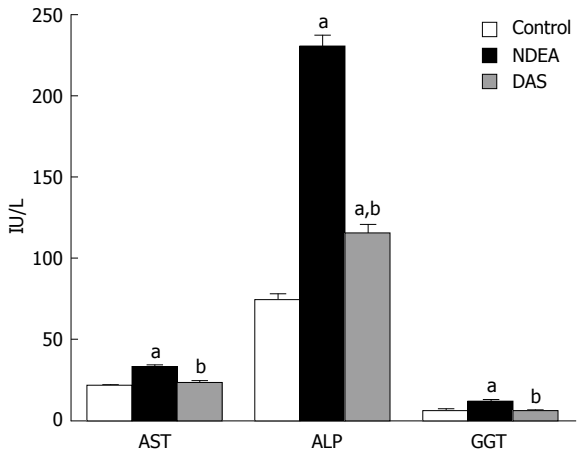

Figure 2 Enzymatic liver functions in rats treated with NDEA in absence or presence of DAS (mean ± SE) differed significantly compared to the control and NDEA-treated group ($^aP = 0.048$, $^bP = 0.044$, respectively).

$MgCl_2$), pH 7.5, to prepare a 15% homogenate. Then 0.1 mL of 0.3 mol/L perchloric acid was added, left to stand at 0℃ for 15 min, centrifuged at 2000 × *g* at 4℃ for 10 min, and the precipitate was used for the estimation of DNA content[31].

Determination of liver aldose reductase (AR) activity: Liver tissue was homogenized in potassium phosphate buffer, pH 7 (20% homogenate), centrifuged at 105000 × *g* for 45 min at 4℃, and the resultant supernatant was used for the estimation of AR activity[32].

Determination of protein concentrations: Protein concentrations of the above supernatants were estimated by the method of Lowry *et al*[33].

Histopathological examination

The portions of liver tissue embedded in paraffin were sectioned at 5 μm. Following sectioning, liver tissue was stained with hematoxylin and eosin. Light microscopy was used to evaluate the pathological changes in liver tissue.

Statistical analysis

The values were expressed as mean ± SE. Statistical analysis was performed by one way analysis of variance (ANOVA) followed by Kruskal-Wallis comparison test. $P \leqslant 0.05$ was considered significant.

RESULTS

The results showed that there were no differences between the various control groups (vehicle-treated groups). Thus, the data from all of the control animals were po-oled and are shown as one normal group.

Effect of NDEA in absence or presence of DAS on non-enzymatic liver functions

NDEA significantly decreased total protein, albumin, and A/G ratio. Co-administration of DAS restored total protein, albumin and A/G ratio (Figure 1). Moreover, NDEA significantly increased total bilirubin (2.43 ± 0.151 mg/dL), compared to their control counterparts (1.19 ± 0.090 mg/dL). DAS significantly decreased total bilirubin (1.68 ± 0.078 mg/dL, $P = 0.045$) when compared to the NDEA-treated group value.

Effect of NDEA in absence or presence of DAS on enzymatic liver functions

NDEA significantly elevated serum AST, ALP and GGT activities when compared to the normal group. DAS co-administration restored serum AST and GGT activities, together with a significant decrease in ALP activity, compared to the NDEA group value ($P = 0.048$) (Figure 2).

Changes in liver energy metabolism indices following NDEA in absence or presence of DAS

Table 1 showed that NDEA significantly decreased ATP level and increased G6PD activity compared to normal group values ($P = 0.046$). Treatment with DAS resulted in a significant increase in ATP level compared to the NDEA-treated group value. In addition, DAS significantly elevated and reduced pyruvate and lactate levels respectively, with a consequent significant reduction in lactate/pyruvate ratio compared to both the NDEA and control counterparts. Also, DAS significantly increased LDH and G6PD activities compared to either NDEA or control groups.

Changes in oxidative stress and membrane disintegration indices following NDEA in absence or presence of DAS

As shown in Table 2, NDEA treatment significantly ($P = 0.048$) elevated MDA and NO contents and reduced G6Pase, CAT and SOD activities when compared to control counterparts. Administration of DAS restored MDA level and G6Pase activity, significantly decreased NO level, and non-significantly changed SOD and CAT activities when compared to NDEA-treated rats.

Table 1 Effect of NDEA in absence or presence of DAS on liver energy metabolism indices (mean ± SE)

Parameters	Normal	NDEA	DAS
Lactate (μmol/g liver)	2.27 ± 0.16	2.08 ± 0.094	1.41 ± 0.08[a,b]
Pyruvate (μmol/g liver)	0.11 ± 0.007	0.103 ± 0.008	0.15 ± 0.007[a,b]
Lac/Pyr	20.6 ± 1.65	17.37 ± 0.9	11.31 ± 0.76[a,b]
LDH (μmol/mg protein per min)	0.9 ± 0.021	0.9 ± 0.043	1.05 ± 0.028[a,b]
ATP (μmol/g liver)	5.69 ± 0.32	4.04 ± 0.12[a]	4.91 ± 0.085[a,b]
G6PD (μmol/mg protein per min)	27.9 ± 2.29	47.4 ± 1.48[a]	54.1 ± 4.04[a,b]

Significantly different from baseline values at [a]P = 0.046; Significantly different from NDEA treatment at [b]P = 0.043.

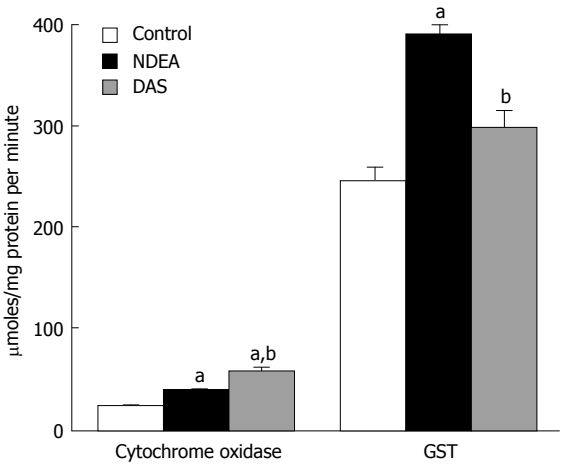

Figure 3 Changes in cytochrome oxidase and GST activities in rats treated with NDEA in absence or presence of DAS (mean ± SE) differed significantly compared to the control and NDEA-treated group values ([a]*P* = 0.043, [b]*P* = 0.045, respectively).

Effect of NDEA in absence or presence of DAS on DNA fragmentation indices

NDEA significantly elevated DNA level (3.97 ± 0.189 mg/gt) compared to control level (2.5 ± 0.199 mg/gt) (P = 0.043). DAS normalized DNA levels (2.38 ± 0.08 mg/gt). NDEA significantly elevated cytochrome c oxidase and GST activities. DAS significantly lowered GST , which approached the normal values. However, DAS significantly enhanced cytochrome c oxidase activity when compared to either control or NDEA-treated group levels (Figure 3).

Effect of NDEA in absence or presence of DAS on AR activity

NDEA significantly elevated AR activity (P = 0.045). Co-administration of DAS restored such enzymatic activity (Figure 4).

Histopathological findings

Examination of liver sections of the different groups illustrated that: Liver tissue of the normal group showed hepatic lobules with normal architecture (Figure 5A). Liver tissue of the NDEA-treated rats showed pleomorphism. Some cells exhibited multiple nucleoli, some of the cells were pyknotic, while others showed

Table 2 Effect of NDEA in absence or presence of DAS on oxidative stress and membrane disintegration indices (mean ± SE)

Parameters	Normal	NDEA	DAS
MDA (nmol/g liver)	55.6 ± 3.4	90.4 ± 8.01[a]	66.8 ± 2.4[b]
NO (nmol/g liver)	139 ± 9.7	344 ± 14.9[a]	187 ± 9.2[a,b]
G6Pase (nmol/mg protein/min)	6.39 ± 0.46	3.38 ± 0.26[a]	7.36 ± 0.3[b]
CAT (IU/mg protein)	173 ± 9.1	141 ± 6.44[a]	138 ± 6.64[a]
SOD (IU/mg protein)	88.3 ± 6.55	55.7 ± 2.7[a]	57.8 ± 5.38[a]

Significantly different from baseline values at [a]P = 0.048; Significantly different from NDEA treatment at [b]P = 0.044.

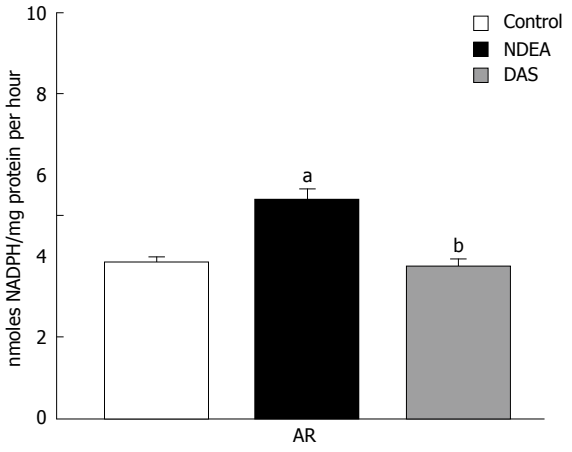

Figure 4 Changes in AR in rats treated with NDEA in absence or presence of DAS (mean ± SE) differed significantly compared to the control and NDEA-treated group values ([a]*P* = 0.045, [b]*P* = 0.046, respectively).

intranuclear vacuoles and cellular infiltration (Figure 5B). Other sections showed massive areas of vacuolated hepatocytes, cellular infiltration, and some cells possessed pyknotic nuclei (Figure 5C). Other section showed hyperchromatic nuclei and numerous Kupffer cells (Figure 5D). In other sections, hyperchromatic malignant nuclei were evident (Figure 5E). Liver tissue from the DAS-treated rats showed fewer degenerative changes, such as vacuolated cytoplasm, few pyknotic nuclei and dilated sinusoids (Figure 5F). Other section showed more or less normal hepatic lobular architecture (Figure 5G).

DISCUSSION

The liver is a multifunctional organ that plays essential roles in metabolism, biosynthesis, excretion, secretion and detoxification. These processes require energy, making the liver a highly aerobic, oxygen-dependent tissue. These processes also cause vulnerability of the liver to anoxia, increased susceptibility to noxious insults, and create a demand for cell replacement after tissue loss. Enhanced liver cell death and impaired regeneration are indeed features of most liver disorders. Proteins play a big role in fighting off infections and building or repairing muscle tissue. Low albumin is a sign of poor health and a predictor of a bad outcome. Thus, a

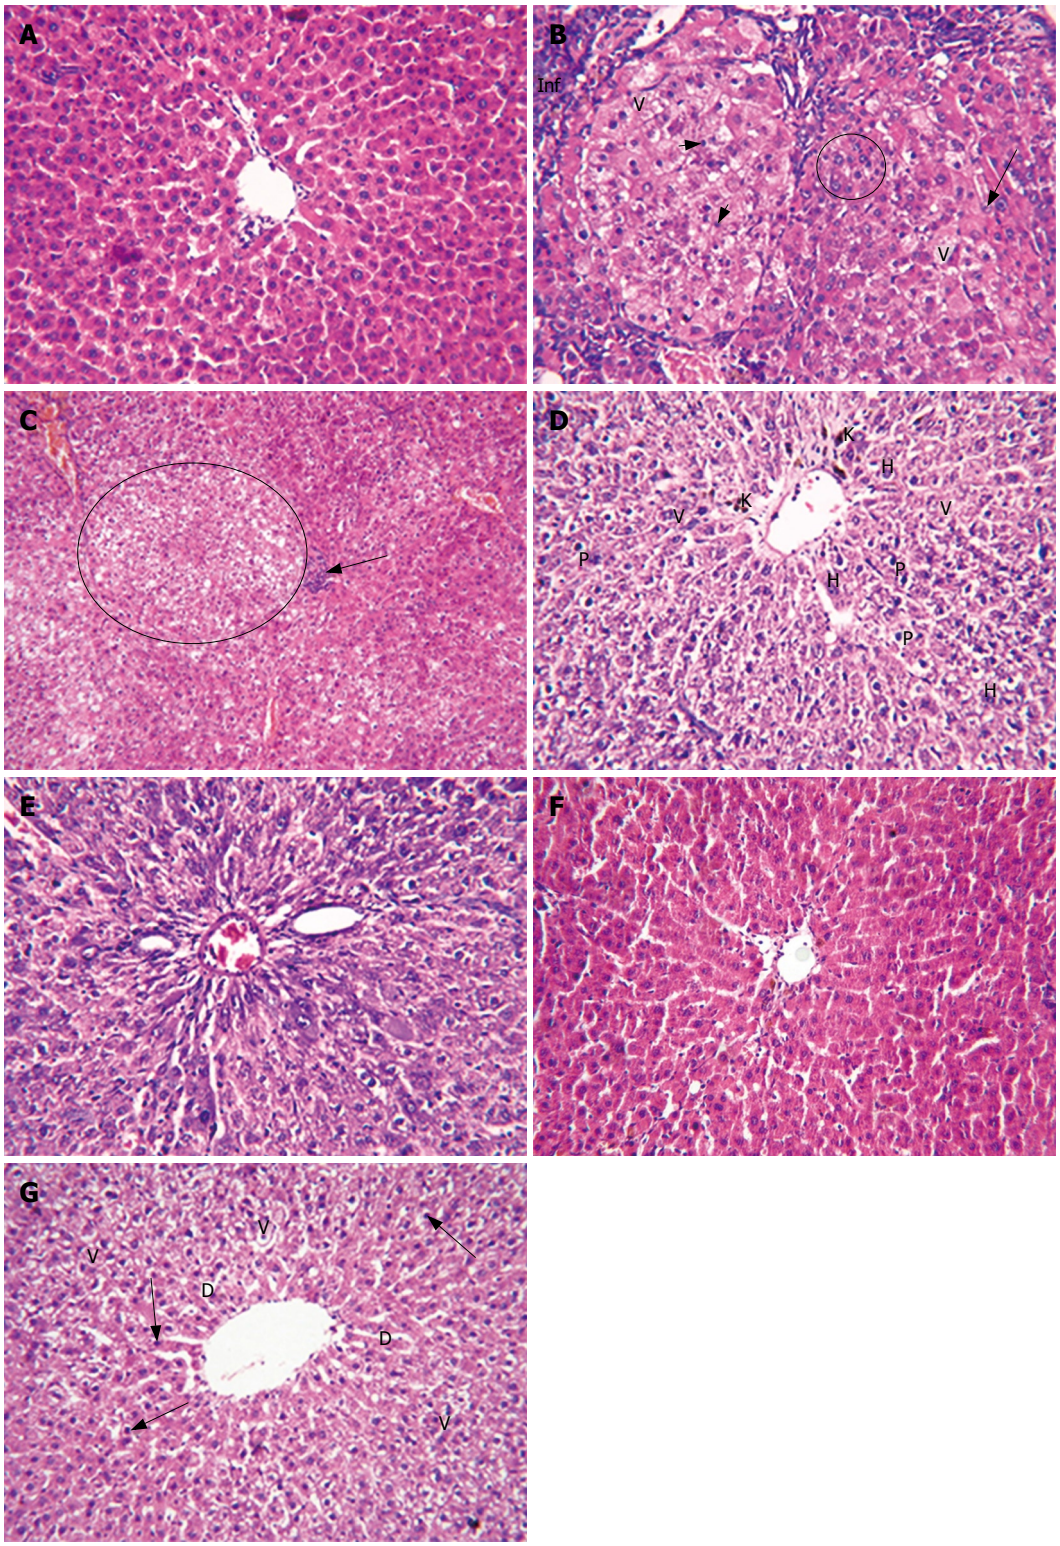

Figure 5 Liver sections of the different groups. A: Liver tissue of the normal group (control) showed hepatic lobule having normal architecture; B: Liver tissue of the NDEA-treated rats showed nuclear pleomorphism; some cells exhibited multiple nucleoli (encircled), pyknotic cells (short arrows), intranuclear vacuoles (arrow), some showed cytoplasmic vacuoles (V) and cellular infiltration (Inf); C: Other sections showed massive areas of vacuolated hepatocytes (encircled); cellular infiltration (arrow) and some cells possessed pyknotic nuclei; D: Other slides showed vacuolated cytoplasm, hyperchromatic nuclei, pyknotic nuclei and numerous Kupffer cells; E: Other section showed hyperchromatic malignant nuclei (H); F: Liver tissue of the DAS-treated rats showed some degenerative changes, vacuolated cytoplasm (V), few pyknotic nuclei (arrows) and dilated sinusoids (D); G: Other slides showed more or less normal hepatic lobular architecture.

decrease in the A/G ratio often indicates the presence of impaired liver function. As shown in our results, NDEA decreased significantly total protein, albumin and A/G levels, which was indicative of poor liver function and inability to fight infections. On the contrary, DAS administration normalized total protein, albumin and A/G levels, indicating the ability of DAS to improve liver function in face of NDEA-induced liver damage.

Serum AST, ALP and GGT are sensitive indicators of hepatic injury. Several reports have shown an increase in the activities of AST and ALT during NDEA-induced hepatocarcinogenesis[34]. Elevated activities of serum AST, ALP and GGT observed in NDEA-treated rats may be due to the NDEA-induced hepatic damage and the subsequent leakage of these enzymes into the circulation. Administration of DAS restored the activities of these enzymes to near normal values, which may be an indication of the hepatoprotective role of DAS.

As shown in our results, NDEA produced a significant decrease in hepatic ATP level. Oncotic necrosis is most often the consequence of metabolic injury, leading to ATP depletion. ATP depletion in hepatocytes is associated with ATP-depletion-dependent cytoskeletal alterations, after which a metastable state develops, characterized by mitochondrial depolarization and lysosomal breakdown. This metastable state culminates in outright rupture of plasma membrane, irreversible breakdown of the plasma membrane permeability barrier, and leakage of cytosolic enzymes and metabolic intermediates[35]. Treatment with DAS resulted in a significant decrease in lactate and lactate/pyruvate ratio, along with significant elevation of pyruvate, ATP levels and liver LDH activity, compared to NDEA-treated rats. The increased activity of LDH could favor pyruvate (aerobic carbohydrate metabolism) against lactate (anaerobic), thus enhancing energy metabolism in the cell and reflecting restoration of normal cellular/metabolic function. The histopathological findings observed in this study support the biochemical ones that liver tissue of the NDEA-treated rats showed drastic changes in the morphology of the liver cells, whereas the DAS-treated rats showed more or less normal hepatic lobular architecture. Accordingly, we presented evidence that DAS substantially improved the liver cell metabolic indices, as well as its synthetic capacity, and further protected against its malignant transformation.

The present data revealed that NDEA produced significant increases in the activity of liver G6PD, which agrees with findings from other studies[36,37]. G6PD is a housekeeping enzyme that produces riboses, which are incorporated into nucleotides and nucleic acids, and NADPH, the major cytoplasmic reducing compound[38]. NADPH is necessary for reduction of oxidized glutathione by glutathione reductase[39], and is a substrate for phase I and Ⅱ biotransformation and detoxification enzymes[36]. G6PD is elevated in response to external stimuli, toxic and oxidative stress[40,41]. G6PD activity is strongly upregulated in proliferating cells such as malignant cells[42]. There is increasing evidence that G6PD activity is of major importance for NADPH production for defense against oxidative stress, rather than for ribose production during proliferation[43]. Interestingly, treatment with DAS resulted in further elevation in the activity of G6PD. This result provides new evidence that DAS might exhibit a compensatory mechanism in enhancing the production of NADPH as a further defense mechanism against proliferating cancer cells, as well as for enhancing cellular antioxidant capacity.

In hepatocellular carcinoma, there is disequilibrium between oxidant and antioxidant balance, which is tilted towards the oxidant side[44]. Reactive oxygen species (ROS) are believed to cause genetic oxidation and damage to DNA and other macromolecules. Unchecked, this oxidative damage may lead to a host of conditions including cancer. Normally, this process is held in check by elaborate endogenous or exogenous antioxidant processes. Various enzymatic and non-enzymatic systems have been developed by the cell to cope with ROS and other free radicals[45]. Since many of the anomalies that are induced by NDEA can arise from oxidative stress, which is also known to accompany cancer development, it was of a prime interest to evaluate oxidative stress levels under those circumstances. As shown in the present study, NDEA produced a significant increase in hepatic MDA and NO levels, along with significant decreases in SOD and CAT activities. MDA was one of the main lipid peroxidation products; its elevated levels can reflect the degree of lipid-peroxidation-induced injury in hepatocytes[46]. On the other hand, it has been reported that SOD and CAT constitute a mutually supportive defense against ROS[47]. The decreased activity of SOD in liver of NDEA-treated rats may have been due to the enhanced lipid peroxidation or inactivation of the antioxidative enzymes. This may have caused an increased accumulation of superoxide radicals, which could have further stimulated lipid peroxidation[48]. Decreased activities of SOD and CAT in NDEA-treated rats, which is in agreement with other reported studies[49], could have been due to over-utilization of these enzymatic antioxidants to scavenge the products of lipid peroxidation. Tumor cells have been reported to sequester essential antioxidants from the circulation in order to meet the demands of the growing tumor cells. On the other hand, the current data demonstrated the ability of DAS to reduce formation of ROS and reactive nitrogen species, measured as MDA and NO, which agrees with findings from other laboratories[7]. These findings conform to previous results on the established, specific antioxidant profile for DAS as an inhibitor of the hepatic ROS generating enzyme CYP2E1. The latter enzyme is known as a prominent trigger of hepatic oxidative stress[50]. Treatment with DAS showed no significant enhancement of the activity of the endogenous antioxidant enzyme SOD or CAT.

G6Pase plays a critical role in blood glucose homoeostasis and its activity can also be considered as an index of the stability of the microsomal membrane[51]. Decreased activity of liver G6Pase was shown in the NDEA-treated rats, which might be attributed to the increased lipid peroxidation caused by NDEA. Consistent with previous studies[52], DAS administration enhanced G6Pase activity significantly, compared to the NDEA-treated group value, suggesting the ability of DAS to preserve membrane integrity.

In this study, an increased activity of liver GST was observed in NDEA-treated rats, with respect to their control counterparts. In addition, we also showed an increased activity of serum GGT in the NDEA-treated

rats, which might have been responsible for the increased level of GST in this group of animals[44]. Initial reports from nitrogen-mustard-resistant cell lines have shown these cells to over-express GST, which also holds true for a number of tumors. The increased level of GST is likely to be the key mediator of drug resistance in cancer chemotherapy[44]. Restoration of GST activity was observed with DAS treatment, suggesting a preservation of the redox system, which reflects a decrease in free-radical production, as well as improving cancer cell sensitivity to chemotherapy.

Cancer is well known to induce uncontrolled cellular proliferation. In this context, our results demonstrated that NDEA increased total DNA level, suggesting enhanced cellular proliferation. Notably, treatment with DAS significantly reduced DNA levels to near normal values, suggesting interference with mitotic pathways and enhancing apoptosis of cancer cells[53]. In addition, the current results showed an enhanced activity of cytochrome c oxidase enzyme in the NDEA-treated rats, which was further enhanced by the co-administration of DAS. However, for this investigation, we measured total cytochrome c oxidase, so it was difficult to delineate whether the increase we observed in the levels of cytochrome c oxidase was attributed to the mitochondrial or cytosolic fraction. According to the observed elevation in hepatic MDA and NO contents in the NDEA-treated group, a state of oxidative stress can exist in such animals, which contributes to mitochondrial membrane leakage and in turn, allows the translocation of cytochrome c oxidase to the cytosolic fractions. Thus, we suggest that the increase in cytochrome c oxidase with NDEA treatment might be of cytosolic origin. Interestingly, we demonstrated, and to the best of our knowledge, for the first time, that DAS markedly enhanced the activity of cytochrome c oxidase. We suggest that such increased cytochrome c oxidase activity might be attributed to a mitochondrial rather than cytosolic origin, which is supported by the observed increase in ATP and decrease in oxidative-stress biomarkers shown in DAS-treated animals. DAS might induce direct perturbation of mitochondria, resulting in apoptotic damage of the cancer cells. This effect has been reported recently with some anticancer agents[54,55].

Our results showed an almost 1.5-fold increase in AR activity in NDEA-treated animals. AR belongs to the aldo-keto reductase (AKR) superfamily. Most of the AKR superfamily proteins are involved in the detoxification of a wide variety of substrates. Several reports have shown that over-expression of AR, in many tumor cells, renders these cells resistant to chemotherapy, and also demonstrate that inhibition of AR enhances cancer cell sensitivity to chemotherapeutic drugs[56,57]. In addition, over-expression of AR enhances production of ROS, which cause membrane damage and cellular leakage[58]. To the best of our knowledge, the present study is the first to show enhanced production of AR in an *in vivo* model of liver tumorigenesis. To our knowledge, this is the first report that identifies the ability of DAS to reduce the expression of AR in NDEA-treated rats. This provides new evidence for its very important potential role in cancer protection. The ability of DAS to reduce the expression of AR suggests that DAS is effective against *in vivo* tumorigenesis by suppressing AR production and subsequently lowering the production of ROS, as well as enhancing cancer cell sensitivity to chemotherapeutic drugs.

Our findings were further supported by the histopathological examination of liver sections, which illustrated that liver tissue of NDEA-treated rats showed damage, manifest as nuclear pleomorphism, intranuclear vacuoles, cellular infiltration, hyperchromatic nuclei, pyknotic nuclei, numerous Kupffer cells and hyperchromatic malignant nuclei. On the contrary, liver tissue of the DAS-treated rats showed more or less normal hepatic lobular architecture.

To conclude, we provide evidence that DAS exerts a protective role on liver tissue in face of enhanced tumorigenesis caused by NDEA, as demonstrated by the following points: (1) DAS could normalize almost all the non-enzymatic and enzymatic liver function tests, indicating its ability to improve liver functions; (2) DAS significantly decreased lactate and lactate/pyruvate ratio, along with elevating pyruvate, ATP levels and liver LDH activity, thus enhancing energy metabolism in the liver tissue and reflecting restoration of normal cellular/metabolic functions; (3) DAS elevated the activity of G6PD, so it might exhibit a compensatory mechanism in enhancing the production of NADPH as a further defense mechanism against proliferating cancer cells, as well as enhancing cellular antioxidant capacity; (4) DAS reduced the formation of free radicals, measured as MDA and NO, providing specific antioxidant profiles for DAS as an inhibitor of the hepatic ROS-generating enzyme; (5) DAS enhanced G6Pase activity significantly, suggesting its ability to preserve liver cell membrane integrity; (6) DAS restored GST activity, suggesting a preservation of the redox system, as well as improving cancer cell sensitivity to chemotherapy; (7) DAS significantly reduced DNA level comparable to that in the NDEA-treated group, and close to the normal value, suggesting interference with mitotic pathways and enhancing apoptosis of cancer cells; (8) DAS markedly enhanced cytochrome c oxidase activity, thus, DAS might induce direct perturbation of mitochondria, resulting in apoptotic damage of the cancer cells; (9) to the best of our knowledge, this is the first report that identifies the ability of DAS to reduce the expression of liver AR in NDEA-treated rats, which suggests a very important potential role in cancer protection and subsequently lowering the production of ROS, as well as enhancing cancer cell sensitivity to chemotherapeutic drugs; (10) our biochemical findings were further supported by the histopathological examination of liver sections, which illustrated that liver tissue of the NDEA-treated rats showed damage, resulting in malignant cell formation. On the contrary, liver tissue of the DAS-treated rats showed more or less normal hepatic lobular architecture.

ACKNOWLEDGMENTS

The authors thank Dr. Sohair Assad, Professor of Histology, Faculty of Medicine, Cairo University, Cairo, Egypt, for her valuable assistance with the staining and the interpretation of the histological slides.

COMMENTS

Background

Diallyl sulfide (DAS), a biologically active garlic constituent, has been demonstrated as a potential cytoprotective agent in many animal models. Garlic (*Allium sativum*), an important flavoring agent, exhibits medicinal properties that include immunomodulatory, hepatoprotective, antioxidant, antimutagenic and anticarcinogenic effects.

Research frontiers

Oncotic necrosis is most often the consequence of metabolic injury, leading to ATP depletion, culminating in leakage of cytosolic enzymes and metabolic intermediates. In hepatocellular carcinoma, disequilibrium exists between oxidant and antioxidant balance, which is tilted towards oxidants. Tumor cells sequester essential antioxidants from the circulation to meet the demands of the growing tumor cells. We showed that DAS reduced formation of ROS, which agrees with reported findings. Aldose reductase (AR) belongs to the aldo-keto reductase (AKR) superfamily involved in the detoxification processes of a wide variety of substrates. Over-expression of AR, in many tumor cells, renders these cells resistant to chemotherapy.

Innovations and breakthroughs

DAS protects against *N*-nitrosodiethylamine (NDEA)-induced liver cancer. DAS markedly enhanced, cytochrome c oxidase activity, thus inducing direct perturbation of mitochondria, culminating in apoptotic damage of the cancer cells. The expression of liver AR in NDEA-treated rats was reduced by DAS, subsequently lowering the production of ROS and enhancing cancer cell sensitivity to chemotherapeutic drugs. Histopathological examination illustrated that liver tissue of the NDEA-treated rats showed malignant cell formation, which was prevented by DAS.

Applications

The population of Egypt has a heavy burden of liver disease and the use of synthetic chemoprotective agents has potential risks in this population. Dietary habits may modify carcinogenesis initiation, promotion and progression. Hence, this study indicates the potential protective effect of DAS against NDEA-induced liver cancer. This could be used as a protective method to prevent exacerbation of cancer in developed countries that cannot afford the burden of expensive chemotherapy.

Terminology

DAS: Diallyl sulfide (a major constituent of garlic); NDEA: *N*-nitrosodiethylamine (inducer of liver cancer); LDH: Lactate dehydrogenase; G6PD: Glucose-6-phosphate dehydrogenase; MDA: Malondialdehyde; NO: Nitric oxide; G6Pase: Glucose-6-phosphatase; CAT: Catalase; SOD: Superoxide dismutase; GST: Glutathione-S-transferase; AST: Aspartate aminotransferase; ALP: Alkaline phosphatase; GGT: Gamma-glutamyl transferase; AR: Aldose reductase.

Peer review

The authors demonstrated in this study that DAS had anti-oxidant properties in NDEA-treated rats. This work is very interesting. The authors bring some novelty and innovation to their research. The references are appropriate and updated.

Abstract

AIM: To investigate the usefulness of transient elastography by Fibroscan (FS), a rapid non-invasive technique to evaluate liver fibrosis, in the management of chronic hepatitis B virus (HBV) carriers.

METHODS: In 297 consecutive HBV carriers, we studied the correlation between liver stiffness (LS), stage of liver disease and other factors potentially influencing FS measurements. In 87 chronic hepatitis B (CHB) patients, we monitored the FS variations according to the spontaneous or treatment-induced variations of biochemical activity during follow-up.

RESULTS: FS values were 12.3 ± 3.3 kPa in acute hepatitis, 10.3 ± 8.8 kPa in chronic hepatitis, 4.3 ± 1.0 kPa in inactive carriers and 4.6 ± 1.2 kPa in blood donors. We identified the cut-offs of 7.5 and 11.8 kPa for the diagnosis of fibrosis ⩾ S3 and cirrhosis respectively, showing 93.9% and 86.5% sensitivity, 88.5% and 96.3% specificity, 76.7% and 86.7% positive predictive value (PPV), 97.3% and 96.3% negative predictive value (NPV) and 90.1% and 94.2% diagnostic accuracy. At multivariate analysis in 171 untreated carriers, fibrosis stage (t = 13.187, P < 0.001), active *vs* inactive HBV infection (t = 6.437, P < 0.001), alanine aminotransferase (ALT) (t = 4.740, P < 0.001) and HBV-DNA levels (t = -2.046, P = 0.042) were independently associated with FS. Necroinflammation score (t = 2.158, > 10/18 *vs* ⩽ 10/18, P = 0.035) and ALT levels (t = 3.566, P = 0.001) were independently associated with LS in 83 untreated patients without cirrhosis and long-term biochemical remission (t = 4.662, P < 0.001) in 80 treated patients. During FS monitoring (mean follow-up 19.9 ± 7.1 mo) FS values paralleled those of ALT in patients with hepatitis exacerbation (with 1.2 to 4.4-fold increases in CHB patients) and showed a progressive decrease during antiviral therapy.

CONCLUSION: FS is a non-invasive tool to monitor liver disease in chronic HBV carriers, provided that the pattern of biochemical activity is taken into account. In the inactive carrier, it identifies non-HBV-related causes of liver damage and transient reactivations. In CHB patients, it may warrant a more appropriate timing of control liver biopsies.

INTRODUCTION

Transient elastography by Fibroscan (FS)[1] has been proposed as a rapid, non-invasive technique to detect liver fibrosis[2], and many studies have confirmed its clinical usefulness, demonstrating good reproducibility

and high correlation between FS and liver fibrosis at histology[3-7]. Nevertheless, liver stiffness (LS) is influenced by factors other than fibrosis, such as major variations of alanine aminotransferase (ALT) levels[8]. We showed that during hepatitis exacerbations, LS increased, paralleling the kinetics of ALT, whereas FS values were lower than expected according to the histological stage in patients with long-lasting (≥ 12 mo) ALT normalization[8]. Similar LS profiles have been reported in patients with acute viral hepatitis[9,10].

Thus, the biochemical status (ALT levels) of the patient has to be taken into account for an accurate interpretation of LS values in clinical practice. This might be highly relevant in chronic hepatitis B virus (HBV) infection where intervening phases of disease activity and remission and asymptomatic hepatitis reactivations are observed[11-14].

In order to assess the usefulness of FS in the clinical management of chronic HBV carriers, we studied prospectively LS and evaluated its variations according to the changes of the virological, biochemical and histological profiles of liver disease.

MATERIALS AND METHODS

Patients

We studied 288 consecutive chronic HBV carriers (192 males, mean age 48.4 years, range 20-78 year) and nine patients with acute hepatitis B followed-up at the Hepatology Unit of the University Hospital of Pisa, Regional Reference Center for Chronic Liver Disease and Hepatocellular Carcinoma. The study was approved by the Ethical Committee of the hospital and patients gave their written informed consent.

HBV carriers were classified, after a monthly follow-up of at least 12 mo, as inactive or active according to their virological profile. Inactive carriers had serum HBV DNA persistently < 10^5 copies/mL (by COBAS Amplicor HBV Monitor, Roche, Basel, Switzerland) and IgM anti-HBc levels < 0.200 (by Core-M™ Axsym System, Abbott, Sligo, Ireland). Chronic hepatitis patients showed the presence of active viral replication (serum HBV-DNA levels persistently or intermittently ≥ 10^5 copies/mL during the follow-up), IgM anti-HBc ≥ 0.200 and liver histology consistent with chronic hepatitis. Exclusion criteria: hepatitis D virus (HDV) or hepatitis C virus (HCV) coinfections, Child B or C cirrhosis.

Cross-sectional study

We studied the correlation between LS and the stage of liver disease with single point FS measurements in 297 HBV carriers (288 with chronic infection: 208 untreated and 80 treated; nine with acute hepatitis B) and 50 blood donors as controls. Transient elastography was performed within 6 mo (median 3 mo, 75% of cases between 0 and 4.6 mo) from liver biopsy in 157 patients with biochemical and/or virological signs of liver disease and 21 inactive carriers. In 47 HBV carriers with inactive infection, 63 patients with cirrhosis (with previous histological diagnosis and actual ultrasonographic signs of cirrhosis) and nine patients with acute hepatitis, who did not undergo liver biopsies, FS was performed within 1 wk from US and Doppler examinations of the liver.

Prospective study

To study the correlation between LS and spontaneous or treatment-induced variations of biochemical activity, we enrolled 87 patients who underwent monthly blood controls and FS measurements at least every 6 mo. In case of ALT flares (ALT values ≥ 300 IU/L with increments of at least 2 SD above previous values), patients were monitored with blood and FS test every 2 wk for the first month and monthly thereafter until flare resolution. Transaminases and virological markers (HBV DNA and IgM anti-HBc) were tested on the same day of FS measurements. In treated patients, FS was monitored every 3 mo.

LS

Transient elastography was measured by Fibroscan (EchoSens, Paris, France). All measures were performed by trained physicians on the right liver lobe through intercostal spaces in the patient lying on his back, with right arm in maximal abduction. The US guide was used to identify a target liver area, at least 6 cm thick, without major vascular structures. The procedure was considered valid if at least 10 validated measurements were performed, with a success rate (ratio between numbers of validated and total measurements) ≥ 60% and interquartile range (IQR) < 20%. LS was recorded in kPa as the median value of all measurements.

Liver histology

Liver biopsies were obtained using 16 G disposable needles (Hepafix B; Braun, Melsungen, Germany). Liver specimens (median 27 mm, range 11-50 mm) were stained with hematoxylin and eosin. Necro-inflammatory activity and liver fibrosis were scored according to Ishak[15]. Steatosis was graded semiquantitatively, as reported previously[4]. Patients in whom liver biopsy yielded specimens shorter than 15 mm and/or with less than 11 portal tracts were excluded from the analysis.

Database

The included variables were sex, age, virological profile (HBeAg/anti-HBe status), liver disease co-factors [alcohol intake (≤ 60 or > 60 g/d), iron overload (present, in case of staining at histology and serum iron > 150 g/L and/or ferritin > 400 μg/L), hyperlipemia (cholesterol > 240 mg/dL and/or triglycerides > 250 mg/dL), diabetes (fasting plasma glucose > 140 mg/dL), overweight [body mass index (BMI) > 25 kg/m^2]. The biochemical profiles were defined as: (1) persistently elevated ALT; (2) biochemical remission (persistently normal ALT for at least 12 mo, at monthly controls); (3) ALT flares (when ALT values increased ≥ 300 IU/L, with increments of at least 2 SD above previous values). Virological profiles included HBV-DNA and IgM anti-HBc levels. Liver biopsy features were: length; number

of fragments; portal tracts number; necro-inflammation, fibrosis and steatosis scores. Cirrhosis at ultrasound (US cirrhosis) was defined when enlargement of left/caudate lobes, nodular liver boundaries, and micro-macronodular liver structure were present. We recorded in addition: the signs of portal hypertension (portal vein diameter > 12 mm; spleen volume > 45 cm^2; esophagus or gastric varices); the transient elastography performance (values, rate of successful measurements and IQRs); the characteristics of therapy (schedule, dose, duration and response).

Statistical analysis

Data are expressed as mean ± SD. The logarithmic transformation was used for quantitative data when their distributions were not normal. The Pearson's correlation coefficient was used to analyze the correlations between values of liver elastometry and fibrosis. Differences between subgroups were analysed using one-way ANOVA, Mann-Whitney rank sum test or Kruskal-Wallis test when appropriate. To identify factors independently correlated with LS, variables with statistical associations ($P < 0.05$) or trends ($P < 0.10$) at univariate analysis were included in multiple regression analyses. The diagnostic performance of transient elastography was evaluated by receiver operating characteristic (ROC) curve. By using the cut-off values with the highest sensitivity + specificity sum, we defined two different cut-off values of liver transient elastography to identify patients with significant fibrosis (Ishak score ⩾ 3/6) or cirrhosis. Statistical analysis was performed by SPSS (version 10.0, SPSS Inc., Chicago, IL, USA) software package.

RESULTS

Cross-sectional study

Overall 277 of 297 (93.3%) HBV carriers were suitable for the analysis: nine had acute hepatitis, 68 inactive infection, and the remaining 200 had chronic hepatitis. Six patients (2.1%) were excluded because their liver biopsies were < 1.5 cm and 14 (4.9%) because their elastographic measures failed (seven cases had BMI > 28). Eighty patients were under treatment [61 nucleos(t)ides, NA; 19 interferon, IFN]. Demographic and clinical characteristics of the 268 chronic carriers are reported in Table 1.

FS values were 4.6 ± 1.2 kPa in 50 blood donors, 12.3 ± 3.3 kPa in nine patients with acute hepatitis and 10.3 ± 8.8 kPa in 268 chronic HBV carriers ($P < 0.001$) (Table 2).

In 68 inactive carriers, the mean FS value was 5.0 ± 1.8 kPa. Seventeen of them had abnormal ALT and at histology showed steatohepatitis or steatosis. Their mean LS values were significantly higher as compared to HBV carriers with normal ALT and without dysmetabolic profile (6.9 ± 2.3 kPa *vs* 4.3 ± 1.0 kPa, $P < 0.001$) (Figure 1). As a result of chronic liver damage caused by factors other than HBV, these 17 inactive carriers were excluded from further analysis.

In the 171 untreated chronic HBV carriers, LS correlated significantly with fibrosis stage ($r = 0.706$, $P < 0.001$). At univariate analysis, in the 171 untreated HBV carriers, LS significantly correlated with age, sex, phase of infection (inactive *vs* active), BMI, ALT levels, biochemical remission and fibrosis stage, showing a correlation trend for HBV-DNA levels, alcohol intake and hyperlipemia (Table 3). At multivariate analysis, the phase of HBV infection ($P < 0.001$), ALT levels ($P < 0.001$), HBV-DNA levels ($P = 0.042$) and fibrosis stage ($P < 0.001$) were independently associated with LS (Table 3). In the separate analysis of the 83 untreated patients with chronic hepatitis, but without cirrhosis, the factors independently associated with LS were ALT levels ($P = 0.001$), fibrosis stage (S3-S4 *vs* S0-S2, $P = 0.001$) and necroinflammation score (⩾ 10/18 *vs* < 10/18; $P = 0.035$) (Table 4).

In 80 treated patients, LS correlated with fibrosis stage ($r = 0.453$, $P < 0.001$), but the mean values were lower than untreated patients with a comparable stage of

[1]CHB S0-S2 *vs* S3-S4; NS: No significance.

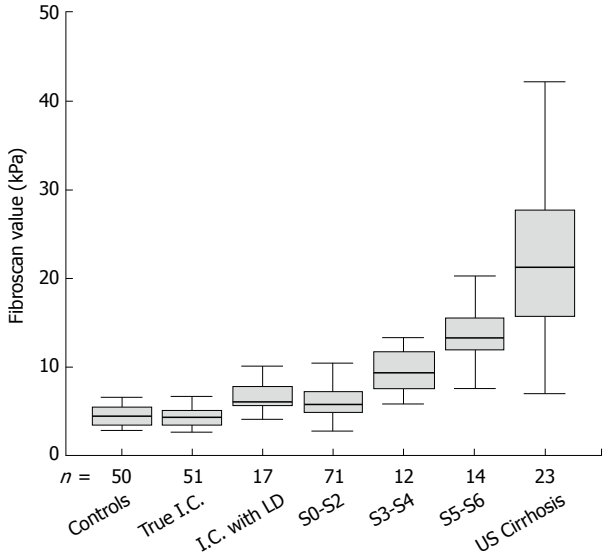

Figure 1 Distribution of Fibroscan values in Blood donors (Controls), Inactive carriers without (True I.C.) or with dysmetabolic liver disease (I.C. with LD) and in CHB patients by fibrosis stage (S0-S2, S3-S4, S5-S6, US Cirrhosis).

fibrosis (6.1 *vs* 6.4 kPa in S0-S2 patients; 8.5 *vs* 10.1 kPa in S3-S4 patients; 11.7 *vs* 15.7 kPa in S5-S6 patients; 17.2 *vs* 23.6 kPa in US cirrhosis patients) (Table 2), and the difference reached the statistical significance in patients with US cirrhosis only ($P = 0.035$). Fifty of them were under long-term NA treatment and in long-term biochemical remission, which was independently associated with FS values ($P < 0.001$, Table 5).

Diagnostic accuracy for identification of fibrosis ⩾ S3 and cirrhosis

To identify the FS cut-offs for fibrosis ⩾ S3 and cirrhosis, we analyzed untreated patients only. Area under ROC curve (AUROCs) for fibrosis ⩾ S3 and cirrhosis were 0.966 and 0.973 (95% CI 0.942-0.989 and 0.952-0.994) (Figure 2) and their cut-off values were 7.5 and 11.8 kPa, respectively.

Fibrosis ⩾ S3: The diagnostic performance of 7.5 kPa cut-off is reported in Table 6. Overall, 46 of 60 patients with elastography ⩾ 7.5 kPa had fibrosis ⩾ S3 (76.7% PPV) and 108 of 111 patients with FS < 7.5 kPa had S0-S2 fibrosis (97.3% NPV). Among the 14 patients with FS ⩾ 7.5 kPa, but a fibrosis stage < S3, five patients had ALT levels > 300 UI/L at the time of FS measurement. None of the three patients with FS < 7.5 but fibrosis ⩾ S3 had cirrhosis: one had S3 and two had S4 fibrosis at liver histology.

IC + UT CHB: Inactive carriers + untreated CHB (171 patients); T CHB: Treated chronic hepatitis B (80 patients).

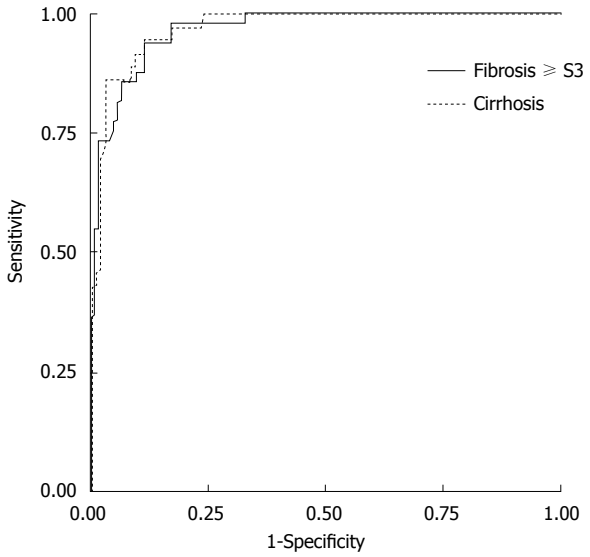

Figure 2 FS diagnostic performance: AUROCs for fibrosis S3 and cirrhosis were 0.966 and 0.973 (95% CI 0.942-0.989 and 0.952-0.994).

Cirrhosis: The diagnostic performance of 11.8 kPa cut-off is shown in Table 6. Thirty-two of 37 patients with elasticity ⩾ 11.8 kPa had histological or US cirrhosis (86.5% PPV); 129 of 134 patients with FS values < 11.8 kPa did not have cirrhosis (96.3% NPV). All but one of the five non-cirrhotic (two with S3 and three with S4 fibrosis stage) patients with FS values ⩾ 11.8 showed LS values ranging from 11.8 and 13.3 kPa; the remaining patient with 20 kPa FS value had S4 fibrosis and ALT levels > 300 UI/L at the time of FS measurement. Two of five cirrhotic patients with low FS (7.0 and 7.6 kPa respectively) were in prolonged spontaneous remission; the remaining three had elastometry values ranging between 8.9 kPa and 11.3 kPa.

Prospective study

In 87 patients, LS was monitored for a mean period of 19.9 ± 7.1 mo (range 6-36 mo): Seventy eight patients had chronic hepatitis (43 untreated and 35 treated) and nine had acute hepatitis. All patients underwent at least three FS measurements (mean 5.6, range 3-10).

Untreated patients: Thirty patients showed stable biochemical and virological profiles without disease progression: their LS did not change, showing minor fluctuations (12 mo/baseline FS mean ratio 1.00 ± 0.20; 24 mo/baseline FS mean ratio 0.99 ± 0.26). The remaining 13 patients experienced hepatitis flares. During flares, FS values increased 1.2 to 4.4-fold as compared to baseline values (mean variation 2.1 ± 1.0-fold), mean FS value during flares being 20.7 ± 12.3 kPa (range 8.6-42 kPa). LS variations paralleled the dynamic profiles of ALT: FS values reached the peak simultaneously with ALT in eight patients (61.5%), later, with 15-30 d of delay, in the remaining five (38.5%). Thereafter, FS values decreased with a latency of 30 d from the initial ALT decrease and returned to baseline values within 3 to 6 mo (Figure 3A). Patients with disease profiles characterised by ALT flares intervened by complete biochemical remission showed major variations of FS values during their hepatitis exacerbations, as compared to patients with persistent ALT elevations between flares (FS variation ranging from 1.4 to 4.4 in the former and from 1.2 to 1.6-fold in the letters, $P = 0.019$).

Acute hepatitis: In nine patients with acute hepatitis B, FS values at presentation ranged from 8.2 to 16.6 (mean

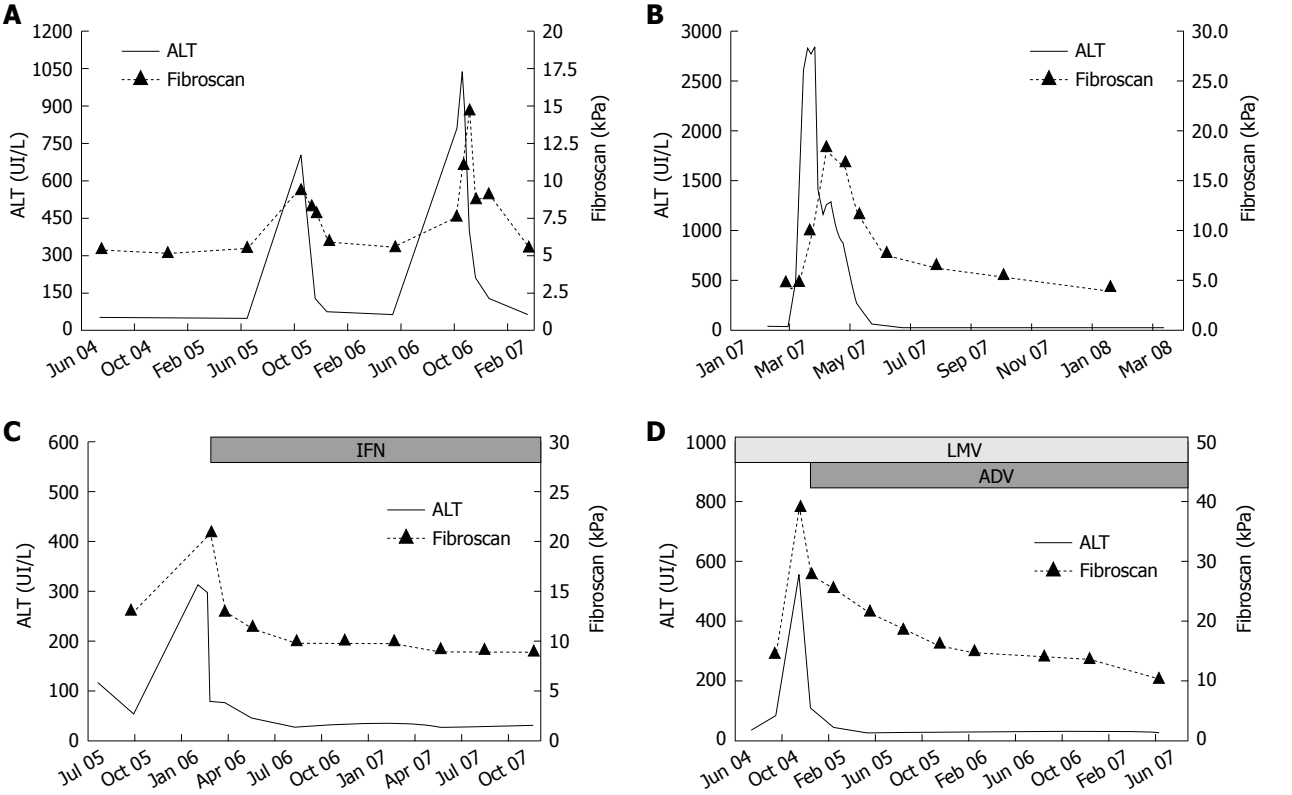

Figure 3 FS and ALT kinetics in four patients. A: CHB with S2 fibrosis stage and recurrent hepatitis flare; B: Acute hepatitis B; C: CHB with S6 fibrosis stage responding to IFN treatment; D: Cirrhosis with biochemical break-through due to lamivudine resistance and response to rescue therapy with adefovir.

12.3 ± 3.3) kPa and reached a peak of 11.8 to 45.7 kPa (20.0 ± 11.6 kPa) at the time of ALT peak. They then declined progressively to 5.6 ± 1.1 (range 4.4-6.9) kPa, in association with the reduction of ALT levels (Figure 3B).

Treated patients: The FS monitoring started with treatment in 18 patients, when treatment was already ongoing in the remaining 13. Overall, FS values showed progressive declines during therapy, with a mean on-treatment/baseline ratio of 0.9 ± 0.4 at 6 mo and 0.7 ± 0.2 at 12 mo. In patients with persistent response to long-term nucleoside/nucleotide analogues treatment, FS values decreased progressively during their follow up, with mean yearly reduction (ratio between two consecutive FS values registered at 12 mo intervals) of 0.8 ± 0.2 at 24 mo, 0.8 ± 0.1 at 36 mo and 0.7 ± 0.1 at 48 mo from the beginning of therapy.

All responders showed decreased FS values during therapy (Figure 3C and D): 0.8 ± 0.2 at 6 mo and 0.6 ± 0.2 at 12 mo, as compared to baseline values, respectively. FS value declines were similar in responders to IFN as compared to responders to NA: 0.7 ± 0.2 *vs* 0.8 ± 0.2 6 mo/baseline ratio and 0.6 ± 0.1 *vs* 0.7 ± 0.2 12 mo/baseline ratio, respectively. Two non-responder HBeAg-positive patients showed an increase of 1.1 and 2.4 times the FS values between 3 and 6 mo, during hepatitis flares, followed by a progressive decline that reached baseline values after 12 mo.

DISCUSSION

Transient elastography[1] is an easy to perform, reproducible method for the rapid and objective evaluation of LS in clinical practice[2,16] and it is proposed as a reliable, non-invasive, surrogate marker of fibrosis[3-7,17,18]. In fact, LS is a physical parameter that correlates primarily with fibrosis, but it is influenced also by other factors that modify the elasticity of the liver, such as significant variations of inflammatory infiltrate, edema and vascular congestion of the liver[8-10,19]. Accordingly, we showed that LS variations parallel ALT values during hepatitis exacerbations in the setting of both acute and chronic liver damage[8]. This evidence has important implications in clinical practice since the interpretation of the LS measure has to take into account the concurrent biochemical profile of the patient[8]. Thus, the interpretation of LS might be more difficult in the setting of CHB when major fluctuations of necrosis and inflammatory activity occur in a significant proportion of patients[11,12,18,19]. On the other hand, the availability of an easy to perform, non-invasive measure for fibrosis might improve the management of the HBV carrier. In the HBV carrier, the repeated measures of LS might help to identify the candidates for liver biopsy and to define both the phase of HBV infection and stage of liver disease that are mandatory to warrant the most appropriate treatment strategy, and to monitor liver disease progression in the single patient[20,21].

Addressing the issue of the clinical usefulness of

LS in the management of the HBV carrier we found a highly significant correlation between transient elastography and fibrosis stages ($P < 0.001$). Using 7.5 and 11.8 kPa as cut-off values for fibrosis ⩾ S3 and cirrhosis, the FS specificities were 88.5% and 96.3%, sensitivities 93.9% and 86.5%, and diagnostic accuracies 90.1% and 94.2%. These results confirm that FS is a reliable method to assess fibrosis in carriers with chronic HBV infection and disease[8].

Additional factors were independently associated with FS, such as active HBV infection ($P < 0.001$), HBV-DNA ($P = 0.042$) and ALT ($P < 0.001$) levels. In inactive HBV carriers, mean FS values were similar to normal controls and significantly lower than in CHB patients (4.3 ± 1.0 *vs* 4.6 ± 1.2 *vs* 11.2 ± 9 kPa; $P < 0.001$). These findings qualify LS as a promising tool to provide an important diagnostic assessment of the HBV carrier with inactive viral profile when the increased FS values suggest the presence of liver damage caused by factors other than HBV. In such cases, liver biopsy can be proposed for the precise characterization of liver disease. Indeed, in our study, 17 inactive carriers with metabolic liver disease had FS values higher (6.9 ± 2.3 kPa) than inactive carriers without liver disease.

In addition to the phase of HBV infection, only two other parameters, namely HBV DNA and ALT, were independently correlated with LS. Since both these parameters are linked with the extent of liver disease activity in the immune competent HBV carrier, our results further support the hypothesis that the extent of necrosis and inflammation influence LS significantly[20,22-24]. Accordingly, in the 83 untreated patients without cirrhosis, multivariate analysis showed that intra-hepatic necrosis and inflammation scores and ALT values were the only factors influencing FS ($P = 0.035$ and $P < 0.001$ respectively), in addition to the stage of liver disease.

The LS values identified as cut-offs for histological stage ⩾ S3 and cirrhosis are lower than those proposed for chronic hepatitis C. A slight variable difference between cut-offs would not be surprising when different cohorts of patients are compared, but FS values in CHB patients with cirrhosis (11.8 kPa) are consistently and persistently lower than in chronic hepatitis C (CHC) cirrhosis[4-6,8,16]. Accordingly, lower values of LS cut-offs have been proposed in preliminary reports[25,26]. These findings are consistent with the specific features of histopathology of hepatitis C, in which the combination of portal lymphoid follicles, bile duct damage, lobular activity and steatosis may contribute to the different LS, as compared to hepatitis B histopathology[27].

