Animal and human studies showed that abdominal decompression laparotomy can reverse the cardiopulmonary and abdominal effects of ACS[9,10]. In our patients, decompression laparotomy led to decreasd IAP levels, improved Horowitz indices and increased lung compliance (Figure 3). Ventilation pressures could be reduced in order to re-achieve a lung protective ventilation regime. In addition, all three patients benefited from improving renal perfusion (rising urine volume and decreasing creatinine and urea levels), mesenterial perfusion (declining lactate levels) and cardiac output (less need for catecholamines). Moreover, patients with SAP may specifically profit from decompression laparotomy since elevated IAP influences pancreatic and intestinal perfusion and might therefore contribute to pancreatic necrosis[14].

Although decompression laparotomy can lead to

recovery of patients with SAP from respiratory failure, its complications, such as massive intra-abdominal bleeding, need to be taken into account. Moreover, not only surgical complications but also persisting open abdomen is associated with risks and subsequent extensive abdominal wall reconstruction. New surgical concepts like subcutaneous anterior abdominal fasciotomy[15] may minimize complications and reach comparable clinical improvement in patients with SAP and ACS. Randomized studies are few so far, and the use of decompression laparotomy for ACS has been criticized by several authors since the mortality remains high in these patients[5,16].

Abdominal decompression laparotomy may help to overcome respiratory failure in patients with abdominal compartment syndrome and severe acute pancreatitis. Therefore, serial indirect measurement of IAP through an indwelling transurethral bladder catheter should be used routinely in critically ill patients with SAP in order to detect ACS. We hold that decompression laparotomy should be performed in patients with SAP and IAH/ACS with severe limitation of mechanical ventilation. However, prospective randomized studies are needed to further define the role of surgical decompression in SAP.

Abstract

Piodermal gangrenosum (PG) is an uncommon ulcerative cutaneous dermatosis associated with a variety of systemic diseases, including inflammatory bowel disease (IBD), arthritis, leukaemia, hepatitis, and primary billiary cirrhosis. Other cutaneous ulceration resembling PG had been described in literature. There has been neither laboratory finding nor histological feature diagnostic of PG, and diagnosis of PG is mainly made based on the exclusion criteria. We present here a patient, with ulcerative colitis (UC) who was referred to the emergency section with a large and rapidly evolving cutaneous ulceration. Laboratory and microbiological investigation associated with histological findings of the ulcer specimen allowed us to exclude autoimmune and systemic diseases as well as immuno-proliferative disorders. An atypical presentation of PG with UC was diagnosed. Pulse boluses of i.v. methyl-prednisolone were started, and after tapering steroids, complete resolution of the skin lesion was achieved in 3 wk. The unusual rapid healing of the skin ulceration with steroid mono-therapy and the atypical cutaneous presentation in this patient as well as the risk of misdiagnosis of PG in the clinical practice were discussed.

INTRODUCTION

Piodermal gangrenosum (PG) is an uncommon ulcerative cutaneous dermatosis associated with a variety of systemic conditions including inflammatory bowel disease (IBD), arthritis, haematological malignancies, paraproteinemia and hepatitis[1-5]. Many other cutaneous ulcerations resembling PG have been described in literature[6-10]. There has been neither laboratory finding nor histological feature diagnostic of PG, and diagnosis of PG is mainly established by exclusion criteria. We described here a patient with ulcerative colitis (UC) who manifested atypical presentation of PG. After diagnosis, a rapid healing of the large and painful skin ulceration was obtained by high doses of i.v. steroid therapy.

CASE REPORT

An 82-year-old man was referred to the emergency section with a round painful cutaneous ulcer of 15 cm in diameter in the left mammary region. The edges were undermined and presented with granulated tissues, crusts, and purulent exudates (Figure 1A). One month before a lesion appeared in the same skin area presenting as a small red plaque with surrounding erythema. This was supposed to be a consequence of a mosquito bite according to his family doctor. The lesion rapidly progressed to a wider and painful cutaneous ulceration over the past month. Antimicrobial treatment with amoxicillin and ciprofloxacin was totally ineffective and the patient required paracetamol and codeine every 6 h for pain relief.

The patient was admitted to our hospital 3 years before due to rectal bleeding and anaemia. UC was

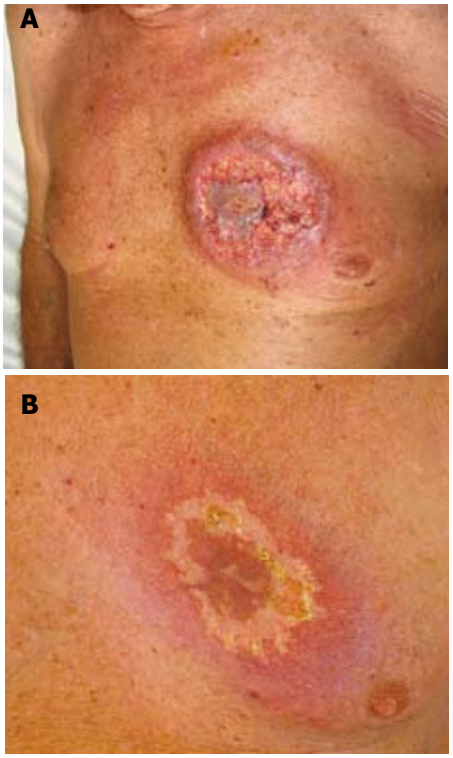

Figure 1 **A**: Patient with chronic ulcerative colitis presenting a round and painful cutaneous ulcer of 15 cm in diameter in the left mammary region. The edges were undermined. diagnosed. Therefore, the patient received prednisone and mesalazine therapy (10 mg/d and 800 mg thrice/d, respectively). Prednisone was tapered and stopped after 3 mo, whereas mesalazine administration was continued.

On examination, the patient presented with mild hyperthermia (37.5-38℃). He complained of 3-5 daily episodes of diarrhoea but without rectal bleeding. No lymphoadenopathy was observed. The lesion was very painful. A swab and microbiological examination of the specimen from the ulcer was negative for bacteria and fungi. Routine laboratory investigations revealed white cell count of 13.8×10^9/L with neutrophilia. The erythrocyte sedimentation rate was 32 mm/h. Liver and kidney function tests, immunoglobulin, protein electrophoresis, anticoagulation panel were normal. Venereal Disease Research Laboratory (VDRL) test, HIV test, anti-neutrophilic cytoplasmic, antinuclear and anti-DNA antibodies, rheumatoid factor, LE test, were all negative, and cryoglobulins were absent.

Chest X-ray, venous and arterial functional studies were normal. A skin biopsy of the lesion was performed under local anaesthesia. Histological analysis showed focal necrotizing flogosis associated with ulceration and peripheral lymphocytic and neutrophilic infiltration extending through the dermis and subcutaneous tissue; extravascular red blood cell infiltration was also present.

Necrotizing vasculitis was not observed and the histological changes were consistent with pioderma gangrenosum. Methylprednisolone pulse boluses (500 mg/d for 3 d) were given i.v. Steroid was reduced to 80 mg/d and then tapered to 20 mg/d for 3 wk. The patient healed from skin lesion 20 d after beginning of steroid therapy (Figure 1B).

DISCUSSION

Brunsting *et al*[11] in 1930 first described five patients with rapidly progressive and painful suppurative skin ulceration with necrotic and undermined borders that were called PG. This lesion is a neutrophilic dermatosis associated with a variety of systemic diseases, such as paraproteinemia, arthritis, and myeloproliferative diseases, and IBD. In about 50% of the cases, UC is the underlying condition and PG may parallel the severity of the disease[1,9,12]. The pathogenesis of PG is poorly understood and over-expression of interleukin (IL)-8 and IL-16 has been reported, suggesting an over-reactive inflammatory response to a traumatic process. Although the lesion can occur in any surface it is more common on the legs in perineal, vulvar, penile and neck region. Atypical presentations are considered on the arms or in the chest. Weenig *et al*[6] reported two cases of livedoid vasculopathy, a rare thrombo-occlusive disease of post-capillary venules, which may occur with cutaneous ulcers of the legs characterized by a very similar macroscopic and histological pattern. These lesions may be confused with PG. However, livedoid vasculopathy is not responsive to steroid therapy. Therefore, PG is an excluded diagnosis on the basis of laboratory findings and histology, associated with a high rate of clinical suspicion. The good and rapid clinical responses to steroids associated with other immunosuppressive therapy such as cyclosporine, azathioprine and ciclophosphamide are also important "*ex-adiuvantibus*" criteria.

Patients with vasculitis associated with or not associated with cryoglobulinemia or those with antiphospholipid-antibody syndrome, and those with Wegener granulomatosis and poliartrite nodosa, may present lesions resembling PG[5,6,8,9,13]. These lesions may be misdiagnosed with PG due to initial response to steroid therapy, but without evidence of complete healing. The clinical pattern of a patient with very painful skin lesion, suffering from IBD should raise the suspicion of PG; however laboratory findings and functional and radiologic analysis to rule out other systemic disease are mandatory for a correct diagnosis.

Other rare malignant lesions, such as lymphoma, leukaemia cutis and Langherans cell hystiocytosis can be ruled out according to the histological studies of the specimen.

PG is a diagnosis of exclusion and its misdiagnosis can result in serious clinical consequences.

The chronic UC in our patient based on the exclusion criteria, convinced us to start therapy with a high dose of corticosteroid. The rapid healing of such a large skin lesion is unusual. Some patients refractory to steroid treatment can benefit from the combination of steroid with cyclosporine[14,15]. At the moment, our patient is disease free at 12 mo after diagnosis without

clinical symptoms related to UC under a maintenance therapy of 7.5 mg/d prednisone.

Abstract

A 43-year-old woman with multiple sclerosis (MS) was treated with pulsed methylprednisolone and interferon β at a hospital. Four weeks after initiating treatment, liver dysfunction occurred and she was referred and admitted to our hospital. Clinical and laboratory findings were consistent with and fulfilled the criteria for drug-induced hepatitis, but not for autoimmune hepatitis (AIH). She was successfully treated with corticosteroids. As ataxia developed after 1 year, she was treated with pulsed methylprednisolone for 3 d, then readmitted to our hospital when liver dysfunction occurred. Clinical and laboratory findings led to the diagnosis of AIH. To the best of our knowledge, this is the second case of AIH developed after pulsed methylprednisolone for MS.

INTRODUCTION

Intravenous methylprednisolone pulse therapy is the standard treatment for relapsing multiple sclerosis (MS). Interferon (IFN)-β is the most commonly used drug in the treatment of MS, and has been proven to reduce the disease activity, progression and relapse rate[1,2]. IFN-β is associated with hepatotoxicity, although it rarely induces severe liver injury. It was reported that autoimmune hepatitis (AIH) occurs during IFN-β therapy for MS[3,4], but only one report has described the occurrence of AIH after intravenous methylprednisolone pulse therapy for MS[5]. We describe herein a case of a MS patient who developed AIH after treatment with IFN-β and pulsed methylprednisolone.

CASE REPORT

A 43-year-old woman with abdominal discomfort and nausea was referred to our hospital on August 7, 2006. She was diagnosed with MS on the basis of clinical and laboratory findings 7 years ago. Three years ago, she was treated with pulsed methylprednisolone (1000 mg/day for 3 d) followed by 50 mg/day of oral prednisolone because of ataxia. Although oral prednisolone was tapered and stopped for 1 month, she remained healthy until June 2006, when ataxia developed again. On June 28, 2006, she was treated with pulsed methylprednisolone (1000 mg/day for 3 d) followed by 50 mg/day of oral prednisolone. Despite pulsed methylprednisolone therapy, symptoms did not improve. She was therefore retreated with pulsed methylprednisolone (1000 mg/day) for 3 d from July 5, 2006. Moreover, she was treated with IFN-β 8 at MU every other day from July 11 to 26, 2006. After pulsed methylprednisolone, oral prednisolone was not administered. On August 3, 2006, the patient

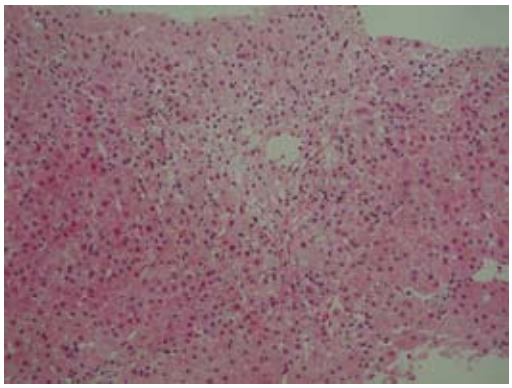

Figure 1 Histological examination of a liver biopsy specimen showing bridging perivenular necrosis and infiltration of inflammatory cells including eosinophils (hematoxylin-eosin staining × 100).

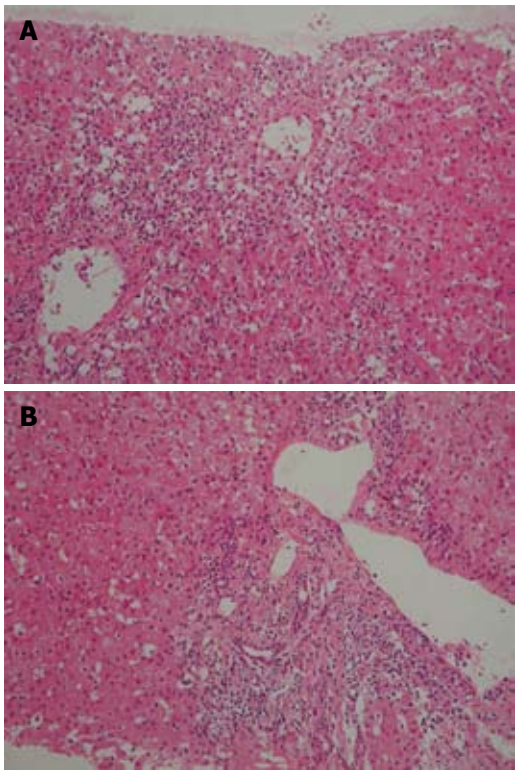

Figure 2 Histological examination of a liver biopsy specimen showing bridging perivenular necrosis (**A**) and interface hepatitis (**B**) (HE staining × 100).

became nauseous and vomited, and these symptoms did not improve. On August 7, 2006, she was referred to our hospital and admitted after blood testing revealed severe liver dysfunction. Three years ago, she developed acute hepatitis due to Epstein-Barr (EB) virus after treatment with pulsed methylprednisolone. Since then, she had been free of liver dysfunction.

On admission, her blood pressure was 156/89 mmHg and heart rate was 102 beats/min, body temperature was 37.3℃, and the areas of skin at sites of IFN-β injection became welts. Her conjunctivae were not jaundiced, heart and respiratory sounds were normal. No abnormalities were noted in the chest or abdomen. The liver and spleen were not palpable. Neurological examination showed no abnormalities suggestive of MS. Laboratory findings were as follows: 1102 IU/L aspartate aminotransferase (AST) (normal, 10-35 IU/L), 1067 IU/L alanine aminotransferase (ALT) (normal, 12-33 IU/L), 377 IU/L alkaline phosphatase (ALP) (normal, 300-500 IU/L), 3.4 mg/dL total bilirubin (TB) (normal, < 1.1 mg/dL), 2.2 mg/dL direct bilirubin (DB) (normal, 0.2-0.4 mg/dL), 26 IU/L γ-glutamyl transpeptidase (γGTP) (normal, 10-47 IU/L), 6.4 g/dL total protein (TP) (normal, 6.0-8.5 g/dL), 3.7 g/dL albumin (normal, 4.0-5.3 g/dL), 1370 mg/dL serum immunoglobulin (Ig)G, 147 mg/dL IgA, 272 mg/dL IgM, and 71.4% prothrombin time (PT). Anti-nuclear antibody (ANA), anti-smooth muscle antibody and anti-LKM-1 antibody were all negative. HBs antigens, IgM-HA and HCV antibodies were negative. Other viral infections including EB virus and cytomegalovirus infection were excluded by serological testing. Abdominal computed tomography showed no abnormalities. Biopsy specimen of the liver showed bridging perivenular necrosis with infiltration of inflammatory cells including eosinophils (Figure 1). A lymphocyte-stimulation test for IFN-β yielded negative results, but the patient displayed a score of 9 according to the criteria for drug-induced liver injuries[5], indicating a high probability of drug-induced liver injury. All these findings led to the diagnosis of drug-induced liver injury caused by IFN-β. Despite intravenous administration of stronger neo-minophagen C (60 mL/day) and prostaglandin, jaundice developed with a serum TB level of 19.1 mg/dL. Methylprednisolone (125 mg/day for 3 d) and ursodeoxycholic acid (UDCA, 600 mg/day) were therefore administered. Symptoms subsequently improved and serum TB level normalized. Prednisolone was decreased gradually and stopped on April 10, 2007. UDCA was stopped on May 10, 2007. Liver function remained normal even after withdrawal of prednisolone and UDCA.

However, ataxia developed and the patient was again treated with pulsed methylprednisolone (1000 mg/day) for 3 d from October 1, 2007. After pulsed methylprednisolone, oral prednisolone was not administered. Two weeks later, she was readmitted to our hospital due to fatigue and liver dysfunction. Laboratory findings on admission were as follows: 566 IU/L AST, 875 IU/L ALT, 214 IU/L ALP, 1.7 mg/dL TB, 12 IU/L γGTP, 1785 mg/dL IgG, and 71.4% PT. Anti-nuclear antibody (ANA) titer was × 80 with a homogeneous pattern, positive results were obtained for anti-smooth muscle antibody, and HLA DR was 4. Viral infections were excluded by serological testing. Biopsy specimen from the liver revealed bridging perivenular necrosis and interface hepatitis (Figure 2A and B). In this case, IgG was not elevated, which is atypical for AIH. However, according to the criteria for AIH[6], the patient had a score of 16 on the second admission, indicating definite AIH, compared to a score of 9 on the first admission. Conversely, according to the criteria for drug-induced liver injury[7], our patient displayed a score of 2, indicating a low possibility that this case represented drug-induced liver injury. Moreover,

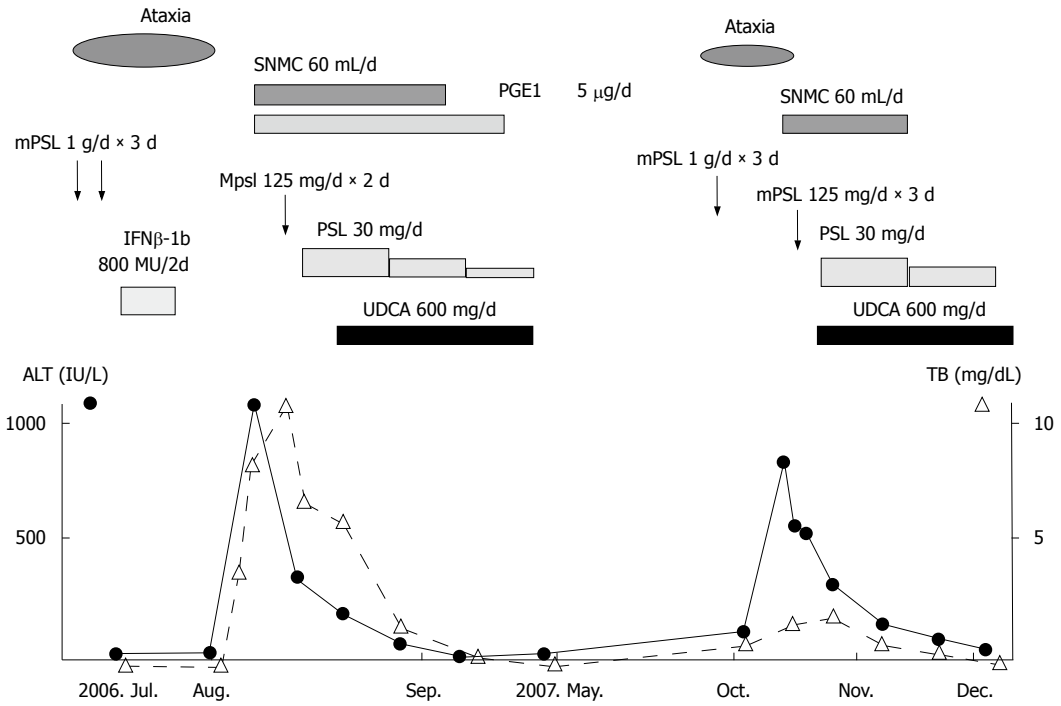

Figure 3 Clinical course of the disease. SNMC: Stronger neo-minophagen C, PGE1: Prostaglandin, mPSL: Methylprednisolone, PSL: Prednisolone, IFN-β: Interferon β.

lymphocyte-stimulation testing for methylprednisolone yielded negative results.

These clinical and laboratory findings supported the diagnosis of AIH. After administration of prednisolone and UDCA, symptoms and liver function improved. The charts for the overall clinical course are shown in Figure 3. Her condition is now under control with prednisolone, 10 mg/day.

DISCUSSION

MS is an inflammatory demyelinating disease of the central nervous system. Liver dysfunction is not always caused by MS itself, but can result from many factors, such as drug toxicity, fatty infiltration and viral infection. Liver dysfunction in patients with MS is most commonly caused by drugs. IFN-β, which raises serum ALT level as a side effect, is one of the drugs well known to cause liver injury in patients with MS.

Tremlett *et al*[8] reported that 36.9% of patients with MS develop new elevations of ALT, although only 1.4% reach grade 3 hepatotoxicity (> 5-20 upper limit of normal). In patients with MS receiving IFN-β, if *de novo* elevation of aminotransferases is mild, IFN-β treatment is often continued, and elevated aminotransferases return to almost normal[4]. However, severe liver dysfunction does not resolve simply after stopping IFN-β, and prompt treatment is needed. A case of fulminant liver failure occurring during IFN-β treatment has been reported[9]. Our patient satisfied the criteria for drug-induced hepatitis, but not for AIH on the first admission. Byrnes *et al*[10] have also reported drug-induced liver injury secondary to IFN-β in patients with MS. However, the precise mechanisms underlying IFN-β-induced hepatotoxicity remain unclear.

IFN-β may cause autoimmune complications including thyroiditis, lupus erythematosus and rheumatoid arthritis[11]. Duchini *et al*[3] have reported a case of AIH occurring during treatment with IFN-β. Conversely, Reuβ *et al*[5] have reported a case of AIH that developed after high-dose intravenous methylprednisolone pulse in MS and speculated that AIH may occur in patients with multiple autoimmunity as an immune rebound phenomenon after immunosuppressive regimens.

The typical histological pattern of AIH is chronic active hepatitis that shows portal inflammation with fibrosis, interface hepatitis and rosette formation of hepatocytes. However, few cases of AIH with centrilobular necrosis (CN) as the dominant finding have been reported[12]. Recently, some cases of CN with autoimmune features have been confirmed as early-stage AIH[13,14]. Acute-onset AIH sometimes does not satisfy AIH criteria serologically and shows CN histologically[14-16]. Although our patient showed a typical pattern of AIH at the second admission, liver dysfunction at the first admission may have been due to early-stage AIH.

The cause of AIH in this patient was an immune rebound phenomenon after pulsed methylprednisolone, because the second episode of liver dysfunction occurred after pulsed methylprednisolone therapy rather than after IFN-β therapy. In fact, some reports have described AIH occurring in patients with multiple autoimmunity after pulsed methylprednisolone therapy[5,17-18]. In particular, withdrawal of glucocorticoids after pulsed methylprednisolone therapy might have induced immune rebound phenomenon in the present

case. However, we cannot deny the possibility that AIH was induced by IFN-β in this patient. She received IFN-β treatment before the first admission. Moreover, Misdraji *et al*[12] reported that AIH with CN occurs after IFN-β therapy in patients with MS.

In conclusion, the prevalence of AIH seems to be about 10-fold higher in patients with MS than in the general population[19]. Attention should be paid to the development of AIH after pulsed methylprednisolone or IFN-β treatment in patients with MS, and if AIH develops, immediate treatment with corticosteroids or azathioprine should be initiated. Moreover, administration of corticosteroids or azathioprine after pulsed methylprednisolone might be effective for preventing the development of AIH.

Abstract

Diffusion-weighted imaging (DWI) is an established diagnostic method of acute stroke. The latest advances in magnetic resonance imaging (MRI) technology have greatly expanded the utility of DWI in the examination of various organs. Recent studies have revealed the usefulness of DWI for imaging of the liver, kidney, ovary, and breast. We report a patient with acute pancreatitis detected by DWI and discussed the efficacy of DWI in diagnosing acute pancreatitis. A 50-year old man presented with a primary complaint of abdominal pain. We performed both DWI and computed tomography (CT) for this patient. The signal intensity in a series of DWI was measured and the apparent diffusion coefficient (ADC) values were calculated to differentiate inflammation from normal tissue. Two experienced radiologists evaluated the grade of acute pancreatitis by comparing the CT findings. Initially, the pancreas and multiple ascites around the pancreas produced a bright signal and ADC values were reduced on DWI. As the inflammation decreased, the bright signal faded to an iso-signal and the ADC values returned to their normal level. There was no difference in the abilities of DWI and CT images to detect acute pancreatitis. However, our case indicates that DWI can evaluate the manifestations of acute pancreatitis using no enhancement material and has the potential to replace CT as a primary diagnostic strategy for acute pancreatitis.

INTRODUCTION

Acute pancreatitis is a potentially fatal disease with an overall mortality rate of 7%-11%[1-3]. Patients suffering from acute pancreatitis (AP) often have additional complications such as sepsis, systemic inflammatory syndrome (SIRS) and multiple organ failure (MOF), resulting in a life-threatening condition[4-6]. Therefore, it is important to accurately evaluate the grade of inflammation and absence of necrotizing pancreatitis to improve its prognosis. Diffusion-weighted imaging (DWI) is an established diagnostic tool of acute stroke and brain tumors[7-11]. Due to the latest technical advances in magnetic resonance imaging (MRI), DWI has also been applied in detecting various disorders of abdominal organs[12-16]. This report describes the efficacy of DWI in evaluation of acute pancreatitis.

CASE REPORT

A 50-year-old man presented with a primary complaint of epigastric pain after drinking alcohol. Laboratory tests upon admission revealed slightly higher levels of white blood cells (108 × 10^2/mL), C-reactive protein (53.3 mg/L),

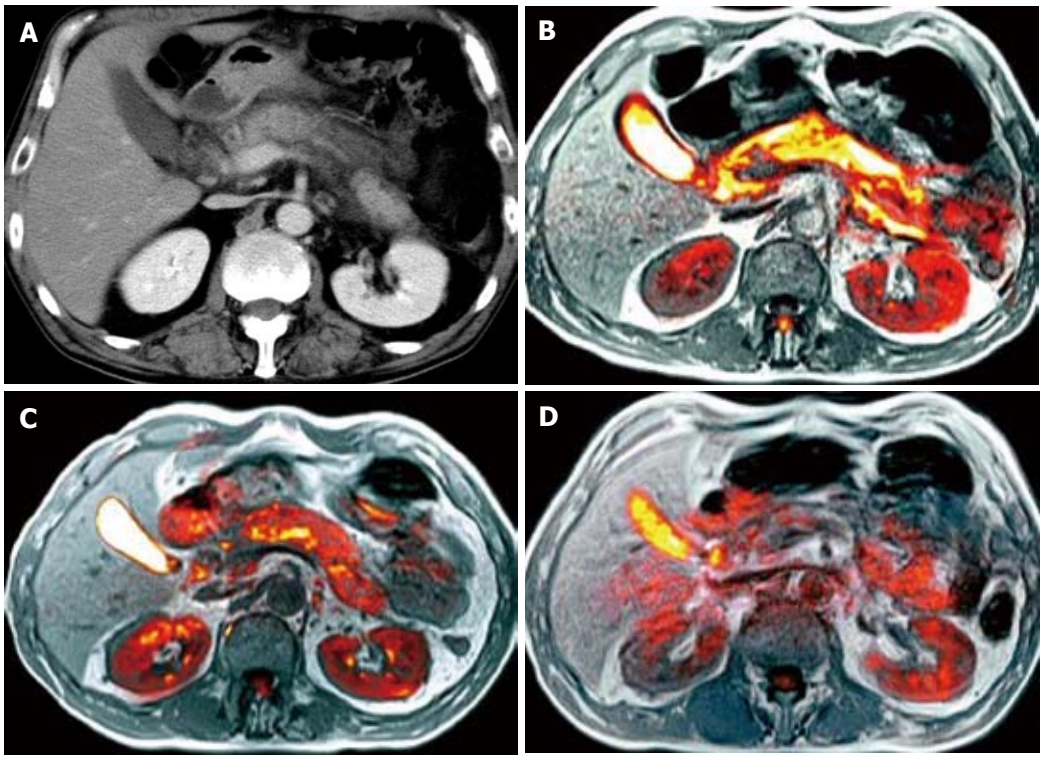

Figure 1 A CT scan at admission revealing enlarged pancreas complicated by acute multiple ascites (**A**), a fusion image at admission (**B**), on days 10 (**C**) and 50 (**D**) showing bright signals in the whole pancreas and ascites around it, diminished pancreatic enlargement and slightly decreased signal-intensity, as well as disappearance of all signs of acute pancreatitis, respectively.

serum amylase (276 IU/L). His APACHI Ⅱ score and Ranson score were 2 and 0, respectively. An enhanced abdominal computed tomography (CT) scan revealed an enlarged pancreas complicated by multiple acute ascites (Figure 1A). An abdominal DWI at 1.5 T (Toshiba; Excelart vantage AGV, screw ratio 130 mT/m per ms) showed bright signals in the whole pancreas and multiple ascites around it (Figure 1B). Furthermore, the apparent diffusion coefficient (ADC) map in that area revealed a reduced ADC value. Following admission, the patient received drip infusion of 300 mg gabexate per day. Seven days after admission, laboratory tests revealed almost normal levels of WBC (54×10^2/mL), CRP (4.1 mg/L) and serum amylase (93 IU/L). Ten days after admission, DWI revealed diminished pancreatic enlargement, slightly decreased signal-intensity (Figure 1C), slightly increased ADC values and disappearance of ascites. His symptoms improved significantly at that time. After 50 d, DWI showed complete disappearance of the manifestations of acute pancreatitis (Figure 1D).

DISCUSSION

Severe acute pancreatitis is often associated with pancreatic necrosis and has a rather high mortality rate. It was reported that necrotizing pancreatitis and inflammatory changes are related to its various complications and prognosis[4-6]. To improve its mortality, it is essential to accurately evaluate the grade of inflammation and the absence of necrotizing pancreatitis. Plane CT can show the changes in inflammation around the pancreas, but cannot detect necrotizing pancreatitis without the use of enhancement material[17]. However, enhancement material has been reported to aggravate acute pancreatitis[18] and it is hard to employ enhanced CT in patients with renal failure due to severe acute pancreatitis. At present, CT is the only available diagnostic imaging method of acute pancreatitis. Clearly, it is urgent to develop new diagnostic strategies for this condition. DWI is a MR imaging technique that provides information about the diffusion of water protons, such as brownian motion in living tissues. DWI has been applied in the diagnosis of brain ischemia and brain tumors[7-11]. Recent technical development in MRI has expanded the utility of DWI in examinations of the liver, kidney, breast, *etc*[12-16]. The apparent diffusion coefficient (ADC) is a quantitative parameter, which reflects the microenvironment of diffusing water molecules. It was reported that reduced ADC is observed in most malignant tumors[8,12,13,15,16]. This present study demonstrated that DWI could detect acute pancreatitis with reduced ADC values at the time of diagnosis. As serum WBC, CRP, and amylase became normal, the signal-intensity and ADC values returned to their normal levels. The decreased ADC value is thought to result from the increased number and size of cells. Therefore, intercellular spaces become smaller, restricting the movement of water molecules[15,16]. If a malignancy is found in abnorm, the ADC value would remain low. These results suggest that inflammation may be closely related to the bright signal. In addition, changed ADC values are useful in differentiating malignant from benign tumors. DWI has a potential to evaluate the manifestations

of acute pancreatitis. Furthermore, the greatest advantage of DWI in diagnosing this condition is that no enhancing material is needed.

In conclusion, DWI is a powerful tool for evaluating acute pancreatitis and has a potential to replace CT as a primary diagnostic strategy for acute pancreatitis.

Abstract

We describe a 74-year-old man with a colonic metastatic squamous cell carcinoma (SCC) from the lung. His chest X-ray revealed an abnormal shadow in the right upper lobe. Computed tomography (CT) of the chest demonstrated a large lung tumor in the right upper lobe obstructing the right upper bronchus. Bronchoscopy revealed an easy-bleeding tumor in the right upper bronchus that was diagnosed as poorly differentiated squamous cell lung carcinoma. He underwent colonoscopy because he had a positive fecal occult blood test. Colonoscopy revealed a large protruding lesion with central ulceration in the descending colon. Histological examination of the biopsy specimen obtained from the colonic lesion revealed SCC. The lesion was diagnosed as metastatic colonic SCC. He had no abdominal symptoms. He underwent chemotherapy with an infusion of cisplatin 130 mg i.v. day 1, and docetaxel hydrate 100 mg i.v. day 1, repeated every 4 wk, followed by 4 courses of chemotherapy. The primary lesion shrank by less than 10% and was judged to be "Partial Response" (PR) after 3 courses of treatment. The patient still lived 23 wk after the diagnosis of metastatic colonic SCC. Colonic metastasis of primary SCC of the lung is rare.

INTRODUCTION

Primary lung cancer is a common neoplasm, and frequently metastasizes to internal organs such as the lung, liver and adrenal gland; however, it is relatively rare for lung cancer to metastasize to the gastrointestinal (GI) tract. Colonic metastasis from primary carcinoma of the lung has rarely been described. Clinically, patients may present with symptoms of colonic obstruction, lower GI bleeding, bowel perforation, or GI fistula[1-4]. Herein, we describe a rare case of metastatic colonic squamous cell carcinoma (SCC) from the lung.

CASE REPORT

A 74-year-old man presented with the symptom of shoulder pain. His chest X-ray revealed an abnormal shadow in the right upper lobe (Figure 1A). He was in good health with no specific family or past medical history. His body temperature was 36.7℃, blood pressure was 148/82 mmHg, radial pulse rate was 72 beats/min and regular. He had anemia, but no jaundice. Neurological examination revealed no abnormal findings or lymphadenopathy. Abdominal palpation revealed tenderness in the left lower quadrant. Laboratory tests showed a red blood cell count of $318 \times 10^4/\mu L$ [normal range (NR), $430\text{-}570 \times 10^4/\mu L$], a white blood cell count of 7600 /μL, and a platelet count of $30.8 \times 10^4/\mu L$, and a hemoglobin concentration of 8.9 g/dL (NR, 14-18 g/dL). Liver function tests were normal except for lactate dehydrogenase (LDH) of 340 IU/L (NR, 106-211 IU/L). A test for C reactive protein revealed a level of 0.8 mg/dL (NR, < 0.5 mg/dL). Renal function tests showed that blood urea nitrogen

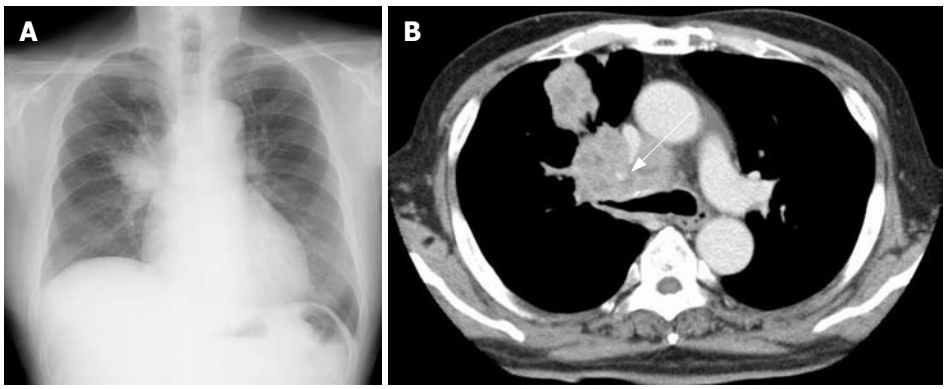

Figure 1 **A**: Chest X-ray revealed a large abnormal shadow in the right upper lobe; **B**: A computed tomography (CT) of the chest demonstrated a large lung tumor in the right upper lobe obstructing the right upper bronchus.

Figure 2 Endoscopic appearance of the descending colon. A large protruding lesion with central ulceration, about 40 mm in diameter, was seen.

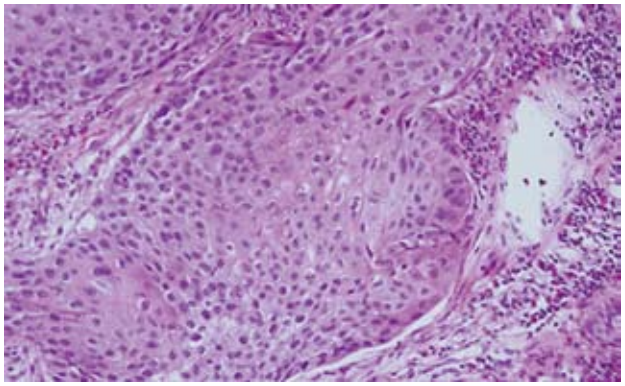

Figure 3 Histological examination of the biopsy specimen obtained from the colonic protruding lesion revealed tumor cells diagnosed as SCC (× 50).

and creatinine were normal. Computed tomography (CT) of the chest demonstrated a large lung tumor in the right upper lobe obstructing the right upper bronchus (Figure 1B). Bronchoscopy revealed an easy-bleeding tumor in the right upper bronchus. Poorly differentiated SCC was diagnosed by punch biopsy.

Colonoscopy revealed a large protruding lesion with central ulceration in the descending colon (Figure 2). This finding suggested a clinical diagnosis of metastatic colonic tumor. Biopsy specimens obtained from the lesion showed SCC (Figure 3). Based on these findings, the patient was diagnosed with metastatic colonic SCC from primary lung cancer. Subsequent positron emission tomography (PET) with radiolabeled-18 fluorine fluorodeoxyglucose (FDG) imaging revealed an abnormal lesion in the descending colon. The patient underwent chemotherapy with an infusion of cisplatin 130 mg i.v. day 1, and docetaxel hydrate 100 mg i.v. day 1, repeated every 4 wk, followed by 4 courses of chemotherapy. The primary lesion shrank by less than 10% and was judged to be "Partial Response" (PR) after 3 courses of treatment. The patient still lived 23 wk after the diagnosis of metastatic colonic SCC.

DISCUSSION

GI metastasis from lung cancer is considered to be rare, although there is about 4.7%-14% prevalence at autopsy[5-7]. A recent report described by Kim *et al*[8] revealed that GI metastases were detected in 10 (0.19%) of 5239 lung cancer patients. In an autopsy study from Japan, the rate of GI tract metastasis, excluding the esophagus, was 1.8% and the colonic metastasis rate was only 0.5%[6]. The histological type of lung cancer that causes colonic metastasis varies according to different studies. The most common types were large cell or SCC[5,9,10]. We believe that it is hard to pinpoint the type of primary lung cancer causing colon metastasis because of the small number of cases. Reviewing the English literature, there are several reports on colonic metastasis[11-14]. Patients with GI metastasis of lung cancer are often asymptomatic, as in the present case. Yang *et al*[14] reported that the clinical prevalence of symptomatic GI metastasis of lung cancer is 1.77% (6/339). Habesoglu *et al* described that about 1/3 of colonic metastases from lung cancer are asymptomatic and the diagnosis is made at autopsy[4]. The most common symptoms are abdominal pain, nausea, vomiting, anemia, and weight loss[1,5]. Other symptoms of colonic obstruction, lower GI bleeding, bowel perforation, or GI fistula may occur[1-4]. These findings generally present after the diagnosis of primary disease but can occur synchronously or before diagnosis of the primary lesion[1,4,10].

Lung cancer with intestinal metastasis has been reported to have a poor prognosis of less than 16 wk in several studies[4,6,12,14]; however, because of advanced improvement in chemotherapy, supportive care for lung cancer, and extending life expectancy, we may come across an increasing number of GI metastasis in the future.

Thus, we should pay attention to GI metastatic signs such as GI bleeding, abdominal pain, nausea, vomiting, or less commonly, ileus. Development of GI symptoms after chemotherapy should be carefully managed in patients with GI metastasis because of the possibility of chemotherapy-induced perforation. The present patient underwent colonoscopy for further evaluation of a positive fecal occult blood test, and a metastatic colonic lesion was detected before chemotherapy. He has been receiving chemotherapy without chemotherapy-induced perforation or abdominal symptoms. If we aggressively examine lung cancer patients with a positive fecal occult blood test by colonoscopy, more latent patients with metastatic colonic tumor from the lung might be discovered in the future.

Recently, PET-FDG imaging has become useful to diagnose the extent of GI metastasis[13]. Cases of small intestinal[15] and large intestinal metastasis[13] from lung cancer have been reported. In the present case, we could also detect colonic metastatic lesions with PET-FDG; however, the definite role of PET-FDG in the diagnosis of GI metastasis from primary lung cancer is still controversial because of the few cases and lack of clinical data. To clarify the usefulness of PET-FDG for the diagnosis of GI metastasis from lung cancer, we should accumulate and analyze more cases of GI metastasis from primary lung cancer.

In conclusion, we reported a rare case of metastatic colonic SCC from the lung with a positive fecal occult blood test. It is necessary to be aware that primary SCC of the lung may cause colonic metastasis, although lung SCC rarely causes colonic metastasis.

ACKNOWLEDGMENTS

Acknowledgments to Reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

Kyoichi Adachi, MD
Department of Gastroenterology and Hepatology, Shimane University, School of Medicine Shimane, 89-1 Enya-cho, Izumo-shi Shimane 693-8501, Japan

Minoti V Apte, Associate Professor

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

World J Gastroenterol 2008 September 21; 14(35): 5486-5488
World Journal of Gastroenterology ISSN 1007-9327

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology* and *Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Format

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903
Ocean International Center, Building D
No. 62 Dongsihuan Zhonglu
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

Time, times and timing are key words in inflammatory bowel diseases (IBD). The leitmotif of this issue or *World Journal of Gastroenterology* is time. We have asked experts to review on the epidemiology of these diseases over time, the changes in innate immunity that could be present in the first time, and then the timing of key treatments. The correct time of using azathioprine, mercaptopurine, infliximab, cyclosporine and surgery are reviewed. We have chosen experts with not only great clinical expertise but also personal interest in clinical and basic investigation. Our goal in this monograph is to get an idea not only of the present but of the immediate future in some of the key management issues in IBD. To this end, we think that the authors are the most adequate.

Key words: Inflammatory bowel diseases; Epidemiology; Innate immunity; Treatment

Gomollón F, Gisbert JP, Gassull MÁ. Crohnology: A tale of time and times and inflammatory bowel diseases. *World J Gastroenterol* 2008; 14(36): 5489-5490 Available from: URL: http://www.wjgnet.com/1007-9327/14/5489.asp DOI: http://dx.doi.org/10.3748/wjg.14.5489

Life and time are concepts that can not be apart[1]. In fact, from a medical point of view, life, time and disease are inseparable concepts. The importance of time in life is being clarified by basic scientists and chronobiology is an area of knowledge steadily growing[2]. As we are writing on inflammatory bowel diseases (IBDs) we have misspelled on purpose the word *crohnology*, as new additional tribute to Burrill Bernard Crohn[3]. In fact, we borrowed the fundamental idea from another great expert, not only on Beethoven's piano sonatas, but on IBDs: David Sachar. He wrote some years ago an excellent editorial on this subject[4], and although he thinks that, at the end, no one reads his articles, he was wrong this time: we do. David Sachar wrote (sic): … *"time course* of disease progression should enter into our phenotyping schemes as elements in their own right" and also: "to understand the time course of Crohn's disease …, we have to figure out when and where to start the clock". Time is the *leitmotif* of this monographic issue of the *World Journal of Gastroenterology*.

First, IBDs are diseases of our times. Diseases affecting human beings have greatly changed over time[5]. In Spain, Crohn's disease could not to be found in most standard textbooks as late in the twentieth century as 1975. Now the Spanish working group on IBD (GETECCU, http://www.geteccu.org) has more than 300 gastroenterologists as active members. Of course, this can not be taken as an epidemiological figure, but it may be an idea about the quick changes in some of the health needs in our current world. Whatever the complex reasons for these dramatic changes, environmental factors must be a prominent influence, because the time taken to these changes is too short to blame genetics to explain them (at least in full). It is difficult to forget the similarities with cigarette smoking. "The IBDs' century "could be a very adequate title for a book on Crohn's disease (CD) and Ulcerative Colitis (UC)[6].

Second, we take a look to a very interesting hypothesis: "the first precursors of recognizable Crohn's disease"[3]. Professor Eduard Stange and co-workers, from Germany, suggests that IBDs are in fact the final consequence of a defective innate immunity against bacteria. Their data on defensins have been the matter of controversy in most recent meetings on IBDs. He has written a short review on the topic. The disturbances of adaptative immunology in advanced IBDs were first recognized; however, innate immunity errors are emerging as key clues to chronic inflammation[7]. The "defensins hyphothesis" is not unique, but it is very attractive and gives a refreshing point of view to the pathogenesis of IBD. In fact, human brain is more adapted to see what it is there, but has

serious difficulties to think of absent things[8]. Could it be possible that the lack of adequate defense mechanisms being the primary phenomenon, explain the final excess of inflammation? Certainly this seems an interesting and attractive way to explore.

Most of the chapters in this issue are directly related to the real life situations for a clinician in care of IBDs' patients. Clinicians have to take, or at least help to take, many decisions. Ideally, these decisions should be taken on time and always trying to avoid delays; that is, the time elapsed to take these decisions has to be the correct and needed time. Time is important for us, but much more for our patients. In certain occasions taking decisions on time it is not easy at all and we make errors[9]. These mistakes have sometimes very undesirable consequences to our patients. Timing of decisions is a key factor in our practice. In this issue the answer to some critical questions has been addressed.

In the very difficult clinical scenario of severe ulcerative colitis, there are two crucial questions: how long, if no response is obtained, should steroids be maintained to define *resistance*? and if steroids do not work: it is time for cyclosporine or for infliximab? These points are often discussed in meetings, but we do want the best answers. Therefore, we have asked these questions to real experts. Dr. María Esteve has been working for years both in basic and clinic research and at the same time she has great clinical experience; she is a real translational physician. She can approach steroid resistance from both points of view, and this was exactly our aim. The same can be said from Drs Gert van Asche and Severine Vermeire. Of course we know that currently there is not a formal clinical trial comparing cyclosporine and infliximab in severe UC, but patients are there and we have to help them just on time; today, not tomorrow. We expect that these two experts help us to understand the pros and cons for using these drugs at the proper time and for how long.

Azathioprine and mercaptopurine are the most important drugs in the maintenance treatment of IBDs[10]. Much has been written on these very useful old friends. However, do we start these treatments at the proper time or do delay theis use too much? This is a common and important clinical question, not very easy to answer. It is about prediction, a rather difficult science. Can we predict clinical course and therefore select the adequate timing for starting treatment? In any case, many patients are finally on immunomodulators, and many do stay quite well during years: so, is it a time to withdraw them?

Biologics are newer therapies[11], but are here to stay. There are, at least, two very different points of view. Many clinicians, as well as regulatory agencies[12], do think that these drugs should be used at later stages in therapy, after the failure of conventional treatments; high cost and high risks are the main arguments for this position. However, this way if thinking it seems rather intuitive (intuition is of course not sort of scientific proof) that administering treatment earlier could beneficially modify the natural history of disease. So many clinicians, as well as pharmaceutical companies, think that the earlier biological are administered, clearly the better. In fact there is some recent evidence supporting this argument[13]. The timing of this treatment seems critical. We think that giving both points of views would be interesting and useful for the clinician.

Finally, few decisions are as difficult as timing surgery in IBDs. Sometimes we decide too late (don't you have at least one patient telling you: Hey doc, why did we go through surgery so late?), perhaps sometimes the decision was taken too early (some refractory pouchitis could comment on this side). Few tips may help in those difficult clinical nodes. In addition, after surgery it is also time to act: you need to prevent recurrence. How is not easy to say, but we also need to know when.

Words are almost living beings. We have chosen times, time and timing, to think over IBDs. But, it is time to finish. It is time to continue working to help our IBDs' patients.

Abstract

Inflammatory bowel diseases (IBD) are a heterogeneous group of diseases, not always easy to diagnose, even more difficult to classify, and diagnostic criteria are not always uniform. Well done population-based studies are not abundant, and so comparisons among different geographical areas or populations are not always very reliable. In this article, we have reviewed epidemiological studies available on the world's population while making a critical review of published data.

INTRODUCTION

There is no doubt about the key role of epidemiology in modern medicine. The burden of inflammatory bowel diseases (IBDs) is changing so quickly, and shows such geographical heterogeneity, that the challenge for epidemiologists is a formidable one. The main goal of this review is to furnish a *panorama* of these studies all over the world.

First, we have to underline some methodological difficulties. IBDs are a heterogeneous group of diseases, not always easy to diagnose, even more difficult to classify, and diagnostic criteria are not always uniform. And we can not forget that in many countries IBD were rare only 30 years ago. In these stages, hospital based studies are rather common, but of course with many bias. Well done population-based studies are not abundant, and so comparisons among different geographical areas or populations are not always very reliable. The heterogeneity of genotypes and phenotypes has been confirmed in the most recent reports. So, sound studies should be based on clear definitions and internationally accepted classification. Otherwise, some common misconceptions will be perpetuated.

For instance, it is common to find in the introduction of epidemiological reports these type of sentences: "One of the few aspects of the epidemiology of inflammatory bowel disease that seems indisputable is the emergence of both ulcerative colitis and Crohn's disease in the economically developed nations of Western Europe and North America during the past century"[1] or "It has been suggested that the incidence of inflammatory bowel disease (IBD), which includes Ulcerative colitis and Crohn's disease, is three or more times higher in Northern than in Southern Europe"[2]. It is the widespread idea that incidence of this group of diseases is low in Africa and Asia, as opposed to the more developed countries, particularly in Northern Europe and Central and North-America. However, other authors are critical with the geographical difference theory and try to clarify the concept: "The incidence figures for Ulcerative colitis and Crohn's disease have been difficult to interpret, and geographical variations may be due to differences in classification criteria and study design."[3]

We can see in Figure 1, how epidemiological studies published so far with high quality in methodology (clear definitions, prospective, population-based), are mostly grouped in the same areas[2,4-45] while in areas considered low incidence, coinciding with areas of low socioeconomic level, there are no relevant studies. In most undeveloped countries there are few epidemiological studies and the few published until now are limited to very specific areas for a centralized hospital and often retrospectively. The authors of these reports emphasize

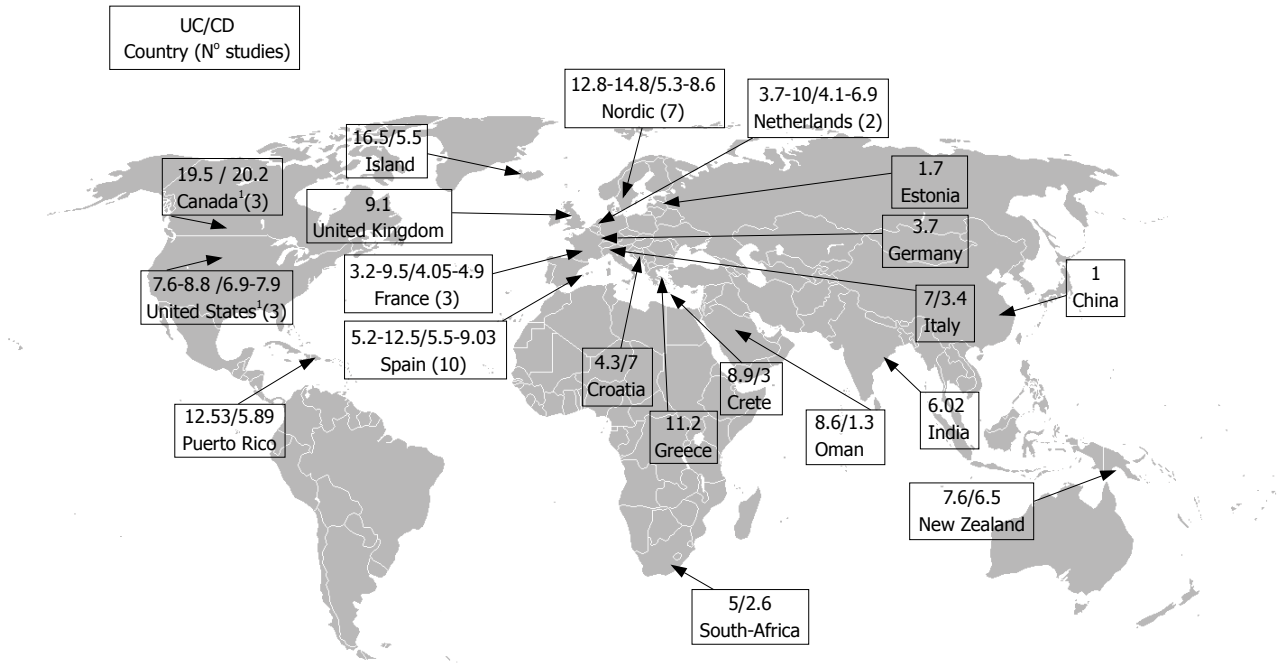

Figure 1 Prospective and population-based studies: UC and CD. [1]Retrospective but population-based data base of inflammatory bowel disease. Nº studies: Number of published studies.

the probable bias of their results[46].

In Asia, there is only 1 prospective study in Hong Kong[41] and 4 retrospective studies in Japan[47], Singapore[48] and Korea[46,49]. Just one study in India[42] and another one in the Arabian Peninsula, in Oman[43]. Studies of Israel are included in Europe. In Africa, data arrive from Cape Town[44]. Recently, a study conducted in New Zealand[45] describes incidence rates similar to those described in "developed" countries or "Northern Europe".

In the United States, where the health system is not ideal for conducting population studies because 45 million inhabitants are not covered by a health care system, the available studies, though retrospective, are based on the implementation of a "population-based data base of inflammatory bowel disease" which allows the identification of these diseases with a high sensitivity and specificity with the advantage of results over extensive periods of time[7-9]. In Canada it is been used the same methodology for collecting data[4-6].

After all, the general data are not very consistent, so it is difficult to make comparisons. In this article, we have reviewed epidemiological studies available on the world's population while making a critical review of published data.

INCIDENCE RATES IN DIFFERENT EPIDEMIOLOGICAL STUDIES

Retrospective studies

We show in Table 1 a summary of retrospective studies published until now[4-9,46-92] and the different rates of incidence: as you can see, many of the them are hospital-based[47,48,54,64,77,88,90], not surprisingly showing a worse clinical course with increased morbidity. Population-based studies demonstrate that at least 50% of patients do not require hospital admission, so hospital-based studies are clearly biased showing only the most severe group of patients. We would like to note also that incidence rates are highly variable even in the same geographical areas (for example in UK, incidence varies from 7.1 to 15 for UC)[52,53], a fact explained by methodological heterogeneity.

Prospective and population-based studies

The results of prospective studies (Figure 1) show much more homogeneity. However, there are high incidence areas such as Iceland[11] and Puerto Rico[10] and very low incidence areas such as China[41] and Oman[43]. The other studies do show intermediate rates and, in general the more recent the study the higher the incidence rates[12,20,27]. In most prospective studies, the incidence rates are higher for UC than for CD; only in the Croatian study[39] this ratio is reversed, as is found also in pediatric studies. In Canadian reports incidence rate of UC and CD tend to equalize[4-6], reflecting the high incidence of CD in this country.

In Europe we have multiple population-based and prospective studies, allowing us to comparing different areas (Figures 1, 2 and 3)[2,11-40]. In a multicenter, international, and well designed study led by Shivananda[2] from 1991 to 1993 and covering several areas of Europe comparing the incidence rates of inflammatory bowel disease (IBD) between North and South, the authors did confirm higher incidence rates for Northern (UC = 11.4 and CD = 6.3) than for Southern Europe (UC = 8 and CD = 3.6); however, when you take off extreme data studies (Iceland, Oslo, Lisbon and Ioannina), this difference loses its significance: for Northern Europe (UC = 9.5 and CD = 5.83) *vs* (UC = 8.79 and CD = 3.84) in Southern

Europe. It is worth to remember that in 1991 the socioeconomic status varied greatly in Europe, with Northern countries considerably more wealthy, a gap that is considerably less profound in 2008. With these results, we would like to highlight data from different areas: Exceeding 10 UC patients/100 000 habitants/year: Iceland[11], Norway[15-17], Copenhagen[12], Heraklion (Greece)[34] and more recent Spanish studies[27,28]; Between 5 and 10 UC patients/100 000 habitants/year: Leicester (UK)[21], Maastricht[33], France[20], Italy[38], and most Spanish studies[23-25]; Below 5 UC patients/100 000 habitants/year: Croatia[39], North of France[18,19], Brussels[32], Germany[37] and Estonia[40].

Spain is one of the European countries with more prospective and population-based published studies[22-31] (Figure 3). The results are fairly uniform in the studies made at the same time periods, with high incidence areas in the latest published studies as Navarra[28] and Asturias[27]. The results of Spanish studies are not different from those presented throughout Europe (data varying from 5 to 10 cases of UC/100 000 habitants/year and from 3.5 to 6.5 cases

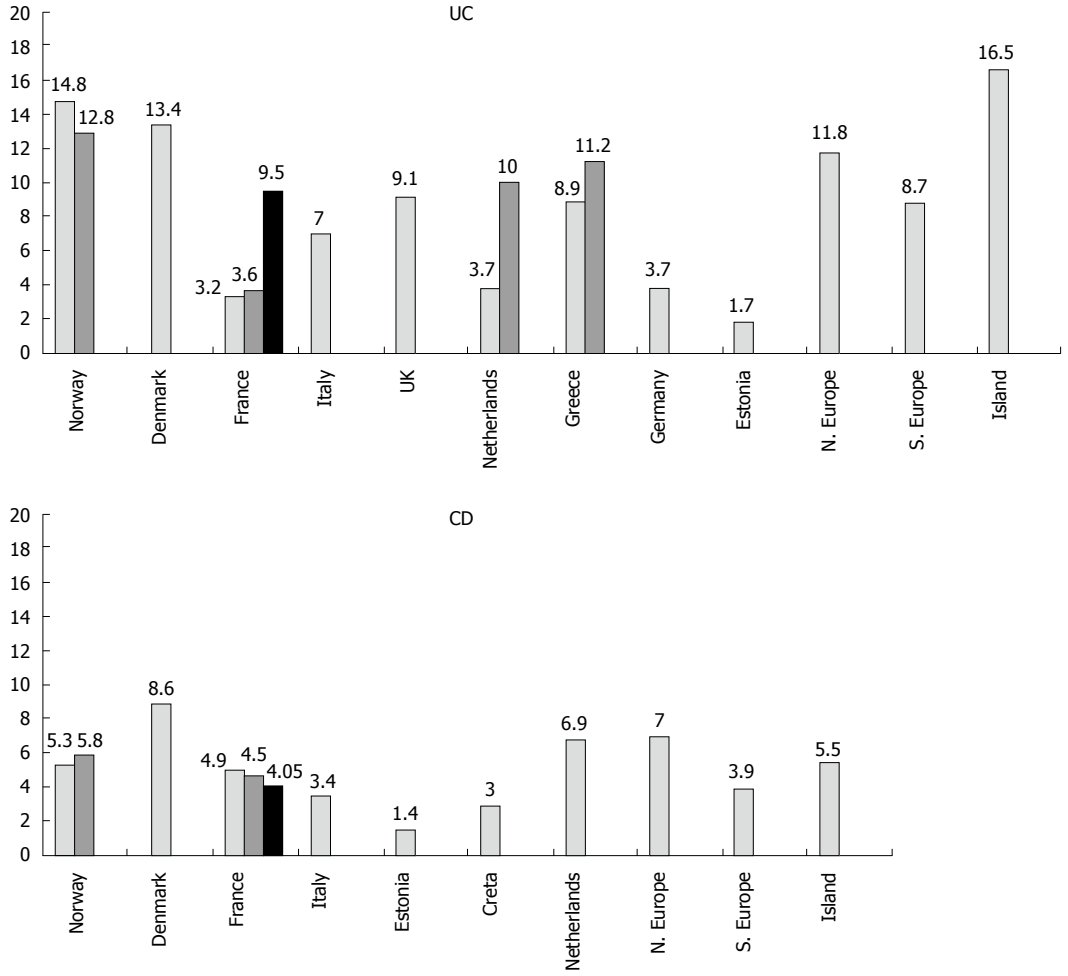

Figure 2 UC and CD incidence in prospective and poblational. European studies excepting Spain. Different color means there is more than one study in the same country and goes in chronological order from the first published study to the last.

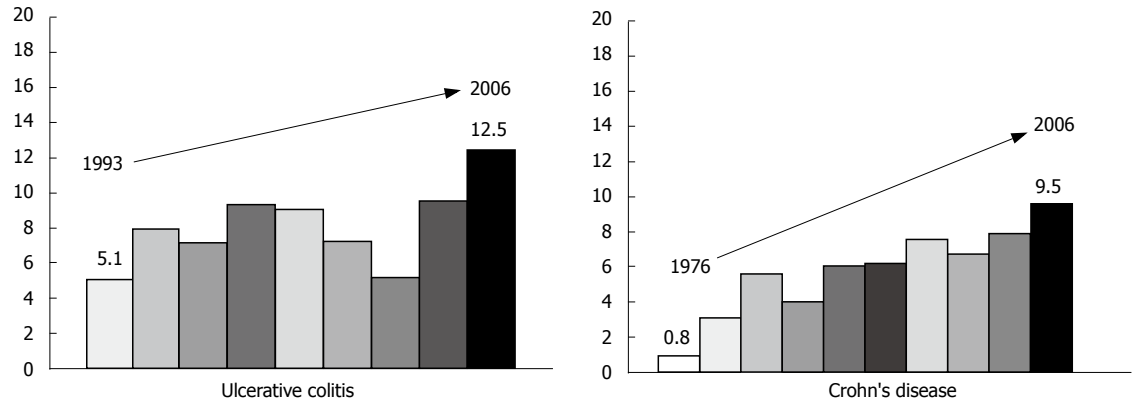

Figure 3 Prospective and population-based Spanish studies over time. UC: Incidence rates from 1993 to 2006; CD: Incidence rates from 1976 to 2006.

of CD/100 000 habitants per year). When comparing the results of the European study, data from Spanish studies are similar: North Europe (UC-CD = 9.5-5.83/100 000 habitants per year) *versus* (UC-CD = 8.79-3.84/100 000 habitants per year) in southern Europe versus (UC-CD = 7-9.3/4.8-6.08/100 000 habitants per year) in Spain.

VARIATIONS IN INCIDENCE OVER TIME

The general observations in northern Europe and America show that incidence of UC increased substantially in the early and middle third of 1900's, without changes afterwards, while the incidence of CD has been rising since the mid-1900s[5]. In Western world, it has been a clear increase in incidence in both CD and UC during the sixties and seventies after reaching a plateau between 7 and 12 new cases/100 000 habitants per year, respectively. Nowadays, rates tend to stabilize in areas of high incidence as in northern Europe and America, while in areas with low incidence as southern Europe, Asia and developing countries[93] these incidence

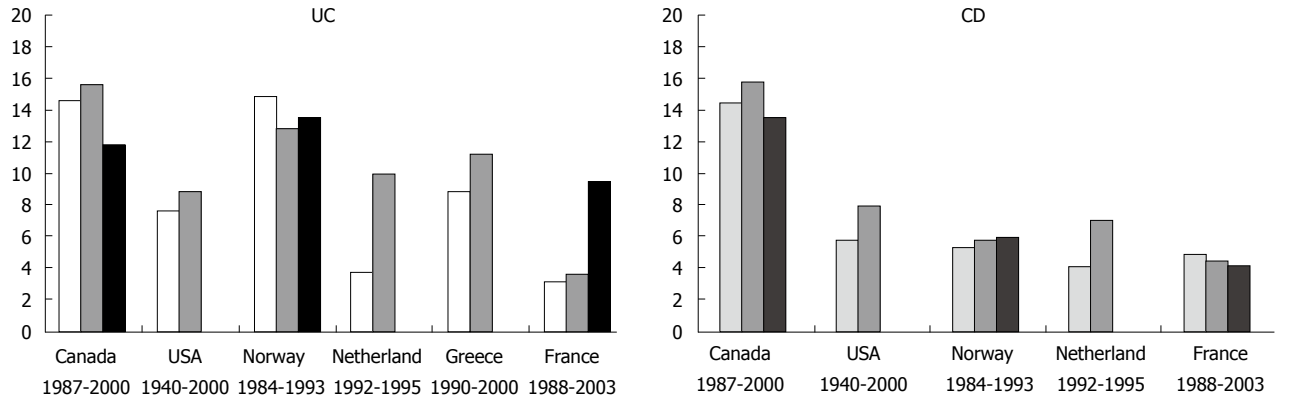

Figure 4 Incidence studies through time.

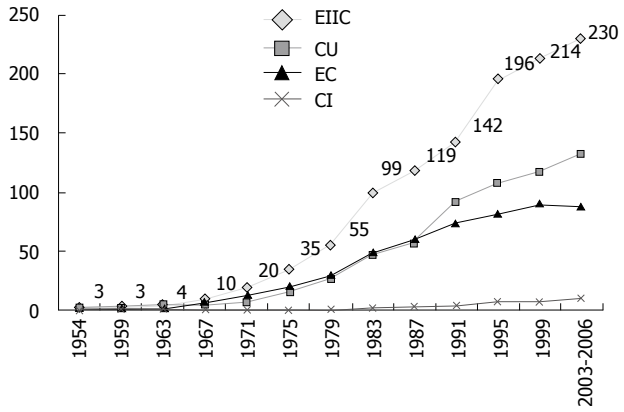

Figure 5 UC and CD incidence rates in Asturias from 1954 to 2006.

dada keep raising.

However, the truth is that we do have little reliable data to establish these comparisons. Few studies are repeated in the same areas and with the same diagnosed criteria or at different consecutive periods or long-term monitoring. In many cases, rates come indirectly from studies with records of hospital admissions and mortality studies. Moreover no less than 12% of patients diagnosed of UC have to be reclassified, as it has been described in some studies[3]. In Figures 3 and 4 we show the studies in the same areas at different periods of time describing differences in incidence rates over time.

In Canada and the United States, and although we have already commented that the methodology is retrospective, data collection of incident cases is comprehensive and based on a database created specifically to collect all incident cases of inflammatory bowel disease; the advantage of these studies is to be able to observe how incidence of these diseases varies over time because data are collected using the same methodology and results are easily comparable. The American Group has published 3 studies[7-9] analyzing the incidence of UC and CD between 1940 and 2000, describing a progressive increase since 1940 in both diseases, afterwards their data remain stable about 30 years, and later on, incidence starts increasing again mainly with CD (increase of 31%) since 1991 remaining UC incidence stable and even declining (7%). The Canadian group has also published 3 studies[4-6] showing the higher incidence of CD never published and described since 1987, remaining stable since then until now; the incidence rates of UC are also high, but similar to other European countries (Iceland, Denmark) and also remains stable.

Analyzing the evolution of incidence rates in European countries we can see that in most of them both rates of UC and CD have been increasing over the years. In relation to UC, we see how the population studies conducted in France[18-20], Greece[34-36] and Netherlands[32,33] show a gradual increase over time; in Norway remains stable and even "declining" but with very high levels (14.8-13.6/100 000 inhabitants per year). In relation to CD, we can see analogous evolution as UC except in France where this trend seems to be the opposite, but with little difference between the studies (4.9-4.05/100 000 habitants per year).

In Spain, we can see how incidence of UC increases gradually with the only exception of one study[29] and also, we can see how clearly CD incidence has increased progressively since 1978 in which the first prospective and population study of CD[22] was conducted in our country with rates of 0.5 patients/100 000 habit per year. The 2 studies conducted more recently in Spain, show really high incidence rates of both UC and CD: Arin *et al*[28] in Navarra observed an incidence between 2001 and 2003 from UC and EC of 9.57 and 585 patients/100 000 habit per year respectively; the Asturian study (Figure 5), with a long-term follow-up (historical cohort from 1954 until December 2006)[27] noted how since 1954 incident cases of IBD have been gradually increasing, with two points of inflection in the 80's and in 1991. The first coincides with the introduction of endoscopy in our hospitals as a diagnostic method and the second coincides with the beginning of the prospective study. You can see a clear increase of incidence in the second period of the study, but these results may be biased, since in the first period, the data are retrospective. Finally, in prospective study (1991-2006) there are no significant differences in incidence rates ($P = 0.08$).

CONCLUSION

To summarize, we can conclude that: Incidence rates have been increasing in developed countries and finally reaching a plateau in most studies. Data from underdeveloped countries are scarce and of low methodological quality, but most suggest lower incidence rates of IBDs in these areas.

The geographical variability is, in part, the consequence of differences in methods and diagnostic resources. However, when sequential and reliable data are available from the same area, incidence rates do really change.

The rather quick change of incidence does strongly suggest that environmental factors have a clear etiological role in IBDs. The factor (or factors) has something in common with economical development: those diseases seem to raise in parallel with per capita income[94].

New, methodologically sound studies are needed. We need transversal studies, but longitudinal ones with long-term follow-up will be probably more important to reveal new clues for etiological investigation.

Abstract

Crohn's disease may prinicipally involve the whole gastrointestinal tract. Most commonly, the inflammation occurs in the small intestine and/or in the colon with stable disease location over the years. The pathogenesis of both disease phenotypes is complex, the likely primary defect lies in the innate rather than adaptive immunity, particularly in the chemical antimicrobial barrier of the mucosa. Crohn's ileitis is associated with a reduced expression of the Wnt signalling pathway transcription factor T-cell factor 4 (TCF4), which is regulating Paneth cell differentiation. As a result, the alpha-defensins and principal Paneth cell products HD5 and HD6 are deficiently expressed in ileal disease, independent of current inflammation. In contrast, Crohn's colitis is typically associated with an impaired induction of the beta-defensins HBD2 and HBD3 caused by fewer gene copy numbers in the gene locus of the beta-defensins on chromosome 8. This ileal and colonic defect in innate defence mediated by a deficiency of the protective alpha- and beta-defensins may enable the luminal microbes to invade the mucosa and trigger the inflammation. A better understanding of the exact molecular mechanisms behind ileal and colonic Crohn's disease may give rise to new therapeutic strategies based on a stimulation of the protective innate immune system.

Key words: Crohn's disease; Intestinal stem cell; Differentiation; Defensins; Transcription factor T-cell factor 4

INTRODUCTION

Crohn's disease is characterized by a chronic inflammation of the whole intestine most commonly occurring in the distal ileum and/or in the colon[1]. Since both disease locations contain high concentrations of intestinal bacteria (10^7-10^8 organisms/gram luminal content in the distal ileum and 10^{11}-10^{12} in the colon as compared to 0-10^3 organisms/gram luminal content in the stomach, duodenum, jejunum and proximal ileum)[2] it is conceivable that luminal microbes are suggested to play an important role in the pathogenesis of Crohn's disease[3]. For example, it was demonstrated that surgical diversion of the fecal stream effectively resolves Crohn's disease inflammation distal to the surgical site[4]. Moreover, an abnormal microbial composition was found in intestinal bowel disease[5,6], especially with an enhanced *E.coli* virulence in Crohn's disease[7]. The most convincing evidence for the involvement of enteric microbiota in the pathogenesis of Crohn´s disease was demonstrated by Swidsinsky *et al* by fluorescent in situ hybridization studies (FISH) showing a drastic increase of mucosa-associated and invasive bacteria in active Crohn's disease, whereas these bacteria are absent from the normal small and large bowel epithelium[8].

In the past few years, several investigations implicated a central role for the adaptive immunity mediated by defensins and other antimicrobial peptides in Crohn's disease[9]. A relative deficiency of secreted defensins in Crohn's disease was shown in several human and animal studies shifting the balance between antimicrobial peptides and luminal bacteria towards the microbial flora[9]. As a result, an abnormal microbial composition in Crohn's disease allows the intestinal microbes to adhere and invade into the mucosa triggering the inflammation[10].

Since Crohn's disease is characterized by different

disease locations, such as small intestinal *versus* colonic disease, we discuss in this review not only the concept of a defective antimicrobial shield in both phenotypes of Crohn's disease, but also focus on the mechanisms behind ileal and colonic defensin deficiency beginning with the intestinal stem cell.

INSTESTINAL STEM CELLS

The whole intestinal tract undergoes a rapid epithelial cell turnover maintained by a population of intestinal stem cells. These enigmatic cells are characterized by a relatively undifferentiated, immature phenotype, which makes them difficult to be clearly identified even if recent studies found leucine-rich-repeat-containing G-protein-coupled receptor 5 (Lgr5) as a marker for these cells[11,12]. The stem cell compartment is located at the base of the crypts, in the small intestine intermingled with the Paneth cells[12]. They are surrounded by epithelial and mesenchymal cells, which regulate stem cell behaviour by paracrine secretion of extra-cellular substrates, such as growth factors and cytokines[13].

In this optimal microenvironment, the intestinal stem cells can give rise to four epithelial cell types[13]: The most abundant cells in the epithelium are the columnar cells, which are specialised for absorption by the presence of apical microvilli. Goblet cells are mucin producing and secreting cells forming the protective luminal mucosal layer. Neuroendocrine cells release hormones in an endo- and paracrine fashion, and finally the Paneth cells, which are found in the crypt base of the small intestine and ascending colon. Their main function is to secrete defensins and other antimicrobial molecules to keep the crypts sterile[14].

Stem cell behaviour is regulated by several cell signalling pathways, such as Wnt, Notch, Hedgehog and BMP[15,16]. Derangement of these pathways plays a crucial role in the development of malignancy within the intestinal tract[13,16,17]. The role of these pathways in inflammatory diseases, such as inflammatory bowel disease, is a new finding. In our recent work we focused on the differentiation from intestinal stem cells towards Paneth cells in ileal Crohn's disease as a potential pathogenetic mechanism of this disease[18].

PANETH CELLS

Paneth cells are located at the crypt base adjacent to the stem cells. Their main function is to protect the intestinal mucosa against microbes by the secretion of several antimicrobial molecules into the lumen of the crypt. The principal Paneth cell products are the alpha-defensins HD5 and HD6, but also other antimicrobials like lysozyme and phospholipase A2[19]. These secretory molecules enable the Paneth cells to defend the small intestine against a broad spectrum of agents, including gram-positive and gram-negative bacteria, fungi and even some viruses[20].

The differentiation from the intestinal stem cell to the Paneth cell is mainly controlled by the Wnt signaling pathway[21]. As shown by embryonic mouse intestine studies, the Wnt transcription factor TCF4 seems to be essential for the Paneth cell gene program[21]. The activation of Wnt signaling leads to the formation of an intracellular β-catenin-TCF4-complex. This complex translocates into the nucleus, where TCF4 acts as a transcription factor to control the expression of several downstream target genes, such as Paneth cell alpha-defensins[21]. In TCF4 null mice, a direct link exists between TCF4 and cryptidins (the mouse homolog to human alpha-defensins)[21], whereas in humans, especially in Crohn´s disease evidence was missing. Therefore, we looked at the expression of Paneth cell defensins and the Wnt signaling transcription factor TCF4 in ileal Crohn's disease.

THE ALPHA-DEFENSIN DEFICIENCY IN ILEAL CROHN'S DISEASE IS LINKED TO A REDUCED EXPRESSION OF THE TRANSCRIPTION FACTOR TCF4

In ileal Crohn's disease, we demonstrated in two independent cohorts a decreased expression of the alpha-defensins HD5 and HD6, whereas the other Paneth cell products were unchanged or even increased when compared with controls[19,22]. Remarkably, this observation was independent of the degree of inflammation and not detected in colonic biopsies from patients with Crohn's disease and ulcerative colitis, as well as in pouchitis samples, which were used as inflammatory controls[19,22]. Since the antibacterial activity in intestinal mucosal extracts from patients with ileal Crohn's disease was also reduced, the decreased expression of HD5 and HD6 results in a defective antimicrobial shield in humans[19]. Transgenic mice with human HD5 expression levels (reflecting the antibacterial conditions in Crohn's disease) had an abnormal composition of the luminal microbial flora, which also supports the relevance of alpha-defensins in regulating the bacterial flora[19]. Mutations in the NOD2 (nucleotide-binding oligomerization domain containing 2) gene, an intracellular receptor for bacterial muramyl dipeptide, are clearly associated with ileal Crohn's disease[23,24]. It is noteworthy that Paneth cells, which are responsible for a good effective antibacterial shield in the small intestine, also express NOD2[25]. Interestingly, we found an even more pronounced decrease of alpha-defensin transcripts in patients with a NOD2 mutation as compared to the wild types[19,22]. The low defensin synthesis in those patients has been confirmed by Elphick *et al*[26]. Another study confirmed the low defensin formation in Crohn's disease but linked it to inflammation and loss of Paneth cells[27]. However, this study was flawed by using different tissue samples such as biopsies *versus*

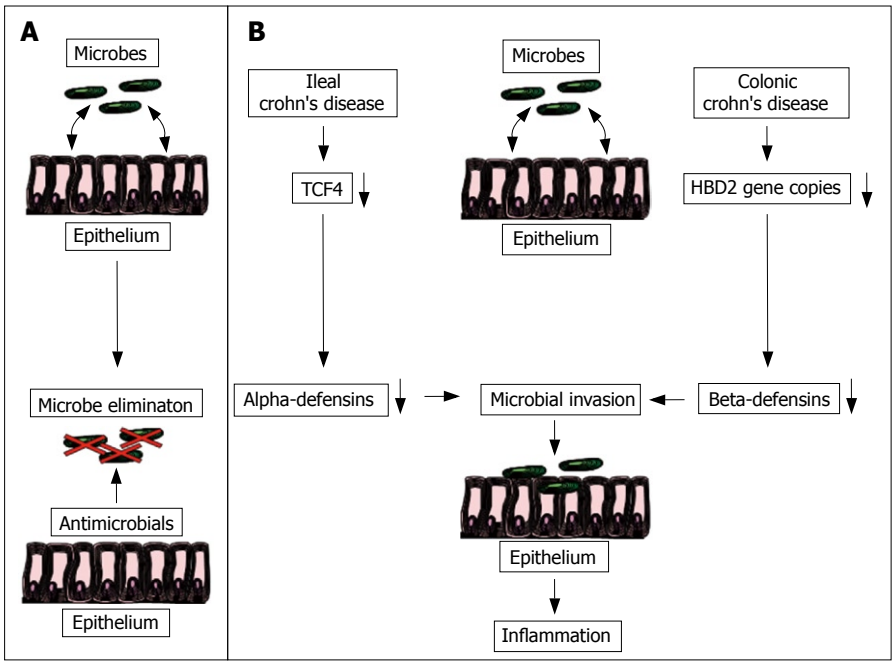

Figure 1 Proposed model for the pathogenesis of ileal and colonic Crohn's disease. In the healthy ileal and colonic mucosa, luminal microbes are sufficiently eliminated by an adequate secretion of antimicrobials peptides (**A**). In ileal Crohn's disease, a reduction of the Wnt transcription factor TCF4 leads to a decreased alpha-defensin secretion. In colonic Crohn´s disease a reduced HBD2 copy number causes a weakened antimicrobial barrier mediated by the beta-defensins. Both changes may allow the luminal microbes to attach and invade in the mucosa triggering the inflammation (**B**).

segments from controls *versus* diseased patients as well as other methodological problems in normalizing their data.

In summary, these studies above implicate that the specific deficiency of Paneth cell defensins in ileal Crohn's disease, which is even more pronounced in case of NOD2 mutations, results in a dysfunction of the mucosal barrier. The defect in innate immune defense of the ileal mucosa appears to be primary and could cause and/or maintain this inflammatory disease.

Wnt signaling is one of the crucial pathways in the differentiation from the intestinal stem cell towards the Paneth cell. In particular the Wnt transcription factor TCF4 is a known regulator of Paneth cell differentiation and also alpha-defensin expression[21]. We were able to show a reduced expression of TCF4 in patients with ileal Crohn's disease as compared to colonic Crohn´s disease and ulcerative colitis[18]. Remarkably, this decrease of TCF4 in ileal Crohn's disease was independent of the degree of inflammation and independent of the NOD2 genotype[18]. In accordance to prior animal models[21], TCF4 expression correlated also in human samples significantly with HD5 and HD6[18]. Moreover, we were able to demonstrate the functional relevance of this TCF4 decrease in heterozygous TCF4-knockout mice. These mice were characterized by a reduced TCF4 expression leading to a significant decrease of Paneth cell alpha-defensins and also bacterial killing[18]. We were also able to detect a high-affinity binding site in the HD5 and HD6 promotor for TCF4, which showed a significantly reduced activity in ileal Crohn's disease[18]. Overall, a defect in intestinal stem cell differentiation towards Paneth cells mediated *via* the Wnt signaling transcription factor TCF4 could results in a defective antibacterial shield in ileal Crohn's diseases by the absence of a sufficient expression of the protective Paneth cell defensins HD5 and HD6 (Figure 1).

THE BETA-DEFENSIN DEFICIENCY IN COLONIC CROHN'S DISEASE IS RELATED TO FEWER HBD2 GENE COPY NUMBERS

Since Paneth cells are rare in the colon, the contribution of the alpha-defensins to the antimicrobial defence in the large intestine is only limited. Therefore, it is not surprising that colonic HD5 and HD6 expression was weak and almost equal in Crohn´s disease and ulcerative colitis[22,28]. In contrast, the beta-defensins HBD1-3 are preferentially expressed in the colon. HBD1 is constitutively expressed in Crohn's disease independent of the grade of inflammation[29,30], whereas HBD2 and HBD3 are inducible in intestinal bowel disease [30-32]. As shown in two separate cohorts, the induction of both beta-defensins, HBD2 and HBD3, was less pronounced in colonic mucosa of Crohn's disease patients as compared to ulcerative colitis[31,32]. This deficiency of HBD2 expression in Crohn's colitis was also confirmed on the protein level by immunohistochemistry[30]. HBD2 and HBD3 are strongly correlated to each other, especially in case of inflammation[31,32]. Similar to these two beta-defensins, other antimicrobial peptides like elafin, SLPI and LL37 also followed the pattern of diminished induction in Crohn's disease compared to ulcerative colitis[33,34]. This observed colonic defect of the antimicrobial barrier caused by a diminished expression of beta-defensins and other antimicrobials was supported by a recent study, where we found a significantly lower bacterial killing using biopsy extracts from Crohn's disease patients compared to ulcerative colitis and healthy controls[35].

In humans, the beta-defensins HBD2 and HBD3 are neighbouring genes on chromosome 8p23.1. The DNA copy number of this beta-defensin gene cluster is highly polymorphic within the healthy population[36].

A genome wide copy number profiling using a DNA microarray showed that the defective induction of HBD2 and HBD3 in colonic CD may be due to a lower gene copy number in this gene area[37]: The median number of HBD2 gene copies in the control group and in patients with ulcerative colitis was 4. In contrast, two different cohorts (an exploratory surgical cohort with ileal or colonic CD and a large confirmatory cohort with inflammatory bowel diseases those with ileal resections/ disease) showed a median of only 3 copies per genome in colonic CD. Taken together, the number of HBD2 gene copies was shifted to lower numbers in colonic CD as compared to controls (3 *vs* 4)[37]. Since patients with 3 or less HBD2 gene copies were shown to have a significantly higher risk of developing colonic CD as compared to individuals with four or more copies (OR: 3.06, 95% CI: 1.46-6.45), the number of HBD2 gene copies seems to be functionally relevant. It is not surprising that HBD2 gene copy numbers of < 4 are associated with a diminished mucosal HBD2 mRNA expression[37]. In conclusion, a lower HBD2 gene copy number in the beta-defensin locus predisposes to colonic CD, which is most likely mediated through a diminished beta-defensin expression (Figure 1).

WHAT ABOUT ULCERATIVE COLITIS?

In active ulcerative colitis the epithelial expression of the inducible beta-defensins HBD2 (about 1000-fold), HBD3 (about 300-fold) and other antimicrobials is enhanced[9,34]. Accordingly, we were able to demonstrate an increase of the antibacterial activity toward various bacteria of the normal gut flora in cationic biopsy extracts of patients with ulcerative colitis suggesting an intact antibacterial shield in ulcerative colitis[35]. Interestingly, psoriasis, which is a non-bacterial inflammatory disease of the skin, is linked to an increased gene copy number in the beta-defensin locus[38]. It could be possible that the tremendous induction of defensins and other antimicrobials in ulcerative colitis may lead to a better antibacterial protection at the expense of enhancing the inflammatory process, since many antibacterials have proinflammatory and sometimes chemokine like effects.

CONCLUSION

The exact mechanisms behind both phenotypes of Crohn's disease are certainly complex but the presented concept has already opened new avenues of thinking. The long nurtured alterations in adaptive immunity may be secondary to this defect in innate mucosal immunity allowing mucosal invasion of bacteria. In addition to the defect in Paneth cell differentiation in ileal disease, and a lower HBD2 gene copy number in colonic disease other mechanisms are likely to exist which may require a more systematic study of the antibacterial mucosal peptide system. Nevertheless, in the future new therapeutic strategies in the treatment of Crohn's disease should focus on a stimulation of the protective innate immune system rather than broadly suppressing the adequate immunological response at the expense of opportunistic infections.

Abstract

Corticosteroids are still the first-line treatment for active ulcerative colitis more than 50 years after the publication of trials assessing their beneficial effect, with about a 50% remission rate in cases of severe disease. The mortality related to severe attacks of ulcerative colitis has decreased dramatically, to less than 1%, in experienced centers, due to the appropriate use of intensive therapeutic measures (intravenous steroids, fluids and electrolytes, artificial nutritional support, antibiotics, *etc*), along with timely decision-making about second-line medical therapy and early identification of patients requiring colectomy. One of the most difficult decisions in the management of severe ulcerative colitis is knowing for how long corticosteroids should be administered before deciding that a patient is a non-responder. Studies assessing the outcome of acute attacks after steroid initiation have demonstrated that, in steroid-sensitive patients, the response generally occurs early on, in the first days of treatment. Different indexes to predict treatment failure, when applied on the third day of treatment, have demonstrated a high positive predictive value for colectomy. In contrast to this resolute approach, which is the most widely accepted, other authors have suggested that in some patients a complete and prolonged response to steroids may take longer. Either way, physicians taking care of these patients need to recognize that severe ulcerative colitis may be life-threatening, and they need to be careful with excessively prolonged medical treatment and delayed surgery.

RESISTANCE TO CORTICOSTEROIDS RELATED TO DOSE OR ROUTE OF ADMINISTRATION

The wide use of glucocorticosteroids in the management of active ulcerative colitis (UC) in the second half of the twentieth century had a major role in dramatically reducing the high mortality rate of this condition, from 75%[1] to less than 1%[2]. In 1955 Truelove and Witts published a summary of controlled trials using cortisone in 109 UC patients, most of them with moderate disease[3]. In 1978, Truelove *et al*[4] reported, in an uncontrolled study, a 60% remission rate in 87 patients with severe UC by using 60 mg intravenous prednisolone. More than 50 years after the publication of the initial trial, Corticosteroids are still the first-line treatment for moderate to severely active UC. Similar percentages of response and remission rates were reproduced in a number of subsequent studies[2]. However, little evidence-based data are available indicating the optimal dose and route of administration in severe disease. Only one study performed in outpatients with moderate disease compared doses of 20, 40 and 60 mg of oral prednisone, and demonstrated a similar effect for 40 and 60 mg, and significantly higher than that for

20 mg/d[5]. No trials assessing a dose-response rate have been performed in severe UC, and the majority of studies have used fixed doses, not adjusted to body weight, ranging from 40-80 mg of methylprednisolone and 100-400 mg of hydrocortisone. A recently published systematic review of cohort studies and controlled clinical trials assessing the response to Corticosteroids in severe UC addressed the issue of dose-related efficacy of steroids[2]. The dose administered was reported in 24 studies, and no relationship was found between the dose administered-standardized as methylprednisolone equivalent while using a mean adult weight of 70 kg and colectomy rate. However, the mean daily dose was 68 ± 13 mg (range 40-100 mg); only 3 studies have used doses lower than 50 mg/d. Therefore, doses equivalent to 1 mg of prednisone per kg body weight seem to be the most effective, with higher doses apparently not adding more benefit. However, supraphysiological doses (equivalent to 1000 mg methylprednisolone), as used in other immunomediated inflammatory disorders, were evaluated in only one pilot study that used 100 mg dexamethasone pulse therapy for 3 d with good short term outcome[6].

Previous to establish the criteria of steroid resistance, it is accepted that corticosteroids should be administered intravenously when a lack of response to oral treatment is observed. This recommendation is based on classical pharmacokinetic studies, performed with limited numbers of patients, which demonstrated delayed prednisolone absorption after an oral dose in patients with acute colitis as compared to healthy controls, and better plasma levels after intravenous administration[7,8]. In addition, intravenous administration in the hospital setting ensures good treatment compliance.

Hospital admission for intensive intravenous treatment is consequently mandatory for those patients with moderate disease who have failed to respond to oral prednisone or those having clinical criteria of severe disease as defined by the classical clinical index[3,9]. In addition to the life-saving benefit of corticosteroid administration, the decreased morbidity and mortality in severe UC was thought to be due to the appropriate use of intensive supportive measures (fluid and electrolyte replacement, artificial nutritional support, antibiotics, *etc*) and early identification of patients requiring colectomy[10,11]. In fact, unacceptably high mortality rates have recently been reported in non-specialized centers, probably due to delayed decisions in perioperative management[12,13]. Physicians treating UC patients should be able to recognize the severity of the condition and related complications and to be aware of the limits of all the therapeutic armamentarium, thereby avoiding unnecessary exposure to ineffective treatment. In this sense, the availability of several therapeutic alternatives such as cyclosporine, infliximab and granulocyteapheresis stimulated the search for predictive factors of treatment failure at an early stage. Thus, one of the most difficult questions in the management of severe UC is not deciding when corticosteroids should be administered, but rather for how long they should be administered, and with what limits for their efficacy.

AT WHAT POINT SHOULD WE DEFINE RESISTANCE TO STEROIDS: 3, 7 OR 21 DAYS AFTER INITIATION?

The colectomy rate in severe UC (30%-35%), as well as percentages of remission and response, have remained unchanged since the introduction of corticosteroids in UC treatment, and similar results have been reported in both clinical trials[2] and in the clinical setting[14]. The classic limit of 7-10 d for establishing the criteria of steroid resistance was based on the results of historical series showing that the median time of remission was 7.5 d and that prolonged administration beyond 10 d did not increase the percentage of remission[15].

However, some authors have argued in favor of a more conservative approach since a group of "slow responders" have been identified[16,17]. These patients showed a partial response within 10 d of admission, defined as a decrease in stool frequency, with little or no blood. In the largest retrospective series of a single experienced hospital (149 episodes in 115 patients), 19% fulfilling this criteria entered into remission within the first 21 d of treatment[16]. More importantly, the long-term follow-up of these "slow-responders" showed that none of them required colectomy within a median follow-up period of 49 mo. These data are in contrast with the high colectomy rate of corticoesteroid refractory patients one year after ciclosporin-induced remission when azathioprine is not administered to maintain it[18].

In contrast with this point of view, a more resolute approach is based on the results of several studies which have identified factors predictive of treatment failure soon after corticosteroid initiation[19-22]. The study of Travis *et al*[19] was a pioneer in this area, demonstrating a prospective day-by-day evolution, during the first days after admission, of several inflammatory parameters (C reactive protein (CRP), erythrocyte sedimentation rate (ESR), platelets, *etc*) and clinical symptoms (bowel movements, blood in stools, pulse rate, *etc*) in 51 consecutive episodes of severe UC. This study identified a turning point in the disease outcome on the third day of treatment, establishing a critical limit for deciding whether patients are responders or non-responders. Two simple parameters (stool frequency of > 8 per day or 3-8 bowel movements per day and CRP > 45 mg/dL on the third day of therapy) have a positive predictive value (PPV) of 85% for colectomy. Similar results (decreased CRP and Montreal classification[23] of UC activity as independent predictive factors for response on the 3rd day of treatment) have been obtained in a recent validated prospective study published as an abstract form[20]. Two additional studies retrospectively analyzed clinical and biochemical data at 1, 3 and 7 d[21], or within the first 3 d[22] of medical therapy, to obtain

predictive models of the likelihood of colectomy. In one of these, a value higher than 8 obtained by the formula *stool frequency/d + 0.14 × CRP (mg/dL)* calculated on the 3rd day after initiation of treatment had a PPV for colectomy of 72%[21]. This study confirmed that a regression formula including the same simple parameters used in the Travis *et al* study allows prediction of treatment failure and colectomy in a high percentage of severe UC patients. These results were prospectively validated in the only randomized, placebo-controlled study assessing infliximab as rescue therapy in severe UC, showing that patients fulfilling an index criteria of fulminant colitis (value ⩾ 8) in the placebo arm had a PPV for colectomy of 69%[24]. In the other retrospective study, a risk score was proposed to identify patients who are at low, intermediate or high likelihood of not responding to intensive medical treatment, aiding in the early selection of patients for second-line medical therapy or colectomy[22]. Multiple logistic regression analysis identified mean stool frequency (graded from 0 to 4 points) and colonic dilatation (4 points) within the first three days and hypoalbuminemia (1 point) on day 1 of treatment, as significantly predictive of the need for surgery within the hospitalization period. The risk score allowed the stratification of patients into those with low (11%; score 0-1), intermediate (45%; score 2-3) and high risk (85%; score ⩾ 4) of not responding to medical therapy. With a cut-off of ⩾ 4 points, the sensitivity and specificity in predicting non-response to medical therapy were 85% and 75% respectively.

The results of these studies are in agreement with previous observations showing that complete remission, which takes longer than response, is achieved, in the majority of steroid-sensitive cases, within 7 to 8 d of beginning corticosteroid treatment[15].

In conclusion, to evaluate steroid resistance, steroids must be intravenously administered, in the hospital setting, at a dose equivalent to 1 mg/kg per body weight of prednisone. The lack of response at day three of steroid treatment, as defined by well-established clinical parameters, suggests a high probability of colectomy and should be used in general as a limit point to define steroid resistance. Whether 3, 7 or 21 d are used as a limit marker for steroid resistance, judicious decisions by physicians, skilled in Inflammatory Bowel Disease management, should prevail. The risks and benefits of any decision have to be carefully weighed, taking into account that the priority in the management of severe UC is to save the patient and, if possible, the colon.

Abstract

Although systemic steroids are highly efficacious in ulcerative colitis (UC), failure to respond to steroids still poses an important challenge to the surgeon and physician alike. Even if the life time risk of a fulminant UC flare is only 20%, this condition is potentially life threatening and should be managed in hospital. If patients fail 3 to 5 d of intravenous corticosteroids and optimal supportive care, they should be considered for any of three options: intravenous cyclosporine (2 mg/kg for 7 d, and serum level controlled), infliximab (5 mg/kg IV, 0-2-6 wk) or total colectomy. The choice between these three options is a medical-surgical decision based on clinical signs, radiological and endoscopic findings and blood analysis (CRP, serum albumin). Between 65 and 85% of patients will initially respond to cyclosporine and avoid colectomy on the short term. Over 5 years only 50% of initial responders avoid colectomy and outcomes are better in patients naive to azathioprine (bridging strategy). The data on infliximab as a medical rescue in fulminant colitis are more limited although the efficacy of this anti tumor necrosis factor (TNF) monoclonal antibody has been demonstrated in a controlled trial. Controlled data on the comparative efficacy of cyclosporine and infliximab are not available at this moment. Both drugs are immunosuppressants and are used in combination with steroids and azathioprine, which infers a risk of serious, even fatal, opportunistic infections. Therefore, patients not responding to these agents within 5-7 d should be considered for colectomy and responders should be closely monitored for infections.

Key words: Ulcerative colitis; Steroids; Corticosteroids; Azathioprine; Cyclosporine; Infliximab; Immunosuppressants

INTRODUCTION

Some patients with ulcerative colitis (UC) remain symptomatic despite optimal doses of oral 5-aminosalicylic acid (5-ASA) drugs, topical therapy with either 5-ASA or steroids, and systemic corticosteroids. This can occur regardless of the extent of colonic involvement. However, steroids are highly efficacious in UC. Failure to induce remission will occur in only 40% of patients after a first course of oral systemic steroids and only 20% will have no improvement of symptoms whatsoever[1,2]. In patients with early relapse after an initial successful course of systemic steroids, subsequent courses of steroids are probably less efficacious, but this has never been studied in a controlled trial. The term "steroid refractory" has been used to define patients whose symptoms never responded to corticosteroids and those who respond initially but developed recurrence while continuing treatment. The distinction can be important since treatment options in the two settings may differ. In patients who have initially responded, the dose of oral steroids can be temporarily increased to the dose level that controlled symptoms before, whereas patients never responding need alternative options on the short term.

GENERAL TREATMENT RECOMMENDATIONS

The approach to treatment should be based on the severity of the disease flare. Moderately ill patients can usually be managed in an outpatient setting with the approaches summarized below. Disease flares are considered to be moderate or moderate-to-severe when

symptoms impair with activities of daily life, but are not necessitating immediate hospitalization. Fulminant UC necessitates IV therapy in hospital as described below and regardless of previous oral steroid use[3].

APPROACH TO SEVERE ATTACKS OF ULCERATIVE COLITIS

Only 15 to 20 percent of patients with UC will ever experience an attack of fulminant colitis[4]. Patients with pancolitis appear to be predisposed to severe flares (Figure 1). Severe UC is a serious, potentially life threatening condition and hospitalization should be considered in all patients who have more than 6-10 bloody stools per day, associated with fever, dehydration, tachycardia malaise and/or increased C-reactive Proteine (CRP)[3,4,5]. Patients entering hospital with fulminant colitis should be evaluated for other causes of severe colitis. We always perform an unprepped sigmoidoscopy to assess disease severity, to obtain mucosal biopsies, and to provide a baseline assessment. Total colonoscopy and ileoscopy should not be attempted as it carries the risk of inducing toxic megacolon. As a rule sigmoidoscopy in fulminant colitis should be performed by an experienced endoscopist with minimal inflation and at the first sign of discomfort from the patient no further proximal progression should be attempted. Infectious colitis should be excluded with stool culture for bacterial pathogens, C. difficile toxin test in stools and ova/parasites in a fresh stool sample and careful assessment of the mucosal biopsies. The likelihood of infectious colitis is geographically determined but should be considered in all patients. Although the precise role of active cyto-megalo virus (CMV) replication in fulminant colitis is still debated, the presence of CMV inclusions in a colonic biopsy should be ruled out. In the recent patient history foreign travel and non steroidal anti inflammatory drugs (NSAID) use should be recorded. Clinically disease severity should be assessed using the criteria in the Lichtiger score including stool frequency, nocturnal diarrhea and fecal incontinence, rectal bleeding, abdominal cramping and tenderness and general well being. Others signs of fulminant colitis include fever, lethargy and dehydration. Blood analysis should include: serum albumine, electrolytes, hemoglobin, white blood cell count (WBD) and differential, CRP, blood urea nitrogen (creatinine) (BUN) and liver tests[2]. A plain abdominal X-ray should be obtained initially and at regular intervals during the hospitalization. We generally treat those patients with IV prednisolone (60 mg daily) or equivalent as a continuous infusion regardless of prior oral corticosteroid therapy. Pioneering studies by Truelove *et al*[1] have shown that applying this strategy 64 percent of patients will enter clinical remission and only 23 percent require rescue total procto-colectomy. Doses higher than 60 mg or 1 mg/kg prednisolone equivalent are not recommended. Although recent controlled evidence failed to show superiority of a continuous infusion of methyl-

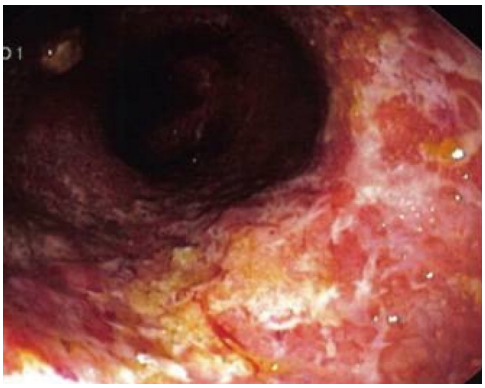

Figure 1 Endoscopic lesions compatible with severe colitis.

prednisolone 1 mg/kg IV daily over and IV bolus therapy at the same dose, most centers still prefer continuous infusion. Supportive therapy for this condition includes relative bowel rest and parenteral nutrition if needed. The value of antibiotics as a prophylactic or adjuvant therapy in the setting of fulminant colitis has not been established. However, patients with high fever, signs of peritonitis or high CRP levels should receive broad spectrum antibiotics (e.g. ciprofloxacin + metronidazole). Even so, initiation of antibiotics should never postpone the decision for procto-colectomy.

If patients fail to respond to three to five days of IV steroids, they should be considered for intensified medical therapy (described below) or colectomy[3,4]. Daily clinical follow up of these patients by both an expert surgeon and physician is required from that stage on and colectomy should be considered if the clinical condition of a patient worsens. Addition of rectal hydrocortisone drips or mesalamine enemas can be considered at this stage particularly in patients with symptoms secondary to left sided colitis.

THERAPY OPTIONS FOR PATIENTS FAILING IV CORTICOSTEROIDS

When patients fail three to five days of IV corticosteroids at adequate doses and continue to report frequent bloody diarrhea with fever or high CRP levels, they should be considered for surgical colectomy or rescue medical treatment[3,4]. Complications such as toxic megacolon or uncontrolled bleeding should favor the decision towards surgical intervention.

Intravenous cyclosporine has been shown to be an effective rescue therapy for severe UC attacks in two controlled trials[6,7]. In the trial by Lichtiger *et al*, 9 out of 11 IV 4 mg/kg cyclosporine treated patients avoided colectomy versus none of the 9 placebo treated patients. Data from one mono center controlled trial in 73 patients indicate that 2 mg/kg per day IV cyclosporine initial treatment may prove as effective for severe attacks of UC, although not all of these patients were failing intravenous corticosteroids[8]. When results from controlled and non-controlled trials are pooled 76 to 85 percent of patients will respond to IV

cyclosporine and avoid colectomy short term. Before the initiation of Ⅳ cyclosporine hypomagnesemia and hypocholesterolemia should be corrected to decrease the risk neurologic toxicity. After an initial dose of 2 mg/kg, daily cyclosporine doses should be adjusted to achieve therapeutic blood levels from day two onwards. Therapeutic ranges for cyclosporine blood levels may vary based on the assay used. The median time to response for Ⅳ cyclosporine is four to five days and in patients responding, initiation of oral cyclosporine therapy at 5-8 mg/kg divided in two doses should be considered along with gradual steroid tapering and initiation of azathioprine or 6-mercaptopurine. While patients are on a triple immunosuppressive regimen prophylaxis against *Pneumocystis carinii* pneumonia should be given and alertness for opportunistic infections in general should be high. Cyclosporine use in UC has been associated with mortality and most of the fatalities were due to opportunistic infections[9]. Other complications of cyclosporine therapy include nephrotoxicity, tremor and convulsions, hypertension, gingival hyperplasia and hypertrichosis. Rare cases of anaphylaxis are contributed to the solvent in Sandimmun, the commercially available formulation of cyclosporine, and occurrence of anaphylaxis allows treatment with oral cyclosporine.

Following initial response to cyclosporine for fulminant UC about 50 percent of patients avoid colectomy at three years[9-12]. Lower colectomy free rates have been recently reported with follow up extending to seven years[11]. The patient population already failing adequate courses of azathioprine or 6-MP is most prone to colectomy following initial response to cyclosporine[10,11].

Tacrolimus an oral cyclosporine can be considered to treat severe attacks of ulcerative colitis but only retrospective uncontrolled data are available[13-15].

INFLIXIMAB

The efficacy of infliximab in the setting of severe UC not responding to therapy with intravenous steroids has been demonstrated recently in a small placebo controlled trial. Significantly more patients treated with placebo (14/21) required surgical colectomy by three months as compared to those treated with a single dose of infliximab 5 mg/kg Ⅳ (7/24)[16]. Open label experience in patients with severe UC attacks has been inconsistent[17,18]. In a recent publication from the colorectal surgery group at the Mayo Clinic, Rochester, MN, an increased risk of infectious postoperative complications was found in a group of infliximab treated patients as compared to controls[19]. It should be noted however, that disease severity, use of immunosuppressives and Ⅳ steroids was higher in the infliximab group. Other retrospective cohorts and the controlled Scandinavian trial have not confirmed this increased complication risk. However, preliminary results from a cohort of patients treated at the Mount Sinai hospital in New York suggest that patients receiving infliximab followed by cyclosporine or vice versa have a substantial risk of serious adverse events including mortality[20]. Data on long term avoidance of colectomy with infliximab are as of yet not available, but there is no indication that infliximab would increase surgical complications.

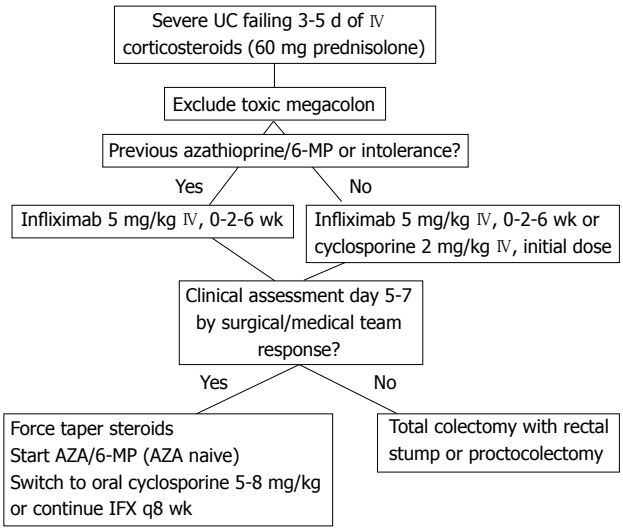

Figure 2 Proposed treatment algorithm for the management of severe steroid refractory ulcerative colitis.

SURGICAL COLECTOMY

Surgical proctocolectomy with ileo-anal pouch anastomosis is a valid option for patients with moderate to severe UC failing medical therapy. Patients should be counseled about the option of surgery, short term complication and long term outcomes of pouch surgery, early in the course of a severe flare of UC. Also from the first day of hospitalization the surgical team should be involved in the management of the patient with fulminant UC.

EXPERT OPINION

Patients with severe attacks of UC should be hospitalized and closely monitored. After failing three to five days of intravenous corticosteroids, patients should be considered for intravenous cyclosporine (2 mg/kg per day), for infliximab (5 mg/kg Ⅳ) or for surgical colectomy. Cyclosporine is most useful as a bridge to the effect of azathioprine or 6-MP and should be considered particularly in this setting. Long term colectomy free survival rates after initial response to cyclosporine are far from optimal and we have no long term data with infliximab yet. However, in patients with a dramatic response to any of the two immune therapies a delayed elective colectomy later in the disease course may be a noble goal *per se*. In patients failing Ⅳ steroids, he risk of, even fatal, serious infections with cyclosporine is clearly increased and also patients responding to infliximab should be closely monitored for opportunistic infections. Finally, only a head to head comparison of cyclosporine and infliximab in a prospective trial will be able to conclusively guide us in immediate decision making (Figure 2).

Abstract

Inflammatory bowel disease (IBD) includes two entities, Crohn's disease and ulcerative colitis. Both are chronic conditions with frequent complications and surgical procedures and a great impact on patient's quality of life. The thiopurine antimetabolites azathioprine and 6-mercaptopurine are widely used in IBD patients. Current indications include maintenance therapy, steroid-dependant disease, fistula closure, prevention of infliximab immunogenicity and prevention of Crohn's disease recurrence. Surprisingly, the wide use of immunosuppressants in the last decades has not decreased the need of surgery, probably because these treatments are introduced at too late stages in disease course. An earlier use of immunossupressants is now advocated by some authors. The rational includes: (1) failure to modify IBD natural history of present therapeutic approach, (2) demonstration that azathioprine can induce mucosal healing, a relevant prognostic factor for Crohn's disease and ulcerative colitis, and (3) demonstration that early immunossupression has a very positive impact on pediatric, recently diagnosed Crohn's disease patients. We are now awaiting the results of new studies, to clarify the contribution of azathioprine, as compared to infliximab (SONIC Study), and to demonstrate the usefulness of azathioprine in recently diagnosed adult Crohn's disease patients (AZTEC study).

Key words: Inflammatory bowel disease; Crohn's disease; Ulcerative colitis; Immunosuppressants; Azathioprine

INTRODUCTION

IBD and azathioprine

Inflammatory bowel disease (IBD) includes two main entities, ulcerative colitis (UC) and Crohn's disease (CD). Both are chronic, inflammatory disorders of the gastrointestinal tract, with an increasing prevalence in developed countries. IBD affects patients early in life, resulting in an enormous personal, social and economic burden. Although the etiology of IBD remains unknown, major progress has been done in our understanding of IBD pathophysiology in recent years. We now believe that IBD develops in genetically predisposed individuals, due to an abnormal recognition of microbiota antigens by certain elements and cells of the innate immunity, leading to a deregulated immune reaction and, ultimately, resulting in bowel inflammation and injury [1].

Treatment of IBD has greatly evolved in the last two decades. A better understanding of IBD pathophysiology has progressively resulted in a more frequent use of inmunossupressants, such as azathioprine (AZA), mercaptopurine and methotrexate and the arrival of the so called "biological therapy", represented by the anti-TNF-α antibodies. Whether this "more aggressive" approach has really had any impact on IBD patient's outcome is still a matter of controversy. As an example, an interesting work by Cosnes and colleagues revealed that, in spite of the striking increase in the azathioprine use in CD patients, the natural history of CD, as judged by the percentage of CD patients requiring surgical resection, had remain unchanged over the last 40 years

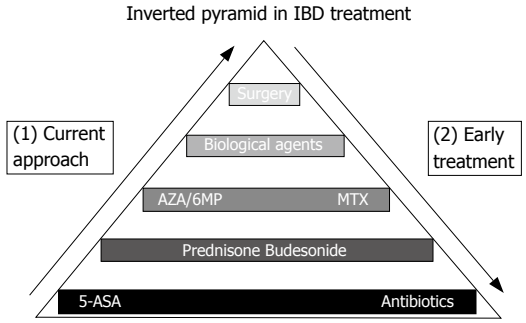

Figure 1 Inverted pyramid. Represents two different treatments approaches in IBD: (1) Current practice: Initially treatment with 5-ASA and antibiotics and then depends on the responsiveness scale to steroids, immunomodulators and biological agents. (2) Top-Down strategy: New tendencies. Initially aggressive treatment with early immunosuppresion and biological therapy.

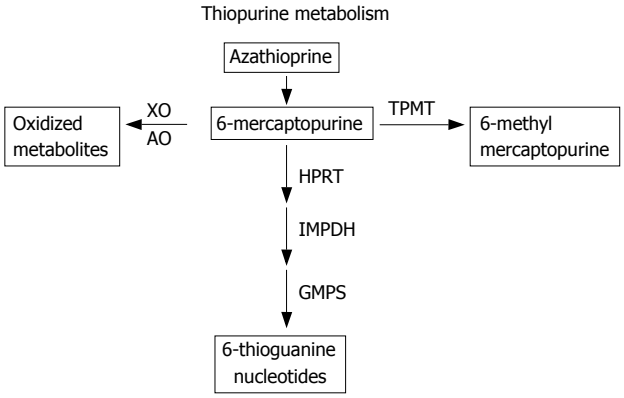

Figure 2 Metabolism of azathioprine (AZA): AZA is converted to 6-mercaptopurine (6-MP). 6-MP by thiopurine methyltransferase (TPMT) and xantino oxidase (XO) in inactive metabolites, but phosphoriboxyltransferase (HPRT), inosine monophosphate dehydrogenase (IMPDH) and guanosine monophosphate synthetase (GMPS) catalize the synthesis of active 6-thioguanine nucleotides (6-TGNs).

and until our days[2]. Although the results of this study might indicate indeed that azathioprine is unable to modify CD natural history, a closer view of this study reveals that in most CD patients azathioprine had been introduced really late in the patient's course, often after the development of a penetrating phenotype or following a surgical procedure. This fact sets the notion that an early use of immunosuppressants might result in a significant impact on IBD patient's natural course.

The aim of this article is to make a critical analysis of the current use of thiopurines, but also attempts to analyze the new tendencies in terms of optimal time to initiate immunosuppression with antimetabolites in IBD (Figure 1).

Pharmacology of azathioprine

6-Mercaptopurine (6-MP) and its prodrug azathioprine are thiopurine analogues and are immuno-modulatory agents. Of the AZA compound, 88% is converted *via* nonenzymatic process to 6-MP. Then 6-MP undergoes several enzymatic pathways and is transformed to active and inactive metabolites (Figure 2). The first step in the 6-MP metabolism is a catabolic process by xanthine-oxidase, which is present in the intestinal mucosa and liver, resulting in inactive oxidized metabolites, such as 6-thiouric acid. 6-MP also serves as a substrate for the thiopurine methyltransferase (TPMT) which, by methylation, converts 6-MP into inactive metabolites, such as 6-methyl mercaptopurine. Anabolic processes led to the synthesis of active metabolites. First hypoxanthine phosphoribosyltransferase initiates the transformation of 6-MP into active metabolites, or 6-thioguanine nucleotide[3-4]. These nucleotides act as purine antagonists interfering DNA and RNA synthesis which has been demonstrated to result in a significant inhibition of lymphocyte proliferation and a decreased immunity response.

Not all individuals methylate thiopurines equally, a series of processes that depend on the genetic variability in the TPMT activity. The TPMT gene is inherited as an autosomal co-dominant trait. Most of the Caucasian population (about 89%), have normal to high enzyme activity (known as homozygous wild-type TPMT), 11% have intermediate enzyme activity (heterozygous TPMT) and 0.3% have low or absent enzyme activity (homozygous mutated TPMT). The two last groups are associated with major elevations of 6-TGN levels and an increased risk of adverse effects[3,5]. This genetic variation can be studied at different levels. First, the genetic study will ascertain the patient's genotype. Second, it is also possible to measure the enzyme activity in a blood sample. Third, also the blood levels of active and inactive, methylated metabolites can be quantified. A widely accepted consensus on the best way to address this issue has not been achieved to date.

Safety of azathioprine

There is little doubt that patients treated with azathioprine have a higher rate of adverse events than placebo treated patients. A Cochrane meta-analysis, by Sandborn and colleagues, analyzed the usefulness and safety of AZA and 6-MP when used to induce remission in CD patients[6]. In this meta-analysis, adverse events occurred in 9.3% of patients taking AZA or 6-MP *versus* 2.3% of those taking placebo. The number needed to harm (number of patients that should be treated to develop a single adverse event) was 14. Pearson and colleagues also addressed the issue of azathioprine safety in another Cochrane meta-analysis, but specifically devoted to patients receiving this drug as maintenance therapy for CD. Drug withdrawal due to adverse effects were found in 5.8% of patients receiving thiopurines, as compared to 1.3% of patients without treatment. In this case, the number needed to harm was 19[7].

Classically, AZA-related adverse events have been categorized in two types: allergic, idiosyncratic or none dose dependent, and dose-dependent. Allergic reactions include, among others, malaise, rush, fever, pancreatitis and hepatitis. All of them are infrequent, occurring in a 5%-10% of AZA-treated patients. These adverse events are not related to the dose of AZA used or the variations in drug metabolism. In general, dose dependant adverse effects are much more frequent than the previous.

Table 1 Vienna classification of Crohn's disease[12]

Parameter	
Age at diagnosis	A1 < 40 yr A2 ⩾ 40 yr
Maximal location of disease prior to first surgery	L1 Terminal ileal L2 Colonic L3 Ileocolonic L4 Any upper GI, regardless of disease elsewhere in bowel
Disease behavior	B1 Nonstricturing, nonpenetrating (inflammatory) B2 Stricturing B3 Penetrating disease Behavior could be defined at any time after diagnosis

Table 2 Montreal classification of Crohn's disease[13]

Parameter	
Age at diagnosis	A1 ⩽ 16 yr A2 17-40 yr A3 ⩾ 40 yr
Maximal location of disease prior to first surgery	L1 Terminal ileal L2 Colonic L3 Ileocolonic L4 Upper GI only +L4 Additional designation to be added if patient has upper GI and distal disease
Disease behavior	B1 Nonstricturing, nonpenetrating (inflammatory) B2 Stricturing B3 Penetrating disease *P* = Perianal penetrating disease Recommended behavior assessed > 5 yr after diagnosis

Bone marrow suppression is the most common dose-dependent adverse effect. Leukopenia appears in 2% to 15% of AZA-treated patients, depending on the cut-off used for its definition, is influenced by the degree of TPMT activity and can modified by other concomitant drugs if they impact the enzyme activity. Such myelosuppression is reversible upon AZA dose reduction or transient suspension of the drug.

Another potential source of AZA-related adverse reactions steam from the immune suppression caused by the drug. AZA and 6-MP therapy is associated with an increased risk of infections ranging from 0.3% to 7.4%[8]. The most common are viral infections, such as cytomegalovirus, Epstein-Barr virus, varicella zoster virus and herpes simplex virus. Noteworthy, infections can occur in the absence of leukopenia. Thiopurine-induced liver toxicity is also a relevant issue. It's incidence varies between 3% and 10% of AZA-exposed patients and it can be classified into different entities: hypersensitivity, idiosyncratic cholestatic reaction, and endothelial cell injury (the later resulting in raised portal pressures, veno-occlusive disease or peliosis hepatis)[9]. The majority of these syndromes respond to drug withdrawal.

Finally the relationship between thiopurines and development of cancer, and specially hematologic malignancies such as lymphomas, remains a controversial topic. A meta-analysis of risk of malignancy associated to the use of immunosuppressive drugs in inflammatory bowel disease identified 9 studies reporting colorectal cancer, malignant melanoma, leukemia and lymphoma cases. The weighted mean difference of malignancy incidence in IBD patients who received immunosuppressive agents, as compared to IBD patients not exposed to immunosuppressants, was -0.3×10^{-3}/person per year. There was no significant difference when the authors analyzed the length of exposure to immunosuppressants or whether the patients had CD or UC[10]. The issue of relationship between lymphoma and IBD is complex, because the effect caused by the disease "*per se*", by disease activity, and by different IBD therapies clearly overlap. In a Meta-analysis of Kandiel and colleagues[11] they identify 6 cohort studies with AZA or 6-MP exposure that have been specifically designed to evaluate cancer as adverse outcome. The total number of observed cases was 11 with a pooled relative risk of 4.18. Because these data were obtained from observational studies it is not possible to fully exclude the possibility of severity of the disease as confounding factor. As a global conclusion, the consensus about the relationship between immunosuppressants and lymphoma is that, if any association exists, it would be of small magnitude and, in any case, the beneficial effects exerted by these drugs on IBD patient's outcome would clearly overweight the risk caused by the drug itself.

PRESENT USE OF AZATHIOPRINE IN IBD

Use in Crohn's disease

Crohn's disease is a heterogeneous entity that requires an individual approach. Several attempts have been done to homogenize CD evaluation. The classification obtained as result of the consensus effort held in Vienna, in 1998[12], categorize CD in subgroups according age at diagnosis, disease location and disease behavior (inflammatory, fistulating or stenosing) (Table 1).

In spite of its initial usefulness, significant advances have been made in recent years. It has become clear that children have different presentation, disease location can be simultaneous in different segments of the bowel and disease behavior is dynamic. Because of these in 2005 the Montreal classification[13] added a separate category for children with onset at ⩽ 16 years, acknowledged the coexistence of CD in the upper GI tract with distal disease and differentiated between internal and perianal penetrating disease (Table 2).

AZA to induce CD remission

Because of the delayed onset of action of thiopurines analogues, even with intravenous administration[14], this drugs have been most frequently used, with concomitant use of steroids or more recently with infliximab[15], in patients with active disease in the context of corticosteroid-dependent CD. A Cochrane database meta-analysis[6] found eight randomized,

placebo-controlled trials in adults that evaluated the use of azathioprine or 6-mercaptopurine in active Crohn's disease. The outcome measure was the proportion of patients with clinical improvement or remission (as defined by the CDAI score, the Harvey-Bradshaw Index, subjective evaluation or steroid sparing effect). The pooled response rate was 54% for the group with thiopurine analogues *versus* 34% for the placebo treated patients, with a peak response odds ratio reached at 17 wk of therapy. The number needed to treat is 5 in order to benefit 1 patient.

In clinical practice the use of azathioprine as monotherapy to induce remission in active CD is very rarely indicated, due to its delayed action. In mild-to-moderate, chronically active CD, AZA can be an option in selected patients.

AZA to obtain a steroid–sparing effect in CD

The efficacy of AZA and 6-MP, as compared with placebo, in the subgroup of corticosteroid-dependent CD is well established. This effect is observed in patients with active CD and in patients with quiescent but corticosteroid-dependent disease. Both scenarios were analyzed in two Cochrane Database Meta-analyses.

In active disease, five studies showed that the use of antimetabolites results in a pooled reduction from 65% to 36% in the percentage of patients receiving steroids, as compared to the placebo group. In this case, the number needed to treat to obtain a steroid-sparing effect was 3 patients[6].

In patients with clinical remission but corticosteroid-dependent behavior, only two small studies (overall 30 patients) were randomized, double-blind, placebo-controlled. The global effect in reduce steroid consumption was 87% (13/15) for the AZA group *versus* 53% (8/15) for the placebo group with a number needed to treat for one reduction in steroid consumption of 3[7].

AZA to maintain remission in CD

Once CD is quiescent, the thiopurine analogues are a very effective therapeutic option to maintain disease remission. This situation was analyzed by Pearson and colleagues in a Cochrane Meta-analysis. They found five trials that satisfied the inclusion criteria as randomized, double-blind, and placebo-controlled. In spite the variability in terms of doses and duration of therapy, the overall remission maintenance was 67% with AZA compared with 52% of the placebo group. It's worth to mention that the effect is dose-dependent with optimal benefit at dose of 2.5 mg/kg per day[7]. All these data support the use of antimetabolites as maintenance therapy.

In the pediatric study by Markowitz and colleagues[16], only 4% of patients (1 children) of the 6-MP group required another course of steroids within 540 d, after being weaned off of prednisone, clearly in contrast to the 57% of pediatric CD patients receiving placebo which need to restart prednisone within 360 d ($P < 0.0001$).

AZA to prevent disease recurrence after surgery in CD

The incidence of surgery in the course of CD is very high, reaching a cumulative risk of 78%-91% in some classic studies[17-18]. Postoperative recurrence approaches the 100% of patients, at 3 years, when assessed endoscopically[19]. Fortunately, clinical recurrence and the need for repeated surgery are lower (15%-45% after 3 years). AZA and 6-MP are effective as a therapy to prevent disease recurrence. AZA or 6-MP are probably more efficacious than 5-ASA compounds, but the design of the studies aimed at clarifying this issue does not allow a strong statement in that respect[20-21].

AZA to induce remission in fistulizing CD

The risk of developing internal or perianal fistulas is really high in CD patients and close to 50% of them will develop any form of penetrating behavior in a lifetime. The rate of complete healing with the available medical treatments is 50% and multiple relapses are frequents. In the Cochrane Database Meta-analyses perfomed by Sanborn and colleagues, 55% of the patients with AZA compared with 29% of the placebo treated patients achieved a response. The number needed to treat to observe one patient with fistula healing was 4, which confirms that AZA is a potent therapeutic strategy for this type of CD-related complications[6].

Use in ulcerative colitis

There are less robust data of the use of thipurine analogues in UC compared to CD. In active disease most of the studies evaluated the remission of the disease in the context of corticosteroid-dependant or resistant disease with co-medication with aminosalicylates, steroids or biological agents, not as monotherapy treatment. In a prospective trial of Ardizzone *et al*[22], 72 patients with steroid dependant UC were randomized to receive azathioprine 2 mg/kg per day or oral 5-aminosalicylic acid (5-ASA) 3.2 g/day for a 6 months follow up. The AZA group achieved a clinical and endoscopic remission of 53% compared with 19% of the 5-ASA group ($P = 0.006$). There is no doubt of the efficacy of AZA and 6-MP as steroid-sparing agents in subjects with corticoid- dependence and for maintenance in patients with remission induced by cyclosporine or in whom have failed or cannot tolerate standard maintenance therapy with aminosalicylates. A recent Cochrane Database Meta-analyses by Timmer *et al*[23], found 6 studies which examined the efficacy of purine antimetabolites compared to placebo or standard maintenance therapy in ulcerative colitis. In the pooled analysis, azathioprine was superior to placebo for maintenance of remission. 56% of patients treated with AZA were on disease free after one year of treatment compared to 35% of patients who received placebo. The number needed to treat is 5 in order to benefit 1 patient. In summary, azathioprine is effective in maintenance therapy for patients who have failed or cannot tolerate aminosalicylates and patients who require repeated courses of steroids.

Length of AZA treatment

The question how long thiopurines should be continued and until how long there is a really benefit of this therapy in patients that achieved remission is not

complete resolved. The study's results are contradictory. The first who evaluated this issue was O'Donoghue in 1978 in 51 CD patients who were receiving AZA for at least 6 mo. The cumulative probability of relapse at 1 year was 5% for the AZA treated group *versus* 41% in the placebo group ($P < 0.01$)[24]. After this first report, several studies tried to further clarify this issue. A multicenter, randomized, double-blind, noninferiority withdrawal trial in CD patients who were in remission on AZA treatment for $\geqslant$ 3.5 years showed that the mean relapse rate at 18 mo in patients who stopped the drug was nearly 3 times that observed in those who were maintained on treatment (21.3% *vs* 7.9%). Therefore the authors recommended continuing with AZA maintenance therapy beyond 3.5 years[25]. Another retrospectively study in 1176 patients with IBD (CD and UC) from 16 European centers showed that within the first 4 years of treatment, AZA diminished the incidence of flares and steroid consumption in both diseases and continuation beyond 4 years improved clinical activity and steroid requirements[26]. Conversely to the mentioned study, Bouhnik Y and colleagues found that in CD patients who were in clinical remission taking AZA or 6-MP after 4 years of remission on these drugs, the risk of relapse is similar whether the therapy was maintained or stopped[27]. Recently, Mantzaris *et al* published a prospective, investigator-blind study in patients with steroid-dependant Crohn's disease in remission on AZA. They stratified patients in two groups: Group A, consisted of patients receiving continuously azathioprine for between 2 and 4 years and Group B; which consisted of patients receiving azathioprine for between 4 and 8 years. The annual relapse rate in Group A was 19.6% *versus* 11.9% in the Group B without significant difference ($P = 0.67$)[28]. For the clinician's point of view, and taking into account the published evidences, an individual decision is often required.

THE FUTURE: TOWARDS AN EARLIER USE OF AZATHIOPRINE IN IBD

Why early azathioprine? Natural history of CD

CD is a progressive condition, characterized by a frequent development of CD-related complications, such as internal fistulas and abscesses, perianal fistulas and bowel strictures. This results is a high surgical requirement, with a significant proportion of CD patients receiving bowel resection at some point. One of the key factors determining the natural history of CD is the disease duration, since an increasing number of complications have been described over time. Louis *et al* assessed retrospectively the evolution of the disease after 1 to 25 years since diagnosis. At diagnosis, 73.7% of patients had an inflammatory phenotype while at 20 years only 12% had this phenotype and 32% and 48.8% had structuring and penetrating behavior respectively. The proportion of patients who had surgery over a 10 year period was 30.4% being higher in the subgroups B2 and B3[29].

In the study of Cosnes *et al*, they evaluated retrospectively 2002 patients with CD. The rate of complication was 80% at 20 years. At 5 and 20 years after diagnosis, the actuarial risks for stricturing disease alone were 12% and 18% respectively, whereas they were 40% and 70% respectively for penetrating disease[30].

Two main conclusions can be obtained from these results, both supporting an early use of AZA/Immunossupressants in CD. First, overall, CD patients have a poor outcome, regardless of the present medical therapy offered to them, and development of complications occur in three out of four patients in their lifetime. Second, CD offers a great opportunity for aggressive, earlier treatment, because almost all patients are complication-free at diagnosis. The mentioned penetrating and stenosing complications will slowly develop in the years following diagnosis which offers physicians a wide timeframe to introduce more efficacious drugs, early in CD course.

Mucosal healing

Mucosal healing (MH) is defined as a normal or mildly altered endoscopic appearance of the mucosa. The clinical relevance of MH has been recently underlined by different authors. In a Norweigan population cohort they prospective analyzed 740 incident patients diagnosed with UC and CD and evaluated MH at 1 and 5 years. At 5 years UC patients with MH had significant low risk of future colectomy ($P = 0.02$) and for patients with CD, MH was significantly associated with less inflammation ($P = 0.02$) and decreased future steroid treatment[31].

Not all IBD therapies impact equally MH. Glucocorticosteroids are not very effective in achieving MH in CD patients and a poor correlation between clinical and endoscopical parameters has been described. Moreover, endoscopic remission in colonic CD is of 29% and in ileal disease almost null[32-33]. Conversely to steroids, immunosuppressants and biological agents are associated with a high rate of MH. In a study of D'Haens *et al* of 19 patients with recurrent Crohn's ileitis treated with azathioprine, 15 could be re-evaluated at 6 mo, of them 6 patients had complete MH and 5 near complete healing[34]. Another study from the same group analyzed 20 patients with Crhon's colitis or ileocolitis who achieved symptoms relief with corticosteroids and in clinical remission with at least 9 mo of treatment with AZA. The ileocolonoscopy at 24.4 mo show 70% of complete healing and 10% of near-complete healing[35]. In respect to infliximab therapy, several studies have demonstrated efficacy for these drug in MH[36-38]. Two other studies demonstrated recently that combined immunosuppression with azathioprine and infliximab are more effective in terms of bowel MH respect to each one separately[15,39], but both were done at relative short term (1 and 2 years respectively).

If we believe that MH is indeed a relevant clinical outcome, as a growing body of evidence seem to suggest, then we have a strong reason to recommend an earlier and wider use of both immunosuppressants and biological agents, which have clearly demonstrated their

ability to induce MH. Although not formally proven yet, it seems very reasonable to admit that maintaining an endoscopically normal mucosa over time should result in a higher proportion of patients maintaining disease remission and also in a lower risk of developing CD-related complications, such as fistulas and strictures.

First results as proof of concept

The most solid, evidence-based prove to recommend an earlier use of immunosuppressants come from the pediatric study by Markowitz and colleagues[16]. They conducted a prospective, double-blind, placebo-controlled, 18 mo clinical trial in children newly diagnosed of CD. 55 subjects were included and were randomized to receive 6-mercaptopurine 1.5 mg/kg body weight daily in the treatment group, or placebo. Both groups received corticosteroids to achieve the control of the first flare of their CD. In the 6-MP group, the duration of steroid use was shorter (observed-to-expected ratio of days with prednisone of 0.73 *versus* 1.34 in the control group, $P < 0.001$). This results supports the use of 6-MP as induction therapy in combination with corticosteroids in active Crohn's disease.

The "step-up *vs* top-down" study, by D'Haens and colleagues[39] is also very relevant to support the notion that introducing the most efficacious IBD drugs early in disease course has a significant impact on CD patients outcome. This randomized study compared the conventional therapeutic approach ("step-up") with a newer, more aggressive strategy ("top-down"). In the "step-up group" patients were treated first with steroids and, in case of steroid dependency or resistance, immunosuppressants and infliximab were used. In the "top-down group" patients received upfront a combined treatment of immunossupressants and infliximab. This study clearly demonstrate the superiority of the "top-down" over the "step-up" approach, as demonstrated by a significantly higher proportion of patients in remission and showing MH in the "top-down", as compared to the "step-up" group. Interestingly, this higher efficacy did not carry a higher proportion of side effects in the "more aggressively", "top-down" treated patients. One of the drawbacks of this study is the lack of long-term follow up, especially in respect to the potential impact of prolonged, intense immune suppression on the risk of developing severe infections or cancer.

Several studies, ongoing at present, will help to clarify this issue and, maybe, will provide further evidence to support an early use of azatioprine in IBD. One is the SONIC study, aimed at comparing the use of AZA alone *versus* infliximab alone *versus* combined therapy. The other, the AZTEC study, a Spanish multicenter randomized study aimed at reproducing the efficacy of AZA in recently diagnosed CD, but in adults.

Abstract

Azathioprine is currently the key drug in the maintenance treatment of inflammatory bowel diseases. However, there are still some practical issues to be resolved: one is how long we must maintain the drug. Given that inflammatory bowel diseases are to date chronic, non-curable conditions, treatment should be indefinite and only the loss of efficacy or the appearance of serious side effects may cause withdrawal. As regards to efficacy and their maintenance over time, evidence supports the continuous usefulness of the drug in the long term: in fact its withdrawal very substantially increases the risk of relapse. About side effects, azathioprine is a relatively well tolerated drug and even indefinite use seems safe. The main theoretical risks of prolonged use would be the myelotoxicity, hepatotoxicity, and the development of cancer. In fact, serious bone marrow suppression or serious liver damage are uncommon, and can be minimized with proper use of the drug. Recent metanalysis suggests that the risk of lymphoma is real, but the individual risk is rather low, and decision analysis suggests a favorable benefit/risk ratio in the long term. Therefore, in patients with inflammatory bowel diseases in whom azathioprine is effective and well tolerated, the drug should not be stopped. This recommendation concerns the use of azathioprine as a single maintenance drug, and is not necessarily applicable to patients receiving concomitant biological therapy.

Key words: Azathioprine; Inflammatory bowel diseases; Maintenance treatment

INTRODUCTION

Azathioprine (AZA) is an effective drug in the treatment of inflammatory bowel disease (IBD), particularly in the maintenance of remission of patients with a complex clinical course, and there is little doubt that once indicated should be maintained for an extended period of time. However, when it takes some time without symptoms or signs of disease activity, both clinicians and patients often arise: should I withdraw the drug? After this question lies another: if I should withdraw it, when it's time? Given the chronic nature of these diseases, only two reasons could actually lead to the withdrawal: a loss of efficacy over time or appearance of adverse events that exceed the benefits of the drug. Our goal is to review the available evidence for answering the main question posed by the title of the article. Note that although we refer in the article usually only to AZA, all the above aspects are also valid for its active metabolite, mercaptopurine.

DOES AZATHIOPRINE MAINTAIN ITS EFFECTIVENESS IN THE LONG-TERM?

The long-term effectiveness of AZA in the maintenance of Crohn's disease (CD) is demonstrated in several clinical trials (5 randomized control trials[1-5]), a meta-analysis[6] and a Cochrane review[7]. In this last review, the rate of remission with and without AZA was 67% and 52% respectively, with an odds ratio of 2.16 (95% CI 1.35-3.47) and an NNT of 7 to prevent a relapse. These figures greatly improve if you use the adequate dose of the drug (using 2.5 mg/kg odds ratio increases to 4.13). This same study reflects its value in saving steroids with an NNT of approximately 3[7]. In addition, observational studies corroborate these findings. Thus, in one of the most important of these studies (many patients included and longer follow up), which include CD and ulcerative colitis patients, the life table analyses show that maintenance with AZA is clearly useful for up to 5 years

in both entities[8]. In another multicenter european study, aimed to evaluate the long-term effectiveness of the immunomodulators in IBD, results are quite similar[9]. It included 818 CD and 358 CU IBD patients treated with thiopurinic immunomodulators. The prolonged treatment with these drugs was associated with a lower relapse rate and steroid use. In the case of ulcerative colitis (UC), the data are somewhat more limited but also demonstrate long-term effectiveness of AZA as a maintenance therapy. Several randomized studies have been published although the number of included patients is usually low. A recent Cochrane meta-analysis examines 6 randomized controlled studies (286 patients) of at least 12 mo of duration, which compare AZA (or mercaptopurine) against placebo or mesalazine for UC[10]. The meta-analysis concludes that AZA is more effective than placebo (4 trials) while it is not possible to analyse properly the comparison with the salicylates, due to the significant heterogeneity of studies included (2 trials). The effect of saving steroids, although not evaluated in this meta-analysis, is evident in other 3 controlled trials. In the first of them, a recent study not included in the previous meta-analysis and may be the best trial of AZA in UC to date, effectiveness of AZA in active steroid dependent UC is demonstrated[11]. In this study 72 patients with steroid dependent active UC, are randomized to receive mesalamine or AZA plus prednisolone. At 6 mo, clinical and endoscopic remission free of steroids was achieved in 53% of patients on AZA compared to 21% on mesalamina (OR 4.78, 95% CI 1.57-14.5). In the second trial, 30 patients with steroid dependent UC were treated with AZA or placebo for 6 mo[12]. While in the placebo group was not possible to reduce the doses of steroids, in the AZA group did it. In the third study, with very similar design, the results were similar but even more marked: in the placebo group steroid dose was decreased to 13 mg/day and up to 2.3 mg/day in the AZA group[13]. The observational data provided similar results in support of AZA for UC maintenance. The best evidence of these studies comes from the 30-years cohort from Oxford[8]. In this study the proportion of patients on strict remission at 5 years were 62%, and the median time to relapse 1.5 years. Another important data is that derived form a recent Spanish study[14]. In this prospective study, AZA therapy results in a clear steroid sparing effect and reduction in the number of hospitalizations and surgery in 394 IBD patients (CD and UC, with similar effectiveness). In addition we must emphasize that both in CD and UC, we have over 40 years of clinical experience which confirms the results of the studies previously mentioned.

Once established the effectiveness of AZA in the long-term maintenance, we will analyze what happens if the drug is withdrawn. Virtually all papers reveal a marked increase in the rate of relapse following the discontinuation of AZA. In the case of Crohn's disease, three randomized controlled trials specifically analyze the impact of withdrawing AZA, in CD patients in remission with this drug over a period of time more or less prolonged[4,15,16]. The three trials clearly show the damage that causes the withdrawal of AZA. First study included 51 patients with CD in remission for more than 6 months on AZA, which are randomized to continue on or discontinue AZA[4]. One year of follow up, the cumulative risk of relapse was 5% against 41% in groups with and without AZA ($P < 0.01$). In the second study, open one-year trial, CD patients treated with AZA in remission for 2 or more years, were randomized to continue or not with the drug[15]. At one year, 11/13 patients on AZA and 7/15 without AZA maintained remission ($P = 0043$), being the differences more pronounced when higher doses of AZA were used. In the third trial results are similar, but even when the patients maintained remission on AZA for longer period of time. In this study, 83 CD patients in remission on AZA at least 3.5 years ($\geq$ 42 mo), were randomized to continue or not the drug. One year and a half later, relapse rate was 8% in patients continuing AZA and 21% in patients that stopped the drug[16]. Observational studies commented previously, show similar data, although some with longer surveillance. This is the case study of Fraser, in which the proportion of patients (both CD and UC) still in remission after 12, 24, 36, 48 and 60 mo was 0.63, 0.44, 0.34, 0.28 and 0.25 respectively[8]. Duration of remission on prior AZA did not affect the relapse rate after stopping the drug. However, some authors initially suggested the withdrawal of AZA if the patient maintains remission for a prolonged period (about 4 years). This idea comes essentially from a study published in 1996[17], which showed that while the effectiveness of AZA is maintained over time, extended therapy more than 4 years could have no additional clinical benefit. Although this study had a surprising impact, it is retrospective and has important limitations (does not take into account factors such as smoking or causes of withdrawal of the drug, number of patients followed over 5 years was very small). Only appear somewhat similar results in another study, also commented previously[9]. These data contrast sharply with those offered by controlled studies and other observational studies, which show clearly beneficial to continue indefinitely AZA in the CD (see previously). In the case of ulcerative colitis, available data may be considered weaker again, although there are one controlled trial and some observational studies. The controlled study showed that withdrawal of AZA was associated with a higher relapse rate than when the drug was maintained[18]. It was a randomized trial although did not use a double blind design. Seventy nine UC patients on AZA for more than 6 mo were randomized to continue or not with the drug. The one year relapse rate was 36% and 59% in group with and without AZA respectively. Observational data clearly suggest that AZA treatment is useful, maintain this efficacy over time and that discontinuation of AZA is followed by higher rate of relapse, even in patients being in prolonged remission with the drug[19,20,8,9].

In short, solid evidence sustains that AZA (or mercaptopurine) is effective long-term maintenance

treatment of IBD and that their withdrawal is followed by a clear increase of relapse rate. No "safe" period of time being in remission on AZA (or mercaptopurine) has been established after which these drugs could be stopped with no risk of relapse.

WHICH IS THE SAFETY OF USING AZATHIOPRINE INDEFINITELY?

The safety profile of AZA is well known and we have very extensive follow up and long term data with this drug. Side effects are relatively common and can lead the withdrawal of treatment between 10% and 20% (for example in the Cochrane review for CD, adverse effects that conditioned the withdrawal of AZA were at 9.3%)[7]. However, most adverse events are seen at the beginning of treatment and once after the first few weeks, tolerance to the drug is generally very good. The main risks of indefinite use of AZA are myelotoxicity, hepatotoxicity and perhaps development of neoplasms. Myelotoxicity has an incidence of 3 cases per patient and year, is serious in only a small proportion (less than 10%), and can be prevented partly with proper analytical monitoring[21]. Serious hepatotoxicity is also rare, and usually less relevant from a clinical point of view[22]. Regarding to a theoretical increase of cancer, lymphomas especially, it is an issue still unresolved after years of use of the drug, but has made questioned long-term use of AZA. The results of individual studies are inconclusive. A recent meta-analysis assesses the results of the 6 cohort studies designed to analyze cancer as a side effect of treatment[23]. In this study, the pooled relative risk in IBD patients treated with AZA versus general population was 4.18 (95% confidence interval 2.07-7.51; 11 cases observed, 2.63 expected). As the studies are all observational, the increased risk of lymphoma could be a result of the medications, the severity of the underlying disease, or a combination of the two previous factors. The only real way to evaluate this risk at this moment is through a decision analysis, which suggests that the benefits clearly outweigh the risk[24]. This decision analysis was planned to evaluate the impact of AZA therapy on survival and quality-adjusted life expectancy, taking into account both benefits of therapy and potential risk of lymphoma. In the base-case analysis, CD treatment of patients with a steroid-induced remission with AZA resulted in an increase in average life expectancy of 0.04 years and 0.05 quality-adjusted years. The incremental gain in life expectancy decreased with increasing patient age and increasing risk of lymphoma. These results show that AZA in CD patients results in increased quality-adjusted life expectancy. This benefit was greatest in young patients who have the lowest baseline risk of lymphoma and who have the greatest life expectancy in the absence of a CD-related death. However, even in the worst scenario, the absolute individual risk is very low. Finally, in the extensive data available from registries as TREAT[25] and other recent safety studies[26,27], AZA is not associated with increased mortality as an independent factor, and there is no increase in mortality.

In short, the safety profile of AZA is well known, both by the wide experience in clinical use as by the great amount of available published data, and we can say that it is a relatively safe drug when used long term. Of course, these data are valid for AZA (or mercaptopurine) given alone. The association with other drugs, particularly biologics, could result in different risks, and long-term follow-up data are relatively few yet.

CONCLUSION AND RECOMMENDATIONS

When AZA alone (not associated with biological agent), adequately indicated, is maintaining remission in a patient with inflammatory bowel disease, we should not withdraw it, even after several years of treatment maintaining remission, except if significant adverse effects appear (grade recommendation: A; level of evidence: I). The withdrawal of AZA is one of the frequent mistakes in the treatment of IBD, as shown by various studies (see previously). As the professor Sacha'r said "no safe number of years has been determined after which these medications can be withdrawn without risk of relapse…", and "azathioprine works when you take it (and you take it enough amount of it), so do not stop AZA (and give it soon)"[28].

As regards to the use of AZA associated with biological agents, the questions are more and it is not possible to establish strong recommendations. The rationale to add AZA to biologics is to minimize antibody formation and thereby to enhance agent efficacy (or at least to prolong it) and reduce infusion reactions. Any case, we do not know yet the real impact of associating AZA to biologics in these items, and even less is known about the potential increase in adverse events, especially long term. The advantages of long term treatment maintaining the two drugs, in terms of efficacy and safety, must be demonstrated, especially when biologics are used as regularly scheduled infusions.

Only time (once again time…) will answer some of the questions raised about the use of AZA in inflammatory bowel disease. Until then, it is necessary to recognize current key role of AZA in this scenario to use it properly in our clinical practice, providing a significant benefit to our patients[29,30].

Abstract

Corticosteroids and immunomodulators have been the mainstay therapies for Crohn's disease. Corticosteroids are highly effective to control symptoms in the short-term, but they are not effective in maintaining remission, they heal the mucosa in a reduced proportion of cases, and long-time exposure is associated with an increased risk of infections and mortality. Immunomodulators, azathioprine and methotrexate, heal the mucosa in a higher proportion of patients that corticosteroids but their onset of action is slow and they benefit less than half of patients with Crohn's disease. In the last decade, medical therapy for Crohn's disease has experienced a remarkable change due to the introduction of biologic therapy, and particularly the use of anti-tumour necrosis factor-alpha agents. Infliximab, adalimumab, and certolizumab pegol have demonstrated efficacy for induction and maintenance of remission in active Crohn's disease. These agents have raised the bar for what is a suitable symptomatic response in Crohn's disease and modification of the natural history of the disease has become a major goal in the treatment of Crohn's disease. There are several data in the literature that suggest that early use of biologic therapy and achievement of mucosal healing contribute to disease course modification. However, many questions on early biological therapy for Crohn's disease remain still unanswered.

Key words: Biologic therapy; Crohn's disease; Corticosteroids; Immunomodulators

INTRODUCTION

To date, medical therapy for Crohn's disease has been restricted to treat the signs and symptoms of the disease, to prevent steroid dependence by using immunomodulating agents (azathioprine, 6-mercaptopurine, methotrexate), to maintain clinical remission, and to minimize medication toxicity. The introduction of biologic therapy, particularly the use of anti-tumor necrosis factor alpha (TNFα) agents (infliximab, adalimumab, certolizumab pegol), has provided a poweful instrument in the treatment and management of Crohn's disease that has lead to an expansion of goals in Crohn's disease therapy. These include a rapidly achieved and sustained clinical remission, complete and sustained healing of the bowel mucosa, reduction in steroid use, reduction in hospitalizations and surgeries, avoidance of complications of the disease (stenoses, fistulas), and improvement of patients' overall quality of life. Infliximab, adalimumab, and certolizumab pegol have demonstrated efficacy for induction and maintenance of remission in Crohn's disease. However, biologic agents are still used with reluctance, being the high cost and the uncertainty about long-term safety of these agents the most frequently cited reasons. An important question facing physicians that take care of Crohn's disease patients is at what point of the disease should biological therapy be used.

STEP-UP APPROACH

The standard treatment in Crohn's disease is based on a step-up approach in which "traditional" therapies thought to be more secure are used early and then successive therapies are added in case of lack of response or toxicity. Under this scheme, agents with low efficacy such as aminosalicylates may be used for long periods of time without any benefit. Patients who fail to respond to aminosalicylates are then treated with prednisone or budesonide if the disease is limited

to the ileum or the right colon. Corticosteroids are efficacious to induce remission in Crohn's disease patients but do not induce long-lasting remission[1]. About 40% of patients will develop a steroid-dependent or steroid-refractory course of the disease. In these cases, treatment with immunomodulating agents such as azathioprine, 6-mercaptopurine or methotrexate is started. Immunomodulation has long-term efficacy in inflammatory bowel disease but has limited value for induction of remission and benefits to less than half of the patients dependent or resistant to corticosteroids[2-6]. Under this therapeutic approach, population-based studies show that only 42% of Crohn's disease patients are symptom-free at 2 years after the initial diagnosis and 12% after 10 years, and that 10% of patients have chronically active disease in 2 years and 1% in 10 years[7]. Relapsing or chronically active disease leads to complications that often require surgical treatment that, unfortunately, does not cure or interrupt the progression of the disease[8]. Rates of surgical intervention remain high, with as many as one third of patients requiring surgey within a year of beginning oral corticosteroids[1] and with no significant decrease in the need of surgery in the last decades despite the earlier and increasing use of immunomodulators[9]. In the last years it has become also apparent that immunomodulators carry a significant safety risk for patients treated long term, including the risk of infection[10], lymphoma[11], cervical carcinoma[12], and nodular regenerative hyperplasia[13].

TOP-DOWN APPROACH

The ability of anti-TNFα agents to rapidly control disease symptoms and to heal the mucosa has raised the question of whether the early use of biological therapy in patients with newly diagnosed Crohn's disease can alter the course and natural history of the disease. In patients with early rheumatoid arthritis, initial combination therapy with high doses of prednisone and methotrexate or initial combination therapy with infliximab and methotrexate has shown to be more effective than sequential monotherapy or step-up combination therapy to prevent disease progression[14-18].

This concept, applied to Crohn's disease, has been tested in a trial carried out in Belgium, Holland and Germany by D'Haens *et al*[19]. This study included 133 patients with early Crohn's disease (defined as a diagnosis within the past 4 years) not previously treated with corticosteroids, immunomodulators or biological agents. Patients were randomly assigned to receive combined immunosuppression induction with azathioprine and three infusions of infliximab at weeks 0, 2, and 6 (n = 65) (top-down group), or to conventional therapy with two tapering courses of corticosteroids, and if indicated with azathioprine and then with infliximab (n = 64) (step-up group). Patients who were intolerant to azathioprine in both groups received methotrexate. Patients in the top-down group were given additional infliximab infusions in an "on-demand" basis and corticosteroids, if necessary, to control disease activity. The primary outcome was the combination of remission without corticosteroids and without bowel resection at weeks 26 and 52. At week 26, 39/65 (60%) of patients in the top-down group were in clinical remission without corticosteroids and without surgery compared to 23/64 (36%) in the step-up group (P = 0.0062) with an absolute difference of 24% (95% CI 7.3-40.8). At week 52, 40/65 (61.5%) in the top-down group were in remission compared to 27/64 (42.2%) in the step-up group (P = 0.0278), with an absolute difference of 19.4% (95% CI 2.4-36.3). After week 52, the proportion of patients in remission did no differ between the two groups. The median time to relapse was longer for patients in the top-down group (329 d, IQR 91-not reached) compared to patients in the step-up group (174.5 d, IQR 78.5-274, P = 0.031). Results from the IBDQs paralleled those of disease activity. At week 10, mean IBDQ score increased by 59.2 ± 36.6 points from baseline in the top-down group and by 37.4 ± 32.8 points in the step-up group (95% CI 8.7-34.9, P = 0.0014). Patients in the top-down group received significantly less methylprednisolone than patients in the step-up group. The 95th percentile of the daily methylprednisolone dose was 35 mg for patients in the step-up group and 0 mg for those in the top-down group. On the contrary, by the end of the trial 76% of patients in the step-up group were receiving an immunomodulator agent. After the completion of the induction course of infliximab in the top-down group, the proportion of patients on infliximab was similar in both groups. There were not important differences in the occurrence of adverse avents between the two groups, although the study was not primarly designed to address safety differences between the two strategies. The strongest argument for the top-down approach changing the natural history of Crohn's disease lies in the findings of the endoscopic studies performed in 49 patients of the study. At week 104, no ulcers were seen in 19/26 (73.1%) of patients in the top-down group compared with 7/23 (30.4%) in the step-up group (P = 0.0028). Endoscopic scores were 0.7 ± 1.5 and 3.1 ± 2.9, respectively (P < 0.001). This difference was marked despite the fact that there was no difference in disease activity scores between the top-down and step-up approaches at this timepoint. This leads to the notion that early introduction of biological therapy has direct benefits at an specific organ level (bowel) that far outreach the benefits of steroid sparing and overall clinical efficacy. The benefit of the early use of biological therapy has been demonstrated in rheumatoid arthritis, where the early introduction of biological therapy results in less joint damage on X-ray compared to a standard therapeutic approach using disease-modifying agents, regardless of similar clinical activity scores[16]. Mucosal healing has been associated with a reduction in hospitalizations and surgery for complications of Crohn's disease[20,21]. In the ACCENT I (A Crohn's disease Clinical study Evaluating Infliximab in a New long term Treatment regimen) trial[20], patients with short-term (week 10) and long-term (week 54) mucosal healing did no require hospitalization and patients with mucosal

healing at only one visit required fewer hospitalizations compared with patients without mucosal healing (18.8% *vs* 28%, respectively). If mucosal healing predicts a true change of natural history of the disease, these findings are of major significance.

This study has a number of aspects that should be pointed out. First, patients in the top-down group did not receive maintenance therapy with both azathioprine and infliximab. Rutgeerts *et al*[21] reported a significantly higher proportion of patients with mucosal healing in a maintenance infliximab group compared with those patients who received episodic treatment (50% *vs* 7%; $P = 0.007$). Thus, the study may have underestimated the benefit of combination therapy with an immunomodulator and infliximab administered on a regular basis. Second, the data suggest that infliximab might be used as a bridge to maintenance of remission with azathioprine. In a study by Lémann *et al*[22], 113 patients with steroid-dependent active Crohn's disease were randomized to azathioprine plus placebo or infliximab 5 mg/kg at weeks 0, 2, and 6. At weeks 24 and 54, the percentage of patients in remission and off steroids was higher in the infliximab group compared to the placebo group (57% *vs* 29%; $P = 0.003$ at week 24, and 40% *vs* 22%; $P = 0.04$ at week 54). However, episodic treatment is associated with immunogenicity that leads to hypersensibility reactions and loss of response to infliximab[23]. Third, in this study, azathioprine was started after two courses of corticosteroids, that may have underestimated the benefit of early introduction of conventional therapy with azathioprine. In a pediatric study by Markowitz *et al*[24], 55 children with newly diagnosed Crohn's disease were randomized to receive prednisone 40 mg/d with either 6-MP or placebo. Only 9% of the 6-MP treated group relapsed during a 18-mo follow-up period compared with 47% of the controls ($P = 0.007$). Candy *et al*[3] reported similar results in 63 adult patients with active Crohn's disease that were treated with a 12 wk diminishing dose of prednisolone and at the same time entered into a randomized, double blind 15 mo trial of either azathioprine (2.5 mg/kg) or placebo. Remission rates between the two groups were compared at 12 wk and at 15 mo. There was no significant difference in the proportion of patients who achieved and maintained remission by week 12, but at 15 mo there was a highly significant difference in the proportion of patients in remission (42% receiving azathioprine *vs* 7% receiving placebo, $P = 0.001$). Recent practice guidelines suggest that azathioprine should be introduced with the first course of corticosteroids[25]. Fourth, this study also underscores the fact that a proportion of patients will have a good clinical outcome at 12 mo irrespective of which treatment they receive. In other words, there is a proportion of patients with newly diagnosed Crohn's disease who do not require early intense treatment with biologic therapy.

BIOLOGICS IN EARLY CROHN'S DISEASE

Beyond achieving mucosal healing, the time of initiation of therapy might be crucial considering that a longer duration of the disease leads to more irreversible damage. There are several data in the literature that suggest higher response and remission rates to biologics in patients with a recent diagnosis of Crohn's disease compared to those patients with long-lasting disease. In a pediatric study that included 22 children, Lionetti *et al*[26] observed that the best response to infliximab was seen in children with a disease duration < 1 year. In addition, 5/6 children with early Crohn's disease had a complete closure of all fistulas compared with 2/7 children with a disease duration of more than 1 year. Kagathasan *et al*[27] showed a remarkably prolonged duration of response after a single infusion of infliximab in children with early compared to late Crohn's disease. In this study, among the 14/15 patients who responded, three of six children (50%) with early disease maintained clinical response through the 12-mo trial period, compared with none of eight children with late disease.

