Abstract

End-stage liver disease, due to cholestatic liver diseases with an autoimmune background such as primary biliary cirrhosis (PBC) and primary sclerosing cholangitis (PSC), is considered a good indication for liver transplantation. Excellent overall patient and graft outcomes, based mostly on the experience from deceased donor liver transplantation (DDLT), have been reported. Due to the limited number of organ donations from deceased donors in most Asian countries, living donor liver transplantation (LDLT) is the mainstream treatment for end-stage liver disease, including that resulting from PBC and PSC. Although the initial experiences with LDLT for PBC and PSC seem satisfactory or comparable to that with DDLT, some aspects, including the timing of transplantation, the risk of recurrent disease, and its long-term clinical implications, require further evaluation. Whether or not the long-term outcomes of LDLT from a biologically related donor are equivalent to that of DDLT requires further observations. The clinical course following LDLT may be affected by the genetic background shared between the recipient and the living related donor.

Key words: Liver transplantation; Primary biliary cirrhosis; Primary sclerosing cholangitis; Living donor; Recurrence

INTRODUCTION

Primary biliary cirrhosis (PBC) is characterized by the destruction of interlobular and septal bile ducts, leading to cholestasis and fibrosis[1]. Primary sclerosing cholangitis (PSC) is also a chronic cholestatic liver disease, characterized by inflammatory and fibrotic bile duct lesions forming multiple strictures and dilatations of the intra- and extrahepatic bile ducts[2-4].

Disordered immune regulation is considered to have a role in both PBC and PSC, though the specific immunologic mechanisms are yet to be clarified despite recent advancements[2,5]. In both PBC and PSC, there is a gradual progression of cholestasis, which results in end-stage liver disease (ESLD). In PBC, the administration of ursodeoxycholic acid (UDCA) starting at an early stage of the disease improves the prognosis and is, therefore, recommended[6,7]. On the other hand, effective medical treatment for PSC remains a matter of debate. UDCA administration, with or without the use of immunosuppressive agents, seems to have

a beneficial effect on liver function tests, assessed by blood chemistries. But, it is not clear whether there is a beneficial effect on delaying the progression of the disease and improving the overall survival rate[8].

Liver transplantation is the optimal treatment for patients with PBC or PSC presenting with ESLD and associated complications, such as severe manifestations of portal hypertension[5,8]. The short-term mortality rate, due to disease recurrence following transplantation, is lower in patients with PBC or PSC than in those with hepatitis C or hepatic malignancy. Longer follow-up, however, has revealed that both PBC and PSC can recur. But, the impact of a recurrence on long-term patient survival seems to be insignificant in deceased donor liver transplantation (DDLT)[9].

Living donor liver transplantation (LDLT) has been accepted with greater enthusiasm in Asia, especially in the Far East where organs from deceased donors remain extremely scarce. Technical innovations driven by necessity have enabled the development of LDLT and extended its indications to adult populations[10,11]. In November, 1993, the first successful LDLT for an adult recipient was performed at Shinshyu University by Makuuchi and colleagues[12]. A 53-year-old woman with end-stage cholestatic liver disease due to PBC received a left liver graft from her son. The patient remains the longest survivor of this epoch-making success.

In LDLT, there is no waiting time. There is no competition between recipients for the availability of organs, unlike in DDLT. Liver transplantation becomes an option as soon as a socially-acceptable and medically-suitable dedicated living donor becomes available[13]. Although a transplant with anatomically challenging features and smaller graft size may pose some difficulties, LDLT has some clear advantages when compared with DDLT. LDLT may be performed in a planned manner after thorough preparation at an earlier stage of the liver disease. In addition to the recipients' surgical risk, potential risks to the living donor cannot be overlooked. Transplantation should be considered when there is a clear survival benefit; that is, when the estimated risk of mortality for a patient on medical treatment alone exceeds that of the expected peri-operative mortality. We consider that LDLT becomes a beneficial option for patients with ESLD including that from PBC or PSC, who have a Model for End-stage Liver Disease (MELD) score of 15-17 (a calculated 3-mo mortality rate of approximately 5%), balancing the risk and benefit to the recipient and prospective living donor[14]. LDLT for patients with co-existing hepatocellular carcinoma may be considered at an earlier stage.

PBC

Whether the combined symptoms of intractable pruritus, lethargy, or osteoporosis encountered in PBC should be considered an indication for LDLT in patients without significant signs of portal hypertension or liver failure remains an open question. At our institution, the indication of LDLT for PBC is based on the potential for improvement or benefits in life expectancy. Unlike in DDLT[15,16], less importance may be placed on quality of life in LDLT. We have considered that quality of life issues in the recipient do not outweigh even the slightest possibility of donor mortality or morbidity that may result in disability. In addition to the above-mentioned MELD score, the results obtained from the Mayo model are taken into account[17]. Although the model was developed prior to the MELD era, and is not considered a factor for organ allocation in DDLT, we find that the Mayo model is very useful in the LDLT setting. As reported by Kim and colleagues[18,19], there is a window of opportunity appropriate for LDLT, expressed as risk scores of 6 to 7.8. Risk scores higher than 10 are related to longer hospitalization after LDLT and mortality[20,21]. When the risk of death by the natural disease course is predicted to outweigh the surgical risks of liver transplantation, LDLT may be planned and performed.

The 5-year survival rate after DDLT for PBC is approximately 80%[18,22]. The anti-mitochondrial antibody (AMA) status does not change after liver transplantation and, therefore, is not diagnostic of recurrent disease after transplantation[5]. PBC recurrence is currently defined according to the agreed criteria, including patient transplanted for PBC, persistence of AMA, and compatible liver biopsy[23]. The largest single-center series with a mean follow-up period of 56 mo indicated a rate of such confirmed recurrence to be 17% at a mean follow-up period of 36 mo after transplantation. Interestingly, although histologically recognizable recurrence of the disease may be common, its effect on survival seems insignificant in DDLT[22]. Liermann and colleagues[15,22] demonstrated that patients with recurrent disease tended to be younger and receive organs from younger donors, and to have a longer warm ischemia time. But, such differences were considered to be clinically insignificant. The effect of a human leukocyte antigen (HLA) match between the donor and recipient remains unknown.

PBC is reported to recur after LDLT. Hashimoto and colleagues presented the first series of recurrent PBC after LDLT[24]. All patients remained positive for AMA as in DDLT. The presence of mixed portal inflammatory infiltrates with granulomatous cholangitis was considered a definite histologic finding suggestive of recurrence. In 2 of 6 (33%) patients, such findings were established by protocol biopsy 1 to 2 years after LDLT. In the study, immunosuppression consisted of tacrolimus and steroids. Mycophenolate mofetil was not used. UDCA (600 mg/d) was administered to all patients.

The number of patients in Hashimoto's study[24] is too small to draw a definitive conclusion. The high rate of recurrence (33% in 2 years) is in sharp contrast with that in an earlier DDLT series. As recently reviewed by Neuberger, early reports in DDLT in which the recurrence of PBC was evaluated in a smaller patient population and a shorter observation period indicated a tendency to underestimate the risk of disease recurrence, a finding that was later reversed by a larger series with a longer follow-up period[15]. Compared to DDLT,

the history and volume of cases of LDLT for PBC is extremely limited. The rate of histologically confirmed recurrence at this very early stage is, therefore, somewhat disturbing.

Two single-center studies, both with 50 patients, were recently presented[21,25]. Hasegawa and colleagues[21] presented 3 and 5-year overall survival rates of 88% and 80%, respectively, with a median follow-up period of 35 mo. Before transplantation, AMA was positive in 42 patients (84%). AMA remained positive in 33 patients (66%) at 6 mo after transplantation. Multivariate analysis indicated that a lower updated Mayo risk score was a significant favorable factor for shorter hospitalization following LDLT, confirming the usefulness of the model in LDLT, as in DDLT[21]. In the study, periodic liver biopsies were not performed, and occasional biopsy in cases of abnormal liver function did not present with findings suggestive of recurrent PBC. Biopsy-proven acute cellular rejection was observed in 18 (36%) patients. Because histologic findings are indispensable for the diagnosis of recurrent PBC, the study provides little information on disease recurrence, though the excellent midterm patient survival warrants further application of LDLT for PBC.

On the other hand, Morioka and colleagues[25] presented 5-year overall survival rates of 67%. The recurrence of PBC was confirmed in 18% of patients within a median of 36 mo after LDLT (range 12-123 mo). The results of the study suggested that a lower number of HLA mismatches between donor and recipient, and a younger donor age resulted in better survival, though a lower number of HLA mismatches were also suggested to be a risk factor for PBC recurrence.

The study by Morioka and colleagues[25] included ABO incompatible cases, which were not included in the study by Hasegawa and colleagues[21], and recipients presented with higher MELD scores. The median MELD score in Hasegawa's study[21] was 13, whereas that in Morioka's series[25] was 23. Of the 50 patients, 14 (28%) died within 6 mo after LDLT in Morioka's series[25], whereas 3 (6%) died within 6 mo after LDLT in Hasegawa study[21]. It is not clear how the lower number of HLA mismatches affects short-term (6 mo) survival in the latter study. Recurrent PBC seems to be of less importance during this period as it was described to occur after 12 postoperative months. In fact, data more recently presented indicated that a simple comparison of HLA matching has little or no impact on survival[26]. Clearly, the impact of HLA mismatches on PBC recurrence in LDLT requires further study.

The most recent registry study from Japan, in which 221 PBC patients were analyzed, reports a 5-year survival rate of 79%. Histologic evaluation was available for 70 patients, among whom 7 presented with findings compatible with recurrent disease with a median follow-up period of 36 mo[27]. The information is limited, however, and it is, therefore, difficult to draw a universally acceptable conclusion on the overall long-term outcome of LDLT for PBC.

PSC

As for PBC, the indication for LDLT for PSC at our institution is based on the improved life expectancy. Although MELD score is considered more appropriate for DDLT, the new Mayo Model[28] may be helpful for deciding the optimal timing of LDLT and preparation once a living donor candidate becomes available. Development of the model was based upon a large cohort of patients followed for two decades. Histologic evaluation by liver biopsy is not required and the score is easily obtained from readily available clinical variables. Its validity among the Far East Asian population, however, requires further analysis. At our institution, we currently consider a MELD score > 15 and/or a Mayo risk score > 2.0 as good starting points to prepare for LDLT.

PSC is considered to be a good indication for DDLT with an excellent 5-year graft survival rate of approximately 80%. A higher rate of re-transplantation compared to that for other indications (9.6% *vs* 4.9% within 2 years), however, has been recognized. But, its relation with recurrent disease is unclear. Recurrence of PSC after DDLT has been reported at rates between 1% to 33%, depending on the diagnostic criteria and follow-up duration[8]. Graziadei and colleagues[29] proposed combined cholangiographic and hepatic histologic criteria with strict exclusion criteria (cases with ABO incompatibility between donor and recipient, nonanastomotic strictures before posttransplantation day 90, anastomotic strictures alone, hepatic artery complications, or ductopenic rejection were excluded) and reported that PSC recurs after DDLT in 20% with typical radiologic manifestations found within a year, and histologic presentation within 3 years after DDLT. In their study, 5-year patient and graft survival rates were comparable between patients with recurrent PSC and patients with PSC without signs of recurrence.

A case suspected of recurrent PSC following LDLT was first reported by Kita *et al*[30]. There have been sporadic case reports from Asian regions[31-34], as well as from the West[35-39], of LDLT for PSC from living related donors since then, but none reported recurrence; follow-up periods were less than 2 years in most case reports. Aside from the above case reports, cases of LDLT for PSC are found in moderate to large registries worldwide[40-44]. Moon *et al*[40] reported 2 cases of LDLT for PSC among their large series of 580 LDLTs. Soejima *et al*[41] also reported 2 cases of LDLT for PSC in their series of 52 LDLTs. Both, however, lacked a specific description of the long-term outcome. The largest registry analysis by Maheshwari *et al*[44] reported the outcome of 3309 PSC patients who underwent liver transplantation, among whom 69 underwent LDLT. Only 10 of those presented with a follow-up period longer than a year, however, and details regarding the outcome were not provided.

Thus, there is a significant lack of information specifically on the long-term outcome of LDLT for PSC, especially regarding recurrence. One explanation may be the rare incidence of PSC in the Far East

Table 1 Recurrence of PSC following LDLT

Series	No.	Rate of blood related donors	No. rec. PSC	Median period to dx. of rec.
Tokyo[47]	9	89% (5 out of 9)	4 (44%)	40 mo (range 14-66 mo)[2]
Kyoto[48]	22	82% (23 out of 28[1])	13 (59%)	31 mo (range 22-71 mo)[3]

No.: Number of patients; rec.: Recurrence; dx.: Diagnosis. [1]Twenty-eight patients underwent LDLT for PSC. Among them 22, (79%) survived for more than a year and were the subject of the analysis for recurrent PSC; [2]Diagnosis based on radiologic findings. No protocol liver biopsies were performed; [3]Diagnosis based on pathologic findings obtained from protocol liver biopsies and later confirmed by radiologic findings.

where LDLT is far more common than DDLT. Unlike in Nordic countries or in the United States, where PSC is one of the most important indications for liver transplantation[45], this indication accounts for less than 3% of the total liver transplantations performed in Japan[46].

Recently, two additional studies on LDLT for PSC were published from high volume centers in the region[47,48]. The Tokyo group described the outcome of 9 adult LDLT cases, of which 8 were living-related. The median follow-up period was 3.5 years after LDLT. No ABO blood type-incompatible cases were performed. The outcome in terms of patient survival was satisfactory with a 5-year rate of 90%. When recurrence of PSC was evaluated according to Graziadei's criteria[29], however, recurrent PSC was diagnosed in four patients. Rates of freedom from recurrent PSC at 1, 3, and 5 years were 100%, 73%, and 49%, respectively. The mean time to recurrence was 3.3 years. When limited to biologically related donor-recipient cases, recurrent PSC was diagnosed in 50% of cases. Interestingly, none of the patients presented with the HLA haplotypes associated with a higher susceptibility for developing PSC in the Caucasian population[47].

The Kyoto group reported 28 patients with PSC who underwent LDLT. Among the 22 patients who survived for more than a year, 13 (59%) presented with PSC recurrence with a mean follow-up period of 31 mo, 5 of whom died or required re-transplantation for graft failure. The HLA haplotypes that may affect recurrence of the hepatic condition remain unclear, although HLA-DR15 is positively associated with ulcerative colitis. The group concluded that unlike PBC, the recurrence of PSC adversely affects the outcome in LDLT[48]. Although there is a difference in the short-term mortality between the two reports, the high rate of recurrence reported in both studies requires further attention. Key features of the two series are summarized in Table 1. The clinical manifestations of recurrence described in both series seem more aggressive than those in patients that underwent LDLT for in PBC. The risk factors and susceptible genetic characteristics in LDLT remain unclear. Further prospective study with a protocol cholangiogram and genetic considerations with an HLA haplotype analysis is necessary.

CONCLUSION

LDLT provides a satisfactory short-to-midterm outcome for PBC and PSC. Both PBC and PSC, however, can recur after LDLT. The incidence of recurrence appears to be higher in LDLT compared to DDLT. The long-term impact of recurrence on survival, however, remains unknown at this point. PSC may present with a poorer long-term outcome, but further studies are necessary.

Abstract

Signal transducers and activators of transcription 3 (STAT3) play an important role in various autoimmune disorders including inflammatory bowel disease (IBD). Recent studies have revealed that STAT3 activation plays distinctly different roles between innate immune responses and acquired immune responses in colitis. STAT3-mediated activation of acquired immune responses plays a pathogenic role in colitis by enhancing the survival of pathogenic T cells. In contrast, STAT3-mediated activation of innate responses contributes to the suppression of colitis. This review will summarize the current understanding of the roles of STAT3 in IBD and the potential of targeting STAT3 for the treatment of IBD, emphasizing recent observations.

Key words: Inflammatory bowel disease; STAT3; Inflammation; Innate immunity; Acquired immunity

INTRODUCTION

Inflammatory bowel disease (IBD) is a group of idiopathic chronic relapsing immune-mediated inflammatory disorders, which is characterized by two major forms of intestinal inflammation: ulcerative colitis (UC) and Crohn's disease (CD)[1]. Although the precise mechanisms of the pathogenesis of IBD still remain unclear, accumulating studies have shown that multiple cytokines, including interleukins (ILs) and interferons, are involved in the pathogenesis of IBD[2,3]. Most of these cytokines activate various members of a family of cytoplasmic transcription factors such as signal transducers and activators of transcription (STATs)[4,5]. Indeed, several recent studies have focused on the role of STATs on IBD. Among STATs, the role of STAT3 in IBD has been most well documented by recent studies obtained from human IBD studies[6-8] and experimental IBD models[9-12]. These studies have revealed that STAT3 is in a unique position for pathogenesis of IBD, because STAT3 plays distinct roles between innate immune cells and acquired immune cells. This review will focus on the roles of STAT3 in IBD from a different point of view, namely, innate immune systems *versus* acquired immune systems.

STAT3 AND IBD PATIENTS

STAT3 was initially identified as an acute phase response factor, an inducible DNA binding protein that binds to the IL-6 responsive element within the promoters of hepatic acute phase protein genes[13]. Subsequent studies indicate that STAT3 becomes activated in response to a wide variety of cytokines and growth factors[4,5,14]. After ligation of their specific receptors by these cytokines and growth factors, STAT3 is immediately phosphorylated, resulting in their dimerization and migration to the nucleus to induce several gene expressions encoding molecules that play a role in a variety of biological functions such as cell growth, anti- and pro-apoptosis, cell motility, negative feedback loop (suppression of cytokine productions), regulatory cytokine production and anti-bacterial activity depending on cell types[4,5,14-17].

Although the role of STAT3 activation in the pathogenesis of IBD is still not very clear, the expression and activation of STAT3 protein in the mucosa of human IBD patients has been well studied. Lovato *et al* demonstrated constitutive activation of STAT3 in five out of seven CD patients in a small case series[6]. Musso *et al* demonstrated that STAT3 activation was confined to actively inflamed colons from not only CD, but also UC patients[7]. Accordingly, activated STAT3 was detected in isolated lamina propria mononuclear cells from inflamed IBD tissues, but not in peripheral blood mononuclear cells from control subjects or IBD patients. In this study, immunofluorescence demonstrated that the sources of activated STAT3 were macrophages and T lymphocytes, but not neutrophils. Mudter *et al* also showed that an increased amount of total STAT3 protein appeared in both UC and CD compared to noninflammatory control cells, and total STAT3 correlated with increased activated pSTAT3 in tissue sections from both UC and CD[8]. They also showed that increased pSTAT3 also directly correlated with the histological degree of inflammation of tissues. Importantly, this activation is observed in both acquired cells such as T cells and innate cells such as colonic epithelial cells (CECs).

THE ROLE OF STAT3 ON ACQUIRED IMMUNE CELLS IN IBD

Since classical knockout of the *STAT3* gene in mice resulted in early embryonic lethality[18], various cell type-specific STAT3 knockout mice were generated to elucidate the functional relevance of STAT3[15,19-23]. Acquired immune cells, especially $CD4^+$ T cells, have a considerable ability to induce the development and exacerbation of not only CD-like, but also UC-like experimental colitis[24-27]. Importantly, Takeda *et al* showed that T cell specific STAT3 knockout mice showed impaired T cell proliferation[19]. Moreover, they showed that STAT3 activation is involved in IL-6-dependent T cell proliferation through prevention of apoptosis. Atreya *et al* also showed that activation of IL-6/STAT3 cascade in lamina propria T cells can also induce prolonged survival of pathogenic T cells and, indeed, inactivation of this cascade contributes to the attenuation of chronic intestinal inflammation[9]. These observations indicate that activation of STAT3 in the acquired cells plays a pathogenic role in chronic colitis by inducing prolonged survival of pathogenic T cells and disruption of immune tolerance. Indeed, inactivation of IL-6 or leptin/STAT3 cascades results in the suppression of acquired immune (T cell) mediated colitis[9-12].