In this prospective study of CHB patients, we observed 1.2 to 4.4-fold increases of FS values with ALT flares, and similarly, LS values fluctuated in parallel with ALT values in nine patients with acute hepatitis. Interestingly, the extent of FS fluctuations during the hepatitis exacerbations differed according to the biochemical patterns of CHB. The range of LS variations were significantly wider in patients with ALT flares intervened by complete biochemical remissions, as compared to patients with persistent ALT elevations between flares (FS variations ranged from 1.4 to 4.4-fold in the former and 1.2 to 1.6-fold in the latter group, $P = 0.019$). Altogether these findings confirm our original observation and other more recent reports on the major influence of the biochemical profile on LS in the setting of both acute and chronic liver damage[8-10]. Finally, we found that prolonged biochemical remissions were associated with progressive reductions of FS values. LS declined yearly at about 0.2-fold in treated patients followed-up prospectively for 48 mo, and a proportion of patients who maintained evidence of cirrhosis at US achieved values of FS < 11.8 kPa. This was responsible for the worse diagnostic performance of FS in treated patients in whom the sensitivity for detecting cirrhosis fell from 86.5% to 54.2% in untreated *vs* treated patients with fibrosis ⩾ S5 (Table 6). Altogether, these data suggest a non-linear correlation between the overall kinetics of LS and histological staging during antiviral treatment. Future studies should be addressed to understand the relations among the reductions of LS, necrosis, inflammation and fibrosis in the separate settings of different fibrosis stages (i.e. ⩾ S3/< S3 and presence/absence of cirrhosis) and liver disease etiology (i.e. HBV and HCV). In fact, much of the LS changes depend on the different elastic relations among fine blocks of the liver structure. Thus, the interplay between the extent and structure of the collagen septa within the fine liver block, and the different type and extent of liver inflammatory infiltrate within them, might account for both the different FS cut-offs between CHB and CHC patients and for the different kinetics of FS and fibrosis decline during antiviral therapy.

In conclusion, our study suggests that the LS provides a useful non-invasive tool to monitor liver disease in the chronic HBV carrier. In the inactive carrier, it helps to identify non-HBV-related causes of liver damage and transient reactivation of HBV liver disease. In the CHB patient, provided that the pattern of biochemical activity is taken into account, LS values < 7.5 exclude the presence of significant fibrosis (⩾ S3) with a high NPV (97.3%) and low negative likelihood ratio (0.07). FS values ⩾ 11.8 kPa are highly specific (96.3%) for cirrhosis and show good PPV (86.5%) and positive likelihood ratio (23.18). In the HBV carrier with LS values ranging from 7.5 to 11.8 kPa, which are indicative of significant liver disease, liver biopsy remains the gold standard for an accurate grading and staging of liver disease. Finally, in CHB patients the monitoring of LS appears useful to highlight major changes in intrahepatic liver disease and warrants a more appropriate timing for control liver biopsies.

COMMENTS

Background

The old measure of liver stiffness (LS) by hand palpation has had a new appraisal after the recent introduction of the objective measure of the speed of transmission of an elastic wave across the liver (transient elastography) registered by the new instrument Fibroscan® (EchoSens, Paris, France). Originally, the new technique was proposed in clinical practice as a non-

invasive, surrogate marker of fibrosis and many studies demonstrated good reproducibility and a high correlation between LS and liver fibrosis at histology. However, liver elasticity is influenced not only by fibrosis, but also by the presence and extent of liquid, lipid and inflammatory infiltrates within the liver. The evidence that Fibroscan (FS) is significantly influenced by major variations of liver inflammation (as we previously showed), in addition to variations of staging, prompted the new frontier of testing FS values in the management of patients with chronic hepatitis.

Research frontiers

The course of liver disease in a significant proportion of chronic hepatitis B (CHB) patients is characterized by hepatitis exacerbations, intervened by prolonged remissions whose biochemical and virologic patterns can be mistaken with those of chronic inactive carriers. Thus, measuring LS might be useful to distinguish active from inactive HBV carriers. We addressed this question and present here the results of the cross-sectional and prospective studies of a large cohort of pedigreed hepatitis B virus (HBV) carriers (68 inactive carriers, 200 CHB and nine acute hepatitis B patients).

Innovations and breakthroughs

FS correlates with fibrosis in CHB patients and FS provides a reliable method to assess the overall status of liver disease in the carrier with chronic HBV infection. The mean FS values of HBV-inactive carriers were comparable to those of normal controls and significantly lower than those of CHB patients. Interestingly, in HBV inactive carriers with metabolic liver disease FS values were significantly higher than in HBV-inactive carriers without liver disease. All factors stemming for activity of liver disease, namely the phase of infection (active or inactive), HBV-DNA and ALT levels influenced LS at multivariate analysis. Accordingly, in untreated patients without cirrhosis, histological necrosis and inflammation and ALT were the only factors influencing FS in addition to fibrosis. Thus both necrosis and inflammation influence LS that qualifies as a very promising tool for the non-invasive diagnostic assessment of the liver in the HBV carrier. The best cut-off values for fibrosis and cirrhosis were significantly lower than in chronic hepatitis C (CHC) patients, studied in identical conditions (same center, instrument, operators and test timing), suggesting that FS is influenced also by the different histopathology features of CHB and CHC. This prospective study on patients with hepatitis B exacerbations confirmed 1.2 to 4.4-fold increases of FS values at the time of ALT flares. Similarly, LS paralleled ALT fluctuations in patients with acute hepatitis B. Finally, in treated patients followed up for 48 mo, LS declined yearly at about 0.2-folds, reaching values below the cirrhosis cut-off (11.8 kPa) in a proportion of patients who maintained evidence of cirrhosis. This observation may explain the worse diagnostic performance of FS in treated versus untreated patients. Altogether, these data indicate the non-linear correlation between the kinetics of LS and histological staging during antiviral treatment.

Applications

This study suggests that LS provides a useful non-invasive tool to monitor not only fibrosis, but overall liver disease in the chronic HBV carrier. In monitoring CHB patients, LS appears useful to highlight major changes of liver disease and to warrant a more appropriate timing for control liver biopsies.

Terminology

HBV-inactive carriers mean chronic HBV infection without liver damage caused by HBV, characterized by low HBV-DNA serum levels, persistently normal ALT and undetectable levels of IgM anti-HBc, a marker of HBV-induced liver disease (below the cut-off for CHB). Biochemical remission means transient ALT normalization (spontaneous or induced by antiviral treatment) in patients with CHB.

Peer review

In this study, authors perform a cross-sectional and longitudinal analysis of LS in HBV carriers, correlating this variable with stage of disease, liver inflammation and other factors that could influence FS measurements. They found a good diagnostic accuracy to detect cirrhosis and fibrosis higher than S3. The work is well performed and conclusions are correctly sustained.

Abstract

AIM: To explore whether acute cellular DNA damage response is induced upon hepatitis B virus (HBV) infection and the effects of the HBV infection.

METHODS: We incubated HL7702 hepatocytes with HBV-positive serum, mimicking a natural HBV infection process. We used immunoblotting to evaluate protein expression levels in HBV-infected cells or in non-infected cells; immunofluorescence to show ATR foci ands Chk1 phosphorylation foci formation; flow cytometry to analyze the cell cycle and apoptosis; ultraviolet (UV) radiation and ionizing radiation (IR)-treated cells to mimic DNA damage; and Trypan blue staining to count the viable cells.

RESULTS: We found that HBV infection induced an increased steady state of ATR protein and increased phosphorylation of multiple downstream targets including Chk1, p53 and H2AX. In contrast to ATR and its target, the phosphorylated form of ATM at Ser-1981 and its downstream substrate Chk2 phosphorylation at Thr-68 did not visibly increase upon infection. However, the level of Mre11 and p21 were reduced beginning at 0.5 h after HBV-positive serum addition. Also, HBV infection led to transient cell cycle arrest in the S and the G2 phases without accompanying increased apoptosis. Research on cell survival changes upon radiation following HBV infection showed that survival of UV-treated host cells was greatly increased by HBV infection, owing to the reduced apoptosis. Meanwhile, survival of IR-treated host cells was reduced by HBV infection.

CONCLUSION: HBV infection activates ATR DNA damage response to replication stress and abrogates the checkpoint signaling controlled by DNA damage response.

Key words: Hepatitis B virus; DNA damage response; Cell cycle; p21; Mre11

INTRODUCTION

Eukaryotic cells employ multiple strategies of checkpoint signaling and DNA repair mechanisms to monitor and repair damaged DNA[1-5]. There are two branches of the checkpoint response pathway, ataxia telangiectasia-mutated (ATM) pathway and ATM-Rad3-related (ATR) pathway. The major difference between ATM and ATR is the type of DNA damage to which each responds. For example, ATM responds to ionizing radiation (IR) and other agents that cause double-strand breaks (DSBs) in DNA. ATR responds to ultraviolet radiation (UV) radiation and other agents that induce the accumulation of stalled replication forks and subsequent single-stranded breaks (SSBs) in DNA. The DSBs are recognized by the Mre11-Rad50-Nbs1 complex, which recruits and activates ATM kinase[6]. The SSBs are coated

by replication protein A, and it recruits a complex of ATR kinases and ATR-interacting protein, which is then activated by the Rad9-Rad1-Hus1 complex and other factors. Accumulating evidence suggests that checkpoint signaling through ATR is intimately linked to the process of DNA replication[7,8].

A variety of checkpoint and DNA repair proteins have been identified as substrates for ATM and ATR kinases, including the checkpoint kinases Chk1 and Chk2, as well as p53, Smc1 and H2AX. Chk1 was first identified in *Schizosaccharomyces pombe* because of its role in the checkpoint arrest at G2/M, and it is mainly phosphorylated by ATR in response to UV, hydroxyurea and aphidicolin[9-11]. p21 was initially identified as a component of quaternary complex containing cdk-cyclin kinases and PCNA. Previous study has shown that p21 protein is degraded after low doses of UV; this degradation is essential for optimal DNA repair and is ATR-dependent[12]. The MRN complex consisting of Mre11, Rad50, and Nbs1 is a target of both ATM and ATR and is involved in both pathways[13-15].

Virus replication presents the host cells with large amounts of exogenous genetic material, including DNA ends and unusual structures. Therefore, infected cells recognize viral replication as a DNA damage stress and elicit DNA damage signal transduction, which ultimately induces apoptosis as part of host immune surveillance. However, recent reports have shown that viruses evolve a variety of mechanisms to manipulate DNA damage signaling for their replication and propagation. For example, Epstein-Barr Virus (EBV)[16] abrogates the p53 checkpoint signaling pathway through the interaction of the BZLF1 protein and p53 to avoid apoptosis. Other viruses such as human immunodeficiency virus type 1 (HIV-1)[17-20], herpes simplex virus type 1 (HSV-1)[21,22] and human cytomegalovirus[23] can activate and exploit a cellular DNA damage response, which aids viral replication. Adenovirus blocks ATM signaling and concatemer formation through targeting the DNA repair complex of MRN for degradation and mislocalization[24,25]. Thus, under some circumstances, viruses have co-opted endogenous checkpoint regulators to ensure their own efficient replication[26,27].

Hepatitis B virus (HBV) is a partially enveloped double-stranded DNA virus with a genome of 3.2 kb. Upon infection, the viral genome is transported into the cell, where it is converted into a covalently closed circular DNA (cccDNA). The cccDNA serves as a template for transcription by host cell RNA polymerase Ⅱ. The pregenomic RNA is then reverse transcribed into DNA replicative intermediates in the cytoplasm within immature viral core particles, by the virally encoded polymerase. Integration into host chromosome may happen during its replication.

There is no evidence thus far that the ATM/ATR kinases or their downstream pathways are triggered by HBV infection. The present study was undertaken by culturing normal hepatocyte cell line HL7702 and primary hepatocytes from a healthy liver donor with HBV-positive serum, mimicking natural HBV infection. We showed here, perhaps for the first time, that HBV infection elicited acute cellular DNA damage response dependent on ATR. However, the ATR checkpoint signaling was blocked downstream of p53-dependent and p53-independent pathways to evade apoptosis.

MATERIALS AND METHODS

Chemicals

Mimosine and aphidicolin were obtained from Sigma. The stock concentration of mimosine was 100 mmol/L, the stock concentration of aphidicolin was 10 mmol/L; both were dissolved in Dimethyl Sulphoxide (DMSO).

Cell culture, synchronization and infection

The human hepatocyte cell line HL7702, which was isolated from a HBV-seronegative individual, was obtained from Shanghai Biochemistry Institute. HL7702 were cultured in RPMI-1640 with 10% heat-inactivated FBS (Gibco). Serum samples from HBV carriers were analyzed. The patient was anti-HBsAg-positive, as detected by ELISA (SIIC Ke-Hua, Shanghai), and HBV DNA in the serum sample was quantified using FQ-PCR (Da-An Gene Corp). The patient had received no antiviral therapy prior to the study and was not infected with HCV or HIV. The number of serum HBV viral particles was 7×10^9 copies/mL, as quantified by FQ-PCR. Normal serum was obtained from healthy non-infected individuals as a control. The sera were stored at -80℃ until use.

When synchronized, the HL7702 cells were cultured in RPMI-1640 containing 0.1% FBS for 2 d; the culture medium was then replaced with fresh RPMI-1640 including 10% FBS and 200 μmol/L mimosine for 24 h, in order to arrest the cells at G1-S phase. The arrested cells were then washed twice, and the culture medium was replaced with RPMI-1640 containing normal or HBV-positive serum. The cells were then harvested at different times after mimosine release. All procedures were performed under level P2 biosafety conditions to minimize the possibility of cross-contamination.

Primary culture of human hepatocytes

Hepatocytes were prepared from a 35-year-old healthy male liver donor according to previously described procedures[28]. Briefly, the liver tissues were cut with scissors into 0.1-0.5 mm^3 pieces and were shattered with a 5-mL syringe into single cells or cell aggregates. Cells were seeded into 12-well culture dishes and incubated with 1 mL of 10% FBS in RPMI-1640 at 37℃ under 50 mL/L CO_2. The medium was changed after the first 48 h with serum-free medium. The serum-free medium was composed of DMEM/F12 (1:1) and 0.01 nmol/L nicotinamide, 0.02 ng/L epidermal growth factor (EGF), 0.02 ng/L basic fibroblast growth factor (bFGF), 0.365 ng/L glutamate, B27 (1:50, Sigma), 0.1 U/L penicillin, 0.1 ng/L streptomycin, and 0.1 ng/L fluconazole. HBV-positive serum was added to the culture medium 2 wk after hepatocyte phenotype cell development, and cells were harvested for immunoblotting assay 3 h later.

Immunoblotting assay

Cell extracts were lysed in ice-cold Tris buffer (50 mmol/L, pH 7.5) containing 5 mmol/L EDTA, 300 mmol/L NaCl, 0.1% Igepal, 0.5 mmol/L NaF, 0.5 mmol/L Na_3VO_4, 0.5 mmol/L PMSF, and antiprotease mixture (Roche Molecular Biochemicals) for 30 min on ice and centrifuged at 13 000 *g* for 10 min. The supernatant protein concentration was determined by the Bradford procedure (BioRad). The proteins were resolved on 15% SDS-PAGE and transferred onto nitrocellulose membranes. Blots were blocked in TBST containing 5% non-fat dried milk (NFDM) and incubated with primary antibodies as follows: antibodies against p21, Mre11, ATR, (Santa Cruz) and tubulin (Sigma) were incubated at room temperature for 1 h. Antibodies against ATM phosphoserine 1981 (ATMp), Chk2 phosphothreonine 68 (Chk2p), Chk1 phosphoserine 345 (Chk1p), p53 phosphoserine 15 (p53p) and H2AX phosphoserine 139 (H2AXp) (Cell Signaling) were incubated at 4℃ overnight. Secondary antibodies were from Jackson Laboratories. Horseradish-peroxidase-based detection was performed using a chemiluminescence reagent (Amersham Biosciences), according to the manufacturer's instructions.

DNA damage sensitivity assays

For radiation sensitivity assays, cells were irradiated with the indicated doses of γ rays from a ^{137}Cs source for indicated times, or 254 nm UV light with complete medium plated in triplicate. HBV-positive serum was added to the cultures before indicated doses of UV or IR radiation. Cells were washed extensively to remove viral inputs 24 h after HBV-positive serum addition, and then treated with different dose of UV or IR radiation. After 48 h of UV and 4 d of IR treatment, cells were collected and surviving cells were counted with Trypan blue staining. The percentage survival was determined by quantization of the relative viable number of treated cells divided by the viable number of untreated cells.

Flow cytometry

For propidium iodide staining, cells were harvested by trypsinization, fixed with ice-cold 70% ethanol, and resuspended in a solution containing 50 mg/L propidium iodide, 0.1% Triton X-100, 50 mg/L RNase A, and 5 mmol/L EDTA at room temperature (RT) for 1 h. Cells were then diluted 1:1 in 1% BSA PBS for cytometric analysis.

Immunofluorescence assay

HL7702 cells were grown on glass coverslips for 12 to 18 h prior to infection. At 0.5 h post-infection, cells were washed briefly in phosphate buffered saline (PBS) and fixed in 4% paraformaldehyde (PFA) in PBS for 10 min, then permeabilized for 10 min in 1% Triton X-100 in PBS. For the visualization of detergent-resistant or chromatin-associated nuclear proteins, an *in situ* extraction method that removed the cytoplasm and nucleosolic proteins was used. Cells were pre-extracted for 5 min on ice with 0.5% Triton X-100 in cytoskeletal buffer as described previously[29] then fixed in 4% PFA for 10 min. After washing with PBS and blocking in 2% fetal bovine serum (FBS) in PBS, cells were incubated with primary antibodies diluted in 2% FBS overnight at 4℃. Anti-Chk1p was used at a concentration of 1:100, while anti-ATR was used at 1:400. After washing with PBS three times, cells were incubated with secondary antibodies diluted 1:200 in 2% FBS for 30 min, then washed again three times with PBS. Next, the nuclei were stained with DAPI diluted in PBS for 10 min. After a final wash in PBS, samples were preserved in glycerol and images were captured by using a Zeiss LSM510 confocal microscope.

RESULTS

HBV infection induced a cellular DNA damage response dependent on ATR

To explore whether acute cellular DNA damage response was induced upon HBV infection, we incubated HL7702 hepatocytes with HBV-positive serum to examine the phosphorylation status of DNA damage response proteins. 10^5 HL7702 monolayer cells in a 6-cm plate were infected with HBV-positive serum containing 10^6 HBV at 37℃ under 50 mL/L CO_2. Serum from uninfected individuals was used as a non-infected control. Cells were washed eight times to remove excess viral inputs before harvesting. Whole-cell lysates from the HBV-infected and non-infected cultures were examined for the status of the DNA damage response proteins. Figure 1A reveals that HBV infection induced an increase in the steady state levels of the ATR protein and in the phosphorylation levels of its downstream substrates Chk1, p53 and H2AX. An increase in Chk1 phosphorylation at Ser-345 was evident at 3 h from the start of HBV-positive serum addition, with further increase from 6 h of infection (hoi) to 48 hoi. The phosphorylation of p53 Ser-15 was elevated beginning at 24 hoi and increased greatly at 48 hoi. Finally, there was a sharp increase in the amount of phosphorylated H2AX Ser-139 beginning at 24 hoi. To confirm these results, primary hepatocytes from a healthy male liver donor were obtained and incubated with HBV-positive serum for 3 h; obvious Chk1 phosphorylation was detected in HBV-infected cells (Figure 1B). We then used immunofluorescence to examine the localization of these proteins early after infection. Figure 1C shows that ATR foci as well as the Chk1 phosphorylation foci in non-infected cells were very faint, as opposed to the HBV infected cells where the foci were larger, more numerous and much brighter.

In contrast to ATR and its targets, the phosphorylated form of ATM at Ser-1981 was not visibly increased upon infection, and phosphorylation of its downstream substrate Chk2 at Thr-68 began to decrease starting from 3 hoi (Figure 1A), with slight recovery at later time points, indicating that the p53-independent pathway was blocked. Phosphorylation of p53 at Ser-15 in response to DNA damage usually correlates with the ability of p53 to trans-activate downstream target genes. Therefore, we examined expression levels of p53 transcriptional targets $p21^{cip1/waf1}$, a cyclin-dependent kinase inhibitory protein. Figure 1A

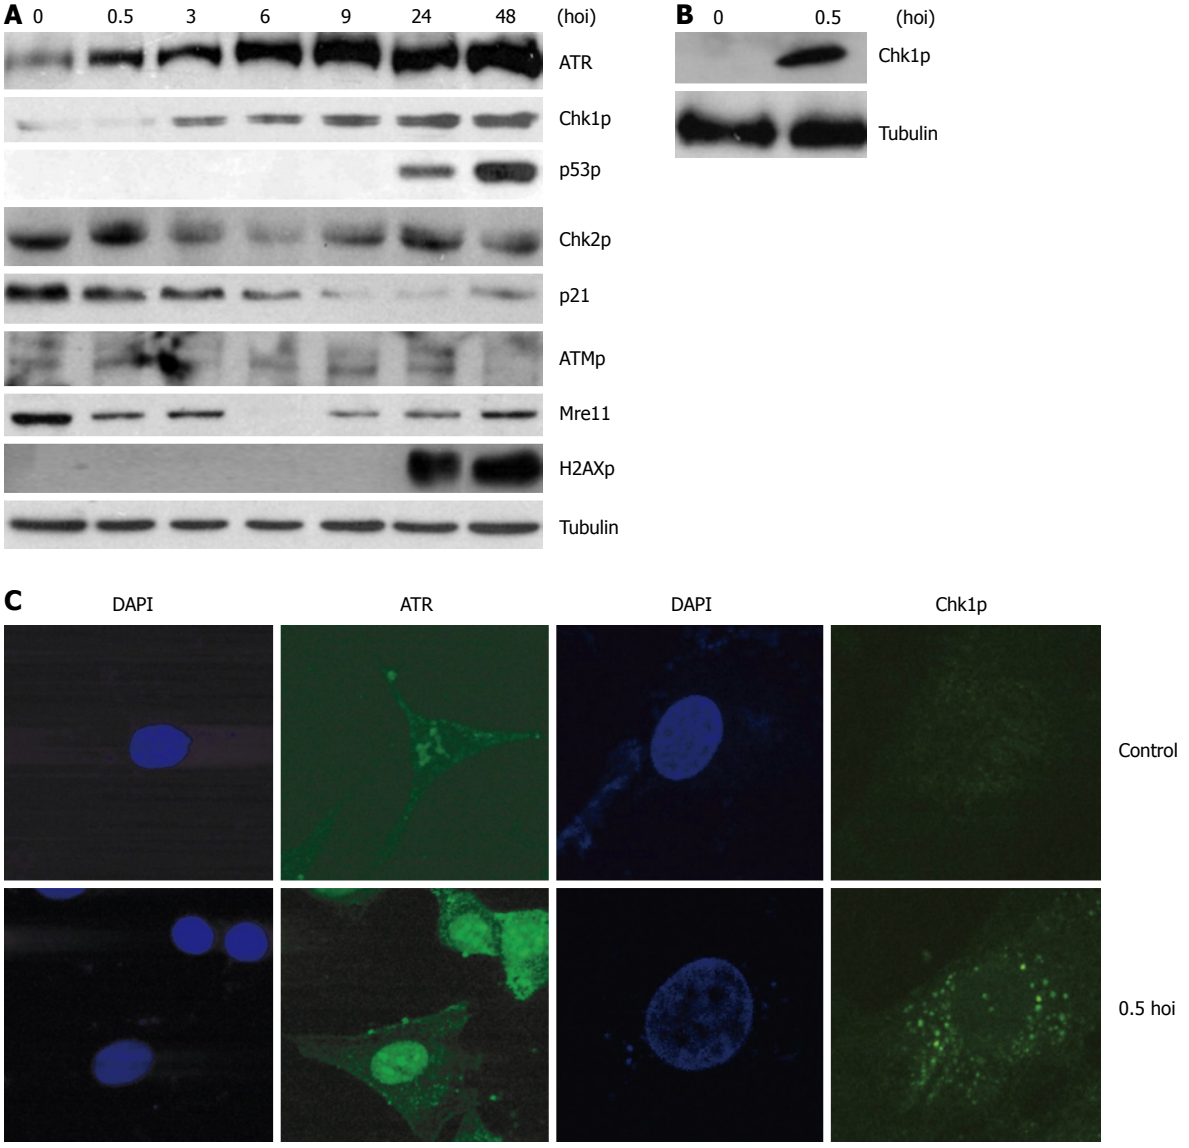

Figure 1 HBV infection activates a cellular checkpoint response dependent on ATR. A: 105 human hepatocyte HL7702 monolayer cells in a 6-cm plate were infected with 106 virus particles from HBV-positive patients at 37℃ under 50 mL/L CO_2; normal serum from healthy individuals was used as a non-infected control. Prior to cell harvesting, the cells were washed eight times thoroughly to remove excess viral input. Whole-cell lysates were prepared at various times of infection (hoi) and subjected to an immunoblotting assay by using antibodies against the indicated proteins. Tubulin was used as the equal loading control; B: Primarily cultured hepatocyte cells were prepared and were harvested 3 h after HBV-positive serum addition. Whole cell lysates were prepared and subjected to immunoblotting assay by using Chk1 phosphorylation antibody; tubulin was used as the equal loading control; C: HL7702 cells were infected with HBV-positive serum for 0.5 h. Normal serum from healthy individuals was used as a non-infected control. Immunofluorescence with antibodies to Chk1 Ser-345 and ATR (green) were monitored. DNA was stained with DAPI (blue).

shows that the amount of p21 decreased substantially with time after infection, suggesting that p53-dependent downstream signaling was blocked during HBV infection, despite the appearance of phosphorylated p53. By 0.5 h after HBV-positive serum addition, downregulation of Mre11 began to be detected. This reduction in Mre11 protein occurs shortly after HBV infection, implying that an incoming virion protein may lead to this degradation. Further investigation is required to explain this phenomenon.

Since HBV infection activated DNA damage checkpoint pathway that responded to replication stress, we asked if HBV infection would effect cell cycle progression and cell death. Cells were synchronized in G1 phase by mimosine, an inhibitor of DNA synthesis initiation, for 24 h. Arrested cells were then washed twice and media replaced with RPMI-1640 containing HBV serum or normal serum. Cells were harvested at different times after mimosine release. The results of fluorescence-activated cell sorting (FACS) analysis showed that approximately 5% of the cells were in early S phase with 95% in G1 after synchronization (Figure 2A), indicating that the synchronization was fulfilled. Control cells treated with normal serum had approximately 44.4% of cells in S phase after 12 h release from mimosine, whereas cells treated with HBV-positive serum still had 56.6% of cells in S phase (Figure 2A and B). The percentage of total cells in S phase indicates the effect of virus in extending the period of DNA synthesis. Toward the end of the cell cycle, there was an accumulation of cells

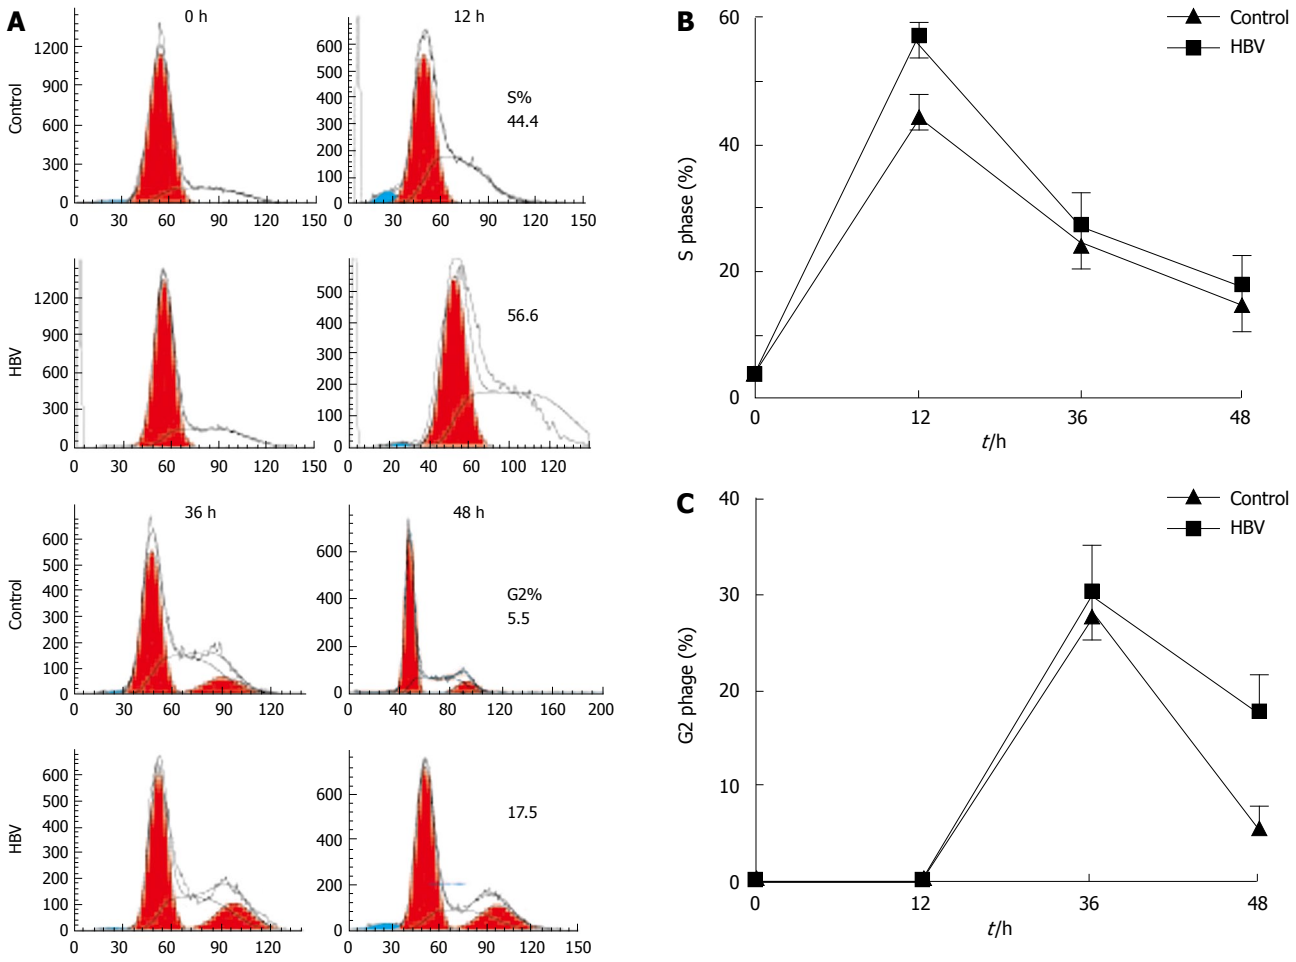

Figure 2 HBV infection caused transient cell cycle arrest in the S and the G2 phase. The duration of the S and G2 phase were measured in HBV-infected or non-infected cells. Cells were synchronized with mimosine for 24 h, and then media were replaced with RPMI-1640 containing 10% HBV serum or normal serum. At indicated times, cells were harvested and examined for cell cycle profile using propidium iodide staining and flow cytometry. A: Cell cycle profile in HBV-infected cells and in non-infected cells; B: Percentages of cells in the S phase; C: Percentages of cells in the G2 phase. Mean and standard error are presented for three independent experiments.

in G2 phase in HBV-infected cells (5.5% for control cells versus 17.5% for HBV infection cells) without the appearance of fragments with less than 2N DNA (Figure 2A and C). These findings indicate that DNA damage pathway responding to replication stress induced by HBV infection will lead to transient cell cycle arrest without accompanying increased apoptosis.

Checkpoint signaling pathway was compromised in HBV-infected cells

Previous results show that HBV infection did not show increased apoptosis even though a cellular DNA damage response dependent on ATR was activated (Figure 2A). To better understand the consequences of the ATR signaling pathway triggered by HBV infection, we examined if HBV infection had an impact on host cell survival after IR and UV radiation. Cells were washed extensively to remove viral inputs 24 h after HBV-positive serum addition and then treated with different doses of UV or IR radiation. After 48 h of UV and 4 d of IR treatment, cells were collected and surviving cells were counted with Trypan blue staining. Figure 3A and B showed that the survival rate of UV-irradiated cells was enhanced by HBV infection, while the survival rate of IR-irradiated cells was reduced by HBV infection. Figure 3C shows that while the cell survival rate after 8 s of UV or 4 Gy of IR was about 30%, the survival rate of HBV-infected cells after 8 s of UV radiation increased from 30% to 49%. By contrast, HBV infection pre-treatment with 4 Gy of IR radiation reduced the cell survival rate from 31% to 21%, suggesting that survival of UV-treated cells was enhanced by HBV infection (Figure 3C). Based on this result, we analyzed the difference in apoptosis between UV radiation only and combined treatment of UV with HBV infection. Decreased apoptosis was seen in combined treatment cells (Figure 4A and B). Twenty-four percent apoptosis was seen in UV-radiation-only cells, while about 8% apoptosis was detected in cells treated with UV radiation followed by HBV infection. It is known that cell cycle checkpoint triggered by DNA damage response induces cell apoptosis if damaged DNA cannot be repaired. The inhibitory effect of HBV on cell survival was reduced in cells treated with UV, indicating that checkpoint signaling controlled by the ATR DNA damage pathway was at least partially compromised in HBV-infected cells; therefore, the ATR signal pathway did not function completely.

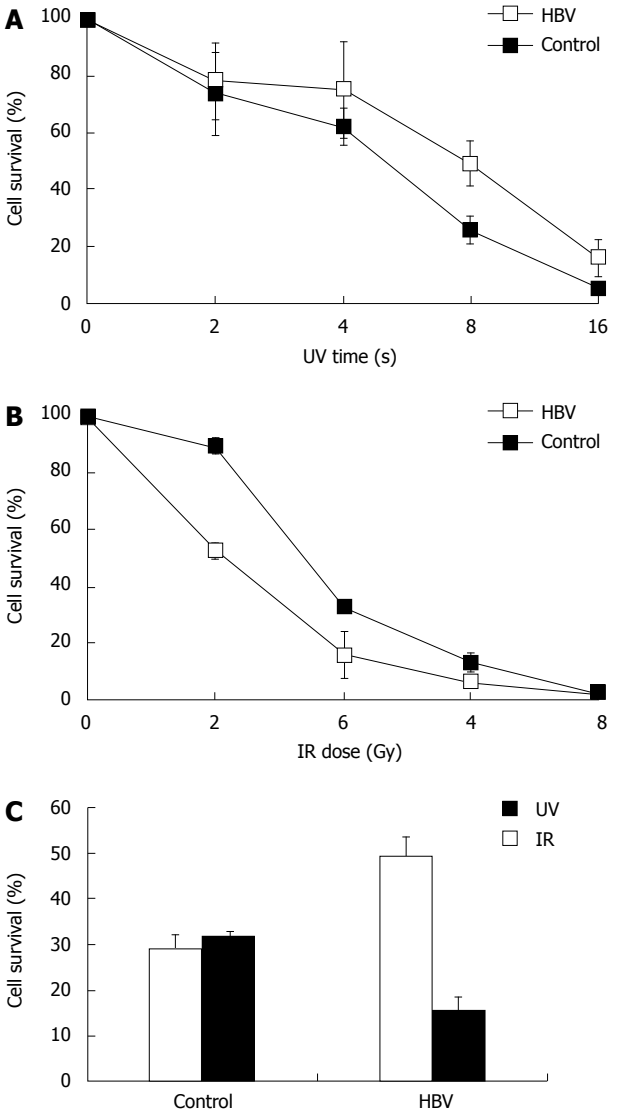

Figure 3 HBV infection hypersensitizes host cells to IR and causes hyper-resistance of host cells to UV. A: HL7702 cells were treated with indicated doses of IR followed HBV positive serum addition for 24 h, and continued in culture for another 4 d, trypan blue staining was used for viable cell counting; B: HL7702 cells were treated with indicated doses of UV followed by HBV-positive serum addition for 24 h, and continued culture for another 48 h, trypan blue staining was used for viable cell counting; C: HL7702 cells were treated with 8 s of UV or 4 Gy of IR followed HBV infection, and viable cells were counted. Percentage survival was determined by the number of treated cells normalized to untreated cells. Mean and standard error are presented for three independent experiments.

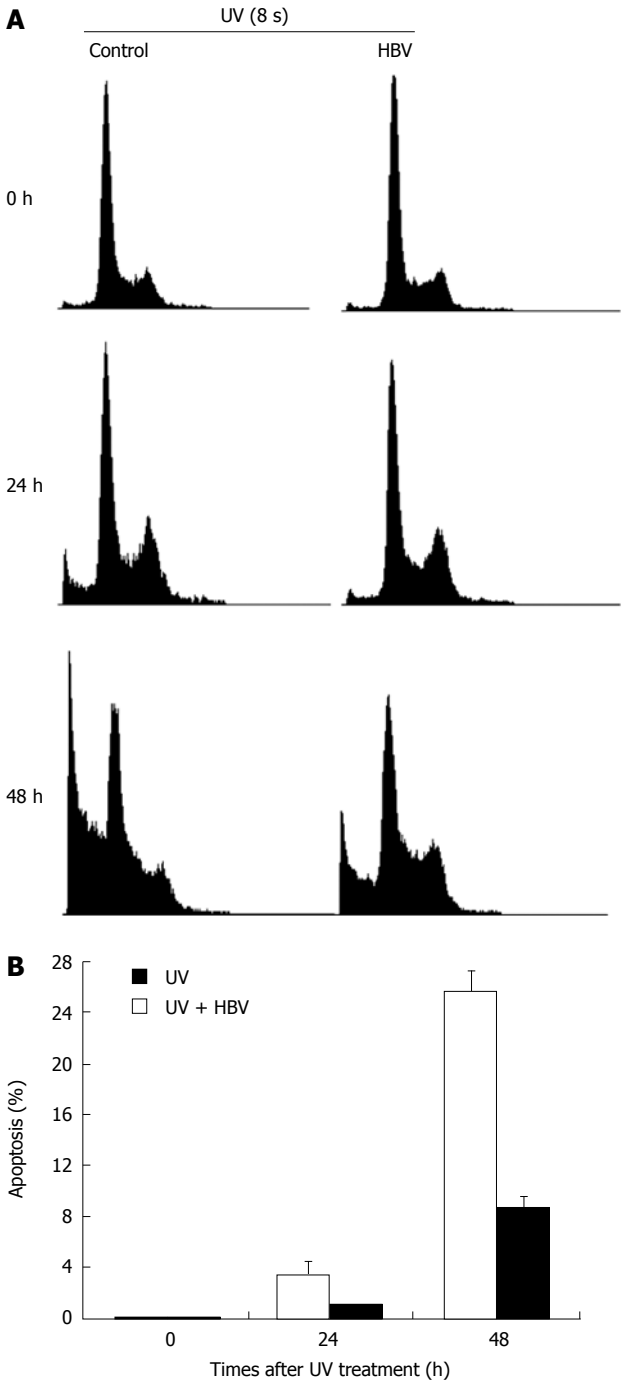

Figure 4 HBV infection followed by UV radiation led to decreased cell apoptosis. A: HBV-positive serum was added to the culture medium before UV radiation treatment. Cells were washed extensively 24 h after HBV-positive serum addition and then treated with 8 s of UV radiation. Cell cycle profile was examined by propidium iodide staining and flow cytometry at indicated times after UV treatment; B: Apoptosis percentage after UV radiation followed HBV infection. Mean and standard error are presented for three independent experiments.

DISCUSSION

The induction of cell cycle checkpoints and activation of the ATM/ATR-dependent pathway have been reported to accompany infection by a number of different viruses. Recent reports have shown that viruses have evolved a variety of mechanisms to manipulate DNA damage signaling for their replication and propagation. In this study, HL7702 cells and primarily cultured hepatocytes were inoculated with HBV-positive serum (10^6 particles per 10^5 cells), mimicking the HBV infection process. Serum from healthy individuals was used as a non-infected control. We propose that HBV infection induces acute cellular DNA damage response dependent on ATR, as demonstrated by ATR protein and increased phosphorylation of Chk1, p53 and H2AX. Since Chk1 phosphorylation, ATR foci formation, and Mre11 and p21 degradation happened shortly after HBV-positive serum addition, we propose that incoming virion protein and genetic materials triggered this response. p53 and

H2AX phosphorylation did not begin to accumulate until 24 h after HBV serum addition, implying HBV replication inside the infected cells may be responsible for these phenomena. Interesting questions are raised and need further investigation.

Although ATM/ATR kinase phosphorylates Chk2 at Thr-68 and p53 at Ser-15, the ATR kinase predominantly targets Chk1 at Ser-345, leading to increased Chk1 activity. Our results indicate that HBV infection preferentially activates ATR DNA damage response signaling, as is the case with human adeno-associated-virus type 2[30-36].

As a latent virus, HBV abrogates checkpoint signaling controlled by ATR, to prevent triggering of signals for apoptosis in multiple ways. The mechanism of regulation of apoptosis by HBV was *via* both p53-dependent and p53-independent pathways. p53-dependent cell cycle checkpoint features p21-mediated inactivation of cdk2/cyclinE; HBV abrogates p53 dependent checkpoint activation by p21 degradation. Chk2 inhibition inhibits cdk2/cyclin E activity by phosphorylation of cdk2 at Tyr-15 in a p53-independent fashion, and the virus-decreased phosphorylation of Chk2 by Mre11 degradation inhibits the p53-independent DNA damage signaling pathway. It is known that ATM and MRN complex function in a common pathway, and the MRN complex can function to activate ATM kinase activity, so degradation of Mre11 protein by virus would inhibit ATM kinase activity, and thus affect phosphorylation of its downstream target Chk2. Therefore, like adenovirus[24,25], HBV appears to have evolved double check mechanisms to block cell cycle checkpoint signaling pathways. Consistent with this, HBV has been reported to express an additional anti-apoptotic gene HBV X that mislocates p53 to the cytoplasm, in order to evade host cellular DNA damage response and modulate apoptosis. HBX has also been reported to sensitize liver cells to environmental carcinogens, including diethylnitrosamine and aflatoxin B and UV. We observed that HBV virus enhanced cell survival upon UV radiation but hypersensitized host cells to IR; this discrepancy may be due to the complex interactions between the virus as a whole and DNA repair machinery, indicating that the virus mainly blocks cellular signaling checkpoint dependent on ATR. The risk of acquiring mutations would be enhanced by compromised cellular DNA repair caused by HBV infection. Accordingly, exposure to other environmental risk factors should act synergistically to favor the carcinogenesis process[37-39].

In summary, HBV induces cellular DNA damage response dependent on ATR, but escapes the consequences of activation of the DNA damage checkpoint by degradation of checkpoint proteins at different levels. The implication of this is that with time, persistent HBV infection may lead to the accumulation of a variety of mutations which would ultimately give rise to hepatocellular carcinoma.

COMMENTS

Background

Eukaryotic cells employ multiple strategies of checkpoint signaling and DNA repair mechanisms to monitor and repair damaged DNA. There are two branches of the checkpoint response pathway, ataxia telangiectasia-mutated (ATM) pathway and ATM-Rad3-related (ATR) pathway. Virus replication presents the host cells with large amounts of exogenous genetic material, including DNA ends and unusual structures. Thus, infected cells recognize viral replication as a DNA damage stress and elicit DNA damage signal transduction, which ultimately induces apoptosis as part of host immune surveillance. However, recent reports have shown that viruses evolve a variety of mechanisms to manipulate DNA damage signaling for their replication and propagation.

Research frontiers

Epstein-Barr virus (EBV) abrogates p53 checkpoint signaling pathway through the interaction of the BZLF1 protein and p53 to avoid apoptosis. Other viruses such as human immunodeficiency virus type 1 (HIV-1), herpes simplex virus type 1 (HSV-1) and human cytomegalovirus can activate and exploit a cellular DNA damage response, which aids viral replication. Adenovirus blocks ATM signaling and concatemer formation through targeting the DNA repair complex of MRN for degradation and mislocalization. Thus, under some circumstances, viruses have co-opted endogenous checkpoint regulators to ensure their own efficient replication.

Innovations and breakthroughs

There was no evidence indicating that the ATM/ATR kinase or their downstream pathways were triggered by hepatitis B virus (HBV) infection. The present study was undertaken by culturing normal hepatocyte cell line HL7702 and primary hepatocytes from a healthy liver donor with HBV-positive serum, mimicking natural HBV infection. We showed, perhaps for the first time, that HBV infection elicited acute cellular DNA damage response dependent on ATR. However, the ATR checkpoint signaling was blocked downstream of p53-dependent and p53-independent pathways to evade apoptosis.

Applications

Since DNA damage response is an acute response that happens quickly after virus infection, we assume that early intervention of the DNA damage pathway will function more efficiently and can be used clinically as HBV infection therapy during its early infectious stage or fulminant HBV infection.

Peer review

In this interesting study the authors investigated whether exposure to HBV infection will upregulate DNA damage checkpoint signaling pathways. They show that ATM-Rad3 is upregulated as well as several downstream targets.

Abstract

AIM: To study the possible association between chronic pancreatitis (CP) and liver cirrhosis (LC) of alcoholic etiology, after excluding any other causes.

METHODS: One hundred and forty consecutive alcoholic patients were subdivided into three groups: CP (n = 53), LC (n = 57), and asymptomatic alcoholic (n = 30). Clinical, biochemical and morphological characteristics, Child-Pugh index, indocyanine green test, and fecal pancreatic elastase-1 test were assessed.

RESULTS: In patients with cirrhosis, major clinical manifestations of CP such as pancreatic pain and steatorrhea, as well as imaging alterations of CP such as calcifications, duct dilation and pseudocysts were absent; insulin-dependent diabetes was present in 5.3% of cases, and elastase-1 test was altered in only 7%, and severely altered in none. In patients with CP, clinical characteristics of cirrhosis such as ascites, encephalopathy and gastrointestinal hemorrhage were present in one case, Child-Pugh grade > A in 5.7%, and altered indocyanine green test in 1.9% cases. In asymptomatic alcoholism, there was only a non-coincident alteration of elastase-1 test and indocyanine test in 14.8% and 10%, respectively, but other characteristics of cirrhosis or CP were absent. An inverse correlation (r = -0.746) between elastase-1 test and indocyanine test was found in alcoholic patients.

CONCLUSION: There is a scarce coincidence in clinical and morphological alterations among patients with CP or LC of alcoholic etiology, but an inverse correlation between pancreatic and liver function tests. These findings support that these alcoholic diseases evolve in a different manner and have different etiopathogenesis.

Key words: Alcoholic chronic pancreatitis; Alcoholic liver cirrhosis; Alcoholism; Pancreatic function; Hepatic function

Does an association exist between chronic pancreatitis and liver cirrhosis in alcoholic subjects? *World J Gastroenterol* 2008; 14(40): 6171-6179 Available from: URL: http://www.wjgnet.com/1007-9327/14/6171.asp DOI: http://dx.doi.org/10.3748/wjg.14.6171

INTRODUCTION

Chronic alcoholism is a well-known etiologic factor associated with chronic and irreversible pancreatic and liver disorders. Excessive alcohol consumption is the most frequent cause of chronic pancreatitis (CP) in Western countries[1]. There is a correlation between increased ethanol consumption over many years and the risk of developing CP[2,3]. Nevertheless, it has recently been estimated that < 5% of alcoholic subjects develop CP[1,4,5]. This low percentage, together with the absence of adequate experimental models of alcoholic CP, suggest that ethanol is only a cofactor in the development of CP, and therefore other predisposing

factors may be involved[6].

An excessive consumption of alcohol is also associated with liver cirrhosis (LC), again with a correlation between increased ethanol consumption and the risk of LC[7,8]. The development of LC also requires chronic alcoholism over several years[8,9]. For decades, it was considered that around 10%-35% of subjects with chronic alcoholism developed alcoholic LC[10]. However, more recent prospective studies have shown that the prevalence in alcoholics is indeed much lower, around 2%[7,8], once having excluded the confusing cases of hepatitis B or C[11,12]. Experimental models of chronic alcoholism have not provided insights into the pathophysiological mechanisms responsible for the different outcome in CP and LC[13].

There is still controversy about the frequency of coincidence between CP and LC in alcoholic patients. This lack of coincidence may rely on differences in methodology, retrospective *versus* prospective studies[14], and evaluated parameters such as clinical[15], functional[16], imaging[17] or histopathological[18,19]. In addition, there are diagnostic difficulties in the initial stages[20], as well as several confounders hindering this question, such as the presence of hepatitis B or C virus[14,19], and age-related pancreatic alterations[21,22].

It is worth noting that pancreatic function is often increased in patients with alcoholic LC, leading to the hypersecretory status of the pancreas[16,23]. Thus, Hayakawa *et al*[24] have reported that pancreatic secretion, measured with the pancreozymine-secretine test, increases with severity of liver damage in alcoholic liver disease. It has been suggested that this hypersecretory status diminishes protein and calcium concentration in pancreatic juice, protecting against formation of protein plugs and pancreatic stones[16].

In clinical practice, the coincidence of both diseases, LC and CP, is rare[15,24]. Furthermore, these two diseases do not share risk factors apart from alcohol consumption[15]. In alcoholic CP, the duration of chronic alcoholism is shorter than in LC, and liver disease is found at older ages[14]. Nakamura *et al*[15] have recently assessed the genotypes of alcohol dehydrogenase (ADH), ductal anatomy by endoscopic retrograde cholangiopancreatography (ERCP) and the Child-Pugh classification in Japanese alcoholics, and reported a lack of association between the risk of LC and CP. In addition, no clear genetic predisposition has been found so far in studies of genetic polymorphisms in alcoholic CP[25] and alcoholic LC[26].

To the best of our knowledge, there are no previous studies comparing clinical, functional, morphological and biochemical parameters in alcoholic subjects with a definitive diagnosis of CP or LC. In this study, we therefore aimed to assess the association of CP and LC, both with definitive diagnosis, in subjects with chronic alcoholism, based on clinical, functional and morphological parameters.

MATERIALS AND METHODS

Case-control study with two groups of consecutive patients who attended the University Clinic Hospital of Valencia, Spain for 3 years included: (1) alcoholic CP (n = 53); and (2) alcoholic LC (n = 57). Controls were 30 asymptomatic alcoholic (ASA) patients. The diagnosis of CP was based on the Cambridge and Marseille criteria[27,28]. The diagnosis of cirrhosis was histologically proven in 27 patients and based on compatible clinical, laboratory and ultrasonographic finding in the others[29]. Daily ethanol intake was over 40 g for more than 5 years in alcoholic subjects[7,8] and before entering the study a period of 60 d of alcohol abstinence was required. Exclusion criteria for alcoholic LC were the presence of antigens or antibodies against B or C virus, as well as liver diseases not related to chronic alcoholism such as hemochromatosis or any other causes. Exclusion criteria for CP were the presence of toxic-metabolic (other than alcohol), genetic, autoimmune, and obstructive factors considered as confounders[6]. Other exclusion criteria for the study were gastric or liver surgery, pancreatic surgery prior to diagnosis, and gastrointestinal neoplasia. Smoking was considered when more than 10 cigarettes were consumed daily[30,31].

Characteristic manifestations of LC[13] were assessed in all patients, including hemorrhage in the digestive tract secondary to portal hypertension, ascites, hepatic encephalopathy, alterations of the Quick index, and Child-Pugh index (PI)[32]. PI was classified according to the following scoring system: A (5-6 score), B (7-9 score), and C (10-15 score)[32]. The following characteristic manifestations of CP[27,28] were also assessed in all patients: pancreatic pain, non-insulin-dependent diabetes mellitus (NIDDM), insulin-dependent diabetes mellitus (IDDM), and chronic diarrhea/steatorrhea. Liver function was assessed by indocyanine green clearance test (ICG test). Pancreatic function was assessed by determination of fecal pancreatic elastase-1 test (E1 test) and oral glucose tolerance test (OGTT). The presence of esophageal varices, splenomegaly, portal hypertension, pancreatic calcifications, pseudocysts or alterations of the pancreatic duct were assessed by ultrasonography (US), computer tomography (CT), magnetic resonance cholangiopancreatography (MRCP), or ERCP. Splenomegaly was considered when the size of the spleen was $\geqslant$ 135 mm. Portal hypertension was established according to the following criteria: Portal vein diameter > 12 mm and/or presence of esophageal varices and/or splenomegaly. Alterations in the Quick index were established when the international normalized ratio (INR) was higher than 1.2[33].

The ICG test was performed by pulsidensitometry (Limon PC5000, Pusion Medical Systems, Munich RFA). Briefly, ICG was intravenously administered at a dose of 0.5 mg/kg, monitoring the blood concentration of ICG to determine the plasma disappearance rate (PDR, %/min). It was considered that the ICG clearance was altered when PDR was < 15%, and severely altered when PDR was < 10%[34,35].

Pancreatic fecal elastase-E1 activity was determined by ELISA (Pancreatic Elastase stool test, Schebo-Biotech, Giessen RFA). E1 activity was considered altered when it was < 200 μg/g, and severely altered when it was <

Table 1 General characteristic of patients with ACP, ALC or ASA

	ACP (n = 53)	ALC (n = 57)	ASA (n = 30)	P
Age at the beginning of the study	51.8 ± 9.7	56.1 ± 9.9	49.9 ± 7.9	CP *vs* LC, CP *vs* ASA, NS; LC *vs* ASA, P = 0.010
Men (%)	98	84	70	CP *vs* LC, P = 0.011; CP *vs* ASA, P = 0.001; LC *vs* ASA, NS
Age at diagnosis	39 ± 9.2	51.5 ± 9.6	-	P = 0.001
Alcohol intake (g/d)	120 ± (75-250)	118 (70-255)	121 (70-400)	NS
Years of alcoholism	20 (10-35)	25 (10-52)	18.5 (9-36)	CP *vs* LC, P = 0.01; LC *vs* ASA, P = 0.006; CP *vs* ASA, NS
Ethanol, kg of total intake	876 (273-2920)	1095 (481-3832)	965 (229-3358)	NS
Smoking	94.3%	80.7%	96.7%	CP *vs* LC, P = 0.030; CP *vs* ASA, NS; LC *vs* ASA, P = 0.035
BMI	23.4 ± 3.6	26.5 ± 4.4	24.8 ± 4.6	CP *vs* LC, P = 0.001

Data are expressed as mean ± SD, percentage or median (minimum-maximum). NS: Not significant.

100 μg/g[36] in at least two consecutive determinations. Fecal fat was determined by the van de Kamer method[37].

The body mass index (BMI) was measured in all subjects as index of nutritional status. BMI values < 20 were considered malnutrition, whereas values > 28 were considered as indicative of being overweight[38].

Statistical analysis

Proportions for qualitative variables and mean ± SD for quantitative variables were calculated. Means were compared by t test or ANOVA and post-hoc Scheffe test. According to the Kolmogorov-Smirnov test, when quantitative variables did not fit a normal distribution, medians and ranges and consequently Kruskal-Wallis test were used. Qualitative variables were analyzed by χ^2 test or Fisher's exact test when appropriate. Odds ratios (ORs) with 95% confidence intervals (95% CI) were also calculated. Spearman's rank correlation coefficient between E1 test and indocyanine green test (ICG test) or PI was calculated. $P < 0.05$ was considered statistically significant.

RESULTS

General characteristics of patients: Alcohol consumption, smoking, and nutritional status

Table 1 shows the general characteristics of each group of subjects. Although the age of patients when entering the study was not different between CP and LC, the age at the moment of diagnosis was significantly lower in CP than LC patients. Most patients were men in all groups, especially in the CP group.

Regarding the alcohol consumption, the daily alcohol intake did not differ among groups. The percentages of heavy drinkers (daily consumption > 150 g) were 30.2%, 33.3%, and 45.0% for CP, LC and ASA groups, respectively, without significant differences among the groups. The duration of alcohol consumption was lower in CP than in LC patients. However, there was no significant difference between CP and LC in the percentage of patients with more than 20 years of alcohol consumption (41.6% and 52.6% for CP and LC subjects, respectively). The percentage of patients with more than 20 years of alcohol consumption was significantly higher in LC than in ASA patients (52.6% *vs* 33.7%). The total amount of ethanol consumed before diagnosis did not differ among groups (Table 1).

Table 2 Potential risk factors for CP or LC: Distribution of frequencies and OR in patients with ACP or ALC n (%)

	ACP 53	ALC 57	OR (95% CI)	P
Gender (female)	1 (1.9)	9 (15.8)	9.7 (1.1-79.8)	0.017
BMI > 28	4 (7.5)	15 (26.8)	4.5 (1.4-14.5)	0.008
BMI < 20	7 (13.2)	4 (7)	0.49 (0.13-1.8)	0.280
Age > 45 yr at diagnosis	14 (26.4)	41 (71.9)	7.1 (3.1-16.6)	0.001
Smoking	50 (94.3)	46 (80.7)	0.25 (0.06-0.95)	0.044
Alcohol > 150 g/d	16 (30.2)	19 (33.3)	1.12 (0.5-2.5)	0.775
Years alcoholism > 20	22 (41.5)	30 (52.6)	1.56 (0.73-3.32)	0.243

The percentage of cigarette smokers was slightly higher in CP than in LC patients. The BMI was higher in LC than in CP patients. The percentage of patients with overweight (BMI > 28) was also higher in LC than in CP group, but it was no different when compared to ASA patients (7.5%, 26.8% and 9% for CP, LC and ASA subjects, respectively) (Table 2). The percentage of patients with malnutrition (BMI < 20) was low in all groups, without significant differences among them (13.3%, 7.0% and 13.3% for CP, LC and ASA subjects, respectively).