The CHARM (Crohn's trial of the fully Human antibody Adalimumab for remission Maintenance) study[28] was a double-blind, placebo-controlled phase 3 trial designed to determine the efficacy and safety of adalimumab 40 mg weekly *versus* every other week for maintenance of clinical remission in patients with moderate-to-severe Crohn's disease. A subanalysis of the CHARM study showed that disease duration was a significant contributor to the likehood of achieving remission. Remission rates at weeks 26 and 54 were highest when adalimumab was started in patients within the first 2 years after Crohn's disease diagnosis compared with patients diagnosed within > 5 years (59% *vs* 41%, respectively at week 26; 51% *vs* 35%, respectively at week 54). The PRECISE 2 (The Pegylated Antibody Fragment Evaluation in Crohn's disease: Safety and Efficacy 2) study was a randomized, double-blind, placebo-controlled trial that evaluated the efficacy of certolizumab pegol maintenance therapy in adults with moderate-to-severe Crohn's disease[29]. In a subanalysis of the study, a high rate of response and remission was observed at week 26 in patients with Crohn's disease diagnosed within the last 2 years and treated with certolizumab pegol compared with all patients included in the study (83.5% *vs* 62.8%, respectively; 61.5% *vs* 47.9%, respectively; $P < 0.02$)[30,31].

TOP-DOWN TREATMENT: LIMITATIONS

There is a growing evidence that suggests that the benefits of anti-TNF therapy extend beyond just the measure of clinical efficacy and that they may have the potential to alter the natural history of the disease. However, to date, several factors limit the use of biologic agents as primary therapy for Crohn's disease patients and early intense therapy needs to be balanced against the potential risks of increased infections and malignancy. Approximately 50% of all patients with inflammatory bowel disease will never require corticosteroids. Thus, first-line therapy with biologic therapies in this group would expose patients to toxicity or immunogenicity

without the benefit of potentially changing the natural history of their disease. The TREAT registry in North America has not shown, to date, an increased risk for malignancies or serious infections related to the use of infliximab in Crohn's disease[32] but clinicians should be aware that opportunistic infections such as tuberculosis, hystoplasmosis or *Pneumocytes carinii* do develop in anti-TNFα-treated patients. Nevertheless, the TREAT registry also shows that in the overall population of the registry, steroid used but not infliximab treatment was an independent predictive factor for infectious complications, and this point has been confirmed in the prospective European ENCORE registry[33]. The recently reported cases of hepatosplenic T-cell lymphoma[34], a rare and aggressive tumour, which most frequently develops in young male adults treated with infliximab and concomitant immunosuppresive therapy, has raised the question of whether it is the best strategy to discontinue the immunomodulators after certain period of combined therapy, or to stop the biologic therapy and try to maintain remission with immunomodulators alone[35]. Clinicians should also balance the side effects of the new biological therapies against the well-known and frequent toxicity of both corticosteroids and immunomodulators.

CONCLUSION

At present, Crohn's disease therapy is based in a sequential step-up strategy and biologic therapies are placed on a late position in this treatment strategy, mirroring the design of pivotal randomized controlled trials. However, the failure of many patients to respond to conventional therapy and the assessment that step-up strategy does not significantly alter the natural course of the disease has encouraged clinicians and investigators to question whether this late position is the most appropriate for biologics. Challenge is to identify those Crohn's disease patients who will develop a complicated course of the disease in whom the introduction of early and more intensive treatment from the beginning of the disease can be justified. In a recent report by Beaugerie *et al*[36], young age at time of disease onset, presence of perianal disease, early need for corticosteroids, and isolated small bowel involvement were identified as clinical factors associated with poor clinical outcomes and disability. Combination of genetic and serologic profiles may have an additive value in stratifying the disease outcome[37,38] and this may help clinicians categorize patients into subgroups to better guide therapeutic decision-making.

Abstract

The optimal duration of biological treatment, particularly anti-TNF, in inflammatory bowel disease (IBD) is a very important question both for patients and physicians. There is no published evidence to clearly and definitely answer this question. However data on natural history of IBD, long term safety of biologics, immunosuppressors (IS) cessation and some preliminary studies on biologics cessation may help us to discuss this topic. The decision to stop a biological treatment is currently based on a compromise between the benefits and risks associated with the prolongation of this treatment. IBD, more particularly CD, are characterized by the development of complications and the need for recurrent hospitalizations and surgeries in approximately 2/3 of cases. In these patients potentially in need of biological treatments, it is probable that, as it has been demonstrated for IS, the longer a stable remission has be achieved under treatment, the lower the risk of relapse is after treatment cessation. Further prospective studies should now aim at disclosing patient characteristics associated with a low risk of relapse to implement this strategy.

INTRODUCTION

The question of treatment duration in inflammatory bowel disease (IBD) is certainly a very important one and is one of the greatest preoccupations of patients. When starting a new treatment in IBD, one of the first questions of the patients is usually: "when will I be able to stop this treatment"? While the question is very important, we actually have very little data to give a clear answer, because the controlled data we have with pivotal trials usually give us efficacy data for remission and response induction and for remission and response maintenance over a one year period[1-3].

However we have most often indirect elements to help us and discuss this point of optimal duration of biological treatment in IBD: these elements are the natural history of the disease, the available data with immunosuppressive drugs, the long term safety of biologics, and a few investigator-initiated studies having started to address this question. Beyond that, the cessation of a biological treatment in IBD must be decided on a case-by-case basis and adapted strategies must be proposed.

NATURAL HISTORY OF IBD

IBD are chronic relapsing diseases. There is probably a difference between UC and CD, the latter being more often a chronic active disease. In CD, population-based and cohort studies have showed that a small half of the patients have little evolutive disease with low prevalence of relapses, hospitalizations, or complications[4-7]. These patients probably do not need biologics and if a biological treatment has been used, an arrest must certainly be discussed as soon as the flare has been controlled. The other patients will develop complications including strictures and internal or perianal fistulas over the course of the disease[8,9]. These will lead to hospitalizations and surgeries and will considerably interfere with patients every day life and long term projects. For these patients a sustained control of the disease process is strongly warranted and an effective treatment can only be stopped if reasonable evidence shows absence of activity of this process. There is probably a difference between early disease and long-lasting disease, the reversal and control of the disease process being more difficult and unstable in the latter situation. Long-lasting disease are

indeed characterized by anatomical damages including mucosal and submucosal architectural changes, fibrosis, strictures and complex fistulas that will favour clinical relapse and that will render an asymptomatic remission more difficult to achieve. Furthermore, immunological status of the patients may change over the course of the disease[10]. In parallel, immunization against luminal material may increase, enhancing the potential reactivation of the immune process[11,12]. As a correlate, a stable remission will usually be more difficult to obtain in long-lasting diseases[13] and these diseases will usually be more treatment-dependent. This certainly represents an argument for earlier treatment with biologics in CD. These patients being treated earlier with biologics and in whom a more complete reversal of the immune process and the tissue lesions can be achieved are also probably better candidates for treatment cessation.

The problem of ulcerative colitis is a little bit different. There is usually less tissue damage in UC, the disease affecting only the mucosa. Strictures and fistulas are unusual and the biggest long term complication is cancer development. This risk of cancer is linked to several factors, including disease extent and chronic uncontrolled inflammation. In UC, flares can be separated by long period of full remission with both endoscopic and histological normalisation of the mucosa. Therefore, apart from patients with chronic active disease and incomplete mucosal healing, biological treatment cessation could be attempted when the flare has been controlled and a mucosal healing has been achieved.

AVAILABLE DATA WITH IMMUNOSUPPRESSIVE DRUGS

Little data exist on immunosuppressive drug cessation in CD. In an observational GETAID study of relapse after azathioprine cessation in CD, it was shown that the longer the duration of remission under azathioprine, the lowest the risk of relapse was[14]. Particularly, the risk of relapse seemed particularly low after 4 years of sustained remission. The same group then embarked a placebo-controlled trial of azathioprine prolonged treatment beyond 42 mo of sustained remission[15]. This trial showed that the strategy of treatment cessation was not equivalent to treatment prolongation. Particularly, 18-mo relapse rate were around 20% in the cessation group as compared to 10% in the prolongation group. This study indicates that even in patients in stable remission, the cessation of an immunosuppressive drug is associated with an increased risk of relapse. The risk of relapse in the cessation group remains however reasonably low and one could consider it on a case-by-case basis after discussion with the patients. No such data are available with methotrexate in CD or more generally in ulcerative colitis.

LONG TERM SAFETY OF BIOLOGICS

While short and mid term safety and tolerance of biologics is usually very good, the fear of long term complication is generally the reason why both patients and physicians would like to stop the drug when the disease has been completely stabilized. This fear is based on the mechanism of action of these drugs. For IBD, we currently only have anti-TNF treatments. These drugs block the tumor necrosis factor alpha which is a pivotal cytokine in some anti-microbial and anti-tumoral physiological processes. Indeed, the best documented side-effects are the increased risk of tuberculosis[16] and of other infections, mainly with intra-cellular pathogens (mycobacteria, listeria, histoplasmosis…), as well as a probable slight increase in the risk of lymphoma[17]. The active and systematic search for latent tuberculosis has already significantly decreased the incidence of active tuberculosis under anti-TNF treatment. Furthermore, a recent meeting of the European Crohn and Colitis Organisation on infections and biologics has proposed a series of guidelines, including vaccination against herpes zoster, hepatitis B, influenza and streptococcus pneumoniae as well as avoiding some aliments potentially containing germs as lysteria (i.e. unpasteurized milk or insufficiently cooked meat). These guidelines, not yet published, should also in a near future help and diminish fatal complications linked to biologics. Another measure that gains more and more support is the avoidance of long term combined treatment with immunosuppressors. While there is currently very little evidence for a cumulative benefit of these drugs[1,2], combined therapies were associated in a retrospective study with a very significant increase in the risk of opportunistic infections with a relative risk of 12 when two treatments were combined[18]. Furthermore in a recently reported pediatric series of nearly universally fatal hepato-splenic T cell lymphoma in infliximab treated patients, all the patients affected had been treated with combined therapy with thiopurines[19]. All together, these measures should lower the risk profile associated with biologics and allow the physician to prescribe them for enough time to achieve stable and durable remission of the disease.

AVAILABLE STUDIES ON BIOLOGICAL TREATMENT CESSATION IN IBD

Early data with infliximab in CD were only short term induction data[20]. Only one single infusion was used at that time and it is striking to note the some patients had a very prolonged clinical response or even remission after such isolated infusion[21]. These data already suggested that prolonged treatment was probably not necessary in all the treated patients. Since then however, it has become clear that such one-shot treatment was not a good option for the majority of patients because the median time to relapse was 10 wk and because re-use of infliximab more than 4 mo after a single infusion was associated with high risk of allergic reaction. More recently the "bridge" study of the GETAID explored the idea of a 3-dose infliximab induction given in parallel with immunosuppressor that would then maintain the remission[22]. The results of this study were rather disappointing. While the short term effect of infliximab was very strong, the maintenance effect with immuno-

suppressor was globally rather weak. After one year, the overall sustained remission rate in these patients was low and actually close to the one of patients receiving a placebo induction. Only in the patients who were immunosuppressor-naïve at the time of infliximab induction, the benefit was more consistent with a reasonable 40% remission rate after one year. This study clearly shows that in patients who have failed under immunosuppressors, a longer period of anti-TNF treatment is necessary to obtain a durable remission and allow treatment cessation. This has been explored in a recent GETAID study, not yet fully completed. In this cohort study, over 100 patients with a stable remission on combined immunosuppressor-infliximab therapy for more than one year had their infliximab stopped, while pursuing immunosuppressor treatment. An interim analysis indicates that after one year more than half of the patients are still in sustained remission. A multivariate analysis of predictive factors for such sustained remission should allow to better identify the subgroup of patients in whom such strategy may be proposed.

PRACTICAL CONSIDERATION FOR STOPPING BIOLOGIC TREATMENT IN IBD

Usually, a biological treatment is started in patients who do no longer respond to conventional therapies. In patients responding to the treatment, it is certainly not wise to contemplate a treatment cessation as long as a complete clinical remission has not been achieved. In patients who have been in clinical remission for a sufficient period of time, it is probably useful to assess biological as well as endoscopic signs of disease activity. In several models and clinical situations, C-reactive protein (CRP) serum concentration has been associated with the risk of relapse[23]. More sophisticated serum or stool markers have also been proposed, but their added value as compared to CRP has not been clearly demonstrated[24-26]. A stable value of CRP within normal range should therefore also be obtained before biologics cessation. Correlation between clinical indexes of activity or biological markers of inflammation and mucosal healing is not very strong[27]. Mucosal healing under anti-TNF treatment has been associated with a decrease in relapse rate, hospitalisation and surgeries[28]. A third condition for biologics cessation is thus the existence of a mucosal healing in patients with ileo-colonic disease accessible to endoscopic control. For patients with proximal small bowel disease, there is not universally accepted exploration to assess the control of inflammation at the tissue level. However, entero-MRI could be a good candidate[29]. An absence of mucosal lesion (not always easy to detect), and of contrast enhancement of the bowel wall or the mesenterium could be interpreted as tissue healing.

CONCLUSION

Globally, the decision to stop or carry on with biological treatment in IBD is based on an estimated benefit-risk ratio. The patient must certainly be informed at the highest levels on both advantages and risks linked to any therapeutic strategy that is proposed. In patients with unstable chronic active disease, stopping an effective treatment will put the patients at risk of worsening and complications development and should probably not be attempted. However in patients stabilized for a reasonably long period of time, a careful assessment of the clinical, biological and endoscopic situation may help to take a thoughtful decision in collaboration with the patient himself.

Abstract

The timing of the decision for operation in Crohn's disease is based on an evaluation of the several factors such as the failure of medical treatment, complications due to the Crohn's disease or to the farmacological therapy, development of dysplasia or cancer and growth retardation. A complete evaluation of these factors should result in operation timed to the patient's best advantage, achieving maximal relief of symptoms with improvement of quality of life. Given the complexity and heterogeneity of the disease and the different options for treatment, is difficult to systematize when the optimal moment for the surgery is arrived. A very important factor in the management of Crohn's disease is the multidisciplinary approach and the patient preference should be a significant factor in determining the choice of therapy. The surgery should be considered such another option in the sequential treatment of Crohn's disease. We have analyzed the factors that are involved in the decision taking of the surgical treatment regarding to the experience and the published literature. When did the medical therapy fail? when is the appropriate moment to operate on the patient? Or which complications of Crohn's disease need a surgery? These are some of the questions we will try to answer.

Key words: Crohn's disease; Surgical treatment; Medical therapy

INTRODUCTION

Over fifty years ago, the introduction of corticosteroids in management of active inflammatory bowel disease meant a radical shift in patient management, both from the medical and the surgical standpoints[1]. Steroids brought about a drop in mortality rates and reduced the need of surgery in flare-ups[2]. Some forty years later another outstanding leap forward took place in terms of patient management with the introduction of biological therapies[2,3]. However, despite these advances, it is estimated that approximately 80% of patients with Crohn's disesase (CD) will require surgery at some point during their lifetime, especially when the disease is located in the ileocecal region[4]. In general, the indication for surgery in CD depends on a number of factors-complications, clinical course, relapse and location. Broadly speaking we could say that surgery is timely in any of the following situations: (a) failure of medical treatment, (b) onset of specific complications related to the disease or to pharmacological treatment, (c) dysplasia or cancer and (d) stagnated or retarded growth in children. In some cases it is fairly straightforward to decide when is the best time for surgery- free perforation or abdominal fistula, for instance. However, CD invariably poses a genuine challenge to the team treating the patient. The broad clinical heterogeneity of the disease, the various complications that arise and evolutionary possibilities are all so diverse that it is hard to generalise or adopt a systematic approach when it comes to determining when to operate. Each case should be assessed individually and that is why it is vital to have multidisciplinary teams involved in decision-making together with patients. With these teams it is still possible to improve outcomes[5], because all the physicians involved have common goals in mind, namely to avoid diagnostic delays, to establish the ideal moment for surgery, to attain the best possible pre-operative conditions and to optimise medical-surgical outcomes; given that this is a chronic disease affecting young

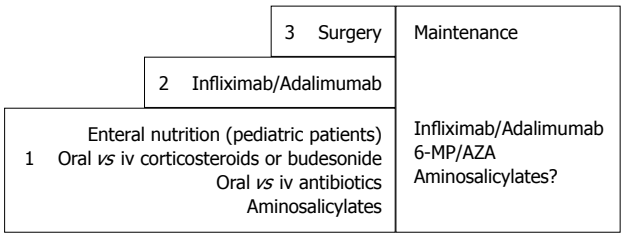

Figure 1 Suggested steps in active (left boxes) and inactive (right box) Crohn's disease. 6-MP: 6 Mercaptopurine. AZA: Azathioprine.

patients, medical-surgical management is crucial.

Recent advances in biological therapies have allowed substantial clinical improvements and better monitoring of patients-especially in fistulizing perianal disease-reducing hospitalizations, number of operations and prolonging the time that elapses between diagnosis and surgery[6]. Colombel *et al*[7] and Marchal *et al*[8] suggest that these drugs do not increase post-operative complications in patients with CD, although the same cannot be said in the case of proctocolectomy in ulcerative colitis where the risk of post-op complications is far higher if Infliximab is administered[9,10]. So, further studies are required to determine the risk of post-operative complications when these drugs are used to treat CD. On the other hand, although a recent meta-analysis of anti-TNF versus placebo did not demonstrate that there is a higher risk of death, tumours or severe infections[11], one must not forget that biological therapy is not innocuous. The risks/benefits should always be weighed up, bearing in mind that the goal of pharmacological treatment is not to avoid surgery but rather to improve quality of life. If the latter cannot be achieved then surgery will have to be considered as the next step in treatment (Figure 1).

More than half of patients with CD present with affected terminal ileum, with or without extension to the proximal colon, and around 90% will require surgery at some point in their lifetime. Far less frequent-around 10% of all CD patients-are cases presenting with affected proximal areas of the small intestine and the duodenum whereas location in the colon and/or anorectum oscillates around 30%[12,13]. In these other regions-i.e. not the terminal ileum-the probability of patients requiring surgery is estimated at 60%. According to the classical study by Farmer *et al*[12] and the more recent review by Bernell *et al*[4] overall it is estimated that 74% of patients will require initial surgery within the first 13 years from onset of the disease and that around 50% of relapses will require further surgery within the first 10 years of follow-up after the first operation.

Medical treatment failure and/or patients' impaired quality of life are ultimately the reasons leading to surgical treatment. But what do we mean by medical treatment failure? When precisely is it best to conduct surgery? In the face of which complications is it necessary to operate? What other reasons may lead us to decide to opt for surgery? Or, when is quality of life so severely impaired that surgery is called for? These questions remain mooted points in many cases. Answers to these questions will depend on the consensus and protocols of multi-disciplinary teams, but patients must always be informed and involved in decision-making.

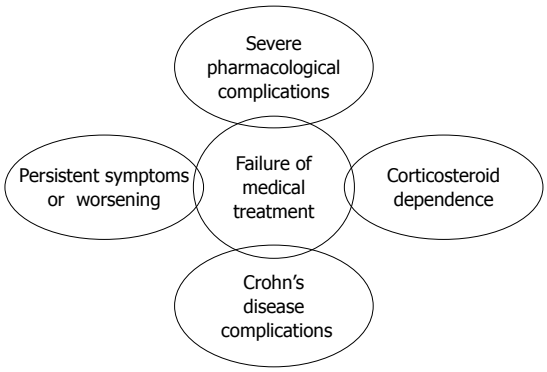

Figure 2 Clinical situations when medical treatment has failed and there is indication for surgery.

WHAT DO WE MEAN BY MEDICAL TREATMENT FAILURE?

Once the disease becomes medically untreatable it is necessary to resort to surgery. Failure of medical treatment or "untreatability" of CD is hard to define[14] and the concept does not bear the same meaning for all physicians or patients. We may consider four scenarios in which surgery is indicated (Figure 2).

(a) Persistence or worsening of symptoms despite correct treatment. In many cases, recognising medical treatment failure on these grounds requires experience and the right clinical judgement. In addition, there are times when it is necessary to consider each patient's individual circumstances since if partial clinical improvement occurs, residual symptoms may or may not be tolerated by patients, in which case subjectivity is a primary factor in deciding to operate. Although biological therapy has meant a remarkable step forward in management of situations involving patients refractory to corticosteroids with mild to severe flare-ups, it is crucial to define response times in order to determine the optimal time for surgery in these particular clinical cases. Non-response to induction with Infliximab or Adalimumab should be considered as therapeutic failure.

(b) Onset of unacceptable drug-related complications and there is no other efficacious medical alternative. This occurs especially with steroids which may trigger severe adverse effects-aseptic femoral necrosis, cataracts, compression-related fractures, *etc*. In rarer cases the same applies with azathioprine or 6-mercaptopurine which may produce medullar aplasia. With the introduction of biological agents, the chances of septic complications or reactivation of latent infections (tuberculosis, viral hepatitis, *etc*) are high, so extreme caution is necessary[15]. As to the presence of abdominal or perirectal septic foci these must always be drained before administering Infliximab otherwise severe sepsis may occur[15].

(c) In cases of steroid-dependence. These drugs

are used to tackle acute crises and not for maintenance purposes; so if after remission of flare-ups the drugs cannot be discontinued after two successive attempts over a six month period, or after three attempts over one year, the case should be considered as untreatable as a result of steroid-dependence. One of the two existing population-based studies included 173 patients with CD, of which 74 (43%) required treatment with steroids and 21 (28%) of these presented with steroid-dependence after a year[16]. This roughly represents 12% of all patients with CD and the results are similar to those of an earlier trial[17]. In children, CD is more aggressive and these percentages are higher-more than 60% require steroids and 16% of the total number of patients are steroid-dependent[17].

(d) Onset of complications associated to the disease that compromise patient's quality of life.

WHEN IS THE OPTIMAL TIME FOR SURGERY?

There is a good deal of controversy surrounding the issue. Those advocating early surgery argue that if medical treatment does not achieve substantial improvement there is no reason to await the onset of a serious, potentially life-threatening complication, or to increase surgery-related risk. Along these lines, one particular study adopted an active surgical approach in 136 patients with mean follow-up of 16.6 years concluding that morbidity and mortality are lower when following this approach, with good functional outcomes and complete remission of symptoms[18]. Another retrospective study with 74 patients who had undergone various first and subsequent operations for CD between 1975 and 2000 showed that the number of operations increased every 5-year[19] period, suggesting that the threshold to establish an indication for surgery has dropped with the passing of time (years) in that particular setting. On the other hand, authors critical of early surgery argue that since relapse and re-operation rates are high, the chances of short bowel syndrome are very low. From our point of view, this argument does not hold because since small resections and strictureplasties are being conducted this syndrome is highly unlikely to occur. In an attempt to identify the factors that increase the probability of surgery in the early stages of CD, Sands *et al*[20] reached the conclusion that the following have a significant impact: smoking, affection of the small intestine only, nausea and vomiting or abdominal pain as the main form of presentation, neutrophilia and use of steroids within the fist six months after diagnosis. In addition, the authors note that the percentage of early interventions is high (20%) and suggest that treatment with rapid action drugs should be initiated in order to change the disease's natural course hence reducing the number of patients requiring surgery. Contrarily, the same authors conclude that when only the colon is affected, blood in faeces, the use of 5-ASA and lymphocytosis are linked to later interventions, although the only independent factor turned out to be affection of the colon alone. More recently, Morimoto *et al*[21] noted that the only independent risk factors determining whether a patient should be operated are gender (female), and that the disease is located exclusively in the ileum. So, the presence or absence of one or more of the factors described may help us decide how early surgery should be conducted.

Table 1 Influencing factors in the choice of optimal time to operate on a patient

Severity of symptoms
Type of symptoms
Failure of medical treatment
Adverse effects of medical therapy
Risk of complications due to Crohn's disease
Established complications
Obvious benefits (or no disadvantages) of surgery
Gastroenterologist
Surgeon
Patient and family

On the other hand, the use of drugs that may potentially increase the risk of surgery-related complications should not be an obstacle to surgery if this becomes necessary at some point. In this regard there are few publications addressing steroid-related risk in postoperative CD complications although experience suggests that prolonged preoperative use is an adverse factor in itself. Two recent articles agree in pointing out that there is a higher risk of dehiscences and septic complications if these are administered pre-operatively over more than three months[22,23]. However, the same authors note that there are other more significant factors that come into play in the onset of post-op septic complications, as is the case with malnourished patients. Regarding treatment with Infliximab, as discussed above, it is highly likely that it has no role in CD post-op complications[7,8] although further studies are needed. The use of other immunosuppressants does not influence surgery-related complications either[7].

On the basis of what has been discussed so far, in order to determine the best time for surgery we should assess the severity and type of symptoms, failure of medical treatment, the onset of adverse effects and surgical risk/benefit. All this together will enable gastroenterologists, surgeons and patients to agree on optimal time for surgery with a view to ensuring that the operation will resolve symptoms with no or minimal disadvantages for patients (Table 1). To assess the importance of patients' views in decision-making we note the study by Scott and Hughes[24] in which they interviewed 70 patients who underwent ileocolic resection to ascertain when surgery should have taken place-earlier, later, or at the time it was conducted. None of the patients declared preference for a later operation, and 77% would have preferred earlier surgery, with a median of at least 12 mo sooner. Almost 100% of interviewees said that the main reason for wanting to bring surgery forward was severity of their symptoms.

Identifying the best time for surgery is not always an easy task. To be as sensible as possible, we should always remember that it is as inappropriate to indicate surgery before having resorted to all the drugs available-selected on the basis of clinical status-as unnecessarily delaying surgery until the onset of a serious complication.

IN THE FACE OF WHICH COMPLICATIONS IS SURGERY REQUIRED?

One of the features of CD is that it may give rise to a number of complications throughout its clinical course (Table 2) that may require surgery.

Intestinal obstruction: This is the most frequent indication for surgery when CD is located in the ileocecal area. This may also occur when CD is located in the jejunoileal area with one or multiple stenoses and, in these cases it may progress with greater severity and a higher probability of large resections[25]. Approximately 25% of all CD operated patients have undergone surgery due to intestinal obstruction[13] and commonly further interventions are required following a number of sub-occlusion flare-ups, although urgent operations are the exception. If occlusion occurs as a result of inflammatory events with edema in the intestinal wall and there is some response to crisis and maintenance medical therapy then there will be no need for surgery. However, if obstruction is due to fibrosis or reactive scarring changes, an operation is called for once absence of activity has been confirmed. In general terms obstruction is never complete, and responds to conservative treatment with gastric decompression and therapy with fluids and steroids, so surgery can be scheduled in the best possible conditions. In chronic situations, which should be avoided, a large prestenotic dilation of the intestine will appear, palpable as an abdominal tumour, which can cause severe nutrition-related problems.

Although there is no rule of thumb, we may affirm that surgery is indicated when two sub-occlusion flare-ups occur over a period of one year, requiring hospitalisation, or if the steroid treatment prescribed after a crisis cannot be discontinued at three months, or if dosages higher than 15 mg of Prednisone/day are required in the period three to six months following the occlusive crisis[26]. Delaying surgery in this particular case will lead to patient decline and further complications such as perforation, with an increase in surgery-related morbidity and mortality. In certain cases-single stenosis not larger than 8 cm in length, especially following post-op relapses-if the area is accessible with an endoscope, surgery can be replaced by endoscopic dilation either alone or associated with local steroid infiltration[27,28].

Abdominal abscess: Abdominal abscess is characterised by the presence of an inflammatory "mass" that always originates in micro-perforations of the intestinal wall; the mass may be an abscess, phlegmon or a combination of both. Excluding perianal disease, this complication is almost exclusive to the ileocecal region. More than a quarter of patients with ileocecal CD need to undergo surgery for this reason. Of these abscesses or phlegmons, 40% are associated with fistulae. In general terms, these are septic patients whose initial treatment, as well as broad spectrum anti-biotherapy and anaerobicides, involved CT or ultrasound-guided percutaneous drainage which allows improving patients' clinical status. The success rate of drainage exceeds 90% and avoids short-term surgery in 50% of patients[29], whereas those who will ultimately need to undergo an operation will only require single-stage elective surgery, under far more favourable conditions[30,31]. If even despite drainage, septic status shows no improvement, urgent surgery should be considered. Likewise, surgery is indicated in the event of multiple abscesses for which radiological drainage is not feasible. Normally when an inflammatory "mass" is detected through palpation, it means that the disease has attained such degree of severity that it is very unlikely to respond to medical treatment. Some authors have even reported initial improvement after percutaneous drainage of an abscess in small series of patients, but even so, surgery becomes necessary sooner or later[32].

Abdominal fistulae: Occur in their majority when CD

Table 2 Complications of Crohn's disease and treatment approaches

Complication	Treatment
Acute intestinal obstruction	Conservative
Recurrent intestinal obstruction	Elective surgery
Abdominal abscess	Percutaneous drainage Total recovery: medical therapy No improvement: urgent surgery Improvement: elective surgery
Abdominal fistula	Enteroenteric Asymptomatic: conservative Symptomatic: elective surgery Enterourologic o enterogynecologic Elective surgery Enterocutaneous Improve nutritional status and elective surgery
Free perforation or massive bleeding	Urgent surgery
Severe acute colitis	Medical therapy No response in 3-5 d: urgent surgery Obvious improvement: medical therapy
Toxic megacolon	Complication of acute colitis: urgent surgery Debut: medical therapy No response in 1-3 days: urgent surgery Response: elective surgery
Perianal disease	Individual treatment and interdisciplinary approach Surgery Failure medical therapy Symptomatic lesions Complications

is located in the ileocecal region. They may be internal, between neighbouring organs-the most frequent- or external, towards any cutaneous abdominal area-these are almost always post-operative. In the case of a spontaneous enterocutaneous fistula, or one that occurs following abscess drainage, there is consensus in so far that surgery is indicated because closure does not occur spontaneously[33,34], although some authors report good results in isolated cases with the use of Infliximab[35]. In the event of malnutrition and sepsis these have to be addressed before the operation since surgery on a fistula of this kind is not an urgent matter. If the fistula is post-operative it must be managed like that of a normal patient. If it occurs prematurely, within the first seven days post-op, in all likelihood it will require surgery; however, if it occurs at a later date but within sixty days one should adopt an expectant approach to treatment,-with enteral or parenteral nutrition-because they do tend to close provided there is no associated obstructive process. A special situation we have had to deal with sometimes, involves CD patients with long course of the disease, presenting with multiple enterocutaneous fistulae and with variable nutritional status, complexity of fistulae, degree of sepsis and food tolerance. In these cases, the decision whether to operate or not has to be assessed individually, on the basis of the factors mentioned.

Internal or enteroenteric fistulae are the most frequent, and alone they are not an indication for surgery, except if they exclude a large segment of the intestine and they are symptomatic, as in ileosigmoid or gastrocolic fistulae[36,37]. Less frequent are fistulae in the vagina, bladder, urethra and ureter; here the indication is scheduled surgery as the definitive solution[38].

Free perforation: May occur both in the case of CD in the small intestine or CD in the colon, although it is often associated with toxic colitis or megacolon[39]. Incidence is low, oscillating between 1%-3%. In this situation, peritonitis occurs, requiring resuscitation and urgent surgery. Some authors have described rupture of an abscess in the abdominal cavity, and obviously this would also require urgent surgery[40].

Massive bleeding: Occurs in 1%-13% of patients with CD. The first measure is to determine the site where haemorrhaging originates, *via* examination such as endoscopy, arteriography *etc*. The first option is conservative treatment, although probabilities of surgery exceed 60% as shown by the scant series of patients published in the literature[41,42]. If the bleeding can be stopped it is quite possible that further bleeding will occur, in which case surgery is recommended[43]. Ideally, it should be possible to ascertain the site of haemorrhaging perioperatively in order to avoid massive resections in this type of patient. To this aim, some authors have used selective arteriography injecting methylene blue tincture to highlight the bleeding intestinal segment[44].

Severe acute colitis: Here treatment criteria are similar to those for severe acute flare-ups in ulcerative colitis. Active treatment is required with intravenous fluids, thromboembolic prophylaxis, steroids and broad spectrum antibiotics, and considering sequential introduction of Infliximab in the event of steroid-resistance[45]. Urgent surgery will be conducted in the event of worsening of status in the 24-h period following treatment or within five days if there is no clear recovery[46]. Joint monitoring-by physicians and surgeons-and the approach outlined above will significantly reduce surgery-related mortality. By analogy with ulcerative colitis, we can affirm that predictive factors for surgery in the severe acute case should be identical to those in CD. Along these lines, Travis *et al*[47] noted that the presence of gas in three or more loops of the small intestine, and more than eight motions or stools daily, or a PCR above 45 mg/L predicts poor response to medical treatment, whereas Lindgren *et al*[48] conclude that persistently high body temperature, rectal bleeding or diarrhoea and elevated PCR increases the probability that surgery will be required. The presence of these factors should alert us to the need to conduct stricter surveillance.

Toxic megacolon: Occurs in 4%-6% of all patients with CD in the colon and although it can be controlled initially with medical treatment, in almost all cases delayed surgery should be considered since half of patients will present with a new megacolon flare-up and the other half will be poorly controlled. It occurs more frequently in the case of severe acute flare-up in extensive colitis; in this case, urgent surgery is indicated[49]. It is rarer as a debut manifestation and if this were the case, intensive medical treatment similar to that applicable to a severe flare-up should be initiated, but if there is no clear improvement, surgery should be indicated after 24-48 h. Immediate action-which reduces mortality rates to 2%-8%[50]-will prevent the onset of multiple organ dysfunction syndrome and perforation, which yields high mortality rates-close to 40%.

Perianal Crohn's disease: This is sometimes a complex problem which is hard to manage. Treatment must always be designed on a case-by-case basis and symptoms and complications should be treated surgically[51]. Here the major problems are perianal fistulae and sepsis. In the event of perianal abscess, urgent surgical drainage is always the approach to take. In an attempt to summarise such a complex problem, if the rectum presents no activity or is healthy and the fistulae are straightforward, scheduled fistulotomy is indicated; if they are complex medical treatment is preferable and rarely scheduled surgery for an advanced flap. If the rectum is diseased or there is genuine perianal sepsis, seton drainage appears to be the method favoured by most authors[51,52]. All septic foci should be drained and drainage seton sutures should be placed along with treatment using Infliximab, since results are better than with Infliximab alone[53].

In very severe cases that fail to respond to medical treatment, a relatively urgent ileostomy will be needed, in an attempt to control sepsis. Normally, if the rectum is affected and sepsis cannot be controlled, a proctectomy will be required[54].

WHAT OTHER REASONS MAY LEAD US TO OPT FOR SURGERY?

Dysplasia and cancer. Carcinoma-related risk in colon CD, with long course of the disease, seems to be similar to that associated to ulcerative colitis. A recent meta-analysis suggests that the relative risk of cancer in colon CD is equal to 4.5[55], so a monitoring programme including colonoscopy and biopsies will be beneficial *a priori*. The same criteria as in ulcerative colitis apply regarding monitoring and indication for prophylactic colectomy. So, surgery is indicated in the event of multi-focal low degree dysplasia, or high degree dysplasia confirmed by two different pathologists[56]. As with ulcerative colitis, the efficacy of monitoring programmes is controversial[57]. If CD is located in the ileum the risk of cancer is no higher than that of the normal population[55]. Under special circumstances risk appears to increase significantly, as is the case of patients diagnosed with CD before the age of 30 and with affected regions of the colon-here the relative risk is 20[58]. Once the carcinoma is established it may be difficult to determine why it triggers the symptoms that may be confounded with the disease, especially if it located in the ileum. Once diagnosed, surgery is called for following the same oncological principles that apply to any kind of neoplastic tumour. At any event, a significant percentage of cancers are found intraoperatively or during histological examination of the surgical specimen[26].

Retarded or stagnated growth occurs as a result of the complex interaction between nutritional status, inflammation, severity of the disease and genotype[59]. In addition, if treatment is based on the continued use of steroids, bone epiphysis will close prematurely. So poorly controlled CD, or that which requires steroid treatment, should be operated on as soon as possible, and in all cases before puberty.

WHEN IS QUALITY OF LIFE SO SEVERELY IMPAIRED THAT SURGERY IS NEEDED?

This question is extremely difficult to address given that no studies have come up with an answer. In addition, the evolution of CD with flare-ups, remissions, and exacerbations means that quality of life (QL) will vary over time. However, measuring QL is a useful tool to gain insight into response to pharmacological treatment, impact of the disease, assessment of healthcare services, contribution of surgical treatment, *etc*. One of the aims of treatment-whether medical or surgical-is to improve QL of CD patients. A plethora of factors impact QL, such as the fear of relapse, the fear of not enjoying good health and being unable to work, the impact of the disease on body image, infertility, *etc*. Moreover, determining when QL is so severely affected that surgery has be resorted to is also difficult to establish given that each patient may have very different perceptions in terms of how his or her own QL has altered. An organisational change is needed, with the introduction of health education programmes for patients[60], and dedicated units should be set up to provide comprehensive assistance[61]. This would improve the quality of healthcare assistance, while optimising healthcare resources[62]. According to the study conducted by Casellas *et al*[63], QL improves in a similar manner both if CD remission is attained *via* medical or surgical treatment, so it may be concluded that the important issue is to achieve remission, regardless of the method of choice.

In some situations, QL is severely affected. For instance, when CD is diffusely located in the small intestine, or when-regardless of location-it leads to nutritional problems or growth impairment, its impact on patients' social life is so great that surgery will have to be considered[64,65]. In general terms, the factors that patients rank highest as life-limiting factors are: number of motions or stools, appetite and dietary options, sleep, depending on others, mental health and psychosexual morbidity. To assess and measure these factors, a QL questionnaire, specifically designed for inflammatory bowel disease, is used[66]. The score obtained is closely linked to flare-ups of the disease, so that during remission phases patients refer maximum scores-similar to scores during phases when the disease is under control-whereas greater or lesser activity alters scores, worsening QL proportionally to the magnitude of the flare-up[63].

CD and ulcerative colitis should not be assessed on the basis of clinical criteria alone. We should use a QL questionnaire to understand patients' genuine status of wellbeing. All factors-both clinical and QL related-taken together will help us decide whether to continue with medical treatment or to indicate surgery.

CONCLUSION

Deciding whether to operate on a patient with CD may be relatively easy although in a variety of cases it can be a difficult call. In these complex cases, an organization based on multi-disciplinary teams, while also bearing in mind patients' opinions, plays an extremely relevant role in order to attain the best possible outcomes. The goal of all those involved is to achieve better quality of life for patients. Hence, surgery should be seen as another treatment option and not as an approach to avoid at all costs. Deciding when is the best time for surgery will essentially depend on a number of factors such as medical "untreatability", symptom severity, types of complications, drug-related adverse effects and adequate risk/benefit assessment of surgery at a given

point in time. An overall view of clinical status along with analysis of each of these factors from an integral standpoint will enable us to adopt the most appropriate decision.

Abstract

Crohn's disease is a chronic inflammatory condition that may involve any segment of the gastrointestinal tract. Although several drugs have proven efficacy in inducing and maintaining disease in remission, resectional surgery remains as a cornerstone in the management of the disease, mainly for the treatment of its stenosing and penetrating complications. However, the occurrence of new mucosal (endoscopic) lesions in the neoterminal ileum early after surgery is almost constant, it is followed in the mid-term by clinical symptoms and, in a proportion of patients, repeated intestinal resections are required. Pathogenesis of postoperative recurrence (POR) is not fully understood, but luminal factors (commensal microbes, dietary antigens) seem to play an important role, and environmental and genetic factors may also have a relevant influence. Many studies tried to identify clinical predictors for POR with heterogeneous results, and only smoking has repeatedly been associated with a higher risk of POR. Ileocolonoscopy remains as the gold standard for the assessment of appearance and severity of POR, although the real usefulness of the available endoscopic score needs to be revisited and alternative techniques are emerging. Several drugs have been evaluated to prevent POR with limited success. Smoking cessation seems to be one of the more beneficial therapeutic measures. Aminosalicylates have only proved to be of marginal benefit, and they are only used in low-risk patients. Nitroimidazolic antibiotics, although efficient, are associated with a high rate of intolerance and might induce irreversible side effects when used for a long-term. Thiopurines are not widely used after ileocecal resection, maybe because some concerns in giving immunomodulators in asymptomatic patients still remain. In the era of biological agents and genetic testing, a well-established preventive strategy for POR is still lacking, and larger studies to identify good clinical, serological, and genetic predictors of early POR as well as more effective drugs (or drug combinations) are needed.

INTRODUCTION

Crohn's disease (CD) is a chronic inflammatory intestinal disease that frequently requires surgical bowel resection due to refractory activity in spite of medical treatment or complications such stenosis or fistulae. Approximately, 80% of patients need intestinal resection during their lifetime[1]. Nevertheless, resectional surgery is not definitively curative and disease frequently reappears at the site of the anastomosis and/or proximally. The term recurrence defines the presence of new objective intestinal lesions of CD after a radical or curative resection. Radical resection is considered as a complete excision with a sufficient length (5-15 cm) of macroscopic normal margins from both ends of the diseased bowel segment, together with local lymph nodes, to remove the whole involved gut[2]. Although some alternative surgical techniques such as stricturoplasty are emerging, according to the European consensus on definitions and diagnosis of CD, *recurrence* is best used to define the reappearance of lesions after surgical resection while *relapse* refers to

the reappearance of symptoms[3]. Early studies by the Leuven group showed a symptomatic recurrence rate of 20%-30% one year after ileal or ileocolonic resection, with a 10% increase in each subsequent year[4]. Moreover, the same group reported an endoscopic and histological recurrence rate of 72% within one year of the operation[5]. These key studies marked the basis of knowledge about postoperative recurrence (POR) in CD.

DEFINITION OF POSTOPERATIVE RECURRENCE

POR rates vary according to the criteria used for its definition: clinical, endoscopic, morphologic, or surgical (Figure 1). *Morphological* POR refers to the occurrence of new lesions assessed by imaging techniques; since radiological explorations are less accurate in detecting small or superficial mucosal lesions, morphological POR has been replaced by *endoscopic* POR. The occurrence of new mucosal (endoscopic) lesions in the neoterminal ileum early after surgery is almost constant, and it is followed in the mid-term by clinical symptoms and, in a proportion of patients repeated intestinal resections are required. As recently reviewed, *clinical* POR rates, assessed by conventional clinical activity indexes, varies between 17%-55% at 5 years, 32%-76% at 10 years and 72%-73% at 20 years[6], whereas *surgical* POR rates (patients requiring re-operation) are of 11%-32% at 5 years, 20%-44% at 10 years and 46%-55% at 20 years[6-8].

Although the real relevance of endoscopic POR is yet to be known, the emergence of mucosal healing as one of the most important therapeutic targets in CD increases the interest for endoscopic POR prevention as the main goal after resectional surgery, at least in the setting of clinical trials.

NATURAL HISTORY OF POSTOPERATIVE RECURRENCE

The physiopathology of POR still remains unknown and its course is unpredictable. Reasonably, pathogenic mechanisms of recurrence should be the same of CD itself, but even a more relevant role of luminal microorganisms is suspected. It is known that if ileocolonic anastomosis is protected by a proximal ileostomy and no faecal stream passes through the anastomosis, mucosal lesions rarely appear[9]. The infusion of intestinal luminal contents into the excluded ileum results in inflammatory mucosal changes, as shown in a classical interesting study by the Leuven group in 3 CD patients who were studied by histopathology and electron microscopy[10]. The authors demonstrated that, as soon as 8 d after the reinfusion of intestinal fluids, focal infiltration of mononuclear cells, eosinophils, and polymorphonuclear cells in the lamina propria, small vessels, and epithelium appeared in the previously normal excluded neoterminal ileum. Furthermore and considering this hypothesis, the same group showed some years later that nitroimidazolic antibiotics are efficient in preventing POR, as will be later discussed[11,12].

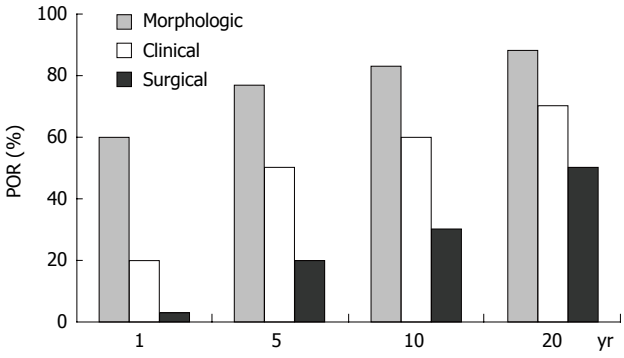

Figure 1 Mean rates of postoperative recurrence of Crohn's disease assessed by clinical relapse, imaging techniques (morphologic), and re-operation (surgical).

The onset of disease recurrence begins by the appearance of new mucosal lesions (morphologic recurrence) that can be assessed by means of radiological or endoscopic techniques and the evolution of these lesions mimics the previous phenotypic pattern in every particular patient, as shown when the indication for reoperation is evaluated[13].

Ileocolonoscopy is a very useful diagnostic tool for examination of neoileum after ileocolonic resection and it determine the presence or absence of new lesions. There is a sequence of endoscopic lesions in the anastomotic and preanastomotic regions followed by the development of clinical symptoms. The earliest lesions detected are aphthoid ulcers and it is possible to detect a disruption of capillary basement membrane with haemorrhaging and rails of fibrinogen in the surrounding lamina propria empting into the bowel lumen[14]. The presence of extensive lesions in the neoileum by endoscopic examination within some months after surgery predicts a rapid evolution to recurrent symptoms and eventual complications, and there is evidence that these early lesions do not originate from microscopic inflammation prior to surgery[15].

RISK FACTOR FOR POSTOPERATIVE RECURRENCE

Even though the determinants for disease recurrence remain as speculative as for the initial CD lesions, several risk factors for POR have been reported. The identification of such factors is very important in order to select those patients who may benefit the most from active preventive measures. Clinical parameters that influenced outcome are listed in Table 1, and they can be grouped in those related to the patient's and disease's characteristics, and those that depend on surgical questions. However, it has to be pointed out that most studies evaluating risk factors for POR are retrospective, and that prospective RCTs designed to evaluate different preventive treatment for POR (mostly with a smaller sample size than retrospective studies) have not confirmed these results.

Table 1 Clinical parameters that may influence the development of postoperative recurrence

Age (at onset of disease)
Gender
Family history of CD
Smoking
Duration of disease before surgery
Location
Genetic factors
Involvement of disease at the resection margin
Indication for surgery
Length of resected bowel
Anastomotic technique
Histological findings

Patient and disease characteristics

Smoking: It is known that smoking habits play an important role in the pathogenesis of inflammatory bowel diseases and it is maybe the only environmental factor extensively evaluated in both CD and ulcerative colitis. The effect of smoking and its cessation on disease location, behaviour, and disease progression in CD has been recently analyzed through a systematic *Medline* research[16]. The conclusions were that smoking duplicates the risk of recurrence after surgery and smoking cessation should be encouraged as one of the most useful measures for the management of the disease. Cigarette smoking may not be only a risk factor for development of CD but also may influence disease activity following surgery[17]. The risk of surgery as well as the risk for further resections during disease course is increased among smokers in most studies. The first study that analyzed the effect of cigarette smoking on POR (defined by the need for repeated surgery) in a historical cohort of 174 CD patients who had been operated on, found that the rate of reoperation after 5 and 10 years was significantly different for smokers (36% and 70%, respectively) that for nonsmokers (20% and 41%, respectively). When patients were stratified by gender, this increased risk was more apparent in women[18]. In another study, significant differences in surgical recurrence rates between smokers and non-smokers and for both male and female were also found. Five and 10-year recurrence rates were 43% and 64%, respectively, for smokers, with corresponding figures for non-smokers of 26% and 33%[19]. In addition, it has been shown that macroscopic lesions at the neoileum are present in 70% of smokers one year after surgery, for only 35% in non-smokers and 27% in ex-smokers. Finally, an Italian study correlated the risk of recurrence to the severity of smoking habits, with a more marked increase in the risk of symptomatic POR among heavy smokers than among mild smokers[20]. No interventional study evaluating the impact of smoking cessation has been performed and it is unlikely to occur.

Genetic factors: *NOD2/CARD15* gene variants play an important role in the susceptibility to CD. Studies of genotype-phenotype relationship suggest that these variants are associated with ileal location and the development of intestinal strictures. In a study evaluating the influence of NOD2/CARD15 variants on CD outcomes including 170 patients (70 of who had been operated on), Alvarez-Lobos and co-workers found that those patients carrying gene variants had a higher risk of surgical POR[21]. Recently, in another Mediterranean area study including a total of 110 patients, although these findings were not completely reproduced, those patients the L1007fs mutation also had higher rates of reoperation[22].

Disease phenotype-related factors: Early onset of CD might be associated to a higher recurrence rate. However, results were controversial in the largest series in which this item was evaluated, and age at diagnosis should not be considered as a definitive predictive factor. Similar results have been found regarding family history of CD[23].

Clinical parameters that have been associated to postoperative outcomes are preoperative disease activity[14] and location of disease at diagnosis[24]. When recurrence was defined by the need for reoperation, patients with disease affecting only large bowel had a higher risk when compared to those with isolated small bowel involvement or ileal and colonic disease[24]. The presence of jejunal CD is associated with a higher rate of early disease recurrence as compared to ileocecal disease, but long-term recurrence rates do not differ significantly[25]. In a European study, phenotype at diagnosis had a strong predictive value for clinical relapse or recurrence, upper gastrointestinal disease being the most important positive predictor; although the study did not focus on POR, it seems that these results agree with those obtained in the Japanese study[13].

Perforating disease seems to be associated with a more rapid or aggressive POR. In a recent meta-analysis, a trend for earlier reoperation in patients who were firstly operated on for perforating complications as compared to patients operated on for non-perforating indications was found[26]. However, there was a significant heterogeneity among the included studies, limiting the value of the results.

Histopathological factors: Although microscopic involvement of the resection margins was not associated to a higher risk of surgical POR in a RCT in which patients were randomized to have a limited or an extended resection from the macroscopically affected margin[27], recent data suggest that the presence of myenteric plexitis in the resection margins may be a relevant predictor of POR. Ferrante and colleagues studied the surgical specimen and the clinical and endoscopic outcome of 59 patients who were operated on and included in the placebo arm of two RCTs for POR prevention. Those patients with myenteric plexitis in the surgical specimen had significant higher rates of endoscopic POR at both 3 and 12 mo after surgery[28].

Surgery-related factors: Several prognostic factors related to surgical aspects have been investigated. The length of resected bowel does not appear to be a predis-

posing factor to POR[29,30]. As long as recurrence rate is unaffected by the presence of microscopic active disease at the surgical margins, the current surgical approach is that only macroscopically affected tissue must be removed in order to minimize the risk of a further short bowel syndrome.

Based on data suggesting that anastomotic stapling techniques result in a localized ischemic injury that might increase disease recurrence, the studies evaluating this topic show different results[31]. Firm conclusions are difficult to achieve because of the retrospective nature and heterogeneity of studies. Recently, a meta-analysis evaluated the incidence of recurrence and indication for reoperation between patients undergoing end-to-end anastomosis and patients with another anastomotic configuration after intestinal resection[32]. Eight studies (only two were prospective and randomized) reported data from 661 patients who underwent 712 anastomosis. Almost half the patients had end-to-end anastomosis and recurrence rate was significantly reduced in those patients who had other anastomotic configurations.

Laparoscopic resection is more adequate in CD since patients are usually young, with cosmetic and working concerns. This technique can be performed safely and effectively and it shows a faster resumption of oral feeds, lesser postoperative pain, and shorter hospital stay when compared to open surgery. No differences were found in the recurrence rate or the disease-free interval when laparoscopic technique was compared with open surgery in a retrospective analysis of 61 consecutive patients performed in a tertiary Canadian centre[33]. Similar results were obtained in a retrospective study involving a larger cohort of 113 patients[34]. Recently, long-term results of laparoscopic-assisted or open ileocolic resection for Crohn's disease have been compared in terms of surgical recurrence, quality of life, body image, and cosmetics[35]. Although surgical recurrence and quality of life were comparable, a better body image and cosmetic appearance favored laparoscopy.

ASSESSMENT OF POSTOPERATIVE RECURRENCE

Clinical monitoring should be the easiest way to assess the occurrence of POR (clinical recurrence). However, ileocecal resection (especially in cases of extensive ileal resection) may be associated with the development of abdominal symptoms such as diarrhoea or abdominal cramps secondary to bacterial overgrowth, bile salts malabsorption, or short bowel syndrome, and these might be misinterpreted as a disease recurrence. Unfortunately, no clinical activity index has been validated for patients with previous ileocolonic resection, and the value of the changes in the CDAI or the Harvey-Bradshaw indices in this clinical setting is still to be established.

Histology (histological recurrence) could also be used to diagnose POR, but microscopic inflammatory mucosal changes have been described to occur early after surgery[10] and the relationship with the timing or severity of clinical recurrence has not been adequately evaluated.

As mentioned before, Rutgeerts and colleagues showed that the severity of mucosal lesions correlated with the likeliness to develop clinical recurrence. Although these lesions should be detected radiologically or endoscopically, the higher accuracy of endoscopy to detect small lesions makes ileocolonoscopy the gold standard for POR assessment. Moreover, these authors proposed an endoscopic index to specifically describe and grade POR[15]. Since then, the so called Rutgeerts' endoscopic index has been used to define the primary endpoint in most RCTs evaluating preventive strategies for POR performed in the last decade, as a surrogate for clinical recurrence. This index scores recurrent ileal lesions as i0 (no lesions), i1 (less than 5 aphthous lesions), i2 (more than 5 aphthous lesions with normal mucosa between the lesions, or skip areas of larger lesions or lesions confined to < 1 cm from the ileocolonic anastomosis), i3 (diffuse aphthous ileitis with diffusely inflamed mucosa), and i4 (diffuse inflammation with larger ulcers, nodules, and/or narrowing). Although POR was initially defined as a Rutgeerts score $\geqslant$ i1, most RCTs use i2 as the cut-off to define endoscopic recurrence and i3 for defining "significant" or "severe" endoscopic recurrence, suggesting that i1 and i2 are of low value to predict clinical recurrence in the short-term.

The meaning of those endoscopic lesions confined to the anastomosis is still under debate. These lesions, although included in the Rutgeerts index as i2, have been questioned by some authors who claimed that they could be related to staples and/or ischemia[36]. In a recent prospective study, when considered apart, these lesions did not become symptomatic and showed a low probability to progress to more severe endoscopic lesions in the mid-term (22% and 42% after 3 and 5 years of surgery, respectively)[37]. Certainly, some authors already had not considered these lesions as disease recurrence in the setting of clinical trials[38]. Moreover, a careful reading of the initial paper by Rutgeerts *et al* in which the index was first defined, shows that whereas the clinical outcome was markedly different in patients with an endoscopic index greater or lesser than i2, patients with i2 had an unpredictable outcome. Therefore, the possibility that these lesions may be a confounding factor rather than a 'true' disease recurrence should be kept in mind, and their clinical relevance should be revisited.

Finally, although POR usually occurs at the neoterminal ileum after ileocecal resection, some patients (mostly after segmentary colonic resections) may develop mucosal lesions in the colon. This is not considered in the Rutgeerts score, and in a recently published RCT a modified version of this index including recurrent lesions in the colon has been used[39]. For all these reasons, and despite a Rutgeerts' index of $\geqslant$ 3 has been strongly associated with a poor prognosis, many authors do not recommend its use neither in clinical practice nor in the setting of RCTs since data supporting its clinical relevance are still lacking[36].

Table 2 Characteristics of available preventive measures of post-operative recurrence

Preventive measure	Pros	Cons
Smoking cessation	Many colateral beneficial effects Synergistic effect with thiopurines?	Lack of specifically designed prospective studies and RCTs (data coming from retrospective studies) Low adherence
Enteral nutrition	Excellent safety profile	Preliminary results Adherence?
5ASA compounds	Safety profile	Marginal benefit (high number needed to treat –NNT-)
Nitroimidazolic antibiotics	Proven efficacy in RCTs	High rate of intolerance/side effects (not applicable in a long-term basis)
Thiopurines	Strong positive results in open and retrospective studies Proven efficacy in RCT when combined with metronidazole Particularly efficient after second resection? Synergistic effect with smoking cessation?	Safety profile/intolerance Efficacy in monotherapy not conclusive (RCTs)

Alternative non-invasive imaging techniques to assess POR have been evaluated in recent years. Wireless capsule endoscopy (WCE) has potential advantages over ileocolonoscopy: it is more comfortable and better tolerated by patients, it does not need sedation, and it is less influenced by technical limitations (impossibility to access the neoterminal ileum). In small-sized controlled trials, WCE demonstrated a similar efficacy to ileocolonoscopy to detect mucosal lesions in the neoterminal ileum[38,40,41]. Furthermore, WCE is able to detect mucosal lesions one year after surgery in 60%-70% of patients in upper segments of the gastrointestinal tract that are outside the scope of ileocolonoscopy. The significance of these lesions is uncertain; whereas some authors defend that they must be considered as disease recurrence, the lack of a careful assessment of the upper gastrointestinal tract prior to surgery makes impossible to know if they were already present before surgery. In the early nineties, Lescut *et al* performed a perioperative retrograde endoscopy through the enterotomy and up to the angle of Treitz in 20 CD patients undergoing ileal and/or colonic resections, and found that 65% of patients had mucosal lesions[42]. Furthermore, a prospective endoscopic evaluation of these patients did not find any relationship between endoscopic recurrence 12 wk after surgery and the presence of small bowel lesions left in place after a "curative" surgery[43]. The spreading use of WCE for POR assessment may be additionally restricted by two major concerns: first, there are no studies evaluating the correlation between those mucosal lesions seen at WCE and the clinical outcome and, second, WCE interpretation is associated to a significant interobserver variability[44].

Abdominal ultrasonography is an attractive alternative to assess POR. It has the advantage over ileocolonoscopy to be non-invasive and well-tolerated, and it is cheaper than WCE. However, conventional transabdominal ultrasonography has the inherent technical limitations of the virtual lumen and the presence of gas in the intestinal loops for assessing intestinal lesions. To overcome these limitations, the administration of polyethylene glycol as an anechoic luminal contrast (the so called small intestine contrast ultrasonography -SICUS-) has proven to be able to dissociate intestinal loops, thus allowing the measurement of the bowel wall thickness and lumen diameter. In a recently published study in which SICUS was compared to ileocolonoscopy and WCE, even though it was found to be useful in assessing POR, it had a low diagnostic specificity and there was a poor correlation between wall thickness evaluated by SICUS and the Rutgeerts index[38]. In addition, it has to be kept in mind that, even when using improved modifications of abdominal ultrasonography, an experienced sonographist is always required to detect small intestine lesions.

Granulocyte-labelled scintigraphy has also been evaluated in a small study to assess POR suggesting that, although with a lower specificity, this technique might be useful[45]; nevertheless, it is time-consuming and it is not available in all centres.

The usefulness of inflammatory faecal markers for early and non-invasive evaluation of POR is still to be established. Recently, faecal markers have shown to be superior to CDAI and CRP in predicting endoscopic disease activity as measured by the CDEIS[46]. However, although promising results in pilot studies are available[47,48], the role of inflammatory faecal markers has not been appropriately evaluated in the post-operative setting.

PREVENTION OF POSTOPERATIVE RECURRENCE

Several different approaches have been unsuccessfully evaluated in the prevention of POR (Table 2). The preventive use of conventional drugs such as budesonide has not proven efficacy[49], although one single study suggested that this drug might be beneficial in those patients operated on for refractory inflammatory activity[50].

Despite they may be more appealing from a physiopathogenic point of view, neither the administration of anti-inflammatory cytokines such as interleukin-10[51], nor the use of probiotics[39,52,53] or a cocktail of probiotics and prebiotics[54], have demonstrated to be superior to placebo in preventing POR in RCTs.

As in many other clinical scenarios in CD, the role of mesalazine in the prevention of POR remains controversial. Many RCTs have been published, some of them with a large sample size, but with heterogeneous results.

Repeated meta-analyses suggest that 5-ASA compounds offer just a marginal benefit in this setting[55,56] and their use is only advised in patients with low-risk of POR or in non-treated patients with grade i1-i2 of endoscopical recurrence[2,57].

Enteral nutrition, although with a lesser effect than conventional steroids, is able to induce remission in up to 50% of patients with active CD with almost no associated serious adverse effects[58]. In fact, enteral nutrition is considered as the treatment of choice at the onset of paediatric CD. Some studies suggest that supplementation with enteral nutrition may also be beneficial for maintaining clinical remission[59]; however this strategy has been poorly explored after surgically-induced remission. Yamamoto and colleagues found in a prospective, controlled, open, pilot study that long-term nocturnal enteral nutrition administered by nasogastric self-intubation resulted in a significant reduction in the 12-mo rates of clinical and endoscopic POR[60].

Similarly, the efficacy of biological agents in this setting has not been assessed yet. Sorrentino and colleagues reported the results of a prospective, parallel, non-randomized study in which 7 patients were treated with a conventional dosing of infliximab plus low-dose oral methotrexate and compared to 16 patients treated with 2.4 g/d of mesalazine, to prevent POR. None of the infliximab-treated patients had evidence of disease recurrence by means of endoscopy, MRI and small-bowel enteroclysis 2 years after surgery, whereas 75% of the patients in the mesalazine group had endoscopic recurrence, 25% of them with concurrent clinical recurrence[61].

Even though it is well established that smokers have an increased risk of POR in comparison to non-smokers, the impact of smoking cessation on the risk of developing POR has only been evaluated in retrospective studies in which patients who quit smoking had a reduced risk for both clinical[62] and surgical[63] recurrence. Prospective, controlled studies evaluating the usefulness of smoking cessation to prevent POR will never be performed but, taking into account that the impact of this therapeutical measure has been compared to the start of immunomodulator therapy[64], it should be the first line therapy for POR prevention.

Nitroimidazolic antibiotics are the only drugs with clearly proven efficacy at preventing endoscopic and clinical POR. However, side effects are a major drawback for their long-term administration. In the two RCTs that evaluated metronidazole (for 3 mo) and ornidazole (for 12 mo) in the prevention of POR, almost one half of the patients developed unequivocal drug-related side effects, leading to treatment discontinuation in 13% and 21% of patients, respectively[11,12]. Therefore, nitroimidazolic antibiotics are not appropriate as monotherapy for maintaining postoperative remission.

Many arguments suggest that thiopurines may work in preventing CD recurrence. First, thiopurines (azathioprine and 6-mercaptopurine) are, together with infliximab and adalimumab, the only drugs that have proven efficacy for maintaining CD in remission[65-67]. Second, Rutgeerts *et al*, in the ornidazole trial, already found that discontinuation of immunomodulators at the time of operation was the only clinical parameter predicting clinical recurrence, irrespective of the treatment during the trial. This led the authors to suggest that patients receiving thiopurines before surgery should continue on these drugs after intestinal resection[12]. Finally, azathioprine may lead to healing or improvement of endoscopic lesions in a great proportion of patients with severe postoperative recurrence, as described by D'Haens *et al*[68]. However, thiopurines have not been appropriately evaluated in this clinical setting. Several retrospective studies reported good results with AZA to prevent POR[69-72]. The largest RCT published up to date compared thiopurines to mesalazine and placebo, and found that 6-mercaptopurine was more effective than placebo for preventing both endoscopic and clinical POR over 2 years[73]. Nevertheless, the study was strongly criticized because of a lower than expected efficacy of 6-mercaptopurine (maybe related to the low dose used) and the high rate of dropouts from the study. A previous small-sized RCT did not demonstrate any superiority of low-dose azathioprine over mesalazine 3 g/d[74]. In addition, the use of thiopurines seems to merely delay but not avoid the development of mucosal lesions in the neoterminal ileum, as stated in two recently published prospective, open studies[38,72], suggesting that the efficacy of these drugs should be improved. Despite that, thiopurines are the best drugs to prevent and treat POR and they are still considered the first line treatment in patients with severe endoscopic lesions or at high risk.

Given the limited efficacy and/or applicability of the available preventive measures, alternative or combined strategies must be investigated. Recently, D'Haens and colleagues reported positive results with azathioprine when associated to metronidazole for the first 3 mo after surgery in patients at high risk for POR. Such an association resulted to be better than metronidazole alone, with 12-mo endoscopic recurrence rates of 44% and 69%, respectively[75]. Smoking cessation might have a synergistic effect with thiopurines on the prevention of POR. In a retrospective study, Papay and co-workers found that treatment with thiopurines and non-smoking were the only factors associated with a lower risk of surgical recurrence in a large cohort of CD patients who had been operated on, although non-smoking did not reach statistical significance in the multivariate analysis (OR 1.6, 95% CI 0.99-2.7)[76].

A PRACTICAL APPROACH: WHICH PATIENTS MUST START PREVENTION TREATMENT AFTER SURGERY?

Whether POR must be prevented in all patients after intestinal resection and how, is still under debate. Even though everyone agrees in treating those patients at "high risk", it is difficult (if not impossible) in clinical practice to classify patients as being at "low" or "high" risk; therefore, this is not applicable in most instances.

As long as smoking is harmful not only for Crohn's evolution (and, of course, for the risk of developing POR) but also for developing cardiovascular and neoplastic diseases, smokers have to be earnestly encouraged to give up smoking once surgery have been planned. Those patients who continue smoking despite medical advice should be considered as being at high risk and, consequently, treated with thiopurines. It also seems clear that patients with previous intestinal resections must follow active prevention; in this setting, azathioprine has shown to be superior to no-treatment[71] or high-dose of mesalazine[77] at preventing clinical recurrence. There are no other clinical or epidemiological factors clearly associated with a high risk of POR; thus, studies in large cohorts of patients evaluating not only clinical and epidemiological but also genetic and serological factors are warranted. In the meantime, some authors are prone to endoscopically monitor or even prescribe mesalazine to those patients with no risk factors (mainly smoking, second resection, and/or penetrating disease pattern). Our opinion is that all patients must be given thiopurines. Crohn's disease is a chronic condition with a relapsing course and most patients will develop penetrating or stenosing complications within the first 5 to 10 years from diagnosis. This has led to the thought that maintenance treatment must be started right from the diagnosis of CD, and it has been already shown that early introduction of thiopurines is beneficial in both paediatric[78] and adult[79] CD patients. From this point of view, it makes no sense to leave untreated those patients who already had a complication of the disease. Even if this policy is chosen, many questions remain unanswered: must thiopurines be started together with a 3-mo course of metronidazole? Which are the alternatives in those patients intolerant to thiopurines or with a previous failure of these drugs to prevent POR? Can we stop thiopurines in smokers some months after smoking cessation?

Abstract

AIM: To study the relationship between nm23H1 gene genetic instability and its clinical pathological characteristics in Chinese digestive system cancer patients.

METHODS: Polymerase chain reaction-single strand conformation polymorphism (PCR-SSCP) was used to analyze the microsatellite instability (MSI) and loss of heterozygosity (LOH). Immunohistochemistry was employed to detect the expression of nm23H1.

RESULTS: The MSI was higher in TNM stage Ⅰ + Ⅱ than in stage Ⅲ + Ⅳ of gastric, colonic and gallbladder carcinomas. The LOH was higher in TNM stage Ⅲ + Ⅳ than in stage Ⅰ + Ⅱ of gastric, colonic and hepatocellular carcinomas. Lymphatic metastasis was also observed. The expression of nm23H1 protein was lower in TNM stage Ⅲ + Ⅳ than in stage Ⅰ + Ⅱ of these tumors and in patients with lymphatic metastasis.The nm23H1 protein expression was higher in the LOH negative group than in the LOH positive group.

CONCLUSION: MSI and LOH may independently control the biological behaviors of digestive system cancers. MSI could serve as an early biological marker of digestive system cancers. Enhanced expression of nm23H1 protein could efficiently inhibit cancer metastasis and improve its prognosis. LOH mostly appears in late digestive system cancer.

Key words: nm23H1; Gastric cancer; Colonic cancer; Hepatocellular carcinoma; Gallbladder carcinoma

INTRODUCTION

Digestive malignant tumor remains one of the commonly seen tumors in clinical practice, accounting for 70% of all digestive tumors. The mortality rate of gastric, colonic, liver and gallbladder tumors are the highest. Malignant tumors increase with the changing eating habit and environment changes. Since early diagnosis is always a challenge, the disease threatens the life of more and more patients. Therefore, great attention should be paid to finding new early markers and effective treatment methods for this disease.

Growing evidence suggests that accumulation of multiple alterations, such as activation of proto-oncogenes and inactivation of tumor suppressor genes, is responsible for the development and progression of digestive system cancer. Genetic instability of oncogenes, such as microsatellite instability (MSI) and loss of heterozygosity (LOH), is probably associated with mutations of genes

responsible for tumor-genesis, which play an important role in tumor pathology[1-5]. Studies on MSI and LOH of digestive system cancer have been focused on genetic instability of P53[6], P16 and FHIT[7]. However, few studies are available on gene nm23H1[8-11]. nm23H1 is a metastasis-associated gene of various tumors and its coding protein has the NDPK function, which determines the biological behaviors of cell proliferation, differentiation and migrations. Inhibited expression of nm23H1 shows malignant behaviors of melanoma[12], gastric[13], colon[14] and breast carcinomas[15]. The present study was to investigate the MSI and LOH of gene nm23H1 at locus D17S396 in Chinese patients with colon, gastric, hepatocellular and gallbladder cancers, and their influence on nm23H1 protein expression.

MATERIALS AND METHODS

Tissue sample

Tissue samples were obtained from 40 gastric, 30 colon, 48 HCC and 47 gallbladder carcinoma patients. The final pathological diagnosis was based on the result of histological examination. No patient received radioactive therapy or chemotherapy prior to operation. Fresh surgical tissue samples were fixed immediately in formaldehyde solution for 12-24 h and paraffin-embedded for polymerase chain reaction-single strand conformation polymorphism (PCR-SSCP) and immunohistochemistry study.

DNA extraction and PCR amplification

DNA was extracted with a Qiagen's kit according its manufacturer's instructions. Designed primers were designed as previously described[16] and synthesized by Shanghai Shengyou Biology Company. The primer sequences are sense: 5'-TTGACCGGGGTAGAGA-ACTC-3', antisense: 5'-TCTCAGTACTTCCCGT-GACC-3'. The PCR mixture contained 200 ng of template-DNA while the PCR reaction buffer contained 50 mmol/L KCl, 10 mmol/L Tris-HCl (pH 8.4), 1.5 mmol/L $MgCl_2$, 0.5 μmol/L each of two fragment-specific primers, 100 μmol/L each of dATP, dGTP, dTTP and dCTP, and 2 units of Taq DNA polymerase (Shanghai Shengyou Biology Company) for a reaction volume of 50 μL. The conditions for PCR amplification were as follows: a pre-denaturation at 94℃ for 5 min, then 35 cycles at 94℃ for 45 s, at 62℃ for 45 s, at 72℃ for 45 s, and a final extension at 72℃ for 10 min. The amplified fragments were run on 1% agarose gel.

SSCP analysis

SSCP analysis of fragments was performed on a mini electrophoresis unit (Bio-Rad Company, USA). Ten microlitres of the PCR product was diluted with 10 μL of sample buffer containing 90% formamide, 0.05% bromophenol blue dye and 0.05% xylene cyanol. The samples were heated at 100℃ for 8 min, transferred into an ice-cold water bath for 3 min, and analyzed by 10% polyacrylamide gel electrophoresis (PAGE) in 45 mmol/L-Tris-borate (pH 8.0) of 1 mmol/L-EDTA (TBE) buffer under 13 v/cm at 10℃.

DNA silver staining

Gels were stained with silver as follows. In brief, gels were fixed in 100 mL/L alcohol for 10 min, and then oxidized in 100 mL/L nitric acid for 3 min. After washed for 1 min with double distilled water, they were stained in 2 g/L silver nitric acid for 5 min and washed for 1 min with double distilled water. Gels showed an appropriate color in 15 g/L anhydrous sodium carbonate and 4 mL/L formalin. The reaction was terminated by 7.5 mL/L glacial acetic acid, and finally, the gels were washed with double distilled water.

Immunohistochemical assay

Immunohistochemical study was performed using the Envision method. Briefly, 5 μm thick tissue sections were deparaffinized and dehydrated. Endogenous peroxide activity was blocked with 3% hydrogen peroxide for 20 min. After three times of rinsing with 0.01 mol/L phosphate-buffered saline (PBS, pH = 7.4), the sections were incubated with 10% normal goat serum at room temperature for 10 min to block the nonspecific reaction followed by 2 h with anti-nm23H1 antibody. After rinsed in PBS for 5 min, the sections were incubated with Envision complex for 2 h at room temperature, and stained with 3,3-diaminobenzidine (DAB) after washed in PBS.

Imaging analysis and data collection

After immunohistochemistry staining, the sections were analyzed with Leica-Qwin computer imaging techniques. We selected 20 continuous high microscopical views that did not overlap. Then we tested the gray-value of background and named it as GA. The gray-value of nm23H1 positive granules was named as Ga and area density of BRCA1 positive cells as A_{Aa}. We used Excel function to compute the value of positive unit (PU) which represents the expression intensity of nm23H1 protein in gastric cancer cells. The highest gray value was 255 in Leica-Qwin system.

Statistical analysis

Statistical analysis was performed using analysis of variance (AVONA). $P < 0.05$ was considered statistically significant.

RESULTS

Relationship between clinical pathological parameters and nm23H1 genetic instability in gastric cancer

The positive rate of D17S396 MSI (Figure 1A), LOH (Figure 1B) and nm23H1 protein (Figure 1C) was 20.00%, 17.50% and 55.00%, respectively, in 40 cases of gastric cancer (Table 1).

MSI and LOH were independent of the histological type of gastric cancer, the degree of differentiation and serosa infiltration. MSI was related to the clinical

Table 1 Relationship between clinical pathological parameters and nm23H1 genetic instability in gastric cancer

Clinical pathological factors	Cases (*n*)	MSI+ (%)	LOH+ (%)	nm23H1+ (%)	nm23H1 expression intensity (mean ± SD)
Histological type	40	8 (20.00)	7 (17.50)	22 (55.00)	40.63 ± 2.95
Tubular adenocarcinoma	33	7 (22.21)	6 (18.18)	21 (63.64)	41.56 ± 2.78

[1]P < 0.0001 *vs* differentiation degree of tubular adenocarcinoma; [2]P = 0.017 *vs* tubular adenocarcinoma; [3]P = 0.039 *vs* positive serosa infiltration; [4]P = 0.017, [5]P = 0.038, [6]P = 0.001 *vs* negative lymph node metastasis; [7]P = 0.04, [8]P = 0.017, [9]P = 0.001 *vs* TNM stage Ⅰ + Ⅱ.

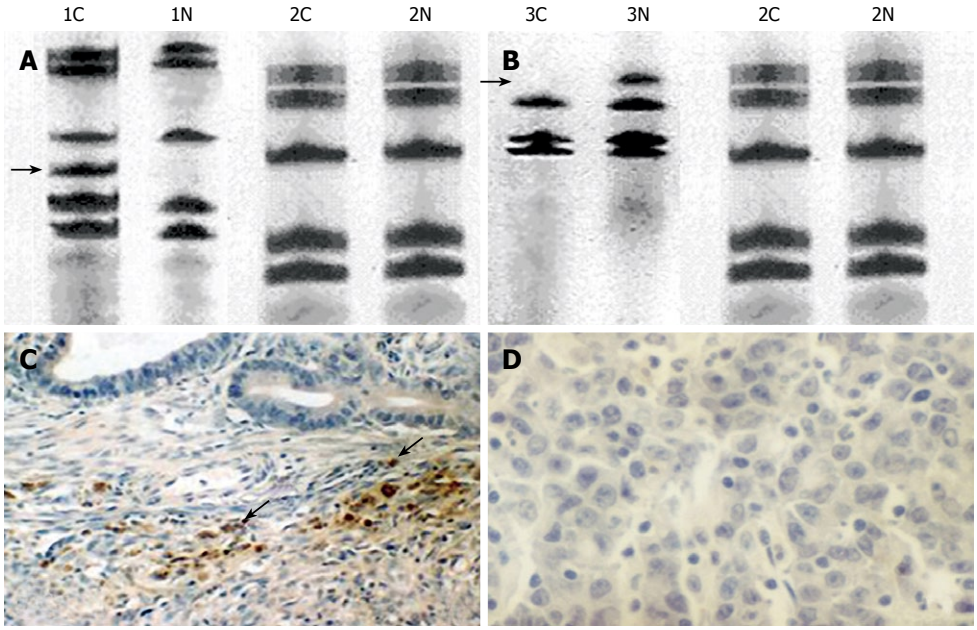

Figure 1 PAGE of D17S396 locus and immunohistochemistry of nm23H1 protein in gastric cancer. **A**: No difference in tumor tissue (2C) and normal tissue (2N). MSI (arrow) was positive when an allele band was added (1C) as compared with normal tissue (1N); **B**: No difference in tumor tissue (2C) and normal tissue (2N). LOH was positive when an allele band was added (arrow) in tumor tissue (3C) as compared with normal tissue (3N); **C**: Brown-yellow granules of nm23H1 protein mostly located in cytoplasm. The stained nucleolus and membrane of cells were observed (arrow, x 200); **D**: Control group, PBS replaced anti-nm23H1 protein as the first antibody (x 400).

TNM stage. The frequency of MSI was higher in stage Ⅰ + Ⅱ than in stages Ⅲ + Ⅳ of gastric cancer (31.82% *vs* 5.56%, P = 0.04). In contrast, LOH was higher in stage Ⅲ + Ⅳ than in stage Ⅰ + Ⅱ of gastric cancer (33.33% *vs* 4.55%, P = 0.017). In addition, MSI tended to decrease with lymph node metastasis (5.00% *vs* 35.00%, P = 0.017), while LOH did not (30.00% *vs* 5.00%, P = 0.038).

The positive rate of nm23H1 protein was closely correlated with the histological type, differentiation degree and clinical stage of gastric cancer. The expression of nm23H1 protein was significantly higher in tubular adenocarcinoma than in mucous adenocarcinoma (63.64% *vs* 14.29%, P = 0.017), and tended to increase with the differentiation degree of tubular adenocarcinoma (P < 0.0001). The positive rate of nm23H1 expression was higher in stage Ⅰ + Ⅱ than in stage Ⅲ + Ⅳ of gastric cancer (77.27% *vs* 17.86%, P = 0.001), and so was in negative than in positive lymph node metastasis. The same phenomenon was observed in patients with positive or negative MSI (87.50% *vs* 46.88%, P = 0.04, Table 2). On the contrary, the expression of nm23H1 protein was lower in LOH positive patients than in LOH negative patients (14.29% *vs* 63.64%, P = 0.017, Table 2). Computer imaging analysis showed that there was no statistical difference in nm23H1 protein expression between the two groups of patients (Table 3).

Relationship between clinical pathological parameters and nm23H1 genetic instability in colon cancer

Microsatellite fragments of D17S396 were amplified. The positive rate of D17S396 MSI (Figure 2A), LOH (Figure 2B) and nm23H1 protein (Figure 2C) was 26.67%, 20.00% and 53.33%, respectively, in 30 cases of colon cancer (Table 4).

MSI and LOH were independent of the histological type, the degree of differentiation and serosa infiltration

Table 2 Relationship between MSI, LOH and nm23H1 protein expression in different cancers of digestive system

Group	Positive frequency of nm23H1 protein % (*n*/*n*)			
	Gastric cancer	Colon cancer	HCC	Gallbladder cancer
MSI positive	87.50 (7/8)	75.00 (6/8)	83.33 (5/6)	63.64 (7/11)
MSI negative	46.88 (15/32)[1]	45.45 (10/22)	52.38 (22/42)	41.67 (15/36)
LOH positive	14.29 (1/7)	33.33 (2/6)	27.27 (3/11)	11.11 (1/9)
LOH negative	63.64 (21/33)[2]	58.33 (14/24)	64.86 (24/37)[3]	55.26 (21/38)[4]

[1]$P = 0.04$ *vs* MSI positive group; [2]$P = 0.017$, [3]$P = 0.027$, [4]$P = 0.016$ *vs* LOH positive group.

Table 3 Relationship between MSI, LOH and nm23H1 protein expression in different cancers of digestive system (mean ± SD)

Group	nm23H1 protein expression intensity ($n = 10$)			
	Gastric cancer	Colon cancer	HCC	Gallbladder cancer
MSI positive	26.34 ± 2.17	29.34 ± 2.14	29.34 ± 2.14	26.34 ± 2.17
MSI negative	25.78 ± 2.34	24.78 ± 2.06	24.78 ± 2.06	25.78 ± 2.34
LOH positive	27.64 ± 2.38	22.64 ± 2.38	22.64 ± 2.38	27.64 ± 2.38
LOH negative	25.88 ± 2.52	26.88 ± 2.52	26.88 ± 2.52	25.88 ± 2.52

Table 4 Relationship between clinical pathological parameters and nm23H1 genetic instability in colon cancer

Clinical pathological factors	Cases	MSI+ (%)	LOH+ (%)	nm23H1+ (%)	nm23H1 expression intensity (mean ± SD)
Histological type	30	8 (26.67)	6 (20.00)	16 (53.33)	40.21 ± 3.29
Tubular adenocarcinoma	25	7 (28.00)	5 (20.00)	15 (60.00)	40.76 ± 2.74

TNM stage					
Ⅰ + Ⅱ	16	7 (43.75)	1 (11.76)	13 (81.25)	41.49 ± 2.01
Ⅲ + Ⅳ	14	1 (7.14)[4]	5 (35.71)[5]	3 (21.43)[6]	39.53 ± 2.61

[1]$P = 0.004$ *vs* differentiation degree of tubular adenocarcinoma; [2]$P = 0.003$, [3]$P = 0.074$ *vs* positive lymph node metastasis; [4]$P = 0.023$, [5]$P = 0.046$, [6]$P < 0.0001$ *vs* TNM stage Ⅰ + Ⅱ.

of colon cancer. MSI was related to the clinical TNM stage. In TNM staging, the frequency of MSI was higher in stage Ⅰ + Ⅱ than in stages Ⅲ + Ⅳ of colon cancer (43.75% *vs* 7.14%, $P = 0.023$). In contrast, LOH was higher in stage Ⅲ + Ⅳ than in stage Ⅰ + Ⅱ of colon cancer (35.71% *vs* 11.76%, $P = 0.046$). In addition, LOH tended to decrease with lymph node metastasis (5.26% *vs* 45.45%, $P = 0.003$).

The positive rate of nm23H1 protein was closely correlated with the biological behaviors, differentiation degree and clinical stage of colon cancer. The expression of nm23H1 protein trended to increase with the differentiation degree of tubular adenocarcinoma ($P = 0.004$). The positive rate of nm23H1 was higher in stage Ⅰ + Ⅱ than in stage Ⅲ + Ⅳ of colon cancer (81.25% *vs* 21.43%, $P < 0.0001$), and higher in negative than in positive lymph node metastasis patients (68.42% *vs* 27.27%, $P = 0.074$). Computer imaging analysis showed that there was no difference in nm23H1 protein expression level between the two groups of patients (Table 3).

Relationship between clinical pathological parameters and nm23H1 genetic instability in HCC

The positive rate of D17S396 MSI (Figure 3A), LOH (Figure 3B) and nm23H1 protein (Figure 3C) was 12.50%, 22.92% and 56.25%, respectively, in 48 cases of HCC (Table 5).

MSI and LOH were independent of the differentiation degree, liver infiltration and lymph node metastasis of HCC. The frequency of MSI showed no correlation to the differentiation degree, liver infiltration and lymph node metastasis of HCC. However, LOH was higher in stage Ⅲ + Ⅳ than in stage Ⅰ + Ⅱ of HCC (52.63% *vs* 3.45%, $P < 0.0001$).

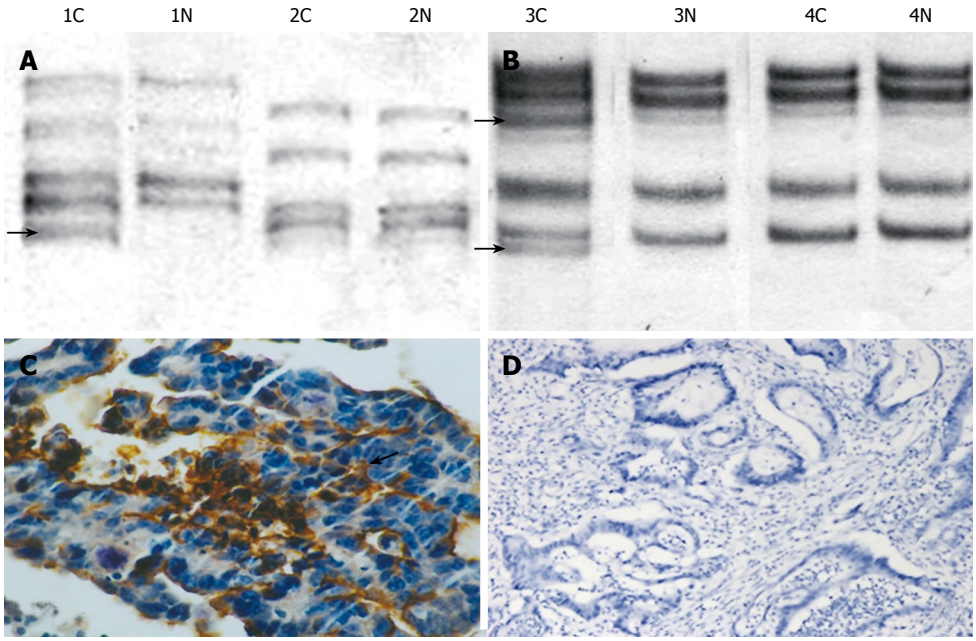

Figure 2 PAGE of D17S396 locus and immunohistochemistry of nm23H1 protein in colon cancer. **A**: No difference in tumor tissue (2C) and normal tissue (2N). MSI was positive when an allele band was added (arrow) in tumor tissue (1C) as compared with normal tissue (1N); **B**: No difference in tumor tissue (4C) and normal tissue (4N). LOH was positive when an allele band was added (arrow) in tumor tissue (3C) as compared with normal tissue (3N); **C**: Brown-yellow granules of nm23H1 protein mostly located in membrane. The stained nucleolus and cytoplasm of cells were observed (arrow, x 400); **D**: Control group, PBS replaced anti-nm23H1 protein as the first antibody (x 200).

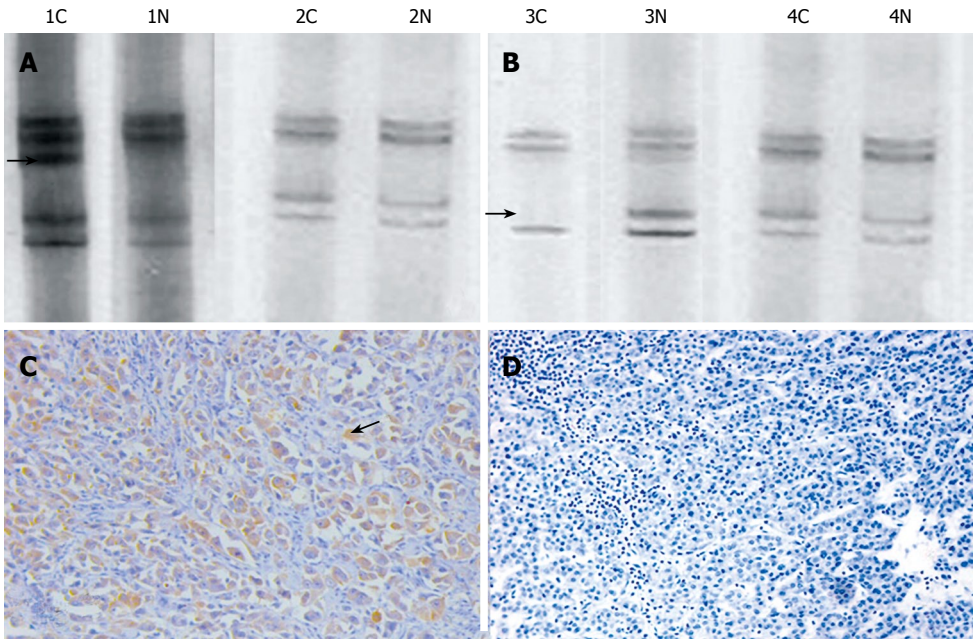

Figure 3 PAGE of D17S396 locus and immunohistochemistry of nm23H1 protein in HCC. **A**: No difference in tumor tissue (2C) and normal tissue (2N). MSI was positive when an allele band was added (arrow) in tumor tissue (1C) as compared with normal tissue (1N); **B**: No difference in tumor tissue (4C) and normal tissue (4N). LOH was positive in the absence of an allele band (arrow) in tumor tissue (3C) as compared with normal tissue (3N); **C**: Brown-yellow granules of nm23H1 protein mostly located in cytoplasm. The stained nucleolus and membrane of cells were observed (arrow, x 400); **D**: Control group, PBS replaced anti-nm23H1 protein as the first antibody (x 200).

The positive rate of nm23H1 protein was related with lymph node metastasis and clinical stage of HCC. The expression of nm23H1 protein was higher in stage Ⅰ + Ⅱ than in stage Ⅲ + Ⅳ of HCC (75.86% *vs* 26.32%, $P < 0.0001$), and in negative lymph node metastasis patients than in positive lymph node metastasis patients (82.14% *vs* 20.00%, $P < 0.0001$). The same phenomenon occurred in negative and positive LOH patients (64.86% *vs* 27.27%, $P = 0.027$, Table 2). However, MSI had no effect on the expression of nm23H1 protein (Table 2). Computer imaging analysis showed that there was no difference in the nm23H1 protein expression level between the two groups of patients (Table 3).

Relationship between clinical pathological parameters and nm23H1 genetic instability in gallbladder carcinoma

In gallbladder carcinoma, the positive rate of D17S396 MSI (Figure 4A), LOH (Figure 4B) and nm23H1 protein (Figure 4C) was 22.40%, 19.14% and 46.81%, respectively, in 47 cases of gallbladder carcinoma (Table 6).

MSI and LOH were correlated to the differentiation degree, liver infiltration, lymph node metastasis and TNM staging of gallbladder carcinoma. MSI trended to increase with the differentiation degree of gallbladder carcinoma ($P < 0.0001$). Furthermore, MSI was higher in negative than in positive liver infiltration patients (34.48% *vs* 5.56%, $P = 0.023$), and in negative than in positive lymph node metastasis patients (37.04% *vs* 5.00%, $P < 0.0001$). The frequency of MSI was higher in stage Ⅰ + Ⅱ than in stage Ⅲ + Ⅳ of gallbladder carcinoma (43.48% *vs* 4.17%, $P = 0.001$). On the other hand, the frequency LOH was lower than that of MSI (6.90% *vs* 38.89%, $P = 0.006$).

The positive rate of nm23H1 protein was higher in

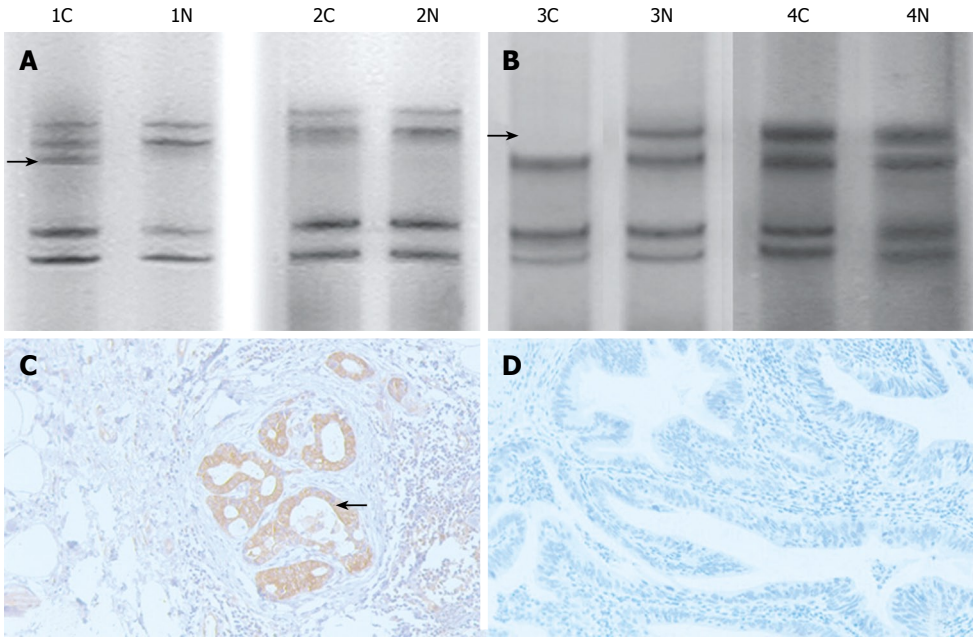

Figure 4 PAGE of D17S396 locus and immunohistochemistry of nm23H1 protein in gallbladder carcinoma. **A**: No difference in tumor tissue (2C) and normal tissue (2N). MSI was positive when an allele band was added (arrow) in tumor tissue (1C) as compared with normal tissue (1N); **B**: No difference in tumor tissue (4C) and normal tissue (4N). LOH was positive in the absence of an allele band (arrow) in tumor tissue (3C) as compared with normal tissue (3N); **C**: Brown-yellow granules of nm23H1 protein mostly located in cytoplasm, and part of the stained nucleolus and membrane of cells were observed (arrow, × 200); **D**: Control group, PBS replaced anti-nm23H1 protein as the first antibody (× 200).

Table 5 Relationship between clinical pathological parameters and nm23H1 genetic instability in HCC

Clinical pathological factors	Cases	MSI+ (%)	LOH+ (%)	nm23H1+ (%)	nm23H1 expression intensity (mean ± SD)
Differentiation degree	48	6 (12.50)	11 (22.92)	27 (56.25)	25.96 ± 2.53

[1]$P < 0.0001$; [2]$P = 0.008$ *vs* differentiation degree; [3]$P = 0.023$; [4]$P = 0.006$ *vs* positive liver infiltration; [5]$P < 0.0001$, [6]$P = 0.001$, [7]$P = 0.009$ *vs* positive lymph node metastasis; [8]$P = 0.001$; [9]$P < 0.0001$; [10]$P = 0.013$ *vs* TNM stage Ⅰ + Ⅱ.

stage Ⅰ + Ⅱ than in stage Ⅲ + Ⅳ gallbladder carcinoma (65.22% *vs* 29.17%, $P = 0.013$), and in negative than in positive lymph node metastasis patients (62.96% *vs* 25.00%, $P = 0.009$). The same phenomenon occurred

in the negative and positive LOH patients (55.26% *vs* 11.11%, $P = 0.016$, Table 2). However, MSI had no effect on the expression of nm23H1 protein. Computer imaging analysis showed that there was no difference in nm23H1 protein expression level between the two groups of patients (Table 3).

DISCUSSION

Microsatellites are short tandem repeat sequences with unknown functions scattered throughout the human genome. LOH and MSI are the phenotypes with genetic instability caused by abnormalities of tumor suppressor and DNA mismatch repair (MMR) genes. MSI is associated with slippage of DNA polymerase during DNA synthesis resulting in changing units of repetitive sequences, while LOH is allelic loss in a certain region of chromosome. Genetic instability of oncogenes, such as MSI and LOH, is probably associated with mutations of genes responsible for tumor-genesis, and plays an important role in tumor pathology[17].

MSI was first found in hereditary non-polyposis colorectal cancer (HNPCC), and then in some kinds of sporadic tumors, such as colon cancer[18], gastric cancer[19], uterus cancer[20], breast cancer[21], prostate cancer[22] and pancreatic cancer[23]. Alexander[24] examined the utility of histopathology for the identification of MSI-H cancers by evaluating the features of 323 sporadic carcinomas using specified criteria and comparing the results to MSI-H status, showing that MSI is more often found in patients with early stage cancers. In our experiment, the MSI frequency was significantly correlated with the clinical TNM staging and lymph node metastasis of gastric, colonic and gallbladder cancers. The frequency of MSI was higher in stages Ⅰ and Ⅱ than in stages Ⅲ and Ⅳ of these cancers. Furthermore, the frequency tended to decrease with lymph node metastasis. Our data indicate that MSI of nm23H1 may be a molecule marker of early digestive system cancer.

Berney[25] investigated the relationship between LOH and MSI in liver metastasis and nm23 protein expression, showing that the increasing proportion of LOH in nm23H1 is positively associated with liver metastasis. Candusso[26] found that LOH often occurs in later stage cancer with lymph metastasis. The frequency of LOH in 4 kinds of digestive system cancer in our study was significantly higher in stage TNM Ⅲ + Ⅳ than in stage TNM Ⅰ + Ⅱ. Moreover, the frequency of LOH was significantly higher in patients with lymph node metastasis than in those without lymph node metastasis, suggesting that LOH of nm23H1 gene may occur in later stage digestive system cancer and accelerate lymphatic metastasis, and thus can be used as an estimate marker for malignant degree, lymphatic metastasis and prognosis. In the present study, the difference in pathology of MSI and LOH had a strong influence on the four digestive system cancers, indicating that MSI and LOH can control the carcinogenesis and metastasis through different pathways.

Lower expression of nm23H1 is closely associated with high metastasis potential and poor prognosis of human mammary cancer, gastric cancer, lung cancer, melanoma, and ovary cancer. The lower the nm23H1 expression is, the poorer the prognosis is. Steeg[27] found that nm23H1 can prevent tumor metastasis by inhibiting the ability of cancer cells to clone. In our study, TNM stage, lymphatic metastasis, and local expression of nm23H1 protein were significantly reduced in gastric cancer, colonic cancer, HCC and gallbladder cancer. Also, the expression of m23H1 protein was higher in gastric and colon cancer, which was associated with the degree of differentiation. These findings suggest that nm23H1 is actively involved in cancer metastasis as a prohibitive gene, and restrains the digestive system cancer, and can serve as a valuable biological marker in the evaluation of tumor development and prognosis.

In our study, the frequency of nm23H1 protein was higher in negative than in positive LOH patients, suggesting that LOH on D17S396 can induce loss or aberrance of anti-oncogenes, and decrease the expression of nm23H1 protein, which endows cancer with a high invasiveness and a poor prognosis. In contrast, the frequency of nm23H1 protein was higher in positive than in negative MSI patients, suggesting that MSI can accelerate the expression of nm23H1 protein. However, its molecular mechanism is not clear, and remains to be elucidated.

COMMENTS

Background

nm23H1 has been regarded as a metastasis-associated gene in various tumors. Genetic instabilities of oncogenes, such as microsatellite instability (MSI) and loss of heterozygosity (LOH), are probably associated with mutations of genes responsible for tumor-genesis, and play an important role in tumor pathology. Studies on MSI and LOH of digestive system cancer have been focused on the genetic instability of P53, P16 and FHIT, but few studies are available on gene nm23H1.

Research frontiers

The present study investigated the MSI and LOH of gene nm23H1 at locus D17S396 in Chinese patients with digestive system cancers and their influence on the nm23H1 protein expression, to reveal their clinical pathological characteristics.

Innovations and breakthroughs

The results of this study indicate that MSI and LOH may independently control the biological behaviors of digestive system cancers. Enhanced expression of nm23H1 protein could efficiently inhibit cancer metastasis and improve the prognosis.

Applications

MSI could serve as an early biological marker of digestive system cancers. The data strongly suggest that LOH usually appears in the late digestive system cancer, indicating a higher malignancy and a poor prognosis.

Peer review

This is an interesting study, which showed a certain significant correlation between nm23H1 genetic instability and clinical pathological characteristics of different kinds of digestive system cancer, which may serve as a marker for the diagnosis of such cancers.

Abstract

AIM: To investigate the dynamic characteristics and the correlation between PCNA, Bax, nm23, E-cadherin expression and apparent diffusion coefficient (ADC) on MR diffusion-weighted imaging (DWI) after chemoembolization in rabbit liver VX-2 tumor model.

METHODS: Forty New Zealand rabbit liver VX-2 tumor models were included in the study. DWI was carried out periodically after chemoembolization. All VX-2 tumor samples in each group were examined by histopathology and Strept Avidin-Biotin Complex (SABC) immunohistochemical staining.

RESULTS: The PCNA expression index in VX-2 tumors was higher than in the normal parenchyma around the tumor ($P < 0.001$). Nm23, Bax or E-caderin expression index in VX-2 tumors were lower than in the normal parenchyma around the tumor (all $P < 0.001$). PCNA and nm23 expression in the VX-2 tumor periphery first increased and then decreased ($P < 0.001$ and $P = 0.03$, respectively), while the expression of Bax and E-cadherin before and after chemoembolization was insignificant. When b-value was 100 s/mm^2, there was a linear correlation between PCNA expression and ADC in the area of VX-2 tumor periphery ($P < 0.001$), and PCNA expression in VX-2 tumor periphery influenced the ADC.

CONCLUSION: The potential of VX-2 tumor infiltrating and metastasizing decreases, while its ability to proliferate increases for a short time after chemoembolization. To some degree, the ADC value indirectly reflects the proliferation of VX-2 tumor cells.

Key words: Rabbit liver; VX-2 tumor; Chemoembolization; Diffusion-weighted imaging; Gene expression

INTRODUCTION

Hepatocellular carcinoma is one of the most common malignant tumors worldwide. The genetic mutation and abnormal gene expression of hepatocellular carcinoma during its origin, progression and after transcatheter arterial chemoembolization (TACE) have been investigated in several clinical and experimental studies, with respect to PCNA, Bax, E-caderin (E-cad) and nm23 gene expression

The expression of Proliferating Cell Nuclear Antigen (PCNA) is high in the S, G_2 and M stages of cell division, and low in the G_0 and G_1 stages. The degree of PCNA expression reflects cellular reproductive activity, which correlates significantly and positively with

the pathological grade, the potential for recurrence, and survival time of malignant tumors. Therefore, it is important to measure the degree of PCNA expression in evaluating the malignant potential and prognosis of tumors[1-5]. Shi *et al*[4] observed that the degree of PCNA expression correlated with the size, invasive potential and degree of enhancement on CT scan of hepatocellular carcinoma. As a member of the Bcl-2 family, Bax gene is an important apoptotic controlling gene. Most investigations have demonstrated that Bax is a protein-inducing apoptosis, which promotes cell apoptosis and suppresses cell proliferation through multiple mechanism[6-9]. The nm23-H1 gene expresses nucleoside diphosphate kinase (ndpk), and has a significant impact on tumor metastasis. As reported in several studies, low expression of nm23 and the absence of alleles correlates with a high rate of infiltration and metastasis in many tumors, including hepatocellular carcinoma[4-10]. The coding product of E-cad gene is a transmembrane glycoprotein that is calcium depended and is able to mediate adhesion between cells. When it is low or absent, the adhesion between cells decreases, enabling the cancer cells to separate easily from the primary tumor, resulting in local infiltration and distant metastasis[10].

Diffusion-weighted imaging (DWI) is used much less frequently in the diagnosis of hepatic tumor and for the evaluation of tumor progression, because of its poor imaging quality[11-14]. With the development of MRI software and scanning technology, especially for echoplanar imaging (EPI) in recent years, many deficiencies, such as poor imaging quality and slow scanning speed, have been resolved[15-17]. As reported by several workers (Ichikawa *et al*[18,19], Yamashita *et al*[20], Taouli *et al*[21], Sun *et al*[22] and Yang *et al*[23,24]), the apparent diffusion coefficient (ADC) of hepatic cysts, hemangioma, hepatocellular carcinoma, metastatic lesions, normal parenchyma and liver cirrhosis decrease gradually on DWI. The ADC of hepatic cysts is the highest, while ADC of benign tumors is higher than that of malignant tumors. Colagrande *et al*[25] demonstrated that coagulation necrosis had low signal compared to viable tumor. Kamel *et al*[26] confirmed these findings in a study on 8 patients with hepatocellular carcinoma; ADC increased with the degree of tumor necrosis, and in 6 tumors the DWI values were higher compared to the normal parenchyma. Based on these observations, DWI, and especially ADC have potential value of differentiating benign tumor from malignant tumor.

However, few studies have been carried out to investigate the dynamic characteristics of hepatocellular carcinoma gene expression after chemoembolization. Moreover, the ADC of hepatocellular carcinoma on DWI has not been investigated by image-pathology-gene expression.

The purpose of the present study was to investigate the dynamic characteristics of PCNA, Bax, nm23 and E-cad expression after chemoembolization, and to evaluate the correlation between ADC on DWI and gene expression in rabbit VX-2 tumor model. However, the signal dynamic characteristics on DWI and the pathological mechanisms will be discussed in separate report.

MATERIALS AND METHODS

Animals and establishment of VX-2 tumor model

Animal studies were carried out under the supervision of a veterinarian according to the guidelines on the Use of Laboratory Animals of the Ministry of Public Health of China. All animals were provided by the Laboratory Animal Center of the Second Xiangya Hospital and all protocols were approved by the Animal Use and Care Committee of the Second Xiangya Hospital.

Forty New Zealand rabbits were included in the study. Twenty-two were male and eighteen were female rabbits. The weight ranged from 1.7 kg to 2.5 kg, and the ages from 5 mo to 6 mo. All New Zealand white rabbits were healthy. Forty-seven rabbit VX-2 tumor models were developed by implanting directly into the liver, after opening the abdominal cavity. The rabbit VX-2 tumor strain was provided by the Fourth Military Medical University.

Forty VX-2 tumor models were chosen randomly from forty-seven VX-2 tumor models and were divided into four groups, a control group (non-interventional group, group A) and three investigation groups (group A, 16 h after chemoembolization; group B, 32 h after chemoembolization; and group C, 48 h after chemoembolization).

Interventional protocol

After DWI was performed on the 21st day after implantation, trans-hepatic artery catheterization chemoembolization was carried out in the animal operating room of the Second Xiangya Hospital, in study groups B, C and D.

First, the rabbits were anesthetized by injecting 3% soluble pentobarbitone. The abdominal skin was then disinfected, and the abdomen was opened by incising through the skin and the musculi recti abdominis. The organs of hepatic hilar region were exposed and the different structures such as arteria coeliaca, arteria hepatica communis, arteria hepatica propria, arteria gastroduodenalis and portal vein were recognized. The distal end of arteria gastroduodenalis was occluded, and a drop of aethocaine was placed on it. The arteria gastroduodenalis was punctured and a plastic transfixion pin was introduced and advanced into arteria hepatica propria, followed by infusion of iodized oil (0.3 mL/kg) and pharmorubicin (2 mg/kg). Finally, after making certain that there was no bleeding from the liver and other structures, the abdominal membrane, musculature and skin were sutured layer by layer.

Magnetic resonance imaging protocol

After the animals were anesthetized with 3% soluble pentobarbitone at a dose of 1 mL/kg or with different

Table 1 Gene expression of different areas of VX-2 tumour and the normal parenchyma around the tumor (%)

	PCNA	nm23	Bax	E-cad
Normal parenchyma	8.28 ± 5.61	16.53 ± 14.66	40.00 ± 23.72	78.15 ± 18.35
Tumor outer layer	65.45 ± 3.43	1.74 ± 4.07	1.91 ± 2.66	6.18 ± 7.55
Tumor periphery area	72.73 ± 14.23	0.42 ± 0.64	1.05 ± 1.09	1.96 ± 1.79
Tumor center area	58.37 ± 15.25	6.74 ± 10.13	2.16 ± 4.59	1.55 ± 3.65

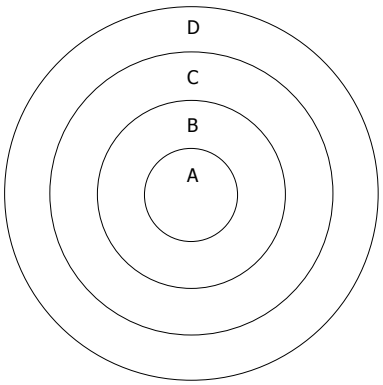

Figure 1 A-D represent VX-2 tumor center, VX-2 tumor periphery, VX-2 tumor outer layer and normal liver parenchyma around tumor respectively. The ADC levels and signal were measured on DWI, and the samples were investigated by histopathology.

doses based on the animal status, in order to make certain that the animals had stable breathing, DWI(axial) was performed on a 1.5-Tesla Signa Twinspeed MR scanner (General Electron Medical Systems, USA), using a small diameter cylindrical brain radiofrequency coil. The scans were done before chemoembolization, and again at 6 h, 16 h, 32 h and 48 h after chemoembolization. The DWI scanning parameters included spin echo echoplanar imaging (SE-EPI) series, *b*-value 100 and 300 s/mm^2, repetition time (TR) 6000 ms, echo time (TE) 45 ms, 20 cm × 15 cm field of view (FOV), 8 NEX, 2 mm thickness layer, and 0.5 mm Space, 128 × 128 matrix.

The ADC values and signal values were obtained in the VX-2 tumor periphery, VX-2 tumor center and normal liver parenchyma around the tumor (Figure 1) using Function software in GE workstation. Three different regions of interest (ROIs, 50 mm^2 each area) were chosen in the normal liver parenchyma (area D in Figure 1). The average reading was considered as the ADC value or the signal value of the normal liver parenchyma around the tumor. The thickness of the area A and B in Figure 1 was respectively two fifth of the diameter of the VX-2 tumor. Similarly, the average readings of three different ROIs ADC values or signal values in area B were considered as the ADC value or the signal value of VX-2 tumor periphery. The ADC value or signal value of area A was the center of the VX-2 tumor. All measurements were made by two senior attending physicians or associate professors.

Immunohistochemical staining protocol

DWI was performed before chemoembolization, and 16 h, 32 h and 48 h after chemoembolization. The rabbits were then sacrificed by injecting an overdose of 3% soluble pentobarbitone. Under aseptic conditions, we obtained layer by layer VX-2 samples (Figure 1). Each VX-2 tumor was divided into the outer layer area, the periphery area and center area (Figure 1). All tissue samples were fixed in formaldehyde for 24 h before embedding in mineral wax.

Immunohistochemical staining was performed, using the SP method. Monoclonal antibody against PCNA, Bax, nucleoside diphosphate kinase (ndpk, expression product of nm23 gene) and e-cadherin endogenous avidin and biotin block ade solution, biotin-marked SP were used for immunostaining. PBS was used as a negative control, and all the results were negative. A known positive specimen of mammary adenocarcinoma was used as a positive control for PCNA, Bax and ndpk instead of PHC tissue, while pancreatic carcinoma was used for E-cad; the results were all positive.

Expression index was used to estimate the degree of gene expression, which was based on the contrast of positive cells with the total number of cells, as seen under the microscope. When the cell nucleus appeared as brown-yellow with PCNA immunohistochemical staining, the PCNA expression was considered as positive. When cytolymph appeared as brown-yellow in Bax, nm23 or E-cad immunohistochemical staining, the test was considered as positive. Ten random locations were examined under a 400 × microscope in non-necrotic areas, and the number of PCNA, Bax, nm23 and E-cad expressing cells as well as the total number of cells were counted in a double blind fashion by two investigators who were not part of our study group. The average value was considered as the expression index. When the antibody was replaced by the balanced solution, all the gene expressions were negative.

Statistical analysis

Based on the apparent diffusion coefficient (ADC) value of ROIs and expression index of PCNA, Bax, nm23 and E-cad, the differences between the different areas, the different time groups and the correlation between ADC and gene expression was assessed. The statistical significance was calculated by analysis of variance (ANOVA), non-parameter and multiple linear regression, using the SPSS 12.0 software.

RESULTS

Gene expression information of VX-2 tumor

The results of PCNA, nm23, Bax and E-cad expression in VX-2 tumors and in the normal parenchyma around the tumor before chemoembolization are shown in Table 1 and Figure 2.

The differences in the PCNA, Bax, nm23 and

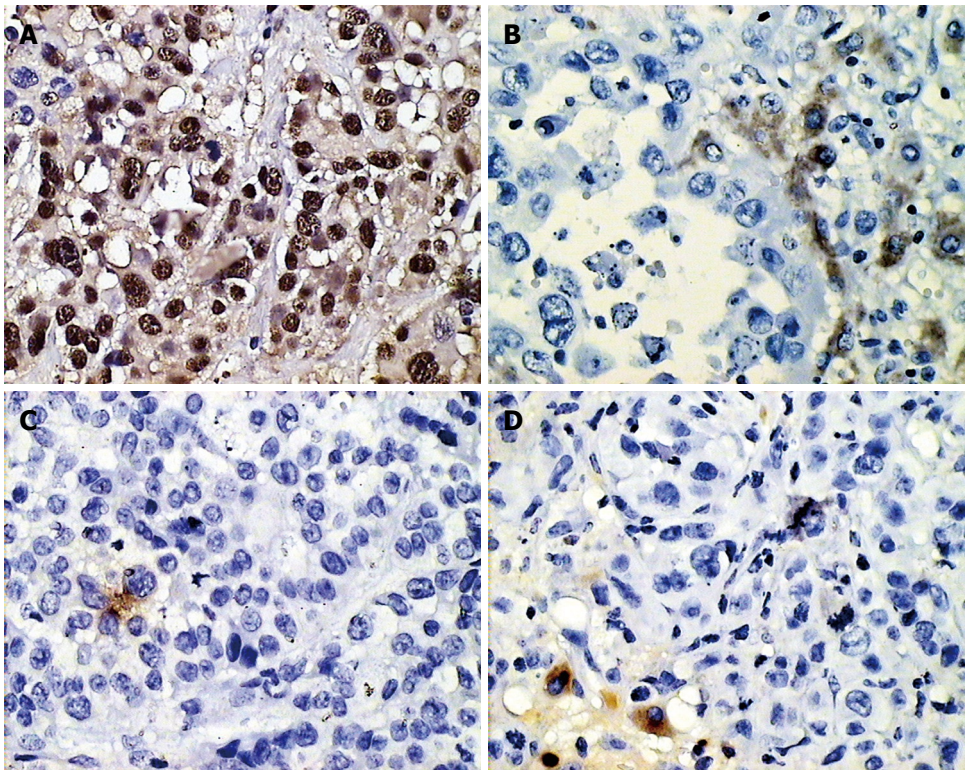

Figure 2 Positive gene expression in VX-2 tumor. **A**: PCNA; **B**: Bax; **C**: nm23; **D**: E-cad.

Table 2 Dynamic information of the gene expression in the peripheral area of VX-2 tumor and the normal parenchyma around the tumor (%)

Time	Area	PCNA	nm23	Bax	E-cad
A time	E	72.73 ± 14.23	0.42 ± 0.64	1.05 ± 1.09	1.96 ± 1.79
	F	8.28 ± 5.61	16.53 ± 14.66	40.00 ± 23.72	78.15 ± 18.35
B time	E	80.04 ± 22.84	2.29 ± 1.58	0.86 ± 1.44	2.87 ± 2.04
	F	4.04 ± 2.06	57.35 ± 28.36	81.22 ± 23.31	86.41 ± 12.65
C time	E	92.60 ± 4.76	7.56 ± 8.88	0.45 ± 0.57	0.93 ± 1.48
	F	21.87 ± 24.59	67.64 ± 30.54	85.63 ± 20.51	91.03 ± 9.65
D time	E	87.63 ± 7.12	4.14 ± 4.71	0.78 ± 1.05	1.07 ± 0.81
	F	19.38 ± 17.74	40.84 ± 34.90	87.08 ± 10.16	91.03 ± 5.11

A time is before chemoembolization or on 21th day after implantation. B time, C time, and D time represent samples obtained after 16 h, 32 h and 48 h after chemoembolization respectively. E indicates the peripheral area of VX-2 tumor and F normal parenchyma around VX-2 tumor.

E-cad expression index in the different areas before chemoembolization were statistically significant (χ^2 = 19.08, $P < 0.001$; χ^2 = 20.165, $P < 0.001$; χ^2 = 12.86, $P < 0.001$; χ^2 = 22.20, $P < 0.001$). The differences in the PCNA, Bax, nm23 and E-cad expression index between the tumor periphery and the normal parenchyma around the tumor were statistically significant (Z = -5.51, $P < 0.001$; Z = -5.39, $P < 0.001$; Z = -5.51, P = 0.003; Z = -5.511, $P < 0.001$).

The results of PCNA, nm23, Bax and E-cad expression in groups A, B, C, and D in the VX-2 tumor periphery and normal parenchyma around the tumor are shown in Table 2 and Figure 2.

The differences in the PCNA, nm23 and Bax expression in the normal parenchyma between groups A, B, C, and D were statistically significant (χ^2 = 10.92, P = 0.04; χ^2 = 14.83, $P < 0.001$; χ^2 = 17.28, P = 0.03), but E-cad expression was not significant (χ^2 = 3.410, $P > 0.05$). The differences in PCNA and nm23 expression in the tumor periphery between groups A, B, C, and D were significant (χ^2 = 14.37, $P < 0.001$; χ^2 = 8.94, P = 0.03) but that for Bax and E-cad were not significant (χ^2 = 1.98, $P > 0.05$; χ^2 = 3.88, $P > 0.05$).

Table 3 ADC values of the tumor and normal parenchyma (mean ± SD, × 10^{-3} mm^2/s)

	ADC in tumor periphery area		ADC in normal parenchyma	
	b = 100	b = 300	b = 100	b = 300
A time	1.71 ± 0.27	1.48 ± 0.23	2.71 ± 0.42	2.30 ± 0.40
B time	1.24 ± 0.22	1.12 ± 0.20	2.10 ± 0.54	1.65 ± 0.37
C time	1.48 ± 0.37	1.23 ± 0.16	2.10 ± 0.49	1.97 ± 0.29
D time	1.57 ± 0.23	1.40 ± 0.18	2.43 ± 0.33	2.06 ± 0.23

A time is before chemoembolization or on the 21th day after implantation. B time, C time, and D time represent samples obtained after 16 h, 32 h and 48 h after chemoembolization respectively.

Dynamic ADC values before and after chemoembolization (Table 3, Figures 3 and 4)

When the b-value was 100 s/mm^2, there was a significant correlation between the expression index of PCNA, nm23, Bax, E-cad and ADC values in the normal parenchyma around VX-2 tumor (r = -0.50, $P < 0.001$; r = -0.38, P = 0.08; r = -0.27, P = 0.04; r = -0.25; P = 0.04) . There was a linear correlation between PCNA and nm23 expression index and ADC value (F = 8.15, $P < 0.001$), and PCNA and nm23 expression influenced ADC. There was a linear correlation between PCNA expression index and ADC value in the VX-2 tumor periphery (F = 32.69, $P < 0.001$), while PCNA

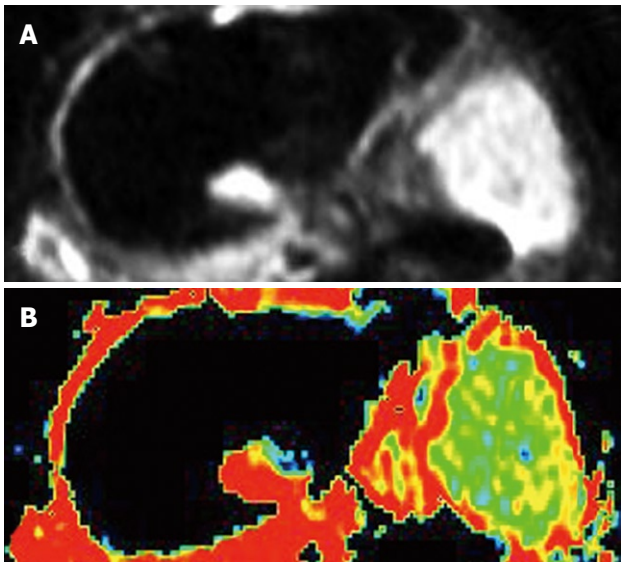

Figure 3 Image manifestations of hepatic VX-2 tumor on DWI and ADC map when b-value was 100 s/mm^2, 6 h after chemoembolization. **A**: High signal and distinct margins of VX-2 tumor on DWI; **B**: Low signal on the ADC map.

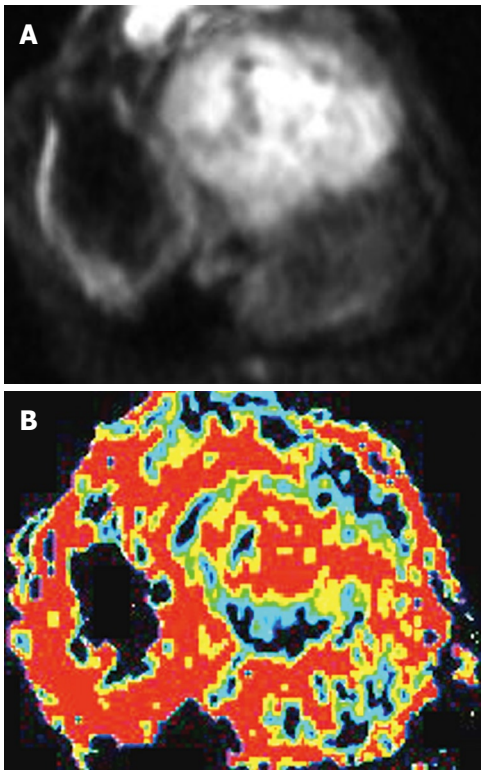

Figure 4 High uneven signal and distinct margins of hepatic VX-2 tumor on DWI and ADC map when b-value was 100 s/mm^2, 32 h after chemoembolization. **A**: High and uneven signal and distinct margins on DWI; **B**: Low or equal signal on ADC map.

expression influenced ADC. However, there was no correlation between nm23, Bax and E-cad expression index, and ADC value (r = -0.20, P = 0.11; r = 0.17, P = 0.15; r = -0.10, P = 0.28).

When the b-value was 300 s/mm^2, there was a correlation between PCNA, nm23, Bax and E-cad expression index, and ADC value in the normal parenchyma around VX-2 tumor (r = -0.37, P = 0.01; r = -0.37, P = 0.01; r = -0.28, P = 0.04; r = -0.31, P = 0.03), and there was a linear correlation between PCNA and nm23 expression index and ADC value (F = 5.00, P < 0.05), and PCNA and nm23 expression influenced ADC. There was a linear correlation between PCNA expression index and ADC value in the VX-2 tumor periphery (F = 29.08, P < 0.001), and PCNA expression influenced ADC, but there was no correlation between nm23, Bax and E-cad expression index and ADC value in the VX-2 tumor periphery (r = -0.15, P = 0.18; r = 0.14, P = 0.19; r = -0.04, P = 0.40).

DISCUSSION

Before and after chemoembolization, PCNA expression was significantly higher in VX-2 tumors compared with the normal parenchyma, whereas nm23, Bax and E-cad expression in the normal parenchyma was significantly higher. PCNA expression in the VX-2 tumor periphery was higher compared to the tumor outer layer and its center, while nm23 and Bax expression in the VX-2 tumor center were higher compared to the outer layer and the peripheral area of the tumor. The high level of PCNA expression indicated that the VX-2 tumor cells had powerful heteromorphism and reproductive activity. The considerable reduction in Bax expression resulted in a decrease in cell apoptosis such that the cell reproductive activity increased, while the reduction in nm23 and E-cad expression led to a marked increase in the ability of the tumor to infiltrate and metastasize. In general, the VX-2 tumor had a high malignant potential, with capacity for rapid reproduction, infiltration and metastasis.

At the same time, the ADC values of VX-2 tumor were significantly lower than the normal parenchyma, and ADC showed an inverse correlation with PCNA expression, but not with nm23, Bax and E-cad expression. These findings suggest that the ability of cell proliferation increases because gene expression increases relative to tumor proliferation such that water molecular diffusion is limited and ADC decreases. In other words, reduction in ADC indirectly increases the gene expression relative to the tumor proliferation. Similarly, Ding *et al*[27] reported that decrease in E-cad expression leads an increase in tumor reproductive activity and Luo *et al*[5] demonstrated that nm23 expression had an inverse correlation with PCNA. To a certain extent, tumor ADC can reflect its ability to infiltrate and metastasize.

After chemoembolization, PCNA expression in VX-2 tumors was slightly higher than before chemoembolization. PCNA expression increased gradually until 32 h, and then decreased slightly. PCNA expression in the normal parenchyma was significantly lower than that in VX-2 tumors, and its expression increased after chemoembolization. Soon after chemoembolization, the tumor reproductive activity may increase, but then decreases which may be related to the stimulation caused by chemoembolization. Therefore, the frequency of chemoembolization should be determined

carefully because viable tumor cells may have powerful reproductive activity. In the present study, the increase in the reproductive activity of normal parenchyma cells may be related to nonselective catheterization, indicating the importance of selective catheterization. After chemoembolization, nm23 expression in the VX-2 tumor or normal parenchyma was higher than before chemoembolization, and it continued to increase until 32 h, followed by decreased expression. These findings indicate that the risk of tumor metastasis may decrease after chemoembolization. The expression of E-cad and Bax in the tumors did not show a significant change after chemoembolization, while E-cad and Bax expression increased in the normal parenchyma. On the other hand, both with b-value 100 s/mm^2 and b-value 300 s/mm^2, the ADC levels in the VX-2 tumor periphery decreased gradually until 16 h after chemoembolization, and then increased gradually. The ADC level in the tumor was inversely related to PCNA expression. Besides water molecules "Brownian Motion", to a certain degree the ADC value indirectly impacts the reproductive activity of cells. With an increase in tumor cell reproduction, the diffusion motion of water cells becomes limited, such that the ADC value decreases. This may be one of the reasons why the ADC of malignant tumors is lower than that of benign tumors. Therefore, the ADC value has potential in the diagnosis and differentiation of tumors, as reported in previous studies by Ichikawa *et al*[18,19], Yamashita *et al*[20] and Kim *et al*[28].

COMMENTS

Background

Diffusion-weighted imaging (DWI) has not been extensively used in the diagnosis as well as in the evaluation of the progression and outcome of hepatic tumors, and few studies have been carried out to investigate the dynamic characteristics of hepatocellular carcinoma gene expression after chemoembolization. We believe that DWI has the potential value of differentiating benign tumors from malignant tumors after chemoembolization. In the present study, we investigated the characteristics of proliferating cell nuclear antigen (PCNA), Bax, nm23 and E-cadherin (E-cad) expression after chemoembolization, and evaluated the correlation between the apparent diffusion coefficient (ADC) on DWI and gene expression, in the rabbit VX-2 tumor model.

Research frontiers

There are very few studies on hepatic pathological changes on DWI. The ADC value of benign lesions, such as hepatic cysts and hemangiomas was higher than that of malignant lesions such as hepatocellular carcinoma and metastasis. Several studies have shown that signals from areas of tumor coagulation necrosis are lower compared to tumor viable areas. Several studies have reported on the PCNA, Bax, nm23 and E-cad expression after chemoembolization. However, few studies have investigated the dynamic characteristics of hepatocellular carcinoma gene expression after chemoembolization, using image-pathology-gene expression

Innovations and breakthroughs

The present study clearly demonstrates that DWI has the potential application of detecting and differentiating viable tumors from necrotic tumors after chemoembolization. PCNA expression in VX-2 tumors was slightly higher compared to the level before chemoembolization. The nm23 expression in VX-2 tumor was higher, such that the potential for VX-2 tumor to infiltrate and metastasize decreases, while the ability to proliferate increases for a short period after chemoembolization. To some extent, the ADC value is able to indirectly reflect the proliferation of VX-2 tumor cells.

Applications

Physicians can apply this knowledge to evaluate hepatic tumors that are clearly progressive in nature, and accurately differentiate areas of necrotic tumor from viable tumor after chemoembolization, as well as determine to some extent the proliferation of VX-2 tumor cells on ADC.

Peer review

This is an interesting, well designed and written study on the clinical significance of diffusion-weighted imaging. The manuscript contains important information on the manifestations of viable, necrotic and liquefied or cystic areas in liver tumors.

Abstract

AIM: To investigate the effects of interferon-alpha (IFN-α) to restrain the growth and invasive potential of hepatocellular carcinoma (HCC) induced by hepatitis B virus (HBV) X protein.

METHODS: The pcDNA3.1-HBx plasmid was transfected into Chang cells by Lipofectamine *in vitro*, and Chang/HBx was co-cultured with IFN-α. Cell survival growth curve and clonogenicity assay were used to test the growth potential of Chang/pcDNA3.1, Chang/HBx and IFN-α-Chang/HBx *in vitro*. Growth assay in nude mice was used to detect the growth potential of Chang/pcDNA3.1, Chang/HBx and IFN-α-Chang/HBx *in vivo*. Wound healing and transwell migration assays were used to detect the invasive ability of Chang/pcDNA3.1, Chang/HBx and IFN-α-Chang/HBx.

RESULTS: Compared with CCL13 cells transfected with pcDNA3.1, CCL13 with stable expression of hepatitis B virus X protein showed the characteristics of malignant cells with high capability of growth and invasion by detecting their growth curves, colony forming efficiency, wound healing , transwell migration assays and growth assays in nude mice. Its capability of growth and invasion could be controlled by IFN-α.

CONCLUSION: IFN-α can restrain the growth and invasive potential of HCC cells induced by HBx protein, which has provided an experimental basis for IFN-α therapy of HCC.

Key words: Hepatitis B virus X protein; Interferon-alpha; Hepatocellular carcinoma; Growth; Invasion

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most prevalent malignant tumors in Asia, especially in China, where hepatitis B virus (HBV) is the major etiologic factor for it[1-3]. The HBV X protein (HBx), a small regulatory protein, that is required for the establishment of viral infection[4,5], is believed to contribute to the development of HCC[6-8].

Interferon-alpha (IFN-α) has been used clinically for the treatment of viral infections[9-11] and malignances[12-14], for it plays an important role in both antiviral and antitumor host defenses. IFN-α also delays or prevents HCC in patients with HBV-related cirrhosis[15]. Therefore, IFN-α may exhibit an antitumor activity in HBV-related HCC through inhibiting the HBx-mediated cellular responses.

In this study, we aimed to explore the strong effect of IFN-α to restrain the growth and invasive potential of HCC induced by HBx protein through transfection of the HBx gene expression to human hepatoma cells.

MATERIALS AND METHODS

Cell lines and interferon

pcDNA3.1-HBx Chang liver cells (Chang/HBx) and pcDNA3.1 Chang liver cells (Chang/pcDNA3.1) were kindly donated by Liver Cancer Laboratory, Department of Surgery, Xiangya Hospital, Central South University (Changsha, Hunan Province, China). The IFN-α was

purchased from Roche Pharmaceuticals Ltd. (Guangxi, China).

Cell culture and passage

The Chang/HBx and Chang/pcDNA3.1 were cultured and subcultured in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum and incubated in 5% CO_2 at 37℃ for further research. The IFN-α concentration in the nutritive medium of IFN-α-Chang/HBx was 1000 ku/L.

Growth curve

The growth curve was designed to compare the proliferative ability of Chang/HBx cells with that of Chang/HBx cells cocultured with IFN-α and Chang/pcDNBA3.1 cells. First, 2×10^4 cells per well were placed into 24-well plates. Next, the cells in 3 wells were counted daily during the 8 d of culture for evaluation of cell proliferation. Finally, the viability of the cells was determined by Trypan blue exclusion.

Clonogenic assay

Chang/HBx, IFN-α-Chang/HBx and Chang/pcDNA3.1 cells were plated onto 60-mm Petri dishes at a density of 2×10^3 cells per dish and cultured in conditioned medium for 2 wk. The formed colonies were stained with Giemsa to allow calculation of their average colony-forming efficiency.

Wound healing assays

Six-well plates (Costar) were coated overnight with 10 mg/mL fibronectin (Becton Dickinson) in phosphate-buffered saline (PBS) and blocked with 1% bovine serum albumin (Sigma) in DMEM. Chang/HBx, IFN-α-Chang/HBx and Chang/pcDNA3.1 cells were suspended with 0.05% trypsin and 5.3 mmol/L ethylene diaminetetraacetic acid (EDTA) (Gibco) and then counted. Next, 5×10^5 cells per well were plated in serum-free DMEM with applicable inhibitors or DMSO for 3 h. Monolayer cultures were wounded with a P-200 pipette tip, and the medium was replaced with DMEM, 5% fetal bovine serum, and 2 mg/mL G418. Cells were photographed at a magnification of × 20 adjacent to a reference line etched onto the bottom of the plate. Cells were allowed to grow and migrate for 24 h at 37℃ in 5% CO_2 before being photographed a second time. DMSO levels were adjusted to be equal in all wells within each experiment and were never higher than 0.5% DMSO. Each experiment was performed in triplicate and repeated three times.

Transwell migration assay

Matrigel-coated filter inserts with 8-μm pores that fit into 24-well invasion chambers were obtained from Becton Dickinson. Chang/HBx cells, IFN-α-Chang/HBx cells, and Chang/pcDNA3.1 cells were detached from the tissue culture plates, washed, resuspended in conditioned medium (5×10^4 cells/200 μL), and then added to the upper compartment of the invasion chamber with or without plasmin (1.8 μg). Conditioned medium (500 μL) was added to the lower compartment of the invasion chamber. The Matrigel invasion chambers were incubated at 37℃ for 24 h in 5% CO_2. After incubation, the filter inserts were removed from the wells, and the cells on the upper side of the filter were removed using cotton swabs. The filters were fixed, mounted, and stained according to the manufacturer's instructions. The cells that invaded through the Matrigel were counted on the underside of the filter. Three to five invasion chambers were used for each experimental condition. The values obtained were calculated by averaging the total number of cells from three filters.

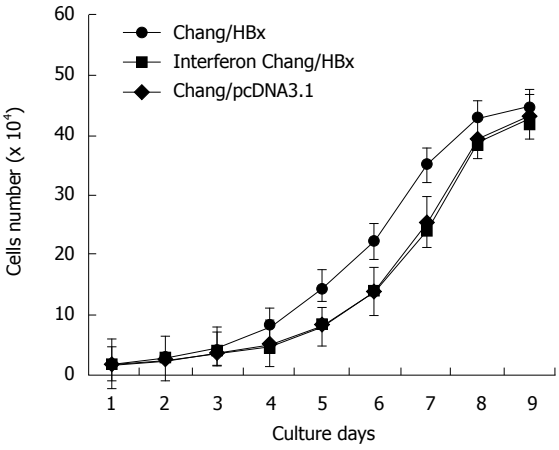

Figure 1 The growth curve of Chang/HBx cells shows a shift to the left from that of Chang/pcDNA3.1 and IFN-α-Chang/HBx cells.

Growth assays in nude mice

Male BALB/C-nu/nu athymic nude mice were obtained from Shanghai Laboratory Animal Center (China) at 4 wk of age. The Chang/HBx, IFN-α-Chang/HBx and Chang/pcDNA3.1 cells were collected by trypsinization and were washed with D-Hank's solution. To produce experimental metastasis, 1×10^7 cells from each culture were injected into the right forelimb armpit of the mice. IFN-α was administrated subcutaneously at dosage of 1.5 × 10 U/kg per day in the group of IFN-α-Chang/HBx cells. After 2 wk, 2 mice from each group were killed and analyzed per week. Neoplasms were removed, rinsed in ice-cold PBS, fixed, stained with hematoxylin and eosin, and photographed.

Statistical analysis

All the data were presented as the mean ± SE. The significance of differences from the control values was determined with Student's t test or the χ^2 test. $P < 0.05$ was considered statistically significant.

RESULTS

Cell survival growth curve and clonogenicity assay

The cell survival growth curve of Chang/HBx cells showed faster growth than that of Chang/pcDNA3.1 cells and IFN-α-Chang/HBx cells (Figure 1). Their average colony-forming efficiency was also significantly different (Figure 2). These findings showed that Chang/

Figure 2 Cell proliferative ability comparisons. The average colony-forming efficiency of Chang/HBx (**A**) was 29.3 ± 4.5, which was significantly different from that of Chang/pcDNA3.1 (**B**) (12.8 ± 2.6) and IFN-α-Chang/HBx (**C**) cells (13.5 ± 2.3) ($P < 0.05$).

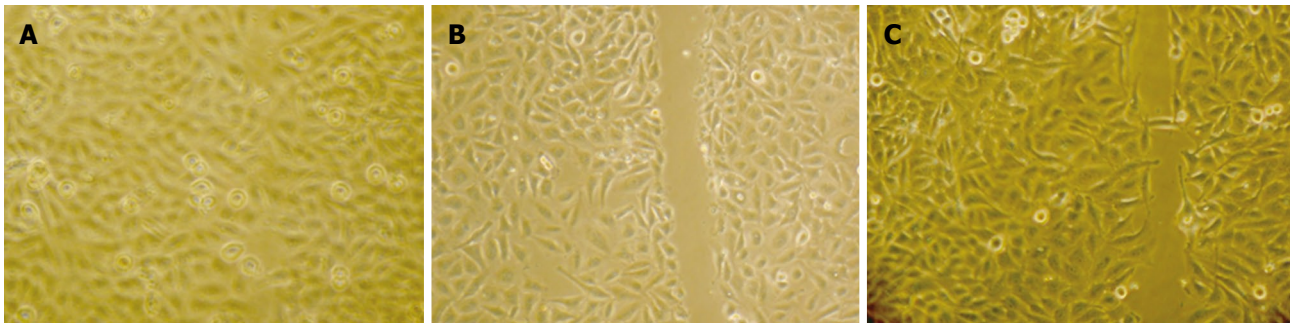

Figure 3 HBx promotes the invasive capacity of Chang liver cells *in vitro*. Wound-healing assays were performed at 0 and 24 h and observed under a phase-contrast microscope (x 100). **A**: Chang liver cells with pcDNA3.1-HBx were disrupted, and wound healing occurred after 24 h; **B**: IFN-α-Chang/HBx cells were disrupted, and the wound did not heal completely after 24 h; **C**: Chang cells with pcDNA3.1 were disrupted, and the wound did not heal completely after 24 h.

HBx was more proliferative than Chang/pcDNA3.1 and IFN-α-Chang/HBx cells.

HBx promotes invasion of chang cells in vitro

The wound-healing assay showed that Chang/HBx cells had a higher ability to heal themselves than the control cells and IFN-α-Chang/HBx cells (Figure 3).

In the transwell migration assay, edge collection phenomena was found on cells in the transwell chamber, with few cells in the center of the wells; therefore, we selected superior, inferior, left, right, and center sites so as to represent the migration assay correctly. The assay showed that the Chang/HBx cells also had greater migration ability than the control cells and IFN-α-Chang/HBx cells ($P < 0.05$) (Figure 4A-C). The average number of Chang/HBx cells that migrated through the Matrigel was 41.6 ± 3.1 cells/site compared with 7.4 ± 1.2 cells/site in the control cells and 9.2 ± 1.6 cells/site in IFN-α-Chang/HBx cells (Figure 4D).

IFN-α inhibits proliferation of chang/HBx cells in vivo

The growth assay in nude mice showed a 100% growth rate of neoplasms after inoculation of the HCC cells. The average latency period was 5 d, and the growth rate was 65.5 ± 7.6 mm^3/d. There was no distant metastasis from the transfectant. The sizes of the neoplasms from IFN-α-Chang/HBx were obviously smaller than the tumors of Chang/HBx injected mice ($P < 0.05$), and the neoplasms from Chang/HBx grew more slowly than those from Chang/pcDNA3.1 ($P < 0.05$), but there was no statistical difference between them in our test. Although Chang liver cells contained the Hela marker, the formed tumor indeed was hepatoma (Figure 5), which could progress to HCC.

DISCUSSION

Interferons are a family of cytokine that are produced by cells of the immune system. Three classes of interferons have been identified: α, β and γ. Each class has different effects though their activities overlap. The interferons direct the attack of the immune system on viruses, bacteria, tumors and other foreign substances that may invade the body[16]. IFN-α is known to have antiproliferative effects on human HCC cells, both *in vivo* and *in vitro*[17,18]. The effectiveness of IFN-α in treating HCC patients has been reported to be positive in a few previous clinical trials[19-21]. It was also shown that IFN-α delayed or prevented HCC in patients with HBV-related cirrhosis[15]. In addition, combination of IFN-α and 5-FU significantly prolonged the survival rate of patients with HCC[22]. These observations suggest that IFN-α has a capability of anticancer agents against HCC. But the precise mechanisms remain poorly understood. To investigate weather IFN-α could regulate the function of HBx protein and inhibit the growth and invasion potential of HBV-related HCC cells, we investigated Chang hepatocytes encoding *HBx* gene and observed that the transfected cells had acquired growth and invasive properties *in vitro*, but these properties could be

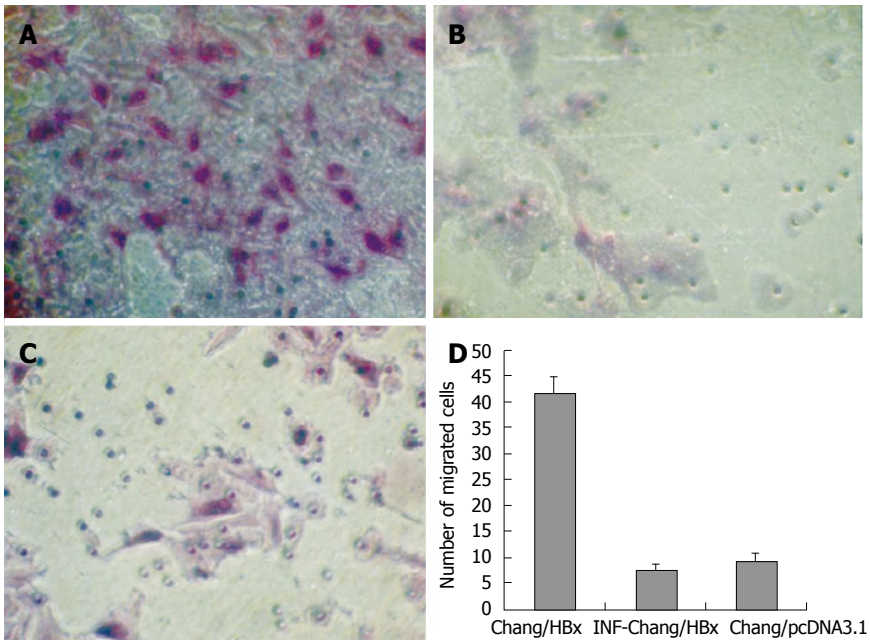

Figure 4 HBx promotes the invasive capacity of Chang liver cells *in vitro*. **A**: Chang cells transfected with pcDNA3.1-HBx invaded through the Matrigel were counted on the underside of the transwell filter and compared with Chang/HBx cells (**B**) and control cells Chang/pcDNA3.1 (**C**) (x 200). There was no difference between IFN-α-Chang/HBx cells and Chang/pcDNA3.1; **D**: The average number of migrated cells per site seen under a high-power microscope (x 400) was 41.6 ± 3.1 for the transfected Chang/HBx cells and 7.4 ± 1.2 for IFN-α-Chang/HBx cells and 9.2 ± 1.6 for the control Chang/pcDNA3.1 cells.

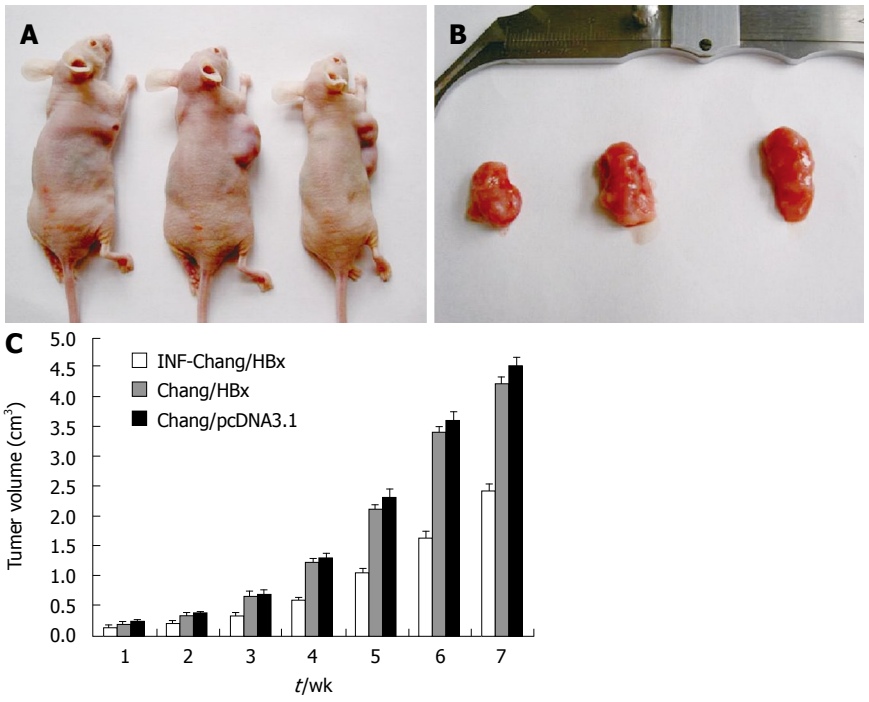

Figure 5 **A**: A nude mouse migration model with pcDNA3.1-HBx Chang cells, IFN-α-Chang/HBx cells and Chang/pcDNA3.1 cells were constructed on the 7th wk; **B**: The volume of neoplasms in the three groups were observed. The sizes of the hepatomas from Chang/pcDNA3.1 and IFN-α-Chang/HBx injected nude mice were obviously larger than the tumors of Chang/HBx injected mice; **C**: Neoplasm growth in the Chang/HBx-inoculated nude mice compared between IFN-α-Chang/HBx and the control Chang/pcDNA3.1-inoculated mice.

controlled by IFN-α effectively.

Through cell survival growth curve and clonogenic assays, we found that Chang cells encoding HBx had higher dynamics for growth than the Chang cells. These cells also showed multilaminar growth. Because they had lost contact inhibition completely, their colony-forming ability was greater than that of the parental cell line. However, the growth and colony-forming ability of Chang-HBx could be inhibited by IFN-α obviously.

Our study also showed that HBx-transfected Chang had higher wound healing ability than the control cells. The transwell migration assay showed that Chang/HBx had a more obviously invasive ability than the control cells. But IFN-α could inhibit these malignant biologic behavior of Chang/HBx induced by HBx protein.

Nude mice were used as the mimic system in our study for observing the effects of cell tumorigenicity of HBx protein in Chang liver cells *in vivo*. However, in the growth assays of nude mice, we found that Chang/HBx cells grew more slowly than Chang/pcDNA3.1 cells. At the same time, Chang/HBx cells treated with IFN-α were found growing more slowly than Chang/HBx cells without IFN-α treatment, which inhibited the tumorigenicity of Chang/HBx cells.

Some studies have shown that HBx can induce tumor proliferation and invasion through down-regulating the function of P53[23,24], up-regulating the expression of survivin[25], activating with several important cell signaling pathways, including PKB/Akt[26], RAS/RAF/MAPK[27], wnt/β-catenin[28] and NF-κB[29]. It has also proved that

IFN-α can induce p53-dependent apoptosis[30], down-regulate the expression of survivin[31] and inactive NF-κB[32] respectively. It is possible that IFN-α could control the growth and invasive potential of HBV-related HCC by inhibiting the function of HBx. The reason why Chang/HBx cells grew more slowly than Chang/pcDNA3.1 cells, is the growth of Chang/HBx cells in nude mice need more nutrient than Chang/pcDNA3.1 cells, however, as the early tumorigenesis of Chang/HBx cells formed, the nutrient was not sufficient and the cells might enter into rest phase as proliferation ceases.

In conclusion, IFN-α could inhibit the growth and invasive potential of Chang cells induced by HBx. IFN-α is a main drug for type B hepatitis and can delay and prevent HBV-related cirrhosis effectively. Postoperative IFN-α therapy can improve the survival of patients with HBV-related HCC. IFN-α therapy might be a very important means for preventing and curing HBV-related HCC. Our study provides a new evidence for this.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is one of the most common cancers in the world, especially in China. About 53% of HCC cases in the world are related to hepatitis B virus (HBV) infection. Chronic HBV infection is a leading risk factor for HCC. It has been proved that IFN-α could control the infection of HBV, prevent HBV-related cirrhosis, lower tumor recurrence rate after surgical resection or ablation of HCC and prolong the survival rate of patients with HCC. IFN-α therapy has been applied to treat HBV-related HCC as an effective drug, but its precise mechanism remains poorly understood.

Research frontiers

Some studies have proved that IFN-α could inhibit the growth of HCC cells *in vivo* and *in vitro*. It could regulate expression of VEGF, bFGF and angiopoietins and inhibit tumor angiogenesis in human HCC cells. But there are few reports about the impact of IFN-α on the malignant characteristics of HCC cells induced by HBx protein.

Innovations and breakthroughs

Our results reveal that the liver cell lines CCL13 containing HBx gene expression have the characteristics of malignant cells, which was verified by means of detecting their growth curve, colony forming efficiency, wound healing, transwell migration assays and growth assay in nude mice. All of these could be controlled by IFN-α.

Applications

IFN-α therapy is a very important means for preventing and curing HBV-related HCC. This study provides some experimental evidence for it.

Terminology

Interferons are natural proteins produced by the cells of the immune system of most vertebrates in response to challenges by foreign agents such as viruses, parasites and tumor cells. Three classes of interferons have been identified: α, β and γ. The interferons direct the attack of immune system on viruses, bacteria, tumors and other foreign substances that may invade the body. The JAK-STAT signaling pathway is the most specific and commonly accepted IFN signaling pathway.

Peer review

This is an interesting article which investigated the effect of IFN-α on the malignant characters of human liver cell lines CCL13 containing HBx gene expression. The design of experiment is novel and the result is significant. It would be helpful to explore the mechanism of IFN-α therapy for HCC and direct the clinical therapy of HCC.

Abstract

AIM: To analyze the ability of nine different potentially probiotic bacteria to induce maturation and cytokine production in human monocyte-derived dendritic cells (moDCs).

METHODS: Cytokine production and maturation of moDCs in response to bacterial stimulation was analyzed with enzyme-linked immunosorbent assay (ELISA) and flow cytometric analysis (FACS), respectively. The kinetics of mRNA expression of cytokine genes was determined by Northern blotting. The involvement of different signaling pathways in cytokine gene expression was studied using specific pharmacological signaling inhibitors.

RESULTS: All studied bacteria induced the maturation of moDCs in a dose-dependent manner. More detailed analysis with *S. thermophilus* THS, *B. breve* Bb99, and *L. lactis* subsp. *cremoris* ARH74 indicated that these bacteria induced the expression of moDC maturation markers HLA class Ⅱ and CD86 as efficiently as pathogenic bacteria. However, these bacteria differed in their ability to induce moDC cytokine gene expression. *S. thermophilus* induced the expression of pro-inflammatory (TNF-α, IL-12, IL-6, and CCL20) and Th1 type (IL-12 and IFN-γ) cytokines, while *B. breve* and *L. lactis* were also potent inducers of anti-inflammatory IL-10. Mitogen-activated protein kinase (MAPK) p38, phosphatidylinositol 3 (PI3) kinase, and nuclear factor-kappa B (NF-κB) signaling pathways were shown to be involved in bacteria-induced cytokine production.

CONCLUSION: Our results indicate that potentially probiotic bacteria are able to induce moDC maturation, but their ability to induce cytokine gene expression varies significantly from one bacterial strain to another.

Key words: Probiotic bacteria; Immune response; Cytokine; Chemokine; Dendritic cell; Human; Gene expression; Signal transduction

INTRODUCTION

The importance of the intestinal microbiota, and the ways in which it can be modified, has been under intensive investigation in recent years. Evidence from randomized and placebo-controlled clinical trials and molecular studies has attracted significant interest to the use of probiotic bacteria as therapeutic substances. Probiotics are live microbial food supplements that have a beneficial effect on human health. They can

change the composition or metabolic activity of the intestinal microbiota and modulate the immune system of the host. This seems to be dependent on the probiotic bacterial species used and the overall health status of the host[1]. Probiotic bacteria have been used as an alternative form of therapy for various diseases and symptoms[2,3]. Probiotic supplement containing *L. rhamnosus* GG, *L. rhamnosus* LC705, *P. freudenreichii* JS, and *B. breve* Bb99 alleviated the symptoms of irritable bowel syndrome (IBS) and improved eradication of *H pylori*[4,5]. The best studied probiotic bacterium, *L. rhamnosus* GG has been found to be effective in the treatment of antibiotic-associated[6] and nosocomial diarrhea[7] in children. In addition, *L. rhamnosus* GG has been used to reduce the onset of atopy[8]. It has also been shown to have immunomodulatory effects on the host by decreasing the production of IL-6 and TNF-α in healthy individuals[9] and TNF-α production in allergic children[10]. All bacteria used in the present work are Gram-positive bacteria and some of them are widely used in the food industry. *S. thermophilus* THS, *L. mesenteroides* subsp. *cremoris* PIA2, and *L. lactis* subsp. *cremoris* ARH74 are used for the fermentation of milk products. *L. rhamnosus* GG and *B. animalis* subsp. *lactis* Bb12 are used as supplements in dairy products due to their proved probiotic effects. *B. animalis* subsp. *lactis* Bb12 is shown to be effective in reducing the risk of diarrhea and modulating the immune response[11,12]. Although many probiotic bacterial strains are used as food supplements, their mechanisms of action have remained poorly characterized.

The gut is rich in antigen-presenting cells such as dendritic cells (DCs), which reside underneath the epithelial cell layer in an immature state being constantly on alert for foreign antigens or invading pathogens[13,14]. DCs can reach their dendrites through the tight junctions of epithelial cells and in this manner sample the gut for different antigens[14,15]. Upon contact with microbes or foreign antigens, DCs undergo a maturation process, which is associated with the expression of cell surface costimulatory molecules CD80, CD83, and CD86 and migration from the peripheral tissues into local lymph nodes. In the lymph nodes mature DCs present antigens to naive T cells, and the development of adaptive immune responses is initiated[16-18]. Depending on the nature of the antigen, the magnitude of the activation of innate and adaptive immune responses can vary greatly. Cytokine production profile and the maturation status of DCs depend on the nature of the stimulus and determine whether T cells are polarized towards T helper (Th) 1, Th2, or T regulatory (Treg) type responses[19-21].

DCs have multiple receptor systems including scavenger receptors, lectin-binding molecules, Toll-like receptors (TLRs), and nucleotide-binding oligomerization domain (NOD) molecules that recognize different types of bacterial structural components or genetic material[22-24]. Activation of DCs *via* TLRs leads to the activation of intracellular signal transduction pathways and to the activation and nuclear translocation of NF-κB, interferon regulatory factor (IRF), or mitogen-activated protein kinase (MAPK)-regulated transcription factors, which ultimately regulate the activation status of DCs and enhance the expression of cytokine genes[25-27]. However, it still remains elusive how DCs can differentiate between commensal and pathogenic bacteria.

In the present study we have analyzed the ability of nine different, potentially probiotic bacteria to induce maturation and cytokine gene expression in human moDCs. By analyzing the cytokine production profiles in moDCs induced by these bacteria, we hope to gain insight into different immunomodulatory effects of probiotic bacteria. This information is of value for selecting new probiotics for *in vivo* trials.

MATERIALS AND METHODS

Bacterial strains

Two well-known probiotic strains *L. rhamnosus* GG (ATCC 53103)[7,10] and *B. animalis* subsp. *lactis* Bb12 (DSM15954)[12], and seven potentially probiotic strains *L. rhamnosus* LC705 (DSM 7061)[4,5], *L. helveticus* 1129 (DSM 13137)[28], *B. longum* 1/10, *B. breve* Bb99 (DSM 13692)[4,5], *S. thermophilus* THS[29,30], *L. lactis* subsp. *cremoris* ARH74 (DSM 18891)[31], and *L. mesenteroides* subsp. *cremoris* PIA2 (DSM 18892)[29] were obtained from Valio Research Centre (Helsinki, Finland). Pathogenic *S. pyogenes* serotype T1M1 (IH32030)[32], isolated from a child with bacteremia, was from the collection of National Public Health Institute (Helsinki, Finland), and was used as a positive control[33,34]. Bacteria were stored in skimmed milk at -70℃ and grown to the end of logarithmic growth phase before they were used in experiments. *S. pyogenes* and *L. rhamnosus* GG were grown as previously described[32,34]. All strains were passaged three times, except for the Bifidobacterium strains which were passaged four times, before they were used in stimulation experiments. The number of bacteria was determined by counting them in a Petroff-Hausser chamber.