THE ROLE OF STAT3 ON INNATE IMMUNE CELLS IN IBD

Dysregulated host/microbial interactions have been postulated to play a crucial role in the development of IBD by inducing uncontrolled activation of acquired immune responses[24,28-30]. Innate immune responses mediated by CECs and phagocytic cells such as macrophages play a crucial role in the initial defense to maintain the appropriate host/microbial interactions[15,22]. Accumulating studies have demonstrated that several mechanisms are involved in the maintenance and/or enhancement of the barrier function by CECs[15,31,32]. Among these mechanisms, activation of STAT3 is considered to be an important pathway that can enhance and maintain not only the barrier function of epithelial cells, but also the activation of macrophage[15,22]. Indeed, disruption of innate immune responses by genetically engineered either inactivation of STAT3 cascade in the CECs, or else macrophages induce intestinal inflammation[15,21-23]. This observation is further supported by a recent study using a conditional STAT3 knockout mouse strain in which STAT3 deletion is induced during the adult life[23]. This mouse strain shows efficient elimination of STAT3 protein in innate cells (macrophages and CECs), but not acquired cells (T and B cells), and develops a lethal colitis immediately after the deletion of STAT3 in the adult life. These findings indicate that, in contrast to acquired immune cells, activation of STAT3 in innate cells plays a regulatory role in colitis. Interestingly, inactivation of STAT3 in both CECs and macrophages results in lethal damage[18,23], whereas such fatal inflammation is not observed in mice in which the inactivation is specifically induced in either CECs or macrophages[15,22]. This raises a possibility that transient inactivation of STAT3 in both CEC and macrophage may cause lethal damage.

THE ROLE OF STAT3-ACTIVATORS ON IBD

Several cytokines and growth factors including IL-6, IL-7, IL-9, IL-10, IL-11, IL-15, IFN-α/β, leukemia inhibitory factor (LIF), hepatocyte growth factor (HGF), oncostatin M (OSM), leptin and growth hormone (GH) have been identified to activate STAT3 cascade with a different efficiency depending on the cell types[4,5,14]. Among these, roles of IL-6, IL-11, IL-15, HGF, GH and leptin in experimental colitis have been demon strated[9-12,33-36]. For example, IL-6, IL-15 and leptin play a pathogenic role in colitis by activating STAT3 predominantly in the acquired immune cells[9,10,12,36,37] (Figure 1).

In contrast, GH and IL-11, both of which activate STAT3 predominantly in CECs, contribute to the suppression of experimental colitis[33-35]. Of note, human trials utilizing GH, IL-11 and anti-IL-6R mAb have been conducted and have shown that the strategies using these products are beneficial to IBD patients[38-40] (Figure 1).

IL-22 has recently been shown to be preferentially expressed by the Th17 subset[41,42] and has been demonstrated as a strong activator of STAT3[43-45]. Recently, we have demonstrated that IL-22 contributes to rapid amelioration of local inflammation associated with a Th2-mediated colitis through activation of STAT3 in CECs[46] (Figure 1). Since IL-22 specifically targets innate immune pathways[16,45-47], selective activation of

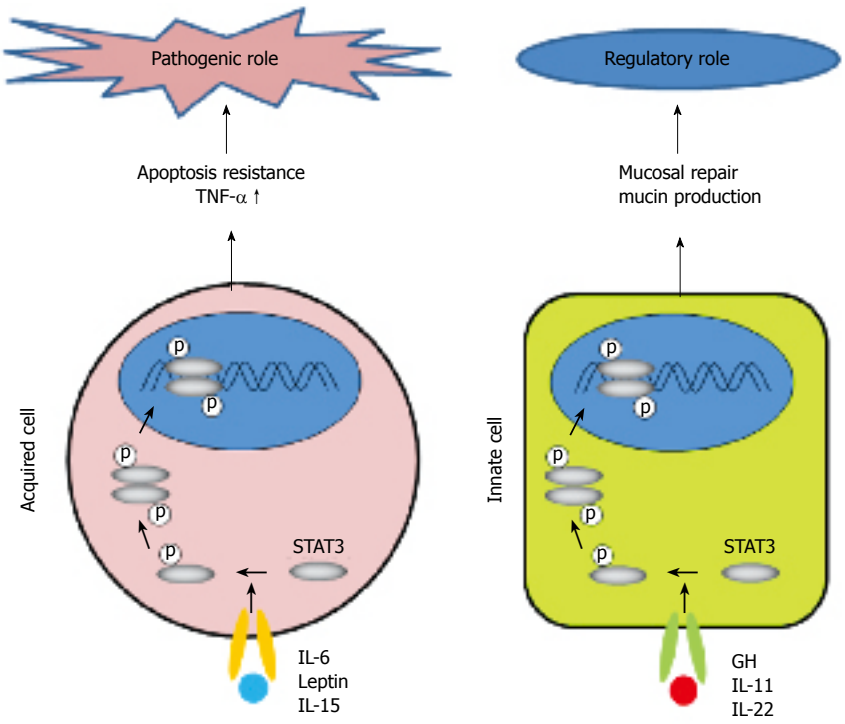

Figure 1 STAT3 plays distinct roles between innate immune cells and acquired immune cells. STAT3-mediated activation of acquired immune responses plays a pathogenic role in colitis by enhancing survival of pathogenic T cells and by inducing TNF-α. In contrast, STAT3-mediated activation of innate responses contributes to the suppression of colitis by enhancing the mucosal repair and by inducing mucin production.

	STAT3 activator	Target cell	Effect	Regulatory or pathogenic	Reference
Acquired	IL-6	$CD4^+$ T cell	Apoptosis resistance	Pathogenic	9
	Leptin	IEL, LPMC	TNF-α ↑, MIP-1α ↑, MIP-2 ↑	Pathogenic	12
	IL-15	$CD8^+$ T cell	IFN-γ ↑, TNF-α ↑	Pathogenic	36
Innate	GH	CEC	Mucosal repair	Regulatory	33
	IL-11	CEC	Crypt cell proliferation after injury	Regulatory	40
	IL-22	CEC	Mucin production	Regulatory	46

STAT3 in CECs, but not acquired immune cells by IL-22 may contribute to amelioration or chronic Th2-mediated colitis.

These findings suggest that it is possible to activate or inactivate STAT3 in specific cell populations for the treatment of human IBD.

THE ROLE OF MOLECULES INDUCED BY STAT3 ON IBD

STAT3 has been shown to induce anti-apoptotic genes such as *bcl-2* and *bcl-xl* in T cells, and increase to resistance of lamina propria pathogenic T cells to apoptosis[9]. In contrast, STAT3 can induce several molecules involved in the regulation of inflammation in CECs. Recent studies have demonstrated that STAT3 is required for the induction of IL-10, a well-known regulatory cytokine that is involved in the suppression of several inflammatory processes[48] including experimental colitis[15,49,50]. Local, but not systemic administration of this cytokine is of benefit in human IBD[51,52]. Impaired IL-10 production in macrophage by the STAT3 deletion is involved in the development of colitis[15], and enhanced production of this cytokine by CEC contributes to the suppression of colitis[53]. Importantly, IL-22, a strong activator of STAT3, has been shown to induce IL-10 production by CEC lines[45]. In addition to IL-10, STAT3 activation can also induce the expression of suppressors of cytokine signaling (SOCS) 3 that has been shown to play an important role in the suppression of acute colitis[11,17]. Furthermore, STAT3 has been recently demonstrated to induce trefoil factors that regulate intestinal epithelial homeostasis[22]. Moreover, IL-22-mediated STAT3 activation contributes to the improvement of colitis-associated mucus layer destruction associated with goblet cell depletion by enhancing the production of membrane-bound mucins (MUC1, -3, -10, and -13)[46]. Membrane-bound mucins form a static external barrier at the epithelial surface and are stored in goblet cell vacuoles[54-56]. Therefore, our recent study suggests that the enhanced mucus barrier formation participates in the IL-22/STAT3-mediated attenuation of Th2-mediated colitis[46].

CONCLUSION

Recent data indicate that STAT3 is one of the crucial targets for the treatment of IBD. However, as the receptors of these cytokines and growth factors are present on both innate and acquired cells, activation of STAT3 is likely to occur in both cell types[5,14,34-36,57,58]. Therefore, as the function of STAT3 is a double-edged sword, careful attention should be directed toward the cell population that is being targeted when one contemplates STAT3 inhibition or activation in human IBD[59].

Abstract

Serological biomarkers in inflammatory bowel disease (IBD) are a rapidly expanding list of non-invasive tests for objective assessments of disease activity, early diagnosis, prognosis evaluation and surveillance. This review summarizes both old and new biomarkers in IBD, but focuses on the development and characterization of new serological biomarkers (identified since 2007). These include five new anti-glycan antibodies, anti-chitobioside IgA (ACCA), anti-laminaribioside IgG (ALCA), anti-manobioside IgG (AMCA), and antibodies against chemically synthesized (∑) two major oligomannose epitopes, Man α-1,3 Man α-1,2 Man (∑Man3) and Man α-1,3 Man α-1,2 Man α-1,2 Man (∑Man4). These new biomarkers serve as valuable complementary tools to existing biomarkers not only in differentiating Crohn's disease (CD), ulcerative colitis (UC), normal and other non-IBD gut diseases, but also in predicting disease involvement (ileum *vs* colon), IBD risk (as subclinical biomarkers), and disease course (risk of complication and surgery). Interestingly, the prevalence of the antiglycan antibodies, including anti-Saccharomyces cerevisiae antibodies (ASCA), ALCA and AMCA, was found to be associated with single nucleotide polymorphisms (SNPs) of IBD susceptible genes such as NOD2/CARD15, NOD1/CARD4, toll-like receptors (TLR) 2 and 4, and β-defensin-1. Furthermore, a gene dosage effect was observed: anti-glycan positivity became more frequent as the number of NOD2/CARD15 SNPS increased. Other new serum/plasma IBD biomarkers reviewed include ubiquitination factor E4A (UBE4A), CXCL16 (a chemokine), resistin, and apolipoprotein A-IV. This review also discusses the most recent studies in IBD biomarker discovery by the application of new technologies such as proteomics, fourier transform near-infrared spectroscopy, and multiplex enzyme-linked immunosorbent assay (ELISA)'s (with an emphasis on cytokine/chemokine profiling). Finally, the prospects of developing more clinically useful novel diagnostic algorithms by incorporating new technologies in serological biomarker profiling and integrating multiple biomarkers with bioinformatics analysis/modeling are also discussed.

Key words: Serological biomarkers; Inflammatory bowel disease; Ulcerative colitis; Crohn's disease; Anti-chitobioside IgA; Anti-laminaribioside IgG; Anti-manobioside IgG; Anti-synthetic mannoside antibodies; Multiplex enzyme-linked immunosorbent assay; Proteomics

INTRODUCTION

Biomarkers of inflammatory bowel disease (IBD) are measurable substances in body fluids [such as blood (serological)], stool, or other parts of the body, as tools for disease diagnosis and/or prognosis. Application of IBD biomarkers is cheaper, less laborious, less invasive, and more objective compared to the endoscopy/biopsy-based approach[1]. Current IBD biomarkers include serological, fecal and genetically predisposed gene polymorphisms[2-5], as well as imaging biomarkers in conjunction

with imaging technologies such as optical, ultrasound, magnetic resonance imaging (MRI), X-ray, computer tomography (CT), position emission tomography (PET), single photon emission computed tomography (SPECT)[6-9]. Among those, fecal[10,11] and serological biomarkers, including systemic level of specific antibodies and other serum proteins[4,12-14], have been most widely explored and/or used in clinical studies. However, none of the current commercially available biomarker tests/assays, including all of those mentioned in this highlight, can be used as stand-alone tools in clinics and, therefore, can only recommended as an adjunct to endoscopy in diagnosis, and prognosis of the disease[1,15]. Considering that endoscopy is a highly resource-intensive process (involving frequent invasive, labor-intensive and expensive colonoscopic procedures), new IBD biomarkers and more comprehensive bioinformatic algorithms with multiple biomarkers are in great need.

The focus of this highlight is on new serological IBD biomarkers. However, the remarkable rapid development of IBD biomarkers in the last decade have made it impossible to separate the "old" from the "new", since multiple biomarkers, both old and new, are being integrated in clinical studies. For example, 5 serum biomarkers, including ASCA, pANCA, anti-OmpC, anti-Cbir and anti-I2 (see below), were the most widely studied in the past decade, but are still being characterized and validated for their clinical utility. Since the status of these biomarkers has been reviewed extensively elsewhere[4,12-14], they will be listed as "old" markers and only briefly reviewed, along with many other serological biomarkers reported before 2007. Anti-glycan antibodies, a newer panel of serum biomarkers, first reported in 2006[16,17] and being validated since 2007, will be one of the major "new" biomarkers in this highlight. Serum cytokines, which are among the earliest inflammatory mediators studied, but are yet to be recognized as useful IBD biomarkers, will be reviewed and discussed. The prospects of developing new serological IBD biomarkers and integrating existing ones will also be discussed, particularly regarding the application of novel molecular approaches and proteomic technologies in biomarker screening and identification, as well as novel bioinformatic analyses of clinical utilities of multiple biomarkers.

"OLD" SEROLOGICAL IBD BIOMARKERS: A BRIEF OVERVIEW

Anti-Saccharomyces cerevisiae antibodies (ASCA) and perinuclear antineutrophil cytoplasmic antibodies (pANCA) were the first extensively characterized serological IBD markers[18,19]. ASCA is more associated with Crohn's disease (CD) while pANCA is more associated with ulcerative colitis (UC)[4,13,20,21]. Three additional serum biomarkers were introduced later, including antibodies against outer membrane porin C (anti-OmpC), Pseudomonas fluorescens bacterial sequence I2 (anti-I2), and bacterial flagellin (anti-CBir 1)[12,13,22,23]. These are five most extensively studied serological biomarkers to date. Although exact data from independent studies vary, combinations of more than one of the 5 serological markers have been shown to have the most clinical value (see reviews[4,12-14,24]). For example, ASCA and pANCA together have a specificity of approximately 90% for both CD and UC[21,25-27]. These markers have been demonstrated as not only being useful for differentiating IBD *vs* healthy control or CD *vs* UC, but also as potential indicators and/or predictors for disease activity/location, disease course/complication, need for surgery, and prognosis of therapy. For example, CD patients who are positive in multiple anti-microbial antibodies (ASCA, anti-OmpC, anti-CBir, and anti-I2) have increased risk of having more complicated disease. Patients who are positive in all four of these biomarkers have 11-fold increased risk to develop penetrating and/or stricturing disease[28-32]. CD patients positive with three markers (anti-OmpC, anti-CBir, and anti-I2) are more likely to have small bowel surgery than those who were negative (72% *vs* 23%). No similar association of serotype was found with disease phenotype of UC[32].

Elevated levels of serological biomarkers were shown to be associated with IBD-susceptible gene variants. Family members of CD patients with NOD2/CARD15 3020insC variant was reported to have increased intestinal permeability, which has been positively associated with elevated serological biomarkers[33,34]. However, reports on this relationship have been inconsistent[35-38], even though more studies presented a positive association between serological biomarkers and susceptible gene variants[32,37,38]. Future studies by independent groups with larger cohorts, well-defined clinical characteristics and patient populations (such as ethnicity) are necessary to resolve this discrepancy.

Other note-worthy aspects of these serological biomarkers include their potential value as subclinical biomarkers and their inherent geographic/ethnic heterogeneity. (1) Independent studies have shown that the prevalence of ASCA positivity is significantly higher (20%-25%) in unaffected first-degree relatives of patients with CD[18,39] compared to general healthy populations (0%-10%), indicating a familial association. A much stronger indication that ASCA may be a potential subclinical biomarkers for CD came in 2005. In a serological analysis of a large serum depository, Israeli *et al* reported that ASCA reactivity was found 38 mo before clinical diagnosis in 32% of the CD patients studied[40]; (2) The diagnostic value of serological biomarkers can vary significantly among different ethnic or geographic populations. For example, both ASCA and pANCA were found to be less sensitive in Chinese and Japanese patients[41,42]. On the other hand, positivity of pANCA was shown to be higher in Mexican-American UC patients: all Mexican-Americans with UC tested had positive pANCA compared to only 40% of Caucasians[42]. These studies suggest that physicians must factor the patients' ethnic background when serological biomarkers are applied in the clinical settings.

At least two dozen non-antibody serum biomarkers have also been reported, including, C-reactive protein,

calprotectin, and PMN-elastase, soluble selectins, adhesion molecules, and procalcitonin (PCT)[4,5,43-45]. However, it is necessary to point out that most of these markers have not been extensively characterized. Many of them are also elevated in a variety of other inflammatory or pathological conditions with a low specificity to IBD. Therefore, their actual clinical value needs to be further investigated or validated.

"NEW" SEROLOGICAL IBD BIOMARKERS

New anti-glycan antibodies: ACCA, ALCA and AMCA

New diagnostic and predicting value: Three new anti-glycan antibodies were first reported as potential novel serological biomarkers in the diagnosis of IBD by Dotan *et al* in 2006 from Glycominds Ltd in Israel[16,17]. Now, as major components of IBDXTM Panel marketed by Glycominds Ltd (http://www.ibdx.net/index.html), this new set of biomarkers contains three anti-glycan antibodies, including anti-chitobioside IgA (ACCA), anti-laminaribioside IgG (ALCA), and anti-mannobioside IgG (AMCA) (Table 1). The fourth component in the IBDXTM Panel is gASCA (ASCA IgG), virtually the same as ASCA, which is the first antiglycan IBD serological biomarker identified. Since 2007, several independent studies on these anti-glycan antibodies have been reported, and their clinical utility has been validated by independent laboratories (see below). Glycan, a generic term for all molecules bearing glycosidic bonds, includes mono-, oligo- and ploy-saccharides or carbohydrates[17]. Glycans are major building blocks of cell surface components and immunogens (erythrocytes, immune cells, and microorganisms) that lead to generation of a variety of anti-glycan antibodies, including IgG, IgA, IgE and IgM, which have been demonstrated in a number of inflammatory and autoimmune diseases[16]. Mannobioside (AMCA) is a dimer of 1,3 linked mannose, and is a component of mannan from pathogenic fungi and yeast[12]. Laminaribioside (ALCA) is the building block of laminarin, a polysaccharide of the β-1-3-glucan family and is found in the cell walls of fungi, yeast, and algae[16,46]. Chitobioside (ACCA) is a component of chitin, found in the insect cuticle and cell walls of infectious pathogens such as bacteria and yeast[16]. Both β-1-3 glucans and chitin modulates the immune system by binding to receptors on neutrophils, macrophages, and natural killer (NK) cells, thereby stimulating cell proliferation, phagocytosis and cytokine secretion[47]. The resultant antibody production specifically against chitin and glucan, and their association with CD also suggests the intrinsic modulation of the adaptive immune system. However, the individual diagnostic differences between ALCA, AMCA, and ACCA have not yet been clearly established.