Features of alcoholic CP in CP, LC and ASA subjects

It is worth noting that there was absence of the two major clinical manifestations of CP, pancreatic pain and diarrhea/steatorrhea in patients with LC (Table 3). IDDM was frequent in CP (35 cases, 68%), but was found only in three LC cases (5.3%) and in none with ASA. Among these three LC patients with IDDM, one exhibited reduced E1 test (164 μg/g) as the unique altered pancreatic parameter. However, the percentage of patients with NIDDM was higher in the LC group (19.3%) than in the CP group. Diarrhea/steatorrhea was present in many patients with CP (54.7%), but absent in the other two groups (Table 3).

The major morphological alterations such as calcification, dilatation of the pancreatic duct, and pseudocysts were found only in CP patients.

Features of alcoholic LC in CP, LC and ASA subjects

Clinical manifestations characteristic of LC such as ascites, encephalopathy, or upper gastrointestinal

Table 3 Clinical manifestations, functional parameters and imaging characteristics of CP in patients with ACP, ALC or ASA

	ACP (n = 53)	ALC (n = 57)	ASA (n = 30)	P
Pancreatic pain	85%	0%	0%	< 0.001
IDDM	68%	5.3%	0%	< 0.001
NIDDM	5.7%	19.3%	10%	CP *vs* LC, P = 0.03; CP *vs* ASA, LC *vs* ASA, NS
Diarrhoea/ steatorrhoea	54.7%	0%	0%	< 0.001
Calcifications	77.4%	0%	0%	< 0.001
Dilatation of pancreatic duct	67.9%	0%	0%	< 0.001
Pancreatic pseudocysts	58.5%	0%	0%	< 0.001

NS: Not significant.

Table 4 Clinical manifestations, functional parameters and imaging characteristics of LC in patients with ACP, ALC or ASA

	ACP (n = 53)	ALC (n = 57)	ASA (n = 30)	P
Ascites	0%	66.7%	0%	
Haemorrhage in upper digestive tract	1.9%	45.6%	0%	< 0.001
Child-Pugh index > 5	5.7%	98.2%	0%	< 0.001
INR > 1.2	0%	73.7%	0%	< 0.001
Esophageal varices	1.9%	77.2%	0%	< 0.001
Splenomegaly	1.9%	77.2%	0%	< 0.001
Portal hypertension	3.8%	96.5%	0%	< 0.001

hemorrhage were found in most patients with LC, in one case (1/53) with CP and in none with ASA (Table 4). This particular case with CP exhibited gastrointestinal hemorrhage and portal vein thrombosis secondary to pancreopathy, splenomegaly, a PI of 6, with serum albumin level of 2.9 g/dL, severe steatorrhea, severe diabetes mellitus and malnutrition. Nevertheless, his ICG test was normal (23.8%/min).

The PI was > 5 in almost all cases (56/57) with LC, in three (3/53) with CP and in none (0/30) with ASA (Table 4). According to Child-Pugh classification, 35% (20/57) of LC patients were ascribed to class A, 35% (20/57) belonged to class B, and 30% (17/57) belonged to class C. Three cases of CP had a PI of 6. One was the previously described patient with gastrointestinal hemorrhage. In another case, a liver biopsy was available and ruled out the diagnosis of cirrhosis; however, the patient had an elevated Quick index (1.5 INR) at the moment of inclusion which could be attributed to severe steatorrhea because it normalized after parenteral treatment with vitamin K. The third CP case had a CPI of 6, and at the moment of inclusion exhibited cholestasis (total serum bilirubin = 2.6 mg/dL) due to compression of the common bile duct secondary to pancreopathy. This patient had a normal ICG test (28.9% min) and did not exhibit signs of hepatopathy.

Esophageal varices were found in 77% of LC patients, in one case (1/53) with CP and in none with ASA (Table 4). In this CP patient, there were no manifestations of hepatopathy, and varices were secondary to pancreopathy involving portal vein thrombosis. This patient had a large pseudocyst (50 mm × 50 mm) in the head of the pancreas, which caused obstructive jaundice that required surgical treatment, but the ICG test later at the moment of inclusion was normal (PDR = 28.9%/min).

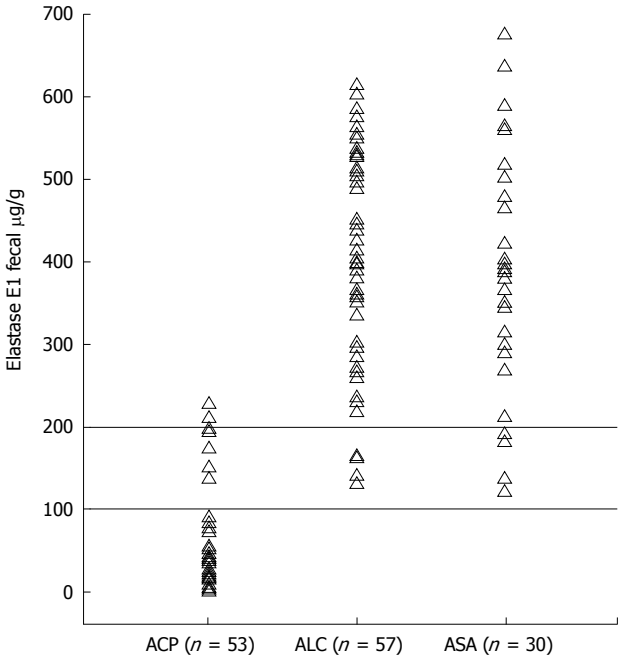

Figure 1 Fecal E1 test (μg/g feces) in patients with ACP, ALC or ASA. Reference lines for altered E1: < 200 μg/g, and severely altered E1: < 100 μg/g. ACP *vs* ALC, P < 0.001; ACP *vs* ASA, P < 0.001; ALC *vs* ASA, P = 0.747.

Splenomegaly was also found in 72.2% of LC patients, in one case with CP and in none with ASA (Table 4). This CP case was the one with upper gastrointestinal hemorrhage, which has been previously described.

Portal hypertension was present in almost all LC patients (96.5%), in two patients with CP and in none with ASA (Table 4). In these two CP cases, portal hypertension was secondary to pancreatic disease, as previously described, with normal ICG test.

Pancreatic fecal elastase E1 in CP, LC and ASA subjects

Fecal E1 test was significantly lower (P < 0.001) in CP patients [9 (0.1-228) μg/g feces] than in LC patients [400.0 (130-614) μg /g feces] and ASA subjects [388 (121-675) μg/g feces] (Figure 1). Moreover, 94.3% of CP patients (50/53) exhibited E1 test lower than the normal limit of 200 μg/g feces, whereas 84.9% (45/53) had very low levels (i.e. < 100 μg/g feces), and among them 29, (64.4%) with diarrhea/steatorrhea. All these percentages were markedly higher (P < 0.001) than those in the LC and ASA groups.

In the LC group, E1 test was < 200 μg/g only in four of 57 cases (7%), and in none of them was it < 100 μg/g. As mentioned before, none of the LC patients exhibited diarrhea/steatorrhea or pancreatic alterations assessed

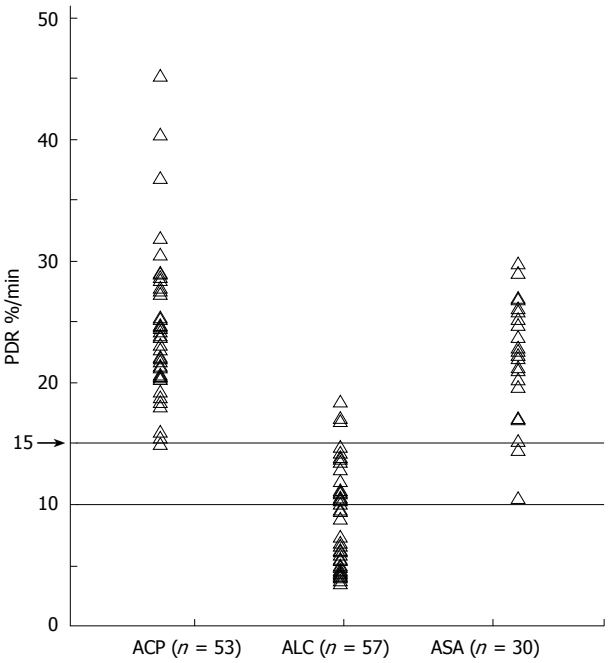

Figure 2 PDR, %/min of ICG in patients with ACP, ALC or ASA. Reference lines for altered PDR: < 15%/min, and severely altered PDR: < 10%/min. ACP *vs* ALC, $P < 0.001$; ACP *vs* ASA, $P = 0.048$; ALC *vs* ASA, $P < 0.001$.

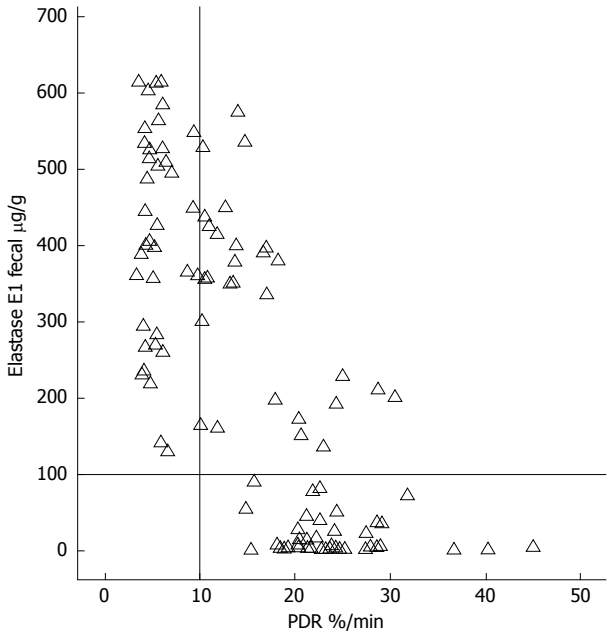

Figure 3 An inverse correlation ($r = -0.746$, $P < 0.001$) between indocyanine clearance (PDR, %/min) and fecal E1 test (μg/g feces) in patients with ACP, ALC or ASA. Reference lines: PDR (%/min) = 15; E1 test = 100. Vertical line for PDR (%/min) = 10, and horizontal line for E1 test = 100 are marked in the figure.

by imaging studies.

Among the 27 ASA subjects, E1 test was reduced only in four (14.8%), but it was never < 100 μg/g. As mentioned, none of the ASA subjects exhibited diarrhea/steatorrhea or pancreatic alterations assessed by imaging studies.

ICG clearance test in CP, LC and ASA subjects

PDR values of the ICG test were markedly more reduced in LC patients [6.1 (3.4-18.2)%/min] than in CP patients [22.6 (14.8-45)%/min] and ASA subjects [22.1 (10.4-30.2)%/min] (Figure 2). Ninety-three percent of LC patients (53/57) had a PDR lower than the normal limit (< 15%/min), and 64% of them exhibited a severe PDR reduction (< 10%/min). However, only one patient with CP (1.9%) showed PDR < 15%/min and none had PDR < 10%/min.

In the ASA group, three of 29 subjects (10%) had reduced PDR (< 15%/min) and none had PDR < 10%/min. These ASA subjects had a normal E1 test, and had no pancreatic or hepatic alterations assessed by imaging studies compatible with CP or LC; all had PI of 5.

It is worth noting that a significant inverse correlation ($r = -0.746$; $P < 0.001$) was found between E1 test levels and PDR values in patients with CP or LC (Figure 3). A significant correlation was also found between E1 test levels and PI ($r = 0.759$; $P < 0.001$). Therefore, in general, the reduction of functional hepatic reserve was associated with normal pancreatic function, and vice versa.

The analysis of potential risks of developing CP or LC showed significantly different values for gender, overweight (BMI > 28), age > 45 years at the time of diagnosis, and smoking (Table 2). Nevertheless, these differences were too low to explain the different evolution towards CP or LC. No significant differences were found regarding malnutrition (BMI < 20), elevated alcohol consumption (> 150 g/d) or long-term chronic alcohol consumption (> 20 years).

DISCUSSION

Chronic ethanol consumption is a common and frequent etiological factor in both CP and LC, and their risk correlates very well with the amount of ethanol daily consumed[2,7]. However, only a minority of alcoholics develop these diseases[1,4,5,7,8]; this together with the requirement of several years of ethanol intake, racial factors[39], and the difficulty of developing adequate experimental models have led to the consideration of other associated etiological factors[26].

The presence of a common etiological factor, i.e. alcoholism, for CP and LC could lead to the assumption that both diseases may coincide in some patients. The study of the presence and coincidence of these two diseases and their risk factors may provide new insights into their etiopathogenesis. Nevertheless, there is controversy about the frequencies of the coincidence between CP and LC in the studies published so far[15-19]. Differences in methodology, and particularly, the presence of hepatitis B or C virus are important confounders which hinder an accurate and reliable interpretation of the data. In fact, more than one-third of patients with alcoholic LC exhibit antibodies against hepatitis C virus[11,12].

In the present study, the frequency of the association between alcoholic CP and LC has been assessed after exclusion of main confounders (hepatitis B or C virus,

non-alcoholic liver or pancreatic diseases, or surgery) and taken into account the major clinical manifestations, the morphological alterations detected by imaging studies, and the alterations of pancreatic and hepatic functions assessed by specific tests.

Our results clearly showed no overlapping between patients with alcoholic CP and alcoholic LC, not only regarding clinical manifestations, but also in imaging studies and functional tests. Furthermore, an inverse relationship was found between pancreatic and liver function in patients with CP or LC.

In our clinical study, the median age of patients at the moment of diagnosis was around a decade higher in LC than in CP (Table 1), due to the different natural history of these diseases[1,2,6,40]. Nevertheless, the age of patients at the time of inclusion in the study was not significantly different. As previously reported in other studies, the percentage of men was higher than that of women in all groups of alcoholics[21,41].

Regarding ethanol consumption, only the duration of ethanol intake was different among groups (20, 25 and 18.5 years for CP, LC and ASA, respectively) (Table 1). However, the mean daily ethanol intake and the total amount of ethanol consumed before diagnosis were not significantly different among groups, which is in agreement with those reported by other authors[2,8,19,42]. Moreover, the percentage of patients with ethanol intake > 150 g/d and the percentage of drinkers for more than 20 years were not significantly different. Therefore, the populations of the three groups in this study were homogeneous regarding ethanol intake.

The percentage of smokers was higher in CP (94.3%) and ASA (96.7%) than in LC (80.7%) (Table 1). Previous studies have reported that smoking is a risk factor for CP in alcoholics, which promotes the progression of the disease[31,43-45]. In addition, smoking has also been considered a risk factor in LC induced by hepatitis C virus[46]. The present study demonstrates that smoking is a risk factor not only for alcoholic CP but also for LC.

The BMI was slightly but significantly lower in CP than in LC, but not when compared with ASA. This slight difference may be ascribed to the presence of steatorrhea and diabetes mellitus in CP. In addition, the percentage of patients with BMI > 28 was significantly higher in LC than in CP and ASA, and these differences may by ascribed to retention of liquids in advanced LC.

The diagnosis of alcoholic CP is hindered in the initial stages of the disease due to the lack of specificity of clinical manifestations. Because of the difficulty in obtaining pancreatic biopsy, the diagnosis is established by combination of clinical manifestations, morphological alterations and impairment of the pancreatic exocrine and endocrine function[27,28].

In our study, 94.3% CP patients showed low E1 levels together with a high percentage of steatorrhea and IDDM, indicating that most patients were at an advanced stage of the disease. However, only four LC patients (7%) had E1 levels between 100 and 200 μg/g (Figure 1), and they neither exhibited steatorrhea nor any clinical or morphological manifestations of CP. In a similar fashion, only three LC patients (5.3%) exhibited IDDM, without the other clinical and morphological manifestations of CP. Only one of these patients exhibited 164 μg/g E-1 level; hence, the presence of CP in this patient could not be ruled out. Eleven LC patients exhibited NIDDM, which is common in LC[47] with normal E-1 level, but not a characteristic manifestation of CP[48]. In the ASA group, three subjects exhibited NIDDM, without symptoms of pancreopathy and normal E-1 and ICG tests.

The former studies that assessed the frequency of pancreatic alterations in patients with LC showed contradictory results. The frequency of pancreatic fibrosis compatible with CP in autopsies of LC patients was between 2% and 20% when the presence or absence of hepatitis B or C was not taken into account[14,16,18,19]. In addition, the age-related changes in morphofunctional parameters of the pancreas may be another confounder when the diagnosis of CP is based only on these parameters[49-53]. In a study using endoscopic ultrasonography and ERCP, Hastier *et al*[17] reported only moderate pancreatic alterations in 5.5% patients with alcoholic LC, without evolution to CP.

Some previous studies[51,54,55] on necropsies of patients with alcoholic LC showed very low frequency of the fibrotic pancreatic alteration characteristic of CP, which is predominantly perilobular fibrosis with heterogeneous distribution. In contrast, these patients exhibited diffuse and intralobular pancreatic fibrosis without calcifications or pseudocysts. Accordingly, these authors suggested that pancreatic morphological lesions in alcoholic LC correspond to a pathological process different from that of alcoholic CP.

It is worth noting that many studies on the association of CP and LC involve patients older than 50 years. It is well known that normal subjects at this age exhibit some morphofunctional pancreatic alterations[21,22,49-51,53] that could be taken for those characteristic of CP, but without evolution towards this disease. Consequently, morphofunctional pancreatic alterations with age may be another confounding factor. These findings might explain some of the discrepancies reported by different authors.

On the other hand, regarding the hepatic alterations, most LC patients in our study were at an advanced stage of the disease and showed ascites, encephalopathy and/or gastrointestinal hemorrhage as well as Child-Pugh B or C and markedly reduced PDR in the ICG test. However, only a few CP patients exhibited these manifestations, which were not ascribed to any hepatic disorder (Table 4).

There is also controversy concerning the frequency of LC in CP patients. Previous studies have reported that the presence of LC in patients with CP was variable, ranging between 5% and 30%[56]. Later, Angelini *et al*[19] found 12.5% of LC cases in CP patients. Although, in this study, cases with hepatitis C virus were not excluded, the authors did not find any relationship between the grade of hepatic histological alteration and the degree of pancreatic functional severity. Recently, Nakamura

et al[15] found no association between liver and pancreatic disease in a population of alcoholics with abdominal pain, after exclusion of patients with viral hepatitis[15]. Accordingly, only 5% of patients who had altered ERCP also exhibited Child-Pugh class B or C[15].

It should be taken into account that many hepatic alterations in patients with alcoholic CP are ascribed to cholestasis secondary to pancreatitis[57,58], and indeed, they are not characteristic of advanced alcoholic liver disease[19,55]. Moreover, most of these cases exhibit regression of liver fibrosis after biliary drainage[59].

In our study, there was no coincidence at all between severe alterations of the pancreatic function assessed by fecal E-1 test and severe alterations of the liver function assessed by ICG test. Furthermore, we found a strong inverse correlation ($r = -0.752$; $P < 0.001$) between these functions (Figure 3). Similarly, we found a significant correlation between PI and fecal E-1 test ($r = 0.759$; $P < 0.001$). These findings support the hypothesis of a different and independent etiopathogenesis of CP and LC associated with alcoholism[25]. Hayakawa *et al*[24] reported a negative correlation between pancreatic and liver functions, but only in patients with alcoholic liver disease. In this regard, a general increase in exocrine pancreatic secretion in LC patients has been reported[19,60]. Thus, Dreiling *et al*[23] have suggested a hypersecretory state of the pancreas in alcoholic LC, with increased volume output[16] and maintaining either normal or elevated bicarbonate and enzyme outputs[16,19,23,24]. This has been considered a washout phenomenon, resulting in a decreased tendency of ductal protein and calcium precipitation in these patients[16].

Hayakawa *et al*[24] have reported that pancreatic secretion increases in patients with different degrees of alcoholic liver disease, assessed by the cholcystokinin-secretin test, ICG test and liver histopathology. Moreover, these authors have found a significant inverse correlation between bicarbonate secretion and ICG clearance[24].

The hypersecretory state of the pancreas in alcoholics with LC has been ascribed to a reduced inactivation of secretin[60] or even to the increased portal pressure[24]. Recently, it has been confirmed by an experimental result that chronic alcoholism impairs the neurohormonal control of the pancreas, both at the central nervous system and acinar levels, promoting the secretory response to feeding or other stimuli[61]. All these findings regarding the inverse correlation between the alterations of liver and pancreatic function tests may be a reflection of some correlation in the etiology of both diseases.

In summary, the present study demonstrates the scarce coincidence in clinical manifestations, morphological alterations and organ function between CP and LC in alcoholic subjects. This finding, together with the inverse correlation between indexes of pancreatic and liver functions in these patients, supports the hypothesis that alcoholic CP and LC evolve in a different manner and have different etiopathogenesis. Accordingly, chronic alcoholism, although a necessary factor, is not a sufficient cause in their etiopathogenesis. Further studies should provide new insights into the different risk factors-other than alcoholism-involved in the etiopathogenesis of alcoholic CP and LC.

COMMENTS

Background

Despite sharing similar risk factors, medical literature regarding the simultaneous occurrence of chronic pancreatitis (CP) and liver cirrhosis (LC) in patients with chronic alcoholism is scarce and the results are uncertain. This lack of coincidence may rely on differences in methodology such as retrospective *versus* prospective studies, and the evaluated parameters such as clinical, functional, imaging or histopathological. However, it may also reflect the hypothesis that alcoholism is not a sufficient cause, but a cofactor, for the development of such diseases.

Research frontiers

This study has been carefully designed to investigate the coincidence in clinical manifestations, morphological alterations and organ function between CP and LC in alcoholic subjects. The results support the hypothesis that alcoholic CP and alcoholic LC evolve in a different manner and have different etiopathogenesis, despite sharing a common risk factor.

Innovations and breakthroughs

There is a lack of coincidence between CP and LC in alcoholic subjects. There is an inverse correlation between indexes of pancreatic and liver functions in these patients, supporting the hypothesis that chronic alcoholism, although a necessary factor, is not a sufficient cause in their etiopathogenesis.

Applications

This paper suggests the necessity for researching other factors together with chronic alcoholism involved in the development of CP or LC.

Peer review

Authors studied the possible association between CP and LC of alcoholic etiology, after excluding any other causes. This is an interesting study. It was undertaken according to a carefully designed plan and with adequate statistical considerations. The authors successfully provided the evidence, suggesting that CP and LC evolve in a different manner, which will be useful for clinical researchers of these diseases.

Abstract

AIM: To evaluate measurements of intragastric pH with the Bravo capsule system over a prolonged time.
METHODS: A Bravo capsule was placed inside the rat gastric body and pH was studied for periods up to five consecutive days. For comparison, a gastric fistula model was used. Effects of ghrelin and esomeprazole, with or without pentagastrin, on gastric pH were studied. In addition, effects of esomeprazole on plasma ghrelin, gastrin and somatostatin were analyzed.
RESULTS: All rats recovered after surgery. The average 24-h pH during free feeding was 2.3 ± 0.1 (n = 20) with a variation of 18% ± 6% over 5 d. Ghrelin, 2400 pmol/kg, t.i.d. increased pH from 1.7 ± 0.1 to 3.1 ± 0.3 (P < 0.01) as recorded with the Bravo system. After esomeprazole (1 mg/kg, 3 mg/kg and 5 mg/kg) there was a dose-dependent pH increase of maximally 3.4 ± 0.1, with day-to-day variation over the entire period of 8% ± 3%. The fistula and pH studies generated similar results. Acid inhibition with esomeprazole increased plasma ghrelin from 10 ± 2 pmol/L to 65 ± 26 pmol/L (P < 0.001), and somatostatin from 10 ± 2 pmol/L to 67 ± 18 pmol/L (P < 0.001).
CONCLUSION: pH measurements with the Bravo capsule are reliable, and comparable to those of the gastric fistula model. The Bravo system optimizes accurate intragastric pH monitoring over prolonged periods and allows both short- and long-term evaluation of effects of drugs and hormones.

INTRODUCTION

In the past, different techniques have been employed to study gastric acid secretion in rodents. The main principle for these methods has been collection of gastric juice, and in order to measure acid secretion, pH titration has been carried out. One of the earliest methods was the pylorus ligation technique[1]. The principle of this method is distension of the stomach as a potent stimulus of acid secretion. Later, this method was altered with an esophageal ligature[2,3], after which the stomach of the rat was removed and secretions analyzed. Esophageal ligation in the pylorus-ligated rat has been shown to significantly inhibit acid secretion by inhibition of central vagus function[2]. Since then,

the most reliable method has been the chronic fistula method[4-6] where a gastric fistula is implanted at the greater curvature of the stomach. This technique requires movement restriction of the animal which is in a conscious state during the study. The gastric contents are collected and acid output measured. This technique allows re-use of animals following a recovery period from the experimental procedure. Other methods used today are perfusion of the gastric lumen[7] and isolated perfused, as well as vascularly perfused rat stomach[8-10].

Most of the above studies have the drawback that they do not measure intragastric pH directly and are not very physiological, as the animal is either restrained or anesthetized. The main goal of this study was to test the feasibility of a capsule normally used in the clinical setting in humans to measure gastroesophageal reflux disease (Bravo system) for monitoring intragastric pH in the rat. The Bravo capsule system has primarily been used in humans[11-14], but also in animals[15] for diagnosis of gastroesophageal reflux disease.

The aim of the study was to evaluate the Bravo capsule for pH monitoring in the rat. To validate the method, we compared the data to those of the standard gastric fistula model.

MATERIALS AND METHODS

Animals

Sprague-Dawley male rats (300-350 g) were purchased from Scanbur B&K AB (Sollentuna, Sweden). The rats were housed in wire-meshed cages at 24℃ with constant humidity and 12:12 h light-dark cycle. The animals were fed *ad libitum* with a commercial rat diet consisting of pellet (LABFOR, Lactamin R36, Kimstad, Sweden) and tap water prior to the studies. The experiments were approved by the Animal Ethics Committee in northern Stockholm.

Surgery

Surgery was performed under anesthesia with pentobarbital sodium (50 mg/kg; Apoteket AB, Stockholm, Sweden) intraperitoneally, and Hypnorm (fentanyl citrate, 0.315 mg/kg and fluanisone 10 mg/kg; Janssen, Oxford, USA) intramuscularly. Marcain (bupivacaine hydrochloride, 2.5 mg/kg; AstraZeneca, Södertälje, Sweden) was given subcutaneously after surgery along the abdominal incision.

For the Bravo system studies, a midline incision was performed, and a small opening created in the proximal greater curvature, and gastric contents were evacuated. An externally pre-calibrated (buffers pH 1.07 and 7.1) Bravo capsule (an electronic sensor encapsulated in PVC-plastic, 25 mm × 5 mm × 5 mm; Synmed Medicinteknik AB, Spånga, Sweden) was placed inside the stomach with the pH sensor pointing distally and anchored with a suture. An indwelling silastic catheter (Dow Corning Co., Midland, MI, USA) was inserted into the external jugular vein.

For the gastric acid fistula studies, rats were provided with a plastic gastric fistula placed immediately proximal to the oxyntic gland area near the greater curvature. The fistula was closed between experimental periods. A silastic catheter was implanted into the external jugular vein for drug administration.

Studies of intragastric pH (Bravo system)

Studies of intragastric pH began in the morning 2 d after surgery. The studies were carried out in conscious rats, one experiment for each rat, under normal conditions, or after a 16-h fasting period in wire-bottom cages with free access to water. The animals gained weight (10 ± 3.4 g during 1 wk) and behaved in a normal fashion, with a normal feeding pattern throughout the experiments. At post-mortem examination, no mucosal lesions, obstruction of the pylorus or gastric distension were seen. Drugs were administered through the external jugular vein in all experiments.

The pH recorded by the Bravo capsule was transmitted to the Bravo receiver placed directly outside the cage. The sampling frequency was 6 Hz. The Bravo system was set for a 48-h registration period, after which the data were downloaded, batteries replaced and recording continued. This procedure was then repeated in two more 48-h periods.

All test compounds were dissolved and diluted in isotonic saline solution (sodium chloride, 9 g/L; 300 mosm/kg H_2O, Fresenius Kabi, Halden, Norway).

The effect of ghrelin on pH: The effect of ghrelin on intragastric pH was studied with ghrelin (2400 pmol/kg) given t.i.d (08:00, 12:00 and 16:00) for 5 d in a row (n = 7).

Evaluation of basal pH: Baseline pH was studied over 24 h under fed (n = 20) and fasting (n = 8) conditions.

Effect of esomeprazole on pH: The effect of increasing bolus doses of esomeprazole (AstraZeneca) (1 mg/kg, 3 mg/kg or 5 mg/kg iv, n = 10) or saline (iv, n = 8) was studied for 24 h in fed rats. Furthermore, the effect of esomeprazole (3 mg/kg iv, n = 10) or saline (iv, n = 8) was studied for 24 h in fasting rats.

The effect of pentagastrin and esomeprazole on pH: The effect of esomeprazole (3 mg/kg iv, n = 10) or saline (iv, n = 8) was studied under pentagastrin (NeoMPS, Strasbourg, France) infusion (90 pmol/kg per min, iv) over 6 h in both fed and fasting rats. In these experiments, the rats were restrained in Bollman cages to mimic the gastric fistula studies and for infusion of pentagastrin.

The effect of a 24-h infusion of pentagastrin (90 pmol/kg per min iv, n = 6), of esomeprazole (9 pmol/kg per min, n = 6), or saline (0.154 mol/L, n = 6) on pH was studied.

Plasma levels of gut hormones: The effect of esomeprazole (3 mg/kg iv) on plasma levels of ghrelin, gastrin and somatostatin was studied. A group of animals (n = 10) was divided into two treatment groups (each n = 5). All animals were treated with esomeprazole

daily during 1 wk. The first group of animals was then euthanized, while the other group was followed for another week without esomeprazole and then euthanaized. Blood was drawn and centrifuged, and plasma assayed for concentrations of ghrelin, gastrin and somatostatin.

For ghrelin measurements, the ghrelin (active) radioimmunoassay kit (Linco Research, St. Charles, MI, USA) was used, which utilizes ^{125}I-labeled ghrelin and ghrelin antiserum to determine the level of active ghrelin in plasma. For the analysis, a Gamma Master 1277 (LKB-Wallac, Perkin-Elmer Inc, Massachusetts, NH, USA) was used. The intra- and interassay coefficients of variation were 7% and 14%, respectively.

Somatostatin was analyzed using an EIA kit (EK-060-03) from Phoenix Pharmaceuticals, Burlingame, CA, USA), which reacts 100% to somatostatin-14 and somatostatin-28. The intra- and interassay coefficients of variation were 5% and 14%, respectively.

Gastrin was analyzed using C-terminal-directed CCK/gastrin antiserum 2609/10 (Rehfeld, 1978). Chloramine-T-labeled and HPLC-purified gastrin-17 (NeoMPS) was used as radioligand and gastrin-17 as calibrator/standard. The intra- and interassay coefficients of variation were 6% and 8%, respectively.

Studies of gastric acid secretion (fistula)

Studies of gastric acid secretion began 7 d after surgery. The animals gained weight (8 ± 2.6 g during 1 wk) and had normal behavior during the experimentation periods. Prior to each experiment, food was withheld for 18 h, but with free access to water. At the start of the experiments, the stomach was rinsed with 10-15 mL luke-warm tap water to evacuate remaining food, followed by a 30-min period before the experiments were started. During the experiments, the conscious rats were placed in Bollman cages. Gastric juice was collected at 30-min intervals, and volumes measured to the nearest 0.1 mL. pH was calculated by back-titration using 0.1 mmol/L sodium hydroxide. Acid output was calculated by multiplying the secretion volumes with hydrogen ion concentrations and expressed as μmol per 30-min period.

Baseline acid secretion was studied for 60 min followed by esomeprazole (3 mg/kg iv), after which acid secretion was studied for another 2 h. During the experiment, saline was administered in the same amount as collected from the gastric fistula to compensate for the volume loss during the experiment. Furthermore, baseline acid secretion was studied for 60 min, followed by an infusion of pentagastrin (90 pmol/kg per min) for 4 h. After 1 h of pentagastrin infusion, a bolus of esomeprazole (3 mg/kg iv) was administered and acid secretion studied for another 3 h.

Data and statistical analysis

The data obtained with the Bravo capsule analyzed using (POLYGRAM NET™ pH Testing Application software, Synmed Medicinteknik) in 48-h periods. Results of studies with esomeprazole were analyzed by calculating changes in pH at various timepoints from baseline (defined as 0.5 h prior to onset of studies). For analysis of the fistula studies, the first 30-min collection was discarded and the second collection used as baseline for comparison with esomeprazole and pentagastrin.

All data are mean ± SE. A Kruskal-Wallis test followed by Mann-Whitney *U* test was used for statistical comparisons using specific time points for pH. $P < 0.05$ was considered statistically significant. For comparison of the variability between the fistula and the Bravo system the Bland-Altman analysis was used[16,17]. The Prism software package 4.0 (GraphPad Software Inc., San Diego, CA, USA) was used for the statistical comparisons.

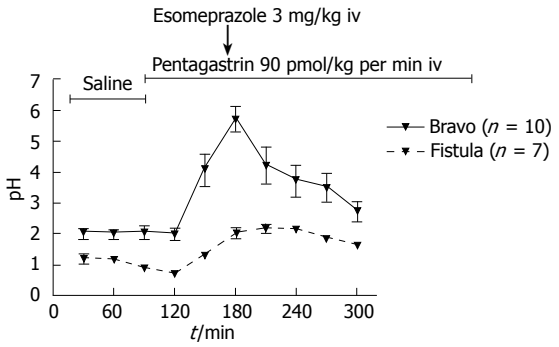

Figure 1 Change in pH ± SE in the Bravo system and gastric fistula model during fasting conditions after iv bolus of esomeprazole (3 mg/kg) and pentagastrin infusion (90 pmol/kg per min) for 2 h.

RESULTS

Comparison between the Bravo system and the fistula model

Pentagastrin resulted in a marked increase, 83 ± 9 mmol/L to 132 ± 8 mmol/L ($P < 0.05$) of acid output in the fistula model, which was not evident as a corresponding decrease in pH with the Bravo system. During esomeprazole treatment, there was a marked increase in pH from 2.0 ± 0.2 to 3.7 ± 0.5, as recorded with the Bravo system and correspondingly, a marked decrease in acid secretion from 105 ± 21 mmol/L to 31 ± 7 mmol/L in the fistula model ($P < 0.05$; Figure 1). Bland-Altman analysis of these conditions showed a high degree of agreement between the Bravo system and the fistula method as shown in Figure 2.

Evaluation of basal pH

A typical 120-h baseline registration including dose of esomeprazole (day 1, 3 and 5) with the Bravo system is shown in Figure 3. The feeding status did not alter the mean pH over 24 h, but increases in pH were observed during afternoon and night-time when animals were fed. The mean 24-h pH was 2.3 ± 0.1 during fed conditions and 2.5 ± 0.3 during fasted conditions, with 18% ± 6% variation during the next four 24-h periods. There was no difference in pH between daytime and night-time (1.4 ± 0.1 and 1.7 ± 0.2, respectively).

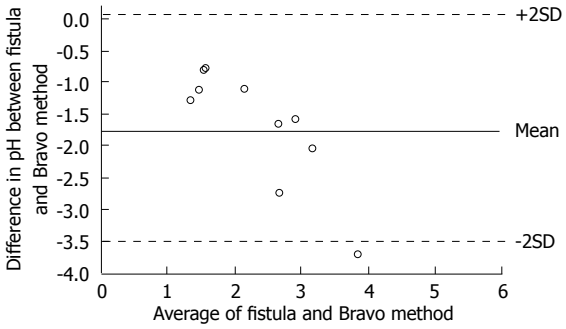

Figure 2 Bland-Altman analysis comparing the Bravo system with the fistula method. Mean value -1.7 with 2SD from -3.5 to 0.12.

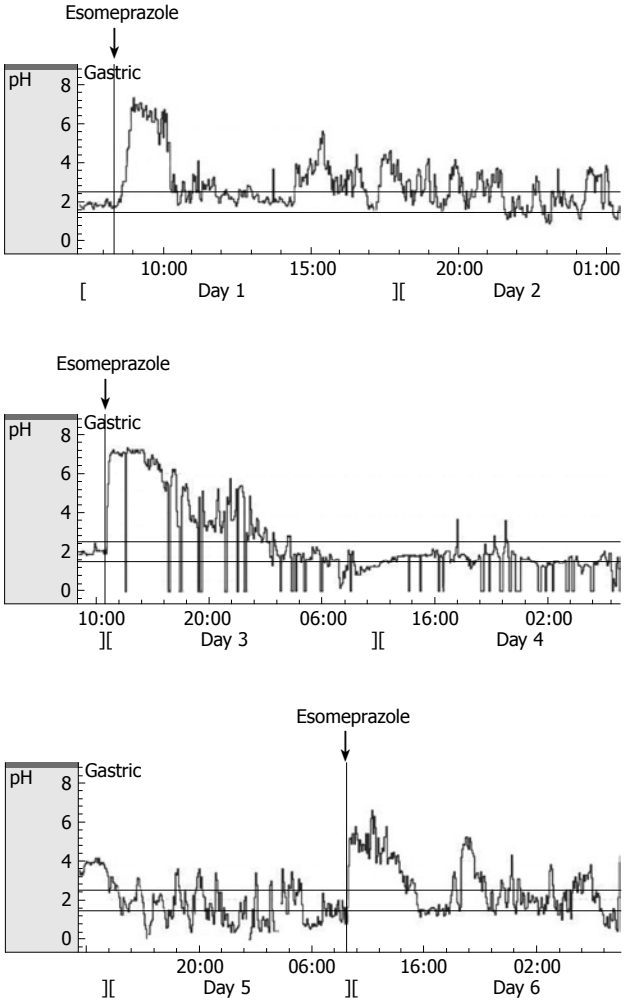

Figure 3 Standard recording with the Bravo system of intragastric pH in a rat during 6 d. The solid line indicates bolus doses of esomeprazole (3 mg/kg) given iv during 3 min under fed conditions.

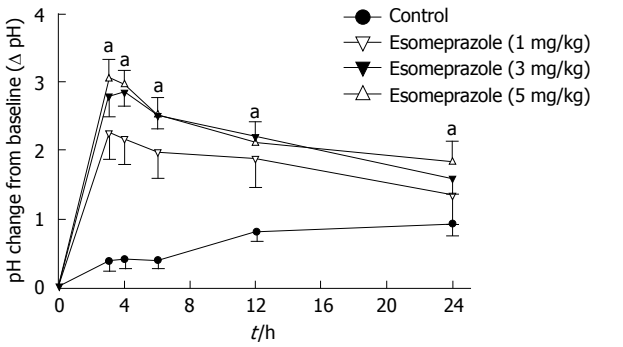

Figure 4 Change from baseline of intragastric pH ± SE after an iv bolus of esomeprazole in three different doses and saline studied for 24 h during fed conditions. Mean for all doses *vs* control and for dose 1 mg/kg vs 5 mg/kg ($^aP < 0.05$).

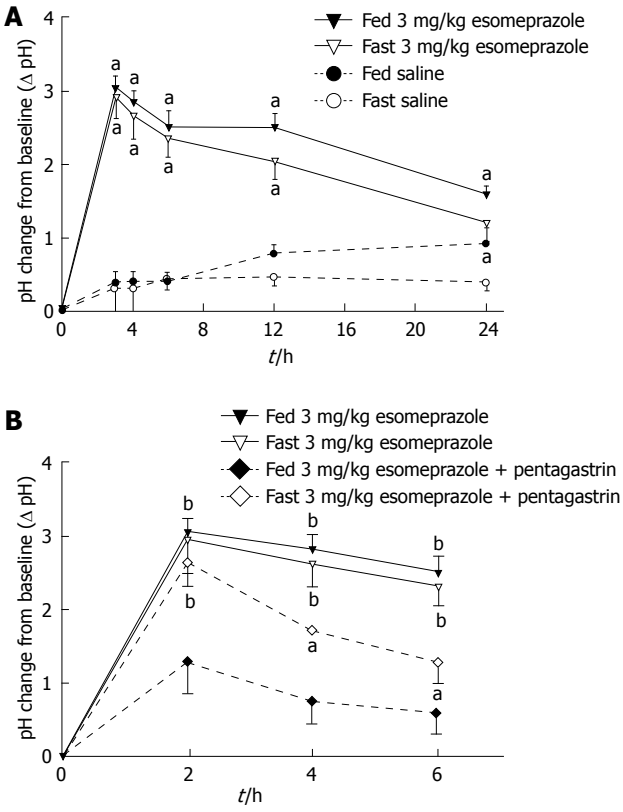

Figure 5 Changes of intragastric after an iv bolus of esomeprazole. A: Change from baseline of intragastric pH ± SE after an iv bolus of esomeprazole (3 mg/kg) or saline during fed or fasting conditions for 24 h ($^aP < 0.05$); B: Change form baseline of intragastric pH ± SE after an iv bolus of esomeprazole (3 mg/kg) or saline during pentagastrin (90 pmol/kg per min) infusion during fed or fasting conditions during 6 h. Mean esomeprazole *vs* esomeprazole and pentagastrin for fed ($^bP < 0.01$). Mean esomeprazole fed *vs* fasting esomeprazole and pentagastrin ($^aP < 0.05$). Mean esomeprazole fed *vs* fasting esomeprazole and pentagastrin ($^bP < 0.01$).

The effect of bolus esomeprazole on pH

As studied over 24 h, there was a dose-dependent increase of pH after esomeprazole, 1 mg/kg, 3 mg/kg, and 5 mg/kg, during free roaming conditions (Figure 4). Already 3 h after administration of esomeprazole, pH was significantly higher with 5 mg/kg, 3.1 ± 0.4, than with 1 mg/kg, 2.2 ± 0.4 ($P < 0.05$). Esomeprazole (3 mg/kg) increased intragastric pH during saline infusion over a 6-h period (2.5 ± 0.2) compared to baseline pH (1.6 ± 0.2), whereas saline did not ($P < 0.01$; Figure 5A).

Esomeprazole was equally effective during fed or fasting conditions (Figure 5A). As a control, saline did not change intragastric pH during either fed (baseline pH 1.4 ± 0.1) or fasting (baseline pH 1.6 ± 0.2) conditions (Figure 4, Figure 5A).

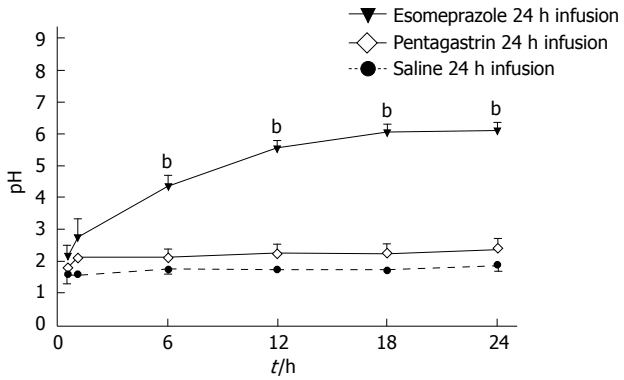

Figure 6 Change in mean pH ± SE over time. Mean esomeprazole (9 pmol/kg per min) 24 h infusion and pentagastrin (90 pmol/kg per min) infusion. ($^bP < 0.01$ *vs* control).

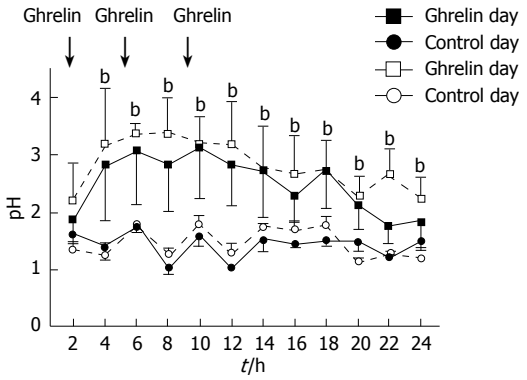

Figure 7 Change in mean pH ± SE during treatment with bolus dose ghrelin t.i.d. (2400 pmol/kg, $^bP < 0.01$ ghrelin *vs* control). There was no day-to-day difference in variation of the ghrelin response during the 5 d.

The effect of pentagastrin on pH

Pentagastrin alone did not change pH over 6 h compared with fed (baseline pH 2.1 ± 0.2) or fasting (baseline pH 2.4 ± 0.2) conditions. After esomeprazole (3 mg/kg), pentagastrin infusion markedly decreased pH from 2.0 ± 0.3 to 1.0 ± 0.2 ($P < 0.05$, Figure 5B). This effect was most marked in fed animals.

The effect of 24-h infusion of esomeprazole on pH

After esomeprazole (9 pmol/kg per min) the average 24-h pH was substantially higher than in the controls, 5.7 ± 0.3 and 2.1 ± 0.2, respectively ($P < 0.01$). Pentagastrin alone did not change pH over the 24-h infusion period as compared to saline (Figure 6).

The effect of ghrelin on pH

Administration of ghrelin, t.i.d markedly increased gastric 24-h pH from day 1 (2.5 ± 0.6) to day 5 (2.8 ± 0.5) compared to control day 1 (1.4 ± 0.1) and day 5 (1.5 ± 0.2) ($P < 0.01$; $n = 7$). There was no significant day-to-day variation of the ghrelin effect during the five days (Figure 7).

Plasma levels of gut hormones

Esomeprazole (3 mg/kg) t.i.d resulted in a marked increase in plasma ghrelin and somatostatin concentrations as shown in Figure 8 ($P < 0.001$). Plasma gastrin, however, remained stable over the same time period (Figure 8).

DISCUSSION

This study demonstrates that the Bravo system can be used for studies of intragastric pH in rats and that the results are comparable to those of a standard fistula model. The system allows for long-term studies during unrestrained living conditions. There are several advantages with the use of the Bravo system. Previous models for studies of gastric acid secretion do not allow measurements of pH over a long time. Furthermore, during these studies, the animals are kept under stressful conditions, which to a certain degree, may influence the responsiveness of the animals to different stimuli. The Bravo system uses a telemetric system that records gastric pH during 24 h for up to five consecutive days. The day-to-day variation was within acceptable limits. The system allows for real-time recordings of intragastric pH with the ability to record from the start of a treatment until a detectable effect is seen. The system is suitable for long-term studies with continuous infusions that are difficult to perform using the fistula model, as the animals do not tolerate being restrained in cages during prolonged studies. The Bravo recording system is also a digital recording system, which means that primary data are logged, and permits detailed measurements as determined by the set sampling frequency.

The data are, however, limited to pH-values as no secretion volumes are obtained. With the gastric fistula model, recordings are made over no less than 15-min periods, which can be a limiting factor as regards rapid changes in pH, i.e. drug effects. However, in the fistula model, secretion volumes are recorded, which permit calculation of a true acid output. The Bravo system has a few drawbacks. It is expensive, the battery life of the capsule is short (5 d) and therefore, the animals can only be used in studies for about a week. This means that experiments must start immediately after the operation (in this case 2 d after the surgical procedure), and the recovery from surgery may influence the results and the comparison with the fistula model. Despite this, the Bravo system seems to be well tolerated, as the stomach of the rats did not show any abnormalities or mucosal lesions upon autopsy. The animals also gain weight and behaved in a normal fashion during the experiments.

From a physiological viewpoint, our results demonstrated expected results; intragastric pH in rodents was stable over time, with a slight increase during the night during fed conditions.

In addition, treatment with esomeprazole and pentagastrin gave expected results. The agreement between the Bravo system and the established fistula method was evaluated employing a Bland-Altman analysis. When the two methods were compared, the pH results obtained with the Bravo system were comparable to those obtained using the fistula model. The differences lie within acceptable limits of agreement approximately 95% of the time, and the variability

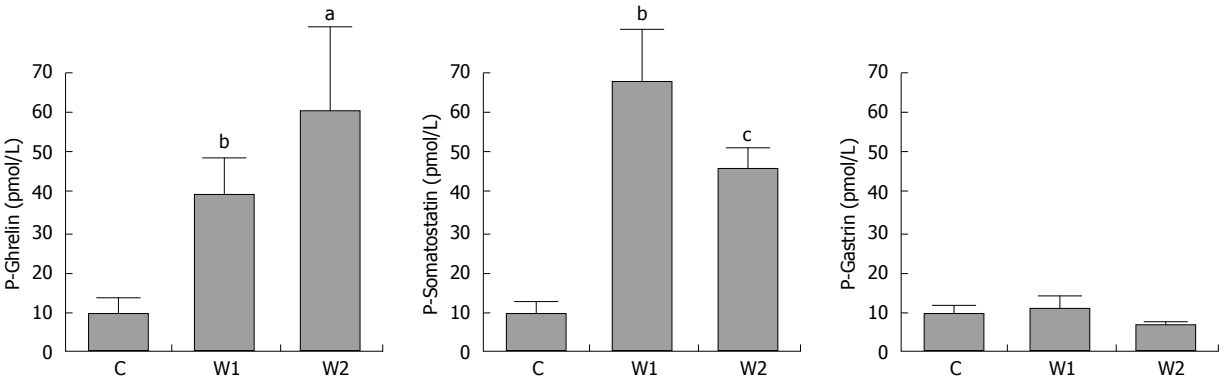

Figure 8 Gut peptide concentrations during treatment week 1 (W1) and week 2 (W2). The two groups of animals (n_{tot} = 10) were treated during one week with esomeprazole (3 mg/kg). After the first treatment week the first group (n = 5) were euthanaized and plasma were taken for peptide measurements. The other group (n = 5) went on for another week without any drug treatment and then euthanaized and plasma taken for analysis of peptides. $^{a}P < 0.05$; $^{b}P < 0.01$; $^{c}P < 0.001$ *vs* control.

was consistent across the graph; the scatter around the baseline (mean) did not increase with increasing means.

During comparative studies, the animals were restrained in Bollman cages for infusion of pentagastrin, so the experimental conditions were the same. During esomeprazole treatment, pH rose and gastric acid output decreased accordingly. There seemed to be a slight delay in response to esomeprazole when studied by the fistula method as compared to the Bravo system. The reason for this is probably related to the fact that the secretory response depends on the physical emptying of gastric contents from the fistula until measurements can be done. As judged from our experiments, this causes a delay of the recorded response of about 30 min. Pentagastrin increased acid output, but no change was seen in intragastric pH with the Bravo system. This is explained by the fact that a change in secretion volume does not affect the pH recorded, even though acid output is changed. The fact that pH does not change when introducing pentagastrin may be due to the constantly low basal pH level in the rat stomach.

The gut hormones assayed in this study, ghrelin, gastrin, and somatostatin, are all found in the mucosa of the stomach[18]. They operate in a coherent inhibitory/stimulatory fashion against one another, i.e. increasing levels of somatostatin stimulates ghrelin, while gastrin is inhibited[19,20]. Pentagastrin acts as an agonist on acid secretion and has a stimulatory effect on somatostatin, which in turn down-regulates the release of gastrin so that excessive amounts of acid are not produced[20]. The fact that basal plasma gastrin levels remained stable with the Bravo system indicates that the Bravo capsule by itself does not distend the stomach to such a degree that gastrin levels are affected[21].

Our results using the Bravo system, with an increase of intragastric pH during 1 wk after three times daily, administration of ghrelin, are in accordance with earlier studies[19,22], but at variance with another[23]. This may be explained by the fact that different methods for studying gastric acid secretion have been employed, some of which are dependent on gastric motility for the emptying of gastric secretions through the fistula. By using the Bravo system, we found no desensitization of the pH response to ghrelin. This is at variance with our previous studies on intestinal motility, in which a loss of the ghrelin response was shown[19,24]. This might be due to the fact that motility was stimulated by a continuous infusion of the hormone, whereas the pH effect was brought about by repeated injections of ghrelin, a form of administration that is considered less liable to desensitization effects. As ghrelin not only increases intragastric pH, but also stimulates gastric emptying in rodents[22,23,25,26]. This may be an erroneous factor in determining acid secretion using the fistula method.

With esomeprazole treatment, plasma concentrations of ghrelin and somatostatin were increased. This effect was maintained for 1 wk after esomeprazole treatment. The underlying mechanism for this increase in plasma ghrelin and somatostatin is not yet fully understood, but may be due to a direct effect of esomeprazole on ghrelin and somatostatin, but also by an indirect effect through changes in gastric pH. The counter-balancing effects between pentagastrin (low pH) and esomeprazole (high pH) as regards ghrelin levels point to a physiological role of ghrelin in the control of gastric acid secretion[27,28]. The rise in somatostatin concentration is likely due to a direct effect of the continuous doses of ghrelin, as pH was not affected. The lack of elevated levels of gastrin for the two groups are probably attributed to the increase in somatostatin[29] or, although less likely, low doses of esomeprazole[30,31].

To conclude, the Bravo capsule system is to be used for prolonged studies of gastric pH in free roaming conscious rats over days and is well tolerated, and could serve as a complement to the gastric fistula model, as shown by acid and gut hormone secretion measurements.

COMMENTS

Background

The pharmacological treatment of gastrointestinal acid-related diseases aims at providing ulcer and mucosal healing, symptom relief and improved quality of life. Gastric acid inhibitory compounds are widely used in the clinical setting in order to treat not only benign gastric and duodenal ulcers, but also gastritis and reflux esophagitis. Over the past two decades, there has been a number of reports on the use of proton pump inhibitors (PPIs) such as omeprazole and the following competitors. The PPIs are activated in the acid environment in the stomach and inhibit the final step of gastric acid secretion. They bind in a non-competitive way to the H^+, K^+ -ATPase and inhibit secretion. Even though the PPIs have many good properties compared to other treatment regims, and are considered the treatment of choice in acid-related gastrointestinal diseases, there are drawbacks with PPI treatment. For instance, the onset of action is slow as compared to that of H2-receptor antagonists, which induce an immediate acid inhibition, and the duration of action may be too short giving room for night-time acid breakthrough. So far, treatments have got around this problem by recommending a two-dose regimen. Pharmaceutical development has been directed against finding a compound with profound acid inhibitory action over prolonged periods of time, not permitting night-time acid breakthrough to take place. The development of such drugs, however, require new methods of studying gastric acid secretion over prolonged periods, up to 120 h over or more.

Research frontiers

Research concerning acid-related diseases has been focused on PPIs targeted against the H^+, K^+ -ATPase of the stomach and H2-receptor antagonists. Recent studies have shown that the proton pump is the most likely candidate for a sustainable therapeutic application in the regulation of acid suppression. One of the hurdles in this field is the possibility to perform long-term measurements of acid secretion in the development of pharmacological treatment of acid diseases. Although PPIs are highly effective as a class, differences in their pharmacokinetics, such as bioavailability, metabolism, and elimination half-life, may translate into differences in clinical outcomes.

Innovations and breakthroughs

Over the latest years, new drugs have emerged on the market, such as being PPIs (3rd generation), new potassium channel blocking agents that inhibit gastric secretion (P-CAP), and even combinations of PPIs and H2-receptor antagonists. A second line to this further development is to be expected and with this new method, developed as a tool for evluation of such long-acting drugs, may become a feasible tool in the clinical setting for treatment of acid-dependent diseases.

Applications

Our research demonstrates stable recordings with the Bravo capsule system in the rat. The animals were given PPI and ghrelin and this resulted in an almost immediate response in pH, sustained during approximately 6 h. The capsule model was compared with the fistula model and showed agreement in compliance between the two methods. This indicates that the capsule model could eventually replace the fistula model. It seems better to use the former method because of less strain on the rats, and easier and more gentle handling and experimental procedures. Furthermore, the Bravo system set-up is easy to manage and the information recorded allows many different analysis variables. The system also records over five consecutive days, which previously has not been possible in this setting.

Terminology

Bravo capsule system: A catheter-free system used to measure esophageal pH (acidity) levels in patients who have or are suspected of having gastroesophageal reflux disease, but has now also been used for intragastric titration of pH.

Peer review

The measurement of intragastric pH with the Bravo capsule system is comparable to that of the gastric fistula model, and is useful for prolonged studies of gastric pH, even in free roaming conscious rats over days, as described. Although further studies are required, this study indicates the novel possibility for investigating the acid and gut hormone secretion under more physiological conditions.