Frozen stocks of *L. rhamnosus* GG, *L. rhamnosus* LC705, and *L. mesenteroides* subsp. *cremoris* PIA2 strains were inoculated in deMan, Rogosa, and Sharpe (MRS) medium (Lab M, Topley House, Lancashire, UK) and grown under aerobic conditions at 37℃. *L. helveticus* 1129 was grown at 42℃ under aerobic conditions in MRS medium (Lab M, Topley House). Bifidobacterium strains were grown anaerobically in MRS (Lab M, Topley House) supplemented with 5 g/L L-cysteine (Merck, Darmstadt, Germany) at 37℃. *S. thermophilus* was grown aerobically at 37℃ on M17 agar (Lab M, Topley House) supplemented with 20 g/L D (+) lactose monohydrate (J.T. Baker B.V., Deventer, Holland), and transferred to M17 broth (Difco, Beckton Dickinson, MD, USA) containing 20 g/L lactose (J.T. Baker B.V.). *L. lactis* was grown on calcium citrate agar (Valio Ltd.) and M17 broth (Difco) containing 20 g/L lactose (J.T. Baker B.V.) at 22℃ under aerobic conditions. For stimulation experiments bacteria were grown to a late logarithmic growth phase, and the indicated amount of bacteria was collected by centrifugation. After this cells were

suspended to RPMI-1640 medium (Sigma, St. Louis, MO, USA) and added to moDC cultures.

DC purification and differentiation

Monocytes were purified from freshly collected, leukocyte-rich buffy coats obtained from healthy blood donors (Finnish Red Cross Blood Transfusion Service, Helsinki, Finland) as described previously[33]. Human peripheral blood mononuclear cells were isolated by density gradient centrifugation over a Ficoll-Pague gradient (Amersham Biotech, Uppsala, Sweden) followed by purification of monocytes in Percoll gradient (Amersham Biotech) centrifugation. Monocytes were collected from the top layer of the gradient, and T and B cells were depleted using anti-CD3 and anti-CD19 magnetic beads (Dynal, Oslo, Norway). Purified monocytes were allowed to adhere to six-well plates 2.5×10^6 cells/well (Falcon, Becton Dickinson, Franklin Lakes, NJ, USA) for 1 h at 37℃ in RPMI-1640 supplemented with 0.6 μg/mL penicillin (Gibco, BRL, Paisley, Scotland), 60 μg/mL streptomycin (Gibco), 2 mmol/L L-glutamine (Sigma), and 20 mmol/L HEPES. For inhibitor assays, 24-well plates were used (1.25×10^6 cells/well). To differentiate monocytes into immature DCs, they were grown in RPMI-1640 medium (Sigma) supplemented as above, plus 100 mL/L fetal calf serum (FCS) (Integro, Zaandam, Holland), 10 ng/mL recombinant human granulocyte macrophage-colony stimulating factor, GM-CSF (Biosource, Camarillo, CA, USA), and 20 ng/mL recombinant human interleukin (IL)-4 (R&D Systems, Abingdon, UK). Fresh medium was added every 2 d, and the cells were used in experiments after 6 to 7 d of cultivation. Cultured cells were $CD1a^+$, $CD14^-$, $CD80^+$, $CD83^-$, and $CD86^+$ as analyzed by flow cytometry, and they showed a typical DC morphology (data not shown).

Stimulation experiments

All stimulation experiments were carried out with cells obtained from three to four blood donors and conducted in RPMI-1640 medium containing 100 mL/L FCS. MoDCs were stimulated with a bacteria:host cell ratio of 2:1, 10:1, or 40:1. Cells were collected either for flow cytometric analysis (FACS) or for isolation of total cellular RNA. Supernatants were collected and stored at -20℃.

In cytokine priming experiments moDCs were pre-treated with IL-6 (Biosource), TNF-α (Biosource), or IFN-γ (Finnish Red Cross Blood Transfusion Center) for 16 h prior to bacterial stimulation. IL-6 and TNF-α were used at a concentration of 10 ng/mL, and IFN-γ at 100 IU/mL. Supernatants were collected at 24 h after bacterial stimulation for cytokine measurements.

In inhibitor experiments moDCs were treated with different signaling inhibitors for 30 min prior to bacterial stimulation. Five different inhibitors were used at two concentrations: PD98059 (10 μmol/L or 2 μmol/L) and LY294002 (50 μmol/L or 10 μmol/L) both from Calbiochem (San Diego, CA, USA), and cyclosporin A (CsA) (1 μg/mL or 0.2 μg/mL), SB202190 (10 μmol/L or 2 μmol/L), and pyrrolidine dithiocarbamate (PDTC) (100 μmol/L or 20 μmol/L) all from Alexis Biochemicals (Lausen, Switzerland). Supernatants were collected at 24 h after stimulation, and cytokine levels were determined.

Cytokine-specific enzyme-linked immunosorbent assays (ELISAs)

Cytokine and chemokine levels from cell culture supernatants were analyzed by a sandwich ELISA method as previously described[34]. TNF-α, IL-6, IL-10, and CXCL10 levels were determined by using antibody pairs and standards obtained from BD Pharmingen (San Diego, CA, USA). IL-12p70 and IFN-γ levels were determined with Eli-pair kits (Biosite, Täby, Sweden), and CCL19 and CCL20 levels with Duoset kits (R&D Systems) as instructed by the manufacturer. Cytokine levels in the bacterial dose response experiments were measured using FlowCytomix human Th1/Th2 10plex kit (Bender Medsystems, Vienna, Austria) according to the manufacturer's instructions.

FACS analysis

MoDCs were stimulated with different bacteria for 24 h. Cells were collected, washed once with PBS, and fixed with 10 mL/L paraformaldehyde for 15 min in PBS. After fixation, cells were washed twice with PBS and suspended in PBS + 20 mL/L FCS. For staining of cell surface marker proteins FITC- and PE-conjugated monoclonal antibodies against CD86, HLA class Ⅱ, and isotype matched control antibodies (Caltag Laboratories) were used. Paraformaldehyde-fixed moDCs were stained with mAbs for 30 min at 4℃. The cells were washed twice with PBS + 20 mL/L FCS, suspended in the same solution and analyzed with FACScan flow cytometric device using CellQuest software (Becton Dickinson).

In inhibitor experiments the viability of the cells was confirmed by dead cell discriminator (DCD) (Caltag Laboratories, Burlingame, CA, USA), containing propidium iodide (PI). PI integrates with DNA in non-viable cells with compromised membranes and can be detected by flow cytometry. DCD was added to a suspension of non-fixed cells, 5 μL of DCD per 10^6 cells, immediately prior to FACS, performed as previously described[35].

RNA isolation and Northern blot analysis

For RNA analysis, cells were collected, washed once with PBS, and total cellular RNA was isolated with Rneasy Midi kit (Qiagen). RNA was quantified spectrophotometrically (A_{260nm}) and samples containing equal amounts of RNA (10 μg) were separated by size on 1% formaldehyde-agarose gels and transferred to hybond-N-membranes (Amersham Pharmacia Biotech). To control equal RNA loading, ethidium bromide staining was used. The following human cytokine cDNA probes were used for hybridization: CCL20[36], TNF-α (American Type Culture Collection, Manassas, VA), IL-12p35[33], IFN-γ[37], and IL-10 (DNAX, Palo Alto, CA, USA).

Table 1 Bacteria used in the study

Bacterial species/subspecies	Strain abbreviation	ATCC/DSM number	Ref.	Use in dairy products

NA: Not applicable.

The probes were labelled with [α-^{32}P] deoxy-adenosine 5'-triphosphate (3000 Ci/mmol, Amersham Pharmacia Biotech) using a random-primed DNA labelling kit (Fermentas, Burlington, Ontario, Canada). Membranes were hybridized o/n in Ultrahyb buffer (Ambion, Austin, TX, USA) at 42℃. Membranes were washed three times with 1 g/L SDS in 1 × saline sodium citrate at 42℃ for 30 min and once at 65℃ for 30 min. Membranes were exposed to Kodak X-Omat AR films (Eastman Kodak, Rochester, NY, USA) at -70℃ with intensifying screens.

RESULTS

Bacteria-induced cytokine production in human moDCs

MoDCs were stimulated with different doses of probiotic bacteria to determine the optimal bacterial dose for further stimulation experiments (Figure 1). The bacteria used in the present study are summarized in Table 1. *S. thermophilus* THS efficiently induced TNF-α, IL-6, and IL-12 production. The two Bifidobacterium strains, *B. animalis* subsp. *lactis* Bb12 and *B. breve* Bb99, were potent inducers of all measured cytokines TNF-α, IL-1β, IL-6, IL-10, IL-12, and IFN-γ. In contrast, *B. longum* strain 1/10 was not as efficient as *B. animalis* subsp. *lactis* Bb12 and *B. breve* Bb99 in inducing cytokine, production. *L. lactis* subsp. *cremoris* ARH74 and *L. helveticus* 1129 were as good as bifidobacteria at inducing cytokine production in moDCs. *L. rhamnosus* strains GG and LC705 as well as *L. mesenteroides* subsp. *cremoris* PIA2 were poor inducers of cytokine production and stimulation of moDCs with these bacteria did not result in increased cytokine production compared to unstimulated cells. There was a direct correlation between bacterial dose and cytokine response. Bacteria: host cell ratio of 40:1 showed the highest cytokine production levels (Figure 1).

All studied bacteria induced CCL20 production in a dose-dependent manner (Figure 2), while none of the bacteria were able to induce CCL19 production. *S. thermophilus* was the most efficient probiotic bacterium in inducing CXCL10 production in moDCs. The dose-dependent responses demonstrated that the bacteria: host cell ratio of 40:1 was also most effective in inducing moDC chemokine production.

The effects of bacteria on moDC maturation

Since different probiotic bacteria are able to induce variable cytokine and chemokine responses in human moDCs (Figures 1 and 2), we analyzed whether these bacteria would also differ in their ability to induce moDC maturation. Maturation of DCs is characterized by up-regulation of cell surface maturation marker proteins CD80, CD86, and HLA class Ⅱ[38]. For these studies we chose *B. breve* Bb99, *S. thermophilus* THS, and *L. lactis* subsp. *cremoris* ARH74 that represent different genera and were able to stimulate a variety of moDC cytokine responses (Figure 1). MoDCs were stimulated with selected bacteria at bacteria:host cell ratio of 2:1, 10:1, or 40:1. After stimulation the expression of CD86 and HLA class Ⅱ was analyzed by flow cytometry. Cells from different donors were pooled before the analysis. In *S. thermophilus* THS and *B. breve* Bb99 stimulated moDCs highest up-regulation of HLA class Ⅱ was observed with bacteria:host cell ratio of 10:1, whereas with *L. lactis* subsp. *cremoris* ARH74 a ratio of 40:1 was required for maximal HLA class Ⅱ induction (Figure 3A). The highest CD86 expression was seen at bacteria:host cell ratio of 40:1 (Figure 3B) with all studied bacteria. It is noteworthy that even the lowest bacterial dose (2:1) increased the expression of HLA Ⅱ and CD86. MoDCs stimulated with probiotic bacteria matured equally well as cells stimulated with pathogenic *S. pyogenes*, a known inducer of moDC maturation[33]. The majority of the bacteria-stimulated cells were HLA class Ⅱ/CD86 double positive (Figure 3C). Maturation of moDCs was also observed with all other studied bacteria (data not shown).

Kinetics of bacteria-induced cytokine and chemokine mRNA expression

To further compare the cytokine gene expression profiles induced by *S. thermophilus* THS, *B. breve* Bb99,

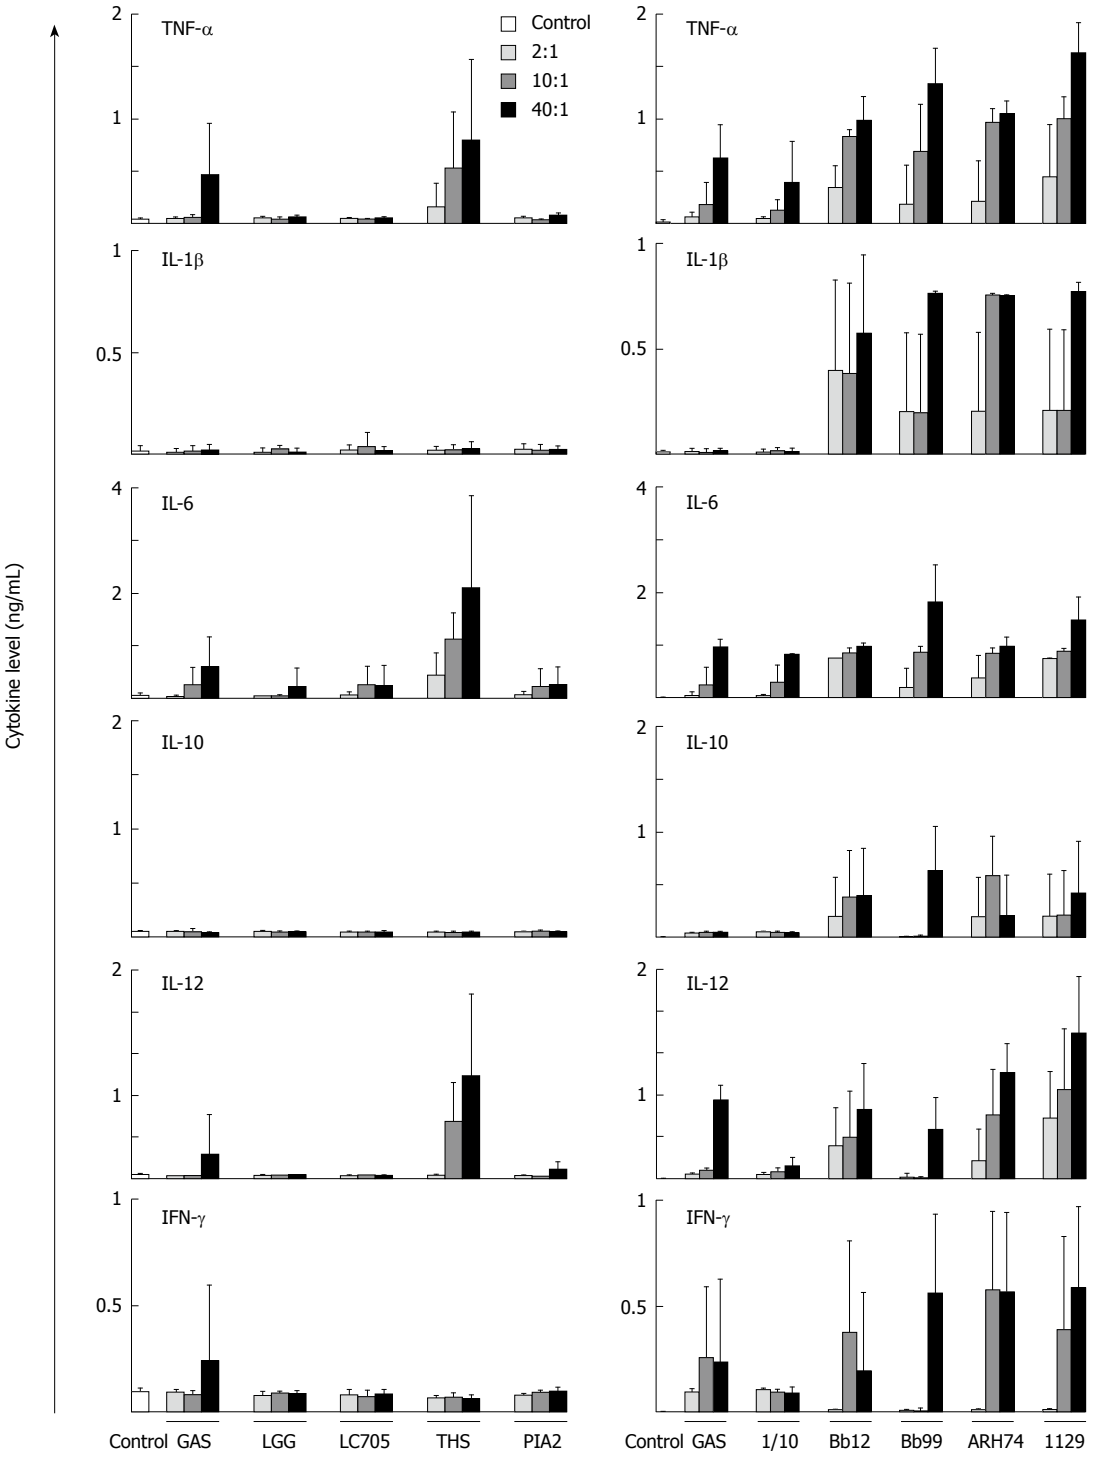

Figure 1 Probiotic bacteria induce cytokine production in human moDCs in a dose-dependent manner. MoDCs were stimulated with bacteria:host cell ratio of 2:1, 10:1, or 40:1. At 24 h after stimulation cell culture supernatants were collected and cytokine levels were determined by ELISA. The experiment was carried out with cells obtained from four different blood donors, and the columns represent means and error bars indicate the standard deviations. The data is from a representative experiment out of two. GAS: *S. pyogenes*; LGG: *L. rhamnosus* GG; LC705: *L. rhamnosus* LC705; THS: *S. thermophilus* THS; PIA2: *L. mesenteroides* subsp. *cremoris* PIA2; 1/10: *B. longum* 1/10; Bb12: *B. animalis* subsp. *lactis* Bb12; Bb99: *B. breve* Bb99; ARH74: *L. lactis* subsp. *cremoris* ARH74; 1129: *L. helveticus* 1129.

and *L. lactis* subsp. *cremoris* ARH74, moDCs were stimulated with these bacteria at a 40:1 bacteria:host cell ratio for 8, 24, or 48 h. Cells from different donors were collected and pooled. Total cellular RNA was isolated for Northern blot analysis (Figure 4A). The mRNA expression of CCL20 and TNF-α was enhanced 8 h after stimulation with *S. thermophilus* THS, *B. breve* Bb99, and *L. lactis* subsp. *cremoris* ARH74. The expression of IL-12p35 or IFN-γ mRNA was not enhanced by any of the potentially probiotic bacteria. CCL20 mRNA level was highest in *B. breve* Bb99 stimulated cells at 8 h after stimulation. Low levels of CCL20 mRNA were detected in *S. pyogenes* and *S. thermophilus* THS stimulated cells at 8 h after stimulation. CCL20 protein level was highest at the 48 h time point in *B. breve* Bb99 stimulated cells (Figure 4B). TNF-α mRNA expression was strongest in

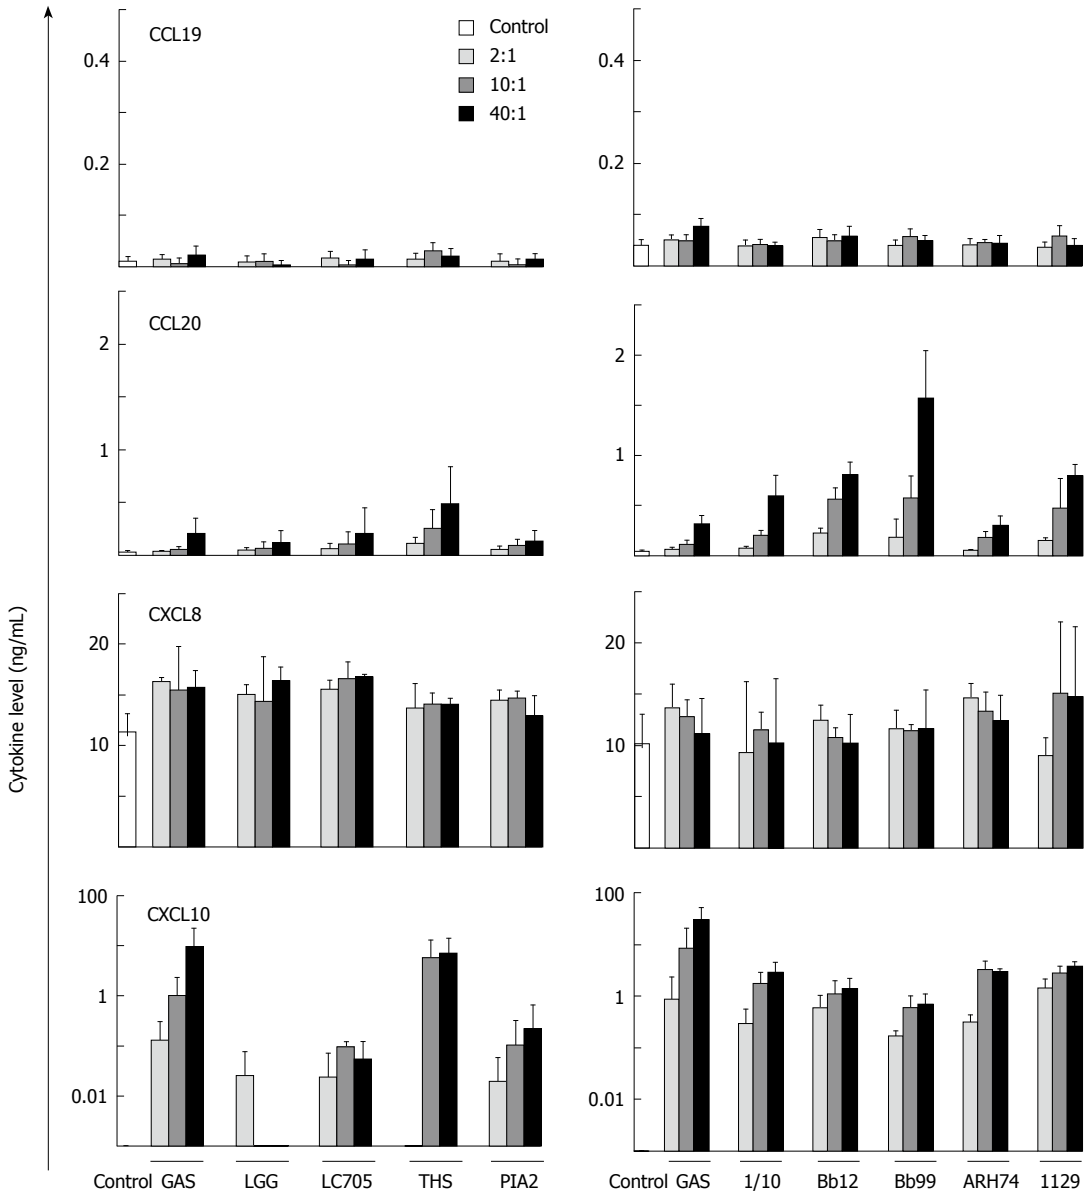

Figure 2 Probiotic bacteria induce chemokine production in moDCs. MoDCs were stimulated with bacteria:host cell ratio of 2:1, 10:1, or 40:1. Cell culture supernatants from four blood donors were collected at 24 h after bacterial stimulation and the chemokine levels were determined by ELISA. The data is shown as means and error bars indicate standard deviations. Note the differences in scales. The data is from a representative experiment out of two.

B. breve Bb99 stimulated moDCs. In moDCs stimulated with *S. thermophilus* THS and *L. lactis* subsp. *cremoris* ARH74 TNF-α mRNA levels were lower than in *B. breve* Bb99 stimulated moDCs. Cell culture supernatants were also collected and cytokine levels were determined by ELISA. The cytokine production patterns correlated with the kinetics and magnitude of bacteria induced mRNA expression profiles (Figure 4B). IL-12 and IFN-γ mRNAs were not detectable in cells stimulated with probiotic bacteria, and also protein levels remained lower than in *S. pyogenes* stimulated moDCs. IL-10 mRNA and protein expression was best induced by *B. breve* Bb99.

Pharmacological signaling inhibitors affect the cytokine production of probiotic bacteria-stimulated moDCs

In order to obtain insight into the mechanisms of probiotic bacteria-induced cytokine gene expression in human moDCs, we used different pharmacological inhibitors for MAPK, PI3K, NF-κB, and nuclear factor of activated T cells (NFAT) signaling pathways to study whether they interfere with cytokine production in bacteria-stimulated cells.

B. breve Bb99 was chosen for these experiments due to its ability to effectively induce cytokine production in moDCs. Cells were treated with the inhibitors 30 min prior to bacterial stimulation and the inhibitors were present throughout the stimulation experiment. The p38 MAPK inhibitor SB202190[39] decreased the production of TNF-α, IL-6, IFN-γ, and IL-10 production in a dose-dependent manner (Figure 5). The inhibitor of PI3 kinase, LY294002[40], abolished CXCL10, TNF-α, IFN-γ, and IL-10 production at a concentration of 50 μmol/L. Concentration 100 μmol/L of NF-κB inhibitor PDTC reduced CXCL10 and IFN-γ production, whereas no significant inhibition in the production of other

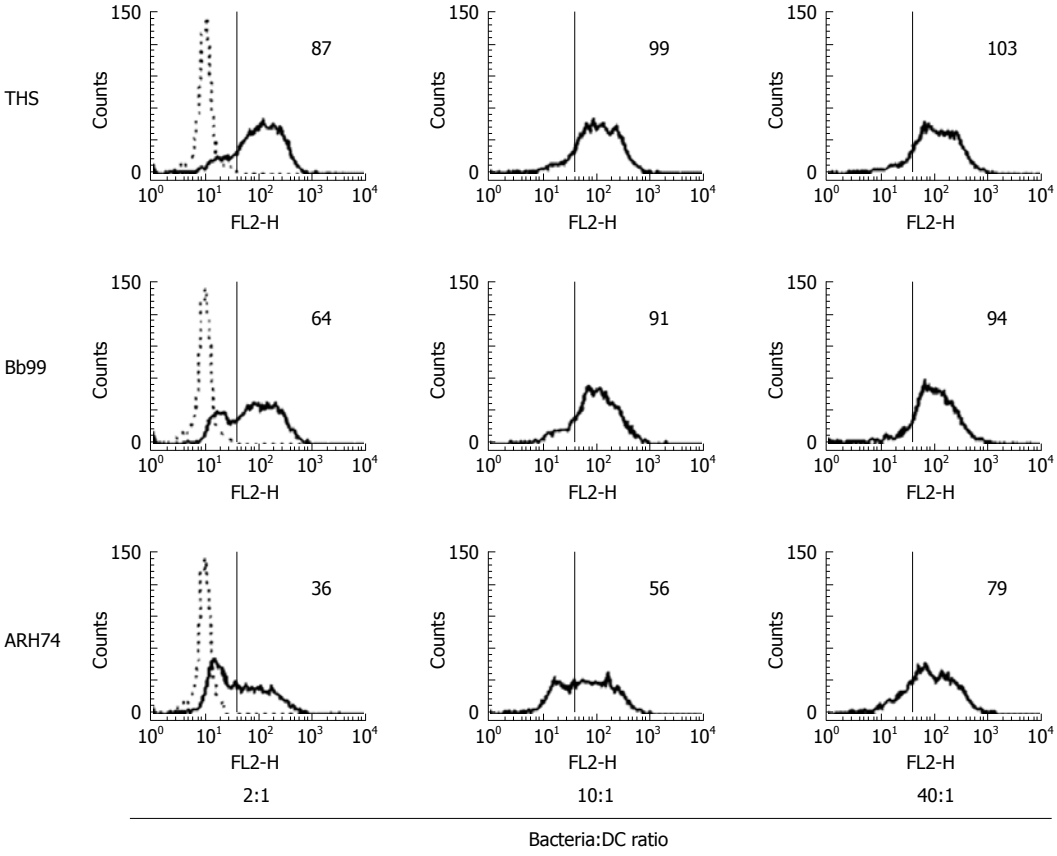

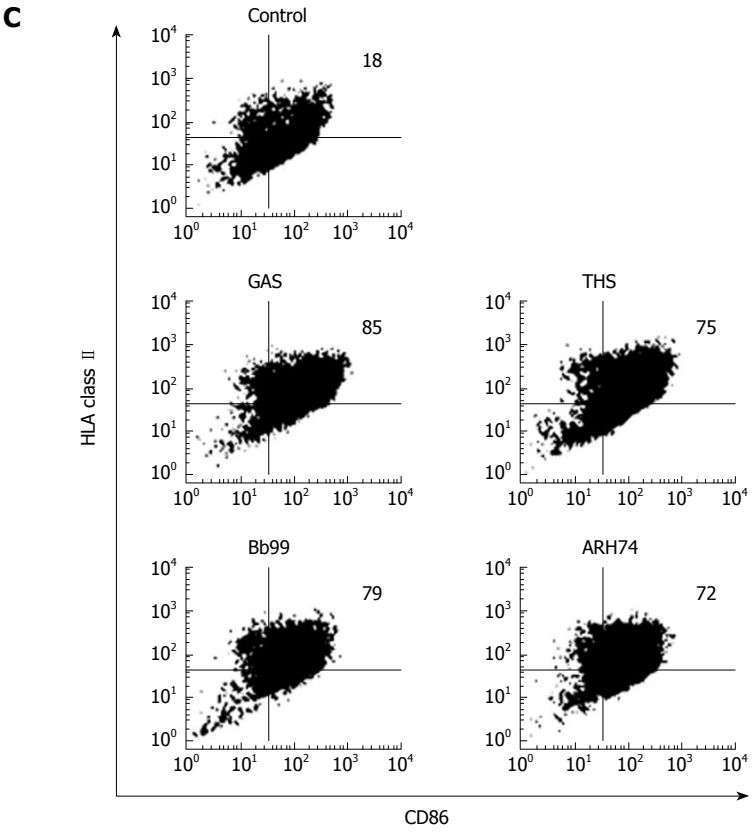

Figure 3 The effect of bacterial dose on the maturation of moDCs. MoDCs were stimulated with bacteria:host cell ratio of 2:1, 10:1, or 40:1. Cells from four different donors were collected, pooled, and stained with antibodies against (**A**) HLA class Ⅱ and (**B**) CD86. The expression of co-stimulatory molecules was analyzed by flow cytometry. The values represent mean fluorescence intensities (MFIs). Results from a representative experiment out of two are shown. Dotted lines indicate respective isotype controls. The staining profiles of HLA class Ⅱ/CD86 double-positive (percentages included in the profiles) cells (**C**). GAS: *S. pyogenes*; THS: *S. thermophilus* THS; Bb99: *B. breve* Bb99; ARH74: *L. lactis* subsp. *cremoris* ARH74.

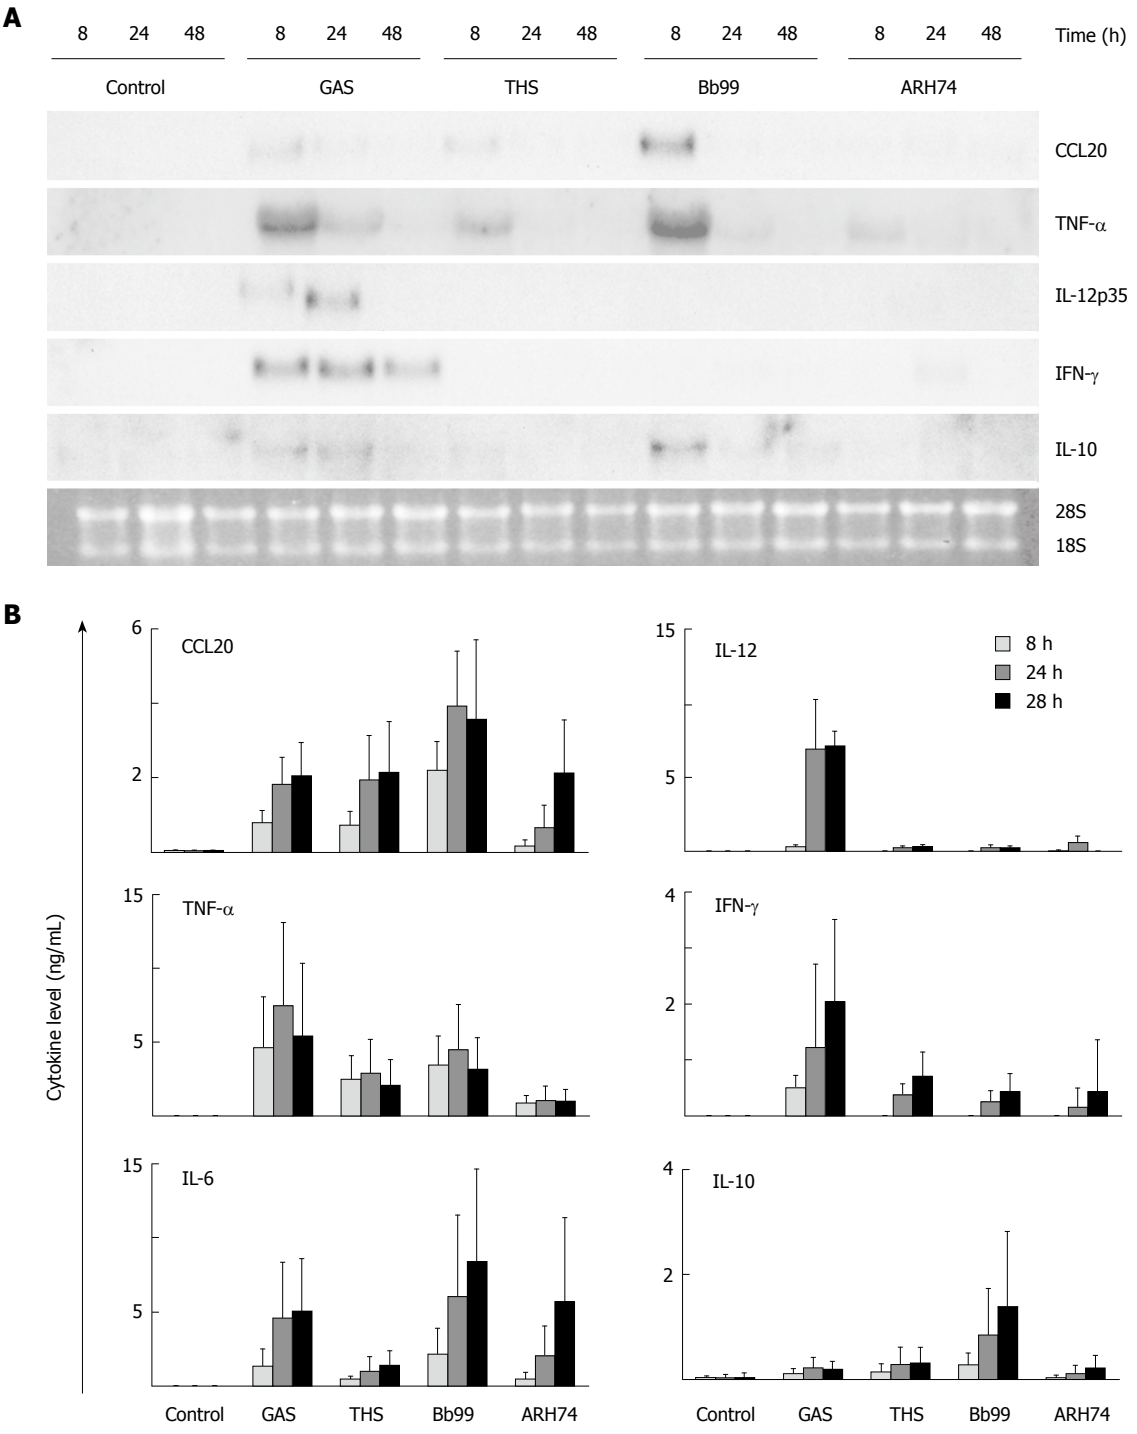

Figure 4 Kinetics of probiotic bacteria induced cytokine gene expression in human moDCs. MoDCs were stimulated with GAS and indicated probiotic bacteria with a bacteria:host cell ratio of 40:1. **A**: Cells were collected at 8, 24, and 48 h after stimulation and total cellular RNA was isolated. mRNA expression was analyzed with Northern blotting using CCL20, TNF-α, IL-12p35, IFN-γ, and IL-10 cDNA probes. Ethidium bromide staining was used to control equal sample loading and the integrity of RNA; **B**: Cell culture supernatants from the experiment described in panel A were collected and cytokine levels in the supernatants were determined by ELISA. The bars and error bars represent the means and standard deviations from four different blood donors. One representative experiment out of two is shown. See Figure 3 for abbreviations of bacteria.

cytokines was observed (Figure 5). The ERK MAPK inhibitor PD98059[41] had no effect on cytokine production in *B. breve* Bb99 stimulated moDCs. The NFAT inhibitor CsA had a weak inhibitory effect on Bb99-induced IFN-γ production. The production of CCL20 was enhanced in the presence of LY294002, PDTC, and CsA. Likewise, TNF-α production was enhanced in the presence of PDTC and CsA (Figure 5). The viability of inhibitor-treated moDCs was monitored with propidium iodide (PI) staining. Treatment of moDCs with signaling inhibitors LY294002 or PDTC had a minor effect on cell viability, and approximately 70% of cells were alive at 24 h after the use of these inhibitors. P38 or NFAT inhibitors did not have effects on cell viability. In untreated control cells 86% of the moDCs were viable (data not shown).

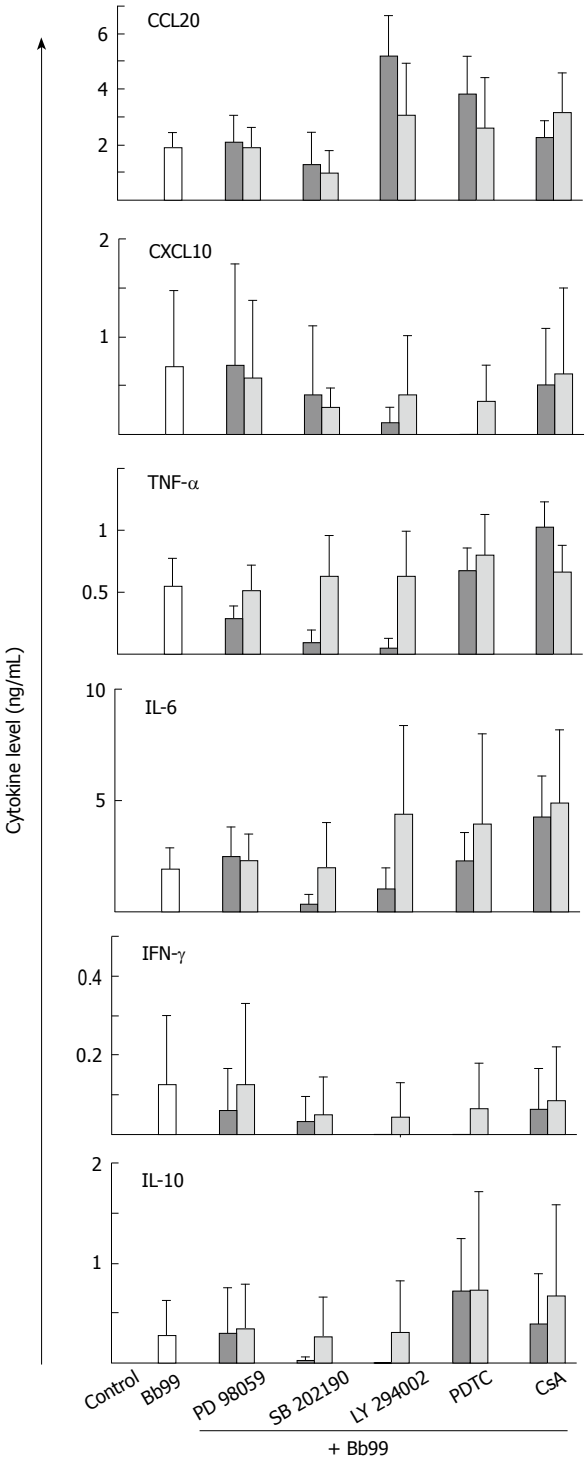

Figure 5 Pharmacological signaling inhibitors interfere with *Bifidobacterium breve* Bb99 induced cytokine production in moDCs. moDCs were left untreated or treated with different pharmacological inhibitors for 30 min prior to stimulation with Bb99 (bacteria:host cell ratio of 40:1). Cell culture supernatants from four blood donors were collected at 24 h after stimulation, and cytokine levels were determined by ELISA. The used inhibitors were: p38 MAP kinase inhibitor SB202190, PI3-kinase inhibitor LY294002, ERK MAP kinase inhibitor PD98059, NF-κB inhibitor pyrrolidine dithiocarbamate (PDTC), and NFAT inhibitor cyclosporinA (CsA). Inhibitor concentrations decrease from left to right.

Cytokine priming regulates cytokine production in bacteria stimulated moDCs

Since *B. breve* Bb99 and other studied bacteria were able to induce cytokine production in moDCs (Figure 1) we analyzed whether proinflammatory cytokines could further contribute to probiotic bacteria-induced cytokine production and whether they would autoregulate their own production by positive or negative feedback mechanisms. MoDCs were pre-treated with IL-6, TNF-α, or IFN-γ for 16 h followed by stimulation with *B. breve* Bb99 or *S. pyogenes* for 24 h (Figure 6). IL-6 priming had a minor stimulatory effect on *S. pyogenes* induced IFN-γ and IL-10 production, whereas such an effect was not seen in *B. breve* Bb99 stimulated cells. TNF-α priming reduced IL-6, IL-10, IFN-γ, and CXCL10 production in *S. pyogenes* stimulated cells, and IL-6 and IL-10 production in *B. breve* Bb99 stimulated cells. In IFN-γ primed cells the production of IL-6, IL-10, and TNF-α was enhanced after *B. breve* Bb99 or *S. pyogenes* stimulation. In addition, the production of CCL20 and CXCL10 chemokines was enhanced in *B. breve* Bb99 stimulated cells after IFN-γ priming (Figure 6).

DISCUSSION

In the present study cytokine production profiles after probiotic bacterial stimulation were analyzed in a model system using *in vitro* cultured human moDCs. In the gastrointestinal tract bacteria are in close contact with gut epithelial cells and various types of immune cells that reside in lamina propria and the luminal side of the mucosal epithelium[42]. Mucosal DCs participate in sampling the gut microbiota by extending dendrites through the gut epithelium[15]. They have a central role in regulating both innate and adaptive immune responses during microbial infections. Therefore, it is important to study the interactions between DCs and potentially probiotic bacteria. Mucosal DCs primarily consist of myeloid DCs, which presumably are of monocyte origin[43].

We have compared the ability of two well characterized probiotics *L. rhamnosus* GG and *B. animalis* Bb12 and seven potentially probiotic bacteria to induce maturation of human moDCs. We observed that moDCs stimulated with these probiotic bacteria matured as well as moDCs stimulated with a significant human pathogen, *S. pyogenes*, as indicated by the expression of costimulatory molecules CD86 and HLA class Ⅱ. The results are well in line with previous studies which show that *S. pyogenes*, different lactobacilli, and bifidobacteria can induce DC maturation[19,33,44]. Our data shows that also *L. rhamnosus* LC705, *L. helveticus* 1129, *B. longum* 1/10, *B. breve* Bb99, *S. thermophilus* THS, *L. lactis* ARH74, and *L. mesenteroides* subsp. *cremoris* PIA2 with potential probiotic characteristics can enhance the expression of DC maturation markers. Lactobacilli seem to be able to induce DC maturation but cytokine production remains low after stimulation with *L. rhamnosus* strains LGG and LC705. Our data demonstrates that some lactobacilli are poor inducers of proinflammatory cytokines while others can stimulate cytokine production in human moDCs (Figures 1 and 2), as previously observed[44,45]. The ability of bacteria to induce moDC maturation but not cytokine production could mean that they stimulate the development of partially- or semi-mature DCs[33].

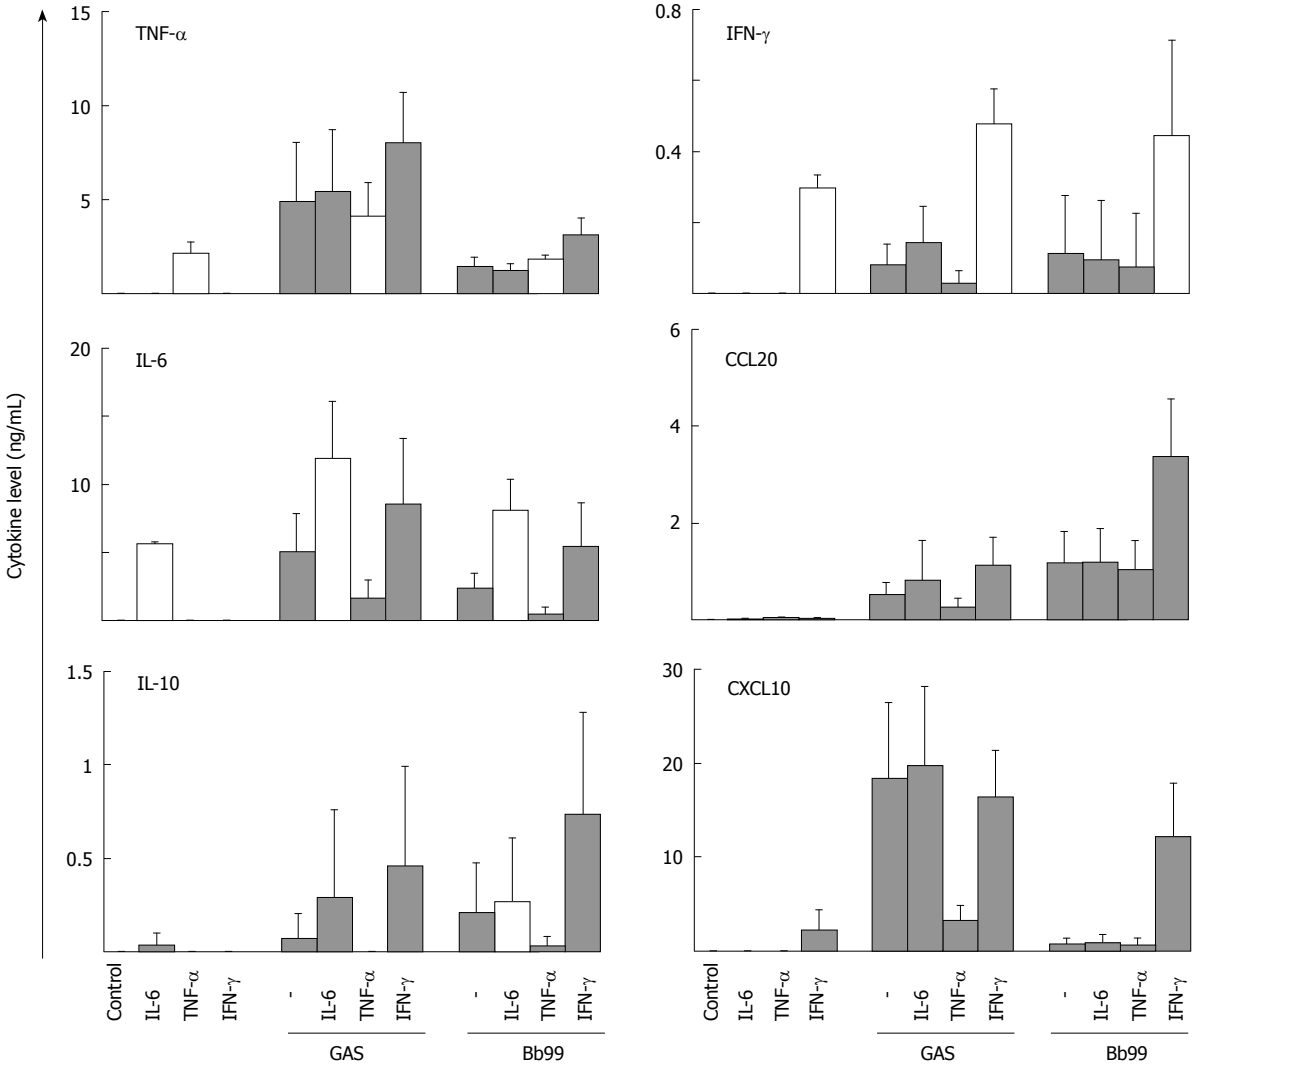

Figure 6 Pre-treatment of human moDCs with proinflammatory cytokines affects bacteria induced cytokine production. MoDCs were primed with IL-6, TNF-α, or IFN-γ for 16 h. Unprimed or cytokine primed cells were stimulated with GAS or Bb99 (bacteria:host cell ratio of 40:1). Cell culture supernatants were collected at 24 h after stimulation, and cytokine levels in supernatants were determined by ELISA. The experiment was done with cells obtained from four blood donors, and results of a representative experiment out of two are shown. The data is shown as the means, and the error bars represent standard deviations. White bars indicate cytokine priming. GAS; *Streptococcus pyogenes*; Bb99: *Bifidobacterium breve* Bb99.

This type of DCs may be involved in the induction of tolerance, as previously suggested[46].

The potentially probiotic and probiotic bacteria used in our study were previously analyzed by Kekkonen *et al*[29] in peripheral blood mononuclear cells (PBMC). In PBMC, *L. mesenteroides* subsp. *cremoris* PIA2 and *S. thermophilus* THS were potent inducers of IL-12 and IFN-γ production. However, in moDCs *S. thermophilus* THS was a potent inducer of IL-12 but not that of IFN-γ. *L. mesenteroides* subsp. *cremoris* PIA2 did not induce IL-12 or IFN-γ production in moDCs. This data demonstrates that *S. thermophilus* THS can induce a proinflammatory cytokine response in several primary cells analyzed. As shown in the present study, we are the first ones to demonstrate IFN-γ production in human moDCs in response to stimulation with potentially probiotic *B. animalis* subsp. *lactis* Bb12, *B. breve* Bb99, *L. lactis* ARH74, and *L. helveticus* 1129.

We observed that *B. animalis* subsp. *lactis* Bb12 and *B. breve* Bb99 were good inducers of IL-10 production in moDCs. *B. animalis* subsp. *lactis* Bb12 and *B. breve* Bb99 have been reported to induce IL-10 also in PBMCs[29] and other bifidobacteria in human colonic lamina propria DCs[45]. IL-10 has anti-inflammatory effects by decreasing IL-12 production and thereby also IFN-γ production which leads to the development of Th2 or Th3 type immune responses[19]. The ability of bifidobacteria to induce IL-10 production may be one factor contributing to their observed anti-inflammatory activities[45,47]. The proinflammatory cytokines produced by probiotic bacteria stimulated moDCs are suggested to induce low-grade inflammation that might protect allergy prone people from the development of allergy[48]. The ability of probiotics to induce distinct moDC cytokine production profiles in a genera or a strain-specific manner could be due to different molecules and structures expressed on the surface of these bacteria. Bacteria can also secrete active proteins or peptides that can stimulate host cells[49-51]. Recognition of these components by receptors on host cell surface can result

in the activation of diverse signaling pathways and trigger differential cytokine production.

Probiotic bacteria used in our study differentially induced moDC cytokine gene expression. *L. rhamnosus* strains LGG and LC705, and *L. mesenteroides* subsp. *cremoris* PIA2 were weak in inducing moDC cytokine responses. Bifidobacteria, *S. thermophilus* THS, *L. lactis* ARH74, and *L. helveticus* 1129 induced the production of proinflammatory cytokines TNF-α, IL-6, IL-12, and IFN-γ as well as anti-inflammatory IL-10. Pathogenic *S. pyogenes* and *S. thermophilus*, a streptococcus used in yogurt fermentation induced production of proinflammatory cytokines and chemokines TNF-α, IL-6, IL-12, CCL20, and CXCL10. IL-10 production was not observed suggesting that at least these two streptococcal species have a tendency to enhance inflammatory cytokine production. It has previously been shown that some streptococci or their components utilize TLR2 pathway to activate host cells[52,53]. Since these bacteria are good inducers of IL-12, that can not be efficiently triggered through TLR2[54], it is likely that other receptor/signaling systems apart from TLR2 are also activated. It is of interest that *L. lactis* subsp. *cremoris* ARH74 and *L. helveticus* 1129 were able to induce both strong inflammatory cytokine/chemokine and anti-inflammatory IL-10 responses.

The kinetics of bacteria-induced cytokine mRNA expression was studied with *S. thermophilus* THS, *B. breve* Bb99, and *L. lactis* subsp. *cremoris* ARH7. The expression of CCL20 and TNF-α mRNAs, and CCL20, TNF-α, and IL-6 protein production was detected at early time points after stimulation with these three probiotic bacteria. Fast TNF-α and IL-6 production enhances inflammatory responses. CCL20 attracts immature DCs to the site of infection where they can be activated[55]. The fact that *S. thermophilus* THS, *B. breve* Bb99, and *L. lactis* subsp. *cremoris* ARH74 can induce efficient TNF-α, IL-6, and CCL20 production suggests that they all can trigger efficient inflammatory responses. CCL19 is a chemokine produced by activated DCs that attracts immature T cells to the local lymph nodes where their activation takes place[55]. It was of interest that none of the bacteria used in this study could induce CCL19 mRNA or protein expression. The lack of CCL19 production could indicate that the immune response triggered by probiotic bacteria may be incomplete compared to moDC responses to pathogenic bacteria, such as *S. enterica* serovar Typhimurium which is known to induce CCL19 production[56]. Th1 type cytokines IL-12 and IFN-γ were produced at later time points after stimulation with *S. pyogenes* and probiotic bacteria as shown previously with *S. pyogenes*[33]. Our results are well in line with previous experiments done with human moDCs showing that TNF-α, IL-12, and CCL20 production is induced in response to *S. pyogenes* stimulation, while a probiotic *L. rhamnosus* GG was weak in activating moDC cytokine production[33].

We used pharmacological signaling inhibitors to analyze the host cell signaling pathways regulating probiotic bacteria-induced cytokine production. Our results show that p38 MAPK, PI3 kinase, and NF-κB signaling pathways play an essential although a differential role in the ability of probiotic bacteria to induce moDC cytokine gene expression. MAPK and PI3K pathways are involved in TNF-α, IL-6, IL-10, IFN-γ, and CXCL10 production in *B. breve* Bb99 stimulated moDC. Inhibition of NF-κB and NFAT pathways led to a more limited effect on CXCL10 and IFN-γ production induced by *B. breve*. Surprisingly, the use of some inhibitors resulted in enhanced *B. breve* Bb99 induced cytokine production. Blocking one signaling pathway likely leads to stimulation of an alternative signaling pathway thus increasing cytokine production[57].

Since *B. breve* Bb99 was efficient in inducing moDC cytokine production (Figure 1), we studied the effects of different cytokines on the ability of this bacterium to induce the production of other cytokines. IFN-γ priming enhanced *B. breve* Bb99 and *S. pyogenes* stimulated production of cytokines. The effects of IFN-γ are likely due to the enhanced expression of TLRs and other signaling components, which are under the transcriptional regulation of IFNs[58]. Since IFN-γ priming increased moDC responsiveness to *B. breve* Bb99 and *S. pyogenes* it may be that identical signaling pathways are involved in cytokine production in response to stimulation with non-pathogenic *B. breve* Bb99 and pathogenic *S. pyogenes*. TNF-α priming had an opposite effect on moDC cytokine production. TNF-α is involved in moDC maturation, which decreases the capacity of moDCs to take up microbes or their components[59]. Therefore, TNF-α primed cells could be less responsive to *B. breve* stimulation. However, further studies are needed to reveal the mechanisms and co-operativity of signaling pathways involved in cytokine production in bacteria-stimulated moDCs.

In the present study carried out with human primary DCs we compared nine potentially probiotic bacteria in their abilities to induce cytokine and chemokine production in moDCs. We demonstrate that these bacteria have strain-specific effects on moDC cytokine production and they all induce moDC maturation as efficiently as pathogenic bacteria. This data is valuable for selecting new probiotic bacteria. The knowledge of unique cytokine production profiles may help in targeting specific probiotic strains for clinical applications.

COMMENTS

Background

Probiotic bacteria are widely used to relieve the symptoms of many disorders. However, the mechanisms that cause these beneficial actions are yet to be characterized. One of the factors contributing to the health promoting effects of probiotic bacteria could be their capacity to induce cytokine production that further regulates the development of innate and adaptive immune responses.

Innovations and breakthroughs

At present the cytokine production profiles of different probiotic strains, some of which have already been used in clinical trials, are poorly characterized. Also comparative data from same experimental model systems is limited. In this study we have systematically analyzed the ability of nine different potentially probiotic bacteria to induce maturation and cytokine production in human monocyte-derived dendritic cells (moDCs) in order to compare their capacities to activate innate and adaptive immune responses.

Applications

Data shows that probiotic bacteria induced the maturation of moDCs in a dose-dependent manner. They induced moDC maturation as efficiently as pathogenic bacteria but differed in a genera-specific manner in their ability to induce moDC cytokine gene expression. *S. thermophilus* induced the expression of pro-inflammatory (TNF-α, IL-12, IL-6, and CCL20) and Th1 type (IL-12 and IFN-γ) cytokines, while *B. breve* and *L. lactis* were also potent inducers of anti-inflammatory IL-10. Mitogen-activated protein kinase (MAPK) p38, phosphatidylinositol 3 (PI3) kinase, and nuclear factor-kappa B (NF-κB) signaling pathways were shown to be involved in bacteria-induced cytokine production. The cytokine profiles of probiotic bacteria can be useful in selecting new probiotic bacteria for *in vivo* trials and help to understand the mechanisms behind probiotic actions.

Peer review

This paper describes the induction of cytokines and DC maturation by different potentially probiotic bacteria. The study clearly describes the potential of probiotic bacteria to induce DC maturation, dose-dependent responses, cytokine production kinetics, and signaling pathways involved in cytokine gene expression. It's interesting.

Abstract

AIM: To evaluate fecal calprotectin (FC) as a surrogate marker of treatment outcome of relapse of inflammatory bowel disease (IBD) and, to compare FC with fecal myeloperoxidase (MPO) and fecal eosinophil protein X (EPX).

METHODS: Thirty eight patients with IBD, comprising of 27 with ulcerative colitis (UC) and 11 with Crohn's disease (CD) were investigated before treatment (inclusion), and after 4 and 8 wk of treatment. Treatment outcomes were evaluated by clinical features of disease activity and endoscopy in UC patients, and disease activity in CD patients. In addition, fecal samples were analyzed for FC by enzyme-linked immunosorbent assay (ELISA), and for MPO and EPX with radioimmunoassay (RIA).

RESULTS: At inclusion 37 of 38 (97%) patients had elevated FC levels (> 94.7 μg/g). At the end of the study, 31 of 38 (82%) patients fulfilled predefined criteria of a complete response [UC 21/27 (78%); CD 10/11 (91%)]. Overall, a normalized FC level at the end of the study predicted a complete response in 100% patients, whereas elevated FC level predicted incomplete response in 30%. Normalized MPO or EPX levels predicted a complete response in 100% and 90% of the patients, respectively. However, elevated MPO or EPX levels predicted incomplete response in 23% and 22%, respectively.

CONCLUSION: A normalized FC level has the potential to be used as a surrogate marker for successful treatment outcome in IBD patients. However, patients with persistent elevation of FC levels need further evaluation. FC and MPO provide superior discrimination than EPX in IBD treatment outcome.

Key words: Fecal markers; Calprotectin; Myeloperoxidase; Eosinophil protein X treatment; Inflammatory bowel disease; Ulcerative colitis; Crohn's disease

INTRODUCTION

Inflammatory bowel disease (IBD), including ulcerative colitis (UC) and Crohn's disease (CD), is a chronic, idiopathic inflammatory condition of the gut with a typically relapsing and remitting course. Exacerbations are characterized by symptoms of diarrhea, urgency of defecation and occasionally rectal bleeding and abdominal pain. The aim of treatment is to induce and maintain disease remission[1]. Currently, the most reliable method to assess intestinal inflammation is endoscopy with mucosal biopsy. These techniques are costly, invasive, time consuming and unpopular with patients. Furthermore, the site of inflammation is not always reached by endoscopy as in the case of small bowel disease in CD. Simple, inexpensive and objective tools for the assessment of mucosal inflammation are therefore desirable. Previous studies have indicated that fecal markers may be used in the differentiation of IBD from functional gastrointestinal disorders. However,

the usefulness of these markers in monitoring therapy of patients with disease relapse in IBD needs further evaluation[2-4].

A prominent feature of mucosal histology in patients with active IBD is infiltration by neutrophil granulocytes[5]. Calprotectin is a major protein of neutrophils and macrophages, accounting for about 60% of the cytosol of these cells[6]. Several workers have shown that elevated fecal calprotectin (FC) levels correlate with intestinal inflammation, both in adults and children[7-9], and has the ability to predict relapse in IBD[10,11]. Moreover, FC levels remain stable in stools, and stool samples are easy to collect[12-17].

Other fecal proteins of interest in monitoring IBD are myeloperoxidase (MPO) and eosinophil protein X (EPX). MPO is mainly derived from neutrophil granulocytes and has been observed both in the intestinal mucosa[18-20], and in gut lavage, and has the potential of monitoring treatment outcome[21]. EPX is released by activated eosinophil granulocytes, which are abundant in the mucosa in active IBD[22-25]. We have previously reported that fecal levels of EPX and MPO have the potential of monitoring therapy in UC[26].

The primary aim of the present study was to assess FC as a surrogate marker of treatment outcome of relapse in patients with IBD compared to the standard criteria of response. The second aim was to compare FC with fecal MPO and EPX, with respect to their applicability in monitoring treatment outcome.

MATERIALS AND METHODS

Patients

Forty adult patients (19 females and 21 males, mean age 40 years, range 21-70 years), seeking medical advice for symptoms of relapse of previously diagnosed IBD were consecutively recruited at the department of Gastroenterology, University Hospital, Uppsala, Sweden, between October 2002 and April 2003. Two patients were excluded: one patient had salmonella enteritis, while the other patient dropout after 8 wk of treatment. Before entry into the study, the patients had to fulfil standard diagnostic criteria of UC (n = 27) and CD (n = 11)[27]. Details of the clinical date of the study population are provided in Table 1.

At inclusion, all patients had mild to moderate disease activity, and the endoscopic examination was consistent with active disease. The exclusion criteria were: pregnant or lactating women, enteritis due to infections, and intestinal biopsies performed within 3 d before inclusion. The project was approved by the Ethical Committee of the Medical Faculty, Uppsala University, and all patients gave their written informed consent before participating in the study.

The patients were examined according to the study protocol at inclusion and after 4 and 8 wk of treatment (Table 2).

In patients with UC, a semi-quantitative four-grade (normal, mild, moderate and severe) scale was used for clinical and endoscopic score[28]. In patients with CD, the Harvey-Bradshaw's clinical activity index (HBI) was used[29]. Histopathology was graded as active or inactive inflammation, based on the number of neutrophil granulocytes in the mucosa as judged by an experienced pathologist, according to the criteria of Truelove and Witts[30]. At inclusion, 7 of 27 (26%) patients with UC were on no treatment, 14 (52%) were receiving systemic 5-aminosalicylic acid (5-ASA), and 6 (22%) were under treatment with different combinations of systemic 5-ASA, prednisone, azathioprine and topical prednisone. In CD patients, at inclusion 4 of 11 (36%) patient were on no treatment, 6 (54%) were receiving systemic 5-ASA, and one patient was under treatment with a combination of 5-ASA, azathioprine and Metronidazole.

Treatment of a relapse was individualized, according to standard recommendations for the management of IBD. Topical and/or systemic 5-ASA was administered to 26 of 27 (96%) patients with UC, and to 9 of 11 (82%) patients with CD. Topical and/or systemic prednisone was given to 22 of 27 (81%) UC patients, and 7 of 11 (81%) CD patients. Azathioprine was used in 3 of 27 (11%) UC patients and in 3 of 11 (27%) CD patients, while methotrexate was prescribed to one patient with CD.

Table 1 Clinical data of the study population

	UC	CD
Number of subjects	27	11
Gender (female/male)	15/12	3/8
Age (yr, mean)	42.5 (21-66)	34.6 (21-70)
Disease duration (yr, mean)	9.3 (0-38)	5.6 (0-18)
Extent of disease:		
Colon	9[1]	8
Left side colitis	14	-
Proctitis	4	-
Ileocolitis	-	1
Prior surgery	1	1
Treatment at inclusion:		
No treatment	7	4
5-ASA (topical/systemic)	19	4
Azathioprine	1	1
Prednisone (topical/systemic)	5	-
Metronidazole	-	1

[1]Extensive colitis means disease extending from proximal to the splenic flexure.

Table 2 Study protocol

Procedure	Inclusion	4 wk	8 wk
Stool sample	Done	Done	Done
Clinical score	Done	Done	Done
Endoscopy and biopsy	Done[1]	Done[2]	Done[3]
Histopathology	Done[1]	Done[2]	Done[3]

[1]Not done in 2 CD patients; [2]Not done in 4 CD patients; [3]Not done in 2 CD patients.

Definition of treatment outcome

In UC, a complete response to treatment was defined as return of the clinical and endoscopic scores to normal. A partial response was defined as reduction in both the clinical and endoscopic scores, but their failure to return

Table 3 FC levels (μg/g, mean, 10-90th percentile) in patients with a relapse of IBD at inclusion, and after 4 and 8 wk of treatment

[1]Friedmans Test for 3 variables.

to normal. A non-response was defined as a decrease in only clinical or endoscopical score or an unchanged or increased clinical and/or endoscopic score. In CD, a complete response was defined as decrease in HBI score to ⩽ 5 points; partial response was a decrease in the clinical score, but not < 6 points; and a non-response was defined as an unchanged or increased HBI score.

Fecal inflammation markers

Stool samples were collected in screw-capped plastic containers at inclusion (visit 1), and after four (visit 2) and 8 wk of treatment (end of study, visit 3). Stool samples were kept at 4℃ for up to 2 d before freezing at -70℃. Stool extracts for EPX and MPO measurement were prepared as described previously[31]. Calprotectin in fecal extracts was analyzed, using the calprotectin enzyme-linked immunosorbent assay (ELISA), according to the manufacturer's instructions (Calprest; Eurospital SpA, Trieste, Italy). Before testing, the supernatants were thawed, diluted 1:50 with assay buffer and then analyzed with Calprest. Calprotectin was expressed as microgram per gram of feces. According to the manufacturer, a calprotectin level > 50 μg/g is pathological. FC was determined in samples from 44 apparently healthy adults, and the normal range was 9.2-94.5 μg/g (5-95th percentile). EPX and MPO were determined using radioimmunoassay (RIA) (Pharmacia Diagnostics, Uppsala, Sweden), and the intra- and inter-assay variations were less than 9% for both assays. Marker levels in faeces were adjusted for fecal water content, as described previously[31], and were expressed as μg/g semidry faeces. The concentration of fecal markers in healthy adults for fecal MPO (1.3-8.8 μg/g, 5-95th percentile) and fecal EPX (0.2-1.7 μg/g, 5-95th percentile) (median age 44 years, range 18-73, n = 44) have been reported recently[31].

Statistical analysis

Non-parametric tests of Kruskal-Wallis ANOVA and the Mann-Whitney *U*-test were used for unpaired comparisons. For paired analyses we used Friedman ANOVA and Wilcoxon matched pairs test. Spearman rank order correlations were used to express relationship between variables. $P < 0.05$ was considered as significant. All calculations were performed on a personal computer by means of the statistical software Statistica (Statsoft Inc, Tulsa, Oklahoma USA). We used the 95th percentile concentration level of respective fecal marker as the cut-off level for normal and elevated values i.e. concentration was set at 94.5 μg/g for FC, at 8.8 μg/g for MPO, and at 1.7 μg/g for EPX.

RESULTS

FC levels at inclusion and during the study period

At inclusion, 37 of 38 (97%) patients manifested elevated FC levels. There was no difference in the FC levels between UC and CD at any time point during the study. Overall, a significant decline in FC levels was seen during the study ($P < 0.01$) in patients with UC ($P < 0.01$), but not in CD ($P = 0.367$) (Table 3).

Analysis based on the extent of the disease showed that patients with proctitis had lower levels of FC ($P < 0.01$) compared with more extensive disease. This difference was noted in patients with UC ($P < 0.05$), but was not analyzed in CD since only one patient had proctitis.

FC levels in correlation to clinical scores

In patients with UC, there was no correlation between the clinical score and FC levels at inclusion, and at the end of the study (8 wk of treatment). However, correlation was noted after 4 wk of treatment ($R = 0.0424$, $P < 0.01$).

In CD patients, there was no correlation between FC and the HBI score at inclusion, and after 4 wk of treatment, but correlation was present at the end of the study (8 wk of treatment) ($R = 0.7804$, $P < 0.01$).

FC levels in relation to endoscopical score

In patients with UC, the endoscopic score was calculated and correlated with FC levels. No correlation was seen at inclusion, but after 4 and 8 wk of treatment a correlation was noted ($R = 0.5045$, $P < 0.01$) and ($R = 0.6659$, $P < 0.01$), respectively.

FC levels in correlation to histopathology

At inclusion, all patients with UC (27/27) showed histological signs of active disease, whereas 12 of 26 (one missing value) and 13 of 27 showed inactive histology after 4 and 8 wk of treatment, respectively. Patients with UC with histologic evidence of active inflammation, demonstrated higher levels of FC compared to UC patients with inactive inflammation after 4 and 8 wk of treatment ($P < 0.05$). In CD patients, no difference was found during the study period.

FC in relation to treatment outcome

In UC patients, a complete response was observed in 14 of 27 (52%) and 21 of 27 (78%) patients after 4 and 8 wk of treatment, respectively. Two patients were classified as partial responders and four patients as non responders at the end of the study. In complete responders, there was a significant decline in FC levels ($P < 0.01$), which was not observed in partial or non responders (Figure 1). The decline in FC levels was already significant after 4 wk of treatment in complete responders ($P < 0.01$).

Table 4 Correlation between fecal FC, MPO and EPX at inclusion, and after 4 and 8 wk of treatment in patients with UC and CD

Patients	Fecal marker	Inclusion	4 wk	8 wk
All	FC and MPO	$R = 0.884$, $P < 0.01$	$R = 0.941$, $P < 0.01$	$R = 0.924$, $P < 0.01$
All	FC and EPX	$R = 0.592$, $P < 0.01$	$R = 0.724$, $P < 0.01$	$R = 0.642$, $P < 0.01$
UC	FC and MPO	$R = 0.868$, $P < 0.01$	$R = 0.927$, $P < 0.01$	$R = 0.940$, $P < 0.01$
UC	FC and EPX	$R = 0.556$, $P < 0.01$	$R = 0.762$, $P < 0.01$	$R = 0.602$, $P < 0.01$
CD	FC and MPO	$R = 0.936$, $P < 0.01$	$R = 0.818$, $P < 0.01$	$R = 0.903$, $P < 0.01$
CD	FC and EPX	$R = 0.654$, $P < 0.05$	$R = 0.636$, $P < 0.05$	$R = 0.854$, $P < 0.01$

All: $n = 38$; UC: $n = 27$; CD: $n = 11$.

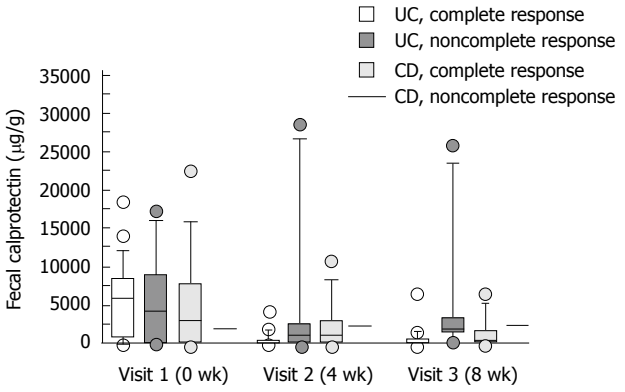

Figure 1 FC levels (box displays median, 25-75th percentile and lines 10-90th percentile with dots displaying outliers), and treatment outcome in terms of complete and incomplete response in patients with UC and CD treated for 8 wk.

Table 5 PPV and NPV of a complete response after 8 wk of treatment in UC or CD calculated by using fecal marker levels above the 95th percentile as the cut-off value

Fecal marker	Patients	PPV (95% CI)	NPV (95% CI)
FC	All $n = 37$[1]	30 (13-53)	100 (77-100)
FC	UC $n = 27$	38 (13-65)	100 (71-100)
FC	CD $n = 10$[1]	14 (2-58)	100 (30-100)
MPO	All $n = 37$[1]	23 (10-42)	100 (59-100)
MPO	UC $n = 27$	27 (10-50)	100 (48-100)
MPO	CD $n = 10$[1]	12 (2-53)	100 (19-100)
EPX	All $n = 37$[1]	22 (8-42)	90 (56-98)
EPX	UC $n = 27$	25 (8-49)	85 (42-98)
EPX	CD $n = 10$[1]	14 (3-58)	100 (30-100)

[1]One missing value. FC cut-off value 94.5 μg/g, MPO cut-off value 8.8 μg/g, EPX cut-off value 1.7 μg/g.

In CD patients, a complete response was observed in 9 of 11 (81%) and 10 of 11 (91%) patients after 4 and 8 wk of treatment, respectively. There was a trend in the decline in FC levels in complete responders but the difference was not significant ($P = 0.13$) (Figure 1). One CD patient, who was a partial responder, manifested increasing levels of FC during the study (2030, 2220, 2460 μg/g, respectively).

FC in correlation with MPO and EPX

There was a good correlation between FC, and both MPO and EPX, at all the study visits in the group as a whole, as well as on sub-group analyses of patients with UC and CD (Table 4).

FC, MPO and EPX as predictors of treatment outcome

In order to predict treatment outcome, positive predictive value (PPV) and negative predictive value (NPV) were calculated at the end of the study (after 8 wk of treatment). All patients with a normalized FC value at the end of the study fulfilled the predefined criteria of a complete response, irrespective of the diagnosis of UC or CD. However, an elevated FC value was noted in 10 of 21 patients with UC and 6 of 9 patients with CD who fulfilled criteria for complete response at the end of the study. The same pattern was observed in patients with UC and CD with regard to MPO, however, for EPX this was only seen in CD patients (Table 5).

DISCUSSION

In the present study, we evaluated FC as a surrogate marker of treatment outcome in IBD. FC levels were monitored before and during treatment of patients with a relapse of IBD. In both UC and CD, patients with normalized FC level after 8 wk of treatment fulfilled predefined criteria of a complete response. However, elevated FC levels at the end of the study did not rule out response to treatment. As described by other workers, we also observed elevated FC levels in all but one patient presenting with disease relapse[8,9].

It has been reported that FC levels in UC patients reflects the degree of inflammation rather than the extent of the disease[8]. By contrast, in the present study, we observed higher FC levels in UC patients at inclusion with extensive disease compared to those with proctitis.

Endoscopic findings have been shown to correlate with FC levels in patients with IBD[32]. In the present study, no such correlation was observed in UC patients at inclusion, however, a correlation was noted after 4 and 8 wk of treatment. It is well known that there are difficulties in endoscopic grading of inflammation due to inter-observer variations[33], and with the use of different scoring systems. In the present study, we used a four-grade score[28], which may be inadequate in distinguishing between mild and moderate inflammation.

In patients with UC, the clinical activity index and FC levels showed a correlation after 4 wk of treatment, but not at inclusion or at the end of the study. In patients with CD, clinical activity and FC showed a correlation only at the end of the study. These weak correlations between clinical indices and FC levels are in accordance with previous reports[9,34,35]. By contrast, a recent study reported significantly higher FC levels in patients with severe disease compared to those with moderate

disease[7]. Since our patients manifested only mild to moderate disease, the present study cannot clarify this matter.

The histological findings in present study confirmed previous reports that patients with active UC manifest higher FC levels compared to those with inactive disease[8,32]. However, this finding was not seen in CD patients. These observations should be interpreted with caution, since the number of patients was small. One may speculate that one explanation for these findings may be that biopsies are more prone to sampling error in CD because of the patchy mucosal inflammation in CD compared to UC. Using FC values below ULN (95th percentile of the normal range) as a negative predictor of active disease after 8 wk of treatment, revealed a NPV of 100%. This is in line with previous reports showing that normalisation of FC predicts mucosal healing in patients with IBD[4].

However, using an elevated level of FC as a positive predictor to detect ongoing active disease or treatment failure after 8 wk of treatment, showed a PPV of 38% in UC and only of 14% in CD. In children with active IBD treated with prednisone, FC levels declined in line with clinical improvement but seldom fell within the normal range[36]. A persistently high level of FC suggests ongoing inflammation in clinically silent disease and may predict relapse of IBD[11,37]. It is possible that our patients who responded to therapy but continued to have elevated FC, may have normalized the FC levels if the study had been prolonged. Another explanation is that these patients may relapse again soon after termination of the study. After the completion of the present study, we followed our patients retrospectively but did not find any relapsers over the following 3 mo (data not shown). At present, there is insufficient data to conclude that patients without clinical or endoscopic signs of active IBD but with elevated FC levels, may benefit from more aggressive anti-inflammatory treatment.

In the present study, fecal MPO and EPX were also evaluated in order to monitor treatment outcome compared with FC levels. A recent study showed that MPO and EPX may be used to detect active UC[26]. In the present study, we observed a close correlation between FC, MPO and EPX, and treatment outcome; FC and MPO provided better assessment of treatment outcome compared to EPX in patients with UC. Interestingly, normalized levels of EPX after 8 wk of treatment indicated a complete response, especially in patients with CD.

In conclusion, normalized FC level may be used as a surrogate marker for treatment response in patients with IBD. However, the significance of persistent elevation of FC needs further evaluation.

ACKNOWLEDGMENTS

We are grateful to Ingrid Stolt for expert handling of samples and for skilful technical assistance, and to Maria Lampinen for valuable views on the manuscript.

COMMENTS

Background

Ulcerative colitis (UC) and Crohn's disease (CD) are chronic, idiopathic inflammatory conditions of the gut with a typically relapsing and remitting course. Exacerbations are characterized by symptoms of diarrhea, urgency of defecation, and occasionally rectal bleeding and abdominal pain. At present, the most reliable method of assessing intestinal inflammation is endoscopy with biopsy. These techniques are costly, invasive, time consuming and unpopular with the patients. Furthermore, the site of inflammation is not always reached by endoscopy as in patients with CD of the small bowel. Simple, inexpensive and objective tools for the assessment of mucosal inflammation are therefore desirable. Previous studies have indicated that fecal markers may be used in the differentiation of inflammatory bowel disease (IBD) from functional gastrointestinal disorders. However, the usefulness of these markers in monitoring therapy of patients with relapse of IBD needs further evaluation.

Research frontiers

The present study suggests that a normalized fecal calprotectin (FC) level may be used as a surrogate marker for successful treatment outcome in IBD patients. However, patients with persistently elevated FC levels need further evaluation.

Innovations and breakthroughs

The present study confirmed previous observations that patients with a relapse of IBD had elevated fecal markers, and normalized FC levels may be used as a surrogate marker for treatment response in IBD. We evaluated patients diagnosed previously with UC or CD before starting treatment, and after 4 and 8 wk of treatment. Treatment outcome, based on clinical activity and endoscopic findings in UC patients, and clinical activity in CD patients, were evaluated together with fecal samples analyzed for FC, and compared with fecal myeloperoxidase (MPO) and eosinophil protein X (EPX). It was observed that FC and MPO provided better assessment of treatment outcome compared to EPX in patients with UC. Interestingly, normalized levels of EPX after 8 wk of treatment indicated a complete response, especially in patients with CD.

Applications

These findings suggest that fecal markers can be used as surrogate markers for successful treatment outcome in IBD patients. Fecal markers are simple, inexpensive and objective tools for the assessment of mucosal inflammation.

Peer review

This study provides good data on material and methods. The results are based on sufficient experimental evidence. The discussion is well organized, and the conclusions are reliable and valuable.

Abstract

AIM: To evaluate the efficacy of resection and primary anastomosis (RPA) and RPA with modified blow-hole colostomy for sigmoid volvulus.

METHODS: From March 2000 to September 2007, 77 patients with acute sigmoid volvulus were treated. A total of 47 patients underwent RPA or RPA with modified blow-hole colostomy. Twenty-five patients received RPA (Group A), and the remaining 22 patients had RPA with modified blow-hole colostomy (Group B). The clinical course and postoperative complications of the two groups were compared.

RESULTS: The mean hospital stay, wound infection and mortality did not differ significantly between the groups. Superficial wound infection rate was higher in group A (32% *vs* 9.1%). Anastomotic leakage was observed only in group A, with a rate of 6.3%. The difference was numerically impressive but was statistically not significant.

CONCLUSION: RPA with modified blow-hole colostomy provides satisfactory results. It is easy to perform and may become a method of choice in patients with sigmoid volvulus. Further studies are required to further establish its role in the treatment of sigmoid volvulus.

Key words: Acute sigmoid volvulus; Anastomosis; Primary resection; Surgical technique

INTRODUCTION

The epidemiology and clinical presentation of sigmoid volvulus are well established. Although the clinical manifestations of acute volvulus are often clear-cut, a diagnostic dilemma is not uncommon. Sigmoid volvulus is the third most common cause of large-bowel obstruction in the western world, after cancer and diverticular disease[1]. It accounts for 4% of all cases of large-bowel obstruction in the United States and United Kingdom[1,2]. Sigmoid volvulus is relatively more common in Eastern Europe, India and Africa, accounting for 50% of all cases of intestinal obstruction[1,2].

The precise etiology of sigmoid volvulus remains speculative, and several etiological factors have been suggested including chronic constipation, high fiber diet, bowel habit, high altitude, and enemas containing ginger, pepper and herbal extracts[3]. Patients with sigmoid volvulus present with abdominal distention, pain, nausea, vomiting, and obstipation, while peritoneal signs are noted infrequently[4]. The colon is distended often to enormous proportions, particularly when the patient is symptomatic. Plain abdominal X-rays are often diagnostic of volvulus. Air-fluid levels are present, and a "bird's beak" deformity is often seen at the site of the torsion[5].

Sigmoid volvulus has been described since ancient times, but its treatment continues to evolve[6,7]. Several therapeutic approaches such as: resection, non-operative

reduction with the help of a colonoscope, sigmoidopexy and mesosigmoidoplasty have been employed[8]. There is no consensus with regard to the optimal surgical management in patient with an acute presentation. Proximal decompressive blow-hole colostomy has been used in patients with toxic megacolon secondary to inflammatory bowel disease and *clostridium difficile* colitis, with a view to avoid manipulating the colon and to tide over the critical phase[9]. This procedure is also performed in hemodynamically unstable patients with malignant bowel obstruction[10-12].

Resection and primary anastomosis (RPA) has emerged as the treatment of choice for sigmoid volvulus over the past two centuries[6,7]. Particularly in elderly and hemodynamically unstable patients, anastomotic leakage may occur due to co-morbid risk factors with this approach. In such situations, a blow-hole colostomy may play a protective role in avoiding anastomotic leakage.

The aim of the present study was to compare the results of RPA with or without modified blow-hole colostomy in an unprepared bowel in patients with acute sigmoid volvulus.

MATERIALS AND METHODS

From March 2000 to September 2007, 77 patients with acute sigmoid volvulus were treated in the department of general surgery, school of medicine, Inonu University. Colonoscopic derotation was attempted in 27 patients, and was successful in 19 patients. In 10 of the 19 non-operatively reduced patients, semi-elective one-stage resection was performed; the remaining 9 patients refused surgery after non-operative decompression. Hartmann's operation was performed in 11 patients who were not in stable condition. After excluding these 30 cases, the remaining 47 patients who underwent RPA with or without a modified blow-hole colostomy were included in this study.

The diagnosis of sigmoid volvulus was made on the basis of clinical features and plain abdominal radiographs. Laparotomy was performed in all patients after active fluid resuscitation and correction of electrolyte imbalance was obtained. Seftriacson 1000 mg and metronidazole 500 mg were administered intravenously at the time of induction of anesthesia, and were continued every 12 h after the operation for 5 d in patients with viable bowel and for 7 d in those with gangrenous bowel.

None of the patients included in the study were treated with preoperative decompression techniques. At laparotomy, the distended bowel was decompressed by using a rectal tube, and any residual feces was milked digitally into the segment of the bowel to be resected. Although the bowel was unprepared, on-table lavage was not performed in any patient. Informed consent was obtained from each patient prior to the surgery. In 25 patients, RPA (Group A) was performed and in the remaining 22 patients, a modified blow-hole colostomy was performed with RPA (Group B). All the anastomoses were inverting and two-layered.

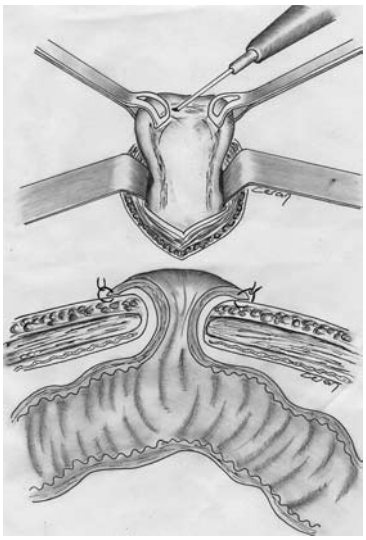

Figure 1 The cut edges of the colon were sutured to the skin with 3/0 vicryl, without fascial or peritoneal sutures. Therefore, the procedure was called "modified blow-hole colostomy technique".

The clinical course and postoperative complications were documented. Wound infection was defined as spontaneous discharge of pus from the wound or a wound that requires drainage. Anastomotic leak was defined as the presence of fecal fistula or the presence of feces in the drain.

Surgical technique of modified blow-hole colostomy

In group B, a proximal stoma was performed to protect the anastomoses. A 3 cm longitudinal incision was made through the tenia libera, and into the transverse colon. An abdominal wall aperture intended for the colostomy was made in the right upper quadrant using a rectus splitting incision. The collapse of the colon allowed it to reach the incision, and facilitated performing a skin-level colostomy. In the blow-hole colostomy technique which has been previously reported, the omentum and seromuscular layers of the colon were attached to the peritoneum and the rectus fascia with interrupted or continuous sutures[9]. In the present study, the cut edges of the colon were sutured to the skin with 3/0 vicryl without fascial or peritoneal sutures. As a result, we call it a "modified blow-hole colostomy technique" (Figure 1). In these patients, oral intake was started on postoperative day 1. On postoperative day 10, the anastomotic integrity was checked using water-soluble radiological studies, and if intact, colostomy closure was performed.

Statistical analysis

Statistical analyses were performed using SPSS for Windows version 11.0 program. Continuous variables were reported as mean ± SD. Categorical variables were reported as percent. Normality for continued variables in groups was determined by the Shapiro Wilk test. The variables showed normal distribution ($P > 0.05$). Therefore, unpaired *t*-test was used for comparison of variables (age and length of hospital stay) between the two groups. Fisher's Exact and Pearson χ^2 tests were used for comparison of categorical variables between the groups. $P < 0.05$ was considered as significant.

Table 1 Operative procedure, morbidity and deaths in 47 patients

Procedure	No. of patients	Wound infection	Anastomotic dehiscence	Deaths
RPA (Group A)	25 (16V, 9G)	6V, 2G	2V, 1G	1V, 1G
RPA with modified blow-hole colostomy (Group B)	22 (17V, 4G, 1P)	2V	-	1V, 1G
Total	47 (33V, 13G, 1P)	10 (8V, 2G)	3 (2V, 1G)	4 (2V, 2G)

V: Viable; G: Gangrenous; P: Perforation; RPA: Resection and primary anastomosis.

Table 2 Comparison of confounding variables between Group A (RPA) and Group B (RPA with modified blow-hole colostomy)

Variable	Group A (n = 25)	Group B (n = 22)	Statistical test and significance
Age (yr)	66.12 ± 14.17	62.27 ± 16.26	Unpaired t-test, P = 0.391
Sex: Female ratio	4/25 (16%)	3/22 (13.6%)	Fisher's exact test, χ^2-test, P = 0.574
Hospital stay (d)	13.68 ± 8.47	16.72 ± 4.90	Unpaired t-test, P = 0.145
Wound infection	8 (32%)	2 (9.1%)	χ^2-test, P = 0.11
Anastomotic leak	3 (12%)	-	Fisher's exact test, χ^2-test, P = 0.142
Mortality	2 (8%)	2 (10%)	Fisher's exact test, χ^2-test, P = 0.645

RESULTS

Forty-seven consecutive patients (7 women and 40 men), who had undergone RPA (25 patients) or RPA with modified blow-hole colostomy (22 patients) were evaluated. There was no significant difference between the two groups in the mean age or the sex ratio. The operative procedures and postoperative outcomes are shown in Table 1. Nine (36%) patients in group A and 5 (22%) in group B had gangrenous bowel. The mean hospital stay, wound infection and mortality did not differ between the groups (Table 2). However, superficial wound infection was almost four times more common in the group A (32% *vs* 9.1%), and nearly two times more common in patients with a viable colon. All the infected wounds healed with conservative measures. Three patients (12%) developed anastomotic leak in group A; two had viable colon and one had gangrenous sigmoid colon. At re-laparotomy, Hartmann's procedure was performed in patients with anastomotic dehiscence. No anastomotic leak was observed in group B. The time to resumption of oral intake was postoperative day 4 in group A, and day 1 in group B, due to the presence of a protective stoma. All patients in group B, had stoma closure performed on postoperative day 10, after radiological studies were carried out. Development of leak or wound infection secondary to stoma closure was not observed in any patient.

The mortality rates were identical in the two groups. One patient died of myocardial infarction and one of sepsis resulting from anastomotic dehiscence in group A on the 1st and 4th postoperative day respectively. In group B, one patient died on the 6th postoperative day due to pulmonary embolism, and one patient died secondary to multi-system organ failure on the 16th postoperative day.

DISCUSSION

The management of sigmoid volvulus involves relief of obstruction and prevention of recurrence. Several operative procedures have been used in the emergency management of sigmoid volvulus. However, permanent cure involves resection of the sigmoid colon, with or without anastomosis[7,13,14]. Less extensive procedures are not always successful and are contraindicated if gangrene or compound volvulus is present[15]. Colonoscopic detrortion and laparotomy with detorsion and colopexy are associated with appreciable morbidity[16]. A recent study reported on the use of laparoscopic recto-sigmoidectomy following colonoscopic decompression in nine patients[17]. Although further studies with larger number of patients are required, this technique appears to be a good option, but can only be applied in decompressed patients.

Traditional surgical teaching has dictated that a primary anastomosis should not be undertaken in an unprepared, obstructed bowel[18-20]. A number of studies on sigmoid volvulus explored the feasibility of one-stage resection using on-table lavage[13,21-24]. The advantages of this approach include single stage procedure, no need for a colostomy, possible lower morbidity and mortality, and shorter hospital stay. The disadvantages include prolonged operative time, need for several liters of irrigation solution, and risk of contamination. However, clinical and experimental evidence supports the view that a clean bowel has an important advantage in surgery of the left colon and rectum, which are parts of the bowel containing solid feces, with a high bacterial count[19,25]. Therefore, an emergency RPA of an unprepared left colon is a controversial subject. Traditionally, obstruction of the left colon is managed by a multi-stage defunctioning colostomy and resection. However, there is a growing acceptance of one-stage primary resection and anastomosis with the use of on-table antegrade irrigation[24,26-28]. However, several studies have suggested that on-table lavage may not be necessary for a safe emergency RPA of unprepared left colon[26-29]. Most experts agree that temporary proximal fecal diversion or decompression can reduce the risk of sepsis resulting from anastomotic leakage[30,31]. All patients in the two study groups, had RPA after intra-operative decompression without any on-table lavage.

Symptomatic anastomotic leak is the most important postoperative complication following emergency colorectal resection with intestinal anastomosis. De *et al*[26] reported 197 patients who had a single stage primary anastomosis without colonic lavage for left-sided colonic obstruction due to acute sigmoid volvulus; only 2 (1.01%) patients developed symptomatic anastomotic leak. In a similar prospective study by

Raveenthiran[29], 57 consecutive patients with acute sigmoid volvulus had emergency RPA without on-table lavage or caecostomy. The anastomotic leak was seen in 10% patients, with higher leak rate in patients with gangrenous colon. Factors such as acute anemia, shock and peri-operative whole blood transfusion are believed to be associated with major anastomotic leaks in patients with gangrenous colon. Due to these co-morbid risk factors, particularly in patients presenting with gangrenous sigmoid volvulus, the addition of a modified blow-hole colostomy appears to be a promising procedure in order to avoid anastomotic leak. Early diet consumption is another advantage of this procedure and may improve the postoperative course. In the present study, anastomotic leakage occurred in 3 (6.3%) patients in group A, compared to none in group B. The difference was numerically impressive but not statistically significant. Comparison of hospital stay, mortality and wound infection did not reveal any significant difference between the two groups. The lower rate of wound infection in group B is a controversial subject. In our opinion, this is probably due to the beneficial effect of early dietary consumption. Previous studies have clearly shown the advantages of early enteral nutrition in surgical patients in reducing septic complications and the overall morbidity compared to parenteral nutrition[32,33].

In conclusion, RPA with modified blow-hole colostomy provides satisfactory results in patients with sigmoid volvulus. This procedure is safe and effective in preventing anastomotic leaks, and may become the treatment of choice in patients with sigmoid volvulus. Further studies are required to definitively establish its role in sigmoid volvulus.

COMMENTS

Background

Although the diagnosis of sigmoid volvulus is not difficult, the emergent surgical approach to sigmoid volvulus is a subject of much debate. There is a growing acceptance of one-stage primary resection and anastomosis of sigmoid colon. However, with this approach, anastomotic leakage may occur, particularly in elderly and hemodynamically unstable patients. Blow-hole colostomy can play a protective role to avoid anastomotic leakage. In the present study, we compared the results of resection and primary anastomosis (RPA), with or without the use of a modified blow-hole colostomy in unprepared bowel in patients with acute sigmoid volvulus.

Research frontiers

Anastomotic leakage is the most important postoperative complication following emergency colorectal resection with intestinal anastomosis. Temporary proximal fecal diversion or decompression can reduce the risk of sepsis from anastomotic leakage. The present study showed that RPA with modified blow-hole colostomy in unprepared bowel with sigmoid volvulus is effective in preventing anastomotic leakage.

Innovations and breakthroughs

This is a new technique for use in patients with sigmoid volvulus. We believe that this technique will decrease the rate of complications such as anastomotic leakage, especially in high risk patients.

Applications

The present study has shown that RPA with modified blow-hole colostomy for sigmoid volvulus is a safe procedure, which enables successful decompression and avoids high mortality rates, particularly in elderly and hemodynamically unstable patients. Future studies will be required to verify the effectiveness and safety of this technique.

Peer review

The authors compared the efficacy of two different type of surgery in patients with sigmoid volvulus. The observations are interesting.

Abstract

AIM: To investigate the frequency and risk factors for acute pancreatitis after pancreatic guidewire placement (P-GW) in achieving cannulation of the bile duct during endoscopic retrograde cholangio-pancreatography (ERCP).

METHODS: P-GW was performed in 113 patients in whom cannulation of the bile duct was difficult. The success rate of biliary cannulation, the frequency and risk factors of post-ERCP pancreatitis, and the frequency of spontaneous migration of the pancreatic duct stent were investigated.

RESULTS: Selective biliary cannulation with P-GW was achieved in 73% of the patients. Post-ERCP pancreatitis occurred in 12% (14 patients: mild, 13; moderate, 1). Prophylactic pancreatic stenting was attempted in 59% of the patients. Of the 64 patients who successfully underwent stent placement, three developed mild pancreatitis (4.7%). Of the 49 patients without stent placement, 11 developed pancreatitis (22%: mild, 10; moderate, 1). Of the five patients in whom stent placement was unsuccessful, two developed mild pancreatitis. Univariate and multivariate analyses revealed no pancreatic stenting to be the only significant risk factor for pancreatitis. Spontaneous migration of the stent was observed within two weeks in 92% of the patients who had undergone pancreatic duct stenting.

CONCLUSION: P-GW is useful for achieving selective biliary cannulation. Pancreatic duct stenting after P-GW can reduce the incidence of post-ERCP pancreatitis, which requires evaluation by means of prospective randomized controlled trials.

INTRODUCTION

Endoscopic retrograde cholangio-pancreatography (ERCP), which was first reported in the late 1960's[1], is a well-accepted technique for evaluating pancreato-biliary diseases. Although selective cannulation of the bile duct is mandatory for therapeutic ERCP of biliary diseases, anatomical difficulties or papillary spasm sometimes preclude it. Numerous techniques have been developed for selective biliary cannulation[2,3]. Pancreatic guidewire placement (P-GW) has been reported to be effective in patients with difficult cannulation of the bile duct[4-7]. Since P-GW is usually attempted in patients with difficult cannulation of the bile duct, this technique entails a possible increased risk of post-ERCP pancreatitis. The aim of this study was to investigate the frequency and risk factors for acute pancreatitis after P-GW in achieving cannulation of the bile duct during ERCP.

MATERIALS AND METHODS

Study population

Between December, 2001 and January, 2008, 3955 ERCPs were performed at Sendai City Medical Center. P-GW was performed in patients with pancreato-biliary diseases in whom cannulation of the bile duct was difficult and guidewire insertion into the pancreatic duct was achieved. Difficult cannulation of the bile duct was defined as unsuccessful cannulation with a cannula or a sphincterotome within 15 min. Wire-guided cannulation was not performed in this study. Patients in whom an insertion of a guidewire into the pancreatic duct could not be achieved were excluded from the study. Written informed consent was obtained from all patients before the procedure. This study was approved by the Institutional Review Board of Sendai City Medical Center. Prophylactic pancreatic stenting was performed in selected patients after P-GW. Indication for pancreatic duct stenting was determined by each operator during the procedure. Established criteria for pancreatic duct stenting after P-GW was not determined in this study.

Endoscopic procedures and patient care after the procedure

Before endoscopic procedures, all patients were given a standard premedication consisting of intravenous administration of pentazocine (7.5-15 mg) and diazepam (3-10 mg) or midazolam (3-10 mg), the doses depending on age and tolerance. The procedures were carried out with side-viewing duodenoscopes (JF200, 230, 240, 260V: Olympus Optical Co., Tokyo, Japan). When selective biliary cannulation with a cannula or a sphincterotomy was regarded as difficult, P-GW was attempted. A 0.025-inch or 0.035-inch guidewire (Jagwire: Microvasive, Boston Scientific Corp., Natick, MA, USA) was inserted into the pancreatic duct via the cannula in order to stabilize the papilla of Vater and straighten the bile duct terminal. Alongside the guidewire, a second cannula was passed into the same working channel of the scope with the two-devices-in-one-channel method[8], and cannulation of the bile duct was attempted. After successful cannulation of the bile duct, additional procedures such as endoscopic sphincterotomy, biliary stent placement, intraductal ultrasonography, biopsy of the bile duct, and so on were performed as necessary. Pancreatic duct stenting was performed for prophylaxis of post-ERCP pancreatitis. The pancreatic duct stent used was a 5 Fr, 4-cm-long stent with a single duodenal pigtail (Pit-stent: Cathex, Co., Ltd., Tokyo, Japan). All procedures were performed by operators with experience in more than 500 ERCPs. Abdominal radiographs were obtained to assess the stent position after deployment within 14 d after the ERCP. Endoscopic stent removal was performed if necessary.

Patients continued to fast after the procedure for a minimum of 24 h with drip infusion of 2000 mL and remained in the hospital for at least 48 h. They received 8-h infusion of protease inhibitor (nafamostat mesilate, 20 mg/d) and antibiotics (SBT/CPZ, 2 g/d) for 2 d. Serum amylase levels were measured before the procedure and 3 h, 6 h and 24 h afterwards. The reference range was 42-130 IU/L for the amylase. Symptoms (abdominal pain, nausea, *etc.*) and physical findings (abdominal tenderness) were clinically evaluated.

Main outcome measurements

The success rate of bile duct cannulation, the frequency and risk factors of post-ERCP pancreatitis, and the frequency of spontaneous migration of the pancreatic duct stent were investigated.

A diagnosis of post-ERCP pancreatitis was made based on the presence of abdominal pain 24 h after the procedure and an increase in serum amylase level greater than three times the upper normal limit[9]. The severity of pancreatitis was classified as mild if prolongation of fasting was within 1-3 d, moderate for fasting 4-10 d long, and severe for fasting more as 10 d, as well as in cases of hemorrhagic pancreatitis, phlegmon, or pseudocyst.

Statistical analysis

Fisher's exact probability test was used for statistical analyses where appropriate. Variables found to be possibly significant ($P < 0.5$) in univariate analysis were chosen for entry into a multiple logistic regression. A P value less than 0.05 was regarded as significant. Statistical analysis was performed with StatMate Ⅲ (ATMS Co. Ltd., Tokyo, Japan) and StatView Ver.5.0 (SAS Institute, Cary, NC, USA).

RESULTS

Table 1 shows the characteristics and diagnoses of the patients. Selective biliary cannulation with P-GW was achieved in 73% of the patients (82 patients, Figure 1). Of the remaining 31 patients with unsuccessful biliary cannulation, eight underwent precut sphincterotomy in the same session, biliary cannulation being subsequently achieved in two of them. The other patients underwent a second ERCP including precut sphincterotomy, percutaneous biliary drainage, surgical treatment, or substitute diagnostic procedures. Selective biliary cannulation was finally achieved in 86% of the patients (97 patients).

Prophylactic pancreatic duct stenting was attempted in 59% of the patients (69 patients). Although stenting was successful in all patients, five developed migration of the stent during the procedure.

Post-ERCP pancreatitis occurred in 12% (14 patients: mild, 13; moderate, 1). All of them improved with conservative therapy in a few days. Of the 64 patients who successfully underwent pancreatic duct stenting, three developed mild pancreatitis (4.7%). Of the remaining 49 patients without a stent, 11 developed pancreatitis (22%: mild, 10; moderate, 1). Of the five patients with stent migration, two developed mild pancreatitis (40%).

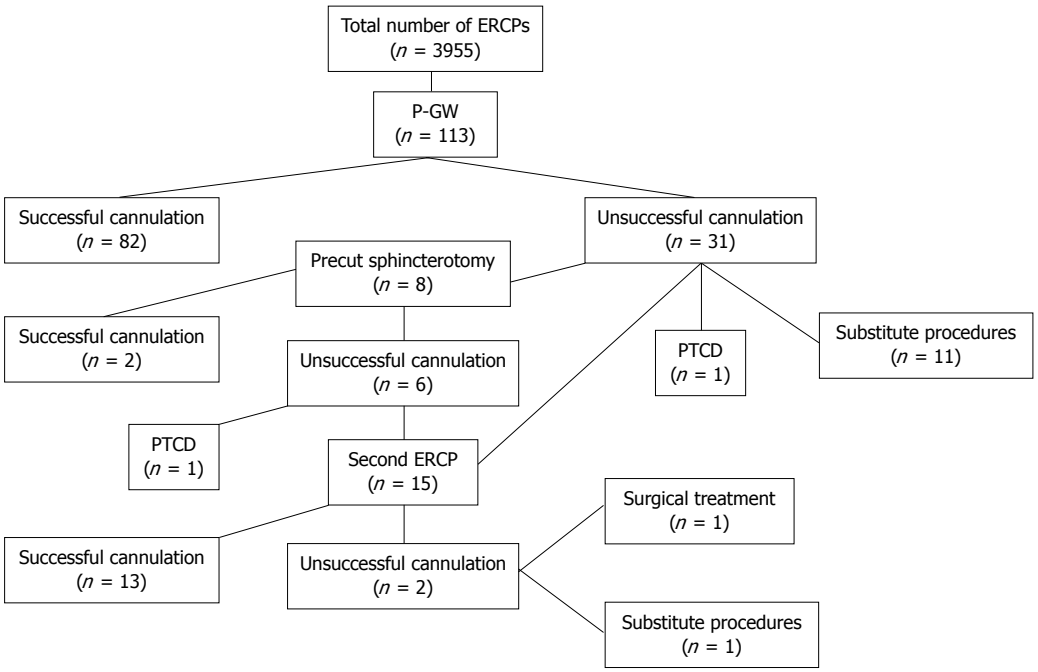

Figure 1 Flow chart showing clinical course of the patients. P-GW: Pancreatic guidewire placement; PTCD: Percutaneous transhepatic cholangio-drainage.

Table 1 Characteristics and diagnosis of the patients (*n* = 113)

Characteristics and diagnosis	Number of patients
Mean age (range, yr)	70 (33-90)
Male/Female	63/50
History of pancreatitis	8 (7%)
History of post-ERCP pancreatitis	0%
Normal bilirubin level	67 (59%)
Duodenal diverticulum	32 (28%)
Pancreatic duct stenosis	7 (6%)
Mean procedure time (range, min)	46 (17-98)
Procedure time > 45 min	52 (46%)
Therapeutic ERCP	75 (66%)
Pancreatic duct opacification	100 (100%)
Pancreatic duct stenting	64 (57%)
Biliary sphincterotomy	39 (35%)
Precut	8 (7.1%)
Intraductal ultrasonography	25 (22%)
Biliary stent placement	24 (21%)
Papillary balloon dilatation	2 (1.8%)
Cytology of bile/pancreatic juice	11 (9.7%)
Biopsy of the bile duct/pancreatic duct	10 (8.8%)
Choledocholithiasis	42 (37%)
Cholecystolithiasis	26 (23%)
Cholangiocarcinoma	9 (8.0%)
Pancreatic cancer	8 (7.1%)
Chronic pancreatitis	5 (4.4%)
Intraductal papillary mucinous neoplasm	4 (3.5%)
Ampullary cancer/adenoma	4 (3.5%)

Post-ERCP pancreatitis occurred in 13% of the 31 patients with unsuccessful biliary cannulation. Of the patients with unsuccessful biliary cannulation, pancreatic duct stenting was performed in 24 patients. The frequency of post-ERCP pancreatitis of the patients without pancreatic duct stenting was significantly higher than that of the patients with pancreatic duct stenting (43% *vs* 4.2%, $P = 0.041$; odds ratio, 17; 95% CI, 1.4-210).

Hyperamylasemia at 24 h after ERCP was observed in 68% (68 patients) of the 100 patients with normal serum amylase level before the procedure. Of these patients, the peak serum amylase level was seen at 3 h after ERCP in 8.8% (6 patients), at 6 h in 50% (34), and at 24 h in 41% (28). All of them showed a decrease in serum amylase level at 48-72 h after ERCP. Of the 14 patients who developed post-ERCP pancreatitis, none showed a peak serum amylase level at 3 h after ERCP, six patients showed a peak at 6 h, and eight patients showed a peak at 24 h after ERCP.

Univariate analysis revealed no pancreatic stenting to be the only significant risk factor for post-ERCP pancreatitis ($P = 0.011$; odds ratio 5.9; 95% CI, 1.5-22; Table 2). Multivariate analysis also revealed no pancreatic stenting to be the only significant risk factor for post-ERCP pancreatitis ($P = 0.017$, Table 3).

Among the 64 patients who underwent pancreatic duct stenting, five patients who required additional ERCP due to various reasons underwent endoscopic removal of the stent at the time of the procedure. Estimation of stent passage was not performed in six patients. Spontaneous migration of the pancreatic stent was observed within two weeks in 92% (49/53) of the patients who had undergone pancreatic duct stenting. In the four patients without passage of a pancreatic stent, two underwent additional endoscopy for removal of the stent. The other two patients refused additional endoscopy. No complications concerning spontaneous passage of the stent occurred.

DISCUSSION

Selective biliary cannulation is mandatory for therapeutic ERCPs in patients with biliary diseases. Since difficulties in selective cannulation are sometimes encountered due to anatomical constraints or papillary spasm, numerous techniques (papillotome cannulation,

precut sphincterotomy, or guidewire cannulation) and pharmacologic aids (cholecystokinin or nitroglycerine spray) have been developed for this purpose[2,3].

Dumonceau *et al*[4] first reported P-GW for selective biliary cannulation in a patient with surgically altered anatomy. Gotoh *et al* reported a second case of successful biliary cannulation with P-GW in a patient with a tortuous common channel[5]. P-GW serves several functions advantageous for selective bile duct cannulation, including opening a stenotic papillary orifice, stabilizing the papilla and lifting it up towards the working channel, straightening the pancreatic duct and the common channel, draining the pancreatic duct, potentially minimizing repeated injections into the pancreatic duct, and providing access for placement of a pancreatic stent if necessary[2].

Maeda *et al*[7] carried out a randomized controlled trial with 53 patients in whom conventional cannulation failed within 10 min, these patients being were assigned to either P-GW (n = 27) or continuation of ordinary techniques (n = 26). Successful biliary cannulation was achieved in 93% of the patients with P-GW compared with 58% in the group of continuation of ordinary techniques (P = 0.0085). They reported a significantly high frequency of hyperamylasemia in the P-GW group, with no incidence of acute pancreatitis. We retrospectively estimated the efficacy and safety of P-GW for biliary cannulation. Although the success rate of biliary cannulation with P-GW in our study was inferior to that of their study (73% *vs* 93%), the final cannulation rate (86%) in our study was comparable. Patients included in our study were only 2.9% of the patients who underwent ERCP during the same period, and thus they were considered to be extremely difficult cases for biliary cannulation, thus allowing the assessment of success rate of biliary cannulation to be acceptable. It is often emphasized that precut sphincterotomy, which is generally followed by conventional sphincterotomy, should be performed only by expert endoscopists. On the other hand, P-GW can be performed even by endoscopists with less experience in both diagnostic and therapeutic ERCPs without the need for sphincterotomy. Although it entails a potential risk of failure to place a guidewire deeply in a tortuous main duct, P-GW is worth attempting in patients with

difficult biliary cannulation before precut sphincterotomy or other invasive techniques are undertaken.

Post-ERCP pancreatitis occurred in 12% of the patients in our study, in contrast to 0% in Maeda's study[7]. This is thought to be due to the number of patients included, differences in study population, and definitions of post-ERCP pancreatitis. Deviere commented in his review that Maeda's data are not sufficient to claim that the risk of pancreatitis will not be increased by this technique because of the small number of patients and the use of confounding medications such as isosorbide dinitrate and urinastatin[10]. One of the major mechanisms of post-ERCP pancreatitis is insufficient pancreatic duct drainage as a result of papillary edema after repetitive manipulation or contrast injections. Therefore, difficult cannulation of the bile duct is given as a risk factor[11]. Since P-GW is attempted in patients with difficult biliary cannulation, it entails a possible increased risk of this particular complication. The efficacy of prophylactic pancreatic stent placement to prevent post-ERCP pancreatitis has been reported by prospective randomized controlled trials[12-16]. Fazel *et al*[13] reported that pancreatic stent (5 Fr, 2 cm or 5 Fr nasopancreatic catheter) insertion reduced the frequency of post-ERCP pancreatitis from 28% to 5% in patients at high risk for this complication following difficult cannulation, sphincter of Oddi manometry, and/or sphincterotomy. In our study, post-ERCP pancreatitis occurred in 4.7% of patients with pancreatic duct stenting in contrast to 22% of patients without stenting. Non-performance of pancreatic duct stenting was found to be the only significant risk factor for post-ERCP pancreatitis by univariate and multivariate analysis. Based on these results, we suggest that pancreatic duct stenting is indispensable for P-GW in order to prevent post-ERCP pancreatitis. Of course, our study had some limitations. First, it was not a randomized or prospective study. Second, routine administration of protease inhibitor might have influenced the frequency of post-ERCP pancreatitis. Third, the usefulness of P-GW was not compared with other methods such as precut sphincterotomy, guidewire cannulation, and so on. Forth, repeated attempts at entering the pancreatic duct with a wire might increase pancreatitis risk. Unfortunately, this study cannot evaluate the risk as patients in whom insertion of a guidewire into the pancreatic duct cannot be achieved were excluded. Further randomized controlled trials are necessary for the evaluation of these points. Nevertheless, our study yielded significant information as regards prophylaxis of post-ERCP pancreatitis by pancreatic duct stenting in patients who undergo P-GW.

In conclusion, P-GW is useful for achieving selective cannulation of the bile duct. Pancreatic duct stenting after P-GW can reduce the incidence of post-ERCP pancreatitis, which should be verified by prospective randomized controlled trials.

COMMENTS

Background

Selective biliary cannulation is mandatory for therapeutic endoscopic retrograde cholangio-pancreatography (ERCP) in patients with biliary diseases. Since difficulties in selective cannulation are sometimes encountered due to anatomical constraints or papillary spasm, numerous techniques (papillotome cannulation, precut sphincterotomy, or guidewire cannulation) and pharmacologic aids (cholecystokinin or nitroglycerine spray) have been developed for this purpose.

Research frontiers

Pancreatic guidewire placement (P-GW) is reported to be effective in patients with difficult cannulation of the bile duct. However, this technique entails a possible increased risk of post-ERCP pancreatitis.

Innovations and breakthroughs

In a single-center, retrospective study, selective biliary cannulation with P-GW was achieved in 73% of the patients. Post-ERCP pancreatitis occurred in 12% after P-GW. Univariate and multivariate analyses revealed no pancreatic stenting to be the only significant risk factor for pancreatitis. Pancreatic duct stenting after P-GW may reduce the incidence of post-ERCP pancreatitis.

Applications

P-GW is useful for achieving selective biliary cannulation. Pancreatic duct stenting after P-GW can reduce the incidence of post-ERCP pancreatitis, which requires evaluation by means of prospective randomized controlled trials.

Peer review

It's an interesting paper. The authors clarified that pancreatic P-GW is useful for achieving selective biliary cannulation in patients with difficult cannulation of the bile duct.

Abstract

AIM: To assess the occurrence of gastric acid reflux into the esophagus in endoscopically confirmed prolapse gastropathy syndrome (PGS).

METHODS: Using ambulatory esophageal pH measurement (BRAVO™ wireless esophageal pH monitoring system), twenty-six patients with PGS were compared with twenty-one patients with erosive esophagitis (EE) as controls. We assessed several reflux parameters, including the percentage of total time at pH < 4, and the DeMeester score.

RESULTS: There were no statistical differences between the PGS group and the EE group as to mean age, sex ratio and pH recording time. The EE group showed more severe reflux than the PGS group, as evaluated in terms of the longest duration of reflux, the number of reflux episodes, the number of reflux episodes lasting > 5 min, the total time with pH < 4 during acid reflux episodes, and the DeMeester score, but none of these parameters showed statistically significant difference. Although 53.8% (14/26) of the PGS group and 76.2% (16/21) of the EE group demonstrated pathologic acid reflux (DeMeester score > 14.72), there was no statistically significant difference between the two groups in the incidence of pathologic acid reflux (P = 0.11).

CONCLUSION: There was no statistically significant difference in pathologic acid reflux between the PGS and EE group. These data suggest that endoscopically diagnosed PGS might be a predictor of pathologic acid reflux.

INTRODUCTION

In 1984, Shepherd[1] proposed the term "prolapse gastropathy syndrome (PGS)", defining the diagnostic criteria for PGS as persistent and recurrent retching symptoms combined with hematemesis or abdominal pain, an endoscopic finding of prolapse of tense, inflamed, congested gastric mucosa into the esophageal lumen during retching, and an unusually strong gag and retch at endoscopy. PGS has been considered as one of the causes of upper gastrointestinal bleeding[2-6]. In addition, it has been regarded as esophageal pseudotumor[7] and retrograde gastroesophageal intussusception[8], combined with several severe complications such as Mallory-Weiss syndrome and esophageal rupture[9]. Besides the above conditions, it is thought that gastric acid might be regurgitated into the esophagus along with prolapsed gastric mucosa.

However, there have been no studies of pathologic gastric acid reflux into the esophagus associated with PGS. Therefore, we investigated whether gastric acid into the esophagus may occur in endoscopically confirmed PGS.

MATERIALS AND METHODS

Subjects

Subjects were selected from patients undergoing upper endoscopy at the gastrointestinal endoscopy center of Uijeongbu St. Mary's Hospital as part of a medical checkup or because of upper abdominal discomfort between May 2005 and May 2006. All patients with endoscopically confirmed PGS and erosive esophagitis (EE) were considered for inclusion in the study. Written informed consent for participation in the study was obtained from all patients. We prospectively enrolled 47 patients in two groups. The inclusion criteria for the PGS (n = 26) group were endoscopically confirmed prolapse of inflamed gastric mucosa into the esophageal lumen during retching and symptoms of recurrent retching and nausea over 3 mo. Patients were excluded if they had endoscopically confirmed esophagitis or hiatus hernia, or were alcohol or drug abusers, pregnant, or obese (BMI > 25). The inclusion criterion for the EE group (n = 21) was evidence of grade A or B (Los Angeles Classification) esophagitis at endoscopy. There was no specific exclusion criterion for the EE group. Endoscopic procedures were performed with videoendoscopes (GIF-Q260, GIF-XQ260, Olympus Optical Co. Ltd, Tokyo, Japan, EG-450WR5, Fujinon Corporation, Saitama, Japan).

48-hour esophageal pH measurement

All patients were studied after discontinuation of histamine-receptor antagonists, proton pump inhibitors, and prokinetics for at least 7 d. The BRAVO wireless esophageal pH monitoring system (Medtronic, Minneapolis, MN, USA) was used to measure esophageal pH in both groups within one week of gastroscopy. During gastroscopy, all subjects were assessed in order to locate the pH electrode exactly between the squamocolumnar junction and the incisors. According to the manufacturer's instructions, the pH electrode was passed through the mouth and positioned 6 cm above the squamocolumnar junction. In order to maintain this position, a vacuum pump was connected to apply suction to the esophageal wall. Successful capture of the esophageal mucosa was assumed when the vacuum gauge on the pump stabilized at a value of > 510 mmHg for 30 s. Before the pH capsule was inserted, it was calibrated with the receiver in pH buffer solutions of pH 7.01 and pH 1.07 at room temperature. During the 48 h pH-recording period, patients were asked to keep a detailed diary of activity, food intake, symptoms, wake and sleep periods and posture. Upon completion of the study, the pH monitoring tracings were analyzed using PolygramTM NET software (Medtronic, version 4.01). For each patient, the following reflux parameters were determined: percentage of total time at pH < 4; upright time at pH < 4; supine time at pH < 4; the total number of reflux episodes; the number of reflux episodes longer than five minutes; and the mean duration of reflux episodes. A DeMeester score > 14.72 was defined as pathologic acid reflux. If the pH capsule detached within 16 h, it was reinserted and recorded again 2 wk later.

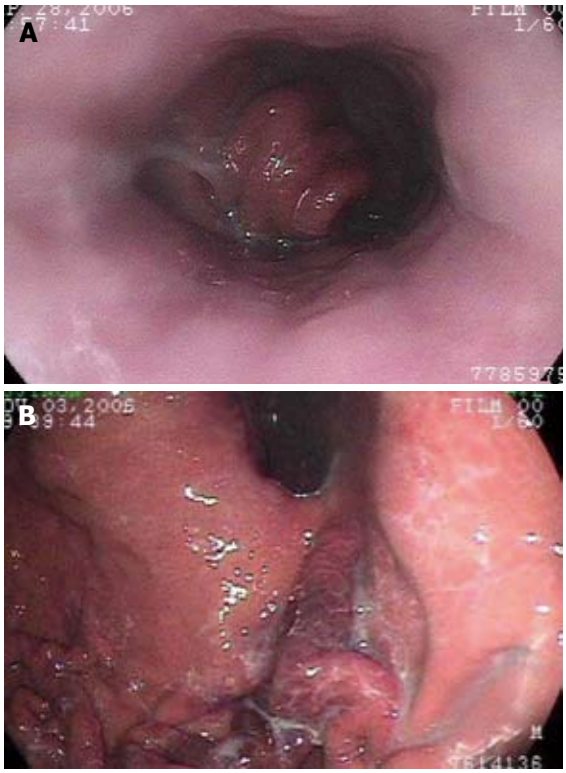

Figure 1 Endoscopic finding of the prolapse gastropathy syndrome group. **A**: Inflamed gastric mucosal prolapse viewed during retching; **B**: Congested and inflamed gastric mucosa secondary to prolapse gastropathy viewed in the gastric fundus.

Statistical analysis

Data presented in this manuscript are expressed as mean ± SD. Comparisons between groups were performed using unpaired Student's t test, Fisher's exact test and chi-square test. A P value < 0.05 was considered as indicating statistical significance. All statistical analyses were performed using SPSS 11.0 for Microsoft Windows (Chicago, IL, USA).

RESULTS

Forty-seven patients were included in the study, 26 patients with PGS and a control group of 21 patients with EE. The patients in the PGS group had a characteristic gastric mucosal prolapse due to retching (Figure 1A) and severe mucosal congestion and localized mucosal inflammation in the fundus (Figure 1B). Among the patients of the EE group, 17 (80%) showed grade A esophagitis and 4 (20%) showed grade B. The two groups were comparable in terms of mean age (41.5 ± 6.7 years for the PGS group and 46.9 ± 11.7 years for the EE group) and gender ratio (male/female, 15/11 and 15/6,

Table 1 Clinical characteristics and reflux parameters of patients in the PGS and the erosive esophagitis (EE) groups

	PGS group (n = 26)	EE group (n = 21)	P value

respectively) ($P > 0.05$). Data from pH recording of the two groups are shown in Table 1. The mean recording time for the two groups was 41.9 ± 6.7 h for the PGS group and 40.9 ± 6.1 h for the EE group ($P > 0.05$). The results of parameters of reflux in the PGS and EE groups showed no statistically significant differences in the percentage of total time at pH < 4 (5.1% ± 4.5% and 6.9% ± 3.9%, respectively), the total number of reflux episodes (77.3 ± 46.4 and 98.2 ± 56.5, respectively), the number of reflux episodes longer than five minutes (5.6 ± 4.0 and 8.5 ± 6.8), the duration of the longest reflux (19.6 ± 13.6 min and 24.3 ± 15.7 min), total duration of time with pH < 4 (123.2 ± 93.6 min and 173.7 ± 105.4 min), or DeMeester score (15.9 ± 12.5 and 20.7 ± 10.8). As far as the incidence of pathologic acid reflux (based on DeMeester score > 14.72) is concerned, there was no significant difference between the PGS group (14/26 or 53.8%) and the EE group (16/21 or 76.2%) ($P > 0.05$). Three patients developed complications related to the pH recording procedure. One patient in the PGS group experienced severe epigastric pain 48 h after placement of the pH capsule that resolved spontaneously. In two patients (7.7%) of the PGS group, early detachment of the pH capsule occurred as identified by a persistent decrease of pH to close to 2 followed by a rise above pH 7 after passage through the pylorus. For these patients, capsules were reinserted 2 wk later and pH recording was successful over 40 h.

DISCUSSION

Retrograde prolapse of an area of gastric mucosal from the proximal stomach into the distal esophagus can occur during retching or vomiting and can result in prolapse gastropathy and bleeding. In 1984, Shepherd[1] proposed the term "prolapse gastropathy syndrome" and reported 22 patients who presented with epigastric pain alone or with hematemesis associated with a previous history of recurrent early morning retching or postprandial retching. He defined the characteristic endoscopic finding in these patients as a knuckle of inflamed and sometimes bleeding gastric mucosa in the proximal stomach several centimeters distal to the gastroesophageal junction that repeatedly prolapsed into the esophageal lumen during retching[2,10,11]. The incidence of PGS has been reported to be 0.4%-2.4% in the general population, and it has been described in almost 2% of adults who undergo endoscopy for evaluation of hematemesis[1,12,13]. The mechanism of PGS is obscure although various factors such as relaxation of the esophagogastric junction, excessive redundancy of the gastric mucosa, retrograde peristalsis of the stomach and repeated regurgitation and vomiting have been suggested[7,14]. In this study, we investigated whether acid reflux into the esophagus may occur in PGS patients, because it is likely that regurgitation of acid accompanies the prolapsed mucosa. PGS patients were selected according to Shepherd's diagnostic criteria[1]. Patients with endoscopically confirmed esophagitis or hiatus hernia, who were alcohol or drug abusers, pregnant women, or obese (BMI > 25), were excluded to eliminate other factors that may contribute to pathologic acid reflux. In addition, a wireless ambulatory pH monitoring device was used rather than a traditional catheter-based esophageal pH monitoring system, because more throat and swallow discomfort, which might induce retching and pathologic acid reflux in PGS patients, has been reported with the catheter type than with the wireless monitoring device[15,16]. EE patients were chosen as a positive control for acid reflux because nonerosive gastroesophageal reflux disease (NERD) is often not related to pathologic acid reflux[17-20].

Although, based on the DeMeester score, the positive rate of pathologic acid reflux in the EE group was higher than in the PGS group (76.2% *vs* 53.8%), our data show a meaningful rate of pathologic reflux in PGS patients, based also on the fact that we excluded other possible factors leading to reflux. In previous reports, hiatus hernia, which has been regarded as predictor of gastroesophageal reflux disease (GERD)[21,22] and NERD, revealed incidences of acid reflux of 26%-57%[23,24] and 40%-63%[25,26], respectively. By comparison with these previous reports, the incidence of pathologic acid reflux in the PGS group is substantial.

With respect to complications associated with wireless pH recording, epigastric pain developed in one PGS patient 48 h after placement of the pH capsule that spontaneously resolved, and might be associated

with esophageal ulceration after placement of the pH capsule[27]. In addition, the pH capsule detached early in two patients of PGS group (7.7%, 2/26) but there was no case of detachment in the EE group. The detachment rate of the pH capsule in the PGS group was higher than in previous studies [3.2% (7/217), 3.7% (3/80)][28,29]. The early detachment of the pH capsule may result from the prolapsed mucosa striking the attached pH capsule, meaning that an increased possibility of early detachment should be considered in PGS. However, further studies are necessary to confirm this.

Until now, there has been no report of the long-term prognosis for PGS patients, and it is not known whether long-lasting exposure of the esophagus to acid in PGS would progress to EE, esophageal stricture, Barrett's esophagus or other complications of GERD. Moreover, it is unknown whether a proton pump inhibitor or other medication is necessary to inhibit acid reflux in PGS patients. However there have been reports of a relationship between prolonged acid exposure and the degree of esophageal injury[30,31], while recent cohort studies with prolonged follow-up showed progression from NERD to EE and from uncomplicated to complicated GERD[32,33]. We therefore recommend future studies to observe disease progression and response to medication in PGS over a long duration.

In conclusion, there was no statistically significant difference between PGS and EE groups in reflux parameters and presence of pathologic acid reflux. By comparison with previous reports of acid reflux in hiatus hernia and NERD, the incidence of pathologic acid reflux in the PGS group is substantial. This result suggests that PGS might be a predictor of pathologic acid reflux.

COMMENTS

Background

Prolapse gastropathy syndrome (PGS) occurs in patients with prolonged retching and vomiting. This disease is a clinical syndrome involving the invagination of part of the gastric mucosa into the lower esophagus, resulting in well demarcated hemorrhagic mucosa and severe mucosal congestion. Excessive gastric redundancy and prolapse of the mucosa may contribute to extended acid reflux of the esophagus. We aimed at investigating the acid reflux parameters in PGS compared with endoscopically confirmed erosive esophagitis.

Research frontiers

There have been several studies and case reports about PGS which are focused on upper gastrointestinal bleeding.

Innovations and breakthroughs

It seems to be that gastric acid might be regurgitated into the esophagus along with prolapsed gastric mucosa. However, there has been no study of acid reflux associated with PGS. This study is the first one designed to investigate the presence of pathologic acid reflux in PGS using the BRAVO wireless esophageal pH monitoring system to prevent acid reflux caused by pH monitoring probe of conventional method.

Applications

Pathologic acid reflux in PGS may contribute to patient symptoms and progression to erosive esophagitis. Based on this study, the effectiveness of proton pump inhibitors in PGS will be considerable.

Peer review

This is the first report designed to investigate the presence of pathologic acid reflux in PGS. It concludes that the parameters of pathologic acid reflux in PGS are not different from those of erosive esophagitis. This result suggests that PGS may be a predictor of pathologic acid reflux.

Abstract

AIM: To search candidate tumor suppressor genes (TSGs) on chromosome 4q through detecting high loss of heterozygosity (LOH) regions in sporadic colorectal carcinoma in Chinese patients.

METHODS: Thirteen fluorescent labeled polymorphic microsatellite markers were analyzed in 83 cases of colorectal carcinoma and matched normal tissue DNA by polymerase chain reaction (PCR). PCR products were electrophoresed on an ABI 377 DNA sequencer. Genescan 3.7 and Genotype 3.7 software were used for LOH scanning and analysis. Comparison between LOH frequency and clinicopathological factors were performed by χ^2 test.

RESULTS: Data were collected on all informative loci. The average LOH frequency on 4q was 28.56%. The D4S2915 locus showed highest LOH frequency (36.17%). Two obvious deletion regions were detected: one between D4S3000 and D4S2915 locus (4q12-21.1), another flanked by D4S407 and D4S2939 locus (4q25-31.1). None case showed complete deletion of 4q, most cases displayed interstitial deletion pattern solely. Furthermore, compared with clinicopathological features, a significant relationship was observed between LOH frequencies on D4S3018 locus. In tumors larger than 5 cm in diameter, LOH frequency was significantly higher than tumors that were less than 5 cm (56% *vs* 13.79%, $P = 0.01$). On D4S1534 locus, LOH was significantly associated with liver metastasis (80% *vs* 17.25%, $P = 0.012$). No relationship was detected on other locus compared with clinicopathological features.

CONCLUSION: By high resolution deletion mapping, two high frequency regions of LOH (4q12-21.1 and 4q25-31.1) were detected, which may contribute to locate TSGs on chromosome 4q involved in carcinogenesis and progression of sporadic colorectal carcinoma.

Key words: Loss of heterozygosity; Colorectal carcinoma; Chromosome; 4q; Tumor suppressor gene

INTRODUCTION

Colorectal Cancer (CRC) is one of the most common malignant tumors threatening people's health[1,2]. After lung cancer in men and breast cancer in women, it is the most common cause of cancer related death. Improvement in its prognosis will not be achieved without a better understanding of its etiology and tumor molecular biology. In recent years, the genetic basis of human tumors has been increasingly elucidated. As a modal for both multistep and multipathway carcinogenesis, colorectal neoplastic progression provides paradigms of both oncogenes and tumor suppressor gene (TSG) in epithelial tumors[3,4]. The latter changes predominate. In addition to the allelic loss noted on chromosome 5q, 17p and 18q, many other chromosome losses can be observed in colorectal

carcinoma. Regions from chromosome 1q, 4p, 6p, 6q, 8p, 9p and 22q were lost in 25%-50% of the cases studied[3].

Chromosome losses in colorectal tumor were first detected by cytogenety, later, by probes of restriction fragment length polymorphisms (RFLPs), and now by loss of heterozygosity (LOH) in analyzing allelic loss so far. The loss of TSGs is believed to be one of the key steps to carcinogenesis of CRC[5]. The loss of one allelic at a specific locus is caused by deletion mutation or loss of a chromosome from a chromosome pair[6]. When this occurs at a TSG locus where one of the allelic is already abnormal, it can result in neoplastic transformation. The LOH analysis, based on polymorphic microsatellite DNA, has currently become an effective and powerful tool currently to find informative loci and then to find candidate TSGs[7,8].

Many studies reported frequent loss on 4q in couples of carcinoma. But much less studies has been done on 4q in colorectal carcinoma. In this study, we performed LOH analysis using high resolution microsatellite markers on chromosome 4q in 83 sporadic colorectal carcinoma cases, in an effort to identify additional TSGs involved in colorectal tumorigenesis.

MATERIALS AND METHODS

Patient sample and DNA extraction

This study was based on eighty-three consecutively collected tumors, including 40 males and 43 females, from unrelated patients with CRC, treated at the Surgical Department in Shanghai First People's Hospital, China. The patients' ages ranged from 31 to 84 years with a median of 66. The cancerous tissue and adjacent normal tissue were fresh frozen. These tissues were cut into cubes of approximately 2 mm^3 and immediately frozen in liquid nitrogen. DNA was extracted using standard methods with proteinase K digestion and phenol/chloroform purification[9]. All patients were confirmed by pathology, and were staged by Duke's criterion. Each patient gave his or her informed consent for the use of his or her tissue in this study.

Microsatellite markers and polymerase chain reaction (PCR)

Initially, 83 cases of CRC were analyzed by PCR using thirteen microsatellite markers which map to 4q. DNA samples were analyzed as tumor and matched normal pairs using primers of the following microsatellite loci (hereditary location): centromere--D4S3000 (4q12)--D4S3018 (4q13.2)--D4S2915 (4q21.1)--D4S1534 (4q21.23)--D4S2986 (4q23)--D4S407 (4q28.1)--D4S430 (4q28.1)--D4S2939 (4q31.1)--D4S3046 (4q32.2)--D4S2979 (4q32.3)--D4S415 (4q34.3)--D4S1535 (4q35.1)-qter (Figure 1). The average hereditary distance from genothon map is 10.4cM (centi-Morgan)[10].

LOH analysis

A portion of each PCR product (0.5 μL) was combined with 0.1 μL of Genescan 500 size standard (PE Applied Biosystems Foster city CA, USA) and 0.9 μL of formamide loading buffer. After denaturation at 96℃ for 5 min, products were electrophoresed on 5% polyacrylamide gels on an ABI 377 DNA sequencer (PE Applied Biosystems Foster city CA, USA) for 3 h. Genotype 3.7 software displays individual gel lanes as electropherograms with a given size, height, and area for each detected fluorescent peak. Stringent criteria were used to score the samples. Alleles were defined as the two highest peaks within the expected size range. A ratio of T1:T2/N1:N2 of less than 0.67 or greater than 1.50 was scored as a LOH (Figure 2). Most amplification of normal DNA produced two PCR products indicating heterozygosity. A single fragment amplified from normal DNA (homozygosity) and those PCR reactions in which fragments were not clearly amplified were scored as not informative. The LOH frequency of a locus is equal to the ratio of the number between allelic loss and informative cases. The average LOH frequency of chromosome 4q is the average value of each locus LOH frequency.

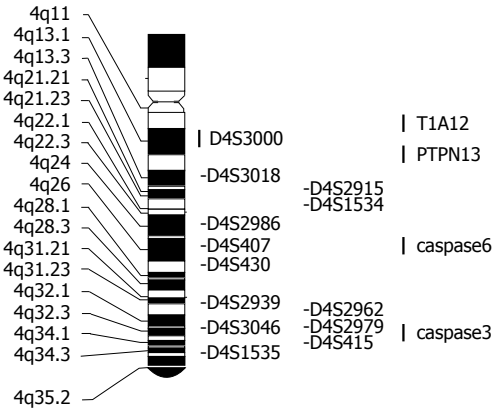

Figure 1 Microsatellite markers on chromosome 4q and putative TSGs.

Statistical analysis

Date was statistically analyzed using the SPSS software package, version 11.5 (SPSS Inc). Comparisons between LOH and clinicopathological data were performed by χ^2 test. $P < 0.05$ was considered as statistically significant.

RESULTS

LOH analysis of CRC on 4q

Eighty-three CRCs were analyzed for LOH at thirteen marker loci spanning chromosome 4q. All loci got informative messenger (Table 1). Tumors exhibiting wide microsatellite instability were excluded from deletion mapping. The average LOH frequency on 4q was 28.56%. Seventy-two samples (86.75%) showed LOH event on at least one locus. The D4S2915 locus showed highest LOH frequency (36.17%). Two distinct region of frequent allelic loss were observed on chromosome 4q, one between D4S3000 and D4S2915 locus (4q12-21.1), another flanked by D4S407 and D4S2939 locus (4q25-31.1). None case showed complete deletion of 4q,

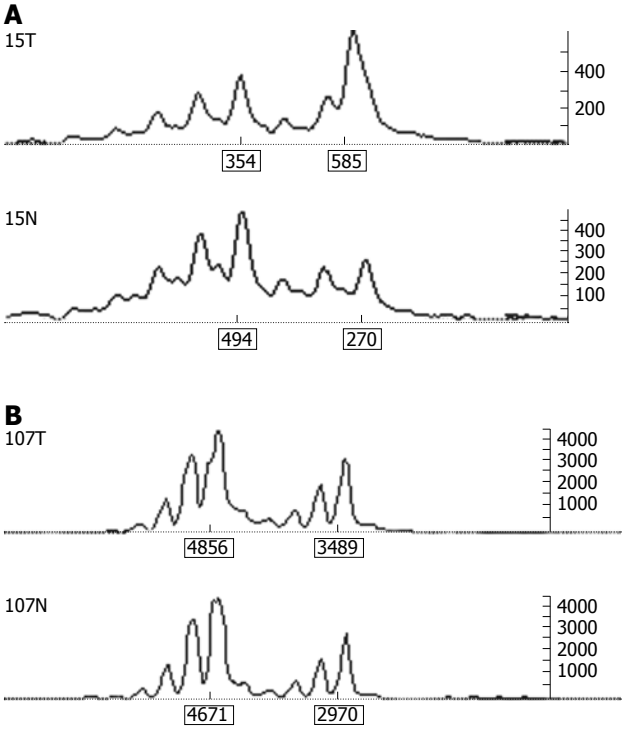

Figure 2 LOH demonstrations. **A**: The typical peak of LOH: Allele ratio = (T1/T2)/(N1/N2) = (354/585)/(494/270) = 0.33 < 0.67; **B**: The normal peak: Allele ratio = (T1/T2)/(N1/N2) = (4856/3489)/(4671/2970) = 0.67 < 0.89 < 1.5. T: Tumor; N: Normal.

most cases displayed interstitial deletion pattern solely. It can be speculated that putative TSGs may locate on 4q12-21.1 and 4q25-31.1.

Relationship between clinicopathological features and LOH on 4q

Compared with clinicopathological features, by statistics, a significant relationship was observed between LOH frequency on D4S3018 and tumor diameter. LOH frequency in tumors larger than 5 cm in diameter (56%, 14/25) was significantly higher than tumors that were less than 5 cm in diameter (13.79%, 4/29; $P = 0.01$). On 4S1534 locus, LOH frequency was 80% (4/5) in cases with liver metastasis, which was significantly higher than that without liver metastasis (17.25%, 5/29) ($P = 0.012$). No relationship was detected on other locus compared with these clinicopathological features.

DISCUSSION

Inactivation of TSGs appears to be one of the genetic mechanisms involved in the development of CRC[3,11,12]. Deletion of TSGs occurs frequently in human malignances. Such events can be detected using markers from the region of genomes that include a TSG. Allelic loss detected as LOH have been proved useful for mapping regions of DNA that contain TSGs. LOH at specific chromosomal regions strongly suggests the existence of TSGs at the relevant segment.

Studies conducted thus for have focused on known TSG, particularly, APC, p53, DCC, MCC, Smad4 and so on. The genetic events that led to the development and progression of CRC on chromosome 4q have not been elucidated. There were a lot of evidence that multiple genetic abnormalities on 4q contribute to development of a serials of tumors, and that supported the presence of TSGs in the long arm of chromosome 4.

Table 1 LOH frequency statistics result on 4q

Marker	Location	LOH case	Normal case	Informative case	Distance (cm)	LOH rate
D4S3000	4q12	22	42	78.05	-	34.38
D4S3018	4q13.2	18	36	65.06	9.7	33.33
D4S2915	4q21.1	17	30	56.63	10.6	36.17

D4S1535	4q35.1	14	45	71.08	14	23.73

Loss of chromosome 4q has been found in the majority of breast carcinoma[13], cervical cancer (4q21-q25)[14]. In oral squamous cell carcinoma[15] and relapsed childhood acute lymphoblastic leukemia[16], 75% and 20% cases showed LOH on at least one of the loci, with frequent loss region centered on 4q25 in the former. In esophageal adenocarcinoma, Hammoud *et al*[17] found LOH frequency was 54.5%-65% on 4q21-35 with a lower resolution allelotyping studying. Rumpel *et al*[18] found LOH was 80% on at least one marker on 4q, and discerned three non-overlapping areas (4q21.1-22, 4q32-33, 4q35), whose total spanning length is quite coincident with Hammoud[17]. Hurst *et al*[19] found that in bladder cancer, 4q loss was the most frequent loss (83%) in all arms of chromosome by microarry-based comparative genome hybridization, with the minimal region of deletion at 4q13.1 and 4q31.3. This result was compatible with previous report of LOH analysis in bladder tumors[20,21]. In malignant mesothelioma and small cell lung cancer, two non-overlapping loss region on 4q were at 4q33-34 (> 80%) and 4q25-26 (> 60%)[22]. In primary small cell lung cancer, Cho *et al*[23] defined five commonly deleted region all more than 50% on 4q, namely, 4q24, 4q27-28.3, 4q33, 4q34.1 and 4q34.3-35.2. In the research of hepatocellular carcinoma, much work has been done. Piao *et al*[24] made a detailed deletion mapping and identified seven independent, frequently lost regions. In fact, a high frequency of LOH on chromosome 4q in hepatocellular carcinoma has been reported by several study groups[25-27]. Recent years, LOH frequency was found 33.3% (at 4q26-27)[28], 50%[29], and 38%[30] for at least two adjacent markers in hepatocellular carcinoma. These study results strongly suggested that 4q may locate more than one putative TSG.

The research of LOH on 4q in colorectal carcinoma was much less in this decade. LOH at telomere markers have been reported less than 10% on 4q[31]. Analysis of

mid-position microsatellite markers on 4q arm showed moderate of allelic imbalances (< 25%) in colorectal tumors[32]. Comparative genomic hybridization analysis of a serial of colorectal adenomas and carcinomas identified chromosome 4 losses as of the recurrent alterations observed in malignant stages[33]. Arribas *et al*[34] found frequent loss on 4q21-28 in CRC by using AP-PCR method. However, detailed mapping of the long arm of chromosome 4 has not been reported in colorectal carcinoma thus far.

With high resolution markers, we performed detailed LOH analysis and observed two obvious deletion regions: one between D4S3000 and D4S2915 locus (4q12-21.1), another flanked by D4S407 and D4S2939 locus (4q25-31.1). The first region included 4q12-21.1, 4q13.1[19], furthermore, the region was adjacent with 4q21-25[14], 4q21-35[17], 4q21.1-22[18], 4q33-34[22] detected before. The second region was adjacent with 4q21-25[14], 4q25[15], 4q31.3[19], covered by 4q21-35[17], and completely spanned 4q32-33[18], 4q25-26[22], 4q27-28.3, 4q33[23], 4q26-27[28], partially overlapped with 4q21-28[34], 4q24-26[35] as well. Because of different LOH judge criteria and different density markers used, the minimal deletion region in different tumors displayed discrepancy.

LOH on chromosome 4q seems to be correlated with aggression features and a late genetic event involved with the progression rather than the initiation of cancer. In hepatocellular carcinoma, a study by Okabe *et al*[36] showed that the high rate of LOH on 4q are associated with a poor differentiation of tumors, vascular invasion and intrahepatic metastasis in hepatocellular carcinoma. A similar finding was made by Konishi *et al*[37], LOH was found in 71% of poorly differentiated hepatocellular carcinoma. Rashid *et al*[29] found 4q was preferentially lost in hepatocellular carcinoma containing p53 mutation, that is, LOH of 4q was present in 75% of hepatocellular carcinoma with, but only 25% of hepatocellular carcinoma without a p53 gene mutation ($P = 0.01$), indicating a possible interaction between *p53* gene mutation and 4q loss in the pathogenesis of hepatocellular carcinoma. Loss of 4q34-35 regions showed a significant association with alcohol intake ($P = 0.05$) and with high grade of differentiation ($P = 0.02$) in hepatocellular carcinoma[30]. Investigators[22] thought TSG on 4q play an important role in pathogenesis of malignant mesothelioma and small cell lung cancer, because non-small cell lung cancer had lower frequency at this region. Similarly, the result of primary bladder cancer correlated allelic loss with advanced tumor stage and grade of the lesions[14]. Piao *et al*[24] found five regions among seven common deleted regions was associated with tumor differentiation, suggesting that allelic loss on chromosome 4q is a late genetic event involved in the progression rather than in the initiation of hepatocarcinogenesis. Pershouse *et al*[35] reported that the allelic deletion involving 4q may represent an early event in head and neck squamous cell carcinoma oncogenesis.

A significant relationship was detected between LOH frequency on D4S3018 and tumor diameter. LOH frequency in tumors larger than 5 cm was significantly higher than tumors less than 5 cm in diameter ($P = 0.01$). On D4S1534 locus, LOH rate was significantly associated with liver metastasis ($P = 0.012$). It can be speculated that these events were associated with progression after tumorigenesis, indicating a late event in colorectal carcinoma.

No statistical significant correlation was found between the presence of LOH and clinicopathological data in oral squamous cell cancer[15], esophageal adenocarcinoma[17] and in Taiwanese hepatocellular carcinoma[28].

By scanning GeneMap' 99 database, and searching www.gdb.org, four genes should be studied further. PTPN13 (4q21.3) is a Fas-associated protein, tyrosine phosphate that binds to a negative regulatory domain in the FAS protein and inhibits Fas-induced apoptosis[38]. Caspase3 (4q34) and caspase6 (4q24-35), mammalian homologues of Ced-3 gene, are responsible for cleavage and inactivation of key homeostatic protein during apoptosis[39]. T1A12/mac25 (4q12-13) expression is abrogated during breast cancer progression concomitant with LOH on chromosome 4q, indicating its tumor suppressor function[40]. All of these three genes are putative TSGs.

In summary, this is the first detailed LOH analysis on chromosome 4q in CRC by using high resolution microsatellite markers. We detected two non-overlapping deletion region (4q12-21.1 and 4q25-31.1), which may contain TSGs. Additional attempts will aide in the discovery of the genes inactivated by these deletion events. The elucidation of the biochemical property of these gene products will be an important step in understanding the biology of this highly lethal and common cancer.

COMMENTS

Background

Cancer arises from the accumulation of inherited polymorphism (i.e. SNPs) and mutation and/or sporadic somatic polymorphism (i.e. non-germline polymorphism) in cell cycle, DNA repair, and growth signaling genes. Neoplastic progression is generally characterized by the accumulation of multiple somatic-cell genetic alterations as the tumor progresses to advanced stages. The classic mechanism of tumor suppressor gene (TSG) inactivation is described by two-hit modes in which one allele is mutated (or promoter hypermethylation or a small intragenic deletion) and the other allele is lost through a number of possible mechanisms, resulting in loss of heterozygosity (LOH) at multiple loci. LOH is the most common molecular genetic alteration observed in human cancers. In the model of colorectal tumorigenesis, mutational inactivation of TSGs predominates.

Research frontiers

Most genome-wide scans for LOH have been conducted at low resolution with a relatively small number of polymorphic markers. For example, an average of 120 microsatellites have been used to determine the allelotype of multiple different human neoplasms in a series of studies since 1995, and the highest density microsatellite allelotype was approximately 280 polymorphic markers before the year 2000. SNPs are the most common form of sequence variation in human genome, occurring approximately every 1200 bp. High density mapping of genetic losses reveals potential tumor suppressor loci and might be useful for clinical classification of individual tumors. SNP array has been introduced recently for genome-wide screening of chromosome imbalance. Higher density SNP array can effectively detect small regions of chromosomal changes and provide more information regarding the boundaries of loss regions.

Innovations and breakthroughs

A great deal of evidence supported the presence of TSGs in the short arm of chromosome 4. Fewer studies have been reported in colorectal cancer. Previous allelotyping analysis of cancer by many groups was used with a relatively low density of markers. By deletion dense markers mapping, authors detected two obvious high frequency LOH regions spanning D4S3013 and D4S405 locus in colorectal cancer (CRC). Candidate TSG might be located between D4S3017 and D4S2933 (about 1.7 cm).

Applications

This method could be used to detect some major allelic loss regions in genome-wide scans of LOH in patients with CRC.

Terminology

LOH is caused by a variety of genetic mechanisms, including physical deletion of chromosome non-disjunction and mitotic non-disjunction followed by republication of the remaining chromosomes, mitotic recombination and gene conversion. The mechanisms of LOH are remarkably chromosome-specific. Some chromosomes display a complete loss. However, more than half of the losses are associated with only a partial loss of a chromosome rather than a whole chromosome. LOH is also a common form of allelic imbalance and the detection of LOH has been used to identify genomic regions that harbor TSGs and to characterize different tumor types, pathological stages and progression.

Peer review

This is a report that describes the LOH events on 4q in sporadic CRC in Chinese patients, further studies will benefit from this paper. The data presented is clear and concise in the text.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

World Journal of Gastroenterology ISSN 1007-9327

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology* and *Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903
Ocean International Center, Building D
No. 62 Dongsihuan Zhonglu
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

During the last decades the concept of bile secretion as merely a way to add detergent components to the intestinal mixture to facilitate fat digestion/absorption and to eliminate side products of heme metabolism has evolved considerably. In the series of mini-reviews that the *World Journal of Gastroenterology* is to publish in its section of "Highlight Topics", we will intend to give a brief but updated overview of our knowledge in this field. This introductory letter is intended to thank all scientists who have contributed to the development of this area of knowledge in gastroenterology.

Key words: Bile flow; Cholestasis; Hepatocyte; Liver; Transport

Marin JJG. How we have learned about the complexity of physiology, pathobiology and pharmacology of bile acids and biliary secretion. *World J Gastroenterol* 2008; 14(37): 5617-5619 Available from: URL: http://www.wjgnet.com/1007-9327/14/5617.asp DOI: http://dx.doi.org/10.3748/wjg.14.5617

INTRODUCTION

During the last decades the concept of bile secretion as merely a way to add detergent components to the intestinal mixture to facilitate fat digestion/absorption and to eliminate side products of heme metabolism has evolved considerably. In the series of mini-reviews that the *World Journal of Gastroenterology* is to publish in its section of "Highlight Topics", we intend to give a brief but updated overview of our knowledge in this field. The first opening title by Esteller[1], in addition to review the mechanisms of bile formation, will serve as an introduction to the rest of mini-reviews. Therefore, I will skip this task here and devote this letter to thank all scientists who have contributed to the development of this area of knowledge in gastroenterology. First of all, I wish to apology because only a limited number of them will be cited here and also for the fact that, in most cases, I will cite them by the main investigator of the group. I assume that we all know, in some cases personally, what excellent scientists have participated in the contributions published by these teams. Nevertheless, I hope that every important contribution and research group will be cited in the appropriate mini-review of the series. Let me start this brief historical overview by reminding you the important initial steps in understanding bile acid physiology given by Schiff[2] and Wheeler[3], which permitted the establishment of the bases for further investigations by Boyer[4], Erlinger[5], Anwer[6] and others on the role of osmotic mechanisms accounting for bile acid-dependent and-independent fractions of bile flow. The elucidation of the physical-chemical characteristics of bile acids has been determinant in understanding the role of different bile acid species in bile formation, bile acid-induced injury of liver tissue and cholestasis or, in contrast, hepatoprotection, as well as the process of gallstone formation or prevention, *etc.* This has been possible thank to the investigations carried out by many groups, including those of Hofmann[7], Carey[8], Small[7,8], Paumgartner[9], Reichen[9], Danielsson[10], Sjovall[10], Reyes[11], Setchell[12], Poupon[13] and others. It has been with the help of molecular biology techniques that Meier[14,15], Stieger[14], Hagenbuch[15,16], Keppler[17], Thompson[18] and others have been able to identify transport proteins involved in the efficient uptake and secretion of bile acids by the liver. Similar studies by Dawson[16] and others have also contributed to our understanding of the role of intestinal transporters in the so-called enterohepatic circulation of bile acids. Advances in the research of substrate-transporter interactions by many important groups, including several mentioned above in addition to those of Sugiyama[19], Klaassen[20] and Petzinger[21], has lead to Kramer[22] and others, including

our own laboratory[23,24] to undertake the development of promising new drugs based on the substrate selectivity of plasma membrane transporters and the possibility of either blocking their function or targeting bile acid derivatives toward healthy liver tissue or toward tumours located in the enterohepatic circuit. Over the last few years the novel concept of bile acids as signalling molecules in several cell types has emerged. Thus, the possibility that bile acids, as well as other oxysterols, may activate nuclear receptors and regulate the expression of enzymes and transporters was suggested from results obtained at the same time by three different groups[25-27], and developed by these groups, and others, such as those of Karpen[28], Kullak-Ublick[29], Chiang[30] and Houten[31]. These findings are helping us to understand how liver cells may respond to endocrine signals (e.g. during pregnancy) or to the accumulation of bile acids occurring in cholestasis, which is the subject of research currently carried out by several groups, including those of Trauner[32,33], Suchy[33,34], Ananthanarayanan[33,34], Lammert[35], Williamson[35], Accatino[33], Arrese[33,36] and others. Moreover, bile acids can also interact with plasma membrane elements and therefore participate in autocrine and paracrine functions, interacting with several signalling pathways as it is being brilliantly investigated by Haussinger, Kubitz, Keitel and the rest of this group[37], as well as by Dent[38], Fujino[39], Beuers[40], Dufour[41] and others. A complete view of biliary physiology also needs to consider the participation of cholangiocytes in bile formation and the knowledge of mechanisms of bile secretion of other important endogenous compounds, such as cholesterol, bilirubin, glutathione and xenobiotics, such as drugs and toxins. We owe many important contributions in these fields to LaRusso[42], Ballatori[43], Arias[44], Keppler[17], Sugiyama[19], Wolkoff[45], Oude Elferink[46], Meijer[46], Kuipers[46], Jansen[46], Groen[46], Groothuis[46], Ostrow[47], Fevery[48], Coleman[49], Berenson[50], Vore[51] and many others. As I said this editorial letter of gratitude is highly incomplete, but it would be even more so without mentioning the appreciation of many hepatologists to the supporting role of Dr. Falk and the Falk Foundation e.V. to the research in this field.

Abstract

Bile acids are not only important for the absorption of dietary lipids and fat soluble vitamins but are signalling molecules with diverse endocrine and paracrine functions. Bile acids regulate bile acid, lipid and glucose metabolism and modulate temperature and energy homeostasis. Furthermore, bile acids can not only promote cell proliferation and liver regeneration but can also induce programmed cell death. Bile acid functions are mediated through different pathways which comprise the activation of nuclear hormone receptors, of intracellular kinases and of the plasma membrane-bound, G-protein coupled bile acid receptor TGR5/Gp-bar-1.

Key words: Bile acids; Farnesoid X receptor; TGR5; Glucose metabolism; Lipid metabolism

INTRODUCTION

Bile acids are synthesized from cholesterol in the liver and secreted into bile and the small intestine, where they enable the absorption of dietary lipids and fat soluble vitamins. Most of the bile acids are reabsorbed in the terminal ileum, carried through the enterocytes into the portal blood and returned to the liver, where uptake into the hepatocytes and subsequent transport into bile completes their enterohepatic circulation[1,2]. However, bile acids are not only important for the absorption of dietary lipids but are also signalling molecules, which regulate bile acid synthesis, conjugation and transport and modulate lipid, glucose and energy homeostasis. Bile acids can activate nuclear hormone receptors, such as the farnesoid X receptor (FXR)[3,4], which is a ligand-activated transcription factor[5]. FXR is highly expressed in liver, intestine and kidney[6], and regulates the expression of proteins involved in bile acid synthesis, detoxification and secretion in these organs thereby maintaining bile acid homeostasis[7-9].

Bile acid effects can also be mediated by transcription-independent pathways through the activation of intracellular protein kinases, such as mitogen-activated protein kinases and protein kinase C[10-15]. Furthermore, bile acids can modulate ion fluxes leading to an increase in intracellular ceramide levels, activation of NADPH oxidase, cell shrinkage and apoptosis[16,17]. Recently, the first plasma membrane bound, G-protein coupled bile acid receptor TGR5 (Gpbar-1, M-Bar) has been described[18,19]. *TGR5* mRNA was detected in many tissues, the highest expression being present in macrophages/monocytes, placenta, gallbladder, liver and intestine[18-20]. While FXR has been identified as important regulator of bile acid, lipid and glucose homeostasis, the role of TGR5 in bile acid mediated signalling is largely unclear. However, it has been suggested that bile acids *via* TGR5 induce energy expenditure in brown adipose tissue and skeletal muscle[21], modulate hepatic microcirculation[22], and suppress cytokine release in macrophages[18].