Using GlycoChip glycan array technology[48,49] and enzyme-linked immunosorbent assay (ELISA), Glycominds Ltd developed the new IBD serological markers (ACCA, ALCA, and AMCA)[16,17]. The initial study of these 3 new markers, which involved a total of 194 patients with CD, 162 with UC and 142 healthy controls, showed that ACCA, ALCA, and AMCA exhibited the highest discriminative capability between CD and UC[16]. Approximately one third of CD patients are positive for each of the 3 new markers[16] (Table 1). More significantly, 44% (12/27) of ASCA-negative CD patients were positive for ALCA or ACCA. Therefore, although the prevalence of each of the individual new biomarker is relatively poor (Table 1), together they are a significant complement to ASCA. In patients that were positive with one of the 3 markers, the sensitivity and specificity for diagnosis of CD were 77.4% and 90.6%, respectively. In patients with 2 or 3 of these antibodies, the specificity increased to 99.1%. Higher levels of ALCA and AMCA were significantly associated with small intestinal disease.

Ferrante *et al*[46] reported a study that involved a larger cohort, including 1225 IBD patients (913 CD, 272 UC, and 40 IC), 200 ethnically matched healthy controls, and 113 patients with non-IBD intestinal inflammation (diverticulitis, infectious colitis, ischemic colitis and pseudomembranous colitis). In this study, IBDX™ Panel (ACCA, ALCA, AMCA, and gASCA) and anti-OmpC were analyzed. 76% of CD patients are positive for at least one of the 5 markers. All antiglycan and anti-OmpC were specific for CD (80.5%-93%). The sensitivity was calculated as: gASCA = 56.4%; ALCA = 17.7%; ACCA = 20.7%; AMCA = 28.1%; and anti-OmpC = 29.1%. Among all 913 CD patients, only 13 (1.4%) were positive for all the 5 CD-associated markers. Fifty percent of CD patients (n = 435) who were either sASCA negative/OmpC positive (n = 93) or gASCA positive/OmpC negative (n = 342), were positive for at least one of the antiglycan markers. Sixty-seven percent of gASCA/OmpC-positive CD patients were also positive for at least one of the other anti-glycan

Table 1 New serological IBD biomarkers

		CD	UC	Control	Ref.
1	ALCA	Approximately 19%-38%	Low (approximately 7%)	Low	16, 17 18, 50
2	ACCA	Approximately 21%-40%	Low	Low	16, 17 18, 50
3	AMCA	Approximately 28%	Low	Low	16, 17 46
4	A∑MA: Anti-∑Man3 Anti-∑Man4	38.60% 22.10% 28.50%	Low	Low	55
5	UBE4A	46.20%	7.10%	3.30%	56
6	CXCL16	Elevated	Elevated		57
7	Apolipoprotein A-IV	Elevated in active CD			58
8	Resistin	Elevated	Elevated		59
9	PF4, MRP8, FIBA and Hpα2				68, 69
10	Cytokines/ chemokines & their receptors				

ACCA: Anti-chitobioside IgA; ALCA: Anti-laminaribioside IgG; AMCA: Anti-mannobioside IgG; A∑MA: Anti-∑Man3 or ∑Man antibodies; ∑Man3: Synthetic Man α-1,3 Man α-1,2 Man; ∑Man4: synthetic Man α-1,3 Man α-1,2 Man α-1,2 Man; UBE4A: Ubiquitination factor E4A; CXCL16: A transmembrane protein functioning as a chemokine and a scavenger receptor.

antibodies. Of 305 sASCA/OmpC-negative CD patients, 7% were ALCA positive, 12% ACCA positive, and 13% SMCA positive. Although addition of ALCA (gASCA/pANCA/ALCA combination) resulted in only minor improvement in differentiating CD from UC compared to the classic gASCA/pANCA combination, it significantly enhanced the accuracy of differentiating IBD from healthy controls and non-IBD intestinal inflammation. Increasing levels of all 5 markers (gASCA, ALCA, ACCA, AMCA, and OmpC) were significantly associated with more complicated disease behavior, including stricture, fistula and need for surgery. However, a recent report by Simondi *et al*[50] found that, while the level of ASCA appeared to be associated with ileal disease and penetrating/structuring disease, level of ALCA has a similar trend, but did not reach statistic significance ($P = 0.07$ and $P = 0.09$, respectively). This discrepancy may arise from the smaller cohort in Simondi D's study, which involved only 265 subjects (116 CD, 53 UC, 51 healthy controls, and 45 other intestinal diseases).

Similar results on antiglycan antibodies were reported by Papp *et al*[22] in another study that involved 557 CD patients, 95 UC and 100 healthy controls. 66.2% of CD patients were positive for at least one of the 5 biomarkers tested, including gASCA, ALCA, ACCA, AMCA, and anti-OmpC, all of which were highly specific for CD (79%-100% sensitivity). The sensitivities for each of the 5 markers are gASCA = 50.4%; ALCA = 15.2%; ACCA = 11.3%; AMCA = 11.5%; and anti-OmpC = 31.2% (the 3 new markers, ALCA, ACCA and AMCA were all lower than the results of most other studies[16,17,46,50]. Overall, increasing levels of these markers were again associated with more complicated disease behavior and incidence of surgery. Among CD patients, gASCA and ALCA were associated with early disease onset (occurring at younger age ($P < 0.0001$ and $P = 0.0012$, respectively, while gASCA was associated with perianal disease ($P < 0.0001$) and azathioprine use ($P = 0.016$). However, no association was found between these serological biomarkers and gender, familial disease, smoking habit and extraintestinal manifestations (EIM). It is interesting to mention that in Simondi D's report[50], (1) among CD patients, AMCA was found to be significantly higher in women and in smokers than in men ($P = 0.02$) and non-smokers ($P = 0.03$); and (2), CD patients with at least one affected first-degree relative exhibited significantly higher levels of ALCA than those without familial cases (59.8% *vs* 34.7%, $P = 0.0005$), suggestive of a familial association of ALCA.

Association of the antiglycan antibodies with variants of IBD susceptible genes: NOD2/CARD15. Like ASCA[32,37,38], the newly identified antiglycan antibodies were also found to be associated with single nucleotide polymorphisms (SNPs) of IBD susceptible genes. The first study, reported by Henckaerts *et al* in 2007[51], examined the influence of mutations in several innate immune receptor genes on the development of anti-glycan and anti-OmpC antibodies in IBD, including NOD2/CARD15, NOD1/CARD4, TUCAN/CARDINAL/CARD8, Toll-like receptor (TLR) 4, TLR2, TLR1 and TLR6. The study involved 1163 unrelated IBD patients (874 CD, 259 UC, and 30 IC) and 312 healthy controls. CD patients with at least one NOD2/CARD15 variant (1) were more frequently gASCA or ALCA positive than those with no mutation (gASCA: 66.1% *vs* 51.5%, $P < 0.0001$; ALCA: 43.3% *vs* 34.9%, $P = 0.018$); and (2) had higher gASCA titers (85.7 *vs* 51.8 ELISA units, $P < 0.0001$). This association was independent of ileal involvement. More interestingly, a gene dosage effect was observed when positivities of antiglycan antibodies in CD patients carrying 0, 1 and 2 NOD2/CARD15 variants were compared. Anti-glycan positivity became more frequent as the number of NOD2/CARD15 mutations increased (Table 2).

Table 2 A gene dosage effect: % positivity of antiglycan antibodies in CD patients carrying zero, one and two NOD2/CARD15 variants

	CD patients with 0 NOD2/CARD15 variant	CD patients with 1 NOD2/CARD15 variant	CD patients with 2 NOD2/CARD15 variants	*P*	Ref.
gASCA	51.50	64.20	72.30	< 0.0001	51
	41.60	64.60	67.50	< 0.0001	22
ALCA	34.90	42.10	46.70	< 0.04	51
AMCA	9.80	14.10	30	< 0.001	22
Any antiglycan	52.40	69.70	80	< 0.0001	22

A remarkably similar gene dosage effect on gASCA was observed by Papp *et al*[22] in 2008 (Table 2) as compared to Henckaerts L's study[51]. They analyzed the association of antiglycan with NOD2/CARD15 variants from studying 557 CD patients, 95 UC and 100 healthy controls. When comparing CD patients with NOD2/CARD15 variants to those with wild type alleles, positivity of gASCA is 65.2% *vs* 41.8% ($P < 0.0001$), AMCA is 18.8% *vs* 9.7% ($P = 0.009$), and any antiglycan is 72.5% *vs* 52.5% ($P < 0.0001$). In addition, Papp M's report also showed the gene dosage effect on AMCA and any antiglycan antibodies (Table 2).

NOD1/CARD4, TLR2, and TLR4: In Henckaerts L's report[51], CD patients carrying one GG-indel allele in NOD1/CARD4 had a higher prevalence of gASCA than those with wild type allele (63.8% *vs* 55.2%, $P = 0.014$). Gene dosage effect of NOD1/CARD4 was also evident as the number of mutant alleles increased, but did not reach statistical significance. Interestingly, CD patients with at least one mutation TLR4 (D299G) had a lower prevalence of ACCA compared with TLR4 wild type (D299A) (23.4% *vs* 35%, $P = 0.013$), and a lower ACCA titer (39 *vs* 49 EU, $P = 0.05$). An inverse gene dosage effect of TLR4 was observed: the prevalence of ACCA is 34.9%, 21.1% and 9.1% in CD patients with 0, 1 and 2 NOD1/CARD4 variants, respectively. A similar inverse gene dosage effect was also seen for anti-OmpC prevalence gene in relation to the number of TLR2 mutations. Of note, other reports did not find any

significant association of TLR4 (25) or NOD1/CARD4 (variant E266K)[52] with the positivity of any antiglycan antibodies.

DEFB1: Lakatos *et al*[52] recently reported an association of the antiglycan antibodies with specific variants of β-defensin-1 (DEFB1). In this study of a sex-matched cohort of 276 CD patients and 100 healthy controls, four IBD susceptible genes were tested, including NOD2/CARD15, NOD1/CARD4, DLG5, and DEFB1. Two DEDB1 variants, G20A and C44G, were found to be inversely associated with the positivity of antiglycan antibodies. For example, 29.6% of DEFEB1 20A carriers were antiglycan positive compared to 46% positivity in non-carriers ($P < 0.038$). However, no association of antiglycan positivity was found with either DEFEB1 G52A variant or DLG5 (R30Q), although both were shown to be associated with increased risk for CD[53,54]. Furthermore, in contrast to other reports[32,51], no gene dosage effect was observed on any of the antiglycan antibodies.

Anti-synthetic mannoside antibodies: Evidence for the existence of a new subset of antiglycan antibodies

Based on the chemical structure of mannose epitopes for ASCA, the antibodies against mannose residues [Man α-1,3 (Man α-1,2 Man) 1-2] that are the most widely recognized biomarkers for CD, Vandewalle-El Khoury *et al* recently[55] chemically synthesized (∑) two major oligomannose epitopes, Man α-1,3 Man α-1,2 Man (∑ Man3) and Man α-1,3 Man α-1,2 Man α-1,2 Man (∑ Man4). Their goals were to test the immuno-reactivity of the ∑Man3 and ∑Man4 with specific serum antibodies (termed "A∑MA" for anti-synthetic mannoside antibodies) and compared A∑MA with ASCA for their values as serological biomarkers for CD. An impressively large cohort was used in the study, including a total of 1365 subjects (772 CD, 261 UC, 43 IC and 289 controls).

Overall, while the specificity of A∑MA for CD was quite similar to that of ASCA (89% *vs* 93%), the specificity was lower (38% *vs* 55%). 16% of CD patients were positive for both ASCA and ∑Man3, and 24% positive for ∑Man4. Interestingly, 11% of ASCA-negative CD patients were A∑MA positive (5% for ∑Man3, 4% for ∑Man4, and 2% for both). Together 24% of CD patients who were negative for ASCA and/or other CD-associated serological biomarkers were positive for A∑ MA, suggesting a previously unrecognized new subset of anti-mannose antibodies are present in patients with CD. Therefore, it is conceivable that a combination of A∑MA with ASCA, ACCA, ALCA and AMCA would significantly increase the diagnostic value of the existing panel of antiglycan biomarkers.

A∑MA was analyzed for its predictive value for the evolution of IC patients as well as the involvement of disease location of CD (small bowl *vs* colon). Twenty IC patients (out of a total of 43) evolved to a final diagnosis of CD ($n = 11$; UC = 7; UC-like CD = 2). Among 11 patients with final diagnosis as CD, one was ASCA-positive/A∑MA-negative, two were ASCA-positive/A ∑MA-positive, and three were ASCA-negative/A∑MA-positive. None of the UC patients were A∑MA-positive. Therefore, A∑MA was more sensitive (45% *vs* 27%) and more specific (100% *vs* 71%) than ASCA for predicting evolution of IC toward CD. As for the predictive value of disease location, although positivity of A∑MA had no association with any particular disease phenotype, among the ASCA-negative CD patients, A∑MA positivity was significantly associated with colonic involvement. This indicates that A∑MA may provide new diagnostic value to colonic CD, for which ASCA is less frequently detected.

Other serum/plasma biomarkers

Ubiquitination factor E4A (UBE4A): By screening a phage library from normal terminal ileum with sera from patients with CD, Sakiyama *et al*[56] identified a strongly immunoreactive cDNA clone encoding the C-terminal subunit of the UBE4A, a U-box-type ubiquitin-protein ligase. To investigate the specificity of the serum anti-UBE4A autoantibodies in CD patients *vs* UC patients *vs* healthy controls, a GST-C-terminal UBE4A fusion protein was made, and used to test the immunoreactivity of sera from 39 patients with CD, 28 with UC, and 60 healthy controls. The prevalence of anti-UBE4A IgG was significantly higher in CD than that in UC or healthy controls (46.2% *vs* 7.1% *vs* 3.3%, respectively; $P < 0.0006$) (Table 1). The levels of anti-UBE4A IgG were correlated well with the disease activity ($P < 0.0001$). More interestingly, higher level of anti-UBE4A IgG was associated with complicated disease behavior (stricturing and penetrating) ($P = 0.0028$), and patients positive with anti-UBE4A IgG were more likely to undergo surgery ($P = 0.0013$). Although UBE4A expression was low in the cytoplasm of enterocytes and goblet cells, immunohistological analysis showed that UBE4A expression was highly elevated only in enteroendocrine cells of ileal, mucosa from CD patients, but not in normal subjects. It was speculated that production of anti-UBE4A autoantibodies might be a result of increased expression of UBE4A in the inflamed ileal mucosa. The exact role of UBE4A elevation and production of anti-UBE4A autoantibodies in the pathogenesis of CD remains to be determined.

CXCL16, apolipoprotein A-IV, and resistin: These newly reported serum/plasma IBD biomarkers were reported by the same working group in Germany[57-59]. It appears that the same cohort of study subjects was used for all three studies, or at least cohorts might have some overlapping subjects. Further validation study of these markers by other independent laboratories is necessary to evaluate their usefulness.

CXCL16 (Table 1), an intriguing transmembrane protein composed of an extracellular chemokine domain fused with a mucin stalk that extends through cell surface, functions as a chemokine and a scavenger receptor and has been implicated in various inflammatory diseases. It becomes soluble after being cleaved by metalloproteinase ADAM 10 and exerts chemokine functions[60].

Lehrke *et al*[57] reported that CXCL16 could potentially be a surrogate IBD biomarker after having examined the serum levels of soluble CXCL16 in a cohort of 239 patients with CD, 114 UC, and 144 healthy controls. Soluble CXCL16 levels were found to be the highest in CD patients ($P < 0.001$) compared with UC and healthy controls. UC patients had a relatively modest, but significant elevation of CXCL16 compared with healthy controls ($P < 0.001$). No significant difference was seen between active and inactive state of CD or UC.

Apolipoprotein A-IV (Table 1), a structural component of intestine derived triacylglycerol-rich chylomicron particles with anti-oxidant, anti-atherogenic, and anti-inflammatory properties, has been recently shown to inhibit DSS-induced mouse colitis[61]. For this reason, Broedl *et al*[58] tested if plasma level of apolipoprotein A-IV was associated with IBD, and found that it was inversely associated with disease activity and CRP levels in patients with CD (but not UC) ($P < 0.005$). However, since the actual difference in the level of apolipoprotein A-IV between active and inactive CD is quite small, the clinical value of this marker remains to be determined.

Resistin (Table 1), also known as adipocyte secreted factor or FIZZ-3, is a peptide hormone that is associated with multiple inflammatory conditions[62]. Studies by Konrad *et al*[59] showed that patients with both CD and UC had significantly higher plasma levels of resistin compared to healthy controls ($P < 0.0001$). The levels of resistin in both CD and UC were significantly associated with white blood cell count ($P < 0.0001$), CRP ($P < 0.0001$), and disease activity ($P < 0.0001$).

Application of proteomic and infrared spectroscopic technologies in serological IBD biomarker profiling

The rapid development of proteomic technologies recently has revolutionized the way and capacity by which biomarker discovery is performed[63-67]. Current proteomic methodologies include three sub-categories: mass spectrometry (MS)-based technologies, array-based technologies and imaging MS (see review[66]). Blood is the most explored source for disease biomarkers by proteomics[63-65,67]. Proteomics of IBD was recently reviewed[80].

SELDI-TOF-MS and MALDL-TOF-MS: Unlike the quests for biomarkers of other major diseases (such as cancers), application of proteomic technologies in IBD biomarker discovery is only in its infancy. So far (as of June 17, 2008) only three full original MS-based reports are available, of which, two used SELDI-TOF-MS by Merville/Louis groups[68,69] and one used MALDI-TOF-MS by Roda's group[70]. Using SELDI-TOF-MS (Surface Enhanced Laser Desorption Ionization-Time of Flight-Mass Spectrometer), Meuwis *et al*[68] analyzed protein profiles of 120 serum samples collected from a cohort of 30 CD, 30 UC, 30 inflammatory controls and 30 healthy controls. Multivariate analysis generated models that could classify samples with minimum 80% sensitivity and specificity in discriminating groups of patients. Four peptides were identified from potential peaks that could best discriminate the four groups, leading to the identification of 4 serum biomarkers, including platelet aggregation factor 4 (PF4), MRP8 (S100A8), FIBA (a peptide released during clotting from fibrinogen precursor) and Hpα2 (haptoglobin α2) (Table 1). The diagnostic value of these markers remains to be further examined. Using similar approaches, the same group piloted a study of sera from 20 CD patients who showed either response or no response to infliximab[69]. PF4 was again identified as a potential marker. The intensity level of SELDI peak in which PF4 was identified was inversely associated with infliximab non-responders. Unfortunately, such association could not be confirmed by ELISA measurement of PF4. Also, PF4 did not exhibit a significant correlation with other disease markers (sCD40L, IL-6, and CRP) or CDAI, casting doubt that PF4 probably would have any clinical diagnostic value.

The third MS-based profiling of serum IBD markers was reported by Nanni *et al*[70] using MALTI-TOF-MS (Matrix-Assisted Laser Desorption/Ionization Time of Flight-Mass Spectrometer). The study, which involved a small cohort (15 CD, 26 UC and 22 healthy controls), found the revered-phase extraction and selection of 20 m/z value gave the best overall predictive value (96.9%). In another study, reported at Digestive Disease Week (DDW) 2008, Subramanian *et al*[71] analyzed sera from a cohort of 62 UC and 48 CD by SELDI-TOF MS. Biostatistical analysis identified 12 discriminative peaks, with specificity and sensitivity approximately 95% (compared to 80.9% of the sensitivity of ASCA for CD and 64.5% of pANCA for UC). Four serum proteins were identified as inter alpha trypsin inhibitor 4, apolipoprotein C1, platelet activated factor 4 variant, which are expected to be further analyzed for their clinical utility.