Abstract

AIM: To investigate the effect of *Gardenia jasminoides* (GJ) on cerulein-induced acute pancreatitis (AP) in mice.
METHODS: C57BL/6 mice weighing 18-20 g were divided into three groups. (1) Normal saline-treated group, (2) treatment with GJ at a dose of 0.1 g/kg, (3) treatment with GJ at a dose of 1 g/kg. GJ was administered orally (n = 6 per group) for 1 wk. Three hours later, the mice were given an intraperitoneal injection of cerulein (50 μg/kg), a stable cholecystokinin (CCK) analogue, every hour for a total of 6 h as described previously. The mice were sacrificed at 6 h after completion of cerulein injections. Blood samples were obtained to determine serum amylase, lipase and cytokine levels. The pancreas was rapidly removed for morphologic examination and scoring. A portion of pancreas was stored at -70℃ and prepared for the measurement of tissue myeloperoxidase (MPO) activity, an indicator of neutrophil sequestration, and for reverse-transcriptase PCR (RT-PCR) and real-time PCR measurements.
RESULTS: Treatment with GJ decreased significantly the severity of pancreatitis and pancreatitis-associated lung injury. Treatment with GJ attenuated the severity of AP compared with saline-treated mice, as shown by reduction in pancreatic edema, neutrophil infiltration, serum amylase and lipase levels, serum cytokine levels, and mRNA expression of multiple inflammatory mediators.
CONCLUSION: These results suggest that GJ attenuated the severity of AP as well as pancreatitis-associated lung injury.

Key words: Gardenia jasminoides; Acute pancreatitis; Cerulein

INTRODUCTION

Acute pancreatitis (AP) is an acute inflammatory process of the pancreas that frequently involves peri-pancreatic

tissues and remote organ systems. The severity of the disease varies widely, the clinical course is unpredictable, and specific therapy is limited[1-4]. It is generally believed that the severity of pancreatitis is determined by events that occur after acinar cell injury. Pancreatic acinar cells synthesize and release cytokines and chemokines, resulting in the recruitment of inflammatory cells such as neutrophils and macrophages. This leads to further acinar cell injury, resulting in the elevation of various pro-inflammatory mediators such as interleukin (IL)-1β, IL-6, tumor necrosis factor (TNF)-α[5,6]. The release of inflammatory mediators such as TNF-α and IL-1β during AP propagates a complex cascade of events between tissue vasculature and inflammatory cells. These inflammatory cells and mediators play a role in the systemic manifestations besides modulating pancreatic acinar cell injury; blocking the cytokine cascade in its early stage, and ameliorating the disease and its systemic complications.

Gardenia jasminoides (GJ) is widely employed in several Asian countries as a natural colorant, and has been used in Chinese traditional medicine for its homeostatic, antiphlogistic, analgesic and antipyretic effects. Its main components include geniposide and crocin[7]. These components exhibit antioxidant, cytotoxic, antitumor and neuroprotective effects[8-10]. However, the impact of GJ and its components on cerulein-induced AP have not been examined.

The present study was designed to confirm the preventive effects of GJ in a mouse model of cerulein-induced AP. In order to gain a better insight into the mechanism of action of the observed anti-inflammatory effects of GJ, we investigated the effects of GJ on (1) pancreas weight/body weight (PW/BW) ratio, (2) pancreatic histology, (3) serum amylase and lipase levels, (4) serum level of pro-inflammatory mediators, such as TNF-α, IL-1β and IL-6, and (5) lung histology.

MATERIALS AND METHODS

Materials

Avidin-peroxidase and 2'-AZINO-bis (3-ethylbenzithiazoline-6-sulfonic acid) tablets, cerulein, Tris-HCl, NaCl, Triton X-100, hexadecyltrimethylammonium bromide and etramethylbenzidine were purchased from Sigma (St. Louis, MO, USA). Anti-mouse TNF-α, IL-6 and IL-1β antibodies, recombinant TNF-α, IL-6 and IL-1β were purchased from R&D Systems (Minneapolis, MN, USA).

Preparation of GJ

GJ was prepared by decocting the dried prescription of herbs with boiling distilled water. The decoction time was about 3 h. Their voucher specimens were deposited at the Herbarium at the College of Oriental Medicine, Won-Kwang University.

Animal models

All experiments were performed according to protocols approved by the Animal Care Committee of the university. Female C57BL/6 mice (6-7-wk old, weighting 18-20 g) were purchased from Orient Bio Co. (Sungnam, KyungKiDo, Republic of Korea). All animals were bred and housed in standard shoebox cages in a climate-controlled room with an ambient temperature of 23 ± 2℃ and a 12-h light-dark cycle for 7 d. Animals were fed standard laboratory chow, given water and randomly assigned to control or experimental groups. The mice were fasted for 18 h before induction of AP. Six mice were included in each experimental group.

Experimental design

AP was induced by supramaximal concentration of cerulein (50 μg/kg), a stable CCK analogue, by administering it intraperitoneally every hour for a total of 6 h as described previously[11]. The mice were fed orally with GJ (1 g/kg, 0.1 g/kg, $n = 6$ each) or normal saline (control group, $n = 6$), followed by intraperitoneal injection of cerulein (50 μg/kg) or saline every hour for a total of 5 h. The mice were sacrificed at 12 h after the completion of cerulein injections. Blood samples were obtained to determine serum amylase, lipase and cytokine levels. The pancreas was rapidly removed for morphologic examination and scoring. A portion of pancreas was stored at -70℃ and prepared for the measurement of tissue myeloperoxidase (MPO) activity, an indicator of neutrophil sequestration, and for reverse-transcriptase PCR (RT-PCR) and real-time PCR measurements.

Histological analyses

The entire pancreas of at least six mice from each treatment group was examined and semi-quantitated based on the degree of necrosis, vacuolization, inflammation, and edema. Using the previously described method of Ethridge *et al*[12], entire sections (a minimum of 100 fields) of pancreas were examined from each sample and scored on a scale of 0-3 (0 being normal and 3 being severe), based on the number of necrotic acinar cells, and the presence of vacuolization, interstitial edema, and interstitial inflammation. The characteristics included were: presence of acinar-cell ghosts, vacuolization and swelling of the acinar cells, and/or the destruction of the histo-architecture of the whole or parts of the acini.

Enzyme-linked immunosorbent assay (ELISA)

ELISA for TNF-α, IL-1β and IL-6 (R&D Systems) was carried out in duplicate in 96-well plates (Nunc, Denmark), coated with each of the following: 100 μL aliquots of anti-mouse IL-6, IL-1β and TNF-α monoclonal antibodies at 1.0 μg/mL in PBS at pH 7.4, and incubated overnight at 4℃. The plates were washed in PBS containing 0.05% Tween-20 (Sigma) and blocked with PBS containing 1% BSA, 5% sucrose and 0.05% NaN_3 for 1 h. After additional washes, the standards were added and incubated at 37℃ for 2 h. After incubation for 2 h at 37℃, the wells were washed, and the following were added: 0.2 μg/mL of biotinylated anti-mouse TNF-α, IL-1β and IL-6, and again incubated at 37℃ for 2 h. After the wells were washed, avidin-peroxidase

was added and the plates were incubated for 20 min at 37℃. The wells were again washed and ABTS substrate was added. Color development was measured at 405 nm using an automated microplate ELISA reader. A standard curve was run on each assay plate using recombinant TNF-α, IL-1β and IL-6 in serial dilutions.

Measurement of serum amylase and lipase

Arterial blood samples for determination of serum amylase and lipase were obtained 12 h after induction of pancreatitis. The mice were anesthetized with an intraperitoneal injection of ketamine (80 mg/kg) and xylazine (4 mg/kg). After anesthetization, blood samples were withdrawn from the heart. Serum amylase was measured using ADIVA 1650 (Bayer, USA). Serum lipase was measured using a Cobas-mira (Roche, USA).

mRNA expression

mRNA transcripts were analyzed by RT-PCR in mouse pancreatic tissues. Total RNA was isolated from the mouse pancreas using Qiagen RNeasy kit and subjected to reverse transcription using SuperScript Ⅱ RT (Invitrogen). Taqman quantitative RT-PCR with a 7700 Sequence Detection System was done according to the instructions of the manufacturer (Applied Biosystems). For each sample, triplicate test reactions and a control reaction lacking reverse transcriptase were analyzed for expression of the gene of interest, and results were normalized to those of the 'housekeeping' HPRT mRNA. Arbitrary expression units were calculated by division of expression of the gene of interest by ribosomal protein HPRT mRNA expression. The forward, reverse and probe oligonucleotide primers for multiplex real-time TaqMan PCR were as follows: for mouse TNF-α (forward, 5'-TCTCTTCAAGGGACAAGGCTG-3'; reverse, 5'-ATAGCAAATCGGCTGACGGT-3'; probe, 5'-CCCGACTACGTGCTCCTCACCCA-3'), for mouse IL-1β (forward, 5'-TTGACGGACCCCAAAAGAT-3'; reverse, 5'-GAAGCTGGATGCTCTCATCTG-3'; universal probe, M15131.1-Roche Applied Science), for mouse IL-6 (forward, 5'-TTCATTCTCTTTGCTCTTGAATTAGA-3'; reverse, 5'-GTCTGACCTTTAGCTTCAAATCCT-3'; universal probe, M20572.1-Roche Applied Science), for mouse HPRT (forward, 5'-GACCGGTCCCGTCATGC-3'; reverse, 5'-CATAACCTGGTTCATCATCGCTAA-3'; probe, 5'-ACCCGCAGTCCCAGCGTCGT-3').

MPO estimation

Neutrophil sequestration in the pancreas was quantified by measuring the tissue MPO activity[11,12]. Tissue samples were thawed, homogenized in 20 mmol/L phosphate buffer (pH 7.4), and centrifuged (10000 × *g*, 10 min, 4℃), and the resulting pellet was resuspended in 50 mmol/L phosphate buffer (pH 6.0) containing 0.5% hexadecyltrimethylammonium bromide (Sigma). The suspension was subjected to four cycles of freezing and thawing and was further disrupted by sonication (40 s). The sample was then centrifuged (10000 × *g*, 5 min, 4℃), and the supernatant used for the MPO assay. The reaction mixture consisted of the supernatant, 1.6 mmol/L tetramethylbenzidine (Sigma), 80 mmol/L sodium phosphate buffer (pH 5.4), and 0.3 mmol/L hydrogen peroxide. The mixture was incubated at 37℃ for 110 s, the reaction was terminated with 2 mol/L of H_2SO_4, and the absorbance was measured at 450 nm. This absorbance was then corrected for the DNA content of the tissue sample (fold increase over control).

Statistical analysis

The results were expressed as means ± SE. The significance of change was evaluated using Student's *t* test. Differences between the experimental groups were evaluated by using analysis of variance. Values of $P < 0.05$ were accepted as statistically significant.

RESULTS

Effect of GJ on PW/BW ratio, serum amylase and lipase activity in cerulein-induced AP

To assess the effect of GJ on the PW/BW ratio, the pancreatic weight was divided by the body weight of the mice. GJ reduced significantly the PW/BW ratio, compared with the normal saline-treated group, in a dose-dependent manner ($P < 0.05$) (Figure 1A). The serum levels of amylase and lipase are commonly used as markers of AP[13,14]. GJ reduced significantly the serum amylase and lipase levels in cerulein-induced AP (Figure 1B and C).

Effect of GJ on serum levels of TNF-α, IL-1β and IL- in cerulein-induced AP

The serum levels of pro-inflammatory cytokines, such as TNF-α, IL-1β and IL-6 were increased in cerulein-induced AP[15-17]. GJ decreased significantly the levels of TNF-α and IL-1β in the cerulein-induced AP. Moreover, GJ was associated with a trend towards suppression of IL-6, although the difference was not statistically significant (Figure 2).

Effect of GJ on mRNA expression of TNF-α, IL-1β and IL-6 in cerulein-induced AP

The GJ-pretreated group showed significant reduction of pancreatic tissue mRNA expression of pro-inflammatory cytokines such as TNF-α, IL-1β and IL-6, in a dose-dependent manner, compared with the saline pretreated group in cerulean-induced AP (Figure 3).

Effect of GJ on pancreatic histology in cerulein-induced AP

In normal mice, the histological features of the pancreas were typical of a normal architecture. Mice treated with i.p. injections of cerulein developed acute necrotizing pancreatitis. Histological examination of the pancreas (at 12 h after the injection of cerulein) revealed tissue damage characterized by inflammatory cell infiltrate and acinar cell necrosis. GJ pretreatment resulted in significant reduction in pancreatic injury (Figure 4A). The presence

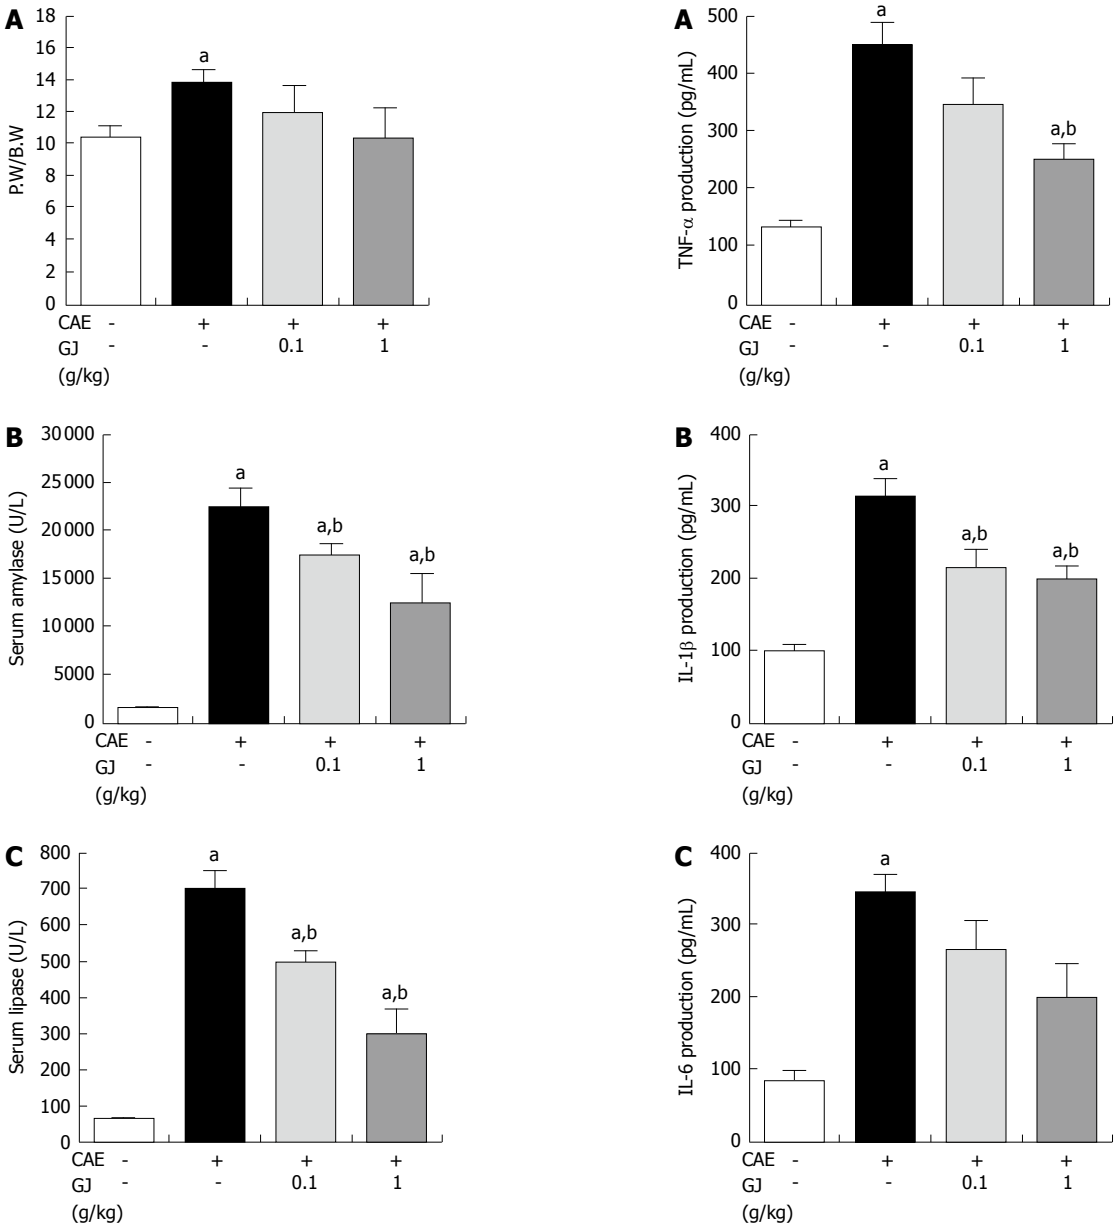

Figure 1 Effects of GJ pretreatment on the (A) PW/BW, (B) serum amylase activity, and (C) serum-lipase activity in cerulein induced AP. The study groups were treated as indicated in the experimental protocol. The mean ± SE of the six animals are shown. [a]*P* < 0.05 *vs* saline treatment; [b]*P* < 0.05 *vs* cerulein treatment alone.

Figure 2 Effect of GJ on (A) TNF-α, (B) IL-1β and (C) IL-6 secretion in cerulein-induced AP. Mice were treated as indicated in the experimental protocol. The mean ± SE of six animals are shown. The study groups were treated as indicated in the experimental protocol. [a]*P* < 0.05 *vs* saline treatment; [b]*P* < 0.05 *vs* cerulein treatment alone.

of edema, inflammation, vacuolization, and necrosis were reduced significantly in the GJ-pretreated group compared with the normal saline-pretreated group, in a dose-dependent manner (Figure 4B).

Effect of GJ on lung histology in cerulein induced AP

Lung injury commonly develops early in AP. AP-associated lung injury is characterized by edema and inflammation[18]. In addition to the pancreas, we assessed the lungs after cerulein administration. Histological examination of lung sections (at 12 h after the injection of cerulein) revealed tissue damage characterized by edema and inflammatory cell infiltrate. GJ pretreatment resulted in significant reduction in lung injury. The histological sections were scored for edema and inflammation. The lungs of the GJ-pretreated mice had significantly less edema and inflammation compared with lungs from saline-injected control animals (Figure 5).

Effect of GJ on MPO activity of lung and pancreas in cerulein induced AP

As an additional quantitative assessment of the severity of the inflammatory response, we measured MPO activity, an indicator of neutrophil sequestration, in the pancreas and lung following induction of AP in the GJ-pretreated mice and saline-injected control animals. MPO activity in the pancreas and lung in the GJ-pretreated mice was significantly less compared with the saline-injected control animals (Figure 6).

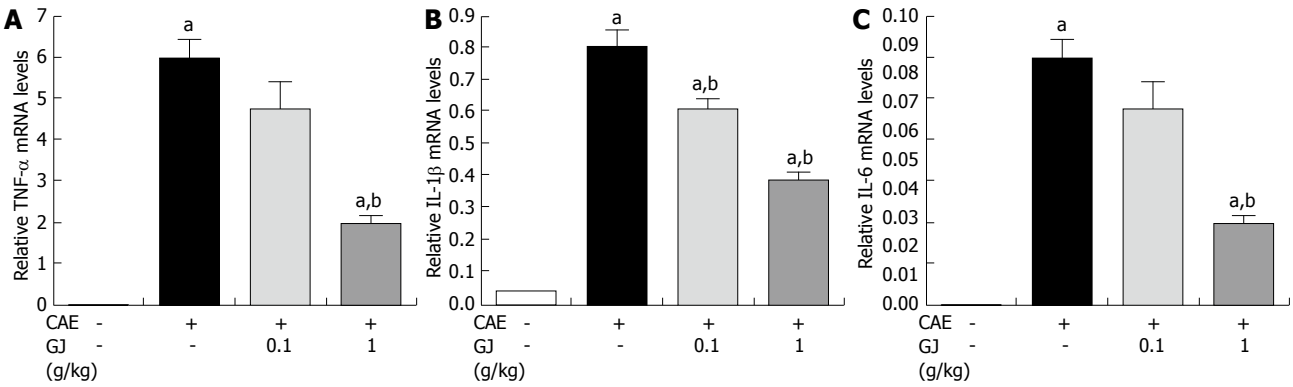

Figure 3 Effect of GJ on TNF-α, IL-6 and IL-1 mRNA levels in cerulein-induced AP. The mice were sacrificed at 1, 3 and 6 h after six injections. Levels of pancreatic mRNA were quantified by real-time PCR for (A) TNF-α, (B) IL-1β, and (C) IL-6. The mean ± SE of six animals are shown. [a]*P* < 0.05 *vs* saline treatment; [b]*P* < 0.05 *vs* cerulein treatment alone.

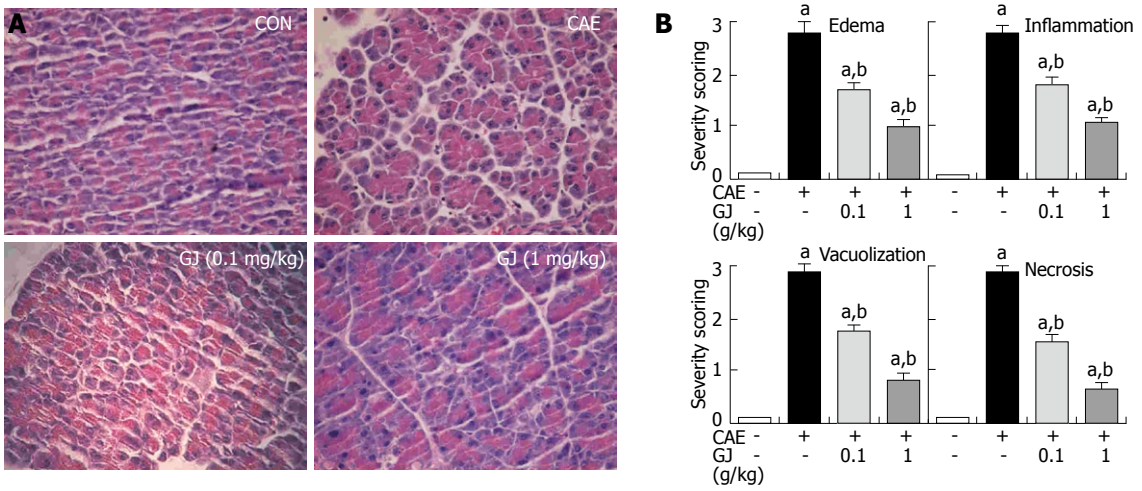

Figure 4 Effects of the GJ on pancreatic inflammatory changes following pancreatitis. A: Representative H&E-stained sections of pancreas in control mice (CON) who were not given cerulein, in mice given cerulein (CAE), and in mice given GJ (1 mg/kg) at the same time as the first cerulein injection; B: Histological sections of pancreas harvested 12 h after injection of saline (CON), cerulein alone, or GJ (1 or 0.1 mg/kg) given at the same time as the first injection of cerulein. The results were scored from 0 (normal) to 3 (severe) for edema, inflammation, vacuolization, and necrosis. [a]*P* < 0.05 *vs* saline treatment; [b]*P* < 0.05 *vs* cerulein treatment alone. The figure shows the results of one experiment in which 4-5 mice were tested per group. The results obtained were similar to those in three additional experiments (x 200).

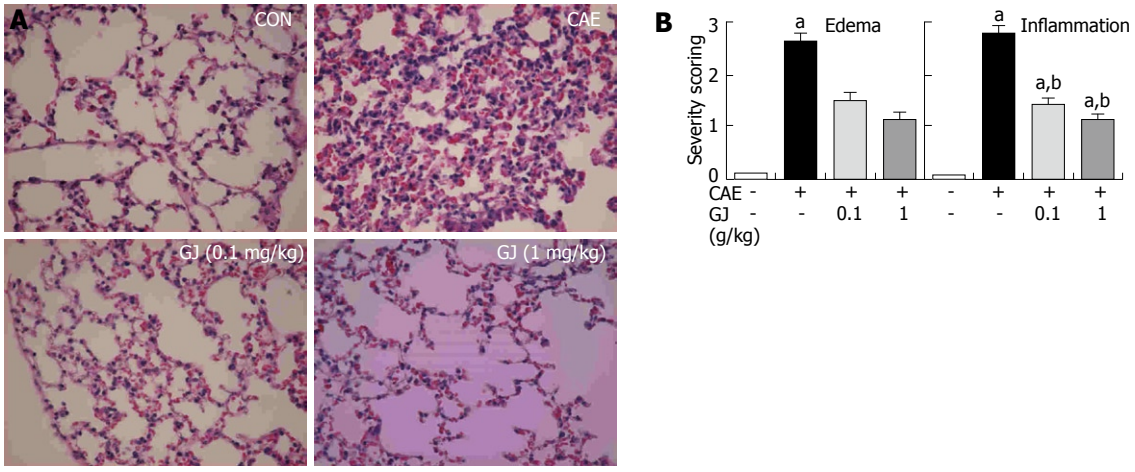

Figure 5 GJ reduced the severity of AP-associated lung injury. A: Representative H&E-stained sections of the pancreas in control mice (CON) not given cerulein, in mice given cerulein (CAE), and in mice given GJ (1 mg/kg) at the same time as the first cerulein injection; B: Histology sections of the lung harvested 12 h after administration of saline (CON), cerulein alone, or GJ (1 or 0.1 mg/kg) given at the same time as the first injection of cerulein. The results were scored from 0 (normal) to 3 (severe) for edema, inflammation, vacuolization, and necrosis. [a]*P* < 0.05 *vs* saline treatment; [b]*P* < 0.05 *vs* cerulein treatment alone. The figure shows one experiment in which 4-5 mice were tested per group. The results obtained were similar to those in three additional experiments (x 200).

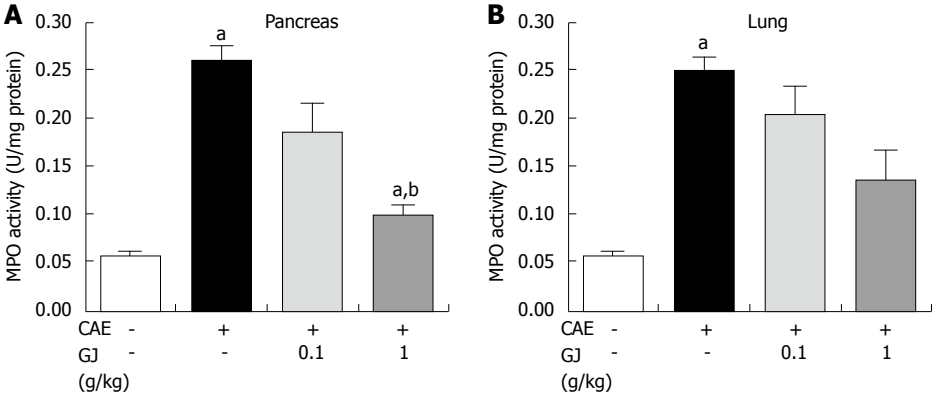

Figure 6 MPO activity was measured in the pancreas 6 h after completion of the cerulein injections and in saline-injected control mice (CON). The data are expressed as MPO activity (U/mg protein). [a]*P* < 0.05 *vs* saline treatment; [b]*P* < 0.05 *vs* cerulein treatment alone. The figure shows the results of one experiment in which 5-6 mice were tested per group.

DISCUSSION

AP is associated with a high rate of morbidity and mortality. The mortality rate in patients with severe AP is as high as 20% to 30%[1,2]. AP, characterized by interstitial edema, vacuolization, inflammation and acinar cell necrosis, is commonly caused by excessive ethanol consumption, biliary tract disease, certain medications, and invasive procedures of the biliary and pancreatic ducts[19-22]. The pathophysiology of AP is poorly understood, and the clinical course is unpredictable[7].

The fruit of GJ has been used as an oriental herbal medicine in traditional formulations. It has been employed in the treatment of inflammation, jaundice, headache, edema, fever, hepatic disorders, and hypertension. In addition, the pigments obtained from the fruit are used as food colorants. The pharmacologic actions of GJ, such as protective effect against oxidative damage, cytotoxic activity, anti-inflammatory actions, and fibrolytic activity have been described in detail[23,24]. The present study was carried out to determine whether GJ could inhibit the severity of cerulein-induced AP.

Several markers of AP such as PW/BW, amylase and lipase activity were reduced (Figure 1). There is much evidence to implicate the involvement of inflammatory mediators, such as cytokines, TNF-α, IL-1β, and IL-6 in the development of pancreatitis[25]. In experimental pancreatitis, the serum levels of TNF-α and IL-1β are elevated and their blockade attenuates the disease process[18,25]. IL-6 is one of the principal cytokine mediators of the acute-phase response, and has been suggested as a marker for predicting the severity of AP[25]. As shown in Figures 2 and 3, GJ may inhibit these cytokines in AP.

The results of the present study indicate that cerulein caused significant morphological abnormalities in the pancreas, as demonstrated by the appearance of vacuolization, inflammatory infiltration and changes in histo-architecture of the pancreatic acini. Pretreatment with GJ inhibited acinar cell death as well as infiltration by inflammatory cells in cerulein-induced AP. To rule out interference by the binding of cerulein to CCK receptors on pancreatic acinar cells, we examined the effect of GJ in pancreatic acinar cells. GJ itself did not have any cytoxicity at 6 h. However, GJ inhibited cerulein-induced aciniar cell death in a dose-dependent manner (data not shown).

Lung injury commonly develops early in AP. AP-associated lung injury is characterized by edema and inflammation[12]. Therefore, we also assessed the lungs after cerulein administration. Histological examination of lung sections (at 12 h after the injection of cerulein) revealed tissue damage characterized by edema and inflammatory cell infiltrate. GJ pretreatment resulted in a significant reduction in lung injury. The histology sections were scored for edema and inflammation and, as shown in Figure 5, the lungs of the GJ pretreated mice had significantly less edema and inflammation compared with lungs from the saline treated control animals.

In conclusion, the present study shows that GJ pretreatment ameliorated the severity of cerulein-induced AP in rats. Additionally GJ pretreatment ameliorated many of the laboratory and biochemical parameters of the disease. Our findings suggest that GJ may be beneficial in the treatment of acute pancreatitis.

Abstract

AIM: To evaluate the impact of therapeutic education on adherence to antiviral treatment and sustained virological response (SVR) in a real-life setting in genotype 2/3 hepatitis C, as there are few adherence data in genotype 2/3 infection, even from randomized trials.

METHODS: This prospective survey included genotype 2/3 patients who received peg-interferon alfa-2b and ribavirin. There was no intervention. Adherence was self-reported over the past 4 wk (peg-interferon) or 7 d (ribavirin). Adherence to bitherapy was defined as adherence to the two drugs for ⩾ 20 wk. SVR was defined as undetectable RNA ⩾ 12 wk after the end of treatment.

RESULTS: 370/674 patients received education during the first 3 mo of treatment. After 6 mo, adherence to bitherapy was higher in educated patients (61% *vs* 47%, $P = 0.01$). Adherence to peg-interferon was 78% *vs* 69% ($P = 0.06$). Adherence to ribavirin was 70% *vs* 56% ($P = 0.006$). The SVR (77% *vs* 70%, $P = 0.05$) and relapse (10% *vs* 16%, $P = 0.09$) rates tended to be improved. After adjustment for baseline differences, education improved adherence [Odds ratio (OR) 1.58, $P = 0.04$] but not the SVR (OR 1.54, $P = 0.06$).

CONCLUSION: In genotype 2/3 patients, therapeutic education helped maintain real-life adherence to bitherapy.

Key words: Viral hepatitis; Adherence; Therapeutic education; Real life; Peg-interferon; Ribavirin

Patient education improves adherence to peg-interferon and ribavirin in chronic genotype 2 or 3 hepatitis C virus infection: A prospective, real-life, observational study. *World J Gastroenterol* 2008; 14(40): 6195-6203 Available from: URL: http://www.wjgnet.com/1007-9327/14/6195.asp DOI: http://dx.doi.org/10.3748/wjg.14.6195

INTRODUCTION

As pointed out by the WHO[1], poor adherence to treatment is a worldwide issue in all chronic conditions, which results in poor health outcomes and increased health care costs[2,3]. Even in clinical trials, mean adherence rates are low (43%-78%) in chronic conditions[4-6]. In clinical practice, adherence rates of

about 50% are usually reported[7].

Adherence to therapy is critical in the treatment of chronic hepatitis C virus (HCV) infection. The current gold standard therapy is a combination of peg-interferon alfa and ribavirin[8,9]. Patients with genotype 1 infection have a 42%-51% likelihood of achieving a sustained virological response (SVR) after 48 wk of therapy; 78%-82% of patients with genotype 2 or 3 infection respond to 24 wk of treatment, whereas patients with genotype 3 infection and high viral load are difficult to treat (< 70% responders)[10,11]. Non-responders to prior standard bitherapy respond to retreatment in 13% of the cases (29% in non-1 genotype), and relapsers in 58.5% of the cases[12]. Therapy requires weekly subcutaneous injections, twice-daily oral dosing and frequent visits, with blood tests. Side effects occur in nearly all patients. As a result, 15%-20% of patients in clinical trials and > 25% in clinical practice discontinue therapy.

In clinical trials, SVR was significantly improved in those patients with HCV genotype 1 infection who received > 80% of their total peg-interferon dose and > 80% of their ribavirin dose for > 80% of the scheduled treatment duration, in comparison with those who failed these adherence criteria[13]. A review of the 2002-2007 literature confirmed that treatment response is influenced not only by HCV genotype and viral load, but also by patient-related factors including adherence[14]. Moreover, optimal HCV healthcare requires further efforts from providers in communicating with patients, as advocated in France by hepatitis C experts and the Health Ministry[15,16], and shown in studies using patient questionnaires in North America[17,18].

We carried out a large survey named CheObs to evaluate adherence to chronic hepatitis C treatment in the real-life setting in France. We observed that some patients received therapeutic education by a third party (other than the investigator), at the discretion of the investigators, during the study period. According to the consensus that efforts to boost treatment adherence improve SVR rates, we performed the present analysis to evaluate the impact of patient education on real-life adherence and response to treatment with peg-interferon alfa-2b and ribavirin. This analysis was carried out in patients with genotype 2/3 HCV infection (one third of the CheObs cohort), as there are few adherence data for these patients even from randomized trials, and because their data were available before those of patients with other genotypes, due to shorter treatment duration.

MATERIALS AND METHODS

The prospective, multicenter, CheObs survey was carried out in teaching hospitals, non-teaching hospitals, and private practice offices highly involved in the management of hepatitis C in France, and supervised by a Scientific Committee. Consecutive patients aged ⩾ 18 years with chronic hepatitis C were enrolled if initiation of bitherapy with peg-interferon alfa-2b and ribavirin was scheduled. They could be naive for any chronic hepatitis C therapy or non-responders/relapsers to previous therapy. In accordance with French law, the Ethics Committee's approval was not required as the protocol was strictly observational and usual practice was unchanged. However, all patients gave informed consent to participate.

Included patients saw their physician at a frequency corresponding to the usual practice in the center. The investigator and the patient completed a questionnaire each at inclusion, at the visits occurring approximately every 3 mo during treatment, and at the visit occurring approximately 6 mo after the end of treatment. Patients filled in their questionnaires in the waiting room and either gave it back to the investigator in a sealed envelope or returned it using a prepaid envelope.

The investigators recorded socio-demographic data, history of HCV infection (including previous treatments), risk factors, comorbidities, patient therapeutic education (provided or not), planned/prescribed hepatitis C treatment, modification of treatment during follow-up, concomitant medications, and adverse events. The virological status, documented by qualitative PCR (Amplicor™, Roche) and test date, was recorded at the last visit.

The patient questionnaires concerned adherence to peg-interferon and ribavirin, and the persons involved in the management of their disease (e.g. health professionals of any discipline, patient associations). The following parameters relating to the past 4 wk were recorded to evaluate adherence to peg-interferon: date of injections (or reason for not having an injection), frequency of and reason for taking peg-interferon at a higher/lower dose than prescribed. The following parameters relating to the past 7 d were recorded to evaluate adherence to ribavirin: number of (200 mg) capsules prescribed morning and evening, date of dosing and number of capsules taken in the morning and evening, reasons for missing doses, reasons for and frequency of taking more/less capsules than prescribed.

As for any survey, there was no protocol-specific intervention. Therapeutic education was defined by intervention of a third party (healthcare professionals other than the prescribing physician) and distribution of support documents and educational material during individual sessions. It was provided at the discretion of the physician. No instruction was given related to which patient should be considered or how education should be provided.

Adherence to bitherapy was defined as adherence to both peg-interferon and ribavirin over a sufficient time period, as self-reported by the patients. According to the "80/80/80" criteria previously defined[13], patients were considered to have adhered to peg-interferon if they had received three or four injections during the past 4 wk, and to have adhered to ribavirin if they had taken at least 22 (200 mg) capsules over the past week. Patients were considered to have adhered to bitherapy if they had adhered to the two drugs for at least 20 wk. These rules were defined according to the recommended number of peg-interferon injections (one per week), the recommended ribavirin daily dose (at least 800 mg/d),

and the recommended duration of bitherapy in genotype 2/3 HCV infection (24 wk).

SVR was defined as undetectable HCV RNA in the serum 12 wk after the end of treatment or later. This time interval was considered to be sufficient for this evaluation, since relapse after 12 wk of follow-up is rarely (2%) observed whatever the HCV genotype[19], and the dates of the visits and laboratory tests could not be forced in this observational protocol. Non-response was defined as detectable RNA at the end of treatment, and relapse as undetectable RNA at the end of treatment but detectable at a later time point.

Statistical analysis

Due to the lack of data in the literature, the CheObs sample size calculation was based on real-life adherence observed in chronic conditions other than chronic HCV infection, such as HIV infection[20], diabetes[21], or hypertension[22]. A total of 1537 patients were required to estimate a 50% adherence rate, with a precision of 2.5% and a type I error of 0.05. Assuming 25%-30% of patients were lost to follow-up or discontinued treatment early, approximately 2000 patients were included overall.

The present analysis was carried out in the subset of patients with genotype 2/3 HCV infection from the CheObs cohort. Statistical analysis was conducted using SAS 8.2 (SAS Institute Inc, Cary, NC, USA). Tests were two-sided and type I error was set at 0.05. Descriptive statistics were performed using all available data. Group comparisons were carried out using Kruskal-Wallis or Fisher's exact tests. The relationships between adherence or virological response and a set of potential explanatory variables were analysed by forward stepwise logistic regressions. These variables included not only those for which groups differed significantly at baseline ($P < 0.05$), but also those expected to have a significant impact according to the literature.

RESULTS

Patients' characteristics

Between 2002 and 2006, 184 investigators enrolled 2001 HCV patients in the CheObs survey, including 705 patients infected with the genotype 2/3 HCV (Figure 1). Of these, 674 patients were analyzed. We observed that 370/674 (55%) patients received therapeutic education during the first 3 mo of treatment and 304 (45%) did not. Among the 82 centers which included the analyzed population, 24 (29%) did not educate any patient, 18 (22%) educated > 0 to 50% of their patients, 19 (23%) educated > 50% to < 100% of their patients, and 21 (26%) educated 100% of their patients. The 31 patients excluded from analysis were similar to the analyzed population for the therapeutic education rate (58%) and all other baseline variables, except for the Metavir activity score, which was more frequently A2/A3 (78% *vs* 50%, $P = 0.009$).

In the analyzed population, educated patients had a higher body weight (70.5 ± 14.0 kg *vs* 67.9 ± 14.3 kg, $P = 0.02$) than patients without therapeutic education,

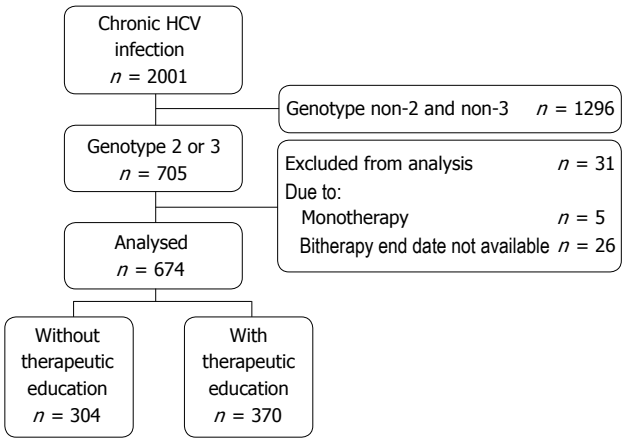

Figure 1 Patient flow.

but a similar body mass index (BMI) (Table 1). They more frequently had a past history of depression ($P = 0.01$) and current psychiatric disorders ($P = 0.04$, mainly depression and anxiety), though there was no difference for the nature or proportion of each disorder. Educated patients were also more frequently psychoactive drug users ($P = 0.02$, mainly cocaine and heroin), but the profile of consumption (injecting behavior and frequency of abuse) was similar. Regarding HCV infection, although educated patients had more frequently significant liver fibrosis than those without therapeutic education ($P = 0.04$), the proportion of cirrhotic patients was similar (13% and 15%).

Treatment

A 24-wk bitherapy was scheduled in most patients (571/667, 86%), with no marked difference between groups (Table 2). Treatment for 48 wk was more frequently planned in non-responders/relapsers to previous therapy (43/125, 34%) than in naive patients (49/542, 9%, $P < 0.001$). The planned weekly dose of peg-interferon was higher in educated patients ($P = 0.01$), at 1.5 μg/kg per week in most cases (82% *vs* 75%) whereas patients without therapeutic education were more frequently prescribed lower doses. However there was no difference between the groups for the proportion of retreated patients (Table 1) or that of relapsers/non-responders to previous treatment ($P = 0.95$). The ribavirin dose prescribed was similar in both groups. It was 800 mg/d in half of the patients (344/669, 51%) and < 800 mg/d in 18 (3%) patients.

The actual duration of bitherapy was shorter than 20 wk in 85/674 (13%) patients ($P = 0.20$ between groups, Table 2), with an average of 11.1 ± 4.9 wk (median 12) in these patients. Reasons for premature discontinuation were: lost to follow-up ($n = 28$), safety ($n = 27$), patient's request ($n = 14$), virological (HCV RNA detectable or decrease < 2 log, $n = 7$), unknown ($n = 3$), investigator's request ($n = 2$), and other ($n = 4$). They were similar in nature and occurrence ($P = 0.79$) in both groups. These patients, who were not included in the analysis of virological response, did not differ significantly from those who received a longer bitherapy

Table 2 Treatment planned and actually received (n = 674): Univariate analysis

	Therapeutic education		
	No (n = 304)	Yes (n = 370)	P
Duration of bitherapy (wk)[1]			
Planned	27.7 ± 8.9	27.1 ± 8.2	0.49
Actual	28.4 ± 12.7	30.3 ± 14.2	0.25
Premature discontinuation (< 20 wk)	44/304 (15)	41/370 (11)	0.20
Peginterferon weekly dose (μg/kg)			
Planned	1.35 ± 0.29	1.41 ± 0.22	0.01
Actual at 3 mo[2]	1.31 ± 0.30	1.38 ± 0.25	0.006
Actual at 6 mo[2]	1.18 ± 0.35	1.25 ± 0.31	0.02
Ribavirin daily dose (mg)			
Planned	897 ± 147	906 ± 154	0.67
Actual at 3 mo[2]	871 ± 166	885 ± 175	0.25
Actual at 6 mo[2]	771 ± 201	803 ± 209	0.06

Data are expressed as mean ± SD, or proportions of patients. [1]Date of end of bitherapy minus date of inclusion; [2]Cumulated over the past 3 mo (AUC, investigator report).

with regards to the main variables.

Physicians modified the peg-interferon dose less frequently in educated patients (16% *vs* 22% without therapeutic education, P = 0.046), whereas the ribavirin dose was changed in similar proportions of patients in both groups (17% *vs* 18%, P = 0.28) nearly always because of adverse effects and weight loss and depression in particular. The difference in the dose between groups remained constant for peg-interferon whereas it increased over time for ribavirin, in particular after the third month of treatment (Table 2). The occurrence of adverse events over the whole study was 82% of patients in each group (P = 0.92).

Adherence to bitherapy

Overall adherence to bitherapy was 64% (301/468) at 3 mo and 55% (209/383) at 6 mo of treatment. Adherence to peg-interferon (80% and 74% at 3 and 6 mo, respectively) was higher than to ribavirin (72% and 64%, respectively). Patients prescribed high doses of ribavirin (⩾ 1000 mg/d) did not differ significantly from those with lower doses with respect to premature treatment discontinuation and adherence to peg-interferon and/or ribavirin.

At 3 mo, the proportion of adherents to both drugs was 66% with therapeutic education and 63% without therapeutic education (non-significant difference) (Figure 2 and Table 3). At 6 mo, this proportion was still 61% in educated patients, whereas it dropped down to 47% without therapeutic education (P = 0.01). Multivariate analysis showed that, after adjustment, therapeutic education increased the probability of adhering to bitherapy at 6 mo by a factor of 1.58 (95% CI: 1.02 to 2.46).

At 6 mo, the adherence rate was still 78% for peg-interferon and 70% for ribavirin in educated patients, whereas it was reduced to 69% (P = 0.06) and 56% (P = 0.006), respectively, in patients without therapeutic

Table 3 Adherence to treatment, virological response (univariate analysis) and their association with therapeutic education (multivariate analysis)

	Therapeutic education					
	Univariate analysis			Multivariate analysis		
	No (n = 304)	Yes (n = 370)	P	OR	95% CI	P
Adherence[1] at 3 mo						
Bitherapy	137/218 (63)	164/250 (66)	0.56	1.04	0.69 to 1.56	0.87
Peginterferon	175/218 (80)	201/250 (80)	1.00	0.94	0.57 to 1.53	0.79

Adherence[1] at 6 mo						
Bitherapy	83/175 (47)	126/208 (61)	0.01	1.58	1.02 to 2.46	0.04
Peginterferon	121/175 (69)	162/208 (78)	0.06	1.78	1.07 to 2.96	0.03
Ribavirin	98/175 (56)	145/208 (70)	0.006	1.67	1.05 to 2.65	0.03
Virological response[2]						
SVR	171/246 (70)	230/298 (77)	0.05	1.54[3]	0.99 to 2.40	0.06
Nonresponse	37/246 (15)	37/298 (12)	0.38			
Relapse	38/246 (16)	31/298 (10)	0.09			

Data are expressed as proportions of patients. Multivariate analyses were adjusted for sex, weight, BMI, educational level (adherence only), history of depression, psychiatric disorders, alcohol consumption, drug abuse, duration of HCV infection, previous anti-HCV treatment, HCV genotype (SVR only), and peginterferon dose prescribed at inclusion. [1]≥ 3 peginterferon injections during the last 4 wk and/or ≥ 22 ribavirin capsules of 200 mg each during the last 7 d (self-report); [2]≥ 12 wk after the end of treatment; [3]The rate of SVR was used as dependent variable.

education. After adjustment, therapeutic education increased the probability of adherence by a factor of 1.78 for peg-interferon and 1.67 for ribavirin after 6 mo of bitherapy.

Educated patients more frequently reported contacting persons in the hospital for management of their disease, with a median of three persons *vs* two for patients without therapeutic education during the first 3 mo of treatment (P=0.016), and three persons *vs* one during the next 3 mo (P = 0.003). Conversely, patients without therapeutic education reported more frequent contacts with office-based persons, with a median of two persons *vs* one in educated patients during the first 3 mo (P = 0.012), and two persons *vs* none during the next 3 mo (P < 0.001).

Virological response

The overall SVR rate was 74% (401/544). There were 13.6% of non-responders and 12.7% of relapsers. The virological response was better, though not significantly, in educated patients (Figure 2 and Table 3). The SVR rate was higher (77% *vs* 70%, P = 0.05) and the rate of relapse was lower (10% *vs* 16%, P = 0.09) in these patients than in patients without therapeutic education. Multivariate analysis confirmed that, after adjustment, the relationship between SVR and therapeutic education was borderline significant (P = 0.06). Response was better in patients whose ribavirin dose was not reduced during the first 3 mo of treatment (P < 0.001), mostly due to an increased SVR rate (362/473, 77% *vs* 37/67, 55%, P = 0.001) and a decreased rate of non-response (51/473, 11% *vs* 21/67, 31%, P < 0.001).

The virological response is shown taking into account genotype and baseline viral load (> or ≤ 800 000 IU/mL) in Figure 3. Though this effect was not significant, therapeutic education was found to have a beneficial impact in all patients. In those with genotype 2 and low viral load, an impact on the SVR (P = 0.038) and relapse (P = 0.047) rates was observed, but the sample size was small (n = 80).

Moreover, although favorable trends were observed, therapeutic education had no significant impact on the virological response in patients treated for the first time (P = 0.27) or in non-responders/relapsers to previous therapy (P = 0.22).

DISCUSSION

We evaluated the impact of patient therapeutic education by a third party on adherence and virological response to peg-interferon alfa-2b and ribavirin in 674 patients with chronic genotype 2/3 HCV infection. This is the first time that adherence has been evaluated in patients carrying these genotypes, and also the first time that adherence has been assessed in a real-life setting.

Therapeutic education given during the first 3 mo of treatment significantly improved the proportion of patients adhering to bitherapy at 6 mo (OR 1.58, P = 0.01 after adjustment for sex, weight, BMI, educational level, history of depression, psychiatric disorders, alcohol consumption, drug abuse, duration of HCV infection, previous anti-HCV treatment, and peg-interferon dose prescribed at inclusion). The proportion of adherents was stable above 60% until the sixth month of treatment in educated patients, whereas it dropped by more than 10% between the third and sixth month of treatment when there was no therapeutic education. The virological response was also improved in educated patients, with an increased SVR rate (77% *vs* 70%) and a lower relapse rate (10% *vs* 16%), though this effect was statistically not significant (P = 0.06 after adjustment for sex, weight, BMI, history of depression, psychiatric disorders, alcohol consumption, drug abuse, duration of HCV infection, previous anti-HCV treatment, HCV genotype, and peg-interferon dose prescribed at inclusion). Since a 12-wk treatment may be very effective

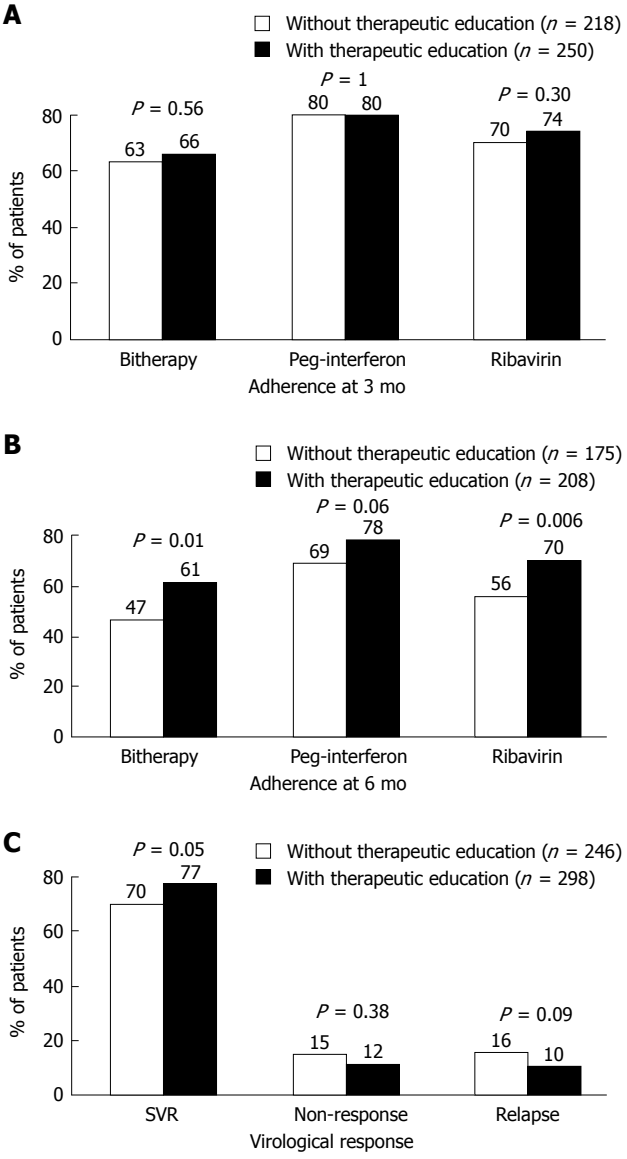

Figure 2 Impact of patient therapeutic education on adherence to treatment (A and B) and virological response (C). At 3 mo of treatment, the proportion of patients adhering to treatment (patient self-report) was similar in the two groups. At 6 mo, the proportion of adherents dropped in patients without therapeutic education only. The virological response was better in educated patients, with an increased rate of SVR and a lower relapse rate.

in naive genotype 2/3 patients, the fact that adherence was the same over 12 wk may explain why adherence in the later part did not translate to significantly higher SVR rates. As suggested by the borderline *P* value, this might also be due to the fact that inclusion of one-third of the CheObs cohort in this analysis limited the power to detect statistical significance.

The overall adherence rate to ribavirin (64%-72%) was consistently lower than that to peg-interferon (74%-80%), as expected from their regimen. The ribavirin regimen is somewhat complex (twice-daily oral dosing) whereas peg-interferon alfa-2b adherence is facilitated by the low frequency of administration (weekly injections) and availability of an injecting pen device. Therapeutic education significantly enhanced adherence to ribavirin, which is particularly important for obtaining an SVR[23]. A positive impact was also observed on adherence to peg-interferon, showing that an improvement can still be obtained.

Our results are consistent with the general consensus that patient therapeutic education in clinical practice effectively improves adherence to treatment in chronic disease[2,15,16] and that adherence, even to placebo, is essential to achieve health outcome goals[3]. It should be noted however, that education required the cooperation of specialists and nursing staff, and therefore probably affected both patient-related and health care team-related factors, which are recognized to improve adherence.

The adherence rate to bitherapy (64%) was low compared to the rates of > 70% reported in clinical trials[13]. The SVR rate observed here (72%) was however, in line with that reported in clinical trials (80%) in genotype 2/3 HCV patients treated with similar therapy[24]. Apart from the fact that results are usually more marked in randomized trials, our population included a high proportion of patients with psychiatric disorders and/or drug addicts. This suggests that in real-life situations such comorbidities and high-risk behavior do not have an impact on adherence or response to treatment, so that they may not be as difficult to treat as usually believed.

Unlike during clinical trials, patients in this observational study were not selected or obliged to follow specific procedures and physicians were not instructed on which patient should be considered for therapeutic education. This may be considered to be a weakness of the study, as comparisons were performed on non-randomized groups. The CheObs study was not designed to perform comparisons, but aimed to provide a picture of the real-life setting. The use of multivariate analysis in the present evaluation reduced such bias by taking into account the differences between groups observed at baseline.

The method used to assess adherence may also be criticized. When the study was designed, we chose to use data reported by patients rather than by investigators, to best reflect the real-life situation. However, asking patients to fill a diary each day would have influenced their behavior and led to an unquantifiable overestimation of our primary endpoint. Adherence data were therefore collected over limited time periods. We also chose not to take into account body weight when calculating adherence to ribavirin. Theoretically, we overestimated adherence to ribavirin in patients over 65 kg body weight, i.e. in approximately half the study population at baseline. This bias was however reduced, as weight is known to decrease markedly over time in most treated patients and, as expected, dose reductions occurred for safety reasons in a large proportion of patients (17%-18%) in both groups.