BILE ACIDS REGULATE BILE ACID HOMEOSTASIS

Sustained elevation of bile acid levels leads to severe liver damage and may promote the development of liver tumors. Patients with progressive familial intrahepatic cholestasis type 2 (PFIC-2), which is caused by mutations in the bile salt export pump (BSEP, ABCB11)[23], as well as FXR knockout mice[24] have chronically elevated

serum bile acid levels and spontaneously develop hepatocellular carcinomas[25-27]. In order to prevent bile acid-dependent liver damage and carcinogenesis the bile acid pool size needs to be tightly regulated.

It is well established that bile acids regulate their own biosynthesis, detoxification and transport both in the liver and the intestine. The identification of bile acids as natural ligands for the FXR[3,4] led to the discovery that FXR is essential for the maintenance of bile acid homeostasis, and protects the organism from the accumulation of potentially toxic bile acids (for reviews see[7,28-30]).

In the liver bile acids suppress the transcription of the CYP7A1, the rate-controlling enzyme of bile acid synthesis in the neutral pathway, and of the CYP8B1, the enzyme controlling the production of cholic acid[30]. This repression is mediated through several distinct, mainly FXR-dependent pathways. Activation of FXR by bile acids leads to an upregulation of the small heterodimer partner-1 (SHP)[31,32], which in turn interacts with several transcription factors, including hepatocyte nuclear factor-4α (HNF-4α) and liver receptor homolog-1 (LRH-1), which both bind to the bile acid-response elements (BAREs) in the promoters of the *CYP7A1* and *CYP8B1* genes[31-35]. Using SHP knockout mice, it has become apparent that the bile acid-dependent repression of CYP7A1 is mediated through several redundant pathways, since loss of SHP impaired but did not abolish bile acid-dependent feedback repression of CYP7A1 in these mice[36,37]. Activation of FXR by bile acids leads to the increased expression of fibroblast growth factor 19 (FGF-19) in hepatocytes, which is subsequently secreted and binds its receptor FGFR4 on adjacent hepatocytes. Stimulation of FGFR4 by FGF-19 leads to receptor dimerization, autophosphorylation and activation of the c-Jun N-terminal kinase (JNK) pathway resulting in the repression of CYP7A1 transcription[38]. Therefore FXR can inhibit bile acid synthesis through tow independent pathways. The importance of the FXR-dependent feedback mechanisms on bile acid synthesis is underscored by the finding, that FXR knockout mice failed to downregulate CYP7A and CYP8B in response to bile acid feeding, resulting in an elevation of serum bile acid levels and death of 30% of knockout mice by day 7[24]. Besides the FXR-dependent feedback regulation, bile acid signalling through the G-protein coupled bile acid receptor TGR5 (Gpbar-1) may also contribute to the regulation of bile acid synthesis and bile acid homeostasis. TGR5 knockout mice showed a significantly reduced bile acid pool size[39] and feeding of cholic acid to these mice did not repress the expression of CYP7A1 as observed in wild type littermates[20], indicating that TGR5 may play a role in the regulation of bile acid synthesis and bile acid pool size.

Conjugation of bile acids with taurine and glycine is mediated by the enzymes bile acid coenzyme A (CoA) synthetase and bile acid-CoA amino acid N-acetyltransferase and controlled by FXR[40]. Bile acids are secreted from the hepatocyte into bile across the canalicular membrane by the BSEP. Bile acids induce transcription of BSEP through FXR thereby promoting their own excretion[41,42]. Besides BSEP, two other canalicular transport proteins MDR3 (ABCB4), which is a phospholipid flippase, and MRP2 (ABCC2), which excretes bilirubin and organic anions, are also positively regulated by FXR[43,44]. Thus FXR facilitates bile flow and excretion of cholephilic compounds from hepatocytes. Short-term regulation of canalicular bile secretion occurs through exocytic insertion and endocytic retrieval of transport proteins into and from the plasma membrane and is differentially regulated by hydrophobic and hydrophilic bile acids (for reviews see[45-49]). Hydrophobic bile acids such as taurolithocholylsulfate (TLCS), glycochenodeoxycholate (GCDC) and taurochenodeoxycholate (TCDC) induce NADPH oxidase-dependent hepatocyte shrinkage[16]. Hepatocyte shrinkage is known to lead to the rapid retrieval of MRP2 and BSEP from the canalicular membrane and thus impairs bile formation[50-54]. On the contrary, taurocholate induces hepatocyte swelling and subsequent choleresis, which in the presence of increased hepatocyte bile acid load may serve as a feed-forward regulation leading to the insertion of BSEP into the canalicular membrane and enhanced bile acid excretion[52,54,55]. The choleretic effect of tauroursodeoxycholate, which is widely used for the treatment of cholestatic liver diseases, is mediated through integrins and Src, which trigger the downstream activation of mitogen-activated protein kinases resulting in the recruitment of BSEP to the canalicular membrane[12,13]. Therefore bile acids can alter bile flow both on the long-term scale on the transcriptional level *via* activation of FXR as well as on the short-term scale at the posttranscriptional level through alteration in hepatocyte hydration and subsequent translocation of transporter proteins.

In the intestine bile acid uptake is mediated by the apical sodium dependent bile salt transporter (ASBT, SLC10A2)[56]. While marked interspecies differences in the regulation of ASBT exist[7], human ASBT expression is controlled by FXR[57,58]. The ileal bile acid binding protein (IBABP) binds bile acids within the enterocytes and transfers them to the basolateral membrane for secretion into the portal blood. Despite the regulation of IBABP by FXR[3,59] and the downregulation of IBABP in FXR knockout mice[24], the enterohepatic circulation of bile acids in these mice is increased[60], suggesting the existence of further, FXR-independent pathways for the regulation of bile acid absorption in the ileum.

In the liver bile acids are taken up from the portal blood into hepatocytes across the sinusoidal membrane by several transport proteins. The sodium-dependent sodium taurocholate cotransporting peptide (NTCP, SLC10A1) accounts for the uptake of more than 80% of conjugated bile acids into hepatocytes. Similar to CYP7A1 and ASBT, bile acids repress the expression of NTCP *via* FXR-SHP-dependent mechanisms[61,62]. However, further SHP-independent mechanisms for the regulation of NTCP expression must exist, since *NTCP* mRNA levels in SHP knockout mice were unchanged[36]. Bile acid uptake by NTCP may also be regulated posttranslationally at the protein level, in an FXR-

independent way, since livers from patients with PFIC showed a significant downregulation of the NTCP protein, while *NTCP* mRNA levels were similar to control livers[63]. The other bile acid uptake transporters in the liver belong to the family of organic anion transporters (OATPs). While OATP1B1 expression is downregulated by FXR[64,65], OATP1B3 expression is enhanced[66]. The repression of bile acid uptake transporters (NTCP, OATP1B1) may protect hepatocytes from accumulation of toxic bile acids, while the upregulation of OATP1B3 may help to maintain excretion of xenobiotics under cholestatic conditions[66]. Upregulation of the basolateral bile acid export pumps multidrug resistance protein 4 (MRP4, ABCC4) and the organic solute transporter α/β (OSTα/β) is also observed under cholestatic conditions in humans and rodents[63,67,68]. While the expression of Ostα/β is induced by bile acids *via* FXR[69], the upregulation of MRP4 by bile acids is independent of FXR and is observed both on the translational and posttranslational level[63,67,69]. Bile acids increase the expression of different detoxification enzymes through FXR, such as the UDP-glucuronosyltranserase UGT2B4 and the sulfotransferase SULT2A1[40,70,71]. In hepatocytes, bile acids activate FXR, which in turn induces suppression of de novo synthesis, enhances conjugation and detoxification and increases efflux both across the canalicular as well as the basolateral membrane thereby preventing hepatic accumulation of bile acids and liver damage. This is supported by the finding that administration of a synthetic FXR agonist (GW4064) reduced liver injury in rat models of cholestasis[72].

BILE ACIDS MODULATE GLUCOSE HOMEOSTASIS

A link between bile acids and glucose homeostasis was recognized when patients with type Ⅱ diabetes were treated for dyslipidemia with cholestyramine, a bile acid sequestrant[73]. Besides lowering total cholesterol and LDL cholesterol, cholestyramine also improved glycemia and reduced blood glucose levels by 13%[73]. Treatment of isolated rat hepatocytes with glucose increased *FXR* mRNA levels and target gene expression through activation of the pentose phosphate pathway[74] and thus may interfere with bile acid metabolism. Insulin counteracted the glucose effects in these experiments[74]. Vice versa, several recent studies indicate that bile acids modulate hepatic gluconeogenesis, however, the data are controversial. While the expression of the rate-limiting enzyme of gluconeogenesis phosphoenolpyruvate carboxykinase (PEPCK) was upregulated by bile acids *via* FXR in both primary hepatocytes and hepatoma cell lines in one recent study[75], bile acids repressed PEPCK expression in an FXR-dependent and FXR-independent, SHP-dependent mechanism in both HepG2 cells and mouse liver in several other studies[76-79]. Other enzymes involved in gluconeogenesis, such as the glucose-6 phosphatase (G6Pase) and the fructose 1,6-bisphosphatase (FBP1) were also downregulated by bile acids through SHP[77]. Furthermore, activation of FXR may not only reduce gluconeogenesis, but also increase glycogen synthesis the liver, thereby lowering blood glucose levels[80]. These findings are supported by studies with FXR knockout mice, which show increased gluconeogenesis in the liver and reduced glucose uptake in the skeletal muscle, resulting in elevated blood glucose levels[79]. Inhibition of gluconeogenesis by bile acids was ameliorated in FXR knockout mice but observed in wildtype mice, however, a synthetic FXR agonist (GW4064) failed to repress gluconeogenesis in wildtype animals[79]. The authors give two possible explanations for these observations. Either, the *in vivo* pharmacokinetics of the synthetic agonist prevented long term effects on glucose homeostasis, or bile acids alter gluconeogenesis not only through activation of FXR but also through additional signalling pathways, which together lead to the suppression of gluconeogenesis[79]. The later seems more likely and it has recently been described that bile acids stimulated secretion of glucagon-like peptide 1 through activation of the membrane bound bile acid receptor TGR5[81] and thus may lower serum glucose levels and improve insulin resistance in non-insulin dependent diabetes[82].

Furthermore, bile acids can modulate glucose homeostasis through alteration of the cellular hydration state. Hypo-osmotic hepatocyte swelling, which can be induced by taurocholate[52], stimulates within minutes glycogen synthesis[83] as well as flux through the pentose phosphate pathway[84] and inhibits glycolysis and glycogenolysis[85-87]. Besides these rapid mechanisms, cell swelling leads to an increase in *PEPCK* mRNA expression thus linking hepatocyte hydration to carbohydrate metabolism[88]. Hydrophobic bile acids, such as taurolithocholylsulfate (TLCS) and glycochenodeoxycholate (GCDC), can confer insulin resistance in hepatocytes through inhibition of insulin-dependent phosphorylation of the insulin receptor and impaired recruitment of phosphoinositide-3 (PI-3) kinase as well as protein kinase B activation[89]. Tauroursodeoxycholate (TUDCA) restored insulin signalling under these conditions[89]. Cell shrinkage induced by hydrophobic bile acids independently contributes to insulin resistance since hepatocyte shrinkage itself has insulin-antagonistic effects, stimulating glycogenolysis, proteolysis and inhibiting glycogen and protein synthesis[46,85,86,90,91]. However, hyper-osmolarity does not affect insulin-dependent activation of the insulin receptor but rather acts on the level of or downstream to the PI-3 kinase[92]. These data suggest that hydrophobic bile acids confer insulin resistance in the liver through several distinct pathways.

Taken together, these data demonstrate that bile acids through FXR regulate gluconeogenesis, glycogen synthesis and insulin sensitivity[93], therefore FXR agonists may be useful in the treatment of type Ⅱ diabetes. Apart from FXR, the bile acid receptor TGR5 may also influence glucose metabolism and insulin sensitivity *via* GLP-1 secretion, but additional *in vivo*

studies are required to elucidate the role of TGR5 for glucose homeostasis. Furthermore, hydrophobic bile acids confer insulin resistance in the liver, which may be ameliorated by TUDCA treatment.

BILE ACIDS AFFECT LIPID HOMEOSTASIS

The existence of an inverse relationship between bile acid and triglyceride levels has been recognized over three decades ago, when patients with cholesterol gallstones were treated with chenodeoxycholic acid (CDCA)[94]. The administration of CDCA was accompanied by a reduction in plasma triglyceride levels, which was more pronounced in patients with endogenous hypertriglyceridemia[94], therefore CDCA has been suggested for treatment of hypertriglyceridemia[94-96]. The opposite effect was observed in patients who took bile acid binding resins, which lead to an increased production of very low density lipoproteins (VLDL) and an elevation of serum triglyceride levels[97,98]. The mechanisms underlying this bile acid effect on lipid metabolism remained largely unknown, however, the recent findings that FXR knockout mice have elevated liver and plasma triglyceride levels[24,99] and that the expression of a variety of lipid homeostasis-modulating proteins is regulated by FXR (summarized in[7,100]) suggest, that bile acids modulate lipid homeostasis mainly through activation of FXR.

The triglyceride lowering effect of bile acids involves different pathways downstream of FXR. Activation of FXR increases the expression of SHP, which in turn inhibits the liver X receptor (LXR) mediated upregulation of the sterol regulatory element-binding protein-1c (SREBP-1c) and its target gene expression[100]. SREBP-1c serves as master regulator of fatty acid and triglyceride synthesis[101,102]. Both, basal and inducible expression of SREBP-1c is controlled by LXR[101]. Activation of SREBP-1c positively regulates the expression of genes involved in fatty acid synthesis, such as acetyl CoA synthetase, acetyl CoA carboxylase and fatty acid synthetase[102]. Bile acids inhibit SREBP-1c mediated lipogenesis in an FXR-SHP dependent manner, since the effect was also observed after administration of a synthetic FXR agonist and was attenuated in SHP knockout mice[100]. Besides the inhibition of fatty acid and triglyceride synthesis, bile acids can also stimulate the triglyceride clearance from serum through activation of lipoprotein lipase and subsequent hydrolysis of triglycerides in VLDL and chylomicrons. Bile acids activate FXR and subsequently induce the expression of the apolipoprotein CⅡ (ApoC Ⅱ)[103], which serves as an activator of lipoprotein lipase[104,105]. Furthermore, the expression of another apolipoprotein, ApoCⅢ, which is known to inhibit LPL activity[106], is repressed by activation of FXR[107], thus enhancing the hydrolysis of triglycerides from VLDL. The expression of angiopoetin-like protein 3 (Angptl3), which can also inhibit lipoprotein lipase function[108], was decreased by bile acids[100] and may contribute further to bile acid induced triglyceride hydrolysis. Bile acids, such as CDCA, repressed the expression of the microsomal triglyceride transfer protein (MTP) and ApoB[109], which are essential for the assembly of chylomicrons and VLDL particles[110]. A synthetic FXR agonist failed to lower MTP levels[109] and MTP expression in FXR knockout mice was reduced[100] suggesting a FXR-independent action of bile acids on MTP.

Bile acids may also influence lipid metabolism through cross-talk with peroxisome proliferator-activated receptor α (PPARα)-dependent pathways. PPARα is a nuclear receptor, which plays an important role in lipid and lipoprotein metabolism and controls several enzymes critical for fatty acid oxidation[111]. Expression of human PPARα is directly regulated by bile acids and a synthetic FXR agonist, however, murine PPARα expression is not responsive to bile acids[112]. Furthermore, expression of pyruvate dehydrogenase kinase-4 (PDK4) is upregulated by bile acids *via* FXR, which leads to inactivation of the pyruvate dehydrogenase complex with subsequent suppression of glycolysis and increased fatty acid oxidation[113]. Thus, bile acids may lower triglyceride levels *via* FXR-dependent activation of PPARα and PDK4 eventually leading to increased fatty acid oxidation.

Not only VLDL synthesis and turnover is affected by bile acids, but also HDL clearance is modulated through activation of FXR. FXR knockout mice have increased serum VLDL, LDL and HDL levels[24,99]. Reduced expression of the scavenger receptor BI (SRBI) and subsequent delay in hepatic uptake of HDL cholesterol esters account for the increase in plasma HDL in FXR knockout mice demonstrating that SRBI is a target gene of FXR[99].

In summary, bile acids reduce triglyceride levels through several mechanisms. Besides inhibition of triglyceride and VLDL synthesis *via* SREBP-1c-dependent mechanisms and FXR-independent repression of MTP and ApoB, bile acids also promote VLDL clearance *via* effects on ApoCⅡ, ApoCⅢ and Angptl3 and induce fatty acid oxidation *via* PPARα and PDK4. Furthermore, the close connection between bile acid synthesis and cholesterol elimination, underscores the important role of bile acids in the regulation of triglyceride and cholesterol homeostasis.

BILE ACIDS INCREASE ENERGY EXPENDITURE

Bile acids not only regulate lipid and glucose homeostasis but also modulate energy metabolism *via* the membrane-bound bile acid receptor TGR5 (Gpbar-1). TGR5 is coupled to stimulatory G-protein and activation of the receptor by bile acids increases intracellular cyclic AMP levels[18,19]. Administration of bile acids to mice increased energy expenditure in brown adipose tissue and prevented development of obesity and insulin resistance[21]. The stimulation of TGR5 induced an increased expression of the cAMP-dependent iodothyronine deiodinase type 2 (D2), which converts inactive thyroxine (T4) to active 3,5,3'-triiodothyronine and is crucial for adaptive

thermogenesis in brown adipose tissue. The observed metabolic effect of bile acids was abolished in D2 knockout mice. In isolated brown adipocytes and human skeletal myocytes bile acids stimulated TGR5, increased intracellular cAMP, activated deiodinase D2 and lead to an increase in oxygen consumption[21]. Tissues important for thermogenesis, such as brown adipose tissue in rodents and skeletal muscle in humans co-express TGR5 and deiodinase 2 and the TGR5-cAMP-D2 pathway may be activated in these tissues in response to plasma bile acid levels, which rise after food intake, and may therefore regulate diet induced thermogenesis[21]. The important role of TGR5 for energy homeostasis was confirmed by studies with TGR5 knockout mice. Administration of a high fat diet to TGR5 knockout mice led to a significant accumulation of adipose tissue and increase in body weight as compared to wild type littermates[39].

FURTHER ENDOCRINE EFFECTS OF BILE ACIDS

Bile acids have immunomodulatory functions as oral administration of bile acids successfully reduced endotoxin-related complications following surgery in patients with obstructive cholestasis[114-116]. This beneficial effect of bile acids was attributed to inhibition of endotoxin-induced TNF-α production[117].

The bile acid receptor TGR5 is highly expressed in CD14-positive monocytes, alveolar macrophages[18] and Kupffer cells[118], which are resident macrophages in the liver. Bile acids can alter macrophage function by affecting phagocytic activity as well as cytokine production[119-123]. Bile acids inhibited LPS-induced cytokine production in alveolar macrophages and Kupffer cells in a TGR5-cAMP-dependent manner[18,118], thus supporting the hypothesis that TGR5 plays an important role for macrophage function. Activation of TGR5 in Kupffer cells may prevent excessive cytokine production in sepsis-associated or obstructive cholestasis thereby alleviating liver injury.

Bile acids can prevent bacterial overgrowth and mucosal injury in the small intestine of mice. Subsequently, in mice elimination of bile acids from the intestine through bile duct ligation resulted in bacterial propagation, disruption of the epithelial barrier and translocation of bacteria across the mucosa into lymph nodes. These effects could be prevented by the administration of a synthetic FXR agonist, revealing a novel mechanism of bile acid dependent enteroprotection[124]. The antibacterial action of the FXR agonist (GW4064) were indirect since no bacteriostatic effects were observed when ileal contents were cultured in the presence of GW4064[124].

Bile acids may also interfere with interleukin-6 (IL-6) signalling in hepatocytes. IL-6 has hepatoprotective properties and can ameliorate liver injury induced by obstructive cholestasis[125,126]. It has been shown recently, that the hydrophobic bile acid glycochenodeoxycholate (GCDC) impairs IL-6 induced activation of the signal transducer and activator of transcription (STAT) 3 through caspase-dependent cleavage of the IL-6 receptor glycoprotein 130 as well as through MAP kinase-dependent inhibition of STAT3 phosphorylation, thus contributing to the bile acid-induced liver injury[127,128].

Taken together, bile acids may influence immune functions in the intestine and the liver through activation of FXR-, TGR5-, MAP-kinase- and caspase-dependent pathways.

A role for bile acids in regulation of hepatic microcirculation has also been recently suggested. TGR5 is localized in the plasma membrane of sinusoidal endothelial cells of rat liver and is responsive to bile acids[22]. Stimulation of TGR5 increased cAMP levels, activated protein kinase A and lead to a serine phosphorylation of endothelial NO synthetase and subsequent elevation of NO production[22]. Furthermore, activation of TGR5 resulted in an enhanced serine phosphorylation of the CD95 receptor[22], which may promote the internalization of the receptor from the plasma membrane thereby preventing CD95-induced apoptosis as it has been observed in hepatocytes[129].

A role for bile acids in liver regeneration has also recently been identified[130]. Increased bile acid levels after partial hepatectomy promoted liver regeneration which was attenuated in FXR knockout mice, suggesting that these effects are mediated by FXR[130]. Bile acids have been shown to affect cell proliferation, survival and cell death. These effects of bile acids are reviewed in another article in this issue.

Protein metabolism in the liver can also be affected by bile acids *via* alterations in cell hydration. Taurocholate can induce hepatocyte swelling, which is sensed by integrins and leads to the activation of Src-type kinases and mitogen-activated kinases and subsequent inhibition of autophagic proteolysis at the level of autophagosome formation[131-133] (for reviews on hydration-dependent pathways see[46,86,90,91]).

PARACRINE ROLE OF BILE ACIDS

After excretion into bile, bile acids are in close contact with cholangiocytes, the bile duct forming epithelial cells. Bile acids modulate cholangiocyte secretion, proliferation and survival in a paracrine manner (for a recent review see[134]). Taurocholic acid and taurolithocholic acid increased secretin stimulated intracellular cAMP levels and Cl^-/HCO_3^- exchanger activity thus promoting ductal secretion and bile flow[135,136]. These effects were dependent on bile acid uptake into the cholangiocytes and led to an activation of phosphatidylinositol 3-kinase (PI3-K), followed by an increase in cAMP[135,137]. Ursodeoxycholic acid induced ductal secretion through CFTR-dependent secretion of ATP into bile, which in turn activated apical purinergic P_{2Y} receptors and stimulated chloride efflux and fluid secretion[138]. While taurocholic and taurolithocholic acid stimulated proliferation of bile ducts and increased bile duct mass up to 3-fold[135,136], ursodeoxycholic acid has been shown

to inhibit cholangiocyte proliferation in bile duct ligated rats[139], and to prevent cholangiocyte apoptosis in vagotomized, bile-duct ligated rats[140].

Recently, TGR5 has been detected in cholangiocytes of rat liver[118]. Among the endogenous bile acids taurolithocholic acid represents the most potent TGR5 agonist with an EC_{50} of 0.29 μmol/L[141]. The finding that hydrophobic bile acids, such as taurolithocholic acid, increase cAMP in cholangiocytes[135] suggest, that TGR5 may play a role in cholangiocyte secretion and proliferation and prevention of apoptosis[22].

Abstract

Bile acids (BAs) have a long established role in fat digestion in the intestine by acting as tensioactives, due to their amphipathic characteristics. BAs are reabsorbed very efficiently by the intestinal epithelium and recycled back to the liver *via* transport mechanisms that have been largely elucidated. The transport and synthesis of BAs are tightly regulated in part by specific plasma membrane receptors and nuclear receptors. In addition to their primary effect, BAs have been claimed to play a role in gastrointestinal cancer, intestinal inflammation and intestinal ionic transport. BAs are not equivalent in any of these biological activities, and structural requirements have been generally identified. In particular, some BAs may be useful for cancer chemoprevention and perhaps in inflammatory bowel disease, although further research is necessary in this field. This review covers the most recent developments in these aspects of BA intestinal biology.

Key words: Colitis; Bile acid absorption; Colon cancer

INTRODUCTION

Separate chapters in this series of minireviews are devoted to cover various aspects of bile acids (BAs) chemistry, physiology and pathophysiology, including the hepatic synthesis and handling of BAs and their implications in health and disease. Here we will deal with the normal and pathological roles of BAs in one of the traditionally known natural sites of action, i.e. the intestine. It is well known that BAs are secreted into the duodenal lumen after meals in order to act as tensioactives and facilitate fat digestion. This is possible because of the amphipathic characteristics of BAs, which are molecules with a highly hydrophobic core and a number of hydroxyl groups attached. Because these groups may extend to one of the two sides of the basically planar structure formed by the hydrocarbon rings of the BA molecule, its polarity is maximal when all hydroxyl groups are set out in the same side. Thus cholic acid (CA), deoxycholic acid (DCA) and chenodeoxycholic acid (CDCA), all of which have alpha hydroxyl groups, are more efficient tensioactives than ursodeoxycholic acid (UDCA), which has hydroxyls with both alpha and beta conformation. In order to act efficiently as tensioactives BAs must work in coordination with other amphipathic compounds, namely phospholipids, which are another essential component of bile.

Once their physiological function is accomplished, most BA molecules are efficiently reabsorbed in the distal part of the small intestine and reach the liver *via* portal blood, where they are avidly taken up by hepatocytes. Thus BAs are not wasted but recycled with an almost perfect yield (approximately 95%). The molecular details of this enterohepatic cycle have been elucidated (Figure 1). The type and amount of BAs thus

reabsorbed, as well as of those that pass into the colon, are not constant but subject to variation as a result of diet, transit time, drugs, disease, *etc*. This in turn has an impact on the effects of BAs because they are not equivalent in terms of bioactivity. Certain BAs have been involved in colon cancer, but also in other conditions such as intestinal inflammation, diarrhea, *etc*.

The dynamics of BAs transport and metabolism is tightly regulated. This is necessary because intracellular accumulation of BAs, as happens in cholestasis, may result in cytotoxicity. Because BAs are synthesized in the liver, an important part of the control of their homeostasis takes place in hepatocytes, the details of these processes are covered in other chapters of this series. However, in part of the regulatory system the intestine plays important direct (transport/metabolism) and indirect (endocrine response of intestinal epithelium to BAs) roles.

BA IN THE INTESTINE

As mentioned above, the liver synthesizes BAs at the expense of cholesterol and also retrieves reabsorbed BAs from the blood. From hepatocytes they are secreted against steep concentration gradients into bile, together with cholesterol and phospholipids. Thus, between meals, most of the pool of BAs resides in the gallbladder ready to be used at short notice. The mechanisms whereby hepatocytes take up BAs from the bloodstream and synthetize and secrete them into bile have been reviewed in other chapters of this series. When food is ingested (more precisely if the meal is rich in fat) the gallbladder contracts in response to cholecystokinin. It has been proposed that intraduodenal BAs exert a negative feedback control on postprandial cholecystokinin release and the resulting gallbladder contraction. Thus the acute (but not chronic) intraduodenal bile salt depletion with cholestyramine affects gallbladder and also antroduodenal motility, possibly by enhanced motilin release[1].

The mix of BAs contained in bile represents a balance of primary and secondary compounds. Primary BAs are those synthesized as such by the liver, and comprise predominantly CA and CDCA. These are secreted to bile mainly conjugated with glycine and taurine, thus having enhanced water solubility. Secondary BAs are derived from primary BAs by modifications carried out by intestinal bacteria. The main modifications are deconjugation, oxidation of hydroxyl groups in 3, 7 and 12 positions, and 7-dehydroxylation[2]. The main secondary BAs are lithocholic acid (LCA) and DCA. The overall result is an increase in the hydrophobicity of BA pool. The transformation of BAs by bacterial enzymes has several important consequences. First, it favors passive absorption in the colon of those BAs escaping the active uptake that takes place in the ileum. If both mechanisms operate normally, only 1%-3% of the amount of BA that is secreted by the liver is ultimately excreted in faeces (deconjugated and otherwise transformed). Second, it increases the potentiality of BAs to cause noxious effect, like carcinogenicity and cholesterol gallstone disease[3]. Third, the composition

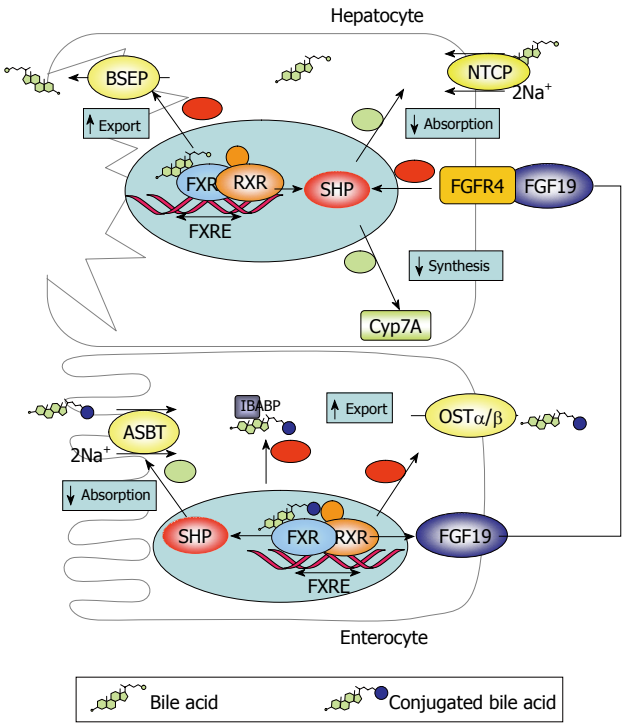

Figure 1 Diagram showing the mechanisms of BA transport and regulation at the intestinal and hepatic level.

of the BA pool will vary when the conditions of biotransformation are altered, for instance by changes in transit time or alterations in the microbiota brought about by drugs, diet, *etc*.[3,4]. For instance, a high fat diet and a long (slowed) transit time favor DCA generation from CA and absorption, which in turn is associated with higher risk of cholesterol gallstones and cancer (see below). In addition, diets rich in fat and poor in fiber can increase more than 10-fold the amount of taurine conjugated BAs reaching the colon, due to higher conjugation and production (higher conjugation reduces ileal absorption)[5,6]. Taurine dietary intake (meat, seafood) also contributes to this result. Overweight and accelerated intestinal transit reduce BA absorption and may cause idiopathic BA malabsorption[7]. Drugs such as cholestiramine bind BAs and reduce absorption.

Owing to the fact that 7-dehydroxylation cannot be reversed by the host enzymatic machinery, LCA and DCA tend to accumulate in the BA pool. However, LCA is 3-sulfated and conjugated at C-24 by the liver, resulting in a derivative that is poorly absorbed from the colonic mucosa, and consequently LCA is not present in significant amounts in the bile[8]. Thus major BAs in human bile are CA, CDCA and DCA, which are accompanied by minor amounts of UDCA, LCA and other BAs, whereas faeces contain mainly DCA, LCA, minor amounts of CDCA, CA and UDCA and a variety of bacteria transformed derivatives[2]. Concentrations of BAs in the intestinal lumen are variable but usually high, estimated in the medium millimolar range. This is consistent with their critical micellar concentration (e.g. 6-10 mmol/L for TCA), i.e. the concentration corresponding to spontaneous formation of micelles[9].

BA TRANSPORT BY EPITHELIAL CELLS

As mentioned above, BAs are efficiently taken up from the lumen of the ileal segment, leaving only approximately 5% (or approximately 0.5 g/d) in the lumen[10]. This fraction is in part passively absorbed in the colon, a process facilitated by bacterial deconjugation, and in part transformed and extruded with faeces. In contrast, ileal uptake is predominantly an active process carried out by the apical sodium-dependent BA transporter (ASBT, gene symbol *SLC10A2*), which imports BAs coupled to Na^+ absorption (1:2 stoichiometry)[11]. ASBT is highly homologous to the hepatocyte Na^+/taurocholate cotransporting polypeptide transporter (NTCP, gene symbol *SLC10A1*), which plays a pivotal role in BA uptake by the liver from the portal bloodstream. BAs species are not equally transported by ASBT. Thus, conjugated (more hydrophilic) BAs are transported more efficiently than unconjugated forms[12,13]. This is physiologically consistent with the fact that deconjugation normally takes place in the colon. The affinity of ASBT is also higher for dihydroxy BAs (CDCA and DCA) than for trihydroxy BAs (CA, taurocholic acid-TCA-, glycocholic acid-GCA-)[12].

BAs are believed to be transferred directly from ASBT to an intracellular 14 kDa protein called ileal BA binding protein (IBABP/FABP6) through the formation of a 2:1 stoichiometric complex[14]. IBABP is supposed to facilitate transport of BAs within the cell to the basolateral membrane. This is suggested by data showing coordinated expression of both ASBT and IBABP in the postnatal development in the intestine and in cholangyocytes, as well as by the fact that IBABP and ASBT form complexes with a defined stoichiometry[15]. It should be noted however that ASBT is expressed in the kidney without being accompanied by IBABP[16], and also that FXR knockout mice, which do not express IBABP, show enhanced rather than inhibited intestinal BA absorption, suggesting that IBABP may function as a negative regulator of intestinal BA reabsorption, at least in the mouse[17]. Interestingly, low IBABP expression has been linked to the risk of necrotizing enterocolitis in an animal model, suggesting that inefficient transfer of BA to the basolateral membrane may ultimately result in epithelial damage and inflammation[18].

Finally, BAs exit the enterocyte *via* the recently characterized OSTα/β transporter[19], an obligate heterodimer which functions in a Na^+-independent manner and also transports prostaglandin E_2, estrone-3-sulfate, dehydroepiandrosterone sulfate[13].

Developmentally ileal transport has been described to be preceded by active colonic absorption in rabbits[20]. This differs markedly from adult animals, which show net colonic secretion. The expression of IBABP and ABST is known to be subjected to distinct changes early in life, which are dependent on the species and protein considered. Thus, in rats and mice, ASBT is highly expressed in the ileum of the fetus before birth but is downregulated or entirely absent in the newborn and later upregulated again. IBABP shows a similar ontogenic profile in mice, while in rats it first appears postnatally[20]. The induction of ABST after birth is stimulated by thyroxine in rats[21].

It is interesting to examine the effects of interference with normal transporter function in the intestine. Genetic disruption of ASBT activity or pharmacological inhibition with SC-435 results in BA malabsorption and diarrhea[22-24]. Conversely, Ostα -/- mice show reduced intestinal capacity to take up BAs but unaffected fecal BA output, which is secondary to a marked shrinkage of the BA pool[19]. On the other hand, there are significant numbers of patients with idiopathic ileal BA malabsoprtion who suffer of unexplained chronic diarrhea[25].

The exact role of other transporters is controversial. They may play a minor role in BA handling by the intestine. These include MRP3 and an alternatively spliced form of ASBT, t-ASBT[13].

REGULATION OF INTESTINAL BA TRANSPORT

The intestinal (ileal) absorption of BAs is tightly regulated to meet physiological demands. In addition, intestinal BA uptake has direct and indirect impact on hepatic BA homeostasis. The main factor involved in both functions is the farnesoid X receptor (FXR/NR1H4), which was originally identified as an orphan nuclear receptor that was activated by farnesol, an intermediate in the mevalonate biosynthetic pathway[26]. FXR is expressed in ileal enterocytes and also in the liver, as well as in other tissues, such as the adrenal gland and the kidney[27]. Interestingly, the intestine seems to have the most intense FXR expression in the body[28]. Agonists of the FXR include BAs, particularly CDCA, followed by DCA, LCA and many other BAs with minor efficacy (conjugation does not affect binding)[29]. The α-position of OH groups in BA molecule is very important for interaction with FXR[30]. Upon activation, FXR modulates gene transcription acting in concert with another nuclear receptor, the retinoid X receptor alpha (RXRα), by recognizing a specific promoter sequence called the FXR responsive element. FXR is pivotal in the BA regulation both in the liver and in the intestine. In hepatocytes FXR increases expression of the bile salt export pump (BSEP) and downregulates the expression of NTCP and CYP7A. Since NTCP and BSEP mediate BA uptake from blood and export to bile in hepatocytes and CYP7A catalyzes the limiting-rate step in the classical BA biosynthetic pathway, this leads to reduced BA uptake, decreased synthesis and enhanced export to bile. Thus BA accumulation in hepatocytes tends to be self-limiting. In enterocytes, FXR is coupled to reduced ASBT and increased IBABP and OSTα/β expression, resulting in inhibition of intestinal absorption of BAs and prevention of intracellular BA accumulation.

The repressing effects of FXR are mediated by the transcription factor SHP (Small Heterodimer Partner), which is induced by FXR but lacks a DNA binding domain[31,32]. Instead, SHP binds to other nuclear receptors such as RXR/RAR (retinoic acid receptor),

LRH1 (liver receptor homolog 1) and LXR (liver X receptor), inhibiting their transcriptional effects[11,33]. IBABP seems to interact with ASBT and FXR to promote FXR transcription[34].

An important feature of FXR role in regulation of BA homeostasis is that it is not limited to local effects. Rather, sensing of the enterocyte BA pool by FXR affects the liver by way of the endocrine factor FGF19 (Fgf15 in mice)[32,33]. FGF19 is released to the portal circulation and activates fibroblast growth factor receptor 4 (FGFR4) in hepatocytes, which results in downregulation of CYP7A1 and therefore inhibition of the classical BA synthetic pathway, both by SHP induction and possibly other pathways[33]. Thus BAs modulate their own synthesis both by local hepatic and remote intestinal negative feedback. Tissue specific FXR gene knockdown experiments suggest that both pathways are similarly important[27]. The importance of the latter pathway is exemplified by the fact that administration of TCA downregulates CYP7A1 in the liver only when administered intraduodenally, but not after intravenous or portal instillation[35]. However, alternative pathways for feedback control have been proposed[33].

Physiologically, lack of BA uptake by ASBT inhibition leads to increased fecal BA (and diarrhea) and reduced FXR stimulation, lower FGF19 synthesis, and consequently enhanced BA synthesis, expanding the BA pool and lowering plasma cholesterol[24]. In contrast, Ostα -/- mice do not exhibit increased fecal BA output and have downregulated Cyp7a1 expression and a reduced BA pool[19]. This is due to increased Fgf15, secondary to FXR activation by "trapped" BAs.

In addition, FXR activation has been claimed to participate in the regulation of bacterial growth within the intestine. This hypothesis is supported by the findings that cholestasis results in bacterial overgrowth in the small intestine and increased translocation, which are counteracted in experimental models by oral BAs[36,37]. The FXR mediated induction by BAs of antibacterial genes such as angiogenin, carbonic anhydrase 12 and inducible nitric oxide synthase may account for this effect[38].

Other nuclear factors are regulated by BAs, including the pregnane X receptor (PXR/NR1I2), the Vitamin D receptor (VDR/NR1I1) and the androstane constitutive receptor (CAR)[33]. Thus LCA binds and activates intestinal and systemic VDR[39]. It has been proposed that the effects brought about by LCA are essentially local, directed to induce CYP3A genes and to aid in detoxification[40], but at any rate it can substitute for Vitamin D systemically. PXR and CAR activation leads to the upregulation of secondary BA transporters such as MRP2, MRP3 and MDR1. For instance, CA induces MRP2 and MRP3 in the intestine[41]. In addition, BAs have been reported to activate a G-protein associate receptor, named after the fact G protein-coupled BA receptor 1 (also known as TGR5), which is expressed in many tissues including the gastrointestinal tract[42].

IBABP is also regulated by PPARα/β in humans but not mice[43], and can also be indirectly up-regulated by cholesterol through the activation of sterol-responsive element-binding protein 1c (SREBP1c) by LXR[44]. ASBT is also regulated by PPARα[45]. These changes are expected to increase BA uptake and possibly reduce cholesterol absorption, a putative mechanism of action of the hypolipemic drugs fibrates[43]. Corticoids are also known to upregulate ASBT expression[46]. Because BA ileal uptake is inhibited in intestinal inflammation and probably contributes to diarrhea, corticoid treatment may be specifically useful in this setting.

Among the pathological conditions affecting BA homeostasis, cholestasis downregulates ASBT expression[47,48]. The mechanism is unclear, but it may be related to PPARα inhibition by BAs (possibly because of high blood levels), given that PPARα has been reported to transactivate ASBT transcription, as mentioned above[45,49]. Intestinal MRP2 but not MRP3 is decreased by cholestasis in rats[50] and in humans[48,51], although the significance of these findings is uncertain. In contrast, increased absorption has been reported in primary biliary cirrhosis, thus contributing to cholestasis in this condition[52]. Hypertriglicerydemia also reduces ASBT expression and inhibits BA absorption[53], an effect which in turn might exacerbate hypertriglyceridemia[54]. Interestingly, gallstones have been associated with lower intestinal ASBT and IBABP expression in normal weight but not overweight women[55]. These changes are accounted for by lower hepatic FXR and thereby increased BA synthesis.

BA AND COLORECTAL CANCER

There is wide epidemiological evidence linking BA exposure (for instance due to high fat diet) and gastrointestinal (specially colorectal) cancer[56-58]. Patients with colorectal adenomas and carcinomas exhibit high blood and fecal levels of secondary BAs[59,60]. Diets rich in fat are powerful stimulants of BA secretion, as mentioned above. Thus many investigators have studied the effects of BAs, particularly secondary BAs (DCA and LCA) on intestinal epithelial cell proliferation, apoptosis and mutagenesis *in vitro*, as well as on cancer promotion *in vivo*. Paradoxically DCA, but not CA or UDCA, exhibit proapoptotic effects on cell lines, which appear to depend on a variety of mechanisms[61,62]. The ability of BAs to induce apoptosis has been linked to their hydrophobicity, so that unconjugated DCA and CDCA are the most powerful inducers[63]. This makes sense, since only hydrophobic BAs can gain access to colonic cells *via* passive diffusion.

Different mechanisms have been involved in the proapoptotic effect of BAs. Direct increase in mitochondrial membrane permeability has been suggested, leading to mitochondrial swelling, release of cytochrome c and apoptosis[64]. Alterations in plasma membrane composition with subsequent up-regulation of caveolin-1 may underlie also the activation of protein kinase C by BAs[65]. DCA and UDCA have opposing effects on PKC translocation, affecting a number of isoenzymes including PKC alpha, epsilon and beta1[66,67]. DCA also acti-

vates NF-κB and AP-1 in colonic epithelial cells, downstream of PKC stimulation[68]. As expected, UDCA has the opposite effect. ERK activation has been involved in DCA proapoptotic effects, inasmuch as genetic or pharmacological inhibition blocks them[69]. In addition, DCA (and CDCA) induce c-Fos and COX2 in intestinal epithelial cells[70].

Despite these observations, it is important to note that epithelial cells may develop resistance to DCA induced apoptosis, which is achieved partly *via* the NO pathway[71] and is correlated with shifted expression of multiple proteins, as assessed by proteomic analysis[72]. Alternatively, additional factors may protect against DCA induced apoptosis, such as glutathione-S-transferase P1-1[73]. The expected result would be the selection of transformed cells, favoring the formation of adenomas and predisposing to subsequent development of cancer.

BAs also exert direct actions that can lead to tumorigenesis. Thus, DCA has genotoxic effects, which are believed to be secondary to induction of oxidative stress in the cell[74], and suppresses the p53 response to DNA damage, an action that is at least partly dependent on ERK signaling[75]. Moreover, inhibition of BRCA-1 by relatively high DCA concentrations contributes to defective DNA repair[76]. Recently DCA and LCA (in conjugated form) were shown to elicit transactivation of the epidermal growth factor receptor *via* interaction with muscarinic receptors and phosphorylation of ERK[77]. Another gene target of DCA *via* ERK is the tumor marker EphA2 receptor protein tyrosine kinase[78]. In general, these actions are not shared by UDCA and may be opposed by it[61,79,80]. Taken together, these data indicate that DCA may behave as a co-carcinogenic and/or cancer promoter agent, which may potentiate the activity of any primary carcinogen or cancer initiator. In addition, DCA may increase tumor invasiveness by activation of beta-catenin signaling[81]. An interesting observation is that FXR expression is diminished in colon cancer[82]. Under these circumstances, FXR-mediated mechanisms involved in the prevention of BA accumulation in these cells could be expected to be completely or partly inactive, thus exacerbating BA-induced effects.

We also count on substantial *in vivo* evidence about the effects of BAs on colorectal cancer. Thus colonic grafts from mice with an APC gene mutation do not develop adenomas if they are removed from the fecal stream[83]. In the standard Min mouse model UDCA produces a dose dependent decrease in the number of intestinal tumors, showing synergism with the cycloxygenase 2 inhibitor sulindac[84]. In the azoxymethane model of cancer associated to chronic colitis, UDCA lowered the multiplicity of colonic adenocarcinoma, while sulfasalazine had no significant effect[85]. Similar results were obtained in the regular (without colitis) azoxymethane model[86]. The chemopreventive effect of UDCA is associated with decreased Ras activation and COX2 expression[87].

This type of observations can be extended to human disease. Thus, a study carried out in patients with primary biliary cirrhosis undergoing surveillance by colonoscopy revealed a non-significant reduction in the prevalence of colorectal adenomas and, more importantly, a lower probability of recurrence (7% *vs* 28% at 3 years, $P = 0.04$)[88]. UDCA lowers cancer mortality (but not incidence) in ulcerative colitis patients with sclerosing cholangitis[89]. In a clinical trial on the secondary prevention of colorectal cancer, UDCA caused a non-significant 12% decrease in recurrence rate but a significant reduction (39%) in the subgroup with high-grade dysplasia[90]. In clinical trials of cancer associated to inflammatory bowel disease, a condition which increases the risk of developing cancer, UDCA has been shown to be beneficial, ranging from a mild chemoprotective effect[91] to a clear decrease in the relative risk of developing colorectal dysplasia or cancer[92]. Mechanistically, UDCA has been reported to reduce mucosal proliferation in cancer naive patients[88] but to have no effect in adenoma patients[93]. From a pharmacokinetic point of view, the main effect of UDCA administration in humans is an increase of luminal (fecal) UDCA/DCA ratio, although DCA absolute levels remain unaltered[94].

An intriguing possibility is that taurine, which is bound to a substantial fraction of the BA pool, contributes to cancer risk. Taurine, which can be released in the intestinal lumen from conjugated BAs due to the metabolic activity of several bacterial strains, is metabolized by the intestinal flora yielding hydrogen sulfite, which increases colonocyte turnover and inhibits butyrate metabolism. Although these cells oxidize efficiently this compound to thiosulfate, taurine derived hydrogen sulfite may be involved in carcinogenesis. In fact, defects in the hydrogen sulfite detoxification pathway may increase the risk of UC, a significant risk factor for colon cancer[95,96]. It is interesting to note that taurine conjugation and sulfite production are increased in meat consumers, thus providing another link to colon cancer[2]. In addition, sulfite promotes DCA generation by bacteria through stimulation of 7α-dehydroxylation.

EFFECT OF BA ON ION TRANSPORT

It is well known that BAs elicit fluid secretion and also increased permeability in the gastrointestinal tract[97-101]. BAs also affect intestinal motility, although this field of study has received relatively little attention[1,102]. The effect of BAs on permeability is primarily due to their detergent action on tight junctions, which is reversible. However, at high BA concentrations epithelial lesions may occur. This effect is to a large extent indirect, induced by intramural reflexes containing nicotinic receptors, but probably it does not involve histamine or nitric oxide pathways[97,103,104]. However, this question is controversial, because in some cases histamine has been suggested to be involved[98].

The secretory effect of BAs has been studied in the small and large intestine, and in both cases the mechanism of secretion appears to be largely indirect[99]. In the small intestine BAs elicit serotonin release by enterochromaffin cells in the mucosa by a Ca^{2+}-dependent mechanism, initiating a neural reflex that stimulates ion secretion, as well as inhibited absorption[105]. In ileal

perfusion experiments permeability and fluid transport were studied in parallel, finding that the effect is dependent on nicotinic receptors in both cases[97,103]. On the other hand, in the colon BA-induced secretion has been claimed to be prostaglandin dependent[106]. More specifically, prostaglandins may account for the early response to BA stimulation observed *in vitro*[98]. Mast cells have also been involved in this process[98]. Indeed, BAs have been shown to induce prostaglandin[107] and histamine secretion[108] *in vitro*. Some of these actions may be secondary to direct mucosal injury[100,109]. Considering the variety of mediators proposed to participate in these events, it is not surprising that multiple intracellular signaling pathways have also been involved.

As with other biological activities of BAs, not all molecular species are equivalent. Dihydroxy BAs, and in particular DCA and CDCA, exhibit prosecretory/antiabsorptive and mucosal damaging effects in the colon, particularly in their unconjugated forms[100,101]. Conversely, other important BAs such as CA and UDCA are generally considered to have no significant bioactivity at this regard. In the small intestine, these differential species-dependent effects are not so well characterized, but they certainly differ from those in the colon. For instance, CDCA is a relatively poor secretagogue in the ileum[110-113]. It should be noted that ileal BA absorption is electrogenic, even in the absence of chloride/bicarbonate secretion, due to the 2:1 stoichiometry of ASBT-mediated Na^+:BA symport[111,114,115].

However, BAs also exert direct actions on intestinal epithelial cells. Using the prototypic T84 cell line TDCA was shown to elicit chloride secretion by a Ca^{2+} dependent mechanism[116]. This pertains to the actions of BAs in the large intestine, since T84 cells have a colonic epithelium phenotype. More recently, BA were described to induce ion secretion *via* transactivation of the cystic fibrosis transmembrane conductance regulator (CFTR)[113]. CFTR is the main chloride/bicarbonate channel in intestinal epithelial cells and is pivotal to ion secretion in the gastrointestinal tract, among other tissues. Transactivation requires apical colocalization of both CFTR and ASBT, which does occur in the distal ileum but also in cholangiocytes. Moreover, CFTR also plays a role in bile flow, as suggested the presence of plugging and dilatation of bile ducts in cystic fibrosis. Interestingly, BA ileal uptake is compromised in this condition, leading to BA waste and diarrhea[113,114,117], suggesting that CFTR has a reciprocal influence on ASBT. Moreover, this provides an additional meaningful link to inhibited BA absorption in intestinal inflammation, where CFTR has been shown to be downregulated, as is ASBT itself[118,119]. Although the relationship between the expression of CFTR and that of ASBT has been previously demonstrated also for other transporters[120], the underlying mechanism has not been elucidated yet.

One interesting question arises as to what is the physiological role of BA-induced ileal and colonic secretion. The simplest explanation is that ileal secretion, which is evoked in normal conditions, may be useful to aid in intestinal propulsion or to prevent the formation of micelles and the consequent epithelial damage during the absorptive process[113]. In contrast, colonic secretion occurs only in pathologic conditions and may be part of a nonspecific mechanism aimed to eliminate invading microorganisms. In addition, BA ileal absorption is compromised in conditions such as irritable bowel syndrome, Crohn's disease, cystic fibrosis and surgical resection (short bowel syndrome)[117], producing diarrhea because of the presence of high (millimolar) concentrations in the colonic lumen. BAs (CDCA, UDCA) can also induce diarrhea in their own right when given to gallstone patients[121,122].

BA AND INTESTINAL INFLAMMATION

Certain BAs have been shown to exert intestinal antiinflammatory actions *in vivo*. Thus UDCA reduces intestinal permeability and oxidative stress in the indomethacin model of ileitis in the rat[123]. Similarly, UDCA counteracts ibuprofen intestinal ulceration in rats[124]. These effects may be related to the actions of BAs on intestinal epithelial cells. Thus DCA induces IL-8 and activates NF-κB in HT29 cells, actions that are opposed by taurine-conjugated UDCA[125,126]. The mechanism for IL-8 induction is probably *via* the classical NF-κB pathway for DCA and *via* RelA phosphorylation in the case of TDCA[126]. The stimulatory effect of DCA is reproduced in other[127,128] but not all cell lines[129]. Thus UDCA might exert antiinflammatory actions in the intestine by inhibiting epithelial stimulation. Conversely, DCA is predicted to aggravate inflammation, but this has not been tested. On the other hand, BAs have also been described to enhance epithelial wound healing, an action dependent on NF-κB activation and the release of transforming growth factor β[130]. This effect is shared by TDCA, DCA and TCA. Unfortunately UDCA was not investigated[130]. It cannot be ruled out that this effect may also form part of the mechanism of action of this beneficial compound.

INTESTINAL APPLICATIONS OF BA

The main clinical application of BAs is in the management of gallstones and cholestasis (primary biliary cirrhosis, cystic fibrosis liver disease, drug induced cholestasis)[88,131,132]. UDCA and to a lesser extent CDCA have been used. Cholylsarcosine is an artificial derivative that has been proposed as an alternative. However, BAs have no current application for intestinal conditions. UDCA has been studied in the clinical setting for cancer chemoprevention as discussed above. Specific artificial BA derivatives have also been studied for chemopreventive application[133]. Interestingly, it may be feasible to increase UDCA intestinal exposure by the use of a specific type of probiotic (living bacteria) that epimerizes CDCA to UDCA within the intestinal lumen[134]. BAs have been used in some cases as a replacement to reduce steatorrhea due to short bowel syndrome or secondary to metabolic genetic diseases, frequently at the price of enhanced diarrhea[135,136]. Conversely, diarrhea without steatorrhea benefits from treatment with ion exchange

resins such as cholestiramine that bind and act as sequestrant of BAs during their intestinal transit[137].

Moreover, BAs are being considered as galenic agents to improve intestinal absorption of drugs compounds such as nucleotides, heparin or insulin[138-140].

CONCLUSION

Owing to their tensioactive properties BAs play an important role in the intestine, facilitating fat digestion and the absorption of lipids and liposoluble vitamins. Efficient intestinal uptake, mainly at the ileum, permits to recover most of the secreted BA molecules, which are sent back to the liver with the portal blood. The existence of the enterohepatic circulation maintains appropriate levels of BAs ready to be used after meals and prevents exposure of other tissues to high levels of these dangerous detergents. In this respect, due to the potential toxicity of BAs and, at the same time, their biological relevance the homeostasis of BAs is tightly regulated, in part by specific plasma membrane receptors and nuclear receptors. The function, transport and regulatory mechanisms regarding BAs and the intestine have been elucidated in great detail, although some questions remain unanswered, such as the exact physiological role of IBABP. Some BA species have peculiar biological or pharmacological effects, which have been characterized to a great extent. Nevertheless, their role in colon cancer and intestinal inflammation requires further study, which is especially interesting considering the potential therapeutical applications.

Abstract

The formation of bile depends on the structural and functional integrity of the bile-secretory apparatus and its impairment, in different situations, results in the syndrome of cholestasis. The structural bases that permit bile secretion as well as various aspects related with its composition and flow rate in physiological conditions will first be reviewed. Canalicular bile is produced by polarized hepatocytes that hold transporters in their basolateral (sinusoidal) and apical (canalicular) plasma membrane. This review summarizes recent data on the molecular determinants of this primary bile formation. The major function of the biliary tree is modification of canalicular bile by secretory and reabsorptive processes in bile-duct epithelial cells (cholangiocytes) as bile passes through bile ducts. The mechanisms of fluid and solute transport in cholangiocytes will also be discussed. In contrast to hepatocytes where secretion is constant and poorly controlled, cholangiocyte secretion is regulated by hormones and nerves. A short section dedicated to these regulatory mechanisms of bile secretion has been included. The aim of this revision was to set the bases for other reviews in this series that will be devoted to specific issues related with biliary physiology and pathology.

Key words: Hepatocytes; Cholangiocytes; Bile flow; Bile acid; Transport

INTRODUCTION

In 1924 Cramer and Ludford[1] published a paper in which they indicated: "liver cells present an unusual problem of secretory cellular activity. The cells of all other secreting glands are functionally unipolar, but hepatocytes are bipolar". Furthermore they wrote that "all the known facts compel a return to the old conception of Claude Bernard that glycogenic function represents an internal secretion of the liver". It is clear that bile secretion is the external one. Finally, regarding this functional bipolarity, those authors reported "it is difficult to form a mental conception of the cellular mechanism which enables one cell to pass two different specific secretions in different directions"; towards sinusoids or towards canaliculi. In that paper they offered morphological evidence that the Golgi apparatus is involved in secretion by hepatocytes in both directions.

Since then our understanding of bile secretion has evolved, and differerent attempts have been made to resolve diverging conceptual theories. In the fifties we learned that bile flow is not the result of a hydrostatic perfusion[2] but the result of osmotic forces[3]. In the sixties we began to distinguish between canalicular and ductular bile[4,5] and showed that bile flow is related to the amount of bile salts secreted to the canaliculi[6]. Shortly after, it was shown that the canalicular bile may be either dependent or independent of bile salts[7,8].

The use of different methods and techniques, such as chronic bile fistula[9], isolated and perfused livers[10], couplets of hepatocytes[11], isolated bile duct units[12], separation of membranes from basolateral and apical domains[13] and several other experimental approaches have helped us to advance our knowledge of the different mechanism involved in the formation of bile flow.

Over the last two decades molecular biology

techniques have allowed the cloning of different proteins expressed in cholangiocytes[14] and/or hepatocytes; such proteins may be involved in the transport of endogenous or exogenous organic anions and cations[15]. The overall role of these transporters depends on whether they are targeted from the Golgi apparatus to the apical or basolateral poles of the epithelial liver cells[16,17]. This may help to resolve the conceptual problem of bipolarity, pointed out by Cramer and Ludford. The discovery of nuclear receptors and plasma membrane receptors for bile acids (BAs)[18,19] has opened a new field of investigation regarding the role of these molecules in the control of secretory and metabolic mechanisms[20,21] that somehow links different aspects of endogenous and exogenous secretions to metabolic functions in parenchymal liver cells. This issue will be the matter of a separate review in this series.

In this introductory review, a brief revision is made of the structural bases that permit bile secretion as well as several aspects related to its composition and flow rate under certain physiological conditions. Knowledge of the role in bile flow generation of cholangiocytes has increased exponentially over the last few years[22,23] and is therefore reviewed here. Finally, a short section dedicated to the regulatory mechanisms of bile secretion is included. This should set the bases for other reviews in this series that will be devoted to specific issues related to biliary physiology and pathology.

STRUCTURAL BASES

The biliary apparatus is a convergent system of canals that begins in the canaliculi, followed by the bile ducts, and ending with the common bile duct (coledochus). Bile secretion depends on the function of membrane transport systems in hepatocytes and cholangiocytes and on the structural and functional integrity of the biliary tree. The hepatocytes, constituting the most abundant liver cell population (65%), generate the so-called primary bile in their canaliculi[4]. Biliary canaliculi are blind tubular structures, with a very high surface/volume ratio that favors-by means of osmotic gradients-the formation of bile flow[5]. Cholangiocytes, which constitute 3%-5% of the liver cells[24], modify the canalicular bile by secretory and reabsorptive processes as bile passes through the bile ducts[22], and they are responsible for approximately 30% of bile volume[25]. In contrast to hepatocytes, where secretion is constant and poorly controlled[26], cholangiocytes secretion is broadly regulated[22,27].

Hepatocytes exhibit structural and functional polarity, three different zones being distinguished in their membranes. The sinusoidal membrane, which faces Disse's space, covers 37% of the total surface of the hepatocyte. There is no lamina basal between hepatocytes and endothelial cells, which are fenestrated and show abundant vacuole of endocytosis and exocytosis, accounting for the intense exchange of substances between blood and hepatocytes[28]. In the lateral membrane (50% of the total surface) there are specialized structures that allow adhesion (desmosomes and tight-junctions) and comunication (gap-junctions) between adjacent hepatocytes. The tight-junctions determine the exchange of fluids and electrolytes between Disse's space and the canalicular space through the paracelular pathway[28]. Together, the sinusoidal and lateral membranes cover the basolateral surface (basolateral membrane). The canaliculi are tiny ducts delimited by the canalicular or apical membrane membrane of two adjacent hepatocytes[28] and they represent a small fraction of the total hepatocyte surface area.

Table 1 Membrane transporters in hepatocytes

Abbreviation	Function
Basolateral membrane (sinusoidal)	
NTCP/SLC10A1[1]	Takes up BAs
OATP/SLC21A[1]	Takes up BAs and OA^- and exports BAs, GSH, HCO_3^-
MRP3/ABCC3	Export OA^- conjugates, GSH
MRP4/ABCC4	Export BAs, GSH
OSTa /OSTb	Organic solute transporter: Exports BAs
NBC4c/SLC4A5[1]	Na^+-HCO_3^- symporter, acid extruder
NHE1/SLC9A1[1]	Na^+/H^+ exchanger, acid extruder
SK2	Potassium channel, potassium efflux
SLC12A2	Na^+-K^+-Cl^- symporter: Sodium, potassium, chloride uptake
Apical membrane (canalicular)	
BSEP/ABCB11[1], formerly SPGE	Bile salt export pump
MRP2/ABCC2[1], formerly cMOAT	Export non BAs OA^-, GSH
MDR1	Efflux of lipofilic cations
MDR3/ABCB4	Phospholipid flipase
ABCG5/ABCG8	Export sterols
AE2/SLC4A2[1]	Cl^-/HCO_3^- anion exchanger: Acid loader
Cl- channel[1]	Export chloride
AQP8[1]	Water channel
NHE3/SLC9A3[1]	Na^+/H^+ exchanger: Acid extruder

[1]Transporters relevant to bile flow under physiological basal conditions.

Currently, the molecular biology and genetic characteristics of many transporters of the basolateral and apical membranes are known (Table 1). Such transporters take part in the transfer of substances between blood and hepatocytes and between hepatocytes and bile, respectively. Likewise, many transporters expressed in cholangiocyte membranes are also known (Table 2). In this review only those transporters with a clear role in the genesis of physiological bile flow are addressed. More comprehensive reviews are available elsewhere[29-31].

The Golgi complex and the network of microtubules and microfilaments are important structures for the exocrine function of hepatocytes and also for the mechanisms of bile formation. The pericanalicular space, free of cellular organelles, contains actin microfilaments that reach to the microvilli of the canalicular membrane. Microtubules are distributed throughout the cytoplasm. The vesicles from the Golgi complex are vehicles for substances to be excreted in bile as well as plasma proteins, including transporters, to be placed at apical or basolateral membranes[17,32]. Newly synthesized apical

Table 2 Membrane transporters in cholangiocytes: Abbreviations and function

Abbreviation	Function
Basolateral membrane	
NDCBE/SLC4A8[1]	Na^+-dependent Cl^-/HCO_3^- exchanger: Import HCO_3^- and Na^+, Export H^+ and Cl^-
NHE/SLC9[1]	Na^+/H^+ exchanger: Acid extruder
AQP4[1]	Water channel
tASBT/SLC10A2	Export BAs and Na^+
SK2	Potassium channel, potassium efflux
SLC12A2	Import Na^+-K^+-$2Cl^-$
MRP3/ABCC3	Export OA^- conjugates, GSH
MRP4/ABCC4	Export BAs, GSH
Apical membrane	
AE2/SLC4A2[1]	Cl^-/HCO_3^- anion exchanger: Acid loader
CFTR[1]	Cl^- channel: Export chloride
AQP1[1]	Water channel
NBCe/NBC4/SLC4A5	Na^+-HCO_3^- symporter: Acid extruder
ASBT/SLC10A2	BAs-Na^+, symport: Uptake of BAs and Na^+

[1]Transporters relevant to bile flow under physiological basal conditions.

ABC (ATP-binding cassette) transporters are transferred from the Golgi apparatus to the canalicular membrane[16]. This traffic is dependent on intact microtubule and microfilament systems[17,32].

The hepatocytes and the biliary system are closely related to the blood vascular elements, both forming a functional unit: the hepatic acinus[33]. The blood flow generates concentrative gradients of oxygen and nutrients along the sinusoids. These gradients allow a division of the hepatic acinus into three different zones according to its distance from the portal space: the periportal or zone Ⅰ, zone Ⅱ and the centrilobular or zone Ⅲ. Moreover, these gradients cause functional heterogeneity between the hepatocytes of the different zones[34,35].

BILE COMPOSITION

Bile mainly consists of water, in which there are organic and inorganic substances in suspension, dissolved, or in equilibrium between both states. In bile samples, collected from the human common bile duct, the concentrations of the inorganic electrolytes sodium (Na^+), potassium (K^+), calcium (Ca^{2+}) and bicarbonate (HCO_3^-) are slightly higher than their plasmatic concentrations, whereas biliary chloride (Cl^-) concentrations are slightly lower than these found in plasma. BAs concentrations range between 2 and 45 mmol/L. The concentrations of biliary pigments range from 50 to 200 mg/100 mL. Proteins and peptides, such as glutathione, are also found in bile[36]. It is also possible to detect glucose and small amounts of endogenous substances such as thyroid and steroid hormones[37]. Human bile is rich in lipids. Thus, phospholipids concentrations seem to range between 25 and 810 mg/100 mL, whereas these of cholesterol vary between 60 and 320 mg/100 mL, with average ratios of phospholipids to BA of 0.3 and cholesterol to BA of 0.07 (Figure 1). Humans differ from other animals in the fact that our species eliminates cholesterol from the body to a greater extent as cholesterol itself rather than by converting it into BAs[38].

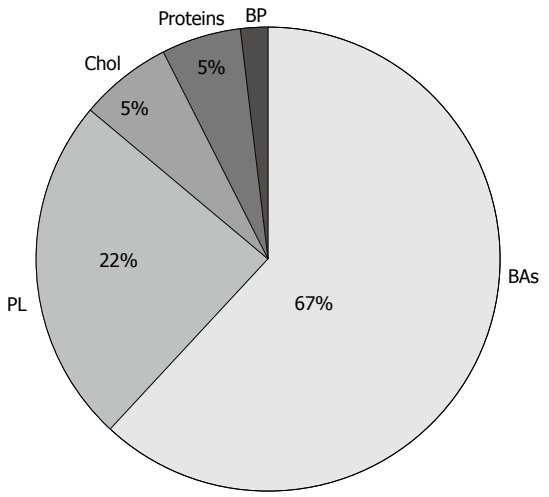

Figure 1 Organic composition of bile. Perceptual distribution of BAs, Phospholipids (PL), Cholesterol (Chol), Proteins and biliary pigments (BP).

BILE FLOW

The mean basal flow of bile in humans is approximately 620 mL/d. One portion of this flow (220 mL/d, 35%) is determined by the secretion of BAs and is called the BAs-dependent canalicular fraction -BADFc-[8]. In addition, there is a linear correlation between the amount of BAs secreted into bile and the amount of water that follows them (7-25 mL/mmol). This choleretic activity of individual BAs is species-dependent and varies according to its chemical structure, conjugational condition and relative concentrations. Choleretic activity is lower for BA species that have a higher tendency to form micellar aggregates in bile[39]. These findings explain the different contributions of BADFc to the bile flow among species (30%-60%)[3,40]. Certain BAs (ursodesoxycholic and the nor-derivatives of ursodesoxycholic and quenodeoxycholic acids) generate a volume of bile higher than that expected from their osmotic force. In order to explain such hypercholeresis, it has been proposed that these BAs would be reabsorbed, in their protonated form, by cholangiocytes. From there, they would be effluxed to blood to reach the sinusoids, where they would be taken up again by hepatocytes and re-secreted to bile, increasing the magnitude of the BADFc[41,42]. This phenomenon, so-called "the cholehepatic shunt pathway" is discussed below in the section devoted to ductular processes.

The amount of canalicular bile independent of the osmotic force of BAs (235 mL/d, 38%) has been designated the BA-independent canalicular fraction (BAIFc)[7,8]. Quantitatively, in humans the BAIFc represents up to a 40% of total primarily formed bile[43]. In other species it varies between 30% and 60%[5,40,44]. The ductular fraction of bile flow has a high value (30%) in humans[25], although it also varies among different species[8,24].

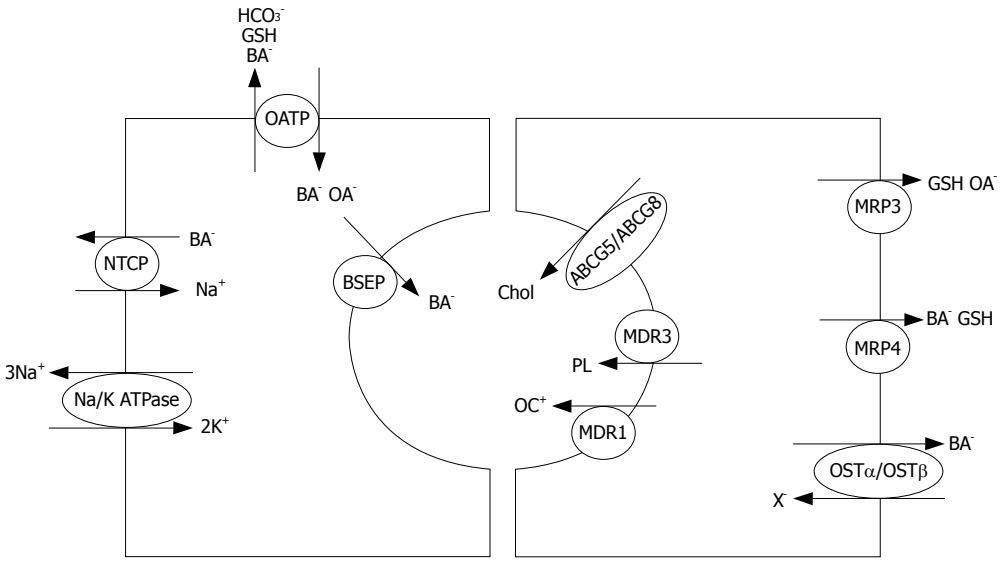

Figure 2 Sinusoidal transport and canalicular secretion. Left: BA dependent canalicular fraction of bile (BADFc). Right: canalicular and sinusoidal secretion of anionic and cationic organic molecules.

THE BA-DEPENDENT CANALICULAR FRACTION (BADFc)

BAs are supplied either by synthesis in liver cells or from the sinusoidal blood as part of *de* enterohepatic circulation (EHC).

Sinusoidal uptake

The BAs in sinusoidal blood are efficiently taken up by hepatocytes from Disse's space despite being highly albumin bound, due to the existence in the basolateral membrane of transporters[45,46]. This uptake is carried out against an electrochemical gradient, is saturable[37] and depends on the structure of the BA. Thus, it is more efficient for trihydroxyl- than for dihydroxyl-BA and for conjugated more than for unconjugated BAs[47]. The sodium taurocholate-cotransporting polypeptide (NTCP), the main Na^+-dependent BAs transporter[30,48] is only expressed in the basolateral membrane[49]. The uptake of BAs by Na^+-independent mechanisms seems to be mediated by less specific transporters, known as organic anion-transporting polypeptides (OATPs), which exchange these molecules for other anions, such as HCO_3^-, glutathione (GSH) or even other BAs[30,47]. These transporters may take up BAs (mainly non conjugated forms), endogenous OA^- (thyroid hormones, monoconjugated bilirubin) and xenobiotic compounds (toxins, drugs, food components, *etc*)[50]. The quantitative relevance of the different isoforms of these transporters in sodium-independent BA uptake by hepatocytes is still not completely understood (Figure 2). The heterodimeric protein OSTalpha/OSTbeta is expressed at the basal membrane of hepatocytes and cholangiocytes[51]. This is a sodium-independent BA transporter that may play a role in BA efflux from hepatocytes toward blood when these compounds get accumulated in cholestatic conditions. Moreover, in cholangiocytes, in addition to play a similar role, this transporter may also be involved in the cholehepatic shunting of BAs.

Transcellular transport

In order to explain the transit of BAs from the sinusoidal membrane to the pericanalicular region, two different, not mutually excluding, mechanisms have been proposed: (1) simple diffusion of BAs bound to intracellular proteins[52]; (2) and/or vesicular transport of BAs driven by cytoskeleton contractile activity[53,54]. Two arguments have been raised against the role of the second mechanism. One is that hepatic transit of labeled BAs is too fast[54]. The second one is that the baseline secretion of BAs is not modified by microtubules disruption[53]. However, the overload of BAs intensify the vesicular trafficking from the Golgi complex to the pericanalicular zone[55], and under these circumstances the alteration in the functional integrity of the cytoskeleton results in impaired BA secretion[56] and subsequently cholestasis[57].

The quantity of ABC transporters in the apical membrane is regulated by the amount of biliary components available for secretion[58,59]. The regulated intracellular vesicular traffic of canalicular ABC transporters[59,60] is crucial for normal bile secretion. The bile salt export pump (BSEP, formerly SPGE, a sister of P-glycoprotein) is the main, if not the only, canalicular BA transporter[61], and it is also located in subcanalicular vesicles that may act as an intracellular pool. It is therefore probable that the impaired secretion of BAs observed in overloaded conditions would be an indirect result of the distortion of the increased vesicular traffic of transporters to the canalicular membrane[56]. These and other studies[17,62] have established not only the actual role of vesicular trafficking in hepatocytes, but also that a specific vesicle trafficking machinery is required for membrane polarity. The overall functions based on hepatocyte polarity are not attributable to the mere presence of transporters in both poles of these cells[63] but also to their intracellular trafficking and temporary anchorage to the different hepatocyte membranes (Figure 2).

Canalicular secretion

At the end of the eighties it was believed that BAs were extruded to the canalicular lumen by an electric gradient, being negative inside hepatocytes (around -37 mV)[64]. However, this gradient is not strong enough

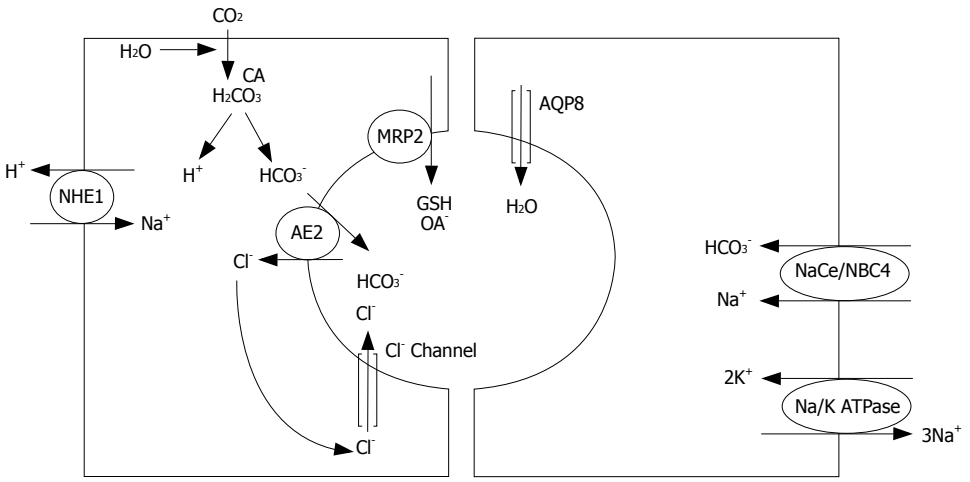

Figure 3 Sinusoidal transport and canalicular secretion. Left: BA independent canalicular fraction of bile (BAIFc). Right: Water an electrolyte movement. CA: carbonic anhydrase.

to impose higher concentrative differences, such as BAs up to 200 times more concentrated in canaliculus than in hepatocyte[26]. It is now known that the secretion of BAs to the canalicular lumen is a saturable phenomenon mediated by a transporter[65]. The energy-dependent bile secretion of BAs is mediated by BSEP[30,58,63]. This export pump was cloned in1998[54] and since them it has been studied in detail[66,67]. It is currently known that BSEP transports both conjugated and unconjugated BAs, sulfated lithocholyl conjugates[68], and a variety of drugs[69]. Other apical ATP binding cassette (ABC) transporters are required: multidrug resistance-P glycoprotein 3 (MDR3) for phospholipids, MDR1 for lipofilic cationic drugs, multidrug resistance-associated protein 2 (MRP2) for non-BA organic anions[70,71] and the heterodimeric protein ABCG5/G8 involved in the secretion of cholesterol and other sterols, such as fitosterols[72] (Figure 2).

BAIFc

The osmotic activity of BAs is not the only determinant of bile flow. Certain substances with osmotic activity, both endogenous and exogenous, may also play a role in canalicular bile generation, without modifying the BA secretion rate[73]. In certain situations, such as diabetes mellitus, there appears to be a reduction in bile flow, without impairment in BA secretion[74]. Glutathione and bicarbonate seem to play a similar quantitative role in BAIFc formation[13].

Multidrug resistance-associated protein 2 (MRP2, formerly cMOAT, canalicular multispecific organic-anion transporter) transports a broad range of amphipathic anionic substrates, including glutathione conjugates, glucuronosyl bilirubin and sulfated BA derivatives[63]. The ATP-dependent canalicular excretion of GSH is one of the main forces responsible for the generation of BAIFc[75]. Under basal conditions, the biliary levels of this tripeptide reache up to 5 mmol/L. This is a sufficient amount to account for the formation of bile by osmotic force[36]. Rats heterozygous and homozygous for inactivating mutations in *Mrp2* secrete less GSH to bile, 37% and 99% below control levels, respectively[76].

The secretion of HCO_3^- is carried out by the canalicular antiporter named AE2[13,77]. This system functions in connection with the canalicular water channel aquaporin (AQP8) and the apical chloride channel, the cystic fibrosis transmembrane regulator (CF^-TR)[13,77]. However, the force that maintains favorable Cl^- gradients remains to be defined. The AE2 antiporter requires the existence of suitable internal levels of HCO_3^- through cotransport of the anion with sodium in the basolateral membrane by the NBCe symporter[78,79] and/or by its formation activated by the carbonic anhydrase (CA) pathway[80]. This latter mechanism is linked to H^+ extrusion *via* Na^+/H^+ antiporters (NHE) working in both the basolateral (NHE1)[81] and canalicular (NHE3)[82] membranes. In turn, sodium cations are extruded *via* a sodium pump. This is why bicarbonate secretion is said to be is a concentrative mechanism that indirectly requires metabolic energy. Canalicular bicarbonate excretion is upregulated by glucagon[83], which also enhances AQP8-mediated water permeability at the canaliculi[84]. These choleretic effects are microtubular-dependent and involve mobilization of intracellular vesicles[83,84]. The other osmotically active inorganic components of bile are not as important as HCO_3^- in generating BAIFc[37,85] (Figure 3).

DUCTULAR PROCESSES

Cholangiocytes exert a series of reabsorptive and secretory processes that dilute and alkalinize the primary (canalicular) bile during its passage along the biliary tract[24,86,87]. Cholangiocytes secrete fluid, HCO_3^-, Cl^- and carry out the reabsorption of glucose, BAs (cholehepatic shunt), glutamate, conjugated bilirubin, BSP, and small OAs^-[87]. As a result, osmotic gradients generate an extra flow of bile known as the ductular BA-independent fraction (BAIFd). These processes are regulated by bile constituents, nerves and hormones[86,88]. The biliary transport of bicarbonate is a relevant function of the cholangiocytes. An electroneutral sodium-independent Cl^-/HCO_3^- exchange activity (AE2) has been observed in the apical membrane of cholangiocytes[77]. There is also a cAMP-responsive Cl^- channel (CFTR) that is coordinated with AE2 to play a role in biliary excretion of HCO_3^-[27,89]. These apical fluxes of anions, in the

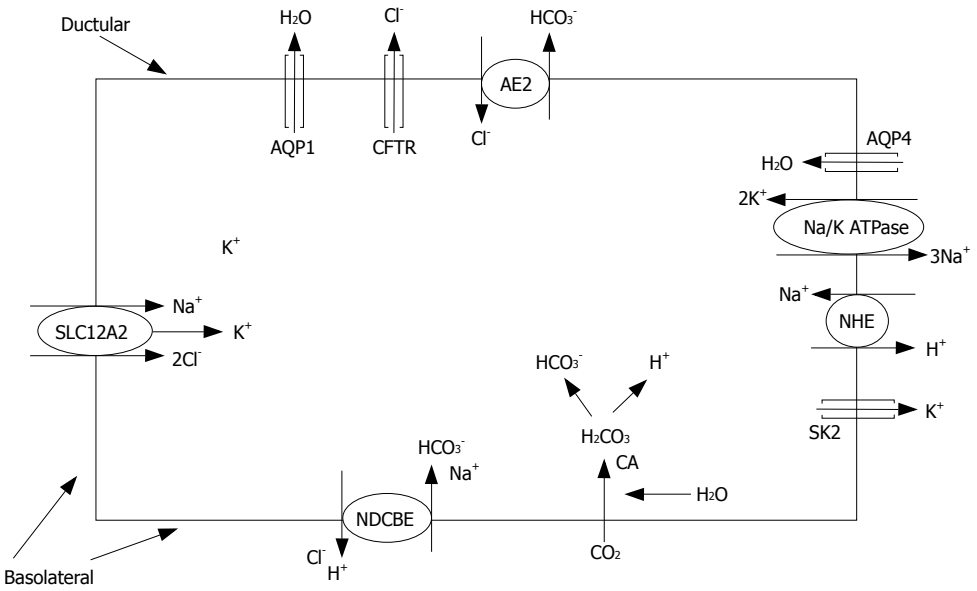

Figure 4 Ductular secretion and reabsorption. BA independent ductular fraction of bile (BAIFd).

presence of aquaporins (AQP1) contribute to the BAIFd[90]. This coordinated function became more evident after discovering that a pool of AE2, CFTR and AQP1 is stored in cholangiocyte intracellular vesicles, which are co-redistributed to the apical membrane under secretin stimulation[90]. The CA pathway and an Cl^-/HCO_3^- exchanger provide the required level of HCO_3^- and the H^+ is subsequently extruded by a coupled carrier-mediated basolateral H^+/Na^+ exchanger (NHE)[91,92]. In humans, the import of HCO_3^- into cholangiocytes occurs mainly through electroneutral Na^+-dependent Cl^-/HCO_3^- anion exchange (NDCBE)[93] (Figure 4).

Lipophilic, unconjugated BAs, such as ursodeoxycholic acids, are passively reabsorbed in cholangiocytes, which constitutes the first essential step in the cholehepatic shunt model[94]. An active transport for conjugated BAs has been described in rat cholangiocytes[95], which expands the idea of cholehepatic shunting of BAS. With the identification of apical (ASBT) and basolateral (tASBT) BAs carriers in cholangiocytes[96], the hypothesis of the cholehepatic BA shunt received additional support[97].

Regulatory factors

Secretin receptors (SCTRs) are exclusively expressed at the basolateral membrane of cholangiocytes[98] and when they are stimulated intracellular levels of cAMP are increased[99]. The pool of AE2, CFTR and AQP1 stored in intracellular vesicles is redistributed to the apical membrane under cAMP or secretin stimulation[90] and secretin stimulation activates CFTR through cAMP. Both effects together explain the increase in HCO_3^- efflux[37]. Most experiments with rats and rabbits have used animals with induced bile duct proliferation[100], since normal rats[23,90] and rabbits[101] respond very poorly to secretin. ASBT activity increases acutely upon secretin stimulation[102], which may accentuate the cholehepatic BAs shunting in the postprandial period.

On cholangiocytes, acetylcholine increases both secretin-stimulated cAMP synthesis and Cl^-/HCO_3^- exchanger activity[103,104]. Vagotomy in BDL rats inhibits secretin-stimulated ductal secretion and decrease cholangiocyte cAMP levels[88]. Bombesin can act either by increasing the secretin release in dogs[105], or inducing ductal secretion with activated Cl^-/HCO_3^- exchange *via* secretin-independent mechanisms in isolated rat cholangiocytes[86]. VIP increases secretin-stimulated bile flow and HCO_3^- excretion in humans[106]. Dopamine, somatostatin and, gastrin to some extent, inhibit basal and secretin-stimulated bicarbonate-rich choleresis[86,107,108].

Abstract

AIM: To clarify the expression and role of Ephrin receptor A4 (EphA4) in gastric cancer in relation to clinicopathological characteristics and the expression of fibroblast growth factor receptor 1 (FGFR1) and ephrin ligands.

METHODS: Eleven gastric carcinoma cell lines, 24 paired surgical fresh specimens of gastric adenocarcinoma and adjacent nontumor tissue, 74 conventional formalin-fixed, paraffin-embedded tumor specimens, and 55 specimens spotted on tissue microarray (TMA) were analyzed. Reverse transcription-PCR (RT-PCR), real-time RT-PCR, immunohistochemistry, and cell growth assays were performed.

RESULTS: Overexpression of EphA4 mRNA expression was observed in 8 (73%) of 11 gastric cancer cell lines and 10 (42%) of 24 gastric cancer tissues. Overexpression of EphA4, analyzed by immunohistochemistry, was observed in 62 (48%) of 129 gastric cancer tissues. EphA4 overexpression, at the protein level, was significantly associated with depth of invasion and recurrence. EphA4 overexpression was also correlated with FGFR1 overexpression. Patients with EphA4-positive cancer had significantly shorter overall survival periods than did those with EphA4-negative cancer (P = 0.0008). The mRNAs for ephrin ligands were coexpressed in various combinations in gastric cancer cell lines and cancer tissues. Downregulation of EphA4 expression by siRNA in EphA4-overexpressing gastric cancer cell lines resulted in a significant decrease in cell growth.

CONCLUSION: Our results suggest that overexpression of EphA4 plays a role in gastric cancer.

Key words: Ephrin receptor A4; Gastric cancer; Ephrin; Fibroblast growth factor receptor 1; Prognosis

INTRODUCTION

Gastric cancer is the fourth most common cancer and the second leading cause of cancer-related death in the world[1]. Genetic and epigenetic alterations play important roles in the development and progression of gastric cancer[1,2]. Considerable attention has been given to the potential role of tyrosine kinases in gastric cancer[3-6].

The Ephrin (Eph) receptors constitute the largest family of tyrosine kinase receptors[7-10]. The Eph receptors interact with a second family of cell surface-anchored ligands, ephrins. The Eph receptors and ephrin ligands are divided into the two subclasses, A and B. Type A ephrins and type B ephrins are attached to the plasma membrane *via* glycosyl phosphatidyl inositol linkages and transmembrane sequences, respectively.

Eight EphA receptors (EphA1-A8), five EphB receptors (EphB1-B4, B6), five type A ephrins (EphfrinA1-A5), and three type B ephrins (ephrinB1-3) are known in the human genome. EphA receptors usually bind to type A ephrins and EphB receptors binds to type B ephrins. The combinations for the Eph receptors and ephrin ligands are considered to occur in a tissue-type and/or cancer-type specific manner[7-10].

The potential role of Eph receptor and ephrin ligand family in human cancer is receiving increasing attention. Altered expression patterns of Eph/ephrin have been correlated with tumor behavior, such as invasiveness, vascularization, metastatic potential, and patients' prognosis[7-10]. Generally, the upregulation of Eph/ephrin has been reported in various types of cancer[7-10]. Overexpression of EphB2, ephrinB1, EphA2, and ephrinA1 has been reported in gastric cancer[11-13]. On the other hand, the concept that Eph receptors are oncogenes needs a new look on the basis of recent findings of downregulation of Eph receptors in certain types of cancer[14-17]. However, because functions of Eph receptors can overlap, loss of one receptor can be partially compensated for by other Eph receptors that have similar ligand-binding specificities and expression patterns[7].

Thus, it seems important to characterize the role of Eph/ephrin with specific characteristics. In this regard, EphA4 is an engaging target for research. Compared with other Eph receptors, EphA4 is distinguished by its ability to bind to both type A ephrins and most type B ephrins[7-10]. Indeed, overexpression of EphA4 has been recently reported in human prostate and pancreatic cancers[18,19]. Moreover, it has been reported that EphA4 forms a hetero receptor complex with fibroblast growth factor receptor (FGFR) 1 and that EphA4/FGFR1 complex potentiates FGFR-mediated downstream signal transduction. It is well known that FGFR signal pathway plays important roles in gastric cancer[20,21].

Thus, it seems important to clarify the relevance of EphA4 in gastric cancer. Using reverse transcription-PCR (RT-PCR), real-time RT-PCR, immunohistochemistry, and cell growth assays, we analyzed the expression and role of EphA4 in gastric cancer, in relation to clinicopathological characteristics and the expression of FGFR1 and ephrin ligands.

MATERIALS AND METHODS

Cell culture

Gastric carcinoma cell lines, NUGC3, NUGC4, SNU1, SNU638, MKN28, MKN45, MKN74, KATOⅢ, HGC27, GC1Y, and AZ521 were purchased from the Japanese Cancer Research Resources Bank (Tokyo, Japan), Riken Cell Bank (Tokyo), or the American Type Culture Collection (Rockville, MD), and were grown in Dulbecco's modified Eagle's medium or RPMI1640 supplemented with 10% fetal bovine serum (Cansera, Ontario, Canada). Cells were maintained at 37℃ in an atmosphere of humidified air with 5% CO_2.

Tissue samples

Twenty-four paired surgical fresh specimens of Japanese gastric adenocarcinoma and adjacent nontumor tissue and 74 formalin-fixed, paraffin-embedded tumor specimens were obtained from Japanese patients who had undergone surgical treatment. pTNM stages were as follows: 14 stage I cancers; 24 stage Ⅱ cancers, 33 stage Ⅲ cancers, and 3 stage Ⅳ cancers. No patients received chemotherapy or radiation therapy before surgery. No patients received adjuvant treatment until diagnosis of the recurrence of cancer. Recurrent patients received chemotherapy (fluorouracil, S-1, or S-1/cisplatin). An analysis of the effect of chemotherapy for recurrent patients showed no significant effect on survival in this study (data not shown). Tissue microarray (TMA) of Korean gastric cancer tissues was purchased from SuperBioChips Laboratories (Seoul, Korea). pTNM stages were as follows: 23 stage I cancers, 13 stage Ⅱ cancers, 9 stage Ⅲ cancers, and 10 stage Ⅳ cancers. Each fresh tissue specimen was divided into two pieces after resection. For total RNA extraction, one sample was immediately frozen in liquid nitrogen at the time of surgery and stored at -80℃ until extraction. The other sample was processed for pathological examination using hematoxylin and eosin staining for the evaluation of the tumor cell content. Only specimens containing more than 80% tumor cells were used for analysis. The tumor-node-metastasis (TNM) system of the American Joint Committee on Cancer and the International Union against Cancer was used for the pathologic diagnosis and classification of variables. Informed consent was obtained from each patient.

Semiquantitative RT-PCR and real-time RT-PCR

Semiquantitative RT-PCR was done as described previously[22]. Briefly, total RNA was extracted from cancer cell lines and tissue specimens using Trizol reagent (Invitrogen, Carlsbad, CA, USA) according to the manufacturers' instructions. Extracted RNA was treated with DNase I (Roche, Mannheim, Germany) and reverse-transcribed to cDNA using random hexamers with Superscript Ⅱ reverse transcriptase (Invitrogen). PCR amplification was performed with published PCR primers. The primer sequences used were 5'-CGTTATGTGGGAAGTGATGTCATA-3' and 5'-TTCCTCAATGGCTTTAATCACA TCT-3' for EphA4[9] and 5'-TCCTAGTGCCACAATCCCAGTCCT-3' and 5'-AGGGCATTAGAGGCCCAGAGA-3' for FGFR1[23]. The other primer sequences were provided by Dr. Nakagawa[19]. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) served as an internal control of the reaction. Standard curves for semiquantitative RT-PCR were drawn as described previously[22]. PCR products were resolved on 2.5% agarose gels and signal intensities were quantified using a computer imaging system. All reactions were controlled without reverse transcriptase. The levels of gene transcripts were quantified as the ratio of the intensity of the target gene to the intensity of GAPDH. Overexpression was judged when the target

gene expression in the tumor sample was at least 3 times higher than that in the corresponding normal sample. In cases without target gene expression in the corresponding normal sample, overexpression was judged when the target gene expression in the tumor sample was at least 3 times higher than the highest ratio among the 24 normal samples analyzed. Downexpression was judged in a reversed way. Real-time RT-PCR for EphA4 was done by using TaqMan real-time PCR system as described previously[9]. The amount of EphA4 mRNA was displayed as the x-fold gene expression compared with the corresponding normal tissue.

Immunohistochemistry

Five mm-thick sections of formalin-fixed and paraffin-embedded tissue and TMA were dewaxed in xylene and rehydrated in alcohol. The sections were then heated to 105℃ in target retrieval solution (DakoCytomation, Carpinteria, CA) in an autoclave for 10 min for antigen retrieval. Endogenous peroxidase activity was suppressed using a solution of 3% hydrogen peroxide in methanol for 5 min. After being rinsed twice in phosphate-buffered saline (PBS), the sections were incubated for 18 h at 4℃ with a rabbit anti-EphA4 polyclonal antibody (Santa Cruz, CA, USA) or a mouse anti-FGFR1 monoclonal antibody (Abcam, Cambridge, UK). The antibodies were diluted in antibody diluent with background reducing components (0.05 mol/L Tris-HCl buffer containing 0.1% Tween and 0.015 mol/L sodium azide, DakoCytomation). Normal rabbit or mouse immunoglobulins were substituted for each primary antibody as negative controls. After washing 3 times in PBS, the sections were treated with biotinylated goat anti-rabbit or anti-mouse immunoglobulin (DakoCytomation) for 10 min and then with horseradish peroxidase-avidin complex, diluted as recommended by the manufacturer, for 10 min. The slides were then washed in PBS and developed in 0.05 mol/L Tris-HCl (pH 7.5) containing 0.6 mg/mL 3-3' diaminobenzidine at room temperature. The sections were counterstained in Mayer's hematoxylin and mounted.

siRNA transfection and cell growth analysis

siRNAs for EphA4 mRNA (Silencer® Pre-designed siRNA) were purchased from Ambion (Austiin, TX). Unrelated nonspecific siRNAs (Silencer® Negative Control siRNA) were used as control. siRNA transfection was performed following manufacturers' instructions. After incubation for 72 h, siRNA-transfected SNU638 and AZ521 cells were analyzed by RT-PCR to validate knockdown effect on EphA4. These cells were used for cell growth assay. Tumor cell growth assay was done using the tetrazolium compound WST-8 (Cell Counting Kit-8; Dojindo Laboratories, Kumamoto, Japan).

Statistical analysis

The results were assessed for associations with clinicopathological parameters using the following statistical tests: Student's *t* test for age, the Mann-Whitney test for depth of invasion, lymph node metastasis, and pTNM stage, and the Chi-square test or Fisher's exact test for the remaining parameters. Survival analysis was carried out for 71 patients (pTNM stages were as follows: 14 stage Ⅰ cancers; 24 stage Ⅱ cancers and 33 stage Ⅲ cancers). Since information on preoperative and postoperative treatment was not available for 55 specimens spotted on TMA, these patients were not involved in survival analysis. Cumulative survival rates were calculated by the Kaplan-Meier method. The difference between survival curves was analyzed by the logrank test. Multivariate analysis was performed using Cox's proportional hazard model. A *P* value of less than 0.05 was considered significant.

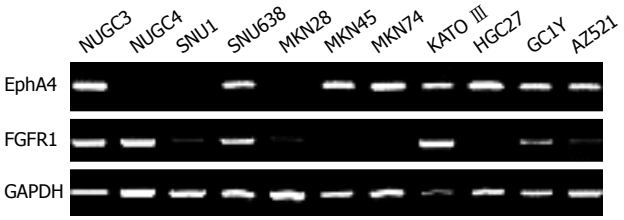

Figure 1 RT-PCR analysis of the EphA4 and FGFR1 in gastric cancer cell lines.

RESULTS

Expression of EphA4 and FGFR1 mRNA in gastric cancer cell lines

Expression of EphA4 mRNA was analyzed in 11 gastric cancer cell lines by RT-PCR. EphA4 expression was detected in 8 (73%) of 11 gastric cancer cell lines (Figure 1). There was no correlation between EphA4 positivity and histopathology. Expression of FGFR1 mRNA was detected in 8 (73%) of 11 gastric cancer cell lines (Figure 1). Expression levels of FGFR1 were low in SNU1, MKN28, GC1Y, and AZ521. There was no correlation between FGFR1 positivity and histopathology. Five of 11 gastric cancer cell lines expressed both EphA4 and FGFR1.

Overexpression of EphA4 and FGFR1 mRNA in gastric cancer tissues

Expression of EphA4 mRNA was analyzed in 4 paired gastric cancer and corresponding normal tissues by both real-time RT-PCR and semiquantitative RT-PCR. The mRNA expression of EphA4, analyzed by real-time RT-PCR, was upregulated in cancer tissues compared with normal tissues (Figure 2A). Concordant results were obtained by semiquantitative RT-PCR (data not shown). Therefore, expression of EphA4 mRNA was further analyzed in 20 paired gastric cancer and corresponding normal tissues by semiquantitative RT-PCR. In 10 (42%) of total 24 cases, the mRNA expression of EphA4 was upregulated in cancer tissues compared with normal tissues (Figure 2B). Similarly, in 12 (50%) of 24 cases, the mRNA expression of FGFR1 was upregulated in cancer tissues compared with normal tissues (Figure 2B). Overexpression of EphA4 was significantly correlated

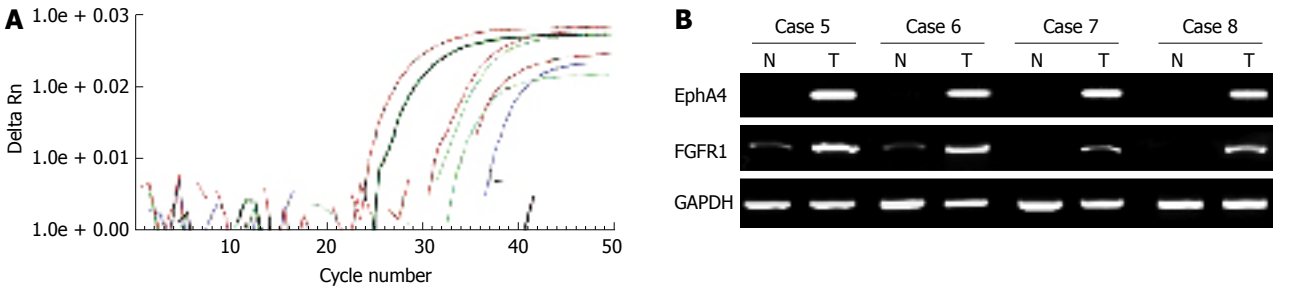

Figure 2 Real time RT-PCR (**A**) and semiquantitative RT-PCR (**B**) analysis of the EphA4 in gastric cancer tissues. **A**: From left to right; case 1 tumor, case 2 tumor, case 3 tumor, case 4 tumor, case 3 normal, case 1 normal, and case 2 normal; **B**: N and T = matched samples from non-tumor and tumor tissue, respectively.

with FGFR1 overexpression ($P < 0.01$; data not shown).

Immunohistochemical expression of EphA4 and FGFR1 in gastric cancer tissues

Figure 3 shows representative results of immunohistochemistry for EphA4 in gastric cancer tissues. The EphA4 protein was strongly expressed in the cytoplasm and/or membrane of cancer cells, whereas normal gastric epithelium from the same patient showed no, or very weak, expression of EphA4 protein. There was no detectable immunoreactivity with the control normal rabbit immunoglobulins (data not shown). EphA4 expression was positive in 62 (48%) of the 129 cases. EphA4 overexpression was confirmed in those cases in which EphA4 mRNA overexpression was shown by using RT-PCR. The relationship between EphA4 positivity and clinicopathological characteristics was then analyzed. EphA4 positivity was significantly associated with depth of invasion and recurrence. Moreover, patients with EphA4-positive cancer had significantly shorter overall survival periods than did those with EphA4-negative cancer ($P = 0.0008$, Figure 4). Multivariate analysis, including EphA4 expression, depth of invasion, lymph node metastasis, and vascular invasion, showed that EphA4 expression was an independent marker of poor survival for gastric cancer (relative risk 2.1, 95% confidence interval 1.0-4.2, $P = 0.038$).

Immunohistochemistry for FGFR1 was done in 55 gastric cancer samples spotted on TMA and six conventional sections of gastric cancer. FGFR1 protein was strongly expressed in the cytoplasm and/or membrane of cancer cells, whereas normal gastric epithelium from the same patient showed no, or very weak, expression of FGFR1 protein. FGFR1 protein was overexpressed in 37 (61%) of 61 gastric cancer specimens. There was no significant correlation between FGFR1 expression and clinicopathological characteristics. FGFR1 expression was significantly correlated with EphA4 expression ($P = 0.009$).

Expression of ephrin ligands in gastric cancer cell lines and tissues

Expression of ephrin A1-A5 and ephrin B1-B3 mRNA was analyzed in 11 gastric cancer cell lines by RT-PCR. The extent of expression of each gene was considerably differed among the cell lines (Figure 5). Expression of ephrin A2 was relatively concordant with that of EphA4. The relative amounts of the transcripts of ephrin ligands also varied considerably among tumor tissue samples. None of the expression of ephrin ligands was clearly concordant with that of EphA4 (data not shown).

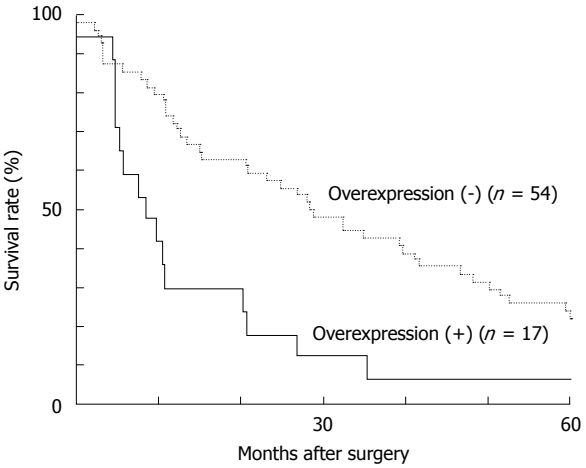

Figure 4 Kaplan-Meier survival curves of patients with gastric cancer according to the expression of EphA4 ($P = 0.0008$).

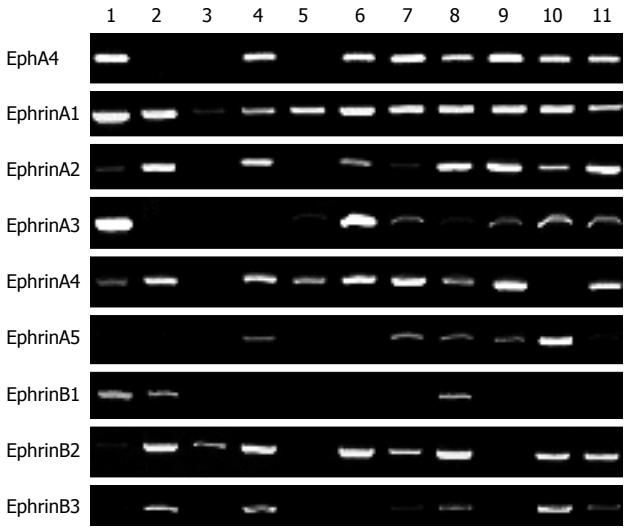

Figure 5 RT-PCR analysis of the type A ephrins and type B ephrins in gastric cancer cell lines. 1: NUGC3; 2: NUGC4; 3: SNU1; 4: SNU638; 5: MKN28; 6: MKN45; 7: MKN74; 8: KATOIII; 9: HGC27; 10: GC1Y; 11: AZ521.

Suppression of cell growth by EphA4 siRNA treatment

Cell growth assay after treatment with specific siRNA for EphA4 gene was done to assess the role of EphA4 expression in gastric cancer cells. Transfection with siRNA resulted in over 80% inhibition of mRNA expression (data not shown). Transfection with EphA4-specific siRNA significantly suppressed cell growth of SNU638 and AZ521cells compared with control siRNA-transfected counterparts ($P = 0.008$; data not shown).

DISCUSSION

In this study, we found overexpression of EphA4 mRNA in gastric cancer cell lines and cancer tissues. Previous microarray and Northern blot analyses have shown that EphA4 expression in normal adult tissues is very restricted[19]. Moreover, overexpression of EphA4 in gastric cancer was observed at the protein level as analyzed by immunohistochemistry and this correlated with depth of invasion. These results suggest that EphA4 plays a role in gastric cancer.

The implication of EphA4 expression in gastric cancer was further substantiated by its correlation with recurrence and short overall survival time. Moreover, EphA4 expression provided significant predictive value for overall survival in the multivariate analysis, suggesting that EphA4 expression could be a useful predictor of recurrence and poor prognosis. Prognostic significance of EphA4 expression has not previously reported in human cancer. Moreover, EphA4 is the first Eph/ephrin family member of which prognostic significance was shown in gastric cancer.

It has been reported that EphA4 forms a hetero receptor complex with FGFR1 and that the EphA4/FGFR1 complex potentiates FGFR-mediated downstream signal transduction. Since FGF/FGFR signal pathway has been reported to play an important role in gastric cancer[20,21], we analyzed the relationship of EphA4 expression with FGFR1 expression. The frequency of FGFR1 overexpression in this study was consistent with the frequencies reported previously[20]. FGFR1 expression was correlated with EphA4 expression. Therefore, EphA4 may play a role in gastric cancer, at least in part, through the interaction with FGFR signaling. EphA4 has also been shown to phosphorylate FGFR2 and 3. Overexpression of mRNA for FGFR-2 and FGFR-4 has been reported in gastric cancer[20]. Further analysis is necessary to clarify the relationship between EphA4 and FGF/FGFR signaling pathway in gastric cancer.

To search for potential candidate ligands for the EphA4 receptor in gastric cancer cells, we examined the expression patterns of members in the type A and type B ephrin ligand families by semiquantitative RT-PCR. The mRNAs of ephrin ligands were coexpressed in various combinations in gastric cancer cell lines and cancer tissues. Expression of ephrinA2 was relatively concordant with that of EphA4 in gastric cancer cell lines. However, expression of ephrin ligands was not clearly concordant with that of EphA4 in cancer tissue samples. On the other hand, coexpression of ephrinA3 and EphA4 has been reported to play an important role in pancreatic cancer[19]. These results further support the notion that combinations for the Eph receptors and ephrin ligands depend on tissue-type and/or cancer-type[7-10]. Moreover, the interaction of EphA4 expressed on gastric cancer cells and ephrin ligands expressed on nontumour cells, such as mesenchymal cells and vascular cells, could play a role in gastric cancer through the interaction between these cells[19]. Further studies are necessary to clarify these issues.

By using the small interfering RNA strategy, we investigated whether EphA4 expression was associated with growth of gastric cancer cells. Downregulation of EphA4 expression in gastric cancer cells resulted in a reduction in cell viability, suggesting that the overexpression of EphA4 plays a role in gastric cancer cell growth.

Taken together, these results suggest that EphA4

overexpression plays a role in gastric cancer. As a target gene for molecular therapy, its expression in normal adult tissues is important. Although EphA4 was found to be highly expressed in the adult brain, it has been thought that therapeutic antibody targeting membrane molecules could not pass through the blood brain barrier and were unlikely to affect the central nervous system[18]. Considering the expression pattern of EphA4 together with its oncogenic function, EphA4 could be a target for molecular therapy by a therapeutic antibody and/or by small molecule approach targeting its kinase activities[24].

COMMENTS

Background

The Ephrin (Eph) receptors constitute the largest family of tyrosine kinase receptors. EphA4 is distinguished by its ability to bind to both type A ephrins and most type B ephrins. It has been reported that EphA4 forms a hetero receptor complex with fibroblast growth factor receptor (FGFR) 1 and that the EphA4/FGFR1 complex potentiates FGFR-mediated downstream signal transduction. The potential role of Eph receptor and ephrin ligand family in human cancer is receiving increasing attention.

Research frontiers

Altered expression patterns of Eph/ephrin have been correlated with tumor behavior, such as invasiveness, vascularization, metastatic potential, and patients' prognosis. Generally, the upregulation of Eph/ephrin has been reported in various types of cancer.

Innovations and breakthroughs

The expression profiles of EphA4, FGFR1, and ephrins were systematically analyzed in gastric cancer cell lines and/or tissues by using RT-PCR, immunohistochemistry, and tissue microarray analysis.

Applications

This study demonstrated that overexpression of EphA4 and FGFR1 may be involved in gastric tumorigenesis. EphA4 overexpression could be a poor prognostic marker for gastric cancer.

Terminology

Ephrin receptor: The Ephrin receptors constitute the largest family of tyrosine kinase receptors. The Eph receptors interact with a second family of cell surface-anchored ligands, ephrins. Eight EphA receptors (EphA1-A8) and five EphB receptors (EphB1-B4, B6) are known in the human genome. Ephrin: The ephrins are divided into the two subclasses, A and B. Type A ephrins and type B ephrins are attached to plasma membrane *via* glycosyl phosphatidyl inositol linkages and transmembrane sequences, respectively. Five type A ephrins (Ephrin A1-A5) and three type B ephrins (Ephrin B1-B3) are known in the human genome.

Peer review

This paper studied expression of EphA4 and FGFR1 in gastric cancer. The authors showed that overexpression of EphA4 is a frequent feature in cell lines (73%) and less common in gastric cancer samples (around 40%-50%). They show a correlation between the expression of such molecular aspect and shorter survival. This study has the potential to become interesting to the scientific community.

Abstract

AIM: To isolate and identify differentially expressed proteins between cancer and normal tissues of gastric cancer by two-dimensional electrophoresis (2-DE) and matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF-MS).

METHODS: Soluble fraction proteins of gastric cancer tissues and paired normal tissues were separated by 2-DE. The differentially expressed proteins were selected and identified by MALDI-TOF-MS and database search.

RESULTS: 2-DE profiles with high resolution and reproducibility were obtained. Twenty-three protein spots were excised from sliver staining gel and digested in gel by trypsin, in which fifteen protein spots were identified successfully. Among the identified proteins, there were ten over-expressed and five under-expressed proteins in stomach cancer tissues compared with normal tissues.

CONCLUSION: In this study, the well-resolved, reproducible 2-DE patterns of human gastric cancer tissue and paired normal tissue were established and optimized and certain differentially-expressed proteins were identified. The combined use of 2-DE and MS provides an effective approach to screen for potential tumor markers.

INTRODUCTION

Gastric carcinoma is one of the most common malignancies worldwide and is the first most common cause of cancer-related death in China[1]. The main barrier for improving the survival rate is the lack of useful markers for early diagnosis. The cells' fate depends on which gene expresses and how much it expresses. When a cell malignantly transforms, its gene expression profile and their respective protein products may have changed. So it is necessary to isolate and identify genes and proteins that are differentially expressed in gastric cancer.

With the completion of human genome project, the practice of medicine was altered fundamentally, which includes the identification of genes that are involved in the appearance, progression, and treatment of cancer, the answers to what those specific genes do and how they interact in communication networks, and the roles played by their protein products in molecular pathways. However, in most cases, although studies of differential mRNA expression are informative, they do not always correlate with protein concentrations because proteins are often subject to proteolytic cleavage or posttranslational modifications (such as phosphorylation or glycosylation). Cancer biomarkers discovery strategies

that target expressed proteins are becoming increasingly popular because proteomic approaches can characterize the proteins, modified or unmodified, involved in cancer progression[2-6].

Recent years, proteomics analysis was has been applied in many kinds of tumors, such as breast cancer[7-9], lung cancer[10,11], prostate cancer[12], liver cancer[13-15] and ovarian cancer[16], *etc*. In this study, we tried to find biomarkers in human gastric cancer tissue *via* proteomics as high throughput method. The results presented here will no doubt provide clues to further study of the carcinogenic mechanisms, diagnosis, and therapy of gastric cancer.

MATERIALS AND METHODS

Materials

Stomach cancer tissues were prepared from ten patients with gastric cancer (the clinical-pathological characteristics are described in Table 1) in Ruijin Hospital. The paired normal gastric tissues were prepared from non cancerous regions at least 5 cm apart from primary tumor. Protean IEF Cell, Protean Plus Multi-Casting Chamber, PROTEAN Plus Dodeca Cell, Fluor-S^{TM} Multimager, Immobilized pH gradient (IPG) strips, iodoacetamide, 40% w/v Bio-Lyte pH 3-10 Ampholyte, CHAPS, DTT, urea, acrylamide, N,N'-methylene-bis-acrylamide and RC DC Protein Assay Kit were purchased from Bio-Rad (Richmond, CA, USA). Tris-base, TEMED and SDS were from Promega. Thiourea, DNase, ammonium persulfate and phenylmethyl-sulfonylfluoride (PMSF) were from Sigma-Aldrich (Missouri, USA). 4700 Proteomics Analyzer was from ABI (USA).

Sample preparation

Proteins were extracted from human gastric tissue as instructed by the Ha[17] method. Gastric tissue (100 mg) was homogenized in 2 mL buffer (50 mmol/L Tris-HCl, pH 7.2) containing 1 mmol/L PMSF using an homogenizer at 26 000 r/min. The mixture was centrifuged at 1000 *g* for 5 min to remove debris. Then, the homogenate was centrifuged at 20 000 r/min for 30 min at 4℃. The supernatant was taken as the soluble fraction and TCA (50% w/v) was added to a final concentration of 10% w/v (containing 20 mmol/L DTT) and the solution was allowed to stand on ice for 30 min. The protein precipitate was collected and centrifuged in a microcentrifuge at 14 000 rpm for 10 min at 4℃, and washed three times in 10% TCA (containing 20 mmol/L DTT). The precipitate was washed twice in acetone (containing 20 mmol/L DTT) and dried under an air stream. The dry pellet was dissolved with vortex in the lysis solution (7 mol/L urea, 2 mol/L thiourea, 2% w/v CHAPS, 2% w/v SB3-10, 40 mmol/L Tris, 2 mmol/L TBP, 0.2% w/v Bio-Lyte pH 3-10, 1050 U/mL DNase, 25 μg/mL RNase) and allowed to stand for 1 h at room temperature. After centrifugation at 14 000 r/min for 10 min at 15℃, the supernatant was used as the two-dimensional polyacrylamide gel electrophoresis (2-DE) sample for the soluble fraction. The protein samples were stored in aliquots at -80℃ until use. Protein concentration of 2-DE samples was determined using RC DC Protein Assay kit.

2-DE

The first-dimensional gel separation was carried out with 17 cm IPG strips (pH 3-10, pH 4-7, pH 5-8) following the manufacturers' protocol with minor modifications. Samples containing up to 100 μg protein were diluted to 320 μL with rehydration solution (7 mol/L urea, 2 mol/L thiourea, 2% CHAPS, 100 mmol/L DTT, 0.2% w/v Bio-Lyte pH 3-10, trace bromophenol blue), and applied to strips by overnight rehydration at 50 V. Proteins were focused succeedingly for 1 h at 150 V, 1 h at 250 V, 1 h at 1000 V, then a gradient was applied from 1000 to 10 000 V in 5 h, and focusing was continued at 10 000 V for 6 h to give a total of 88 kVh on a Protean IEF Cell. After IEF, strips were equilibrated for 15 min in 6 mol/L urea, 2% SDS, 0.05 mol/L Tris-HCl, pH 8.8, and 30% glycerol containing 2% DTT, and then equilibrated again for 15 min in the same buffer containing 2.5% iodoacetamide. Equilibrated IPG strips were transferred onto 12% uniform polyacrylamide gels and then were run in Protean Plus Dodeca Cell (Bio-Rad, USA) at 24 mA per gel for 5 h and 30 min. The gels were visualized using silver staining method. After staining, 2D gels were scanned using Fluor-S^{TM} Multimager (Bio-Rad, USA) and images were analyzed using PDQuest 7.1.1 (Bio-Rad, USA).

In-gel digestion of proteins

Protein spots of interest were cut manually from the gel and placed into siliconized microcentrifuge tubes. The gel fragments were destained in solution that consisted of 100 mmol/L $Na_2S_2O_3$ and 30 mmol/L $K_3Fe(CN)_6$ (V/V, 1:1) and dehydrated by washing two times for 10-15 min with 25 mmol/L NH_4HCO_3 in 50% acetonitrile until shrunken and white. The protein-containing gel-spots were reduced in the reduction buffer (25 mmol/L NH_4HCO_3 and 10 mmol/L DTT) for 1 h at 56℃ and then alkylated in the alkylation buffer (25 mmol/L NH_4HCO_3 and 55 mmol/L iodoacetamide) in the dark for 30 min at room temperature. The gel pieces were washed twice with 100 mmol/L NH_4HCO_3 and dehydrated

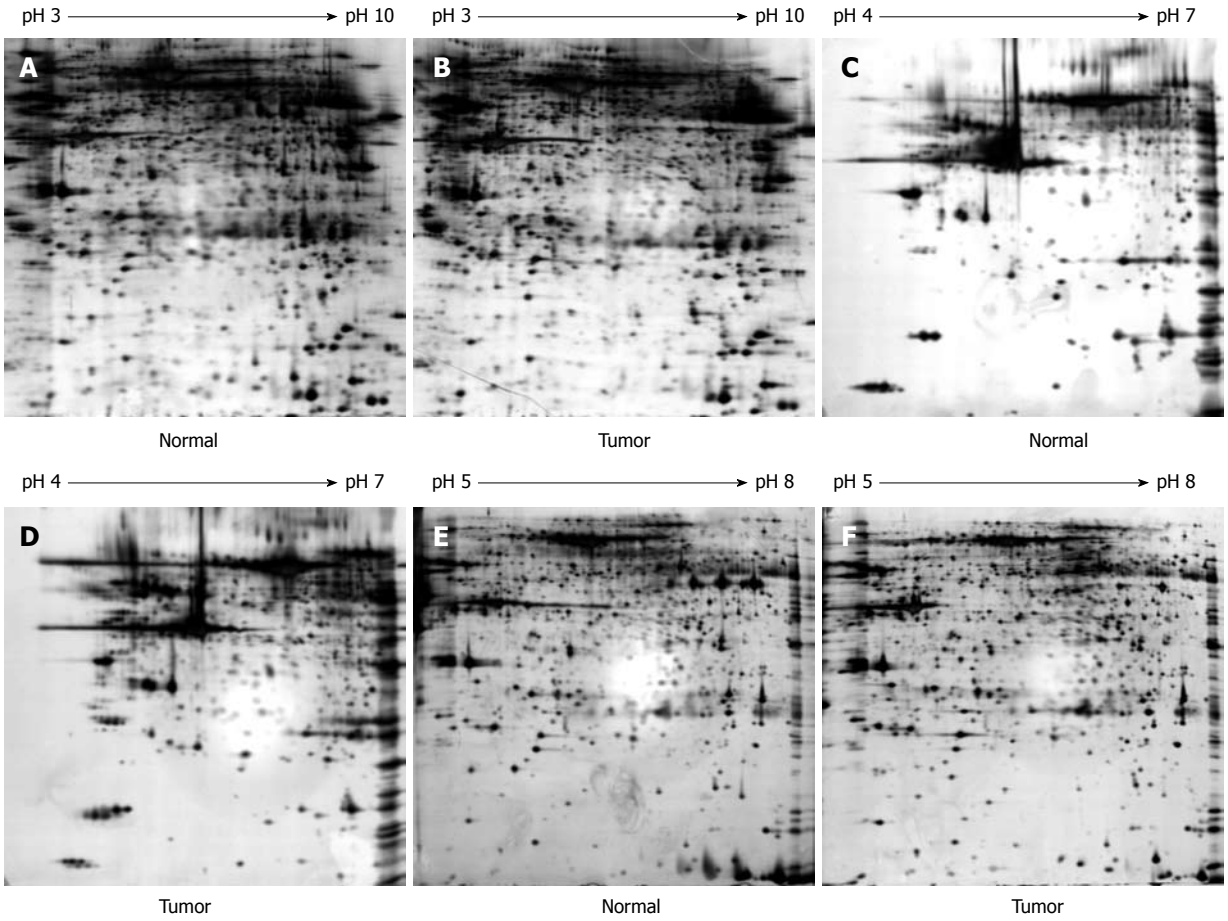

Figure 1 2-DE maps of human gastric tissue separated by IPG with different pH intervals (silver staining). **A** and **B**: Normal and cancer tissues of stomach separated by pH 3-10 IPG strips; **C** and **D**: Normal and cancer tissues of stomach separated by pH 5-8 IPG strips; **E** and **F**: Normal and cancer tissues of stomach separated by pH 4-7 IPG strips.

by 100% acetonitrile. Ten microliters modified trypsin (8 μg/mL) was added to each tube. Tubes were sealed with parafilm and digestion was performed for 16 h at 30℃. When digestion was completed, 100 μL of 100 mmol/L NH_4HCO_3 was added and tubes were sonicated for 10 min. The supernatant was removed from each tube and transferred into a fresh tube. Further recovery of the peptides was accomplished by two extractions with 50% acetonitrile/5% TFA. All supernatants were pooled and concentrated and desalted by ZIPTIPS (Millipore, USA) prior to applying on to the sample plate.

MALDI-TOF MS and database search

A small fraction (0.5 μL) of the sample was mixed with a-cyano-4-hydroxycinnamic acid matrix (1:1, v/v) and the mixture solution was then spotted on the plate and dried, then analyzed on a 4700 MALDI-TOF-TOF mass spectrometer (Applied Biosystems, USA). The laser wavelength was 355 nm, and the laser repetition rate was 200 Hz. External calibration was employed. Samples that did not get positive identification by MALDI were subjected to MALDI-TOF-TOF-MS using a 4700 Proteomics Analyzer equipped with a special analysis software GPS and local databases. The following parameters were used in the searches: SWISS-PROT was used as the protein sequence database; trypsin digest (one missed cleavage allowed); mass accuracy 0.2 Da; species: *Homo sapiens*; acetylation of the N-terminus, alkylation of cysteine by carbamidomethylation and oxidation of methionine were considered as possible modifications.

RESULTS

Overview 2-DE maps of human gastric tissue

Resolution and reproducibility of 2-DE have been improved significantly since the introduction of IPG strips[18,19]. However, it is still a time-consuming and laborious job. In this study, we firstly separate the soluble proteins of human gastric tissue in IPG strips with different pH intervals. All maps (Figure 1) were constructed on silver-stained gels with protein loadings of 100 μg. Proteins from normal and tumor tissues of stomach were separated in pH 3-10 IPG strips. After SDS-PAGE, about 850 protein spots could be detected (Figure 1A and B). While, about 670 protein spots could be detected which separated by pH 4-7 IPG strips (Figure 1C and D). The well-resolved, reproducible 2-DE patterns of human gastric cancer tissues and paired normal tissues were obtained with pH 5-8 IPG strips (Figure 1E and F). About 1400 spots were detected, respectively, and about a total of 1100 spots

were matched each other. We got better resolution and more protein spots with pH 5-8 IPG strips; therefore, in the succeeding studies, we chose pH 5-8 IPG strips to analyze proteins of human gastric tissues.

Comparing proteomic patterns of cancer tissue and normal tissue by 2-DE

After 2-DE, the differential proteins between human gastric cancer tissues and paired normal tissues were found by PDQuest 7.1.1 2-D gel analysis software (BIO-RAD, USA). To compare 2-DE maps, it is important to have a representative sample. Hence, an average electrophoresis map of human gastric cancer tissues was constructed by the combination of the 2-DE maps from 10 tumor tissues with the PDQuest 7.1.1 2-DE gel analysis software. Similarly, an average electrophoresis map of 10 normal gastric tissues was also established. These average electrophoresis maps were used to perform the differential expression analysis. The differential protein spots with at least five-fold discrepancy, which were present in at least four paired tumor and normal tissues, were detected by comparing the 2-DE protein patterns of the average gels of tumor and control tissues. Figure 2 shows differentially expressed proteins of N4, T8 between tumor and control tissues in four patients. Twenty three protein spots were selected to be identified by mass spectrometry (MS). Among these, 16 spots were over expressed and other 7 spots were under expressed in gastric cancer tissue.

Protein identification by MALDI-TOF MS or tandem MS

Fifteen proteins out of the selected 23 proteins were identified successfully by MALDI-TOF MS or tandem MS (Figures 3 and 4) and there were ten over expressed and five under expressed proteins in stomach cancer tissues compared with normal tissues. The identified proteins are shown in Tables 2 and 3.

Proteins which were up-regulated in gastric cancer tissue includes: (1) transcriptional regulation proteins, such as zinc finger protein; (2) signal transduction regulator, such as regulator of G-protein signaling 3 (RGS3); (3) cancer-related proteins, such as ras-related protein; (4) cytoskeleton proteins, such as bullous pemphigoid antigen 1 isoforms 1/2/3/4/5/8; (5) tissue-

specific proteins, such as Calcium-binding protein CaBP5. Proteins which were down-regulated in gastric cancer tissue includes: (1) transcriptional regulation proteins, such as zinc finger protein and transcriptional repressor CTCFL; (2) cytoskeleton proteins, such as bullous pemphigoid antigen 1 isoforms 6/9/10; (3) metabolic enzymes, such as peroxiredoxin 2.

DISCUSSION

Genomics-based techniques, such as expressed sequence tag (EST) sequencing, serial analysis of gene expression (SAGE)[20], cDNA expression array hybridization[21], were widely used to find out potential cancer biomarkers. However, a major limitation to these approaches is detection of high levels of mRNA transcripts of a specific gene may not necessarily mean that high levels of the corresponding protein product will be present. Now, proteomics-based techniques can help us find cancer-related biomarkers at the protein level.

In this study, we obtained ten over expressed proteins (Bullous pemphigoid antigen 1 isoforms 1/2/3/4/5/8,

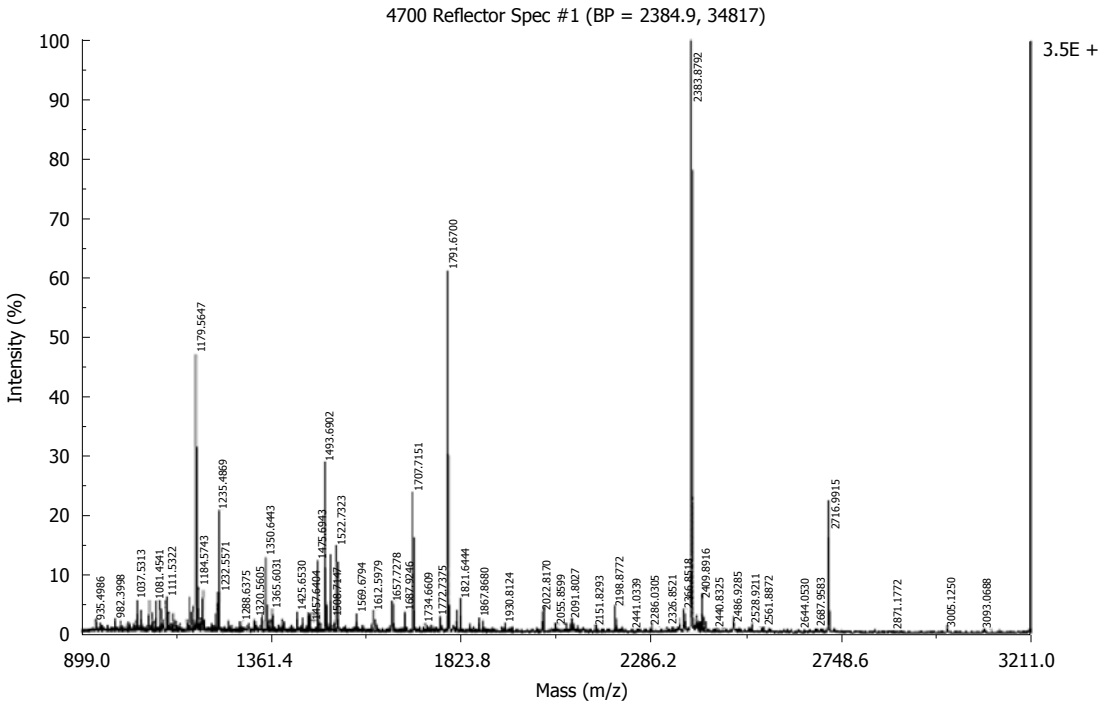

Figure 4 MALDI-TOF mass spectrum of the mixture of tryptic peptides derived from N4 (Bullous pemphigoid antigen 1 isoforms 6/9/10).

Ras-related protein Rab-30, Zinc finger protein 268, Calcium-binding protein CaBP5, RGS3, membrane-associated guanylate kinase (MAGUK) p55 subfamily member 3, Zinc finger protein 134, Actin alpha cardiac, Nebulin, Vacuolar protein sorting 33B) in gastric cancer tissue.

RGS3 inhibits signal transduction by increasing the GTPase activity of G protein alpha subunits thereby driving them into their inactive GDP. A recent study revealed that *RGS3* gene was up-regulated in highly migratory clones selected from U373MG glioma cells compared with that of the original cells using oligonucleotide microarrays comprising 12 625 genes. U373MG glioma cell clones with over-expression of RGS3 or RGS4 showed an increase of both adhesion and migration. These findings expand the spectrum of possible molecular pathways underlying the invasion of neoplastic astrocytes[22].

MAGUK p55 subfamily member 3 (MPP3) belongs to the MAGUK protein family. Shins' study showed MPP3 was identified by cell surface biotinylation and MS in the cell surface proteome of A549 lung adenocarcinoma cells and LoVo colon adenocarcinoma cells[23].

Nebulin may be involved in maintaining the structural integrity of sarcomeres and the membrane system associated with the myofibrils. The nebulin gene was found up-regulated in non small cell lung carcinoma-derived cell lines D51 and lung cancer cell lines (H2170 and H526) compared with human bronchial epithelial cell lines by suppression subtractive hybridization (SSH). But the relations between nebulin and gastric cancer is not clear[24].

We also obtained five under-expressed proteins (Peroxiredoxin 2, Zinc finger protein ZFP-36, Zinc finger protein 64 isoforms 3 and 4, Bullous pemphigoid antigen 1 isoforms 6/9/10, Transcriptional repressor CTCFL).

Peroxiredoxins (Prxs) are a novel group of peroxidases containing high antioxidant efficiency and some of them having also effects on cell differentiation and apoptosis. The mammalian Prx family has six distinct members located in various subcellular locations. Peroxiredoxin 2 (Prx 2) is known not only to protect cells from oxidative damage caused by hydrogen peroxide (H_2O_2), but also to endow cancer cells with resistance to both H_2O_2 and cisplatin and to grant them radioresistance[25]. Somiari *et al*[26] analyzed human breast infiltrating ductal carcinoma (IDCA) using two-dimensional difference gel electrophoresis and MS and found peroxiredoxin 2 was less abundant in four breast IDCAs (Stage Ⅰ, ⅡA, ⅡB and ⅢA) compared with non-neoplastic tissue. But recent studies showed Prx family were over expressed in some kind of carcinomas suggesting that Prx has a proliferative effect and may be related to cancer development or progression[27-30].

The transcriptional repressor, CTCFL, acts as a transcriptional regulator binding to some gene promoters and may be associated with epigenetic reprogramming events in the male germ line. But the role that transcriptional repressor CTCFL plays in gastric cancer is still not demonstrated.

Because of different protein processing and posttranslational modifications, protein isoforms of individual protein can be identified on 2D gels. Interestingly, our study revealed Bullous pemphigoid antigen 1 isoforms 1/2/3/4/5/8 were over expressed in gastric cancer tissue while Bullous pemphigoid antigen 1 isoforms 6/9/10 were under expressed in cancer tissue.

This finding suggests that the different protein isoforms may be correlated with specific features of gastric cancer and play different roles in the progression of cancer.

In conclusion, the identified proteins, both up-regulated and down-regulated, may participate in the progression of malignant growth or in the maintenance of normal conditions of gastric tissue. The functions of these proteins in the carcinogenesis of gastric cancer remain to be studied. We hope they may provide useful information for early detection and therapy of gastric cancer.

ACKNOWLEDGMENTS

We thank Dr. Qun-Ye Zhang and Qiu-Hua Huang (Shanghai Institute of Hematology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine) for their assistance in the identification of proteins.

COMMENTS

Background

Gastric carcinoma is one of the most common malignancies worldwide and is the most common cause of cancer-related death in China. The main barrier for improving survival rate is the lack of useful markers for early diagnosis.

Research frontiers

Identification differential proteins between tumor tissue and normal tissue by proteomics to be candidate tumor markers for gastric cancer.

Innovations and breakthroughs

Twenty three differential proteins were found between tumor and normal tissues of gastric cancer, among these fifteen proteins were identified.

Applications

The differential proteins may be tumor markers for gastric cancer.

Peer review

The authors utilized two-dimensional electrophoresis (2-DE) and matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF-MS) to isolate and identify differentially expressed proteins between gastric cancer tissues and paired normal mucosa. This is an interesting paper using new technology to identify gastric cancer characteristics.

Abstract

AIM: To examine the immunoreactivity of E-cadherin and four subtypes of catenin family in human hepatocellular carcinomas (HCCs) and to investigate the correlation between expression of E-cadherin/catenin complex and clinicopathologic parameters of HCC patients.

METHODS: An immunohistochemical study for E-cadherin and catenins was performed on 97 formalin-fixed, paraffin-embedded specimens of HCC.

RESULTS: Reduced expression of E-cadherin, α-, β-, γ-catenin and p120 was observed in 69%, 76%, 63%, 71% and 73%, respectively. Both expressions of E-cadherin and catenin components were significantly correlated with tumor grade (P = 0.000). It showed significant difference between expression of catenin members and tumor stage (P = 0.003, P = 0.017, P = 0.007 and P = 0.000, respectively). The reduced expression of E-cadherin in HCCs was significantly correlated with intrahepatic metastasis (IM) and capsular invasion (P = 0.008, P = 0.03, respectively). A close correlation was also observed between the expression of catenins and the tumor size (P = 0.002, P = 0.034, P = 0.016 and P = 0.000, respectively). In addition, the expression of each catenin was found correlated with IM (P = 0.012, P = 0.049, P = 0.026 and P = 0.014, respectively). No statistically significant difference was observed between the expression level of E-cadherin/catenin complex and lymph node permission, vascular invasion and satellite nodules. Interestingly, only expression of p120 showed correlation with AFP value (P = 0.035). The expression of E-cadherin was consistent with α-, β-, γ-catenin and p120 expression (P = 0.000). Finally, the abnormal expression of E-cadherin/catenin complex was significantly associated with patients' survival (P = 0.0253, P = 0.0052, P = 0.003, P = 0.0105 and P = 0.0016, respectively). Nevertheless, no component of E-cadherin/catenin complex was the independent prognostic factor of HCC patients.

CONCLUSION: Down-regulated expressions of E-cadherin, catenins and p120 occur frequently in HCCs and contribute to the progression and development of tumor. It may be more exact and valuable to detect the co-expression of E-cadherin/catenin complex than to explore one of them in predicting tumor invasion, metastasis and patient's survival.

Key words: E-cadherin; Hepatocellular carcinomas; Histologic feature; Survival

INTRODUCTION

E-cadherin is a transmembrane glycoprotein and plays an important role in the contact between epithelial cells depending on calcium. Homophilic interaction of the extracellular part of E-cadherin mediates cell-cell adhesion[1]. The adhesion mediated by E-cadherin is significantly implicated in the establishment of cell polarity, the transformation of epithelial/interstitial cells

and the classification of cell types in the development[2,3]. The cytoplasmic part of E-cadherin is linked to the actin cytoskeleton *via* the catenins, including α-catenin, β-catenin, γ-catenin and p120[4]. E-cadherin/catenin complex is widely acknowledged as both tumor and metastasis suppressor, and the search for strategies to repress metastasis has led to intense studies of the mechanisms and molecules regulating E-cadherin function[2,3]. In addition, several recent trials have displayed the bright future of E-cadherin/catenin complex as a targeted therapy for human cancers[5-7].

The expression of E-cadherin/catenin complex has been shown to associate with tumor histological features (tumor size, grade, stage, invasion, metastasis, prognosis, *etc*.) in several cancers[8-12]. For liver cancer, some studies have reported that E-cadherin gene methylation or β-catenin exon 3 mutation occurred frequently and there was significant correlations between these abnormal biologic behavior and tumor development and progression[13-15]. In addition, some studies have explored the relationship between the clinicopathologic parameters of hepatocellular carcinoma (HCC) and the expression of E-cadherin/catenins complex, but the conclusions are still controversial. Endo *et al*[16] revealed over-expression of α-, β-, and γ-catenins in most HCCs, which was inversely correlated with histological grade of HCC, whereas E-cadherin expression was down-regulated and displayed a significant positive correlation with HCC grade. However, Ihara *et al*[17] showed over-expression of E-cadherin in their 66 HCCs, which was inversely correlated with tumor histological grade.

At present, there are little reports to demonstrate the relationship between the co-expression of above-mentioned five cell adhesion molecules and the clinicopathologic parameters (including patients' prognosis) in HCC. Especially, there was no report about expression of p120 catenin in HCC patients. In the present study, we used immunohistochemical staining of E-cadherin/catenin complex in the primary lesion of surgically resected HCC specimens to clarify the correlations between the expression of E-cadherin/cadherin complex and the development and progression of HCC.

MATERIALS AND METHODS

Patient selection and definition of clinicopathologic parameters

In this study, we selected 97 cases of HCC that had been collected and diagnosed at the Eastern Hepatobilliary Surgery Hospital, the Second Military Medical University between October 1998 and March 2004. The patients consisted of 67 men and 30 women and ranged in age from 34 to 72 years, with an average age of 54 years. In each case, HCC tissues and nontumorous liver tissues were obtained for pathological examination. The detailed pathologic results were gained from the department of pathology of our hospital. Background liver showed cirrhosis in 72 cases (74.2%) and chronic hepatitis in 69 cases (71.1%) which included hepatitis B virus in 60 cases and hepatitis C virus (HCV) in 5 cases, and cryptogenic in 4 cases.

Clinicopathologic parameters include histological grades, stages, size, capsular and vascular invasion (portal vein cancer thrombus), satellite nodules, IM, lymph node permission, AFP value and patients' survival. HCC was classified into grade Ⅰ, Ⅱ, Ⅲ and Ⅳ according to Edomndson and Steiner[18]. Histological types of HCC were adopted according to the system of World Health Organization. HCC staging was performed according to TNM staging system of the International Union against Cancer UICC[19]. IM was defined as recurrent tumors consisting of moderately or poorly differentiated HCC with the same or lower degree of differentiation compared with the differentiation of the primary tumors[20]. The satellite nodules of this HCC represent either intrahepatic spread of the tumor or multicentric origin of the tumor. The patients were followed up for 8-68 mo.

Immunohistochemistry

All samples were collected from 5-μm-thick histological sections. They were cut from the formalin-fixed paraffin-embedded material. Dako EnVision™ Kit (Dakocytomation Company, Denmark) was used for the immunohistochemical staining of E-cadherin, α-, β- and γ-catenins and p120. Sections were dewaxed, and incubated with mathenol containing 30% H_2O_2 for 20 min to block endogenous peroxidase activity. To enhance antigen retrieval, sections were treated at this stage in a microwave oven. Briefly, sections were immersed in 0.01 mol/L citrate buffer (pH 6.0) and heated in a microwave oven at 100℃ for 20 min. Subsequently, they were washed three times with distilled water, and then blocked with 1% BSA for 30 min. Sections were incubated overnight at 4℃ with rabbit polyclonal IgG of E-cadherin, α-catenin and p120 (Santa Clauze Corporation, USA, dilution 1:200) and mouse monoclonal IgG of β-catenin and γ-catenin (Santa Clauze Corporation, USA, dilution 1:200). A subsequent reaction was carried out using second antibodies ((Dakocytomation Company, Denmark, dilution 1:200) for 30 min at 37℃. Sections were washed three times with PBS buffer and subsequently displayed color with DAB for about 5 min. Nuclei were lightly counterstained with hematoxylin. No staining was obtained when nonimmune serum or PBS was used instead of the primary antibodies, thus confirming the specificity of each primary antibody.

Evaluation of immunostaining

We used a scoring system[21] to evaluate semiquantitatively the immunoexpression. The expression of non-tumorous tissue served as an internal control. Briefly, immunoractivities were assessed by the extent (broadness) and intensity (color strength). Depending on the percentage of positive cells, the extent score was classified as follows: 0, no positive cell or less than 5%; +1, 5%-25%; +2, 26%-50%; +3, 51%-75% and +4, 76%-100% positive cells. The intensity score was also

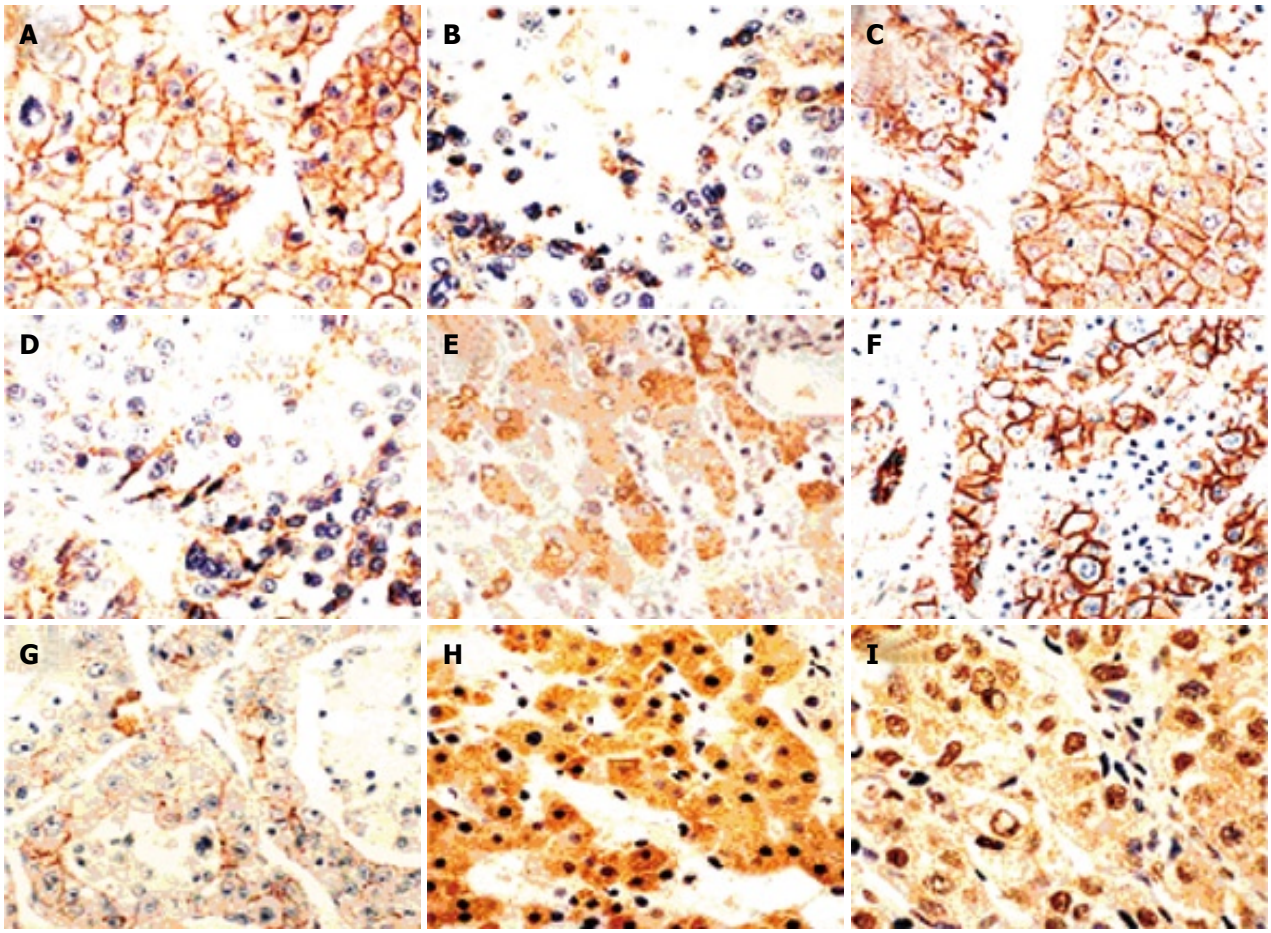

Figure 1 Immunoreactivity of E-cadherin, α- and β-catenins in HCCs. **A** and **B**: Stained for E-cadherin: preserved type (+), reduced type (-); **C-E**: Stained for α-catenin: preserved type (+), reduced type (-) and staining in the cytoplasm; **F-I**: Stained for β-catenin: preserved type (+), reduced type (-) and staining in the cytoplasm and the nucleus (× 200).

Table 1 Expression of five cell adhesion molecules in HCCs *n* (%)

	E-cadherin	α-catenin	β-catenin	γ-catenin	p120
Normal	40 (41.2)	32 (35.0)	42 (35.0)	37 (37.5)	35 (42.5)
Reduced	41 (42.3)	46 (65.0)	42 (65.0)	50 (62.5)	47 (57.5)
Absent	16 (16.5)	19	13	10	15

categorized into four groups: 0, no immunoreaction; +1, mild immunoreaction; +2, moderate immunoreaction; and +3, marked immunoreaction. Preserved E-cadherin or catenin expression was defined when the composite score was 6 or 7. In contrast, the expression of E-cadherin or catenin was also defined as "absent or loss" when the total score was 0.

Statistical analysis

Results from immunohistochemistry were analyzed by Yates' correction or Fisher's exact tests and statistical significance was accepted when $P < 0.05$. For survival analysis, log-rank test was used with a significant level of $P < 0.05$. Survival curves were computed according to the method of Kaplan-Meier. The prognosis value of these five molecules was evaluated with univariate and multivariate analysis. The SPSS 10.1 software package for Windows (SPSS, Inc., Chicago, IL) was used.

RESULTS

Microscopic observations

In nontumorous liver tissues, both E-cadherin and catenins were expressed strongly at cell membrane, but the staining strength gradually weakened from nontumoral tissue to the tumor region. In addition, bile ducts, proliferated ductiles and intrahepatic vessels strongly expressed these two molecules at the cell membrane. There was no expression in other cell types in the liver.

In 97 specimens of HCCs, the abnormal expression of E-cadherin, α-, β-, γ-catenin and p120 was found in 57, 65, 55, 60 and 62 cases (completely absent in 16, 19, 13, 10 and 15 cases), respectively (Table 1). The immunostaining distribution of E-cadherin was only presented at cell membrane, whereas catenins were found at the membrane in the cytoplasm and/or nucleus (Table 2, Figures 1 and 2).

Relationship between expression of E-cadherin/catenin complex and histological features in HCCs

As shown in Table 3, expression of both E-cadherin and catenin components was significantly related with tumor grade ($P = 0.000$). There was a greater tendency for the expression of E-cadherin/catenin complex to reduce in

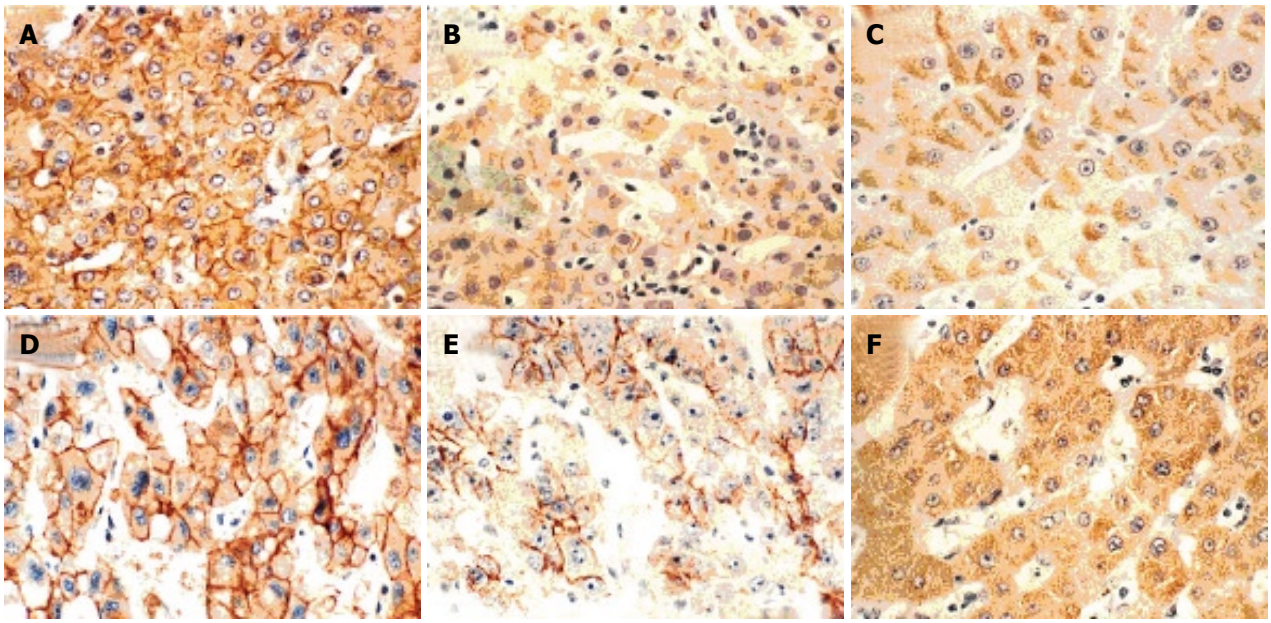

Figure 2 Immunoreactivity of γ-catenin and p120 in HCCs. **A-C**: Stained for γ-catenin: preserved type (+), reduced type (-) and staining in the cytoplasm; **D-F**: Stained for p120: preserved type (+), reduced type (-) and staining in the cytoplasm (× 200).

Table 2 Distribution of complex expression in HCCs

	Membrane	Cytoplasm	Nucleus
E-cadherin	97	0	0
α-catenin	70	27	0
β-catenin	55	36	6
γ-catenin	63	34	0
p120	65	32	0

poorly differentiated tumors than in well and moderately differentiated tumors. Except for E-cadherin, significant difference was found between expression of catenin members and tumor stage ($P = 0.003$, $P = 0.017$, $P = 0.007$ and $P = 0.000$, respectively).

Relationship between expression of E-cadherin/catenin complex and clinical parameters in HCCs

In Table 3, the reduced expression of E-cadherin in HCCs was significantly correlated with IM and capsular invasion ($P = 0.008$ and $P = 0.03$, respectively). A close correlation was also observed between expression of α-, β-, γ-catenin and p120 and the tumor size ($P = 0.002$, $P = 0.034$, $P = 0.016$ and $P = 0.000$, respectively). In addition, the expression of each catenin was found correlated with IM ($P = 0.012$, $P = 0.049$, $P = 0.026$ and $P = 0.014$, respectively). No statistically significant difference was observed between the expression level of E-cadherin/catenin complex and lymph node permission, vascular invasion and satellite nodules. Interestingly, only p120 expression was correlated with AFP value ($P = 0.035$).

Relationship between expression of E-cadherin and catenins in HCCs

As shown in Table 4, the expression of E-cadherin was significantly correlated to the expression of all kinds of catenins ($P = 0.000$). There was a significant concordance between the expression of E-cadherin and catenins.

Relationship between expression of E-cadherin/catenin complex and patients' survival

The overall patient survival according to the expression of E-cadherin and catenins in tumor is shown in Figure 3. Analysis of the survival for all patients showed that abnormal expression of E-cadherin and α-, β-, γ- and p120 catenins were correlated with poor survival ($P = 0.0253$, $P = 0.0052$, $P = 0.003$, $P = 0.0105$ and $P = 0.0016$, respectively). However, when E-cadherin/catenins complex status and other clinicopathological parameters were analyzed by the Cox regression model, abnormal expression of the E-cadherin/catenin complex was not found to be an independent prognostic factor (data not shown).

DISCUSSION

In accordance with previous reports[22,23], the expressions of all the members of E-cadherin/catenin complex were down-regulated in HCC, among of which the reduced expression of α-catenin was found most frequently. The expression of these five molecules was inversely correlated with tumor differentiation degree, thus all of them may be considered as good differentiation markers of HCC. Our result, however, is different from the reports of Endo and Ihara *et al*[16,17], which respectively showed over-expression of E-cadherin or α-, β- and γ-catenins in most HCCs. Therefore, together with CpG methylation of E-cadherin in HCC[13], it can be concluded that E-cadherin may act as a modulator of the maintenance of HCC histological architecture.

In addition, the reduced expression of all catenins,

but E-cadherin, was significantly associated with tumor stage and tumor size in our study. The mechanism of these findings was unknown, but they were consistent with tumor clinical features, the small liver cancers have a relatively better clinical course. Interestingly, p120 expression was also correlated with AFP value. It is well known that AFP is only an indicator of malignant liver tumor, and its value is not always related to the classification of tumor cells, so it may be a coincidence and needs to be investigated in the future. However, the findings above may further demonstrate that E-cadherin/catenin complex, at least catenins, correlate with HCC's biological behavior to some degree.

We found some distinct locations for different molecules of complex in HCC, especially for β-, γ-, and p120 catenin. In this study, hepatocytes, endothelial cells of bile ducts, proliferated ductiles and intrahepatic vessels of nontumorous liver tissue strongly expressed all of five molecules at cell membrane, but the staining strength gradually weakened from nontumorous tissue to tumor region. Besides expressing mostly at the membrane, these three members of armidillo protein family were also found in the cytoplasm or nucleus. It has been shown to be important in the development of several tumors that constitutionally activated the Wnt/Wingless signaling pathway by stabilization and accumulation of β-catenin in the nucleus and cytoplasm[24-27]. Like β-catenin, γ-catenin can also bind to APC protein and is able to translocate into the nucleus participating in the Wnt signaling pathway[28].