Protein and antibody arrays/chips: Compared with other proteomic approaches, protein/antibody array (or chip) array technologies offer the advantages of being highly specific with high-throughput nature and capacity. The application of these technologies in IBD biomarkers discovery has just begun, and thus, the data are limited. Since 2006, our laboratory began using proteins that were robotically spotted on array slides as bait to screen serum IBD biomarkers[72]. Since the currently known major serological IBD biomarkers or antibodies are against microbes or protein of human origin, including ASCA, ANCA, OmpC, Cbir, and the new antiglycan antibodies, we hypothesized that disease-specific antibodies to microbial or to human protein (autoantibodies) are present in patients' sera (manuscript in preparation). We found to our surprise that human sera contain antibodies immuno-reactive to hundreds of proteins from *E. coli*, yeast, and even humans. The numbers and immunoreactivity of these antibodies vary greatly among IBD patients and even among healthy individuals. From our experiences, when protein arrays are used, the serum quality must be high, the screening process must be standardized, and sufficient number of subjects (at least approximately 30 per comparing group) should be included. This results in a high cost of experiments due to the expense of the commercial protein- or antibody arrays (unless made using assembled robotic ar-

rayers). One presentation by Vermeulen *at al*[73] at DDW 2008 reported a study of using commercial human protein arrays to profile serum IBD biomarkers from a very small cohort of subjects (10 UC, 15 CD and 5 healthy controls). They found that 75 proteins reacted more strongly with sera from IBD than those from healthy controls, while reactivity of another 88 proteins was just opposite. One identified antigen, described as an autoantigen in IBD was pleckstrin homology-like domain, family A, member 1 (Phla1). Validation experiment using a larger cohort of subjects found that approximately 46% of IBD [UC: 42.8% (27 of 63); CD: 50.0% (33 of 66)] were positive for anti-Phla1 antibodies, compared to 28.7% healthy controls (19 of 66) and 33.3% non-IBD gastrointestinal controls (22 of 66). Therefore, the discriminative power of this anti-Phla1 for CD *vs* UC or IBD *vs* controls is poor.

So far, antibody arrays were used in only one report by Kader *et al*[74] for identifying IBD serum biomarkers. In this study, antibody arrays containing 78 cytokines, growth factors, and soluble receptors were used to screen 65 patients with CD and 23 with UC. Univariate analysis found that the levels 4 cytokines (PLGF, IL-7, IL-12p40, and TGF-β1) were significantly elevated in patients with clinical remission compared to active disease ($P < 0.01$). However, only the difference in IL12p40 reached statistical significance ($P < 0.02$).

Fourier transform near-infrared spectroscopy: Haas *et al*[75] reported at DDW 2008 a new application of Fourier Transform Near-Infrared Spectroscopy (FT-NIR) in serum biomarker profiling. Specific spectra or fingerprints of serum samples from 139 patients with CD and 120 with UC were obtained by FT-NIR, and analyzed by Artificial Neural Networks (ANN) and cluster analyses. ANN-analysis showed that the sensitivity, specificity and accuracy for IBD *vs* healthy controls were 94.5%, 99.1%, and 96.7%, respectively, compared to cluster analysis (71.8%, 66.6%, and 70.1%). Cluster analysis correctly identified 80% of UC and 61.5% of CD, while ANN-analysis was 69.8% and 91.8%, respectively. This proof-of-concept study suggests a potential usefulness of this technology in identifying serum "fingerprints" as serological biomarkers for IBD diagnostics.

Serum cytokines/chemokines and their receptors

Serum cytokines and their soluble forms of receptors have been extensively studied, both as markers for IBD diagnosis and as molecules for IBD pathogenesis, as well as IBD therapeutic targets[4,76-78]. A long list of cytokines/chemokines and their receptors have been shown to up-regulated in active and even inactive IBD, including IL-1α, IL-1β, IL-1R (R: receptor), IL-1Ra (Ra: receptor antagonist), IL-2, sIL-2R (s: soluble), IL-6, IL-6R, IL-7, IL-8, IL-10, IL-12, IL-15, IL-16, IL-17, IL-18R, IL-27, IFN-α, IFN-β, TGF-β, TNF-α, TNF-αR, as well as most chemokines. However, the diagnostic value of cytokines/chemokines has been limited, at least in part due to studies based on the analysis of individual or only a few selected cytokine/chemokines. The ideal situation would be to profile a large number of serum cytokines/chemokines from well characterized cohorts. An example of this is the utility of a more robust and high-throughput multiplex sandwich ELISA (which allows simultaneous analysis of up to 100 analytes), in conjunction with biostatistical analysis tools [such as that of discriminant functional analysis (DFA) and multidimensional scaling (MDS)], as we and others have described[79-83]. As a proof-of-concept in the context of IBD, we recently analyzed 16 serum cytokines by multiplex ELISA from a cohort of 64 mice with or without induced experimental colitis[84]. Distinctive disease-specific cytokine profiles were identified with significant correlations to disease activity and duration of disease. Our data showed that CD-like TNBS colitis exhibits heightened Th1-Th17 response (increased IL-12 and IL-17) as the disease becomes chronic. In contrast, UC-like DSS colitis switches from a Th1-Th17-mediated acute inflammation (increased TNFα, IL6, IL-17 and KC) to a predominant Th2-biased chronic inflammatory response (increase in IL-4 and IL-10 with concomitant decrease in TNFα, IL6, IL-17 and KC). DFA identified 5 discriminatory cytokine biomarkers (IL-6, 12, 4, 17, INF-γ) that can sufficiently distinguish healthy controls from diseases, and one disease type from another[84]. A pilot study profile of 17 human cytokines/chemokines from a small cohort of 33 IBD patients (19 CD and 14 UC) with 33 matched healthy controls using multiplex ELISA also identified patterns of cytokines/chemokines that were correlated with disease phenotypes (CD *vs* UC) and severity[82]. A similar human cytokine profiling study using 24 cytokines/chemokines from a larger cohort of 400 IBD patients (with various levels of disease severity) is near completion. It will be interesting to see if the cytokine profiles can: (1) enable disease subtype stratification; (2) correlate with disease severity; and (3) if the profiles that were identified in murine experimental colitis would be similar to those of human IBD.

CONCLUSION

It is evident that while current serological IBD biomarkers are useful, their clinical utility has been limited. New technologies, such as those described in this highlight, demonstrate the significant potential for identifying previously unrecognized IBD biomarkers. Future direction is predicted to be, in addition to the continuation of ongoing efforts in developing novel biomarkers using conventional and new technologies, the integration of multiple biomarkers with extensive bioinformatics analysis/modeling. This will be the key to eventually developing specific "endpoint-oriented" serological biomarker kits. These may include, but not be limited to, individual biomarker sets that are specific for one or more of the following: (1) differentiating CD *vs* UC *vs* normal *vs* other non-IBD gut diseases that share some similar clinical presentations (such as abdominal pain and diarrhea in infectious colitis or IBS); (2) predicting IBD risk (before disease onset; subclinical biomarkers) and disease course (risk of complication and surgery); (3) predicting therapeutic efficacy even before initiation of specific

medication(s); and (4) monitoring therapeutic efficacy and predicting relapse. One can envision that such kits will rely on "integrated algorithms", rather than absolute differences, to enhance the accuracy of diagnosis and/or prognosis of IBD.

ACKNOWLEDGMENTS

The authors thank the generous support of Mr. & Mrs. Morton Hyatt.

Abstract

Evidence from epidemiological studies indicates an inverse correlation between the incidence of certain immune-mediated diseases, including inflammatory bowel diseases (IBD), and exposure to helminths. Helminth parasites are the classic inducers of Th2 responses. The Th2-polarized T cell response driven by helminth infection has been linked to the attenuation of some damaging Th1 driven inflammatory responses, preventing some Th1-mediated autoimmune diseases in the host, including experimentally induced colitis. Helminth parasites (the porcine whipworm, *Trichuris suis*) have been tested for treating IBD patients, resulting in clinical amelioration of the disease. As a result, there is a great deal of interest in the research community in exploring the therapeutic use of helminth parasites for the control of immune-mediated diseases, including IBD. However, recent studies have provided evidence indicating the exacerbating effects of helminths on bacterial as well as non-infectious colitis in animal models. Therefore, a better understanding of mechanisms by which helminths modulate host immune responses in the gut may reveal novel, more effective and safer approaches to helminth-based therapy of IBD.

Key words: Helminths; Innate and adaptive immunity; Intestinal inflammation

HELMINTH INFECTIONS

Helminths are divided into two major phyla, and all members of each phylum have distinct structural features that separate them from the others. The nematodes (also known as roundworms) include the major intestinal worms and the filarial worms that cause lymphatic filariasis (LF), whereas the platyhelminths include the trematodes (flukes), such as the schistosomes, and the cestodes (tapeworms). Humans and helminths have co-existed throughout our evolution. The history of helminthiases can be tracked back to the earliest record of human beings[1]. Although effective preventive and therapeutic measures have been developed for most parasitic worms, helminth infections are still very common in the developing world today. It has been estimated that one billion people worldwide are infected with one or more helminths. Most of the victims live in regions of sub-Saharan Africa, Asia, and Latin America[2-3]. The most common forms of helminthiasis are infections caused by intestinal helminths, ascariasis, trichuriasis and hookworm, followed by schistosomiasis and LF[4]. Clinical features of helminthiases vary a lot depending on the helminth species, intensity of infection, and host age. *Taenia solium* can cause neurocysticercosis with mass lesions in brain. Ingested eggs of *Echinococcus granulosis* will lead to cysts in the liver and cause life-threatening anaphylaxis if antigens are released from the cysts. Chronic infection with *Schistosoma* causes granulomas, fibrosis, and inflammation of the spleen and liver. Hookworm and schistosomiasis can infect pregnant women, cause neonatal prematurity and increased maternal morbidity and mortality[5]. Children at school-age or younger tend to harbor the greatest numbers of intestinal worms and schistosomes compared with any other age group. As a

result, the young patients suffer from growth retardation and diminished physical fitness, as well as memory and cognition impairment[6]. Most helminth infections, if left untreated, result in multi-year, chronic inflammatory disorders that will eventually cause disability. The chronic, disabling and disfiguring consequences of helminth infections, together with their high prevalence, make them a global problem of significant medical, educational, and economic impact.

HELMINTH INFECTION INDUCES TH2 AND T REG DEVELOPMENT

Since parasitic worms constitute a very heterogenous collection of organisms, a multitude of mechanisms may be expected when they stimulate and modulate host immune responses. However, examination of the immunology of helminth infections reveals a number of characteristics that are generally conserved across all species. Our current understanding of the immune response to helminth infections has largely come from the study of well-defined laboratory models of infection in rodents. Protective immunity to helminths depends on T lymphocytes. It is now well established that the CD4+ subset of T cells plays a major role in the generation of the host protective response that expels the worms, and that CD4+ T cells regulate many of the inflammatory and immune parameters that accompany expulsion of the parasites from the gut. Based on cytokine production profiles, CD4+ T cells can be divided into distinct functional sub-populations, Th1, Th2 and Th17. Th1 cells produce cytokines such as IFN-γ, IL-12 and IL-2 that are involved in controlling of intracellular pathogens. These cells also contribute to inflammatory responses. Recently, a new lineage of Th cells, that selectively produce the cytokine IL-17 (Th17) has been identified, and those cells are thought to be key regulators of inflammation[7,8]. It has also been reported that IL-17 is required for the optimal induction of Th1 and Th2 immune response, although the mechanism has not yet been clarified[9]. IL-17 is a proinflammatory cytokine, which is produced predominately by activated T cells. This cytokine can enhance T cell priming and induces the activation of many cell types including fibroblasts, macrophages and epithelial cells, resulting in the production of multiple proinflammatory mediators by these cells, including IL-1, IL-6, TNF-α and chemokines[8,10]. In the majority of cases, the immune responses of the hosts to worm infections are strikingly dominated by Th2-like T-helper cell responses with a significant production of IL-4, IL-5, IL-10, IL-13, IL-25, and IL-31[7,8,11,12]. Th2 cells contribute to B cell activation and antibody production, eosinophil differentiation and recruitment. Therefore, parasitic worm infection is often associated with high levels of IgE, IgG1 and IgG4, and robust eosinophil and mast cell responses. Th2 immune responses to helminth infections can prevent the survival of invading parasites during a homologous secondary infection[9], expel adult parasites from the gut[10], and allow host survival when the immune responses are not able to clear the parasites. These responses are the basic host protective mechanisms against worms and are highly conserved through evolution. However, Th2 immune responses to helminth infections may also cause host pathology and organ damage. For example, Th2 immunity can mediate pathological fibrotic responses in chronic parasitic infections[13]. This can be understood as the detrimental effects of host immunity to helminths. Cross-regulatory suppression of the Th1 responses by a strong Th2 response has been considered to play a role in modulating diseases that are characterized by a Th1 response. Multiple studies[14-16] have revealed that helminth-induced Th2 responses can attenuate damaging Th1-driven inflammatory responses in the host. However, suppression of Th1 response may also lead to the impairment of host protective Th1 immunity against concurrent infections caused by bacterial, viral and parasitic pathogens, exacerbating the diseases they induce.

In addition to stimulating a vigorous Th2 response, helminth infections are also capable of inducing suppressive T cell populations known as regulatory T cells (Tregs)[17], which may help control morbidity and dampen resistance to re-infection through their potent immune regulatory mechanisms. Several types of Treg cells have been described (natural Tregs, Tr1 and Th3). These regulatory cells constitute 5% to 10% of peripheral CD4+ T cells in naive mice and humans and suppress several potentially pathogenic responses *in vivo*, particularly T cell responses directed to self-antigens. These cells express markers such as Foxp3, CD25, CTLA-4 and GITR, and often secrete IL-10 and/or TGF-β[18-20]. Tregs have been shown to play an important role in regulating immune responses and maintaining homeostasis under various disease conditions including autoimmune disease, inflammation, cancer, and microbial infections. Treg regulate immunity through both cytokine-dependent and independent mechanisms[21]. Th3 cells make TGF-β, which inhibits development of both Th1 and Th2 cells. Tr1 cells regulate immunity through IL-10-dependent mechanisms, which inhibit both Th1 and Th2 responses[22-24]. A recent study has provided a link between the well-established immunoregulatory capacity of Th2 cells and Tregs showing that the Il-4Ra binding cytokines, IL-4 and IL-13 induce FOXP3 expressing Treg from CD4+CD25- precursors[25].

Existing data indicate that helminth infections induce the development of Th2 and/or Treg responses. A polarized Th2 type immune response as well as up-regulated regulatory T cell activity induced by helminths may have a significant impact on the host's ability to cope with concurrent or subsequent viral[26,27], bacterial and parasitic infections[28], by suppressing host protective Th1 responses to microbial pathogens. Consistent with the hygiene hypothesis, helminth-induced responses may also underlie the observed reverse associations between helminthiases and asthma, allergy, IBD, and

other autoimmune diseases[29-31]. A better understanding of immune modulation by helminth infection, therefore, can have significant practical implications for the prevention and treatment of immune-mediated as well as microbial disease.

HELMINTHS AFFECT HOST RESPONSES TO OTHER ANTIGENS AND PATHOGENS

The major importance of helminth infections includes not only the direct pathogenic effect of the worms as described above, but also the modulation of the host immune system, which may alter the response to other pathogens and antigens and cause additional immunopathology. The distribution of several pathogenic helminth infections coincides geographically with many devastating microbial diseases, such as HBV, HCV, HIV/AIDS[26,27,32-34] and malaria[35-37]. Coinfection with helminths increases the transmission of and susceptibility to these infections, and also increases the severity of the associated diseases[27,33-38]. Recently we have demonstrated that an intestinal nematode parasite, *Heligomosomoides polygyrus (H. polygyrus)* infection impairs host Th1 defense against enteric bacterial infection and exacerbates *Citrobacter*-mediated intestinal injury[28,39]. This observation is keeping with a report showing that infection with the helminth *Fasciola hepatica* reduced the protective Th1 response to coinfected *Bordetella pertussis* and exacerbated the bacterial infection[40]. Likewise, infection with *Schistosoma mansoni* downregulated antigen-specific Th1 cytokines and cytotoxic-T-lymphocyte responses, resulting in a delay in vaccinia virus clearance[41]. Moreover, it has been shown that a combined infection with *Trichuris suis* and *Campylobacter jejuni* in immunologically naive, germfree piglets, resulted in an enhanced invasion of the colon by *C. jejuni*, leading to the development of more severe pathology[42]. These observations provide strong evidence to demonstrate that helminth infection can dampen Th1 reactions to other infections and cause impaired immune responses to concurrent viral, bacterial, and parasite infections, as well as to vaccination. The Th2-inducing helminth infection has also been shown to inhibit the development of CD8+ T cell responses[43].

HELEMINTHS MODULATE INFLAMMATORY DISORDERS OF THE HOST

It has been observed that there is an increased incidence of autoimmune disorders and allergic diseases in the developed world. This phenomenon is thought to be the consequence of eradication of major infectious diseases, including helminth infections in this part of the world, a theory termed the hygiene hypothesis. The inverse correlation observed between helminth infection and certain immune-mediated diseases has led to the suggestion that lack of helminth infections favors the induction of Th1 responses, which may, in turn, result in the clinical appearance of gastrointestinal diseases, including inflammatory bowel diseases (IBD)[44-46]. IBD, including Crohn's disease and ulcerative colitis are chronic immune diseases of the gastrointestinal tract with unknown etiology. The current hypothesis indicates that IBD results from an uncontrolled immune response to the normal gut flora[47]. Genetic factors and environmental factors both contribute to the damaging mucosal immune response[48]. The hygiene hypothesis suggests that microbes and worms are important for shaping and tuning the development and function of our immune system[49]. The growing body of epidemiological and experimental data strongly suggest that a reduction in helminth infection is linked to rising rates of autoimmunity and atopy.

The initial work by Elliott *et al*[50] showing a protective response of *Schistosoma mansoni* infection on trinitrobenzene sulphonic acid (TNBS)-induced colitis in mice, a chemically induced Th1-type colitis used as an experimental model of human IBD, have led to several animal studies determining the role of helminth infections in different IBD models. In 2001, Reardon *et al*[51] showed that infection of mice with the tapeworm *Hymenolepis diminuta* ameliorated dextran sodium sulphate (DSS)-induced colitis. Khan *et al*[52] showed that mice that were infected with the nematode, *Trichinella spiralis* are protected from colitis induced by intrarectal challenge with dinitrobenzene sulphate (DNBS). Furthermore, schistosome eggs also provide a protective effect on TNBS-induced colitis in mice[53] and infection with *H. polygyrus* or *T. muris* can prevent or reverse the chronic spontaneous Th1-type colitis in IL-10 deficient mice[46]. A protective effect of infection with *Schistosoma mansoni* on TNBS-colitis in rats was also reported[54]. These observations provide evidence to suggest that helminth parasites (nematode, cestode and trematode) can ameliorate chemically induced colitis in different models. In line with these observations, the Th2 polarized T-cell response driven by helminth infection has also been linked to the amelioration of some Th1-mediated diseases that develop concurrently, such as *Helicobacter*-induced gastritis[14].

Evidence not only suggests that helminths can attenuate experimentally induced IBD in animal models[42,53,54], but also the pioneering work of Weinstock *et al* shows promise using *Trichiuris suis,* a pig helminth, to treat Crohn's patients[16]. Therapeutic potential has also been indicated in CD patients who were infected with the human hookworm *Necator americanus*[55]. The effects of helminth on host intestinal Th1 function could be mediated through several mechanisms, including helminth-induced Th2 response and induction of Tregs. We have shown that infection with the intestinal helminth *H. polygyrus* results in an upregulation of colonic IL-4 expression[28]. Recently Setiawan *et al*[56] have provided evidence to show that *H. polygyrus* infection promotes Th2 cytokine responses (IL-4, IL-5 and IL-13) of colonic lamina propria mononuclear cells. Helminths also induce production of powerful immune modulatory

molecules like IL-10 and TGF-β[57] that can affect both Th1 and Th2 function.