Our results demonstrate that, although patients with HCV genotype 2/3 are those who usually show the best response rates, further efforts may be made to improve outcomes. There is more than one barrier preventing patients from optimal compliance to their treatment regimen[1]. Five interacting dimensions affect adherence: social and economic factors, and factors related to the

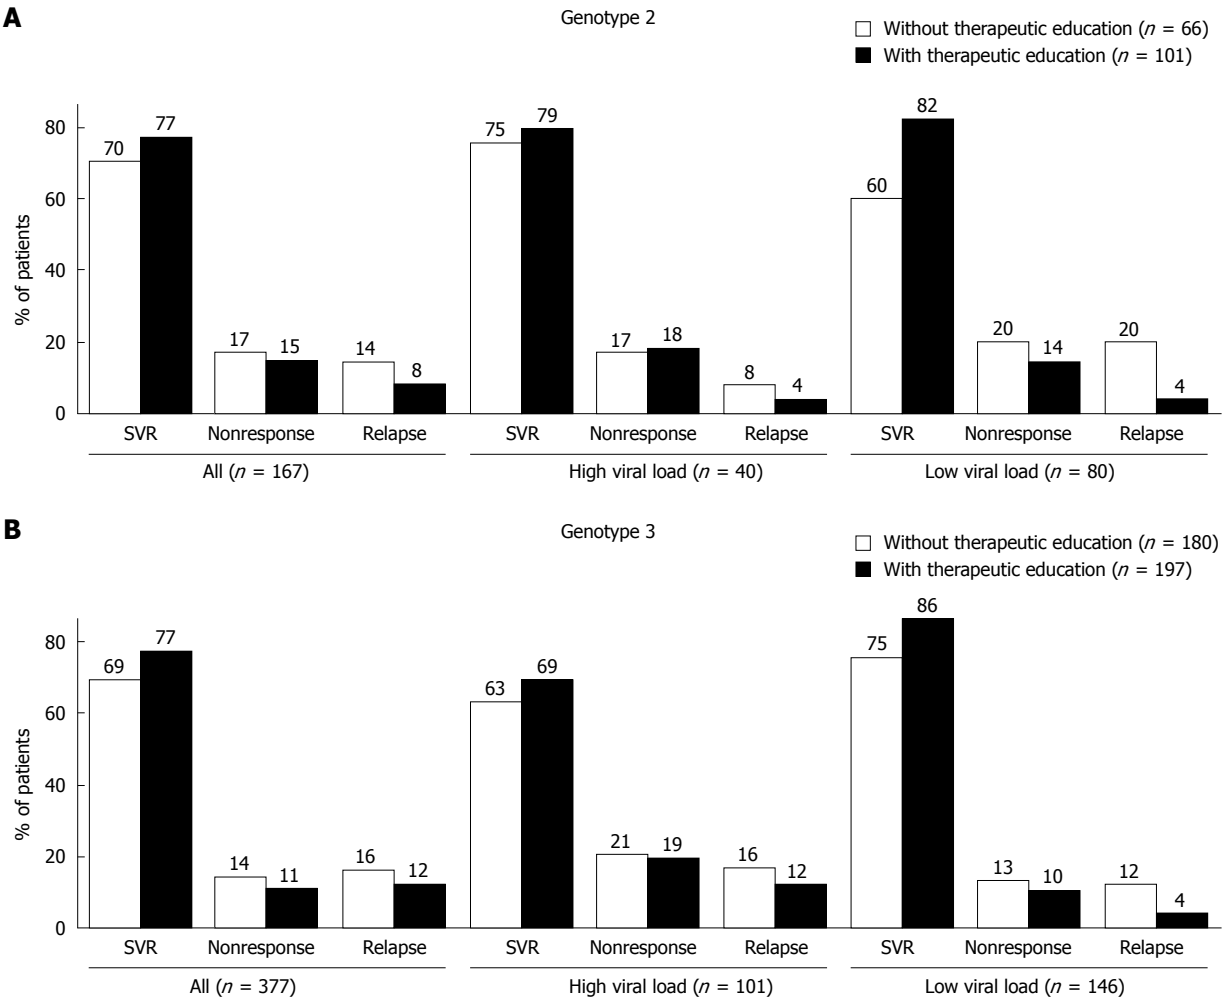

Figure 3 Virological response in patients infected with genotype 2 (A) or genotype 3 (B), and according to viral load (> or ⩽ 800 000 IU/mL). Although not statistically significant, patient therapeutic education was beneficial in all patient subgroups, especially in those with genotype 2 and low viral load, with a marked impact on the SVR (SVR, $P = 0.038$) and relapse ($P = 0.047$) rates.

health care team and system, the condition, treatment, and the patient[2,15,16]. Increasing the impact of interventions aimed at patient-related factors and/or health care team-related factors is essential. Methods that have been shown to be effective in improving therapy include: educational interventions involving patients[25,26]; strategies to improve dosing schedules[6]; interventions that enlist ancillary health care providers such as pharmacists, behavioral specialists, and nursing staff[27,28]; and enhancing communication between physicians and patients[29-31].

To conclude, in the real-life setting, therapeutic education helped maintain adherence to bitherapy in patients with genotype 2/3 infection. There was a trend for a benefit on virological response. This analysis of the real-life impact of patient education by a third party on health outcomes may help to further improve patient quality of life and outcome. The importance of adherence and the role of education should now be studied in a randomized controlled trial in genotype 1/4 infection.

ACKNOWLEDGMENTS

The authors are grateful to Ceri Medical (Garches, France), who helped in field monitoring, Florence Colin-Mercier (Stat Process, Pont Mort, France), who analysed the data, as well as all investigators for participating in this study (the CheObs Study Group).

COMMENTS

Background

Adherence to therapy is critical in the treatment of chronic hepatitis C virus (HCV) infection. The current gold standard therapy is a combination of peg-interferon alfa and ribavirin. Patients with genotype 2 or 3 infection have a 78%-82% likelihood of achieving a sustained virological response (SVR) after 24 wk of therapy, whereas patients with genotype 3 infection and high viral load are difficult to treat (< 70% responders). Therapy requires weekly subcutaneous injections, twice-daily oral dosing and frequent visits, with blood tests. Side effects occur in nearly all patients. As a result, 15%-20% of patients in clinical trials and over 25% in clinical practice discontinue therapy.

Research frontiers

In clinical trials, the SVR rate was significantly improved in those patients with HCV genotype 1 infection who received > 80% of their total peg-interferon dose and > 80% of their ribavirin dose for > 80% of the scheduled treatment duration. A review of the 2002-2007 literature confirmed that treatment response is influenced not only by HCV genotype and viral load, but also by patient-related factors including adherence.

Innovations and breakthroughs

The authors evaluated, perhaps for the first time, the impact of patient therapeutic education by a third party on adherence and virological response to peg-interferon alfa-2b and ribavirin. The analysis was carried out in the 674 patients with chronic genotype 2/3 HCV infection from the CheObs cohort. Therapeutic education given during the first 3 mo of treatment significantly improved the proportion of patients adhering to bitherapy at 6 mo (odds ratio 1.58). Though not significantly, the virological response was also improved in educated patients, with an increased SVR rate (77% *vs* 70%) and a lower relapse rate (10% *vs* 16%). Therapeutic education significantly enhanced adherence to ribavirin, which is particularly important for obtaining a SVR. A positive impact was also observed on adherence to peg-interferon, showing that an improvement can still be obtained.

Applications

This analysis of the real-life impact of patient therapeutic education by a third party on health outcomes may help to further improve patient quality of life and outcome. Five interacting dimensions affect adherence: social and economic factors, and factors related to the health care team and system, the condition, treatment, and the patient. Methods that have been shown to be effective in improving therapy include: educational interventions involving patients; strategies to improve dosing schedules; interventions that enlist ancillary health care providers such as pharmacists, behavioral specialists, and nursing staff; and enhancing communication between physicians and patients.

Peer review

This is a subgroup analysis of a bigger project. Since the a priori power calculation was based on 2000 subjects for meaningful statistical analysis, the inclusion of only 630 or so patients in this study clearly limits the power to detect statistical significance.

Abstract

AIM: To evaluate the prevalence of lactose intolerance (LI) following a load of 12.5 g in patients diagnosed as high-grade malabsorbers using the hydrogen breath test (HBT)-25.

METHODS: Ninety patients showing high-grade malabsorption at HBT-25 were submitted to a second HBT with a lactose load of 12.5 g. Peak hydrogen production, area under the curve of hydrogen excretion and occurrence of symptoms were recorded.

RESULTS: Only 16 patients (17.77%) with positive HBT-25 proved positive at HBT-12.5. Hydrogen production was lower as compared to HBT-25 (peak value 21.55 parts per million (ppm) ± 29.54 SD *vs* 99.43 ppm ± 40.01 SD; $P < 0.001$). Symptoms were present in only 13 patients. The absence of symptoms during the high-dose test has a high negative predictive value (0.84) for a negative low-dose test. The presence of symptoms during the first test was not useful for predicting a positive low-dose test (positive predictive value 0.06-0.31).

CONCLUSION: Most patients with a positive HBT-25 normally absorb a lower dose of lactose and a strict lactose restriction on the basis of a "standard" HBT is, in most instances, unnecessary. Thus, the 25 g lactose tolerance test should probably be substituted by the 12.5 g test in the diagnosis of LI, and in providing dietary guidelines to patients with suspected lactose malabsorption/intolerance.

Key words: Lactase deficiency; Lactose malabsorption; Lactose intolerance; Hydrogen breath test

INTRODUCTION

The enzyme lactase phlorizin hydrolase, located at the intestinal brush border, is necessary for the hydrolysis of lactose, the main sugar in milk. Due to the genetically programmed decrease in intestinal lactase activity that occurs post-weaning (lactase non-persistence), a large proportion of the human population loses, in adult age, the possibility to digest and absorb lactose[1-3]. In Europe, its prevalence increases with a north-south and west-east gradient. Thus, about 50% of adult Italians cannot digest and absorb lactose normally[4,5].

Lactose malabsorption (LM) may be asymptomatic or induce symptoms similar to those of functional bowel disorders and irritable bowel syndrome, consisting of abdominal pain, gaseousness, flatulence and diarrhea. LM is not necessarily a predictor of the occurrence of symptoms, and the term "lactose intolerance (LI)" refers to a condition in which abdominal symptoms are experienced after the ingestion of lactose, in milk or dairy food.

The test for identifying the genotype responsible for lactase deficiency[6-8] is not widely available and its use for the diagnosis of LM is debatable. Thus, the diagnosis of LM is usually based on a positive hydrogen breath test (HBT) with an oral load of 25 g lactose (HBT-25) and is often followed by the institution of a lactose-free diet, also in those patients who do not experience abdominal symptoms. This approach is debatable, as a reduction of calcium intake below the recommended daily allowance (RDA) may ensue. Moreover, also in those cases in which

symptoms are triggered by the 25 g of lactose ingested during the test, such a strict reduction of milk and dairy products is often unnecessary, as the amount of lactose administered during the test considerably exceeds the amount of lactose ingested daily, by most adults.

The present study was aimed at evaluating whether a reduction in the daily intake of milk and lactose-containing food is really necessary in subjects with LM during a standard HBT-25. To this end, we performed the HBT with an oral load of 12.5 g lactose (HBT-12.5) in a group of patients with marked LM documented by means of HBT-25. Positivity of the test, occurrence and type of symptoms during the two tests were compared.

MATERIALS AND METHODS

During the period January, 2001 to May, 2004, 913 outpatients underwent a lactose tolerance test in our laboratory. The HBT was performed after 24 h on a low-fiber diet and a 12-h fasting period with an oral load of lactose at a dose of 0.5 g/kg body weight, up to a maximum of 25 g. End-alveolar air samples were collected in syringes using a modified Haldane-Priestly tube[9], prior to the administration of lactose, and thereafter every 30 min for 4 h. Hydrogen (H_2) and methane (CH_4) concentrations were measured in parts per million (ppm) by means of a Quintron Model DP Microlyzer gas chromatograph (Quintron Instruments, Milwaukee, WI, USA). The test was defined as "positive" when a H_2 peak exceeding 20 ppm over baseline values was observed in two or more samples. Tests not fulfilling the above-mentioned criteria were defined as negative. Those patients with a negative HBT, who did not excrete increased amounts of H_2 after oral administration of 20 g lactulose in a subsequent HBT (24 patients), were defined as hydrogen non-producers. A positive test identified patients with LM, irrespective of the presence or absence of abdominal symptoms. Positivity of LM was arbitrarily defined as "high-grade" when H_2 excretion exceeded 70 ppm in at least two samples, and "low-grade" in all other instances.

Of the 353 patients with positive HBT-25, 147 fulfilled the above-mentioned criteria for high-grade LM. Of these, 50 were excluded from the study due to the presence of small bowel diseases, such as Crohn's disease and celiac disease, in which medical treatment or dietary modifications could result in variations in lactase activity. The remaining 97 patients were considered eligible for entry to the study and were required to undergo a further lactose tolerance test, with a lactose load of 12.5 g. Only seven refused to enter the study (compliance 92.78%) and the test was performed, 4-12 wk after the first test, in 90 patients (12 male, 78 female, mean age 41.81 ± 15 SD years). Of these, 65 had experienced symptoms during HBT-25 and 25 had not. The excretion of gas during HBT-12.5 was quantified as: (1) peak H_2 concentration; (2) area under the curve (AUC) of H_2 concentration from 60 to 240 min, calculated with the triangular rule and expressed in arbitrary units of ppm/h. During the test, occurrence and type of symptoms were recorded.

Statistical analysis

Data were analyzed using the χ^2 test, the inference between proportions and the *t*-test for paired data, when appropriate.

RESULTS

Positivity of the HBT-12.5 g

Only 16 (17.7%) of the 90 patients enrolled still had a positive test during the HBT-12.5 while the remaining 74 (82.3%) were negative. The difference between HBT-12.5 and HBT-25, evaluated by means of the inference between proportions, was highly significant ($P < 0.001$). Of the 65 LI patients, only five experienced symptoms during the HBT-12.5, while another seven had a positive test, but reported no symptoms. Of the 25 patients with LM, only four had a positive test after an oral load of 12.5 g lactose. None reported symptoms.

Peak H_2 excretion

Considering all 90 patients together, the mean value of peak H_2 excretion during HBT-12.5 was 21.55 ppm ± 29.54 SD, whereas in HBT-25, the mean peak H_2 excretion was 99.43 ppm ± 40.01 SD. As expected, the difference from HBT-25 was highly significant ($P < 0.001$). Considering only the data from the 16 patients who proved positive in both tests, the peak H_2 excretion was 97.68 ppm ± 27.37 during HBT-25 and 69 ppm ± 36.53 SD during HBT-12.5. Thus, even in those patients who had LM during HBT-12.5, the amount of hydrogen excretion was significantly lower as compared to the first test ($P < 0.01$). No difference was found between patients who had symptoms during the test (LI) and those who were LM, but did not experience symptoms, as far as concerning the peak H_2 excretion.

Amount of H_2 excreted (AUC)

The amount of H_2 excreted by the entire population of 90 patients was 18 ppm/h ± 27.12 SD in the HBT-12.5 compared to 97.08 ppm/h ± 40.56 SD in the HBT-25 ($P < 0.001$). Again, taking into account only data from the 16 patients who proved positive in both tests, the amount of H_2 excreted during HBT-12.5, the AUC was significantly lower compared to that of the HBT-25 (54.29 ppm/h ± 41.23 SD *vs* 99.21 ppm/h ± 35.58 SD, respectively; $P < 0.01$). Again no difference was observed between LI and LM.

Symptoms

During the test with 25 g lactose in the 65 patients with LI, gaseousness was present in 36 (55.3%), abdominal pain in 34 (52.3%), flatulence in 16 (24.6%) and diarrhea in eight (13.8%), with some patients reporting more than one symptom (Figure 1). Only five patients with a positive HBT-12.5 experienced symptoms, namely gaseousness in three, flatulence in three and abdominal pain in one. None experienced diarrhea. Eight patients with a negative HBT-12.5 reported experiencing minor symptoms, consisting of gaseousness in five and abdominal pain in five. The relationship between

Table 1 Occurrence of symptoms during positive or negative test with a lactose load of 12.5 g, in relation to the outcome of the test with 25 g lactose

	LI (HBT 25) 65 patients		LM (HBT 25) 25 patients	
	Symptoms +	Symptoms -	Symptoms +	Symptoms -
HBT 12.5 +	5	7	0	4
HBT 12.5 -	8	45	0	21

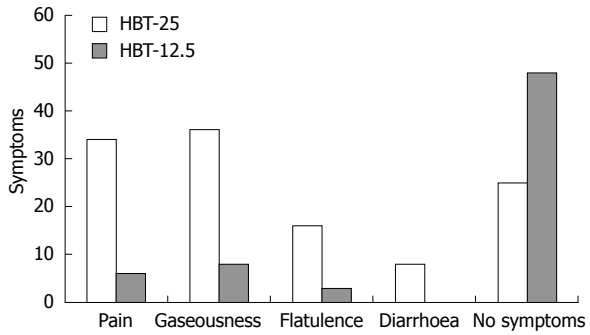

Figure 1 Occurrence of symptoms during the HBT using 25 g lactose (HBT-25) and 12.5 g (HBT-12.5). Some patients reported more than one symptom. It should be noted that, in HBT-12.5, minor symptoms, such as mild abdominal discomfort and abdominal distension, were reported not only by five patients with positive tests, but also by eight patients with a negative one.

positivity/negativity of the low-dose test (HBT-12.5) and occurrence of symptoms during HBT 12.5 is reported in Table 1.

Probability of predicting a positive HBT-12.5

Due to the small number of patients who proved positive during the low-dose test, positivity of HBT-25 does not help predict a positive HBT-12.5 (positive predictive value: 0.17). The occurrence of any symptom during HBT-25 showed only a slightly better positive predictive value for a positive HBT-12.5 (positive predictive value: 0.41). Taking into consideration the occurrence of individual symptoms during HBT-25, the positive predictive value was 0.06 for abdominal pain, 0.25 for gaseousness, 0.31 for flatulence and 0.12 for diarrhea. On the other hand, the absence of abdominal symptoms during HBT-25 had a negative predictive value of 0.84.

DISCUSSION

The diagnosis of LM is usually based upon the positivity of HBT after an oral load of lactose[10-15]. The most commonly used load of lactose is 20-25 g, corresponding to an intake of 400-500 mL of milk, which is rarely ingested in a single dose. Indeed, 400-500 mL of milk exceeds in most instances, the total daily intake of milk and diary products. As HBT has been found to correlate with lactase activity in duodenal biopsies, the HBT-25 is, indeed, useful for population studies[16,17]. HBT, however, is used in the clinical setting with the primary aim of diagnosing LM and LI, the rate of positive tests depending not only upon the degree of hypolactasia, but also the amount in the oral load used for the test. Moreover, the prevalence of symptoms, which is clinically relevant and of great importance for the patient, is dose-related. Thus, the traditional test with 25 g lactose likely overestimates the prevalence of LI. This may lead to unnecessary restrictions in the intake of foods that represent the main source of dietary calcium[18,19]. The present study was aimed at evaluating whether, and to what extent, the use of an oral load of 12.5 g lactose, instead of 25 g, could influence the prevalence of positive tests for diagnosing LI and LM. The present data confirm, in a large series of patients, previous observations showing that high loads of lactose (50 g, corresponding to 1 L of milk) induce abdominal pain and diarrhea in most lactose malabsorbers[20]. Conversely, small amounts of the sugar were usually well tolerated[21-24]. The present data indicates that the absence of abdominal symptoms during an HBT-25 is, in most instances, associated with a negative HBT-12.5. Unexpectedly, the presence of symptoms during HBT-25 was not useful for predicting a positive HBT-12.5. Less than 50% of the patients with abdominal symptoms (LI) display malabsorption of lactose in detectable amounts when the sugar load is reduced and the occurrence of symptoms are relatively rare. Thus, a moderate intake of lactose during a standard HBT-25 may prove harmless in the large majority of patients diagnosed as LI or LM[25].

Interestingly, during the HBT-12.5, eight patients reported symptoms despite a negative test with prevalence similar to that observed in a previous study performed in normal subjects and in patients with irritable bowel syndrome[26-29]. In the present series, symptoms consisted of gaseousness and mild abdominal pain, whereas none of the patients had diarrhea. As patients were asked to report even minor symptoms, a "nocebo", or "inverse placebo", effect may have been elicited by the investigators.

Finally, false-negative results cannot be completely ruled out in these patients, due to a better sensitivity of late (> 240 min) increases in hydrogen excretion, as suggested by Di Stefano *et al*[30]. These data, however, are debatable as these authors, using different hydrogen cutoff levels, considered definitely as lactose intolerant with a false-negative breath test those patients reporting symptoms during the HBT, irrespective of the test results. This is unlikely, as negative expectations often induce non-specific abdominal symptoms not only during lactose HBT, but also after a sham lactose load (personal unpublished data).

In conclusion, these data reaffirm that LI is dose-dependent. Considering the daily mean lactose intake in the general population, 50 or 25 g lactose tolerance breath tests may prove useful for epidemiological studies, looking for lactose deficiency. The widespread availability of genetic testing for lactase polymorphism may render obsolete this technique. Conversely, in the clinical setting, the use of the 12.5 g lactose tolerance test should be probably preferred to the 25 g test, at least in Caucasians and in the populations of the Mediterranean basin, as it may help to identify those patients who would profit from dietary restriction of lactose-containing food, minimizing the risk of inappropriately reducing calcium intake to those who do not need it.

COMMENTS

Background

Hydrogen breath test (HBT), after a lactose load of 25-50 g is widely used in the clinical setting for diagnosing lactose malabsorption (LM) and, when abdominal symptoms are present, of lactose intolerance (LI). The positivity of the test often induces dietary modifications, leading to the reduction of calcium intake.

Research frontiers

The authors confirmed in a large series of patients previous findings suggesting that most patients with LM, documented by HBT, tolerate well small amounts of lactose.

Innovations and breakthroughs

The present data indicates that an oral load of 12.5 of lactose, corresponding to about 250 mL milk, is well tolerated by the majority of patients unable to completely digest and absorb 25 g lactose. Moreover, in the majority of them, an increased excretion of hydrogen was not documented after ingesting an isoosmolar solution of 12.5 g of lactose, indicating that they can normally digest lactose at least up to a dose corresponding to 250 mL milk.

Applications

The authors suggest that 12.5 g lactose HBT should be preferred to the usual oral load of 25-50 g, in order to identify those patients who could really profit from a reduction of lactose-containing food, and minimize the risk of unnecessary reductions of calcium intake.

Terminology

HBTs are indicated by HBT. The positivity of the test defines a subject's LM, irrespective of the occurrence of abdominal symptoms. The coincident occurrence of symptoms is required for defining LI patients.

Peer review

This is an interesting study in which the authors argue that the use of 25 g of lactose to test for LM may be inappropriate, as this is higher than the average dietary intake, and the removal of lactose from the diet may have other deleterious consequences such as reduced calcium intake.

Abstract

AIM: To investigate if sildenafil increases splanchnic blood flow and changes the hepatic venous pressure gradient (HVPG) in patients with cirrhosis. Phosphodiesterase type-5 inhibitors are valuable in the treatment of erectile dysfunction and pulmonary hypertension in patients with end-stage liver disease. However, the effect of phosphodiesterase type-5 inhibitors on splanchnic blood flow and portal hypertension remains essentially unknown.

METHODS: Ten patients with biopsy proven cirrhosis (five females/five males, mean age 54 ± 8 years) and an HVPG above 12 mmHg were studied after informed consent. Measurement of splanchnic blood flow and the HVPG during liver vein catheterization were done before and 80 min after oral administration of 50 mg sildenafil. Blood flow was estimated by use of indocyanine green clearance technique and Fick's principle, with correction for non-steady state.

RESULTS: The plasma concentration of sildenafil was 222 ± 136 ng/mL 80 min after administration. Mean arterial blood pressure decreased from 77 ± 7 mmHg to 66 ± 12 mmHg, P = 0.003, while the splanchnic blood flow and oxygen consumption remained unchanged at 1.14 ± 0.71 L/min and 2.3 ± 0.6 mmol/min, respectively. Also the HVPG remained unchanged (18 ± 2 mmHg *vs* 16 ± 2 mmHg) with individual changes ranging from -8 mmHg to +2 mmHg. In seven patients, HVPG decreased and in three it increased.

CONCLUSION: In spite of arterial blood pressure decreases 80 min after administration of the phosphodiesterase type-5 inhibitor sildenafil, the present study could not demonstrate any clinical relevant influence on splanchnic blood flow, oxygen consumption or the HVPG.

INTRODUCTION

Erectile dysfunction is a common problem affecting about half of all patients with end-stage liver disease[1,2]. The systematic use of beta-adrenergic blockade[3,4], initiated in order to reduce the hepatic venous pressure gradient (HVPG), may also per se induce impotence[5]. Selective phosphodiesterase type-5 inhibitors, such as sildenafil, represent an important advance in management of erectile dysfunction[6,7]. Inhibition of phosphodiesterase type-5, the prominent isoform in corpora cavernosa, leads to diminished degradation of cyclic guanosine monophosphate, relaxation of smooth muscle and blood filling of corpora cavernosa[8].

In rats, phosphodiesterase type-5 is also present in the superior mesenteric artery[9]. Administration of sildenafil

results in a dose-dependent increase in mesenteric blood flow and a minor increase in portal venous pressure, in both the bile-duct-ligated rat, as well as in control rats[10]. It has been suggested that phosphodiesterase type-5 is also present in human mesenteric arteries[11]. The use of sildenafil could, therefore, be hazardous in patients with cirrhosis and portal hypertension. Indeed, acute variceal bleeding has been described after intake of 25 mg sildenafil[12,13]. On the other hand, a more recent study in patients with Child A liver cirrhosis has shown a decrease in portal and sinusoidal resistance after inhibition of phosphodiesterase-5[14], which was introduced as a new potential treatment modality of portal hypertension[14].

Since sildenafil seems to be valuable in the treatment erectile dysfunction[14] and portopulmonary hypertension[15] in patients with cirrhosis, the aim of the present study was to determine if splanchnic blood flow and HVPG are influenced by sildenafil in patients with cirrhosis.

MATERIALS AND METHODS

Twelve patients with biopsy-proven cirrhosis were included in the study during diagnostic work-up and/or evaluation for liver transplantation. None of the patients were treated with nitrates or beta-adrenergic drugs at the time of the study. Furthermore, only patients with an HVPG above 12 mmHg were considered for inclusion in this study. Two patients were excluded due to this last criterion. Thus, 10 patients participated (five females/five males, mean age 54 ± 8 years). The reason for referral to our tertiary liver failure unit was chronic hepatic insufficiency in five, recurrent bleeding from esophageal varices in four, and therapy-resistant ascites in one patient. None of the patients had suffered from variceal bleeding within 14 d of the study. Participation in the study included measurement of the HVPG and the estimation of splanchnic blood flow before and 80 min after oral administration of 50 mg of sildenafil. All patients were included after written informed consent, and after the local scientific-ethical committee had approved the study.

Hepatic venous catheterization (Cordis, MP-A1, open end catheter, Miami, USA) was performed through the right or left intermedian cubital vein. During the advance of the catheter, blood pressure in the right atrium was registered. After location of a hepatic vein, the catheter was advanced to the wedge position. Pressure was measured *via* a pressure monitoring set and was continuously recorded (Hewlett Packard, 78354C) and could be printed (Hewlett Packard, M1125A). The pressure transducer was calibrated to zero pressure at the level of the right atrium. The wedge pressure was only accepted if the wedge position afterwards could be confirmed by visualization of a characteristic wedge pattern on the fluoroscope by use of X-ray contrast media (Omnipaque 240 mg/mL, Amersham Health). Free hepatic venous pressure was measured as close as possible to the inferior caval vein. Pressures, free and wedged, were measured in three different hepatic veins and the mean was used. The catheter was then positioned in a hepatic vein half way between wedge position and the caval vein and used for blood sampling.

Splanchnic blood flow was estimated by use of indocyanine green as previously described[16]. In short, indocyanine green was continuously infused and simultaneously, five paired samples of arterial and hepatic venous blood were drawn at intervals of 5 min. Calculation of hepatic blood flow was based on Fick's principle with correction for non-steady state[16]. Splanchnic oxygen consumption was calculated as the arterio-venous oxygen content difference times splanchnic blood flow.

Patients were given 50 mg sildenafil with 100 mL of tap water. From 60 to 80 min thereafter, blood was again sampled for estimation of hepatic blood flow. HVPG was measured again, as described above, in three different veins. Pressure in the right atrium was recorded during withdrawal of the catheter.

Indocyanine green was determined by use of HPLC as earlier described[17]. To ensure absorption of sildenafil, blood was sampled 80 min after administration and plasma sildenafil concentration was later analyzed using automated sequential trace enrichment of dialyzates and HPLC[18].

Statistical analysis

Data are shown as mean ± SD. Paired *t* test was used for comparison, $P < 0.05$ was considered statistically significant.

RESULTS

Characteristics and clinical data from the 10 participating patients showed that the majority had advanced cirrhosis (Table 1). None of the patients had allergy to sildenafil. The concentration of sildenafil in plasma was 222 ± 136 ng/mL, 80 min after administration of the drug.

There was a statistically significant decrease in mean arterial pressure from 77 ± 7 mmHg to 66 ± 12 mmHg, $P = 0.003$, after sildenafil administration (Table 2). No statistically significant changes were observed in other hemodynamic variables or in splanchnic oxygen consumption (Table 2). In particular, the HVPG remained statistically unchanged, i.e. 18 ± 2 mmHg before *vs* 16 ± 2 mmHg, after administration of sildenafil.

The plasma concentration of sildenafil at 80 min was not statistically significantly correlated to the changes in HVPG, splanchnic blood flow, mean arterial pressure, or right atrial pressure.

Four patients had a decrease in HVPG i.e. 3, 3, 3 and, 8 mmHg, respectively. Two of these where Child class A/B and all four had alcoholic cirrhosis.

DISCUSSION

This study reports the effects of sildenafil on the splanchnic hemodynamics in patients with biopsy proven

Table 1 Patient characteristics and clinical data (mean ± SD)

cirrhosis and manifest portal hypertension. Despite a small decrease in mean arterial pressure, the main finding in this study was that the splanchnic blood flow, oxygen consumption and the mean HVPG did not change 80 min after administration of sildenafil, i.e. at a time-point when a therapeutic plasma concentration of sildenafil[19] could be documented. These data appear to be in accordance with preliminary results testing the effect of an oral dose of 25 mg of sildenafil with which no effect on portal pressure was reported, in spite a decrease in arterial pressure[20]. However, our results appear to be in contrast to an earlier study reported by Deibert *et al*[14], in which vardenafil (another phosphodiesterase type-5 inhibitor) was found to lower portal pressure in four of five patients with Child A cirrhosis. The reason for this discrepancy is not clear, but three of the five patients in that latter study[14] had HVPG < 12 mmHg before administration of vardenafil.

As illustrated in Figure 1, the individual HVPG changes ranged from -8 to +2 mmHg. In an animal study with bile-duct-ligated rats, a statistically significant increase in the HVPG of 3% ± 1% after intramesenteric (10 mg/kg) administration of sildenafil has been reported[10]. Thus, our finding suggests that the effect of sildenafil on splanchnic hemodynamics in humans with cirrhosis is different from that in rats. This could be due to the uncertainty concerning which phosphodiesterase

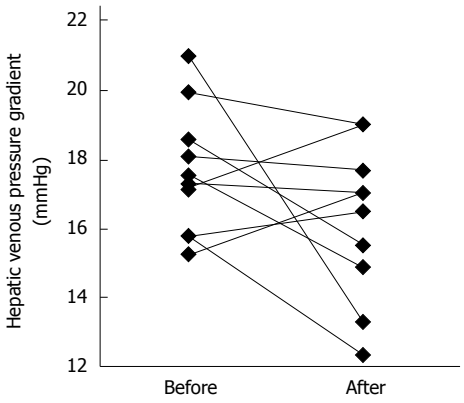

Figure 1 HVPG in ten patients with cirrhosis of the liver before and 80 min after oral intake of 50 mg sildenafil.

isoform, PDE5 and/or PDE1 is present in the human mesenteric artery[11]. It can be argued that even a 10%-15% increase in HVPG, as seen in one out of 10 patients in our study, might be problematic in the individual. However, small changes in the gradient probably take place during everyday life. For example, digestion of food increases hepatic blood flow by almost 100%. In particular, a major increase is seen in the superior mesenteric artery and thus portal blood flow[21]. Moreover, it has been demonstrated in patients with cirrhosis that a meal increases the mean HVPG from 16 to 20 mmHg, corresponding to 25%[22]. This could be even higher in the individual. The risk of experiencing a bleeding episode after intake of sildenafil should, therefore, be interpreted in the light of such everyday events.

The splanchnic hemodynamic data were collected during rest in the present study. However, supposedly the user of sildenafil is rarely in a resting position, but is more likely to increase the level of physical activity, which is known to influence the splanchnic hemodynamics[23]. In fact, physical activity, with an exercise level of 30% of peak workload, appears to increase HVPG from 16.7 to 19.2 mmHg[23]. Working at 50% of peak workload will not increase this HVPG gradient any further. Thus, the physical activity, which often is required to engage in sexual activity, may itself slightly increase the gradient. However, and of importance, the opposite has been observed in patients with cirrhosis during exercise and beta-adrenergic blockade[24]. In these patients, exercise at 30% of peak workload was associated with a decrease in HVPG from 16.3 to 12.9 mmHg[19]. This was explained by a lesser increase in cardiac output and a larger decrease in hepatic blood flow in the propranolol group compared to the non-beta-blocker-treated group of patients.

The possible effect on splanchninc hemodynamics after longer use of sildenafil is elusive and has not been examined. One concern about chronic use may be the possible renal effects. In patients with cirrhosis, administration of a single dose of sildenafil was followed by a decrease in sodium excretion[25]. However, the long-term renal effects may be insignificant as chronic

administration of sildenafil prevented the decrease in sodium excretion seen in bile-duct-ligated rats[26].

The present study shows that sildenafil does not induce any profound clinically relevant changes in splanchnic blood flow, oxygen consumption and HVPG. This indicates that phosphodiesterase type-5 inhibition is of no use as a therapeutic agent for alleviating portal hypertension in patients with chronic end-stage liver disease. On the other hand, the use of sildenafil in such patients, initiated because of erectile dysfunction, appears to be safe per se. However,, clearly more studies on safety are needed, as the use of sildenafil is usually associated with physical activity and often also the use of beta blockers.

COMMENTS

Background

Erectile dysfunction is a common problem affecting about half of all patients with end-stage liver disease. Selective phosphodiesterase type-5 inhibitors, such as sildenafil, represent an important advance in management of erectile dysfunction. In rats, administration of sildenafil results in a dose-dependent increase in mesenteric blood flow and a minor increase in portal venous pressure. The use of sildenafil could, therefore, be hazardous in patients with cirrhosis and portal hypertension and acute variceal bleeding has been described after intake of 25 mg sildenafil.

Research frontiers

Bleeding from esophageal varices is a major contributor to death in patients with end-stage liver disease and it could be hazardous to recommend treatment of erectile dysfunction with sildenafil if this treatment, in turn, leads to an increase in hepatic venous pressure gradient (HVPG).

Innovations and breakthroughs

Another human study addressing the presented problem has been published in abstract form, but the patients investigated all had Child class A cirrhosis whereas, erectile dysfunction as a "quality of life problem" tends to increase with increasing severity of liver disease i.e. Child class B and C, and such patients where investigated in the present study.

Applications

The present study does not support a restrictive use of sildenafil in patients with cirrhosis. Future research should be done with larger patient groups in order to determine the long-term risk of bleeding (if any) during treatment with sildenafil.

Terminology

Liver disease leads to accumulation of fibrous tissue in the liver, and in turn, this leads to increased resistance to the blood flow through the portal vein. The resistance is estimated by the HVPG and the risk of bleeding from esophageal varices in cirrhosis increases with this gradient.

Peer review

This is an interesting and informative study. The authors investigated if sildenafil increases splanchnic blood flow and changes the HVPG in patients with cirrhosis. Phosphodiesterase type-5 inhibitors are valuable in the treatment of erectile dysfunction and pulmonary hypertension in patients with end-stage liver disease.

Abstract

AIM: To evaluate survival rate and clinical outcome of cholangiocarcinoma.

METHODS: The medical records of 34 patients with cholangiocarcinoma, seen at a single hospital between the years 1999-2006, were retrospectively reviewed.

RESULTS: Thirty-four patients with a median age of 75 years were included. Seventeen (50%) had painless jaundice at presentation. Sixteen (47.1%) were perihilar, 15 (44.1%) extrahepatic and three (8.8%) intrahepatic. Endoscopic retrograde cholangiography (ERCP) and/or magnetic resonance cholangiography (MRCP) were used for the diagnosis. Pathologic confirmation was obtained in seven and positive cytological examination in three. Thirteen patients had co-morbidities (38.2%). Four cases were managed with complete surgical resection. All the rest of the cases (30) were characterized as non-resectable due to advanced stage of the disease. Palliative biliary drainage was performed in 26/30 (86.6%). The mean follow-up was 32 mo (95% CI, 20-43 mo). Overall median survival was 8.7 mo (95% CI, 2-16 mo). The probability of 1-year, 2-year and 3-year survival was 46%, 20% and 7%, respectively. The survival was slightly longer in patients who underwent resection compared to those who did not, but this difference failed to reach statistical significance. Patients who underwent biliary drainage had an advantage in survival compared to those who did not (probability of survival 53% *vs* 0% at 1 year, respectively, $P = 0.038$).

CONCLUSION: Patients with cholangiocarcinoma were usually elderly with co-morbidities and/or advanced disease at presentation. Even though a slight amelioration in survival with palliative biliary drainage was observed, patients had dismal outcome without resection of the tumor.

Key words: Cholangiocarcinoma; Surgical resection; Palliative biliary drainage; Survival

INTRODUCTION

Cholangiocarcinoma is the second commonest primary hepatic malignant disease, after hepatocellular carcinoma[1]. Several studies have shown that the incidence and mortality of the disease are rising worldwide[1,2]. The high fatality rate has been attributed to the poor knowledge of the tumor pathogenesis and the paucity of effective methods of diagnosis and management. First, the diagnosis of perihilar and extrahepatic cholangiocarcinoma still remains a clinical challenge, particularly in the presence of primary sclerosing cholangitis. Second, surgical resection is the only curative option for cholangiocarcinoma, but only a minority of patients are suitable for resection[3,4]. Factors that have been considered as contraindications for resectability include, among others, metastatic disease, multiple comorbidities, invasion of the hepatic artery or portal vein and extension of cholangiocarcinoma to involve segmental bile ducts on both liver lobes[3,4,5]. Sometimes the lack of available surgical expertise renders the surgical approach difficult to apply.

We aimed at evaluating the clinical features, diagnostic modalities, therapeutic options and survival rates in a series of 34 patients with cholangiocarcinoma hospitalized

at the Hippokration University Hospital, Athens, Greece. We also attempted to investigate whether there were differences in survival, compared to data published in the literature, and to identify factors associated with survival.

MATERIALS AND METHODS

The medical records of 34 patients diagnosed with cholangiocarcinoma at the Hippokration University Hospital between January 1999 and December 2006 were retrospectively reviewed. The study was approved by the local Ethics Committee. Our hospital has a liver unit and several patients with cholangiocarcinoma are referred from other hospitals. Diagnosis of cholangiocarcinoma was based upon clinical, imaging, cytologic and histopathologic findings. Medical records were scrutinized for epidemiologic characteristics, predisposing factors, initial manifestations of the disease, method of diagnosis, laboratory findings, surgical or palliative therapy, and overall morbidity and mortality.

Cholangiocarcinoma was classified as intrahepatic, perihilar and distal extrahepatic type[3,6]. The staging of the tumor was based on the tumor-node-metastasis system[7]. The perihilar tumors were classified according to the Bismuth classification[8] and the resectability was evaluated according to T-stage criteria[4]. All patients had ultrasound of the liver and gallbladder as the first diagnostic imaging procedure. Metastatic disease was evaluated by imaging of the chest, abdomen and pelvis by helical computed tomography (CT) or magnetic resonance imaging (MRI). No laparoscopic staging was performed.

Statistical data were analyzed using SPSS 13.0 for Windows. Descriptive statistics including mean, ranges and standard deviation values were calculated for all the continuous baseline demographic and laboratory characteristics. We used the Kruskal-Wallis non-parametric test to compare continuous data. The results are presented as means ± 95% confidence intervals (CI). The χ^2 test was used to compare categorical data; the results are presented as counts with percentages. All reported *P* values are based on two-tailed tests of significance. Comparisons were considered significantly different if $P < 0.05$. Overall survival was estimated from the admission of the patient to the hospital until death or last follow-up visit. Survival probabilities were estimated using the Kaplan-Meier method and compared by the log-rank test. Univariate analysis using the Cox regression test was used to determine factors associated with survival.

RESULTS

The study group included 18 men and 16 women, all of Greek origin. Sixteen of 34 (47.1%) were perihilar, 15 (44.1%) extrahepatic and three (8.8%) intrahepatic tumors. Demographic characteristics and laboratory data on presentation are shown in Table 1. Initial manifestations were painless jaundice in 17 patients (50%), whereas 12 (35.3%) presented with abdominal pain and weight loss.

Table 1 Demographic and biochemical characteristics of all patients at baseline (mean ± SD)

Patient characteristics	
Gender (M %)	18/34 (53%)
Age (years)	71.7 ± 13.3
Bilirubin (mg/dL)	13.3 ± 9.1
AST (U/mL)	117 ± 80
ALP (U/mL)	472 ± 237
Albumin (g/dL)	3.6 ± 0.5
Predisposing factor (%)	4/34 (11.7%)
Tobacco use (%)	10/34 (29.4%)

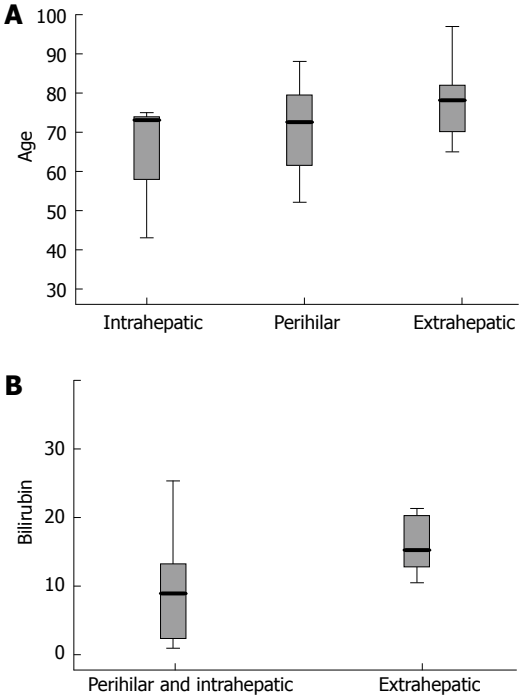

Figure 1 Comparison of baseline characteristics of the patients with respect to site. A: Age distribution with respect to site (intrahepatic, perihilar and extrahepatic) is significantly not different; B: Bilirubin values at presentation with respect to site (intrahepatic, and perihilar *vs* extrahepatic; $P = 0.027$).

Patients with extrahepatic type of cholangiocarcinoma were older than those with perihilar and intrahepatic type, but the difference was not statistically significant (79 ± 8.4 years *vs* 72.5 ± 11 years and 63.6 ± 17.9 years respectively, $P = 0.181$, Figure 1A). Mean values of total bilirubin were higher in the extrahepatic than in perihilar and intrahepatic type (17 ± 9 mg/dL *vs* 8.9 ± 7.5 mg/dL, $P = 0.027$, Figure 1B).

A history of a predisposing factor was recognized in four patients, two with primary sclerosing cholangitis and two with chronic hepatitis B and cirrhosis. No case of Caroli's syndrome, congenital hepatic fibrosis, choledochal cyst or occupation in the chemical industry was found. Moderate consumption of alcohol and use of tobacco were present in four (11.7%) and 10 (29.4%) patients, respectively. Thirteen (38.2%) patients presented with co-morbidities, mostly diabetes mellitus with complications and/or coronary disease.

Intrahepatic tumors were histologically proven using

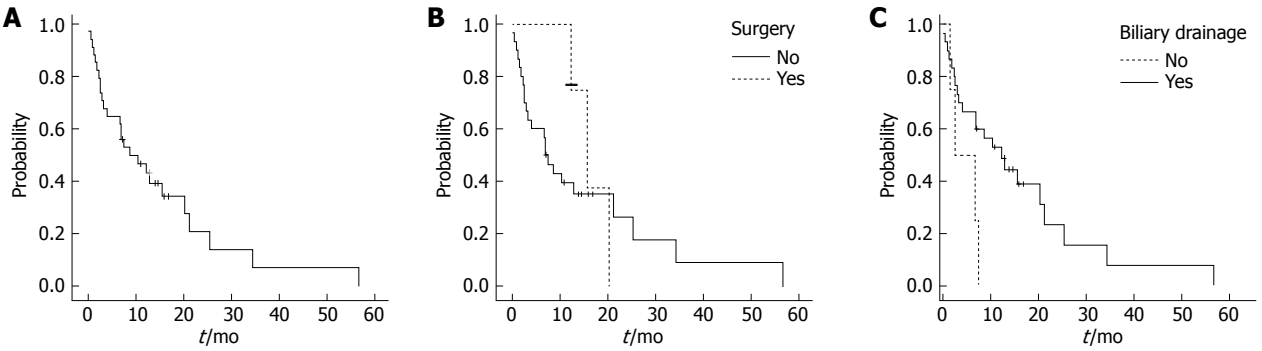

Figure 2 Survival rates in different groups of patients according to treatment. A: Survival of all the 34 patients with cholangiocarcinoma; B: Survival rates of patients with cholangiocarcinoma, stratified by surgical (n = 4) or not surgical resection (n = 30) were not significantly different; C: Survival of patients with unresected cholangiocarcinoma among those who had any kind of biliary decompression (n = 26) and those who had no interventional therapy (n = 4, P = 0.038).

a CT-guided biopsy. Eight of 16 (50%) perihilar tumors were diagnosed by magnetic resonance cholangiography (MRCP) and magnetic resonance imaging (MRI), 4/16 (25%) by endoscopic retrograde cholangiography (ERCP) and 4/16 (25%) by histology (biopsies were obtained at laparoscopy in three cases and at endoscopic ultrasound in one case). Five of 15 (33%) extrahepatic tumors were diagnosed by MRCP/MRI, and 10/15 (66%) by ERCP. Overall, tissue for pathologic confirmation was obtained from seven patients, three with intrahepatic and four with perihilar tumors. A positive cytologic examination was obtained in three further cases.

A local surgical team evaluated the cases as resectable or non-resectable. Four cases were managed with complete surgical resection aiming at histologically negative resection margins (two extrahepatic, one perihilar and one intrahepatic type). All of the remaining cases were characterized as non-resectable. Among the 15 unresectable perihilar tumors, three (20%) were classified as T2-T3 stage, and extension of the hepatectomy was considered too risky compared to the poor patients' performance status; nine others (60%) had evidence of either metastases or extensive local lymphadenopathy or portal vein involvement; and the three remaining patients (20%) had multiple co-morbidities. Two of three intrahepatic tumors were multifocal and were assessed as non-resectable. Three of 13 (23%) cases with unresectable extrahepatic tumors had evidence of either metastases or extensive local lymphadenopathy or portal vein involvement, and 10 (77%) had multiple co-morbidities, including cardiopulmonary disease or diabetes with complications, poor performance status and advanced age (> 80 years) and thus were considered as unsuitable for curative resection.

Palliative biliary drainage to relieve symptoms was performed in the vast majority of cases who did not undergo surgical curative therapy (12/15 perihilar, 13/13 extrahepatic, 1/2 intrahepatic). More specifically, among the perihilar-type cholangiocarcinoma cases who were not resected, eight were managed by stent placement (seven biliary stents were inserted by endoscopic and one by percutaneous routes), three by palliative percutaneous biliary drainage, and one by palliative surgical biliary drainage. No biliary decompression was decided in three cases. Among the two intrahepatic cases not resected, one was managed with palliative percutaneous biliary drainage and no biliary drainage was decided in one case. Among the 13 extrahepatic cases not resected, 12 were managed by stent placement endoscopically and one by palliative percutaneous biliary drainage.

A high number of patients who underwent a palliative biliary drainage (11/26, 42%) were managed with two or more endoscopic or percutaneous sessions for biliary decompression because of stent occlusion (median number of procedures for each patient was two, range 1-7). Metal stents were placed in the vast majority of patients.

Four cases (one intrahepatic, one extrahepatic and two perihilar type) were managed with chemotherapy without surgical resection (two in combination with biliary drainage and two without any other intervention). The causes of death in two-thirds of the patients were infective complications (acute cholangitis) following an occluded biliary stent or acute pancreatitis. Other causes of death were hepatic failure and acute myocardial infarction.

The mean follow-up for all patients was 32 mo, 95% CI 20-43 mo. Overall median survival was 8.7 mo (events, 26/34; 95% CI, 2-16 mo). The probability of 1-year, 2-year and 3-year survival was 46%, 20% and 7%, respectively (Figure 2A). The survival was longer in patients who underwent surgical resection (n = 4) compared to those who did not (n = 30), but the difference failed to reach statistical significance. The probability of survival for the former was significantly higher than for the latter (75% *vs* 39% and 37% *vs* 26% at 1 and 2 years respectively, P = 0.6, Figure 2B). The median survival was 15.7 mo, (95% CI 11-20.6 mo) in the former and 7 mo, (95% CI, 4.4-9.6 mo) in the latter group.

Patients who received any interventional treatment for biliary drainage (either stent replacement or percutaneous biliary drainage or palliative surgical procedure, n = 26) had an advantage in survival in comparison to those who did not (n = 4). The probability of survival for the former was significantly higher than for the latter (53% *vs* 0% at 1 year respectively; median survival, 12.3 mo; 95% CI, 6-18.7 mo and 2.5 mo, 95% CI, 0-7.6 mo, respectively; P = 0.038; Figure 2C). None of the four patients who did not undergo biliary drainage survived beyond 6 mo. None of the following

factors were associated with a statistically significant difference in survival: age, gender, bilirubin, site of the tumour, albumin, stent placement, and chemotherapy.

DISCUSSION

Cholangiocarcinoma is a relatively rare disease accounting for less than 2% of all human malignancies[9]. The specific features of cholangiocarcinoma depend on the anatomical location of the tumor, which are useful to optimize the appropriate therapy. The most common location of these tumors (60%-70%) is the bifurcation of the hepatic ducts (perihilar or Klatskin tumours), while 20%-30% are extrahepatic, arising from the distal common bile duct, and 5%-10% are peripheral or intrahepatic tumors, originating from the small bile ducts of the liver parenchyma[10]. In our series, the perihilar and extrahepatic tumors had the same incidence (47% and 44%, respectively) while intrahepatic tumors accounted for a small minority (8.8%).

The distribution of age among our patients was different in the three types of tumor, with the extrahepatic cases being older, in agreement with the literature[7]. Co-morbidities were common in the extrahepatic type, as older individuals have more illnesses than younger ones. The clinical presentation and risk factors were rather similar with respect to the site of the malignancy. Painless jaundice, abdominal pain, weight loss, use of tobacco and consumption of alcohol did not show predilection for any site of the tumor. It appeared however that jaundice at presentation was more profound in the extrahepatic type of disease than in the perihilar cases. Only a few cases of cholangiocarcinoma were associated with a predisposing factor such as primary sclerosing cholangitis and chronic hepatitis B, a rather low rate compared with other series[11]. Other chronic inflammatory diseases of biliary epithelium such as parasitic infections or intrahepatic biliary stones are not endemic in the Greek population.

At present, only surgical excision of all detectable tumors is associated with improvement in survival. The median survival time for patients with distal bile duct cancers who undergo resection has been reported to be about 38 mo[12,13]. The median survival time for patients with perihilar cholangiocarcinoma varies from 12 to 46 mo[4,14,15,16]. However, factors associated with both the patient and the tumor may preclude surgical resection. It is generally accepted that many patients are not considered surgical candidates because of co-morbidities and advanced age, despite evidence of resectable disease. On the other hand, more than half of cholangiocarcinoma cases usually present with advanced unresectable malignancy[4,17]. In our series, 50% of the patients were considered to have advanced disease and the remaining had multiple co-morbidities and/or advanced age. In the literature, neither a T2 or T3 stage nor portal involvement are considered absolute contraindications for resection for perihilar tumours[4,5]. Similarly, local lymphadenopathy is not a contraindication to resection of extrahepatic tumors[17]. Co-morbidities and advanced age along with the available local surgical expertise determined the low rate of resectability in our series. In an old series from Mayo Clinic, only 22 of 125 patients (18%) underwent curative resection, whereas 82% were candidates for palliative intervention[18]. In another more recent series of 225 patients with hilar cholangiocarcinoma, 80 (35%) underwent resection[4] while resectability rates were higher for intrahepatic cholangiocarcinoma ranging from 45% to 90%[19,20].

No significant survival advantage was found in patients who underwent surgical resection in our series. Curative surgical resection was attempted in only four patients and the disease recurred after resection in three of the four. It is noteworthy that no free-of-cancer surgical margins were found at histology among those three surgical specimens. The natural history of resected cholangiocarcinoma with no disease-free surgical margins is comparable to unresected cholangiocarcinoma receiving palliative therapy[4,21,22]. The overall median survival in our series was 8.7 mo, with a survival rate comparable to that reported for unresected cholangiocarcinoma from previous investigators[18,23,24].

Palliative treatment to relieve symptoms and resolve obstructive jaundice has an important role in the management of cholangiocarcinoma, since the majority of cases are not suitable for resection, as stated above, or they recur after resection[4,25]. Palliation and relief of jaundice can be accomplished by either endoscopic, percutaneous, or operative means. We found that the single factor that may provide a survival benefit in unresected cases is successful biliary decompression. It is noteworthy that of our four patients with cholangiocarcinoma with no interventional procedure for biliary decompression, none survived beyond 6 mo. Similarly, median survival for non-resectable cholangiocarcinoma has been considered as favourable in cases in which biliary drainage is performed, since the median survival has been reported to be 3 mo without and 6 mo with biliary drainage[18,26]. Our attempt to identify other factors associated with survival, e.g. gender or additional palliative therapy (i.e. chemotherapy), failed to show any survival advantage for any of them, even if some were shown to be important in previous studies[18].

Despite the benefit in survival afforded by biliary drainage, the enhancement in quality of life with this kind of intervention seemed to be minimal, since the majority of patients had repeat procedures to ensure the patency of the stents. Patency rates of self-expanding metal stents are higher than those of plastic ones[27]. Even if metal stents remain patent longer, a high percentage of our patients needed the replacement of two or more stents in repeat procedures for resolution of jaundice.

The major limitation of our study was that it involved only a single center and the number of patients was small, and thus the results may not be generalizable.

In conclusion, the present study confirms that cholangiocarcinoma is a tumor with high incidence among the elderly with multiple co-morbidities, which precludes aggressive curative resection. Moreover, survival of patients with unresected cholangiocarcinoma

is short and the benefit in survival, but not in quality of life, from endoscopic or percutaneous biliary drainage, although evident, is rather weak. Therefore, early diagnosis and surgical resection of the tumor are crucial in the management of these patients.

COMMENTS

Background

Cholangiocarcinoma is difficult to diagnose and its prognosis is dismal due to late stage at presentation. The incidence and mortality of the disease are rising worldwide.

Research frontiers

The high fatality rate of cholangiocarcinoma is attributed to the poor knowledge of disease pathogenesis and the paucity of effective methods of diagnosis and management. Surgical resection is the only curative option for cholangiocarcinoma, but only a minority of patients are suitable for resection.

Innovations and breakthroughs

This study confirms that cholangiocarcinoma is diagnosed at an advanced stage, with high incidence among the elderly with multiple co-morbidities, which precludes aggressive curative resection. Survival of patients with unresected cholangiocarcinoma is short and the benefit in survival, but not in quality of life, from endoscopic or percutaneous biliary drainage, although evident, is rather weak.

Applications

The study suggested that early diagnosis and surgical resection of the tumor are crucial in the management of these patients.

Peer review

This is a retrospective study of the outcome of cholangiocarcinoma in a group of 34 patients seen at a single hospital, characterized by a homogeneous ethnic population of Greek origin. The aims are not ambitious and the originality of study is not high. However, the study is still relevant due to the severity of the disease and the scarce information available.

Abstract

AIM: To examine the expression of thymidylate synthase (TS) and oncoprotein Bcl-2 in advanced colorectal cancer (CRC) patients, and to determine their mutual relationship, association to therapeutic response and impact on disease outcome.

METHODS: Tumor samples from 67 patients with CRC, who were treated at advanced stage with either irinotecan alone or in combination with 5-fluorouracil/leucovorin, were analyzed for expression of TS and Bcl-2 using immunohistochemistry.

RESULTS: A significant linear correlation between lower expression levels of Bcl-2 and lower levels of TS expression was found (P = 0.033). Patients with high levels of both TS and Bcl-2 expression had a significantly longer disease-free survival (DFS) (42.6 mo *vs* 5.4 mo, n = 25) than those with low TS/Bcl-2 index (P = 0.001). Tumors with low levels of both TS and Bcl-2 were associated with a longer survival with metastasis (WMS) interval in the whole patients group (n = 67, P = 0.035). TS/Bcl-2 index was not significantly related to disease-specific survival.

CONCLUSION: The present data suggest that CRC patients with low TS/Bcl-2 demonstrate a significantly shorter DFS and longer WMS.

Key words: Thymidylate synthase; Bcl-2; Colorectal cancer; Disease-free survival; Survival with metastases

INTRODUCTION

Colorectal cancer (CRC) is the second most frequent cancer in Europe in 2004, responsible for 13% (376 400) of all incident cancer cases. It is also the second most frequent cause of cancer mortality in Europe, with an annual mortality of 11.9%, 203 700 annual deaths[1]. In the early stages, CRC is often a curable disease, but the overall prognosis is determined by the extent of local and particularly metastatic tumor spread. However, disease outlook is relatively poor for advanced disease and thus is a significant cause of worldwide cancer-related mortality[1]. For locally advanced and metastatic CRC, fluoropyrimidine, 5-fluorouracil (5-FU) has been the standard cytostatic drug for the last 50 years, in recent years used as modulated by leucovorin and in combination with irinotecan or oxaliplatin.

Fluoropyrimidine metabolites form a covalent complex with thymidylate synthase (TS). Formation of this complex prevents biosynthesis of intracellular thymidylate, which is essential for DNA biosynthesis. TS expression has been shown to be an independent prognostic factor in several other cancers. Higher TS levels in hepatic metastases and resection margin are independent predictors of disease progression and survival in patients with metastatic CRC[2]. Comparable results have been reported in other tumors e.g. gastric[3], cervical[4], ovarian, and head and neck cancers, for which TS+ tumors have demonstrated significantly worse outcome as compared to TS-negative tumors.