Several studies demonstrate that p120 can enter the nucleus and the Kaiso may be its receptor in nucleus[29]. Upon loss of E-cadherin, p120 translocates from

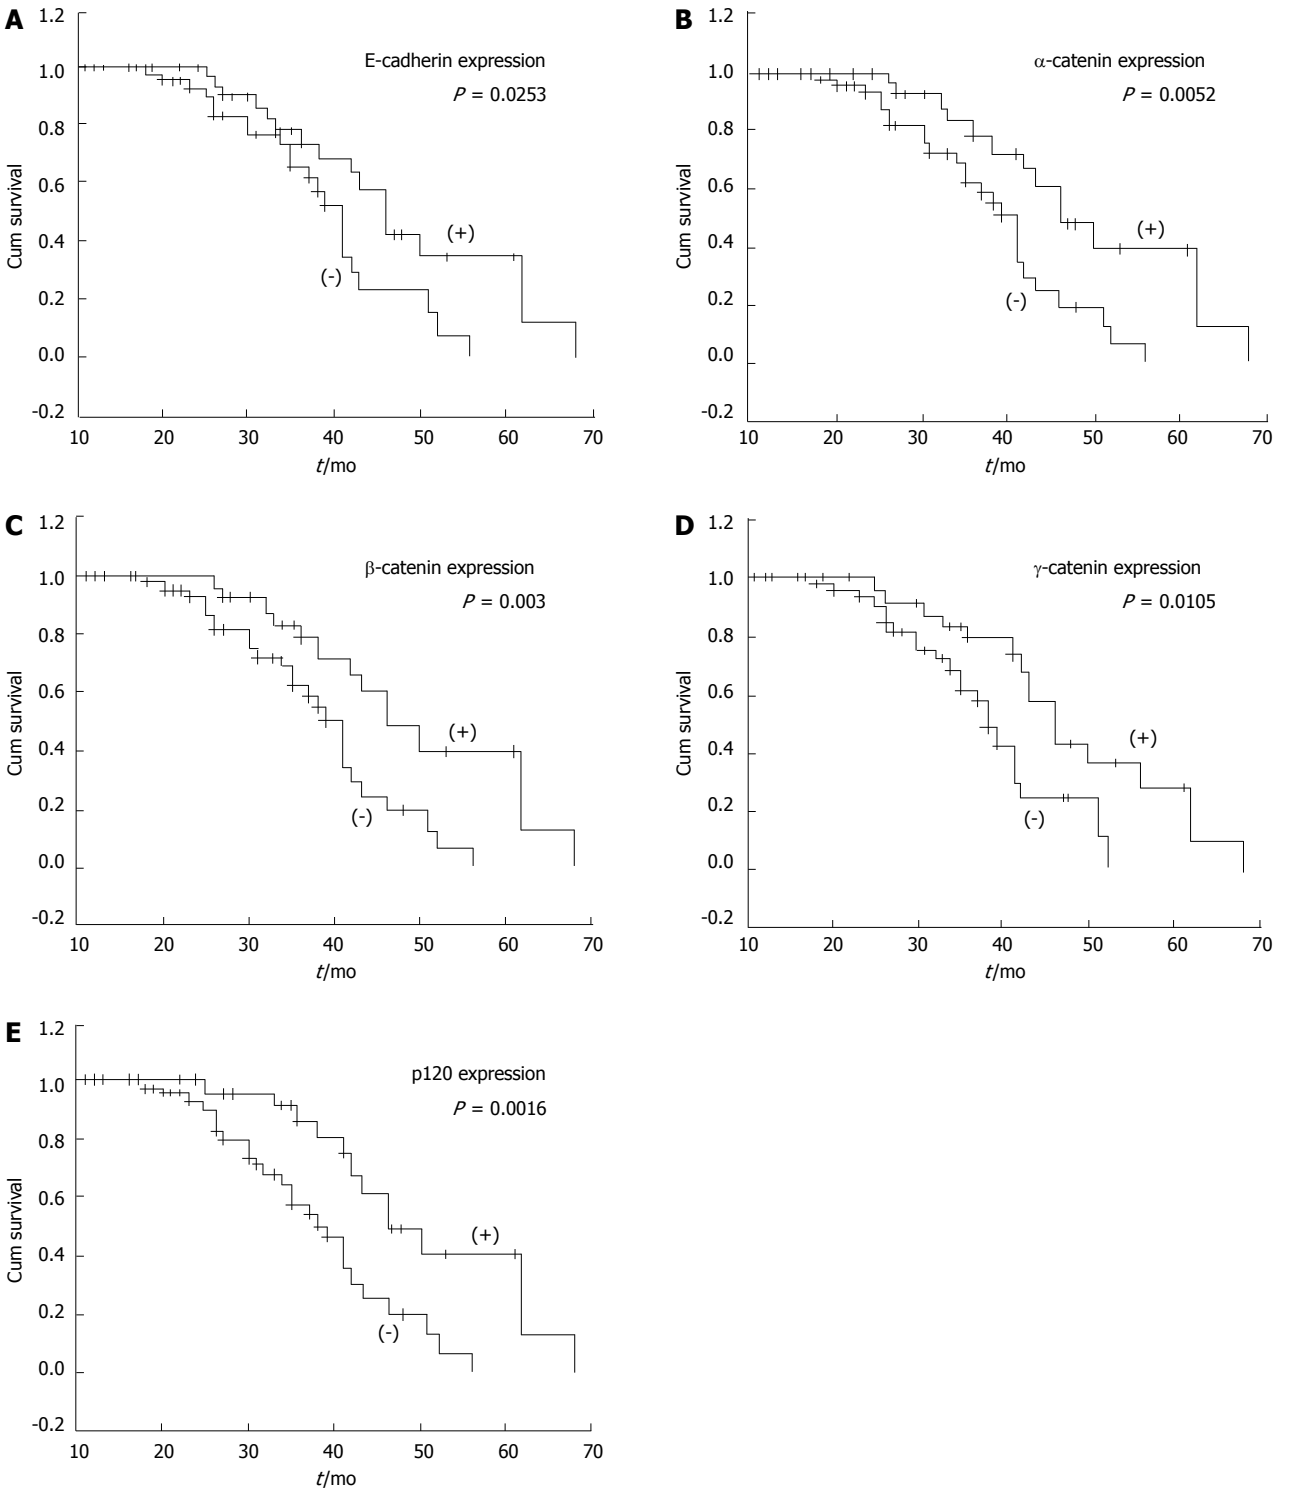

Figure 3 Kaplan-Meier survival curves with normal (pink line) or abnormal (green line), **A**: Expression of E-cadherin (P = 0.0253); **B**: Expression of α-catenin (P = 0.0052); **C**: Expression of β-catenin (P = 0.003); **D**: Expression of γ-catenin (P = 0.0105); **E**: Expression of p120 (P = 0.0016). Abnormal expressions of E-cadherin/catenin complex significantly related with poor survival.

the membrane to the cytoplasm. Alternatively, the cytoplasmic p120 pool may have increased access to the nucleus[30,31]. Therefore, these three molecules may play an important role in cell signal transduction and affect the development and progress of tumor. Unfortunately, there is no further investigation in relationship between p120 nucleus expression and clinicopathologic parameters in HCC due to the small number of cases with positive nucleus expression in our study.

As a focal point, we examined the relationships between expression of E-cadherin/catenin complex and some invasion and metastasis parameters of HCC. The reduced expression of E-cadherin in our experiment was significantly correlated with IM and capsular invasion. There was also a significant correlation between expression of catenins and IM in HCC. Nevertheless, no

statistically significant difference was observed between the expression level of E-cadherin/catenin complex and lymph node permission, vascular invasion and satellite nodules. These results were different from those of the previous studies to some degree. Endo *et al*[16] showed significant positive correlations between γ-catenin high expression and capsular invasion or presence of satellite nodules, and between β-catenin high expression and vascular invasion. Kozyraki *et al*[23] found that E-cadherin and α-catenin expression in HCC was associated with occurrence of capsular and vascular invasion. Unlike most other types of tumors, very few HCC patients in our data had lymph node invasion due to their anatomic characters and complete liver capsule. Because of the small samples in our study (there were only 17 cases of lymph node, 9 cases of complete capsular and 26 cases of vascular invasion among 97 HCC patients), it is difficult to analyze the relationship between these parameters and expression of E-cadherin/catenin complex.

We were astonished that there was a significant correlation between expression of E-cadherin/catenin complex and IM in HCC. The mechanism and pathogenesis of the high frequency of IM in HCC have not yet been elucidated. Mitsunobu *et al*[32] demonstrated that tumor spread in HCC progresses from capsular invasion to intrahepatic invasion and that the portal vein may act as an efferent tumor vessel. Meada *et al*[33] pointed out that the histological features of the intrahepatic metastatic lesions are essentially the same as those of the main nodule. The proliferative activities in the intrahepatic metastatic lesions were generally higher than those in the main nodules. The fact that there are differences in the proliferative activity, despite the similarity in histology between the primary sites and the metastatic lesions, suggests that tumor cells of the metastatic lesions might acquire some characteristic advantages in forming metastasis. Preserved or recovered function of E-cadherin may be one of these advantages. Osada *et al*[34] found that E-cadherin is involved in the IM of HCC. Asayama *et al*[35] had a similar report in HCC-CC patients. These results indicated that E-cadherin/catenin complex might play an important role in the detachment of cancer cells.

To our knowledge, this is the first report of p120 catenin expression in human HCC. p120 was found to strangely correlate with differentiation, IM and patients' survival, and p120 loss was associated with down-regulation of all members of the complex. Thoreson *et al*[30] suggested that it is possible that morphologic and behavioral changes in some tumors are due to p120 loss and consequent destabilization of E-cadherin. The roles for p120 as either tumor suppressor or metastasis promoter during tumor progression differ with the order, in which p120 or E-cadherin was down-regulated first. If p120 is lost first, E-cadherin level will fall significantly[36], which is likely to be paralleled by reduced levels of α - and β -catenins[37]. If E-cadherin is lost first, p120 may directly and actively promote metastasis.

With regard to the relationship between the E-cadherin/catenin complex expression and patients' survival in HCC, we found that patients with low expression of these five molecules had poorer prognosis than those with normal expression. Unlike most previous reports[38-41], which revealed only one or a few members of this complex were associated with patients' survival, our result demonstrated that all molecules of E-cadherin/catenin complex were significantly correlated with HCC patients' survival. However, when E-cadherin/catenin complex status and other clinicopathological parameters were analyzed by the Cox regression model, abnormal expression of the E-cadherin/catenin complex was not found to be an independent prognostic factor. Thus, it may be more exact and valuable to detect the co-expression of E-cadherin/catenin complex than to explore only one of them.

In conclusion, these data indicated that abnormal expression of E-cadherin/catenin complex is common in HCC. The complex expression is mostly located in the cytoplasm of HCCs and correlated with tumor differentiation, IM and patients' survival. E-cadherin/catenin complex may play an important role in development and progression of human HCC.

COMMENTS

Background

The E-cadherin/catenin complex plays a critical role in the control of epithelial differentiation and intercellular adhesion. Altered expression and/or function disruption of its components have been implicated in tumor development and progression.

Research frontiers

The expression of E-cadherin/catenin complex has been shown to associate with tumor histological features in several cancers. E-cadherin gene methylation or β-catenin exon 3 mutation occurred frequently in liver cancer and there was significant correlations between these abnormal biologic behavior and tumor development and progression. Some studies also have explored the relationship between hepatocellular carcinoma (HCC) and the expression of E-cadherin/catenin complex, but the conclusions are still controversial.

Innovations and breakthroughs

The results suggest that down-regulated expressions of E-cadherin, catenins and p120 occurred frequently in HCCs and contributed to the progression and development of tumor. It may be more exact and valuable to detect the co-expression of E-cadherin/catenin complex than to explore only one of them in predicting tumor invasion, metastasis and patient's survival.

Applications

Because down-regulated expression of E-cadherin/catenin complex contributes to the progression and development of HCC, this complex can be used as a valuable biologic marker for predicting the invasion and metastasis of HCC.

Peer review

The authors have shown reduced expression of E-cadherin/catenins in HCC. It is a good study which prognosticates the invasiveness of HCC. The study indicated that E-cadherin/catenin complex may be valuable biological markers for predicting tumor invasion and metastasis. However, its clinical application should be further studied.

Abstract

AIM: To determine whether HBV with the same characteristics causes dissimilar mutations in different hosts.

METHODS: Full-length HBV genome was amplified and linked with pMD T18 vector. Positive clones were selected by double-restriction endonuclease digestion (*Eco*R Ⅰ and *Hin*dⅢ) and PCR. Twenty seven clones were randomly selected from an asymptomatic mother [at two time points: 602 (1 d) and 6022 (6 mo)] and her son [602 (S)], and the phylogenetic and mutational analysis was performed using BioEditor, Clustal X and MEGA software. Potential immune epitopes were determined by the Stabilized Matrix Method (SMM), SMM-Align Method and Emini Surface Accessibility Prediction.

RESULTS: All of the 27 sequences were genotype C, the divergence between the mother and son was 0%-0.8%. Compared with another 50 complete sequences of genotype C, the mother and her son each had 13 specific nucleotides that differed from the other genotype C isolates. AA 1-11 deletion in preS1 was the dominant mutation in the mother (14/18). The 1762T/1764A double mutation existed in all clones of the mother, 3 of them were also coupled with G1896A mutation, but none were found in the son. 17 bp deletion starting at nucleotide 2330 was the major mutation (5/9) in the son, which caused seven potential HLA class Ⅰ epitopes and one B cell epitope deletion, and produced a presumptive new start codon, downstream from the original one of the P gene.

CONCLUSION: The HBV strain in the son came from his mother, and discrepant mutation occurred in the mother and her son during infection.

Shen T, Yan XM, Zou YL, Gao JM, Dong H. Virologic characteristics of hepatitis B virus in patients infected *via* maternal-fetal transmission. *World J Gastroenterol* 2008; 14(37): 5674-5682 Available from: URL: http://www.wjgnet.com/1007-9327/14/5674.asp DOI: http://dx.doi.org/10.3748/wjg.14.5674

INTRODUCTION

Chronic hepatitis B virus (HBV) infection is a significant global public health problem. Approximately 3-4 billion people worldwide have been infected with HBV, and 350-400 million persons have chronic HBV infection. Vertical transmission, especially mother-to-infant transmission is the primary pathway of hepatitis B virus infection, in approximately 90% of the infants born to HBeAg positive HBsAg carrier mothers, if no immunoprophylaxis is given. HBV with the same characteristics in the mother and child interacts with the immune system and may result in different mutations to escape immune pressure.

In the present study, we isolated the full genomic sequence of HBV in an asymptomatic mother and her son by direct sequencing. Phylogenetic and mutational analysis were performed to obtain evidence of mother to infant HBV transmission, and to elucidate distinctive HBV mutations in the different hosts.

MATERIALS AND METHODS

Patient

A 31-year-old female who was first seen at the First People's Hospital of Yunnan Province, Kunming, Yunnan, China in 2005 because of allergic purpura was reevaluated. She was HBsAg and HBeAg positive since at least 1999. Her sera were obtained from two time points: 602 (1 d) and 6022 (6 mo later). When seen again, 6 mo after her initial visit, her 7-year old son's serum [602 (S)] was collected. The alanine aminotransferase (ALT) level and abdominal ultrasound examination of the mother and son were normal. There was no history of alcohol abuse, parenteral drug use and hepatotoxin exposure. Neither the mother nor her son had received immunoprophylaxis or immunotherapy.

Serological markers and HBV DNA

HBV serological markers were evaluated using commercially available enzyme-linked immunosorbent assay (ELISA) kit (Kehua Bio-Engineering Co. LTD, Shanghai, China). HBV DNA in the sera was determined using a commercially available real-time fluorescence quantitative PCR (FQ-PCR) kit (Da An Gene Diagnostic Center, Shenzheng, China). Both subjects were also tested for hepatitis C virus (HCV), hepatitis A virus (HAV) and hepatitis E virus (HEV) infection.

Amplification of full-length HBV genome

HBV DNA was extracted from the sera using proteinase K digestion followed by phenol/chloroform extraction. The complete HBV genome was amplified by polymerase chain reaction (PCR) as described previously[1]. Amplification was performed in a 96-well cycler (Bio-RAD, USA), and 25 μL PCR mixture containing 2.5 mmol $MgCl_2$, 200 μmol/L dNTP, 400 nmol/L of each primer, and 2 U of Ex Taq polymerase (Takara BioTech). The PCR reaction was performed using the following cycles: 94℃ pre-denature for 5 min, 30 cycles of 94℃ for 1 min, 56℃ for 1 min, 72℃ for 2 min; and 72℃ for 10 min as a final extension step. The full-length amplicon were purified using a gel extraction kit (HuaShun Bio-Engineering).

Cloning and sequencing of the full-length HBV genome

Purified full-length HBV-DNA was directly linked with pMD18-T vector (TaKaRa Bio-Tech), using the standard cloning techniques. White colonies were picked and the genomic length of insertions was confirmed with PCR and double-restriction endonuclease digestion with *Eco*R I and *Hin*dⅢ. DNA sequencing analysis of the correct recombinants was performed with BigDye Terminator v3.1 and 3130 Genetic Analyzer (Applied Biosystems). For each patient and time point, 9 recombinants were randomly selected and sequenced for the full-length genome of HBV.

Sequence analysis

Thirty three HBV complete genome sequences (genotypes A to H) were used in as reference[2]. Additionally, 40 complete HBV genome sequences of genotype C from GenBank were used for phylogenetic analysis. The complete genome sequences were assembled from the sequencing data, using the BioEdit sequence alignment editor software, version 7.0.5.2[3]. Alignment was performed using Clustal X software, version 1.83[4]. Phylogenetic and molecular evolutionary analysis and nucleotide differences between the isolate sequences were carried out by the MEGA program, version 3.1[5]. The genetic distance was estimated using the Kimura two-parameter algorithm[6]. The phylogenetic trees were constructed using the neighbor-joining method[7]. Bootstrap re-sampling and reconstruction was carried out 1000 times to confirm the reliability of the phylogenetic trees[8]. The HBV genotype was assigned according to the classification system reported previously.

Potential immune epitopes prediction

For a new deletion fragment (17 bp deletion in Core gene region from nt 2330), Stabilized Matrix Method (SMM) and SMM-Align method were used to predict the potential major histocompatibility classes Ⅰ/Ⅱ[9,10] (Predicted IC50 < 200), and the Emini Surface Accessibility Prediction was used to predict the potential B cell epitope[11].

RESULTS

Serological markers and HBV DNA quantification

Both the mother and son were positive for HBsAg, HBeAg and anti-HBc. They were seronegative for HAV, HCV and HEV. The HBV viral load was 2.4×10^8 copy/mL in the mother (6022) and 4.2×10^8 copy/mL in the son [602(S)]. The 602 sera were not quantified due to insufficient material.

Genotypic and serotypic relatedness

The 27 sequenced clones (Gene Bank accession No: DQ377159-377165, EU306713- EU306729, EU439005-439007) ranged in length from 3036bp to 3254 bp. The divergence of the complete genome of 18 clones for the mother was 0%-0.8%, while the divergence of the 9 clones for the son was 0.1%-0.6 %, and the divergence of the 27 clones for the mother and child was 0%-0.8%. For the 27 clones, the homogenous of S gene was 98.5%-100%. The 27 clones were 51H, 54E, 62A, 73G, 125T and 227S in the large S gene, 136A, 142K, 233R, 236S, 248P, 252R, 304H, and 354H in the P gene, and 122K,160R and 159A in the small S gene. Compared with the 33 global complete genome sequences of HBV from GenBank, phylogenetic analysis showed that with bootstrap values of 100%, the clones were classified into genotype C and C2 subgroup (Figure 1)[12]. The serotype was classified as $adrq^+$[13].

Characterization of the nucleotides and the deduced amino acid sequence

Compared with the other 50 complete sequences of

genotype C, there were 13 specific point mutations in the 27 clones, the nucleotide positions were at 105T, 346C, 855C, 861T, 930G, 951T, 1110T, 1341C, 1972C, 2215C, 2246C, 2480T and 3102A. Except for C105T and G3102A which caused mutation of amino acid A158V in the large S gene and D266N in the P gene, respectively, the other substitutions resulted in the same sense mutation. Within the pre-S1 region, 14 clones of the mother had 18bp deletion from the start codon, which resulted in deletion at codons 1-11. The C-terminal truncated S protein was found in both the mother and son, which caused random point mutation in or near the hydrophilic region of S gene (nt 200, nt361, nt455, and nt565, respectively). Within the X region, 1762T/1764A double mutation was observed in all clones in the mother, but none was found in the son. The hypervariable region (HVR) sequence at positions 1751 to 1755, and the AT-rich region sequence at 1789 to 1795 in the X-ORF was conserved in all of the clones. In the precore and core regions, 3 clones of the mother had G1896A mutation and one clone had 19bp deletion, resulting in a novel stop codon of the C gene. In the P region, the YMDD motif was conserved in all the clones, 5 clones of the son had a 17 bp deletion from nt2330, and produced a 43 aa residue in the N-terminal of polymerase (Figure 2). Other random mutations occurred throughout the sequenced genomes, like a "G" insertion at nt 761 [602 (S)-39] was observed in one clone of the son and a "TT" deletion at nt2012 in one clone of the mother.

Potential immune epitopes caused by 17 bp deletion from nt2330

The 17bp deletion mutant from nt2330 in 5 clones of the son led to the deletion of aa144-183 of the HBcAg, as reported in this study after performing Blastn. By the immune epitope prediction method, potential clustal immune epitopes were located in the deletion region of Core gene, including 7 HLA class I epitopes and one B cell epitope (PRRRRSQ; Table 1, Figures 3 and 4).

DISCUSSION

Using phylogenetic and mutational analysis, clones of the mother obtained at two time points were conserved. The dominant mutants in the mother obtained at two time points were the same (18 bp deletion in preS1 region and BCP double mutation), except for the scattering mutation. Although, the son was infected from the mother, the divergence of the mother and the son was 0%-0.8%, and the dominant mutants in the son were different from the mother.

Universal infant immunization has reduced HBV infection rate in highly endemic countries with a relatively homogenous population. However, HBV transmission continues to occur *via* vertical (mother-to-child) and horizontal (sexual, parenteral and household) routes. In Asia, where genotypes B and C predominate, vertical transmission is common. In the present study, we isolated HBV strains from an asymptomatic mother and her son and analyzed the sequences phylogenetically. All the 27 clones were of the C2 subtype and adrq$^+$ serotype. Compared with 50 other complete sequences of genotype C, there were 13 specific nucleotides belonging to the mother and her son. It should be noted that there was no history of alcohol abuse, parenteral drug use or hepatotoxin exposure, and no immunoprophylaxis or immunotherapy was given to the mother and her son. The son's father was seronegative for HBV markers. Based on these findings combined with the data of divergence in the complete viral genome and homogeneity in the S gene, it can be concluded that the son became infected *via* a mother-to-infant transmission.

The pre-S1 domain is the essential binding site for hepatocyte receptors, and mutations at this region may directly influence HBV infection, and progression of liver disease. In the present study, 14 clones of the mother had aa 1-11 deletion in preS1 caused by a 18bp deletion from the original start codon of preS1. This deletion mutant has previously been reported in different clinical conditions, especially hepatocellular carcinoma (HCC) and chronic hepatitis B (CHB) infection with genotypes C and D, and fulminant hepatitis B (FHB) with genotype A in Africa. It has also been observed in isolates obtained from nonhuman primates (Table 2)[14-32]. Interestingly, there are no reports of this deletion mutation in genotypes B, E, F and G. In a heart transplant recipient who died from fulminate hepatitis B transmitted by the donor, the 18bp deletion was detected in the recipient, but not in the donor[20]. In our case, the 18bp deletion mutants in preS1 were present in 14 clones of the mother (78%), but in none of the sequenced clones in the son (0%). This phenomenon may imply that host immune pressure was the primary cause of aa 1-11 deletion in preS1. In a subsequent study (2 years later), we observed that the

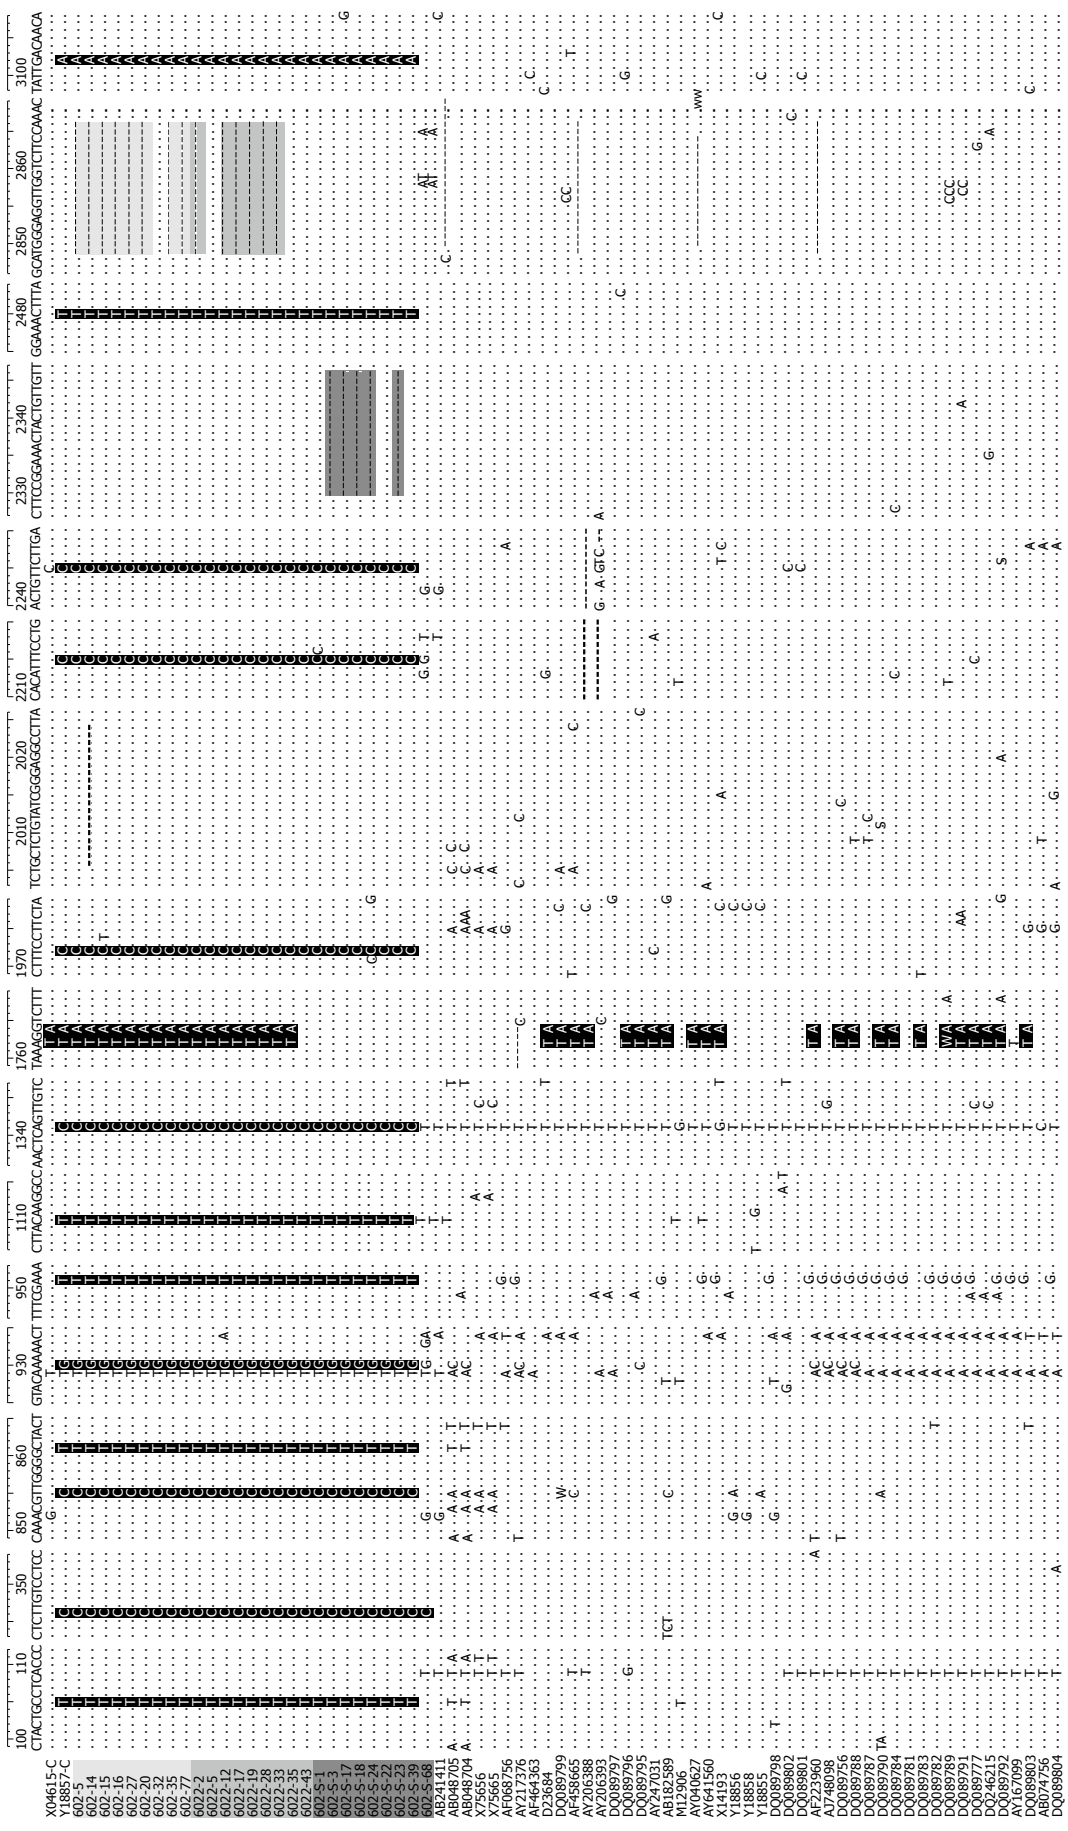

Figure 2 Nucleotide sequences of the 27 HBV/C isolates and 50 other complete genome sequences of genotype C [light gray, Mother: 602 (1 d); Gray, 6022 (6 mo); Dark gray, Son: 602-S; Sequences: Gray (deletion), black (substitution of nucleotides)]. Compared with the 50 complete genome sequences of genotype C, nucleotide positions at 105T, 346C, 855C,861T, 930G, 951T, 1110T, 1341C, 1972C, 2215C, 2246C,2480T and 3102A were specific for the 27 samples. 14 clones of the mother had an 18bp deletion from start codon; 5 clones of the son had a 17nt deletion from nt2330; 1762T/1764A double mutations were found in all clones of the mother, but none in the sequenced clones of the son. Nucleotides A1762A and G1764A double mutation comprised 54.5% of the total genotype C (42/77).

18bp deletion in preS1 had a tendency for substitution by large fragment deletions in preS1, and laboratory tests in the mother showed abnormal values (ALT > 2 times of reference values) (detailed discussion reported in a

separate publication). However, whether the deletion of aa 1-11 mutation in preS1 was a precursor of large fragment deletion mutation or was an isolated event under immune pressure remains to be determined. To our knowledge, no previous study has reported such deletion mutants. This deletion, which disrupts the preS1 start codon, may play an important role in enhancing the progression of chronic liver disease.

The 18 bp deletion mutants in preS1, located in the overlapping region of S/P gene region, caused six amino acid deletions, from 183 to 187 of the HBV polymerase. In the present study, all of these deletion mutants coexisted with the wild-type full-length genome. Transfection experiments in human hepatocells (HuH-7) demonstrated that the polymerase gene function was not affected by the large pre-S1 deletions, and mutant viral genomes were capable of replication[33]. This finding may explain the above observation, although deletion mutation of pre S1 was the major mutation in the mother, and the viral load in the serum remained high.

Cloning and sequence analysis showed that 3 clones of the mother and one clone of the son had premature S protein, caused by random points mutation. These mutations could affect not only the spatial structure, but also the immune reactivity. Some reports have found that C-terminal truncated S proteins exist in patients with chronic hepatitis B infection and hepatocellular carcinoma[34]. The shorted S proteins can stimulate gene expression from the endogenous HBV enhancer I and can also deregulate the expression of oncogenes such as c-myc[35], which may help clarify the tumor development mechanism of HBV. Whether the truncated S proteins

transactivate the oncogenes and/or worsen the clinical status of the subjects remains to be established.

The double mutation of nucleotide A1762T/G1764A in basal core promoter (BCP), and G1986A in the precore region are frequently observed in HBV sequences isolated from patients with chronic HBV infection, fulminant hepatitis, HCC, and in reactivation of HBV with a fulminant course[36-38], which results in mutations at two codons in the carboxyl functional region of X protein (K130M and V131I), and a stop codon at aa 28 of HBeAg, respectively. At present, there are conflicting opinions regarding 1762T/1764A hotspot mutations. Some studies suggest that these mutations decrease HBeAg expression and slightly increase viral DNA replication, and are mostly found in patients who seroconvert to anti-HBe[39,40]. By contrast, other studies indicate that this mutation is not associated with HBeAg/anti-HBe status or HBV DNA[41,42]. The lack of influence of BCP mutation on HBeAg expression was mainly indicated by its higher prevalence in genotype C than genotype B patients. In the present study, all clones of the mother from two time points had these double mutations (Figure 2); genotype C has a tendency for higher prevalence of 1762T/1764A double mutation (42 *vs* 35, 54.5%). Based on our data from two time points, we did not observe any HBeAg/anti-HBeAg seroconversion, and we did not detect the impact of BCP mutation on HBV DNA load, due to insufficient quantity of 602 sera. Besides, the 1762T/1764A double mutation was present in all clones of the mother, 3 of whom were also coupled with G1896A. The G1896A mutation is supposed to increase the stability of the stem-loop structure. Recent reports suggest that HBV subgenotypes Ba, C1, and C2 have an intermediate frequency of 1896A mutation[43]. Interestingly, although the son was infected *via* the mother, none of the BCP and 1896A mutants were found in the son (0/9). This finding is consistent with previous studies in which mutants with 1896A were seldom transmitted to the infant *via* the mother[44]. Whether the BCP and precore mutations in the mother were related to infection with genotype C, or whether she was seroconverting to anti-HBeAg, or may develop severe disease exacerbations remains to be determined.

A heterogeneous population of core antigen internal deletions (CID) has been found to be highly prevalent in chronic HBV carriers[45,46], HCC patients[47] and immune-suppressed patients[48]. Normally, CID coincides with a potent T/B-cell epitope, and is almost always found in the presence of HBV with an apparent full-length core gene[49-51]. HBcAg has been shown to be a major target of T-cell immunity[52]. However, deletion type HBc did not show any antibody response[53].

In the present study, the wild type precore/core protein and deletion type precore/core protein co-existed in the sera of both the mother and son. Out of the 27 clones, one clone in the mother had 19nt deletion at position nt2006, and 5 clones in the son had 17bp deletion at position nt2330, which caused in-frame shift and resulted in a C-terminal truncated preCore/Core protein. To the best of our knowledge, this is the first report on 17bp deletion mutant, resulting in immune epitope deletion based on the immune epitope prediction tools. Interestingly, none of these mutants were found in the mother. Therefore, we concluded that under host immune pressure, due to the loss of HLA class and B cell I epitopes, this deletion variant may evade the immune system and became dominant in the host.

The 17 bp deletion mutation occurred in the overlapping region of P/C gene, and produced 43 aa peptides of HBV polymerase, possibly resulting in a new start codon, downstream of the original one. P-ORF encodes the terminal protein (TP), polymerase (pol) and RNase H. Previous studies have identified that in a protein-primed reaction, the minimal domain of TP ranged from amino acid 20 to 175[54]. In the present report, these 5 clones had incomplete TP, based on the minimal function domain of TP. These mutants have little or no activity. Interestingly, the viral load in the son was high (4.2×10^8 copy/mL), and no similar deletion mutants were found in his mother. Whether this phenomenon coexisted with the wild-type genome, or was the function domain of TP remains to be examined.

In addition, there were other point mutations and deletion/insertion mutations scattered in the complete genome, many of these were located in the T and B lymphocytes epitope, such as P46L, C69R and F73L in X gene[55], and P54T and M132T in C gene[56], while others resulted in truncated surface or preCore/Core proteins (T361A, TT deletion at nt2012, *etc.*). Because these mutants were dissimilar in different clones, they may have been caused by spontaneous mutation or immune pressure during evolution.

In summary, the HBV strain in the son was transmitted *via* maternal-fetal transmission, based on the presence of 13 specific and common nucleotides in both the mother and son. The dominant HBV mutants were different in the mother and son, because of different immune-environments. These mutants were capable of escaping immune-pressure and were present in HBV carriers. These newly discovered variants were located within or close to the functional domains of viral proteins. Whether they can exist "silently" in the hosts, or will cause liver disease remains to be determined.

COMMENTS

Background

Mother-to-infant transmission is the main pathway of hepatitis B virus (HBV) infection. Approximately 90% infants of HBeAg positive HBsAg carrier mothers become carriers, if no immunoprophylaxis is given. HBV with the same characteristics in the child and the mother interacts with the immune system, resulting in the development of different mutations designed to escape the immune pressure.

Research frontiers

Biosoftwares are powerful tools designed to perform virologic and phylogenetic analysis, and to predict immune epitopes. Combining this knowledge with clinical data on HBV-infected patients, may provide new information on the prevention and treatment of HBV infection.

Innovations and breakthroughs

The results of our study suggest that the preS1 deletion of HBV may be

associated with disease progression. Using immune epitope prediction tools, the immune epitope deletion was found to occur in the C gene region.

Applications

Data obtained by virologic and phylogenetic analysis may provide clues to the prevention and treatment of chronic HBV infection.

Peer review

Virologic and phylogenetic analysis provides evidence of mother to infant transmission, and indicates that HBV with the same characteristics has dissimilar mutations in different hosts. Follow-up studies should greatly enhance the significance of the present report.

Abstract

AIM: To evaluate the protective effects of ilomastat, an exogenous matrix metalloproteinase (MMP) inhibitor, on trinitrobenzenesulfonic acid (TNB)-induced ulcerative colitis (UC) in rats.

METHODS: Male SD rats were randomly divided into model group, protective groups A and B, and normal control group. Rats in the model group received only intra-colonic TNB. Rats in the protective groups A and B received intra-peritoneal ilomastat of 10 mg/kg and 20 mg/kg, respectively, beside TNB. Rats in the normal control group received only intra-colonic normal saline. After 3 wk, segments of colon were obtained**.** RT-PCR and immunohistochemistry were used to examine the expression of MMP-1 and TIMP-1. Hematoxylin-eosin (HE) staining was used for pathological study.

RESULTS: The model of UC was successfully induced in rats. Inflammation of colonic mucosa greatly improved in protective groups A and B. Expression of MMP-1 and TIMP-1 in the model group, protective groups A and B was significantly higher than that in the normal control group ($P < 0.0001$) with MMP-1 expression increased more significantly than TIMP-1 expression. Expression of MMP-1 in protective groups A and B was significantly lower than that in the model group ($P < 0.0001$) . Expression of MMP-1 in protective group B was significantly lower than that in protective group A ($P < 0.0001$).

CONCLUSION: Ilomastat improves TNB-induced UC in rats by inhibiting the MMP-1 activity.

Key words: Ulcerative colitis; Trinitrobenzenesulfonic acid; Matrix metalloproteinase-1; Tissue inhibitors of matrix metalloproteinase-1; Ilomastat

INTRODUCTION

Ulcerative colitis (UC) is a chronic nonspecific inflammatory disease of the colon characterized clinically by abdominal pain, diarrhea and mucus-pus stool. It is believed that factors such as heredity, immune disturbance, environment, and inflammatory cytokines, *etc.* play an important role in the development of UC[1]. Pathologically, UC invades mainly mucosa and sub-mucosa of colon with excessive degradation of extracellular matrix (ECM) by matrix metalloproteinases (MMPs) secreted by interstitial cells and activated by various cytokines[2-4]. MMPs possess many important physiological and pathophysiological functions in the gastrointestinal tract, such as implantation of T cells in mucosa, regeneration of epithelium, aggregation of lymphocytes and production of cytokines in the process of inflammation[5,6]. MMPs are regulated by their specific tissue inhibitors at transcription, pre-enzyme activation, ECM, and inhibition levels[7]. Tissue inhibitors of matrix metalloproteinases (TIMPs) are natural inhibitors of MMPs. TIMP-1, extensively present in the human body, mainly inhibits MMP-1. Mckaig BC *et al*[8] found that expression of MMP-1 is significantly higher while expression of TIMP-1 is relatively lower in colonic tissues. Therefore, it is quite possible that exogenous MMP inhibitors exert their inhibitory effects on expression of MMPs and subsequently improve

colonic tissue damages. Disebatiano *et al*[9] utilized batimastat (BB-94), an artificial MMPI, in a rat model of UC to study its protective effect on colonic tissue and found that batimastat is water insoluble with a low bio-availability. Ilomastat is thought to be the most powerful MMPI with a promising future and has been used in trauma healing, tumor inhibition and cornea repair[10-12]. However, no study on its protective effect on UC is available. Therefore, in this study, we used ilomastat to study its protective effect on trinitrobenzenesulfonic acid (TNB)-induced UC in rats.

MATERIALS AND METHODS

Establishment of animal model

Thirty two male Sprague-Dawley (SD) rats, weighing 180-220 g, were used to establish a Morris model of UC. Briefly, the animals were fasted for 48 h before experiment. A 2 mm catheter was inserted into the anus of rats. One hundred mg/kg TNB dissolved in 0.25 mL of 50% alcohol was injected into the colon through the catheter. The animals were inverted for about 3-5 min to prevent backflow of the solution.

Animal grouping

The rats were divided randomly into four groups: UC model group, protective groups A and B, and control group (n = 8). Rats in the model group were given only the mixed solution of TNB and alcohol, rats in protective groups A and B were intra-peritoneally given 10 mg/kg and 20 mg/kg of ilomastat, twice daily beside administration of TNB and alcohol, rats in the control group were given only normal saline. Ilomastat was administered 30 min before enema. All the animals were sacrificed 3 wk after enema.

Treatment of samples

An abdominal midline incision was made to open the abdomen and separate the colon. The colon was cut open to take the diseased colon samples. The samples were washed in 4℃ normal saline to remove stool residues. Then the colon samples were snap frozen in liquid nitrogen for isolation of RNA and RT-PCR, and fixed in 10% formalin and embedded in paraffin for HE staining and immunohistochemistry.

Pathological observation

Paraffin-embedded and formalin-fixed colon samples were cut into 4-μm thick sections for HE staining and pathological observation.

RT-PCR for MMP-1 and TIMP-1

RT-PCR for MMP-1 and TIMP-1 was performed using a TaKaRa RNA PCR kit 3.0 (AMV, supplied by Dalian Baosheng Biotechnology Company) following the manufacturer's instructions. Five μL of PCR product was run on 2% agarose gel electrophoresis. The sequences of primers[13,14] used are as followings: MMP-1 (639 bp): forward TTGTTGCTGCCCATGAGCTT and reverse ACTTTGTCGCCAATTCCAGG; TIMP-1 (495 bp): forward TTTGCATCTCTGGCCTCTG and reverse AATGACTGTCACTCTCCAG; β-actin (357 bp): forward TAAAGACCTCTATGCCAACAC and reverse TAAAGCCATGCCTAATGTCTC.

Immunohistochemistry

Briefly, sample sections were washed 3 times with PBS, 3 min each time after initial treatment. Primary antibodies, mouse anti-human MMP-1 and TIMP-1 monoclonal antibodies (Santa Cruz, USA) were added and incubated at room temperature for about 1.5 h, washed and incubated with peroxidase-conjugated secondary antibody for 15 min and washed. A brown product was developed in diaminobenzidine (DAB) for 10 min.

Result determination and statistical analysis

A bio-imaging system (PALL Company, USA) was employed to analyze the density of PCR product bands. MMP-1 and TIMP-1 mRNAs were semi-quantitatively expressed as the ratio of MMP-1, TIMP-1 and β-actin OD values. All values were expressed as mean ± SD.

Positive results of immunohistochemistry were determined by the appearance of brown substances in cells after DAB staining. An image-pro-plus 4.5 microscopic image analyzing system (Media Cybernetics Company, USA) was utilized to measure the density of brown substances. Five fields in each section were randomly chosen, and the total density and total area in the fields were measured. The mean density was calculated by the ratio of the total density and total area. A bigger ratio indicates a greater expression of the corresponding proteins.

Student-Neuman-Keuls test was used to compare the expressions of MMP-1 mRNA, TIMP-1 mRNA and their corresponding proteins. $P < 0.05$ was considered statistically significant. All statistical analyses were performed using SPSS 11.5 for windows.

RESULTS

Pathological change under light microscope (HE staining)

As shown in Figure 1, the colonic mucosa structure in the normal control group was intact. Mucosa and sub-mucosa defects could be clearly seen with infiltrations of inflammatory neutrophils and lymphocytes in the lamina properia of the model group. Tissue necrosis was obvious. Lobed neutrophils were observed in protective group A and proliferation of new blood vessels was found in protective group B. Regenerated epithelia covered the surface of ulcer and the mucosa tended to be complete. Necrotic tissue was absorbed. The base of ulcer was filled with tissues and scars.

Results of RT-PCR for MMP-1 and TIMP-1

As shown in Table 1 and Figure 2, expression of MMP-1 in the model group, protective groups A and B was significantly higher than that in the normal control group

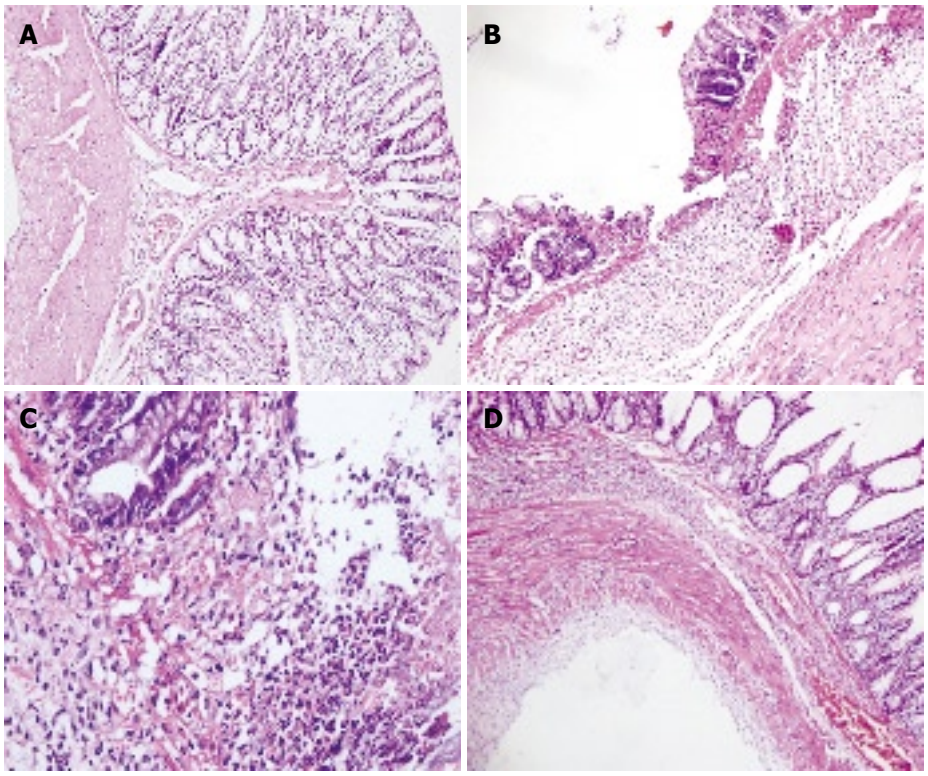

Figure 1 Pathological change under light microscopy (HE staining, × 400) in normal control group (**A**), model group (**B**), protective group A (**C**), and protective group B (**D**).

Table 2 Biosoftwares analysis of MMP-1 and TIMP-1 proteins in different groups of UC in rats (mean ± SD)

Groups	MMP-1	TIMP-1
UC model group	0.0877 ± 0.0088[a,c,e]	0.0841 ± 0.0081[a]
Protective group A	0.0779 ± 0.0059[a,c]	0.0794 ± 0.0058[a]
Protective group B	0.0158 ± 0.0034	0.0705 ± 0.0069
Normal controls	0.0041 ± 0.0009	0.0344 ± 0.0082

[a]$P < 0.05$ *vs* normal control group, [c]$P < 0.05$ *vs* protective group B, [e]$P < 0.05$ *vs* protective group A.

($P < 0.0001$) and the expression of MMP-1 was more significant than that of TIMP-1. Expression of MMP-1 in protective groups A and B was significantly lower than that in the model group ($P < 0.0001$). Expression of MMP-1 in protective group B was significantly lower than that in protective group A ($P < 0.0001$).

Expression of TIMP-1 in the model group was significantly higher than that in protective group B and in the normal control group ($P = 0.004$). There was no significant difference between protective groups A and B ($P > 0.05$).

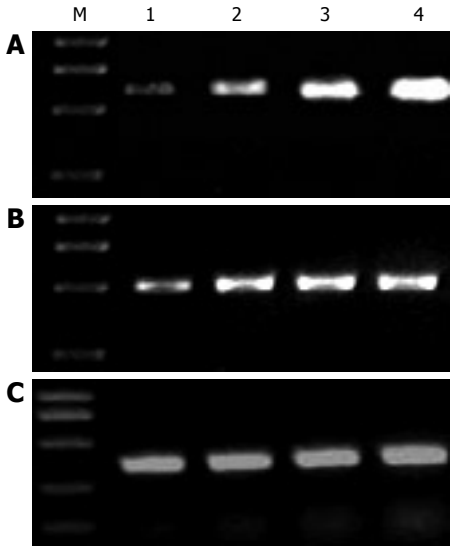

Figure 2 RT-PCR for MMP-1 (**A**), TIMP-1 (**B**) and β-actin (**C**). M: marker; lane1: normal controls; lane 2: protective group B; lane 3: protective group A; lane 4: UC model group.

Results of immunohistochemistry

Immunohistochemistry showed that the expression of MMP-1 and TIMP-1 proteins was basically identical to that at transcription level. The expression of MMP-1 and TIMP-1 in the model group, protective groups A and B was significantly higher than that in the normal control group ($P < 0.0001$, Table 2, Figure 3).

DISCUSSION

Establishment of an appropriate animal model of UC is essential to the study of pathogenesis and treatment of UC. In this study, we utilized the Morris model of UC induced by TNB[15]. The pathological changes in this model which has been extensively used in recent years mimic those of human UC, revealing dynamic changes at

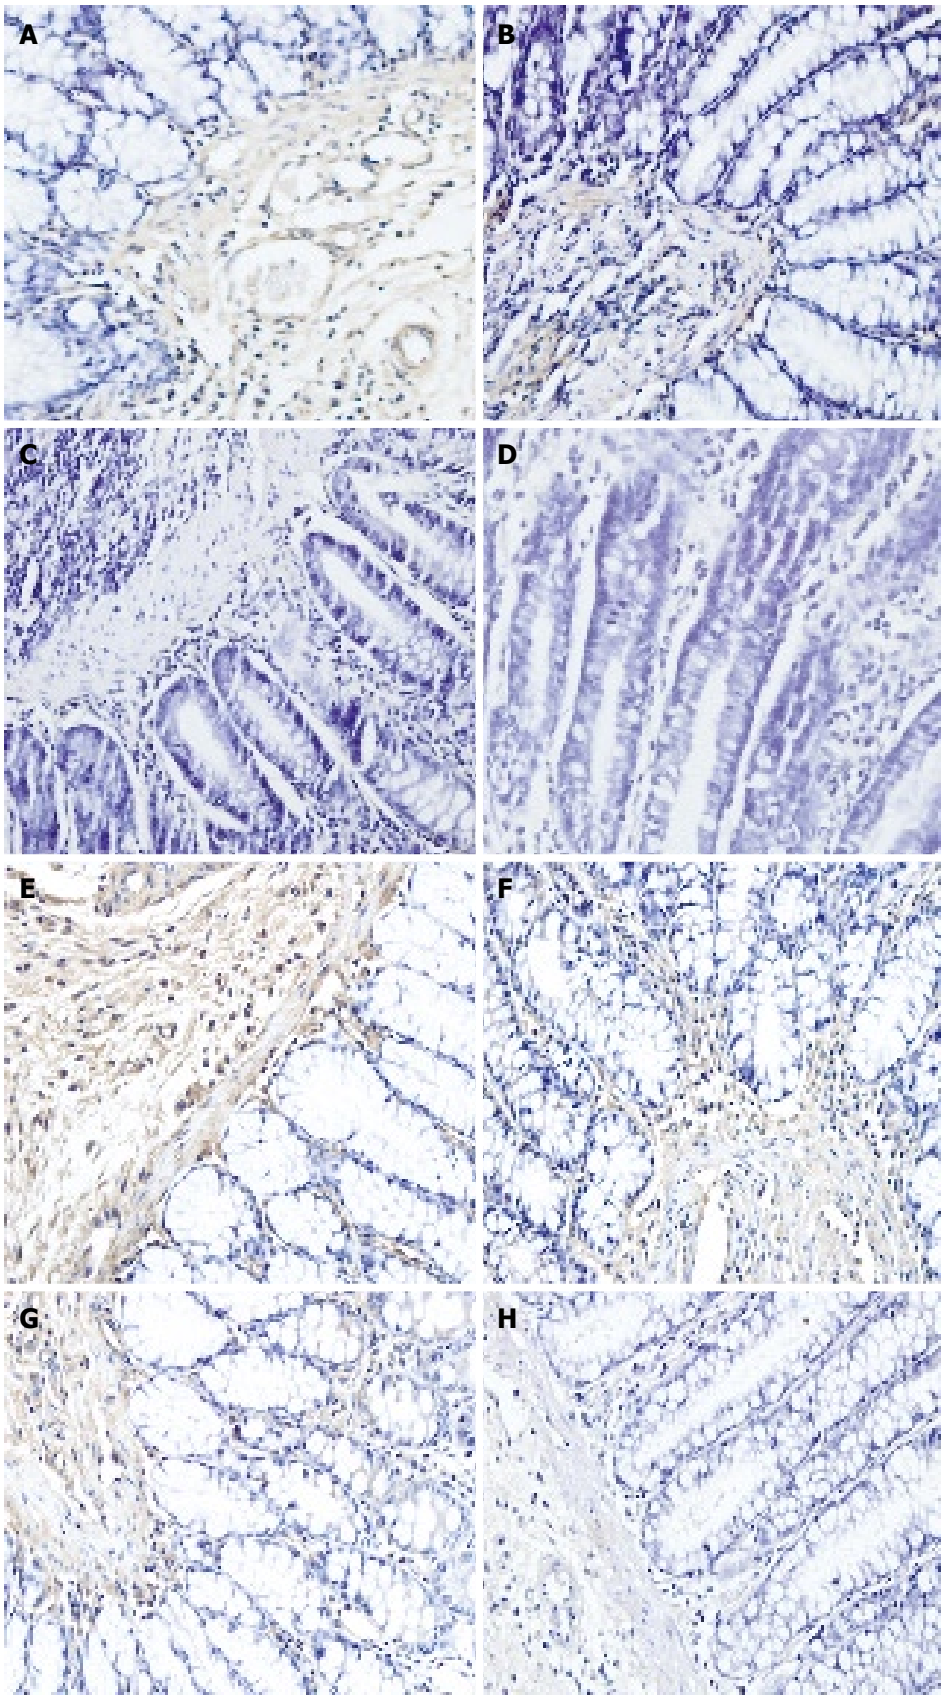

Figure 3 Immunohistochemistry showing MMP-1 in model group (**A**, **E**), protective group A (**B**, **F**), protective group B (**C**, **G**), normal control group (**D**, **H**).

acute and chronic phases. The possible mechanism is that TNB may act as a chemical semi-antigen which combines with keratin protein of the colonic mucosa, thus leading to local cellular immune responses and inflammatory changes when ethanol, an organic solvent, damages the colonic mucosa barrier. Neither TNB nor ethanol is able to produce typical UC[16]. In this study, HE staining revealed erosion and ulceration in the mucosa and submucosa of colon with infiltrations of massive neutrophils and lymphocytes under light microscope. These changes

were correspondent to the features of acute pathological lesions in UC. Allgayer *et al*[17] also suggested that the dividing line between acute and chronic phases in this model is approximately 3 wk after the initiation of TNB administration.

MMPs are a group of zinc-dependent proteases that play an important role in ECM remodeling, connective tissue injury, formation of new blood vessels, and proliferation of inflammatory cells[18]. An excessive degradation of ECM by MMPs is the basic pathophysiological event leading to mucosa ulceration in UC. The activity of MMPs can be inhibited specifically by their natural inhibitor, TIMP. TIMP-1 is the main member of TIMPs inhibiting nearly all MMPs, particularly MMP-1. In this study, we detected the expression of MMP-1 and TIMP-1 at transcription level using RT-PCR. The results showed that expression of both MMP-1 and TIMP-1 was significantly higher than that in the control group and the expression of MMP-1 was significantly increased. Salmela *et al*[19] have also observed similar results using *in situ* hybridization and gene sequence analysis. Our immunohistochemistry results showed that expression of MMP-1 and TIMP-1 was identical to that at transcription level, showing that the expression level of MMP-1 is higher than that of TIMP-1. MMP-1/TIMP-1 ratio was 0.02631 in the control group and 1.1164 in the model group, implying that imbalance between MMP-1 and TIMP-1 is closely related to the ulceration of colonic mucosa in UC patients[20]. Therefore, we speculate that exogenous MMP inhibitors may be able to inhibit expression of MMP-1, thus balancing the expression of MMP-1 and TIMP-1 and relieving, at least partially, the pathological changes in the colonic mucosa of UC patients. Sykers *et al*[21] used marimastat, another artificial MMPI, to treat TNB-induced ulcerative colitis in rats and found that marimastat is capable of relieving colonic injury and decreasing colonic inflammatory score. Medina *et al*[22] showed that inflammation of the colonic mucosa improves to some extent in rat models of inflammatory bowel disease. Disebatiano *et al*[9] found that intraperitoneal injection of batimastat can decrease the activity of MPO and improve colonic tissue damage in TNB-induced ulcerative colitis.

In this study, we used ilomastat, a known most potent artificial MMPI, to observe its protective role in TNB-induced ulcerative colitis in rats. Its intraperitoneal dosage used was 10 mg/kg in protective group A and 20 mg/kg in protective group B as previously described[9,12]. The pathological changes in the protective groups A and B under light microscope much improved compared with the model group. Infiltration of neutrophils and lymphocytes was greatly lessened and the mucosa tended to be perfect in the protective groups A and B, suggesting that ilomastat is able to relieve ulceration of colonic mucosa in UC patients. RT-PCR and immunohistochemistry showed that expression of MMP-1 in the protective groups A and B was obviously decreased when compared with the model group, suggesting that ilomastat is able to inhibit expression of MMP-1. Meanwhile, there was no significant difference in expression of TIMP-1 between protective groups A and B and the model group, indicating that ilomastat does not influence TIMP-1 expression. Therefore, we speculate that ilomastat exerts its protective effects by inhibiting MMP-1 expression and by restoring the balance between MMP-1 and TIMP-1. The possible mechanisms underlying its protective effect on MMP-1 expression and balance between MMP-1 and TIMP-1 may be as follows: (1) ilomastat inhibits the catalytic activity and hydrolysis of ECM by combining the active site of zinc in MMP-1 molecule; (2) ilomastat inhibits hydrolysis of collagens in a dose-dependent manner in the presence of plasminogen; (3) ilomastat inhibits formation of active MMP-1 by suppressing transfer of MMP-1 precursor.

Comparing protective groups A and B, we found that the morphological improvement was different in different dosage groups. In protective group B receiving a bigger dosage of ilomastat, mucosa ulcer was much shallower and infiltration of neutrophils and lymphocytes was fewer than that in protective group A, with regenerated epithelia cells covering the ulcer and granulation and scar tissues filling the base. Furthermore, expression of MMP-1 was also different. The expression level of MMP-1 was obviously lower in protective group B than in protective group A. These results indicate that the protective effects of ilomastat are dose dependent, which is consistent with the reported findings[21].

The protective effects of ilomastat on experimental rat model of UC observed in our study indicate that exogenous MMPI may be used in treatment of UC. Nevertheless, intervention on up-regulation of endogenous TIMP-1 to restore the balance between MMP-1 and TIMP-1 might be another treatment modality for UC.

In conclusion, expression of MMP-1 and TIMP-1 is significantly increased in TNB-induced ulcerative colitis of rats. Both MMP-1 and TIMP-1 play an important role in the pathogenesis of UC. Ilomastat is able to relieve colonic mucosa damage in TNB-nduced ulcerative colitis of rats in a dose-dependent manner by inhibiting expression of MMP-1. Therefore, ilomastat can be used in treatment of UC.

COMMENTS

Background

Matrix metalloproteinase-1 (MMP-1) has been implicated in the development of ulcerative colitis (UC) by the fact that it is over-expressed in this inflammatory bowel disease. Tissue inhibitor of matrix metalloproteinase-1 (TIMP-1), a natural inhibitor of MMP-1, is also believed to be over-expressed, but not parallel to that of MMP-1. Therefore, in this study, ilomastat, an artificial MMP-1 inhibitor (MMPI), was employed to verify its protective effect on the rat model of UC.

Research frontiers

In recent years, intense and extensive studies have shown that MMPs, TIMPs and other inflammatory cytokines play an important role in the development of UC, while studies on the effects of exogenous MMPI on UC are not well documented. Therefore, more studies both in animals and in humans are badly needed to verify the protective and therapeutic effects of artificial MMPI on UC.

Innovations and breakthroughs

Ilomastat, a most powerful artificial MMPI, has been used in experimental and

clinical treatment of tumors of animal and human beings. Ilomastat can inhibit tumor transfer due to its powerful inhibitory effect of on MMPs, especially on MMP-1. However, its protective effects on UC remain largely unknown. Therefore, in this study, we verified the protective effects of ilomastat on UC in rats and provided a new therapeutic approach to UC.

Applications

Up to now, no satisfactory therapy for UC is available. MMPI targeting MMPs may become a new and effective treatment modality for UC.

Peer review

The authors showed that ilomastat could improve the pathological injuries of colonic mucosa in TNB-induced UC in rats by inhibiting the MMP-1 activity, thus providing a new and effective treatment modality for UC. The study is well designed and interesting.

Abstract

AIM: To evaluate the accuracy of automated blood cell counters for ascitic polymorphonuclear (PMN) determination for: (1) diagnosis, (2) efficacy of the ongoing antibiotic therapy, and (3) resolution of spontaneous bacterial peritonitis (SBP).

METHODS: One hundred and twelve ascitic fluid samples were collected from 52 consecutive cirrhotic patients, 16 of them with SBP. The agreement between the manual and the automated method for PMN count was assessed. The sensitivity/specificity and the positive/negative predictive value of the automated blood cell counter were also calculated by considering the manual method as the "gold standard".

RESULTS: The mean ± SD of the difference between manual and automated measurements was 7.8 ± 58 cells/mm^3, while the limits of agreement were +124 cells/mm^3 [95% confidence interval (CI): +145 to +103] and -108 cells/mm^3 (95% CI: -87 to -129). The automated cell counter had a sensitivity of 100% and a specificity of 97.7% in diagnosing SBP, and a sensitivity of 91% and a specificity of 100% for the efficacy of the ongoing antibiotic therapy. The two methods showed a complete agreement for the resolution of infection.

CONCLUSION: Automated cell counters not only have a good diagnostic accuracy, but are also very effective in monitoring the antibiotic treatment in patients with SBP. Because of their quicker performance, they should replace the manual counting for PMN determination in the ascitic fluid of patients with SBP.

Key words: Spontaneous bacterial peritonitis; Ascites; Polymorphonuclear cell count; Automated cell counter; Paracentesis; Cirrhosis

INTRODUCTION

Spontaneous bacterial peritonitis (SBP) is a well-recognized and potentially fatal complication in cirrhotic patients with ascites[1-3]. The prevalence of SBP in hospitalized patients has been reported to range between 10% and 30%[4-6]. The mortality rate related to this complication remains high, approximately 20%, despite the recent improvements achieved in the management of this complication[7-9]. A rapid diagnosis and a prompt treatment are essential for the survival of these patients. SBP symptoms, however, are not always present and may be insidious; in addition, the ascitic fluid cultures require several days to grow and, in the clinical practice, they are negative in more than 60% of patients with SBP[10].

For these reasons, the current guidelines[10] recommend the use of polymorphonuclear (PMN) cell count in the ascitic fluid for diagnosing SBP, suggesting that a PMN cell count greater than 250 cells/mm^3 should be considered highly suspicious for SBP, thus providing an indication to empirically initiate the antibiotic treatment.

To date, PMN cell count is routinely performed

by using the traditional hematological method with a light microscope in a manual counting chamber (Burker chamber). The manual laboratory counting of ascitic PMN is however laborious, time-consuming, and costly. Moreover, it is not always timely available in all hospitals, especially in those small patient care units with limited laboratory facilities, and it cannot be frequently performed on an emergency basis (at night or on weekends). The manual system, therefore, too often delays the initiation of the important sequence of events that should lead to a rapid diagnosis and treatment of this infection.

In the last years, a series of reports proposed the use of urinary reagent strips to achieve an "instant" bedside diagnosis of SBP[11-14] with promising results[15-17]. A recent prospective multicenter study[18] in which 2123 paracenteses were performed in 1041 patients, however, reports the lack of any diagnostic efficacy of the strip-test. The authors concluded that a routine cytological examination remains mandatory for the diagnosis of SBP. Moreover, the urine screening test has never demonstrated to be useful in the monitoring of PMN cell count at follow-up paracenteses performed 48 h after the beginning of the treatment for SBP. According to current guidelines[10], in fact, the antibiotic treatment empirically administered should be changed if a decrease in the PMN count of less than 25% of the pre-treatment value is not obtained. A qualitative method providing only a negative/trace/positive score needs therefore to be always confirmed by standard cytology of the ascitic fluid.

A valid alternative to manual PNM counting is represented by automated blood cell counters, commonly and largely used in all laboratories for blood cell counting; they offer accurate and rapid differential counts of leukocytes, there including PMN. Our previous study[19], published in 2003, demonstrated that automated blood cell counters are a reliable tool for the rapid diagnosis of SBP and our experience was also confirmed by Cereto *et al*[20]. Moreover, automated cell counters, as a quantitative method able to provide a reliable PMN value not requiring further confirmation, could be useful not only for diagnostic purposes, but also for determining the effectiveness of the ongoing empiric antibiotic therapy.

The aim of the present study was therefore to evaluate the validity of the automated blood cell counter not only for SBP diagnosis, but also for monitoring the responsiveness to the ongoing antibiotic treatment. For this purpose, we compared the determination of PMN count in the ascitic fluid obtained by the manual and the automated methods at basal and follow-up diagnostic paracenteses in a group of cirrhotic patients with SBP.

MATERIALS AND METHODS

Patients

A total of 112 ascitic fluid samples was collected from 52 consecutive cirrhotic patients with ascites (36 men and 16 women, mean age 65.3 ± 11.7 years) hospitalized at our Gastroenterology Unit. The diagnosis of liver cirrhosis was based on clinical, biochemical, and/or histopathological data. The severity of the liver disease was classified in each patient at entry, according to the Child-Pugh[21] scores.

Methods

All the patients underwent a routine abdominal paracentesis at the time of hospitalization. Paracentesis was repeated if, during hospitalization, the patient had signs or symptoms compatible with infection (i.e. fever, change in the mental status, abdominal pain, peripheral leukocytosis, development of renal failure, hypotension, *etc.*). In some patients re-admitted for recurrent ascites, a diagnostic paracentesis was also repeated. Two samples of ascitic fluid for each patient were collected under aseptic conditions in tubes containing ethylenediamine tetraacetic acid (EDTA) as anticoagulant. White blood cells (WBC) and PMN counts were determined by both the traditional method with a light microscope in a manual counting chamber, and the automated cell blood counter (Technicon System H*1; Bayer Diagnostics, Milan, Italy), as previously described[19]. The specimens were analyzed within 1 h. Additional samples of ascitic fluid were collected for the determination of albumin and total protein concentrations. Moreover, 10 mL of ascitic fluid were directly inoculated at the patient's bedside into aerobic and anaerobic blood culture bottles for bacteriological examination[22].

For traditional manual WBC and PMN counts, ascitic fluids were collected in tubes containing 0.084 mL of 15% EDTA. Ten milliliters were centrifuged at 1500 r/min for 10 min; 9 mL of the supernatant were discharged and 40 μL of the remaining ascitic fluid were diluted with 800 μL of Turk's fluid and gently shaked; 20 μL were used to fill the counting chamber. The cells were counted (× 40) in one of the nine large squares, and the number of WBC per cubic millimeter was calculated. Another sample of 10 mL of ascitic fluid was used for the PMN percentage determination (× 100), after centrifugation and May-Grünwald-Giemsa staining.

For WBC and PMN cell counts by the automated method, 100 μL of ascitic fluid, collected in tubes containing 0.054 mL of 15% EDTA anticoagulant, were directly injected into the analyzer.

Diagnosis and treatment of patients with SBP

SBP was diagnosed when the PMN cell count in the ascitic fluid was greater than 250 cells/mm^3 and an antibiotic treatment with i.v. cefotaxime (2 g/8 h, for a minimum of 5 d) was empirically initiated in all the patients with these values, regardless of the positivity of the culture. The antibiotic dosage was adjusted to the renal function throughout the treatment period and the efficacy was evaluated by further diagnostic paracenteses 2 and 5 d after the beginning of the treatment. A further paracentesis was performed in the patients with no resolution at 5 d.

Table 1 Demographic, clinical characteristics and outcome of the 16 cirrhotic patients with SBP (mean ± SD)

Variables	Cirrhotic patients with SBP
n	16
Sex (M/F)	11/5
Age (yr)	63.8 ± 10.3
Child-Pugh class (A/B/C)	0/8/8
Alcoholic origin (No/Yes)	10/6
Treatment efficacy at 48 h (No/Yes)	11/5
Resolution of infection (No/Yes)	12/4

In those cases not responding to the initial antibiotic regimen, the therapy was appropriately changed, either according to the in vitro susceptibility of the isolated bacteria, or empirically. For this purpose, a further paracentesis was always performed 2 d after the beginning of the antibiotic treatment. Treatment failure was established when the condition of the patients rapidly deteriorated within the first hours of the antibiotic therapy (i.e. with development of shock), or when no significant decrease in the ascitic PMN count was observed in the follow-up paracentesis. A reduction in the PMN count of less than 25% of the pre-treatment value was considered as suggestive of failure of the antibiotic treatment[10].

At the time of the 48-h paracentesis, as well as at the following paracentesis, WBC and PMN counts were performed by both manual method and automated cell counter.

SBP was considered resolved when PMN count in the ascitic fluid had decreased to less than 250 cells/mm^3.

Statistical analysis

Results are expressed as mean ± SD. The values of PMN count determined by the two methods were compared using the Student's *t* test. The agreement between the two techniques was assessed by using the method suggested by Bland and Altman[23]. The differences between the results of the manual counting and the automated blood cell counter in each patient were plotted against the mean of the two readings observed in each patient. The mean and SD of the differences were calculated. The limits of agreement, defined as the mean ± 2 SDs of the difference, and their 95% confidence intervals (CI) were then calculated.

By considering the PMN count determined by the traditional manual method as the "gold standard", the sensitivity/specificity and the positive/negative predictive value of the automated blood cell counter were calculated according to Ransohoff and Feinstein[24] for the following end-points: (1) diagnosis of SBP defined as a PMN count of more than 250 cells/mm^3; (2) treatment efficacy defined as a decrease in the PMN count of more than 25% of the pre-treatment value at the 48-h diagnostic paracentesis; (3) resolution of the infection defined as a reduction of PMN count to less than 250 cells/mm^3.

The statistical significance was established at a $P < 0.05$. Calculations were performed by using a statistical software program (Number Cruncher Statistical System 97).

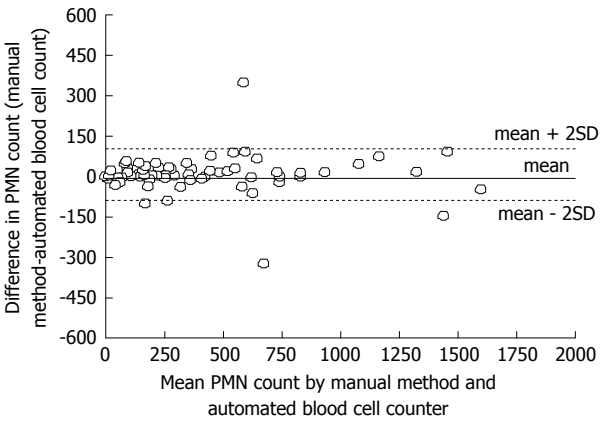

Figure 1 PMN cell count-Scatter plot of the differences between the manual method and the automated blood cell counter against the mean of the two measurements, showing the limits of agreement defined as the mean of the difference ± 2SD.

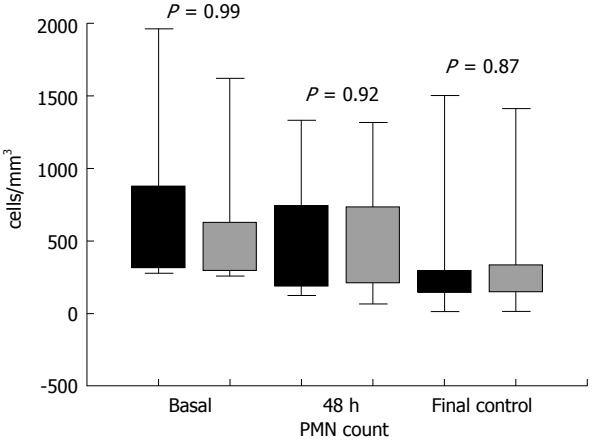

Figure 2 Comparison between PMN cell counts determined with the automated blood cell counters (black bars) or the manual method (gray bars) in the patients with SBP.

RESULTS

A total of 112 samples of ascitic fluid were collected from 52 consecutive cirrhotic patients (36 male/16 female; age: 65.3 ± 11.7 years; Child-Pugh class: 24 B/28 C; alcoholic origin: 29%) with ascites. The degree of agreement between the measurements of PMN count in the ascitic fluid, using the manual method or the automated blood cell counter, is reported in Figure 1. The mean ± SD of the difference between the manual and the automated measurements was 7.8 ± 58 cells/mm^3, while the limits of agreement were +124 cells/mm^3 (95% CI: +145 to +103) and -108 cells/mm^3 (95% CI: -129 to -87).

SBP, as indicated by a PMN count > 250 cells/mm^3 with the traditional manual method, was diagnosed in 16 patients. Demographic, clinical characteristics, and outcome of these 16 patients with SBP are reported in Table 1. No significant differences were observed when PMN counts were determined by using both methods (Figure 2).

As far as the diagnosis of SBP is concerned, the

agreement between the two methods was observed in all the patients but one, who had a PMN count of 270 cells/mm^3 at the automated blood cell counter and of 249 cells/mm^3 at the manual method (false positive result). By considering a PMN count > 250 cells/mm^3 determined by the manual method as the "gold standard" for the SBP diagnosis, the automated blood cell counter had a sensitivity of 100% and a specificity of 97.7%, whereas positive and negative predictive values were 94.1% and 100%, respectively.

As far as the efficacy of the antibiotic treatment is concerned, the agreement between the two methods was obtained in all the patients but one, in whom the therapy was not considered effective by the automated counter only (false negative result). By considering the treatment efficacy as a reduction in the PMN count > 25% of the pre-treatment value (determined by the traditional manual method) as the "gold standard", the automated blood cell counter had a sensitivity of 91% and a specificity of 100%, whereas positive and negative predictive values were 100% and 83.3%, respectively.

By considering the resolution of infection as a reduction of PMN count to less than 250 cells/mm^3 (determined by the traditional manual method) at the final paracentesis as the "gold standard", the automated blood cell counter showed a complete agreement (sensitivity 100%, specificity 100%, positive and negative predictive values 100%).

DISCUSSION

In the guidelines for the diagnosis and treatment of SBP in cirrhotic patients[10] published in the year 2000, the International Ascites Club suggested that a PMN cell count greater than 250 cells/mm^3 should be considered highly suspicious for SBP, thus providing an indication to promptly initiate an empiric antibiotic treatment. Forty eight hours after the initiation of antibiotics, a repeat diagnostic paracentesis is also recommended, either to document the response by a greater-than-25% decrease in the ascitic fluid neutrophil count, or to induce a change in the antibiotic therapy. A further diagnostic paracentesis showing that PMN cell count is below 250 cells/mm^3 is finally indicated to confirm the infection resolution and stop the antibiotic treatment.

To date, PMN cell count is routinely performed by using the traditional hematological method with a light microscope in a manual counting chamber. Urinary reagent strips have been used to make an "instant" bedside diagnosis of SBP with controversial results[12,18]. This screening test, however, is a qualitative method providing only a negative/trace/positive score; it is therefore, by definition, unable to monitor the PMN cell count at follow-up paracentesis (performed 48 h after the beginning of the treatment). In the management of SBP, the cytological examination remains then mandatory. Manual laboratory counting of ascitic PMN is however laborious, time-consuming, costly, and not always timely available in all the hospitals. Automated blood cell counters, commonly and largely used in laboratories for blood cell counting, offer instead an accurate and rapid count of PMN in the ascitic fluid and has proven to be a reliable tool for the rapid diagnosis of SBP[19,20]. This finding is confirmed by the present study in which we analyzed with both methods 112 samples of ascitic fluid collected from 52 consecutive cirrhotic patients with ascites. Although the agreement limits (as reported in Figure 1) may in fact range between +124 and -108 cells/mm^3, SBP was correctly diagnosed by automated blood cell counter in all the cases but one (a false positive result). The use of the automated method as the only diagnostic tool, therefore, would have erroneously submitted this patient to an antibiotic treatment: a less significant error than that of no treating a patient who actually needed to be treated.

However, in order to suggest the use of automated blood cell counters as an alternative to manual counting, its usefulness for the optimization of the antibiotic treatment should be demonstrated. The agreement between the two methods should therefore be obtained not only in the first diagnostic paracentesis, but also in those performed for monitoring the antibiotic treatment. The paracentesis performed after 48 h is in fact particularly significant, since the efficacy of the antibiotic treatment is usually established in this phase. As a matter of fact, in case of SBP, in the large majority of the patients antibiotics are chosen empirically-that is, without the support of the result of the ascitic fluid culture. This is because antibiotics should be started immediately after the result of the PMN cell count[10] (before the result of the culture), and because the ascitic fluid culture outcome-by using conventional culture techniques-may be negative in up to 60% of patients with SBP. The reduction of more than 25% of the initial PMN cell count value is the criterion to establish the efficacy of the antibiotic treatment. The present study showed that, at the diagnostic paracentesis performed 48 h after the start of the antibiotic treatment, the two methods agreed in all the patients but one, in whom a false negative result was obtained. By using the automated cell counter, this patient would then be erroneously considered as a non-responder to the ongoing antibiotic treatment. This would have led to a switch in the antibiotic treatment, a less significant mistake than that of erroneously considering the patient as a responder to the ongoing antibiotic treatment. As far as the infection resolution assessed at the final diagnostic paracentesis is concerned (based on a PMN count below 250 cell/mm^3), an agreement between the two methods was achieved in all the patients. These results suggest that automated cell counters should be considered a reliable tool not only for the diagnosis of SBP, but also in its optimal management; automated methods could therefore definitely replace manual counting. The benefits of a quicker and precise method in the evaluation of the ascitic fluid have been clearly stressed[25].

Another, although less important, advantage of the automated cell counting method over both reagent strips and the manual method is the possibility to precisely

assess the amount of PMN in a bloody (for a traumatic tap or a condition inducing bleeding) ascitic fluid. With the last two methods, the amount of PMN deriving directly from the blood spilled over into the ascitic fluid cannot be differentiated from the amount of PMN due to the infection. A correction factor of 1 PMN per 250 red blood cells has been proposed[10], since this is the maximum expected ratio of PMN to red cell normally present in the peripheral blood. With automated cell counters, a measure of the amount of red blood cells and PMN in both the peripheral blood and the ascitic fluid can be simultaneously obtained. The amount of ascitic PMN due to the infection can be therefore calculated by the real PMN-to-red blood cells ratio in the blood and by the real erythrocytes and PMN number in the ascitic fluid. The simultaneous count of PMN and erythrocytes in the same sample of ascitic fluid cannot be made by manual count, since to obtain a reliable PMN count in a manual counting chamber, erythrocytes should be previously hemolyzed by an acidic solution.

In conclusion, the manual and the automated methods have a good agreement in the determination of PMN in the ascitic fluid. Automated cell counters have a good diagnostic accuracy, not only for the diagnosis, but also for the monitoring of the antibiotic treatment in patients with SBP. Automated cell counters, which offer an easier and quicker PMN count, should therefore replace the manual counting for PMN determination in the ascitic fluid analysis.

COMMENTS

Background

Spontaneous bacterial peritonitis (SBP), a severe complication of ascites, is managed on the results of polymorphonuclear (PMN) cell count in the ascitic fluid, which are used both to test the efficacy of the ongoing antibiotic treatment and to establish the resolution of infection.

Research frontiers

Manual PMN counting is time-consuming, costly, and not always timely available. Automated blood cell counters, commonly used in all laboratories for blood cell counting, may be a valid alternative.

Innovations and breakthroughs

Automated cell counters provide a reliable ascitic PMN count and have a good diagnostic accuracy, not only for the diagnosis, but also for monitoring the effectiveness of the ongoing antibiotic treatment in patients with SBP.

Applications

Automated cell counters, which offer an easier and quicker PMN count, should therefore replace the manual counting for PMN determination in the ascitic fluid analysis.

Peer review

This is a well-written paper. Authors demonstrated that automated cell counters not only have a good diagnostic accuracy, but are also very effective in monitoring the antibiotic treatment in patients with SBP.

Abstract

AIM: To investigate the relationships between Type 2 diabetes mellitus (DM2) and the risk of hepatocellular carcinoma (HCC).

METHODS: We studied the association between DM2 and HCC in a large case-control study that enrolled 465 consecutive Caucasian patients with HCC (78.3% males, mean age 68.5 ± 8.9 years) compared with an age and sex matched control group of 490 subjects.

RESULTS: Prevalence of DM2 was significantly higher in HCC patients (31.2% *vs* 12.7%; OR = 3.12, 95% CI: 2.22-4.43) and in HCC cases with alcohol abuse. DM2 has been diagnosed before the appearance of HCC in 84.1% of diabetic HCC subjects with mean duration of 141.5 mo, higher in cases treated with insulin than in those with oral antidiabetic agents (171.5 *vs* 118.7 mo). Compared to controls, males DM2 with HCC were more frequently treated with insulin (38.1% *vs* 17.6%, $P = 0.009$) and with sulfonylurea with or without metformin than with diet with or without metformin (84% *vs* 68.3%, $P = 0.049$).

CONCLUSION: DM2 in our patients is associated with a 3-fold increase risk of HCC. In most of our cases DM2 pre-existed to HCC. Patients with DM2 and chronic liver disease, particularly insulin treated males, should be considered for HCC close surveillance programs.

Key words: Hepatocellular carcinoma; Type 2 diabetes mellitus; Hepatitis virus B and C; Insulin; Antidiabetic therapy

INTRODUCTION

The incidence of hepatocellular carcinoma (HCC) has increased significantly over the past decades in many parts of the Western world, including Italy. The reasons for this increase are only partially understood. The hepatitis C virus (HCV) epidemics certainly play a role due to the cohort effect of individuals infected in pre-serological age[1,2]. However, approximately 15%-50% of HCC cases are not associated with HCV or hepatitis B virus (HBV), suggesting that other risk factors are responsible for this increase[3]. Diabetes has been suggested to be a risk factor for HCC. During the past two decades the prevalence of Type 2 diabetes mellitus (DM2) has dramatically increased in most developed countries and several epidemiologic studies indicate that it is nowadays epidemic, mostly because of the exponential explosion of obesity[4]. A recent study reported that the prevalence of known diabetes mellitus has increased in Italy from 3.6% to 4.3% during the past 10 years[5]. DM2 is a compensatory high insulin state caused by insulin resistance in fat, muscle tissue and liver[6], associated with an insulin-secretory defect that varies in severity and may lead to a relative insulin deficiency during the patients' lifetime. Therefore, DM2 is initially treated with diet and antidiabetic oral agents; after years, to control glucose metabolism, many patients

are required exogenous insulin treatment. Several studies have shown a relationship between diabetes mellitus and liver diseases[7]. Indeed, diabetes has been recognized as a risk factor for non-alcoholic fatty liver disease (NAFLD), while chronic hepatitis C has been associated with an increased risk of diabetes[8-12]. Several studies have investigated the association of diabetes mellitus and solid malignancies[13-15], and particularly with HCC[3,16-20]. While early studies reported no association[21,22], more recent data have clearly identified DM2 as a risk factor for HCC[20,23]. On this line, a high concentration of insulin could stimulate the IGF pathway in DM2 and molecular studies have shown that insulin and insulin-like growth factor 1 (IGF-1) may have carcinogenetic effects on liver and other tissues[24-28]. Moreover, chronic hyperglycaemia may cause oxidative stress and cellular damage[29]. Although DM2 has been associated in the development of HCC, only few studies have considered the confounding role of HBV and of HCV, two of the major risk factors for HCC. Moreover, diabetes may be secondary to HCC and to the underlying cirrhosis. To our knowledge, there are no studies that have investigated the temporal relationship between the onset of diabetes and the development of HCC. The purpose of the present study was to explore the association between HCC and diabetes in a large cohort of Italian patients with HCC and to describe the temporal relationship between onset of diabetes and development of HCC, and the clinical and metabolic characteristics of patients with DM2 and HCC.

PATIENTS AND METHODS

HCC group

We conducted a population based case-control study recruiting a consecutive cohort of 465 Caucasian patients with HCC seen at the Liver Unit of the Division of Internal Medicine of the Pordenone General Hospital (Pordenone, Italy) between January, 1994 and June, 2006. For the diagnosis of HCC, histological or cytological confirmation was available from the majority (85.6%) of HCC cases. In the remaining HCC cases, the diagnosis was established by coincidental finding of two dynamic imaging techniques [computer tomograghy (CT) scan, magnetic resonance imaging (MRI) and Contrast Enhanced Ultrasound examination in the last 3 years] showing a nodule with arterial hypervascularization followed by portal wash-out, or with a single positive imaging technique associated with alpha-fetoprotein > 400 ng/mL. Patients were divided in two groups: the first group included 305 cases derived from a surveillance program of HCC in cirrhotic patients, consisting of periodical (every 3-6 mo) ultrasound and AFP monitoring (follow-up group, FU); the second group consisted of 160 cases presenting with clinically overt and advanced HCC (clinically overt group, CO).

Control group

A control group of 490 cases was chosen by matching age, sex and time of admission among 28 740 patients seen in our Division in the same period of enrollment of patients with HCC. Patients were excluded if admitted for malignancies, alcohol-related diseases (neuropathy, gastric ulcer), virus-related liver diseases, and diabetes mellitus. However, co-morbidity with these conditions was not considered exclusion criteria. The admission diagnosis of the selected 490 control cases was heart failure (34.9%), hypertension (21.4%), chronic obstructive broncho-pneumopathies or pneumonia (16.5%), atrial fibrillation (7.8%), deep venous thrombosis (6.5%), fever of unknown origin (5.3%), benign tumours (4.1%), and gastritis (3.5%). In order to ensure that the selected control group was indeed well representative of the general population of our region, we considered two main parameters: prevalence of chronic HCV infection, the main risk factor for HCC, and that of DM2. The prevalence of HCV infection in the control group was 5.3%, similar to that reported in our region for individuals aged more than 65 years[30,31]. The prevalence of DM2 by age groups was compared to that reported in Italy[32]. Thus, for the purposes of the present study, our control group could be indeed considered representative of the general population in our region.

Methods

For all HCC patients and control cases the following demographic, clinical and biochemical features were registered in a computerized database: age, gender, race, glycated hemoglobin (HbA1c). Biochemical parameters were determined in the Central Laboratory of our Hospital by standard and validated methods. Anti-HBV surface antigen (anti-HBs), anti-HBV core antigen (anti-HBc), hepatitis B surface antigen (HBsAg), hepatitis B e antigen (HBeAg) were determined using commercial assays (Abbott Diagnostic Division, Wiesbaden; Germany). Sera were also screened for antibodies against HCV (anti-HCV) using a third-generation microparticle enzyme immunoassay (AxSYM HCV version 3.0, Abbott Diagnostic Division)[33]. Positive samples were tested for anti-HCV using a third generation line immunoassay (Innogenetics, Gent, Belgium) and for serum HCV RNA using the Roche Amplicor version 2.0 (Roche Molecular System, Pleasenton, CA). The diagnosis of DM2 was based on the American Diabetes Association guidelines[6,34]. Alcohol abuse was defined as a daily consumption of more than 30 g in males and of more than 20 g in females, considering an average alcohol content of 5% for beer, 12% for wine and 40% for superalcoholics[35].

Statistical analysis

Descriptive results were expressed as mean ± SD or number (percentage) of patients with a condition. The *t*-test or non parametric Mann-Whitney test was used to compare quantitative data and the chi-square test was applied for comparison of frequency data. $P < 0.05$ was considered significant. Odds ratios (OR) and their corresponding 95% confidence intervals (CI) were calculated using simple logistic-regression analysis.

Table 1 Frequency of DM2 in HCC patients and in controls

	Number of subjects	DM2 absent (%)	DM2 present (%)	OR (95% CI)	*P*	*RR*
HCC	465	320 (68.8)	145 (31.2)	3.12 (2.22-4.43)	< 0.001	2.46
Controls	490	428 (87.3)	62 (12.7)			
Males				3.14 (2.14-4.63)	< 0.001	2.45
HCC	364	246 (67.6)	118 (32.4)			
Controls	385	334 (86.7)	51 (13.3)			
Females				3.11 (1.38-7.4)	0.002	2.55
HCC	101	74 (73.3)	27 (26.7)			
Controls	105	94 (89.5)	11 (10.5)			

HCC: Hepatocellular carcinoma; DM2: Type 2 diabetes mellitus; OR: Odds ratio; CI: Confidence interval; RR: Relative risk.

Table 2 Multivariate analysis of variables associated with HCC

	Odds ratio (95% CI)	*P*
Diabetes		
Absent	1	0.01
Present	2.2 (1.2-4)	
HBV		
Absent	1	⩽ 0.001
Present	252.1 (53.7-1183.9)	
HCV		
Absent	1	⩽ 0.001
Present	106.5 (58.2-194.9)	
Alcohol		
Absent	1	⩽ 0.001
Present	121.2 (61.9-233.7)	

Multivariate logistic regression analysis was used to assess the independent role of different variables.

RESULTS

Among the 465 patients with HCC, mean age was 68.5 ± 8.9 years and 364 (78.3%) were males. The corresponding figures for the control group were 69.4 ± 13.8 years and a male prevalence of 78.6%.

Prevalence of DM2

With regard to the type and frequency of diabetes mellitus in our patients[6,34], we found that every HCC patient of our population with abnormal glucose tolerance has the clinical and metabolic characteristics of DM2 and, therefore, nobody of our HCC patients was found affected by insulin dependent DM1. Overall, 145 (31.2%) HCC patients and 62 (12.7%) of control cases had DM2 (Table 1). This difference was statistically significant with an odd ratio of 3.12 (CI: 2.22-4.43). This odd ratio was higher for male than for female patients (3.14 *vs* 3.11, *P* = 0.632). Among DM2 patients, glycated haemoglobin was significantly higher in male HCC cases than in control males (7.8% *vs* 6.9%, *P* = 0.02). Multivariate analysis (Table 2) identified HBV infection, HCV infection, alcohol abuse and also DM2 as independent variables, all associated with an increased risk of HCC. In regards to the duration of DM2 in HCC patients, diabetes had been diagnosed at least 6 mo before the appearance of HCC in 122 of the 145 cases (84.1%). In 89 of these 122 cases, the time interval between diagnosis of DM2 and HCC could be precisely calculated and the mean time interval was 141.5 ± 9.4 mo. Moreover, in the subgroup of patients with pre-existing DM2, mean duration of diabetes was higher in patients treated with insulin than in those treated with oral antidiabetic agents (171.5 ± 87.6 mo *vs* 118.7 ± 95.2 mo, *P* = 0.05). The prevalence of DM2 in the different etiologic groups of HCC is described in Table 3. Patients classified as having cryptogenic cirrhosis had a somehow higher prevalence of DM2 compared to the other groups, but the difference did not reach statistical significance. On the other hand, alcohol related HCC had a significantly higher prevalence of DM2 compared to the HCV-related group of HCC (36.9% *vs* 26.6%, *P* = 0.048). Males HCC patients with DM2 were more frequently treated with insulin than control cases (38.1% *vs* 17.6%, *P* = 0.009). Among HCC cases, those using antidiabetic oral agents were more frequently treated with insulin secretagogues (sulfonylureas), with or without metformin (insulin sensitizer), than with simple diet, with or without metformin (Table 4).

Table 3 Etiology in the 465 HCC patients and prevalence of DM2 [mean ± SD, *n* (%)]

Etiology	N° HCC (%)	Age (yr)	Prevalence of DM2 (%)
HBV	20 (4.3)	63.3 ± 10.3[1]	3 (15.0)
HCV	177 (38.1)	71.5 ± 7.3[1]	47 (26.6)[2]
Alcohol	141 (30.4)	66.7 ± 8.5[1]	52 (36.9) [2]
HBV + HCV	8 (1.7)	60.8 ± 12.8[1]	2 (25.0)
HBV + alcohol	9 (1.9)	62.9 ± 9.3[1]	2 (22.2)
HCV + alcohol	81 (17.4)	67.7 ± 9.3[1]	27 (33.3)
HBV + HCV + alcohol	2 (0.4)	68.4 ± 10.3	0
Cryptogenetic	27 (5.8)	68.6 ± 9.3	11 (40.7)

[1]HCV *vs* HBV + HCV, *P* < 0.001; HCV *vs* HBV, *P* < 0.001; HCV *vs* HBV + alcohol, *P* < 0.001; HCV *vs* HCV + alcohol; HCV *vs* alcohol, *P* < 0.001; [2]HCV *vs* alcohol, *P* = 0.048.

Table 4 Type of therapy with oral antidiabetic agents in HCC patients and controls with DM2

	Number of subjects	Diet with or without metformin N° cases (%)	Sulfonylureas with or without metformin N° cases (%)	*P*
Total				
HCC	88	14 (15.9)	74 (84.1)	0.04
Controls	48	15 (31.2)	33 (68.8)	
Males				
HCC	75	12 (16.0)	63 (84.0)	0.049
Controls	41	13 (31.7)	28 (68.3)	
Females				
HCC	13	2 (15.4)	11 (84.6)	0.5
Controls	7	2 (28.6)	5 (71.4)	

Features of DM2 in FU and CO groups with HCC

The clinical features of DM2 in HCC cases of the FU and CO groups are compared in Table 5. The prevalence of diabetes was similar (30.2% *vs* 33.1%, *P* = 0.51). Mean HbA1c was somehow higher in FU group, but the difference was not statistically significant (8.2% ± 2.78% *vs* 7.1% ± 2.12%, *P* = 0.1). The mean duration of

Table 5 Clinical features of DM2 in HCC patients of the FU and CO groups (%)

	FU group	CO group	*P*
Prevalence of DM2	92 (30.2)	53 (33.1)	0.51
HbA1c (mean% ± SD)	8.2 ± 2.78	7.1 ± 2.12	0.1
Insulin therapy	45 (48.9)	15 (28.3)	0.01
Antidiabetic oral agents	47 (51.1)	38 (71.7)	0.01
Diet with/without metformin	7 (14.9)	4 (10.5)	0.55
Sulfonylureas with/ without metformin	40 (85.1)	34 (89.5)	0.55
Duration of DM2 (mean ± SD, mo)	127.8 ± 80.1	167.1 ± 114.3	0.03
Duration of insulin therapy (mean ± SD, mo)	50.0 ± 50.5	77.8 ± 86.4	0.12

FU: Follow-up group; CO: Clinically overt group; HbA1c: Glycated haemoglobin.

DM2 was higher in CO cases (167.1 ± 114.3 mo *vs* 127.8 ± 80.1 mo, $P = 0.03$). FU cases with DM2 were more frequently treated with insulin compared to CO cases with DM2 (48.9% *vs* 28.3%, $P = 0.01$).

DISCUSSION

The association of type 2 diabetes with solid tumours[36,37] has been long suspected and several studies have reported increased mortality rates for neoplastic diseases in patients with DM2[13,38-41]. Recent studies would suggest that treatments with anti-diabetic drugs, prone to increase circulating insulin levels, might favour tumour development, as shown with sulfonylurea and insulin[42], while treatment with drugs that contrast hyperinsulinemia may in fact be protective, as in the case of metformin[43]. Many reports have described an increased risk for HCC in patients with DM2, particularly males[13]. However, most of these studies did not assess the individual role of DM2 in relation to confounding cofactors such as HBV and HCV infection, particularly in patients with chronic liver disease. In this clinical setting, DM2 may be the consequence rather than the cause of HCC developing in a cirrhotic liver. Thus, precise definition in our study of the temporal relationship between onset of DM2 and of HCC is of major importance, and this information has been lacking in most previous surveys[3,13,19].

Our results confirm that patients with DM2 have a significantly increased risk of HCC, independently of cofactors such as HBV and HCV infection and alcohol intake, and demonstrate that DM2 pre-exists to the development of HCC in most cases, suggesting that DM2 is more likely a concourse rather than merely a consequence of the liver tumour. This conclusion is also supported by the finding of a similar frequency and severity of DM2 in patients with small HCC detected during follow-up of cirrhosis and in those with more advanced and diffuse cancers detected outside of a surveillance program.

Because diabetes may be due to HCC or to the underlying cirrhosis and the liver cirrhosis may be caused by diabetes[7,10], our data cannot fully explain the reciprocal connections between them. Therefore, further studies, including cirrhotic patients, must be planned in the future to evaluate whether the diabetes itself has a direct carcinogenetic effect.

The observation that patients with DM2, particularly males, treated with insulin had an increased frequency of HCC is intriguing and clinically relevant. These patients are those often showing the highest insulin blood levels[44], and this might have contributed to facilitate the development of HCC. It is well known that patients with DM2 treated with insulin are those with more severe hyperinsulinaemia and more complications, including microalbuminuria and ischemic heart disease[45,46]. Our results indicate the need for close surveillance for HCC in patients with chronic liver disease and DM2, particularly when males and treated with insulin. They also suggest that in these patients strategies to improve the metabolic control should be directed primarily against hyperinsulinaemia by avoiding, as much as possible, the use of oral secretogogue drugs and of insulin treatment, giving preference to insulin-sensitizers such as metformin and glitazones.

COMMENTS

Background

The association of type 2 diabetes mellitus (DM2) with solid tumours, and particularly with hepatocellular carcinoma (HCC), has been long suspected and several studies have reported increased mortality rates for neoplastic diseases in patients with DM2. However, the temporal relationship between onset of diabetes and development of HCC, and the clinical and metabolic characteristics of patients with DM2 and HCC are not been well examined.

Research frontiers

Whether the diabetes itself has a direct carcinogenetic effect remains unknown.

Innovations and breakthroughs

This study shown that DM2 is associated with a 3-fold increase risk of HCC. In most of patients DM2 pre-existed to HCC. Patients with DM2 and chronic liver disease, particularly insulin treated males, should be considered for HCC close surveillance programs.

Applications

Further studies, including cirrhotic patients, must be planned to evaluate the complex relationships between DM2, liver cirrhosis and HCC.

Terminology

DM2 is a compensatory high insulin state caused by impaired insulin action in fat, muscle tissue and liver. HCC is the most frequent cancer of the liver that occurs mainly in patients with chronic liver disease.

Peer review

This is a good paper that is well organized. The data shows the association between diabetes and HCC.

Abstract

AIM: We studied the estrogen receptor (ER) and progesterone receptor (PR) isoforms expression in gastric antrum and corpus of female gerbils and their regulation by estradiol (E2) and progesterone (P4).

METHODS: Ovariectomized adult female gerbils were subcutaneously treated with E2, and E2 + P4. Uteri and stomachs were removed, the latter were cut along the greater curvature, and antrum and corpus were excised. Proteins were immunoblotted using antibodies that recognize ER-alpha, ER-beta, and PR-A and PR-B receptor isoforms. Tissues from rats treated in the same way were used as controls.

RESULTS: Specific bands were detected for ER-alpha (68 KDa), and PR isoforms (85 and 120 KDa for PR-A and PR-B isoforms, respectively) in uteri, gastric antrum and corpus. We could not detect ER-beta isoform. PR isoforms were not regulated by E2 or P4 in uterus and gastric tissues of gerbils. ER-alpha isoform content was significantly down-regulated by E2 in the corpus, but not affected by hormones in uterus and gastric antrum.

CONCLUSION: The presence of ER-alpha and PR isoforms in gerbils stomach suggests that E2 and P4 actions in this organ are in part mediated by their nuclear receptors.

Key words: Estrogen receptor; Progesterone receptor isoforms; Gerbil; Stomach; Sex steroid hormones

INTRODUCTION

Mongolian gerbils (*Meriones unguiculatus*) have been used in scientific research for a long time, especially in neuronal protection studies and as a model of human *H pylori* infection. In spite of the numerous publications using Mongolian gerbils, and the characterization of their estrous cycle, which is 4 d to 6 d in duration[1,2], their sexual hormonal levels and receptors have not been characterized to date.

Estradiol (E2) and progesterone (P4) participate in numerous cellular functions, such as proliferation and differentiation in normal and cancer cells. Most of these functions are mediated by their nuclear receptors, ER and PR[3-5].

There are two well characterized isoforms or ER, alpha and beta, that are encoded by different genes[6]. The ER-alpha protein has 595 aminoacids, with a molecular weight of 66 KDa[7]. ER-beta is constituted by 485 amino acids, and has a molecular weight of 54 KDa. The ER-beta isoform is homologous to ER-alpha at the DNA binding domain (95%), and the heat shock protein binding domain (55%). Both isoforms bind estrogens

with high affinity, but regulate different functions[8].

PR has two main isoforms, PR-A (72-94 kDa) and PR-B (108-120 kDa), encoded by the same gene, but regulated by distinct promoters. PR-A is a truncated form of PR-B, lacking 128-164 aminoacids, depending on the species, in the amino terminal end[9,10].

We have previously shown that E2 and P4 have clear and distinct effects on inflammatory response and gastric epithelial changes during early *H pylori* infection[11]. Recently, Ohtani *et al* have shown a protective role of E2 administration in *H pylori*-infected InGas mice[12]. Other studies have demonstrated that E2 and P4 have anti-ulcerative effects in murine gastric mucosa[13-16].

ER and PR have been reported in human, mouse and rat stomach. However, there is no information to date of their expression and regulation in the Mongolian gerbil stomach. Here we demonstrated the presence of ER-alpha, PR-A and PR-B isoforms in gerbil uterine and gastric tissues by Western blot, as well as a differential regulation of ER-alpha by E2 in gastric corpus.

MATERIALS AND METHODS

Animals

Mature (16-week-old) female Mongolian gerbils (*Meriones unguiculatus*) kept in micro isolators under a 12:12 h light-dark cycle, with food and water *ad libitum* were ovariectomized and after 10 d of recovery, subcutaneous injections of vehicle (corn oil/10% ethanol), 17-beta-estradiol (5 μg/100 μL) or E2 + P4 (1 mg/100 μL) where applied as previously reported[17]. Briefly, gerbils were injected with E2 in two consecutive days and then euthanized after 24 h, while E2 + P4 group received an additional P4 injection on the third day and euthanized 24 h later. Adult Sprague Dawley rats, ovariectomized and treated in the same manner, were used as positive controls.

Gerbils and rats were euthanized by exsanguination under anesthesia and uteri and stomach were removed. The stomachs were cut along the greater curvature, antrum and corpus mucosa were excised. All tissues were snap frozen in liquid nitrogen and kept at -80℃ until protein extraction was performed. The experiments were carried out under the guidelines of the Committee for the use of Animals for Research of the Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán.

Protein extraction and Western Blotting

Uteri were homogenized in TDG lysis buffer with protease inhibitors (10 mmol/L Tris-HCl, 1 mmol/L dithiotreitol, 30% glycerol, 1% Triton X-100, 15 mmol/L sodium azide, 1 mmol/L EDTA, 4 μg/mL leupeptin, 22 μg/mL aprotinin, 1 mmol/L PMSF, 1 mmol/L sodium orthovanadate). Gastric samples were homogenized using TDG lysis buffer without EDTA. Supernatants were clarified by centrifugation at 15000 r/min, 4℃ for 15 min, and proteins quantified by the method of Bradford (Biorad, CA USA)[18]. Proteins (150 μg) were separated by electrophoresis on SDS-PAGE gels at 80 V. Prestained and ECL markers (Biorad, CA) were included for size determination. Gels were transferred to nitrocellulose membranes (Amersham, NJ, USA) at 20 V, room temperature, for 120 min, and were blocked at room temperature with 5% non-fat dry milk and 0.5% bovine serum albumin for 2 h. They were incubated at 4℃ overnight with a mix of rabbit polyclonal anti-PR (Neo Markers, Fremont CA) and mouse monoclonal anti-PR (AB-52, sc-810, Santa Cruz, CA, USA) (1 μg/mL each), both antibodies recognize PR-A and PR-B isoforms with similar affinity[19]; 1 μg/mL rabbit polyclonal anti-RE-alpha (Santa Cruz sc-542), 1 μg/mL goat polyclonal anti ER-beta (Y-19, sc-6821, Santa Cruz) or goat polyclonal anti ER-beta (N-19, sc-6820, Santa Cruz) antibodies. Blots were then incubated with a 1:1500 dilution of goat anti-mouse IgG, donkey anti-rabbit IgG or donkey anti-goat IgG antibodies conjugated to horseradish peroxidase (Santa Cruz) for 1 hour at room temperature and detected by enhanced chemiluminescence (ECL, Amersham, NJ, USA).

To correct for differences in the amount of total protein loaded in each lane, blots were stripped with glycine (0.1 mol/L, pH 2.5, 0.5% SDS) overnight at 4℃, and 30 min at 37℃, and reprobed with 1 μg/mL of mouse anti-alpha-tubulin antibody (Santa Cruz) at room temperature for 2 h. Blots were incubated with a 1:1500 dilution goat anti-mouse IgG conjugated to horseradish peroxidase (Santa Cruz) for 1 h. Signals were detected by ECL. The intensity of ER and PR isoforms and alpha-tubulin signals was quantified by densitometry using the Scion Image software (Scion Corp., Maryland, USA).

Statistical analysis

Data were analyzed using one-way ANOVA and Student's-*t* test for group comparisons, after homogeneity of variances was tested. A $P < 0.05$ value was considered as statistically significant. The analysis was performed using SPSS 12.0 for Windows.

RESULTS

We were able to distinguish two bands of 120 and 85 KDa corresponding to PR-B and PR-A isoforms, respectively, and a 66 KDa band corresponding to ER-alpha isoform in the uteri and stomach of the female gerbil (Figure 1), even when ER and PR have not been sequenced or identified before in gerbils tissues and there are no specific antibodies against these receptors in this species. Unfortunately, we were unable to detect the ER-beta isoform with the antibodies tested in this study in any gerbil tissue.

Gerbil uterine samples presented PR-A and PR-B in similar amounts. Interestingly, their expression was not regulated by E2 or P4 (Figure 2A). ER-alpha isoform in uteri (Figure 2B) was detected and, although there is a tendency to an increase after E2 treatment, this was not statistically significant.

In gastric antrum, PR isoforms were present in similar amounts and were not regulated by hormonal

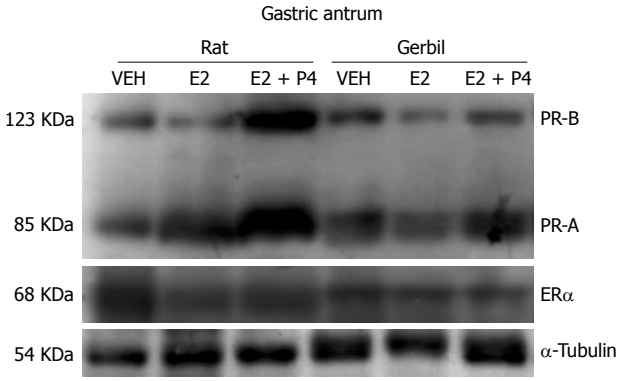

Figure 1 Estrogen and progesterone receptor isoforms expression in gastric tissue. PR isoforms and ER-alpha expressed in gerbil tissues are similar to those present in rats. Ovariectomized adult female gerbils were treated with subcutaneous injections of vehicle (VEH), 17-beta-estradiol (E2) alone and E2+ progesterone (E2 + P4). Gastric antrum lysates were immunoblotted with commercially available antibodies for ER-alpha, and PR. Equally treated rat tissues were used as positive control. The images show representative blots of gastric antrum of rat and gerbil.

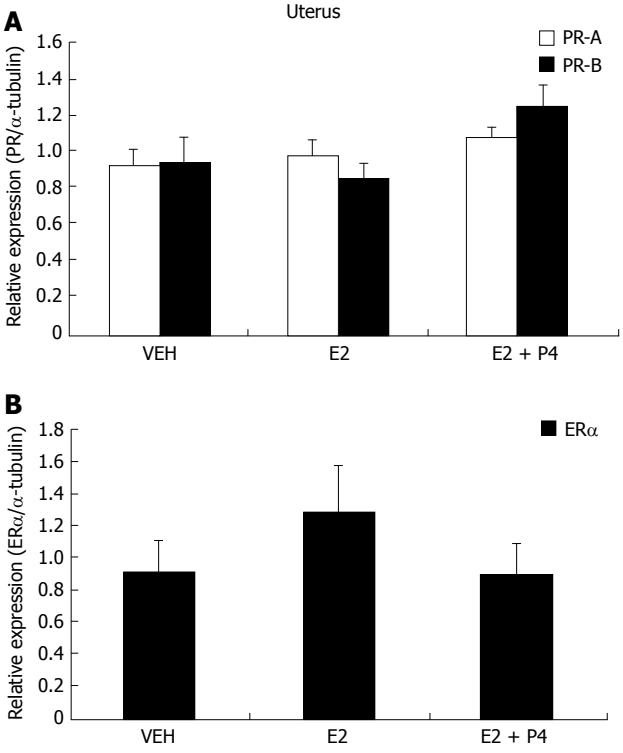

Figure 2 Sex steroid receptors content in gerbil uterus. PR isoforms (**A**) and ERα (**B**) in gerbil uterine lysates is shown. Ovariectomized adult female gerbils were treated with subcutaneous injections of VEH, E2 and E2 + P4. Receptors were detected by immunoblotting and content was adjusted to alpha-tubulin expression (n = 5). Data are mean ± SE.

treatments (Figure 3A). ER-alpha isoform was also present in antrum and showed a tendency to be increased under E2 and E2 + P4 treatments, however, this was not significant (Figure 3B).

Similar results were obtained for PR isoforms in gastric corpus (Figure 4A). Interestingly, ER-alpha isoform in this tissue was significantly diminished after E2 treatment, and this effect was blocked by P4 (Figure 4B).

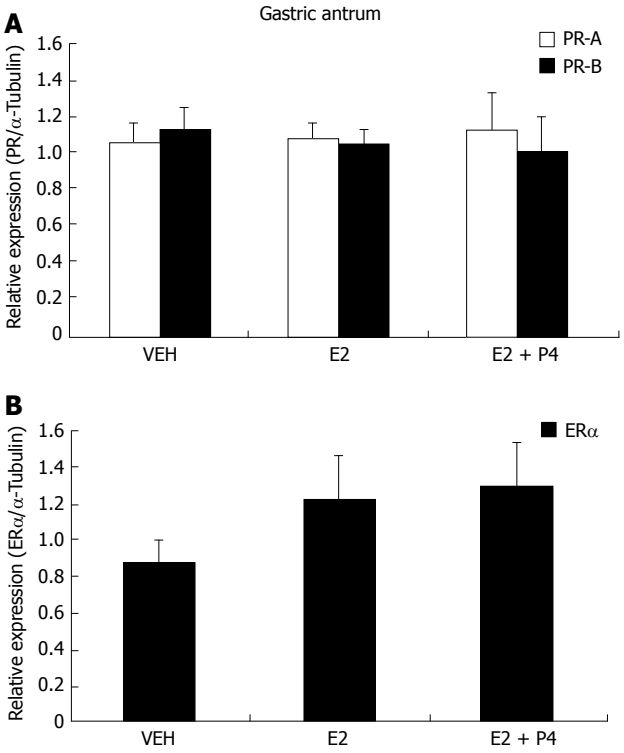

Figure 3 Sex steroid receptors content in gerbil gastric antrum. PR isoforms (**A**) and ER-alpha (**B**) in gerbil gastric antrum lysates is shown. Ovariectomized adult female gerbils were treated with subcutaneous injections of VEH, E2 and E2 + P4. Receptors were detected by immunoblotting and content was adjusted to alpha-tubulin expression (n = 5). Data are mean ± SE.

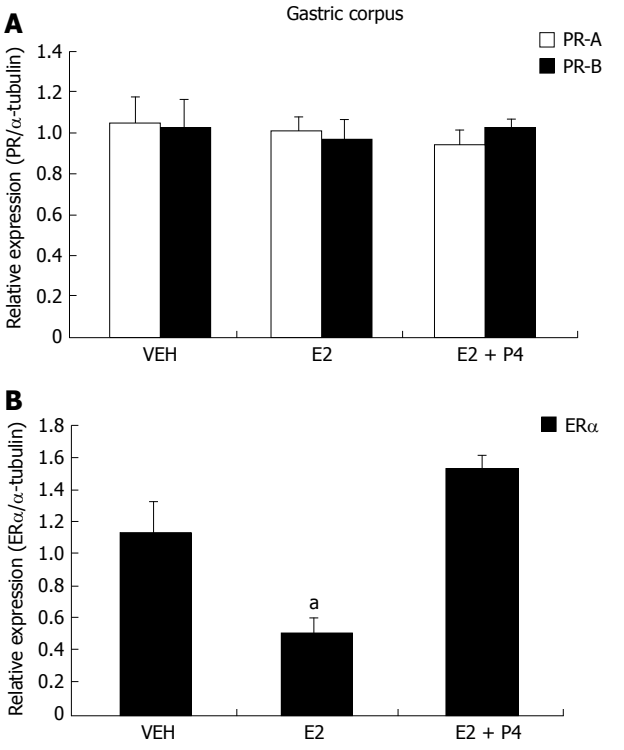

Figure 4 Sex steroid receptors content in gerbil gastric corpus. PR-A (**A**) and PR-B (**B**) ER-alpha in gerbil gastric corpus lysates is shown. Ovariectomized adult female gerbils were treated with subcutaneous injections of VEH, E2 and E2 + P4. Receptors were detected by immunoblotting and content was adjusted to alpha-tubulin expression (n = 5). Data are mean ± SE. $^{a}P < 0.05$ *vs* VEH and E2 + P4.

The antibodies used for Western blot analysis were tested for immunohistochemical staining in both uterine and gastric gerbil tissues, but we were not able to detect ER and PR using this approach (data not shown).

DISCUSSION

Mongolian gerbils (*Meriones unguiculatus*) have become a regular laboratory species, mainly employed in neuronal damage models. However, since 1998, when the *H pylori* infection model was described[12,20], showing persistent *H pylori* infection, and similar gastric damage to that observed in human stomach, their use in research has been constantly increasing.

To our knowledge, this is the first study in evaluating the presence of ER and PR in gerbils. We demonstrated the presence of both PR (PR-A and PR-B) isoforms and ER-alpha in gerbils uteri and stomach. These receptors are similar enough to rat receptors since they can be recognized by commercially available antibodies, rendering same size bands than those observed for rat ER-alpha and PR isoforms.

ER-alpha and ER-beta isoforms have been identified in different tissues and their expression is tissue and species-specific. In rat uteri, ER-alpha expression is down-regulated by E2[21]. P4 also down-regulates ER-alpha expression in rat uteri, but increases ER-beta expression in the decidual tissue[10,21,22].

Both PR-A and PR-B are present in rodents, primates and birds[10,23,24], except for rabbits, where only PR-B isoform has been detected[25]. In humans and rats, both PR isoforms are encoded by the same gene, but transcribed from two different promoter sequences[26,27]. ER and PR isoforms in Mongolian gerbils have not been sequenced to date.

In the gerbil uterus, we observed a similar content of both PR isoforms, but they were not regulated by E2 and P4. This lack of regulation contrasts with the up- and down-regulation of PR expression by E2 and P4, respectively, reported in rat uterus[17].

There was a tendency of E2 treatment to increase ER-alpha content, but it was not significantly different. Since sexual hormone levels in gerbils have not been characterized, it is not known yet whether other hormone doses in gerbils are necessary to regulate ER and PR content.

To date, there are no reports on the regulation of the ER and PR isoforms in either the human or murine stomach; however, it is well known that this regulation is tissue-specific. In our previous study, we demonstrated an important role for E2 and P4 in the Mongolian gerbil gastric mucosa in response to early *H pylori* infection influencing the inflammatory response, proliferation, apoptosis and gastrin producing cell number in the gastric antrum[11]. Although the mechanisms involved in those effects are still unclear, the presence of ER-alpha and both PR isoforms in gastric tissue suggest that their effects are mediated by these receptors.

We have detected ER-alpha and both PR isoforms in gerbil gastric antrum and corpus. In the antrum, none of the receptors was regulated by E2 and P4, but in gastric corpus we observed a down-regulation by E2. Thus, our results show that ER-alpha regulation also depends on the type of cells present in the mucosa. The mechanisms involved in the lack of regulation of PR in gerbil stomach, as well as the differential regulation of ER-alpha by E2, deserve further research.

Parietal cells, the acid producing cells characteristic of gastric corpus, have steroidogenic activity. These cells synthesize E2, P4, testosterone and their metabolites and, therefore, an important role of sexual hormones in hepatic-gastric axis regulation has been suggested[28]. It has been shown that E2 participates in gastric mucous production, epithelial cell exchange, and induces G-cells to release gastrin. E2 produced in stomach is probably processed in the liver[28-30]. Parietal cells are localized only in gastric corpus, thus, it is possible for cells in the corpus to be more sensitive or prone to E2 regulation on ER as compared with antral cells. It is necessary to explore the specific cell types expressing these receptors in both corpus and antrum.

PR and ER expression has been reported in normal human stomach, in human gastric cancer samples[31,32] and in gastric cell lines[33-35]. Also, the differential expression of ER isoforms alpha and beta has been reported in intact rat antrum and corpus, with a higher expression of ER-beta both in human[31,32] and rat[36,37] stomach. In our study, we were unable to detect ER-beta probably due to a lack of cross reactivity of the tested antibodies with this gerbil receptor.

In conclusion, PR isoforms and ER-alpha are expressed in gastric tissue of female gerbils and these receptors are probably involved in E2 and P4 actions in the stomach.

COMMENTS

Background

Sex steroid hormones, estradiol and progesterone in particular, have multiple effects that have been widely described. These hormones act either *via* their nuclear receptors or activating second-messengers pathways. We, and others, have previously reported effects of estradiol and progesterone in the stomach. In this work, we studied the presence of estrogens receptor alpha isoform and progesterone receptors isoforms A and B, and their regulation by their respective ligands in Mongolian gerbils.

Research frontiers

Estradiol and progesterone have shown to have effects on the stomach response to damage and *Helicobacter pylori (H pylori)* infection; Mongolian gerbils are a very useful model for studying the latter. However, the general information available on Mongolian gerbils genome and proteome is scarce. This study will provide basis for further studies on the role of sex steroids on *H pylori* infection and gastric cancer.

Innovations and breakthroughs

In this study, we reported the presence of estrogen receptor alpha isoform, and progesterone receptor A and B isoforms in Mongolian gerbil antrum and corpus, as well as their regulation. The results showed that these receptors are detectable in whole tissue protein with commercially available antibodies, and that the regulation of sex steroid receptors in the stomach is tissue specific.

Applications

This study provides support to the possible genomic mechanism of action of sex steroid hormones in the stomach. Also, it describes an accessible method to detect the presence of these receptors in gastric tissue.

Peer review

In this manuscript, the authors examined the expression of receptors for estrogen (ERs) and progesterone (PRs) in ovarectomized female gerbils. PR isoforms and ER-alpha are expressed in gastric tissue of female gerbils. In humans, male are more prone than female to *H pylori*-related diseases such as peptic ulcer diseases and gastric cancers. These gender-related differences appear diminished after menopausal age. This paper is of special value in considering some interesting and unknown aspects of gastric physiology.

Abstract

AIM: To study the esophageal transit time (ETT) and compare its mean value among three anatomical inclinations of the body; and to analyze the correlation of ETT to body mass index (BMI).

METHODS: A biomagnetic technique was implemented to perform this study: (1) The transit time of a magnetic marker (MM) through the esophagus was measured using two fluxgate sensors placed over the chest of 14 healthy subjects; (2) the ETT was assessed in three anatomical positions (at upright, fowler, and supine positions; 90º, 45º and 0º, respectively).

RESULTS: ANOVA and Tuckey post-hoc tests demonstrated significant differences between ETT mean of the different positions. The ETT means were 5.2 ± 1.1 s, 6.1 ± 1.5 s, and 23.6 ± 9.2 s for 90º, 45º and 0º, respectively. Pearson correlation results were r = -0.716 and $P < 0.001$ by subjects' anatomical position, and r = -0.024 and $P > 0.05$ according the subject's BMI.

CONCLUSION: We demonstrated that using this biomagnetic technique, it is possible to measure the ETT and the effects of the anatomical position on the ETT.

Key words: Transit time; Magnetic marker; Esophagus; Anatomical position; Non-invasive

INTRODUCTION

The esophageal phase is the last phase in the swallow process; it includes the propulsion of the meal through the esophagus toward the stomach. The esophageal transit time (ETT) reported for solid and semisolid meals is between 4 and 8 s, whereas liquid ETT lasts approximately 1 to 2 s in healthy people[1]. A diagnosis of gastroesophageal reflux disease should include the presence of a pathological reflux in patients lacking another motility disorder or damage in the esophagus[2,3]. If this condition can not be met, then the evaluation should include the assessment of disintegration time of oral tablets before they enter the stomach[4]. Currently, diagnosis of gastroesophageal reflux diseases is made with endoscopy[5,6], manometry[3], imaging methods[7], impedance[8], scintigraphy[9] and other techniques[2,10]. These assessments are useful to quantify the liquid and solid volumes retained in the esophagus. Currently, the scintigraphic technique is the gold standard test accepted to assess ETT and it is indicated in cases where the manometric and barometric studies do not give a differential diagnosis[11].

The ETT assessment is used to complete the diagnosis of diseases, such as gastroesophageal reflux[12-14], dysphagia[15,16], esophagitis[17,18], and achalasia[6,19,20]. The latter studies are commonly performed with scintigraphic and manometric techniques[21], in healthy[22], geriatric[23], and pediatric patients[24], despite the use of ionizing radiation and catheters in each test, respectively. Recently, several assessments were performed using the biomagnetic technique, including gastric emptying time[25] and colon

transit time[26]. These studies have the advantage of being non-invasive, comfortable for the patient, and do not use ionizing radiation. Daghastanli *et al*[27] in 1998 reported an ETT study carried out with a biosusceptometer and a magnetic tracer, where they used 5 g of manganese (Mn) and ferrite power. In their study, they also measured the ETT using the scintigraphy technique and found that the ETT was 4.6 ± 0.9 s when biomagnetic technique was used, in comparison to a time of 3.8 ± 0.8 s as measured by the scintigraphy technique. The results of these studies demonstrated the efficacy of the magnetic techniques to carry out the ETT.

In this study, we implemented a novel modality of the biomagnetic technique using modern instruments, which included the monitoring of a magnetic marker (MM) traveling though the length of the esophagus. This was done using a pair of fluxgate magnetometers. We hypothesized that the esophagus motility and the mean ETT are significantly different when they are tested as a function of different anatomical positions of a subject (supine = 0°; fowler = 45°, and upright = 90°, respectively) (Figure 1).

MATERIALS AND METHODS

In Figure 1, we present a schematic set up of the biomagnetic probe used, which consisted of two digital tri-axis fluxgate magnetometers which were placed in an electronic device. They were separated 19 cm and were positioned in a line along the esophagus, just above the subjects' thorax (Figure 2). A 3-mm long and 4-mm high magnet was used as the biomagnetic source or MM. This magnet was enclosed in a polycarbonate sphere 6 mm in diameter (Figure 3) in order to avoid chemical reactions with the gastric acids.

Subjects

Fourteen normal and healthy adult subjects (10 men and 4 women) participated in the study; they did not have clinical antecedents of esophageal or gastrointestinal disease. The subject's mean age and body mass index (BMI) were 21.8 ± 1.5 years and 23.9 ± 2.7 kg/m^2, respectively. All volunteers received instructions before starting the experiment and signed an informed consent approved by the Institutional Review Board of our institution. The experiment was carried out according to the Declaration of Helsinki.

Procedure

Subjects were studied after fasting for 12 h. All of them were assessed in three anatomical positions: (1) upright position, 90°; (2) fowler position, this is a semi-laying position bent at 45°; and (3) supine position, this is a laying position with a bend of 0° (Figure 1). The MM or magnetic particle was introduced inside the mouth of the subjects and swallowed with 20 mL of yogurt (50 kcal), this substance was used as MM vehicle.

Data collection and signal processing

The magnetic signal was registered for 1 min, with a sampling rate of 30 samples/s. Data acquisition was carried out using a routine informatic implemented with software of LabVIEW 7 platform. Then, collected data were exported and graphically analyzed in Matlab 6.5 in order to measure the ETT.

Statistical analysis

We calculated the mean age and BMI of the subjects using descriptive statistics. Using one way ANOVA and Tuckey post-hoc test, we compared the differences among the mean ETT obtained when subjects adopted each of the three anatomical positions. A Pearson correlation was used to determine the correlation coefficient between the ETT and the subject's age, BMI and the angle of inclination of the anatomical position. $P < 0.05$ was considered statistically significant.

RESULTS

Figure 4 shows the raw signals recorded from one subject in three anatomical positions. The time signal shown as a continuous line is the recording with the fluxgate magnetometer added in the upper part of the esophagus, while the dashed line corresponds to the fluxgate magnetometer in the bottom part of the esophagus. The different time between the dominant peaks of each raw signal gives the ETT in each case. In Figure 4, it shows the raw recordings carried out in each anatomical position of one subject. We estimate that the differences in the time seen here was typical of all subjects.

Figure 5 demonstrates the mean and standard deviation values of the ETTs, which were significantly longer at 0° (23.6 ± 9.2 s) than at 45° (6.1 ± 1.5 s), and 90° (5.18 ± 1.8 s). The results of the ANOVA and Tuckey post-hoc test demonstrated the significant differences between the groups (Figure 5). Pearson correlation coefficient test demonstrated an indirect relationship between anatomical position and ETT. This means that when subjects adopt a greater angle of inclination, they will have shorter ETT values. This relationship had a coefficient of $r = -0.716$, $P < 0.001$. However, we did not find any statistically significant difference between the EET and weight, age or BMI.

DISCUSSION

The esophageal phase is the last phase in the swallow process; it includes the propulsion of the meal through the esophagus toward the stomach. The ETT reported for solid and semisolid meals is between 4 and 8 s, whereas liquid ETT lasts approximately 1 to 2 s in healthy people[1]. Using the biomagnetic technique, we demonstrated that ETT is affected by anatomical position, with a significantly larger transit time when subjects adopted an upright position. These results concur with previous reports[1], including studies in which a biosusceptometer magnetometer was used[27].

Previously, researchers reported that ETT in healthy individuals was approximately 4-8 s for solid and semisolid meals, and 1-2 s for liquid meals[11,28,29]. In

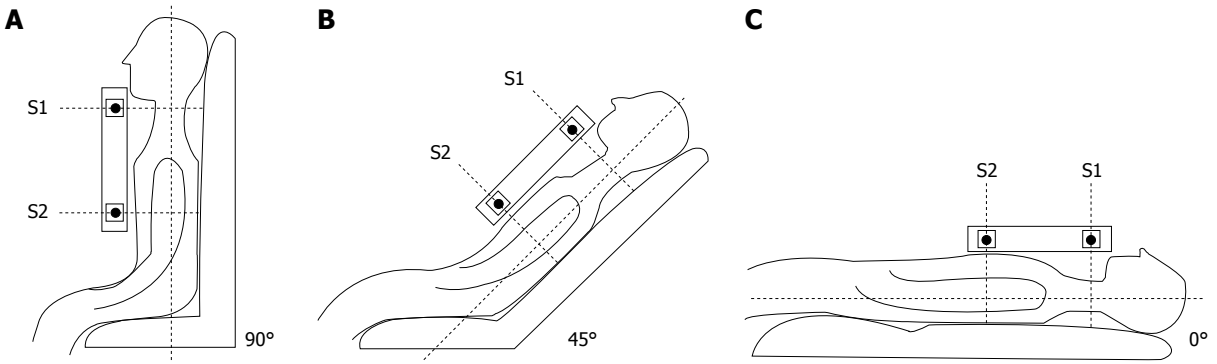

Figure 1 Measurement of ETT at different anatomical positions. **A**: 90° (upright); **B**: 45° (fowler); **C**: 0° (supine). The positions of the magnetic sensors are presented (S1 = sensor one, and S2 = sensor 2).

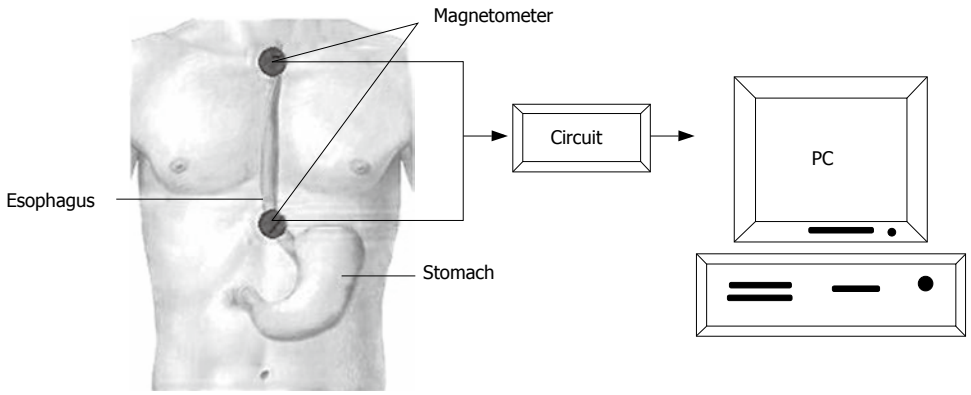

Figure 2 The schematic of the setup, anatomical location of the esophagus, and the circuits for data collection.

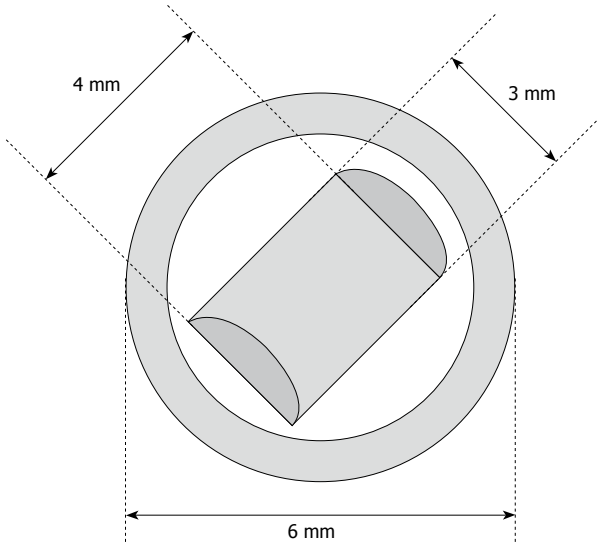

Figure 3 Cross-sectional profile of MM.

agreement with the aforementioned findings, our study demonstrated that the mean ETT was 6.1 ± 1.5 s in the upright position and 5.18 ± 1.8 s in the fowler position. However, the only value which was inconsistent with previous reports was that of the supine position, a transit time of 23.6 ± 9.2 s. This can be explained by the effects of gravity on the test meal and magnets.

Our study demonstrated that ETT is affected by gravity, and therefore, the subjects' anatomical position changes ETT. This phenomenon is explained by the physiology of the esophagus, which combines resistance and contraction to cause movement of the bolus or liquid. When gravity also contributes to the propulsion of the bolus or liquid through the esophagus, transit time is decreased and esophageal transit rates are increased.

Using this biomagnetic modality, we demonstrated that ETT varies depending on the subjects' anatomical position. In this study, we found no relationship between ETT and the subjects' age, which can be explained by the fact that we generally evaluated only young and healthy subjects (mean age: 21.8 ± 1.5 years). However, more studies assessing the ETT in older subjects and patients with different pathologies, such as gastroesophageal reflux[12-14], dysphagia[15,16], esophagitis[17,18], and achalasia[6,19,20], are necessary to determine the differences in ETT of healthy subjects *versus* patients. It is likely that the ETT will differ in patients with a clinical diagnosis of esophageal disease.

In this study, we found no significant correlation between ETT and the subject's BMI, which also may be explained by the samples from a largely homogeneous group of healthy and non-obese subjects (BMI: 23.9 ± 2.7 kg/m^2). Therefore, in order to demonstrate the relationship of BMI and ETT, additional studies are needed using males and females with BMI within normal and obese ranges. Other clinical applications of biomagnetic technique exist in gastro-pharmacology

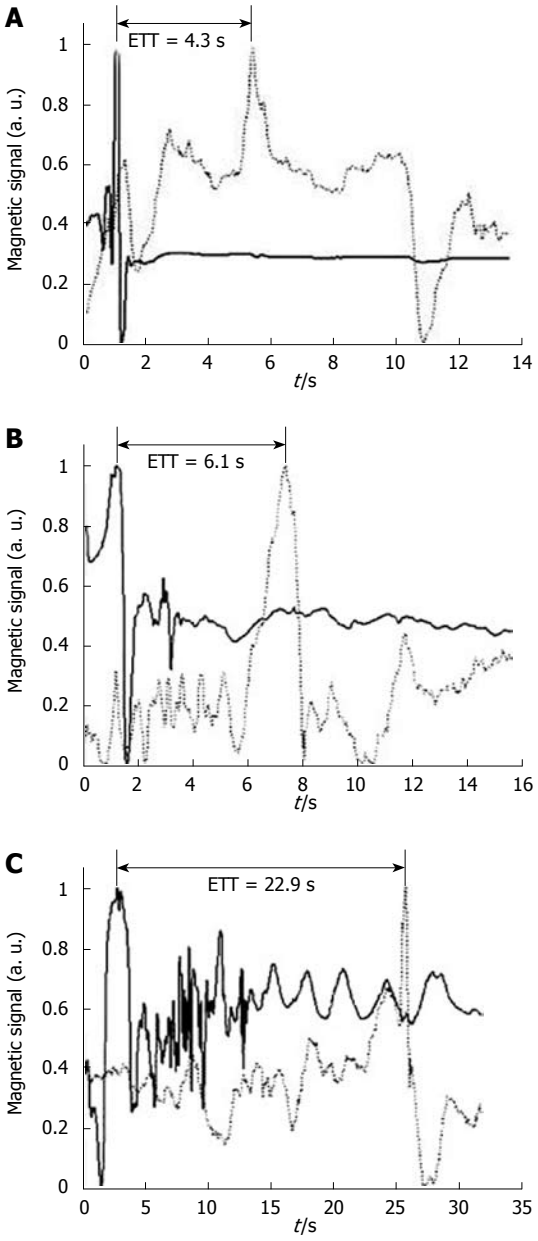

Figure 4 This series of graph showing the raw signal recorded from a single representative subject lying in the three angles of inclination: 90° (**A**), 45° (**B**) and 0° (**C**).

studies, where researchers are testing the efficacy of a drug to increase or decrease ETT.

An advantage of this new application of the biomagnetic technique, implemented for the measurement of ETT, is that it demands little space and hardware, since all that is needed is a low-cost magnetometer. Therefore, this technique could be implemented for clinical assessment of esophageal disorders in general practice medicine, for gastroenterologists studying drug transit time[4,11] and in other specialties. Additionally, because of its low cost and non-invasiveness, this technique could be implemented in small clinical areas and hospitals. Although this technique has already been validated[27], further studies are needed to compare biomagnetism with the most innovative and sophisticated techniques commonly used for esophageal evaluation in order to identify its sensitivity and reproducibility.

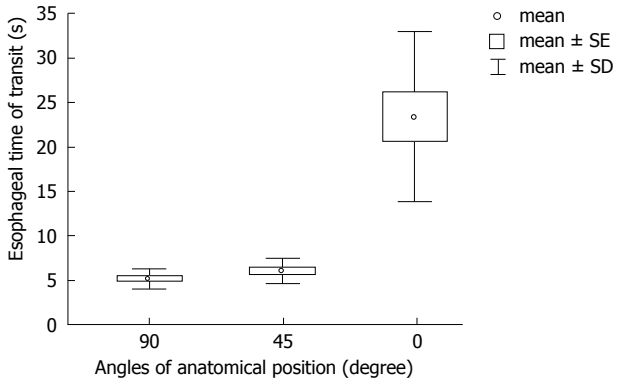

Figure 5 The results of one way ANOVA demonstrate statistically significant differences in the subjects' ETT between the supine position (0°) and both the fowler (45°) and the upright (90°) positions.

ACKNOWLEDGMENT

The authors would like to thank Kathleen M. Capaccione for review and revision of the manuscript.

COMMENTS

Background

Esophageal transit time (ETT) assessment is used to diagnose of gastroesophageal disease, such as esophagitis and achalasia. These studies are carried out using either scintigraphic or manometric techniques, but each has its own disadvantage: scintigraphy uses ionizing radiation, while manometry uses an invasive probe. Recently, several assessments of other body systems were performed using the biomagnetic technique (BMT), including ETT, gastric emptying time, and colon transit time. These studies have the advantage of being non-invasive, comfortable for the patient, and are conducted without ionizing radiation. Recently, researchers have tested the validity of BMT by comparing it with the scintigraphic technique (the gold standard test accepted to assess ETT) in the evaluation of ETT.

Research frontiers

In this study, authors implemented a novel use of the BMT using modern instruments, which included the monitoring of a magnetic marker (MM) traveling though the length of the esophagus. Using the BMT technique, they demonstrated that ETT varies depending on the subjects' anatomical position.

Innovations and breakthroughs

The Fluxgate magnetometer is a small device which functions at room temperature without a magnetic un-shielding room. Its range to precisely identify locations of a small MM is approximately a distance of less than 50 cm. It is possible to record magnetic signals through solid objects including the human body, and therefore, the technique is still valid if the MM is held in one's hand or is passing through the esophagus. Therefore, this is a portable evaluation system that can be implemented for the clinical study and diagnosis of esophegeal disorders in hospitals around the world.

Applications

A major application of this technique is the simultaneous collection of peristaltic activity data from different points along the esophagus. By a subject ingesting an MM similar in size and shape to a pill and following it as it passes through the esophageous by monitoring its progress at several sites along the esophagus, researchers can deduce the peristaltic behavior of the esophagus. Accordingly, ETT and propulsion velocity can accuratly be estimated using this technique.

Terminology

Body anatomical inclinations is an angle of the human body, such as standing upright (90º), fowler (45º) and supine positions (0º). Biomagnetic technique is a technique which uses either external or internal magnetic fields applied to biological materials. Biomagnetism is the phenomenon that involves magnetic fields produced by the human body and other living entities. It is to be distinguished from magnetic fields applied to the body, properly called magnetobiology. Biosusceptometer magnetometer is a probe instrument using room-temperature sensor(s) that can measure variations in magnetic

susceptibilities. MM means external magnetic substance or object used in this case as a vehicle to monitor the passage of an orally taken substance (food, drug, tablet, capsule, *etc*.) through the intestinal tract. Fluxgate sensor is a scientific instrument used to measure the strength and/or direction of the magnetic field in the vicinity of the instrument. Magnetic susceptibility means the magnetization of a material per unit applied field. It describes the magnetic response of a substance to an applied magnetic field.

Peer review

This is an interesting study. Authors used a BMT to monitor ETT to test the hypothesis that esophageal motility and the mean ETT are significantly different when subjects adopt different anatomical inclinations. With this technique, they demonstrated that the mean values of ETT vary depending on the subjects' anatomical inclination.

Abstract

AIM: To investigate the intercellular spaces between the most superficially located esophageal epithelial cells in patients with gastroesophageal reflux disease (GERD).

METHODS: Eighteen patients with erosive esophagitis, 10 patients with non-erosive reflux disease (NERD), and 18 normal asymptomatic volunteers were enrolled. Biopsy specimens were obtained from the lower esophageal mucosa without ulcer or erosion. Scanning electron microscopy was employed to investigate the tightness of the superficial cellular attachment.

RESULTS: The intercellular space between the most superficially located epithelial cells in patients with erosive esophagitis or NERD was not different from that in asymptomatic healthy individuals.

CONCLUSION: Widened luminal intercellular spaces of esophageal superficial epithelium are not responsible for the induction of reflux symptoms in patients with GERD.

Key words: Reflux esophagitis; Non-erosive gastroesophageal reflux diseases; Electron microscopy; Questionnaire

INTRODUCTION

Gastroesophageal reflux disease (GERD) is a symptom complex caused by the reflux of gastric contents into the esophagus with and without complications[1,2]. Patients with esophageal complications, including esophageal erosions and ulcers, are reported to have a higher incidence of gastroesophageal acid reflux than those without complications[3,4]. The esophageal mucosa, composed of stratified squamous epithelium, has limited resistance against gastric juice because its secretion of mucus and bicarbonate is negligible in comparison with the gastric mucosa. Mucus is important for protecting the mucosal surface from pepsin, a protease present in gastric juice. Bicarbonate secretion into the mucus gel layer is necessary to neutralize hydrogen ions diffusing into it[5]. Therefore, when the esophageal mucosa is exposed to acidic gastric juice for a longer period, erosions and ulcers on the esophageal mucosa can easily be formed. GERD with these mucosal complications is known as reflux esophagitis (RE) and that without such complications is referred to as non-erosive reflux disease (NERD)[2]. Patients with NERD suffer significant reflux symptoms including heartburn and acid regurgitation, even in the absence of esophageal complications[2,6]. Afferent neurons with chemoreceptors, including transient receptor potential vanilloid type 1 (TRPV-1), are reported to terminate in the esophageal epithelial

intercellular spaces[7,8]. In healthy individuals, these spaces are narrow and hydrogen ions and pepsin have difficulty to penetrate into them to stimulate noxious receptors on nerve terminals[5,9]. In order for acid and pepsin to penetrate into the intercellular spaces, the intercellular adhesion of the uppermost squamous epithelial cells needs to be damaged or widened[5,9,10]. Several reports have described the widening of intercellular spaces between squamous epithelial cells in mid-stratified epithelial layers by using transmission electron microscopy (TEM)[9-12]. However, there has been no description of intercellular adhesion between cells located in the uppermost part of the stratified squamous epithelium, since intercellular spaces of esophageal superficial epithelium could not be observed by TEM. Thus, this study was designed to investigate the luminal surface of the esophageal squamous epithelium in patients with GERD by using scanning electron microscopy and to examine the relationship between the tightness of esophageal superficial epithelial adhesion and the presence or absence of reflux symptoms.

MATERIALS AND METHODS

Patients

Eighteen symptomatic patients with RE (male/female = 14/4, mean age 58), 10 patients with NERD (male/female = 3/4, mean age 61), and 18 normal volunteers without any gastrointestinal and reflux symptoms (male/female = 13/5, mean age 65) were enrolled in this study. None of the subjects had a history of gastrointestinal surgery or had been taking drugs that would influence gastric acid secretion or esophageal function. Thirteen of the patients with RE were diagnosed as grade A according to the Los Angeles classification[3], 3 as grade B, and 2 as grade C. All the patients with RE or NERD had typical reflux symptoms and their scores for the Japanese version of the Carlsson-Dent self-administered questionnaire (QUEST)[13] were over 4.

This study was performed in accordance with the declaration of Helsinki. Written informed consent was obtained from all the patients and volunteers. The protocol of this study was approved by the ethics committee of Shimane University School of Medicine.

Methods

All the enrolled subjects were investigated by upper gastrointestinal endoscopy for the possible presence of esophageal mucosal breaks and to grade any mucosal breaks according to the Los Angeles classification. One biopsy specimen was taken from the esophageal mucosa without mucosal breaks at the frontal wall 2 cm above the squamous-columnar junction (SCJ), since the evident mucosal injuries are frequently observed at the level of SCJ in patients with RE. Hiatus hernia over a length of 2 cm was not found in any of the subjects.

The biopsy samples were immediately immersed in fixative liquid and routinely processed for scanning electron microscopic observation as described previously[14-16]. The epithelial surface of the processed biopsy specimens was observed at a magnification of × 2000 using a Hitachi S-800 scanning electron microscope (Hitachi Co., Ltd., Tokyo, Japan). Three areas on the epithelial surface of each biopsy sample were randomly selected and electron micrographs were taken for analysis. The photographs were reviewed and graded by three gastroenterologists (KF, KK, and MM) who were blinded to the clinical diagnosis of each case. The reviewers graded the intercellular spaces between the surface epithelial cells on each of three photographs taken from a biopsy sample into 3 grades according to the sample photographs shown in Figure 1. Grade 1 represented a close and tight attachment of the surface epithelial cells. Grade 2 represented a loose attachment evident in some areas of the photo and the presence of widened intercellular spaces. Grade 3 represented looser intercellular adhesion and identifiable large intercellular spaces in over 50% of the area of intercellular attachment. If there was an inconsistency in the reading of photographs between 3 reviewers, the final diagnosis was decided by simultaneous review by the 3 authors. The mean value of these grades determined on each photo was calculated as the representative grade for each individual case. The intercellular space between the surface epithelial cells was also quantified with NIH image software (version 1.61, U.S. National Institute of Health) based on the threshold technique.

The intercellular adhesion, cellular surface structure of the uppermost epithelial cells was also observed and graded (Figure 2). When the cellular surface had regularly shaped multiple folds, the cellular surface structure was graded as 1. When no such regularly shaped folds were observed, it was graded as 3. A cellular surface intermediate between grades 1 and 3 was graded as 2.

Statistical analysis

Statistical comparison between normal controls, patients with NERD, and patients with RE was performed by Kruskal-Wallis test followed by Mann-Whitney *U*-test. Differences at $P < 0.05$ were considered to be statistically significant.

RESULTS

Cellular attachments between surface squamous epithelial cells identified by scanning electron microscopy were remarkably diverse, as shown in Figure 3A. Even in normal asymptomatic individuals, grades of attachment between cells ranged from grade 1.0 to grade 2.4. Attachment grades in patients with symptomatic RE and NERD showed almost the same range of distribution as those in normal individuals. When the median and mean of each group were calculated, there were no statistically significant differences among the three groups. The percentage intercellular space quantified by NIH image in the three groups is shown in Figure 3B. Even quantitative measurement by NIH image revealed no significant difference between patients with GERD and normal individuals.

Grades of epithelial cellular surface structure in individual cases are shown in Figure 3C. The grades of

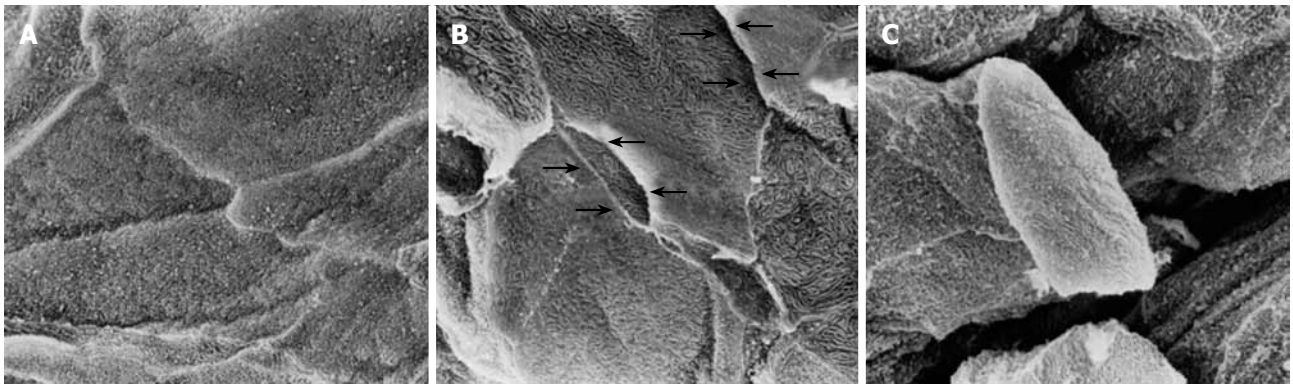

Figure 1 Intercellular spaces between the most superficially located squamous epithelial cells were graded from 1 to 3. Grade 1 (**A**) represents close and tight attachment. Grade 2 (**B**) represents loose attachment in some areas, with widened intercellular spaces (arrows). Grade 3 (**C**) represents further loosening of intercellular adhesion (x 2000).

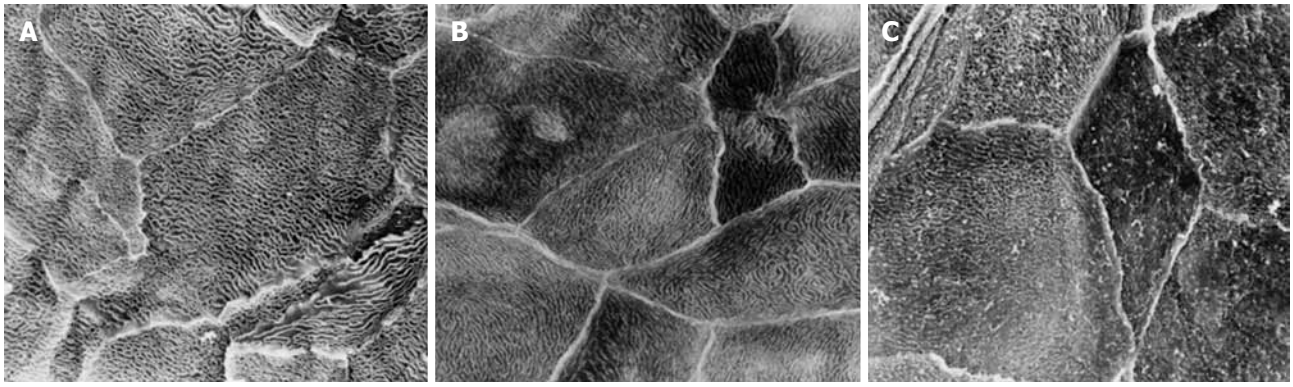

Figure 2 The cellular surface structure of the uppermost epithelial cells was graded from 1 to 3. Grade 1 (**A**) represented regularly shaped multiple folds. Grade 3 (**C**) represented an absence of such regularly shaped folds. A cellular surface intermediate between grades 1 and 3 was classified as grade 2 (**B**).

intercellular attachment and irregularity of the superficial cellular surface structure were distributed over a wide range. The median and mean grades among the three groups showed no statistically significant differences.

DISCUSSION

The presence of esophageal lesions and the presence of reflux symptoms are not well correlated[2]. Many patients with endoscopically evident esophageal erosions have no reflux symptoms[2,17-19]. In fact, our recent study confirmed that 74% of patients with esophageal erosions/ulcers do not have reflux symptoms, including heartburn or regurgitation[20]. Therefore, other pathological changes in the esophageal mucosa may have some role in the induction of reflux symptoms. Tobey and colleagues found widening of squamous epithelial intercellular spaces, not only in patients with RE, but also in patients with NERD[10]. In the epithelial intercellular space, many terminals of afferent neurons are present and convey various noxious stimuli to the central nervous system. When the intercellular spaces become widened, acid and pepsin refluxed from the stomach can easily penetrate the epithelial layer and stimulate noxious receptors on the afferent neurons and induce reflux symptoms[5]. An association between widened intercellular spaces and reflux symptoms has been reported[11,12]. In order to enter the mucosal intercellular spaces, acid and pepsin have to penetrate the intercellular adhesion sites of the uppermost superficial epithelial cells. In this study, the intercellular attachment of the most superficial squamous epithelial cells in the esophagus was investigated by scanning electron microscopy in asymptomatic normal individuals and symptomatic patients with RE or NERD. It was found that the gap between superficial epithelial cells varied markedly in individuals, even in healthy volunteers. Some individuals had tight attachment between superficial cells whereas others had loose intercellular attachment. The tightness of superficial cellular attachment did not differ significantly among normal volunteers, patients with NERD, and patients with RE.

Patients with NERD complain of significant reflux symptoms, even if their gastroesophageal acid reflux is limited[2,21,22]. Some investigators have reported that patients with NERD show hypersensitivity of the esophagus to esophageal extension and acid perfusion[23,24]. Loose attachment between esophageal squamous cells is the most easily suspected cause of esophageal acid hypersensitivity. In the present study, however, it was clarified that loose attachment between the most superficially located squamous cells was not a cause of acid hypersensitivity in patients with NERD.

There were several limitations to this study. The number of subjects investigated in this study was relatively

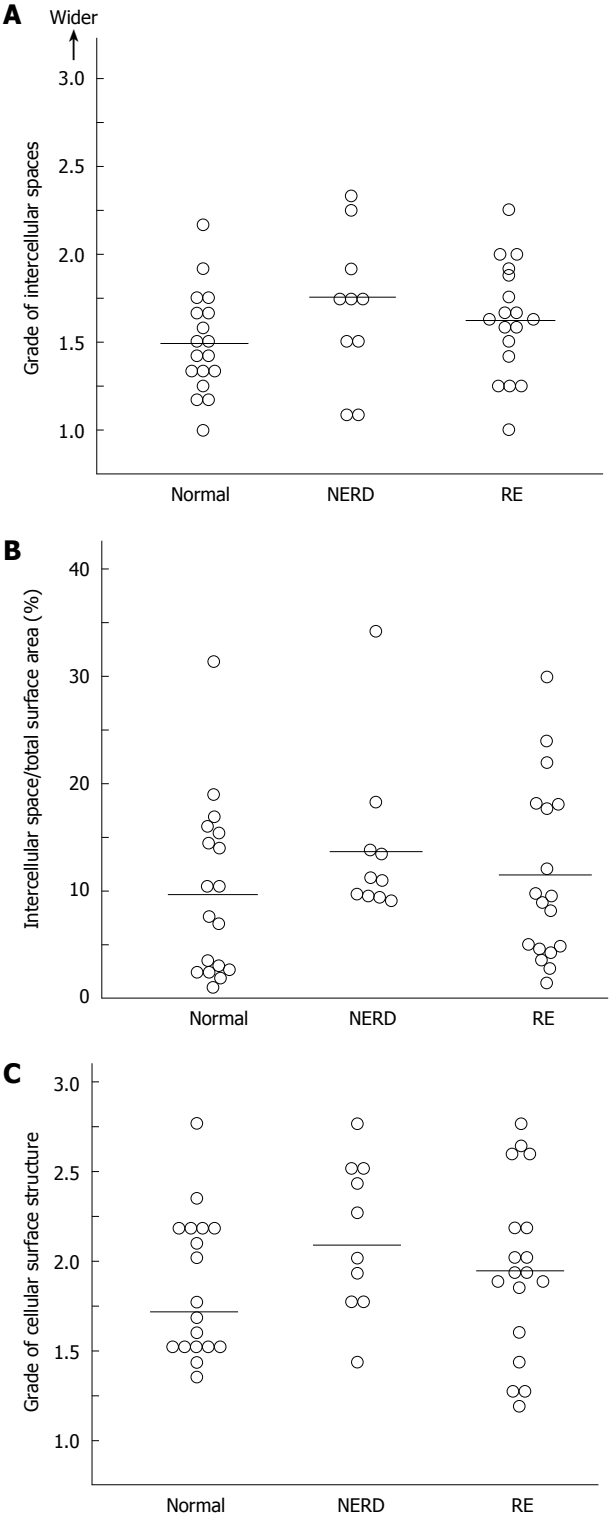

Figure 3 **A**: The intercellular spaces between the most superficially located squamous epithelial cells are shown. Each dot represents an individual case and horizontal lines show the median values. There was no statistically significant difference among the groups; **B**: The intercellular spaces between the most superficially located squamous epithelial cells were quantified using the NIH Image program. The proportion of intercellular space relative to total superficial area was determined in individuals with NERD and RE, and in asymptomatic healthy individuals. Each dot represents an individual case. Horizontal lines show the median values. There was no statistically significant difference among the groups; **C**: The regularity of the luminal cellular surface structure of the squamous cells was compared between normal individuals and patients with RE or NERD. There was no difference in the cellular surface structure between normal individuals and patients with RE or NERD. Each dot represents an individual case and horizontal lines show the median values.

small. In addition, we could not demonstrate the influence of esophageal acid reflux on the attachment of superficial squamous epithelium, since 24-h esophageal pH monitoring study was not performed in this study and the diagnosis of NERD was made by reflux symptoms and endoscopic findings. The location, from which the biopsy samples were obtained, also might influence the results of this study, since we took only one biopsy from the esophageal mucosa without mucosal breaks at the frontal wall 2 cm above the SCJ. Further study will be necessary to clarify the relationship between the attachment of superficial squamous cells and the attachment of more deeply located squamous cells. For this purpose, the combination of transmission and scanning electron microscopy might be useful.

In summary, using scanning electron microscopy, we have clarified that the intercellular adhesion of esophageal superficial squamous cells is diverse among individuals, and does not differ among normal individuals and patients with NERD and RE.

ACKNOWLEDGMENTS

We wish to thank Ms. Rika Tohma and Ms. Keiko Masuzaki for their technical support.

COMMENTS

Background

To investigate the intercellular spaces between the most superficially located esophageal epithelial cells in patients with gastroesophageal reflux disease (GERD).