Unfortunately, the anticolitic effect evoked in response to helminths in mice does not extend to all models of colonic inflammation. In a recent study, the ability of the rat tapeworm *Hymenolepis diminuta* to affect the course of oxazolone-induced colitis was determined. A detrimental effect of helminth infection on colitis was detected, as evidenced by the results showing that *H. diminuta* caused a significant exacerbation of oxazolone-induced colitis[58].

Considering the profound and widespread immune activation and dysregulation induced by helminth parasites, the overlapping geographic distributions of helminth and bacterial infections, and the potential to modulate bacteria-associated intestinal inflammation, we have established a co-infection model system to analyze the effect of an intestinal helminth parasite on a concurrent enteric bacterial infection and bacteria-mediated intestinal inflammation[28]. This model involves two murine enteric infectious agents that induce distinct Th-responses: (1) the Th2-inducing helminth *H. polygyrus*, and (2) the bacterial pathogen, *C. rodentium*, which selectively stimulates a Th1-type immune response[59,60]. *C. rodentium* is a mouse pathogen that colonizes the distal colon and causes pathological changes that are similar to those seen in many mouse models of colitis, including transmissible colonic hyperplasia, goblet cell depletion, and mucosal erosion. *C. rodentium* has been used as a model for studying host responses to human pathogens that employ attaching and effacing (A/E) lesion formation for epithelial colonization, such as EPEC, the most important causative agent of severe infantile diarrhea[59,61-64]. We found that mice co-infected with *H. polygyrus* developed a more severe *C. rodentium*-associated colitis. The exacerbation of bacterial colitis induced by helminth co-infection is STAT6 dependent. These results provide evidence to indicate the possibility that helminth infection may have adverse effects on intestinal inflammation (bacteria-mediated as well as inducible colitis). In addition, it has been also reported that *T. suris* ova treatment resulted in infection in the gastrointestinal tract of a pediatric Crohn's patient[65]. These observed deleterious consequences of helminth parasites in intestinal inflammatory responses, therefore, provide a cautionary note for the therapeutic use of helminths in certain forms of IBD. These observations also highlight the need for a more comprehensive understanding of the mechanisms by which helminths modulate host's responses to enteric bacteria and bacteria-associated as well as immune-mediated intestinal inflammation.

IMPACT OF HELMINTHS ON INNATE IMMUNE OF THE HOST

Innate immune cells such as DCs and macrophages are fundamental to directing immune responses along either a tolerating or activating pathway. As master manipulators of the host immune system, helminths have evolved strategies targeting these cells. To effectively control infection, appropriately developed and functionally polarized subsets of Th effector cells are required. DCs, the most competent antigen presenting cells, play an important role in the initiation of both innate and adaptive immune responses to a wide variety of pathogens and Ags, as well as in tolerance[66-69]. DCs can be activated by microbial products through their high-level expression of evolutionarily conserved pattern recognition receptors, such as Toll-like receptors (TLRs)[70,71]. The signals derived from various types of microbial components, such as those from helminth and bacteria, are translated by the DCs into a stimulus for T cells, leading to a productive T cell response. The T cell stimuli derived from DCs include MHC II-peptide (signal 1), the expression or absence of costimulatory molecules (signal 2), and expression or absence of polarizing cytokines (signal 3)[72,73]. Microbial antigens can activate DCs through ligation of TLRs, leading to the up-regulation of functional surface molecules, and the release of cytokines, such as IL-12, IL-18 and IL-27, resulting in the induction of Th1 immunity[70,71,74]. Although it is less clear, there is also evidence indicating that DC function is modulated during helminth infection[75]. Different helminth-derived molecules have been suggested to be able to induce DC activation, and subsequent Th2 and/or T reg responses. Studies have indicated that two *Schistosome* egg-derived components (the glycolipid lysophosphatidylserine and the carbohydrate determinant lacto-N-fucopentaose Ⅲ) can activate TLR4 and TLR2, respectively, in myeloid DCs[76]. Live schistosoma eggs can activate DCs through TLR2 and TLR3[77]. Parasite secreted compounds like ES-62 from filarial nematodes induce the development of DCs and are capable of driving a Th2 response, modulating cytokine production (IL-12 and TNF-α) in macrophages and DCs *via* the TLR4 pathway[78]. A recent report suggests that helminth infection may alter TLR 4 expression in mucosal T cells, and these T cells when stimulated with LPS produce TGF-β[79]. Additionally, murine bone marrow-derived DCs pulsed with the helminth excretory/secretory antigen can, on transfer to naive recipients, prime mice for Th2 responsiveness[80]. Other studies also indicate that the soluble fractions from S. mansoni eggs may alter TLR ligand-induced activation of DCs[81]. These results clearly indicate the possibility that helminth infection may modulate TLR expression of DCs and responsiveness of DCs to TLR ligands.

In addition to Ag-specific MHC-peptide complexes and costimulatory molecules (B7.1 and B7.2, signal 2), other signals derived from Ag-primed DCs have been thought to be required for the differentiation of naive Th cells into Th1 and Th2 cells[72,73,82]. It has been shown recently by us and by others that intestinal helminth infection induces DC activation and up-regulates the DC IL-10 response[39,83], which may provoke a Th2 and/or T reg dominant response.

HELMINTH INFECTION INDUCES THE DEVELOPMENT OF ALTERNATIVELY ACTIVATED MACROPHAGES

The helminth infection induced-Th2 cytokine response has been suggested to affect macrophages[84]. Although macrophages share some functional similarities with DCs, macrophages have distinct functions. As discussed above, DCs play an important role in initiating and regulating host immune responses, whereas macrophages, contribute significantly to the effector phase, i.e. elimination of bacteria, and are also thought to be critical mediators of many chronic inflammatory diseases. Distinct phenotypes of macrophages have also been reported. Activation of macrophages by bacterial products (through TLR engagement) or pro-inflammatory stimuli such as Th1 cytokines leads to the development of the classically-activated macrophages. We and others have shown that helminth-induced Th2 cytokines induce a different phenotype, namely, the alternatively activated macrophages[85-87]. One of the distinctive characteristics of this type of macrophage is the ability to suppress the proliferation of other cells with which they are co-cultured[88,89]. A recent report suggests that alternative activation of macrophages by IL-4 results in impaired nitric oxide (NO) production and increased expression of the transferrin receptor, supporting intracellular growth of bacteria (*Mycobacterium tuberculosis*)[90]. Recently, we observed that the exacerbated *C. rodentium*-mediated colitis that develops in helminth-coinfected mice correlates with the marked accumulation of alternatively activated macrophages in colonic LP *via* a STAT6-dependent mechanism[85]. Functional analysis indicates that these helminth-stimulated macrophages have an impaired ability to effectively control the multiplication of phagocytosed *C. rodentium*. Presumably as a result of the increased bacterial load, these cells also produce increased amounts of TNF-α, a cytokine that has a well-established role in intestinal and other types of inflammation[91,92]. These observations, therefore, provide evidence to suggest an underlying mechanism for the enhanced bacterial infection and exacerbated bacteria-induced intestinal injury in hosts that are coinfected with helminth parasites.

CONCLUSION

In many developing countries, exposure to helminth infections and simultaneous infection with other pathogens, such as enteric bacteria, are quite common. Recent evidence indicates that in the developed world, a complete absence of helminth infection may be a predisposing factor for the development of certain immune-mediated disorders[45]. The emerging evidence indicates the complexity of immune regulation by helminths in host protective immunity and inflammatory diseases. The differences in the effects of helminths on the development and progression of intestinal inflammation observed in various models emphasize the need for a better understanding of the mechanisms by which helminths modulate host mucosal immunity. It is clear that a more thorough understanding of the complex relationship between the human host and parasitic worms will be required to develop safer, novel and more effective treatments for microbial diseases and immune-mediated disorders such as IBD.

Abstract

Protein/carbohydrate interactions through specific protein families termed lectin control essential biological processes. Galectins, a family of animal lectins defined by shared amino acid sequence with affinity for β-galactosides, appear to be functionally polyvalent in a wide range of biological activity. Recent studies have identified immunoregulatory roles of galectins in intestinal inflammatory disorders. Galectin-1 and galectin -2 contribute to the suppression of intestinal inflammation by the induction of apoptosis of activated T cells, whereas galectin-4 is involved in the exacerbation of this inflammation by specifically stimulating intestinal CD4+ T cells to produce IL-6. We review how different members of the galectins provide inhibitory or stimulatory signals to control intestinal immune response under intestinal inflammation.

Key words: Galectin; Inflammatory bowel disease; Crohn's disease; Ulcerative colitis; Pathogenesis; Apoptosis; Glycosylation

INTRODUCTION

Inflammatory bowel disease (IBD), which is characterized by two forms of intestinal inflammation, Crohn's disease (CD) and ulcerative colitis (UC), is a group of chronic, relapsing, and remitting inflammatory conditions that affect individuals throughout life[1]. Several factors such as immune imbalance, dysregulated host/microbial interaction, and genetic susceptibility are involved in the pathogenesis of IBD[2-4]. Experimental IBD models have provided a useful means to dissect the pathogenesis of this disease[2-4]. Among these models, chronic intestinal inflammation that spontaneously develops in T cell receptor α knockout (TCRα KO) mice shares several features with human UC, e.g. marked increase in autoantibodies such as antineutrophil cytoplasmic antigens and antitropomyosin, predominant Th2 responses and negative association of colitis development with prior appendectomy (resection of cecal patch)[5-7]. Importantly, B cells and autoantibodies in TCRα KO mice are involved in the regulation of this inflammation[8-12]. Therefore, a screening approach utilizing autoantibodies present in TCRα KO mice was proposed to have an ability to provide a useful tool in the identification of molecules, which may have a role in the pathogenesis of UC[13]. Indeed, the screening approach [serological analysis of recombinant cDNA expression libraries (SEREX) for the identification of candidate molecules that are recognized by autoantibodies from TCRα KO mice] has provided us an unexpected opportunity to identify galectin-4 as a potential stimulator of CD4+ T cells under intestinal inflammatory conditions[14,15]. Interestingly, galectin-4 was an unexpectedly discovered carbohydrate-binding protein through our screening approach, emphasizing

the importance of carbohydrate/protein interactions in the pathogenesis of intestinal inflammation. Indeed, a recent study has demonstrated that an alteration of carbohydrate composition (carboxylated glycans) on macrophages and dendritic cells contributes to the early onset of intestinal inflammation[16]. Alternatively, carbohydrate/protein interactions also play a regulatory role in the intestinal inflammation as indicated by a suppressive effect of galectin-1 and galectin-2 on this inflammation[17,18]. We, herein, review recently identified novel roles of galectins in immune responses under intestinal inflammation.

GALECTINS

Several families of glycan-binding proteins or lectins, which include C-type lectins (such as selectin, DC-SIGN, dectin, and serum mannose binding protein)[19-23], S-type lectins (galectins)[24-28] and siglecs[29], have been implicated in a wide variety of immunological functions including first-line defense against pathogens, cell trafficking, cell differentiation and immune regulation. Galectins are a family of 15 members (galectin-1 to galectin-15) characterized by two properties: the ability to bind to lactosamine unit within glycans and the preserved carbohydrate recognition domains (CRD) composed of 130 amino acid residues. The 15 members of galectins are structurally classified into three groups; prototype, chimera-type, and tandem repeat type[30-32]. Prototype (galectins-1, -2, -5, -7, -10, -11, -13, -14, and -15) is non-covalent homodimers that are composed of two identical CRDs. Only galectin-3 is chimera type that is composed of a CRD linked to a proline-, glycine-, and tyrosine-rich N-terminal domain. Tandem repeat type (galectins-4, -6, -8, -9, and -12) possesses two distinct CRDs. The ability of CRDs to cross-link the lactosamine unit within surface glycoreceptors allows galectins to actively participate in several immune responses. A large body of evidence indicates important roles of galectins in the development and progression of cancer[30-33]. Recently, compelling evidence has been accumulated regarding the immunoregulatory effects of galectins in inflammatory disorders[34-36]. We focus on four members of galectins (galectins-1, -2, -3 and -4), which have been studied regarding intestinal inflammation.

REGULATORY ROLE OF GALECTIN-1 IN INTESTINAL INFLAMMATION

Galectin-1 (prototype), which is expressed by a wide variety of cell types, is specifically upregulated on CD4+CD25+ regulatory T cells[37]. Soluble galectin-1 has been demonstrated to interact with a lactosamine unit of mature core 2 *O*-glycan that is assembled within some glycoreceptors including CD7, CD43, and CD45, and its cross-linking ability is crucial for the induction of T cell apoptosis[37-40]. The anti-inflammatory properties of galectin-1 have been evaluated in several models of chronic inflammation and autoimmunity including autoimmune encephalomyelitis[41], arthritis[42], uveitis[43], hepatitis[44], and diabetes[45]. As for the colitis model, galectin-1 expression in the colon is upregulated under an intestinal inflammatory condition that is chemically induced in mouse by rectal administration of 2, 4, 6-trinitrobenzene sulfonic acid (TNBS)[17]. Administration of human recombinant galectin-1 contributes to the reduction of Th1 cytokine (TNF-α, IL-1β, IL-12 and IFN-γ) release and the suppression of this intestinal inflammation by specifically inducing the apoptosis of effector T cells responsible for production of IFN-γ[17]. In addition, a recent study has demonstrated that administration of recombinant galectin-1 also contributes to increase IL-10 production in CD4+ and CD8+ T cells[46]. These data clearly address the therapeutic potential of galectin-1 to skew the balance from a Th1- toward a Th2-polarized immune response that induces a remission state in the evolution of the ongoing inflammatory disorders.

REGULATORY ROLE OF GALECTIN-2 IN INTESTINAL INFLAMMATION

Galectin-2 (prototype) is expressed by various cells including intestinal epithelial cells. Galectin-2, structurally related to galectin-1, has been demonstrated to be an inducer of apoptosis of activated T cells, although it lacks reactivity to CD7 characteristic for galectin-1[47].A recent has study shown that galectin-2 is constitutively expressed mainly in the epithelial compartment of the mouse intestine and binds to lamina propria mononuclear cells[18]. In acute and chronic dextran sodium sulfate (DSS)-induced colitis, and in a Th1-driven model of antigen-specific transfer colitis, galectin-2 expression was reduced, but could be restored to normal levels by immunosuppressive treatment. Administration of human recombinant galectin-2 induced apoptosis of mucosal T cells and, thus, ameliorated. Furthermore, pro-inflammatory cytokine (IL-6, IL-12p70) release was inhibited by administration of galectin-2. Their study provides evidence that galectin-2, as well as galectin-1, induces apoptosis *in vivo* and ameliorates acute and chronic murine colitis.

ROLE OF GALECTIN-3 IN INTESTINAL INFLAMMATION

Galectin-3 (chimera type) is a multifunctional protein detected in the nucleus, cytoplasm and extracellular matrix of a wide variety of cells. Galectin-3 has the dual role of protecting T cells from apoptosis when present intracellularly while promoting apoptosis when acting on T cells from the extracellular space[30-32,36]. Regarding intestinal inflammation, a study showed that the titers of anti-galectin-3 autoantibodies were higher in CD patients with low activity index than with active disease[48]. The pathophysiological significance of the anti-galectin-3 autoantibody in Crohn's disease still remains to be elucidated. The same research group

subsequently showed that expression of galectin-3 was reduced in the intestinal epithelium of CD patients and that colonic epithelial adenocarcinoma cell line HCT-8 cells reduced galectin-3 expression by incubation with TNF-α but not with other cytokines[49]. It was speculated that galectin-3 was consequently downregulated by enhanced TNF-α production in CD. Another research group confirmed the similar findings[50]. More recently, soluble galectin-3, which is secreted by colonic epithelial cells, was identified as an activator of lamina propria fibroblasts[51,52]. The study also indicated that galectin-3 induced NF-κB activation and IL-8 secretion *in vitro*. Its role in pathogenesis of intestinal inflammation, especially involvement in fibrosis formation of CD, has to be clarified in further studies. In a protein expression profile study of Enterococcus faecalis-monoassociated IL-10 KO mice under chronic intestinal inflammation and intestinal epithelial cell lines, galectin-3 expression was reduced in association with the activation of caspase 3, a major executive caspase of apoptosis[53]. Further studies are needed to address whether galectin-3 plays a pro-inflammatory role or an anti-inflammatory role in intestinal inflammation.

PATHOGENIC ROLE OF GALECTIN-4 IN INTESTINAL INFLAMMATION

Galectin-4 (tandem repeat type) is expressed only in the digestive tract[54-56] where epithelial cells are responsible for this production[14,55,56]. Galectin-4 can be secreted from both basolateral and apical sides of the intestinal epithelial cells through a nonclassical secretary pathway. In contrast to galectin-1[17], intestinal inflammatory conditions do not enhance the galectin-4 expression: there is no significant difference in the expression level of galectin-4 in the epithelial cells from control *versus* inflamed colons[14]. Interestingly, through a combined screening approach utilizing humoral (SEREX) and cellular immune responses, we have unexpectedly identified galectin-4 as a potential stimulator of CD4+ T cells to exacerbate intestinal inflammation[14]. Neutralization of galectin-4 activity *in vivo* by administration of the specific antibody suppresses the progression of chronic colitis that spontaneously develops in B cell-deficient TCRα double KO mice[14], whereas pretreatment with this antibody fails to abolish the development of colitis in these mice (A.M., unpublished observation). These data suggest that galectin-4 contributes to the exacerbation, rather than initiation, of chronic intestinal inflammation. Because it could be predicted that both acute (induction of inflammation) and healing (recovery from inflammation) processes are simultaneously involved in the chronic intestinal inflammation, galectin-4-mediated exacerbation of this inflammation may result from a suppression of the healing process. Indeed, treatment with recombinant galectin-4 delays the recovery from an acute intestinal inflammation that is induced by transient administration of DSS, whereas treatment with anti-galectin-4 antibody enhances the recovery from this acute inflammation. In contrast, galectin-1, as mentioned above, contributes to the suppression of acute intestinal inflammation[17]. Galectin-1 (prototype) is structurally characterized by homodimers with identical CRDs, and binds to a lactosamine unit within a mature core 2 *O*-glycan, whereas galectin-4 (tandem repeat type) consists of two distinct CRDs and possesses a unique carbohydrate-binding specificity as indicated by the capability of interacting with an immature core 1 *O*-glycan with 3'-O-sulfation[57]. Therefore, it is highly likely that the binding site (lactosamine unit *versus* core 1) and the structure (prototype *versus* tandem repeat type) are an important determinants of galectin-mediated immune function[30-32,36]. Galectin-4 specifically stimulates CD4+ T cells, but not other immune cells such as B cells or macrophages to produce IL-6[14], a well-known cytokine involved in the pathogenesis of not only intestinal inflammation, but also colon cancer[58-60]. Importantly, only CD4+ T cells that are present in the inflamed, but not non-inflamed, intestine can respond to galectin-4[14]. Splenic CD4+ T cells even from the diseased mice are unable to respond to galectin-4. These findings are consistent with the binding intensity of galectin-4 to the surface of CD4+ T cells; galectin-4 binding is significantly enhanced on the CD4+ T cells from the inflamed colon as compared to noninflamed colon and spleen. In addition, galectin-4 specifically binds to the lipid rafts on the CD4+ T cells to activate the protein kinase C θ-associated signaling cascade[14], a common and fundamental pathway in the different types of intestinal inflammation[61]. Notably, galectin-4 has been demonstrated to interact with lipid rafts of enterocytes as well, and subsequently stabilize the raft formation to generate "superrafts"[62]. A recent study has found that galectin-4 interacts with carcinoembryonic antigen of colon adenocarcinoma[63]. Alternatively, it remains obscure which glycosylated receptor(s) on intestinal CD4+ T cells is crosslinked by galectin-4. Production of galectin-4 by colonic epithelial cells is not enhanced under inflammatory condition, whereas the reactivity of CD4+ T cells to galectin-4 is specifically elicited under these conditions. Therefore, it is possible that a specific receptor that is selectively crosslinked by galectin-4 may be expressed on intestinal CD4+ T cells only under inflammatory conditions. However, galectin-4 can bind to the lipid rafts on both CD4+ T cells from inflamed and normal intestines although the binding intensity is much higher on diseased CD4+ T cells[14]. In addition, expression pattern of the enzymes that are involved in the glycan synthesis is altered by several inflammatory stimuli[27,34,35]. Therefore, it is more likely that an altered enzyme expression pattern by intestinal inflammatory stimuli results in the further exposure of core 1 *O*-glycan (a binding partner of galectin-4) on intestinal CD4+ T cells and consequently allows intensified binding of galectin-4 to them. Indeed, our recent studies have found that some glycosylation-associated enzymes, which are involved in the synthesis of core 2 from core 1, are significantly downregulated in the intestinal CD4+

T cells under inflammatory conditions as compared to a state of health (our unpublished observation). These findings provide an insight into an unexpected role of lectin/carbohydrate interaction in the pathogenesis of T cell-mediated chronic colitis.