Increased expression of the proto-oncogene Bcl-2, a 24-kDa intracellular membrane protein that is able to inhibit programmed cell death without affecting cell proliferation, has been reported in gastrointestinal adenocarcinoma and its precursor lesions[5,6]. Bcl-2

has been shown to prolong cell survival by inhibiting apoptosis in several cell types[7,8]. Abnormal activation of the Bcl-2 gene appears to be an early event in colorectal tumorigenesis[6].

In this study, we examined the expression of TS and the oncoprotein Bcl-2 in locally advanced and metastatic CRC and determined their inter-relationships, as well as their impact on patient survival.

MATERIALS AND METHODS

Patients, treatment and follow-up

A series of 67 patients were diagnosed and treated for Stage Ⅱ, Ⅲ, Ⅳ CRC at the Department of Oncology and Radiotherapy, Turku University Hospital (TUH) and six other hospitals in the same hospital district, between January 1996 and August 2003. The key clinical characteristics of the patients are summarized in Table 1.

At the time of diagnosis, 11 patients had stage Ⅱ, 14 had stage Ⅲ and 42 had stage Ⅳ disease. When patients developed metastases or inoperable local recurrence, they were entered into the chemotherapy protocol. In the protocol, patients received one of two treatment regimens; 18 received irinotecan alone and 49 received a combination of irinotecan, 5-FU and folinic acid (FA) as first line treatment for metastatic disease. Irinotecan (350 mg/m^2) was administered as a 60-90 min intravenous (i.v.) infusion every 3 wk. In the combination regimen, irinotecan (180-210 mg/m^2) was administered as 60-90 min intravenous infusion and 5-FU (500 mg/m^2, i.v. bolus) modulated with folinic acid (FA) (60 mg/m^2, i.v. bolus). The 5-FU/FA administrations were repeated again on the following day. The cycle was repeated every 2 wk[9]. The mean duration of chemotherapy was 6.3 mo (SD, 3.4 mo). Treatment was continued until disease progression, or occurrence of unacceptable toxicity.

The patients were prospectively followed-up until the end of March 2007; mean follow-up time from diagnosis was 34.4 mo (± 26.2 mo). We used three endpoints to calculate the patient survival: (1) disease-free survival (DFS), which was calculated in 26 patients with stage Ⅱ or Ⅲ diseaseat diagnosis; (2) overall disease-specific survival (DSS); and (3) survival with metastases (WMS). DFS is the time from diagnosis to the appearance of metastatic disease and relevant only for those patients with radically operated stage Ⅱ and Ⅲ patients at the time of diagnosis (n = 25). DSS is the time from diagnosis to death or to the time point when last seen alive at the clinic, and was calculable for all patients in the study. WMS was calculated from the date of recording the appearance of disease recurrence/metastases at the clinical visit, until to death or to the time point when last seen alive.

The study was approved by the Ethical Committee and was conducted in accordance with the Declaration of Helsinki. Samples were collected with the endorsement of the National Authority for Medico-legal Affairs.

Immunohistochemical detection of TS and Bcl-2 expression

Sixty-seven formalin-fixed, paraffin-embedded primary tumors were obtained from 67 patients. Sections were cut serially at 5 μm for routine hematoxylin and eosin staining and for immunohistochemical analysis. An experienced pathologist confirmed all histological diagnoses.

TS expression was studied immunohistochemically using monoclonal antibody (Mouse Clone TS 106) from Zymed Laboratory. Bcl-2 protein expression was studied using anti-Bcl-2 monoclonal mouse antibody, which recognizes a peptide comprising amino acids 41-54 of the human Bcl-2 protein (Clone 124, DAKO A/S, Glostrup, Denmark). Signal detection was performed using the streptavidin-biotin method (Vectastain ABC kit). Formalin-fixed, paraffin-embedded sections were deparaffinized in xylene, rehydrated in graded alcohol, immersed in 0.01 mol/L citrate buffer (pH 6.0), heated in a domestic microwave oven at full power for 2 × 5 min, and left in the buffer to cool to room temperature. The sections were incubated in 0.3% hydrogen peroxide for 20 min to block endogenous peroxidase activity. Incubation with the primary antibody diluted in 1%

bovine serum albumin/Tris-buffered saline, TS (1:25) and Bcl-2 (1:50), were carried out overnight in a humid chamber at 4℃. The following day, the slides were washed and incubated first with the biotinylated secondary antibody (30 min, 20℃), then with avidin-biotin-peroxidase complex (30 min, 20℃). Positive staining was visualized with 3,3' diaminobenzidine (DAB) substrate solution and the sections were counterstained with Mayer's hematoxylin. As negative controls, slides were processed with the omission of the primary antibody.

Evaluation of TS and Bcl-2 expression

Expression of TS and Bcl-2 was assessed by an observer blinded to the clinical data. The slides were first screened for an overview of the general staining pattern. Four pictures of each slide, covering most of the tumor area, were taken with a light microscope (4 × magnification) connected to a camera and AnalySIS v 3.00 software (Soft Imaging System GmbH, Munster, Germany). Expression of TS in the four pictures was analyzed using Imaging Research Inc., St. Catharine's, Ontario, Canada), which detected the brown color of the positively stained tumor cells and counted the area of those cells in pixels, and also counted in pixels the total tumor area. The percentage of positively stained tumor cells from the whole tumor area was counted and used in further analysis. This method of evaluating TS expression was able to distinguish between the presence of many cells expressing low amounts and a few cells expressing high amounts of TS, such that the percentage of TS expression reflected total TS expression in the tumor, which may be more relevant biologically.

For statistical purposes, expression profiles of each marker were treated as dichotomous variables, where tumors with negative or weak expression of Bcl-2 was one category (reduced expression), and all those with moderate or strong expression were grouped into the second category. For TS, we used median values as cut-off to build up the dichotomous variable of low- and high TS expression. In addition, combined TS-Bcl-2 indices were created, using the dichotomous Bcl-2 variables and TS variables (median cut-offs), resulting in four possible combinations of TS/Bcl-2: low/low (L/L); low/high (L/H); high/low (H/L); and high/high (H/H). Finally, these were converted to a 3-class index as follows: class 1, TS/Bcl-2, L/L; class 2, TS/Bcl-2, L/H or H/L; and class 3, TS/Bcl-2 H/H.

Statistical analysis

Statistical analyses were performed using the SPSS® (SPSS, Inc., Chicago, IL, USA) and STATA (Stata Corp., TX, USA) software packages (SPSS for Windows, version 14.0.1 and STATA/SE 10.1). Frequency tables were analyzed using the χ^2 test, with likelihood ratio (LR) or Fisher's exact test being used to assess the significance of the correlation between categorical variables. Differences in the means of continuous variables were analyzed using non-parametric tests (Mann-Whitney or Kruskal-Wallis tests) for two and multiple independent samples, respectively. ANOVA was only used for deriving the mean values in each stratum. Univariate survival (life-table) analysis for the outcome measure, DSS, DFS and WMS was based on Kaplan-Meier method, and the groups were compared with the log-rank (Mantel-Cox) test. In all tests, $P < 0.05$ was regarded as statistically significant.

RESULTS

Expression of Bcl-2 and staining of TS are shown in Figure 1. Bcl-2 index and TS index (absolute values) were significantly correlated ($r = 0.286$, Spearman rho, $P = 0.019$). Similarly, using the median-cut off values, there was a significant correlation between Bcl-2 and TS expression profile ($P = 0.039$, Spearman rho or $P = 0.037$, χ^2). In pair-wise comparison, individual samples did not significantly deviate in their Bcl-2 and TS expression profile (median cut-off; $P = 0.841$, Wilcoxon signed ranks test), indicating that in individual tumors, co-detection of H/H and L/L of both markers was a frequent occurrence.

The combined TS-Bcl-2 index was evaluated in relation to all clinical variables recorded, including the response to treatment and survival (DSS, DFS and WMS). Interestingly, for the first time, a significant correlation between TS/Bcl- 2 index and DFS was observed. Among stage Ⅱ and Ⅲ disease ($n = 25$), tumors with H/H profile of TS and Bcl-2 (class 3) were associated with substantially longer DFS (42.6 mo) than those with L/L (5.4 mo) or those with H/L or L/H profile (20.7 mo; $P = 0.031$, Kruskal-Wallis), and this was even more evident in life-table analysis ($P = 0.001$, Mantel-Cox; Figure 2A).

There was a close correlation between TS/Bcl-2 expression and WMS; tumors with L/L profile of TS and Bcl-2 (class 1) were associated with a longer WMS (31.9 mo) than those with H/H (25.7 mo) or H/L and L/H (18.9 mo) in the whole series ($n = 67$, $P = 0.076$, Kruskal-Wallis and $P = 0.092$ Mantel-Cox) (Figure 2B). There was no such difference in DSS among the three TS/Bcl-2 expression profiles, however. TS/Bcl-2 expression was not significantly associated with any other clinicopathological variables, including age, sex, TNM status, grade, stage or carcinoembryonic antigen (CEA) levels.

DISCUSSION

The treatment of CRC has become increasingly complex over recent years. With the emergence of new chemotherapy drugs and targeted agents, there has been a major improvement in the prognosis of patients with metastatic CRC. The identification of prognostic and predictive markers is clinically important, because CRC is a heterogeneous disease with various biological and clinical characteristics.

The present study analyzed the combined TS and Bcl-2 expression in CRC, with particular reference to disease outlook. An increase in TS levels has been

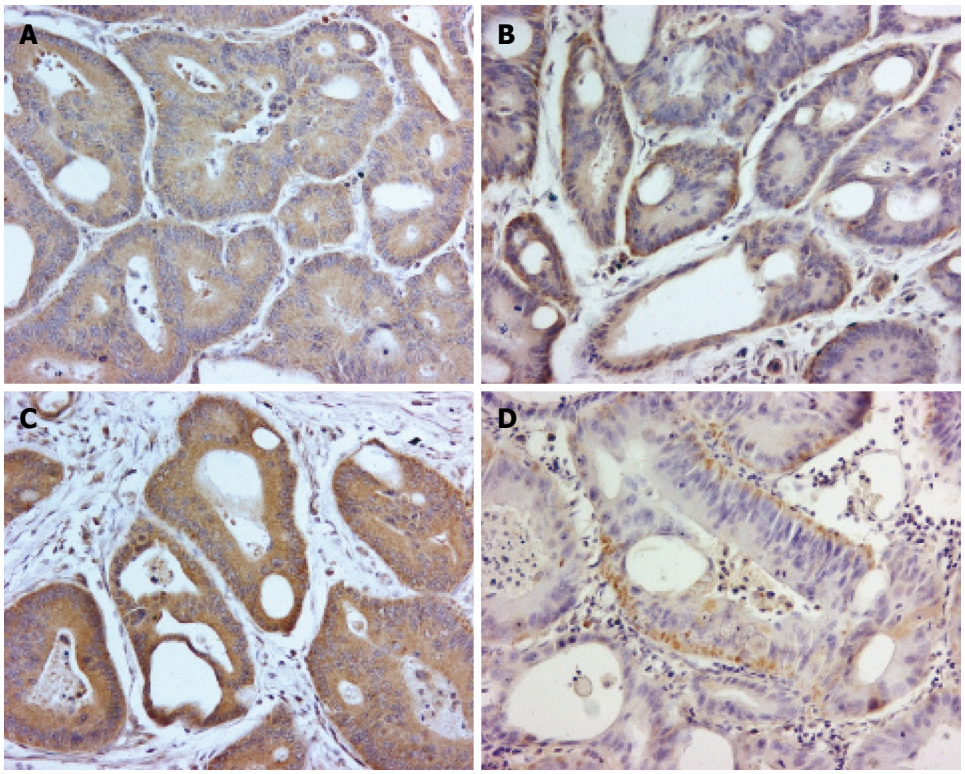

Figure 1 Examples of expression of Bcl-2 and staining of TS. A: High expression of Bcl-2; B: Low expression of Bcl-2; C: High staining of TS expression; D: Low staining of TS expression.

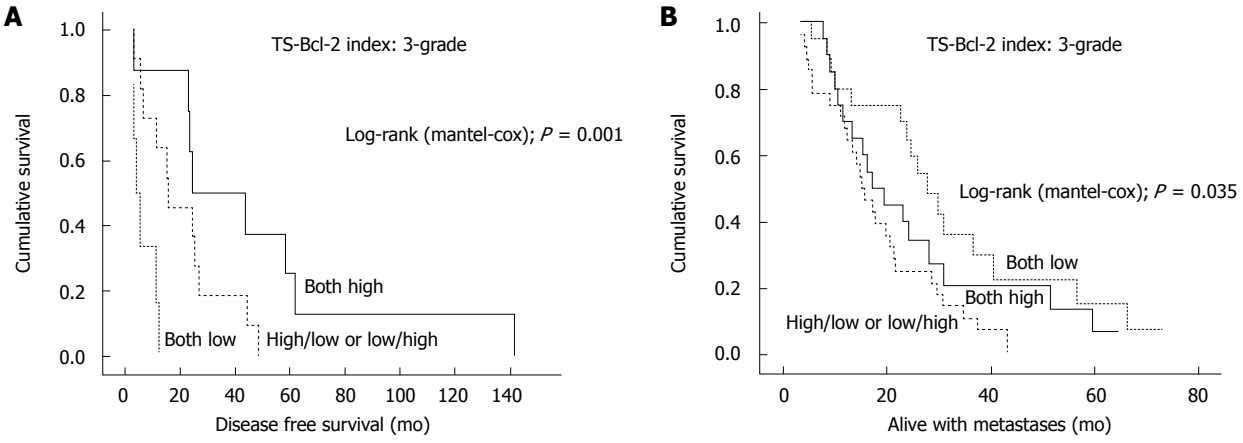

Figure 2 Univariate (Kaplan-Meier) analysis. A:TS/Bcl-2 expression and disease free survival (DFS); B:TS/Bcl-2 expression and survival with metastases (WMS).

suggested to be an important mechanism of resistance to fluoropyrimidine-based chemotherapy[10]. In several studies, TS is reported to be a predictor of both survival in CRC[11-14] and response to 5-FU therapy, with higher levels being associated with poorer prognosis and response to therapy[11,12,15,16]. This suggests that TS levels are not only of importance in predicting the natural course of the disease, but may also predict the sensitivity of cancer cells to 5-FU, which is widely used both in the adjuvant setting and in the treatment of metastases[17,18].

The role of the Bcl-2 family of proteins in chemoresponse has been evaluated extensively in *in vitro* models. Over-expression of Bcl-2 and Bcl-XL has been shown to induce drug resistance[19-21]. In relation to treatment, it has been demonstrated that elevated levels of Bcl-2 protein confers cytotoxic drug resistance to tumor cell lines[7,22]. As Bcl-2 blocks apoptosis *in vitro* and thus contributes to malignant cell accumulation, its over-expression is expected to be associated with more aggressive tumor biology. Indeed, genetic alteration of the Bcl-2 gene located on chromosome 18 is considered to be a key process in the pathogenesis and chemoresistance of human tumors, such as follicular lymphoma[23].

In our previous analysis of Bcl-2 expression in a subset of these tumors (n = 49), we found a weak association of lower levels of Bcl-2 expression with longer overall survival[24]. In another small series (n = 28)[25], we described that lower levels of Bcl-2 expression were significantly associated with lower levels of TS expression. The present study clearly confirmed this observation in a larger series of CRC patients (n = 67), for which a significant linear correlation was established between the two markers (P = 0.039, Spearman). High expression of

TS (above the median) significantly correlated with higher Bcl-2 expression levels. In our previous study, some evidence has suggested that higher levels of TS and Bcl-2 are associated with shorter overall survival[24,25], implicating that elevated levels of TS and Bcl-2 may confer cytotoxic drug resistance among these patients.

To the best of our knowledge, our study shows for the first time the relationship between these two key molecules in a group of patients with locally advanced or metastatic CRC receiving similar treatment. As to the patient survival, there was a significant correlation of TS/Bcl-2 expression with DFS, in that the patients with high TS/Bcl-2 index had a longer DFS (Figure 2A). No such effect was shown for DSS, which was not significantly different among the patients with low- and high TS/Bcl-2 indices.

To conclude, the present data suggest that patients with CRC whose tumors have high TS and Bcl-2 demonstrate a significantly longer DFS and shorter WMS, as compared to patients with low expression of these markers.

COMMENTS

Background

Thymidylate synthase (TS) is reported to be a predictor of both survival in colorectal cancer (CRC) and response to 5-FU therapy, with higher levels being associated with poorer prognosis and response to therapy. Elevated levels of Bcl-2 protein also confer cytotoxic drug resistance to tumor cell lines. We here examined the expression of TS and oncoprotein Bcl-2 in advanced CRC patients, and determined their mutual relationship, association to therapeutic response and impact on disease outcome.

Research frontiers

This study represents a translational study in which a clinical series of CRC samples were analyzed for two important molecular markers: TS and Bcl-2. Accordingly, this study represents a combined molecular analysis and a clinical study, whereby some key molecular pathways were analyzed and their relevance to clinical data was assessed in a series of 67 CRC patients with well-characterized treatment history and long-term follow-up data.

Innovations and breakthroughs

To the best of our knowledge, this is the first study to show the relationship between these two key molecules in a group of patients with locally advanced or metastatic CRC receiving similar treatment. As to the patient survival, there was a significant correlation of TS/Bcl-2 expression with DFS, in that the patients with high TS/Bcl-2 index had a longer DFS.

Applications

The present data suggest that patients with CRC whose tumors have high TS and Bcl-2 demonstrate a significantly longer DFS and shorter WMS, as compared to patients with low expression of these markers. This information should have potential clinical implications in the management of these patients.

Peer review

The importance of this paper to the reader resides in the fact that this study is believed to be the first to suggest that CRC patients with low TS/Bcl-2 demonstrate a significantly shorter DFS, but keep alive longer with a metastatic disease. In relevant cases, one might consider utilizing this type of molecular marker data in more individualized tailoring of the appropriate therapies.

Abstract

AIM: To establish the efficacy and safety of a 7-d therapeutic regimen using omeprazole, bismuth subcitrate, furazolidone and amoxicillin in patients with peptic ulcer disease who had been previously treated with other therapeutic regimens without success.

METHODS: Open cohort study which included patients with peptic ulcer who had previously been treated unsuccessfully with one or more eradication regimens. The therapeutic regimen consisted of 20 mg omeprazole, 240 mg colloidal bismuth subcitrate, 1000 mg amoxicillin, and 200 mg furazolidone, taken twice a day for 7 d. Patients were considered as eradicated when samples taken from the gastric antrum and corpus 12 wk after the end of treatment were negative for *Helicobacter pylori* (*H pylori*) (rapid urease test and histology). Safety was determined by the presence of adverse effects.

RESULTS: Fifty-one patients were enrolled. The eradication rate was 68.8% (31/45). Adverse effects were reported by 31.4% of the patients, and these were usually considered to be slight or moderate in the majority of the cases. Three patients had to withdraw from the treatment due to the presence of severe adverse effects.

CONCLUSION: The association of bismuth, furazolidone, amoxicillin and a proton-pump inhibitor is a valuable alternative for patients who failed to respond to other eradication regimens. It is an effective, cheap and safe option for salvage therapy of positive patients.

Key words: Gastric ulcer; Duodenal ulcer; *Helicobacter pylori*; Retreatment; Furazolidone

INTRODUCTION

Since the discovery of the etiological role of *Helicobacter pylori* (*H pylori*) in peptic ulcer disease[1], its eradication became the main objective of therapy, and several treatment regimens were developed. Currently, triple therapy with omeprazole, amoxicillin, and clarithromycin remains the best therapeutic option[2]. Despite its efficacy, 10% to 20% of the patients present with treatment failure, demanding alternative therapeutic regimes with variable success rates[3,4]. The reasons for this considerable rate of failure are several, including low patient compliance with treatment[5], and bacterial resistance to antimicrobial agents[6,7]. The development of effective salvage treatments is of paramount importance in this situation.

Furazolidone is a synthetic nitrofuran derivative with bactericidal or bacteriostatic activity against Gram-positive and Gram-negative bacteria, and it is well absorbed in the intestine with no tissue accumulation[8]. It has anti-*H pylori* activity and resistant strains appear to be rare or non-existent in many areas[9], characteristics

that make it a potential option for retreatment of peptic ulcer disease caused by *H pylori*. One of the main limitations for its widespread use is the relatively high incidence of significant adverse effects, reported mainly in European studies[10]. In a country such as Brazil, which has large populations with low socioeconomic levels and a high bacterial resistance to metronidazole[11], furazolidone emerges as an interesting option.

This study aimed to establish the efficacy and safety of a 7-d therapeutic regimen for *H pylori* eradication (omeprazole, bismuth subcitrate, furazolidone, and amoxicillin) in patients with peptic ulcer disease who had been previously treated with other therapeutic regimens without success.

MATERIALS AND METHODS

The study was performed in accordance with the declaration of Helsinki, and was approved by the institutional Ethics Review Board for clinical research, and all patients signed an informed written consent form.

Sample size calculation was determined for a descriptive study of a dichotomous variable, considering the prevalence of peptic ulcer with resistant *H pylori* in 2% of the general population.

Patients were selected from the Outpatient Gastroenterology Clinic of Hospital das Clínicas, Faculty of Medicine, University of Sao Paulo. Fifty-one patients with peptic ulcer who had previously been treated unsuccessfully with one or more eradication regimens for *H pylori* were included in the study. Bacterial persistence after treatment was confirmed by positive rapid urease test and histological examination through a modified Giemsa staining method. Gastric mucosa samples were obtained from the antrum and corpus during upper digestive endoscopy.

Patients younger than 18 years of age were excluded, as were those who presented with severe comorbidity, pregnant patients, infants, patients who had previously undergone gastrectomy, patients with a known history of allergy to the therapeutic regimen drugs, and patients who had used non-steroidal anti-inflammatory drugs, antibiotic therapy, or bismuth salts up to 4 wk before study inclusion.

In an open, cohort study, the patients were invited to use a therapeutic regimen for 7 d that consisted of 20 mg omeprazole, 240 mg colloidal bismuth subcitrate, 1000 mg amoxicillin, and 200 mg furazolidone, taken twice a day. Patients were advised not to ingest alcoholic beverages and to avoid foods related to potential side effects determined for drugs similar to monoamine oxidase (MAO) inhibitors. They were also encouraged to take the full medication regularly and were informed about the importance of adequate use of the medication for successful treatment. No other medication was allowed until the end of the treatment, when patients were evaluated regarding compliance by counting the remaining tablets. Adverse effects were recorded in a questionnaire, and each adverse effect was specifically investigated.

Table 1 Clinical data

Clinical data	*n*
Patients	51
Age (yr)	
Mean	49
Median	48
Interval	23-77
Women	32
Duodenal ulcers	39
Gastric ulcers	7
Duodenal and gastric ulcers	5
Tobacco users	16

Treatment efficacy was determined by bacterial negativity at the rapid urease test and histological examination of gastric antrum and corpus mucosa samples taken during digestive endoscopy performed 12 wk after the end of treatment.

A confidence interval of 95% was calculated for the eradication rate percentiles. The χ^2 method with Pearson coefficient was used for the comparison among the variables, eradication rate for previous treatment, gender, and age, with significance value of $P < 0.05$. Statistical analysis was performed with the statistics software, version 10.0 (SPSS Inc., USA).

RESULTS

Among the 51 patients enrolled in the study, there was no predominance regarding gender, and the median age was 48 years. Duodenal ulcer was most commonly observed (Table 1). Five (10%) patients had already undergone three or more previous treatments (32 and 14 had undergone one and two, respectively). Six patients were excluded from the analysis, three for not undergoing follow-up evaluation, and three for early interruption of the treatment due to adverse effects.

The eradication rate was 68.8% (31/45). Eradication rates were similar regardless of the number of previous treatments (one treatment: 21/32, 65.6%; two treatments: 8/14, 57.1%; three or more treatments: 2/5, 40%). Age and gender did not correlate with eradication rates ($P > 0.05$). Adverse effects were reported by 31.4% of the patients, most of which were considered to be slight or moderate. Three patients had to withdraw from the treatment due to the severe adverse effects (one with nausea, one with diarrhea, and one with dizziness).

DISCUSSION

H pylori infection is highly prevalent in Brazil. Among blood donors without gastrointestinal complaints, positive serology for *H pylori* is found in 68%[12]. In a country with more than 200 million inhabitants, we may estimate that 140 millions individuals are currently infected. If we consider a 10% incidence of peptic ulcer disease or gastric cancer, we will find 14 million people in whom eradication of *H pylori* is mandatory. Despite the good eradication rates achieved with the combination

of omeprazole, amoxicillin, and clarithromycin, 10% to 15% of the patients present with treatment failure[2]. In face of this reality, it is interesting to pursue the development of alternative therapeutic regimens with satisfactory eradication rates, low incidence of adverse effects, and low cost.

The efficacy of different regimens varies according to patient compliance and bacterial resistance to the antibiotics[13]. Clarithromycyn, quinolones and metronidazole should not be used more than once, due to *H pylori* intrinsic or induced resistance[14,15]. For patients with primary treatment failure it would be ideal to test the *H pylori* antimicrobial sensitivity, but the high cost and the lack of laboratories capable of adequately performing sensitivity tests limit this strategy. Retreatment must be based on knowledge of the antimicrobial agents previously used.

In our country, *H pylori* strains show an intrinsic resistance to metronidazole that reaches 50%, which decreases the efficacy of schemes containing this drug or other nitroimidazolics[16-19]. Furazolidone is widely available in public health care facilities in Brazil. Despite that no decrease in susceptibility has been observed[20], and bacterial resistance appears to be rare or non-existent in many areas[18,21,22], even among metronidazole-resistant isolates[23]. The main concern regarding its use is the adverse effects observed, especially among individuals who do not adhere to the dietary restrictions recommended, since this drug belongs to the group of the MAO inhibitors. Asian and European studies have reported a relatively high incidence of adverse effects (31.4%-35%)[10,24,25]. Conversely, two South American[26,27] studies have shown fewer undesirable symptoms when compared to the previously mentioned studies. In the present study, despite a comparable incidence of adverse effects during treatment, only three patients had severe symptoms demanding treatment discontinuation. Lower doses of furazolidone could decrease the incidence of undesirable symptoms, but this strategy can also lead to a lower eradication rate[22,28,29].

The prevalence of smokers was similar to that in the Brazilian population and no significant differences in the results were observed when analyzing the number of previous treatments, gender and age. Even though compliance was good, and the length of treatment was short, this regimen ought to be considered only as an alternative for patients with previous treatment failures. Extending the antibiotic course to 10 d or 14 d could improve eradication rates, despite a greater likelihood of adverse effects[30,31].

Furazolidone appears to be an excellent choice for combination therapy for *H pylori* infection, especially as a substitute for metronidazole in quadruple therapy regimens in areas with high prevalence of metronidazole-resistant strains[32]. In our study, the eradication rate was 68.8%, which was superior to that previously reported[33,34], and, considering the efficacy, safety and potential cost-effectiveness, it seems reasonable to introduce furazolidone-based regimens following the failure of initial eradication attempts[32]. The differences regarding the safety profile between South American and American and European studies may be attributed to the limited clinical experience with this drug in the former regions, where it is unavailable and expensive[33].

In conclusion, our study shows that the association of bismuth, furazolidone, amoxicillin and a proton-pump inhibitor is a valuable alternative for patients who failed to respond to an initial therapeutic regime in a country with high prevalence of *H pylori* metronidazole-resistant strains. This scheme is an effective, cheap and safe option for salvage therapy of *H pylori* positive patients.

COMMENTS

Background

Since the discovery of the etiological role of *Helicobacter pylori* (*H pylori*) in peptic ulcer disease, its eradication became essential to allow for adequate healing and prevention of recurrence. It is well established that triple therapy with omeprazole, amoxicillin and clarithromycyn is the first-line treatment, but it fails in 10% to 20% of the patients, demanding alternative therapeutic regimens.

Research frontiers

Furazolidone has anti-*H pylori* activity, low incidence of resistance, is cheap, and is widely available. Despite these characteristics, not many studies have been performed to evaluate its efficacy for retreatment.

Innovations and breakthroughs

This study provides further evidence of the efficacy and tolerability of a short-term furazolidone-based quadruple regimen in South America.

Applications

Furazolidone-based regimens may be an interesting option for retreatment due to their low cost and low resistance rate, especially in developing countries such as Brazil, where metronidazole-resistant strains are common.

Peer review

Quadruple therapy with the medicine used in this study is not a new regimen. It has been used widely in China with good results. Unfortunately, it is not popularly used outside China. The present study was a small series with not very satisfactory results (efficacy rate 68.8%). However, I think it is still worthwhile to be published in our journal, at least indicating that the regime was also used in a South American country with some success.

Abstract

AIM: To confirm the presence of recombination, full-length hepatitis B virus (HBV) from chronic patients was sequenced and analyzed.

METHODS: Full-length HBV genomes from 12 patients were amplified and sequenced in an automated sequencer. Phylogenetic analysis was carried out on full-length, Core and preS2/Surface regions using MEGA software. SimPlot Boot Scanning and amino acid sequence analysis were performed for confirmation of recombination.

RESULTS: Eight patients were infected with genotype D strain; one patient with genotype A and three patients had genotype A and D recombination; two of them had cirrhosis and one had hepatocellular carcinoma. Phylogenetic analysis of core and preS2/surface regions separately showed evidence of genotype A and D recombination. The breakpoints of recombination were found to be at the start of preS2 and at the end of surface coding regions.

CONCLUSION: We identified and characterized recombinant A and D genotype HBV in hepatitis B surface antigen (HBsAg)-positive patients.

Key words: Hepatitis B virus; Genotype; Variation; Evolution; Recombination

Identification and characterization of genotype A and D recombinant hepatitis B virus from Indian chronic hepatitis B virus isolates. *World J Gastroenterol* 2008; 14(40): 6228-6236 Available from: URL: http://www.wjgnet.com/1007-9327/14/6228.asp DOI: http://dx.doi.org/10.3748/wjg.14.6228

INTRODUCTION

Hepatitis B virus (HBV) is an organ-specific virus causing inflammation of the liver, leading to complications such as chronic liver disease (CLD) and hepatocellular carcinoma (HCC). As compared to Europe and North America, the prevalence of HBV infection in Asia is quite high, with 40 million people harboring chronic HBV infection in India[1].

Two features make HBV unique. First, its way of replication, by which it uses the pregenomic RNA as an intermediate step for reverse transcription. Second, the efficient utilization of its compact genome for production of seven different proteins from four open reading frames (ORFs). Major proteins that are encoded from these four ORFs are the envelope, core the X protein and the polymerase.

Nucleotide substitution, deletion, insertion and recombination are the main factors that results in variation of the HBV genome. HBV genotypes are classified into eight genotypes, from A to H, based

on the inter-group divergence of 8% or more in the complete genome nucleotide sequence, or a 4% or greater divergence of the Surface gene[2-4]. Recent studies have reported recombination between the HBV genomes of two genotypes. Two kinds of HBV genotype B have emerged[5-7] i.e. recombinant with genotype C and without recombination with C. Mixed genotype refers to an infection that contains more than one genotype in the same patient and is usually the result of multiple exposures and super-infection, the complete genome of each strain belongs to one genotype. According to Robertson *et al*[8], recombination can be detected when different genes or different regions within the same gene are placed by phylogenetic analysis into different sequence subtypes.

We and others from India have reported the presence of mixed genotype A and D[9-12]. However, despite the presence of mixed genotypes, there are no reports from India about the presence of recombination, especially using the full-length HBV genome sequencing approach.

In the present study, we have identified recombinant genotype A and D in patients with CLD and HCC due to chronic HBV infection.

MATERIALS AND METHODS

Patients and serological markers

Twelve treatment-naive chronic HBV infected patients [five with cirrhosis, five with chronic hepatitis B (CHB), and two with HCC] were enrolled. The serum from these patients was tested for the presence of hepatitis B surface antigen (HBsAg) by ELISA (Abbot Laboratories, North Chicago, USA and Organon Tecknika, Boxtel, Netherlands). In addition, the serum was tested for hepatitis e antigen (HBeAg), antibody to hepatitis e antigen (anti-HBe), hepatitis B core Antigen (IgG anti-HBc) by ELISA (Organon Tecknika, Boxtel, Netherlands). Assessment of the severity of liver disease was made by Child-Pugh score[13]. Approval of the institutional ethical committee was obtained to undertake this study.

HBV DNA quantitation

HBV DNA was quantified by a commercially available hybrid capture assay (Ultra sensitive kit, Digene, USA) with the lower limit of detection being 4700 copies/mL.

Full-length HBV DNA amplification

HBV DNA was extracted by using 0.5 to 1.0 mL of patient's plasma using Sera Lysis Buffer (10 mmol/L Tris, 5 mmol/L EDTA, 50 mmol/L NaCl), SDS (1%) and proteinase K (1 mg/mL), followed by extraction with Tris-saturated phenol (pH 7.9) chloroform and then precipitation with ethanol. The obtained pellet was dried and dissolved in 30 μL of 1 × TE buffer (10 mmol/L Tris 1 mmol/L EDTA), a method described previously[12]. Full-length HBV DNA amplification was done by polymerase chain reaction (PCR), as described by Gunther's method[14]. The Taq polymerase with DNA proof reading activity was used. (Expand high fidelity Taq-Polymerase Roche GmBH Basel, Switzerland). Primers were: P1-CCGGAAAGC TTGAGCTCTTC TTTTTCACCTCTGCCTAATCA (1821-1841), P2-CGGAAAGCTTGAGCTCTTCAAAAAGTTGCA TGGTGCTGG (1823-1806). The reaction conditions for PCR were 94℃ for 5 min, 94℃ for 1 min, 60℃ for 1.5 min; 68℃ for 7 min and extension at 72℃ for 10 min, 35 cycles were performed. Purified full-length HBV DNA from recombinant vector pCF 80 (Tetramer of 3.2 kb HBV cloned in pBR322) was used as a positive control. DNA extracted from serum samples of healthy individuals and commercially available molecular biology grade water served as the negative control. Every set of PCR amplifications included HBV-positive and-negative controls. Primers were designed using the software Primer Express.

Sequencing full-length HBV genomes

PCR-amplified products were purified using the Qiagen Gel purification kit according to their recommended protocol. Internal primers used for sequencing given in Table 1 were used for sequencing in an automated DNA sequencer (ABI Prism 3730 Applied Biosystems, Foster City, USA). The nucleotide sequence data reported in this paper appears in the GenBank/EMBL/DDBJ nucleotide sequence databases with accession numbers EF103275-EF103285 and AY945305. The genome length has been measured according to Galibert *et al*[15].

Data analysis

HBV genotyping was done by phylogenetic analysis using full-length sequences, core and preS2 and surface regions. Briefly, sequences were aligned using the CLUSTALW software[16]. Phylogenetic trees were constructed using the Kimura two-parameter matrix and neighbor-joining (NJ) method by MEGA software version 3.1[17]. To confirm the reliability of the phylogenetic tree analysis, bootstrap resampling and reconstruction were carried out 1000 times. Recombination was investigated by SimPlot[18] distributed by the author Ray at (http://www.welch.jhu.edu/). Boot scanning was performed for each of the strains using four sequences at a time[19], i.e. putative recombinant sequence, two consensus sequences of the parental genotype and one consensus sequence as an out-group.

RESULTS

Patients and virological characteristics

Baseline characteristics of the study population are given in Table 2. The majority of the patients were male (M: 10, F: 2). Of the 12 patients, five had cirrhosis, all diagnosed radiologically; [one decompensated with a Child-Turcotte-Pugh (CTP) score of 8, and four compensated with a CPT score of 5], and five with CHB (all biopsy proven), and two had HCC. Of the 12, eight were HBeAg-positive and the remaining four were anti-HBe positive. The *Eco*RI restriction enzyme site was present in seven of the full-length sequences, whereas it was absent in five. All sequences had a nucleotide (nt.) length of 3182 except genotype A sequence, which had 3221 nt.

Distribution of genotypes

Phylogenetic analysis using complete HBV genomes of genotypes A to H derived from GenBank revealed the presence of genotype A and D in the study population. Genotype D was predominant, accounting for 92% of the study patients (Figure 1). The nature of genotype D was confirmed by the presence of a 33-bp deletion in the preS1 and a 6-bp deletion in the core terminal regions. Whereas in the genotype A sequence, the 33-bp and 6 bp deletions were absent. Phylogenetic analysis of the core revealed the same results as analysis done with complete HBV genomes as shown in Figure 1A and C.

Presence of A and D genotype recombination

Phylogenetic analysis of preS2/surface region of 12 isolates revealed clustering of three more sequences in addition to isolate 60 in the genotype A branch (Figure 1B). Presence of recombination was confirmed by boot scanning SimPlot analysis; all the sequences were subjected to analysis using the consensus sequence of genotype A, D and H as the out-group as shown in Figure 2. Recombination break points, of three recombinant strains were detected in preS2 and surface ORFs. Isolate 113 had break points at nt 595-618; isolate 105 had break points at nt 639-659 and 723-737. Isolate 103 had break points at nt 319-359 and 1170-1184. PreS2 and surface regions showed similarity with genotype A at 18 amino acid positions in the recombinant sequences, whereas it was absent in the surface, core and X ORFs. Four of them were identified in the preS2, whereas 13 in the surface region, as shown in Figure 3A and B.

Major hydrophilic and the "a" determinant regions

As shown in Figure 3C, when analyzed considering only genotype D, the major hydrophilic region (MHR) showed substitutions at 10 amino acid positions. Of the 10 changes, five spanned the "a" determinant region. When similar analysis was done considering genotype A, we could detect a single mutation in isolate 113 at position 144, changing threonine to methionine in the "a" determinant region of the surface region. All the isolates showed the presence of concomitant threonine to proline change at position 131 of the "a" determinant region, which is homologous to the genotype A sequence.

Sequence characteristics of precore/ core and X ORFs

Among the 12 patients, precore stop codon mutation (W28Stop) was found in two patients, and both belonged to the recombinant genotype. We could document the difference in the core nucleotide sequences in the recombinant sequences; however, they were not exactly similar to the typical genotype A pattern. We detected the presence of T1936C nucleotide mutation in the core gene in one of the HCC patients, isolate number 113.

X ORF: In two patients, we detected mutations in X ORF. Both belonged to the recombinant genotype, i.e. isolate 113 mutations were detected at three positions I127T, K130M, V131I, and isolate 105 was harboring a single mutation at position I127L.

DISCUSSION

Phylogenetic analysis based on two different genomic regions, preS2/surface and core, suggested the existence

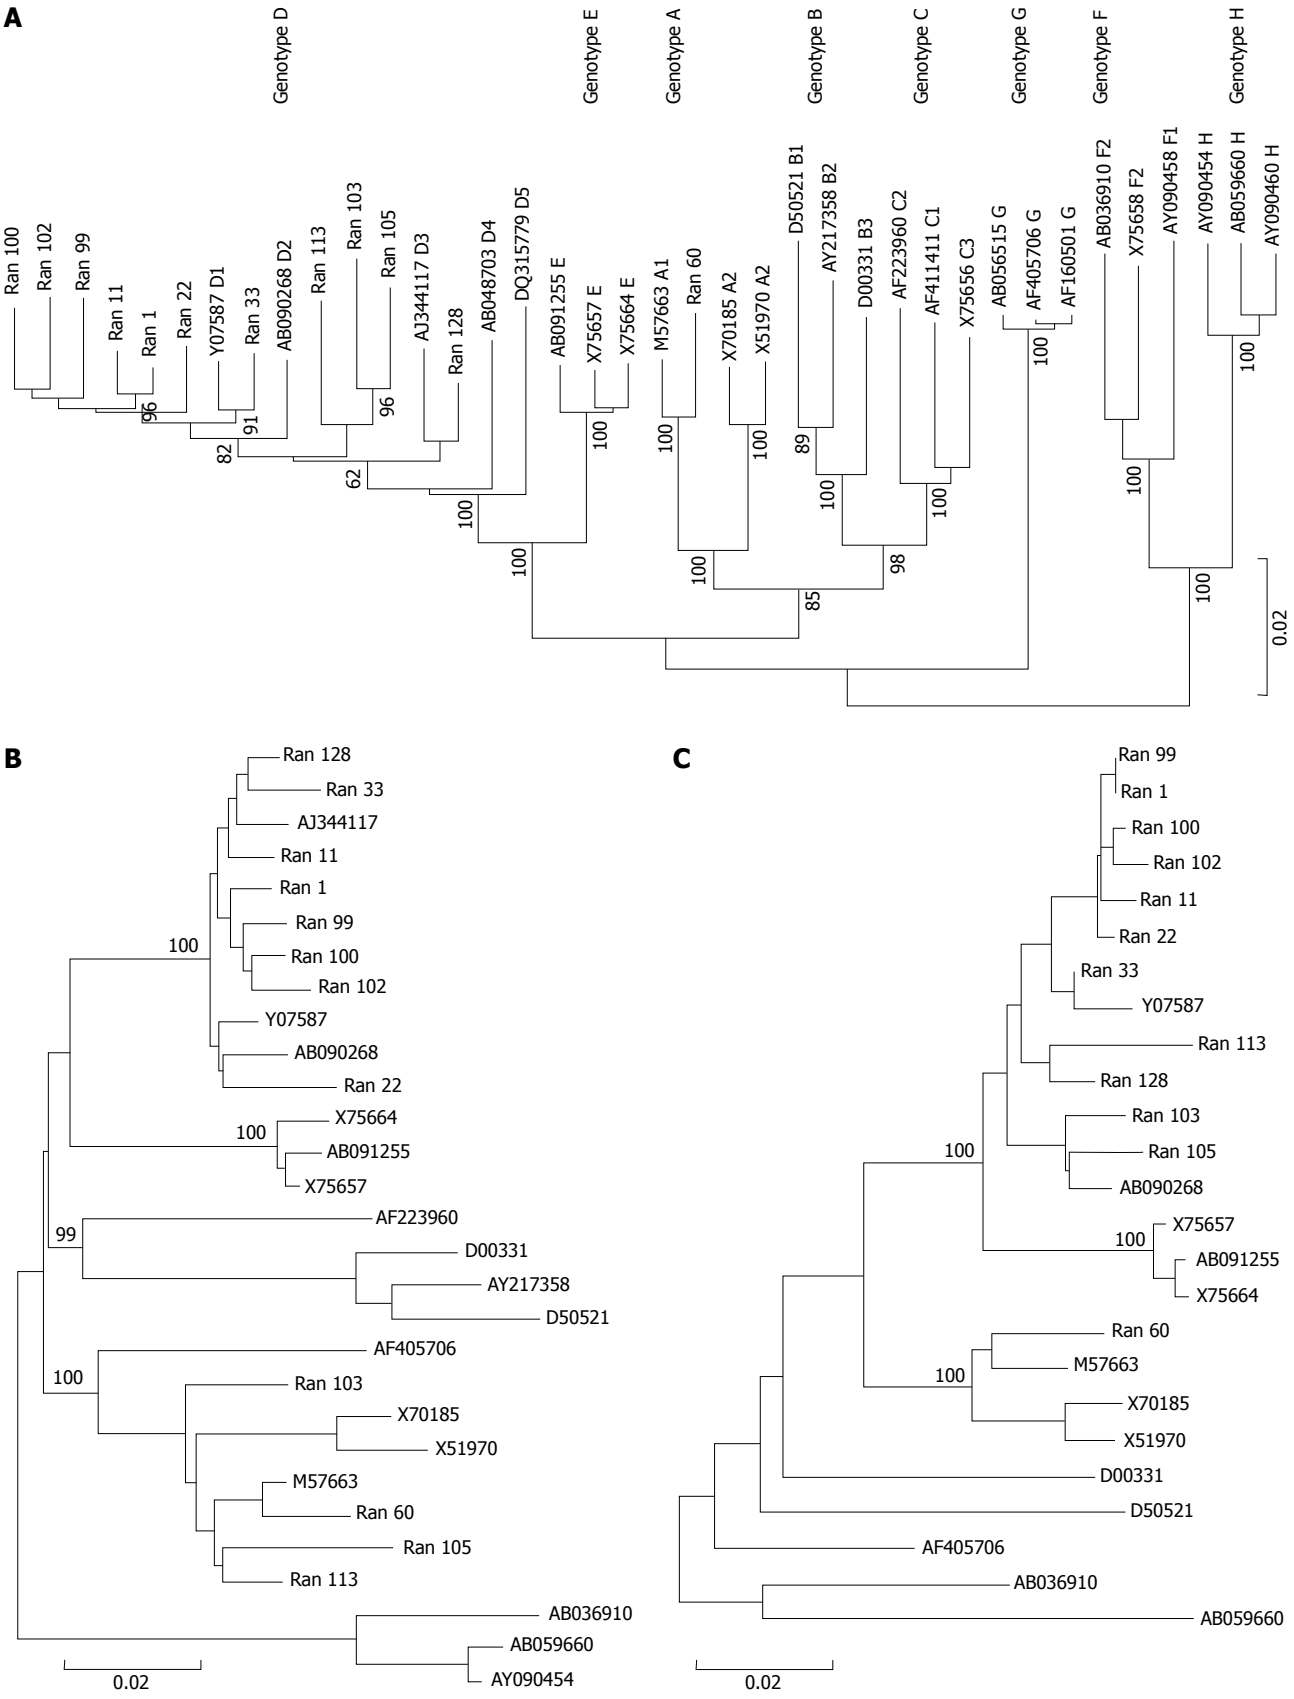

Figure 1 Phylogenetic tree revealed the distribution of genotypes. A: Neighbor joining (NJ) phylogenetic tree was constructed based on the complete genome sequences of 26 HBV reference strains from DDBJ/EMBL/Genbank and 12 Indian HBV isolates in the present study. The bootstrap values obtained from 1000 replicas are shown at the nodes of the main branches. HBV strains from this study are marked as Ran as suffix followed by the isolate number. Reference sequences are denoted by their accession numbers. The capital letter A to H denotes the HBV genotype; B: Phylogenetic analysis done on the PreS2 and surface regions showing three additional (103,105,113) isolates to be grouped in genotype A branch. Phylogenetic trees were constructed by NJ Kimura two-parametric method. Bootstrap values are shown at the nodes of the main branch and at the bottom distance is given; C: Phylogenetic analysis using the Core region. Phylogenetic tree was constructed by NJ Kimura 2-parametric method Bootstrap values are shown at the nodes of the main branch and at the bottom distance given.

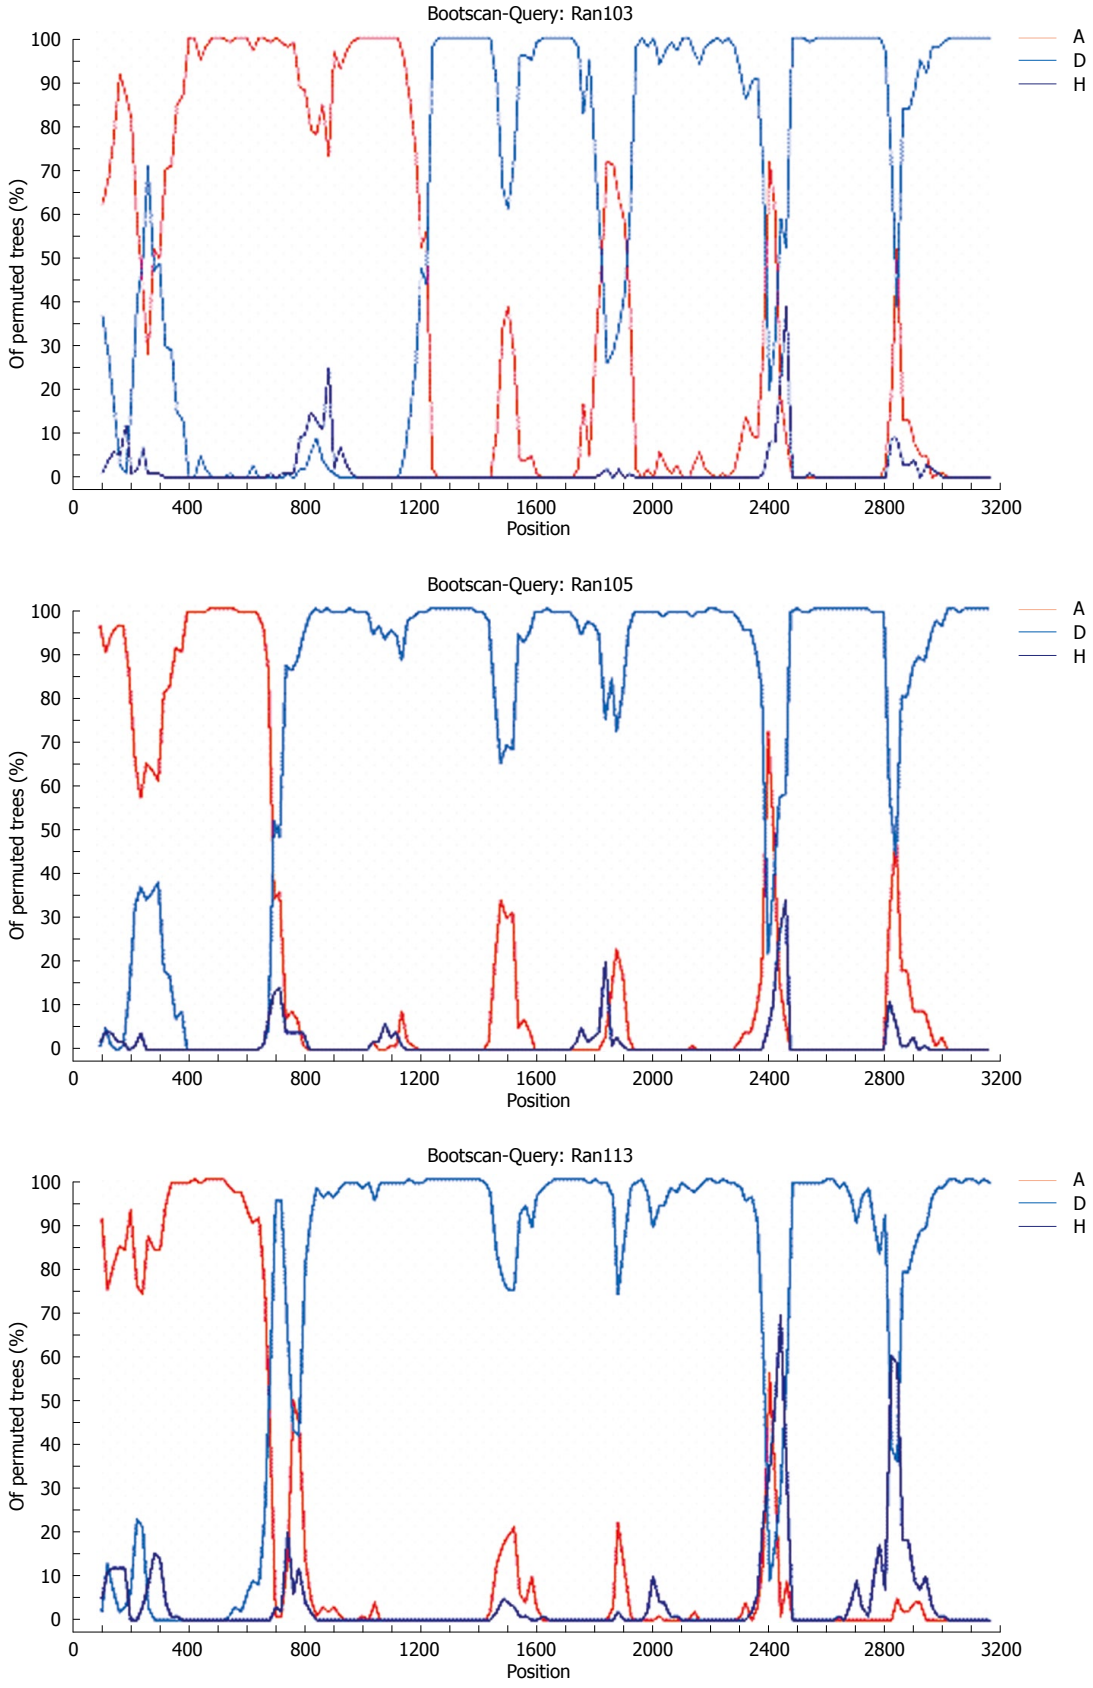

Figure 2 SimPlot analysis demonstrating the recombination in two isolates 103 and105, which were subjected to bootscan analysis over the entire genome using SimPlot program (Lole *et al*[18]).

of recombinant strains in Indian isolates of HBV. On examination of the preS2 and the surface region sequences, a close relation with genotype A sequence was detected in three genotype D sequences respective to core, which was genotype D. Further analysis of corresponding genomes allowed us to map the crossover

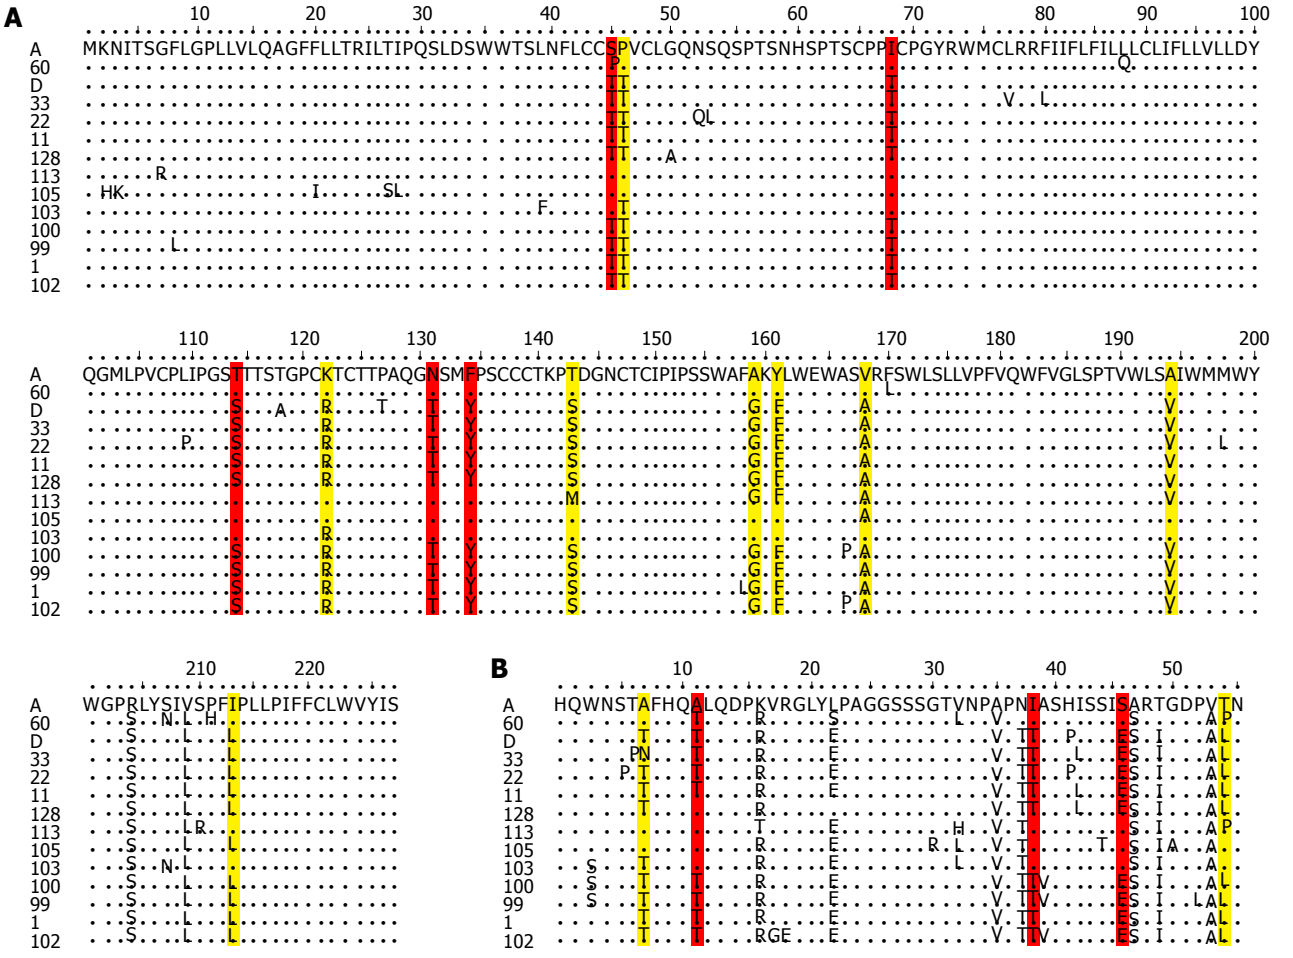

Figure 3 Recombinant sequence similarities with genotype A in PreS2 and Surface region. A: Surface region alignment with genotype A and D amino acids, marked in red shows all three recombinant sequences having similarity with genotype A, whereas yellow marked amino acids shows at least one recombinant sequence similar to genotype A, over all 18 positions; B: Shows same in the preS2 region; C: Shows all the amino acids of MHR of genotype D in black, upward arrow indicates the change of amino acid; D: Shows "a" determinant region and corresponding alignment with 12 isolates.

junctions and to confirm the findings of recombination.