Research frontiers

The widening of squamous epithelial intercellular spaces was demonstrated in patients with reflux esophagitis (RE), but also patients with non-erosive reflux disease (NERD), by using transmission electron microscopy (TEM), and an association between widened intercellular spaces and reflux symptoms has been reported. However, the intercellular attachment of the most superficial squamous epithelial cells in the esophagus was not investigated by using scanning electron microscopy.

Innovations and breakthroughs

The intercellular space between the most superficially located epithelial cells in patients with erosive esophagitis or NERD was not different from that in asymptomatic healthy individuals. Widened luminal intercellular spaces of esophageal superficial epithelium are not responsible for the induction of reflux symptoms in patients with GERD.

Applications

The relationship between the attachment of superficial squamous cells and the attachment of more deeply located squamous cells should be investigated in future by using the combination of transmission and scanning electron microscopy.

Terminology

The majority of patients with reflux symptoms do not have esophageal mucosal injury; these patients are referred to as NERD. Scanning electron microscopy used in this study can reveal the minimal changes of the luminal surface of the esophageal squamous epithelium.

Peer review

This is an interesting study. Authors investigated the intercellular spaces between the most superficially located esophageal epithelial cells in patients with GERD.

Abstract

AIM: To review the surgical outcomes in terms of the surgical indications and relevant prognostic factors.

METHODS: Sixteen patients underwent therapeutic lung surgery between March 1999 and May 2006. The observation period was terminated on May 31, 2007. The surgical outcomes and the clinicopathological factors were compared.

RESULTS: There was no mortality or major morbidity encountered in this study. The mean follow-up period after metastasectomy was 26.7 ± 28.2 (range: 1-99 mo), and the median survival time was 20 mo. The 1- and 5-year survival rates were 56% and 26%, respectively. At the end of the follow-up, 1 patient died from hepatic failure without recurrence, 6 died from hepatic failure with a recurrent hepatocellular carcinoma (HCC), and 4 died from recurrent HCC with cachexia. Among several clinical factors, Kaplan-Meier analysis revealed that liver transplantation as a treatment for the primary lesion, grade of cell differentiation, and negative evidence HBV infection were independent predictive factors. On Cox's proportional hazard model, there were no significant factors affecting survival after pulmonary metastasectomy in patients with HCC.

CONCLUSION: A metastasectomy should be performed before other treatments in selected patients. Although not significant, patients with liver transplantation of a primary HCC survived longer. Liver transplantation might be the most beneficial modality that can offer patients better survival. A multi-institutional and collaborative study would be needed for identifying clinical prognostic factors predicting survival in patients with HCC and lung metastasis.

INTRODUCTION

Pulmonary metastasis from a hepatocellular carcinoma (PM-HCC) is quite frequent occurring in approximately 10% of patients treated with curative surgery for HCC[1-3]. However, its incidence varies according to the diagnostic modality, stage of the HCC, treatment plan, and observation time[1,4,5]. Unlike a PM from other solid

tumors, it is difficult to manage PM-HCC, partly because it is commonly associated with advanced liver disease, or the patients cannot tolerate systemic chemotherapy for an intrahepatic recurrence or extrahepatic metastasis (EHM)[6,7]. In terms of tumor staging, patients who develop an EHM often have a tumor that is too advanced for surgical treatment and are offered systemic chemotherapy with or without combined locoregional therapy for the concurrent intrahepatic tumor[7,8]. Although few experiences have been reported, an active treatment strategy for better outcomes was proposed for an EHM with or without an intrahepatic recurrence[3,9,10]. Regarding the surgical indications for PM, the primary solid tumors should be controlled before or soon after performing a metastasectomy. However, transcatheter or percutaneous local therapy for a primary HCC has excellent therapeutic results. Therefore, a pulmonary metastasectomy with diagnostic or therapeutic intent may provide adequate management plans, such as liver transplantation or local therapy[10,11]. The treatment plans for a PM-HCC can be individualized by taking these factors into consideration. A large series of surgical treatments for PM from solid tumors has increasingly shown that a pulmonary metastasectomy is effective in prolonging the survival rate. Similarly, surgical experience for PM-HCC has increased, and favorable results on a metastasectomy have been reported even though they were from a select group of cases or a small series[2,3,10,12]. Therefore, a more aggressive approach to PM or extended surgical indication has been adopted to extend the survival rates of oncology patients. The aim of this study was to identify the appropriate candidates for aggressive intervention as well as to assess the clinical prognostic factors in patients with PM-HCC.

MATERIALS AND METHODS

From March 1999 to May 2006, 23 patients with a primary HCC were referred to our department for an evaluation of indeterminate pulmonary lesion(s) that had been resected by an open thoracotomy, or thoracoscopy. Patients with benign pulmonary lesions were excluded from the analysis of the survival rate and prognostic factors. The primary HCC was treated or planned to be treated by a hepatic resection, percutaneous or transcatheter local therapy before or after the pulmonary resection[13]. The surgical indications, which were similar to the previously described guidelines at our institution, included those patients who had resectable pulmonary metastases from the HCC before or after the treatment for the primary HCC, with the potential of complete control of the HCC after the metastasectomy or with a lower surgical risk (normal or mild liver dysfunction, acceptable lung function for partial resection or extended resection, normal cardiac function shown by Doppler echocardiography) for a metastasectomy (Table 1). Sixteen of 23 (60%) patients showed a true PM-HCC on the pathologic diagnosis. None of the patients were lost to follow-up and all patients were observed until May, 2007 after the pulmonary metastasectomy.

Table 1 Guidelines for pulmonary metastasectomy[1]

Primary lesion	Metastatic lesion	Patient factor
Completely cured	Therapeutic intents	Tolerable margin of safety in lung function
Controllable surgically or with other modalities after metastasectomy	Diagnostic intents (true malignancy, evaluate chemotherapy)	Good risk for other organ functions (heart and cerebral status)

[1]Modified from others and us[18,19].

The clinical outcomes were evaluated at regular 3-mo intervals with laboratory tests, which included serum α-feto protein and radiological imaging studies, such as a conventional or spiral chest computed tomography (CT) scan. In particular, the PET-CT scan was performed to evaluate the other EHM before thoracic surgery in selective cases. Although general adjuvant chemotherapy after a metastasectomy was not applied to the patients with the exception of one, locoregional therapy, such as percutaneous ethanol injection therapy (PEIT), radiofrequency ablation (RFA) or transcatherter arterial chemotherapy for the primary HCC, or radiation therapy, including tomotherapy for recurrent metastatic tumors in the lung, was used where needed. The overall survival time after the pulmonary metastasectomy was evaluated with respect to the disease-free interval (DFI), which is defined as the interval between the completion of the HCC treatment and the time the PM was diagnosed, the number of lung metastases, the therapeutic modality used for the primary lesion, such as surgical resection or liver transplantation, the number of pulmonary metastasectomies performed, and other clinical factors.

Surgical treatment for PM-HCC

The surgical plan for PM was considered based on the anatomical characteristics of the lung lesions, patients' medical status including the liver function values or potential risk factors for general anesthesia and operation. The tumor was resected conservatively by a pulmonary wedge resection using either a thoracoscopy or an open thoracotomy in order to preserve the lung function and minimize the surgical risk to the patients with chronic liver diseases. There was only one case of an anatomical lobectomy. For such reasons, a limited resection through a thoracoscopy was applied widely to the patients in this study. However, the thoracoscopic technique was modified in that for difficult lesions, such as a small nodule or deep seated pulmonary lesion, barium sulfate or microcoils were injected into or around the nodule under CT guidance[14]. Moreover, metastatic nodules localized using radiopaque materials, in which the radiopacity was visualized on the portable fluoroscopic monitor and was helpful to guide thoracoscopic resection, could be detected and resected easily. This technique enabled us to avoid an open thoracotomy and allowed for an additional repeat thoracotomy with minimal morbidities. In addition, an open thoracotomy was adopted for some specific lesions

Table 2 Clinical findings of 16 patients with HCC who underwent pulmonary metastasectomy

Clinical findings	Number of patients (n = 16)	Percents of patients (%)
Gender: male/female	14/2	87.5/12.5
Age at pulmonary resection (yr)	45 ± 9.8 (31-67)[1]	
Etiology of liver diseases

that were centrally located or recurrent lesions with possible dense pleural adhesion caused by the previous thoracotomy.

Treatment of primary HCC

The treatment for the primary HCC or intrahepatic recurrent tumor was performed before (n = 21) or after (n = 2) the pulmonary metastasectomy: hepatic resection, liver transplantation and local therapy for 5, 7 and 5 patients with an intrahepatic recurrence or concurrent PM-HCC, respectively.

Statistical analysis

The survival curves of 16 patients who were pathologically proven to have a metastatic lesion were calculated using the Kaplan-Meier method, and the survival according to the prognostic factors was compared using a log-rank test. Using Cox's proportional hazard model, clinical prognostic indicators predicting increased survival of patients with HCC and pulmonary metastasectomy were tested. The statistical study was performed with SAS statistical software package (version 6.12, SAS Institute, Cary, NC). $P < 0.05$ was considered statistically significant.

Table 3 Follow-up results of 16 patients with HCC after pulmonary metastasectomy

	Number of patients (n = 16)	Percentages of patients (%)
Status at the last observation period		
Survival without recurrence	4	25.0
Survival with recurrence	1	6.25
Died of recurrence, cachexia	4	25.0
Died of hepatic failure + recurrence	6	37.5
Died of hepatic failure	1	6.25

RESULTS

Sixteen of 23 (60%) patients, who had undergone a pulmonary resection, were diagnosed with a PM-HCC on pathology examination. Of the 16 PM-HCC, 12 patients had a large primary tumor or multicentricity, and 9 patients showed poor differentiation according to the Edmonson-Steiner grading system, which determines the grade of HCC differentiation. Table 2 summarizes the clinical features of the 16 PM-HCC before or after the pulmonary metastasectomy. Of the 16 patients, 2 had a concurrent PM-HCC at the time of the initial presentation, and the PM-HCC was developed in sequence in 14 patients after treatment for the primary lesion. There was a mean 14 ± 4 mo (range: 0-38 mo) DFI between the completion of the HCC treatment and the time the PM was diagnosed. Twenty-five thoracic procedures were performed for 30 pulmonary lesions of PM-HCC. Among them, 4 concurrent nodules showed benign characteristics. There were no surgery-related deaths or major complications but one patient had a prolonged hospital stay in consequence of air leakage after a repeated resection by an open thoracotomy.

Figure 1 shows the overall survival rates after the initial diagnosis of the primary HCC and pulmonary metastasectomy. The median survival time after the pulmonary metastasectomy was 20 mo. The 1- and 5 year survival rates after the pulmonary metastasectomy were 56% and 26%, respectively. When the prognosis after the pulmonary metastasectomy was compared according to the therapeutic modality for primary HCC, the survival was found to be significantly higher in patients who had undergone liver transplantation than in those who had received other treatments, such as a surgical resection, locoregional therapy (Figure 2). In addition, among clinical factors, liver transplantation, negative evidence of an HBV infection (Figure 3) and well differentiation of HCC (Figure 4) showed longer survival by log rank test.

A total of 11 patients died during the follow-up period (Table 3). Six patients developed an intrahepatic recurrence during the follow-up after the metastasectomy: one patient was treated successfully by local therapy but another two developed an extrahepatic metastasis during treatment. This suggests that control of the primary lesion can result in a favorable prognosis even in the advanced stage. Among the 9 patients with recurrent PM-HCC after the pulmonary metastasectomy,

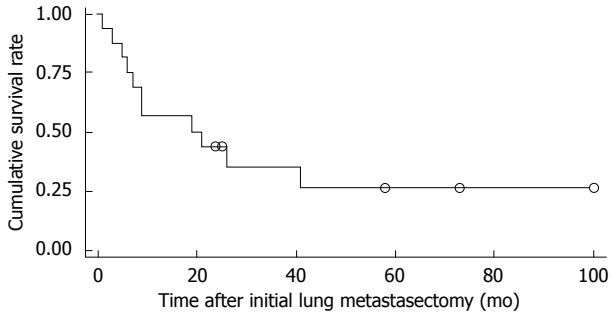

Figure 1 Overall cumulative survival curves of 16 patients with metastasectomy (Open circles indicate censored cases).

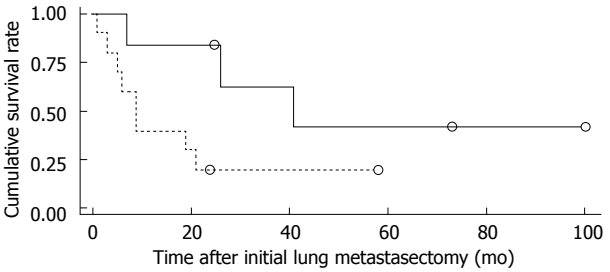

Figure 2 Comparison of survival in patients with HCC after pulmonary metastasectomy by liver transplantation. Patients who had undergone liver transplantation survived longer significantly (log-rank test, $P = 0.014$).

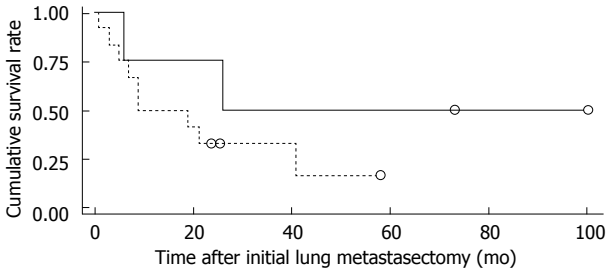

Figure 3 Comparison of survival in patients with HBV hepatitis-related HCC after pulmonary metastasectomy. A significant difference was found between the two groups (log-rank test, $P = 0.0386$).

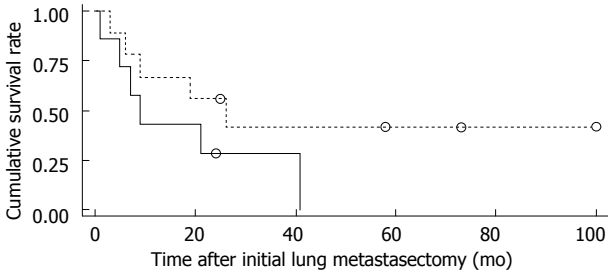

Figure 4 Comparison of survival in patients with HCC after pulmonary metastasectomy by pathologic findings for histologic differentiation. A significant difference was found between the two groups (log-rank test, $P = 0.0392$).

they all underwent repeated pulmonary metastasectomy more than twice, of whom two received tomotherapy for recurrence. Five of these patients are still alive, four of whom show no evidence of recurrent disease (98, 73, 25, 58 mo, respectively).

DISCUSSION

HCC is a major public health problem in Asian countries, including Korea, where HBV infections are endemic[2,6,14]. A longer survival of HCC has been achieved with the recent advances in diagnostic and therapeutic modalities. However, the presence of an extrahepatic metastasis (EHM) of an HCC, which frequently occurs in the lung, regional nodes, bone and brain[4,6], is an indicator of a poor prognosis with a very low 1-year survival rate[6,10]. Despite the advances in therapeutic strategies, an EHM is still a major obstacle for further improving the overall survival and prognosis of the patients. Unfortunately, patients with an EHM do not tolerate systemic chemotherapy well, which is first considered as the therapeutic modality for EHM that finally leads to a shorter survival time[6,8,15,16]. For these reasons, the surgical management of PM-HCC might be a good option. With increasing experience[14], a pulmonary metastasectomy has become more acceptable. Hence, we have developed new guidelines by modifying previous results[17,18] (Table 1).

The incidence or prevalence of PM-HCC depends on the T category, imaging technique, observation time, and therapeutic modality[1,4,5,9]. Because most patients with PM-HCC do not show pulmonary symptoms until they progress to full-blown disease, spiral CT scan is essential for making an early and accurate diagnosis of a PM-HCC. Although PET is effective in detecting distant metastasis in other solid tumors, the diagnostic accuracy of primary HCC showed limited clinical significance[19]. In the present series, 5 true metastatic lesions in 3 patients were confirmed by pathological examination but PET-CT did not show any diagnostic accuracy for these lesions, which might be due to the small lesions or the low standardized uptake values (SUV). By contrast, serial monitoring of the α-feto protein level might help to confirm PM-HCC in the absence of a primary HCC or detect an early recurrence or EHM. However, in this study, the α-feto protein level was elevated by more than 20 ng/mL in only 8 (50%) of the 16 patients with a PM-HCC. The reason why only 50% of patients with an EHM had an elevated α-feto protein level might be due to a small lesion (< 1 cm) or severe liver dysfunction.

The pathological characteristics of the concurrent or sequential pulmonary lesions in patients with a primary HCC can affect the treatment plan and prognosis[15]. Of the 23 patients with a preoperative suspicious metastasis in this series, only 16 (70%) had a true PM-HCC. In addition, the therapeutic plan was consequently changed in 9 of the 23 (39%) patients according to the pathology results. A less invasive or conservative pulmonary resection is recommended for treating a PM from a solid tumor in order to preserve the lung function in the case of a possible PM in future. As shown in this series, the thoracoscopic resection was performed in 10 of 25 (40%) procedures. Although thoracoscopy did not affect the surgical outcome or survival compared with

an open thoracotomy in this and other series, it may allow for better satisfaction and an additional pulmonary metastasectomy[14,20].

The prognosis of patients with a PM-HCC has been reported to be as low as 20%-30% at 1 yr despite receiving systemic chemotherapy[6,16]. A pulmonary metastasectomy of an HCC increases the median survival or long-term survival[2,10]. Although there were no consistent and complete prognostic indicators, several clinical or pathological factors have been reported[2,3,5,16,20]. Generally, patient selection according to the prognostic factors, such as single metastasis and small primary HCC, is essential for a survival benefit by surgery. In this series, liver transplantation, negative evidence of an HBV infection, and well differentiation of HCC were significant prognostic indicators among the other clinical factors. Accordingly, this finding suggests that hepatic factors indicating a complete resection and good liver function might be essential for better survival[11,16]. However, Cox's proportional hazard model (Tables 4 and 5) showed no significant clinical indicators, which might be attributed to small numbers of patients and poor survival due to high virulence of HCC. More importantly, a brain metastasis of HCC is not common but life threatening, and should be detected early, especially in patients with PM-HCC[5,20,21].

During the follow-up after the metastasectomy, EHM or intrahepatic recurrence may be controlled by irradiation therapy[20,22], local therapy[10,13] as well as by a repeated metastasectomy[10,12,20,23]. In this series, a repeated pulmonary resection for a recurrent PM-HCC after a metastasectomy was performed in 6 patients. Although patients with a single metastasis or single pulmonary surgery might show better survival[2,20], multiple metastases or repeated metastasectomies are not risk factors for long-term survival, as shown in this and previous studies[12,24].

When considering the cause of death in this and other reports, hepatic dysfunction complicating liver cirrhosis was one of the most important factors for the long-term survival[2,16,25]. Considerable attention should be paid to patient selection, which may be essential for achieving long-term survival in patients with a PM-HCC according to prognostic analysis. As shown in this study and suggested by others, the prognosis may be affected by many clinical or pathologic parameters, which may be major limitations in clinical reports including these results.

In summary, selected patients without an intrahepatic HCC and with a good hepatic reserve showed that a pulmonary metastasectomy is effective in controlling a PM-HCC and can offer the only chance for long-term survival.

COMMENTS

Background

Treatment of patients with primary hepatocellular carcinoma (HCC) and concurrent or subsequent pulmonary metastasis (PM) has no definite or proper guidelines, but it has been reported that pulmonary metastasectomy has been proven to prolong the survival in a selected group or a small series. Local therapy and surgical resection have been effective in treating the primary HCC. However, systemic chemotherapy for distant metastasis had limitations, such as poor toleration and aggravation of liver function. Although a few clinical prognostic factors affected the survival rate in patients after pulmonary metastasectomy, there were limitations in terms of small number and heterogenosity of patients.

Research frontiers

Diagnostic and therapeutic surgical interventions for PM in patients with HCC affected the treatment plans depending on the result of pathology. In fact, surgical metastasectomy of PM may provide perioperative and anaesthetic risk, particularly in patients with hepatic dysfunction. Moreover, repeat metastasectomy for patients with recurrent PM who had no other distant metastasis may have technical difficulties despite of good results. Adequate guidelines for management of PM-HCC have been proposed based on significant prognostic factors increasing survival. Pulmonary metastasectomy may be a good option for PM-HCC.

Innovations and breakthroughs

A better result on surgical management of PM would be achieved with collaborative investigation and adequate guidelines. This strategy provided better survival and none to minimal surgical risk. Moreover, significant prognostic factors, such as liver transplantation as a treatment modality for

primary disease, absence of HBV infection, and well differentiation in pathology, were identified despite of small numbers of patients.

Applications

Pulmonary metastasectomy or more extended resection should be considered for diagnostic or therapeutic surgical interventions in managing patients with collaborative approaches, otherwise most of them might survive for less than one year. When considering surgery, the adequate guidelines, as proposed in this series should be adopted for better results. Firstly, adequate control over primary liver cancer is prerequisite. Aggressive management has the possibility of better results in patients who had undergone liver transplantation. Secondly, conservative resection or minimally invasive surgery may help to treat recurrent lung lesions or to provide less risk. Lastly, PM usually indicates advanced stage in patients with HCC, therefore other distant metastasis, particularly brain metastasis, should be excluded in surgical indications and be carefully detected by MRI on follow-up.

Peer review

This paper reported the clinical significance of pulmonary metastasectomy to improve the prognosis of patients with HCC. This manuscript arouses interest for readers and provides an important clue to treat such patients and alter the survival rate.

Abstract

AIM: To compare the recovery of thrombocytopenia and splenomegaly during long-term follow-up after liver transplantation in patients receiving a living donor transplant or a cadaveric donor transplant.

METHODS: This was a retrospective cohort study of 216 consecutive liver transplant patients who survived for > 6 mo after transplantation; 169 received a liver transplant from a living donor and 47 from a cadaveric donor. The platelet counts or spleen volumes were examined before transplant, 1, 6, and 12 mo after transplant, and then annually until 5 years after transplant.

RESULTS: The mean follow-up period was 49 mo (range, 21-66). Platelet counts increased continuously for 5 years after orthotopic liver transplant. The restoration of platelet counts after transplant was significantly slower in patients with severe pretransplant thrombocytopenia (< 50 000/μL) until 4 years after transplant (P = 0.005). Donor type did not significantly affect the recovery of platelet count and spleen volume in either patient group. In multivariate analysis, pretransplant severe thrombocytopenia (< 50 000/μL) was an independent factor associated with sustained thrombocytopenia (P < 0.001, odds ratio 6.314; confidence interval, 2.828-14.095). Thrombocytopenia reappeared after transplant in seven patients with portal flow disturbance near the anastomosis site.

CONCLUSION: Our study suggests that severe thrombocytopenia before transplant is closely associated with delayed recovery of platelet count after transplant and donor type did not affect the recovery of thrombocytopenia. The reappearance of thrombocytopenia after transplant should be considered a possible indicator of flow disturbance in the portal vein.

Key words: Liver transplantation; Thrombocytopenia; Splenomegaly; Hypersplenism

INTRODUCTION

Thrombocytopenia develops commonly in the early postoperative period after liver transplantation[1-3], and most instances of early thrombocytopenia recover with restoration of hepatic function[4,5]. By contrast, the recovery of pretransplant long-lasting thrombocytopenia differs among patients, and some patients experience persistent thrombocytopenia even several years after the operation[6]. Persistent thrombocytopenia increases the risk of bleeding-related complications, which worsen the

prognosis for the transplanted patients[1,7,8].

The possible causes of thrombocytopenia soon after the operation include consumption of platelets in the graft liver, impairment of platelet synthesis, small graft, and sepsis[1,3,7-10]. However, the causes or contributing factors of persistent thrombocytopenia (< 100 000/μL) beyond one year after the operation are not well known. A previous report suggested that thrombocytopenia at 3 and 6 mo after transplantation is an independent contributing factor to persistent thrombocytopenia[11].

Patients receiving a living donor transplant restore the liver volume up to 80% of the whole liver, in contrast with cadaveric donor transplant. Because of this deficient restoration in liver volume, the posttransplant recovery of thrombocytopenia or splenomegaly in living donor transplant is assumed to be different than that in cadaveric donor transplant[10].

The aims of this study were to compare the recovery of thrombocytopenia and splenomegaly in patients receiving a living donor liver transplantation (LDLT) and cadaveric donor liver transplantation (CDLT), and to identify the factors contributing to persistent thrombocytopenia during long-term follow-up after orthotopic liver transplantation (OLT).

MATERIALS AND METHODS

Patients

We performed 289 OLTs in our transplantation center between July 1996 and June 2006. Among them, 49 patients had liver transplant from cadaveric donor and 240 patients from living donor who donated right lobe. In addition, 19 patients prepared their transplants with us and then had CDLT performed in China during the same period. They were sent to us soon after transplants and followed up. Ninety-two patients were excluded from this study because of death within 6 mo after OLT (n = 52), post-OLT chemotherapy (n = 21), acute liver failure (n = 7), post-OLT interferon treatment (n = 7), age less than 20 years old (n = 4), and post-OLT portal vein obstruction (n = 1). The remaining 216 patients (169 LDLT, 47 CDLT) were recruited consecutively (Figure 1). Patient's anonymity was preserved and the study protocol conforms to the ethical standards of the responsible committee on human experimentation and with the Helsinki declaration of 1975, as revised in 1983.

The patients comprised 158 men and 58 women with a mean age at transplant of 49.1 ± 7.7 years (range, 21-66 years) (Table 1). The indications for OLT included complications of advanced cirrhosis in 133 patients, hepatocellular carcinoma in 75 patients, and other causes in seven patients. The causes of liver diseases were hepatitis B virus in 188 patients, hepatitis C virus in 9 patients, alcoholic liver diseases in 13 patients, autoimmune diseases in 5 patients, and other causes in 2 patients. The follow-up duration after the operation ranged from 6 to 178 mo, with a mean of 49 mo.

Methods

Serial platelet counts were obtained from the medical

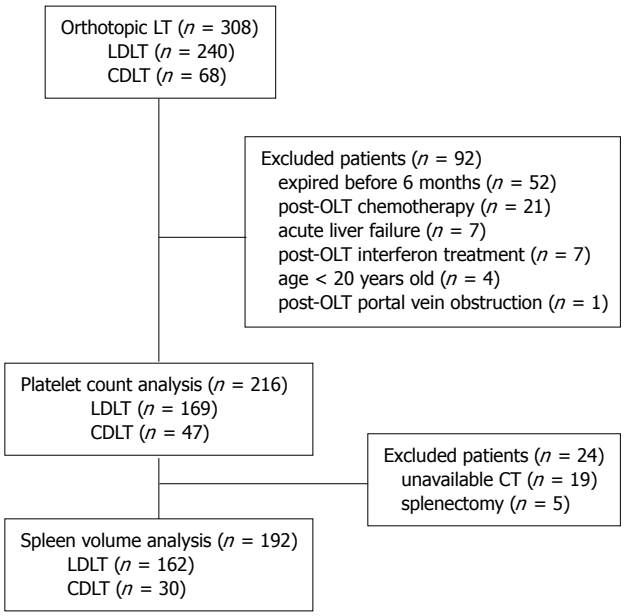

Figure 1 Study design.

Table 1 Baseline characteristics of patients

Characteristics (n = 216)	Data
Age at transplant (range), yr	49.1 ± 7.7 (21-66)
Duration posttransplant (range), mo	49.1 ± 29.5 (6-178)

record before the OLT and 1, 6, 12, 24, 36, 48, and 60 mo after the OLT. Pretransplant thrombocytopenia was classified arbitrarily according to platelet count as follows: group 1 (< 30 000/μL), group 2 (30 000-50 000/μL), group 3 (50 000-100 000/μL), group 4 (≥ 100 000/μL), which was modified according to the WHO adverse event criteria for hematologic toxicity. To evaluate spleen volume, the greatest length, transverse diameter, and thickness at the hilum of the spleen were measured using abdominal computed scanning tomography before the OLT and 1, 6, 12, 24 and 36 mo after the OLT. These values were multiplied together and then by the factor of 0.6 to obtain an estimated spleen volume as described previously[12]. Sustained thrombocytopenia was defined as platelets count < 100 000/μL 12 mo after the OLT. Factors such as demographic and clinical features associated with sustained thrombocytopenia were also assessed.

The immunosuppressive regimen used comprised cyclosporine or tacrolimus combined with or without mycophenolate mofetil, which was withdrawn in patients with severe leucopenia (< 2 000/μL). In addition, corticosteroid was used for 3-6 mo after operation, and then it was tapered. Among 216 patients, 132 (61%) patients had taken cyclosporine, 130 (60%) patients had tacrolimus, and 127 (59%) patients had mycophenolate mofetil. Mycophenolate mofetil was used for short duration, less than 6 mo, in most patients.

Rejection was diagnosed by liver biopsy, which showed Banff rejection activity index more than 3. Patients who had endoscopic retrograde biliary procedures or percutaneous transhepatic biliary procedures performed were diagnosed as those with biliary complication. We defined patients as those with portal flow disturbance if there was clear evidence in abdominal computerized tomography or magnetic resonance imaging.

Statistical analysis

Continuous variables are expressed as mean ± SD unless stated otherwise. Factors associated with sustained thrombocytopenia were analyzed by univariate analysis. Significant factors by univariate analysis ($P < 0.05$) were subjected to multivariate analysis using logistic regression (forward selection). Continuous variables were compared by paired *t* test and repeated-measures analysis of variance (ANOVA), and categorical variables were compared by either the chi-square test or Fisher exact test, as appropriate. The statistical analyses were performed using SPSS for Windows version 14 (Chicago: SPSS Inc., USA). $P < 0.05$ was considered significant.

RESULTS

Ninety-one percent (197/216) of our studied population demonstrated evidence of moderate to severe thrombocytopenia, as indicated by a platelet count < 100 000/μL before the OLT. The percentages of patients according to platelet count before the operation were 13% in group 1 (< 30 000 μL), 37% in group 2 (30 000-50 000/μL), 41% in group 3 (50 000-100 000/μL), and 19% in group 4 (≥ 100 000/μL). The mean platelet counts increased continuously for 5 years after orthotopic liver transplant: 58 000/μL before OLT, 121 000/μL at 1 mo, 128 000/μL at 6 mo, 132 000/μL at 12 mo, 145 000/μL at 24 mo, 148 000/μL at 36 mo, 149 000/μL at 48 mo, and 158 000/μL at 60 mo after OLT. The platelet counts increased significantly during the first month after OLT compared with later periods ($P < 0.001$), and then increased gradually until 5 years after the operation (Figure 2A). The donor type did not affect the recovery of platelet count after the operation and the recovery of platelet count in patients with severe thrombocytopenia before the operation (groups 1 and 2) was also not different between LDLT and CDLT (Figure 2B).

Recovery of platelet count after OLT differed significantly between the four groups classified according to pretransplant thrombocytopenia until 5 years after the OLT ($P = 0.015$, repeated-measures ANOVA) (Figure 3A). In those who survived more than 1 year, 58% (15/26) of patients in group 1, 30% (30/75) in group 2, 12% (10/82) in group 3, and 6% (1/17) in group 4 had moderate to severe thrombocytopenia (< 100 000/μL) one year after the OLT. Five years after the OLT, the mean platelet count in patients with pretransplant severe thrombocytopenia (groups 1 and 2) was < 150 000/μL. In contrast, patients with pretransplant moderate thrombocytopenia (group 3) showed a faster recovery of platelet count to a mean value near 150 000/μL (148 000/μL) 6 mo after the OLT. The restoration of platelet counts after the OLT was significantly slower in patients with severe pretransplant thrombocytopenia (groups 1 and 2) than in the groups with mild or moderate thrombocytopenia (groups 3 and 4) until 4 years after the OLT ($P = 0.005$, Figure 3A).

In univariate analysis, clinical factors associated with sustained thrombocytopenia (< 100 000/μL at 12 mo after OLT) were pretransplant severe thrombocytopenia (< 50 000/μL) and pretransplant large spleen volume (> 2000 mm^3) ($P < 0.001$, respectively; Table 2). In the multivariate analysis, pretransplant severe thrombocytopenia and splenomegaly were independent factors associated with sustained thrombocytopenia ($P < 0.001$ and $P = 0.004$, respectively).

Seven patients with portal vein thrombosis or stenosis showed a decrease in platelet count in proportion to the progression of portal flow disturbance. The disturbance of portal flow appeared between 6 mo and 1 year after the operation. In these patients, the platelet count increased initially as in the other patients but decreased gradually with disturbed portal flow (Figure 3B). The causes of portal flow disturbance were attributed to main portal vein thrombosis (three patients) and stenosis of the portal vein anastomosis site (four patients). The donor types for these patients were three cadaveric donors and four living donors.

All patients with splenomegaly showed decreased spleen volume 6 mo after the operation. The mean volumes of spleens were 1105 ± 636 cm^3 before transplant, 810 ± 469 mm^3 6 mo after OLT, 761 ± 385 mm^3 12 mo after OLT, 711 ± 399 mm^3 24 mo after

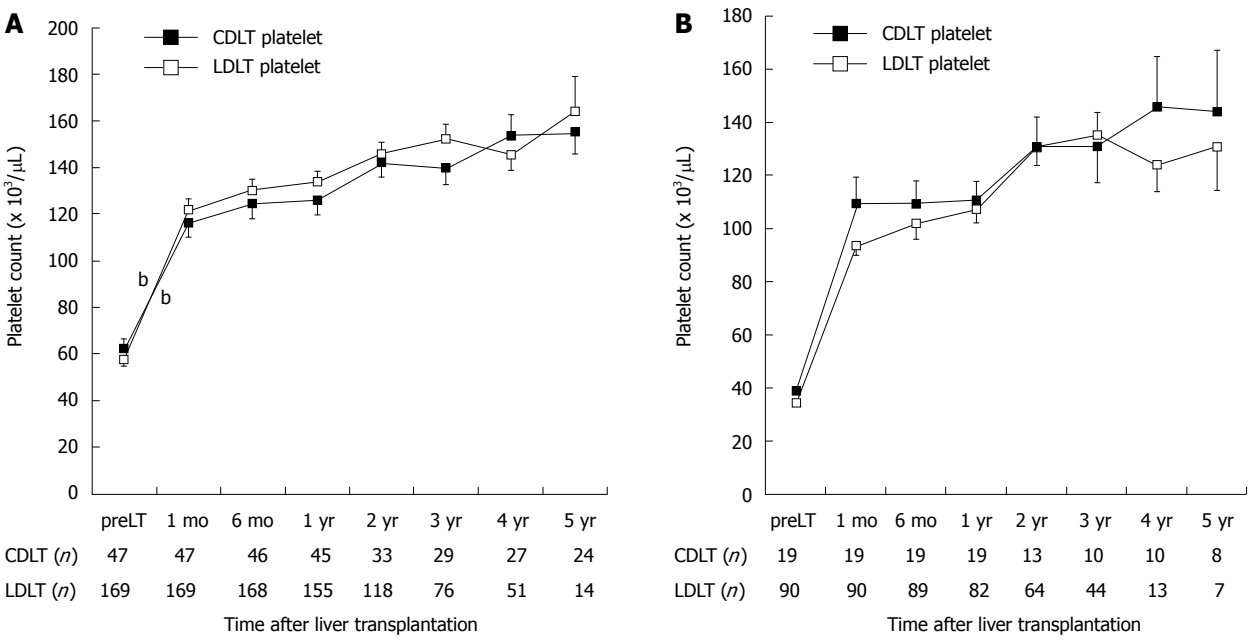

Figure 2 Change in platelet counts during the 5 years after OLT (mean ± SE). **A**: In both LDLT and CDLT, the platelet counts within 1 mo after OLT increased significantly ($^bP < 0.001$). The increase of platelet counts within first 1 mo after OLT was significantly larger than the later periods ($P < 0.001$). Platelet counts in LDLT and CDLT did not differ significantly during the 5 years after OLT ($P = 0.437$, repeated-measures ANOVA); **B**: In patients with severe preoperative thrombocytopenia (< 50 000/μL), donor type also did not affect the recovery of platelet count after the OLT ($P = 0.541$).

OLT, and 648 ± 415 mm^3 36 mo after OLT, and it did not return to normal until 3 years. The reduction rate of spleen volume relative to the pretransplant volume was 26.7% and 31.1% 6 and 12 mo after the operation, respectively. The speed of volume reduction was fastest within the first 6 mo after the operation compared with later periods up to 2 years ($P \leqslant 0.02$; Figure 3C). The rate of reduction in spleen volume did not differ significantly between the LDLT and CDLT groups. The restoration of spleen volume after the OLT was significantly slower in patients who had severe pre-OLT thrombocytopenia (groups 1 and 2) than in those with mild to moderate thrombocytopenia (groups 3 and 4) until 2 years after the operation ($P = 0.006$, repeated-measures ANOVA; Figure 3D).

DISCUSSION

This long-term cohort study clearly demonstrated that liver transplantation affects the rate of recovery of thrombocytopenia. The recovery was fastest within the first month and then decreased gradually for 5 years. Most previous reports have shown the impact of whole liver transplantation from cadaveric donor on hypersplenism during the early postoperative period[13-16]. Recent reports showed that partial liver transplantation from living donor effectively reduces spleen size and resolves thrombocytopenia in adults and children, but the follow-up duration was shorter than in the present study[17-19]. Compared with CDLT, LDLT could not restore the whole liver volume. This suggests that the recovery rate of thrombocytopenia after the operation may differ between patients receiving LDLT and CDLT. However, our study included a large number of LDLT patients, showed that LDLT effectively restored platelet count at a rate similar to that observed in CDLT patients. This indicates that LDLT rapidly resolved the portal hypertension despite the partial restoration of the liver up to 80% of the whole liver volume, and regeneration of a living donor liver is as effective as regeneration after CDLT.

The causes of thrombocytopenia during the early postoperative period include sequestration of platelets in the liver graft, reduced platelet production, immunological reaction, and graft dysfunction[1,3,7-9]. However, the causes of sustained long-term thrombocytopenia for more than 1 year are not fully understood. A previous study suggested that pretransplant variceal bleeding, pretransplant splenomegaly, and thrombocytopenia at 3 and 6 mo after LT are predicting factors of persistent thrombocytopenia[11]. In our study, pretransplant severe thrombocytopenia (< 50 000/μL) and splenomegaly (> 2000 mm^3) were significantly associated with sustained thrombocytopenia. In addition, delayed graft failure, biliary complication, and infections are considered other possible causes of sustained thrombocytopenia lasting more than 1 year. In our study, most biliary complication induced transient thrombocytopenia rather than sustained thrombocytopenia. Almost these patients with biliary complication recovered from thrombocytopenia after biliary intervention.

Splenomegaly is sustained for several years after the operation even though the graft liver restores normal portal hemodynamics relatively soon after the operation[16]. In a prospective hemodynamic study, hemodynamic parameters including cardiac index, mean arterial pressure, portal flow velocity, and hepatic artery resistance index improved within 6 mo after liver transplantation[15]. However, the spleen size decreased gradually beyond 2 years. Our study

is consistent with the results of previous studies in showing that the long-lasting severe splenomegaly takes several years to resolve although liver synthetic function recovers rapidly.

In seven of our patients, thrombocytopenia reappeared after the initial recovery of platelet counts because of disturbed portal flow. The possibility of portal vein complications is considered greater after LDLT than after CDLT[20,21]. Vascular complications in pediatric patients with whole liver grafts and segmental grafts in a large series of 600 transplants was reported[20]. The incidence of portal vein complications was higher in LDLT patients (27%) than in patients receiving reduced-size or split-liver transplantation (1%) or whole liver transplantation (1%) from a cadaveric donor. Portal vein thrombosis or stenosis appearing in immediate postoperative period should be treated with surgical treatment or radiological intervention[22-25]. If the stenosis or thrombosis progresses slowly beyond 1 year, as in our patients, the patients may not have any symptoms because of reopening of the previously established collateral circulation. Thus, the clinician should monitor the recovery of platelet count after the operation carefully. If thrombocytopenia reappears after the initial recovery of platelet count, the degree of portal vein stenosis or collateral circulation should be evaluated by dynamic computed tomography. In addition, biliary tract infection or interferon therapy for recurrent hepatitis C may cause the reappearance of thrombocytopenia[26,27].

Our study has some limitations. First, it is a retrospective cohort study. However, a large number of patients (216 patients) were included consecutively in the cohort and the follow-up duration was longer than that of other studies. Second, we did not perform hemodynamic studies to evaluate the resolution of portal hypertension after the operation and did not measure serum thrombopoietin level to evaluate the synthetic function of the platelet[28-30]. Further study including hemodynamic analysis is needed to identify why the patients with severe pretransplant thrombocytopenia improve slowly after the operation.

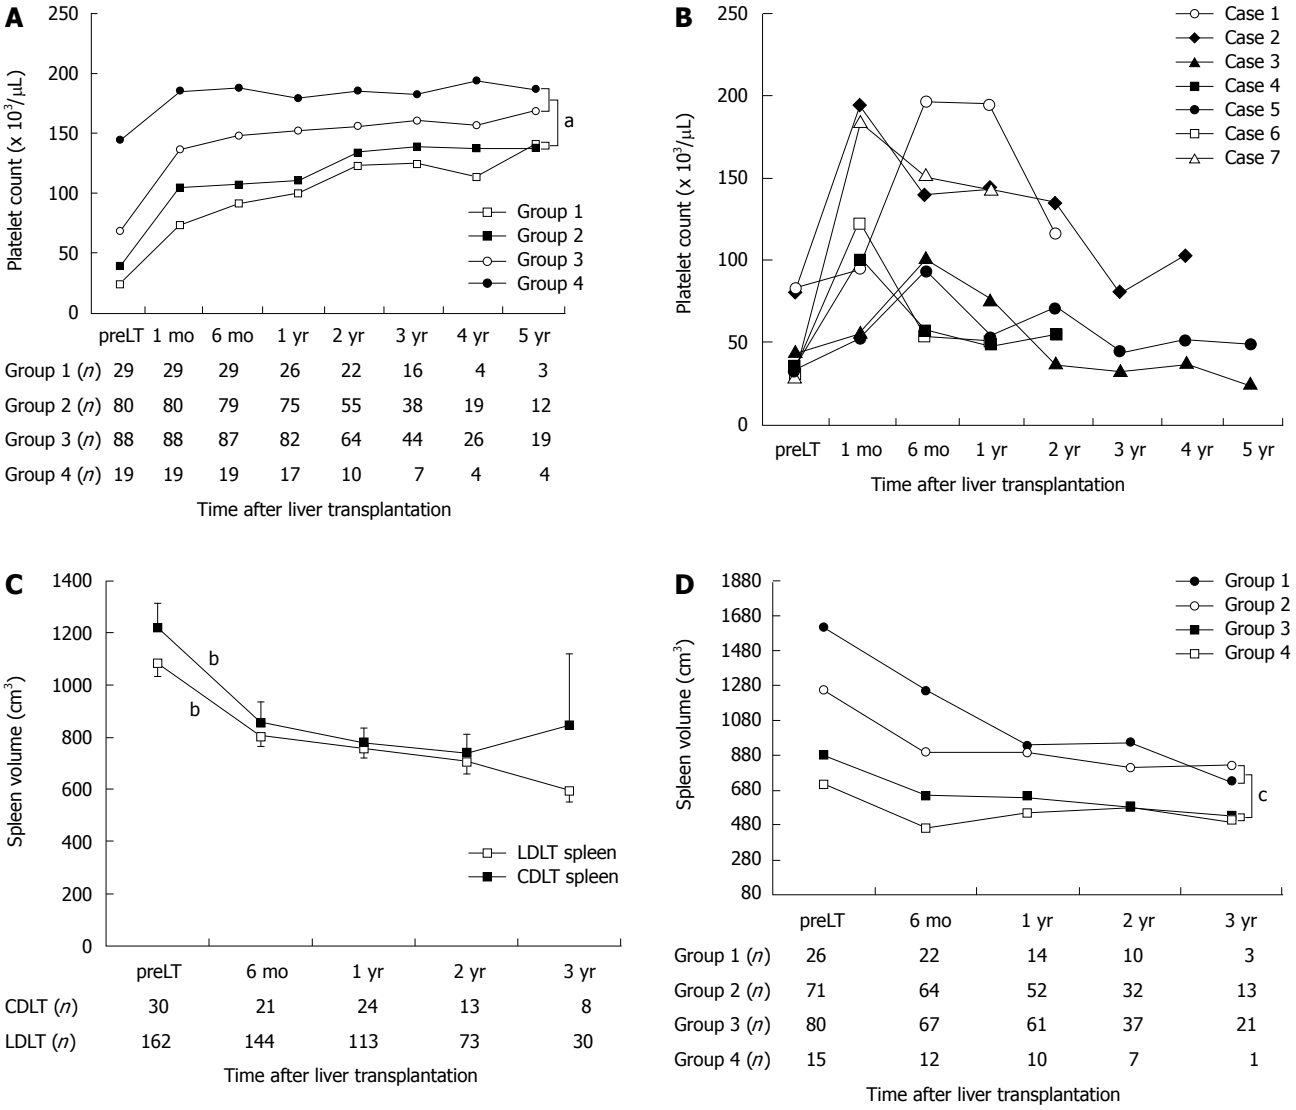

Figure 3 **A**: Change in platelet counts during the 5 years after OLT grouped according to pre-OLT platelet count. Patients with severe pretransplant thrombocytopenia (groups 1 and 2) showed a slower recovery of thrombocytopenia compared with those with mild to moderate thrombocytopenia (groups 3 and 4) until 4 years after the OLT (^{a}P = 0.005, repeated-measures ANOVA); **B**: Change in platelet counts after the OLT in seven patients with portal vein thrombosis or stenosis. The increase of initial platelet count was similar to that observed in the other patients, but the count decreased gradually in proportion to the disturbance of portal flow; **C**: Change in spleen volumes during the first 3 years after the OLT (mean with standard error). In both LDLT and CDLT, the spleen volumes within 6 mo after OLT decreased significantly ($^{b}P < 0.001$). The decrease of spleen volumes within first 6 mo after OLT was significantly larger than the later periods ($P \leqslant 0.02$). The reduction in spleen volume after OLT did not differ significantly between LDLT and CDLT patients until 2 years after the OLT (P = 0.850, repeated-measures ANOVA); **D**: Change in spleen volumes for the first 3 years after the OLT grouped according to the pre-OLT platelet count. Patients with severe pretransplant thrombocytopenia (groups 1 and 2) showed a slower reduction of spleen volume compared with those with mild to moderate thrombocytopenia (groups 3 and 4) until 2 years after the OLT (^{c}P = 0.006, repeated-measures ANOVA).

In conclusion, this study demonstrated that severe thrombocytopenia before transplantation is closely associated with delayed recovery of platelet count after transplantation. Our data also showed that hypersplenism improve at the same rate after LDLT as after CDLT. If thrombocytopenia reappears beyond 6-12 mo without any other cause, disturbance of portal flow, especially in the anastomosis site of the portal vein, should be evaluated.

COMMENTS

Background

The recovery of pretransplant long-lasting thrombocytopenia differs among patients. Because of the deficient restoration in liver volume, the posttransplant recovery of thrombocytopenia or splenomegaly in living donor transplant is assumed to be different from that in cadaveric donor transplant.

Research frontiers

The study has not been done to compare the recovery of thrombocytopenia and splenomegaly in patients receiving a living donor liver transplantation and cadaveric donor liver transplantation during long-term follow-up after orthotopic liver transplantation.

Innovations and breakthroughs

This study suggests at the first that severe thrombocytopenia before transplant is closely associated with delayed recovery of platelet count and spleen volume after transplant, and donor type does not affect the recovery of thrombocytopenia.

Applications

The degree of thrombocytopenia before transplant can be used to predict delayed recovery of platelet count and spleen volume after transplant.

Peer review

This is a retrospective study comparing recovery of thrombocytopenia and sple-

nomegaly in patients receiving a LDLT and CDLT. The manuscript is generally well written and has a concise, simple methodology with good long-term follow-up.

Abstract

AIM: To enrich hepatic progenitors using epithelial cell adhesion molecule (EpCAM) as a marker from human fetal liver and investigate the expression of human leukocyte antigen (HLA) and their markers associated with hepatic progenitor cells.

METHODS: EpCAM +ve cells were isolated using magnetic cell sorting (MACS) from human fetuses (n = 10) at 15-25 wk gestation. Expression of markers for hepatic progenitors such as albumin, alpha-fetoprotein (AFP), CD29 (integrin β1), CD49f (integrin α6) and CD90 (Thy 1) was studied by using flow cytometry, immunocytochemistry and RT-PCR; HLA class Ⅰ (A, B, C) and class Ⅱ (DR) expression was studied by flow cytometry only.

RESULTS: FACS analysis indicated that EpCAM +ve cells were positive for CD29, CD49f, CD90, CD34, HLA class Ⅰ, albumin and AFP but negative for HLA class Ⅱ (DR) and CD45. RT PCR showed that EpCAM +ve cells expressed liver epithelial markers (CK18), biliary specific marker (CK19) and hepatic markers (albumin, AFP). On immunocytochemical staining, EpCAM +ve cells were shown positive signals for CK18 and albumin.

CONCLUSION: Our study suggests that these EpCAM +ve cells can be used as hepatic progenitors for cell transplantation with a minimum risk of alloreactivity and these cells may serve as a potential source for enrichment of hepatic progenitor.

Key words: Epithelial cell adhesion molecule; Human fetal liver; Hepatic progenitors; Human leukocyte antigen; Hepatic cell therapy

INTRODUCTION

Hepatocyte transplantation has been reported as a useful bridge/alternative therapy for the treatment of various types of liver diseases. The potential of hepatocyte transplantation to provide metabolic support for acutely injured liver tissues has been suggested by earlier workers[1,2]. However, due to the scarcity of HLA matched adult human liver donor cells and the inability of hepatocytes to proliferate *in vitro* the usage of hepatocyte-based cell therapy in liver diseases has been limited. The existence of bi-potential progenitor cells in the liver of rodents using different phenotypic markers was demonstrated many years ago[3]. More recently the same markers have been demonstrated in human fetal liver and it has been argued that these progenitor cells are derived from a common cell compartment and they can be referred to as the hepatoblasts[4]. Similar cells obtained from the rat fetus could reconstitute bile ducts and structures resembling hepatocytes after being transplanted in retrosine damaged liver of syngeneic rats[5].

Progenitors isolated from adult or fetal liver can generate hepatocytes *in vitro* and mature liver cells *in vivo*. Fetal liver CD117+/CD34+/Lin-progenitors and their progeny proliferated *in vitro* and also functionally

differentiated into mature hepatic cells in an acute liver injury model[6]. Epithelial progenitor cells (EPC) from human fetal liver possessed highly proliferative ability and sub-passaged for more than 25 passages. Two months after EPC transplantation, the grafted cells differentiate into hepatocyte like cells[7]. Epithelial cell adhesion molecule positive (EpCAM +) cells are 80% hepatoblasts and 0.1%-0.7% is hepatic stem cells in human fetal liver[8]. Transplantation of these EpCAM + cells or hepatic stem cells expanded in culture into NOD/SCID mice results in mature liver tissue expressing human specific proteins[9]. It has been reported that cells in embryonic day (ED) 13.5 fetal mouse liver cells, which co-express CD49f and CD29 (α6, β1 integrin subunits) but do not express c-kit, CD45 or TER 119 are the best candidate for hepatic stem /progenitor cells[10].

Human fetal liver cells also offer an important source for isolating hepatic and hematopoietic progenitors for clinical application. After 5 wk of gestation hematopoiesis starts to shift from the yolk sac to the liver[11], and during the first trimester fetal liver contains both hepatic and hematopoietic progenitors[12-14]. During this period, fetal liver cells express hepatoblasts and biliary cell specific markers, such as albumin, alpha-fetoprotein (AFP), β-1 microglobulin, glycogen, glucose-6-phosphatase (G-6-P), gamma glutamyl transpeptidase (GGT), dipeptidyl peptidase Ⅳ (DPPIV) and cytokeratin (CK) 19; they also express hematopoietic markers such as CD34[15,16]. During the second trimester markers for hepatoblasts continue to be expressed but the expression of hematopoietic precursors is reduced. This offers an opportunity to isolate and study large numbers of hepatic progenitor cells without hematopoietic potential during the second trimester of gestation. Several years ago we, for the first time, had shown the use of human fetal hepatocytes isolated from the second trimester, for the treatment of fulminant hepatic failure patients[17]. Subsequently other investigators have also isolated hepatic progenitor cells from human fetal liver in the second trimester and demonstrated the higher ability to proliferate without changing their karyotypes[4]. It is therefore important to characterize the cells that could be responsible for the regenerative potential of the fetal hepatocytes in the second trimester of gestation.

Recently we have reported the expression of CD34 antigen (a hematopoietic marker) in human fetal liver cells during the second trimester, and the co-expression of hepatic markers such as AFP and albumin in these cells[18]. In this study we have described the expression of hepatic progenitor and HLA markers in the EpCAM +ve cells isolated from the second trimester fetal liver. Our results show that EpCAM +ve fetal liver cells at this stage express nil levels of HLA-DR marker but they show expression of progenitor and liver specific markers suggesting that these EpCAM +ve cells are hepatic progenitors. Our results also indicate that the EpCAM +ve cells include most of the CD34 +ve cells that are seen in the fetal liver during the second trimester.

MATERIALS AND METHODS

Isolation of fetal liver cells

Human fetal liver tissues were obtained from aborted fetuses at 15-25 wk gestation in accordance with the Institute ethical guidelines. The fetuses were collected under sterile condition within 2 h of the termination of pregnancy. The liver tissue from the fetus was initially perfused twice with cold PBS for 5 min to eliminate circulating cell contaminants, followed by digestion with 0.025% collagenase prepared in PBS for 5 min. Then the liver was disintegrated into a single cell suspension by passing through 70 μm cell strainer (BD Biosciences). Viable cell count was determined by the trypan blue dye exclusion test. All donors of the fetus used in the study had been serologically screened for syphilis, toxoplasmosis, rubella, hepatitis B and C, human immunodeficiency virus 1, cytomegalovirus, parvovirus, and herpes simplex types 1 and 2. All cell isolation procedures were carried out under sterile condition in class 100-biosafety cabinet.

Enrichment and culture of EpCAM +ve cells

EpCAM positive cells were sorted by using the magnetic cell sorter Auto MACS according to the manufacturer's instructions (Miltenyi Biotec, Germany, http//www.miltenyibiotec.com). Labeling of EpCAM positive cells was done by incubating with 5×10^7 total fetal liver cells in 500 μL of buffer containing FCR blocking reagent and EpCAM micro beads at 4℃ for 30 min. Cells were filtered using 70 μm cell strainer to remove clumps and loaded on magnetic column. EpCAM +ve cells were collected in the second fraction form the column.

The enriched EpCAM +ve cells were collected and suspended in RPMI 1640 medium (Sigma) supplemented with 10% fetal bovine serum (FBS, Sigma). Cells were plated at 1.5×10^6 per well in a six well plates and maintained at 37℃ in a humidified environment containing 5% carbon dioxide. After 72 h, the nonadherent cells were removed and the medium replaced. Colonies that formed during the culture period were picked after 10 d and 20 d and kept on ice for further study of CK18 and albumin expression by immunofluorescence.

FACS analysis

EpCAM +ve cells were stained with Phycoerythrin (PE) labeled anti-CD29 (Integrin β1, 1:100, BD Biosciences, USA), CD90 (Thy 1) or fluorescein isothiocynate (FITC) labeled anti CD49f (integrin α6) antibodies (1:100, BD Biosciences, USA). Staining for HLA-A, HLA-B, HLA-C and HLA-DR was done incubating with the respective primary antibodies (Chemicon, USA) at 4℃ for overnight. Subsequently the cells were incubated with FITC labeled rabbit anti-mouse IgG FITC (1:100, Sigma) at room temperature for 40 min. Unstained

Table 1 List of primer sequences used in the study

HLA-DR (HLA class Ⅱ)	0.6 ± 0.4	0.35 ± 0.1	0.612

EpCAM positive cells were used as negative control to subtract auto fluorescence.

For albumin and AFP staining in the cytoplasm, cells were fixed with 4% paraformaldehyde in PBS and then permeated with 0.5% Triton X-100 for 10 min. After two washes cells were blocked with 0.5% bovine serum albumin (BSA, Sigma), at room temperature for 1 h. Cells were incubated with primary antibodies at room temperature for 2 h and subsequently incubated with secondary antibodies, FITC labeled rabbit anti-goat IgG (1:200, Bangalore Genei, India) at room temperature for 40 min. Stained cells were analyzed on FACS Calibur flow cytometry (BD Biosciences, USA).

Immunocytochemistry

In addition to phenotyping by flow cytometry, EpCAM +ve cells were stained for albumin and CK18 by immunocytochemistry. For albumin and CK18 staining in the cytoplasm, Cultured EpCAM +ve cells were fixed with 4% paraformaldehyde in PBS and then permeated with 0.5% Triton X-100 for 10 min. After two washes cells were blocked with 0.5% BSA at room temperature for 1 h. Cells were incubated with primary antibodies include albumin (1:100, MP biomedical), CK18 (1:200, Sigma) at room temperature for 2 h and subsequently incubated with secondary antibodies, FITC labeled rabbit anti-goat IgG (1:200, Bangalore Genei, India) at room temperature for 40 min. The signal was detected using a fluorescence microscope (Axio Plan upright; Carl Zeiss Vision Co., Ltd., Hallbergmoos, Germany).

Reverse transcription-PCR analysis

RT PCR analysis of cultured EpCAM +ve cells was done for 3 samples (n = 3). Total RNA from cultured EpCAM +ve cells was isolated using RNAeasy Mini Kit (Qiagen). One μg of RNA was reversed transcribed using Moloney murine leukemia virus Reverse transcriptase and Oligo dT (Promega). PCR reaction was performed using cDNA amount representing 100 ng of total RNA and 1 unit of Taq polymerase (Invitrogen, reaction mixture containing 10 mmol/L Tris-Hcl, 200 mmol/L dNTP and 20 pmol of gene specific primer). PCR was performed in a thermal cycler (Programmable Thermal Controller) following an initial denaturation step of 5 min at 95℃. Thermal program was consisting of 35 cycles of 94℃ for 1 min, 56℃ for 1 min and 72℃ for 2 min. This was followed by a final extension of 10 min at 72℃. PCR products were separated by electrophoresis in 1.5% agarose gel. The primer sequences (Invitrogen) used in the study are listed in Table 1.

Statistical analysis

The data were categorized as group 1, cells obtained from abortuses of gestational age 15 to 20 wk, and group 2, gestational age 21 wk to 25 wk. Student t-test was used to determine the likelihood of a significant difference ($P < 0.05$) between these two groups in the percentage of EpCAM +ve cells that express phenotypes with hepatic and progenitor markers and in the percentage of cells that express HLA classes Ⅰ and Ⅱ.

RESULTS

EpCAM +ve cell recovery fetal liver cells

Fetal liver cells in the study have been divided into two age groups, 15-20 wk (group 1) and 21-25 wk (group 2). The total number of cells obtained from each group was (140.0 ± 30.8) × 10^6 and (193.4 ± 96.8) × 10^6, respectively, and the cell viability in both groups was > 80%. This indicated that the total number of cells in fetal liver during the late second trimester is higher in the early second trimester. Microscopic examination of the cells before EpCAM +ve cell enrichment showed a heterogeneous population in both age groups (Figure 1B). Purification of EpCAM +ve cells was done by using magnetically tagged EpCAM antibodies and MACS as described. The number of EpCAM +ve cells obtained in both fetal age groups were (22 ± 4.8) × 10^6 to (34.4 ± 11.4) × 10^6, thus indicating a decrease in the yield of EpCAM +ve cells during the last part of the second trimester from about 16% to 15% of the total fetal liver cells, during the later second trimester. Morphologically most EpCAM +ve cells were homogenous (Figure 1C). On the contrary EpCAM -ve cells were a mixed population of cells (Figure 1D).

FACS analysis

We have analyzed the expression of HLA class Ⅰ and Ⅱ and hepatic progenitor markers such as CD29, CD49f, CD90 and hepatic specific markers such as albumin and AFP in EpCAM +ve cells by flow cytometry (Figure 2, Table 2). The results are depicted in Figure 2, gives representative histograms of the FACS analysis for HLA and hepatic progenitor markers in

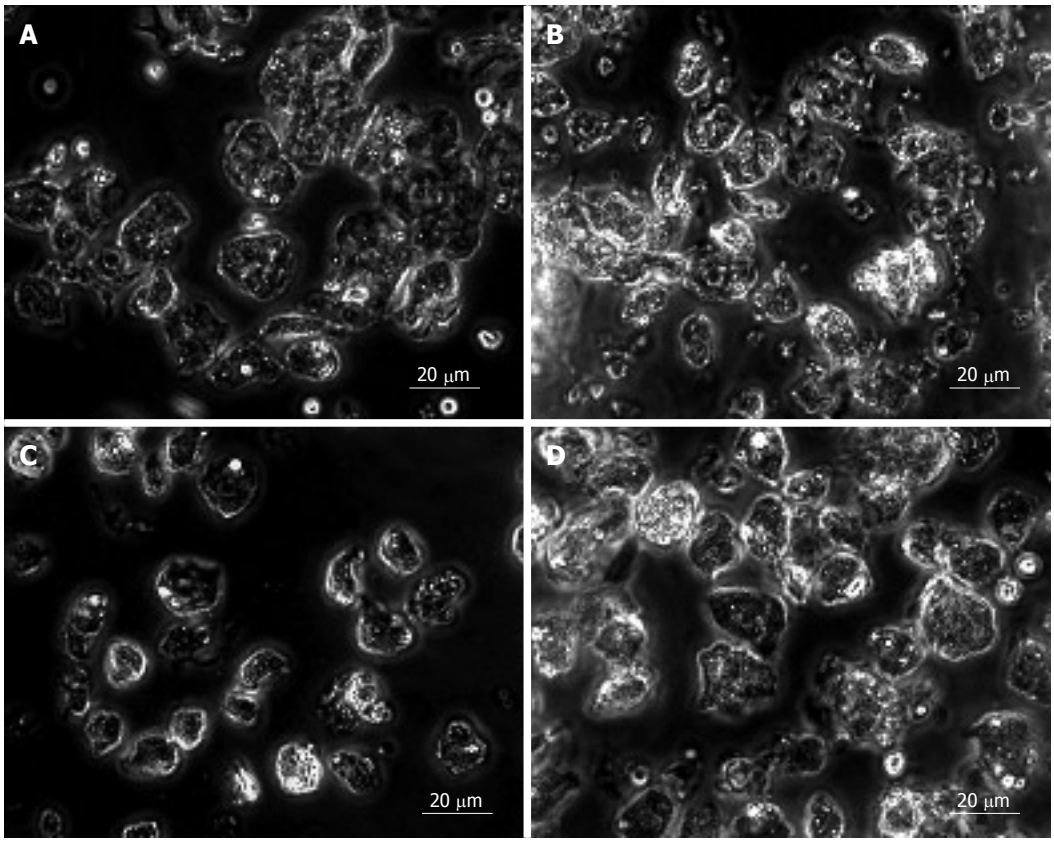

Figure 1 Purification of EpCAM +ve cell population. An unsorted fetal liver cell shows a heterogeneous population in group 1 (**A**) and group 2 (**B**). After double selection, the EpCAM +ve sorted fetal liver cells shows a homogeneous epithelial cell population (**C**). EpCAM -ve sorted fetal liver cells shows irregular shape of cells (**D**).

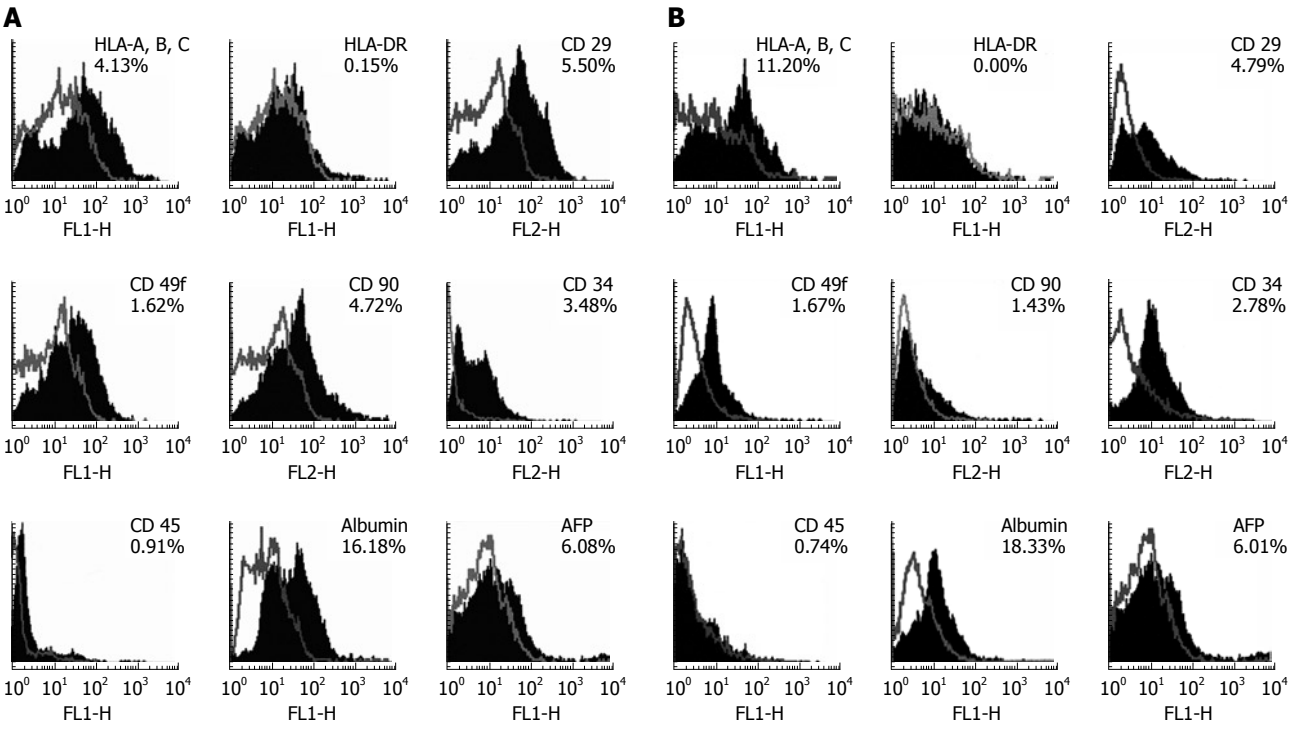

Figure 2 Identification of hepatic progenitor and HLA markers on EpCAM + sorted fetal liver cells by Flow cytometry. **A**: The overlaid histograms of analyzed markers with their unstained controls. Results indicated EpCAM +ve cells expressed surface markers such as, HLA-A, B, C, HLA-DR, CD29, CD49f, CD90, Albumin, AFP, CD34, CD45 By contrast HLA-DR did not express on EpCAM + cells in group 1. **B**: Expression of markers in group 2. In which HLA-A, HLA-B, HLA-C, and albumin was increased but CD90 expression was decreased on EpCAM +ve cells. Other markers such as CD29, CD49f, AFP, CD34 and CD45 expression levels were almost same in both age groups.

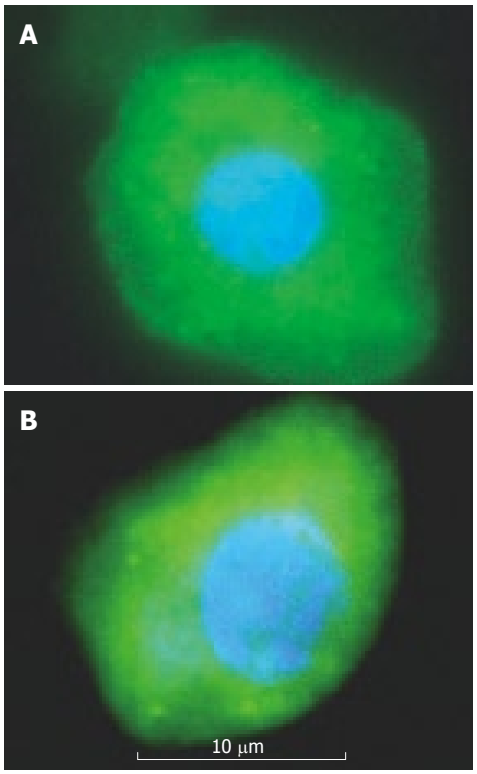

Figure 3 EpCAM + sorted fetal liver cells that are positive for CK18 (**A**) and albumin (**B**) in 18 wk gestation. These cells have high cytoplasm-to-nucleus ratio and observed mononucleated cells.

EpCAM +ve cells in group 1 (Figure 2A) and group 2 (Figure 2B). Numbers indicated in Table 2, gives mean percentage expression of HLA and hepatic progenitor markers in EpCAM +ve cells in group 1 and group 2.

Expression of HLA A, B and C and DR

HLA class Ⅰ expression was seen in approximately 6.52% cells in group 1. 8.2% in group 2. Expression of HLA class Ⅱ expression in the same period was similar 0.6% and 0.4% cells respectively (Table 2). HLA class Ⅰ and Ⅱ expression levels were not significantly different with respect to their gestational age groups.

Expression of integrins (CD29/49f), CD90, albumin and AFP

CD29 (β-1 integrin) and CD49f (α-6 integrin) are cell-adhesion molecules that are important for cell-matrix interactions, these markers are also used to study early hepatocyte differentiation. The expression of β1 integrin was observed in about 3.9% cells in-group 1 and in 2.0% cells in group 2. During the corresponding periods CD49f expression was seen in 2.2% and 1.6% cells. These data indicate the β-1 integrin cells in the EpCAM +ve population reduce by half in group 2 but there is no significant change in α-6 integrin +ve cells (Table 2).

CD90 is a cell surface protein is also one of the hepatic progenitor markers. The expression of CD90 was observed in 3.5% cells in group 1 and in 1.3% cells in group 2 and significant difference of expression of CD90 marker was observed with respect to gestational ages (Table 2).

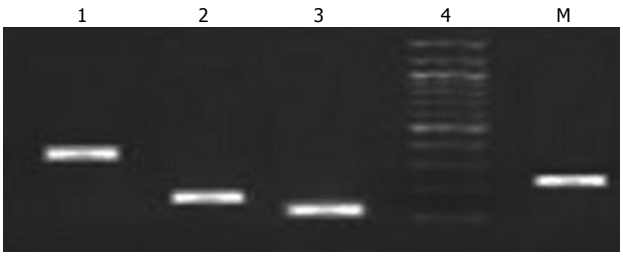

Figure 4 RT-PCR results indicate that the EpCAM + cells expressed hepatic stem cells markers such as CK18, CK19, albumin and AFP. 1: CK 19; 2: Albumin; 3: CK 18; 4: AFP; M: 100 bp Marker.

Albumin is used as a classic hepatic indicative markers differentiation for hepatic stem cells. We observed strong levels of albumin expression in EpCAM +ve but it did not differ significantly in gestational age groups (Table 2). FACS data revealed that albumin expression was 19.2% cells in group 1 and 21.3% cells in group 2.

AFP used as a marker for hepatic stem cells was observed strong levels in EpCAM +ve cells (Figure 2A and B), but it did not differ significantly in gestational age groups (Table 2). FACS data revealed that AFP expression was 7.3% in group 1 and 7.2% in group 2.

Analysis of markers expressed by Immunocytochemistry

On Immunocytochemical staining, EpCAM +ve cells were more strongly stained for CK18 and albumin. Albumin positive stained cells possessed large nuclei and more cytoplasm (Figure 3A). CK18 positive stained cells possessed large nuclei and highly granulated cytoplasm (Figure 3B).

RT-PCR analysis

To confirm that the sorted cells were of hepatic lineage, cultured Epcam +ve sorted cells were further analyzed for the expression of CK18, CK19, albumin, and AFP. These results suggest that EPCAM +ve cells strongly express genotypic CK18, CK19, Albumin, AFP (Figure 4) and these cells were capable of differentiating into hepatic and biliary lineages.

DISCUSSION

A progenitor or precursor for hepatocytes seen in fetal or adult tissues give rise to differentiated cells in a specialized way. Researchers often distinguish progenitor precursor cells from adult stem cells in the following way: when a stem cell divides, one of the two new cells is often a stem cell capable of replicating itself again where as the other cell is commited to differentiation. In contrast, when a progenitor/precursor cell divides, it can either form more progenitor/precursor cells or it can form two differentiated cells directly, neither of

which is capable of replicating itself. During normal homeostasis of tissues progenitor/precursor cells are used to replace cells that are damaged or dead, thus maintaining the integrity and functions of a tissue like liver.

This idea of progenitor cell dependent liver regeneration started with oval cells. Although neither cell replacement during normal tissue turnover nor after injury by partial hepatectomy requires stem cells for organ regeneration, this is not true for all types of liver injury. In some types of liver damage, for example primary biliary cirrhosis Alcoholic liver disease NASH, small cells (oval cells) with a high nuclear/cytoplasmic ratio emerge in the portal zone, proliferative extensively, and migrate into the lobule[19]. But the engraftment of oval cells may be less efficient than for hepatoctyes because of their smaller size and less efficient trapping in the liver[20].

Earlier studies have shown hepatic progenitors that express markers such as CD117/CD34[21], CD90[22], CD34/AFP[18]. Hepatoblasts are common progenitors for hepatocytes and biliary epithelial cells[23]. EpCAM has first been identified as a tumor-specific antigen on several carcinomas of different origin.

In our study we have observed EpCAM +ve cell enrichment of up to 15% after MACS sorting. These cells did not clump during purification and there was no change in the cell morphology or viability before and after sorting. In an earlier study have reported 12% EpCAM + enrichment from human fetal liver[8].

In our recent study we have shown an average of 5% CD34 +ve cells with hepatic progenitor properties on human total fetal liver cells[18]. Interestingly in the present study we observed CD34 expression (an average of 3%) on EpCAM +ve cells also. However these cells showed low or nil (0.91%) expression of CD45, the marker that distinguishes hematopoietic cells from non-hematopoietic cells. Therefore we can say that EpCAM +ve and CD34 +ve cells are not committed to hematopoietic lineage and they may differentiate into hepatic cells in the second trimester of fetal liver. Recently CD90 expressing cells were recognized as hepatic progenitors [22]. In our study progenitor markers such as CD90+, CD34+ expressions were observed on EpCAM +ve cells and these cells were negative for hematopoietic lineage (CD45). Where as CD90 and CD34 double positive expression ranged 0.44%-2.04% in total fetal liver cells and these cells were positive for both hepatic lineage (CK19) and hematopoietic lineage (CD45) markers in the second trimester[22].

In our study we found that positive cells of integrin CD29 (β-1 integrin) and CD49f (α-6) on EpCAM +ve cells. Earlier investigators have reported that CD29 as a specific hepatic stem cell marker, was expressed on an average of 0.08%-2% of the human total fetal liver cells[21]. It has been shown that CD49f +ve cells (an average of 48.51%) are primitive hepatic endodermal cells with the capacity to differentiate into hepatocytes in the mouse fetal liver[24]. Taken together presence of stem cell marker (β-1 integrin) and primitive hepatic endodermal (α-6 integrin) indicate that it is possible to designate our cells as possessing progenitor phenotype.

It has been speculated that progenitor cells are less immunogenic than mature cells; however, immunological rejection would still be an issue. We believe that transplantation of cells having negligible would certainly reduce GvHd development. Earlier investigators reported that high percentage of cells expressing the histocompatibility markers HLA class Ⅰ and HLA class Ⅱ were found in the 5th and 8th wk of gestation in total fetal liver cells after which the expression levels were decreased with advanced gestation age 21 wk This higher expression of HLA molecules in these cells may be because of hematopoietic cell contamination in the fetal liver in early gestation. Therefore in our study, we have enriched the EpCAM +ve cells without hematopoietic cell contamination and investigated the pattern of HLA molecules expressed by EpCAM +ve cells from human fetal liver by using flow cytometry. We found that EpCAM +ve cells expressed intermediate levels HLA class Ⅰ but no HLA class Ⅱ. Although controversial, it seems that, to varying degree, the human fetus can respond to allogenic cells from the beginning of the second trimester[25]. The allogenic response is usually HLA mediated and it is expected that transplantation with cells that do not express HLA class Ⅱ antigen may minimize the risk of alloreactivity. It has been stated that embryonic hepatocytes were still immature cells bearing incomplete MHC Ⅱ surface antigen, thus possessing lower immunogenicity[26].

Earlier investigators reported that EpCAM +ve cells were not immunogenic as they failed to stimulate a significant amount of T cell proliferation. Besides, these cells were not immunosuppressive as they failed to suppress the mixed lymphocyte reaction (MLR) significantly. Therefore EpCAM +ve cells might be an ideal candidate donor cells for hepatic cell therapy in liver disorders.

RT-PCR analysis on the EpCAM +ve cells showed that expression of albumin, AFP, CK18 and CK19 genes was detectable significantly with gestational ages. CK18 expression further confirms that the cells are epithelial lineage. It has been shown that EpCAM sorted hepatic progenitor cells have the high gene expression levels of AFP and albumin on hepatoblasts[8]. This suggests that EpCAM is a hepatic progenitor cell marker.

Fetal liver cells have been shown to be a rich source of progenitor/stem cells. However enrichment of hepatic progenitors from the developing human liver, with more viability and with minimum rejection in allogenic transplantation remains a significant challenge for the advancement of therapeutic approaches to liver disorders.

To summarize, the current study demonstrates that EpCAM is a novel and useful marker for enrichment of hepatic progenitors with moderate expression of HLA-class Ⅰ and negative for HLA- class Ⅱ. Thus this finding supports the use of EpCAM positive fetal liver cells for allogenic transplantation since these cells negative for class Ⅱ HLA antigen on their surface which otherwise can trigger a rejection reaction in allogenic transplantation. In our present study we determined the characteristic of cell type and purity. Further more, MLR and animal model studies are warranted to assess immunogenicity and in vivo engraftment respectively, of enriched EpCAM positive cells of fetal liver prior to pre-clinical transplantation.

ACKNOWLEDGEMENTS

The authors express their deep sense of gratitude to Mr Santhose Tiwari, Mr SM Vali, Mr KS Ahmed, Mr A Rajendraprasad of CLRD and Dr. O G Ram Prasad, Dr. Rajesh Gupta of CCMB for their technical help in the study.

COMMENTS

Background

Liver transplantation is the primary treatment for various end-stage hepatic diseases but is hindered by the lack of donor organs and by complications associated with rejection and immunosuppression. There is increasing evidence to suggest that the aborted human fetal liver is a transplantable source of hepatic progenitors. The aim of this study was to critically analyze the various phenotypic markers to enrich hepatic progenitor cells from human fetal liver. We have previously reported a marker (CD34) to enrich hepatic progenitor from human fetal liver.

Research frontiers

The hepatic progenitors cells offer a potential source for cell therapy and doing bridge transplantation for treatment of liver diseases.

Innovations and breakthroughs

This article helps to enrich hepatic progenitor cells using epithelial cell adhesion molecule (EpCAM) as a marker. We have found that EpCAM +ve cells expressed intermediate levels human leukocyte antigen (HLA) class Ⅰ but no HLA class Ⅱ. Our results provide evidence why enriched EpCAM + cells can be used for the treatment of liver diseases.

Applications

The sorting of stem cells using EpCAM can be used as hepatic as an alternative for hepatic cell therapy in liver cell disorders.

Peer review

This article tries to explore the enrichment of hepatic progenitor using EpCAM as a marker for the treatment of liver diseases. The result revealed that the EpCAM +ve cells can be used as hepatic progenitors for transplantation in patient with liver diseases.

Abstract

AIM: To prospectively assess the changes in parameters of computed tomography (CT) perfusion pre- and post-transarterial chemoembolization (TACE) of hepatocellular carcinoma (HCC) in different treatment response groups, and to correlate the changes with various responses of HCC to TACE.

METHODS: Thirty-nine HCC patients underwent CT perfusion examinations pre-(1 d before TACE) and post-treatment (4 wk after TACE). The response evaluation criteria for solid tumors (RECIST) were referred to when treatment responses were distributed. Wilcoxon-signed ranks test was used to compare the differences in CT perfusion parameters pre- and post-TACE for different response groups.

RESULTS: Only one case had treatment response to CR and the CT perfusion maps of post-treatment lesion displayed complete absence of signals. In the PR treatment response group, hepatic artery perfusion (HAP), hepatic arterial fracture (HAF) and hepatic blood volume (HBV) of viable tumors post-TACE were reduced compared with pre-TACE (P = 0.001, 0.030 and 0.001, respectively). In the SD group, all CT perfusion parameters were not significantly different pre- and post-TACE. In the PD group, HAP, HAF, portal vein perfusion (PVP) and hepatic blood flow (HBF) of viable tumors post-TACE were significantly increased compared with pre-TACE (P = 0.005, 0.012, 0.035 and 0.005, respectively).

CONCLUSION: Changes in CT perfusion parameters of viable tumors are correlated with different responses of HCC to TACE. Therefore, CT perfusion imaging is a feasible technique for monitoring response of HCC to TACE.

INTRODUCTION

Transarterial chemoembolization (TACE) has been widely accepted as a choice of treatment for advanced hepatocellular carcinoma (HCC) and shows promising results[1-3]. The therapeutic efficacy of TACE has been evaluated by various imaging modalities. Digital subtraction angiography (DSA) is probably the most sensitive and effective imaging modality[4,5]. However, angiography is an invasive procedure and its routine use in evaluation of therapeutic effectiveness needs justification[5]. CT examination after TACE has been widely used to assess the efficacy of TACE[6], but its limitation is that a quantitative evaluation cannot be provided and an incomplete lipiodol accumulation may disturb the assessment of viable tumors on contrast-enhanced CT imaging[7].

Alternatively, CT perfusion imaging is a non-invasive technique for assessment of tissue perfusion in locally

advanced HCC[8-10]. The response to TACE may be evaluated by comparing the difference in perfusion parameters pre- and post-treatment[11,12].

To our knowledge, there are few reports on the application of this technique in evaluating the efficacy of TACE based on the quantitative analysis of perfusion parameters. In this study, we prospectively assessed the changes in perfusion parameters of viable tumors after TACE for different treatment response groups, and correlated the changes in CT perfusion parameters to different responses of tumors to TACE.

MATERIALS AND METHODS

Patients

Thirty-nine consecutive patients (28 men and 11 women; age range, 36-82 years; mean, 60.1 years) with histopathologically proven HCC (fine needle aspiration) referred to our center for TACE from September 2007 to June 2008 were included in the study. The average size of HCC was 6.1 ± 3.3 cm, ranging 2.5-16.5 cm. All patients underwent CT perfusion examinations pre-(1 d before TACE) and post-treatment (4 wk after TACE).

CT perfusion imaging technique

CT perfusion was performed with a 64-row multi-detector CT scanner (VCT 64 slices; GE Medical Systems). For initial localization of the tumor, a CT scan of the abdomen was performed without contrast medium during a breath hold at the end of expiration. After tumor localization, a 4-cm tumor region was selected independently for the dynamic study of the tumor maximal diameter. A dynamic study of the selected area was performed in a single breath hold at a static supine position. A total of 40-50 mL of non-ion iodinated contrast medium (Iohexol300, 300 mg of iodine per milliliter) was injected at a rate of 4 mL/s through an 18-gauge intravenous cannula. The following CT parameters were used to acquire dynamic data: 1-second gantry rotation time, 120 kV, 80 mA, acquisition in 264 transverse mode (64 sections per gantry rotation), and 5-mm reconstructed section thickness. The examination was repeated in all patients using the same technique before and 4 wk after TACE.

Imaging data processing

After image acquisition, the data were transferred to an image processing workstation (Advantage Windows 4.3; GE Medical Systems) and analyzed using CT Perfusion 3.0 (GE Medical Systems). For derivation of the functional maps of perfusion parameters, a reference arterial input curve was obtained by placing a region of interest (ROI) in the aorta (range, 10-15 mm^2) manually, and a reference input curve of portal vein was obtained by placing a ROI in the portal vein (range, 8-12 mm^2) manually. A ROI for tumor was hand drawn in a selected section in which the lesion demonstrated the maximal diameter.

The parameters generated by the software included hepatic blood flow (HBF), hepatic blood volume (HBV), mean transit time (MTT), and permeability-surface area product (PS), hepatic arterial fracture (HAF), hepatic artery perfusion (HAP), and portal vein perfusion (PVP).

TACE technique

All TACE procedures were performed by one experienced interventional radiologist. Diagnostic arteriogram of the common, right or left hepatic artery was obtained in all patients prior to TACE. For solitary lesions in liver, TACE with superselective catheterization of the feeding hepatic artery branch was performed. Chemoembolization was performed at the common hepatic artery for multiple lesions involving both lobes of liver. After a combined chemotherapy with an average dose of epirubicin (60 mg), hydroxycamptothecin (20 mg), and fluorouracil (750 mg), an average dose of lipiodol (6 mL) with epirubicin (10 mg) mixture and/or gelfoam particles were used in our study. The total volume of emulsion was judged by the tumor size and achievement of stagnant arterial flow. Follow-up hepatic angiograms were performed in the latter sessions, 4-5 wk and 8-9 wk following the first TACE. Additional chemoembolization would be given at the same session setting if there was evidence of residual hypervascularity in hepatic arteriograms.

Statistical analysis

DSA has been recognized as the gold standard for detection of viable hepatic tumors[5,7]. Therefore, in this study, DSA was used as the assessment method for measuring target lesions responsive to TACE. The first angiogram and follow-up angiograms in the latter sessions 4-5 wk and 8-9 wk following the first TACE were compared. The following response evaluation criteria [complete response (CR): disappearance of all target lesions; partial response (PR): at least a 30% decrease in the sum of the longest diameters (LD) of target lesions; progressive disease (PD): at least a 20% increase in the sum of the LD of target lesions; stable disease (SD): neither sufficient shrinkage to qualify for PR nor sufficient increase to qualify for PD][13] for solid tumors (RECIST) were referred to when it was necessary to assess the therapeutic effect after TACE.

All data were expressed as mean ± SD, and statistical analysis was performed with SPSS 11.0. Wilcoxon-signed ranks test (nonparametric test) of variance was used to compare the differences in CT perfusion parameters pre- and post-TACE for different treatment response groups. $P < 0.05$ was considered statistically significant.

RESULTS

In all patients of our study cohort, only one patient who underwent a period of TACE and CT perfusion examinations pre- and post-treatment had treatment response to CR. His CT perfusion imaging of post-treatment lesion displayed complete absence of blood

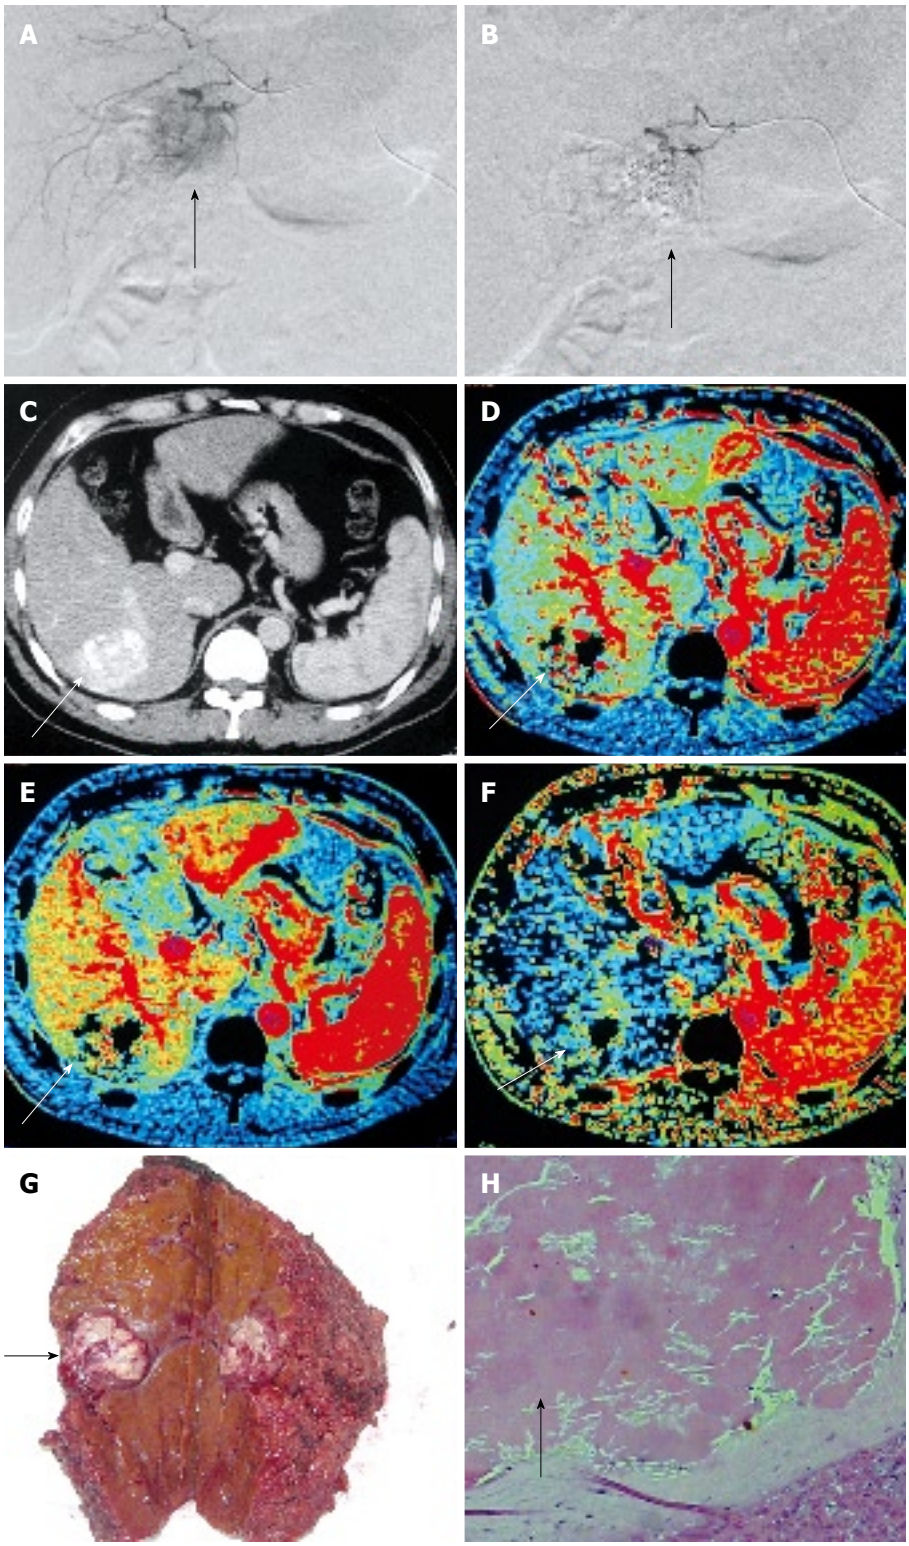

Figure 1 Images obtained in a patient with HCC verified with treatment response of PR. **A**: Pre-TACE angiography showing a tumor with a diameter of 3.5 cm in the right lobe of liver (arrow); **B**: Post-TACE angiography showing a viable region of tumor that was reduced by more than 50% (arrow) compared with pre-TACE; **C**: CT image 4 wk after TACE showing an incomplete lipiodol accumulation in the viable tumor region (arrow); **D**: HBF map of post-TACE CT perfusion showing a significant decrease of HBF in the viable tumor (arrow) compared with pre-TACE; **E**: Post-TACE HBV map showing a significant decrease of HBV in the viable tumor (arrow) compared with pre-TACE; **F**: Post-TACE HAF map showing a significant decrease of HAF in the viable tumor (arrow); **G**: Small necrotic lesions observed (arrow) after two periods of TACE treatment (arrow); **H**: Pathological slides (HE staining, × 40) showing lipiodol embolism in the small vascular cavity (arrow).

perfusion on CT perfusion maps. Therefore, in the CR group, the perfusion parameters of post-treatment tumor could not be generated.

In remaining 38 HCC patients, response to treatment was observed in the PR group (n = 14), SD group (n = 14), and PD group (n = 10).

In the PR treatment response group, some perfusion parameters (HAP, HAF, and HBV) of HCC post-TACE were significantly reduced compared with pre-TACE (Figure 1) and significantly different pre- and post-TACE (P = 0.001, 0.030 and 0.001, respectively), while no significant difference was observed in other perfusion parameters (HBF,MTT,PS, and PVP) pre- and post-TACE (Table 1).

In the SD treatment response group, no significant difference was found in all CT perfusion parameters pre- and post-TACE (Table 1).

In the PD treatment response group, some CT perfusion parameters (HAP, HAF, PVP, and HBF) of HCC post-TACE were significantly increased compared

PVP (mL/min per 100 mL)	19.820 ± 5.546	33.480 ± 8.765	0.035

to pre-TACE (Figure 2) and their difference showed a statistical significance (P = 0.005, 0.012, 0.035 and 0.005, respectively), while no significant difference was found in other perfusion parameters (HBV, MTT, and PS) pre- and post-TACE (Table 2).

DISCUSSION

CT perfusion is a feasible, reproducible technique for assessing tissue perfusion in locally advanced HCC[14]. Measures of tumor perfusion have been correlated with angiogenesis and microvessel density within the tumor[14,15]. It is logical to speculate that high perfusion values indirectly suggest a high rate of angiogenesis and microvessel density within the tumor.

However, to our knowledge, there are few studies on the role of CT perfusion in evaluating the therapeutic efficacy of TACE, although Tsushima *et al*[11] presented their data on CT perfusion and demonstrated decreased values of HAP and HAF in viable tumors post-treatment compared with pre- treatment, which are consistent with our findings.

In our study, the number of cases collected allowed us to divide them into different treatment response groups for observation. In the CR group, CT perfusion imaging of post-TACE lesion displayed complete absence of signal on the CT perfusion maps. We observed significant differences in some CT perfusion parameters of viable tumors per- and post-TACE in the treatment response PR and PD groups. In the PR group of HCC, after TACE treatment, the change in perfusion parameters

was consistent with previous findings[11,16]. The decreased HBV and HBF within liver tumors indicate the reduction of vascular capacity and microvessel density, which are due to the lipiodol embolism (Figure 1G and H). Kan *et al*[16] reported that post-embolization MTT is elongated in intrahepatic lesions of a rat model, while post-embolization PS is significantly decreased. However, we did not find any significant difference in values of MTT and PS pre- and post-treatment, which may be due to the difference in observational time windows, in which the microvascular function within tumors dynamically changes. In the SD group, the perfusion parameters remained unchanged pre- and post-TACE treatment, suggesting a perfusion recovery within the tumor after treatment. In the PD group, HBF, HAF, and HAP were increased after treatment, reflecting the increased angiogenesis and microvessel density within the liver tumor. The value of PVP was further increased in HCC of the PD group after treatment, suggesting involvement of hepatic portal vein during tumor advancement. In our study, the value of HBV was not further increased during tumor advancement, suggesting that the vascular capacity within the tumor mass has reached its limit and thus, cannot further expand. Further histological research is needed to prove this speculation.

In addition, many CT perfusion analyses were performed using a single arterial input[8,9,15], but the liver has a dual arterial-portal blood supply, and the tumor and portal vein could not be consistently included. In our study, 64-rows multi-detector CT was introduced to offer a greater coverage (up to 4 cm), thus overcoming this limitation by including both the tumor and portal vein in dual-input analysis. The introduction of multi-detector CT has stimulated further interest in perfusion CT techniques and their future implementation in clinical practice[14].

We believe that comparison of the results from different CT perfusion studies has to be made cautiously, as the values measured are dependent on mathematic model and pharmacokinetics of the contrast medium used. Thus, application of different models to the same data may well yield different perfusion values. It should be emphasized that our results were specific to the method of analysis and the software employed in this study.

The limitations of our study are as follows. The grouping of patients did not involve factors such as differentiation of HCC, cirrhosis, invasion of portal vein, dosage of chemotherapeutant and lipiodol, and use of gelfoam particles, all of which could influence the therapeutic response of HCC to TACE and change the CT perfusion parameters after TACE. Because the determinants for therapeutic response of HCC to TACE are complicated and numerous, this study did not take into account these determinants of therapeutic response to TACE, but rather it only correlated the changes in CT perfusion parameters with different treatment responses to TACE.

In conclusion, CT perfusion imaging can be used in the assessment of perfusion changes resulting from TACE therapy. Post-treatment changes in perfusion parameters are correlated with different therapeutic efficacies for HCC. Thus, CT perfusion imaging is a feasible and non-invasive technique for monitoring treatment response to TACE.

COMMENTS

Background

Computed tomography (CT) perfusion imaging is a non-invasive and non-invasive technique for assessing tissue perfusion in locally advanced HCC.

Research frontiers

CT perfusion scan for patients with HCC allows assessment of perfusion changes due to transarterial chemoembolization (TACE). There are few reports on the application of this technique in evaluating the efficacy of TACE based on the quantitative analysis of perfusion parameters.

Innovations and breakthroughs

In this study, changes in parameters of CT perfusion pre- and post-TACEwere observed in different treatment response groups.

Applications

CT perfusion imaging, a feasible and non-invasive technique, can be used for monitoring treatment response to TACE.

Peer review

This study reported the changes of CT perfusion parameters in different treatment response groups and provides a useful imaging modality for monitoring treatment response to HCC.

Abstract

AIM: To study the relationship between *MCP-1-2518A/G, IL-8-251A/T* polymorphism and acute pancreatitis (AP) in the Han population of Suzhou, China.

METHODS: A case-control study was conducted to compare the distribution of genotype and genetic frequency of *MCP-1-2518A/G, IL-8-251A/T* gene polymorphism among AP (n = 101), including mild AP (n = 78) and severe AP (n = 23) and control healthy individuals (n = 120) with polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) and DNA sequencing, and analyze the relationship between the *MCP-1-2518A/G, IL-8-251A/T* gene polymorphism and the susceptibility to AP.

RESULTS: Significant differences were found in the distribution of genotype of *MCP-1-2518A/G* between the healthy control group and mild AP group (χ^2 = 32.015, P < 0.001), the same was evident between the healthy control group and severe AP group (χ^2 = 12.932, P < 0.05) in Suzhou. However, no difference of genotypic distribution was noted between MAP and SAP (χ^2 = 0.006, P = 0.997). The genetic frequencies of G allele in mild AP were 72.4% (113/156) and 76.1% (35/46) in severe AP, both were higher than the controls, 47.1% (113/240) (χ^2 = 24.804; P < 0.001, and χ^2 = 13.005; P < 0.001), but no difference was found between severe AP and mild AP (χ^2 = 0.242; P = 0.623). No difference was found in the distribution of genotype of *IL-8-251A/T* between the healthy control group and AP group neither in the frequency of A and T allele.

CONCLUSION: The *MCP-1-2518* AA genotype of the population in Suzhou may be a protective genotype of AP, while one with higher frequency of G allele is more likely to suffer from pancreatitis. But the genotype of AA and the frequency of G allele could not predict the risk of severe AP. No correlation is found between the *IL-8-251* polymorphism and the liability of AP.

Key words: Acute pancreatitis; *MCP-1* DNA; *IL-8* DNA; Polymorphism

INTRODUCTION

Chemokines are the cytokines that can activate or chemoattract leukocytes, and provide a stimulus to direct leukocytes to the areas of injury. They play vital roles in inflammatory reaction, infection of causative organism, trauma and renovation, cytotoxic effect, *etc*[1]. They are 70-90 amino acids in length and approximately 8-10 kDa in molecular weight. They are divided into four subfamilies according to the presence of four cysteine residues in conserved locations of primary structure and the two amino terminal cysteine residues are immediately adjacent or separated by one amino acid. Four subfamilies are CXC, CC, C and CX3C[2]. Up to now, the chemokines we have discovered mainly belong to CXC and CC subgroups, and monocyte chemoattractant

protein-1 (*MCP-1*) and interleukin-8 (*IL-8*) are typical examples of those two subgroups.

Recently it was found that chemokines play an important role in the initiation and development of acute pancreatitis (AP), which takes part in systemic inflammatorome reaction syndrome, remote organ complications, and multiple organ dysfunction syndrome[3-6]. *MCP-1* is regarded as a mediator of inflammatory reaction in early-stage of AP[7]. Studies carried by Rau *et al*[8] found that *MCP-1* serum concentrations increase dramatically in patients who developed local complications and/or remote organ failure. A close correlation was found between the severity of remote organ failure and *MCP-1* elevation. *MCP-1* might play a pivotal role in the pathological mechanism of complicated AP. Studies also found that *IL-8*[9-11] increase in early-stage of acute pancreatitis and the serum concentration is correlated with the severity of pathogenetic condition.

American researchers[12] found that the *MCP-1-2518* polymorphism might be related to the severity of AP, and *MCP-1-2518G* allele is a risk factor for severe AP. Moreover, Hofner[13] drew a conclusion that the frequency of IL-8 polymorphism may predict the risk of SAP. But no similar studies have been done in the ethnic group of China. The polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) and DNA sequencing were carried out in our study to assess the possible correlation between the gene polymorphism of *MCP-1-2518*, *IL-8-251 A/T* and AP in the Han population of Suzhou, China.

MATERIALS AND METHODS

Study population

A total of 101 consecutive patients (60 men and 41 women, mean age 51.57 ± 13.39, range 18-80 years) were analyzed in this study, including 78 patients (50 men and 28 women, mean age 52.46 ± 13.04) with mild AP and 23 patients (16 men and 7 women, mean age 56.83 ± 13.14) with severe AP. The patients were treated in the Department of Gastroenterology of the First Affiliated Hospital of Suzhou University. The diagnosis of AP was established based on abdominal pain or abdominal localizing signs and increased amylase levels increased by at least 3 times that of the upper limit of normal, and CT verification of pancreatitis. Pancreatitis was classified as severe when the APACHE Ⅱ score ⩾ 8[14], and the Balthazar CT severity index ⩾ D[15]. One hundred and twenty healthy volunteers (71 men and 49 women, mean age 51.05 ± 9.37 years, range 25-69 years) served as a control group. All subjects were Han Chinese people, who came from Suzhou city.

DNA isolation

For the examination of *MCP-1* and *IL-8* polymorphisms, genomic DNA purified from peripheral blood was used. Blood samples were collected in ethylenediaminetetraace tic acid-containing tubes for DNA extraction. Genomic DNA was isolated from peripheral blood leucocytes using a commercial Kit (The Wizard® Genomic DNA Purification Kit, Promega) and the genomic DNA was stored at -20℃ for further use.

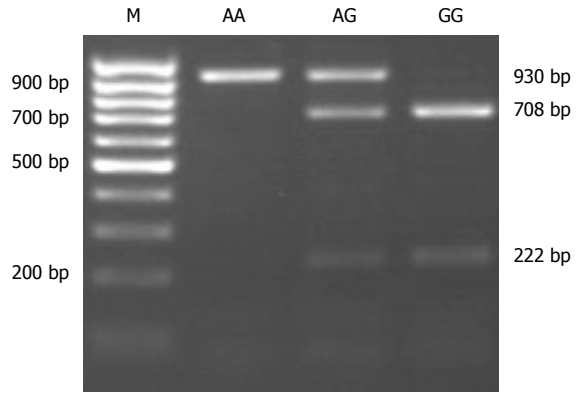

Figure 1 Electrophoresis of MCP-1-2518 polymorphism PCR product cut by *Pvu* Ⅱ. AA sample (930 bp), GG sample (708 bp and 222 bp), and AG sample (930 bp, 708 bp, and 222 bp).

Determination of MCP-1-2518 polymorphism

MCP-1-2518 polymorphism was assessed by means of a polymerase chain reaction procedure using the following primers[16]: sense: 5'-CCAGAGTGTTCCCAGCAC AG-3' and antisense: 5'-CTGCTTTGCTTGTGCCTC TT-3'. The PCR reaction mixture (50 μL) contained 100 ng genomic DNA, 5 μL 10 × Buffer, 1 μL of dNTPs (10 mmol/L each), 0.5 μL of Taq polymerase (Fermentas, 5 U/μL). PCR was performed using a 9700 Gene Amp PCR System Thermal Cycler (Applied Biosystems) under the following conditions: 95℃ for 5 min, followed by 30 cycles of 95℃ for 40 s, 57℃ for 40 s, and 72℃ for 60 s, with a final extension at 72℃ for 10 min. After that the products of PCR were genotyped by restriction fragment length polymorphism (RFLP). Ten μL PCR products were digested with 10 U of *Pvu* Ⅱ in 10 × buffer and H_2O up to a final volume of 20 μL at 37℃ for 16 h. 930 bp PCR product was cut into two bands of 708 bp and 222 bp. These digestion products were visualized in 2% agarose gels, stained with ethidium bromide. Samples showing only a 930 bp band were type AA. Samples showing two bands of 708 bp and 222 bp were considered GG and those showing three bands at 930 bp, 708 bp and 222 bp were designated AG (Figure 1).

Determination of IL-8-251 polymorphism

DNA was extracted from peripheral blood leucocytes, then the IL-8 promoter polymorphism at -251 was amplified with forward primer 5'-ATTGGCTGGCTT ATCTTC-3' and reverse primer 5'-TTCCTGGCTCTTG TCCTA-3', based on GenBank accession No. AF385628. PCR was carried out with the following protocol: 5 min 94℃, 35 cycles of 30 s 94℃, 1 min 52℃, 45 s 72℃, followed by 5 min 72℃, and 10 min 4℃. The product was 485 bp. The sequencing of the PCR products was performed using the M13RP primer and the DNA Big Dye Terminator Sequencing Kit (ABI) on an ABI 377

Table 1 Genotype distribution and allele frequency of *MCP-1-2518 A/G, IL-8-251A/T* polymorphism and Hardy-Weinberg test *n* (%)

automated sequencer, following the manufacturers' protocols.

Statistical analysis

A comparison of the genotypic and allelic frequencies between the groups was performed using the Fisher exact test or χ^2 test when appropriate. Description data of continuous variables were tested by Student's *t* test. Statistical significance was established at $P < 0.05$. There was relationship between the genotypes or carriage of individual alleles and disease severity if presented as odds ratio (OR), with a 95% confidence interval (CI) of odds ratio (95% CI). All statistical calculations were performed with the SPSS 13.0 statistical program. Hardy-Weinberg equilibrium of the allele distribution was tested.

RESULTS

MCP-1-2518A/G polymorphisms

Three genotypes (AA, AG and GG) of MCP-1-2518 A/G polymorphisms were found in Han people of the Suzhou region. Control group AA 24.2% (29/120), AG 52.5% (63/120) and GG 23.3% (28/120); MAP group AA 4.5% (4/78), AG 39.8% (35/78) and GG 55.7% (49/78); and SAP group AA 4.3% (1/23), AG 39.1% (9/23) and GG 56.5% (13/23) (Table 1). There were significant differences in the distribution of genotype of MCP-1-2518 A/G between the healthy control group and MAP group ($\chi^2 = 32.015$, $P < 0.001$), the same was evident between the healthy control group and SAP group ($\chi^2 = 12.932$, $P < 0.05$) in Suzhou. However, no difference of genotypic distribution was noted between MAP and SAP ($\chi^2 = 0.006$, $P = 0.997$). The genetic frequencies of G allele in MAP 72.4% (113/156) and in SAP 76.1% (35/46) were all higher than the controls 49.6% (119/240) ($\chi^2 = 24.804$; $P < 0.001$, and $\chi^2 = 13.005$; $P < 0.001$), but we have found no difference between SAP and MAP ($\chi^2 = 0.242$; $P = 0.623$).

IL-8-251A/T polymorphism

The distribution of the IL-8-251 A and T alleles was as follows: MAP: AA 6.41%, AT 51.28% and TT 42.31%; SAP: AA 4.3%, AT 60.87% and TT 34.78%; Control: AA 10.83%, AT 53.33% and TT 35.83% (Table 1). There were no significant differences in the distribution of genotype of IL-8-251 A/T between the healthy control group and AP group ($P > 0.05$). There was also no difference in the frequency of A and T allele between the healthy control group and AP group ($P > 0.05$).

Hardy-Weinberg equilibrium

In two polymorphisms, the genotype distributions were studied in the Suzhou population (both AP and control subjects) according to Hardy-Weinberg equilibrium (Table 1).

DISCUSSION

MCP-1 and *IL-8* are known as the members of the family of chemokines. CXC chemokines represented by IL-8 exhibit a potent chemotactic activity for neutrophils while CC chemokines represented by *MCP-1* are implicated in the activation of monocytes, macrophages, and lymphocytes[17]. *MCP-1* and *IL-8* play an important role in the cause and development of AP. Ishibashi[18] found that blocking of MCP-1 activity attenuates the severity of AP in rats, which manifests that MCP-1 may be involved in the progression of severe AP. Grady T[19] found that the level of *MCP-1/JE* mRNA elevated in caerulin-induced experimental pancreatitis. In human AP, *MCP-1* expression was found to up-regulate in pancreatic tissues, and monocytic exudation was considered to be caused by this chemokine[20]. *IL-8* as one of the earliest cytokines appearing in the serum of patients with AP remains persistently elevated and therefore it might be of help in assessing the severity of AP after admission[21]. In severe AP patients, *IL-8* could concentrate and activate neutrophilic leukocyte, which could play a vital role in the development of adult respiratory distress syndrome[22]. Experiments in rat models suggested that inhibiting the release of *IL-8* could lower the severity level and case-fatality rate than inhibiting the other inflammatory factors[23]. All these results provide evidences that *MPC-1* and *IL-8* play a key role in the occurrence and development of AP.

In recent years, so many studies found that there is a relationship between the gene polymorphism and AP. Balog *et al*[24] found that high frequencies of the *HSP70-2 G* and the *TNF-α-308 A* alleles were associated wit the risk of severe AP. Genotype assessments may be important prognostic tools to predict disease severity

and the course of AP. He considered that genotype assessments may also be used to guide treatment or to identify risk populations for severe AP. Rahman *et al*[25] found that the functional *GSTT-1*A* genotype was associated with severe attacks of pancreatitis. Intensified oxidative stress characterized by glutathione depletion may be of importance in mediating the progression from mild to severe pancreatitis. All these studies note that variations in the DNA sequence might predispose individuals to AP.

Our study is designed to illustrate the relationship between *MCP-1-2518A/G* and *IL-8-251A/T* polymorphism and the liability of AP. The result showed that not only in MAP group but also in SAP group, the proportion of AA genotype was obviously lower in *MCP-1-2518* than in the control group. However, the frequency of G allele of MAP and SAP group was both higher than the control group. We therefore can conclude that the patients with the GA and GG genotype in *MCP-1-2518* might have higher risks for AP, but the patients with AA genotype in *MCP-1-2518* might have less liability to AP. It is possible that the AA genotype has a function of protecting the organism from AP. Nevertheless, our study found no difference between the MAP group and the SAP group of the AA genotype in *MCP-1-2518*. The study by Papachristou *et al*[12] using the method of PCR showed that the G allele in *MCP-1-2518A/G* of SAP group is obviously higher than the control group and MAP group, while the frequency of homozygote AA in the SAP group is lower than the MAP group and the control group. Therefore, it was suggested that the obvious increase of the frequency of G allele of the AP patients is possibly related with the high risk of developing SAP, moreover, the AP patients with the AA genotype are less likely to suffer from pancreatitis. Both our group and Papachristou GI's group discovered that there is a significant deviation between the AP group and the control group of the genotype and the frequency of allele in *MCP-1-2518*, but we found no difference between the AA genotype of SAP and MAP groups and the frequency of allele in *MCP-1-2518*.

At the same time, we did not discover the relationship between genetic polymorphism of *MCP-1-251* and the occurrence of AP. And this result is completely diverse from the research by Hofner *et al*[13]. They found that the *IL-8-251A/T* had significantly higher frequency in the patients with severe pancreatitis than in the healthy blood donors, while the frequency of the TT genotype was higher in the patients with mild pancreatitis than in the group with severe pancreatitis. We therefore, conclude that the IL-8 polymorphism may identify populations at risk of severe AP. In their study, the distribution of the IL-8 genotypes in control population of Hungary was: TT 82/200 (41%), AA 34/200 (17%) and AT 84/200 (42%), which is similar to ours ($\chi^2 = 4.537$, $P = 0.103$). The distribution of the IL-8 genotypes in our control subjects is also similar to other studies in Beijing and Taiwan[26,27]. But the genetic polymorphisms of IL-8-251 in healthy populations in our and Honfer's studies were different from that in Denmark[28], German[29], and Spain[30].

All those data indicated that the ethnic difference could be found in the genetic polymorphisms of IL-8-251. Although we and Hofner P gained similar results in the distribution of the IL-8 genotypes, it is possible that various results could be obtained in the polymorphisms of IL-8-251 among different countries. It is well known that only one genetic polymorphism cannot determine the final outcome of the diseases. Since all these studies are lack of larger cohorts, further studies are needed to confirm that the polymorphisms of IL-8-251 could affect the course of AP.

In summary, our study suggested that genetic polymorphism possibly determines the occurrence and development of AP. Moreover, ethnic difference in genetic polymorphisms may determine the functions in different populations. Thus, the relationship between genetic polymorphism and AP will need more thorough researches.

COMMENTS

Background

Chemokines play an important role in the pathogenesis of acute pancreatitis (AP). Monocyte chemoattractant protein-1 (MCP-1) and interleukin-8 (IL-8) are typical chemokines. Many researchers have explored the relationship between gene polymorphism and the occurrence and development of AP to reveal whether polymorphisms of *MCP-1* and *IL-8* genes relate with the severity of AP.

Research frontiers

Recently the polymorphism of gene correlated with the occurrence and development of diseases is a hotspot. New methods, for example, gene chip techniques, for the research of polymorphism and new findings have been found.

Innovations and breakthroughs

The polymorphism of *MCP-1-2518* might affect the course of AP, but the genotype of AA and the frequency of G allele could not predict the risk of SAP, which is different from Papachristou GI's research. And no correlation has been found between the *IL-8-251* polymorphism and the liability of AP. The result is obviously diverse from Hofner P's research.

Applications

This study is aimed to find a new way to monitor and evaluate the course of AP, and guide therapy or to identify populations at risk of severe AP.

Terminology

PCR-RFLP: polymerase chain reaction-restriction fragment length polymorphism.

Peer review

The authors have studied MCP-1 and IL-8 polymorphism in MAP and SAP. The recent environmental and genetic researches have added more knowledge in the field of pancreatitis pathophysiology and prognosis. This is an interesting study.

Abstract

AIM: To investigate the role of Livin and vascular endothelial growth factor (VEGF) in human esophageal carcinoma, and analyze its relationship to clinical stages.

METHODS: Expression of Livin in fresh esophageal cancer tissues was detected by immunohistochemistry (IHC), Western blotting and reverse transcriptase-polymerase chain reaction (RT-PCR), and VEGF by Western blotting and RT-PCR. All statistical analyses were performed by SPSS version 11.0.

RESULTS: Livin positivity was also significantly correlated with tumor stages, increasing with tumor progression. Expression of Livin and VEGF increased with the process of esophageal carcinoma. In the fourth clinical stage, expression of Livin and VEGF was the most significant. Expression of Livin was positively correlated with VEGF.

CONCLUSION: Over-expression of Livin and VEGF contributes to the pathogenesis of esophageal carcinoma.

Key words: Esophageal carcinoma; Livin; Vascular endothelial growth factor

Expression of Livin and vascular endothelial growth factor in different clinical stages of human esophageal carcinoma. *World J Gastroenterol* 2008; 14(37): 5749-5754 Available from: URL: http://www.wjgnet.com/1007-9327/14/5749.asp DOI: http://dx.doi.org/10.3748/wjg.14.5749

INTRODUCTION

Livin, also known as inhibitor of apoptosis (IAP) has been identified as a new member of the IAP family proteins[1-3]. Like other IAP family proteins, Livin interacts with downstream caspases, such as caspase-3, caspase-7, and caspase-9, leading to their inactivation and degradation[4,5]. Its overexpression can protect cells from several proapoptotic stimuli. Very importantly, treatment of cancer cells with Livin antisense oligo-DNA causes apoptotic cell death, indicating that Livin expression may be essential for survival of certain cancer cells[6,7]. Vascular endothelial growth factor (VEGF) is a potent mitogen for endothelial cells, and its expression has been correlated with increased tumour angiogenesis[8,9]. VEGF plays a crucial role in tumour expansion by initiating permeabilization of blood vessels, by extravasation of plasma proteins, by invasion of stromal cells, and by causing the sprouting of new blood vessels that supply the tumour with oxygen and nutrients. A number of studies have shown that expression of certain VEGF transcripts are correlated with tumour progression[10]. Although increases of certain VEGF transcripts have been demonstrated to correlate with the progression of various tumours, the actual protein levels of the different VEGF isoforms and their significance during cellular transformation are unknown. Moreover, it has been suggested that elevated protein expression in tumour tissues was mediated by both enhanced transcription and translation. Thus, in order to understand the role of Livin and VEGF in tumour progression, it is important to investigate Livin and VEGF expression of different clinical stages at the protein and mRNA level during tumourigenesis. Esophageal carcinoma is one of the most frequent malignancies in many countries. Despite recent progress in chemotherapeutic, radiotherapeutic, and surgical treatment, the 5-year survival rate of esophageal carcinoma patients is still low, especially in advanced cases. In order to further explore the role of Livin and

VEGF in the development of esophageal carcinoma, we investigated the role of Livin and VEGF in human esophageal carcinoma and analyze its relationship with clinical stages.

MATERIALS AND METHODS

Materials

Specimens of cancer tissues were taken from 67 consecutive patients with esophageal carcinoma from Oct 2004 to Sept 2005 at the Department of Thoracic Surgery, the First Affiliated Hospital of Chongqing Medical University. None of them received irradiation or chemotherapy preoperatively. The patients included 46 men and 21 women with a mean age of 57 ranges from 38-86 years. The clinicopathologic stage was determined according to TNM classification. Six tumors were located in the upper thorax, 6 cases for clinicopathologic stage one, 24 case clinicopathologic stage two, 28 cases clinicopathologic stage three, 9 cases clinicopathologic stage four. All fresh tissues were taken immediately after operation and stored in a nitrogen canister. Informed consent was obtained from all participants, and the study was approved by the ethics committee on human research in Chongqing Medical University, Chongqing, China.

Immunohistochemical (IHC) assay

Tissue samples were collected after surgery and immediately frozen in liquid nitrogen. Prior to IHC assay, frozen sections were prepared with a cryostat (FACS caliber, Becton Dickinson, USA) at -20℃, dried at room temperature, and fixed with acetone. The PBMC were routinely isolated and the slides were prepared with a cytospinner. The ABC immunohistochemical assay was carried out according to the protocols we described before Anti-Livin (Antibody Diagnosis, USA) was prepared in our lab. The second antibody, a goat anti-mouse IgG labeled with biotin, was purchased from Vector Co., USA. Two hundred cells were counted and the intensity of staining for each of those cells was adjusted. Five grades were employed to express the degrees of staining, which represent 5 reaction coefficients respectively. The 5 products of every coefficient and the corresponding cell number were added up, which resulted in the value of a positive score. All slides were measured in duplicate. Those samples with a positive score over 10 or frequency over 5% were considered as positive.

Western blotting

Mouse tissues were dissected and homogenized in T-PER buffer in the presence of protease inhibitors. After homogenization, the lysates were centrifuged at 100 000 × *g*, and the supernatants were saved for Western blot, Ciphergen (BioSource International, Inc., USA) Protein Chip Array. Equal amounts of lysates were subject to SDS-PAGE (Tris-glycine mini gel; 1:2500, BioSource International, Inc., USA) and Western blot analysis using antibodies specific for the following: Livin (1:2500, BioSource International, Inc., USA), VEGF (1:2500, BioSource International, Inc., USA), β-tublin (1:5000; BioSource International, Inc., USA). The optical densities of the specific bands were scanned and measured by image analysis software (HPIAS 2000, Tongji Qianping Company, Wuhan, China).

Table 1 Oligonucleotides used for reverse transcriptase-polymerase chain reaction

Target gene	Primer sequence (5′-3′)	Size (bp)	Annealing temperature (℃)
β-actin	Forward: GTTCGCCATGGA TGACGATATC	266	59

VEGF	Forward: TGCTCAGCATTC GGACTGACCT	228	61
	Reverse: CAGTATGCATGGA CCATGACGG		
Livin	Forward: CTGGTCAGAGCC AGTGTTCCT	312	61
	Reverse: TCATAGAAGGA GGCCAGACG		

Primers were designed using the Primer Express Program and offered by AuGCT Biotechnology, Beijing, China.

Reverse transcriptase-polymerase chain reaction (RT-PCR)

Animals were sacrificed at corresponding time points and total RNA in the treated sections were extracted according to the total RNA extracting kit. 4 μg total RNA was heated at 70℃ for 5 min and then chilled on ice. Samples were incubated at 37℃ for 1 h and the reaction was stopped by heating at 70℃ for 10 min. Specific primers were designed for PCR: *Livin* and *VEGF* (Table 1). PCR was performed using 2 μL cDNA, 2 mmol/L dNTP, a specific pair of primers (20 pmol), 2 U DNA polymerase, 5 × PCR buffer and deionized water were added to the cDNA. The total volume was 25 μL. Amplification was performed for 32 cycles. The PCR products were separated by electrophoresis using a 1.5% (w/v) agarose gel containing 0.5 mg/L of ethidium bromide. Single band corresponding to the predicted size of the amplified product for Livin and VEGF and β-actin were identified under an ultraviolet transilluminator and transferred to a nylon filter membrane, and hybridized with an ECL-labeled probe 10 mL. The probes hybridized only to the bands which corresponded in size to the ethidium bromide stained gels, thereby confirming the amplified PCR products. The band densities were scanned with a densitometer. The relative amount of mRNA in each sample was calculated from the densitometry ratio of Livin and VEGF *A* value/β-actin *A* value.

Statistical analysis

Quantitative data were expressed as mean ± SD. All statistical analyses used the SPSS software for Windows 11.0 (SPSS, Inc., Chicago, IL, USA), using Student's *t*-test for intergroup. For statistical evaluation one-way analysis of variance (ANOVA) were employed. Pearson correlation analysis was also performed to some index. $P < 0.05$ was considered as statistically significant.

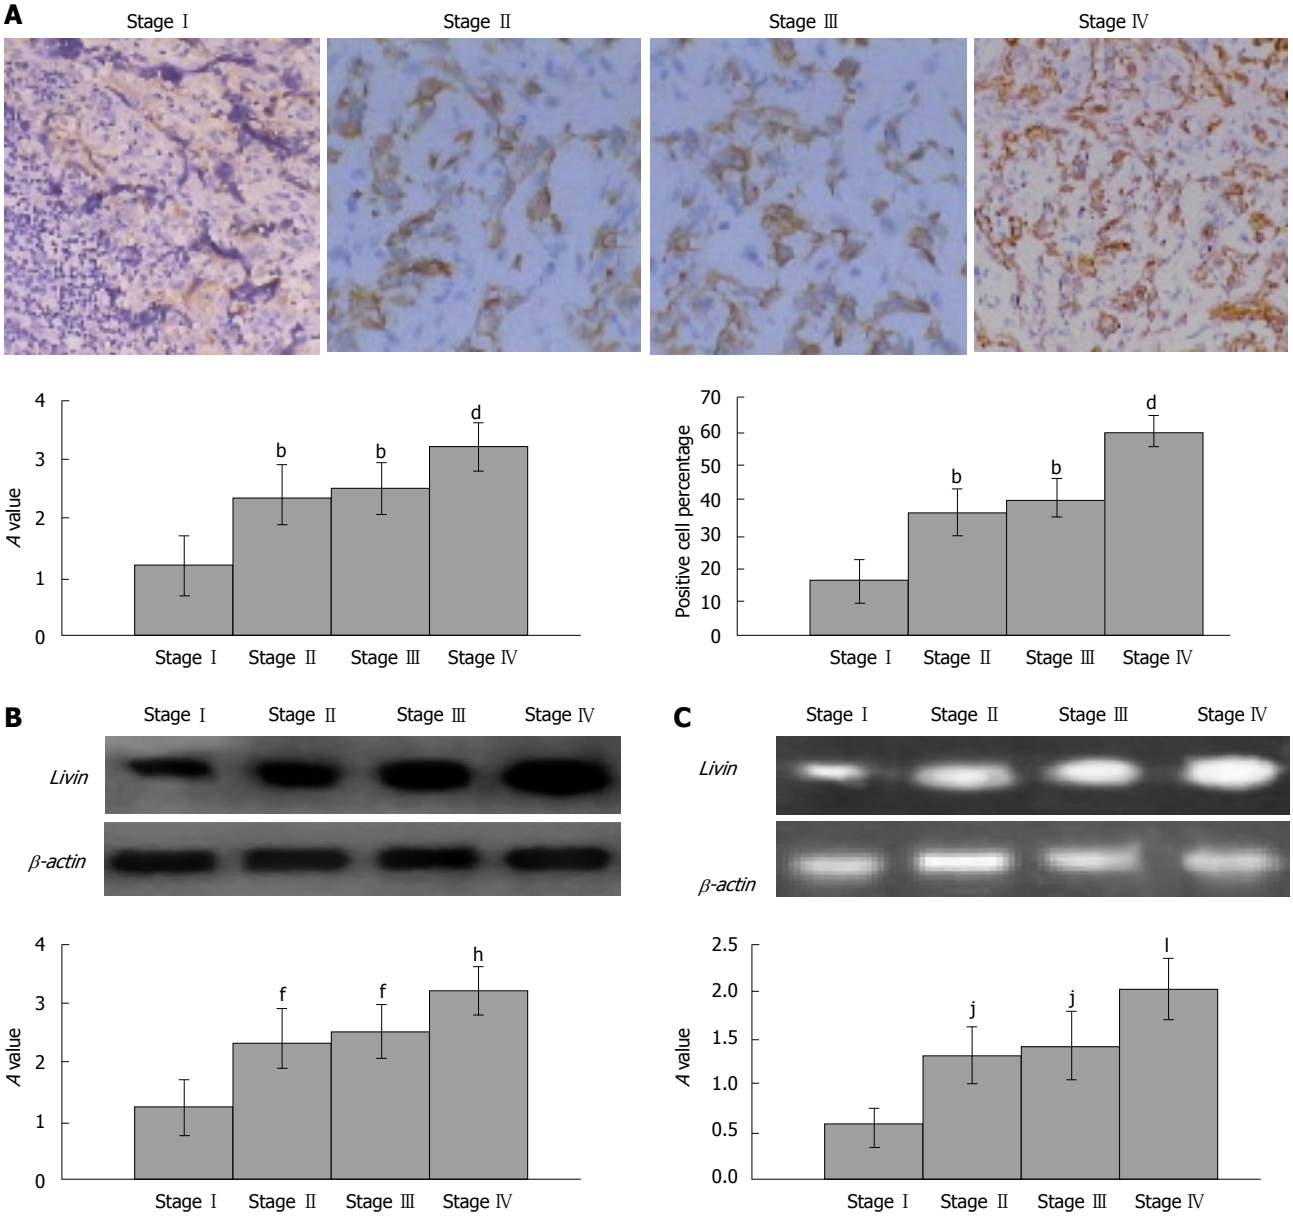

Figure 1 **A**: The expression of Livin was measured by IHC (SP × 400). Optical density value and positive cell percentage in clinicopathologic stage two, three and four was significantly higher than that of stage one ($^{b}P < 0.01$). Furthermore, optical density value and positive cell percentage in clinicopathologic stage four was significantly higher than that of stage two and three ($^{d}P < 0.01$). IHC showed that Livin had significant expression in the cytoplasm and nucleus in the Stage Ⅱ, Ⅲ and Ⅳ (the cytoplasm and nucleus had stained yellow), slight expression in the cytoplasm and nucleus in Stage Ⅰ (the cytoplasm and nucleus had slightly stained yellow); **B**: The expression of Livin by Western blotting showed that expression of Livin in clinicopathologic stage two, three and four was significantly higher than that of stage one ($^{f}P < 0.01$). Optical density value and positive cell percentage in clinicopathologic stage four was significantly higher than that of stage two and three ($^{h}P < 0.01$); **C**: mRNA level of *Livin* was tested by RT-PCR. Up-regulation of *Livin* gene transcription matched with the protein level of Livin that was significantly increased along with the progression of esophageal carcinoma. Optical density value in clinicopathologic stage two, three and four was significantly higher than that of stage one ($^{j}P < 0.01$). Optical density value and positive cell percentage in clinicopathologic stage four was significantly higher than that of stage two and three ($^{l}P < 0.01$).

RESULTS

Expression of Livin in esophageal carcinoma

The expression of Livin measured by IHC showed that expression of Livin in clinicopathologic stage two, three and four was significantly higher than that of stage one ($P < 0.01$). Optical density value and positive cell percentage in clinicopathologic stage two, three and four was significantly higher than that of stage one ($P < 0.01$). Furthermore, optical density value and positive cell percentage in clinicopathologic stage four was significantly higher than that of stage two and three ($P < 0.01$) (Figure 1A). The results by IHC showed that expression of Livin increases along with the progression of esophageal carcinoma. To further determine that Livin contributes to the pathogenesis of esophageal carcinoma, the expression of Livin was tested by Western blotting. In coincidence with IHC results, the expression of Livin by Western blotting showed that expression of Livin in clinicopathologic stage two, three and four was significantly higher than that of stage one ($P < 0.01$). Optical density value in clinicopathologic stage two, three and four was significantly higher than that of stage one ($P < 0.01$). Optical density value and

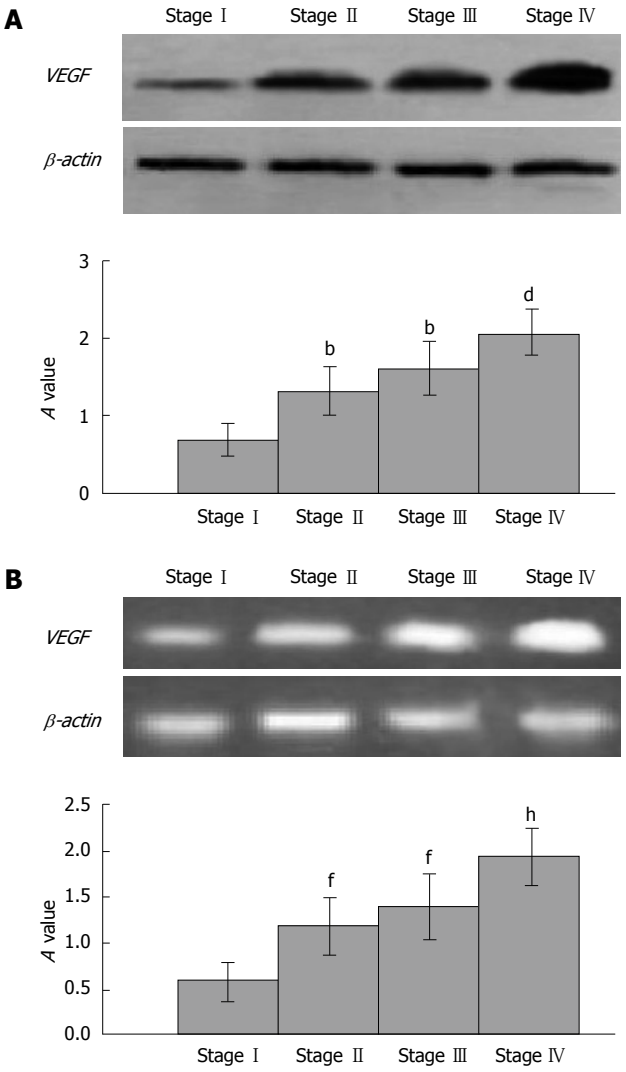

Figure 2 Assay of level of VEGF. **A**: The expression of VEGF by Western blotting showed that expression of VEGF in clinicopathologic stage two, three and four was significantly higher than that of stage one ($^bP < 0.01$). Optical density value in clinicopathologic stage two, three and four was significantly higher than that of stage one ($^bP < 0.01$). Optical density value and positive cell percentage in clinicopathologic stage four was significantly higher than that of stage two and three ($^dP < 0.01$); **B**: Up-regulation of VEGF gene transcription matched with the protein level of VEGF that was significantly increased along with the progression of esophageal carcinoma. Optical density value in clinicopathologic stage two, three and four was significantly higher than that of stage one ($^fP < 0.01$). Optical density value and positive cell percentage in clinicopathologic stage four was significantly higher than that of stage two and three ($^hP < 0.01$).

positive cell percentage in clinicopathologic stage four was significantly higher than that of stage two and three ($P < 0.01$) (Figure 1B). Previously, the protein level of Livin increases the progression of esophageal carcinoma. To further evaluate that Livin contributes to the pathogenesis of esophageal carcinoma, the mRNA level of *Livin* was tested by RT-PCR. Up-regulation of *Livin* gene transcription matched with the protein level of Livin that was significantly increased along with the progression of esophageal carcinoma. Optical density value in clinicopathologic stage two, three and four was significantly higher than that of stage one ($P < 0.01$). Optical density value and positive cell percentage in clinicopathologic stage four was significantly higher than that of stage two and three ($P < 0.01$) (Figure 1C).

Expression of VEGF in esophageal carcinoma

The expression of VEGF measured by Western blotting and RT-PCR showed expression of VEGF increases along with the progression of esophageal carcinoma. The expression of VEGF by Western blotting showed that expression of VEGF in clinicopathologic stage two, three and four was significantly higher than that of stage one ($P < 0.01$). Optical density value in clinicopathologic stage two, three and four was significantly higher than that of stage one ($P < 0.01$). Optical density value and positive cell percentage in clinicopathologic stage four was significantly higher than that of stage two and three ($P < 0.01$) (Figure 2A). Previously, the protein level of VEGF increases the progression of esophageal carcinoma. To further evaluate that VEGF contributes to the pathogenesis of esophageal carcinoma, the mRNA level of *VEGF* was tested by RT-PCR. Up-regulation of *VEGF* gene transcription matched with the protein level of VEGF that was significantly increased along with the progression of esophageal carcinoma. Optical density value in clinicopathologic stage two, three and four was significantly higher than that of stage one ($P < 0.01$). Optical density value and positive cell percentage in clinicopathologic stage four was significantly higher than that of stage two and three ($P < 0.01$) (Figure 2B). Pearson correlation analysis showed that the level of VEGF by Western blotting has a positive correlation with Livin ($r = 0.384$, $P < 0.05$), and VEGF by RT-PCR a positive correlation with Livin ($r = 0.452$, $P < 0.05$) as well. The hypothesis has been made that Livin and VEGF play such an inter-enhancement role in the progress of esophageal carcinoma.

DISCUSSION

Livin may be essential for survival of certain cancer cells[11-13]. Of the IAP family members, CARD-RING domain of cIAP1, CARD-RING domain of cIAP2, X-linked IAP, and NAIP are expressed in normal adult tissues[14,15], whereas Survivin expression is limited to tumor tissues[16-18]. It has been reported that Livin was expressed in some tumor cells and several fetal tissues but not in normal adult tissues. Hence, its expression profiles seem to be very similar to those of Survivin, a cancer-specific IAP family protein. In the present study, we investigated expression of Livin in human esophageal carcinoma and analyze its relationship with clinical stages. The results showed that Livin positivity was also significantly correlated with tumor stages, increasing with tumor progression. Expression of Livin increased with the process of esophageal carcinoma. In the fourth clinical stage, expression of Livin was the most significant. Therefore, over-expression of Livin contributes to the pathogenesis of esophageal carcinoma. Livin is known to play an important role in antiapoptotic cell survival by suppression

of caspase family proteins. The other antiapoptotic proteins, including IAP family and Bcl-2 family[19,20], were also reported to be overexpressed in esophageal carcinoma cells. Namely, Survivin, a member of the IAP family, was overexpressed in esophageal carcinoma specimens, and patients with Survivin expression had significant unfavorable prognosis. Survivin was one of the tumor-associated antigens recognized by both humoral and cellular immunity of cancer patients, and could become a target of CTL. It has been reported that Livin might be involved in the progression of superficial bladder cancer and used as a marker of early recurrence[19,21,22]. Because loss of Livin expression could lead to apoptotic cell death in cervical cancer cells, suppression of Livin should have much advantage in cancer treatment. From this perspective, Livin might be a good candidate as a molecular target for treatment as well as having a prognostic value for esophageal carcinoma.

VEGF plays a crucial role in tumour expansion by initiating permeabilization of blood vessels, by extravasation of plasma proteins, by invasion of stromal cells, and by causing the sprouting of new blood vessels that supply the tumour with oxygen and nutrients. A number of studies have shown that expression of certain VEGF transcripts are correlated with tumour progression[23,24]. Although increases of certain VEGF transcripts have been demonstrated to correlate with the progression of various tumours[25-27], the actual protein levels of the different VEGF isoforms and their significance during cellular transformation are unknown. Moreover, it has been suggested that elevated protein expression in tumour tissues was mediated by both enhanced transcription and translation. Thus, in order to understand the role of VEGF in tumour progression, it is important to investigate VEGF expression of different clinical stages at the protein and mRNA level during tumourigenesis. In the present study, we investigated expression of VEGF in human esophageal carcinoma and analyze its relationship with clinical stages. The results showed that VEGF positivity was also significantly correlated with tumor stages, increasing with tumor progression. Expression of VEGF increased with the process of esophageal carcinoma. In the fourth clinical stage, expression of VEGF was the most significant. Because previous evidence indicated that VEGF plays a crucial role in tumour expansion by initiating permeabilization of blood vessels, our results suggest that over-expression of VEGF contributes to the pathogenesis of esophageal carcinoma. Allowing that VEGF introduces the sprouting of new blood vessels that supply the tumour with oxygen and nutrients, it is a novel strategy for treating esophageal carcinoma, and the results of the ongoing clinical trials in patients with esophageal carcinoma are eagerly awaited. Although encouraging data have emerged to support the use of antiangiogenic therapy in some cancers such as myeloma and glioma, poor tumor response has been reported in others[28-31]. One major problem confronting clinical trials of antiangiogenic therapy is the lack of an established surrogate marker to measure antiangiogenic activity *in vivo* in cancer patients. Tumor response in terms of shrinkage alone might not be an appropriate index of treatment efficacy because of the cytostatic nature of the treatment. Instead, the ability of an antiangiogenic drug to induce prolonged stabilization of the disease and increase survival might be more meaningful end points for clinical trials on antiangiogenic therapy.

Taken together, over-expression of Livin and VEGF contributes to the pathogenesis of esophageal carcinoma. The level of VEGF has a positive correlation with Livin. The hypothesis has been made that Livin and VEGF played such an inter-enhancement role in the progress of esophageal carcinoma. Inhibitors of Livin and VEGF may be potential targets for the prevention or treatment of human esophageal carcinoma.

ACKNOWLEDGMENTS

COMMENTS

Background

Livin expression may be essential for survival of certain cancer cells. Vascular endothelial growth factor (VEGF) is a potent mitogen for endothelial cells, and its expression has been correlated with increased tumour angiogenesis. It is important to investigate Livin and VEGF expression of different clinical stages at the protein and mRNA level during tumourigenesis.

Research frontiers

In order to further explore the role of Livin and VEGF in the development of esophageal carcinoma, it is critical to investigate the role of Livin and VEGF in human esophageal carcinoma and analyze its relationship with clinical stages.

Innovations and breakthroughs

Over-expression of Livin and VEGF contributes to the pathogenesis of esophageal carcinoma. The level of VEGF has a positive correlation with Livin. The hypothesis has been made that Livin and VEGF have an inter-enhancement role in the progress of esophageal carcinoma.

Applications

Inhibitors of Livin and VEGF may be potential targets for the prevention or treatment of human esophageal carcinoma.

Terminology

Livin may be essential for survival of certain cancer cells. Of the IAP family members, Livin interacts with downstream caspases, such as caspase-3, caspase-7, and caspase-9, leading to their inactivation and degradation. Its overexpression can protect cells from several proapoptotic stimuli. Very importantly, treatment of cancer cells with Livin antisense oligo DNA causes apoptotic cell death, indicating that Livin expression may be essential for survival of certain cancer cells. VEGF is a potent mitogen for endothelial cells, and its expression has been correlated with increased tumour angiogenesis.

Peer review

This is an interesting report showing increased expression of Livin and VEGF in late stages (Ⅱ Ⅲ Ⅳ) of esophageal carcinoma compared to early stage (Ⅰ) of esophageal carcinoma. Since Livin expression may affect apoptosis, correlation of Livin with assays of apoptosis will be of interest. In addition, correlation of Livin expression with patient survival in various stages of esophageal carcinoma will also be interesting.

Abstract

Cowden's disease, one of the several hamartoma syndromes, is characterized by hyperplastic lesions and hamartomas distributed in the whole body. About thirty percent of patients with Cowden's disease have been reported to be complicated by malignant tumors. Based on the criteria of the International Cowden Consortium, this disease is mainly diagnosed as trichilemmoma of the face and oral mucosal papillomatosis. However, Cowden's disease patients themselves often do not recognize trichilemmoma of the face and oral mucosal papillomatosis. We report a case of Cowden's disease in a 33-year-old female patient who was diagnosed based on the characteristic findings at gastrointestinal endoscopy. Clinically, the patient was aware of having bloody stools. Multiple polyps found endoscopically in the esophagus, stomach, ileum, colon and rectum showed histopathologically hamartomatous changes and epithelial hyperplasia. Physical examination revealed oral papillomatosis and facial trichilemmomas. A germline mutation in exon 8 of the phosphatase and tensin homolog deleted on chromosome ten (*PTEN*) gene was found in this case. It was a point mutation of C to T at codon 1003 (CGA→TGA, arginine→stop codon). The characteristic findings on gastrointestinal endoscopy led us to a diagnosis of Cowden's disease. It has been reported that gastrointestinal polyposis with esophageal polyposis is found in about 85.7% of Japanese patients with Cowden's disease. The characteristic findings on gastrointestinal endoscopy can be a useful diagnostic clue to Cowden's disease.

Key words: Cowden's disease; Gastrointestinal polyposis; *PTEN*; Early diagnosis; Hamartoma

INTRODUCTION

Cowden's disease was reported for the first time by Lloyd and Dennis in 1963[1]. There have been more than 200 case reports in Japan. Cowden's disease, one of the several hamartoma syndromes, is characterized by hyperplastic lesions and hamartomas distributed on the whole body[2]. About 30% of patients with Cowden's disease have been reported to be complicated by malignant tumors[3]. It was reported that this disease is mainly diagnosed mainly as facial papules and oral mucosal papillomatosis[4] (Table 1). Recently, the criteria of the International Cowden Consortium are commonly used for the diagnosis of Cowden's disease[5] (Table 2). Ninety-nine percent of individuals with Cowden's disease are believed to have developed mucocutaneous lesions at the age of about 30 years[5]. However, Cowden's disease is rarely diagnosed based on the physical findings of typical skin lesions, and the diagnosis of typical

trichilemmoma requires many biopsy specimens[6,7]. Cowden's disease patients themselves often do not recognize the characteristic dermatological findings of Cowden's disease. Furthermore, it is possible that they are not checked for the specific findings of Cowden's disease even when they do notice the lesions[8]. Gastrointestinal polyposis has been reported in about 40% of patients with Cowden's disease in Western countries[9], but it has been reported that this disease is frequently accompanied with gastrointestinal polyposis in Japan[10]. We, here, report a case of Cowden's disease diagnosed based on the characteristic findings at gastrointestinal endoscopy.

CASE REPORT

A 33-year-old female patient had a medical examination at the Department of Internal Medicine, Kurihara Central Hospital, because of bloody stools. The patient underwent total thyroidectomy at the age of 20 years. Her mother died of gastric and breast cancer after she underwent the same operation. The patient was obese with no abnormality in the laboratory data. Colonoscopy showed multiple polyps in the terminal ileum, colon and rectum, which gave the macroscopic appearance of smooth lesions. Moreover, all polyps were within 5 mm in size. All biopsy specimens of these lesions showed epithelial hyperplasia and were diagnosed histopathologically as hyperplastic polyps (Figure 1). Double contrast X-ray study showed multiple small polypoid lesions in the ileum, colon and rectum (Figure 2). Endoscopy of the upper digestive tract showed the presence of whitish polypoid lesions in the esophagus as well as in the stomach and duodenum. Specimens of these polyps were resected by polypectomy. These polyps also had the macroscopic appearance of smooth lesions. Moreover, the size of all these polyps was within 10 mm. The gastric polyps showed hamartomatous changes and epithelial hyperplasia. A specimen was diagnosed as hamartoma by histopathological examination (Figure 3). The esophageal polyps were diagnosed histopathologically as glycogenic acanthosis (Figure 4). Otherwise, no abnormal findings were found both at computed tomography (CT) scan of the abdomen or breast and at abdominal ultrasonography. Papillomatosis of the gingiva was found (Figure 5) in addition to a small papule on the face. It was diagnosed histopathologically as a trichilemmoma by skin biopsy (Figure 6). Genetic analyses performed with informed consent clarified a germline mutation of the phosphatase and tensin homolog was deleted on chromosome ten (*PTEN*) gene (Figure 7). A germline mutation in exon 8 of the *PTEN* gene was found. It was a point mutation of C to T at codon 1003 (CGA→TGA, arginine→stop codon). We diagnosed this patient as Cowden's disease based on the characteristic physical findings and the result of the genetic test described above. This study was approved by the Institutional Ethics Committee of Kurihara Central Hospital.

Table 1 Proposed diagnostic criteria for Cowden's disease

Proposed diagnostic criteria for Cowden's disease
Major clinical criteria
Cutaneous facial papules
Oral mucosal papillomatosis
Minor clinical criteria
Acral keratosis
Palmoplantar keratoses
Family history of Cowden's disease
Definite: 1a+1b,(1a or 1b)+(2a or 2b)
(1a or 1b)+3, 2a+2b+3
Probable: 1a or 1b, (2a or 2b)+3
Possible: 2a and/or 2b

Table 2 Criteria of international Cowden Consortium (Verion 2000) for Cowden's disease

Pathognomonic criteria
Mucocutaneous lesions
Trichilemmomas, facial
Acral keratoses
Papillomatous papules
Mucosal lesions
Major criteria
Breast carcinoma
Thyroid carcinoma (non-medullary), especially follicular thyroid carcinoma
Macrocephaly (megalencephaly) (say, 95th centile)
Lhermitte-Duclos disease (LDD)
Endometrial carcinoma
Minor criteria
Other thyroid lesions (eg, adenoma or multinodular goitre)
Mental retardation (say, IQ 75)
GI hamartomas
Fibrocystic disease of the breast
Lipomas
Fibromas
GU tumours (e.g. renal cell carcinoma, uterine fibroids) or malformation
Operational diagnosis in a person
Mucocutaneous lesions alone if:
There are 6 or more facial papules, of which 3 or more must be trichilemmoma, or
Cutaneous facial papules and oral mucosal papillomatosis, or
Oral mucosal papillomatosis and acral keratoses, or
Palmoplantar keratoses, 6 or more
2 major criteria but one must include macrocephaly or LDD
1 major and 3 minor criteria
4 minor criteria
Operational diagnosis in a family where one person is diagnostic for Cowden syndrome
The pathognomonic criterion/ia
Any one major criterion with or without minor criteria
Two minor criteria

DISCUSSION

Cowden's disease, reported for the first time by Lloyd and Dennis in 1963[1], belongs to a multiple hamartoma syndrome[2], and there have been more than 200 case reports in Japan. The diagnosis of Cowden's disease was originally made b based on the examination of skin and a family history of Cowden's disease[4] (Table 1).

However, the original diagnostic criteria for Cowden's disease were based on dermatological findings. The criteria of the International Cowden Consortium are commonly used for the diagnosis[5] (Table 2). The patient

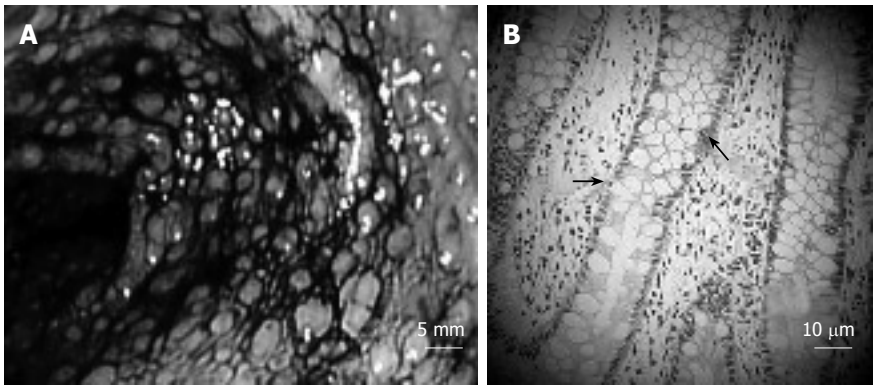

Figure 1 Polyposis in the rectum. **A**: Colonoscopy showing multiple polyps in the terminal ileum, colon and rectum, which gave the macroscopic appearance of smooth lesions. Moreover, the size of all polyps was within 5 mm or smaller; **B**: Pathological appearance of multiple polyps with all biopsy specimens of these lesions showing epithelial hyperplasia. These specimens were diagnosed histopathologically as hyperplastic polyps (arrow).

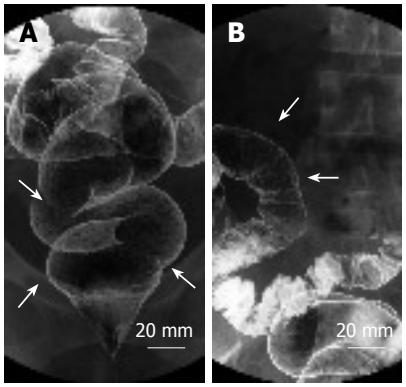

Figure 2 Double contrast X-ray study (**A**) and double contrast X-ray study (**B**) showing multiple small polypoid lesions in the ileum, colon and rectum.

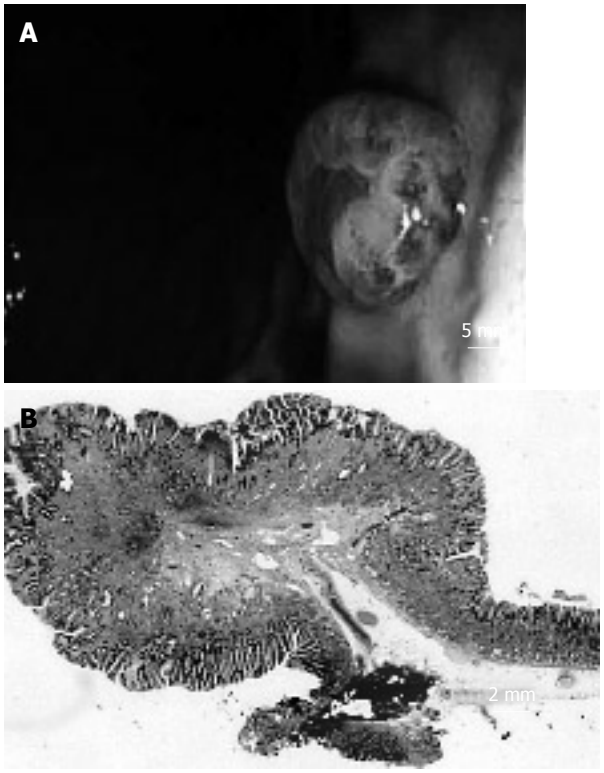

Figure 3 Polypoid lesions in the stomach. **A**: Endoscopy of the upper digestive tract showing whitish polypoid lesions in the stomach. The size of all these polyps was within 10 mm; **B**: Gastric polyps showing histopathologically hamartomatous changes and epithelial hyperplasia. A specimen was diagnosed as a hamartoma by histopathological examination.

was diagnosed as trichilemmoma and oral papillomatosis, thyroid tumor and gastrointestinal hamartoma. This case fulfilled both diagnostic criteria for this disease. Moreover, the patient's mother also had a history of total thyroidectomy and died of gastric and breast cancer. We think that her mother suffered from Cowden's disease, based on the criteria of the International Cowden Consortium.

The criteria of the International Cowden Consortium are useful for diagnosis of Cowden's disease, but such criteria may not be useful for its early diagnosis. Although we diagnosed a case of Cowden's disease based on the criteria of the International Cowden Consortium, we did not recognize the facial papules and oral mucosal papillomatosis at the first examination. The patient also did not recognize them. At first, we considered the possibility that this case was Cowden's disease because of her history of thyroid goiter and the finding of gastrointestinal polyposis including esophagus at gastrointestinal endoscopy. Later, detailed physical examination revealed oral papillomatosis and a small papule of the face. We made a histopathological diagnosis of trichilemmoma. Ninety-nine percent of individuals with Cowden's disease are believed to have mucocutaneous lesions at the age of about 30 years[9]. However, it has been reported that it is difficult to diagnose Cowden's disease only based on the physical finding of a typical trichilemmoma and in fact that it requires many biopsy specimens[6,7]. Cowden's disease patients themselves often do not recognize the characteristic dermatological findings of Cowden's disease. Furthermore, it is possible that they are not checked for the specific findings of Cowden's disease even when they do notice them[8,11].

Gastrointestinal endoscopy is more frequently performed in Japan. Recently, we have often diagnosed Cowden's disease based on the characteristic findings at gastrointestinal endoscopy[12]. It was reported that gastrointestinal polyposis occurs in about 40% of Cowden's disease patients in Western countries[9], but in Japan it occurs in about 95% of Cowden's disease patients[10]. Gastrointestinal endoscopy and double contrast X-ray study endoscopy and double contrast X-ray study can detect gastrointestinal polyposis showing histopathologically hamartomatous changes and

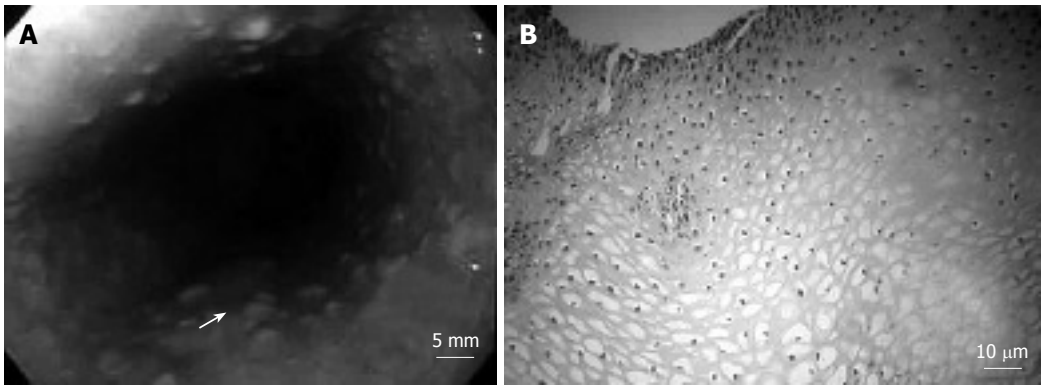

Figure 4 Polypoid lesions in the esophagus. **A**: Endoscopy of the upper digestive tract showing whitish polypoid lesions in the esophagus and macroscopic appearance of smooth lesions. The size of all these polyps was within 5 mm; **B**: Pathological appearance of the esophagus. Histlogically, a specimen confirmed the diagnosis of glycogenic acanthosis.

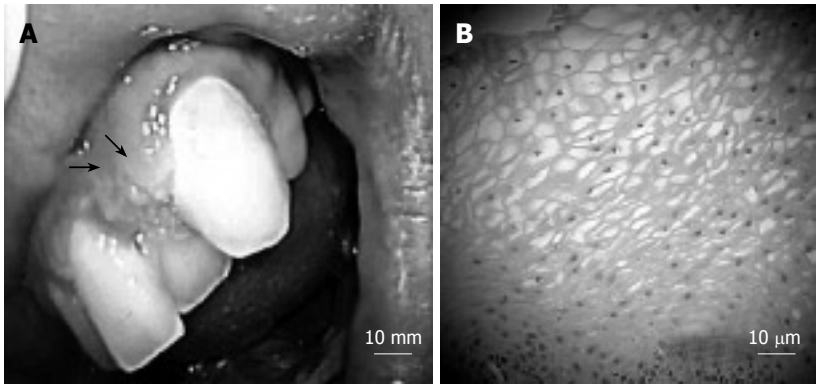

Figure 5 Many polyps in the gingiva (**A**) and pathological appearance of the gingiva confirming the diagnosis of papilloma(**B**).