CONCLUSION

Glycobiology has an exiting impact to molecular biology and clinical fields, given the multifunctional activities of galectins. In this review, we provide novel insights into the role of carbohydrates crosslinked by galectins in the immune responses involved in the pathogenesis of IBD. Different members of the galectin families provide inhibitory or stimulatory signals to control intestinal immune response under intestinal inflammatory conditions. A more thorough understanding of the molecular mechanisms involved in the immunoregulatory functions of galectins is needed before galectin-based therapeutic strategies for IBD can be realized.

Abstract

The gastrointestinal innate and adaptive immune system continuously faces the challenge of potent stimuli from the commensal microflora and food constituents. These local immune responses require a tight control, the outcome of which is in most cases the induction of tolerance. Local T cell immunity is an important compartment of the specific intestinal immune system. T cell reactivity is programmed during the initial stage of its activation by professional presenting cells. Mucosal dendritic cells (DCs) are assumed to play key roles in regulating immune responses in the antigen-rich gastrointestinal environment. Mucosal DCs are a heterogeneous population that can either initiate (innate and adaptive) immune responses, or control intestinal inflammation and maintain tolerance. Defects in this regulation are supposed to lead to the two major forms of inflammatory bowel disease (IBD), Crohn's disease (CD) and ulcerative colitis (UC). This review will discuss the emerging role of mucosal DCs in regulating intestinal inflammation and immune responses.

Key words: Dendritic cells; Commensal; Inflammatory bowel disease; Mucosal immunity; Host defence

INTRODUCTION

The intestinal innate and adaptive immune system has evolved in response to potent stimuli derived from constituents of the commensal microflora. In most cases these local immune responses achieve tolerance to the intestinal microflora and food antigens. Defects of the tightly regulated mucosal immune responses are assumed to result in inflammatory bowel disease (IBD), such as Crohn's disease (CD) and ulcerative colitis (UC)[1,2]. Local T cell immunity is an important compartment of the specific intestinal immune system. T cell reactivity is programmed during the initial stage of its activation by dendritic cells (DCs) that can either initiate (innate and adaptive) immune responses, or control intestinal inflammation and maintain tolerance[3-5]. DCs reside in mucosal tissues or recirculate in the blood and lymphoid tissues[6]. The lamina propria of the small and large intestine are effector sites of mucosal tissues. Inductive sites are Peyer's patches (PP), intestinal lymph follicles (iLFs), DC aggregates and mesenteric lymph nodes (MLNs) (Table 1). The local microenvironment influences the phenotype of DCs, a heterogeneous population that can be divided into conventional DCs ($CD8\alpha^+CD11b^-$, $CD4^+CD11b^+$, $CD4^-CD11b^+$)[7,8] and plasmacytoid DCs ($B220^+CD11c^{low}$) (Table 2) and are characterized by a remarkable plasticity between DCs[9]. In the lamina propria of the small and large intestine, DCs are ideally situated to survey the constituents of the commensal microflora and monitor food antigens[10]. After antigen recognition at peripheral sites DCs migrate to regional draining lymph nodes to initiate (innate and adaptive) immune responses[11]. This review will discuss the emerging role of mucosal DCs in regulating intestinal inflammation and immune responses.

DCs IN THE SMALL INTESTINE

The lamina propria of the small intestine is populated by $CD4^-CD8\alpha^-$ cDCs. Only 2%-5% plasmacytoid DCs reside in the small intestinal lamina propria[12]. Mucosal DCs can be discriminated into DCs that express CX3CR1 (the receptor for fractalkine/

CX3CL1)[12] and into DCs that express the integrin αE chain CD103[13,14]. $CD103^+$ DCs originate from Ly-$6C^{high}CCR2^{high}$ monocytes. Conversely Ly-$6C^{low}CCR2^{low}$ monocytes repopulate $CX3CR1^+CD11b^+$ mucosal DCs[15]. $CX3CR1^+CD11b^+$ DCs directly access the intestinal lumen by extending transepithelial dendrites in a CX3CR1-dependent manner to survey the intestinal lumen[12], whereas $CD103^+$ DCs induce the expression of CCR9 and $\alpha_4\beta_7$ integrin on cognate CD4 and CD8 T cells to facilitate homing of T cells to small intestinal tissues[13,16] and induce the differentiation of regulatory T cells (T_{regs}) in the absence of exogenous cytokines.

DCs IN THE LARGE INTESTINE

The cLP is populated by $CD4^-CD8^-$ DCs which endocytose and process antigens and induce T cell proliferation. Compared to their splenic counterparts TLR-4, -5 and -9 expression by colonic $CD4^-CD8^-$C DCs is low[17]. Only few $CD8^+$ and plasmacytoid DCs are found in the cLP[17]. In human biopsies from colonic tissues, $CD3^-CD14^-CD16^-CD19^-CD34^-$ DCs with an immature state with low TLR-2 and -4 expressions were observed[18]. In addition the presence of $CD83^+$ and DC^-SIGN^+ DCs was described[19]. Human and mouse mucosal DCs are assumed to be less responsive to microbial-derived TLR-ligands compared to spleen or blood born DCs[17] Despite the functional subspecifications of DCs, DCs are characterized by a remarkable plasticity between DCs which is influenced by the local environment, the antigen itself or the activation state of the DC[9,20].

DCs IN PPs

PP, iLF, CP and DC clusters of the small and large intestine belong to the gut associated lymphoid tissues (GALTs)[6], secondary lymphoid structure, which lack in contrast to lymph nodes the afferent lymph and are located in close proximity to the intestinal epithelium. In PP the subepithelial dome regions beneath the follicle-associated epithelium can be discriminated from follicular and interfollicular regions, which serve as inductive sites where immune responses are primed. Specialized epithelial cells, the M cells, deliver luminal antigens to DCs located in the subepithelial dome regions beneath the follicle associated epithelium[21]. The subepithelial dome regions are populated with $CD8\alpha^-$ $CD11b^+B220^-$ DCs and with $CD8\alpha^-CD11b^-B220^-$ DCs[22,23]. By expressing high concentrations of the chemokines CCL20, CXCL16 and CCL9, the follicle-associated epithelium creates a specific micromilleu that allows DCs to selectively migrate towards the follicle associated epithelium[24,25]. Upon pathogen challenge

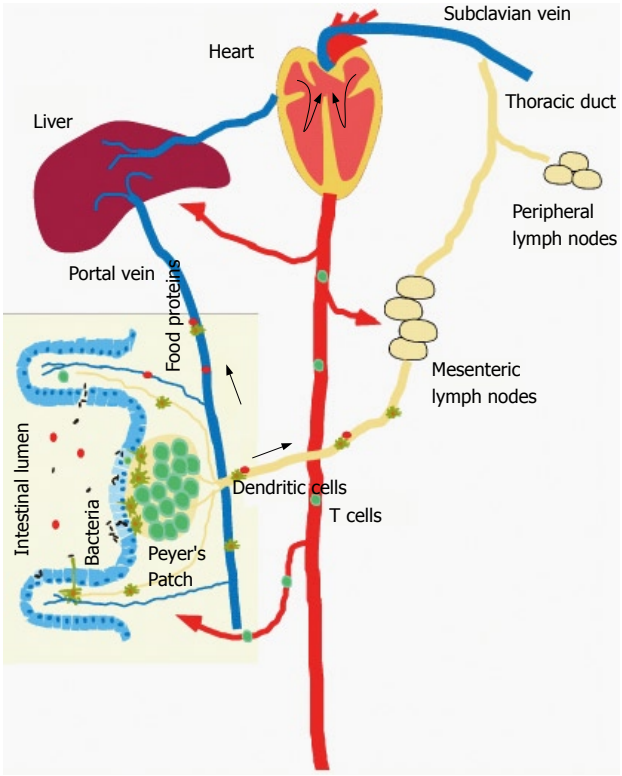

Figure 1 Bacterial and food antigens are continuously surveyed by the mucosal immune system, processed and transported *via* the lymph to mesenteric lymph nodes or *via* the portal vein to the liver. DCs present processed luminal antigens to naïve T cells to achieve tolerance or to initiate host defence to pathogens.

CCR6$^+$ DCs which are located in the interfollicular regions are recruited towards the follicle-associated epithelium to process microbial antigens, and to facilitate rapid local adaptive immune responses[23]. In the absence of CCR6 in CCR6$^{GFP/GFP}$ mice CX3CR1$^+$ DCs that lack CCR6 expression reside in the follicle-associated epithelium[23,26]. In the interfollicular regions CD11b$^-$ CD8α^- and CD11b$^-$ CD8α^+ DCs as well as plasmacytoid DCs are found that produce IL-12 and IL-10, and induce the differentiation of IFN-γ secreting TH1 cells, whereas the CD11b$^+$ subsets produce low IL-12 and high IL-10 levels and prime IL-10 producing T cells[22,27]. CD8$^-$33D1$^+$ DCs, but not CD8α^+DEC205$^+$ DCs are specialized to present processed antigens in a MHC class Ⅱ dependent manner to CD4 T cells[28]. Reoviral antigens are sampled and processed by CD11b$^-$CD8α^- DCs to initiate TH1 adaptive immune responses likely resulting in protective host defence to viral antigens[29].

DCs IN INTESTINAL LYMPHOID TISSUES

Intestinal lymphoid aggregates (iLAs) can be discriminated from PP, which comprises iLF and CP that are closely associated with the epithelial lining in the small and large intestine[30]. CP were defined as tiny aggregates of c-Kit$^+$IL-7R$^+$ cells[31], whereas iLFs are constituted by solitary B follicles that are localized in the anti-mesenteric regions of the intestinal wall, and contain small numbers of mature T lymphocytes, but also c-Kit$^+$ and IL-7R$^+$ cells[32-34]. By analyzing large numbers of such aggregates, the classification of iLA into CP and iLF was recently challenged showing that most of them display properties intermediate between CP and iLF and were termed small intestinal lymphoid tissues (siLT)[35]. In the large intestine, subepithelial DC aggregates locate in the regions of cLP where inflammation develops[36]. DC aggregates are formed by CD8α^+, CD8α^- and B220^{lo} DCs. DCs with high MHC Ⅱ expression, but low expression of the costimulatory molecules CD40, CD80 and CD86 extend transepithelial dendrites into the intestinal lumen[37]. During colitis induced by adoptive transfer of CD45RB^{hi} CD4 T cells into immunocompromised RAG mice, FoxP3 regulatory T cells accumulate in colonic DC aggregates producing TGF-β suggesting that DC aggregates are important structures to regulate inflammation[37].

DCs IN MLN

Luminal antigens are sampled by lamina propria DCs and by DCs located in PP, CP, iLF and DC clusters at the base of intestinal villi. The DCs transport the sampled antigens *via* the lymph to MLN, where naïve T cells are primed and adaptive immune responses are induced[38] (Figure 1). In MLN, blood-born DCs and DCs that originate from PP or the lamina propria are present[6]. In MLN, blood-born DCs are assumed to express CD8α^{hi}CD11b$^-$αL^{int}β7^{int} and CD8α^- CD11b^{hi}αL^{lo}β7^{lo} DCs, whereas DCs derived from mucosal sites are characterized by CD8α^{int}CD11b$^-$ αL^{lo}β7^{hi} and CD8α^-CD11b^{hi}αL^{lo}β7^{hi} expression[39], allowing the discrimination of DCs of distinct origins. CCR7 expression guides lamina propria DCs to MLN[40]. Blood-born DCs enter the MLN *via* interactions with mucosal addressin cellular adhesion molecule (MAdCAM-1) and peripheral node adressin (PNAd) expressed by high endothelial venules (HEVs)[41]. Apoptotic cell bodies derived from intestinal epithelial cells (iECs) are phagocytosed and transported to MLN to induce tolerance against self-antigens[42]. The depletion of MLN results in defective oral tolerance. Lamina propria DCs are continuously carrying commensal bacteria to the MLN[43], which can be further potentate by stimulating DCs with TLR-7/8 agonists[44]. IgA production is induced that is supposed to limit the dissemination of commensal bacteria further than the MLN preventing effectively systemic infections[45].

DCs IN INTESTINAL ANTIGEN ACQUISITION PATHWAYS

Intestinal DCs play a key role in monitoring the intestinal lumen by continuously sampling and processing luminal antigens[46,47]. There are different pathways by which luminal antigens can gain access in the lamina propria[48]. In all pathways, mucosal DCs are supposed to play key roles. Restricted to the ileum DCs extend transepithelial dendrites in a CX3CR1 mediated manner to survey the

intestinal lumen to continuously survey the commensal microflora and to monitor food antigens[12,49]. M cells located in the follicle associated epithelium of PP are specialized epithelial cells which gained the ability to translocate luminal antigens *via* the intestinal barrier and deliver luminal antigens to DCs located in the subepithelial dome regions of PP[21]. Upon pathogen challenge, $CCR6^+$ DCs are recruited to the dome regions to process pathogens, and to trigger rapid local adaptive immune responses[23]. As well $CD11b^-CD8\alpha^-$ $CD11c^+$ interfollicular DCs process antigens derived from luminal reovirus[29]. M cells within the small intestinal villous epithelium are able to translocate pathogens *via* the epithelial barrier to DCs located in the lamina propria[50]. The intestinal epithelium by itself plays an important role in sensing the luminal microenvironment. The intestinal epithelium express Toll-like receptors, such as TLR2[51], TLR-4[52], TLR-5[53] and TLR-9[54] to recognize microbial derived pathogen associated molecular patterns (PAMPs) for the regulation of protective innate immune responses. As well upon LPS-stimulation iECs express the intracellular pathogen recognition pattern NOD1[55] and NOD2[56,57], in which mutations are associated with an increased susceptibility for CD[58,59]. IECs directly participate in intestinal antigen uptake pathways by delivering antigens or exosomes to lamina propria DCs. Secreted IgG binds to cognate luminal antigens to form IgG/antigen complexes that are recycled by neonatal FcRn receptors and delivered to lamina propria DCs[60,61]. IECs also express MHC Ⅱ and may present luminal antigens to CD4 T cells. After luminal exposure with ovalbumin (OVA), OVA is taken up at apical and basolateral surfaces of the epithelial cells. Then, it enters the early endosomes and may be delivered to late endosomes where it is processed in the presence of MHC Ⅱ, and presented in the context of class Ⅱ to T cells[62]. It needs to be dissected in future work whether all or specific luminal antigen acquisition routes are linked to the induction and constant renewal of tolerance and to the development of protective immune responses. DCs are assumed to play key roles in all luminal antigen acquisition routes, and are supposed to represent a major factor for the processing and presentation of orally delivered antigens and the induction of tolerance.

DC MEDIATE INNATE AND ADAPTIVE IMMUNE RESPONSES TO THE COMMENSAL FLORA

The gastrointestinal immune system faces the tremendous challenge to deal with potent stimuli for the innate and adaptive immune system derived from the commensal microflora and food antigens. DCs are sentinels of the mucosal immune system to survey the constituents of the luminal commensals and to trigger host responses to pathogens[63]. It is thought that gastrointestinal diseases, such as IBDs are results of deregulated immune responses to the commensal microflora[1]. Although germ-free (GF) mice and rats generate alloreactive T cell responses[64] and cellular immunity to certain bacteria (after monocolonization)[65,66], the cellularity of their immune system is greatly reduced[67-69]. In this regard, the numbers of IL-17A producing TH17 cells is reduced in the lamina propria of GF animals[70]. Because commensal flora is a major driving force of the homeostatic proliferation of naïve T cells in the periphery, the reduced cellularity in the immune system of GF mice may be the result of the deficient peripheral expansion of recent thymic T cell emigrants[71,72]. When GF mice are fed bacterial carbohydrate polysaccharide A (PSA) CD4 T cells are activated resulting in a TH1 response imprinted by DCs[72]. After conventionalization of GF rats $OX62^+$ DCs increased, whereas $CD4^+$ DCs located in the follicle associated epithelium decreased indicating that $CD4^+$ DCs phagocytose microbial derived antigens, relocate to the follicular regions, and elicit rapid immune responses to the microflora to achieve tolerance[68]. Furthermore, it has been described that the inducible isoform of nitric oxide synthase (iNOS) expressing DCs is markedly reduced in GF or MyD88-deficient animals indicating that the commensal flora is required for the accumulation of iNOS expressing DCs at mucosal sites[73]. In $iNOS^{-/-}$ animals serum IgA levels are reduced suggesting that iNOS expressing DCs play a role in IgA class switching required to prevent the uncontrolled dissemination of the commensal flora into the host.

HEMATOGENOUS DISSEMINATION OF INTESTINAL ANTIGENS

Although the priming of T cells mainly occurs in draining lymph nodes, antigen-rich blood from the small and large intestine is transported to the liver *via* the portal vein, and pressed through a network of sinusoids and scanned by antigen-presenting cells and lymphocytes in the liver[74,75] (Figure 1). One third of liver cells are constituted by non-parenchymal cells (NPCs), which include liver sinusoidal endothelial cells (LSECs), Kupffer cells, biliary cells, stellate cells (Ito or fat-storing) cells and lymphocytes[74,75]. Resident APCs in the liver are Kupffer cells, LSEC[76], Ito cells[77] and DCs[75]. Plasmacytoid $B220^+CD11c^+$ DCs as well as $B220^-CD11c^+$ DCs are found. The latter can be further divided into major immature ($CD40^{lo}$ $CD80^{lo}$ $CD86^{lo}$ MHC class $Ⅱ^{lo}$) $CD11c^{int}$ and minor mature ($CD40^{hi}$ $CD80^{hi}$ $CD86^{hi}$ MHC class $Ⅱ^{hi}$) $CD11c^{hi}$ DCs[78]. Further, the presence of $CD8\alpha^+CD11b^-$ and $CD8\alpha^-CD11b^+$ DCs has been reported[78]. The continuous exposure of resident APCs with the bacterial cell wall derived LPS promotes the induction of CD4 regulatory T cells and may explain the dominance of IL-10 in the liver[79,80]. If Kupffer cells are depleted by gadolonium chloride treatment, liver tolerance becomes impaired raising the possibility that the liver is increasingly recognized as an innate and adaptive immune organ[81].