HBV recombination is not a new phenomenon, it is important from an evolutionary as well as epidemiological point of view. As increasing number of full-length HBV genome sequences are reported, and a higher frequency of recombinant hybrid genomes is being recognized. Evidence of HBV recombination from different parts of the world suggests the presence of recombination of HBV genotypes involving A/C, A/D, A/E, B/C, B/D, G/A and G/C strains[20-23]. In Asia, recombination of genotype C/D has been reported from Tibet and China[21,23], whereas recombination of B and C has been detected in Japan[24]. HBV strains from Vietnamese patients also show evidence of

recombination of C and A genotypes[25]. Genotype A and D recombination has only been documented in CHB patients from South Africa[26]. Although the recombination of A and D genotypes has been detected from Italian and Indian HBV strains, such patients were surface-antigen negative[7]. Furthermore, breakpoints of recombination were different from the presently identified recombinant strains[27,28].

A switch in genotype has been documented during change of HBsAg-positive to serologically negative phase[29]. As we detected recombination in the preS2/surface coding region, we focused on the major hydrophilic region, "a" determinant region of surface ORF, speculating that the changes in the MHR and the "a" determinant region could lead to absence of the surface antigen, using standard serological methods. Our analysis revealed changes at 11 amino acid positions when the analysis was done using genotype D (Figure 3C). When the analysis was carried out considering both A and D genotypes, we could detect changes at only a single position substituting (K) lysine with (M) methionine in the "a" determinant region. However, the amino acid substitutions that are supposed to alter the conformation of "a" determinant region were not found.

Compared to genotype D, genotype A is more prevalent in the HBeAg-positive than in the anti-HBe-positive phase[30,31]. It is known that HBV genotype D virus has a selection advantage to form the precore stop codon mutation, as compared to the genotype A virus, the selection being at the pre-genome encapsidation level. However, in the recombinant sequences identified in the present study, we detected the precore stop codon mutation in two of them. The presence of the stop codon in the precore region and co-infection with other genotypes A, C and H are two important features of HBV genotype G[32]. In presently identified recombinant sequences, we detected the presence of Pc G1896A, and this suggests a possible similar situation and a matter for further investigation.

Recent reports suggest the presence of mixed genotypes in Asia. Europe and Africa in CHB patients, including India[9,11,33]. Moreover, higher levels of HBV replication have been shown to be associated with mixed genotype infection[33].

It is quite possible that the PreS, core, X and P proteins are continually expressed but the preS2 region/protein of genotype D is lost for a short interval during recombination with genotype A sequences, mimicking a molecular window period. It is not yet known whether recombination is advantageous for the virus or the host, but it is quite possible that this phenomenon increases the chances of virus survival and doping the host defense system.

One of the reasons for enhanced HCC development in young African adults could be high HBsAg expression in genotype-A-harboring patients[34] HBV genotype A directs the high level of synthesis of HBsAg in proportion to viral DNA, core protein and HBeAg[35].

The frequency of detection of spliced viral genomes is higher in CHB cases compared to acute and resolved HBV infections. The generation of recombinant HBV could be intracellular, as the ratio of full-length and spliced genomes isolated from the intracellular compartment was significantly higher than from extracellular space. This indicates that, compared to those containing spliced genomes, nucleocapsids containing full-length genomes are preferentially enveloped and released from the cell, and could be one of the reasons for severe liver disease[36]. It would be worth while to study the co-infection of two genotypes, and to establish whether the changes accumulate in one cell or together in the newly infected cells. Genetic exchanges between different viral strains within the infected hepatocytes could be one of the possible reasons for recombination.

HBV infection is the predominant factor for the development of HCC in India[37]. Several reports suggest integration of the preS/S region in cancerous liver tissue[38-40]. Binding of the PreS region with fibronectin and transactivation of TGF α could lead to development of cirrhosis and HCC[41-43]. It is quite unique that HBV uses its strongest promoter preS2/S for expression of the host cellular genes, which are advantageous for the virus itself.

HBV recombinant sequences were analyzed with the orangutan and gibbon monkey hepatitis virus. However, we could not find any association of recombinant sequences with them, and the reason for such transmission was clarified (data not shown). Secondly, phylogenetic analysis was done using the Italian and Indian recombinant sequences reported previously[27,28]. However, they were not clustering in the same region as detected in the present recombinant sequences (data not shown).

There are three theories proposed for evolution of HBV: The new world origin theory[5], co-evolution theory[3,44] and co-speciated theory[45,46]. We postulate a competitive selection theory in which the virus and the host cellular machinery compete, and involvement of various unidentified ways by the virus to combat the host defense mechanisms. A few of these could be the splicing, integration, recombination and down-regulation of MHC I . On the other hand, host APOBEC response to edit the viral genome, CTL proteosome complex and various host genetic factors, taking into consideration ethnicity, may play a part as well. Recombinant detection of mixed genotypes, however, may be the tip of the iceberg as a template switch over, splicing and extensive editing by all APOBEC 3 proteins, which have not been well studied.

It can be argued that, in our study, the HBV sequences were analyzed only at one stage of the disease, the process of sequential changes and the time points were not tracked. This was a preliminary study and such studies are quite cumbersome and expensive.

In summary, we identified new A/D recombinants from Indian CLD and HCC patients. To the best of our knowledge, this is the first report which describes recombinant A and D genotype from HBsAg-positive

patients from Asia, and indicates the association of recombinant HBV genotype with HCC. The results of the present study warrants further larger studies to identify populations of recombinant viruses in different clinical categories of HBV patients.

Authors thank Indian Council of Medical Research for carrying out this study and providing funds through Advanced Center for Liver Diseases project.

COMMENTS

Background

Recombination is common in retroviruses, especially human immunodeficiency virus (HIV). As the hepatitis B virus (HBV) uses the reverse transcription step using the pre-genomic RNA, the rate of mutation accumulation is at a much higher rate compared to other DNA viruses. India, being highly populated, harbors the second largest pool of HBV carriers. Recombination is also one of the mechanisms of sequence variability and could account for the non-response to antiviral therapy as well as vaccine. Though recombination from the Indian subcontinent has been detected, authors for the first time report recombination of A and D genotype in HBsAg-positive chronic HBV patients.

Research frontiers

Non-response to antiviral drugs and vaccine is one of the hot research related to the article.

Innovations and breakthroughs

This is believed to be the first report describing the recombinant genotype on the Indian subcontinent.

Applications

Large-scale studies are warranted to determine the prevalence and profile of the recombinant genotype on the Indian subcontinent. The affect of antiviral therapy on the recombinant virus is also warranted.

Terminology

Mixed genotype refers to an infection that contains more than one genotype in the same patient, and is usually the result of multiple exposures and super-infection, the complete genome of each strain belongs to one genotype. Recombinant genotype can be detected when different genes or different regions within the same gene are placed by phylogenetic analysis into different sequence subtypes.

Peer review

This is an interesting paper, which confirms the presence of recombination, and full-length HBV from chronic patients were sequenced and analyzed. Authors identified and characterized recombinant A and D genotype HBV in HBsAg-positive patients.

Abstract

AIM: To investigate the effect of a fermented milk containing *Bifidobacterium lactis* DN-173010 and yogurt strains (BIO®) on adult women with constipation in Beijing.

METHODS: A total of 135 adult females with constipation were randomly allocated to consume for 2 wk either 100 g of the test fermented milk or 100 g of an acidified milk containing non-living bacteria (control). Stool frequency, defecation condition scores, stool consistency and food intake were recorded at baseline and after 1 and 2 wk in an intention-to-treat population of 126 subjects. In parallel, safety evaluation parameters were performed.

RESULTS: At baseline, no differences were found between groups. Following consumption of test product, stool frequency was significantly increased after 1 wk (3.5 ± 1.5 *vs* 2.4 ± 0.6, $P < 0.01$) and 2 wk (4.1 ± 1.7 *vs* 2.4 ± 0.6, $P < 0.01$), *vs* baseline. Similarly, after 1 and 2 wk, of test product consumption, defecation condition (1.1 ± 0.9 *vs* 1.9 ± 1.2, $P < 0.01$ and 0.8 ± 1.0 *vs* 1.9 ± 1.2, $P < 0.01$, respectively) and stool consistency (1.0 ± 0.8 *vs* 1.5 ± 1.1, $P < 0.01$ and 0.6 ± 0.8 *vs* 1.5 ± 1.1, $P < 0.01$, respectively) were significantly improved. Compared with the control group, stool frequency was also significantly increased (3.5 ± 1.5 *vs* 2.5 ± 0.9, $P < 0.01$ and 4.1 ± 1.7 *vs* 2.6 ± 1.0, $P < 0.01$, respectively), and defecation condition (1.1 ± 0.9 *vs* 1.6 ± 1.1, $P < 0.01$ and 0.8 ± 1.0 *vs* 1.6 ± 1.1, $P < 0.01$, respectively) and stool consistency (1.0 ± 0.8 *vs* 1.4 ± 1.0, $P < 0.05$ and 0.6 ± 0.8 *vs* 1.3 ± 1.0, $P < 0.01$, respectively) significantly decreased after 1 and 2 wk of product consumption. During the same period, food intake did not change between the two groups, and safety parameters of the subjects were within normal ranges.

CONCLUSION: This study suggests a beneficial effect of a fermented milk containing *B. lactis* DN-173010 on stool frequency, defecation condition and stool consistency in adult women with constipation constipated women after 1 and 2 wk of consumption.

Key words: Probiotic; *Bifidobacterium lactis* DN-173010; Fermented milk; Constipation; Stool frequency; Stool consistency

INTRODUCTION

In the Chinese National Product Standard of GB2746-1999, fermented milk is a product prepared with cow's milk or milk powder as raw material by degreasing, partly degreasing or non-degreasing and fermentation. Bacteria used to ferment milk, typically lactic acid bacteria (LAB), are bacteria that can produce lactic acid during the metabolism process. At present, common LAB used as fermentation agents include: *Streptococcus thermophilus*, *Lactobacillus delbruekii sp bulgaricus*,

Lactobacillus acidophilus, and *Lactobacillus casei*. The health effects of yogurt validated by research include: regulation of intestinal and colon flora, prevention or treatment of diarrhea, regulation of immune function, decreasing symptoms of inflammatory bowel diseases, improvement of lactose intolerance, lowering blood cholesterol level, and prevention of certain types of cancers[1,2]. These effects are a result of the yogurt characteristics due to the fermentation by yogurt symbiosis[3].

Constipation is a common problem, and generally refers to less than 2-3 stools per week, accompanied by small, dry, and/or hard defecation and discharge difficulty. This trouble is commonly reported in many regions of the world including Asia[4] North America[5], and Europe[6], Functional constipation is caused by non-organic or drug factors. Constipation can result in some discomforts such as abdominal distension, abdominal pain, headache, dizziness and poor appetite[7]. The symptoms of constipation can interfere with quality of life. An epidemiological study conducted in Beijing concluded that 6.1% of the adult population was suffering from the symptoms of functional constipation[8]. The disorder is more common in women and elderly people[9]. For example, in Beijing, the incidence of constipation in males and females is 1/4.59. High risk factors include anxiety, work fatigue, bad mood and working at a sedentary job[10].

Probiotics are defined as live micro organisms that, when administered in adequate amounts confer a health benefit on the host[11]. *Bifidobacterium lactis* DN-173010 survives complete transit through the digestive tract and is recovered live in stools in large quantities relative to the quantity initially ingested[12-14]. Three separate clinical studies have demonstrated that daily consumption of fermented milk containing *B. lactis* DN-173010 in association with the yogurt starters *L. bulgaricus* and *S. thermophilus* for 15 d improves gastrointestinal transit. This effect is enhanced with increased daily intake (effect of three pots/d > two pots/d > 1 pot/day) in elderly subjects free of any gastrointestinal pathology[15,16], and in a group of healthy women aged 18-45 years[17]. An exploratory study was designed to examine the effect of this product, compared to heat-treated yogurt, on quality of life and symptoms in irritable bowel syndrome (IBS)[18]. This large scale (267 IBS constipation predominant, Rome II criteria), double-blind, randomized, controlled, parallel group study over 6 wk demonstrated that daily consumption of this product alleviates bloating and improves digestive comfort as assessed by the Functional Digestive Disorders Quality of Life questionnaire. An increase in stool frequency was also observed in subjects with the lowest stool frequency (< 3 or 4 bowel movements/wk) without any change of stool consistency. A fifth study performed on fermented milk containing *B. lactis* DN-173010 alone also demonstrated a reduced transit time in healthy men and women[19]. The results of these five studies support a strong link between improved stool frequency and the strain *B. lactis* DN-173010, and indicate that further research should be carried out to investigate the potential use of this fermented milk product for improving stool parameters in subjects with constipation.

The aim of this study was to investigate the effect of a fermented milk (Bio®) combining *B. lactis* DN-173010 and yogurt strains on functional constipation parameters of adult women in Beijing.

MATERIALS AND METHODS

Study population

A total of 135 women, age 25-65 years old, were recruited in Beijing Hospital. They had a diagnosis of constipation according to the following criteria: less than three stools per week; increased stool hardness; non-organic constipation and habitual constipation.

The following were excluded from the study: Those unable to orally ingest or unable to administer according to instruction; those unable to express complaint clearly; those with constipation symptoms caused by surgical operation within 30 d; those with recent defecation difficulty due to severe organic diseases (colon carcinoma, severe enteritis, intestinal obstruction, inflammatory bowel disease); those with defecation difficulty accompanied by pain; those with acute gastrointestinal tract disease developing within 30 d; those who were pregnant or menstruating; with severe whole body diseases such as cardiovascular, liver, kidney and hematopoietic system; those taking short-term products which may have influenced the results.

Study protocol

One week before product consumption (baseline period), general conditions, safety evaluation parameters, dietary intake and defecation functional parameters (stool frequency, defecation condition scores, stool consistency) were recorded. Thereafter, eligible constipated women were randomly allocated to consume, daily for 2 wk, one pot of either the test product (67 cases) or the control product (68 cases). Subjects were stratified by age, daily eating habits, and constipation causes to the extent possible to ensure inter-group comparability, which could possibly have influenced the results. During the study period, subjects maintained their usual lifestyle and eating habits. The study was approved by the Ethical Review Committee of the Chinese Academy of Preventive Medicine, Institute of Nutrition and Food Hygiene. All subjects provided written informed consent before inclusion in the study.

Study products

The test product was a fermented milk (BIO®, Danone (Shanghai) Consulting Co., Ltd, Shanghai, China), containing *B. lactis* DN-173010 [1.25×10^{10} colony forming unit (cfu) per pot], together with the two classical yogurt ferments, *S. thermophilus* and *L. bulgaricus* (1.2×10^9 cfu/pot).

The control product was an acidified milk without any ferments or probiotics. Both the test and control products were without flavor, and had similar appearance,

color, texture, taste and lactose concentration level. Each serving, corresponding to one pot, contained 100 g. Both products were specially prepared for the study and provided by Danone (Shanghai) Consultation Corp., Ltd.

Assessments and study criteria

The general conditions, such as the mental status, sleep, eating habit, and blood pressure, were evaluated 1 wk before product consumption.

The safety evaluation parameters blood, urine, and stool routine examinations [red blood cell (RBC) count, white blood cells (WBC) count, hemoglobin (Hb) in blood; RBC, WBC, protein in urine; stool properties, RBC and worm ova in feces], liver and kidney function examinations [glutamate pyruvate transaminase (GPT), glutamate oxalate transaminase (GOT), urea nitrogen, creatine, and blood sugar)] were examined once 1 wk before and 1 and 2 wk after product consumption.

Chest X-ray, electrocardiography and abdominal B-ultrasound examinations were done 1 wk before product consumption.

Dietary intake was assessed after 1-2 d, 7-8 d, and 13-14 d of product consumption by food record method for 48 h, to monitor eating habits.

Defecation functional parameters: stool frequency, defecation condition scores and stools were recorded at baseline and 1 and 2 wk after product consumption.

According to extent of defecation difficulty, the defecation condition scores were categorized into four grades[20]: Grade Ⅰ (0 points): Normal defecation; grade Ⅱ (1 point): Only bearing down and discomfortable sensation. grade Ⅲ (2 points): Obvious bearing down and discomfortable sensation, or frequent defecation with difficult and little defecation, seldom abdominal pain or anal burning sensation; grade Ⅳ (3 points): Often abdominal pain or anal burning sensation to influence defecation. According to classification method of Bristol, stool consistency was classified into three grades[20]: Grade Ⅰ (0 points): Like sausage or snake, smooth and soft; like sausage, with fissure on the surface; grade Ⅱ (1 point): Sausage-shaped, with lumps; noncohesive lumps, with coarse edges; grade Ⅲ (2 points): Separating hard lumps, like fruit kernel (difficult discharge).

Statistical analysis

All analysis were conducted on the intention-to-treat (ITT) population, corresponding to subjects having consumed at least one pot of product.

Descriptive statistics were reported as mean ± SD or frequency for all variables, unless otherwise stated. Statistical comparative analysis between two groups was performed by *t* test, χ^2 test and the sum of rank, by SPSS statistical software.

RESULTS

General information of the subjects

Female volunteers (n = 135) were recruited for the study; four cases in test group and five cases in control group were withdrawn from the study. The general conditions of the other 126 subjects in two groups are described in Table 1. A *t* test was used for age and weight, χ^2 test for eating pattern and amount, and non-parametric rank sum tests for the three defecation parameters, to compare difference between the two groups. There were no significant differences ($P > 0.05$).

Table 1 General basic information of subjects before product consumption

Parameters		Control group (n = 63)	Test group (n = 63)	P value
Eating pattern	Regular	59	56	0.344
	Irregular	4	7	
Appetite	Good	17	21	0.437
	Common	46	42	
	Poor	0	0	
Eating amount	Large	3	4	0.927
	Common	52	51	
	Small	8	8	
Age (yr)		46.4 ± 6.7	46.4 ± 9.8	0.992
Body weight (kg)		62.5 ± 10.4	61.2 ± 9.6	0.478
Stool frequency (n/wk)		2.4 ± 0.6	2.4 ± 0.6	0.746
Defecation condition score		1.9 ± 1.2	1.9 ± 1.2	0.914
Stool consistency		1.6 ± 1.1	1.5 ± 1.1	0.408

Table 2 Stool frequency (n/wk, mean ± SD)

	n	Baseline	Week 1	Week 2
Control group	63	2.4 ± 0.6	2.5 ± 0.9	2.6 ± 1.0[a]
Test group	63	2.4 ± 0.6	3.5 ± 1.5[b,c]	4.1 ± 1.7[b,c]

Note: Self comparison between before and after product consumption, [b]$P < 0.01$, [a]$P < 0.05$; compared with control group, [c]$P < 0.01$.

Results of blood, urine and stool routine assays, and liver and kidney function examinations were all in normal range before and after product consumption, and there were no clinical changes between the two groups. The chest X-ray, electrocardiogram and abdominal B-ultrasound examinations indicated that the subjects were healthy.

Stool frequency of the subjects

The stool frequency at baseline and after 1 and 2 wk of product consumption is shown in Table 2. Non-parametric rank sum tests were used to compare the difference between groups.

At baseline, no differences were found between groups. Compared to baseline, stool frequency was significantly increased after 2 wk of control product consumption (2.6 ± 1.0 *vs* 2.4 ± 0.6, $P < 0.05$) but no differences were found after 1 wk. In the test product group, stool frequency was significantly improved after 1 (3.5 ± 1.5 *vs* 2.4 ± 0.6, $P < 0.01$) and 2 wk (4.1 ± 1.7 *vs* 2.4 ± 0.6, $P < 0.01$), respectively. Compared with control group, stool frequency was also significantly increased after 1 and 2 wk of product consumption (3.5 ± 1.5 *vs*

Table 3 Defecation condition score (mean ± SD)

	n	Baseline	Week 1	Week 2
Control group	63	1.9 ± 1.2	1.6 ± 1.1[a]	1.6 ± 1.1
Test group	63	1.9 ± 1.2	1.1 ± 0.9[b,d]	0.8 ± 1.0[b,d]

Note: Self comparison before and after test, [a]$P < 0.05$, [b]$P < 0.01$; compared with control group, [d]$P < 0.01$.

Table 4 Stool consistency score (mean ± SD)

	n	Baseline	Week 1	Week 2

Test group	63	1.5 ± 1.1	1.0 ± 0.8[b,c]	0.6 ± 0.8[b,d]

Note: Self comparison before and after test, [a]$P < 0.05$, [b]$P < 0.01$; compared with control group, [c]$P < 0.05$, [d]$P < 0.01$.

Table 5 Food intake amount of the subjects (g, mean ± SD)

	day 1-2		day 6-7		day 13-14	
	Control group	Test group	Control group	Test group	Control group	Test group
Staple food	341 ± 110	324 ± 117	350 ± 109	334 ±115	351 ± 117	353 ± 123
Fruits and vegetables	287 ± 227	341 ± 235	296 ± 212	322 ± 223	305 ± 244	318 ± 201
Meat and egg	118 ± 120	119 ± 100	114 ± 104	123 ± 103	121 ± 95	111 ± 105
Total daily intake	745 ± 343	784 ± 322	761 ± 294	779 ± 316	776 ± 344	783 ± 315

2.5 ± 0.9, $P < 0.01$ and 4.1 ± 1.7 *vs* 2.6 ± 1.0, $P < 0.01$, respectively) as shown in Table 2.

Defecation condition scores of the subjects

Defecation condition scores at baseline and after 1 and 2 wk of product consumption are shown in Table 3. Non-parametric rank sum tests were used to compare the difference between groups.

At baseline, no differences were found between groups. Compared to baseline, defecation condition score was significantly improved after 1 wk of control product consumption (1.6 ± 1.1 *vs* 1.9 ± 1.2, $P < 0.05$), but no differences were found after 2 wk. In the test product group, defecation condition score was significantly improved after 1 (1.1 ± 0.9 *vs* 1.9 ± 1.2, $P < 0.01$) and 2 wk (0.8 ± 1.0 *vs* 1.9 ± 1.2, $P < 0.01$), respectively. Compared with control group, defecation condition scores were also significantly improved (1.1 ± 0.9 *vs* 1.6 ± 1.1, $P < 0.01$ and 0.8 ± 1.0 *vs* 1.6 ± 1.1, $P < 0.01$), respectively, after 1 and 2 wk of product consumption.

Stool consistency scores of the subjects

Stool consistency at baseline and after 1 and 2 wk of product consumption is showed in Table 4. Non-parametric rank sum tests were used to compare the difference between groups.

At baseline, no differences were found between groups. Compared to baseline, stool consistency score was significantly decreased after 2 wk of control product consumption (1.3 ± 1.0 *vs* 1.6 ± 1.1, $P < 0.05$), but no differences were found after 1 wk. In the test product group, stool consistency score was significantly improved after 1 (1.0 ± 0.8 *vs* 1.5 ± 1.1, $P < 0.01$) and 2 wk (0.6 ± 0.8 *vs* 1.5 ± 1.1, $P < 0.01$), respectively. Compared with control group, stool consistency score was also significantly decreased after 1 and 2 wk of product consumption, (1.0 ± 0.8 *vs* 1.4 ± 1.0, $P < 0.05$ and 0.6 ± 0.8 *vs* 1.3± 1.0, $P < 0.01$), respectively.

Food intake of the subjects during product consumption

Food intakes of the subjects was surveyed by 48 h dietary recall at initial stage (1st-2nd day), intermediate stage (6th-7th day) and end stage (13th-14th day) of product consumption. The mean daily intakes of staple food, fruits and vegetables, and meat and eggs of the three times were calculated and statistically analyzed by *t* test between the two groups (Table 5). Food intake throughout the study did not differ between groups.

DISCUSSION

Consumption of the fermented product tested in this study was well tolerated by all the participants, and no adverse effects were reported. An acidified milk was used as the control material in this study. Lactose in milk can cause intolerance characterized by rugitus, abdominal distension, abdominal pain, even diarrhea as a severe symptom. The incidence rate of lactose intolerance reaches 90% in Chinese adults. For example, Yang *et al*[21] have shown that lactose intolerance occurred in 87% of the 7-8 and 11-13 years old Chinese children. In order to prevent diarrhea, due to milk intake in the control group, extrinsic lactase was added to control milk samples during the manufacturing process. This resulted in an equal lactose content between the test and control products.

Several reviews[22-25] have described that some probiotics could improve lactose digestion and eliminate the symptoms of intolerance. A recent study has shown that a yogurt enriched with *B. lactis* DN-173010 and *B. longum* in capsules modifies the composition and metabolic activities of the colonic microbiota and alleviates symptoms in Chinese lactose-intolerant subjects[26].

BIO® is a fermented milk product which contains a mixture of live bacterial cultures; *B. lactis* DN-173010 (1.25×10^{10} cfu/pot) and yogurt starters *L. bulgaricus* and *S. thermophilus* (1.2×10^{9} cfu/pot). It has been shown to increase slow transit and, therefore, was tested in women with constipation to determine whether it would modulate bowel habits. Food intake and blood parameters remained constant throughout the study.

The results of this study indicated that stool frequency was significantly increased by 40% and 58% after 1 and 2 wk of product consumption, respectively ($P < 0.01$). In addition, after 1 wk of consumption, defecation condition scores (31% and 50%, $P < 0.01$) and stool consistency (29%, $P < 0.05$ and 25%, $P < 0.01$) were also significantly improved from baseline values in women consuming test product.

Three separate clinical studies have already demonstrated that daily consumption of a fermented milk containing *B. lactis* DN-173010 improves gastrointestinal transit time in elderly subjects[15,16], and in a group of healthy women with slow transit time[17]. Stool frequency was also significantly improved after product consumption in IBS subjects compared to controls with respect to subjects with a stool frequency < 4 stools per week at baseline[18]. A fifth study performed on fermented milk containing *B. lactis* DN-173010 alone also demonstrated a reduced transit time in healthy men and women with slow transit time[19]. Our finding that probiotics may normalize bowel movements is in line with those in some previous studies[27-30]. Some studies have shown that milk or yogurt fermented with different types of probiotics may increase the daily stool number in constipated subjects. In a double-blind, placebo-controlled study performed in 70 subjects with chronic constipation, a probiotic beverage containing *Lactobacillus casei Shirota* administered for a 4-wk period was significantly better than placebo in improving severity of constipation, stool frequency and consistency[27]. Likewise, a preparation containing *Escherichia coli* Nissle 1917 (a probiotic strain) was compared to placebo in a double-blind clinical trial in 70 subjects with chronic constipation, showing that the *E. coli* preparation was significantly better than placebo in increasing stool frequency[28]. Moreover, intake of a fermented milk product containing *L. casei* strain Shirota for 2 wk in a placebo-controlled double-blind cross-over design improved the state of bowel movements and stool quality in healthy subjects with a stronger tendency to constipation[29]. Finally, in an open trial in elderly subjects, a commercial mixture of *Lactobacillus rhamnosus* and *Propionibacterium freudenreichii* improved defecation frequency by 24%, but no reduction in laxative use was observed[30]. To date, no clinical studies have been performed to measure defecation conditions/straining on constipated subjects. Few studies have been focused on the effects of probiotics on the intestinal function in healthy people, and the observed effects depended on the strain used. Three randomized, double-blind, placebo-controlled human clinical trials[31-33] have been performed to investigate the effect of a fermented product containing probiotic strains. In these clinical studies, product consumption exerted a beneficial effect on the bowel functions, but with no significant effect compared to the placebo. Findings in previous studies are inconsistent possibly due to lesser statistical power, the use of different probiotic strains and different subject population. Thus, probiotics may be effective in subjects with mild to moderate constipation and controlled and well-designed studies in this type of subjects are warranted[34]. In any case, our study is the first showing the significant efficacy of fermented milk consumption on stool frequency and consistency, as well as defecation conditions in constipated subjects.

The patients' ability to achieve normal bowel habits without being in pain, and to control bowel movements, are important elements of physical well-being. This was shown by studies investigating the relationships between quality of life and gastrointestinal symptoms in persons with constipation[35,36]. The surveys revealed an impaired quality of life in constipated individuals in comparison with healthy persons, depending on the severity of the constipation. In addition, Guyonnet *et al*[18] have shown that daily consumption of a fermented milk containing *B. lactis* DN-173010 improves quality of life and symptoms in IBS compared to heat-treated yogurt. These results support the hypothesis of a relationship between improved stool frequency, transit time, quality of life and a fermented milk containing *B. lactis* DN-173010, and indicate that further research should be carried out to investigate the potential use of this fermented milk product in improving quality of life in subjects with constipation.

In conclusion, the present large-scale study showed a beneficial effect of a fermented milk containing *B. lactis* DN-173010 on stool frequency and consistency, as well as on defecation conditions of women with constipation. Further studies are required to elucidate mechanisms of such effects to provide additional scientific evidence to support the use of such probiotic food to relieve constipation.

COMMENTS

Background

In recent years, probiotics have been studied for their efficacy on gastrointestinal disorders. *Bifidobacterium lactis* DN-173010, a probiotic strain, has already demonstrated health benefit on the gastrointestinal transit. Positive results have been obtained with consumption of a fermented milk containing *B. lactis* DN-173010 and yogurt strains on gut transit time in healthy people with normal to slow transit time. Equally, encouraging positive results have been obtained on stool frequency in Irritable Bowel Syndrome subjects with predominant constipation. These results indicate that research should be carried out to investigate the potential use of this fermented milk product in improving stool parameters in subjects with constipation.

Research frontiers

Constipation is reported in many regions in the world. An epidemiological study conducted in Beijing concluded that 6.1% of the adult population was suffering from the symptoms of functional constipation but no clinical study has been carried out in this population. This is why we decided to investigate the effect of a fermented milk (BIO®) combining *B. lactis* DN-173010 and yogurt strains on constipation functional parameters of adult women in Beijing.

Innovations and breakthroughs

This research demonstrates the first positive results on the ability of the *B. lactis* DN-173010 to improve stool frequency, stool consistency and defecation conditions in adult constipated women. It is believed to be the first study to investigate the effect of *B. lactis* DN-173010 leaded in another ethnic population with a different diet than European populations. Finally, this study shows the first evidence of the positive effect of *B. lactis* DN-173010 on constipated subjects.

Peer review

The contribution by Yue-Xin Yang *et al* studied the effect of a fermented milk containing *B. lactis* DN-173010 and yogurt strains (BIO®) in adult constipated women in Bejing China. The authors determined that the fermented milk containing *B. lactis* DN-173010 had a beneficial effect on stool frequency, stool consistency, and defecation of women with constipation. This is a well-written report.

Abstract

AIM: To construct a prokaryotic expression vector carrying *Campylobacter jejuni peb1A* gene and express it in *Escherichia coli*. Immunoreactivity and antigenicity of rPEB1 were evaluated. The ability of rPEB1 to induce antibody responses and protective efficacy was identified.

METHODS: *peb1A* gene was amplified by PCR, target gene and prokaryotic expression plasmid pET28a (+) was digested with *Bam*HI and *Xho*I, respectively. DNA was ligated with T4 DNA ligase to construct recombinant plasmid pET28a(+)-*peb1A*. The rPEB1 was expressed in *E. coli* BL21 (DE3) and identified by SDS-PAGE. BALB/c mice were immunized with rPEB1. ELISA was used to detect the specific antibody titer and MTT method was used to measure the stimulation index of spleen lymphocyte transformation.

RESULTS: The recombinant plasmid pET28a (+)-*peb1A* was correctly constructed. The expression output of PEB1 protein in pET28a (+)-*peb1A* system was approximately 33% of total proteins in *E. coli*. The specific IgG antibody was detected in serum of BALB/c mice immunized with rPEB1 protein. Effective immunological protection with a lower sickness incidence and mortality was seen in the mice suffering from massive *C. jejuni* infection.

CONCLUSION: rPEB1 protein is a valuable candidate for *C. jejuni* subunit vaccine.

Key words: *Campylobacter jejuni*; Prokaryotic expression; Immunogenicity

INTRODUCTION

Campylobacter jejuni is one of the leading causes of bacterial diarrhea in travelers, children, and military personnel in regions where water and food sources are commonly contaminated[1]. Moreover, *C. jejuni* is an infectious agent most often associated with Guillain-Barre syndrome (GBS), a post-infectious polyneuropathy[2-5]. Campylobacter has been reported in many geographic regions and its incidence varies with the season. Campylobacter outbreak and sporadic cases occur in developed countries, but the risk of developing campylobacteriosis is greater in travelers, children, and military personnel in regions where water and food sources are commonly contaminated. Currently, no commercial vaccines are available for the prevention of campylobacter-induced diseases in humans or for the reduction/elimination of colonization in poultry.

The development of vaccines has been hampered because the pathogenesis of campylobacter infections is poorly understood. The live-attenuated or killed whole-cell campylobacter vaccine candidates have raised questions about its safety. The protein PEB1, encoded by *peb1A* genes, is considered a common antigen and a major cell adherence molecule of *C. jejuni*[6]. The *peb1A* gene contains 780 bases encoding a 259-residue polypeptide. The peptide sequence starting at residue 27 matches that determined from amino-terminal sequencing of mature PEB1 from *C. jejuni*. The molecular mass of mature PEBl (amino acids s 27-259) is 25.5 kDa. In this study, we constructed a prokaryotic expression vector carrying *C. jejuni peb1A* gene minus its signal sequence and expressed it in *E. coli*. These

vaccine candidates were evaluated in mice for their ability to induce antibody responses specific to rPEB1 immunization and to protect the candidates against oral challenge with *C. jejuni*.

MATERIALS AND METHODS

Animals

BALB/c mice, at the age of 6-8 wk, were purchased from Center of Experiment Animal of Sun Yat-sen University and housed in cages for 7 d before use.

Bacterial strains and culture conditions

C. jejuni was grown in brucella agar plates at 37℃ in a microaerobic environment. *E. coli* JM109 used for amplification of the recombinant plasmid pET28a (+) was grown in a LB medium supplemented with kanamycin (50 μg/mL) at 37℃.

Construction of pET28a (+)-peb1A

Primers were designed according to the sequence of the *C. jejuni peb1A* gene (Genbank, ATCC700819) minus its signal sequence. The sequence of up primer is 5'-GC GGATCCGCAGAAGGTAAACTTGAGTCTAT-3' and the sequence of down primer is 5'-CCGCTCGAGTTA TAAACCCCATTTTTTCGCT-3'. The restriction sites of *Bam*HI and *Xho*I (underline) were introduced into the sequences of up and down primers, respectively, for gene cloning.

As a first step in amplification of the *C. jejuni peb1A* gene, template DNA was extracted from the *C. jejuni* genome. In a 50-μL Eppendoff tube, 30.5 μL of ddH_2O, 5 μL of 2 mmol/L dNTP, 5 μL 10 × PCR buffer, 0.5 μL of Taq polymerase, 1 μL of template DNA were added. The PCR product was subjected to electrophoresis on 1.5% agarose, purified using a DNA purification kit and then subjected to digestion with *Bam*HI and *Xho*I. The digested PCR product was purified and inserted into pET28a (+) digested with the same restriction enzyme to construct pET28a (+)-*peb1A*. pET28a (+)-*peb1A* was transfected into *E. coli* JM109. After propagation, pET28a (+)-*peb1A* was identified with restriction enzyme by direct sequencing.

Protein expression and purification

The *peb1A* gene from *C. jejuni* was expressed in *E. coli* as hexahistidine tagged proteins in pET-28a (+). *E. coli* BL21 (DE3) containing *peb1A* clone was grown in LB broth containing 30 μg/mL kanamycin. Cells were incubated at 37℃ with shaking at 250 r/min for 3-4 h until the culture reached an OD of 0.3-0.4. Then, IPTG was added to the LB broth at a final concentration of 1 mmol/L to induce expression of the target protein PEB1. Culture was continued for 6 h and BL21(DE3) cells were harvested at 1, 2, 3, 4 and 6 h, respectively, by centrifugation. The pellet of BL21(DE3) cells was resuspended in 1 × LEW buffer containing 50 mmol/L NaH_2PO_4, 300 mmol/L NaCl, pH 8, and subjected to ultrasound in ice water. To evaluate the solubility and inclusion body formation, the resulting supernatant and sediments were separated by centrifugation at 12000 r/min for 10 min at 4℃, and subjected to SDS-PAGE for expression of recombinant PEB1 (rPEB1), which was purified by nickel chromatography under native conditions.

Vaccination

BALB/c mice were injected with 100 μL of PBS or with PBS containing 25, 50 or 100 μg of rPEB1 protein emulsified with an equal volume of CFA or IFA. Mice in each vaccination group (n =10 mice) were immunized four times at 1-wk intervals by intramuscular and subcutaneous injection. Following vaccination, the mice were monitored for adverse effects. Blood was collected from mice at various time points before and after immunization, and allowed to clot. The tubes were spun at 3000 r/min for 10 min, and the serum was collected into a clean microcentrifuge tube. Serum samples were logged in and stored at -20℃.

ELISA was used to evaluate the level of antibody response to anti-PEB1. Briefly, rPEB1 was used as the solid phase. After blocking with PBST supplemented with 10% fetal calf serum, the serum from mice was added. After extensive washing, bound antibodies were detected with goat anti-mouse IgG labeled with horseradish peroxidase. Antibody titers were determined by the serial end-point dilution method. The titer of serum was expressed as group geometric mean ± SD of the mean of individual animal values, which represented the average of duplicate assays.

T-cell proliferation assays

BALB/c mice immunized with rPEB1 or PBS (control) were sacrificed on day 60 after the first immunization. Splenocytes were harvested from the mice, co-cultured with rPEB1 (2 μg/mL) or with PHA in RPMI1640 for 54 h before addition of MTT (10 μL per well), and incubated at 37℃ for 3 h. The supernatant was transferred into a new Eppendorf tube. Absorbance of the converted dye was measured at a wavelength of 570 nm with a spectrophotometer.

Protective efficacy of oral challenge with C. jejuni

BALB/c mice at the age of 7-9 wk without specific pathogen were used in the study. The vaccinated mice were challenged with *C. jejuni* strain 81-176 in the oral model. We compared the protective efficacy of rPEB1 in immunized and non-immunized mice. Deaths occurred in challenged and control mice were recorded for more than 7 d. Illness index was scored as follows: 2 = dead, 1 = lethargic with ruffled fur and lower activity, and 0 = healthy.

RESULTS

Construction of pET28a (+)-peb1A

A single band at the 720-bp site was well shown in *C. jejuni* genome amplified by PCR. Recombinant plasmid pET28a (+)-*peb1A* analyzed by restriction enzyme digestion and DNA sequence was correctly constructed.

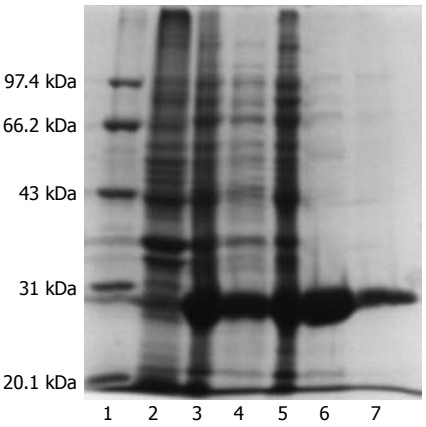

Figure 1 Analysis of expression pattern of recombinant protein by SDS-PAGE. Lane 1: protein marker; lanes 2-3: *E. coli* BL (DE3) transformed with pET28a(+) and pET28a(+)-*peb1A* respectively after induced with IPTG for 4 h; lanes 4-5: supernatant and precipitate of sonicated broken *E. coli* BL (DE3) transformed with pET28a(+)-*peb1A*; lanes 6-7: Purified recombinant protein.

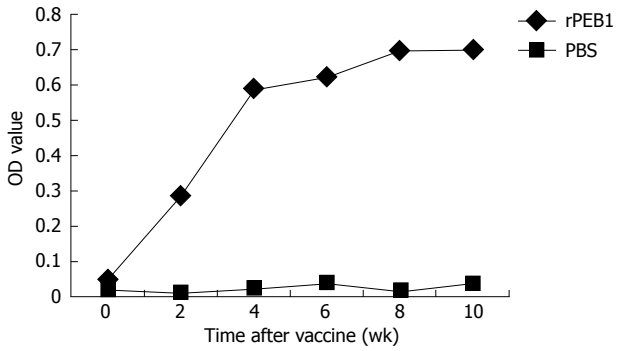

Figure 2 OD values of specific serum IgG antibody levels after immunization with rPEB1.

Expression and purification of recombinant protein

A rPEB1 protein with an expected molecular weight of 29kD was efficiently expressed in *E. coli* BL (DE3). The rPEB1 was mainly observed in supernatant of the *E. coli* BL (DE3) lysate and purified to approximately 96% purity by Ni-NTA resin after ultrasonication. The expression output of PEB1 protein in pET28a (+)-*peb1A* system was approximately 33% of total proteins of *E. coli* (Figure 1).

Strong immune response of BALB/c mice immunized with rPEB1

In subcutaneous and intramuscular injection groups, no apparent side effects were noted in mice and delivery of rPEB1 with CFA caused a ruffled fur appearance in all mice that lasted < 24 h, suggesting that injection of rPEB1 was safe. The mice in subcutaneous and intramuscular injection groups were immunized with rPEB1 interfused in CFA or IFA. PBS was substituted for rPEB1 in the control group. Anti- rPEB1 serum was detected 2 wk after the first immunization in both subcutaneous and intramuscular injection groups (Figure 2). Compared to the PBS group, significantly higher levels of serum IgG were detected in ⩾ 90% of the animals when 50 μg or higher rPEB1 was delivered with the adjuvant. Vaccination with 100 μg rPEB1 with the adjuvant induced antigen specific serum IgG, which was indistinguishable from that in 200 μg recipients (Table 1). A clear vaccine dose-dependent response was seen for the response magnitude and a strong immune response was observed in mice after immunization with rPEB1. The highest end point dilution titer of anti-rPEB1 serum was 1:5600.

Table 1 OD values of specific serum IgG antibody levels in BALB/c mice after immunization with recombinant PEB1 protein vaccine

Groups	Immune route	Serum IgG (mean ± SD)
Control	Subcutaneous	0.157 ± 0.010

J200 μg	6	3	2	1	3.14 ± 0.90	66.7

T-cell proliferation assay of splenocytes in BALB/c mice

The proliferating response of splenocytes was generated in immunized mice when they were stimulated by PHA or rPEB1 protein. The stimulation index (SI) value for the immunized group was significantly higher than that for the control group, suggesting that proliferation of T cells from immunized mice could be stimulated by rPEB1. No difference in SI was observed in different groups immunized with different doses of rPEB1 compared with the PHA control group (Figure 3).

Protective efficacy of oral challenge with wild-type C. jejuni

Fourteen days following vaccination, animals immunized with different doses of rPEB1 were challenged with wild-type *C. jejuni*. The results are summarized in Table 2. Fifty micrograms rPEB1 failed to protect mice against *C. jejuni* infection and no significant difference was observed in illness pattern of PBS recipients. The efficacy of rPEB1 vaccine was significantly higher in animals challenged with *C. jejuni* than in those of the control group, indicating that rPEB1 vaccine could eradicate *C. jejuni* infection (Figure 4).

DISCUSSION

PEB1, a surface-exposed conserved antigen in *C. jejuni*,

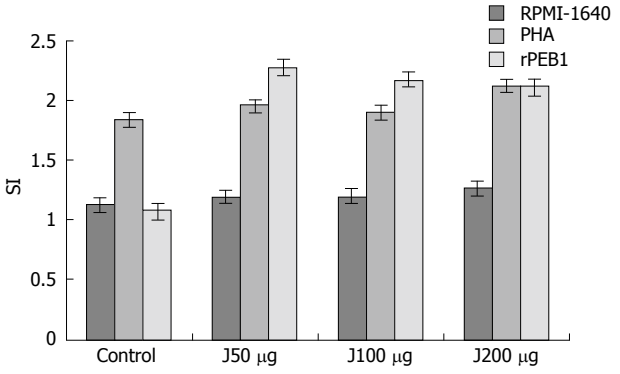

Figure 3 Stimulation index of immunized BALB/c mice spleen lymphocytes stimulated by intramuscular injection of rRPEB1.

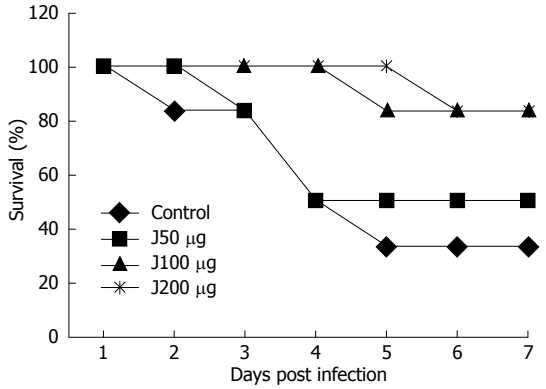

Figure 4 Survival of BALB/c mice immunized with rPEB1 after oral challenge with wild-type *C. jejuni* in control and vaccination groups.

is commonly recognized in convalescent sera from infected patients and involves binding of *C. jejuni* to eukaryotic cells[7]. Pei *et al*[8] have reported that PEB1 is a homolog of cluster 3 binding proteins of bacterial ABC transporters and a *C. jejuni* adhesion cell-binding factor 1. They determined the role of PEB1 in *C. jejuni* adherence and noted that the rate and duration of intestinal colonization by its mutants are significantly lower and shorter than those of the wild-type strain in mouse challenge test[8]. The adherence to epithelial cells is essential for the establishment of colonization in the gastrointestinal tract. It has also been shown that the PEB1 can adhere to Hela cells[9]. Inactivation of the *peb1A* locus significantly reduces *C. jejuni* adherence to Hela cells[10,11]. Moreover, the particulate PEB1 is the only antigen, known to elicit a prominent immune response[12,13]. We believe that PEB1 may be used as a vaccine for *C. jejuni* infection, which was confirmed by the fact that we successfully constructed a fusion gene containing *C. jejuni peb1A* gene and expressed rPEB1 protein in *E. coil* BL21 (DE3). rPEB1 with adjuvant CFA/IFA was used to immunize BALB/c mice, in which strong specific humoral immune responses were induced. High specific anti-rPEB1 and significantly higher specific T-cell proliferation were detected in BALB/c mice 3 wk after their first immunization. Furthermore, rPEB1 vaccination was found to have an effect on reducing the illness index of BALB/c mice after oral challenge with wild-type *C. jejuni*.

Sizemore *et al*[14] have reported that live and attenuated *Salmonella Typhimurium* strains expressing PEB1 can induce antibody responses specific to PEB1 following oral immunization, and have the ability to protect mice against infection with *S. Typhimurium* strains by reducing or eliminating systemic dissemination and intestinal colonization of wild-type *C. jejuni* strain 81-176. However, they noted that attenuated salmonella can stimulate production of serum IgG in mice and cannot protect mice against challenge with wild-type *C. jejuni*[14]. They believe that a small amount of antigen, available at the time of vaccination, may play a role in the absence of serum IgG[14]. Our results indicated that immunization with a low dose (50 μg) of rPEB1 could stimulate specific humoral immune responses and could not protect mice against challenge with wild-type *C. jejuni*.

The results of the animal protection test using 100 μg rPEB1 showed that most immunized mice remained healthy after *C. jejuni* challenge. Eighty percent of the control mice were lethargic with ruffled fur and lower activity and died 2 d post-challenge. The protective rate of rPEB1 immunization was 75% in the 100 μg rPEB1 group.

In conclusion, rPEB1, as a candidate vaccine, offers several advantages. It can lead to strong immune response, and provide a protective efficacy. Further study is needed to address its mechanism.

COMMENTS

Background

Despite the growing importance and widespread recognition of campylobacter enteritis as a major international public health problem, no commercial vaccines are available for the control of campylobacter-associated enteric disease in humans, or for the reduction/elimination of colonization in poultry.

Research frontiers

This study looked for the best induction of protective immune responses when the immunogenic campylobacter protein PEB1 was expressed.

Innovations and breakthroughs

The results of this study showed that rPEB1 was successfully expressed in *Escherichia coli* and immunization of mice through systemic routes could induce strong and specific serum IgG responses and splenocyte proliferation.

Applications

Based on the results of our study, further investigation should be focused on mucosal immune responses, which may be more important to *Campylobacter jejuni* subunit vaccines.

Peer review

The results of this study are interesting. The authors evaluated immunoreactivity and antigenicity of rPEB1, identified the ability of rPEB1 to induce systemic immune responses and its protective efficacy.

Abstract

AIM: To investigate the ultrastructural location of midkine (MK) in nucleolus and function corresponding to its location.

METHODS: To investigate the ultrastructural location of MK in nucleolus with immunoelectronic microscopy. To study the role that MK plays in ribosomal biogenesis by real-time PCR. The effect of MK on anti-apoptotic activity of HepG2 cells was studied with FITC-conjugated annexin V and propidium iodide PI double staining through FACS assay.

RESULTS: MK mainly localized in the granular component (GC), dense fibrillar component (DFC) and the border between the DFC and fibrillar center (FC). The production of 45S precursor rRNA level was decreased significantly in the presence of MK antisense oligonucleotide in the HepG2 cells. Furthermore, it was found that exogenous MK could protect HepG2 from apoptosis significantly.

CONCLUSION: MK was constitutively translocated to the nucleolus of HepG2 cells, where it accumulated and mostly distributed at DFC, GC components and at the region between FC and DFC, MK played an important role in rRNA transcription, ribosome biogenesis, and cell proliferation in HepG2 cells. MK might serve as a molecular target for therapeutic intervention of human carcinomas.

Key words: 45S rRNA; Anti-apoptosis; Proliferation; Midkine

INTRODUCTION

Midkine (MK) is a cysteine-rich basic protein with a molecular weight of 13 Ku, which is strongly expressed during mid-gestation embryogenesis[1]. MK can be detected in most carcinoma specimens at a high level in a tissue type-independent manner, including those of esophageal, gastric, gall bladder, pancreas, colorectal, breast, and lung carcinomas, and Wilms' tumors[2-7]. Furthermore, MK exhibits several cancer-related activities, which include fibrinolytic, anti-apoptotic, mitogenic, transforming, angiogenic, and chemotactic activity[8-10]. Recently, Shibata *et al*[11] have shown that exogenous MK is endocytosed by cultured mouse L cells and then transported to the nucleus. However, more detailed information on the location and biological mechanism of MK within cells still remains to be elucidated. In a previous study, using green fluorescent protein (GFP) as a tracking molecule we have found that MK is exclusively localized to the nucleus and nucleolus in HepG2 cells[12]. We have also found that MK both with and without signal peptide is exclusively localized to the nucleus and accumulats in the nucleolus of DU145 and MCF7 cell lines[13].

In the present study, we demonstrated the ultrastructural location of MK in the nucleolus with immunoelectron microscopy. As is known, the nucleolus is a region of the nucleus that is known to be the locus for ribosomal biogenesis. This prompted us to hypothesize that MK may be involved in RNA

transcription and processing. We studied the effect of MK on rRNA synthesis and found 45S rRNA production level decreased in response to down-regulation of MK expression. Since cell proliferation and cancer survival require continuous protein synthesis that depends on a constant supply of ribosomes[14], 45S rRNA production may be affected by endogenous MK level, suggesting that cell proliferation is directly related to MK level. Investigating this possibility, we demonstrated that cell proliferation was inhibited by down-regulation of MK. Moreover, we reported that exogenous human MK is involved in anti-apoptotic activity of HepG2 cells.

MATERIALS AND METHODS

Immunoelectron microscopy

HepG2 cells were fixed with 3% paraformaldehyde and 1% glutaraldehyde at 4 degree for 2 h, and then sequentially dehydrated with 30%, 50% and 100% ethanol and embedded in Lowicryl K4M. Sections of 50 nm were cut and mounted on nickel grids. Non-specific binding was blocked with 1% BL (50 mmol/L PBS, pH 7.0, 1% BSA, 0.02% PEG20000, 100 mmol/L NaCl, 1% NaN_3) for 30 min at room temperature. Then, sections were incubated for 1 h at room temperature with anti-MK primary antibody (rabbit polyclonal to human MK, Abcam, UK) at a dilution of 1:100. After another treatment with BL, sections were incubated with 15 nm colloidal gold-labeled second antibody (goat polyclonal antibody to rabbit IgG, 15nm gold; Abcam, UK). Finally, sections were stained sequentially with uranyl acetate for 15 min and lead nitrate for 10 min. The ultrastructural distribution of MK was examined and photographed with a Hitachi H-800 transmission electron microscopy.

Antisense treatment

The sequence of MK morpholino antisense oligomer was as follows: MK-As (5'-AGGAAGCCTCGGTGCTGCA TCTCGC-3'). The sequence for MK-Sen was as follows: (5'-CGCTCTACGTCGTGGCTCCG AAGGA-3'). MK-Sen is a control oligonucleotide that has the same base composition as MK-As, but in the reverse sequence, and thus does not hybridize with MK mRNA. MK-As and MK-Sen were transfected into HepG2 cells in the presence of Lipofectamine-Plus (Life Technologies, Inc) in accordance with the manufacturer's instructions.

Real time PCR assay

The real-time PCR was performed with an RT-PCR kit (Takara, Japan) according to the manufacturer's instructions using GAPDH primers (5'-AACGACCCCTT CATTGAC-3' and 5'-TCCACGACA TACTCAGCAC-3'), MK primers (5'-AAACCGAACTCCAGGACCAGAGA C-3' and 5'-AACACTCGCTGCCCTTCTTCAC-3') and 45S primers (5'-CGCCGCTAGAGGTGAAATTC-3' and 5'-CATTCTTGGCAAATGCTTTCG-3'). Samples were amplified in a 7500 Real Time PCR system for 40 cycles using the following PCR parameters: 95℃ for 30 s, 58℃ for 1 min, and 72℃ for 1 min.

Cell proliferation assay

A total of 1.0×10^4 HepG2 cells were added to each well of a 96-well microtiter plate and allowed to attach overnight. Oligonucleotides at concentrations of 0.2, 0.4 and 0.6 μmol/L were transfected into HepG2 cells with Lipofectamine Plus (Life Technologies, Inc) following the manufacturer's instructions. The effects of antisense oligodeoxynucleotide on cellular viability were measured using an MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide] assay.

Analysis of apoptosis through FACS

1.0×10^5 HepG2 cells were seeded in six-well plates. Three wells were pre-treated with 500 ng/mL MK and three wells were treated with PBS as control for 3 h. Cells then were treated with 10^{-6} mol/L adriamycin, harvested 20 h later through trypsinization, and washed twice with cold PBS. The cells were centrifuged at 3000 r/min for 5 min, then the supernatant was discarded and the pellet was resuspended and incubated with FITC-conjugated annexin V and propidium iodide (Pharmingen) for 15 min at room temperature in the dark, and then analyzed by FACS.

RESULTS

The ultrastructural location of MK in HepG2 cells nucleolus

In a previous study, we demonstrated that MK exclusively localizes to the nucleus and nucleolus in HepG2 cells, using GFP as a tracking molecule[12]. At the ultrastructural level, the nucleolus includes three components: the fibrillar center (FC), the dense fibrillar component (DFC), and the granular component (GC)[15]. Although we have found that MK accumulats in the nucleolus, the exact actions that MK performed on the nucleolus are still unclear. Therefore, we employed immunogold-labeling electron microscopy to investigate the ultrastructural location of MK, and found MK mainly localized in the GC, DFC and the border between the DFC and FC (Figure 1).

MK involved in rRNA transcription

In order to make clear that the function of MK corresponds to its ultrastructural location in the nucleolus, we investigated the role that MK plays in ribosomal biogenesis by real-time PCR. We found the production of 45S precursor rRNA in the HepG2 cells was decreased significantly in the presence of MK antisense oligonucleotide (Figure 2). This suggests that endogenous MK plays an important role in cancer cell proliferation.

MK promotes cell proliferation

Due to the central importance of rRNA transcription in cell growth, decreased rRNA transcription will slow cell proliferation. In this study, we showed that MK-As reduced cell proliferation rates by 41%, 48%, 58% after transfection of 0.2, 0.4 and 0.6 μmol/L MK antisense

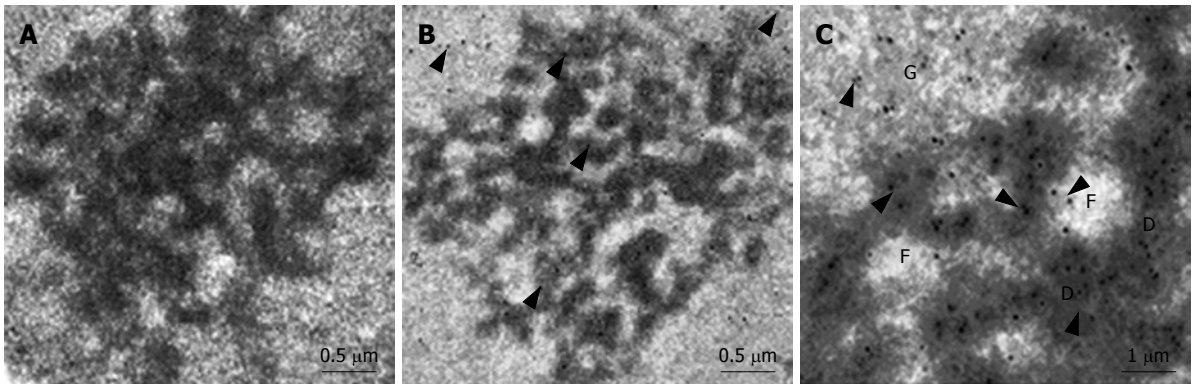

Figure 1 The location of MK in HepG2 cells nucleolus using immunogold labeling electron microscopy. HepG2 cells labelled without MK antibody were performed as the control. No immunogold particles of MK were seen (A). The MK protein (arrow) mostly localized to the DFC, GC and the region between FC and DFC (B, C) [scale bar represents 0.5 μm (A, B) and 1 μm (C)].