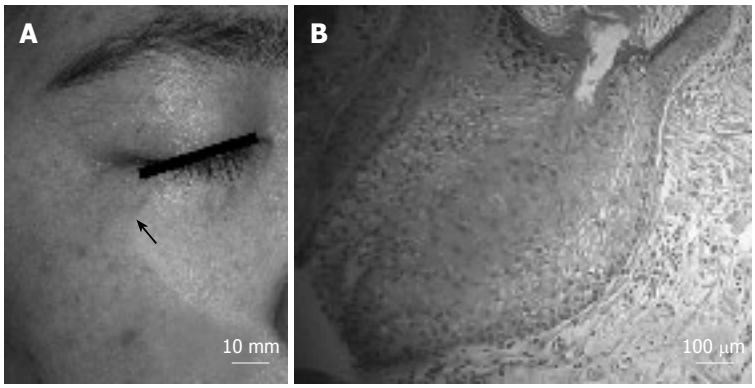

Figure 6 Small papules found on face with their size within 5 mm (**A**) and pathological appearance of small papules confirming the diagnosis of trichilemmoma (**B**).

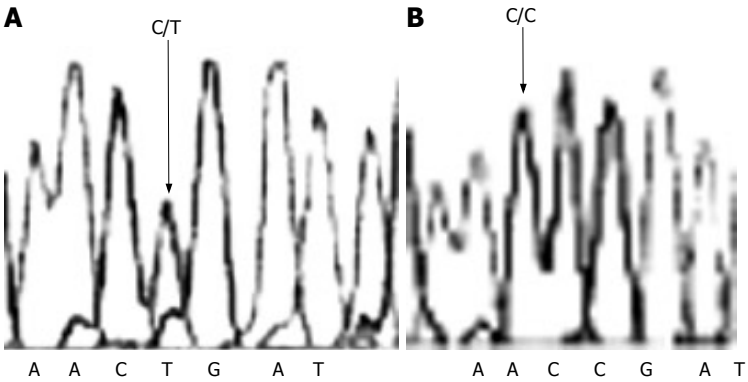

Figure 7 A germline mutation of phosphatase and tensin homolog deleted on chromosome ten (*PTEN*) gene. **A**: Genetic analyses performed with informed consent clarified a germline mutation of the *PTEN* gene in exon 8 of the *PTEN* gene, which was a point mutation of C to T at codon 1003 (CGA→TGA, arginine→stop codon); **B**: Control.

epithelial hyperplasia. Esophageal polyposis found in 85.7% of Cowden's disease patients[10], is a characteristic finding in young patients with Cowden's disease[13,14]. Esophageal polyposis shows histopathologically glycogenic acanthosis[14]. In addition to Cowden's disease, other types of gastrointestinal polyposis

include familial adenomatous polyposis, Peutz-Jeghers syndrome and Juvenile polyposis, which, however, do not show esophageal polyposis[13,14]. Multiple polyps found endoscopically in the esophagus, stomach, ileum, colon and rectum of the present case, showed histopathologically hamartomatous changes and epithelial hyperplasia, suggesting that this case fulfills the diagnostic criteria for Cowden's disease. Gastrointestinal and esophageal polyposis is not described in the criteria of the International Cowden Consortium. However, the characteristic gastrointestinal findings are useful for early diagnosis of Cowden's disease.

In the present case, a germline mutation found in exon 8 of the *PTEN* gene was a point mutation of C to T at codon 1003 (CGA→TGA, arginine→stop codon). Germline *PTEN* mutations were first described in Cowden's disease. The *PTEN* gene encodes a lipid phosphatase on 10q23 that mediates cell cycle arrest and apoptosis. Germline *PTEN* mutations are not described in the criteria of the International Cowden Consortium, but are found in 80% of Cowden's disease patients[12,15-17], indicating that Germline *PTEN* mutations may be useful for the surveillance of Cowden's disease.

In the present case, we could not find any malignant diseases. However, because about 30% of Cowden's disease patients have been reported to be complicated by malignant tumors, early diagnosis of Cowden's disease is necessary[3,9,18]. Recently, 18-fluoro-deoxyglucose positron emission tomography has become useful for cancer surveillance in Cowden's disease patients. We expect that sensitive molecular diagnostic tests for mutations in appropriate genes will become clinically available in the setting of cancer genetics consultation[19].

In summary, we report a case of Cowden's disease diagnosed based on the characteristic findings at gastrointestinal endoscopy. Gastrointestinal and esophageal polyposis is useful for the early diagnosis of Cowden's disease, and the characteristic findings at gastrointestinal endoscopy can be considered useful diagnostic clues to Cowden's disease.

Abstract

Lymphangioma is an uncommon malformation of lymphatic system. Multiple colonic lymphangioma named as lymphangiomatosis is considered an extremely rare disease. Although lymphangioma is a benign tumor and most colonic lymphangiomas do not cause symptoms and do not require treatment, resection of lymphangioma is necessary in the presence of symptoms such as abdominal pain, bleeding, intussusceptions. We report a case of colonic lymphangiomatosis in a man who presented with abdominal discomfort and anemia, which was diagnosed and treated with endoscopic snare polypectomy.

Key words: Colonic lymphangiomatosis; Anemia; Snare polypectomy

INTRODUCTION

Lymphangioma is a lymphatic malformation which shows benign proliferation of lymph vessels, with the characteristics of submucosal tumors covered with normal mucosa[1-5]. It may occur anywhere but rarely in the colon. However, it has been reported more frequently with the increasing prevalence of endoscopy. Multiple colonic lymphangiomas reported as "colonic lymphangiomatosis", are even rarer. We report a case of colonic lymphangiomatosis suspicious of submucosal tumor in a man who presented with anemia and abdominal discomfort, which was treated with endoscopic snare polypectomy.

CASE REPORT

A 48-year-old man with chief complaints of abdominal discomfort and anemia was admitted to our hospital. He had no significant past medical history. Physical examination revealed no remarkable abnormality in the abdomen. Laboratory rests showed hypochromic microcytic anemia, 6.3 g/dL hemoglobin, 24.2% hematocrit, 66.5 fL mean corpuscular volume (normal = 85-99), 17.3 pg mean corpuscular hemoglobin (normal= 26-34), 26.0% mean corpuscular hemoglobin concentration (normal = 32%-36%), 12 ug/dL iron (normal = 65-157), and 3.59 ng/mL ferritin (normal = 16.4-323). Tumor marker levels (CEA, CA19-9), urinalysis and blood chemistry tests were within normal ranges.

Colonoscopy revealed several protruding mucosal lesions covered with normal mucosa raging 10-20 mm in diameter at the proximal transverse colon. These lesions were semi-transparent, and the cushion sign was positive. Some indigested food materials were got in between most protruding lesion and colonic wall (Figure 1A). The most prominent lesion underwent snare polypectomy (Figure 1B), and inner surface of the lesion was filled with seroanguious fluid and yellowish fibroadipose tissue-like materials (Figure 1C). Abdomen computer tomography (CT) was unremarkable. Histopathologic examination showed cystic lumen covered with a single layer of flat endothelial cells (Figure 2). Based on the clinical and histopathologic findings, a diagnosis of colonic lymphangiomatosis was made. Considering that the patient did not show any bleeding signs and symptoms after the mucosectomy, we decided to follow up on an out-patient

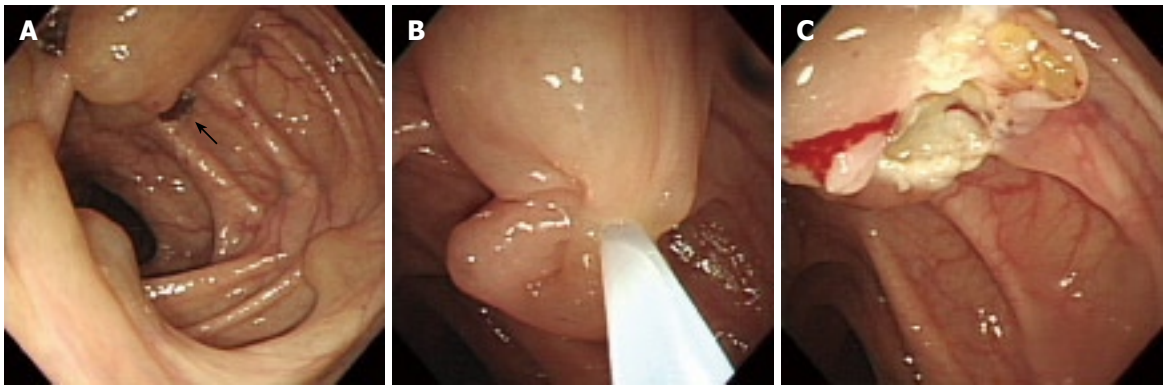

Figure 1 Colonoscopy revealing a semiparent, protruding mucosal lesion covered with normal mucosa with indigested food materials between the lesion and colonic wall (**A**), which underwent snare polypectomy (**B**), and inner surface of the lesion filled with seroanguious fluid and yellowish fibroadipose tissue-like materials (**C**) after the procedure.

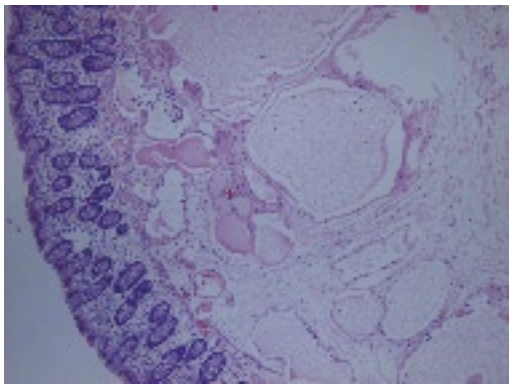

Figure 2 Histopathology showing a cystic lumen covered with a single layer of flat endothelial cells (HE, × 100).

basis. The patient had abdominal pain and anemia when he was followed up 3 mo after mucosectomy.

DISCUSSION

Lymphangioma, a benign tumor of lymphatics, rarely occurs in the abdomin, and most of them arise in the mesentery, omentum, mesocolon and retroperitoneum[6-9]. The incidence of lymphangioma in the intestinal wall is very low, and few cases of multiple colonic lymphangioma have been reported[1-4]. Barium enema, colonoscopy, abdomen CT, endoscopic ultrasonography are useful in its diagnosis[10-12]. Colonoscopic findings of lymphagioma are characterized by a steep rising margin and a somewhat narrow base, the presence of properties of submucosal tumors covered with normal colon mucosa, as well as a smoother, glassier, and more translucent surface than that of adenoma, and soft lesions with their shape changed on postural alterations or compression[1]. Our case also had such characteristics. Imaging studies may be needed to evaluate the wall structure and coexisting extracolonic lesions. Our case did not have any extracolonic lesions.

Because lymphangioma is a benign tumor and most colonic lymphangiomas are asymptomatic, and do not need treatment[2]. However, symptoms such as abdominal pain, bleeding, intussusception or protein losing enteropathy can occur[1,2,13-16]. The cardinal sign of our case was anemia, which may be due to the seroanguinous cystic contents of lymphangiomatosis from the internal bleeding. Endoscopic resection has been recently performed for the diagnosis and treatment of colonic lymphangiomas[1]. Endoscopic mucosectomy has been recommended for pedunculated tumors less than 2 cm in diameter[1,5]. We report a colonic lymphangiomatosis associated with anemia and abdominal discomfort, which was treated with endoscopic mucosal resection.

Abstract

Primary adenocarcinoma of the appendix is a rare malignancy that constitutes < 0.5% of all gastrointestinal neoplasms. Moreover, primary signet ring cell carcinoma of the appendix is an exceedingly rare entity. We have encountered 15 cases of primary appendiceal cancer among 3389 patients who underwent appendectomy over the past 18 years. In the present report, we describe a rare case of primary signet ring cell carcinoma of the appendix with ovarian metastases and unresectable peritoneal dissemination occurring in a 67-year-old female patient. She underwent appendectomy and bilateral salpingo-oophorectomy with a laparoscopy procedure. She then received palliative systemic chemotherapy with 12 cycles of oxaliplatin, 5-fluorouracil, and leucovorin (FOLFOX-4). The patient currently is well without progression of disease 12 mo after beginning chemotherapy.

Key words: Appendiceal neoplasms; Carcinoma; Signet ring cell; Chemotherapy

INTRODUCTION

Primary adenocarcinoma of the appendix, first described in 1882, is an uncommon malignancy of the gastrointestinal tract that constitutes approximately 0.12 cases per one million people per year[1]. Moreover, primary signet ring cell carcinoma of the appendix is an exceedingly rare entity and little information on the discrete characteristics of this tumor has been published[2]. The clinical presentation is usually non-specific, although right lower abdominal pain is the most common symptom, which is indistinguishable from acute appendicitis[3,4]. Therefore, it is invariably difficult to diagnose primary signet ring cell carcinoma of the appendix preoperatively. Usually the diagnosis is made only after histologic examination of a surgically-removed inflamed appendix.

The treatment options for metastatic disease include systemic chemotherapy alone, hyperthermic intraoperative intraperitoneal chemotherapy, cytoreductive surgery with a peritonectomy, and a combination of treatments. However, whether debulking surgery and intraperitoneal chemotherapy are worthwhile for all aggressive, advanced disease cases remains controversial.

There are a few reported cases of primary signet ring cell appendiceal carcinoma[5]. In the case reports published, the patients underwent cytoreductive surgery and intraperitoneal chemotherapy. However, this case report documents the use of systemic chemotherapy with oxaliplatin, and 5-fluorouracil (5-FU) chemotherapy (FOLFOX-4) for the female patient with primary signet ring cell appendiceal carcinoma with ovarian metastases

and unresectable peritoneal dissemination. The indications for systemic chemotherapy for aggressive primary appendiceal carcinoma were discussed. A case report is presented with a review of our 18-year experience at Kangnam St. Mary's Hospital.

CASE REPORT

A 67-year-old female visited her primary physician because of an increasing abdominal distention for 3 mo. She was then referred to our hospital for further evaluation and treatment. Cytology of ascitic fluid showed atypical cells. Her past history was unremarkable, as was her family history.

On examination, the patient appeared well with no signs of anemia. Physical examination performed on admission showed moderate distension of the abdomen without hepatomegaly. Gynecological examination was completely unremarkable. Gastrofibroscopy revealed a gastric ulcer and a biopsy showed chronic gastritis. Colonoscopy showed no positive findings. Abdominal computed tomography showed a moderate amount of fluid collection in the abdomen and pelvis with diffuse omental thickening (Figure 1). However, no other evidence of masses was seen within the abdomen and pelvis. The following tumor markers measured were 13 U/mL carbohydrate antigen (CA) 125, 12 U/mL CA19-9, and 2.55 mg/mL carcinoembryonic antigen (CEA). The results of tumor markers were normal. A diagnostic laparoscopy was performed and intra-operative frozen section analysis of a tumour of the appendix showed a signet ring cell carcinoma. The metastatic deposits extended from the pelvic cavity into the upper abdomen along the surface of the liver and diaphragm. The patient underwent appendectomy and bilateral salpingo-oophorectomy. The final pathologic examination was reported as a signet ring cell carcinoma infiltrating the vermiform appendix and metastasizing to the ovaries. Diffuse, strong immunoreactivity against CEA, cytokeratin 20, MUC2, and CDX-2 was observed in the tumor cells. Focal immunopositivity for MUC-5AC also was detected (Figure 2).

The patient received twelve cycles of FOLFOX-4 and is currently well without progression of disease, 12 mo after beginning chemotherapy.

Over an 18-year period from January 1990 to December 2007, there were 15 cases (an incidence rate of 0.4%) of primary appendiceal carcinoma among 3389 appendectomies performed in our hospital (Table 1). The mean age of patients with mucinous adenocarcinoma and patients with colonic type carcinomas was 58.0 years (range, 43-68 years) and 61 years (range, 42-73 years), respectively. Among the 15 patients, abdominal pain was the most common symptom of primary appendiceal cancer in 9 patients, and 7 of these 9 patients underwent emergency surgery. Histologically, 2 patients had low grade mucinous epithelial tumors, 8 patients had mucinous adenocarcinomas, 4 patients had colonic adenocarcinomas, and 1 patient had a signet ring cell carcinoma. In our series of 10 patients with regular

follow-up, 4 patients developed relapses after debulking surgery. Of the four relapsed patients, two had a high grade colonic type adenocarcinoma and one had a mucinous adenocarcinoma with distant metastases on initial presentation. Ovarian metastases occurred in four of the 7 female cases, including the present case. Extra-abdominal metastatic sites were documented in two patients. Patient 8 had a mucinous adenocarcinoma (well-differentiated) and developed lung metastases and patient 11 had a colonic type adenocarcinoma (poorly differentiated) with liver metastases to the abdominal cavity. Of the six patients with peritoneal metastases, four underwent cytoreductive surgery, including right hemicolectomy. Palliative 5-FU-based chemotherapy was administered in three of seven cases with distant metastases.

DISCUSSION

Primary adenocarcinoma of the appendix is a rare malignancy of the gastrointestinal tract[1]. Smeenk *et al*[6] reported a 0.3% prevalence of primary appendiceal mucinous epithelial neoplasms identified from 167 744 patients who underwent appendectomy. Our 18-year-experience showed a similar incidence rate (0.4%) of primary ap-

pendiceal carcinoma after appendectomy. Moreover, a primary signet ring cell carcinoma of the appendix (the case reported herein, was the first of the 15 cases) is an exceedingly rare entity, comprising only 4% of all appendiceal neoplasms[2].

The demographic characteristics of patients with cancer of the appendix vary by histology. According to report of McCusker *et al*[1], those diagnosed with malignant carcinoids are significantly younger (mean age, 38 years) than those diagnosed with any of the other cancer types. The mean age of patients at diagnosis of mucinous adenocarcinoma, colonic type adenocarcinoma, and signet ring cell carcinoma is approximately 60 years, 62 years, and 58 years, respectively, and an equal number of males and females developed goblet cell carcinoid, mucinous adenocarcinoma, and signet ring cell carcinoma, except for colonic adenocarcinoma which had a male predominance[1]. Our results also showed similar demographic findings.

Reported series of appendiceal adenocarcinoma are difficult to compare, as terminology and classification of these lesions are not consistent[7,8]. The International Classification of Diseases for Oncology (ICD-O) divides the tumors of appendix into five categories: colonic type adenocarcinoma, mucinous adenocarcinoma, signet ring cell carcinoma, goblet cell carcinoma, and malignant carcinoid/adenocarcinoid[1,9]. These carcinomas arise in preexisting adenomas, either by a cystic and colonic growth pattern[10,11]. On the other hand, signet ring cell carcinomas, usually frequent in stomach and intestine, are adenocarcinomas with mucus-producing tumor cells. In this case, the tumor cells showed diffuse, strong immunoreactivity against cytokeratin 20, CDX-2, MUC-2, and CEA, and focal immunopositivity for MUC-5AC (Figure 2). CDX-2 is a useful marker to confirm an appendiceal origin of pseudomyxoma peritonei, particularly when used in conjunction with CK20, MUC-2, and MUC-5AC[12].

Most appendiceal cancers are low-grade neoplasms that are typically relatively indolent. The overall 5-year survival rate for mucinous appendiceal adenocarcinomas reported by Park *et al*[13] is 20.5%. According to report of McCusker[1], except for signet ring cell carcinoma and malignant carcinoid, the histologic type does not have a significant impact on survival. In addition, the extent of disease at diagnosis is a more important predictor of survival than histology. Ronnett *et al*[7,14] reported that the long-term survival of patients with diffuse, peritoneal metastases arising from these carcinomas is poor, with a reported 5-year survival as low as 6.7%-14%. Moreover, in a study by McGory *et al*[2], poorly differentiated adenocarcinoma and signet ring cell carcinoma of the appendix had the highest proportion of distant disease with a 5-year survival rate of 7%. Therefore, signet ring cell carcinoma may be a separate tumor type in the appendix that should be considered apart from other carcinomas, largely because of its poor prognosis.

Right hemicolectomy is considered the optimal treatment for most histologic types of primary appendiceal carcinoma even in the presence of perforation and in Dukes A tumors[15]. The treatment options for metastatic disease include systemic chemotherapy alone, hyperthermic intraoperative intraperitoneal chemotherapy, cytoreductive surgery with peritonectomy, and combination of treatments. Of those treatment options, cytoreductive surgery and hyperthermic intraperitoneal chemotherapy have recently become the treatment of choice for metastatic diseases at most large centers[16]. In the present case, laparoscopic exploration allowed assessment of the

pelvic metastasis which was unresectable and the final pathologic diagnosis was a signet ring cell carcinoma, with aggressive biologic behaviors. Therefore, we did not perform cytoreduction or intraperitoneal chemotherapy, but proceeded with an appendicectomy and bilateral salpingo-oophorectomy followed by systemic chemotherapy. Routine oophorectomy should be considered in all females, especially if post-menopausal. An oophorectomy itself may assist with tumour staging, reduce the likelihood of symptomatic metastases and also provide a survival advantage[17].

Given the predilection for exclusive peritoneal metastasis of mucinous adenocarcinomas of the appendix, in the case of low-grade tumors, cytoreductive surgery and regional chemotherapy are very important. Aggressive cytoreductive surgery for mucinous-type tumours is known to improve the survival rate and reduce the recurrence rate in patients with generalized pseudomyxoma peritonei compared with simple appendectomy[18]. In addition, the most consistent prognostic factor for survival is the completeness of cytoreduction[19,20]. However, whether debulking surgery for all patients with aggressive, advanced disease is worthwhile has not been elucidated. In fact, only limited data are available on surgical debulking for diffuse, peritoneal dissemination from aggressive appendiceal carcinomas, in part because the disease is so rare. Incomplete cytoreduction plus perioperative intraperitoneal chemotherapy for peritoneal dissemination from aggressive appendiceal malignancies can achieve a limited long-term survival[5,20]. Furthermore, Gonzalez-Moreno and Sugarbaker demonstrated that right hemicolectomy does not confer a survival advantage in patients with mucinous appendiceal tumors with peritoneal seeding[21]. These data suggest that in patients with aggressive appendiceal malignancy, routine right hemicolectomy should not be performed unless in conjunction with complete cytoreduction in combination with intraperitoneal chemotherapy.

Considering systemic chemotherapy, an alternative option to metastatic appendiceal carcinomas, although limited, the available data favor integration of systemic chemotherapy, including mitomycin C, fluoropyrimidines and platinum compounds, which has been used as an intraperitoneal chemotherapy[20,22]. Ishibashi *et al*[22] described a case of pseudomyxoma peritonei caused by carcinoma of the appendix, which was successfully treated with multidisciplinary treatment, including oxaliplatin, 5-FU, and leucovorin (modified FOLFOX6 regimen) combination systemic chemotherapy followed by cytoreduction. In a recent randomized phase Ⅲ trial comparing debulking alone to debulking with continuous hyperthermic peritoneal perfusion of cisplatin in patients with low-grade, mucinous tumors of the gastrointestinal tract, all patients who had surgical debulking received four courses of postoperative intravenous chemotherapy (5-FU, leucovorin, and oxaliplatin)[23].

Recently, many targeted drugs have been used as a combination therapy to improve the survival of patients with gastrointestinal malignancies[24]. Mucin genes, which play an important role in the pathogenesis of pseudomyxoma peritonei, are regulated in part by epidermal growth factor receptor (EGFR) signaling[25,26]. Andreopoulou *et al*[27] recently presented that heavily pretreated patients who underwent cetuximab monotherapy showed a transient decrease in tumor markers, with an encouraging time-to-progression (3 mo) in a phase Ⅱ trial of cetuximab in mucinous peritoneal carcinomatosis. In addition, Logan-Collins *et al*[28] demonstrated that in patients who undergo cytoreductive surgery and intraperitoneal hyperthermic perfusion for mucinous adenocarcinoma of the appendix, (n = 32), the average vascular endothelial growth factor (VEGF) counts correlate with survival (P = 0.017), and for patients with recurrence, this correlation is stronger (P = 0.002), indicating that VEGF may predict the survival of patients with peritoneal surface metastases from mucinous adenocarcinomas and that anti-angiogenic therapies may be effective in patients with this devastating disease. In the future, novel targeted therapies, including EGFR inhibitor or anti-angiogenic agents, in combination with regional treatment or systemic chemotherapy should be evaluated.

Abstract

Primary retroperitoneal mucinous cystadenomas (RMCs) are very rare and their biological behavior and histogenesis remain speculative. An accurate preoperative diagnosis of these tumors is difficult because no effective diagnostic measures have been established. We describe a 29-year-old woman with abdominal pain and a palpable mass. Computed tomography (CT) of the abdomen revealed a retroperitoneal cystic mass which was resected successfully at laparotomy. Histopathological examination of the resected mass confirmed the diagnosis of RMC. There was no evidence of disease 2 years after surgery.

Key words: Retroperitoneal; Mucinous cystadenoma; Cystic mass; Clinical features

INTRODUCTION

Primary retroperitoneal mucinous cystadenomas (RMCs) are very rare, even though mucinous cystadenomas are frequent ovarian tumors[1]. Like most retroperitoneal masses, they cause symptoms when growing large enough to exert pressure or obstructive effect on adjacent organs[2]. Because of the limited number of reported cases, the biological behavior and histogenesis of such tumors remain speculative[3]. Laboratory studies and imaging methods cannot achieve an accurate preoperative diagnosis[1]. We describe here a case of a huge RMC presenting with a palpable abdominal mass and a literature review is also given together with discussion.

CASE REPORT

A 29-year-old woman presented at our institution with abdominal pain for 1 wk and a palpable mass on the left side of her abdomen. The abdominal pain was described as intermittently cramping and the intensity of pain was exacerbated as the palpable mass grew. She denied any systemic disease or history of drug abuse. Physical examination and pelvic examination showed no remarkable findings except for a large mobile mass which was palpable over her left flank region. The laboratory data were within reference ranges. Tumor markers, including CA199, CA125 and CEA were normal. The KUB film demonstrated a large hazy mass located over the left side of the abdomen displacing the left-side colon medially. Contrast-enhanced computed tomography (CT) of the abdomen showed a well-defined homogenous hypodense mass, which measured 12 cm × 6.5 cm in size, occupying the left retroperitoneal space with medial displacement of the

Figure 1 Contrast-enhanced CT of the abdomen showing a 12 cm × 6.5 cm homogenous cystic mass in the retroperitoneal space with medial displacement of the descending colon.

Figure 2 Photograph of the resected mass measuring 20 cm × 14 cm × 6 cm in size.

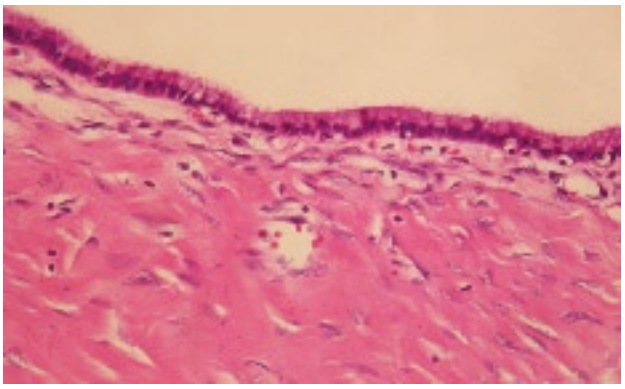

Figure 3 Photomicrograph showing a single layer of mucin-producing columnar epithelium with underlying fibrous connective tissue (HE, × 100).

descending colon (Figure 1). Because a retroperitoneal cystic mass was considered, the patient underwent surgical excision of the tumor. At laparotomy, the mass was located behind the descending colon. The white line of Toldt was divided to expose the cystic mass. A huge retroperitoneal cystic mass was resected, measuring 20 cm × 14 cm × 6 cm in size and 900 mg in weight (Figure 2). The uterus and both ovaries were normal. There was no spread of the tumor in the abdominal cavity. Histopathological assessment of the resected mass disclosed a picture of mucinous cystadenoma lined by a single layer of columnar epithelium with mucin production and surrounded by dense fibrous tissues (Figure 3). A diagnosis of primary RMC was made. The postoperative course was uneventful and she remained asymptomatic with ensuing two years of follow-up.

DISCUSSION

Primary retroperitoneal mucinous tumors are rare. The most common type of retroperitoneal mucinous tumors is the RMC, which shares a histological similarity to ovarian mucinous cystadenomas but can arise at any location in the retroperitoneum without attachment to the ovary [4]. The histogenesis of primary RMCs remains unclear. Three main theories have been proposed to explain the histogenic origin of mucinous cystadenomas in the retroperitoneum. These tumors can arise from teratoma[5,6], heterotopic ovarian tissue[4,5], or mucinous metaplasia of the mesothelial lining cells[4,5,7-9]. Primary RMCs occur exclusively in women[1,4], although three cases of RMC in men have been reported in the literature[10]. Some authors questioned the diagnosis of these lesions as benign because all three patients died of the disease[11]. Furthermore, Subramony *et al*[4] reported that the estrogen receptor is positive in stromal cells of a RMC, which could explain the exclusive occurrence of these tumors in women.

In the present study, we performed a literature review using Medline starting in 1970, and found a total of 19 cases of primary RMCs in the English literature. Based on these cases, including the present one, it was found that all cases were women, with an age range of 14 to 85 years (Table 1). The size of reported tumors ranged from 7 cm to 30 cm. There was no relationship between the age of patients and the size of tumors. The symptoms were nonspecific and most of the patients complained of asymptomatic mass or abdominal discomfort. The preoperative diagnosis was mesenteric cyst in 4 cases, ovarian cyst in 3 cases, and retroperitoneal cystic tumor in one case. Interestingly, preoperative diagnosis of renal cyst was considered in 2 cases. Serum levels of tumor markers were normal in 4 cases. However, two cases demonstrated a slight elevation of CA199 and CA125 levels, respectively. There was no evidence of recurrence after surgical management in 9 patients.

Preoperative diagnosis of primary RMCs is reportedly very difficult due to a lack of pathognomonic clinical features. Based on the review of cases reported in the English literature (Table 1), most patients presented with asymptomatic mass and vague abdominal discomfort. Reported tumors were relatively large, which may be large enough to evoke clinical symptoms or perceived by the patients. However, no cases examined presented with severe abdominal pain. Laboratory studies, including serum tumor markers and cytology study of cystic fluid are not helpful in making diagnosis of the tumors[1,14,20]. However, Motoyama *et al*[21] reported

Table 1 Cases of primary RMC in the English literature since 1970

ND: Not described; NR: No recurrence.

that measurement of CEA level in the cystic fluid may be useful in making the diagnosis. With regard to the imaging characteristics of RMCs, these tumors usually manifest as homogenous unilocular cystic masses at CT of the abdomen[20]. Furthermore, displacement of colon, kidney or ureter may suggest the retroperitoneal location of tumors[1,20]. As for the management of primary RMCs, complete surgical excision is recommended to eliminate the risk of infection, recurrence, and malignant degeneration[1,2], although these tumors seem to behave in a benign fashion with no recurrences after surgical removal, as demonstrated in our study. Exploratory laparotomy with complete enucleation of the cyst is traditionally indicated, although successful laparoscopic excision of a primary RMC has been reported[9].

In conclusion, when confronted with a cystic mass in the retroperitoneum, a primary RMC should be included in the list of differential diagnosis. Complete surgical removal of the tumor is recommended because of high risk of infection, recurrence and malignant potential.

Abstract

In order to have an adequate view of the whole small intestine during capsule endoscopy, the preparation recommended consists of a clear liquid diet and an overnight fast. However, visualization of the small bowel during video capsule endoscopy can be impaired by intestinal contents. To improve mucosal visualization, some authors have evaluated different regimens of preparation. There is no consensus about the necessity of intestinal preparation for capsule endoscopy and it should be interesting to develop adequate guidelines to improve its efficacy and tolerability. Moreover, the effect of preparation type (purgative) on intestinal transit time is not clear. Since a bowel preparation cannot definitively improve its visibility (and theoretically the yield of the test), it is not routinely recommended.

Key words: Capsule endoscopy; Intestinal preparation; Polyethylene glycol; Aqueous sodium phosphate

TO THE EDITOR

In order to have an adequate view of the whole small intestine during capsule endoscopy, it was initially thought that fasting for 12 h and a clear liquid diet 24 h prior to the procedure were an effective preparation. Based on this consensus, each group initiated this new technique, adapting it according to its own experience. Before long, it became evident that the capsule had two problems. One is the percentage of incomplete examinations is up to 15% of all those underwent capsule endoscopy due to a prolonged gastric or intestinal transit time[1], the other is the relatively frequent existence of intestinal content, particularly in its most distal parts of the small intestine. For these two reasons, it was thought that a preparation involving the cleaning of the small intestine prior to an examination would improve the quality of the endoscopic view and, in turn, the diagnostic yield of the technique. Thus, proposals were put forward based on the preparations carried out for other types of exploration, such as colonoscopy[2]. The application of such preparations has led to undesired effects such as the prolongation of gastric and/or intestinal transit time and a consequential rise in the proportion of incomplete examinations. To avoid such a negative outcome, trials have been carried out with prokinetics such as erythromycin, but achieved little effect[3,4]. In another prospective study, in which the prokinetic agent metoclopramide (10 mg) was administered orally 15 min before the capsule was swallowed, the percentage of complete studies was greater[5]. An extended transit time represents a less problem for the new generations of capsules whose batteries last longer. However, the use of metoclopramide could still offer advantages in diabetic patients and those confined to the bed, in whom intestinal transit time is usually longer, insuring that the capsule photographs the entire small intestine. Similarly, a better view of the proximal intestine has been described following administration of 300 mg simethicone 20 min before capsule endoscopy[6,7].

With respect to the preparation of the intestine before an examination, Viazis *et al*[8] carried out a prospective study of 80 patients to whom 2 L polyethylene glycol-based electrolyte solution (PEG) *vs* clear liquids was randomly administrated during the entire day prior to the procedure. No effect on the gastric or intestinal

transit of the endoscopic capsule was detected, though there was a higher level of cleanliness among those patients who received the aforementioned preparation, with a statistically significant improvement in the diagnostic yield. Niv *et al*[9] published a retrospective analysis of the use of oral sodium phosphate in 46 *vs* 23 patients prepared only with overnight fasting. The authors recommended the preparation of oral sodium phosphate after observing a higher level of cleanliness. However, it must be said that their study was retrospective and based on a relatively small series of patients whose results do not warrant a generalisation of the use of said preparation. Similarly, Dai *et al*[10] compared the levels of cleanliness obtained after ingestion of a 4 L PEG solution *vs* a 12 h period of fasting. They observed an acceleration of intestinal transit in patients receiving the PEG preparation, and a better view during the examination as a result of a greater intestinal cleanliness.

Ben-Soussan *et al*[11] did not observe a difference between a preparation of 2 L PEG solution and 12 h fasting with respect to the results achieved. Indeed, they reported that the PEG preparation increased the time of gastric emptying, which does not favour a complete small bowel examination.

Some studies have demonstrated that bowel preparation has a negative influence on gastric emptying and intestinal transit time, though there is a lack of uniformity among their results. Moreover, there is also evidence for the absence of any influence over these parameters. In an attempt to establish some common guidelines, different proposals have been made regarding the best procedure to follow. In this way, a review of the related literature by de Franchis *et al*[12] drew attention to the fact that studies on the subject are scarce and provide inconsistent results. Their analysis highlighted the lack of uniformity both in the methodology of the studies and in the results obtained, and considered it was necessary to develop a large, multi-centre, random, prospective study that would confirm, definitively, the best procedure to follow with respect to preparation prior to capsule endoscopy.

We must not ignore the disadvantages of all types of preparation for cleaning the intestine prior to capsule endoscopy, given the low tolerance of patients to such procedures and the often consequential rejection of a test that, without said interference, would normally be perfectly tolerated. On the other hand, there are no validated scales that allow us to accurately quantify and compare the levels of intestinal cleanliness. This makes any comparison of results difficult and can often invalidate them.

Results such as those of Pons *et al*[13] and Lapalus *et al*[14] tilt the balance in favour of no prior preparation. Lapalus *et al*[14] compared the administration of aqueous sodium phosphate (ASP) *vs* clear liquids and did not observe any difference in the level of cleanliness or in visibility.

The results of the aforementioned Spanish group[13] are a fruit of a multi-centre, random, prospective study that compared the efficacy and tolerability of three different preparations applied prior to capsule endoscopy in a large sample of patients. Observers were blind to the type of preparation employed. The 291 patients included in the study were randomly divided into three groups. All were fasted for 10 h prior to capsule endoscopy. Group A received a liquid diet (CL) (4 L) that excluded strongly-coloured liquids and those with residues. Group B received 90 mL of ASP as part of an abundant diet of liquids. Group C received a solution of 4 L PEG. The examinations were evaluated globally according to four categories: poor, fair, good, and excellent (Table 1). No statistically significant difference was found between the qualities of the examinations following the three preparations. The CL preparation was the best tolerated of the three preparations, followed by that of PEG and, finally, that of ASP ($P < 0.001$). The type of preparation did not influence the diagnostic yield of capsule endoscopy. Next, 32 examinations were randomly selected and re-evaluated by two researchers who were blind to the first result of a medium concordance between the first and second results (kappa 0.45).

Table 1 Score used to evaluate the level of intestinal cleanliness

Categories	Evaluate the level of intestinal cleanliness
Poor	Intestinal content impeding evaluation
Fair	Liquid or solid intestinal content allowing evaluation
Good	No intestinal content or some located in the terminal ileum and/or cecum
Excellent	No intestinal content in any part of the small intestinal tract (including ileum) or the cecum

This is the first study (currently being prepared for publication) that resolved the problem of preparation for capsule endoscopy. Based on the results, and pending verification by other studies, we can affirm that a liquid diet during the day prior to administration of the endoscopic capsule, together with fasting, constitutes a sufficient preparation for achieving a good level of cleanliness in the small intestine. Furthermore, this procedure is well tolerated and, thus, better accepted by the patient.

However, if in the future a product is developed that is capable of maintaining an adequate level of cleanliness in both the small intestine and colon, and which is also well tolerated by the patient, the recommended protocol for carrying out these diagnostic tests will no doubt be modified in order to incorporate the said product, not only in the case of capsule endoscopy but also in colonoscopy, in which preparation continues to be a stumbling block.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

World J Gastroenterol 2008 October 7; 14(37): 5778-5780
World Journal of Gastroenterology ISSN 1007-9327

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology* and *Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903
Ocean International Center, Building D
No. 62 Dongsihuan Zhonglu
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

ISSN 1007-9327

Abstract

Intrahepatic cholestasis of pregnancy (ICP) is the most common pregnancy-related liver disorder. Maternal effects of ICP are mild; however, there is a clear association between ICP and higher frequency of fetal distress, preterm delivery, and sudden intrauterine fetal death. The cause of ICP remains elusive, but there is evidence that mutations in genes encoding hepatobiliary transport proteins can predispose for the development of ICP. Recent data suggest that ursodeoxycholic acid is currently the most effective pharmacologic treatment, whereas obstetric management is still debated. Clinical trials are required to identify the most suitable monitoring modalities that can specifically predict poor perinatal outcome. This article aims to review current achievements and unsolved problems of ICP.

Key words: Cholestasis of pregnancy; Canalicular ABC transporters; Pruritus; Fetal outcome; Ursodeoxycholic acid

Peer reviewer: Dr. Yogesh K Chawla, Professor, Department of Hepatology, Postgraduate Institute of Medical Education and Research, Chandigarh 160012, India

Kondrackiene J, Kupcinskas L. Intrahepatic cholestasis of pregnancy-current achievements and unsolved problems. *World J Gastroenterol* 2008; 14(38): 5781-5788 Available from: URL: http://www.wjgnet.com/1007-9327/14/5781.asp DOI: http://dx.doi.org/10.3748/wjg.14.5781

INTRODUCTION

Intrahepatic cholestasis of pregnancy (ICP) is the most common liver disorder unique to pregnancy. ICP predominantly occurs during the third trimester of pregnancy and characterized by pruritus, and biochemical disturbances in liver tests. While ICP poses little maternal risk, there is an increased risk of preterm delivery and sudden intrauterine fetal death. In spite of the substantial risk, ICP remains widely disregarded as a serious clinical problem[1]. The cause of ICP is not fully understood. Current research on the pathogenesis of ICP focuses on genetic and hormonal factors. The treatment is mainly symptomatic. Ursodeoxycholic acid is currently the most effective pharmacologic treatment, but there is no ideal method for fetal surveillance so far. This review, based on an analysis of the literature and our own experience, attempts to summarize current achievements and unsolved problems of ICP.

EPIDEMIOLOGY

The incidence of ICP varies throughout the world. The highest incidence is considered to be in Chile and Bolivia (5%-15%)[2,3]. In these countries, the incidence of ICP has decreased more recently, whereas it has increased in other parts of Europe, the USA, Asia, Australia and some Latin American countries[3,4]. In Scandinavian and Baltic countries ICP occurs in up to 2% of pregnancies, while in other countries of Europe and North America the incidence is less than 1%[3-5], and in South Asian populations the incidence is 0.8%-1.46%[6]. In Lithuania, a retrospective analysis disclosed a rate of 0.4% of ICP in 16 252 pregnant women over a period of five years[7]. The low incidence of ICP may reflect an underestimation of the problem, and growing awareness of the condition will probably increase the numbers[2].

ETIOLOGY AND PATHOGENESIS

Over the last decade, it has become increasingly apparent that the etiology of ICP is multifactorial, involving genetic and hormonal factors. Hormonal

factors may trigger the transient decompensation of the heterozygous state for genes encoding hepatobiliary transport proteins which fail during pregnancy, leading to ICP[3,8,9].

Estrogens and progesterone

ICP occurs mainly during the third trimester, when serum concentrations of estrogens and progesterone reach their peak. ICP is also more common in twin pregnancies, which are associated with higher levels of hormones than singleton pregnancies[3,10]. All hormones are metabolized by the liver, and an excess of metabolites influences the activity of biliary canalicular transporters. The cholestatic potential of some D-ring estrogens, in particular glucuronides like estradiol-17β-*d*-glucuronide, and mono- or disulfated progesterone metabolites, mainly 3α, 5α-isomers, is supported by experimental and clinical data[11-13]. The formation of large amounts of sulfated progesterone metabolites, possibly related to greater 5-α and 3-α reduction, may result in saturation of the hepatic transport system (s) utilized for biliary excretion of these compounds in some genetically predisposed women[11,14,15]. The function of hepatocellular transporters such as ABCB11 and ABSB4 has been shown to be impaired at the posttranscriptional level *in vitro* by high loads of estrogen glucuronides and progesterone[16-18]. In addition, estrogens impair basolateral as well as canalicular bile acid transporter expression of liver cells *in vitro* by transcriptional mechanisms[19].

Genetic factors

There is increasing evidence that interaction between genetically determined dysfunction in the canalicular ABC transporters, and high levels of sex hormones produced in pregnancy, can predispose for the development of ICP[8,9]. Genetic factors could explain familial cases and the higher incidence in some ethnic groups. Also supporting genetic factors are the high rate of recurrence of ICP in subsequent pregnancies and the susceptibility of affected women to progesterone[3,15,20]. The phospholipid translocator (ABCB4, MDR3) and the bile salt export pump (ABCB11, BSEP) are the main transporters involved in the biliary secretion of cholephilic compounds. The hypothesis that mutations in the canalicular transporters contributes to ICP was first supported by Jacquemin *et al*[21]. Heterozygous mutations in ABCB4 have been found in a large consanguineous family in whom six women had at least one episode of ICP[21,22]. Since then, different studies reported additional mutations in ABCB4 which are associated with the presence of ICP[23-25]. In a recent prospective study on 693 Swedish patients with severe ICP (bile acid levels $\geqslant$ 40 μmol/L), a genetic association with common ABCB4 gene variants was found. These associations were reflected by different frequencies of at-risk alleles of the two tagging polymorphisms [c.711A: Odds ratio (OR) = 2.27, P = 0.04; deletion intron 5: OR = 14.68; P = 0.012][26]. The association between ICP and the SNP c.711A was detected previously in a large UK cohort of 184 ICP patients with bile acid levels > 14 μmol/L[27]. Splicing mutations have been described in ABCB4 with normal gamma-glutamyltranspeptidase (γ-GT) in German women[28], whereas in only a small percentage (7.2%) of Italian women ABCB4 mutations were responsible for the development of ICP[29]. Different genetic background may justify the presence of novel MDR3 gene mutations[30]. It has been suggested that mutations in the ABCB4 are associated with elevated γ-GT levels[25,31], whereas in several recent studies patients with ICP exhibited normal γ-GT activity[28,29]. Floreani and coworkers concluded that γ-GT is not a discriminant for patients carrying ABCB4 mutations[29].

The bile salt export pump (BSEP, ABCB11) and multidrug resistance associated protein 2 (MRP2, ABCC2) have been proposed as alternative candidate proteins involved in the pathogenesis of hormonal cholestasis given their important roles in bile formation and bilirubin secretion[25,32-35]. Meier and coworkers supported a role for the ABCB11 1331T>C polymorphism as a susceptibility factor for the development of estrogen-induced cholestasis[32]. No association was found for ABCC2 in this study[32], whereas Sookoian *et al*[36], found an association between the rs3740066 in exon 28 of the ABCC2 gene and ICP. Also, single British and Finnish patients with ICP carried mutations in the ATP8B1 (or FIC1) gene encoding a potential membrane transporter for phosphatidylserine[37,38].

Other factors

Some characteristics of ICP, such as incomplete recurrence at subsequent pregnancies, the decrease in prevalence and seasonal variations, suggest that environmental factors may contribute to the pathogenesis of this disorder[2,3,39]. Recently Reyes *et al*[40] reported that increased intestinal permeability was detected in ICP patients, and a "leaky gut' may participate in the pathogenesis of this pregnancy disorder by enhancing the absorption of bacterial endotoxin. Could cytokines be the missing link between pregnancy and cholestasis by favoring the absorption of bacterial endotoxin to initiate the liver inflammatory cascade? This hypothesis need to be confirmed in a large group of ICP patients[4]. Future studies may provide a better understanding of the pathogenic mechanisms of ICP.

Fetal pathophysiology

The mechanism underlying poor perinatal outcome is still poorly understood. During ICP there is an increased flux of bile acids from the mother to the fetus[41-43]. The placenta plays a crucial role in protecting the fetus from the adverse effects of potentially toxic endogenous substances including total bile acid (TBA)[44,45]. High levels of maternal TBA affect placental transport, placental hormone production, and chorionic vessel constriction[46]. In animal models,

maternal hypercholanemia may affect the vectorial transfer of bile acids through the creation of inversely directed gradients, as compared with the physiological situation[47], and by impairing the ability of the trophoblast to transport bile acids[48]. Germain *et al*[49] have shown that activation of the oxytocin receptor pathway is possibly caused by a cholic-acid-mediated increase in oxytocin-receptor expression.

CLINICAL FEATURES

ICP is characterized by pruritus starting in the second or third trimester of pregnancy, and disappearing after delivery. It is often generalized but predominates on the palms and the soles of the feet, and is worse at night. Skin lesions are characteristically absent except for excoriations due to scratching[2,3,5]. In approximately 80% of patients pruritus starts in late pregnancy, but there can be unusual forms of ICP[11]: (1) early onset, even in the first weeks; (2) typical pruritus without the usual serum abnormalities; (3) pruritus may fade spontaneously before delivery with or without an improvement in serum liver tests; (4) the disorder exacerbates postpartum with no signs of liver failure, and may last 1-2 mo after delivery, subsiding spontaneously without sequelae. Mild jaundice occurs in 10% to 15% of cases, typically within 4 wk of the onset of itching[50-52]. Subclinical steatorrhea may be seen along with fat malabsorption, which may lead to vitamin K deficiency[53,54]. Abdominal pain is uncommon. Encephalopathy or other features of liver failure are unusual and their presence should initiate a search for other causes of liver disease[39].

The most sensitive laboratory abnormality in ICP is an increase in serum TBA concentrations, which may be the first or only laboratory abnormality[3,5,52]. Serum cholic acid increases more than chenodeoxycholic acid, resulting in a marked elevation of the cholic/chenodeoxycholic acid ratio compared to pregnant women without ICP[55]. Whereas, a study from Argentina has shown that asymptomatic hypercholanemia of pregnancy, defined as TBA > 11 μmol/L in healthy pregnant women, does not necessarily lead to ICP[56]. Serum aminotransferases are elevated, and may reach values greater than 1000 U/L, making distinction from viral hepatitis important. Hyperbilirubinemia, up to 100 μmol/L is observed in 10% to 20% of the cases[3,5,52,53]. During a 3-year period in a prospective study of 84 women with ICP, elevation of aminotransferase activities from 2-fold to 15-fold were noticed in 85% of patients, bilirubin concentration from 2-fold to 4-fold in 14%, fasting serum bile acids from 1.5-fold to 20-fold in 78%, γ-GT was elevated up to 3-fold in 11% and alkaline phosphatase up to 2-3-fold in 60% of patients[51]. Although a sensitive marker of other types of cholestasis, serum γ-GT is usually normal or modestly elevated[3,5,52,53]. Alkaline phosphatase is of poor diagnostic value due to placental and bone production. The prothrombin time is usually normal. When present, prolonged prothrombin times reflect vitamin K deficiency due to cholestasis or to the use of anion exchange resins (such as cholestyramine) rather than liver dysfunction[53,54]. Dann *et al*[57] reported significantly increased levels of low-density lipoprotein cholesterol in ICP, and proposed that this test might be useful to distinguish between ICP and pruritus gravidarum. An upper abdominal ultrasound is considered in patients with biliary colic or other manifestation of gallstone disease. Liver biopsy is rarely necessary for diagnosis. Histology is characterized by cholestasis without inflammation, and bile plugs in hepatocytes and canaliculi predominate in zone 3[58].

DIFFERENTIAL DIAGNOSIS

Pruritus, as the cardinal feature of ICP, helps distinguish it from other types of liver pregnancy-related disease that can share similar laboratory features (such as early HELLP syndrome, acute fatty liver of pregnancy or preeclampsia)[3,7,59]. In patients presenting with jaundice, choledocholithiasis should be excluded, and abdominal ultrasound is indicated in this situation. The differential diagnosis of pruritus without icterus should be focused on skin diseases (eczema, scabies, urticarial papules), allergic reactions, abdominal striae, diabetes and other metabolic diseases. In patients with high transaminases, acute viral hepatitis (A, B, C, E, Epstein-Barr virus, cytomegalovirus, herpes simplex virus), choledocholithiasis, toxic, autoimmune hepatitis might be excluded[3,52,53,59]. In some cases an underlying liver disorder can be diagnosed as ICP[4]. Hormone- and cytokine-induced reduction of expression and function of the principal sinusoidal or canalicular bile acid transporters in late pregnancy could result in the development of symptomatic cholestasis in a previously asymptomatic pregnant woman with hepatitis C or other chronic liver disease[4].

MATERNAL OUTCOME

Maternal prognosis is favourable[5,50,51]. Pruritus usually disappears in the first few days following delivery, accompanied by normalization of serum bile acid concentrations and other liver tests. The patients with ICP generally have no hepatic sequelae. If the pruritus and liver test abnormalities persist after delivery, chronic liver diseases such as primary biliary cirrhosis, primary sclerosing cholangitis or chronic hepatitis must be considered. ICP recurs during subsequent pregnancies in 45% to 70% of cases[5]. Affected women may also be at increased risk for the development of gallstones[60]. Persistent cholestasis frequently leads to malabsorption of fat-soluble vitamins, worsening maternal nutritional status. In addition, ICP is associated with increased incidence of intra- and postpartum hemorrhage. The administration of oral contraceptives to women with a history of ICP rarely results in cholestatic hepatitis. These women should be advised of the risk of cholestasis to use contraceptives with low dose estrogen or progesterone-only products[2,5,61].

FETAL OUTCOME

In contrast to the favourable prognosis for mothers, ICP poses significant risk for the fetus[5,62]. The major complications are premature deliveries in 19 to 60%[5], stillbirths in 0, 4 to 4, 1%[62,63] and fetal distress in 22 to 33% of cases[64,65]. The rate of malformations or abortions is not increased in ICP. Recent data show a marked decrease in fetal complication rates possibly due to greater awareness of the disease, experienced management and treatment[50,51,66]. The mechanism for poor perinatal outcome remains unclear. Because high bile salt levels were found to be associated with more frequent occurrence of fetal distress, this might be of great relevance for fetal prognosis[42]. Autopsies show signs of acute, lethal anoxia with petechial bleeding in pleura, pericardium and adrenal glands, but no signs of chronic anoxia[42,64]. Fetuses of women with ICP have adequate birthweights for gestational age and normal Doppler umbilical artery velocimetry, suggesting that chronic placental insufficiency is not the primary cause of fetal death[67]. Bile acids have been shown to induce vasoconstriction of human placental chorionic veins, and myometrial sensitivity to oxytocin[48,49,68]. In a study from Sweden, a correlation between fetal complications (defined as preterm delivery, asphyxial events, meconium staining of amniotic fluid, placenta, and membranes) and serum bile acid levels ($\geqslant$ 40 μmol/L) was found. The authors reported no increase in fetal risk detected in ICP patients with TBA levels < 40 μmol/L, and proposed that these women can be managed expectantly[50]. Further validation of these results is needed to determine the accuracy of this cutoff value. A recent case of fetal death at 39 wk and 3 d in a patient with ICP, who had low TBA concentrations at the time of diagnosis, has been reported[69]. This raises a crucial question: is the fasting TBA level sufficient to predict fetal outcome? Evaluation of bile acid concentrations may take several days even in major laboratories, making it an impractical tool for immediate risk stratification[70]. Therefore, it is important to evaluate other clinical factors that are possibly associated with prematurity. The risk of prematurity also appears to correlate inversely with onset of pruritus[71]. We recently reported that early onset of pruritus, along with markedly elevation of bile acid levels, may predict premature delivery[72].

MANAGEMENT

Various strategies have been proposed to improve obstetric outcome. Although, there is no ideal method for fetal surveillance in ICP, monitoring of fetal status is recommended in all cases. Nevertheless, in several studies, the investigators have concluded that fetal death in ICP may not be predictable by traditional antepartum surveillance, and that delivery after establishment of fetal lung maturity may reduce fetal mortality rate[62-64]. Obstetric management consists of weighing the risk of premature delivery against the risk of stillbirths. Some obstetricians recommended non stress tests or biophysical assessment[65]. However, no test reliably predicts the risk of fetal demise[62,63]. Intended to recognize a failing placenta, fetal cardiac monitoring cannot forecast an acute event such as an umbilical cord entanglement or a sudden fetal cardiac decompensation or arrhythmia[70]. As the majority of intrauterine fetal deaths in singleton pregnancies complicated by ICP occur after 37 wk, delivery has been recommended no later than 37-38 wk of gestation. Delivery at 36 wk if lung maturity is achieved or as soon thereafter as fetal lung maturity is established[62] or earlier should be considered for severe cases with jaundice and progressive elevation in serum TBA[62,65]. According to UK Guideline for Obstetric Cholestasis (2006), there are insufficient data to support or refute the popular practice of "early" (37 wk of gestation) induction of labour aimed at reducing late stillbirth. The timing and risks of delivery should therefore, be discussed on an individual basis[39]. Because the prognosis remains unpredictable in some cases[69], our current strategy is to begin pharmacological treatment with UDCA after confirmation of diagnosis in all ICP patients[72].

PHARMACOLOGICAL TREATMENT

The goal of pharmacologic treatment in ICP is to reduce maternal symptoms and improve fetal outcome. Antihistamines, benzodiazepines, phenobarbital, dexamethasone, epomediol, S-adenosyl-L-methionine, opioid antagonists, and cholestyramine have been used without clear evidence of efficacy[1-3]. Cholestyramine (8-16 g/d) was a widely used treatment for ICP related pruritus. It binds bile salts and interrupts their enterohepatic circulation. Observational studies suggest that cholestyramine may be associated with improved maternal morbidity without a documented improvement in fetal outcome[73-75]. Cholestyramine may worsen the malabsorption of fat-soluble vitamins, especially vitamin K. A case report of severe fetal intracranial hemorrhage during treatment with cholestyramine for ICP has raised the possibility that severe maternal vitamin K deficiency may lead to fetal vitamin K deficiency and coagulopathy[75].

Currently, the ursodeoxycholic acid (UDCA) is the most promising treatment for ICP. UDCA is hydrophilic bile acid. It is well tolerated by pregnant women, and no adverse effects in mothers or newborns have been observed[50,51,66]. Experimental evidence suggests that UDCA improves impaired hepatocellular secretion by mainly posttranscriptional stimulation of canalicular expression of transporters like the conjugate export pump, MRP2 (ABCC2), or the bile salt export pump, BSEP (ABCB11)[76,77]. In particular, targeting and insertion of these transporter proteins into the canalicular membrane by UDCA conjugates has been demonstrated in experimental models of cholestasis, which led to enhanced elimination of bile acid metabolites and other organic anions as well as steroid mono- and disulfates[76,77]. In addition to effects of UDCA on the maternal liver, UDCA

restores the impaired maternal-placental bile acid transport across the trophoblast. This could be mediated by enhanced expression of plasma membrane transporters involved in the excretory role of the placenta and would prevent structural alterations of the trophoblast induced by maternal cholestasis[78]. Effects of UDCA in ICP resemble the effects observed in other cholestatic diseases, although in ICP the clinical and biochemical effects are obtained faster, and they fade quickly when the drug is discontinued[79]. Following oral administration, approximately 30% to 60% of UDCA is absorbed in the gut[80]. The degree of UDCA enrichment in biliary bile following chronic ingestion correlates with the administered dose. Most clinical trials have used UDCA at a dose of 13-15 mg/kg per day[81,82]. Recently, Mazzella *et al*[83] reported positive results and no adverse reactions of high dose UDCA (1.5-2 g/d). In an open, randomized, parallel group study from Lithuania, 84 patients with ICP were randomized to either UDCA, 8-10 mg/kg body weight per day, or cholestyramine, 8 g per day, for 14 d. The onset of pruritus was approximately 31 wk to 32 wk of gestation while treatment was started at approximately 34 wk of gestation. A significant improvement of pruritus severity, aminotransferase activities, serum TBA concentrations and a more favorable outcome of pregnancy and absence of adverse events after treatment with UDCA was demonstrated. In contrast, cholestyramine alleviated pruritus only mildly and caused side effects[51,84]. In another double-blind, placebo-controlled trial, comparing UDCA (1 g/d for 3 wk) and dexamethasone (12 mg per day for one week) in 130 women with ICP, relief of pruritus was significantly more pronounced in the UDCA subgroup with bile acid levels > 40 μmol/L, and significant improvement of serum alanine aminotransferase and bilirubin levels irrespective of disease severity was observed in the UDCA group only. Dexamethasone produced no alleviation of pruritus or reduction of ALT activity and was less effective than UDCA in reducing bile acids and bilirubin levels[85]. In a retrospective, non-randomized analysis over a 12-year observation period, 32 patients had received UDCA (15 mg/kg per day) for at least 3 wk before delivery. Patients were compared with 16 historic controls who did not receive UDCA. UDCA treatment was associated with improvement in pruritus, serum bilirubin, aminotransferase and TBA levels, higher birth weight, and a greater proportion of deliveries at term. Twenty-six children whose mothers received UDCA were reexamined after 1 year to 12 years of follow-up all of whom were healthy[66].

The efficacy of the glutathione precursor S-adenosyl-methionine (SAMe) is controversial[86,87]. A controlled trial (46 patients) comparing SAMe with UDCA found that UDCA was significantly more effective at improving the concentration of serum bile acids and other liver biochemical tests, whereas both drugs equally reduced pruritus[88]. Another randomized placebo-controlled trial involving 32 patients showed the superiority of the combination of UDCA with SAMe over either drug alone for alleviating pruritus and improving liver tests[89]. A recent randomized prospective comparative study of UDCA (750 mg per day) and S-adenosyl-L-methionine (1000 mg per day intravenously) in 78 patients with ICP suggested that both regimens improved pruritus, but the combined therapy had no additive effect on pruritus as compared to UDCA monotherapy[90].

CONCLUSION

Intrahepatic cholestasis of pregnancy should be considered a high-risk condition, and careful fetal assessment and appropriate medical intervention might improve perinatal outcome. Although genetic research has not yet led to better prediction of the disease course, remarkable progress has been made in our understanding of the pathogenesis of ICP. Genetic risk profiling might help to stratify cases at the time of diagnosis, even before bile acid concentrations exceed levels that indicate an increased fetal risk. Additional studies in ICP populations from different countries are needed to further characterize the genetic background in these patients. UDCA is currently considered as first line therapy for ICP. Future prospective controlled studies may provide a better understanding of the underlying pathophysiological mechanisms of fetal risk, identify the most suitable monitoring modalities, and clarify the obstetrical management near term.

Abstract

Pancreatic resection is the treatment of choice for pancreatic malignancy and certain benign pancreatic disorders. However, pancreatic resection is technically a demanding procedure and whereas mortality after a pancreaticoduodenectomy is currently < 3%-5% in experienced high-volume centers, post-operative morbidity is considerable, about 30%-50%. At present, the single most significant cause of morbidity and mortality after pancreatectomy is the development of pancreatic leakage and fistula (PF). The occurrence of a PF increases the length of hospital stay and the cost of treatment, requires additional investigations and procedures, and can result in life-threatening complications. There is no universally accepted definition of PF that would allow standardized reporting and proper comparison of outcomes between different centers. However, early recognition of a PF and prompt institution of appropriate treatment is critical to the prevention of potentially devastating consequences. The present article, reviews the evolution of post resection pancreatic fistula as a concept, and discusses evolving definitions, the current preventive strategies and the management of this problem.

Key words: Pancreatic fistula; Pancreaticoduodenectomy; Pancreatic anastomosis; Pancreatic anastomotic failure; Complications

INTRODUCTION

Pancreatic resection is the standard treatment for pancreatic malignancy and certain benign pancreatic disorders. However, pancreatic resection is technically a demanding procedure. At diagnosis, more than 85% of pancreatic tumors are at an advanced stage. Thus, potentially curative resections are possible only in 10%-15% patients[1,2]. The standard surgical procedure for a lesion in the pancreatic head is pancreaticoduodenectomy (PD), while distal pancreatectomy (DP) with or without splenectomy, is performed for tumors in the body and tail.

At experienced high-volume centers, mortality after PD is currently 3%-5%. However, there is considerable post-operative morbidity, around 30%-50%[3,4]. At present, the single most significant cause of morbidity and mortality after PD is the development of pancreatic leak and fistula (PF), and rates of up to 20% are reported from centers specializing in pancreatic surgery[4-6]. The development of PF increases the length of hospital stay and the cost of treatment, necessitates the use of additional investigations and procedures, and can cause life-threatening complications.

Various strategies have been employed to decrease the incidence of PF, including pharmacologic manipulation, and modifications and refinements in the surgical technique. These have resulted in varying degrees of success. However, it is clear that early recognition of PF and prompt institution of appropriate treatment is the cornerstone in the prevention of potentially devastating consequences. The present article reviews the evolution of post-resection pancreatic fistula, and discusses the evolving definitions, and current preventive strategies and management approaches.

Table 1 The different components of previously used definitions of pancreatic fistula and the new grading system used by the International Study Group for Pancreatic Fistula (ISGPF)

Commonly used definitions used prior to the ISGPF recommendations

Output > 10 mL/d of amylase rich fluid on post-operative day 5 or for > 5 d.
Output > 10 mL/d of amylase rich fluid on post-operative day 8 or for > 8 d.
Output between 25 mL/d and 100 mL/d of amylase rich fluid after post-operative day 8 or for > 8 d.
Output > 50 mL/d of amylase rich fluid after post-operative day 11 or for > 11 d.

ISGPF Definition: "Output *via* an operatively placed drain (or a subsequently placed percutaneous drain) of any measurable volume of drain fluid on or after postoperative d 3, with an amylase content greater than 3 times the upper normal serum value"

Grade A	"Transient fistula"	No clinical impact	No peri-pancreatic collections on CT scan; little/no change in management	Clinically well; no sepsis; no prolongation of hospital stay; slow removal of operatively placed drains
Grade B		Clinical impact	Peri-pancreatic drains in place or repositioned to drain collections; Change in management is required	Clinically fairly well; degree of infection requiring specific treatment; prolongation of hospital stay; patients often discharged with drains in situ and observed in outpatient setting
Grade C		Severe clinical impact	Worrisome peri-pancreatic collections that require percutaneous drains; major change in management usually in ICU setting; possible re-surgery to salvage a difficult situation (completion pancreatectomy *etc*)	Clinically unwell; associated sepsis requiring aggressive antibiotics, octreotide and other intensive care support; major prolongation of hospital stay; associated complications and possibility of mortality

DEFINITIONS

There is no universally accepted definition of PF. While some workers have emphasized on the volume (and colour) of the drain output, and its duration, others have stressed more on the amylase content of the drainage fluid[7-9]. In a study published in 2004, Bassi *et al*[10] summarized 4 definitions of PF (Table 1) and applied each definition to 242 patients who had undergone pancreatic resection. The results revealed wide variations in the incidence of PF, from 10% to 29% depending upon the definition used. Therefore, it is essential to standardize the reporting of post-PD complications, especially PF. This led to the unified definition, now known as the International Study Group on Pancreatic Fistula (ISGPF) definition[11]. The definition was intended to standardize the reporting of postoperative PF. The essential component of an anastomotic leak was the high amylase content (> 3 times the upper normal serum value), of the drain fluid (of any measurable volume), at any time on or after the 3rd postoperative day. The ISGPF definition also graded PF (Grades A, B and C) according to the clinical impact on the patient's hospital course and eventual outcome. The various components of the previously used definitions and the new grading of the ISGPF are shown in Table 1. More recently, Pratt *et al*[12] sought to validate the ISGPF classification in 176 patients who underwent PD and concluded that with increasing fistula grades, there was a negative clinical and economic impact on patients and their healthcare resources.

However the applicability and utility of the ISGPF definition in allowing uniform comparisons of fistula rates has been questioned by some workers. In a recent publication, Strasberg *et al*[13] proposed that intra-abdominal collections along with hemorrhage and peritonitis are also the result of a pancreatic anastomotic failure. These workers sought to redefine pancreatic fistulae as "pancreatic anastomotic failures (PAF)" which includes the entire spectrum of clinically relevant problems associated with the loss of integrity of a pancreatico-enterostomy. They also sought to categorize fistulae that occur after DP or segmental resection and enucleation, situations which do not involve pancreatico-enterostomy, as an entity that is distinct from fistulae occurring after PD. These fistulae were termed as pancreatic occlusion failure (POF). POF commonly runs a more benign course (compared to PAF), since enzyme activation does not occur in the absence of a pancreaticoenteric anastomosis. Strasberg *et al* also noted that the definition of PAF should only include patients in whom there is a change in the management, whereas asymptomatic fistulae with merely high drain amylase and no change in the clinical course should not be considered as an operative complication, as proposed by the ISGPF definition. They thus defined PAF and graded its severity into 7 categories in 5 grades (Table 2). They proposed the adoption of the definition of PF used by the Johns Hopkins group[14]. These workers considered any intra-abdominal fluid collection after pancreatic surgery as PAF, if it was not found to be caused by the failure of other anastomoses performed during a PD. In addition, any hemorrhage was considered as PAF unless the pancreatico-enterostomy was shown to be intact. With respect to intra-abdominal collections, a recent study concluded that post-operative intra-abdominal collections after PD were PF. In this study, it was observed that when the initial drain amylase levels were normal, repeat estimation of the amylase level helped uncover previously undiagnosed PF or newly developed PF, thus providing a more precise estimate of postoperative PF rate[15]. From the preceding discussion it is evident that the definition of what constitutes a pancreatic fistula or anastomotic failure is still a matter of considerable debate. Clearly, more studies are needed before a common unifying definition of PF can be adopted.

PREVENTIVE STRATEGIES FOR PF

Considering the dismal outcome of a PF, much effort

Table 2 Pancreatic anastomotic failure (PAF) as described by Strasberg *et al*

Definition: "Drainage of greater than 50 mL amylase-rich fluid (> 3-fold elevation above upper limit of normal in serum) per day through the drains on or after postoperative d 10, or pancreatic anastomotic disruption shown radiographically"	
Grade 1	Deviation from normal postoperative course without pharmacologic, endoscopic, surgical or radiologic intervention (certain drugs allowed)
Grade 2	Pharmacologic treatment needed. Includes blood transfusions and total parenteral nutrition
Grade 3 (a/b)	Surgical, endoscopic or interventional radiologic treatment needed a: Not under general anesthesia b: Under general anesthesia
Grade 4 (a/b)	Life threatening complications and organ dysfunction a: Single organ b: Multi-organ
Grade 5	Death due to PAF

has gone into preventing its occurrence. These measures primarily include technical modifications of constructing a pancreatic anastomosis. The correct management of a pancreatic remnant after a PD is a matter of much debate and this is reflected in the variety of techniques that have evolved over the years for the construction of a safe pancreatic anastomosis. Furthermore, the outcome of a pancreatic anastomosis depends, among other factors, on the consistency of the pancreatic parenchyma and the diameter of the main pancreatic duct. Clearly, the outcome is better when the pancreas is hard and the duct is dilated (*e.g.* in chronic pancreatitis) as compared to a soft pancreas with a non dilated duct (*e.g.* in low common bile duct cancer).

Other innovations include the use of biological adhesives designed to seal the anastomosis, ligation or occlusion of the main pancreatic duct, optimization of the blood supply to the pancreatic remnant, use of somatostatin and its analogues to inhibit pancreatic secretion, and even total pancreatectomy[16].

Pancreatic duct occlusion

Occlusion of the pancreatic duct can be achieved by simple suture ligation of the duct or injection of the duct with non-reabsorbable or reabsorbable glues. Simple duct ligation, advocated in the past, has been largely abandoned due to high PF rates, nearing 50%[17,18]. However in a recent prospective randomized controlled trial (RCT) by Tran *et al*[19] which compared pancreaticojejunostomy with duct occlusion alone, there were no significant differences in the morbidity or mortality, but the incidence of diabetes mellitus was higher in patients with duct occlusion.

In a study on 51 patients, Di Carlo *et al*[20] used a nonreabsorbable glue (neoprene) to occlude the pancreatic duct after PD. The authors concluded that intra-ductal injection of Neoprene after pancreaticoduodenectomy was a safer procedure compared to pancreaticojejunal anastomosis and was not associated with post surgical diabetes. In a prospective, multi-center RCT of 182 patients undergoing either PD or DP, 102 patients received pancreatic ductal occlusion with fibrin glue. Analysis showed that duct occlusion had no effect on the rate or severity of intra-abdominal complications after pancreatic resection[21].

Type of pancreatic anastomosis: Pancreaticojeju-nostomy (PJ) versus pancreaticogastrostomy (PG)

The safe reconstruction of pancreaticoenteric continuity is the key to preventing a PF. The risk of fistula formation depends on the consistency of the remnant pancreas, caliber of the main pancreatic duct, pancreatic vascularity and the technique of construction of the pancreatic anastomosis[22,23]. PJ and PG are the two most commonly employed techniques for the reconstruction of pancreaticoenteric continuity. PJ can be performed by the dunking method or the duct-to-mucosal anastomosis. Surgical techniques such as PG and PJ which are employed for the management of the pancreatic remnant after PD have been evaluated in only a few randomized controlled studies[14,24,25]. Earlier uncontrolled studies were in favor of PG[26,27]. Due to the close proximity of the stomach, a PG was believed to be easier to perform and less prone to ischemia as a result of the rich blood supply of the stomach. However, all the RCTs have failed to show any difference in the overall post-operative complication rate or incidence of PF. Two recent meta-analyses have shown that while non randomized observational studies showed a superiority of PG over PJ, RCTs failed to show superiority of any one technique, thereby concluding that both PJ and PG provided equivalent results[28,29]. Thus, it can be concluded that as long as a tension-free anastomosis between well perfused tissues is performed, employing fine sutures and using the same technique, any type of pancreatic anastomosis should result in a good outcome[3,30].

Stenting of the main pancreatic duct

Stenting of the pancreatic duct during pancreaticoenteric anastomosis facilitates the precise placement of mucosal sutures, diverts pancreatic juice away from the anastomotic site and decreases the risk of inadvertent pancreatic duct occlusion. In doing so, it is believed that the anastomotic integrity improves, thereby reducing the PF rate. The results of this strategy have been encouraging[31,32]. In a prospective but non-randomized trial in 85 patients, Roder *et al*[31] demonstrated that stenting the pancreatic duct reduced the PF rate from 68% to 29.3%, and the median hospital stay from 29 d to 13 d. Poon *et al*[33] reported that external drainage of the pancreatic duct with a stent reduced the leakage of PJ after PD. On

the other hand, some well designed studies have shown no benefit of internal stenting in preventing PF[34,35]. Thus, the available evidence is conflicting and the use of stents depends on personal choice and experience of the pancreatic surgeon.

Role of magnification in pancreatic anastomosis

Since a duct to mucosa anastomosis is crucial for good outcome, a meticulous approximation assumes great importance. Operating loupes have been used by many experts to allow precise construction of a pancreatic anastomosis. Wada *et al*[36] in a retrospective analysis highlighted the role of the operating microscope in constructing a pancreatic anastomosis. Technical errors which may occur during anastomosis include crossing of the sutures, including both sides of the pancreatic duct while passing the suture, taking unequal and inadequate amounts of pancreatic duct and jejunal mucosa, and incorrect knot placement resulting in air knots. All these events can be avoided by using magnification. The study by Traverso, reported a markedly reduced incidence of PF with the operating microscope compared to operating loupes.

OTHER SURGICAL TECHNICAL MODIFICATIONS/APPROACHES

Blood supply based technique of PJ

One of the few modifications which have demonstrated a substantial reduction in the rate of PF after PD was proposed by Strasberg *et al*[37]. These workers put forward the concept of vascular watershed in the pancreatic neck and its role in ischemia of the cut surface of the pancreatic remnant. In their technique, the blood supply at the cut surface of the pancreas was evaluated, and if necessary, the pancreas was cut back 1.5 cm to 2.0 cm to improve the blood supply (n = 47; 38% patients). Thereafter, the anastomosis was performed meticulously under magnification. The authors concluded that a combination of optimization of blood supply to the pancreatic remnant, and a meticulous technique resulted in reduced PF rate, from previous reports of 10% to 1.6% in their series of 123 resections.

Duct-to-mucosa versus invagination anastomosis

A number of studies have demonstrated a lower rate of PF using the duct-to-mucosa technique for pancreatic anastomosis[38-40]. However a prospective RCT by Bassi *et al*[41] revealed no significant difference in the morbidity and PF rate between duct-to-mucosa anastomosis and single layer end-to-side pancreatico-jejunostomy.

Total pancreatectomy

The rationale for total pancreatectomy is that it allows a more extensive lymphadenectomy, obviates the risk of leak from the pancreatic anastomosis and decreases the chances of a positive resection margin. However, total pancreatectomy is associated with obligatory diabetes mellitus, decreased immunity because of splenectomy, and loss of pancreatic exocrine function. Most studies have reported either worse survival or no survival difference between total pancreatectomy and standard PD[42-44]. Total pancreatectomy should not be performed in most cases of carcinoma of the pancreatic head, unless serial positive resection margins are obtained on frozen section examination, or the pancreas is deemed to be very soft with a very high risk of pancreatic leak, and in patients with documented family history of multi-centric disease[45].

Stapled or hand-sewn closure of the pancreatic remnant after DP

PF remains a major cause of morbidity after DP. A number of techniques have been used to reduce the incidence of PF after DP, including hand-sewn closure, staple closure, combined staple and suture closure, fibrin glue application, serosal jejunal patch and prolamine injection[46]. While hand-sewn closure has stood the test of time, the use of staplers is gaining increasing acceptance, especially with the advent of laparoscopic DP. Knaebel *et al*[47] performed a meta-analysis that included six studies comparing stapler versus hand-sutured closure, which showed a non-significant combined odds ratio for pancreatic fistula of 0.66 (95% confidence interval 0.35 to 1.26, P = 0.21) in favor of staple closure. However, a large retrospective study of 302 DP's, showed that stapler closure was associated with a higher rate of pancreatic fistula[48]. Thus, the jury is still out and surgeons must follow their own individual experience when dealing with pancreatic remnant after DP. In hand sewn closure, the guiding principle is to make every effort to identify the pancreatic duct, close it with fine sutures and then close the entire stump with sutures.

Role of Octreotide and Somatostatin analogues in decreasing the rate of PF after pancreatic surgery

Octreotide is a synthetic analogue of somatostatin, and like somatostatin inhibits pancreatic exocrine secretion. Several prospective RCTs conducted in Europe evaluated the use of subcutaneous octreotide/somatostatin in patients undergoing elective pancreatic resection for different indications[8,49-52]. The results show that octreotide reduced the development of pancreatic fistula and other complications. However RCTs by Sarr *et al*[9], Yeo *et al*[53] and Lowy *et al*[54], failed to show a similar benefit in the peri-operative use of somatostatin analogues in patients undergoing pancreatic resection. Meta-analysis and systematic reviews of octreotide use have also yielded conflicting results[55,56]. These findings notwithstanding, many surgeons continue to use octreotide in patients undergoing pancreatic surgery. Selective administration of octreotide in patients considered to have high risk pancreas (soft texture, small duct size, and presence of ampullary, duodenal, cystic or islet cell pathology) may be associated with a decreased incidence of PF[57].

MANAGEMENT OF PF (FIGURE 1)

Despite numerous novel strategies designed to prevent the development of postoperative PF, it is clear that in order to minimize the potentially devastating effect of PF,

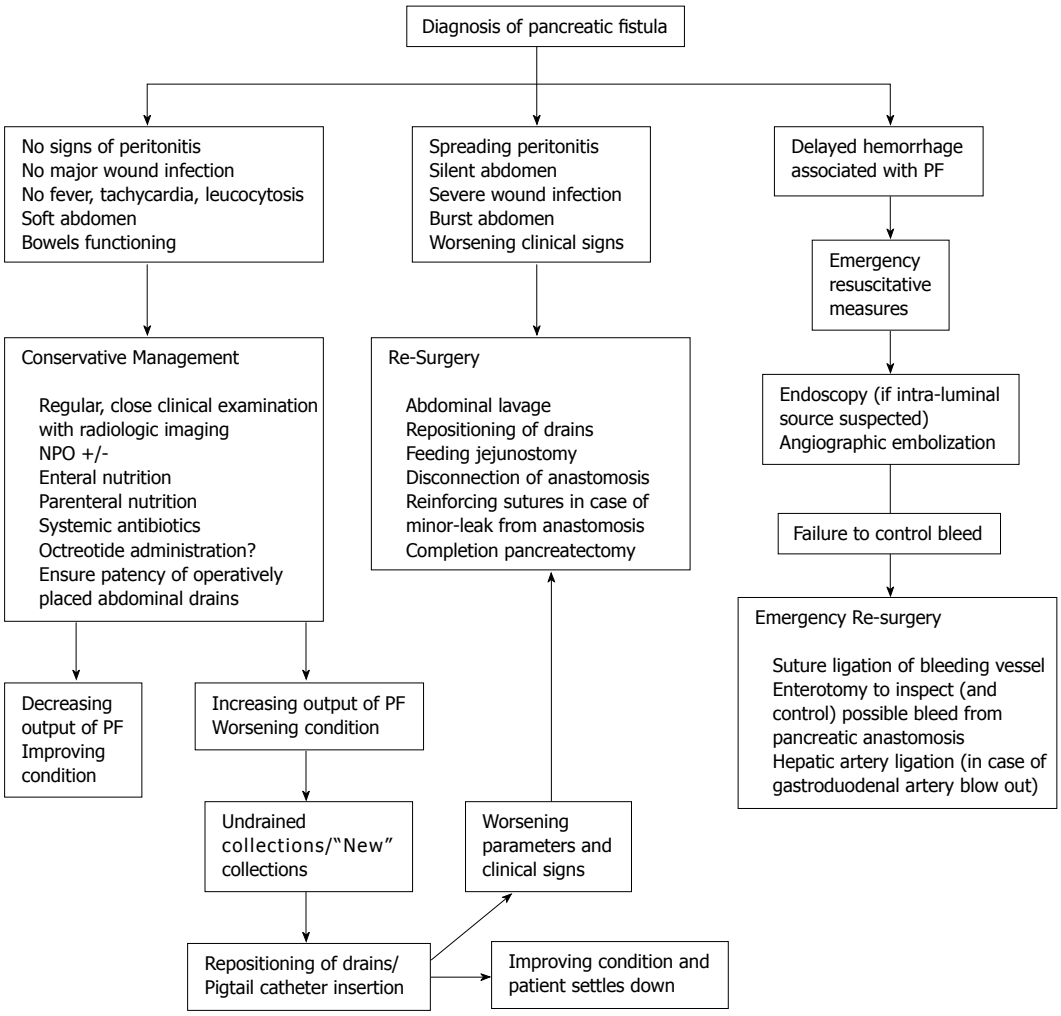

Figure 1 Approach to management of post pancreatectomy PF. Other procedures to manage complex PF may have to be added.

it is essential that this complication is recognized as soon as it develops, and appropriate treatment measures are instituted promptly. The suspicion of PF begins whenever there is a deviation in the normal clinical course of a patient who has just undergone a major pancreatic surgery. This may mean a patient who develops unexpected upper abdominal discomfort (often associated with fever), leucocytosis, increasing tachycardia, or just feels unwell after an apparently "normal" initial post-operative recovery. Furthermore, there may be high amylase content of a drain, a persistently high drain output, altered drain colour and quality, and other complications such as severe wound infection and hemorrhage. Routine radiologic evaluation is neither necessary nor recommended for establishing a diagnosis of PF[57]. What constitutes a PF is a matter of which definition is used, and varies from center to center. Regardless, once a diagnosis of PF is established, aggressive and appropriate conservative management is the key to successful outcome.

The management in the majority of patients is based on conservative measures. However, interventional radiological assistance is sometimes required, but repeat surgery is rarely indicated[16,58].

CONSERVATIVE MANAGEMENT

A conservative approach to the management of PF is successful in over 90% patients[59,60]. This involves clinical evaluation of the patient at short intervals. If the patient does not have any fever, tachycardia, leucocytosis, severe wound infection, and the abdomen is soft (with functioning bowel), and no signs of peritonitis, it is safe to continue with conservative measures. These measures include maintenance of enteral nutrition (through an operatively placed nasojejunal tube or a feeding jejunostomy), nasogastric suction (in the presence of delayed gastric emptying secondary to PF), and appropriate antibiotic coverage. In situations where the abdomen has not "really settled", the option of total parenteral nutrition should be considered. All along, the abdominal drains and the main wound require close attention. The effectiveness of octreotide in aiding the closure of a PF has not provided encouraging results[61]. The interventional radiologist may play a crucial role by image-guided repositioning of operatively placed drains and insertion of percutaneous catheters to drain collections seen on CT scan[60,62]. Delayed hemorrhage following PF is perhaps best managed by angiography and embolization of the bleeding vessel. This treatment is successful in stopping the bleeding in 80% patients[63]. The prognosis of patients with post-pancreatectomy hemorrhage depends on whether or not PF is present. The decision-making should be guided by factors such as the time of onset of the bleeding, presence of PF, vascular pathology, and the

underlying disease process[63]. The failure to successfully control hemorrhage by conservative measures like angiographic embolization may necessitate repeat surgery[63-66]. Obviously, the management of complications associated with PF requires a multidisciplinary approach, involving the pancreatic surgeon, intensive care team, and interventional radiologists. Kazanjian *et al*[59] evaluated 437 patients who underwent PD. A total of 55 (12.6%) developed PF; 52 patients (94.5%) had successful conservative management with prolonged tube drainage, 4 required percutaneous drainage and only 3 patients (5.5%) had repeat surgery.

OPERATIVE MANAGEMENT

Pancreatic resection is now considered a safe procedure when performed in high volume centers. PF can be successfully managed by conservative measures, as described earlier. The indications for surgical intervention in PF include worsening clinical parameters, signs of spreading peritonitis, severe wound infection, wound dehiscence, and delayed hemorrhage. When a decision is made to reoperate a patient with PF, the following measures should be considered: abdominal lavage with repositioning of drains, control of hemorrhage, use of sutures to control a small dehiscence, disconnection of the pancreatic anastomosis, a feeding jejunostomy (if not already in place) and occasionally completion pancreatectomy[61,67]. In patients with delayed hemorrhage who require repeat surgery, a thorough exploration of the resection site is required and if necessary, ligation of the arterial stumps (including occasionally the common hepatic artery) and inspection of the anastomosis by enterotomy[64]. It is worth noting that with improvements in the results of pancreatic surgery and the success of interventional radiology in managing complications, completion pancreatectomy is seldom required, and it has even been suggested that it should no longer be considered in patients with a PF[58].

The approach to the management of a patient with PF is summarized in Figure 1.

Abstract

AIM: To elucidate the distribution of $CD4^+CD25^+$ regulatory T cells (Tregs) in different lymphoid tissues and its local enhancement on tumor growth before and after depletion of $CD4^+CD25^+$ Tregs.

METHODS: Female ICR mice were gavaged with benzo[a]pyrene (BaP) to induce forestomach carcinoma. $CD4^+CD25^+$ Tregs were intraperitoneally depleted with monoclonal antibody PC61. These mice were divided into BaP-only, BaP + IgG, BaP + PC61, and control groups. The forestomach of mice was dissected for histological analysis, and tunnel test was performed for apoptosis of tumor cells. $CD4^+CD25^+$ Tregs were sorted from different lymphoid tissues and expression of Foxp3, IL-10, and chemokine receptors was analyzed by flow cytometry, semi-quantitative and real-time polymerase chain reaction.

RESULTS: The mice gavaged with only BaP showed increased forestomach papilloma and carcinoma at wk 16 and 32. The proportion of $CD4^+CD25^+$ Tregs was significantly higher in peri-stomach regional lymph nodes than in other lymphoid tissues. These $CD4^+CD25^+$ Tregs in regional lymph nodes expressed higher levels of Foxp3 and IL-10, enriched in the CD62L-subset, and CCR1 and CCR5 chemokine receptors. In mice gavaged with BaP + PC61, the number of tumor nodules and tumor volume decreased significantly with massive infiltrating cells and apoptosis of tumor cells. In the draining regional lymph nodes, the number of $CD4^+CD25^+$ Tregs also decreased significantly.

CONCLUSION: Inducible and activated $CD4^+CD25^+$ Tregs in the draining regional lymph nodes suppress host local immunity during tumor growth. Depletion of $CD4^+CD25^+$ Tregs can promote host local immunity to suppress tumor growth.

Key words: $CD4^+CD25^+$ regulatory T cells; Forestomach tumor; Foxp3

Depletion of $CD4^+CD25^+$ regulatory T cells can promote local immunity to suppress tumor growth in benzo[a]pyrene-induced forestomach carcinoma. *World J Gastroenterol* 2008; 14(38): 5797-5809 Available from: URL: http://www.wjgnet.com/1007-9327/14/5797.asp DOI: http://dx.doi.org/10.3748/wjg.14.5797

INTRODUCTION

$CD4^+CD25^+$ regulatory T cells (Tregs) constitute 5%-10% of peripheral $CD4^+$ T cells in humans[1]. The immune regulatory function of these $CD4^+CD25^+$ Tregs has been attributed to their ability to secrete immuno-suppressive cytokines, including IL-10 and TGF-β1[2]. Although beneficial to protecting the host from autoimmune disease, $CD4^+CD25^+$ Tregs may also dampen anti-tumor response. Evidence from various cancers demonstrates that the proportion of $CD4^+CD25^+$ Tregs increases in tumor-infiltrating lymphocytes (TILs) and peripheral circulation of gastric cancers[3-5], and in the peripheral blood of patients with

ovarian and lung cancers, hepatocellular carcinoma, and pancreas/breast adenocarcinoma[6-10]. Local accumulation of $CD4^+CD25^+$ Tregs in tumors is associated with a high death rate and reduced survival of ovarian carcinoma patients[9]. These reports suggest that $CD4^+CD25^+$ Tregs participate in cancer immunopathogenesis and are responsible for impairment of host immune surveillance to cancer. Viguier *et al*[11] reported that accumulation of $CD4^+CD25^+$ Tregs is higher in metastatic melanoma lymph nodes of humans and further demonstrated that these cells inhibit proliferation and cytokine production of infiltrating $CD4^+CD25^-$ and $CD8^+$ T cells *in vitro*. In contrast, Curiel *et al*[9] reported that $CD4^+CD25^+$ Tregs accumulate in ovarian tumors and malignant ascites but not in draining lymph nodes in later cancer stages. Thus, it is necessary to elucidate the potentially differential distributions and effects of $CD4^+CD25^+$ Tregs in local lymphoid tissues during cancer progression.

Preserved, smoked, and salted foods are highly associated with the development of gastric cancer. Polycyclic aromatic hydrocarbons (PAHs) are carcinogens that have been detected in cigarette smoke and in broiled and smoked foods[12]. Among PAHs, benzo[a]pyrene (BaP) is the most extensively studied compound and induces many carcinogen-specific effects[13]. Gavage-delivered BaP induces forestomach tumor in mice, providing a commonly used model for studying the chemopreventive effect of substances on gastric cancer[14-17]. Depletion of $CD4^+CD25^+$ Tregs has been shown to induce immune responses to a variety of different tumors in mice, including myeloma, leukemia, melanoma, and fibrosarcoma[18-20]. Lymphoid metastasis is also the determinative for gastric cancer. In this study, to understand the immunosurveillance effect of $CD4^+CD25^+$ Tregs in local lymphoid tissues during cancer progression, we used the BaP-induced forestomach tumor model to evaluate the differential effect of $CD4^+CD25^+$ Tregs by intervention at the initiation, promotion, or progression stages of multistage carcinogenesis. We first used tumor progression of BaP-induced autochthonous forestomach tumors in female mice to analyze the distribution and characteristics of $CD4^+CD25^+$ Tregs in different lymphoid tissues over time. Second, we used a $CD4^+CD25^+$ Treg-specific antibody to determine whether $CD4^+CD25^+$ Tregs are required for controlling tumor formation.

MATERIALS AND METHODS

Reagents and antibodies

Benzo[a]pyrene and glycerol gelatin were purchased from Sigma-Aldrich (St. Louis, MO). An aminoethyl carbazole substrate kit was purchased from Zymed (San Francisco, CA). The following antibodies (Abs) were purchased from BD PharMingen (San Diego, CA) and used in this study: mouse anti-CD4 PE (H129.19), anti-CD8a PE (53-6.7), anti-CD3e PE (145-2C11), anti-CD25 FITC (7D4), anti-CD62L FITC (MEL-14), and anti-CD62L PE (MEL-14). FITC-anti-Foxp3 (FJK-16s) mAb and FITC rat IgG2a isotype control Ab were purchased from eBioscience.

BaP-induced forestomach tumorigenesis

BaP-induced forestomach tumors were generated in female mice, as previously reported[21]. Eight-week-old ICR mice were purchased from the Laboratory Animal Center of National Cheng Kung University. All animal experiments were carried out with the approval of the ethical committee of our institution. BaP was dissolved in corn oil. Corn oil control mice (n = 14) and BaP-only treated mice (n = 9) received 200 μL of corn oil with or without 3 mg of BaP, respectively, by *po* gavage twice weekly for 4 wk. The mice were then sacrificed at week 7 (n = 3), 16 (n = 3), and 32 (n = 3) after the first administration of BaP.

Buffered formalin-phosphate (10%) was immediately injected into the stomach by oral intubation to distend and fix the stomach. Each stomach was removed and placed on a plastic sheet. The tumor incidence, number, and size in the forestomach were measured under a dissection microscope. Tumor volume was calculated using the following formula: Volume = $4\pi R^3/3$[22]. Stomach samples were excised and immersed in a buffered 10% formalin solution for paraffin block preparation. Four-micron sections were dehydrated, embedded, and stained with hematoxylin and eosin.

In vivo depletion of $CD4^+CD25^+$ Tregs

$CD25^+$ T cell-specific antibody, hybridoma PC61, was a gift from the Laboratory of Dr. Lai, MD. To deplete the $CD25^+$ T cells, BaP-treated mice (n = 19) were injected intraperitoneally with 200 μL PC61 mAb fluid at a concentration of 3 mg protein per mL[23], twice a week beginning 5 wk after the initial BaP treatment until the time of sacrifice. The mice in the BaP + PC61 group were then sacrificed at weeks 7 (n = 3), 16 (n = 7), 24 (n = 5), and 32 (n = 4) respectively, after the first administration of BaP. BaP-treated mice were injected with purified rat IgG antibody as a control (ICN, Pharmaceuticals Inc. Cappel, OH, USA). The mice in the BaP + IgG group were then sacrificed at weeks 7 (n = 4), 16 (n = 6), 24 (n = 5), and 32 (n = 4) respectively, after the first administration of BaP.

To confirm the effectiveness of the depletion, splenocytes, thymocytes, or lymphocytes from the peripheral lymph nodes were harvested on the third and seventh days every week after BaP treatment and incubated with anti-CD4 PE, anti-CD8 PE, and anti-CD25-FITC respectively, at 4℃ for 40 min in the dark. The mixture was washed twice with ice-cold HBSS, and then re-suspended in HBSS containing 2% FCS/0.1% NaN_3. Stained splenocytes, thymocytes, or lymphocytes were analyzed by flow cytometry (FACSCalibur; BD Biosciences, San Jose, CA).

Cell preparations, sorting, and flow cytometry analysis

Lymph nodes were collected from the mice at weeks 7 (n = 10), 16 (n = 12), and 32 (n = 11) respectively, after the initial BaP administration. Lymph nodes around the stomach and in the mesentery were collected and defined as regional lymph nodes (RLNs). Lymph nodes in the axillary, inguinal, brachial, and popliteal areas were collected and defined as PLNs. Cell suspensions

from the lymph nodes, spleen, or thymus were isolated by flow sorting after sterile dissociation, filtration, and washing. Cells were stained using PE-conjugated anti-CD4 and FITC-conjugated anti-CD25 and then purified on a FACSAria-sorting flow cytometer (BD Biosciences, San Jose, CA). The purity of these $CD4^+CD25^+$ and $CD4^+CD25^-$ T cells was > 90%. To determine the expression of cell surface markers in T cells, the cells were incubated with antibodies appropriately diluted for staining and further stained with anti-Foxp3 (Foxp3 regulates Treg development and function) or isotype control Ab according to the manufacturer's protocol. Stained lymphocytes were analyzed by flow cytometry.

Detection of apoptotic cells

Cytotoxic T-cells are able to directly induce apoptosis in cells, which is the one of the host immune surveillances. To identify a host anti-tumor response after depletion of $CD4^+CD25^+$ Tregs, apoptotic cells in tumor nodules were detected by TUNEL labeling detection of free 3'-OH groups in fragmented DNA *in situ* (ApopTag® peroxidase *in situ* apoptosis detection kit, Chemicon). Paraffin-embedded, slide-mounted tissue sections were deparaffinized and treated with proteinase K for 15 min followed by 3% H_2O_2 for 5 min at room temperature. After nick-end labeling with digoxigenin-deoxyuridine triphosphate by terminal deoxynucleotidyl transferase, immunostaining was performed using peroxidase-conjugated anti-digoxigenin Ab. Apoptotic cells were visualized with diaminobenzidine substrate, becoming a dark-brown color. Specimens were then counterstained with hematoxylin.

Semi-quantitative and real-time PCR

We used PCR to assess expression levels of several $CD4^+CD25^+$ Treg-related genes. Total RNA was extracted from 5×10^5 sorted cells and purified using the RNeasy kit according to the manufacturer's instructions (Qiagen, Valencia, CA) and converted to cDNA by moloney murine leukemia virus (M-MLV) reverse transcriptase with oligo(dT) primer in the presence of RNAsin (Promega, Madison, WI). Semi-quantitative PCR for Foxp3, TGF-β_1, IL-10, CCR1, CCR5, CCR6, CCR7, and β-actin was performed as described previously[24-28]. The cDNA generated was subjected to 30-35 cycles of PCR amplification on a DNA thermal cycler (Perkin Elmer, GeneAmp PCR System). PCR was performed with specific primers for CCR4 and CCR8: CCR4 (forward, AGAGGCTCAAGTCCATGACG; reverse, AGTGTTGCAGAGTCCTAATG), and CCR8 (forward, CGGCATGCTACAATGTTTCC; reverse, TCTCTCCTATGAACGCGTAG). The β-actin served as a quantitative control for PCR. PCR products were fractionated by agarose gel electrophoresis, stained with ethidium bromide, and visualized under UV light.

Real-time PCR was performed on a LightCycler detection system (Roche Applied Science). Analyses were performed using primers, an internal fluorescent TaqMan probe specific to Foxp3 or HPRT, and the LightCycler TaqMan Master kit (Roche Applied Science, Penzberg, Germany). The primer and TaqMan probe sequences used as previously described[26] are as follows: *Foxp3* primers (5'-CCCAGGAAAGACAGCAACCTT-3' and 5'-TTCTCACAACCAGGCCACTTG-3'), Foxp3 probe (5'-FAM-ATCCTACCCACTGCTGGCAAATGG AGTC-3'), HPRT primers (5'-TGAAGAGCTACTGTA ATGATCAGTCAAC-3' and 5'-AGCAAGCTTGCA ACCTTAACCA-3'), HPRT probe (5'-FAM-TGCTTT CCCTGGTTAAGCAGTACAGCCC-3'). Standard curves of cDNAs from ICR mice $CD4^+CD25^+$ T cells were used as previously described[27]. The normalized values for Foxp3 mRNA were calculated as the relative quantity of Foxp3 mRNA levels divided by the relative quantity of HPRT mRNA levels. All samples were run in triplicate.

Statistical analysis

Results are expressed as mean ± SE. Because of time constraints involving the large number of antibodies and RNA analyses in this study, values were compared using the Mann-Whitney test for independent experiments. $P \leqslant 0.05$ was considered statistically significant.

RESULTS

Depletion of $CD4^+CD25^+$ Tregs reduced growth of tumor nodules in BaP-treated mice

A total 65 mice used in this study were divided into corn oil control (n = 14), BaP-only (n = 9), BaP + IgG (n = 19), and BaP + PC61 (n = 19) groups. To prove the effect of a short course treatment with PC61, 4 mice in the BaP + PC61 only group received 5 wk of PC61 injection before sacrifice. The tumor incidence was 100% in the forestomach of BaP-treated mice at weeks 16, 24, and 32, respectively. There was no difference in tumor incidence, growth and pathological alternation between the BaP-only and BaP + IgG-treated mice. Formation of some small rash-like tumor nodules and more significant tumor nodules was observed in the forestomach at weeks 16 and 32, respectively (Figure 1B and E), but no tumor growth was detected in the forestomachs of mice in the corn oil control group (Figure 1A and D). Typical pathological alternations in tumor nodules, including papilloma and squamous cell carcinomas, were observed, but few lymphocytes and granulocytes accumulated in and around the tumor nodes (Figure 2B and E). The number of tumor nodules, both papilloma and squamous cell carcinoma, significantly increased in this period (Table 1).

The constituted number of $CD4^+CD25^+$ T cells in PLNs, spleen, and thymus of naïve mice after depletion by PC61 was maintained at less than 1% (Figure 3A and C). These naïve mice treated with PC61 mAb did not develop histologically evident autoimmunity. After a short-course treatment with PC61 for 5 wk, the tumor volume decreased significantly by as much as 60% in individual mice of BaP + PC61 group at week 16 (Table 1). The effect of a long-course treatment, until sacrifice, was more significant. The forestomach tumor growth was more

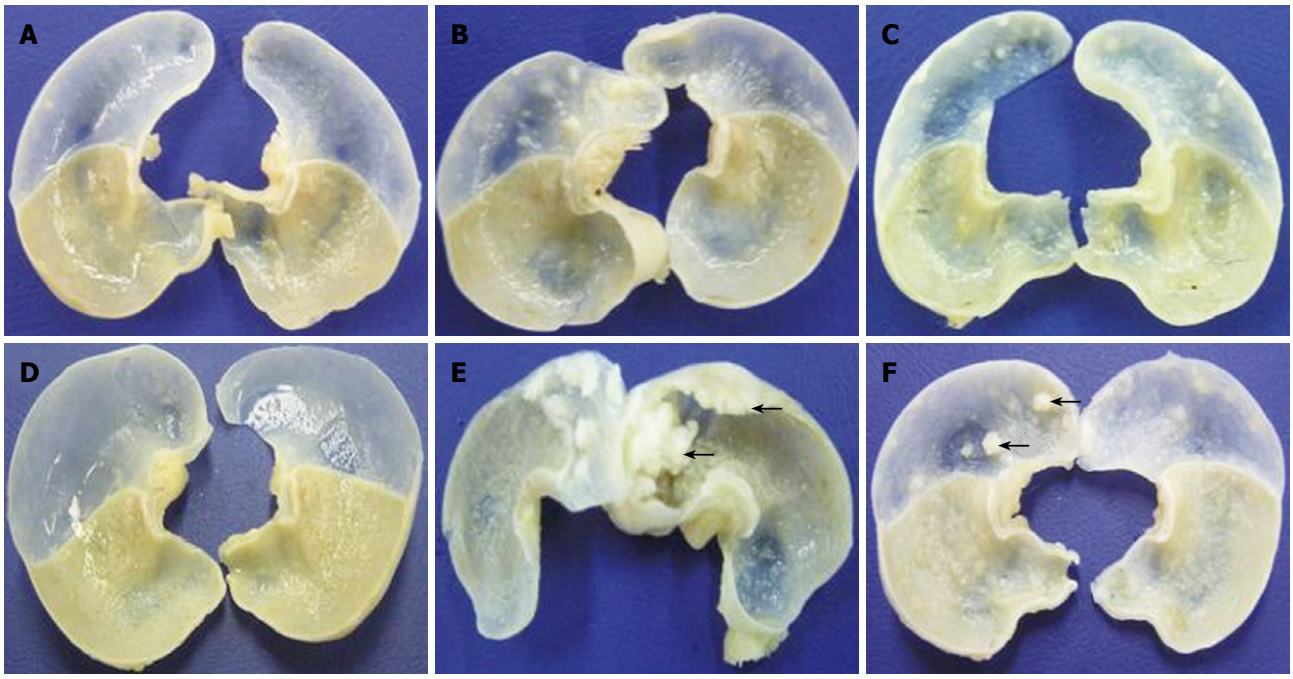

Figure 1 Forestomach tumors (arrow) in BaP-treated mice with/without depletion of Tregs. Mice were sacrificed at wk 16 (**A**-**C**) and wk 32 (**D**-**F**) after the first administration of benzo[a]pyrene (BaP) in control mice (**A** and **D**), BaP + IgG-treated mice (**B** and **E**), and BaP + PC61-treated mice (**C** and **F**). After depletion of Tregs by PC61, the size and volume of forestomach carcinoma reduced significantly.

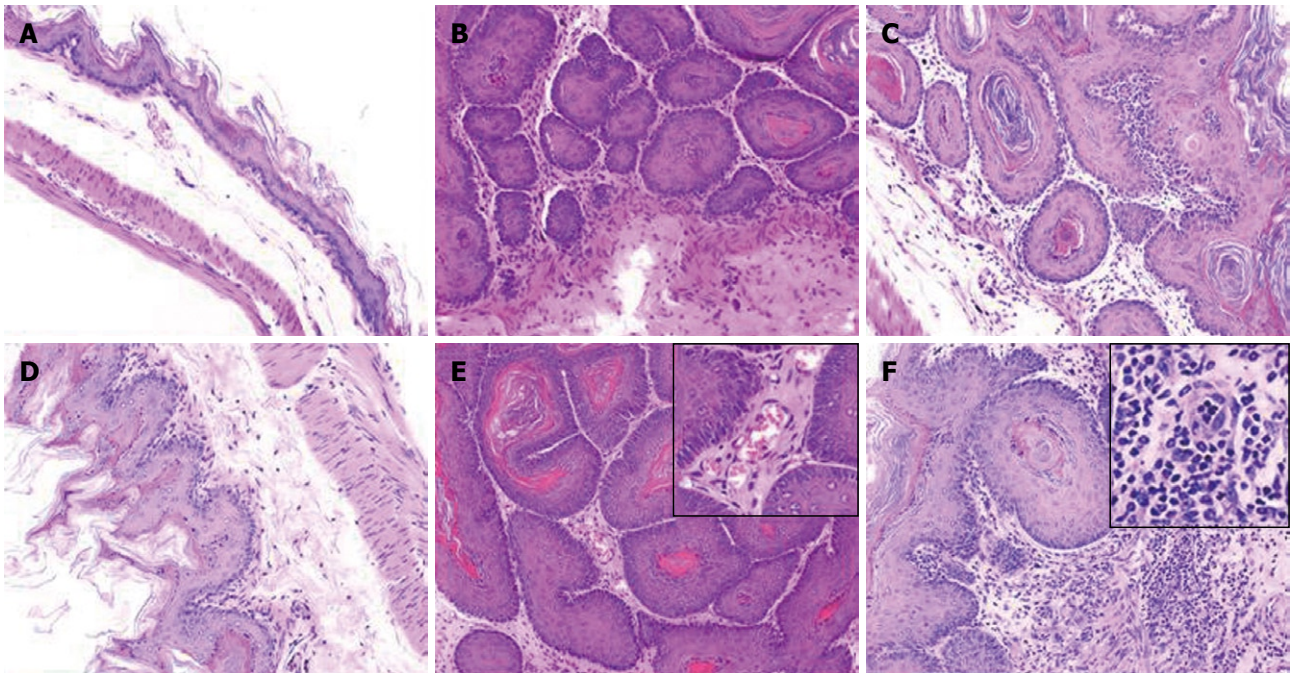

Figure 2 Histology of forestomach carcinoma in mice. Mice were sacrificed at wk 16 (**A**-**C**) and wk 32 (**D**-**F**) with their stomachs excised. The number of squamous cell carcinomas was increased in BaP + IgG-treated (**B**, **E**) and BaP + PC61-treated mice (**C**, **F**). However, there was a significant infiltration of lymphocytes and granulocytes into tumors of BaP + PC61-treated mice (**F**, inset). **A** and **D**: control mice; **B** and **E**: BaP + IgG-treated mice; **C** and **F**: BaP + PC61-treated mice.

progressively reduced (Figure 1C and E), and the tumor volume decreased by as much as 80% per mouse in comparison to the mice in the BaP + IgG group at weeks 16 and 32, respectively (Table 1). A significant increase in infiltration of lymphocytes and granulocytes at the tumor sites in mice of the BaP + PC61 group was also observed upon histological examination (Figure 2C and F).

Depletion of CD4$^+$ CD25$^+$ Tregs enhanced host anti-tumor immunity

We further investigated whether depletion of $CD4^+CD25^+$ Tregs increases host anti-tumor immunity, using apoptosis as a marker. After depletion using PC61, the portion of $CD4^+CD25^+$ Tregs in $CD4^+$ and $CD8^+CD25^+$ in $CD8^+$ was significantly decreased, the tumor infiltrating lymphocytes (TILs) were significantly

increased in the nodules (Figure 4A), and the fraction of $CD4^+$ (3.90% ± 0.99%) and $CD8^+$ (2.25% ± 0.21%) cells in TILs was also observed in mice of the BaP + PC61 group at week 32 (Figure 4B). The tumor size and volume were decreased, and massive apoptotic cells were observed in the forestomach tumors of mice in the BaP + PC61 group (Figure 5C and F), but rare apoptotic cells were found in the tumor mass of mice in the BaP + IgG group at weeks 16 and 32 (Figure 5B and E). The effect of depletion of $CD4^+$ $CD25^+$ Tregs is summarized in Table 2.

$CD4^+CD25^+$ Tregs increased in RLNs responsible for local immune surveillance

To elucidate whether $CD4^+CD25^+$ Tregs are responsible for local immune surveillance during tumor growth, the population of $CD4^+CD25^+$ Tregs in different lymphoid organs was analyzed. The RLNs in mice of the BaP-only group had a significantly higher proportion of $CD4^+CD25^+$ Tregs at weeks 7, 16, and 32, respectively (9.26% ± 1.56%, 9.61% ± 0.52%, 5.09% ± 2.03%) than in mice of the control group (3.72% ± 0.83%, 3.07% ± 1.52%, 2.45% ± 0.70%). The population of total $CD4^+$ Tregs at weeks 7, 16 and 32 (13.51% ± 2.21%, 17.63% ± 2.62%, 9.36% ± 4.75%) was also significantly higher than that in mice of the control group (5.57% ± 1.79%, 5.73% ± 2.95%, 4.51% ± 1.15%) (Figure 6A). The proportion of total $CD4^+$ Tregs (6.42% ± 0.59% and 10.96% ± 0.28%, respectively) in the PLNs of mice of the BaP-only group was significantly higher than that in mice of the control group (3.50% ± 1.11%; 5.52% ± 1.78%, respectively) at week 16 (Figure 6B). In spleen, the proportion of Tregs in total $CD4^+$ T cells was significantly higher at weeks 7 and 32 (Figure 6C). However, a difference in Treg distribution was not observed in thymus (Figure 6D).

The population of $CD8^+CD4^+$ Tregs in different lymphoid organs was also analyzed. The RLNs in mice of the BaP-only group had a significantly higher proportion of $CD8^+CD25^+$ Tregs at weeks 7, 16 and 32, respectively (1.68% ± 0.28%, 5.24% ± 1.90%, 1.14% ± 0.29%) than those in mice of the control group (1.93% ± 0.34%, 0.65% ± 0.36%, 0.46% ± 0.20%). The population of $CD8^+CD25^+$ in total $CD8^+$ T cells at weeks 7, 16, and 32 (9.36% ± 0.52%, 18.54% ± 4.48%,

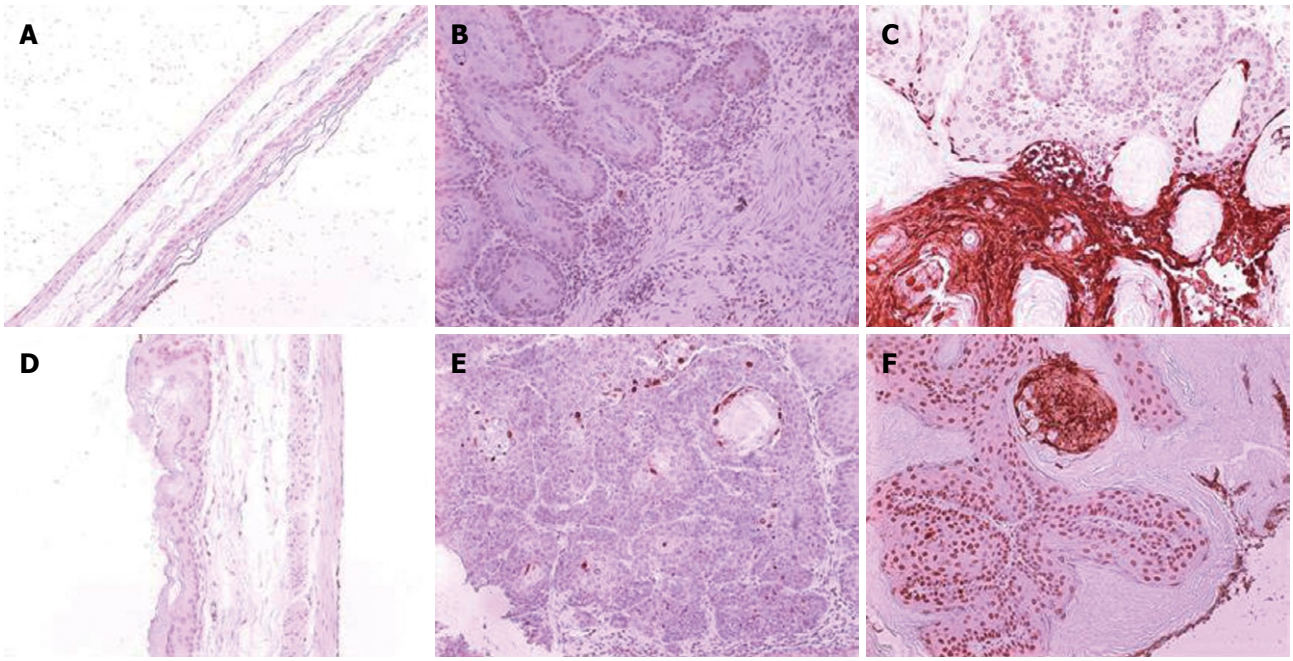

Figure 5 Apoptotic cells in forestomach tumors. Apoptotic cells were detected by TUNEL-staining as described in Materials and Methods. Apoptotic cells were revealed by a brown color. Stomach tumor nodules of mice were surgically obtained at wk 16 (**A**-**C**) and wk 32 (**D**-**F**) after the first administration of BaP. Significant apoptotic cells were found at wk 32 in BaP + PC61-treated mice. **A** and **D**: Control mice; **B** and **E**: BaP+IgG-treated mice; **C** and **F**: BaP + PC61-treated mice.

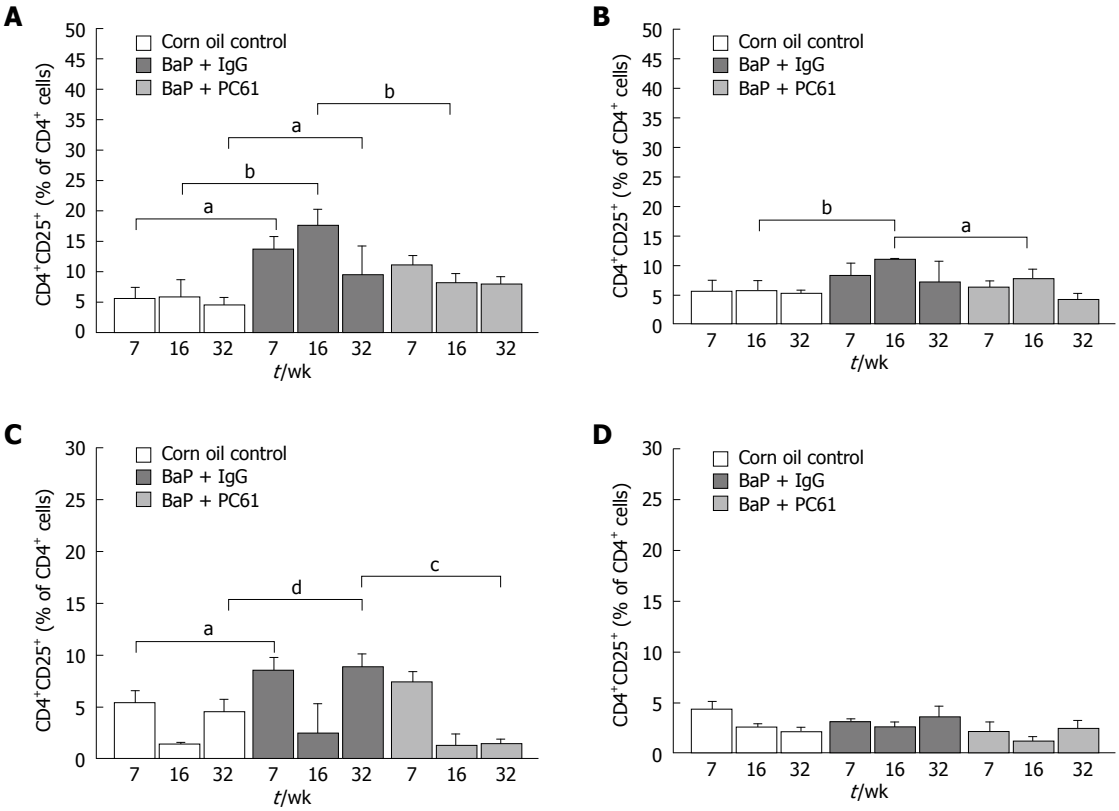

Figure 6 $CD4^+CD25^+$ T cells in distinct microenvironments. Lymphocytes in RLNs (**A**), PLNs (**B**), spleen (**C**), and thymus (**D**) were double-stained with FITC-anti-CD25 and PE-anti-CD4 mAbs and quantified by flow cytometry in the control, BaP + IgG-treated, and BaP + PC61-treated mice at wk 7, wk 16, and wk 32. $^aP < 0.05$, $^bP < 0.01$, $^cP < 0.005$, $^dP < 0.001$ *vs* the control mice.

6.74% ± 2.24%) was also significantly higher in mice of the BaP-only group than in mice of the control group (11.98%± 0.13%, 4.49% ± 1.91%, 2.82% ± 1.32%). The proportion of $CD8^+CD25^+$ and $CD8^+CD25^+$ in total $CD8^+$ T cells in the PLNs of mice of the BaP-only group at weeks 7, 16, and 32, respectively, was significantly higher in mice of the BaP-only group than in mice of the control group (data not shown). In

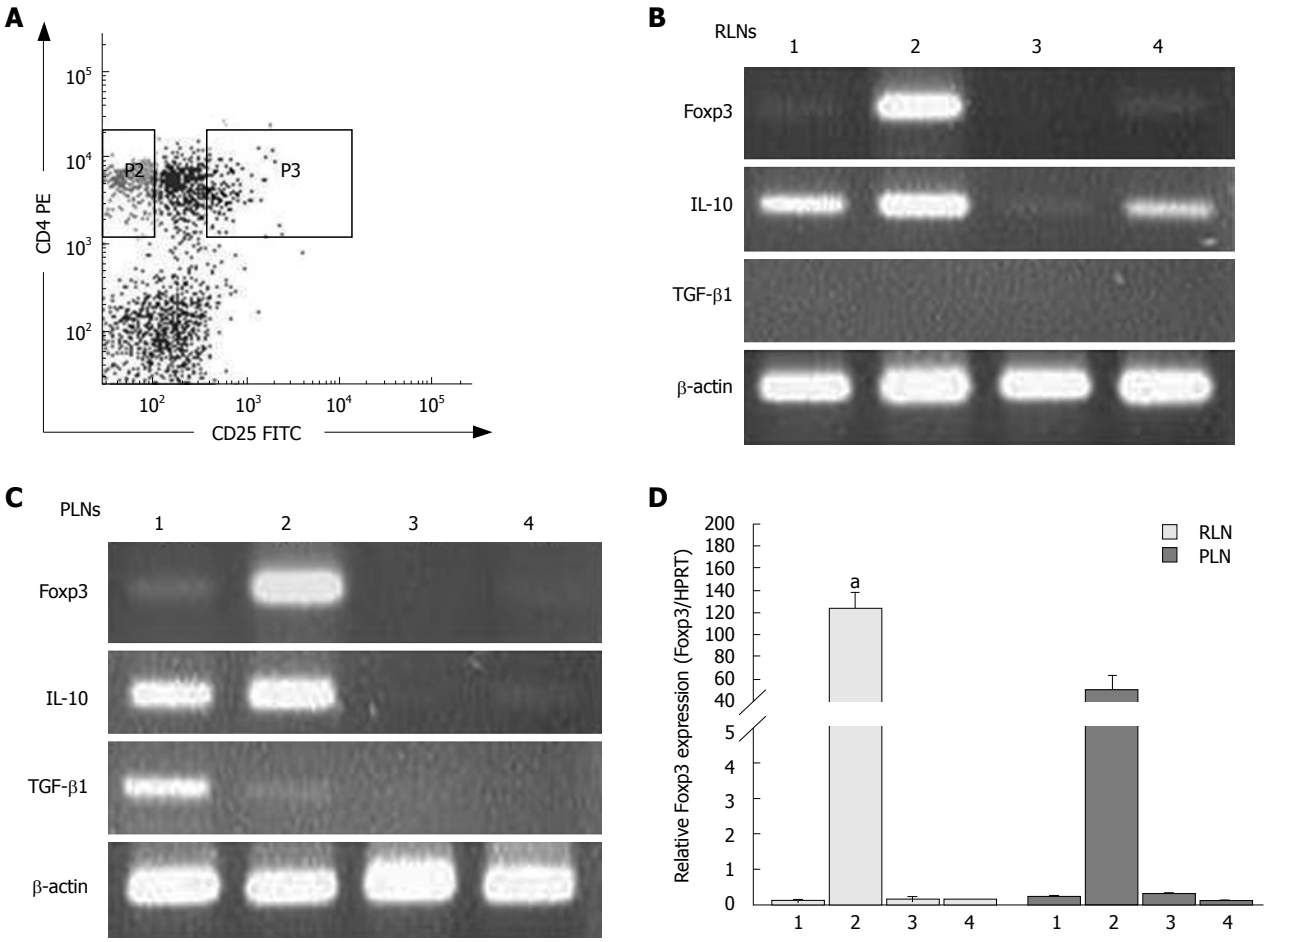

Figure 7 $CD4^+CD25^+$ T cells express high levels of Foxp3 transcripts in RLNs and PLNs of $CD4^+CD25^-$ (P2) and $CD4^+CD25^+$ (P3) T cells (**A**) which were sorted and stained with FITC-anti-CD25 and PE-anti-CD4 mAbs, and of Foxp3, IL-10, TGF-β1, and β-actin mRNA in $CD4^+CD25^+$ and $CD4^+CD25^-$ cells of RLNs (**B**) and PLNs (**C**) in BaP-only-treated and control mice at wk 32 using RT-PCR (Lanes 1 and 2: BaP-only-treated mice; Lanes 3 and 4: control mice; Lanes 1 and 3: $CD4^+CD25^-$ cells; Lanes 2 and 4: $CD4^+CD25^+$ cells), as well as of relative Foxp3 from $CD4^+CD25^-$ and $CD4^+CD25^+$ T cells using real-time quantitative PCR after normalization to HPRT expression (**D**). $^aP < 0.05$ *vs* control mice.

spleen, the proportion of $CD8^+CD25^+$ and $CD8^+CD25^+$ in total $CD8^+$ T cells was significantly higher in mice of the BaP-only group than in mice of the control group at wk 32 (0.75%± 0.14% and 12.99% ± 1.87% *versus* 0.20% ± 0.07% and 3.74% ± 1.40%). However, no difference in $CD8^+CD25^+$ distribution was observed in thymus.

The population of $CD4^+$T cells and the pattern of surface expression for CD3 in RLNs, PLNs, spleen, and thymus was consistent among the corn oil control, BaP + IgG, and BaP + PC61 groups at weeks 7, 16 and 32 (data not shown), revealing that the increased proportion of Tregs and $CD8^+CD25^+$ in the RLNs of BaP-treated mice may be responsible for local immune surveillance during progression of forestomach tumors.

Inducible $CD4^+CD25^+$ Tregs in RLNs suppressed local immunity via secretion of IL-10

Foxp3 is a crucial transcription factor and the specific marker for inducible $CD4^+CD25^+$ Tregs. After enumeration of isolated $CD4^+CD25^+$ (combined $CD25^{int}$ and $CD25^{high}$-expressing cells) and $CD4^+CD25^-$ T cells within RLNs and PLNs (Figure 7A), the expression of Foxp3 in $CD4^+CD25^+$ Tregs and $CD4^+CD25^-$ t cells in the RLNs and PLNs of mice in the BaP-only and corn oil control groups was examined. As expected, $CD4^+CD25^+$ Tregs in the RLNs and PLNs expressed high levels of Foxp3, while $CD4^+CD25^-$ T cells expressed very low levels in mice of the BaP group (Figure 7B and C). Furthermore, the Foxp3 transcripts of $CD4^+CD25^+$ Tregs in RLNs of mice of the BaP group were significantly higher than those in PLNs of mice of the BaP group at wk 32 (Figure 7D).

We further analyzed whether the $CD4^+CD25^+$ Tregs or $CD4^+CD25^-$ T cells in the RLNs and PLNs can produce immunosuppressive cytokines. The two types of T cells in the RLNs and PLNs of the BaP-only treated mice enhanced the expression of IL-10 at transcription levels at wk 32 (Figure 7B and C), but only the $CD4^+CD25^+$ Tregs in the RLNs of mice in the control group expressed low-level IL-10 transcripts at wk 32 . The Tregs in the RLNs and PLNs of mice in the BaP-only and control groups produced few or no IL-10 transcripts at weeks 7 and 16 (data not shown). Regarding the TGF-β1 transcripts, the RLNs and PLNs in mice of the BaP-only and control groups were negative at weeks 7, 16, and 32, and only the $CD4^+CD25^-$ T cells from the PLNs in week of the BaP-only group produced low levels of TGF-β1 transcripts

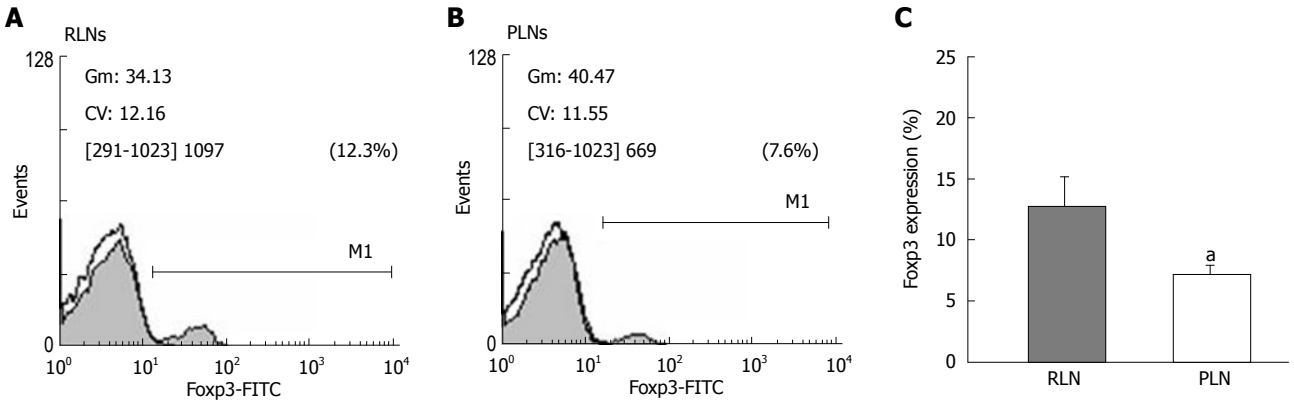

Figure 8 Expression of Foxp3 protein of RLNs (**A**) and PLNs (**B**) in BaP-only-treated mice at wk 32 and quantified by flow cytometry (**C**). Foxp3 expression was determined as described in Materials and Methods. The histogram demonstrates FITC-conjugated Foxp3 staining (solid peak) and isotype control (hollow peak). $^{a}P < 0.05$ *vs* control mice.

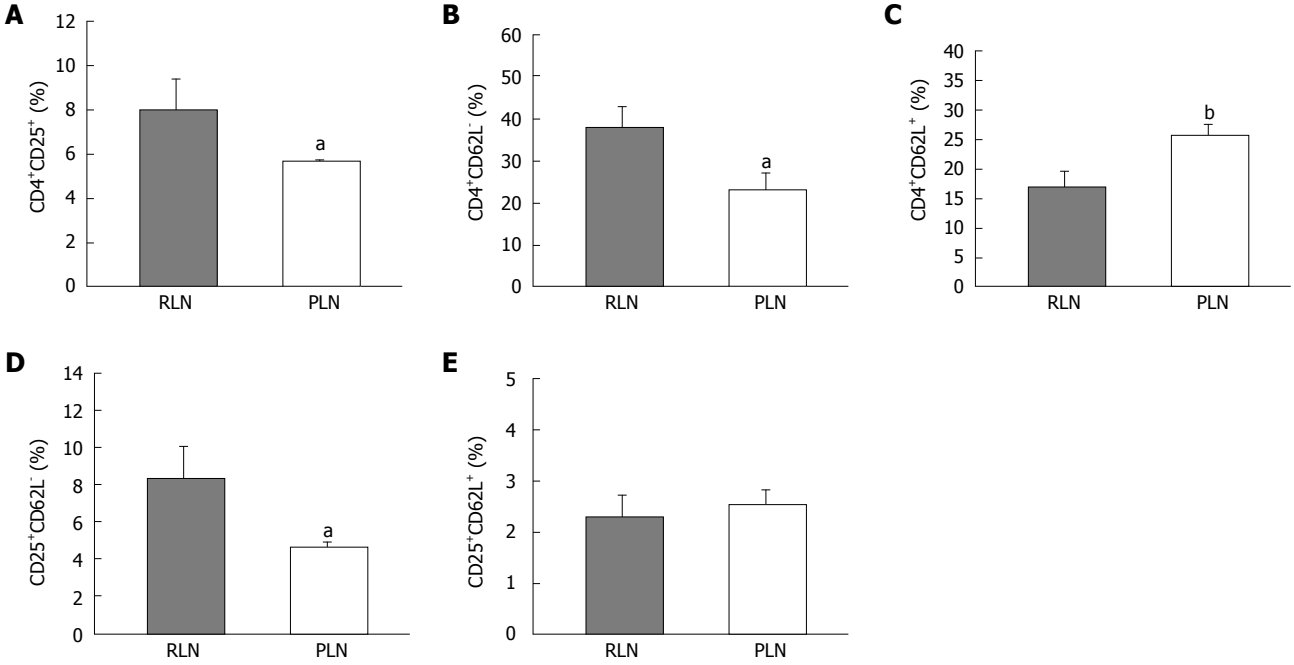

Figure 9 Surface expression of $CD4^{+}CD25^{+}$ (**A**), $CD4^{+}CD62L^{-}$ (**B**), $CD4^{+}CD62L^{+}$ (**C**), $CD25^{+}CD62L^{-}$(**D**), and $CD25^{+}CD62L^{+}$ (**E**) in RLNs and PLNs of BaP-only-treated mice at wk 32. $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* control mice.

at week 32 (Figure 7B and C).

To confirm the difference in the proportion of Tregs between RLN and PLN, we analyzed the expression of Foxp3 by flow cytometry (Figure 8A and B). The expression of Foxp3 in lymphocytes of RLNs was significantly higher than that in lymphocytes of PLNs of BaP-only-treated mice at week 32 (Figure 8C), suggesting that activation of inducible $CD4^{+}CD25^{+}$ Tregs is associated with tumor formation and that $CD4^{+}CD25^{+}$ Tregs secrete IL-10 but not TGF-β1, as a mediator for local inhibition of host immune functions during tumor progression.

Loss of expression of CD62L protein on Tregs of RLNs

The down-regulation of expression of L-selectin (CD62L) on the cell surface depends on cell activation. Loss of CD62L expression is a useful indicator for T cell maturation or terminal differentiation. The RLNs had a significantly higher proportion of Tregs than the PLNs (Figure 9A). The percentage of $CD4^{+}CD62L^{-}$ cells in RLNs was higher than that in PLNs of mice in the BaP-only group at week 32 (Figure 9B), and the percentage of $CD4^{+}$ $CD62L^{+}$ cells in PLNs, belonging to the naïve pool, was higher than that in RLNs (Figure 9C). Furthermore, the percentage of $CD25^{+}CD62L^{-}$ cells in RLNs was significantly higher than that in PLNs, but there was no difference in $CD25^{+}CD62L^{+}$ between RLNs and PLNs (Figure 9D and E), indicating that more Tregs in the RLNs are at the activation stage.

Expression of CCR1 and CCR5 transcripts in Tregs of RLNs

Because chemokine receptors are important for T cell migration to lymph nodes, the expression of these

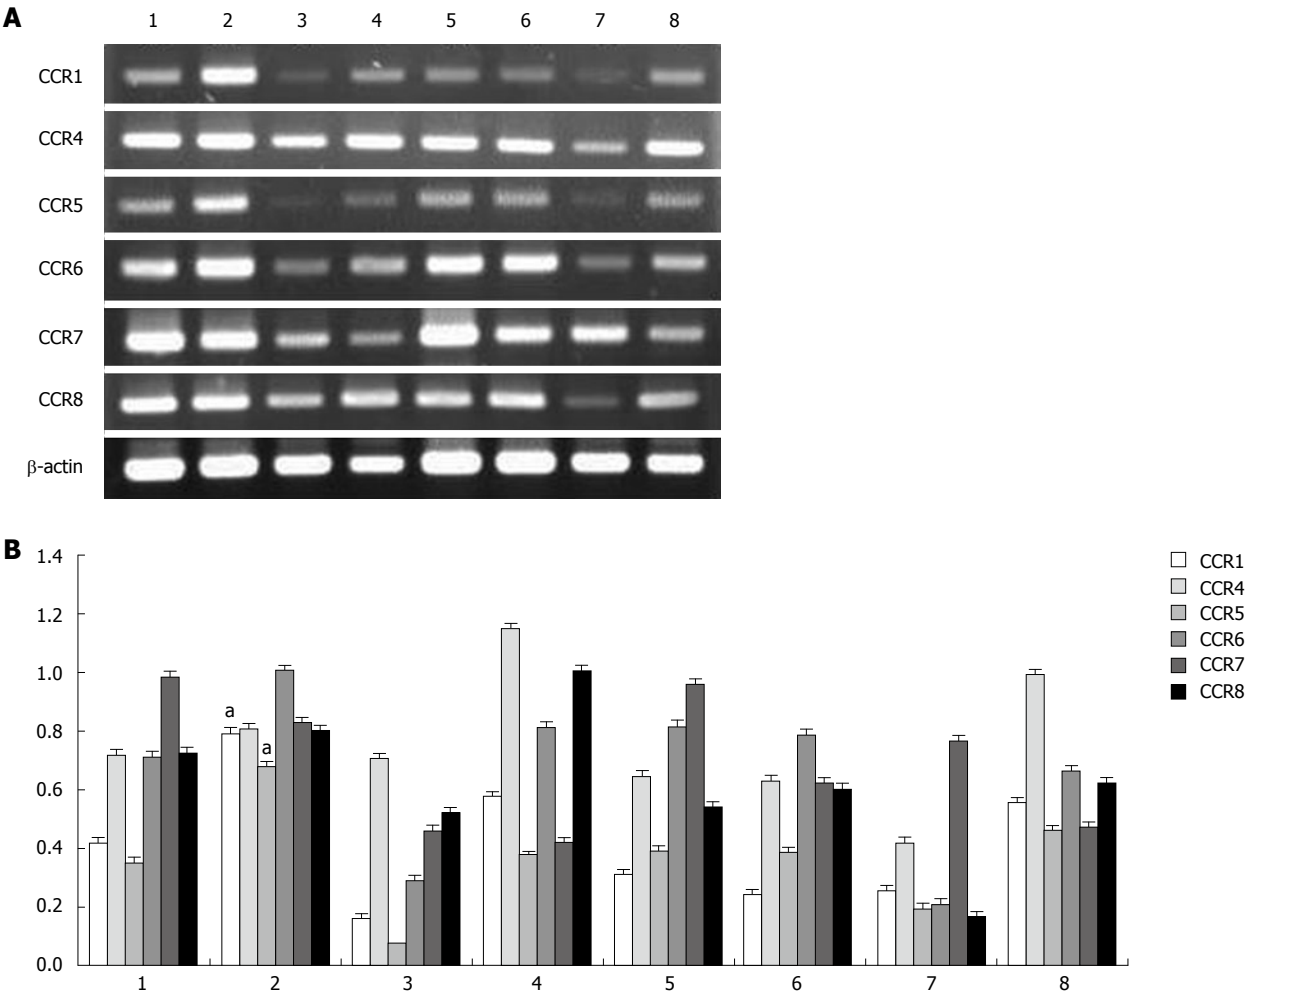

Figure 10 PCR analysis of chemokine receptor transcripts in $CD4^+CD25^-$ and $CD4^+CD25^+$ cells (**A**). CCR1, CCR4, CCR5, CCR6, CCR7, CCR8, and β-actin mRNA expression of $CD4^+CD25^-$ cells (lanes 1, 3, 5, 7) and $CD4^+CD25^+$ (lanes 2, 4, 6, 8) in RLNs (lanes 1-4) and PLNs (lanes 5-8) in BaP-only (lanes 1, 2, 5, 6) and control (lanes 3, 4, 7, 8) mice at 32 wk using RT-PCR. Relative expression of chemokine mRNA was compared (**B**). $CD4^+CD25^+$ cells expressed significantly higher levels of CCR1 (a) and CCR5 (a) mRNA. a: $P < 0.05$

receptors might distinguish the characteristics of $CD4^+$ cell subsets of RLNs and PLNs. To distinguish which factor attracts Tregs migration to RLNs, the expression of CCR1, CCR4, CCR5, CCR6, CCR7, and CCR8 transcripts in purified $CD4^+CD25^+$ and $CD4^+CD25^-$ T cells of RLNs and PLNs was analyzed. According to the results of RT-PCR, $CD4^+CD25^+$ T cells of RLNs specifically expressed a higher level of CCR1 and CCR5 mRNA in mice of the BaP-only group at week 32 (Figure 10). Both $CD4^+CD25^+$ and $CD4^+CD25^-$ T cells of RLNs and PLNs in mice of the BaP-only group exhibited a high expression of CCR4, CCR6, CCR7, and CCR8 mRNA. These results suggest that Tregs of RLNs in the forestomach tumors might possess a unique chemotactic profile for migration of Tregs, which is responsible for local immune suppression during tumor progression.

DISCUSSION

Gastric cancer is one of the most common cancers in the world, and lymph node metastasis is the strongest determinant of patient survival. There are many submucosa-associated lymphoid tissues responsible for immunosurveillance in the gastrointestinal tract. An increase in Tregs has been correlated with immunosuppression and tumor progression in patients with gastrointestinal cancers[4]. So far, there is no evidence that addresses changes in Tregs of lymph nodes at the initial stage of gastric cancer development in human beings or animals. In this study, we clearly demonstrated that the proportion of Tregs increased in the RLNs during tumor progression in BaP-induced mouse forestomach carcinoma. These Tregs significantly displayed enhanced expression levels of Foxp3 mRNA and protein and down-regulation of CD62L, and exhibited a unique chemotactic receptor profile, including high CCR1 and CCR5 mRNA levels, for migration to inflammation sites. These inducible Tregs also expressed high levels of IL-10 for inhibition of host immunity. After depletion of Tregs, the tumor volume decreased, and more infiltrating and apoptotic cells in the tumors were found. Our results indicate that Tregs in RLNs may suppress local host immune response during tumor progression.

Tregs are known to be immunoregulatory, and play an important role in immunological tolerance to self-

antigens and in inhibition of T-cell proliferation[2,29-32]. These observations demonstrate that Tregs are involved in immune dysfunction of cancer patients. Sutmuller *et al*[20] demonstrated that Treg depletion enhances T-cell reactivity to a known tumor-associated antigen. However, depletion of Tregs alone is not sufficient to treat any established cancer. In most of the relevant studies, anti-CD25 mAb was administered to deplete Tregs several days prior to tumor implantation or only 1 day afterwards[19,20,23,33-36]. In this study, although the $CD25^+$ cells in lymph nodes were not completely depleted, forestomach tumor growth was still remarkably reduced, suggesting that increased Tregs in tumor-draining lymph nodes inhibit host local immune response during tumorigenesis. A consecutive course of depleted-antibody injections, for mice without histologically proven autoimmune disease, is sufficient to cause regression of the tumors. It was reported that depletion of $CD25^+$ cells in tumor models could reduce tumor growth as I in our study[37].

Previous studies have shown that Tregs could suppress T cell priming in lymph nodes[30,38,39]. Depletion of Tregs could enhance T cell sensitization in tumor-draining lymph nodes and increase generation of specific immune T cells, and depletion of $CD25^+$ T cells could facilitate infiltration of $CD8^+$ T cells at tumor sites[19,23]. The Tregs are probably the main subset of $CD4^+$ T cells responsible for the observed enhancement of tumor growth[40]. These studies suggest that removal of Tregs can generate tumor-specific CD8 T cells and tumor-nonspecific $CD4^-CD8^-$ effector cells *in vivo*. In this study, Tregs were more abundant in RLNs around the forestomach carcinoma. After depletion, the number of Tregs in the RLNs decreased significantly, more granulocytes, $CD4^+$, and $CD8^+$ cells infiltrated into the tumors, and massive apoptotic cells were found in the tumor mass, proving that Tregs in the RLNs are strongly associated with tumor growth, and that depletion of Tregs can promote effective local tumor-specific immune responses.

Adhesion molecules (such as CD62L) and chemokine receptors are involved in lymphocyte trafficking. Tregs can be subdivided into different functional subsets based on the expression of CD62L. Loss of CD62L expression in Tregs could result from selective migration to forestomach cancer and accumulation at the tumor nodules or in draining lymph nodes after stimulation and activation. Iellem *et al*[40] reported that Tregs specifically express the chemokine receptors CCR4 and CCR8. Bystry *et al*[41] reported that Tregs express CCR5 and respond to the CCL4 ligand, and CCL4 is the most potent chemokine for Tregs. Chemokine receptor CCR1 and its two ligands, CCL5 and CCL7, or CCR5 and its ligand CCL4 may be involved in regulating the trafficking of Tregs. In this study, the expression profile of adhesion molecule and chemokine receptors differed from that of the RLN and PLN Tregs. There were more activated (CD62L negative) Tregs in RLNs, and these Tregs highly expressed the chemokine receptors CCR1 and CCR5, suggesting that a higher expression of CCR1 and CCR5 in activated Tregs may allow their migration toward RLNs or the tumor area to suppress local host immunity.

The above results highly suggest that, during tumor progression, tumor cells may recruit Tregs via a specific subset of chemokines and their receptors to control local host anti-tumor immunity. It is conceivable that it may be advantageous to use antibodies or fusion proteins to reduce the action of Tregs at the local sites in combination with chemoprevention drugs to gain the maximal benefit during treatment of gastric cancer, even though we did not perform functional inhibition studies of Treg cells on host cytotoxic cells. Chen *et al*[42] have induced apoptosis of Tregs in a lymphoma animal model using intratumorally injecting FasL protein to deplete Tregs in the tumor and tumor-draining lymph nodes. Viehl *et al*[43] have also depleted Tregs by intraperitoneal injection with PC61 three times a week, in combination with tumor vaccine. After depletion, the tumor-specific immune response was significantly increased in tumor-draining lymph nodes. Their results are consistent with our studies.

In conclusion, increased Tregs in draining regional lymph nodes suppress host local immunity during tumor growth and depletion of Tregs can promote host local immunity to prevent tumor progression, implying the significance of lymph node dissection in surgery for gastric cancer.

COMMENTS

Background

$CD4^+CD25^+$ regulatory T cells (Tregs) are correlated with the prognosis of malignant tumors and can compromise host immunity surveillance to cancer. Accumulation of Tregs in the drained lymph nodes may reduce host local immunity against gastric cancer. The role of Tregs in the drained lymph nodes was elucidated during cancer development was elucidated in this study.

Research frontiers

Lymph node metastasis is the key factor for prognosis of gastric cancer patients. Lymph node dissection is the radical gastrectomy for gastric cancer, but it is a highly technique-demanding surgery. Intraperitoneal treatment with monoclonal antibody to deplete Tregs in the drained lymph nodes might assist in increasing the curative effect on gastric cancer.

Innovations and breakthroughs

The high incidence of lymph node metastasis is still the milestone of the prognosis of gastric cancer. Decreased host local immunity surveillance might be the determinative for lymph node metastasis. The study established mouse for stomach carcinoma by garage with benzo[a]pyrene (BaP). Then, the mice received anti-CD25 treatment. The results clearly demonstrate that depletion of Tregs with anti-CD25 antibody could decrease Tregs distributed in drained lymph nodes, increase local immune cell infiltration in tumor and reduce tumor growth. This is the first successful treatment of solid tumor with monoclonal antibody to deplete Tregs in mice, thus laying an experimental foundation of development of drugs for treatment of cancer.

Applications

Intraperitoneal injection of anti-CD25 monoclonal antibody is a promising therapeutic approach to forestomach carcinoma. The results implicate that anti-CD25 therapy could be used as a chemoprevention modality for malignan tumors and a local immunity therapy for gastric cancer.

Peer review

The authors of this paper showed that depletion of Tregs can decrease growth of tumor in an animal model of forestomach carcinoma. The study was well designed and its findings are interesting and informative.

Abstract

AIM: To study the inhibitory effect of baculovirus-mediated normal epithelial cell specific-1 (*NES1*) gene therapy on gastric cancer (GC) *in vitro* and *in vivo*.

METHODS: We first constructed recombinant baculovirus vectors and then transfected them into gastric cancer cells (SGC-7901). Efficiency of the baculovirus for gene transfer into SGC-7901 cells and cell growth curves were detected by fluorescence microscopy, Western blot and 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay *in vitro*, respectively. The therapeutic effect of this gene therapy on GC was confirmed in xenografted nude mice. Tumor growth was determined by tumor volume, and expression of NES1 in tumor was analyzed by immunohistochemistry.

RESULTS: Baculovirus vectors were successfully transfected into SGC-7901 cells. SGC-7901 cells transfected with the *NES1* gene inhibited cell growth. In the Bac-NES1 treated group, tumor growth was significantly reduced with a high level of NES1 expression

CONCLUSION: Baculovirus-mediated *NES1* gene can be used in gene therapy for GC.

Key words: Gastric cancer; Normal epithelial cell specific-1 gene; Baculovirus; Gene therapy

INTRODUCTION

Gastric cancer (GC) remains one of the most common cancers and a major cause of cancer-related death worldwide. To date, tumor resection has remained the only curative therapy for GC. Since radiotherapy and chemotherapy have no significant therapeutic effect on GC, new therapeutic strategies are required[1]. Gene therapy represents an interesting alternative treatment for cancers, and a number of studies have demonstrated that gene therapy can effectively reduce tumor growth in animal models[2]. Studies aimed at probing the genetic changes that occur in GC have identified several genes as potential targets of gene therapy for GC[3]. Our previous study suggested that normal epithelial cell specific-1 (*NES1*) gene functions as a tumor suppressor gene in GC and contributes to the malignant progression of GC providing us a promising gene target of gene therapy[4].

The design of vectors for specific gene transfer is a major challenge in medical research. Viral vectors are the most efficient tools for genetic modification of the majority of somatic cells *in vitro* and *in vivo*[5]. Recombinant baculoviruses with a mammalian expression promoter have recently been viewed as a new generation of gene therapy vehicles holding a great promise[6,7]. The baculovirus genome is large and thus large transgenes can be accommodated. In addition, they are easy to scale up and obtain high levels of recombinant gene expression[8]. However, despite a good understanding of all these attractive features of baculovirus, gene therapy with the virus is still in its

infancy, and no practical application in cancer therapy, even in preclinical animal studies, has been reported[9]. In the present study, we developed a recombinant baculovirus vector encoding the *NES1* gene and tested whether intratumoral administration of *NES1* gene has anti-tumor activity in GC models of mice. Our results indicate that GC cells (SGC-7901) are permissive to baculovirus infection and baculovirus-mediated *NES1* gene can be used in the treatment of GC.

MATERIALS AND METHODS

Construction of recombinant vector

Baculovirus plasmid pFBGFPR was a gift from the Institute of Molecular Biology of Hong Kong University. pCMV-NES1 was a gift from Dr. Vimla Band from Division of Cancer Biology, Department of Radiotherapy, New England Medical Center. Recombinant baculoviruses were generated and propagated in spodoptera frugiperda (Sf-9) insect cells by a Bac-to-Bac system according to the standard manual (Invitrogen). Once the viruses were amplified in Sf-9 insect cells, GFP expression was observed under a fluorescent microscope for the CMV promoter activity in these cells. The viruses were amplified to a high titer by propagation in Sf-9 cells and stored in small aliquots at -80℃. Viral titers were determined by plaque assay on Sf-9 insect cells.

Cell line culture and incubation with the vector

SGC-7901 cells were preserved in our laboratory and maintained in RPMI 1640 with 10% FBS. Sf-9 cells were cultured at 27℃ in a spinner culture bottle containing Sf900Ⅱ (Gibco) supplemented with 10% FBS. SGC-7901 cells were plated at a density of 10^5 cells per well in 24-well plates. After 1 d, culture was infected with different multiplicities of infection (MOI) of Bac-GFP, which was defined as the number of virus particles per cell for 1 h. The viruses were then removed, and a fresh medium was added to the wells. Twenty-four hours after transduction, the culture was examined for GFP expression by fluorescence microscopy, and photos were taken with a Nikon coolpix990 digital camera. High levels of GFP expression could be detected in SGC-7901 cells transduced with Bac-GFP. The morphological characteristics and growth of SGC-7901 cells were normal during experiment.

Western blot analysis

Cell lysates were made with standard methods. The protein concentration of each sample was measured using a BCA kit. For SDS-PAGE, 20 μg of protein samples was loaded on 10% polyacrylamide gels. Proteins were transferred to a polyvinylidene difluoride membrane with a tank transfer system (Bio-Rad Laboratory), then blocked with a buffer containing 5% low fat skim milk and 0.1% Tween-20 in Tris-buffered saline (TBST) at room temperature for 1 h. Primary antibodies were diluted in TBST containing 5% skim milk. The membrane was incubated with primary antibodies overnight at 4℃. After washed three times with TBST, the membrane was incubated with a horseradish peroxidase-conjugated secondary antibody (0.02 μg/mL in TBST) for 1 h at room temperature. Chemiluminescence was detected with an ECL Western blot detection kit (Amersham, Little Chalfont, UK) according to its manufacturer's instructions.

Proliferation assay of SGC-7901 cells

SGC-7901 cells were grown in RPMI 1640 medium containing 10% fetal serum. For cell growth measurement, 2×10^3 cells were reseeded into 96-well plates and incubated at 37℃ in 100 mL/L CO_2 for 24 h. The media were then replaced with 0.2 mL of RPMI 1640/10% FBS, and the test sample (Bac-NES1, Bac-GFP or PBS) was applied. The number of SGC-7901 cells was quantified by colorimetric 3,-(4,5-dimethylthiazole-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) assay with a minor modification, as previously described. The proliferation assay was repeated at least three times.

In vivo tumor xenograft studies

Inhibitory effect of the *NES1* gene on tumor growth was observed in xenografted nude mice with GC. Male athymic nude mice (Balb/c nude mice) at the age of five weeks were obtained from Shanghai Experimental Animals Centre of Chinese Academy of Sciences and had free access to sterilized food and autoclaved water. A suspension of SGC-7901 cells (1×10^7 cells in 0.2 mL PBS) was injected subcutaneously into the dorsal flank of each mouse. As the tumor grew larger, it was cut into small even pieces and replanted into the dorsal flanks of each mouse. Tumors were grown in mice to more than passage three. When the tumors were palpable, the mice were randomly divided into three groups (10 in each group). Mice in the two experimental groups were injected with 4×10^8 pfu baculoviruses containing the *NES1* gene (Bac-NES1) and PBS gene, respectively, directly into the tumors every three days. Mice in the control group were injected with 4×10^8 pfu baculoviruses containing the *GFP* (Bac-GFP) directly into the tumors every three days. Body weight and volume of xenografts were measured in a blinded fashion using callipers every three days during the 3 wk treatment period. Tumor size was calculated according to the formula $AB^2/2$, where A is the longest diameter and B is the shortest diameter of the tumor. After therapy, the mice were sacrificed, and tumor tissue was fixed in 10% formalin for subsequent immunohistochemistry examination.

Immunohistochemistry

Formalin-fixed, paraffin-embedded tissue sections (4 μm) were deparaffinized, rehydrated, and washed with PBS. Tests were performed according to the two-step procedure. After incubated with 3% H_2O_2 for 10 min at room temperature, unmasked antigens were heated. The sections were covered with animal serum for 20 min, incubated with rabbit polyclonal NES1 antibody

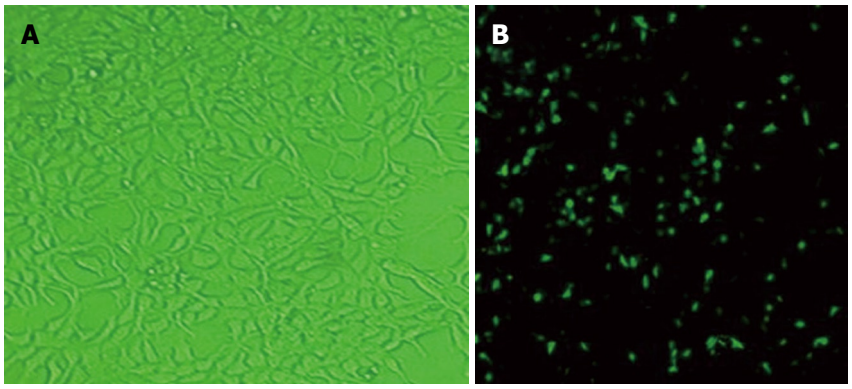

Figure 1 Microscopy (**A**) and fluorescence (**B**) photos of SGC-7901 cells infected with recombinant baculoviruses (Bac-GFP) (× 40).

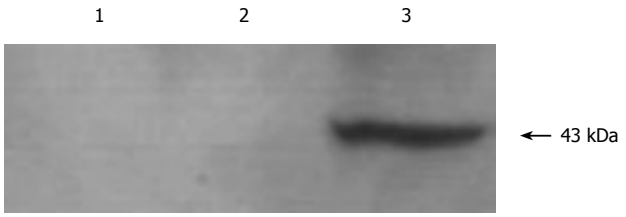

Figure 2 Western blot analysis showing NES1 protein expression in SGC-7901 cells. Lane 1: SGC-7901 cells + PBS; lane 2: SGC-7901 cells + Bac-GFP; lane 3: SGC-7901 cells + Bac-NES1.

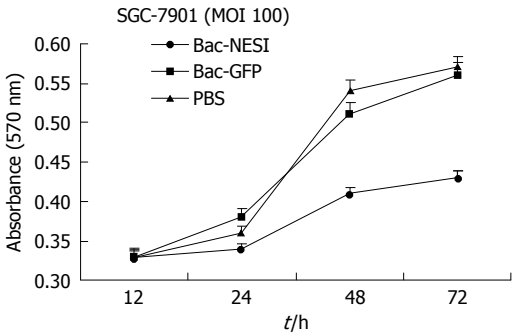

Figure 3 Effect of infection with Bac-NES1 on growth of GC *in vitro*.

(1:200) at 4℃ overnight, and further treated with an EnVision kit for 30 min at room temperature. The sections were visualized by diaminobenzidine (DAB) and counterstained with hematoxylin. TBS primary antibodies were replaced with TBS as a negative control. The sections were observed under a microscope after mounted. At least five thin sections of tumor tissue were used for quantitative immunohistochemistry. The results of staining were analyzed and evaluated with American Image-Pro Plus software.

Statistical analysis

Data were analyzed using the SPSS 10.0 software (Chicago, USA). Each experiment was done in triplicate. The data were presented as mean ± SD. Comparison among experimental groups was performed using ANOVA test. $P < 0.05$ was considered statistically significant. Nonparametric Kruskal-Wallis test and Spearman's correlation test were conducted to compare NES1 staining scores.

RESULTS

Construction of recombinant baculovirus vectors

We developed a baculovirus-derived vector, containing the *NES1* gene under control of the CMV promoter. Propagation of Bac-NES1 and Bac-GFP viruses in Sf-9 cells yielded viral stocks with a titer of 6×10^{12} PFU/mL, respectively. Bac-NES1 virus was purified and tittered as 2×10^{13} PFU/mL by standard end point dilution assay.

GFP expression in SGC-7901 cells transduced with recombinant baculoviruses

The efficiency of baculovirus gene transfer into SGC-7901 cells was assessed by fluorescence microscopy after infection with Bac-GFP. SGC-7901 cells transduced with Bac-GFP (MOI = 200) 24 h after transfection were examined by fluorescence microscopy, showing that SGC-7901 cells could be infected with baculovirus (Figure 1).