DCs IN ORAL TOLERANCE INDUCTION

Mucosal DCs play a key role in the development of oral tolerance, a phenomenon, in which systemic immune responses to a defined peptide/protein are blunted, when the same protein has been orally fed before the rodents were systemically challenged[82]. The triggering of oral tolerance in patients with IBD is impaired[83]; however, the exact mechanism has not been determined. Mucosal DCs are critical for the induction of oral tolerance as shown by studies, in which flt-3 ligand was injected in mice leading to the expansion of DC subsets[84]. After the expansion of the intestinal DC pool, enhanced oral tolerance was observed. Because oral tolerance can be transferred by adoptive transfer of T cells into recipient mice, interactions between DCs and T cells seems to be essential for the development of oral tolerance, in which CD4 CD25 FoxP3 regulatory and IL-10 and TGF-β secreting TH3 cells that suppress systemic immune responses are primed[85]. When spleen DCs are compared to mucosal DCs, the mucosal DCs are more efficient in inducing FoxP3 expression than spleen DCs in the presence of TGF-β[86,87]. Further analyses demonstrated that $CD103^+$ DCs are able to induce the differentiation of T_{reg} cells *via* the production of the Vitamin A metabolite, retinoic acid, in presence of TGF-β, which in addition results in the recruitment of T cells and B cells to intestinal tissues[88-90]. Blocking of TGF-β abrogates the ability of $CD103^+$ DCs to induce T_{reg} cells[91,92]. However, parallel studies have indicated that exogenous TGF-β has not to been added to this system in order to obtain FoxP3 expressing T_{reg} cells[86,87] raising the possibility that gut DCs activates latent TGF-β present in mucosal tissues. In this regard, the integrin $\alpha_v\beta_8$ expressed by DCs is required to activate TGF-β *in vivo*. Mice, in which DCs lack $\alpha_v\beta_8$, develop IBD and autoimmunity[93].

Oral tolerance is not impaired in PP-deficient mice demonstrating that lamina propria DCs play a key role in the development of oral tolerance by sampling the luminal content, and transporting antigens to the MLN[94]. After depletion of the MLN, the development of oral tolerance is reduced indicating that the MLN are a major site for priming tolerance[95]. Interestingly, it has been suggested, that intestinal self antigens can be presented by lymph node stroma cells beyond the MLNs[96]. It also may depend on the presence of certain pathogens within the lumen, because *Heligmosomoides polygyus* infection correlates with DC activation and IL-10 expression[97]. This provides evidence that the studies of intestinal microbial responses not only require the recognition of region- and compartment-specific immune responses, but the consideration of the interplay of different commensals and pathogens in modulating mucosal immune responses.

DC DEPENDENT T_{reg} CELL CONVERSION

T_{reg} cells play a key role for the development of oral tolerance, and the regulation of intestinal inflammation triggered by the intestinal microflora. $CD103^+$ but not $CD103^-$ DCs purified from GALT-induced generation of FoxP3 cells *in vitro*[98]. T_{reg} cells can be distinguished from other T cell populations by the surface expression of the α chain of the high affinity IL-2 receptor (CD25), and the transcription factor FoxP3 that is essential for T_{reg} development. Deadly autoimmunity is prevented by T_{reg} cells as exemplified in X-linked immunodeficiency, polyendocrinopathy, enteropathy (IPEX) syndrome in humans[98]. The conversion of T_{reg} cells in the GALT can be prevented by inhibitors of retinal dehydrogenases, an enzyme that is highly expressed by $CD103^+$ DCs, which converts retinol (vitamine A) into retinoic acid[86,87,91,99]. Retinoic acid binds to nuclear retinoic acid receptors that upon ligation can inhibit the activity of activating protein-1 (AP-1), a transcription factor, which can interfere with nuclear factor of activated T cells (NFAT)-FoxP3 complex[100,101]. However, the exact retinoic acid dependent signal transduction pathways required for the conversion of T_{reg} cells remains to be elucidated. Retinoic acid production by $CD103^+$ DCs also induce the up-regulation of the integrin $\alpha_4\beta_7$, and the CC chemokine receptor CCR9 which binds thymus-expressed chemokine (TECK) permitting the accumulation of T_{reg} cells intestinal tissues[13]. The retinoic acid dependent conversation of T_{reg} cells depends on the presence of TGF-β, a cytokine that, in the presence of IL-6 and IL-23, can also induce the generation of TH17 cells[102] (Figure 2). A small subset of naïve T cells in the small intestine co-express the transcription factors FoxP3 and RORγt[103]. High expression of TGF-β represses IL-23 receptor expression and favours the generation of FoxP3 T_{reg} cells, whereas low TGF-β expression in concert with IL-6, IL-21 and IL-23 relieves FoxP3 mediated RORγT inhibition promoting TH17 cells[103]. TH17 cells accumulate in the lamina propria of patients with IBD indicating that TGF-β can induce regulatory and pro-inflammatory T cell subsets[104].

DCs IN IBD

Various animal models have provided insights that mucosal DCs play a key role in IBD. However, the specific function of certain DCs are unknown and needs to be determined in future work, which will provide information on mechanisms leading to IBD and limiting intestinal inflammation to achieve protective mucosal immune responses. In agreement with animal models DCs accumulate at sites of inflammation in patients with IBD. It was found that the pathogen recognition receptors TLR-2 and -4 as well as the activation/maturation marker CD40 are upregulated by intestinal DCs derived from patients with CD[18]. Furthermore, increased numbers of TNF-α producing $MDC8^+$ monocytes, which may be precursors of mucosal DC populations, were found in patients with IBD and, hence, the treatment CD patients with anti-TNF-α antibodies resulted in reduced DC activation[105,106]. In inflamed tissues DCs are matured and increased in

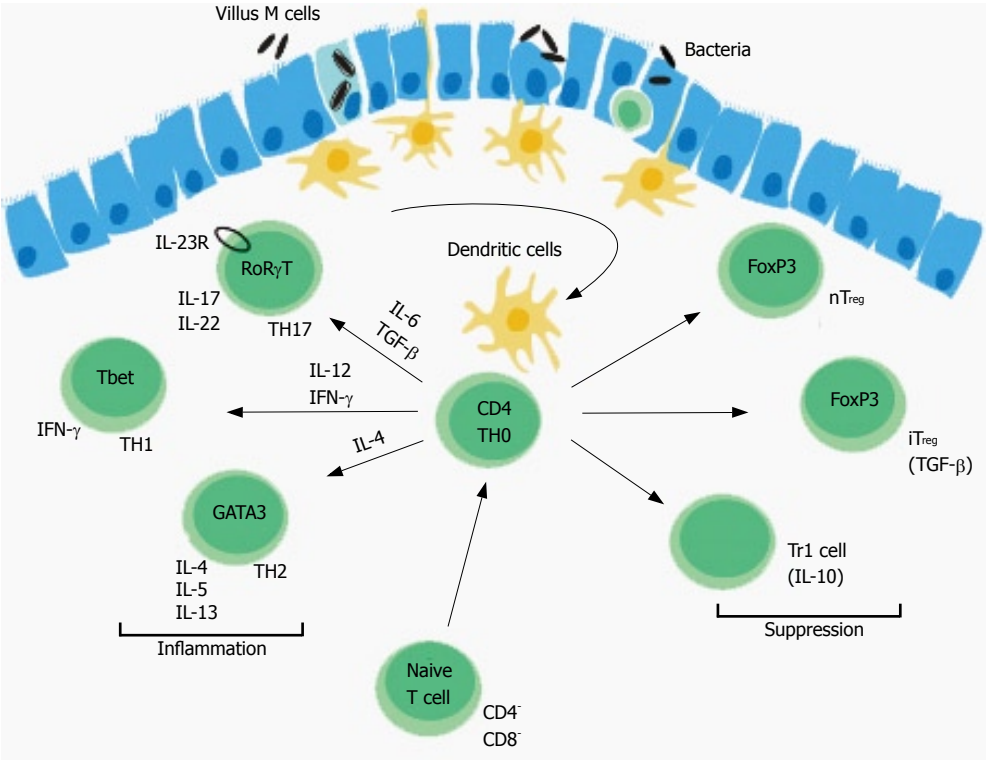

Figure 2 DCs continuously survey the intestinal lumen, phagocytose and process luminal antigens and present them to T cells, which will differentiate in presence of IL-6 and TGF-β to IL-17A and IL-17F producing TH17 cells, in presence of IL-12 and IFN-γ into TH1 cells or in presence of IL-4 into TH2 cells. nTreg, natural occurring regulatory T cell; iTreg, inducible regulatory T cells; Tr1, regulating T cell.

numbers. The $CD83^{-}CD80^{+}DCSIGN^{+}$ DC subsets produce the cytokine IL-12 and IL-18, which promote TH1 development[19]. Also, in the peripheral blood and in the lamina propria of patients with CD or UC the numbers of $CD86^{+}CD40^{+}$ DCs are increased. In addition, DCs generated *ex vitro* from peripheral blood monocytes of IBD patients show increased abilities to stimulate immune responses[107-109]. Mice studies indicated that DCs isolated from inflamed colonic tissues and DCs located in the terminal ileum, which continuously sample commensal bacteria produce IL-23, but little IL-12[110,111]. It was discovered that IL-10 KO mice that spontaneously develop colitis are protected from colitis when bred on IL12p19, but not on IL-12 p35-deficient mice. In similar studies, *Helicobacter hepaticus* infected immunocompromised $RAG^{-/-}$ bred on IL-12 p19 deficient mice, but not on IL-12 p35 deficient background mice were protected from colitis indicating that DC derived IL-23 plays a major role in intestinal pathology[112,113]. The formation of granulomas, histological characteristics of CD, depends on the release of IL-23 by DC-like cell types that are characterized by CD11c and F4/80 expression[114]. Genome-wide association studies showed associations between CD and UC patients, and a gene encoding a subunit for the IL-23 receptor suggested a major role of IL-23 in the pathogenesis of IBD[115,116]. IL-23 seems to be essential for the expansion and maintenance, but not for the initial induction of IL-17 producing CD4 T cells (TH17) cells[117]. Studies in which TH1 and TH17 cells were generated co-cultures, in which naïve T cells were cultured with fecal extracts pulsed DCs, and in the presence of TH1 or TH17 promoting cytokines indicated that TH17 cells are more pathogenic than TH1 cells[118]. Recent published observations report that colitis induced by transfer of IFNγ-deficient T cells in $RAG^{-/-}$ mice is associated with elevated numbers of TH17 cells in the lamina propria[70]. The adoptive transfer of IL-17F, but not IL-17A deficient CD4 T cells ameliorated the IBD in the transfer model[119,120]. Interesting findings implicated that the IL-1 and IL-23 dependent priming of TH17 effector cells required a NOD2 dependent pathway, and that monocyte derived DCs from CD patients with mutated NOD2 failed to efficiently activate TH17 effector cells[121]. In this regard the TH17 cytokine IL-22 mediates mucosal defence to bacterial pathogens, and ameliorates chronic colitis in the TCRαKO model by stimulating mucus production and globlet cell restitution under inflammatory conditions[122]. In addition IL-22, which is released by T and DCs, act together with IL-17 to clear bacterial infections at mucosal sites[123,124]. When conventional DCs are depleted in a CD11c DTR transgenic animal system by diphtheria toxin applications, the severity of colitis is suppressed in the dextran sodium sulfate (DSS) colitis model[125]. Furthermore, in mice with an iEC specific deletion of IKKβ failed to clear *Trichuris muris* infection characterized by severe intestinal pathology[126]. In these mice an increased accumulation of DCs at mucosal sites was observed that produce IL-12/23 p40 and TNF-α. In addition, an accumulation of IFN-γ producing TH1 and IL-17 producing TH17 cells in the MLN was found. Specific depletion of NEMO (IKKγ) or of both IKKα and IKKβ is essential for the activation of NF-κB activation induce IBD[127]. Constitutive NF-κB activation in IECs by commensal flora may condition DCs to prevent tissue inflammation. Thymic stromal lymphopoietin (TSLP) produced by epithelial cells is involved in the

conditioning of DCs to prime less harmful TH2 and T_{reg} responses[126,128]. Together, these data suggest that DCs are conditioned by iECs to promote immunosuppressive T cell responses. However, DCs and their precursors are sensitive to proinflammatory activation signals, which could help to participate into the long persistence of local T cell activation patterns promoting IBD.

CONCLUSION

Mucosal DCs may have several functions in the mucosal immune system to accomplish tolerance and to maintain homeostasis. Tolerance to intestinal self antigens, oral antigens and the commensal flora is achieved by interactions of DCs with regulatory and effector T cells. DCs are also involved in triggering deleterious T cell responses to the endogenous microflora being the basis of IBD. Mucosal DCs express the integrin alpha E (CD103) or the receptor for fractalkine/CX3CR1. CX3CR1 expressing DCs are involved in luminal antigen recognition pathways, whereas CD103 DCs metabolize vitamin A to retinoic acid and are involved in the conversion of T cells to regulatory T cells. Genetically engineered mouse models, and cellular approaches will be increasingly available to study the biology of CD103 and CX3CR1 DCs in immune responses to the commensal flora, and their role in initiating and regulating intestinal inflammation. DCs maintain intestinal homeostasis allowing the peaceful coexistence with the endogenous microflora. The discovery of specific DCs associated with luminal antigen acquisition and oral tolerance will allow developing strategies for targeting defined antigen acquisition routes to design therapeutic treatments for patients with IBD.

Abstract

Ulcerative colitis and Crohn's disease are chronic relapsing-remitting inflammatory processes of the intestinal tract. The etiology of these diseases is currently unknown. However, inflammation is hypothesized to result from inappropriate activation of mucosal immunity by luminal antigens in genetically susceptible individuals. Toll-like receptors (TLRs) are a family of transmembrane proteins that act as microbial pattern recognition receptors. They are crucial initiators of innate immune responses. The role of TLRs in the pathogenesis of inflammatory bowel disease (IBD) has not been fully elucidated. In this review, we aim to analyze the available data connecting individual TLRs to intestinal inflammation and IBD.

Key words: Toll-like receptors; Inflammatory bowel disease; Intestinal inflammation

INTRODUCTION

Inflammatory bowel disease (IBD) is comprised of two major forms of chronic inflammation of the gastrointestinal tract, ulcerative colitis (UC) and Crohn's disease (CD). These two entities differ in their location (colon only *vs* the whole length of the intestinal tract), pattern of distribution (continuous *vs* patchy), depth of involvement (mucosal *vs* transmural) and histology (crypt abscesses *vs* granulomas). The onset of IBD typically occurs in the second and third decades of life, and a majority of affected individuals progress to relapsing and chronic disease[1].

The etiology of IBD is currently unknown. Inflammation is hypothesized to result from inappropriate activation of mucosal immunity by environmental factors in genetically susceptible individuals[2]. There is strong evidence to support the role of intestinal microflora in the pathogenesis of IBD. Mice raised under germ-free conditions do not develop spontaneous colitis in several experimental models[3]. Additionally, antibiotic treatment and probiotic bacteria were shown to induce remission in IBD patients[4-6]. Inappropriate activation of innate immunity is the other arm involved in the pathogenesis of IBD[7,8]. Activation of innate immunity relies at least partially on recognition of conserved microbial motifs known as pathogen-associated molecular patterns (PAMPs) by pattern recognition receptors (PRRs)[9]. There are two major families of PRRs known as Toll-like receptors (TLRs) and nucleotide-binding oligomerization domain (NOD) receptors.

TLRs

There are currently 11 known mammalian TLRs. They are transmembrane receptors that are found either on the cell membrane (TLR1, 2, 4, 5 and 9) or on intracellular organelles (TLR3, 7 and 8)[10,11]. TLRs are expressed throughout the gastrointestinal (GI) tract on intestinal epithelial cells (IECs), myofibroblasts, enteroendocrine cells, and on immune cells within the lamina propria, such as T cells, and dendritic cells (DCs)[12-16]. Extracellular domains of TLRs consist of leucine-rich repeats (LRRs), whereas their intracellular component contains a TIR (Toll/IL-1 receptor) domain, exhibiting homology with the interleukin-1 receptor (IL-1R) superfamily. Most TLR signal *via* the MyD88

adaptor (TLR1, 2, 4, 5, 6, 7, 8 and 9), whereas TLR3 signaling activates an alternative "MyD88-independent" pathway. TLR4 is the only receptor known to activate both MyD88-dependent and -independent pathways[17]. Ligand binding to TLRs initiates signaling cascades that activate NF-κB, MAPK, and interferon response factors. In this review, we will address the role of the TLR family in the pathogenesis of IBD.

TLR4

The Toll-like receptor 4 (TLR4) gene is located on the long arm of human chromosome 9. Its ligand is lipopolysaccharide (LPS), and signal initiation requires the presence of CD14. In mouse models, TLR4 is involved in regeneration of IECs. TLR4 KO and MyD88 KO mice show impaired mucosal healing, and disturbed barrier function in response to administration of the colitis inducing dextran sulfate sodium (DSS) which leads to an increase in intestinal bleeding, colonic damage, bacterial translocation and to increased mortality. A similar aggravating effect of DSS was observed when natural ligands of TLR4 were eliminated either by broad spectrum antibiotic treatment or by raising the mice in a germ-free environment[18]. TLR4 signaling was shown to play a role in the initiation of intestinal inflammation. Treatment with CRX-526, a TLR4 antagonist, inhibited the development of moderate-to-severe colitis in MDR 1a-deficient mice, and TLR signal abrogation by MyD88 KO prevented development of spontaneous colitis in IL-10 KO mice[19]. Human IECs normally express TLR3 and TLR5, whereas TLR2 and TLR4 are only minimally expressed[20]. However, TLR4 expression is upregulated in both CD and UC. In pediatric IBD patients, higher levels of TLR4 mRNA and protein were found in the inflamed colonic mucosa, but not in non-inflamed controls[21].

Epidemiological studies show an association between TLR4 polymorphism and susceptibility to IBD. In a German cohort, the CD14 promoter 1-260C>T single-nucleotide polymorphism (SNP) was associated with UC, but not CD, while the opposite was found in a Hungarian cohort. No association with IBD of the TLR4 896A>G SNP was found in either cohort[14]. In a Belgian study, the allele frequency of the TLR4 A299G polymorphism, affecting the extracellular domain of TLR4 that is associated with an abrogated response, was significantly higher in CD (11% *vs* 5%, $P = 0.004$ in one cohort and 12% *vs* 5%, $P = 0.007$ in another cohort) and in UC patients (10% *vs* 5%, $P = 0.027$) compared with controls[22]. The same SNP was exclusively related to CD in another study[23] and a third study found no association of this SNP with IBD[24]. Another TLR4 polymorphism, T399IL, was exclusively associated with UC, and not with CD[25].

TLR5

TLR5 is highly expressed in colonic epithelial cells (CECs). The bacterial ligand of TLR5 is flagellin, which is present on most motile bacteria. Expression of TLR5 appears to be basolateral in healthy individuals, and CECs in the intact colon do not respond to flagellin. It is suggested that the response of CECs to flagellin is specifically elicited under inflammatory conditions with epithelial barrier disruption[26,27]. Consistent with these findings, rectal administration of flagellin to control mice did not elicit an inflammatory response, but was able to aggravate DSS-induced colitis[26]. Interestingly, flagellin derived from *Salmonella* species, but not commensal bacteria was able to stimulate proinflammatory chemokines secretion by IECs[28]. In CD patients, tolerance to commensal-derived flagellin is lost and serum reactivity to flagellin can be demonstrated[29]. Additionally, CD patients carrying a susceptibility NOD2 mutation exhibit an enhanced flagellin reactivity which was independently associated with distinct CD phenotypes[30]. TLR5 KO mice develop spontaneous colitis, and a marked elevation in pro-inflammatory cytokine levels. This colitis is mediated *via* TLR4 signaling as TLR5 and TLR4 double KO fail to develop spontaneous colitis[31].