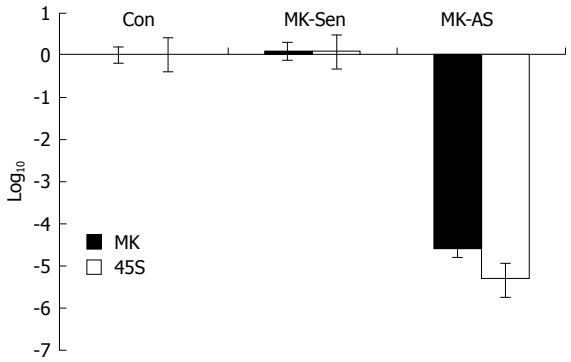

Figure 2 45S rRNA transcription could be regulated by endogenous MK level. It was shown that 45S rRNA transcription was decreased significantly in response to downregulation of MK expression, through real-time PCR analysis ($P < 0.05$).

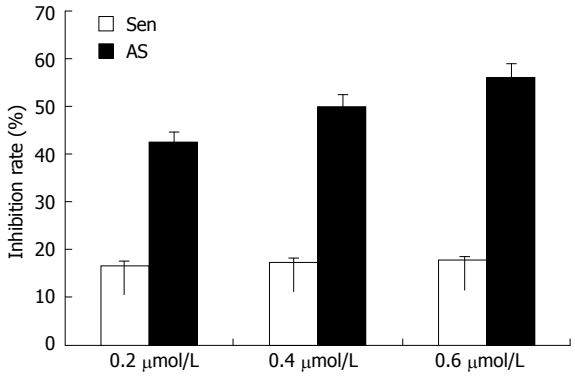

Figure 3 Effect of MK on proliferation of HepG2 cells. HepG2 cells were transfected with 0.2, 0.4 and 0.6 μmol/L MK-As or MK-Sen for 24 h, and were analyzed by MTT assay. Data show that HepG2 cell proliferation and growth were inhibited by downregulating the MK expression with antisense MK transfection ($P < 0.05$).

oligonucleotide into 10^4 HepG2 cells. The control MK-Sen did not inhibit cell proliferation significantly (Figure 3).

MK mediates anti-apoptotic activity

In order to investigate whether MK plays a role in the apoptosis of cancer cells, we added exogenous MK to HepG2 cells in the presence of adriamycin, inducing apoptosis. The results showed that exogenous MK could protect HepG2 from apoptosis significantly (Figure 4). This led us to suggest that MK may be a drug target for curing cancer.

DISCUSSION

In this study, we showed that MK was constitutively translocated to the nucleus of HepG2 cells, where it accumulated (Figure 1) and mostly distributed at the region between the FC and DFC, and GC components of the nucleolus (Figure 2). In a previous study, it has been demonstrated that each component of the nucleolus corresponds to a special biological function: the nascent transcripts appear in the junction region between the FC and DFC and accumulate in the DFC, and continue during the intranucleolar migration of the rRNA towards the GC. This implies that the role of the MK in the nucleolus is possibly related to control of rRNA gene transcription, pre-rRNA processing, and nascent ribosome subunit assembly, which could be the downstream elements of controlling cell proliferation. The finding that MK is involved in rRNA transcription in HepG2 cells in our study is significant for understanding cancer biology. One of the hallmarks of cancer is sustained cell growth and this can only be achieved by increased protein synthesis. To accommodate this need, there must be an increase in ribosome biogenesis. The role MK plays in rRNA transcription in cancer cells suggests that up-regulation of MK expression in various cancer cells not only induces tumor growth, but also directly contributes to cell proliferation. Thus, inhibitors targeting MK will be more effective than those that inhibit cancer cell proliferation alone. rRNA transcription regulates ribosome production and consequently, the translation potential of a cell, and increasingly expressed ribosomal proteins and rRNA transcription is an important factor in cancer transformation[16]. It is conceivable that deregulation of rRNA transcription may be an important determinant in transformation of cancer cells. Continuous nuclear translocation of MK in cancer cells can be possible one of the contributing factors in determinant of transformation. Indeed, inhibiting

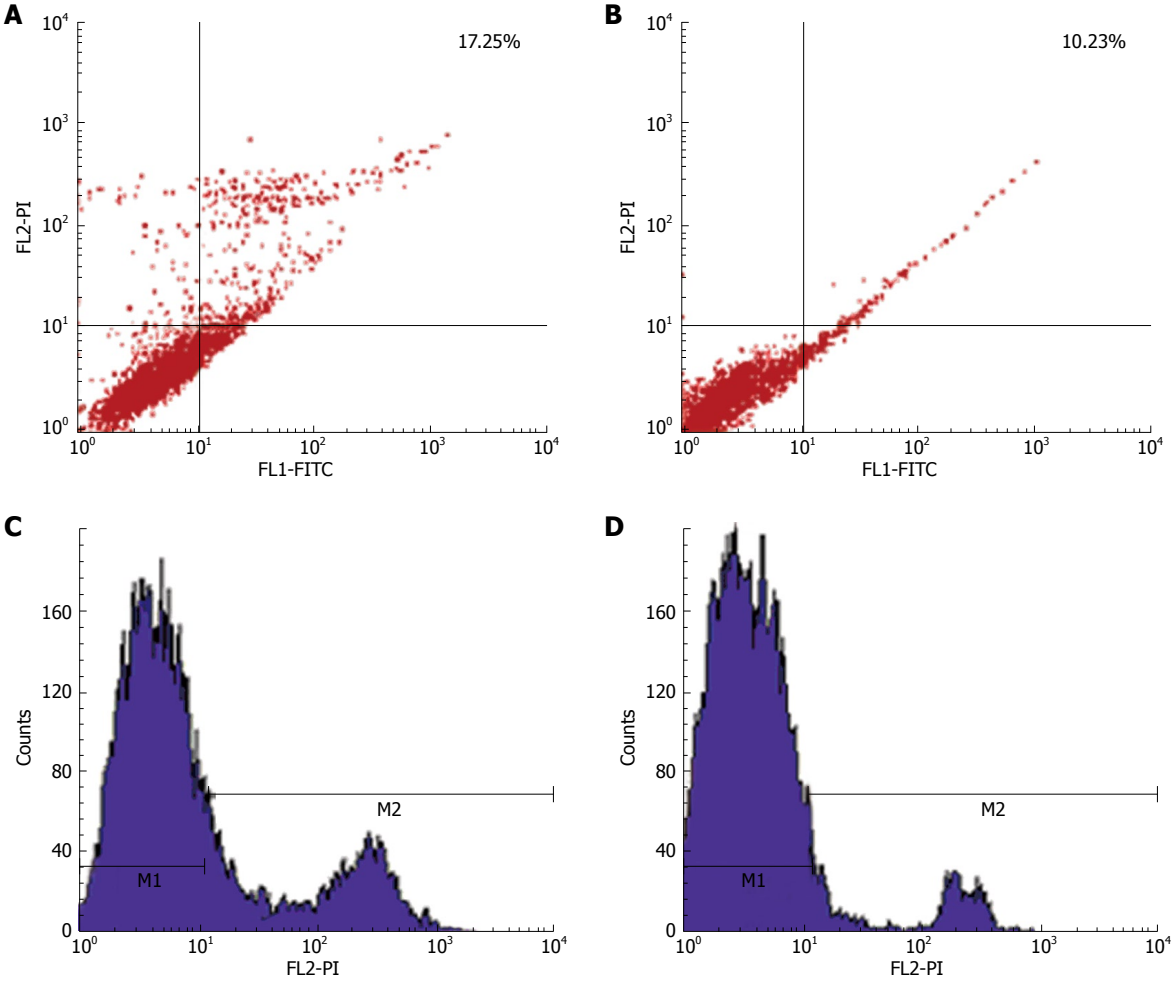

Figure 4 Exogenous MK mediates its anti-apoptotic activity. HepG2 cells are induced to apoptosis by 10^{-6} mol/L adriamycin for 20 h. It shows that about 17.25% of cells enter apoptosis (A, C), while 500 ng/mL exogenous MK showed its anti-apoptotic of activity (B, D).

MK expression reduced tumorigenicity and reversed the malignant phenotype of cancer cells, by antisense oligodeoxynucleotide targeted to MK. It is therefore possible that other effects such as repression of rRNA transcription of cancer cells also contributed to the marked anticancer activity. In conclusion, the results showed that MK played an important role in rRNA transcription, ribosome biogenesis, and cell proliferation in HepG2 cells. However, the mechanism by which MK stimulates rRNA transcription is still unclear at present. More extensive work is needed to understand how MK is translocated to the nucleus, whether it interacts with the RNA polymerase I machinery or binds to DNA.

COMMENTS

Background

Midkine (MK) has been found to play important roles in carcinogenesis, including mitogenic, anti-apoptotic, transforming, fibrinolytic, chemotactic, and angiogenic cancer-related activities. In a previous study, it has been demonstrated that each component of the nucleolus corresponds to a special biological function: the nascent transcripts appear in the junction region between the fibrillar center (FC) and dense fibrillar component (DFC) and accumulate, in the DFC, and continues during the intranucleolar migration of the rRNA towards the granular component (GC). This implies that the role of the MK in the nucleolus is possibly related to control of rRNA gene transcription, pre-rRNA processing, and nascent ribosome subunit assembly, which could be the downstream elements of controlling cell proliferation. In a previous study, we found that MK exclusively localized to the nucleus and nucleolus in HepG2 cells. However, it is unclear what is the function of MK in the nucleus and nucleolus.

Research frontiers

MK expression is increased in many human carcinomas, such as esophageal, stomach, colon, pancreatic, thyroid, lung, breast, urinary bladder, uterine, ovarian, prostate and hepatocellular carcinomas, osteosarcoma, neuroblastoma and glioblastoma. This phenomenon is observed in about 80% of cases in many types of carcinomas. Furthermore, MK exhibits several cancer-related activities, which include fibrinolytic, anti-apoptotic, mitogenic, transforming, angiogenic, and chemotactic activity.

Innovations and breakthroughs

In our study, we demonstrated that MK may be involved in 45S rRNA transcription. Since rRNA transcription is essential for tumor growth and proliferation, inhibition of MK-stimulated transcription of rRNA may be developed into a novel method to inhibit the growth of tumors.

Applications

The results may provide valuable evidence for the further study on the functions of MK in the nuclus and its mechanisms, in which rRNA transcription and ribosome assembly are involved. MK might serve as a molecular target for therapeutic intervention in human carcinomas.

Terminology

FC, DFC and GC are three components of the nucleolus. The nucleolus can be observed with the light microscope and its structure has more recently been clarified using the electron microscope.

Peer review

In this manuscript, authors report that the oncogenic function of MK could be associated with its role in 45S rRNA transcription. This finding is interesting.

Abstract

AIM: To detect the expression of DPC4 in malignant and non-malignant specimens of human pancreas, and observe the inhibition of retroviral pLXSN containing DPC4 on pancreatic carcinoma cells *in vitro*.

METHODS: The expression of DPC4 was determined in 40 pancreatic adenocarcinoma and 36 non-malignant pancreatic specimens by reverse-transcriptase polymerase chain reaction (RT-PCR) and immunohisto-chemistry. Furthermore, we constructed retroviral vectors containing DPC4, which then infected the pancreatic carcinoma cell line BxPC-3. Cell growth *in vitro* after being infected was observed, and the vascular endothelial growth factor (VEGF) mRNA level in the daughter cells was determined by semi-quantitative PCR assay.

RESULTS: The RT-PCR assay showed a positive rate of DPC4 mRNA in 100% (36/36) of normal specimens, compared to 40% (16/40) in adenocarcinoma specimens. The regional and intense positive cases of DPC4 expression in adenocarcinoma detected by immunohistochemistry were 10 and four, whereas it was all positive expression in normal tissues. There was a significant difference of DPC4 expression between them. The stable expression of DPC4 in the pancreatic carcinoma cells BxPC-3 could be resumed by retroviral vector pLXSN transfection, and could inhibit cell growth *in vitro*. Rather, DPC4 could decrease VEGF mRNA transcription levels.

CONCLUSION: The deletion of DPC4 expression in pancreatic carcinoma suggests that loss of DPC4 may be involved in the development of pancreatic carcinoma. The retroviral vector pLXSN containing DPC4 can inhibit the proliferation of pancreatic carcinoma cells, and down-regulate the level of VEGF.

INTRODUCTION

Chromosome 18q is lost in a high proportion of colorectal and pancreatic cancers. Three candidate tumor suppressor genes, DCC (deleted in colorectal carcinoma), DPC4 (deleted in pancreatic carcinoma, locus 4) and Smad2 have been identified in this chromosome region. The tumor suppressor DPC4, which was identified by Scott Kern in 1996[1], is frequently lost in many tumor cells, especially in pancreatic cells. DPC4, also named as Smad4, belongs to the evolutionarily conserved family of Smad proteins that are crucial intracellular mediators of signals from transforming growth factor-β (TGF-β)[2]. TGF-β regulates a wide variety of biological activities. Smad proteins can transduce the TGF-β signal at the cell surface into gene regulation in the nucleus.

Here, we detected the expression of DPC4 in 40 pancreatic adenocarcinoma and 36 non-malignant pancreatic specimens by RT-PCR and immunohistochemistry; then, we reintroduced the DPC4 gene in the pancreatic carcinoma cell line BxPC-3 (null for DPC4[3]), by transferring the retroviral vector pLXSN containing the DPC4 gene, in order to study inhibition of DPC4 gene expression in the pancreatic carcinoma cells *in vitro*.

MATERIALS AND METHODS

Patients and methods

Forty malignant pancreatic carcinoma and 36 corresponding non-cancerous tissues were obtained from the First Affiliated Hospital of Suzhou University and the Wuxi's People Hospital from 2003 to 2006. The clinical and pathological data from this patient population were readily available from pathology reports and a regularly updated clinical database. There were 28 males and 12 females with pancreatic carcinomas, and the average age of the patients was 55.18 ± 11.29 years old (mean ± SD). Tumor fragments were obtained in sterile conditions from different areas of the specimen and immediately placed in supplemented RPMI-1640 medium.

Reverse-transcriptase polymerase chain reaction (RT-PCR) for DPC4 mRNA

Total RNA was extracted from tissues with a single-step method. Randomly primed cDNAs were reverse-transcribed from 4 μg total RNA, which was extracted from about 1 g fresh specimen, using a cDNA synthesis kit in a 20-μL mixture. The 2-μL mixture was increased to 100 μL by adding 10 mmol/L Tris-HCI (pH 8.3), 50 mmol/L KCl_2, 1.5 nmol/L $MgCl_2$, 200 μL of each deoxynucleotide triphosphate, 6 U Taq polymerase, and 50 pmol of each of the specific oligonucleotide primers for DPC4. PCR amplification was performed in a DNA thermal cycler and consisted of 30 or 40 cycles of denaturation for 30 s at 94℃, annealing for 30 s at 58℃, and extension for 90 s 68℃. Final extension proceeded for 1 min at 68℃, Internal control for RNA quality was obtained with β-actin, which was amplified at 94℃ for 1 min, 55℃ for 1 min, and 72℃ for 2 min for 30 cycles. PCR amplification was performed by using primers 5'-CGGAATTCATGGACAATATGTCTATTACG-3' and 5'-GCGGATCCTCAGTCTAAAGGTTGTGG-3' for the DPC4 cDNA fragment. The product was about 1.6 kb. The PCR primers for β-actin were 5'-ACACTGTGCCCATCTACGAGG-3' and 5'-AGGGGCCGGACTCGTCATACT-3'. The product was 621 bp. All the products were run on a 1% agarose gel and visualized by ethidium bromide staining.

Immunohistochemical analysis for DPC4

Tissues were routinely fixed in neutral formalin and embedded in paraffin. After being deparaffinized, the slides were placed in a solution of 3% hydrogen peroxide for 5-10 min to block the activity of endogenous peroxidase. After being washed with distilled water and then dipped in PBS for 5 min, the slides were closed in normal sheep blood serum and then heated to room temperature for 10 min. Non-specific binding was blocked with a protein solution for 10 min, and then each slide was labeled with a 1:100 dilution of monoclonal antibody to DPC4 (murine anti-human; LAB Vision). Anti-DPC4 antibody was detected by adding secondary antibodies (rabbit anti-murine; Maxim Biotech, Fuzhou). After being incubated at 37℃ for 1 h, the slides were washed by PBS. The sections were counterstained with hematoxylin. Positive cells were stained dark brown in the nuclei and/or cytoplasm, and the staining was graded into three categories: no staining, weak staining, or heavy staining. Positive staining was considered as expression of DPC4. Normal pancreatic ducts, islets of Langerhans, acini, lymphocytes, and stromal fibroblasts showing moderate to strong expression of DPC4 served as positive internal controls for each section.

Construction of the retroviral vectors, cell culture and transfection

The human DPC4 cDNA was amplified from Smad4/DPC4-pBluescript plasmid (as a gift from Scott Kern) by PCR. The identity of the amplified fragments was confirmed by cycle sequencing using the manufacturer's directions (Shanghai Sangong Biological Engineering Technology and Servical Co., Ltd), then subcloned to the retroviral vector pLXSN to obtain pLXSN/DPC4+ recombinant with direct insertion, and packaged with GP+E86 and PA317 amphotropic packaging cells. AntiG418 clones were acquired and named as PA317/pLXSN DPC4+ cells. As a control, the empty vector pLXSN also was packaged with GP+E86 and PA317 cells and the antiG418 clones were named as PA317/pLXSN. The virus titer was elevated through cross infection from GP+E86 to PA317 cells and reached 6.0×10^5 pfu/L. DPC4 gene integration in PA317/pLXSN DPC4+ or PA317/pLXSN cells was confirmed by PCR assay.

Retroviral supernatant was obtained from the producer cell lines and maintained at 32℃ in 5% CO_2 atmosphere for 24-48 h. The BxPC-3 lines (purchased from Shanghai Institute for Biological Science, Chinese Academy Science) were transduced using the following protocol. One milliliter of the filtered supernatant was added to 4×10^5 target cells in the presence of 8 μg/mL polybrene. Cells and retroviral supernatant were incubated at 37℃ for 4 h. Medium from producer cells was then replaced by RPMI-1640 medium supplemented with 20% fetal calf serum and then in the presence of 2 μg/mL polybrene at 24-h intervals. After the last infection, the daughter cells were subjected to an initial period of selection in 0.2 mg/mL G418 for 4 d and then in 0.5 mg/mL for 1 wk. The positive cells were named as BxPC-3/DPC4. As a positive control, daughter cells transduced by empty vector were named as BxPC-3/pLXSN. As a negative control, mother cells were named as BxPC-3/-.

Western blot analysis

10^7 cells were lysed at 4℃ in a lysis buffer containing 150 mmol/L NaCl, 1% Triton X-100, 1 mmol/L phenylmethylsulfonyl fluoride (Sigma Chemical Co., St. Louis, MO, USA), and 25 mmol/L Tris (pH 7.5). The lysates were cleared by centrifugation and boiled for 5 min at 100℃ in Laemmli's SDS-PAGE sample buffer containing 100 mmol/L DTT. Proteins were resolved at 100 V on 10% polyacrylamide gels and transferred to Immobilon-P membranes (Millipore Corp., Bedford, MA, USA). The membranes were blocked with 5% non-fat dry milk, incubated with a Smad4/DPC4

monoclonal antibody (Neo Markers), and then incubated with the secondary clonal antibody. An enhanced chemiluminescence kit (Amersham, Arlington Heights, IL, USA) was used for detection.

MTT colorimetric growth assay for cells proliferation in vitro

Cell growth was determined by the MTT colorimetric growth assay as described previously. Cells were plated in three duplicate wells of a 96-well microtiter plate at 5×10^3 cells/well in 100 μL. After incubation at 37℃ in 5% CO_2, the cells were visually determined on each of the microtitration plates and 25 mL of RPMI-1640 containing 5 mg/mL of MTT was added to each well. Incubation was continued at 37℃ for 3 h. The content of each well was removed, and 200 mL of isopropanol containing 5% 1 mol/L HCl was added to extract the dye. After 30 min of incubation at room temperature and gentle agitation, the Absorbance (*A*) was measured with a microtitration plate spectrophotometer at 550 nm. The *A* of the blank, which consisted of an uninoculated plate incubated together with the inoculated plates, was subtracted from the *A* of the inoculated plates.

Semi-quantitative PCR assay

A semi-quantitative RT-PCR assay was performed to confirm the expression of vascular endothelial growth factor (VEGF) mRNA. Total RNA was extracted from the three cells, and 1 mg total RNA was reverse-transcribed into first strand cDNA in a reaction primed by oligo (dT) 12-18 primer using Superscript Ⅱ reverse transcriptase (Invitrogen). Two microliters of the first strand cDNA were used as template for the PCR reactions using Taq polymerase (Life Technologies, Inc.). The PCR reaction started at 94℃ for 2 min, followed by 35 cycles (94℃ for 30 s, 56℃ for 45 s, and 72℃ for 45 s), and ended with a 7-min incubation at 72℃. The primers of VEGF were 5'-GGGCCTCCGAAACCATGAACTT-3' and 5'-CGCATCAGGGGCACACAG-3'. The product size was 259 bp. Expression of β-actin was monitored as an internal control; the primers for β-actin were 5'-ACACTGTGCCCATCTACGAGG-3', 5'-AGGGGCCGGACTCGTCATACT-3', and the products was 621 bp. All RT-PCR products were separated by electrophoresis in 1.2% agarose gels and autoradiographed. All experiments were performed in triplicate.

Statistical analysis

Statistical analysis was performed using the Fisher's exact probability test and χ^2 analysis using the SAS statistical software. A two-tailed Student's *t* test was used for statistical analysis of comparative data. Values of $P < 0.05$ were considered significant.

RESULTS

RT-PCR for the DPC4 expression in the malignant pancreatic tissue

The RT-PCR assay showed a positive rate of DPC4 mRNA in 100% (36/36) in all normal specimens, compared to 40% (16/40) in adenocarcinoma specimens ($n = 76$, $\chi^2 = 31.5692$, $P < 0.0001$; Figure 1).

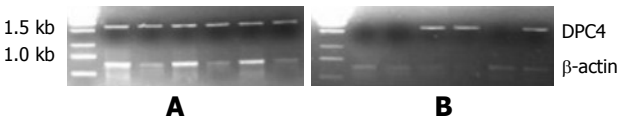

Figure 1 The mRNA of DPC4 by RT-PCR. A: Non-malignant pancreatic species; B: Malignant pancreatic species.

Immunohistochemical analysis for DPC4 expression in the malignant tissue

The regional and intense positive expression of DPC4 protein revealed by immunohistochemistry was 10 and four respectively, and all positive rate accounted for 35% (14/40), whereas there was all positive expression in normal tissues ($n = 76$, $\chi^2 = 35.568$, $P < 0.0001$; Figure 2).

PCR amplification of the DPC4 gene from Smad4/DPC4-pBluescript plasmid

The PCR product was about 1.6 kb in the electrophoresis gel as expected (Figure 3). pucm-T/DPC4 gene sequence was identified by Shanghai Sangong Biological Engineering Technology and Servical Co., Ltd., and agreed with our expected result.

Stable expression of DPC4 in the pancreatic carcinoma cell BxPC-3 after transfection demonstrated by RT-PCR and Western bloting

As an internal control, β-actin segments of about 838 bp were obtained in all three cell lines, which indicated that DNA was distilled effectually. DPC4 was expressed only in BxPC-3/DPC4 cells, but not the other control cells, BxPC-3/- and BxPC-3/pLXSN (Figure 4). An approximately 60-kDa protein blot, DPC4 protein, was obtained in BxPC-3/DPC4, but not in the BxPC-3/pLXSN or BxPC-3/- cells (Figure 5).

MTT for the cells grown in vitro

The BxPC-3/DPC4 cells grew much more slowly than the BxPC-3/pLXSN and BxPC-3/- cells. At day 7, the ratio of proliferation inhibition was about 50% ($F = 9.65$, $P = 0.0209$, BxPC-3/DPC4 *vs* BxPC-3/pLXSN; $F = 11.03$, $P = 0.0160$, BxPC-3/DPC4 *vs* BxPC-3/-; Figure 6).

Semi-quantitative PCR for VEGF mRNA

All three cell types had positive expression of VEGF and β-actin. However, semi-quantitative PCR assay showed the level of VEGF mRNA was much lower in BxPC-3/DPC4 than BxPC-3/pLXSN or BxPC-3/- (Table 1).

DISCUSSION

The majority of patients who present with pancreatic carcinoma have little chance of undergoing operative

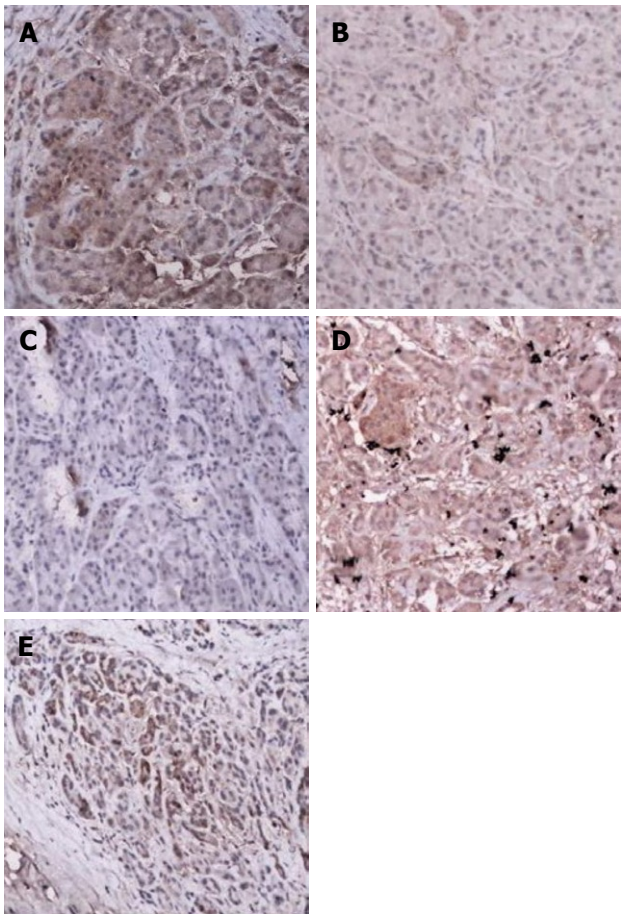

Figure 2 Immunohistochemical staining (x 100). A: Intense positive expression of DPC4 in the nuclei and/or cytoplasm in the normal pancreatic tissue; B: Weak expression of DPC4 in normal pancreatic tissue; C: Pancreatic carcinoma showed loss of DPC4 expression; D: DPC4 expression in an adenocarcinoma with a wild-type DPC4 gene; E: Intense positive expression of DPC4 in the malignant pancreatic tissue.

treatment, and non-operative treatments can offer little survival advantage. It is necessary to look for some other effective treatment for pancreatic carcinoma. TGF-β inhibits cell growth and/or induces apoptosis. In epithelium, disruption of the TGF-β signaling cascade is considered an important mechanism by which tumor cells can escape growth suppression. In a number of cancers, resistance to TGF-β growth inhibition is associated with mutations either in receptor Ⅱ or in the signal transducers. DPC4/Smad4 belongs to the evolutionarily conserved family of Smad proteins that are linked to the TGF-β superfamily of cytokines, forming a complex with R-Smads in response to ligand stimulation. Disruption of DPC4 can result in a TGF-β signal blackout and is involved in the regulation of cell differentiation, as well as the inhibition of cell proliferation. So, DPC4 is an essential signaling intermediate in the TGF-β receptor-mediated pathway. Abrogation of DPC4 function might cause a breakdown in this signaling pathway and loss of transcription of genes critical to cell-cycle control. Cells might therefore become TGF-β resistant and escape from TGF-β-mediated growth control and thereby contribute to tumorigenesis. C-terminal truncation of DPC4 protein

prevents DPC4 homomeric complex formation and heteromeric complex formation with activated Smad2. Furthermore, the mutant protein is unable to be recruited to DNA by transcription factors and hence cannot form transcriptionally active DNA-binding complexes[4]. Otherwise, oligo-ubiquitination positively regulates DPC4 function, whereas poly-ubiquitination primarily occurs in unstable cancer mutants and leads to protein degradation[5].

In the present study the relative contributions of three genes located at the 18q21 region (DCC, Smad2 and DPC4/Smad4) to progression and dissemination of human colorectal and pancreatic tumors were determined. DPC4 inactivation, always accompanied by alteration of all of the other three genes (K-ras, p53, p16)[6], has also been detected in colon, biliary tract, esophageal, gastric, ovarian, head and neck, lung and prostate cancer, especially in pancreatic carcinoma including one mutation and seven homozygous deletions[7-12]. Supporting evidence for the above observation was provided by Takaku and colleagues[13], who constructed knock-out mice with the DPC4 gene. Although DPC4-null mice were embryonically lethal, the heterozygotes of DPC4 were fertile and appeared normal up to the age of 1 year. However, gastric polyps developed in three of 15 heterozygous mice at the age of 50 wk, and in all heterozygous mice at the age of 100 wk. In addition, duodenal polyps were found in mice older than 50 wk. Morphologically, these polyps resembled those of human juvenile polypsis. These results suggest that inactivation of DPC4 is one of the early events in polyp formation in the DPC4 mice, which is analogous to human familial juvenile polyposis. Bartsch *et al*[14] have also revealed that the expression of DPC4 protein is associated with histopathological grades of pancreatic cancer. Meanwhile, DPC4 inactivation is associated with a poor prognosis[15-19]. Consistent with these reports, DPC4 was shown to be inactivated about in half of pancreatic cancer tissue in our study, whether mRNA or protein. Together with its deletion in pancreas carcinomas, these results suggest that DPC4 has the properties of a tumor suppressor gene, which indicates that it is involved in the carcinogenesis and development of pancreatic carcinoma and is a late event in pancreatic carcinogenesis. The present study can clarify the role of DPC4 in the development of pancreatic carcinoma. In a few substantial studies, significant prognostic markers for pancreatic carcinoma have been reported; markers such as tumor size, lymph node involvement, status of resection margins, DNA ploidy, degree of differentiation, and perineural invasion are inconclusive. In addition, preoperative estimation of tumor size and lymph node involvement is difficult. Deletion of DPC4 in pancreatic carcinoma and loss of DPC4 expression in those patients with poorly differentiated adenocarcinomas was significantly higher than that in those with well and moderately differentiated adenocarcinomas. Therefore, DPC4 gene might preserve phenotypic characteristics under normal conditions and control the malignant progression of pancreatic carcinoma. DPC4 may be proposed as a predictor of prognosis. Recently it was reported that expression of DPC4 can enhance the tumor response to drug treatment[20]. Hoever, it is regretable that we can not draw a consistent conclusion because of deficiency of the detailed clinical and survival data about these pancreatic carcinoma patients in our present study.

Since DPC4 plays a pivotal role in regulating all TGF-β superfamily signal pathways, it is reasonable to postulate that resumption of expression of DPC4 in pancreatic carcinoma cells can inhibit cell proliferation. In fact, DPC4 can induce growth inhibition in breast and colon tumor cells[21,22]**.** In order to develop an effective therapeutic intervention for patients with pancreatic cancer, we developed a new gene therapy that targets the genetic character of pancreatic cancer, using retroviruses that are selectively replication-competent in tumor cells. The DPC4 transcripts were cloned and subjected to sequence analysis. We performed reconstitution experiments of DPC4 in human pancreatic adenocarcinoma cell line BxPC-3. The wild-type DPC4 DNA was amplified from Smad4/DPC4-pBluescript plasmid by PCR and was enclosed successfully in the retroviral vector pLXSN. The pancreatic carcinoma cells BxPC-3 stably expressing DPC4 were obtained by retroviral transfection of DPC4 expression vectors and by selecting stable clones with G418. Stable transfection of BxPC-3 cells null for DPC4, accompanied by control vectors with DPC4 expression and an empty vector control, yielded similar numbers of G418-resistant clones. RT-PCR and Western blot analysis revealed restored expression of DPC4 in daughter clones derived from expression vector transfection. It was a feasible way to transfer the wild-type DPC4 gene to the DPC4-null cancer cells by pLXSN transfection. Some have reported that the DPC4 expression can inhibit growth of many tumor cells. In breast and colon carcinoma, DPC4 inhibited cell proliferation and induced anoikis[23,24]. Dai *et al*[25] have explored an inducible system in which DPC4 protein is activated by translocation to the nucleus, when cell lines that stably express wild-type or mutant DPC4 proteins fused to a murine estrogen receptor domain, are treated with 4-hydroxytamoxifen. This induced DPC4-mediated transcriptional activation and a decrease in growth rate, attributable to cell cycle arrest at the G1 phase and induction of apoptosis. In our study, MTT showed that the restored expression of DPC4 in the pancreatic cells can inhibit proliferation by approximately 50% *in vitro*. These data show that restored expression of functional DPC4 can be efficiently obtained via retrovirus-mediated gene transfer. Supporting our hypothesis, we found that restoration of DPC4 significantly delayed tumor growth *in vitro*.

The present study indicates that DPC4-inducible apoptosis has the greater consequence in growth control. Indeed, the period of the greatest growth suppression temporally was better correlated with apoptotic responses than with cell cycle arrest. This induced DPC4-mediated transcriptional activation and a decrease

in growth rate, attributable to cell cycle arrest at the G1 phase and induction of apoptosis in approximately 55% of pancreatic adenocarcinomas[24,25]. To date, two major apoptotic pathways, the death receptor and the mitochondrial pathway, have been well documented in mammalian cells. However, the involvement of these two apoptotic pathways, particularly the death receptor pathway, in TGF-β1-induced apoptosis is not well understood. Kim *et al*[21] have reported that apoptosis of human gastric SNU-620 carcinoma cells induced by TGF-β1 is caused by the Fas death pathway, in a Fas-ligand-independent manner, and that the Fas death pathway activated by TGF-β1 is linked to the mitochondrial apoptotic pathway.

Most solid tumor growth is dependent on angiogenesis, and the tumor growth and invasion can be inhibited through anti-angiogenesis. Serum levels of VEGF can decrease significantly after radical resection of the tumor. Elevated preoperative serum VEGF level is a significant prognostic factor, although not independent of stage, for patient survival[26,27]. A decrease in the levels of VEGF could be observed upon restoration of DPC4 expression in cell lines. This effect of DPC4 was found in the present study, implicating DPC4 for the first time as an inhibitor of pancreatic tumor angiogenesis. We found the level of VEGF mRNA level was decreased in the BxPC-3 cells after DPC4 resumption, as demonstrated by the semiquantitative RT-PCR. The retrovirus transfer of DPC4 in DPC4-null cells restored its expression and function, and may be correlated with the suppression of angiogenesis and invasion. However, it is not clear how DPC4 controls VEGF. Other experimental evidence indicates that DPC4 regulates an angiogenic switch by decreasing the expression of VEGF and increasing the levels of angiogenesis inhibitor thrombospondin-1 (TSP-1). It has been reported that DPC4 downregulates VEGF transcription and the secreted matrix metalloproteinase-2 (MMP-2) and MMP-9 expression levels consistently in pancreatic adenocarcinoma cell lines. There was a significant reduction in the tissue immunoreactivity of MMP-2 (a protease activated in angiogenic vasculature), and MMP-9 in samples from mice bearing DPC4-transfected tumors, compared to those from control groups. MMPs have been implicated in primary and metastatic tumor growth and angiogenesis, as well as in tumor invasion and progression. VEGF is a strong inducer and activator of MMP-2, while MMP-9 has been shown to increase the availability of VEGF to its receptors and identifying TSP-1 and VEGF as relevant tumor targets[21].

In summary, our study describes the deletion of tumor suppressor DPC4 in pancreatic carcinoma, and restoration of expression of DPC4 in human cancer cell lines growing *in vitro* showed the expected results. DPC4 decreased the expression of VEGF. We demonstrated that DPC4 mediates growth inhibition in pancreatic tumour cells even without TGF-β present, and suggest that DPC4 has the potency of a tumor suppressor gene.

We thank Xia Bai for expert technical assistance.

COMMENTS

Background

Pancreatic carcinoma patients have poor survival, even those who have undergone surgery. The tumor suppressor DPC4 belongs to the evolutionarily conserved family of Smad proteins that are crucial intracellular mediators of signals from TGF-β and is frequently lost in many tumor cells, especially in pancreatic cells. The deletion of DPC4 is involved in the carcinogenesis and development of pancreatic carcinoma. How to further study the role of DPC4 and resumption of the DPC4 gene expression in the PC cell line by the transferring of the vectors containing DPC4 gene in order to inhibit PC growth is becoming a hot topic.

Research frontiers

It is necessary to develop a new modality of treatment for pancreatic cancer. Gene therapy strategies may provide therapeutic benefits with a more favorable risk-benefit ratio than the current conventional treatments. With the advances in understanding the pathogenesis, progression, and metastasis of pancreatic carcinoma that have been achieved, studies on gene therapy for pancreatic carcinoma have been attempted in different ways, such as inhibiting oncogenes, and activating tumor suppressor genes. New specific target genes and further development of gene technology may bring a break-through in this field.

Innovations and breakthroughs

We demonstrated that DPC4 can mediate growth inhibition in pancreatic tumor cells even without TGF-β present and reestablish one of the key regulatory controls of cell proliferation. Although numerous attempts have been made and different approaches have been used to identify the target genes, only limited success has been achieved. Our data showed that VEGF may be one of the DPC4-regulated downstream target genes, which will extend our understanding of the mechanism for DPC4 as an inhibitor of pancreatic tumor angiogenesis.

Applications

DPC4 is an important tumor suppressor. Further study on the biological nature of DPC4 may contribute to the study of the etiology of pancreatic cancer, and offer a theoretical basis for gene therapy of pancreatic cancer.

Peer review

In this study the authors demonstrated that deletion of DPC4 in pancreatic carcinoma, and restoring DPC4 expression in pancreatic carcinoma cells could effectively inhibit cancer cell growth *in vitro,* even without the presence of TGF-β. Re-expression of DPC4 in pancreatic carcinoma cells can downregulate VEGF mRNA expression and anti-angiogenesis therapy may represent a promising therapeutic option.

Abstract

A case of a successfully treated solitary fibrous tumor (SFT) of the liver is reported. An 82-year-old female presented with left upper abdominal discomfort, a firm mass on palpation, and imaging studies revealed a large tumor, 15 cm in diameter, arising from the left lobe of the liver. A formal left hepatectomy was performed. Microscopic evaluation showed spindle and fibroblast-like cells within the collagenous stroma. Immunohistochemistry disclosed diffuse CD34 and positive vimentin, supporting the diagnosis of a benign SFT. The patient remained well 21 months after surgery. SFT of the liver is a very rare neoplasm of mesenchymal origin. In most cases it is a benign lesion, although some may have malignant histological features and recur locally or metastasize. With less than 30 reported cases in the literature, little can be said regarding its natural history or the benefits of adjuvant radiochemotherapy. Complete surgical resection remains the cornerstone of its treatment.

INTRODUCTION

Solitary fibrous tumor (SFT) is a rare neoplasm of mesenchymal origin that occurs preferentially in the pleura, meninges, orbit, upper respiratory tract, thyroid and peritoneum. In extremely unusual cases, SFT may arise from the liver parenchyma of adult patients[1]. In the English literature, less than 30 cases of SFTs of the liver have been reported[2-5].

Clinical or radiological findings are not specific and cannot exclude malignancy. Preoperative cytology may be inconclusive or misleading. Immunohistologically, CD34, vimentin and desmin should be used as markers to precisely diagnose an SFT of the liver[3]. In most cases, there is low cellularity with minimal atypia or necrosis, making this a benign entity. Occasionally, a large size, high mitotic rate, cellular pleomorphism, atypia and central necrosis are interpreted as features suggestive of malignant behavior. As a result of its rarity, overall experience is insignificant. The outcome of an SFT of the liver is mostly related to resectability,

although correlated with neither pathological grade nor tumor size[4]. Thus, complete surgical removal of the neoplasm is most commonly proposed. We describe a new case of SFT of the liver and review the literature.

CASE REPORT

An 82-year-old female patient was referred to our institution on account of persistent abdominal discomfort and a palpable firm mass in the left upper quadrant. She had a past medical history of severe sleep-apnea syndrome and was recovering from a recent episode of mild gallstone pancreatitis. Laboratory tests, including liver biochemical profile and tumor markers were within normal range. Ultrasonography revealed an ovoid mass in the left lobe of the liver. Dynamic computed tomography (CT) and magnetic resonance imaging demonstrated a large, space-occupying lesion arising from the left lobe and compressing the stomach, pancreas and hepatoduodenal ligament. The lesion showed an early arterial enhancement and delayed venous washing out. The tumor developed in a polycystic liver parenchyma. It was well defined and measured about 15 cm in diameter. No direct invasion of the great vessels or adjacent intraperitoneal structures was seen (Figure 1). Preoperative fine needle aspiration biopsy under CT guidance, performed in another institution, was suggestive of a primary hepatocellular carcinoma. The patient underwent formal left hepatectomy and cholecystectomy. On gross examination, the resected specimen measured 18 cm × 15 cm × 8 cm and weighed 1275 g (Figure 2A). On the cut section, the tumor was firm, lobulated, well-demarcated, greyish-white, with a whorled and fasciculated surface and focal myxoid degeneration (Figure 2B). No cirrhosis or fibrosis was observed in the peripheral liver parenchyma. Resection margins were free of tumor. Pathological examination showed a highly cellular neoplasm composed of monomorphic spindle and fibroblast-like cells arranged in a storiform pattern. They were intermingled with dense bundles of collagen. In some areas, tumor cells were arranged around ectatic vessels in a hemangiopericytoma-like pattern (Figure 3A). No mitotic figures or nuclear polymorphism were noted. Immunohistochemical studies revealed a strong cytoplasmic positivity for CD34 (Figure 3B), vimentin (Figure 3C), desmin and Bcl-2. An absence of staining for HHF-35, S-100, CD117, muscle-specific actin and cytokeratin was observed. The percentage of ki-67 positive tumor cells was less than 5%. On the basis of the aforementioned results, pathological evaluation ascertained the presence of a benign SFT of the liver.

The patient recovered uneventfully after the procedure. She was discharged home on the 6th postoperative day and followed-up on an outpatient basis. Twenty-one months after surgery, the patient was stll doing well with no evidence of recurrence.

DISCUSSION

SFTs of the liver are unusual neoplasms with fewer than 30 previous cases reported in the world literature. There is a 2:1 female-to-male predominance with the ages of affected individuals ranging from 16 to 83 years. The mean age at diagnosis is 55 years and the average follow-up period reaches 27 months[1]. Most SFTs of the liver are usually found as giant lesions growing in either the right or the left lobe of a non-cirrhotic liver, causing non-specific symptoms of fullness and pressure, gastrointestinal obstruction, weight loss or hypoglycemia[3,5]. In addition, the development of a primary SFT on a background of polycystic liver disease, as in the present case, has never been reported before.

As a result of their extreme rarity, overall experience of SFTs is limited. In addition, the difficulty of

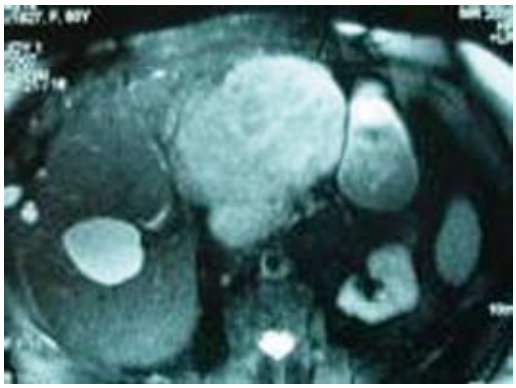

Figure 1 Magnetic resonance imaging demonstrating a large, 15 cm in size, well-circumscribed lesion in the left hepatic lobe, compressing the stomach, pancreas and hepatoduodenal ligament.

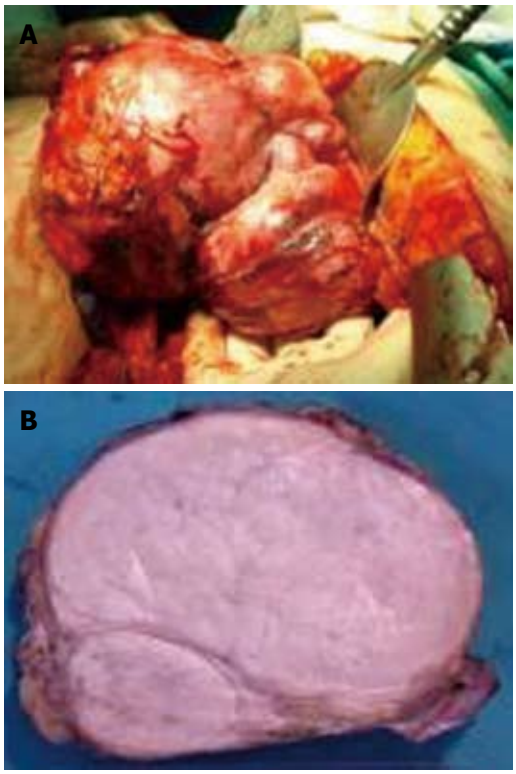

Figure 2 Gross appearance of a firm, well-demarcated and lobulated SFT of the liver (A) and greyish-white SFT of the liver with whorled and fasciculated surface and focal myxoid degeneration on cut section (B).

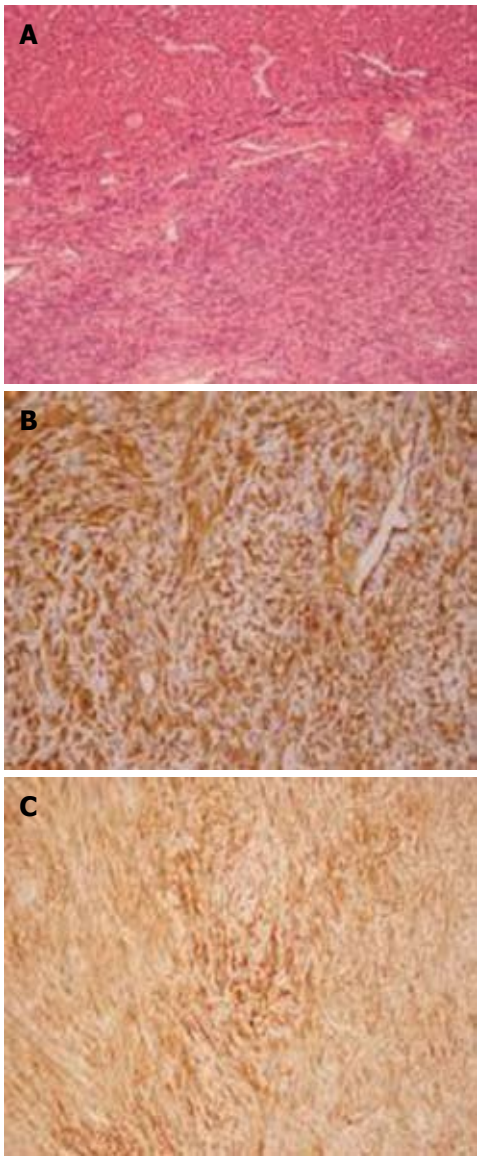

Figure 3 Tumor cells. A: Microscopy showing a tumor composed of uniform collagen-forming spindle cells arranged in interlacing fascicles and well-encapsulated and differentiated from the adjacent non-cirrhotic liver parenchyma (HE, x 100); B: CD34 immunohistochemical staining demonstrating diffusely strong reactivity (x 200); C: Tumor cells showing diffuse immunohistochemical positivity for vimentin (x 200).

interpretation of histological pictures and the huge volume at presentation still raise problems in terms of correct preoperative diagnosis and proper clinical management[6]. In the present case, the diagnosis of SFT of the liver was based on the association of characteristic histological and immunohistochemical features, i.e. high cellular proliferation of spindle cells arranged in a storiform pattern, together with the immunohistochemical staining profile of CD34 (+), vimentin (+), Bcl-2 (+) and cytokeratin (-), which is highly suggestive for SFTs. These characteristics differentiate it from other liver tumors, such as primary hepatocellular carcinoma (CD34-negative), leiomyoma (smooth-muscle actin-positive and CD34-negative), inflammatory pseudotumor (forms fibrous tissue made by collagen fibers with fibro and myofibroblast and plasma cells), fibrosarcoma (forms a "herring bone" pattern), and epithelioid hemangioendothelioma (factor Ⅷ positivity)[7]. The pathological features described for the presented case (low mitotic rate, no nuclear atypia and cellular pleomorphism) are in keeping with those of a benign SFT of the liver. This was confirmed by the favorable course of the patient, who was alive and disease-free 21 mo after surgery.

Radical surgical removal of the tumor with clear margins of resection is the mainstay of treatment. Since most SFTs of the liver are usually found to represent large, well-circumscribed lesions, complete removal necessitates the performance of major hepatectomies (≥ 3 segments). Owing to the size of most SFTs of the liver and their tendency to displace surrounding structures, they are virtually altering the intra-abdominal anatomy in an unpredictable manner. Although an SFT is not a primarily malignant disease, it seems to be of utmost importance that tumor-free resection margins be achieved in order that locoregional recurrence is prevented[8,9]. In light of this, surgical treatment of a hepatic SFT poses a tremendous challenge to the liver surgeon.

Little can be written about the possible benefits of adjuvant radio- and/or chemotherapy in these patients, as reported data are scarce. As SFT of the liver is often a benign neoplasm, postoperative chemotherapy or radiotherapy should not be necessary and is reserved for when resection is incomplete or pathological examination reveals features of malignancy[3,10].

In conclusion, SFTs of the liver are extremely rare neoplasms in adult patients and their incidence is unknown. Precise diagnosis is solely based on the correct interpretation of unique pathological and immunohistochemical features. Aggressive surgical management remains the treatment of choice. The outcome of SFTs is mostly related to resectability, rather than on pathologic grade or tumor size. Since the current number of reported cases is very limited, all efforts should be made to ensure careful follow-up of all identified patients. Only then we can reliably comment on the behavior and definite prognosis of SFTs of the liver.

Abstract

Jejunal diverticulosis is a rare entity with variable clinical and anatomical presentations. Its reported incidence varies from 0.05% to 6%. Although there is no consensus on the management of asymptomatic jejunal diverticular disease, some complications are potentially life threatening and require early surgical treatment. We report a case of an 88-year-old man investigated for acute abdominal pain with a high biological inflammatory syndrome. Inflammation of multiple giant jejunal diverticulum was discovered at abdominal computed tomography (CT). As a result of the clinical and biological signs of early peritonitis, an emergency surgical exploration was performed. The first jejunal loop showed clear signs of jejunal diverticulitis. Primary segmental jejunum resection with end-to-end anastomosis was performed. Histopathology report confirmed an ulcerative jejunal diverticulitis with imminent perforation and acute local peritonitis. The patient made an excellent rapid postoperative recovery. Jejunal diverticulum is rare but may cause serious complications. It should be considered a possible etiology of acute abdomen, especially in elderly patients with unusual symptomatology. Abdominal CT is the diagnostic tool of choice. The best treatment is emergency surgical management.

INTRODUCTION

The majority of jejunal diverticulosis cases are discovered incidentally during radiological investigations. Symptomatic presentations are rare and generally complicated. Jejunal and jejuno-ileal localization is nearly three times less frequent than duodenal, but about four times likely to develop complications[1]. Asymptomatic cases require neither medical nor surgical treatment. Rarity of mild or chronic presentations explains the absence of clear consensus on therapeutic strategy and conservative management[2]. Complicated presentations remain a diagnostic challenge because of non-specific and ambiguous symptomatology. Surgical exploration is the treatment of choice for almost all acute complicated cases[3].

CASE REPORT

An 88-year-old male patient with a 6-year history of hypertensive terminal renal failure managed by hemodialysis was admitted for acute abdominal pain. Physical examination revealed right lower quadrant tenderness. C-reactive protein was 260 mg/L and white blood cell count was 19 g/L. There were no clinical or biological signs of bleeding. Abdominal computed tomography (CT) scan showed multiple small bowel giant diverticula, initially attributed to the ileum because of their localization in right iliac fossa. The diameters of these diverticula were between 3.5 cm and 6 cm and some showed clearly inflammatory infiltration

Figure 1 Axial CT image illustrating multiple diverticula (white arrows) developed on the mesenteric border of the jejunum, surrounded by inflammatory mesenteric fat. The arrowhead shows the communication between the diverticula and jejunal lumen.

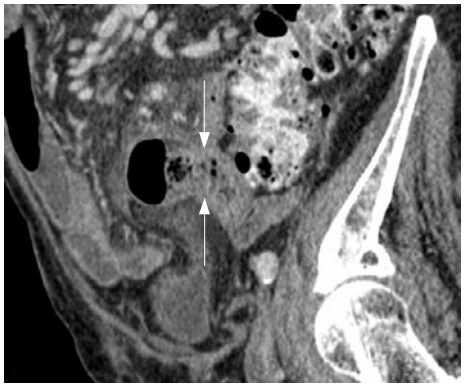

Figure 2 Multiplanar reconstructions on a sagittal view demonstrating a communication between the diverticula and jejunum (white arrow).

(Figures 1 and 2). There was no pneumoperitoneum or intraperitoneal fluid. Emergency laparotomy confirmed the presence of inflamed diverticula on the proximal jejunal portion (Figure 3). Treatment was the resection of a 35-cm jeujunal segment, removing all visible diverticula. End-to-end anastomosis was performed. Histopathology report confirmed an ulcerative jejunal diverticulitis with some areas of perforation and acute local peritonitis. The patient made an excellent postoperative recovery with normalization of inflammatory parameters and rapid intestinal transit recovery. He was discharged on the 12th postoperative day.

DISCUSSION

The present case shows an exemplary preoperative diagnosis and the surgical management of jejunal diverticula in its typical presentation.

The difficulty is that diverticular small bowel disease is an uncommon entity with an incidence between 0.05% and 6%. Jejuno-ileal diverticulosis remains asymptomatic in about 80% of cases, but chronic clinical manifestations may be under-or misdiagnosed with dyspepsia and irritable bowel syndrome. The mean age

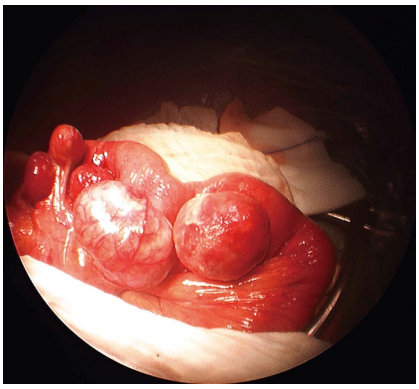

Figure 3 Inflamed giant jejunal diverticula on macroscopic operator view.

of symptomatic patients is up to 60 years in all reported studies. Only less than 10% of the affected individuals develop acute complications such as inflammation, perforation, hemorrhage and obstruction[4].

Complicated jejuno-ileal diverticulosis is generally present in elderly males with non-specific unexplained central abdominal pain, associated with clinical and biological septic syndrome. Some cases have a history of chronic symptoms such as vague abdominal discomfort, fullness, recurrent central and upper abdominal cramping pain caused by pseudo-obstruction or bacterial overgrowth. Yet the diagnostic accuracy of complicated acute jejunal diverticulosis based on simple clinical evaluation is still extremely poor[5,6].

Abdominal CT with double-oral and intravenous contrast may allow the diagnosis based on the following findings: focal area of out-pouching of the mesenteric side of the bowel filled or not filled with feces-like materials, focal asymmetric wall thickening, or inflammatory process adjacent to a loop of jejunum[7,8]. In some cases, use of coronal or sagittal reformatted images is helpful in identifying the bowel segment with diverticula (Figure 2). Today, multi-slice CT is very helpful in diagnosing jejunal diverticulosis and appears clearly superior to conventional enteroclysis for small intestine diseases[9].

Radiology-proven complicated presentations of jejuno-ileal diverticulosis require emergency surgical management. Emergency resection of perforated, inflamed, bleeding or obstructed bowel segment with primary anastomosis is safe and gives the best outcome.

Jejunal diverticulum is rare and generally discovered in complicated presentations only. Interpretation of abdominal CT findings is the key to its correct diagnosis. The treatment of choice is surgical excision of the affected jejunum segment with primary end-to-end anastomosis.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

World Journal of Gastroenterology ISSN 1007-9327

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology* and *Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903
Ocean International Center, Building D
No. 62 Dongsihuan Zhonglu
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