NES1 expression in SGC-7901 cells infected with Bac-NES1

Western blot analysis was performed using antibodies to NES1 was performed fro the expression of NES1 in SGC-7901 cells infected with recombinant baculoviruses (Bac-NES1). A polyclonal antibody to NES1 detected a single protein band at 43 kDa in the SGC-7901 cells + Bac-NES1 group (Figure 2).

Assay of SGC-7901 cell proliferation

SGC-7901 cells (2×10^3/well) were planted in 24 well plates and infected with Bac-NES1 or Bac-GFP at a multiplicity of infection (MOI) of 100 or treated with PBS. Proliferation of cells was quantified at 12 h, 24 h, 48 h, and 72 h, respectively by the modified MTT assay. Data are presented as mean ± SD of six wells. The proliferation of SGC-7901 cells infected with Bac-NES1 was significantly suppressed at MOI of 100 compared with PBS- and Bac-GFP- treated groups ($P < 0.05$), but there was no difference between the two groups at MOI = 100 (Figure 3). The data indicate that NES1 induced by baculovirus vectors had a significant *in vitro* inhibitory effect on proliferation of SGC-7901 cells.

GFP expression in gastric tumor xenografts

To investigate the possibility of using baculoviruses for *in vivo* GC gene therapy, we tested its expression in an

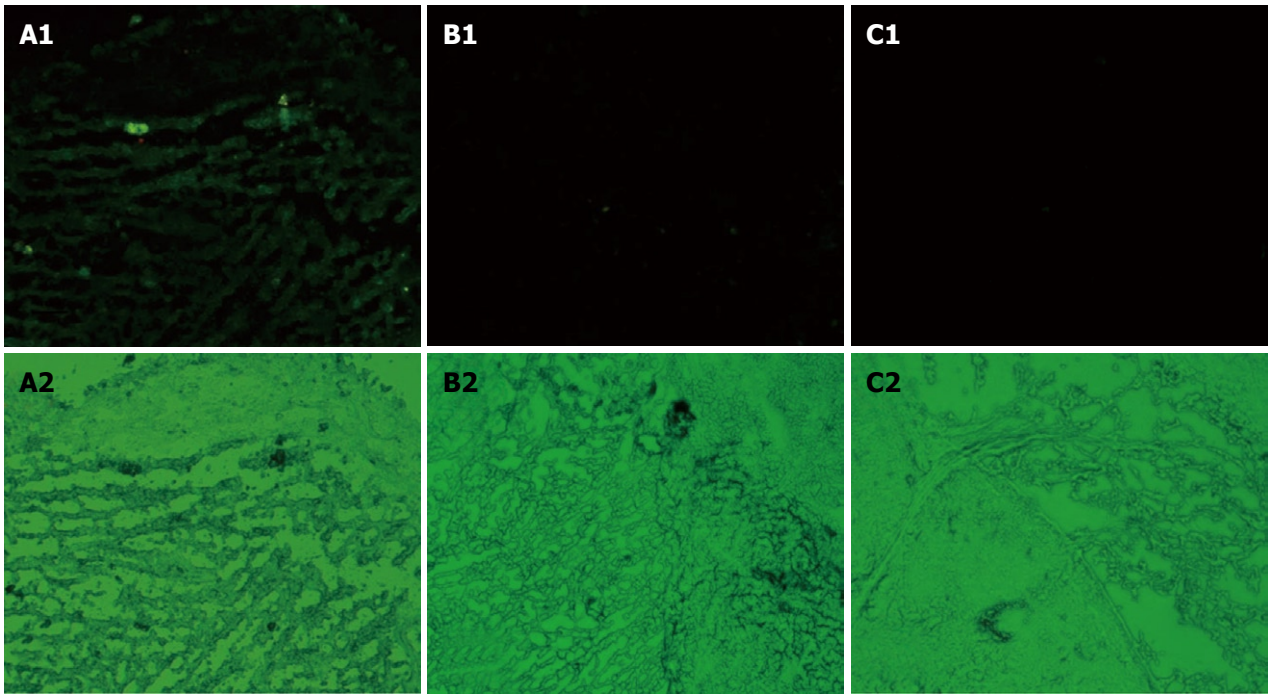

Figure 4 *In vivo* transgene expression in xenografted GC mediated by baculovirus carrying GFP (× 200) in Bac-NES1 treated group (**A**), Bac-GFP treated group (**B**), and PBS- treated group (**C**).

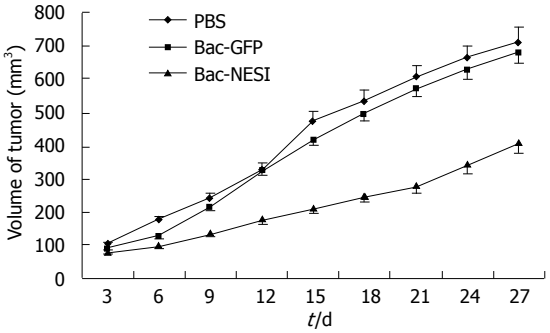

Figure 5 Inhibition of GC growth in nude mice. The mice were assigned to three groups (10 animals in each group). Growth of SGC-7901 xenografted tumor was measured at indicated time points. Relative tumor volume of the treatment groups was significantly different from that of the control group on day 27 of treatment ($P < 0.01$).

animal GC xenograft model. The GFP expression could be visually detected under a fluorescent microscope in the Bac-GFP-treated group (Figure 4). We did not observe any GFP positive cells in the Bac-NES1- and PBS- treated groups. The data indicate that gastric tumor xenografts could be infected with baculovirus.

Effect of NES1 expression on SGC-7901 gastric tumor xenografts

Xenografted GC was induced by injection of SGC-7901 cells into 5-week-old Balb/c nude mice. Treatment consisted of injection with 4×10^8 pfu Bac-NES1, 4×10^8 pfu Bac-GFP, or PBS directly into the tumor every three days. Tumor sizes were measured and presented as a mean. Tumor growth curves are shown in Figure 5. The growth of engrafted tumors was significantly inhibited in the Bac-NES1-treated groups (42.3%) compared with the control group on day 27 ($P < 0.01$). Significant differences in tumor volume were discovered between the control and Bac-NES1 treatment groups on day 9. However, the reduction rate was not significantly different between the Bac-GFP and PBS-treated groups throughout the treatment.

Effect of baculovirus vector-mediated transfer of NES1 gene on SGC-7901 gastric tumor xenografts

The expression of NES1 in SGC-7901 gastric tumor xenografts was assessed by immunostaining with NES1 antibody. Representative images of the three groups are shown in Figure 6. Tumors treated with Bac-NES1 exhibited a significantly higher NES1 expression (54.2 ± 15.7) than those treated with Bac-GFP (6.9 ± 1.7) and PBS (5.6 ± 1.4) ($P < 0.01$). The results suggest that reduced tumor growth and size might be associated with increased NES1 gene expression.

DISCUSSION

GC is one of the most common malignant tumors in the world, especially in Eastern Asia. Although the disease at its early stages is treatable with surgical resection, advanced GC does not generally respond to conventional chemotherapy or radiotherapy. Therefore, gene therapy represents an alternative modality for it[10]. Gene therapy is considered a promising therapeutic modality for cancer and has been successfully applied in animal models using various types of viral vector, gene expression regulation elements, and putative antitumor genes. Autographa californica multiple nucleopolyhedrovirus (AcMNPV)-based vector, traditionally used as a biopesticide to kill infected insects, is recently tested as a new type of

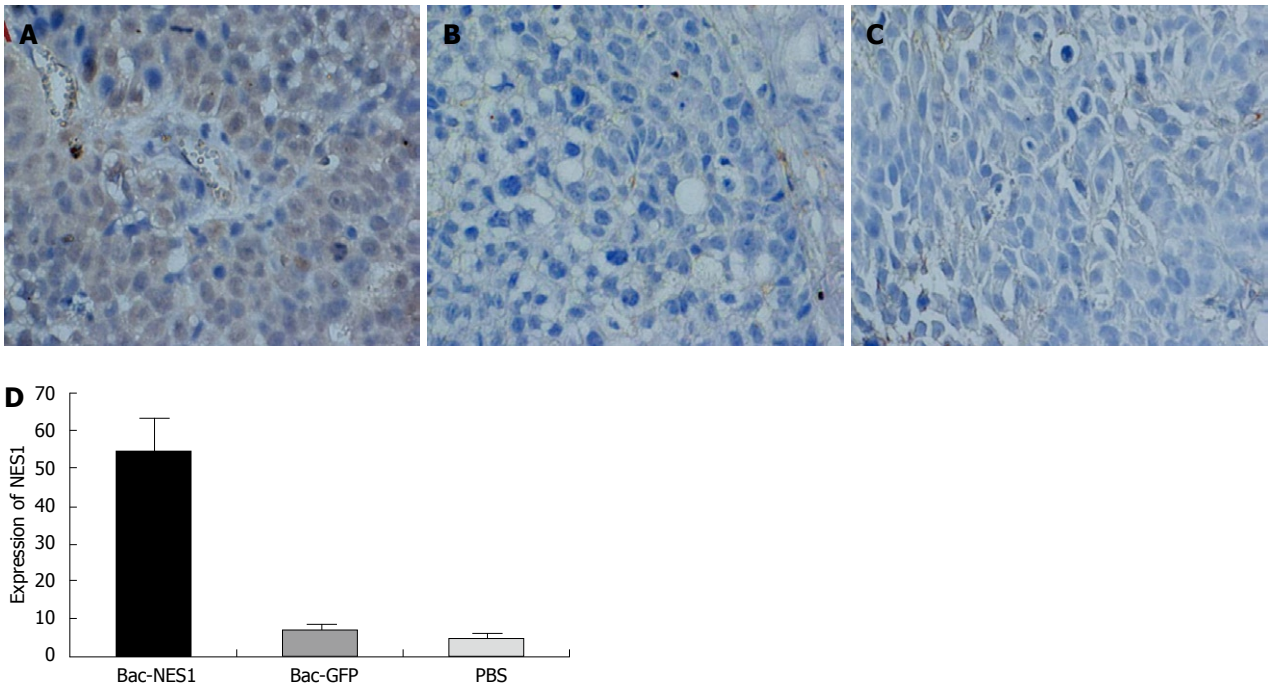

Figure 6 Immunohistochemical staining for tumors treated with Bac-NES1 (**A**), Bac-GFP (**B**), PBS (**C**), and the expression of NES1 protein in Bac-NES1-treated tumors (**D**). Data are presented as mean ± SD.

delivery vehicle for transgene expression in mammalian cells[11]. These viruses can enter but not replicate in mammalian cells. With mammalian expression promoters, recombinant baculoviruses provide a high transduction efficiency in different cells and tissues, including several tumor cell lines[12]. One of the attractive advantages of using AcMNPV as a cancer gene therapy vector is the large cloning capacity conferred by its 130-kb viral genome, which may be used to deliver a large functional gene or multiple genes from a single vector[13]. Other empirical advantages of baculovirus vectors include easy construction of a recombinant viral vector and simple procedure of purifying large quantities of viruses with high titers. It would be possible to scale up the less labor-intensive process to pharmaceutical levels[14].

Human kallikrein 10 (KLK10)/NES1 is a member of the human tissue kallikrein family of secreted serine proteases, encoded by a family of 15 genes clustered in tandem on chromosome 19q13.3-4[15]. The kallikrein gene family has been under intensive study due to its implications in carcinogenesis[16,17] and many members have been used as biomarkers for the diagnosis and monitoring of certain cancers[18-21]. Our previous study suggested that NES1, as a tumor suppressor gene in GC, contributes to the malignant progression of GC[2]. When the NES1 gene is transfected into tumorigenic breast cancer line MDA-MB-231, its anchorage-independent growth is reduced and when this cell line is inoculated into nude mice, tumor formation is significantly decreased[22]. The mechanism of how NES1 induces suppression of the tumorigenic phenotype is currently unknown. Given that NES1 is a secreted protein, it is likely that it functions extracellularly as a regulator of cell growth and/or differentiation in an autocrine or paracrine manner. In this study, the effect of Bac-NES1 on human GC cell lines was examined both *in vitro* and *in vivo*. The extent of baculovirus-mediated gene transfer was evaluated by measuring the expression of the GFP gene under fluorescence microscopy. Baculovirus vectors could transfer the GFP gene into over 90% of GC cell lines examined at MOI 100. Furthermore, Bac-NES1 could successfully deliver and express NES1 protein in Bac-NES1-transfected GC cell lines. These data show that baculovirus can transfer exogenous genes efficiently into GC cell lines. *In vitro*, GC cells infected with Bac-NES1 were significantly suppressed at MOI 100 compared with PBS treated and Bac-GFP infected cells. In order to observe the inhibitory effect of NES1 on tumor growth, a GC model was established. Baculovirus-mediated NES1 gene significantly inhibited the growth of SGC-7901 xenografted gastric tumors. Immunohistochemistry data showed that the reduced tumor growth and size might contribute to the reexpression of NES1 in xenografted gastric tumors.

In conclusion, NES1 gene transfection can inhibit the proliferation of SGC-7901 cells and suppress the transfected GC cells-derived tumor growth *in vivo*. Although further investigation is required to assess systemic *vs* regional issues, systemic adverse effects, and immunological response problems, baculovirus-mediated NES1 gene therapy may be a potent strategy for the treatment of GC.

COMMENTS

Background

Gastric cancer (GC) is one of the most common malignant tumors in the

world, especially in Eastern Asia. Although the disease at its early stages is treatable with surgical resection, advanced GC does not generally respond to conventional chemotherapy or radiotherapy. Therefore, gene therapy represents an alternative modality for GC. Normal epithelial cell specific-1 (*NES1*) gene functions as a tumor suppressor gene in GC and contributes to the malignant progression of GC, thus providing us a promising gene target of gene therapy.

Research frontiers

Gene therapy is considered a promising therapeutic modality for cancer and has been successfully applied in animal models using various types of viral vector, gene expression regulation elements, and putative antitumor genes. Autographa californica multiple nucleopolyhedrovirus (AcMNPV)-based vectors, traditionally used as a biopesticide to kill infected insects, has been recently tested as a new type of delivery vehicle for transgene expression in mammalian cells.

Innovations and breakthroughs

Recombinant baculovirus viruses with a mammalian expression promoter have recently been viewed as a new generation of gene therapy vehicles holding a great promise. The baculovirus genome is large and thus large transgenes can be accommodated. In addition, they are easy to scale up and obtain high levels of recombinant gene expression. Although further investigation is required to assess systemic vs regional issues, systemic adverse effect, and immunological response problems, baculovirus-mediated NES1 gene therapy may be a potent strategy for the treatment of GC.

Applications

Baculovirus-mediated expression of *NES1* inhibits the growth of xenografted GC by 42.3% compared with controls. Thanks to the highly efficient gene delivery, non-cytotoxicity and ease of scaling up, baculovirus may become a novel gene-delivery system for cancer gene therapy.

Terminology

Gene therapy is a promising molecular alternative treatment modality for cancer, including replacement of defective tumor suppressor genes, inactivation of oncogenes, introduction of suicide genes, genetic immunotherapy, anti-angiogenetic gene therapy, and virotherapy.

Peer review

The paper describes that baculovirus-mediated *NES1* gene can be used in treatment of GC in a mouse model. The study is well designed and interesting.

Abstract

AIM: To analyze the metastasis-related proteins in hepatocellular carcinoma (HCC) and discover the biomarker candidates for diagnosis and therapeutic intervention of HCC metastasis with bioinformatics tools.

METHODS: Metastasis-related proteins were determined by stable isotope labeling and MS analysis and analyzed with bioinformatics resources, including Phobius, Kyoto encyclopedia of genes and genomes (KEGG), online mendelian inheritance in man (OMIM) and human protein reference database (HPRD).

RESULTS: All the metastasis-related proteins were linked to 83 pathways in KEGG, including MAPK and p53 signal pathways. Protein-protein interaction network showed that all the metastasis-related proteins were categorized into 19 function groups, including cell cycle, apoptosis and signal transduction. OMIM analysis linked these proteins to 186 OMIM entries.

CONCLUSION: Metastasis-related proteins provide HCC cells with biological advantages in cell proliferation, migration and angiogenesis, and facilitate metastasis of HCC cells. The bird's eye view can reveal a global characteristic of metastasis-related proteins and many differentially expressed proteins can be identified as candidates for diagnosis and treatment of HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common cancers in the world with 626 000 new cases occurred in 2002[1]. Surgical resection remains the primary treatment of choice, but because of the very high rate of metastasis and poor prognosis, the number of deaths is almost the same of new cases (598 000) occurred each year worldwide. Metastasis is a highly complicated biological process involving multiple proteins functioning in a coordinated manner and the molecular mechanism underlying the metastasis of HCC is not completely understood. Investigations on metastasis-related proteins and the molecular mechanism are urgent in the campaign against HCC both in the world and in China[2]. Technology advances in genomics and proteomics would facilitate our understanding of HCC metastasis. Genome analysis with DNA array can be used to scan different gene expressions in different HCC samples and valuable biomarkers have been discovered[3]. However, no well linear correlation has been found between gene and protein expression levels due to splice process of mRNA and post-transcriptional regulation[4,5]. Hence, differential expression profile analysis of a large number of proteins

is an essential step in understanding the mechanism of metastasis and in discovering the diagnostic markers and therapeutic targets for HCC.

Quantitative proteomics using stable isotope labeling has the necessary ability to rapidly identify and quantify differentially expressed proteins in two or more samples with a high throughout, and thus is currently used as the workhorse for discovering and validating proteins related with a special disease in clinical research. In our previous work, the proteome profiles of two HCC cell lines with different metastasis potentials were compared using stable isotope labeling and 223 differentially expressed proteins were identified confidently. In this study, we analyzed these proteins with bioinformatics tools to discover their biological role in the process of metastasis. Our results show that bioinformatics analysis can provide a valuable molecular basis for systematic interpretation of the mechanism underlying HCC metastasis where potential protein markers could be characterized.

MATERIALS AND METHODS

Chemicals and reagents

[5,5,5-d_3] leucine (leu-d_3) was purchased from Cambridge Isotope (Andover, MA). Formic acid (FA) and trifluoroacetic acid (TFA) were from FlukA (Switzerland) and acetonitrile (ACN) was from Merk (Darmastadt, Germany). Trypsins were purchased form Promega (Madison, WI). Dulbecco's modified Eagle's medium (DMEM) and dialyzed fetal bovine serum (FBS) were from Gibco-Invitrogen (Grand Island, NY, USA), and normal FBS was from PAA Laboratories GmbH. All others components of cell culture medium, amino acid kits, inorganic salts, vitamin solution, *etc*, were obtained from Sigma (St, Louis, MO). Other chemicals for SDS-PAGE gel electrophoresis, peptide extraction, and sample preparation for LC-ESI-MS were purchased from Sigma (St. Louis, MO, USA).

Cell culture, sample preparation

HCC cell line MHCC97H with a high metastasis potential was cultured in a normal DMEM, while MHCC97L with a low metastasis potential was cultured in a special DMEM, in which leu-d_3 was supplemented to substitute its unlabeled counterpart depleted in the normal DMEM[6]. Cells were harvested at the 80% confluence and treated with a lysis buffer containing 20 mmol/L Tris-HCl (pH 7.4), 150 mmol/L NaCl, 3 mmol/L $MgCl_2$, 1 mmol/L $CaCl_2$, 10 mL/L NP-40, and 1 mmol/L PMSF. Samples were centrifuged at 10 000 r/min for 30 min at 4℃ and stored at -80℃ for electrophoresis. Samples from MHCC97H and MHCC97L were mixed at 1:1 of total protein mass and separated on SDS-PAGE. Trypsin digestion and peptide extraction were carried out as previously described[6].

LC separation and MS analysis

Peptides were resuspended in 5 μL of 1 mL/L TFA solution and directly loaded onto a 300 μm × 100 mm C18 column (Grace Vydac, Hesperia, CA) using an Agilent 1100 binary pump. The following gradients were used for peptide separation: 50-400 ml/L B from 0 min to 50 min, 400-800 ml/L B from 50 min to 70 min, 800-950 ml/L B from 70 min to 90 min, where solvent A was 1 mL/L FA and solvent B was 1 mL/L FA in ACN. Fractions were collected and deposited on a 12 × 16 array Applied Biosystems plate. Alpha-cyano-4-hydroxycinnamic acid (CHCA) was used as a matrix. Both MALDI-MS and MS/MS mass spectra were obtained with the Applied Biosystems 4700 proteomics analyzer (Framingham, MA, USA). MS/MS data were searched from the international protein index (IPI, version 3.07) human database with Mascot (version 1.9, Matrix Science, Boston, MA). Leu-d_3 modification was added into a modification file. Error tolerance of peptide MS was set at 0.3 U, MS/MS tolerance at 0.6 U. One missed cleavage per peptide was allowed.

Bioinformatics analysis of metastasis-related proteins

UniProt (Swiss-Prot) format file (ipi.HUMAN.dat) of IPI entries and cross-reference file were downloaded from IPI database (human, version 3.07, ftp://ftp.ebi.ac.uk/pub/databases/IPI/). GeneID, gene symbol and Swiss-Prot accession number for each metastasis-related protein were retried from the cross-reference file. Amino acid sequences of IPI entries in ipi.HUMAN.dat were used in prediction of transmembrane segments with Phobius (http://www.ebi.ac.uk/Tools/phobius/)[7].

Protein-protein interactions were extracted from human protein reference Database (HPRD)[8] and interaction network was demonstrated with Osprey (version 1.2.0, http://biodata.mshri.on.ca/osprey/index.html)[9]. GeneIDs were mapped to the KEGG pathway with a Perl script through the API service at the KEGG (http://www.genome.jp/kegg/soap/doc/keggapi_manual.html)[10].

Cross-references to each entry in the online mendelian inheritance in man (OMIM) database were obtained from the UniProtKB/Swiss-Prot subset of IPI entries through a Perl script. The detailed descriptions of OMIM entries were obtained from the OMIM web site (http://www.ncbi.nlm.nih.gov/omim).

Perl scripts were written in the environment of ActivePerl (version 5.8.8, http://www.activeperl.com).

RESULTS

Quantification of differentially expressed proteins between MHCC97H and MHCC97L

HCC cell lines MHCC97H and MHCC97L were subcloned from the same cell line MHCC97, with a high and low metastasis potential, respectively[11]. MHCC97L was cultured in a special medium for 10 passages and thus labeled completely with leu-d_3 while MHCC97H was cultured in a normal medium. Samples from normal (MHCC97H) and leu-d_3-labeled (MHCC97L) cells were combined and analyzed with off-line LC-MALDI-MS. Changes in expression of 506 proteins were quantified as previously described[12]. A high confidence as a single or multiple leucine-containing tryptic peptides

Table 1 Metastasis-related proteins in HCC

Protein name	IPI number	Ratio[1]	NO[2]	Coverage (%)[3]	Category
Filamin C	IPI00178352	2.49 ± 0.15	2	1.28	Cytoskeleton

[1]Ratio calculated as MHCC97H/MHCC97L, [2]number of quantified peptides, [3]protein coverage calculated as the number of amino acid residues for protein identification divided by the total number of amino acid residues of the protein.

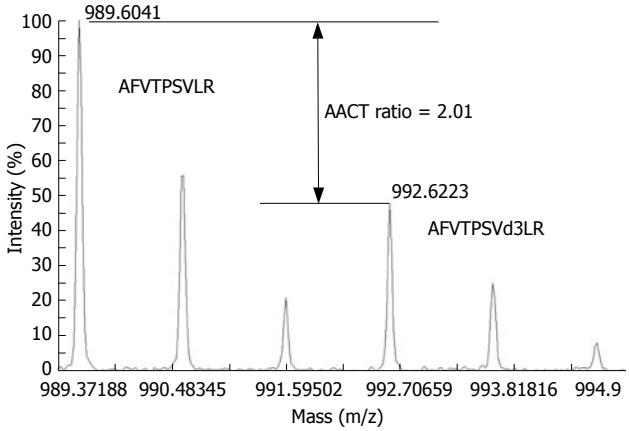

Figure 1 MS spectra of peptide AFVTPSVLR of Pr-domain zinc finger protein 5 (IPI00032997) and its labeled form AFVTPSVd3LR. Quantification was performed by comparing the intensities of peaks of AFVTPSVLR and AFVTPSVd3LR.

was detected for each of these proteins. Peptide AFVTPSVLR from Pr-domain zinc finger protein 5 (IPI00032997) contained one leucine, and the expression ratio was quantified as 2.01:1 (MHCC97H: MHCC97L) by comparing the intensity of peaks 989.6 and 992.6 (Figure 1). The results will be reported in another article in details and some important proteins are listed in Table 1. A total of 223 proteins with an expression ratio > 1.5 or < 0.67 were defined as metastasis-related proteins and further analyzed with bioinformatics tools.

The use of 2DE-MS for profiling the membrane proteins is limited due to the relative insolubility of these proteins under conditions suitable for 2-DE analysis[13,14]. However, membrane proteins are likely to be very import in understanding metastasis. For this reason, we undertook SDS-PAGE to identify more membrane proteins in our study. Phobius is a web tool to predict transmembrane topology of protein with a hidden Markov model[7]. Therefore, it was used to predict the transmembrane segments of metastasis-related proteins in our study. Several membrane proteins with multi-transmembrane segments were identified, such as sodium channel protein type 1 subunit alpha (IPI00216029) containing 24 transmembrane segments, brain calcium channel I (IPI00217499) containing 23 segments, HH1 (IPI00377006) containing 22 segments, hNaN (IPI00513973) containing 20 segments. It was difficult to detect these proteins with multi-transmembrane segments using the 2DE method due to their low solubility in 2DE lysis buffer. In our study, more membrane proteins were detected than in a previous report using 2DE[15]. The dataset of metastasis-related proteins here provided comprehensive biology information on the molecular mechanism of HCC and would facilitate the discovery of biomarkers for its diagnosis and therapy.

Biological pathways

Based on the API service of KEGG (http://www.genome.jp/kegg/soap/doc/keggapi_manual.html)[10], a Perl script was used to associate these metastasis-related proteins with known pathways and disease states (Table 2). All the proteins were linked to 83 biological pathways and human diseases in the KEGG, including antigen processing and presentation, regulation of actin cytoskeleton and signal pathways. Among these pathways, many biological processes were connected with metastasis in previous studies, including MAPK, p53 and ErbB, which are involved in regulating cell proliferation, angiogenesis and migration. In addition, several metastasis-related proteins were suggested to be involved in other types of cancer. For example, PAK7 and PAK 4 functioned in regulation of renal cell carcinoma according to the annotations in the KEGG.

Protein-protein interaction network

With the software Osprey and the protein-protein interaction data from HPRD, protein-protein interaction network of metastasis-related proteins was visualized (Figure 2, Table 3). The network contained 871 proteins (nodes) and 892 interactions (edges), and the edge/node was 1.02. Osprey also provides a functional tool to cluster proteins by their GO process, and proteins sharing the same GO process were grouped together. Based on the GO annotations in Osprey, all the proteins in the network were classed into 19 known biology function groups. For example, 120 proteins were involved in sig-

nal transduction, 57 in DNA repair, and 6 in cell cycle (Table 3). This network could facilitate us to pinpoint the key proteins that play an important role in HCC metastasis and also help us to identify potential markers for the diagnosis and treatment of HCC.

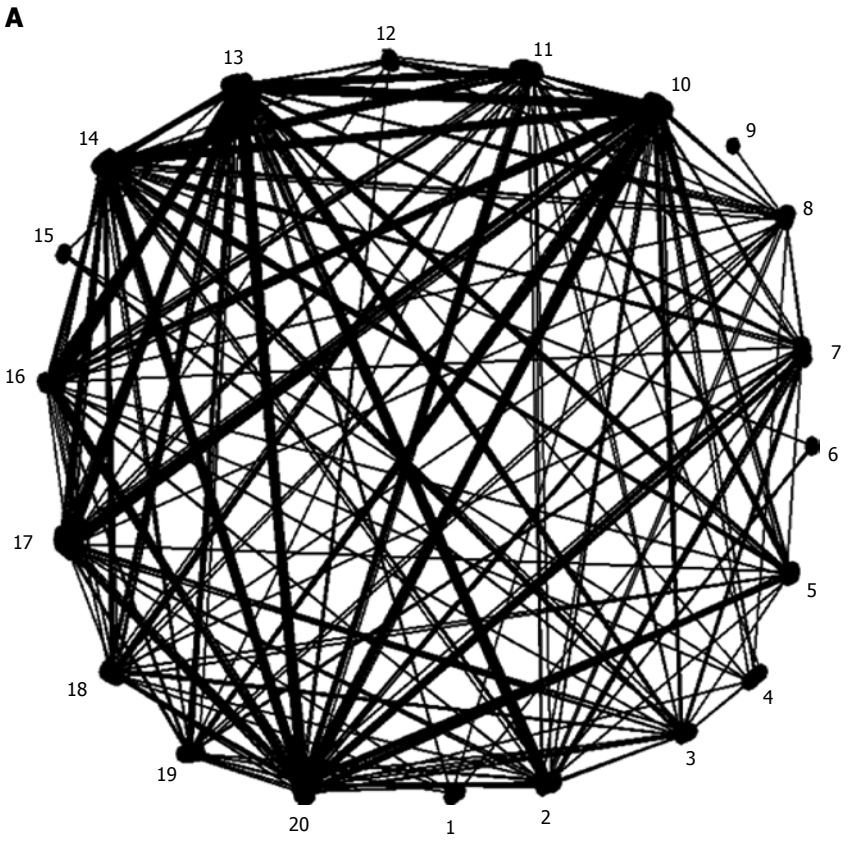
Disease association

OMIM is one of the most comprehensive resources of human genes and genetic disorders to support research in human genomics and proteomics[16]. A total of 145 proteins were linked to 186 OMIM entries, of which 141 described disease genes and 45 disease phenotypes. Among the disease phenotypes, one was cirrhosis (OMIM #215600) which would afford the development of HCC.

DISCUSSION

The accuracy of comparative proteomics using stable isotope labeling can be affected by various factors, such as isotope distribution[17]. When the peptide contains one leucine, M^+ ion peak of labeled peptide overlaps with the isotope distribution of the corresponding normal peptide. In order to eliminate the effect of isotope distribution and ensure the accuracy of quantification, the theoretical intensity of $(M+3)^+$ peak of normal peptide is subtracted from the labeled peak by calculating its isotope distribution[12]. Peaks with a signal-to-noise ratio < 30 are also excluded in quantification to attenuate the effect of noise on quantification. These modifications ensure the reliability of quantification with stable isotope labeling.

It was reported that some differentially expressed proteins function in the process of metastasis and plectin has an essential role in cell migration through MAP kinase signaling cascades[18,19]. Filamin C can organize actin polymerization and its dysregulation has been observed in some cancer samples[20]. Obscurin binding to titin and sarcomeric myosin[21,22] plays a role in the regular alignment of network sarcoplasmic reticulum developing sarcomeres[23]. The gene encoding this protein is interrupted by the translocation in Wilms' tumor and functions as a tumor suppressor[24]. Another study showed that obscurin is involved in gastrointestinal stromal tumor and leiomyosarcomas[25]. Proto-oncogene serine/threonine-protein kinase Mos acts as an up-



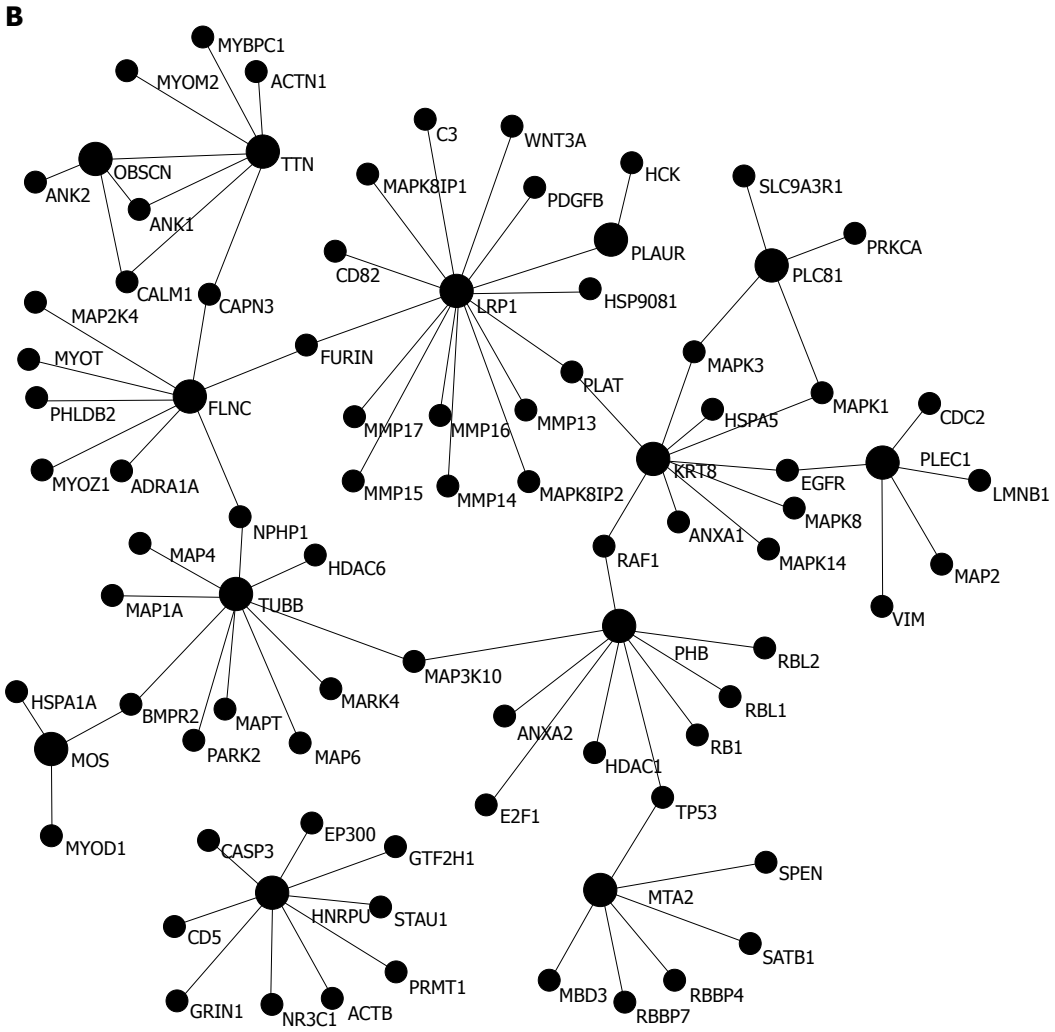


Figure 2 Protein-protein interaction network. **A**: Interactions of metastasis-related proteins. Based on the data from HPRD, protein-protein interactions were plotted using Osprey. Interactors are represented as nodes and grouped according to their biologic function based on Osprey annotation; **B**: A subnetwork displaying important proteins, such as Mos, LRP1, MTA2, and MAPK.

stream activator of the MEK/MAPK/p90Rsk pathway regulating M-phase and G2 arrest[26,27]. LRP1 can mediate growth inhibition by IGFBP-3 and cell migration inhibition by binding to apoE[28]. LRP1-mediated clearance of uPA is one of the mechanisms involved in the control of human thyroid carcinoma cell invasion[29]. It was reported that up-regulation of matrix metalloproteinase-9 by tPA in cell culture and *in vivo* is mediated by LRP1[30]. LRP1 also plays a role in determining the blood vessel structure and angiogenesis[31].

Two biological pathways discovered by KEGG analysis in our study were dysregulated and connected with HCC metastasis. The tumor suppressor protein p53 plays a pivotal role in the regulation of apoptosis and cell cycle arrest. In our study, two p53 regulators, p73 and apoptotic protease activating factor 1, were differentially expressed. MTA2 is a p53-interacting protein that induces p53 deacetylation[32,33]. Dysregulation of p53 function is linked with an unfavorable prognosis of a large number of more aggressive tumor types[34]. Eukaryotic cells possessing multiple MAPK pathways coordinately regulate diverse cellular activities including motility, survival, apoptosis and differentiation[35,36]. The Mos/MAPK/p90Rsk pathway regulates cell cycle progression in oocytes[37], whereas ectopic Mos expression in the early cleavage embryo induces M phase arrest[27]. HSP70 exhibits regulatory functions of c-Jun, ERK and the JNK pathway, thus inhibiting cell apoptosis[38]. The MAPK signaling pathway has long been identified as a convergence point for normal and pathologic signaling inputs, rendering it an appealing target for therapeutic intervention[39]. Various treatment modalities targeting p53 and MAPK pathway are currently under investigation, and dysregulation of p53 and MAPK pathway in HCC metastasis would facilitate finding targets for HCC therapy[39-41].

In conclusion, metastasis-related proteins are dysregulated in HCC metastasis. Biochemical alterations in cell proliferation and migration, angiogenesis and immune response confer selective biological advantages to HCC cells in the process of metastasis. Bioinformatics analysis of metastasis- related proteins provides valuable biological information on the molecular mechanism of metastasis and potential therapeutic targets for HCC.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is one of the most common cancers in the world with a high death rate. Metastasis is the major cause of HCC-related death. Discovering metastasis-related proteins would facilitate the diagnosis and treatment of HCC. Quantitative proteomics with stable isotope labeling is a powerful tool to analyze proteome differences between samples with different metastasis and to discover potential therapeutic targets for HCC.

Research frontiers

Our study showed the differential proteome profiles of two HCC cell lines with metastasis using stable isotope labeling. Based on the functional annotations with bioinformatics tools, metastasis-related proteins were functionally annotated with Kyoto encyclopedia of genes and genomes (KEGG) pathway, protein-protein interactions from human protein reference database (HPRD) and diseases from online mendelian inheritance in man (OMIM). Functional annotations showed that many proteins in the profile were clearly connected with the process of tumor metastasis.

Innovations and breakthrough

To the best of our knowledge, the present study showed the largest differential proteome profile of HCC metastasis. Functional annotations with bioinformatics tools showed that metastasis-related proteins were linked with 82 KEGG pathways, 892 interactions and 186 disease entries in OMIM, suggesting that they play a possible role in metastasis of HCC.

Applications

The differential proteome profile gives more valuable information on the molecular mechanism of metastasis of HCC and provides potential biomarkers for the diagnosis and treatment ofr HCC.

Peer review

This is a well conducted study. The manuscript describes the differential proteome profile that gives more information on the molecular mechanism of metastasis of HCC. The study also invested certain potential biomarkers that can be used in the diagnosis and treatment of HCC.

Abstract

AIM: To examine the expression of pancreatic duodenal homeobox-1 (PDX-1) transcription factor in human colorectal cancer.

METHODS: RT-PCR, Western blotting, and immunohistochemistry were performed to determine the expression pattern of transcription factor PDX-1 in primary colorectal tumor, hepatic metastasis, and benign colon tissue from a single patient.

RESULTS: The highest PDX-1 transcription levels were detected in the metastasis material. Lower levels of PDX-1 were found to be present in the primary tumor, while normal colon tissue failed to express detectable levels of PDX-1. Western blot data revealed a PDX-1 expression pattern identical to that of mRNA expression. Immunohistochemistry confirmed high metastasis PDX-1 expression, lower levels in the primary tumor, and the presence of only traces of PDX-1 in normal colon tissue.

CONCLUSION: These data argue for further evaluation of PDX-1 as a biomarker for colorectal cancer.

Key words: Colorectal cancer; Pancreatic duodenal homeobox-1; Tumor marker; Transcription factor; Diagnostics

INTRODUCTION

In 2008, colorectal cancer is projected to be the third leading cause of cancer-related mortality in USA with an estimated 148 000 new cases and 50 000 deaths[1]. At least 40% of patients with colorectal cancer will experience metastases at some time during their illness[2]. Early detection of disease can improve prognosis, and survival varies significantly between patients with early-stage tumors and patients with metastases[3,4]. A number of studies have shown decreased mortality in populations undergoing colorectal cancer screening[5-8]. There is an increasing demand for colon cancer tumor markers for risk assessment and early diagnosis[9,10].

Pancreatic duodenal homeobox 1 (PDX-1) is a transcription factor with a critical role in pancreatic development[11]. PDX-1 regulates pancreatic cell proliferation and differentiation, and increased expression of this transcription factor has been described in human pancreatic adenocarcinoma and cell lines[12,13]. We recently found increased PDX-1 expression in benign tissues and malignant tumors from patients with pancreas, breast, colon, prostate, and renal cancers[14]. This indicates a possible role of PDX-1 as a tumor marker in patients with these malignancies.

In this report, levels of PDX-1 expression were quantified in a primary colorectal tumor, a metastasis, and in benign tissue from a single patient. Of particular interest were the expression pattern of PDX-1 and its potential use as a tumor marker in colorectal cancer.

MATERIALS AND METHODS

Samples

A 46-year-old male patient presented with a right-sided colorectal adenocarcinoma metastatic to the peritoneum and greater omentum. The patient underwent chemotherapy with capecitabine and oxaliplatin from August 2003 to February 2004 and right hemicolectomy in June 2004 for tumor-related bowel obstruction.

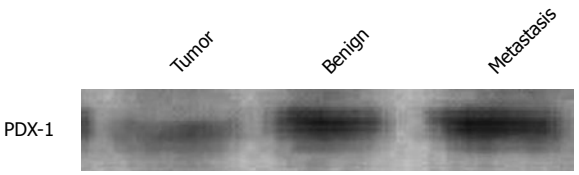

Figure 1 Western blotting results for PDX-1 in the primary tumor, benign colon tissue, and omental metastasis.

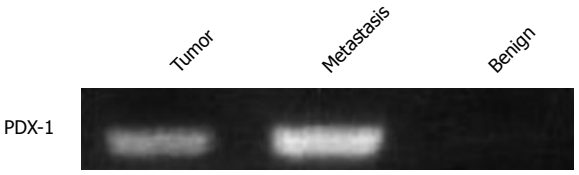

Figure 2 RT-PCR results for PDX-1 in the primary tumor, omental adenocarcinoma, and benign colon tissue.

Samples from the primary cecal tumor, omental metastases, and macroscopically normal colon mucosa from the distal end of the right hemicolectomy specimen (transverse colon) were collected during surgery (n = 16).

Immunohistochemistry

Tissues were fixed in 4% paraformaldehyde overnight at 4℃. Tissue processing, section preparation, and H&E staining were performed as described previously[14].

Western blot analysis

Western blotting was performed as described previously[15].

RNA preparations and RT-PCR

All samples were snap-frozen in liquid nitrogen. RNA was prepared according to procedures described in TRIzol Reagent manual (Cat. NO. 15596-026/-018). RT reactions were carried out according to the protocol of SuperScript Ⅲ First-Strand Synthesis System (Invitrogen Cat. No. 18080-051). PCR products were loaded on a 1.5% agarose gel and visualized and quantified by ethidium bromide staining using an UVP imaging system (UVP, Upland, CA).

RESULTS

As shown in Figure 1 (Western blot), high PDX-1 protein levels were found in the metastasis and the benign colon mucosa distant from the tumor. RT-PCR results in Figures 2 and 3 show that the highest PDX-1 mRNA levels were detected in the metastasis. Significant but lower levels were present in the primary tumor, while normal colon tissue had close to undetectable levels of PDX-1 mRNA. Immunohistochemistry (Figure 4) confirmed the high PDX-1 expression in the metastasis, the lower levels in the primary tumor, and the traces of PDX-1 in normal tissue.

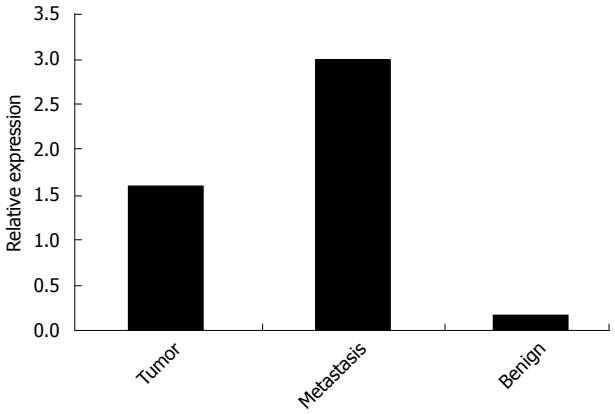

Figure 3 Quantitative RT-PCR results for PDX-1 in the primary tumor, omental metastasis, and benign colon tissue.

DISCUSSION

PDX-1 regulates pancreatic cell proliferation and differentiation[16-19]. Its aberrant expression in a number of human malignant tumors suggests a potential as a molecular marker. Among these malignancies, colorectal cancer is a common and frequently fatal disease for which screening programs are already being used in the United States[20]. Colonoscopy, the most accurate screening method, can cause significant patient discomfort and has risks of perforation and bleeding[21]. Perhaps for these reasons, participation in colorectal cancer screening programs is low[22]. Hence, safer and more acceptable screening methods are needed.

An important finding of this study is that malignant tissue was found to have significantly higher PDX-1 expression than normal colon mucosa outside the tumor. We have previously shown PDX-1 expression in 10 colon cancer specimens to be significantly elevated in both the nucleus and cytoplasm of malignant cells, compared to lower levels found in benign tissues[14]. In that study, six samples of colon tissue from colon cancer patients taken from sites outside the primary tumor were examined and found to express increased PDX-1 levels, although lower than that of tumors. In contrast, our current study showed colon mucosa distant from the primary tumor had nearly undetectable PDX-1 expression. These differences could be due to variations in the benign tissue sample distance from the primary tumor. Unfortunately, this was not recorded in our previous study and hence an accurate comparison is not possible.

Another significant observation is that, despite high levels of mRNA, PDX-1 protein levels are low in the primary tumor. This is consistent with posttranscriptional control of PDX-1 expression, which has been shown to occur in the pancreas[18]. In contrast, metastatic tissues retain high levels of both mRNA and protein expression. Although Western blotting showed lower levels of protein in the primary tumor compared to benign mucosa, immunohistochemistry did confirm high expression of PDX-1 protein in tumor cells. Hence, PDX-1 protein is present in tumor cells

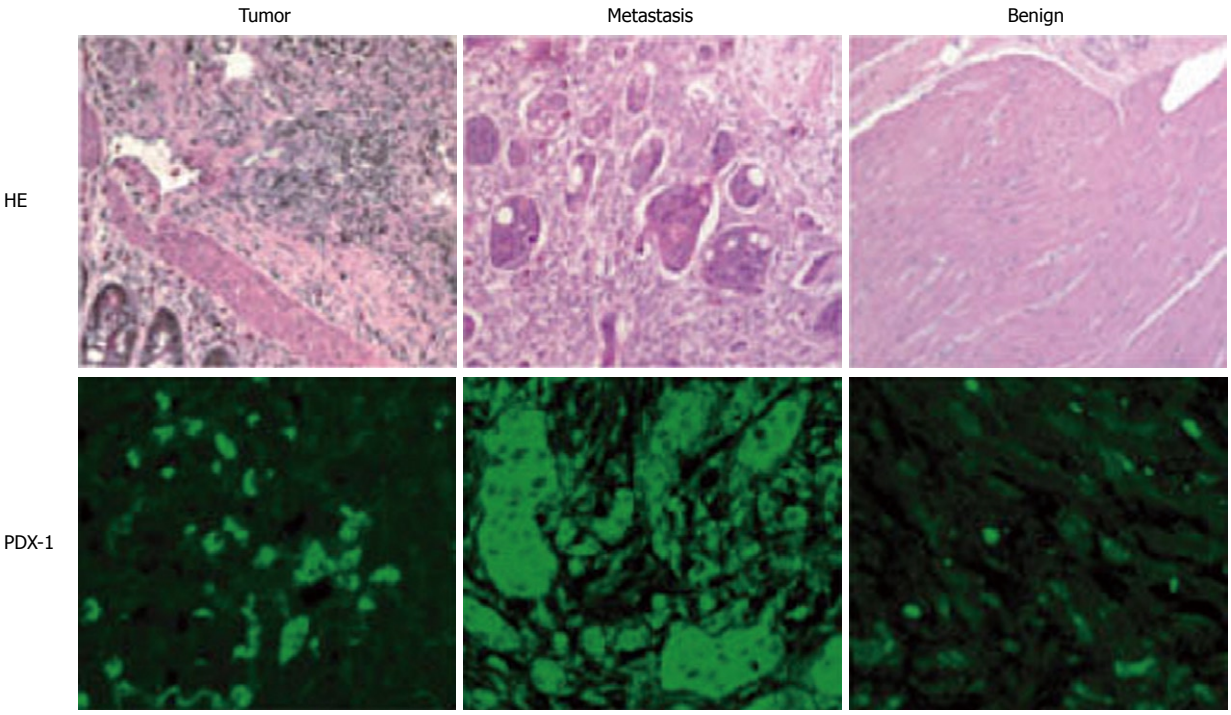

Figure 4 HE staining and immunohistochemistry for PDX-1 in the primary tumor, omental metastasis, and benign colon tissue.

and normal colonocytes, which are excreted in feces. This is a prerequisite for fecal screening for colorectal cancer. Interestingly, others have shown an upregulation of PDX-1 expression in colonic hyperplastic polyps and adenomas, the latter being precursors of adenocarcinomas[23].

Although the etiology of aberrant PDX-1 expression by colorectal cancer cells is unknown, a clue for this comes from its association with caudal homeobox 2 (Cdx-2). The genes for PDX-1 and Cdx-2 are closely linked on chromosome 5[24]. Cdx-2 is expressed in colon epithelium during embryonic development and has a central role in the differentiation of midgut endoderm[24]. It encodes for a transcription factor that is expressed in the proximal colon[25]. Cdx-2 expression is significantly reduced in colorectal adenocarcinoma proximal to the splenic flexure[26] and during the later stages of colorectal carcinogenesis[27]. *In vitro* studies show that PDX-1 physically interacts with and inhibits transcriptional activation by Cdx-2[28].

In this report, we have found expression of PDX-1 in a colorectal adenocarcinoma, its metastases, and macroscopically normal colonic mucosa from the same patient. This indicates a potential for use of this transcription factor as a molecular marker for colorectal cancer. Levels of PDX-1 in primary tumors and metastases from a large number of patients with and without colorectal cancer would need to be measured to confirm these observations. In addition, the levels of PDX-1 in stool samples from these patients need to be determined. This case report is an initial observation that PDX-1 expression could be indicative for colorectal carcinoma. A prospective study would be required to further evaluate its impact.

COMMENTS

Background

Colon cancer is a major cause of cancer-related morbidity and mortality and new diagnostic markers could improve the results of screening. Pancreatic duodenal homeobox-1 (PDX-1) is a transcription factor that regulates differentiation and proliferation. Increased PDX-1 levels have been found in colorectal adenocarcinoma compared to normal colon mucosa from a single patient.

Research frontiers

New molecular markers that could improve the accuracy of colorectal cancer screening are being sought. Development of molecular markers aims at developing non-invasive screening methods for colorectal cancer.

Innovations and breakthroughs

Detection of colorectal cancer-specific mutations in stool has been examined but is laborious and expensive. New molecular markers that will improve the efficiency and accuracy of non-invasive screening are needed.

Applications

Demonstrating overexpression of PDX-1 in the colon of patients with colorectal cancer is the first step in evaluating this molecule as a marker for colorectal cancer. If this observation is confirmed in a large sample of colorectal cancer patients, PDX-1 could prove valuable as a colorectal cancer marker.

Terminology

PDX-1 is a transcription factor essential for normal pancreatic organogenesis. Aberrant PDX-1 expression by a number of malignant tumors has been described.

Peer review

This study is very interesting. It suggests the possibility of PDX-1 as a biomarker for early diagnosis of colorectal cancer, so further study is needed to evaluate this potential.

Abstract

AIM: To explore the antitumor bioactivity of adenovirus-mediated mutant type *p27^{kip1}* gene in a colorectal cancer cell line SW480.

METHODS: We constructed recombinant adenovirus vector expressing a mutant type *p27^{kip1}* gene (ad-p27mt), with mutation of Thr-187/Pro-188 (ACGCCC) to Met-187/Ile-188 (ATGATC), and transduced into SW480 cells. Then we detected expression of p27, Bcl-2 and Bax protein in the transductants by Western blotting, cell cycle of transductants by a digital flow cytometric system, migrating potential with Boyden Chamber and SW480 tumor cell growth inhibition *in vitro* and *in vivo*.

RESULTS: We found that a recombinant adenovirus vector of expressing ad-p27mt, with mutation of Thr-187/Pro-188 (ACGCCC) to Met-187/Ile-188 (ATGATC) has potent inhibition of SW480 tumor cell growth *in vitro* and *in vivo*. Furthermore, ad-p27mt induced cell apoptosis *via* regulating bax and bcl-2 expressions, and G_1/S arrest in SW480 cells and inhibited cell migration.

CONCLUSION: ad-p27mt has a strong anti-tumor bioactivity and has the potential to develop into new therapeutic agents for colorectal cancer.

Key words: *p27*; Adenovirus; Antitumor bioactivity; Colorectal cancer

INTRODUCTION

p27^{kip1}, a member of the Kip/Cip family of cyclin-dependent kinases inhibitors (CKIs), is a putative tumor suppressor gene[1], and promoter of apoptosis[2] that has been demonstrated in cancer cells as well as in normal cells[3]. Simultaneously, *p27^{kip1}* acts as a safeguard inflammatory injury[4] and plays a role in cell differentiation[5]. Furthermore, *p27^{kip1}* was identified as an inhibitor of cyclin E/CDK2 in cells arrested in the G_1 phase by lovastatin, transforming growth factor-beta (TGF-β), serum deprivation and contact inhibition[1,6].

Over the past years, p27^{kip1} protein has attracted our attention as an important prognostic factor in various malignancies. In short, lately, it has been reported that expression of p27^{kip1} protein is associated with poor prognosis in several types of malignancies, including breast, lung, gastric carcinoma[7-10] and colorectal adenocarcinoma[11-13].

The reduced expression of *p27^{kip1}* in cancer cells due to an increase in the rate of its degradation[14]. It is thought that the amount of p27^{kip1} protein is regulated by a posttranscriptional mechanism rather than *p27^{kip1}* gene aberrations because *p27^{kip1}* gene mutation seems to be uncommon in human malignancies[15]. It has been demonstrated that *p27^{kip1}* is poly-ubiquitinated both *in vivo* and *in vitro*, and *p27^{kip1}* ubiquitination requires its phosphorylation on threonine residue 187 (T187) both *in vivo* and *in vitro*[16,17].

Gene therapy is a promising approach to restore *p27* expression using adenoviral vectors[11,18-20]. These agents have induced cell-cycle arrest and loss of cyclinE-

CDK2 activity in cell lines and xenograft models and have triggered apoptosis in cancer cells[2,19,21-24]. The concentration of *p27* is thought to be regulated predominantly by the ubiquitin-dependent proteolytic pathway[25]. Degradation of *p27* triggered by its phosphorylation on Thr187 is required for the binding of *p27* to Skp2, the F-box protein component of an SCF ubiquitin ligase (E3) complex, and such interaction in turn results in the poly-ubiquitylation and degradation of p27[16,25]. Reduction of *p27* levels in various types of malignant tumors results from accelerated proteolytic degradation by this pathway[26].

However, so far no report has been published on the effects of adenovirus-mediated mutant type $p27^{kip1}$ gene on colorectal cancer cell. Thus, we constructed recombinant adenovirus vector expressing a mutant type $p27^{kip1}$ gene (ad-p27mt), with mutation of Thr-187/Pro-188 (ACGCCC) to Met-187/Ile-188 (ATGATC), which will inhibit degradation of p27 protein[11,16,24,25,27], and explored its antitumor bioactivity in a colorectal cancer cell line SW480.

MATERIALS AND METHODS

Cell and cell culture

Human colorectal cancer cell line SW480 was purchased from Shanghai Cell Lines Bank (Shanghai, China). Cells were maintained in RPMI 1640 (Beyotime, China) supplemented with 10% fetal bovine serum (FBS; Beyotime, China).

Preparation of ad-p27mt

Ad-p27mt was constructed in the Institute of Clinical Medicine of Yunyang Medical College (Hubei, China). Briefly, the cDNA of human *p27mt* gene was digested from plasmid of pORF9-hp27mt (Invitrogen) and subcloned into the plasmid of pBluescript Ⅱ SK (+) (Stratagene) and formed plasmid of pBluescript-hp27mt. Then human *p27mt* gene was digested from pBluescript-hp27mt and subcloned into shuttle vector pBluescript-CMV (Stratagene) and gained shuttle plasmid of pShuttle-CMV-hp27mt. Adenovirus genomic DNA plasmid of pAdeasy-1 (Stratagene) was transformed into BJ5183 bacterium (Stratagene) and prepared competent BJ5183 bacterium containing pAdeasy-1. PShuttle-CMV-hp27mt was linearized with Pmel (New England Bio labs) and transformed into competent BJ5183 bacterium containing pAdeasy-1 and positive clone of homologous recombination was selected. Identified recombinant adenovirus plasmid of pAd-p27mt was digested with Pacl and transfected into HEK293 cells (Stratagene) with liposome polyFect (Qiagen) to package adenovirus particles. HEK293 cells were maintained in DMEM with 10% FBS until the onset of the cytopathic effect. PCR technique was used to detect target gene and the titer of the recombinant adenovirus was determined by measuring the absorbance at 260 nm and 280 nm. Ad-p27mt was propagated in HEK293 cells, purified by two cesium chloride density centrifugations, titered and stored at -70℃. Recombinant adenovirus expressing β-galactosidase (ad-β-gal) without any therapeutic gene was used as the control virus in all experiments.

Transduction of SW480 cells with ad-p27mt

Exponential growing of SW480 cells were transduced with ad-p27mt or ad-β-gal at 20 multiplicity of infection for 1 h with gentle frequent shaking and then incubated with complete media for the experiment.

P27mt sequencing assay of transductant

Briefly, transductants were schizolysed and DNA was extracted using phenol/chloroform, and then dehydrated alcohol precipitated DNA. Sequence of DNA was assayed by Shanghai Sangon Company.

Western blotting

Cells lysates were prepared from transductants of ad-p27mt (SW480-ad-p27mt), transductants of ad-β-gal (SW480-ad-β-gal) and parental cells (SW480) as follows: cells were cultured for 96 h, washed three times with 100 mmol/L phosphate-buffered-saline (PBS, Beyotime, China), lysed with RIPA buffer [50 mmol/L Tris-HCl (pH 7.4), 150 mmol/L NaCl, 1% NP-40, 0.1% SDS; Beyotime, China]. The protein concentration of the samples was determined by Bio-Rad protein assay (Bio-Rad, Amersham). Fifty micrograms of protein samples were electrophoresed on SDS-polyacrylamide gel. Proteins from gels were transferred to PVDF membrane (Sigma), and membrane was incubated with a 1:1000 dilution of the monoclonal anti-p27 antibody (Beyotime, China), anti-Bax antibody (Beyotime, China), and anti-Bcl-2 antibody (Beyotime, China), respectively. The blots were developed using the enhanced chemoluminescence (ECL) Western blotting system and protocol (Amersham). In all immunoblotting experiments, blots were reprobed with an anti-β-actin antibody (Sigma) for internal control.

MTT assay

Cells were seeded on 96-well plates (Beyotime, China) at 4×10^3 cells per well in RPMI 1640 supplemented with 10% FBS. After 2 d, 4 d and 6 d, the number of cells was quantitated by an assay in which MTT; 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide (Sigma) was used.

Cell cycle analysis

Cells were seeded in 75 cm^2 culture flask (Beyotime, China) in RPMI 1640 supplemented with 10% FBS. After 96 h, the stuck and floating cells were collected in conical tubes (Beyotime, China). Then, the cells were fixed with 70% cold ethanol and washed with PBS. After treatment with 0.1 mg/mL RNaseA (Sigma), the cells were stained with 40 μg/mL propidium iodine (Sigma), and the cell cycle was analyzed by a digital flow cytometric system (Beckman Coulter EPICS-XL).

Migration assay with Boyden chamber

Migrative potential was evaluated in the Boyden chamber apparatus (Kylin-bell, China). This assay was developed

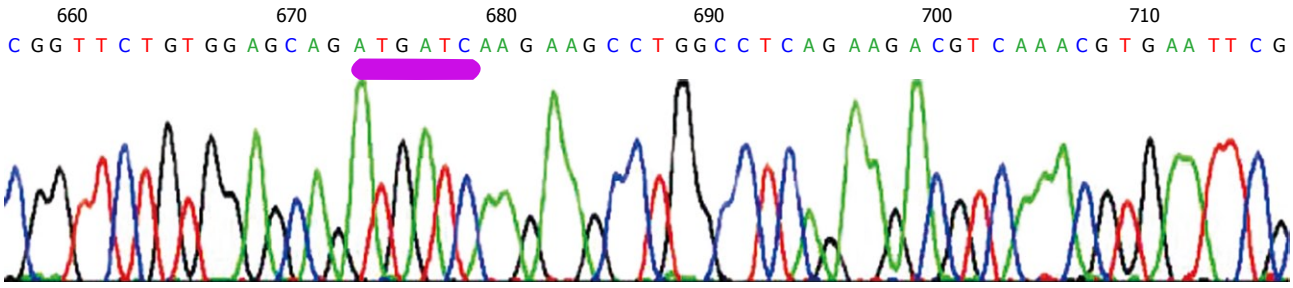

Figure 1 p27mt sequencing assay of transductants. Sequencing result was consistent with p27mt sequence in gene bank. Sequencing result was shown and the underline was mutant site Met-187/Ile-188 (ATGATC).

to facilitate analysis of aspects of cancer invasion and metastasis. Briefly, subconfluence cells were starved for 24 h and harvested with 0.05% trypsin (Sigma) containing 0.02% EDTA (Sigma), washed twice with PBS, and resuspended to a final concentration of 5×10^5/mL in serum-free medium with 0.1% fraction V bovine serum albumin. PVP filters (Kylin-bell, China) of 8 μm pore size were precoated with gelatin, rinsed in sterile water, and were used for assay. Bottom wells of the chamber were filled with 25 μL of RPMI 1640 supplemented with 10% FBS per well and covered with a gelatin coated membrane, and then 50 μL of cells suspension was added to the top wells. After 24 h of incubation, the membranes were stained with Giemsa solution. Cells on the upper surface of the filter were carefully removed with a cotton swab, and the cells that had migrated through the membrane to the lower surface were counted in six different fields under a light microscope at 400 magnification. Each experiment was performed in triplicate wells and repeated 3 times.

In vivo growth inhibition assay

BALB/c nude mice were purchased from Animal experiment center of Hubei (Hubei, China; Qualification number: SCXK: Hubei 2003-0005). All animal experimental procedures were conducted and approved by the Institutional Animal Care and Use Committee of Yunyang Medical College (Approval number: SYXK: Hubei 2004-0021). Briefly, SW480 cells were cultured in RPMI 1640 supplemented with 10% FBS. Cells were harvested through two consecutive trypsinizations, centrifuged at 300 × *g* for 5 min, washed twice, and resuspended in sterile PBS. Cells (1×10^7) in 0.2 mL were injected subcutaneously into a 6-week-old nude mouse between the scapulae of each nude mouse. After 14 days, tumors reached a mean size of 200 mm^3 in the mice's bodies. To test *in vivo* growth suppressive potential of ad-p27mt on nude mouse xenografts of SW480, intratumoral injections of ad-p27mt, ad-β-gal or PBS were made every other day for total 3 times, respectively. There were ten mice in each group. Twenty-eight days after inoculation, mice were sacrificed by cervical dislocation, and tumor specimens were taken, photographed and weighed.

Statistical analysis

Data are mean of at least 3 independent experiments ± SD. Results were compared by one-way analysis of variance (ANOVA). A two-tailed $P < 0.05$ was regarded as statistically significant. All calculations were performed using the SPSS for Windows version 13.0 statistical program on a personal computer.

RESULTS

p27mt sequencing assay of transductant

As shown in Figure 1, sequencing result was consistent with *p27mt* sequence in gene bank.

Expression of p27, Bax and Bcl-2 protein in the transductants

As shown in Figure 2, expression of p27 and Bax protein was increased significantly and Bcl-2 protein level was decreased in the SW480-ad-p27mt when compared with that in SW480-ad-β-gal and SW480. The expression of β-actin as an internal control was approximately the same in all of the cells.

Growth of cells *in vitro*

Relative cell number was evaluated by comparing the absorbance in each cell at day 2, day 4 and day 6. As shown in Figure 3, the growth of SW480-ad-p27mt was markedly inhibited compared with SW480-ad-β-gal and SW480.

Cells cycle analysis

To further determine whether up-regulation of p27 protein can induce apoptosis and or cell cycle arrest, flow cytometric analysis was performed on each transductant. It is suggested that cells containing a sub-G_1 content of DNA reflect the extent to which apoptosis is occurring. Flow cytometric analysis demonstrated that *p27mt* gene transduced into SW480 induced G_1/S arrest and apoptosis. A marked sub-G_1 peak and decreased percentage of cells in S phase were detected in SW480-ad-p27mt. Decreased percentage of cells in S phase suggested G_1/S arrest (Figure 4 and Table 1).

In vitro migration assay

SW480-ad-p27mt significantly showed the poor ability of migration when compared with that of SW480-ad-β-gal and SW480 (Figure 5).

In vivo growth inhibition assay

Twenty-eight days after inoculation, ten mice in each

group all survived. Intratumoral injection of ad-p27mt into established tumors induced marked growth suppression. As shown in Figure 6, the weight of tumors receiving ad-p27mt(SW480-ad-p27mt) was significantly lighter than that of ad-β-gal treated(SW480-ad-β-gal) or PBS treated(SW480).

DISCUSSION

In this study, we found that transduction of ad-p27mt into SW480 cells resulted in induction of overexpression of p27 protein, which suggests that the approach to restore *p27* expressing using adenoviral vectors is available and p27mt protein may be resistant to degradation by ubiquitin and more stable. Other studies also have shown that the p27 (T187A) mutant is not ubiquitinated[11,16,24,25,27], and the control of p27 protein levels is affected by ubiquitin-dependent degradation[17,25,26,28,29], in a ubiquitin-independent and Skp2-independent manner at G_1[30-32], and by Jab1-dependent degradation[33].

We also observed that ad-p27mt induced growth suppression, apoptosis, and G_1/S arrest in SW480 cells *in vitro* as well as the transplanted tumor growth inhibition *in vivo*, as was expected from the nature of *p27* as a CDKIs. These findings are consistent with those of another study in which ad-p27 (T187A) had a greater effect on cell cycle arrest and apoptosis induction because of its resistance to degradation, and suppressed the growth of established lung cancer xenografts[24]. In several studies, intratumoral injections of ad-p27 have

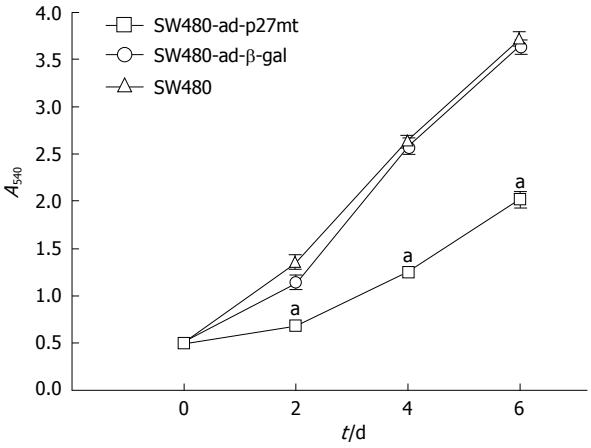

Figure 3 Growth of transductants *in vitro*. Relative cell number was evaluated by comparing the absorbance in each cell at day 2, 4 and 6. The values shown are the mean of eight determinations. [a]P < 0.05, *vs* control cells.

been shown to partially suppress tumor formation in animal models[18,23,24,34]. In other experiments, ad-p27 was the most potent of several cyclin kinase inhibitors in terms of inducing cell-cycle arrest, apoptosis and inhibiting tumorigenesis[2,18,21-23,27,34]. The effect of *p27* on the cell cycle is regulated mainly by its stability[35,36], but recent studies have shown that the function of *p27* is also associated with its subcellular localization[37-39]. Besides Thr187, there are three phosphorylation sites Ser10, Thr157 and Thr198 that are involved in cellular localization[40,41]. Phosphorylation at Ser10 stabilizes p27 protein in G_1[41]. Phosphorylation at Thr157 by protein kinase B/Akt impairs the nuclear import of *p27* but does not affect its stability in breast cancer and other cells[37,38]. Chu *et al*[42] indicating that the oncogenic kinase Src regulates *p27* stability through phosphorylation of *p27* at tyrosine 74 and tyrosine 88. Src inhibitors increase cellular p27 stability, and Src overexpression accelerates *p27* proteolysis.

The relationship between *p27* and induction of apoptosis is still unclear. Katayose *et al*[2] and Naruse *et al*[19] have suggested that the growth-inhibitory effect and apoptosis induction by overexpression of *p27* requires expression of pRb. The pRb-regulated checkpoint in G_1 phase is an important apoptotic checkpoint. CyclinE-CDK2 is the primary complex that phosphorylates pRb, which prevents interactions of it with the E2F transcription factor. To further understand the mechanism of ad-p27mt induced apoptosis in SW480 cells, we examined the expression of apoptosis-related genes Bax and Bcl-2 in each transductant. Results showed that ad-p27mt resulted in a marked increase in protein expression of Bax, a pro-apoptotic factor, and a marked decrease in protein expression of Bcl-2, an anti-apoptotic factor that binds to Bax and antagonizes its function. These results suggest that ad-p27mt-induced apoptosis in SW480 cells involves in induction of Bax.

Cell migration is an essential process involved in tumor invasion and metastasis. In this study, we tested the ability of cell migration in each transductant. We found that ad-p27mt resulted in strong migration

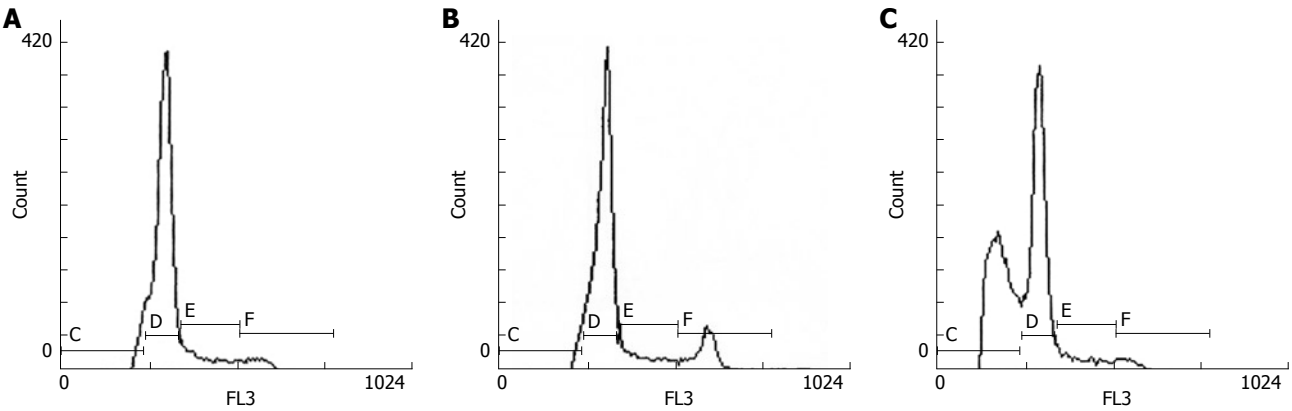

Figure 4 Cell cycle analysis of transductants by flow cytometry. **A**: SW480; **B**: SW480-ad-β-gal; **C**: SW480-ad-p27mt. C-F: Sub-G_1, G_0/G_1, S and G_2/M phase, respectively. The percentage of cells in sub-G_1, G_0/G_1, S and G_2/M phase is shown in Table 1.

Lower: *In vivo* tumor growth inhibition assay. The weight of tumors was measured. The values are mean of the weight of tumors of each group $^aP = 0.002$, *vs* control groups.

inhibition. Supriatno *et al*[11] have reported a similar result in oral cancer cell line. However, its mechanisms remain unclear and need further investigations. We speculate that it may be directly associated with decreased cell proliferation or/and alterations of structural proteins.

In conclusion, ad-p27mt shows a strong anti-tumor bioactivity in a colorectal cancer cell line SW480 and has the potential to develop into new therapeutic agents for colorectal cancer.

ACKNOWLEDGMENTS

We thank Dr. Jia-Ning Wang for his excellent technical assistance.

COMMENTS

Background

The incidence of colorectal cancer is increasing all over the world. However it is short of effective therapeutic approach. Gene therapy to restore *p27* expressing has been promising, furthermore, a mutant type *p27* gene, with mutant of Thr-187/Pro-188 to Met-187/Ile-188, can inhibit degradation of p27 protein by ubiquitin-mediated pathway.

Research frontiers

p27, as a cyclin-dependent kinases inhibitor, tumor suppressor gene, and promoter of apoptosis, has been widely investigated. Furthermore, antitumor activity of *p27* has been demonstrated in breast, lung, and oral cancer. But the antitumor bioactivity of *p27* mt has not been studied on colorectal cancer.

Innovations and breakthroughs

The study indicates that ad-p27mt has a strong anti-tumor bioactivity in a colorectal cancer cell line SW480.

Applications

This will develop into new therapeutic agents for colorectal cancer.

Peer review

This is an interesting manuscript on the antitumor activity of the adenovirus mediated mutant $p27^{kip}$ gene in a colorectal cancer (CRC) cell line. Major finding of the study was that the tumor cell growth was inhibited both *in vitro* and *in vivo* by the gene transfer.

Abstract

AIM: To investigate the function of NOD2 in colonic epithelial cells (CEC).

METHODS: A combination of *in vivo* and *in vitro* analyses of epithelial cell turnover in the presence and absence of a functional NOD2 protein and, in response to enteric *Salmonella typhimurium* infection, were used. shRNA interference was also used to investigate the consequences of knocking down *NOD2* gene expression on the growth and survival of colorectal carcinoma cell lines.

RESULTS: In the colonic mucosa the highest levels of NOD2 expression were in proliferating crypt epithelial cells. Muramyl dipeptide (MDP), that is recognized by NOD2, promoted CEC growth *in vitro*. By contrast, the growth of NOD2-deficient CECs was impaired. *In vivo* CEC proliferation was also reduced and apoptosis increased in *Nod2*$^{-/-}$ mice, which were also evident following enteric *Salmonella* infection. Furthermore, neutralization of NOD2 mRNA expression in human colonic carcinoma cells by shRNA interference resulted in decreased survival due to increased levels of apoptosis.

CONCLUSION: These findings are consistent with the involvement of NOD2 protein in promoting CEC growth and survival. Defects in proliferation by CECs in cases of CD may contribute to the underlying pathology of disrupted intestinal homeostasis and excessive inflammation.

INTRODUCTION

The intestinal epithelium both acts as a physical barrier and senses and responds to commensal bacteria *via* expression of pattern recognition receptors (PRRs) that recognize microbe associated molecular patterns (MAMPs)[1]. There are two distinct groups of PRRs; the Toll-like receptor family (TLRs) and the NOD-like (nucleotide-binding oligomerisation domain) receptors. The leucine rich repeat sequences of the NOD2 protein are implicated in recognition of fragments of bacterial peptidoglycan (PGN) including muramyl dipeptide (MDP)[2,3].

NOD2 is expressed in the cytosol of professional antigen presenting cells and epithelial cells exposed to

microorganisms containing PGN[3-6]. In cell-based models of NOD2 overexpression, MDP stimulation results in NF-κB activation[4,7]. This together with the ability of pro-inflammatory cytokines to influence NOD2 expression[8] suggests NOD2 contributes to the innate immune response to microbial pathogens. As intestinal epithelial cells are generally refractory to TLR signals in the absence of inflammation, NOD2 may have additional functions[9]. In the small intestine NOD2 appears to contribute to Peyer's patch development[10] and paneth cell production of anti-microbial proteins[11], linking NOD2 and host defense at the epithelial interface.

By contrast, little is known about NOD2 function in the colon. It has been proposed that TLRs control epithelial homeostasis[12]. In considering the cross talk between NOD2 and TLR signaling pathways[13], NOD2 expression in IBD[14] and the central role CARD domain-containing proteins play in regulating apoptosis[15], we determined if activation of NOD2 in CECs is important for promoting CEC turnover and maintaining the integrity of the epithelial barrier. We found that NOD2 contributes to regulating CEC proliferation and survival.

MATERIALS AND METHODS

Animals and infections

Six to nine wk old C57BL/6-*Nod2*$^{+/+}$ and C57BL/6-*Nod2*$^{-/-}$ (F8)[16] mice bred and maintained in the same animal facility were infected by oral gavage with 10^6 cfu luciferase-expressing *Salmonella enterica serovar typhimurium* (SL1344-Tn5lux). Biophotonic imaging (Xenogen Corp. Alameda, CA) was used to determine bacterial cfu in tissue homogenates[17]. All animal experiments were conducted in full accordance with the Animal Scientific Procedures Act 1986 under Home Office approval.

CEC isolation and culture

Segments of colon were sequentially incubated three times in dissociation buffer (130 mmol/L NaCl, 10 mmol/L HEPES, pH 7.4, 10% FCS and 1 mmol/L DTT) containing first 1 mmol/L, then 5 mmol/L and finally 10 mmol/L EDTA at 37℃ for 15 min[18]. Aliquots of cells were stained with Wright-Giemsa (Baxter, Miami, FL), CD45 (Caltag Labs, Burlingame, CA), cytokeratin (Sigma-Aldrich, Poole, UK) and Ki67 (Dako, Carpinteria, CA) antibodies and incubated with alkaline phosphatase (AlkP) substrate (Vector Labs, Burlingame, CA) to establish CEC purity and identify proliferating (cytokeratin$^+$, Ki67$^+$, CD45$^-$) and differentiated (cytokeratin$^+$, AP$^+$, CD45$^-$) CECs. CEC monolayer cultures, established from dispase-digested fragments of colonic mucosa[19] were incubated with 1-10 mg/mL MDP (Ac-muramyl-Ala-Disoglutamine) for up to 4 d. Cell growth and viability were assessed by trypan blue exclusion. For NF-κB activation, nuclear extracts of CECs cultured for 2 h with MDP (1 mg/mL) or media alone were analyzed by ELISA (BD-Pharmingen) using specific inhibitors to block NF-κB activation as per the manufacturers' instructions. Recombinant human TNF α (R&D Systems) was added to HT-29 and SW480 human colonic carcinoma cell lines (provided by Prof. Mark Hull, Univ. Leeds) to induce NOD2 expression[8].

Histology

Villous crypt height was determined by measuring the distances from the base of the crypt to the villous tip of at least 20 villi from 3 HE-stained sections of colon from 5 mice of each strain prior to and following infection. Axiovision software (Imaging Associates Ltd, Bicester, UK) was used for scaling and measurements.

Flow cytometry

Antibody staining (cytokeratin and CD45) and flow cytometry was used to assess CEC purity. Apoptotic cells were quantified by Annexin V and propidium iodide (PI) or 7AAD staining[20,21]. Levels of caspase 3 activity in cultured CECs were determined using the NucViewTM 488 substrate (Biotium, Hayward, CA) according to the manufacturers' recommendation. Stained cells were analyzed using a FACSCalibur and CellQuest software (BD).

Immunohistochemistry

Paraffin (5 μm) sections were incubated with Ki67 (Dako), caspase 3 (BD-Pharmingen), BrdU (Oxford Biotechnology Ltd, Oxford, UK) or isotype matched control antibodies followed by biotinylated secondary antibodies (Vector Labs) and streptavidin-horseradish peroxidase plus DAB (Vector Labs) or anti-rabbit EnVision™ labeled polymer (Dako). For BrdU detection sections were pre-treated with 2 mol/L HCl for 30 min followed by neutralization in 0.1 mol/L $Na_2B_4O_7$ for 5 min to denature DNA. Stained cells in sections were enumerated using a Zeiss Axiovert 200 M microscope (Zeiss, Welwyn Garden City, UK) equipped with Axiovision software.

qRT-PCR

NOD2 mRNA was quantified in freshly isolated primary CECs and in HT-29 and SW480 cells using pre-optimized primer sets (Applied Biosystems, Foster City, CA) and an ABI prism 7900HT Sequence Detection System (Applied Biosystems). Threshold cycle (Ct) numbers were determined with Sequence Detection Software (Applied Biosystems) and analysed using the delta Ct comparative method. β-actin was used as a reference gene.

RNAi

NOD2 and scrambled NOD2 shRNA sequences (Dharamacon, Lafayette, CO) were cloned into GFP-expressing lentiviral vector, pLL 3.7. shRNA expressing lentiviruses were prepared using the ViraPower Expression System (Invitrogen). HT-29 and SW480 human colonic carcinoma cells were infected with lentiviruses and 10 mg/mL polybrene (Sigma) for 16 h. Quantitative (Taqman) RT-PCR was used to assess CARD15 mRNA knockdown. Viability and growth of infected (GFP$^+$) and non-infected (GFP$^-$) cells was assessed by flow cytometry as described above.

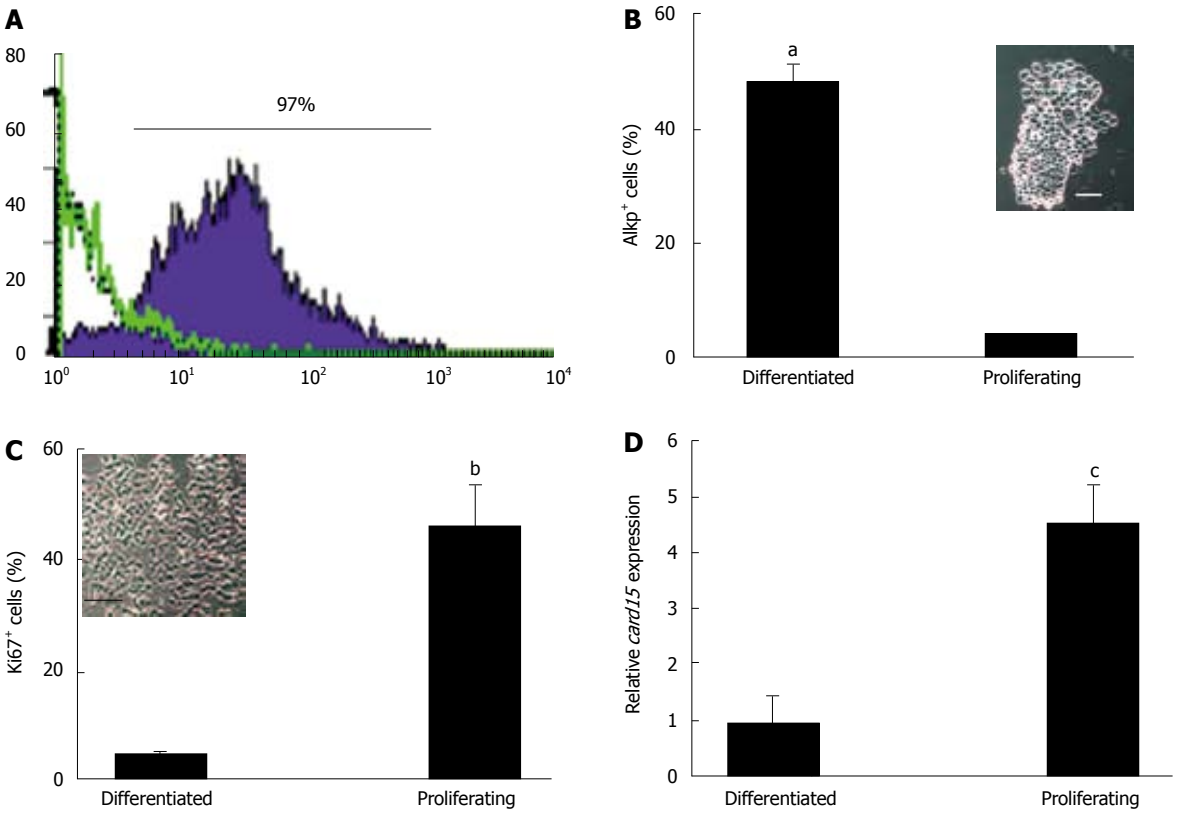

Figure 1 NOD2 expression by CECs. **A**: Colonic epithelial cells were isolated by incubating segments of colon with increasing concentrations of EDTA. Purity was assessed by staining with anti-cytokeratin (filled profile) and -CD45 (green open profile) antibodies and by flow cytometry using isotype matched antibodies to determine levels of background staining (dotted open profile). The % value shown represents the frequency of cytokeratin$^+$ cells in a representative 10 mmol/L EDTA fraction. **B** and **C**: 1 mmol/L and 10 mmol/L EDTA fractions of CECs were evaluated for the presence of differentiated and proliferating epithelial using alkaline phosphatase (AlkP) activity and Ki67 expression, respectively, as described in the Methods section. $^aP < 0.03$ in **B** and $^bP < 0.015$ in **C**. The morphology of cells in 1 mmol/L and 10 mmol/L EDTA fractions is depicted in the phase contrast photomicrograph insets in **B** (10 mmol/L) and **C** (1 mmol/L). Magnification is 160. Scale bar in **B** = 10 μm and in **C** = 40 μm. **D**: The relative levels of Card15 mRNA in fractions of colonic crypts enriched for proliferating and differentiated epithelial cells were determined by real time RT-PCR using β-actin as a reference gene. The data represents averaged values (± SE) of four experiments. $^cP < 0.05$.

Statistical analysis

All data were assessed for normal distribution using a Shapiro-Wilk test. For parametric and non-parametric data, analysis was performed using Student *t*-test and Mann Whitney test, respectively using the Student Package for the Social Sciences software (SPSS). *P* values < 0.05 were considered significant.

RESULTS

Cell turnover is altered in NOD2-deficient CECs

In view of previous reports of NOD2 expression in human colonic epithelial cell lines, isolated colonic crypts and among individual CECs[5,8,14] we sought evidence of NOD2 expression in primary murine colonic crypt epithelia. Initial immunohistochemical studies identified weak immunoreactivity among epithelial cells at the base of colonic crypts in wild type mice with a NOD2 antiserum (data not shown). To verify this finding, quantitative RT-PCR was used to measure NOD2 mRNA levels in CECs from different regions of the crypt. Sequential incubations in EDTA-containing buffers provided two morphologically distinct populations of epithelial cells of high purity (> 97% cytokeratin$^+$) enriched for cells expressing markers of proliferation (Ki67) or differentiation (alkaline phosphatase, AlkP; Figure 1A-C). Preparations enriched for proliferating cells (about 50% Ki67$^+$, < 5% AP$^+$) contained significantly higher (0.95 ± 0.5 *vs* 4.5 ± 0.7, $P < 0.05$.) levels of NOD2 mRNA than fractions enriched for differentiated CECs (about 50% AP$^+$, < 5% Ki67$^+$; Figure 1D).

Consistent with NOD2 involvement in epithelial homeostasis, the length of colonic crypts in adult *Nod2*$^{-/-}$ mice was significantly shorter (143 ± 10 *vs* 93 ± 5, $P < 0.05$) compared to that in *Nod2*$^{+/+}$ mice (Figure 2 and 3A). These differences were also evident after oral infection with a non-lethal dose of *Salmonella enterica serovar typhimurium*. The average length in *Nod2*$^{-/-}$ mice was increased upon infection, but was still significantly shorter (134.74 ± 4.22 *vs* 170.97 ± 6.55, $P < 0.05$) than in infected *Nod2*$^{+/+}$ mice at 32 h.

Nod2$^{-/-}$ mice were more susceptible than wild type mice to invasion by *Salmonella*. During the first 24 h of *Salmonella* infection the colonic bacterial burden of *Nod2*$^{-/-}$ mice (cfu at 4 h: 840 ± 161; at 8 h: 1123 ± 187, at 24 h: 631 ± 202) was significantly higher ($P < 0.0005$) than in *Nod2*$^{+/+}$ mice (cfu at 4 h: 78 ± 52; at 8 h: 88 ± 55; at 24 h: 101 ± 33). *Nod2*$^{-/-}$ animals also manifested severe diarrhea compared to *Nod2*$^{+/+}$ mice, which persisted for 36 h, although they fully recovered after 3 d.

CEC turnover *in vivo* was investigated further by

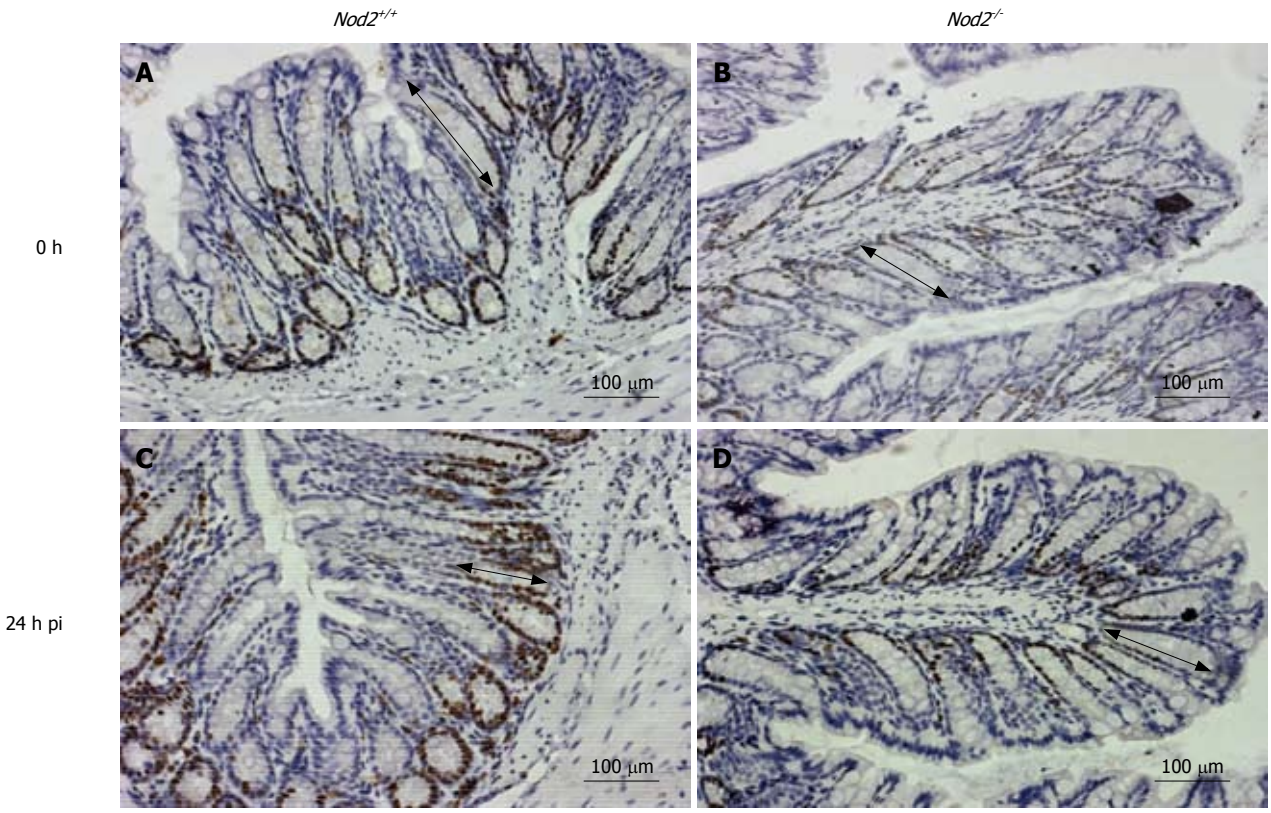

Figure 2 Decreased proliferation of NOD2-deficient CECs. Sections of colon from *Nod2*$^{+/+}$ (wild type: WT) and *Nod2*$^{-/-}$ mice obtained prior to (0 h) and 24 h after enteric *Salmonella* infection were stained with an anti-Ki67 antibody and DAB and then counterstained with H&E. Ki67-reactive cells within the crypt regions are identified by the darkly stained nuclei. The arrows indicate the crypt-villous height with the scale bar representing 100 μm.

BrdU uptake and Ki67 expression. Significantly fewer Ki67$^+$ and BrdU$^+$ CECs were present in *Nod2*$^{-/-}$ mice compared to *Nod2*$^{+/+}$ mice, both prior to and after *Salmonella* infection (Figures 2, 3B and 3C). Proliferating (BrdU$^+$) epithelial cells also migrated shorter distances from the crypts in *Nod2*$^{-/-}$ mice compared to *Nod2*$^{+/+}$ mice (unpublished observations), consistent with reduced CEC proliferation. *Nod2*$^{-/-}$ mice also had significantly higher numbers of apoptotic (caspase3$^+$) CECs compared to *Nod2*$^{+/+}$ mice after *Salmonella* infection (1.52 ± 0.37 *vs* 2.75 ± 0.48, $P < 0.001$, Figure 3D). These *in vivo* studies do not, however, exclude the possibility that the effects of NOD2 deficiency on CEC growth and apoptosis are secondary to changes in the activity of mucosal immunocompetent cells.

Growth and apoptosis of *Nod2*$^{-/-}$ CECs in culture following isolation was analyzed. Primary cultures of *Nod2*$^{-/-}$ CECs (see Methods section) contained significantly higher (11.5 ± 1.1 *vs* 17.7 ± 1.4, $P < 0.0105$) numbers of apoptotic cells compared to *Nod2*$^{+/+}$ CECs (Figure 4A) with consistently more cells expressing caspase3 (Figure 4B). The growth of *Nod2*$^{-/-}$ CEC *in vitro* was also significantly less than *Nod2*$^{+/+}$ CECs at 24 h (10.7 ± 0.4 *vs* 8.3 ± 0.2, $P < 0.026$, Figure 4C). Of note, the addition of MDP to cultures of *Nod2*$^{+/+}$ CEC increased cell numbers, whereas no increase in *Nod2*$^{-/-}$ CEC number was seen in response to MDP (Figure 4C). The defect in *Nod2*$^{-/-}$ CEC growth *in vitro* was correlated with defective MDP-mediated NF-κB activation (Figure 4D).

Neutralization of CARD15 by shRNA reduces human colonic epithelial carcinoma cell survival

Further evidence for the direct involvement of NOD2 in regulating epithelial cell proliferation was sought using RNA interference (RNAi) to knockdown expression of *NOD2* in HT-29 and SW480 human colonic carcinoma cells.

After transfection with lentiviral vectors expressing short hairpin RNA (shRNA) *NOD2* sequences, the level of CARD15 mRNA in both HT-29 and SW480 cells, as determined by quantitative RT-PCR, was reduced by 75%-80%, compared to both non-treated cells and cells infected with control lentivirus expressing scrambled *NOD2* sequences (Figure 5A and data not shown). *NOD2* shRNA treatment led to a significant decline in HT-29 cell survival with < 20% of GFP$^+$ (virus infected) cells surviving beyond 6 days (Figure 5B). The decline in GFP$^+$ cells was explained by decreased cell viability and increased apoptosis (Figure 5C). Similar to primary *Nod2*$^{+/+}$ and *Nod2*$^{-/-}$ CEC, knockdown of *NOD2* mRNA had no effect on cell cycle progression, although the number of cycling cells was reduced (unpublished observations) reflecting the increased levels of cell death. By comparison, the growth and survival of HT-29 cells infected with lentiviral vectors expressing scrambled *NOD2* shRNA sequences was unaffected (Figure 5B). A similar outcome of *NOD2* shRNA on epithelial cell growth was seen in SW480 cells (Figure 5D), although the loss of GFP$^+$ SW480 cells occurred over a longer time period with about 60% reduction in GFP$^+$ cells seen after 4 wk (Figure 5D).

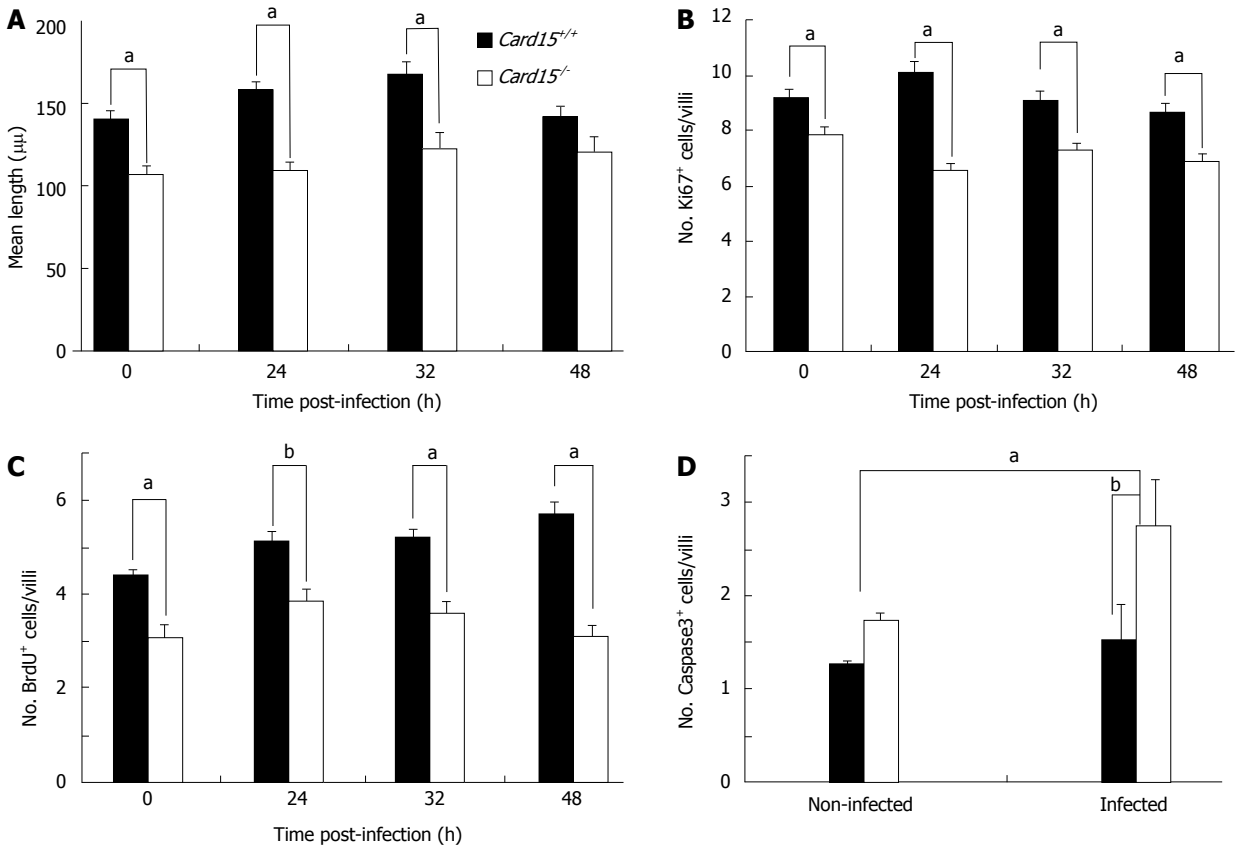

Figure 3 Decreased proliferation of *Nod2*$^{-/-}$ CECs *in vivo*. **A**: Mean crypt-villous height measurements were determined by measuring distances from the base to the tip of the crypt of at least 20 crypts from sections taken at the distal, mid and proximal parts of the colon of *Nod2*$^{+/+}$ and *Nod2*$^{-/-}$ mice (n = 5) prior to (0 h) and at different times after peroral *Salmonella* infection. The mean (± SE) of counting at least 20 crypts in 3-4 sections of 4-5 mice of each strain is shown. **B**: Sections of *Nod2*$^{+/+}$ and *Nod2*$^{-/-}$ colon were stained with anti-Ki67 antibody with the mean (± SE) number of stained cells in 5-6 sections from three mice of each strain shown. $^{a}P < 0.05$. **C**: BrdU-incorporation was assessed by injecting *Nod2*$^{+/+}$ and *Nod2*$^{-/-}$ mice with BrdU 1 h prior to removing the colons, which were then sectioned and stained with an anti-BrdU antibody. The graph represents the mean (± SE) number of BrdU^{+} epithelial cells per crypt as determined by counting stained cells in > 20 crypts from 5-6 sections taken from proximal, mid and distal regions of the colons from three mice of each strain. $^{a}P < 0.05$, $^{b}P < 0.001$. **D**: Sections of colon from *Nod2*$^{+/+}$ and *Nod2*$^{-/-}$ mice were stained with anti-active caspase3 antibodies with the mean (± SE) number of caspase3^{+} cells in 4-5 sections from three mice of each strain shown. $^{a}P < 0.05$, $^{b}P < 0.001$.

DISCUSSION

The integrity of the colonic epithelium is maintained by the continual renewal of epithelial cells as a result of the accelerated division of crypt cells that migrate upwards from the base of the crypts. Little is known about the origin and nature of the factors that regulate these processes. Here, we provide evidence for the involvement of NOD2 in regulating murine CEC turnover.

Expression of NOD2 in preparations of CECs enriched for proliferating cells described here, together with prior accounts of increased epithelial expression under conditions of rapid proliferation *in vitro* and in the inflamed and infected intestine[6,11,14,22] and, the increased severity of chemical-induced colonic mucosal damage in NOD2-deficient mice[10], suggests NOD2 contributes to regulating epithelial cell turnover and promoting epithelial repair. The low amount of NOD2 expression in the colonic mucosa, under steady-state conditions described here and previously[14], is consistent with this hypothesis and that altered epithelial cell proliferation and death[23] and increased epithelial permeability[24] contribute to the development of IBD. The absence of intestinal inflammation in *Nod2*$^{-/-}$ mice[10,11,16,25], or in mice with a knock-in mutation corresponding to the predominant disease-associated mutant form of human *NOD2* in Crohn's disease[25], suggests that while *NOD2* gene mutations and altered epithelial turnover are a prerequisite for developing Crohn's disease, they are not sufficient in themselves[26]. Other additional genetic factors or environmental triggers that disrupt the epithelial barrier[10] must also occur for the development of disease.

The absence of NOD2 in CECs does not completely abolish cellular proliferation. NOD2 may, therefore, function as part of a network of interacting and interdependent factors that includes other PRRs and various cytoprotective and repair factors that collectively regulate epithelial homeostasis with other components partially compensating for the absence of NOD2. NOD2 does, however, appear to play a more essential role in promoting the growth and survival of immortalized HT-29 and SW480 colonic carcinoma cells. Differences in the survival curves of these cell lines after *NOD2* shRNA treatment may relate to differences in the genetic mutations and their impact on the requirement for NOD2 dependent-survival signals. Additional studies, using primary human CECs and colonic specimens from patients bearing CD-associated

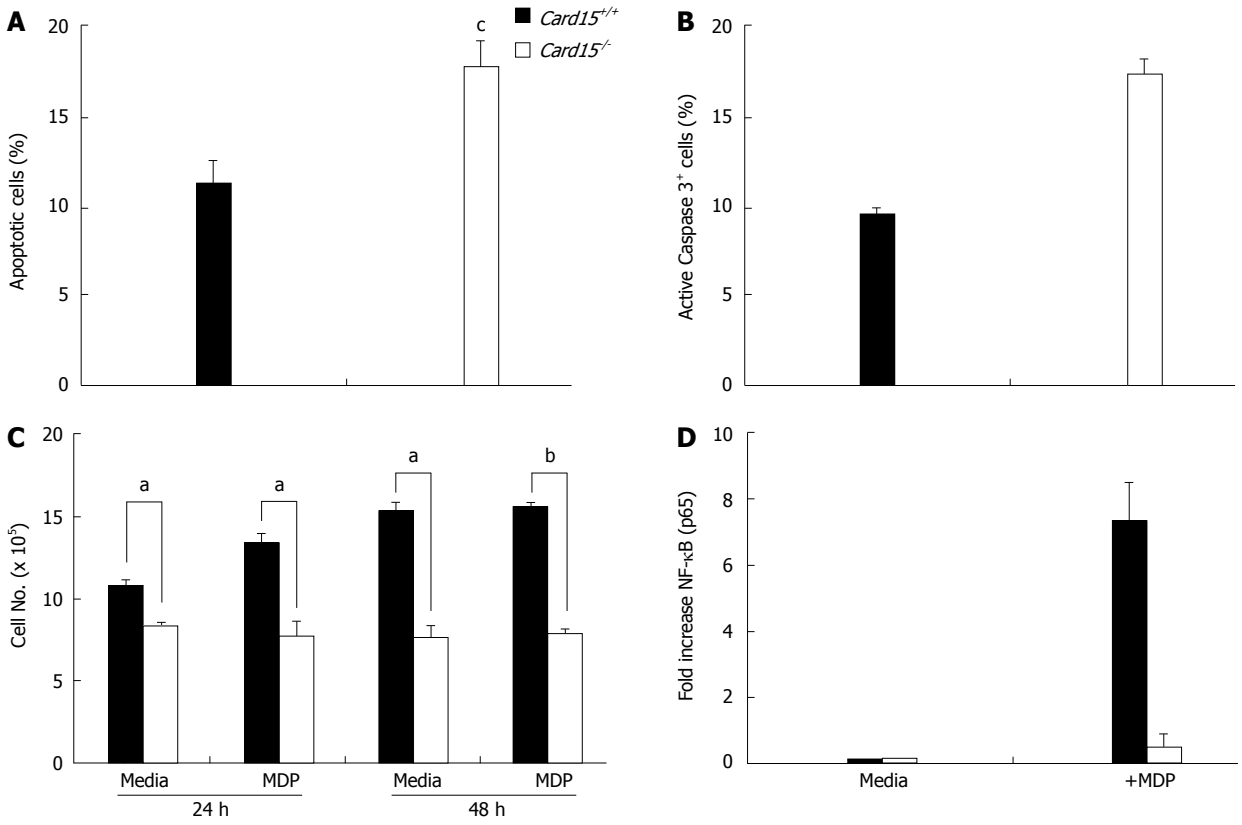

Figure 4 Decreased survival of *Nod2*$^{-/-}$ CECs *in vitro*. **A**: The level of apoptotic cells in cultures of primary CECs from *Nod2*$^{+/+}$ and *Nod2*$^{-/-}$ mice was determined by annexin V and propidium iodide (PI) staining and flow cytometry. Data was collected from 5 experiments and shows the mean (± SE) values. $^{c}P < 0.01$ **B**: The frequency of *Nod2*$^{+/+}$ and *Nod2*$^{-/-}$ CECs containing caspase3 activity was determined using the flow cytometry based NucViewTM488 Caspase-3 assay. The data represents the mean (± SE) values collected from two experiments. **C**: The growth of *Nod2*$^{+/+}$ and *Nod2*$^{-/-}$ CECs in the absence (Media) or presence of 10 μg/mL muramyl dipeptide (MDP) was determined by comparing the number of viable CEC at the initiation of culture and after 24 h and 48 h. The data shown represents the mean (± SE) of 3 experiments. $^{a}P < 0.05$, $^{b}P < 0.001$. **D**: NF-κB activation in *Nod2*$^{+/+}$ (filled bars) and *Nod2*$^{-/-}$ (open bars) CEC after exposure to muramyl dipeptide (MDP) was determined by quantitating NF-κB p65 levels in nuclear extracts using a Transfactor Kit as described in Methods section. Values were normalized to control values of cells grown in media alone. The data shown represents the mean (± SE) values from 3 independent experiments.

NOD2 mutations, are required to substantiate these findings. However, the inability of HT-29 and SW480 cells to survive NOD2 RNAi treatment is consistent with the disrupted growth of *Nod2*$^{-/-}$ primary CECs *in vitro* and *in vivo* and, that the sustained expression of NOD2 is required to maintain high rates of CEC proliferation. Identifying the pathways and mediators of NOD2 signaling in CECs will help establish how NOD2 contributes to CEC and tumor cell survival.

The proposed role of NOD2 in colonic epithelial homeostasis does not necessarily contradict the notion that it is a bacterial sensor and contributes to innate immunity[27,28]. The importance of NOD2 in innate anti-bacterial responses is demonstrated by the increased bacterial burden and inflammation seen here in *Nod2*$^{-/-}$ mice after enteric *Salmonella* infection and previously after infection with *Listeria*[11], both of which disrupt epithelial barrier function. Cell type specific influences and microenvironmental factors may account for contrasting roles for NOD2 in different studies. The importance of environmental influences is perhaps best demonstrated by its divergent role(s) in the very different environment of the small intestine, where it regulates anti-microbial protein production[11] and GALT development[10], and the colon where it regulates epithelial cell turnover. In addition, differences in the expression of NOD2-regulatory proteins[29,30], or endogenous inhibitors of NOD2[31], could also explain different outcomes of NOD2 activation in different cell types. The recent identification of a NOD2 target gene (DMBT1) that is predominantly expressed in epithelial cells[32] is also consistent with cell type specific NOD2 responses.

How NOD2 carries out its diverse array of functions in different regions of the gastrointestinal tract remains to be determined. In the colon, NOD2's effect on CEC growth could be direct by, for example, regulating expression of genes and/or proteins involved in cell growth. mRNA profiling of wild type and *Nod2*$^{-/-}$ CECs by microarray analysis has identified securin (pituitary tumor transforming gene-1) that is required for maintaining appropriate cell division[33] as one of the most underrepresented genes in *Nod2*$^{-/-}$ CECs (unpublished observation). Alternatively, the involvement of PRRs in the production of cytoprotective and reparative cytokines in the colon[12] and reports of altered patterns of cytokine production by NOD2-deficient cells[34-36] suggest an indirect mechanism of action of NOD2. The growth-promoting effect of NOD2 in CECs contrasts with MDP-induced apoptosis of rabbit kidney epithelial cells, which may reflect cell type specific differences in the response to MDP and its interaction

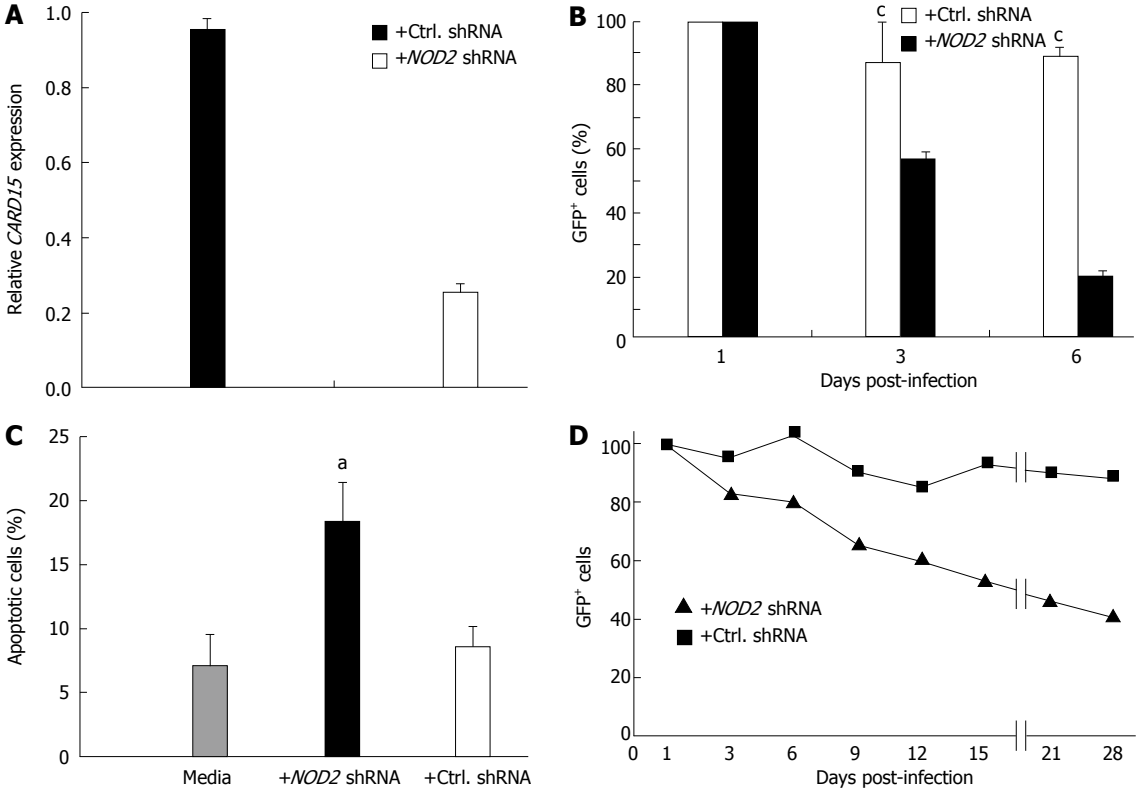

Figure 5 Neutralization of *CARD15* gene expression in colon carcinoma cells reduces their survival. **A**: The level of *NOD2* mRNA in HT-29 cells transfected with green fluorescent (GFP) containing lentiviral vectors expressing either *NOD2* (*NOD2* shRNA) or scrambled *NOD2* shRNA sequences (Ctrl. shRNA) was determined by real time RT-PCR after 4 h stimulation with TNFα. Levels were compared to that of nontreated cells (= 1.0). Data are averaged values (± SE) of 3 experiments. **B**: The impact of CARD15 and control shRNA on the growth of HT-29 cells was assessed by determining the frequency of GFP$^+$ and GFP-cells by flow cytometry at 1 d, 3 d and 6 d post infection. Data are averaged values (± SE) of 3 experiments. $^cP < 0.01$. **C**: Frequency of apoptotic cells in cultures of non-infected HT-29 cells (Media) and in cells 2 d after infection with *NOD2* shRNA or Ctrl shRNA was determined by staining with Annexin V and 7AAD and flow cytometry. The graph represents the averaged frequency (± SE) of apoptotic cells from three experiments. $^aP < 0.05$. **D**: The survival of SW480 cells after transfection with lentiviral vectors expressing either *NOD2* or scrambled shRNA sequences was analysed by determining the frequency of GFP$^+$ cells remaining at various times after infection by flow cytometry. The data is representative of two independent experiments.

with different cellular proteins including NOD2[37]. Further studies aimed at identifying NOD2 signaling pathways in CECs will be important in determining how this protein functions in intestinal epithelial cells.

In summary, we have shown that NOD2 contributes to maintaining epithelial cell homeostasis in the colon. Compromised barrier repair may, therefore, underlie aspects of Crohn's disease where mutant *NOD2* alleles contribute to disease.

COMMENTS

Background

Mutations in *NOD2* alleles are associated with an increased risk of developing Crohn's disease (CD), an Inflammatory Bowel Disease (IBD). However, it is unclear how *NOD2* mutations contribute to the development of CD and in particular to intestinal epithelial homeostasis.

Research Frontiers

Our study has identified a novel function for NOD2 in the regulation of colonic epithelial cell growth and in the survival of colonic epithelial tumor cell lines.

Innovations and breakthroughs

This study is the first to provide direct evidence of a role for NOD2 in epithelial cell growth and survival. Compromised epithelial barrier restitution and repair after injury may, therefore, contribute to the pathogenesis of CD in patients with mutant *NOD2* alleles.

Applications

Further understanding of the function of NOD2 and the role it plays in the pathogenesis of CD will be of benefit in developing new therapies for CD.

Peer review

This interesting study was to determine the molecular mechanisms regulating NOD2 function in colonic epithelial cells. The authors conducted both *in vivo* and *in vitro* studies to show the specific functions of the NOD2 protein. This is an outstanding and clearly written paper that provides strong evidence for a role for NOD2 in murine colonic epithelial survival.

Abstract

AIM: To investigate the potential of bone marrow mononuclear cells (BM-MCs) in the regeneration of hepatic lesions induced by *Schistosoma mansoni* (*S.mansoni*) chronic infection.

METHODS: Female mice chronically infected with *S.mansoni* were treated with BM-MCs obtained from male green fluorescent protein (GFP) transgenic mice by intravenous or intralobular injections. Control mice received injections of saline in similar conditions. Enzyme-linked immunosorbent assay (ELISA) assay for transforming growth factor-beta (TGF-β), polymerase chain reaction (PCR) for GFP DNA, immunofluorescence and morphometric studies were performed.

RESULTS: Transplanted GFP$^+$ cells migrated to granuloma areas and reduced the percentage of liver fibrosis. The presence of donor-derived cells was confirmed by Fluorescence in situ hybridization (FISH) analysis for detection of cells bearing Y chromosome and by PCR analysis for detection of GFP DNA. The levels of TGF-β, a cytokine associated with fibrosis deposition, in liver fragments of mice submitted to therapy were reduced. The number of oval cells in liver sections of *S.mansoni*-infected mice increased 3-4 fold after transplantation. A partial recovery in albumin expression, which is decreased upon infection with *S.mansoni*, was found in livers of infected mice after cellular therapy.

CONCLUSION: In conclusion, transplanted BMCs migrate to and reduce the damage of chronic fibrotic liver lesions caused by *S.mansoni*.

Key words: *Schistosoma mansoni*; Liver injury; Fibrosis; Bone marrow cells; Transplantation; Albumin; Oval cells

INTRODUCTION

Chronic infection by *Schistosoma mansoni* (*S.mansoni*) is one of the experimental models of hepatic fibrosis

used to elucidate the mechanisms involved in the fibrogenic processes. In schistosomiasis, the main immune-inflammatory response is directed against the parasite eggs, which, when led to portal circulation, may become lodged into hepatic portal venules, eliciting a granulomatous response. In the mouse model of schistosomiasis, the persistence of the stimulus leads to the development of two pathological patterns; isolated granulomas or periportal fibrosis, the latter resembling the pipe-stem fibrosis found in the severe hepatosplenic form of human disease[1].

Liver fibrosis occurs in the setting of chronic injury caused by different etiologies constituting a serious worldwide public health problem. Whereas in acute hepatic injury nonviable cells are replaced by normal tissue, during chronic injuries a persistent repair response may lead in fibrosis and scar formation as a result of an imbalance between proliferation and degradation of the extracellular matrix components[2]. In addition to schistosomiasis, hepatopathies due to alcohol, viral hepatitis, drugs, metabolic and autoimmune diseases, and congenital abnormalities are important causes of liver fibrosis[2].

New therapeutic strategies aiming to minimize damages caused by hepatic fibrogenesis in chronic liver diseases are of great interest. Adult bone marrow contains pluripotent stem cells with the ability to differentiate into diverse cell types, including hepatocytes[3]. The regenerative potential of bone marrow stem cells has been tested in experimental models of hepatic injury, demonstrating the ability of bone marrow cells (BMCs) to generate hepatocytes under tissue stress in mice and human[4,5]. In this context, regenerative medicine has emerged as an alternative therapy to improve damaged liver function[5-7].

In this report, we used an experimental model of hepatic fibrogenesis caused by chronic infection with *S.mansoni* in order to evaluate the contribution of cellular therapy in hepatic diseases. We investigated the potential of syngeneic bone marrow mononuclear cells in the modulation of fibrosis, albumin expression and cellular alterations.

MATERIALS AND METHODS

Animals

Female or male C57Bl/6 wild-type and enhance green fluorescence protein (EGFP) transgenic mice (4-6 wk old) were used as recipients and as donors of BMCs, respectively. All the animals weighting 20-23 g were raised and maintained at the Gonçalo Moniz Research Center/ FIOCRUZ in rooms with controlled temperature (22 ± 2℃) and humidity (55% ± 10%) and continuous air renovation. Animals were housed in a 12 h light/12 h dark cycle (6 am-6 pm) and provided with rodent diet and water *ad libitum*. Animals were handled according to the NIH guidelines for animal experimentation. All procedures described here had prior approval from the local animal ethics committee.

Infection with Schistosoma mansoni

C57Bl/6 mice were infected by transcutaneous route with 30 *S.mansoni* cercariae of the Feira de Santana strain[8]. This strain was maintained through successive passages in laboratory-raised *Biomphalaria glabrata* (*B.glabrata*). Two weeks later the animals were exposed to reinfection with 15 cercariae to increase the hepatic injury. The infection was confirmed 40 d after the primary infection by parasitological exam of feces. Only mice presenting viable eggs in the stools were used. For the retreat of the injury stimulus mice were treated with praziquantel (Farmanguinhos, Fiocruz, Rio de Janeiro, Brazil) by gavage in a single dose of 400 mg/kg per wk 4 mo after the primary infection.

Transplantation of BMCs

BMCs were obtained from femurs and tibiae of 4-6 wk old C57Bl/6 EGFP transgenic mice. BMC were purified by centrifugation in Ficoll gradient at 1000 *g* for 15 min (Histopaque 1119 and 1077, 1:1; Sigma, St. Louis, MO). After two washings in RPMI medium (Sigma), the mononuclear cell fraction was suspended in saline, filtered over nylon wool and used for therapy. BMC population was analyzed by flow cytometry using the following conjugated antibodies from Becton Dickinson (San Diego, CA, USA): Sca 1-PE/Cy5, CD45-APC, CD44-PE, CD34-PE, CD11b-PE, and CD117-PE. Acquisition and analysis were performed in a FACScalibur flow cytometer (Becton Dickinson). The following percentages were obtained: 96.51 ± 1.32 for GFP^+ cells; 0.11 ± 0.032 for Sca 1^+ cells; 96.35 ± 3.12 for $CD45^+$ cells; 92.72 ± 3.23 for $CD44^+$ cells; 0.02 ± 0.05 for $CD34^+$ cells; 60.22 ± 5.71 for $CD11b^+$ cells; and 0.17 ± 0.04 for $CD117^+$ cells. For therapy, one group of mice received one administration of BMC (3×10^7 cells/ mouse) directly into the left hepatic lobe (intralobular). In the other experiments, mice were treated with BMC (3×10^7 cells/mouse) intravenous (iv, by retroorbital plexus), once a week, during 3 wk. Control mice received injections of saline in similar conditions to the respective experimental groups. Mice were submitted to euthanasia at different times after therapy, under anesthesia with ketamine and xylazine.

Transforming growth factor-beta (TGF-β) assessment

TGF-β levels were measured by enzyme-linked immunosorbent assay (ELISA) in total protein of homogenized liver tissue (50 mg) in 100 μL PBS containing 0.4 mol/L NaCl, 0.05% Tween 20 and protease inhibitors (0.1 mmol/L PMSF, 0.1 mmol/L benzethonium chloride, 10 mmol/L EDTA and 20 KI aprotinin A/100 mL). The samples were centrifuged at 10 000 r/min for 10 min at 4℃ and the supernatant was frozen at -80℃ for later quantification. TGF-β levels were measured using a sandwich ELISA assay following the manufacturers' instructions (R&D Systems, Minneapolis, MN).

Morphological and morphometrical analyses

Mice were perfused under anesthesia through the heart with 50 mL of PBS followed by 200 mL of 16 g/L paraformaldehyde at 4℃. Liver slices were fixed in

Bouin or formalin at 10% and, after paraffin embedding, 5 μm-thick sections were obtained and stained with conventional hematoxylin-eosin or with picrosirius-red for collagen[9]. Quantification of fibrosis was carried out in sections stained with picrosirius-red examined by optical microscopy, in 10 fields per liver in 5-14 mice per group. Images were digitalized using a color digital video camera (CoolSnap, Montreal, Canada) adapted to a BX41 microscope (Olympus, Tokyo, Japan) and analyzed using Image Pro program (version 6.1; Media Cybernetics, San Diego, CA). For morphometric measurements of granuloma area, a total sectional area of 723255 μm^2 per animal was evaluated. All periocular granulomas were included. Albumin granules and OV-6$^+$ cells were quantified in five liver sections of seven or five animals per group (normal, treated and untreated), respectively, by fluorescence microscopy (BX61 Olympus) and analyzed using Image Pro program. Albumin granules were automatically quantified and the number of hepatocytes was estimated manually by nuclear staining in order to determine the average number of albumin granules/cell. All the analyses were done double-blinded.

Immunofluorescence analyses

Five micrometer frozen sections obtained at various times after transplantation were prepared and fixed in 16 g/L cold paraformaldehyde in 0.1 mol/L phosphate buffer. The presence of transplanted GFP$^+$ BMC in the liver tissue was analyzed by direct fluorescence. Oval cells were stained using a biotinylated anti-OV-6 antibody (R&D Systems, Minneapolis, MN) followed by streptavidin Alexa 568 (Molecular Probes, Carlsbad, CA). For albumin visualization and quantification, liver sections were stained using a rabbit anti-human albumin (DAKO, Glostrup, Denmark) followed by anti-rabbit IgG conjugated with Alexa fluor 568 (Molecular Probes). For collagen I quantification, sections were stained with rabbit anti-human collagen (Novatec, Saint Martin La Garenne, France) followed by anti-rabbit IgG conjugated with Alexafluor 568 (Molecular Probes). Nuclei were stained with 4,6-diamidino-2-phenylindole (VectaShield Hard Set mounting medium with DAPI H-1500; Vector Laboratories, Burlingame, CA). The presence of fluorescent cells was determined by observation in a BX61 microscope with epifluorescence system plus grid to enhance the fluorescence resolution (Optigrid, Structured-light Imaging System, Thales Optem inc, Fairport, NY) using appropriate filters (Olympus). Images were captured using a color digital video SPOT flex camera (15.2, 64 Mp, Shifting Pixel, Diagnostic Instruments inc, Sterling Heights, MI).

Fluorescence in situ hybridization (FISH) in paraffin-embedded tissue sections

Liver sections 3-6 μm thick were prepared on glass slides and dried overnight at 37℃. After dewaxing in xylene and rehydration, sections were incubated with sodium thiocyanate solution for 10 min at 80℃, washed in PBS followed by incubation with pepsin solution for 10 min at 37℃. Sections were washed in PBS, post-fixed in paraformaldehyde solution for 2 min, washed in PBS, and dehydrated through graded alcohols before air drying. Detection of Y chromosome was done using Y-paint probe kit (Cambio, Cambridge, UK), according to the manufacturers' instructions. Slides were mounted with coverslips using Vectashield mounting set with DAPI (Vector), and analyzed by fluorescence microscopy.

Polymerase chain reaction (PCR) for GFP

The presence of donor-derived DNA in liver tissue was analyzed 2 mo after BMC transplantation in *S.mansoni*-infected mice. DNA was extracted from liver tissue using a DNA extraction kit (QIAamp® DNA Mini Kit-50, Qiagen, Hilden, Germany) according to the manufacturers' instructions. DNA concentrations were quantified in 1 μL in a spectrophotometer ND-1000 (Nanodrop Technologies, Wilmington, DE). All samples were diluted to 100-200 ng/μL. PCR amplification of GFP cDNA was performed using Taq polymerase (Invitrogen, Carlsbad, CA) using standard procedures and the following primers pair (Invitrogen): forward, 5'-CGTCGCCGTCCAGCTCGACCAG-3', reverse, 5'-CATGGTCCTGCTGGAGTTCGTG-3'.

Statistical analyses

Data were analyzed using Student's *t*-test, Mann Whitney, ANOVA and Newman-Keuls multiple comparison test with the aid of Prism Software (version 3.0, GraphPad Software, San Diego, CA). Differences were considered significant if $P \leqslant 0.05$.

RESULTS

Transplanted GFP$^+$ BMC are found in livers of S.mansoni-infected mice

Mice chronically infected with *S.mansoni* were treated with GFP$^+$ mononuclear BMC by injection into the left hepatic lobe. Liver sections were obtained at different times after transplantation. Bright GFP$^+$ cells were found around periocular granulomas, in the injected lobe, 2 h after cell infusion (Figure 1A to C). After 24 h of injection, GFP$^+$ cells were also found inside granulomas in sections of injected (Figure 1D) as well as in non-injected lobes (not shown). Five days after transplantation, elongated, spindle shape GFP$^+$ cells were mainly found inside granuloma areas (Figure 1E and F). Bright GFP$^+$ cells were not found in sections of BMC-treated mice 1 or 2 mo after transplantation by iv route, although faint fluorescent cells co-expressing albumin were found in the hepatic parenchyma at this later timepoint (Figure 1G). The presence of donor-derived hepatocyte-like cells was confirmed by detection of Y-chromosome by FISH analysis in parenchymatous cells in liver sections of BMC-treated mice (Figure 1H). Furthermore, the presence of GFP DNA was detected by PCR in liver samples of BMC-treated mice 2 mo after therapy (Figure 2).

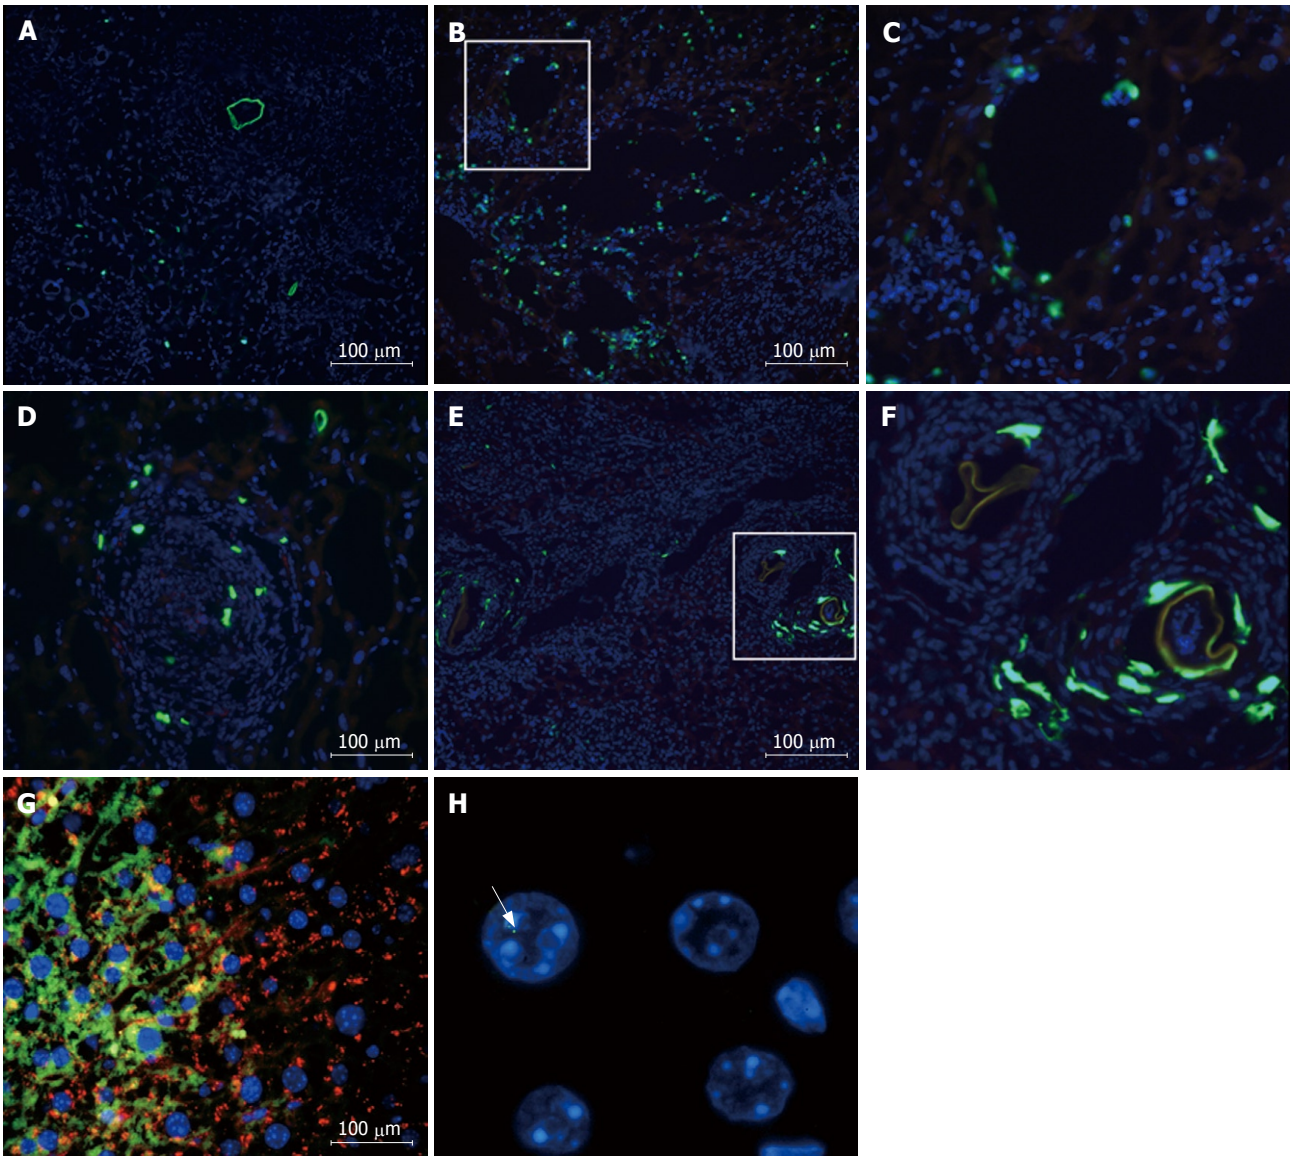

Figure 1 Visualization of donor-derived cells in liver sections of *S.mansoni*-infected mice. Mice chronically infected with *S.mansoni* were treated with GFP$^+$ BMC by injection into the left hepatic lobe (**A**-**F**) or by iv route (**G** and **H**) and sacrificed after different time points for evaluation by fluorescence microscopy. For visualization of GFP$^+$ cells (green), sections were mounted with the nuclear counterstaining with DAPI (blue). **A** and **B**: Sections of injected lobe of mice sacrificed 2 h after transplantation; **C**: Magnification of square area of image **B**. Sections of livers obtained from mice sacrificed 24 h (**D**) or 5 d (**E**) after intralobular BMC injection. **F**: Magnification of square area of image **E**; **G**: GFP$^+$ albumin$^+$ cells found in liver sections 2 mo after iv injection of BMC; **H**: Detection of Y chromosome (arrow) in liver section of BMC-treated mice 1 mo after transplantation by iv route.

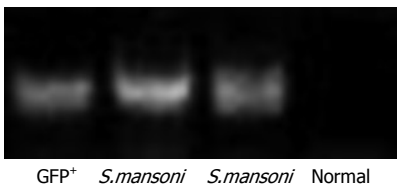

Figure 2 Detection of donor cell DNA in livers of BMC-transplanted mice. *S.mansoni*-infected mice treated with BMC by iv route were sacrificed 2 mo after therapy. Liver fragments were used for DNA extraction and PCR amplification of *GFP* gene. Liver fragments of normal wild-type and GFP mice were used as controls.

Therapy with BMC reduces liver fibrosis induced by S.mansoni infection

Liver sections of *S.mansoni*-infected mice were analyzed, showing a granulomatous inflammatory process in all groups, with periocular granulomas well delimited and homogeneous in shape and cellular infiltrate with predominance of mononuclear cells and with regular and concentric deposits of collagen fibers (Figure 3A to C). After treatment with BMC, we observed a reduction of fibrosis (Figure 3B and D), compared to saline-treated animals. In animals treated by intralobular injection of BMC, a statistically significant reduction of fibrosis was observed in treated lobes 2 mo after treatment (Figure 4A). In addition, a reduction of fibrosis was also found in sections of untreated lobes (% of fibrosis in untreated lobes: 14.1 ± 0.7 compared to livers of saline-treated mice: 17.9 ± 0.7; $P < 0.001$). Fibrosis reduction was also observed when BMC were injected by iv route (Figure 4B). Morphometric evaluation of granuloma area showed a significant reduction after

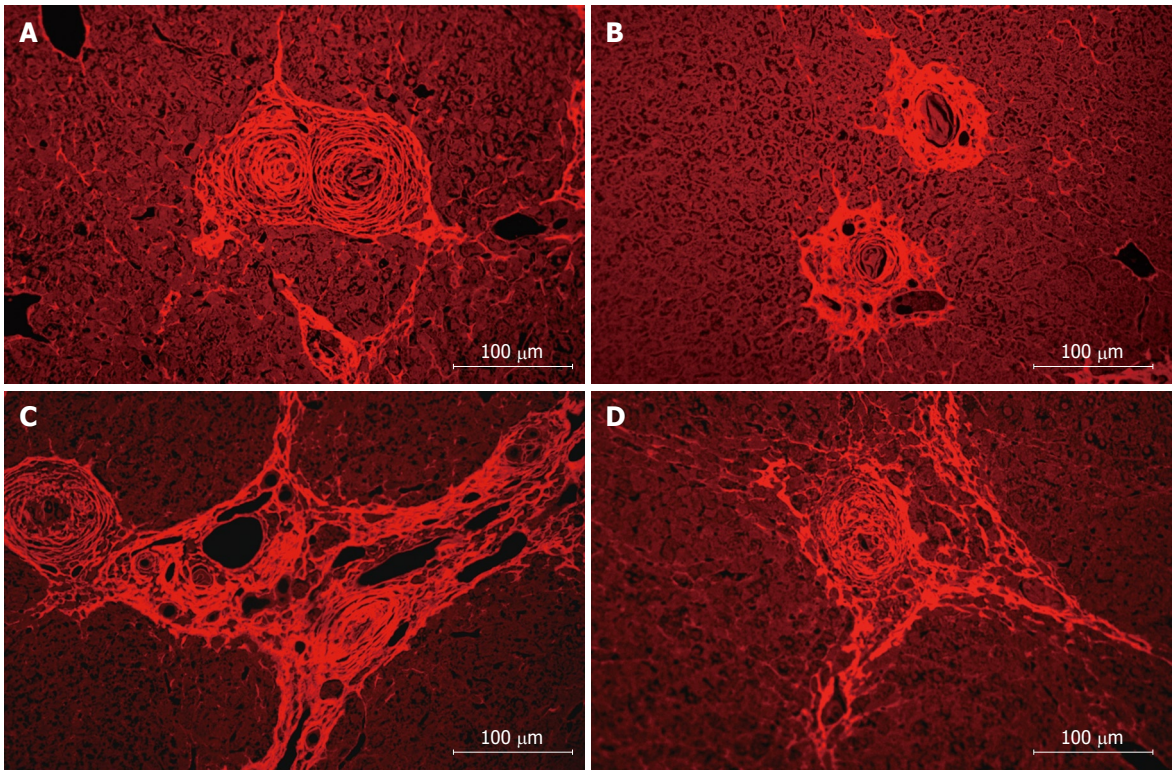

Figure 3 Alterations in liver fibrosis after BMC therapy in *S.mansoni*-infected mice. The morphological aspects of liver sections were detected by fluorescence analyses. Representative images of liver sections stained by Sirius red-Fast green of *S.mansoni*-infected mice 2 mo after saline (**A** and **B**) or BMC (**C** and **D**) treatment by iv route.

therapy in animals treated with BMC by intralobular (Figure 4C) as well as by iv injection (Figure 4D). This reduction was confirmed in sections stained with anti-collagen I antibodies, by morphometry (saline-treated: 7.14% ± 0.45% compared to BMC-treated: 4.20% ± 0.25%; $P < 0.0004$).

TGF-β levels in liver fragments were assessed 2 mo after BMC therapy by iv route. A significant decrease of TGF-β levels was observed in livers of BMC-treated mice compared to saline-treated *S.mansoni*-infected mice. The levels of TGF-β in BMC-treated mice were similar to those of normal mice (Figure 5).

Increase in oval cell numbers after BMC transplantation in S.mansoni-infected mice

The presence of oval cells in liver sections of normal, *S.mansoni*-infected mice treated or not with BMC was evaluated by immunofluorescence using an anti-OV-6 antibody. Sections of normal livers had none or few OV-6$^+$ cells (Figure 6A). Infection with *S.mansoni* caused an increase in the number of OV-6$^+$ cells, which were mainly found in zone 1 areas of the hepatic lobe in saline-treated (Figure 6B), as well as in BMC-treated animals (Figure 4B) 2 mo after iv route. The number of OV-6$^+$ cells, however, was 3-4 times higher in sections of BMC-treated mice (Figure 6C; $P = 0.0027$).

BMC treatment increases albumin production in S.mansoni-infected mice

Immunostaining for albumin in liver sections of mice chronically infected with *S.mansoni* showed an abnormal pattern of albumin expression. A bright intracytoplasmic granular staining is found in sections of uninfected mice (Figure 7A), whereas liver sections of untreated *S.mansoni*-infected mice had few and abnormal albumin granules, preferentially located in the periphery of hepatocytes (Figure 7B). Liver sections of BMC-treated mice also had an altered albumin staining pattern, although more intense than untreated mice (Figure 7C). When the number of albumin$^+$ granules was evaluated, a significant difference between uninfected and infected mice was found, showing a 3-fold higher number of granules in normal mice compared to saline-treated infected mice (Figure 7D; $P < 0.001$). BMC therapy caused a significant increase in the number of granules, compared to saline-treated, *S.mansoni*-infected mice ($P < 0.05$), although the levels where still below those of normal livers (Figure 7D; $P < 0.001$).

DISCUSSION

Cellular therapy for liver regeneration has been intensively investigated mainly in models of hepatic diseases caused by drug administration, surgical interventions and by genetic disorders[10-13]. A number of reports have demonstrated that transplantation of BMCs improves liver function, decreases fibrosis and contributes to parenchyma regeneration[11,14,15]. In this report, we describe for the first time the effects of BMC therapy in a model of chronic liver disease caused by a parasitic infection.

The recruitment of BMCs to liver lesions has

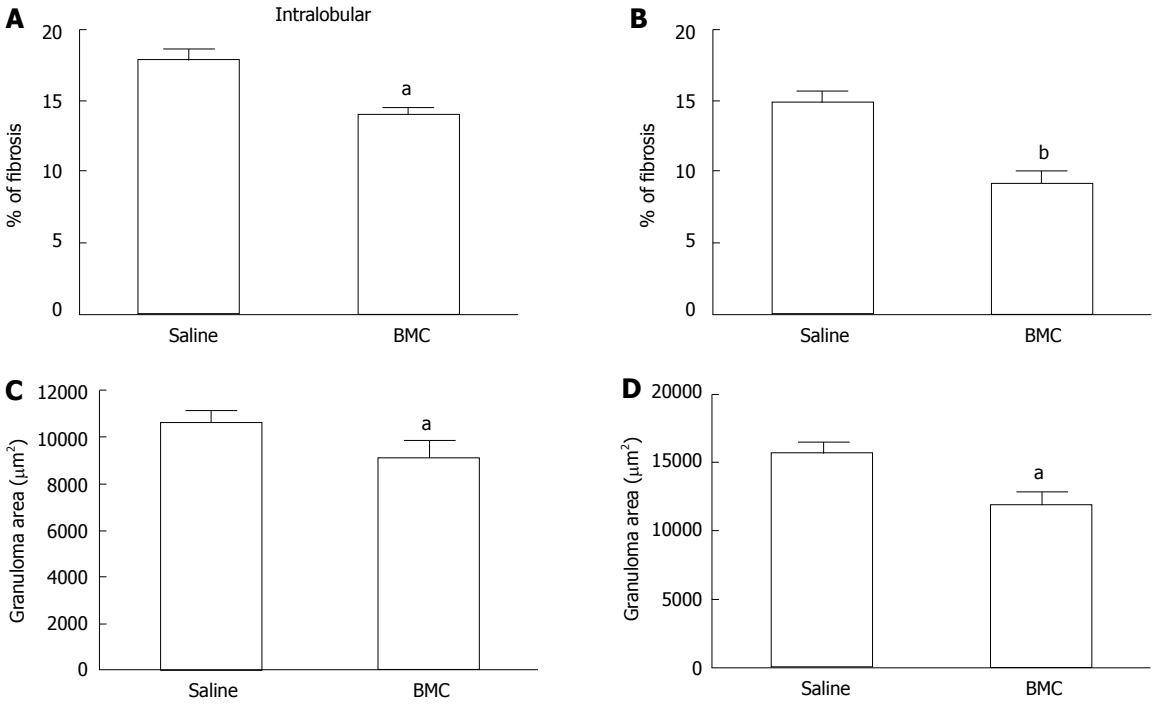

Figure 4 Reduction of fibrosis and granuloma area after BMC therapy. Mice infected with *S.mansoni* and treated with saline or BMC by intralobular (**A** and **C**) or iv **B** and **D** routes were sacrificed 2 mo after treatment. Liver sections sampled randomly and stained with Sirius red-Fast green were examined by optical microscopy. Images were digitalized and analyzed by morphometry. The percentage of fibrosis (**A** and **B**) and the area of periocular granulomas (**C** and **D**) were evaluated. Data were represented graphically as mean ± SE of 5-14 animals per group. $^{a}P < 0.05$ and $^{b}P < 0.01$ compared to saline-treated group.

Figure 5 BMC therapy decreases the levels of TGF-β in the liver. TGF-β levels were assessed in fragments of hepatic tissue of uninfected, saline-treated or BMC-treated *S. mansoni*-infected mice 2 mo after BMC infusion by iv route, by sandwich ELISA. Data represents the mean ± SE of 4-8 animals per group. $^{a}P < 0.05$ compared to uninfected group; $^{b}P < 0.01$ compared to saline-treated group.

been well documented in several models of liver diseases[10-12,14]. In our study, we also found that liver injury caused by *S.mansoni* infection elicits the migration of BMCs, which were able to reach the granuloma areas. Many of the cells observed in the liver sections are probably leukocytes (found in the mononuclear cell fraction used in the cellular therapy), that are chemoattracted by the intense inflammatory reaction around periocular granulomas. Most GFP^{+} cells that migrated inside the granulomas, however, are larger than leukocytes and could be spindle-shaped like fibroblasts or myofibroblasts. Both of these cells are well known to participate in the fibrogenesis associated with *S.mansoni* infection and also to take part in collagen degradation during fibrosis modulation[16-18]. The differentiation of BMCs into myofibroblasts and/or fibroblasts may be an important step in the modulation of fibrosis observed in the present study. Recently, it has been shown that a significant number of myofibroblasts in human hepatic fibrosis are of bone marrow origin[19].

In latter time points, cells expressing weak GFP fluorescence co-expressing albumin were observed. The presence of transplanted BMC-derived parenchymatous cells was confirmed by observation of donor DNA by PCR analysis (for detection of GFP DNA) and FISH (for detection of Y chromosomes in nuclei). These results reinforce a contribution of BMCs in the reconstitution of liver parenchyma, as described before in other models of liver diseases[20,21]. In our study, we found few hepatocyte-like cells bearing Y chromosome (1-2 cells/section). In addition, we did not find binucleated cells with Y chromosome in one nucleus. Although we cannot rule out that fusion of transplanted BMC with resident hepatocytes occurs, these findings indicate that the few hepatocyte-like cells derived from transplanted BMC observed in our model are generated by transdifferentiation. In addition to the population of stem cells, the potential of transdifferentiation into hepatocytes has been recently extended to another cell type present in the bone marrow, the monocytes[22]. Thus, it is possible that more than one cell type present in the cell preparation used in our study take part in the generation of hepatocyte-like cells. It is also likely that the transplanted cells take part in the immune regulation of the liver[23], causing the modulation of fibrosis,

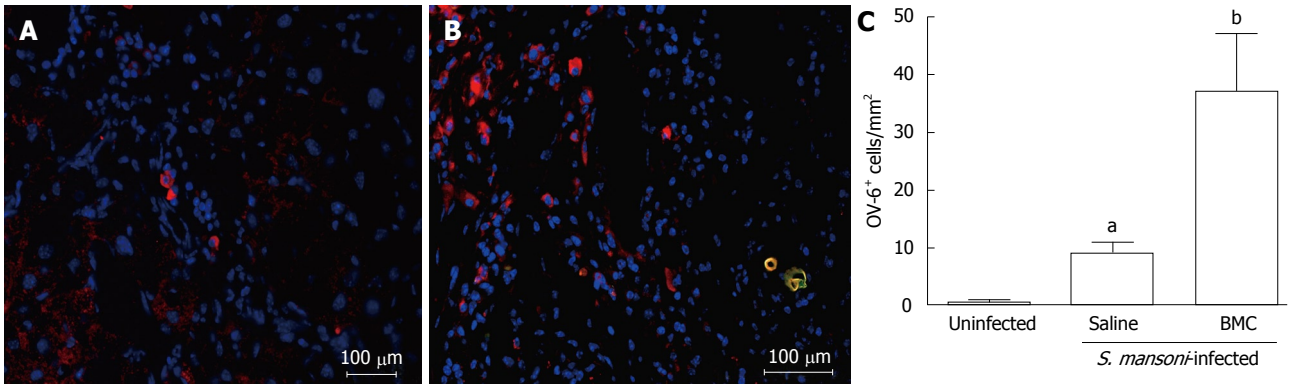

Figure 6 Increased numbers of oval cells after BMC therapy. Oval cells (OV-6$^+$ stained in red) in sections of saline (**A**) or BMC (**B**) treated mice 2 mo after transplantation by iv route. **C**: The number of oval cells in liver sections of uninfected, saline-treated or BMC-treated *S. mansoni*-infected mice 2 mo after cellular infusion by iv route was determined by immunofluorescence analysis using an anti-OV-6 antibody. Data represents the mean ± SE of 5-6 animals per group. $^aP < 0.05$ compared to uninfected group; $^bP < 0.001$ compared to saline-treated group.

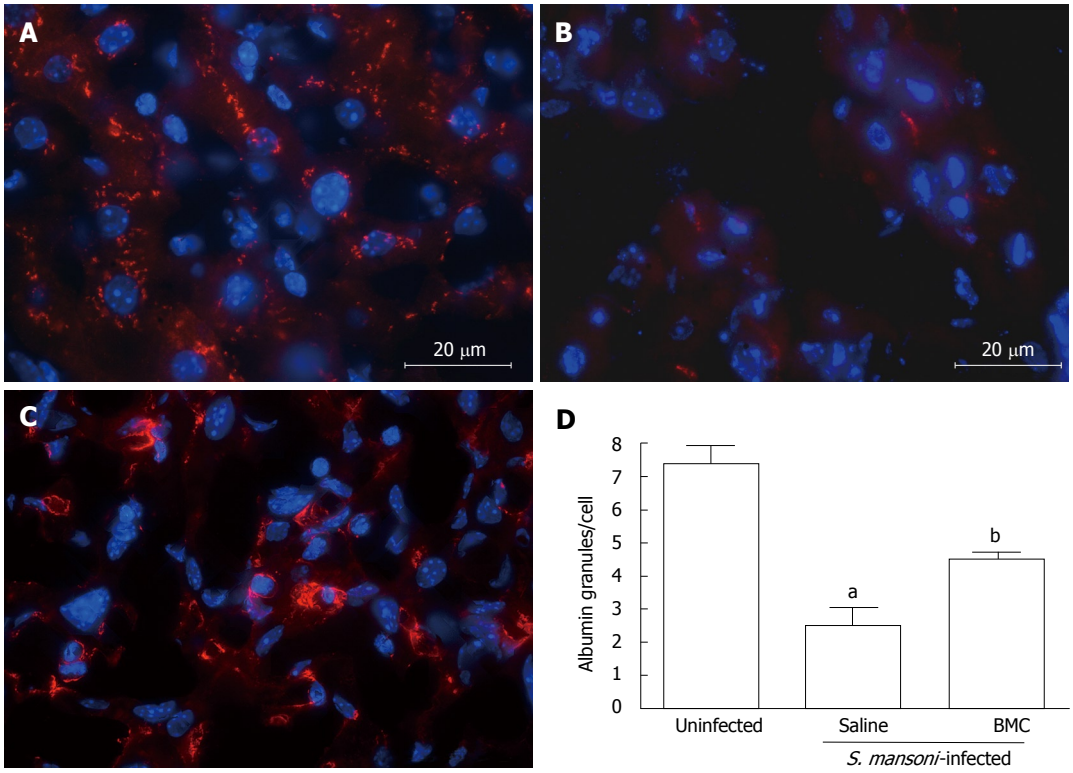

Figure 7 Increased albumin expression after BMC therapy. Albumin (red) and nuclei (blue) staining in sections of uninfected (**A**), saline-treated (**B**) or BMC-treated (**C**), *S.mansoni*-infected mice, 2 mo after treatment by iv route. **D**: Albumin$^+$ granules were quantified by morphometry in liver sections of uninfected, saline-treated or BMC-treated *S.mansoni*-infected mice 2 mo after cellular infusion by iv route. Data represents the mean ± SE of 7 animals per group. $^aP < 0.05$ compared to uninfected group; $^bP < 0.001$ compared to saline-treated group.

cytokine production and albumin synthesis observed in our study.

Fibrosis is a common feature of chronic liver diseases. The increased deposition of extracellular matrix causes structural alterations in the liver and in its function, and portal hypertension due to the obstruction of vessels and focal ischemic lesions. Although spontaneous regression of fibrosis occurs when the stimulus for hepatic liver damage is removed, in diseases such as viral hepatitis the stimulus cannot be completely removed, in addition to being a slow process[24]. Therefore, means to decrease liver fibrosis are extremely relevant to improve liver function and to decrease complications related to chronic hepatopathies. In this regard, schistosomiasis is an interesting model of chronic fibrotic liver disease. In our study, we observed a significant decrease of liver fibrosis after cellular therapy, as demonstrated by morphometrical analysis of granuloma area and total liver fibrosis. This was achieved both by intralobular administration as well as by iv injection, indicating that fibrosis does not hamper the influx of cells to the liver of *S.mansoni*-infected mice. In a recent report, Higashiyama *et al* (2007), demonstrated that bone marrow-derived cells which migrated to

fibrotic livers express matrix metalloproteinases. Thus, the transplanted cells found in the hepatic parenchyma of *S.mansoni*-infected mice may be acting directly to increase the degradation of extracellular matrix components.

One of the main mediators involved on fibrosis deposition during hepatic injury is TGF-β[25]. This cytokine stimulates the transition of stellate cells to myofibroblasts, which secrete high amounts of extracellular matrix and inhibit its degradation[26]. TGF-β levels were lowered after BMC therapy in livers of *S.mansoni*-infected mice, reaching levels close to those found in normal mice. A decrease in TGF-β production was also observed by Fang *et al*[14] after therapy using bone marrow-derived mesenchymal stem cells in mice with liver injury caused by CCl_4 administration.

Oval cells are hepatic precursors of hepatocytes and bile duct cells[27]. An increase in oval cell numbers was found in liver sections of *S.mansoni*-infected mice, compared to those of normal mice. Transplantation of BMC, however, caused a 3-4 fold increase in oval cell numbers in infected mice. This may be explained by the fact that oval cells can be originated from BMCs[4]. Alternatively, the effects of BMC injection on oval cell numbers may be due to their migration to and action in other organs, such as the bone marrow. It is possible that the increase in oval cells contribute to the replacement of areas where fibrosis degradation occurs with functional parenchymatous cells after BMC therapy.

Although alterations in albumin levels in *S.mansoni*-infected individuals are rare, this can be observed in some cases. A study by Cook *et al*[28] reported hypoalbuminemia in *S.mansoni*-infected children, which suggests that this biochemical alterations associated with undernourishment or to effects of repeated digestive hemorrhages. In contrast, chronic infection with *S.mansoni* causes hypoalbuminemia in mice. This phenomenon occurs simultaneously to the increase in collagen deposition and could be associated with the decrease in albumin mRNA found in *S.mansoni*-infected mice[29]. In our study, we also observed a marked alteration of albumin expression in hepatocytes of infected mice, compared to normal controls. BMC therapy significantly increased the expression of albumin in livers of *S.mansoni*-infected mice, although the pattern was still altered in comparison to that of normal livers. An increase in albumin levels was also found after cell therapy in a model of CCl_4-induced lesion in rats[30].

In conclusion, transplantation of BMCs in mice with chronic liver disease caused by *S.mansoni* infection decreased liver fibrosis and contributed to an increase in precursor cells as well as to the generation of new hepatocytes and/or to the improvement of the function of resident hepatocytes. Although there are still many unanswered questions regarding the mechanisms of action of transplanted cells in hepatic lesions, our results reinforce the use of cell-based therapies for patients with chronic liver diseases.

COMMENTS

Background

Liver fibrosis occurs in the setting of chronic injury caused by different etiologies, constituting a serious worldwide public health problem. Chronic infection by *S.mansoni* is one of the experimental models of hepatic fibrosis used to elucidate the mechanisms involved in the fibrogenic processes.