Data connecting TLR5 polymorphism to IBD is limited. Recently a TLR5-stop polymorphism in which a point mutation at nucleotide 1174 generates a stop codon rendering TLR5 inactive was described[32]. It is a relatively common polymorphism with a 5% allele frequency. Healthy subjects carrying the TLR5-stop SNP have significantly lower levels of flagellin-specific IgG and IgA, but similar levels of total and LPS-specific immunoglobulins. Moreover, it was observed that the carriage rate of the TLR5-stop SNP was significantly lower in CD patients as compared with unaffected relatives and unrelated controls[33].

TLR9

Unmethylated cytosine-guanosine dinucleotides (CpG), which are frequently recognized in the DNA of bacteria and viruses, are the ligands for TLR9[34,35]. The role of TLR9 signaling in pathogenesis of IBD is under intense investigation.

It was reported that intragastric and subcutaneous administration of CpG oligodeoxynucleotides (CpG-ODNs) reduced the severity of DSS and TNBS-induced acute colitis and of chronic colitis in IL-10 KO mice[36]. It was further shown that the beneficial therapeutic effect of probiotic bacteria in murine colitis models was mediated *via* the effect of CpG on intact TLR9 signaling[37]. Later, it was suggested that type I interferons may act as immunomodulatory effectors of the TLR9 pathway[38]. Further support for the immunosuppressive role of CpG-ODNs came from studies in which CD4+CD62L+ T lymphocytes from CpG-ODN pretreated donor mice were unable to induce colitis in recipient SCID mice in a transfer model, and were able to suppress CD4+ T cell-mediated colitis when co-transferred. Furthermore, CD4+CD62L+ cells from TLR9 deficient mice induced a significantly more severe colitis in SCID recipients than cells from controls[39]. These data would suggest that TLR9 signaling suppresses intestinal inflammation.

In contrast, a pro-inflammatory effect of TLR9 signaling in colitis models has also been demonstrated.

Intraperitoneal administration of CpG-ODN increased the severity of DSS-induced acute and chronic colitis[40]. Induction of DSS colitis in TLR9-deficient mice resulted in markedly reduced intestinal inflammation and proinflammatory cytokine production. Additionally, treatment with adenoviral ODN, known to block CpG effects, resulted in a significant amelioration of colitis[41].

Recently, a novel mode of TLR9 pathway regulation was described which could, at least in part, explain some of the above mentioned discrepancies. Basolateral TLR9 signaling was shown to activate the NF-κB pathway in CECs, whereas apical TLR9 signaling inhibited its activation by inducing accumulation of ubiquitinated I κB in the cytoplasm. Moreover, apical stimulation of TLR9 prevented activation of NF-κB signaling by other TLRs[8]. These data suggest that different routes of CpG-ODN delivery (intraluminal *versus* systemic) may result in anti- or pro-inflammatory effects, respectively. Additionally, this report provides a possible explanation of the divergent effects of CpGs on colitis depending on the time-point of application. Administration of CpG-ODNs when the epithelial barrier is intact results in a protective effect, while the same administration, when the epithelium, is disrupted leads to aggravation of inflammation[42].

The effect of CpG-ODN stimulation in IBD was assessed using *ex vivo* colonic mucosal biopsies from active UC patients and healthy controls. CpG-ODNs significantly inhibited colonic TNF-α and IL-1β generation in a TLR9-dependent manner in UC, and not in controls[43].

In epidemiological studies, the frequency of the -T1237C SNP of the TLR9 promoter region was significantly increased in patients with Crohn's disease as compared with controls[44].

TLR 1, 2, 6

TLR2 is required for recognition of Gram positive and mycobacterial PAMPs including bacterial lipopeptide, lipotechoic acid (LTA) and peptidoglycan (PGN). Following ligand association, TLR2 and TLR6 ± TLR1 form hetero-dimers that may control signal specificity and enhance signal transduction[45, 46].

TLR2 KO mice display increased susceptibility to DSS-induced colitis. In mice, TLR2 stimulation effectively augments tight junction barrier assembly against stress-induced damage through the activation of PI3K/Akt pathway. Oral treatment of mice with the TLR2 ligand Pam3CSK prior to DSS colitis induction significantly suppressed mucosal inflammation and apoptosis and restored epithelial integrity[47]. In contrast to its anti-inflammatory effect, another report suggested that Pam3CSK administration may actually augment colitis. Suppression of colitis by regulatory T lymphocytes in the CD45RB^{high} T cell transfer model was significantly delayed when the cells were pretreated with Pam3CSK[48].

Baseline expression level of TLR2 on enterocytes was reported to be low, but its levels increased with inflammation. Immunohistochemical analysis showed either a significant increase or no change in TLR2 expression in the terminal ileum of patients with inactive and active IBD compared to controls[20,49]. Another study showed that monocytes isolated from patients with active IBD had higher expression levels of TLR2 on their cell surfaces, and a significantly increased TNF-α production in response to TLR2 agonist stimulation as compared to inactive patients and healthy controls[50]. It was recently suggested that NOD2, which is mutated in 15% of CD patients, and was the first CD susceptibility gene to be discovered, is involved in TLR2 signal regulation. Specifically, it was shown that muramyl-dipeptide (MDP), which is the ligand for NOD2 activation, negatively regulates TLR2 signaling. NOD2 deficient mice adoptively transferred with OVA-specific CD4+ T cells, and stimulated with OVA expressing *E. coli* (ECOVA) developed colitis, whereas wild type controls did not. Importantly, this colitis was TLR2 dependent, since inflammation was suppressed in NOD2-TLR2 double deficient mice[51]. It was later reported that administration of MDP protects mice from the development of experimental colitis by downregulating multiple TLR responses, not just TLR2[52].

Epidemiological data assessing the role of TLR2 in the pathogenesis of IBD are scarce. None of the nonsynonymous SNPs of TLR1, 2 or 6 were involved with IBD susceptibility. However, a number of variants were found to be associated with disease phenotypes. The TLR2 R753G and TLR1 R80T SNPs were found to be associated with pancolitis in UC. The relative risks for heterozygous patients to develop pancolitis were 5.8 and 3.3 for R80T and R753G, respectively[53]. There was a negative association between TLR6 S249P SNP and proctitis in UC patients. In CD there was a negative association between ileal disease involvement and TLR1 S602I SNP.

TLR3

This less studied TLR in the pathogenesis of IBD, signals upon activation by double stranded RNA through a Myd88-independent pathway *via* the adaptor TRIF. Double stranded RNA is produced during viral replication as an intermediate of the replication cycle or as part of the viral RNA genome, and is also produced during apoptosis.

In wild type mice, subcutaneous administration of poly (I:C), a synthetic TLR3 agonist, protected against DSS-induced colitis. In contrast, intragastric administration of poly (I:C) offered no protection in this colitis model nor did its administration activate the innate immune system as assessed by serologic parameters[54].

Activation of TLR3 signaling induced by poly(I:C) was shown to cause an increase in IL-15 secretion leading to mucosal damage in the small intestine. IL-15 is a key regulatory cytokine involved in mucosal homeostasis. IL-15 secretion increased the percentage and number of CD3+NK1.1+ intestinal intraepithelial lymphocytes (IELs) and caused their enhanced cytotoxicity[55]. TLR3 signaling was also shown to induce IEC expression of

Rae1 (a ligand for NKG2D), which mediates epithelial destruction and mucosal injury by interacting with NKG2D expressed on intestinal intraepithelial lymphocytes [56].

In humans, TLR3 expression by IECs of UC patients is comparable to that of healthy controls, while TLR3 expression was significantly downregulated in CD patients, both in inflamed and non-inflamed tissue[20].

CONCLUSION

Inflammatory bowel disease is a chronic relapsing disease of the gastrointestinal tract. Although the etiology is unknown, both innate immunity and the commensal bacterial flora are hypothesized to play a major role in its pathogenesis. The gastrointestinal innate immune system has to recognize, sort and respond to a vast array of microbial products present in the intestinal lumen. TLRs have evolved as the major innate immune surveillance, recognition and response receptors central to efficient host defense and homeostasis of the intestinal mucosa.

The factors directing TLR-regulated immune response in IBD remain poorly understood. TLRs may either enhance or suppress intestinal inflammation. Membrane localization (either basolateral or apical), expression pattern (IECs *versus* regulatory T lymphocytes), parallel signaling by additional TLRs, cytokine combinations and interactions with specific intestinal flora all determine the type and balance of the immune response.

In mouse models, knockout of a single TLR usually does not result in spontaneous colitis. Only after additional genetic and pharmacological interventions does a clear gastrointestinal phenotype emerge. These data suggest that mutations in a single TLR are insufficient to explain the complex pathogenesis of IBD. However, they do suggest that TLRs are crucial for initiation and progression of IBD and play a major role in its pathogenesis.

Abstract

Inflammatory bowel disease (IBD), ulcerative colitis (UC) and Crohn's disease (CD) are characterized by ongoing mucosal inflammation in which dysfunction of the host immunologic response against dietary factors and commensal bacteria is involved. The chronic inflammatory process leads to disruption of the epithelial barrier, and the formation of epithelial ulceration. This permits easy access for the luminal microbiota and dietary antigens to cells resident in the lamina propria, and stimulates further pathological immune cell responses. Cytokines are essential mediators of the interactions between activated immune cells and non-immune cells, including epithelial and mesenchymal cells. The clinical efficacy of targeting TNF-α clearly indicates that cytokines are the therapeutic targets in IBD patients. In this manuscript, we focus on the biological activities of recently-reported cytokines [Interleukin (IL)-17 cytokine family, IL-31 and IL-32], which might play a role through interaction with TNF-α in the pathophysiology of IBD.

INTRODUCTION

Inflammatory bowel diseases (IBD), ulcerative colitis (UC) and Crohn's disease (CD) are chronic intestinal disorders of unknown etiology[1,2]. The most widely accepted hypothesis on the pathogenesis of IBD is that the mucosal immune system shows an aberrant response towards luminal antigens such as dietary factors and/or commensal bacteria in genetically susceptible individuals[1,3,4]. Environmental factors may also precipitate the onset or reactivation of this disease[1,3,4]. The chronic inflammatory process leads to disruption of the epithelial barrier, and the formation of epithelial ulceration. Abnormal bacterial killing based on genetic factors such as the *NOD2* gene mutation also induces mucosal damage. The easy access for the luminal microbiota and dietary antigens into cells resident in the lamina propria thus stimulates pathological immune cell responses.

Cytokines are essential mediators of the interactions between activated immune cells and non-immune cells, including epithelial and mesenchymal cells[5]. The clinical efficacy of targeting TNF-α clearly indicates that cytokines are one of the therapeutic targets of chronic inflammatory disorders such as IBD. Infliximab, a mouse/human chimeric mAb that binds to TNF-α, has shown efficacy in the treatment of moderate-to severe CD and a number of CD-related complications[6-8]. Although the precise mechanism of the action of infliximab is not clear, it neutralizes soluble TNF-α, alters cell signaling, and induces the apoptosis of activated inflammatory cells expressing surface TNF-α *via* multiple pathways. On the other hand, some patients are resistant to anti-TNF-α therapy. In such patients, the disease might be driven by molecular mechanisms dependent on other cytokines distinct from TNF-α. In this manuscript, we focused on recently-reported cytokines [Interleukin (IL)-17 cytokine family, IL-31 and IL-32] which might play a role through interactions with TNF-α in the pathophysiology of IBD.

IL-17 CYTOKINE FAMILY

IL-17 family and Th17 cells

The interleukin (IL)-17 cytokine family is a group of T cell derived cytokines. IL-17A was originally cloned by Rouvier *et al*[9] and named CTLA8. It was subsequently renamed IL-17, and was more recently termed IL-17A. IL-17A stimulates various cell types to secrete various cytokines and chemokines, resulting in the induction of inflammation[10-15]. The IL-17 family may play a role in a number of diseases mediated by abnormal immune responses, such as rheumatoid arthritis[16,17], pulmonary disease[15,18], lupus[19], multiple sclerosis[20], and IBD[21]. Homology-based cloning recently revealed five additional members of the IL-17 family, termed IL-17B to IL-17F[10]. Among the IL-17 family members, IL-17F has the highest degree of homology with IL-17A (40% to 55%), followed by IL-17B (29%), IL-17D (25%), IL-17C (23%), and IL-17E (also named IL-25) is the most distantly related (17%)[10]. The major cellular source of IL-17A was initially described as activated CD4+ memory T lymphocytes. But, it was subsequently demonstrated that CD8+ memory T lymphocytes, eosinophils, neutrophils and monocytes can also produce IL-17A[10,22]. The cellular sources of IL-17B and IL-17C have not been identified. IL-17D is derived from resting CD4+ T cells and CD19+ B cells[15]. But, IL-17E (IL-25) expression is restricted to Th2 cells and mast cells[15]. The cellular source of the last member, IL-17F, has been reported to be activated CD4+ T cells, basophils and mast cells[15].

One recent topic in immunology is the newly identified Th17 lineage of CD4+ T cells[23]. Th17 cells are characterized by the production of a distinct profile of effector cytokines, including IL-17A, IL-17F, IL-6, IL-22 and IL-26, and have probably evolved to enhance immune and host defense responses distinct from those targeted by Th1 and Th2 cells[24-26]. Th17 cells develop from naïve CD4 T cell precursors in the presence of IL-6 and TGF-β, and full differentiation to Th17 cells is dependent on IL-23[23]. Recent studies demonstrated a role for IL-21 in Th17 development[24,27]. IL-21 serves as an autocrine factor secreted by Th17 cells that promotes or sustains the Th17 lineage commitment. On the other hand, Th1 cells develop from naïve CD4 T cell precursors in the presence of IFN-γ, whereas Th2 cells develop under the control of IL-4. Both IFN-γ and IL-4 inhibit Th17 cell proliferation[28]. A recent study showed that the proliferation of Th17 cells is also inhibited by IL-27, an IL-12-related cytokine frequently present at sites of inflammation[29]. Th17 cells are characterized as a source of IL-17A and IL-17F, and much attention has been focused on their functions in normal and pathological immune responses.

We previously demonstrated that IL-17A-positive cells were increased in the inflamed mucosa of IBD patients[21], and a recent study showed that IL-17F mRNA expression in the mucosa was elevated in CD patients[30]. These observations suggest that IL-17F as well as IL-17A might play a role in the inflammatory responses involved in the pathophysiology of IBD.

Table 1 IL-17A-induced genes in human colonic myofibroblasts

Gene name	Ref seq ID.	Fold increase

CCL7 (MCP-3)	NM_006273.2	× 2.77
CCL2 (MCP-1)	NM_002982.2	× 2.24

Human colonic subepithelial myofibroblasts were stimulated with IL-17A (200 ng/mL) for 12 h, and the changes in gene expression were assessed by IntelliGene HS Human Expression Chip (Takara-Bio, Kyoto, Japan). The fold change values were determined as a ratio of Cy5 signal intensity (IL-17A stimulated values)/Cy3 signal intensity (non-stimulated values). The data were average of three independent analysis. The NCBI reference sequence code was presented following the gene name.

Inflammatory responses induced by IL-17A and IL-17F

IL-17A promotes the expansion and recruitment of innate immune cells such as neutrophils, and also cooperates with TLR ligands, IL-1β, and TNF-α to enhance inflammatory reactions, and to stimulate the production of beta-defensins and other antimicrobial peptides[25,27]. Its receptor, IL-17RA, is ubiquitously expressed and shares many features with classical innate immune receptors such as shared intracellular tail motifs and convergence onto common inflammatory transcription pathways[31]. To investigate the genes altered in response to an IL-17A stimulus, we performed a cDNA microarray analysis in human colonic subepithelial myofibroblasts (SEMFs)[32]. Human colonic SEMFs are located immediately subjacent to the basement membrane in the normal intestinal mucosa, juxtaposed against the bottom of the epithelial cells[33,34], and play a role in inflammation and wound healing in the intestine[33-36]. As shown in Table 1, IL-17A up-regulated several genes which have been reported to exert pro-inflammatory actions in the pathophysiology of acute and/or chronic inflammation. In particular, the induction of CXC-chemokines mRNA expression suggests that IL-17A is a potent inducer of innate immune responses *via* the accumulation and activation of neutrophils in the mucosa.

Recently, we found that among the IL-17 family members, IL-17F also strongly induced the secretion of inflammatory cytokines (IL-6, IL-8 and LIF) and matrix metalloproteinases (MMP-1 and MMP-3) in human colonic SEMFs[32]. Like IL-17A[37], IL-17F stimulated IL-6, IL-8 and MCP-1 secretion *via* NF-κB and MAP kinase activation in human colonic SEMFs. The IL-6,

Table 2 IL-17A augmented TNF-α-induced genes in human colonic myofibroblasts

Human colonic subepithelial myofibroblasts were stimulated with TNF-α (50 ng/mL) or TNF-α (50 ng/mL) plus IL-17A (200 ng/mL) for 12 h, and the changes in gene expression were assessed by IntelliGene HS Human Expression Chip. The fold change values were determined as a ratio of Cy5 signal intensity (TNF-α plus IL-17A stimulated values)/Cy3 signal intensity (TNF-α stimulated values). The data were average of three independent analysis. The NCBI reference sequence code was presented following the gene name.

IL-8 and LIF secretion by human SEMFs in response to IL-17F as well as IL-17A emphasizes the importance of Th17 products in the induction of intestinal inflammation. Furthermore, the induction of IL-6 secretion from colonic SEMFs has a particular significance in the regulation of immune responses, and in the pathophysiology of IBD; IL-6 has recently been identified as an indispensable factor for the development of Th17 cells[23]. IL-6 commits naïve CD4 T cell precursors to differentiate into Th17 cells[23]. IL-17A and IL-17F might function as potent stimulators for IL-6 production, suggesting an amplification loop for the local development and maturation of Th17 cells. Therefore, the IL-17-colonic SEMFs-IL-6 axis may be important for local Th17 development in the intestinal mucosa.

IL-17A/IL-17F augments TNF-α-induced inflammatory responses

As more important observations, IL-17A and IL-17F augment the TNF-α-induced IL-6 secretion in human colonic SEMFs[32,37]. This augmentation of TNF-α-induced IL-6 production by IL-17A is mediated by enhanced stability of the IL-6 mRNA[37,38]. A similar molecular mechanism can be postulated for the augmentation by IL-17F. IL-17A/IL-17F also augments the TNF-α-induced expression of granulocyte-colony stimulating factor (G-CSF) and granulocyte/macrophage (GM)-CSF in human colonic SEMFs[39].

To further investigate the effects of IL-17A/IL-17F on TNF-α-induced genes, the alterations in gene expression were analyzed by cDNA microarrays in human colonic myofibroblasts. As shown in Table 2, IL-17A further enhanced the expression of various TNF-α-induced genes, such as IL-6, CXC-chemokines and CSFs. These observations suggest that the interactions between TNF-α and IL-17A/IL-17F potently mobilized neutrophils, partially through granulopoiesis and CXC chemokine induction, as well as through increased survival locally. This interaction also potently stimulated Th17 development through the stimulation of IL-6 secretion. Thus, a modulation of the immunological functions of colonic SEMFs by Th17-derived cytokines may be critical for the development of Th17 cells and the mucosal innate immune responses (Figure 1).

Interactions between IL-17A and IL-22

IL-22 was originally described as an IL-9-induced gene, and was termed "IL-10-related T cell-derived-inducible factor" (IL-TIF)[40,41]. IL-22 has 22% amino acid identity with IL-10, and belongs to a family of cytokines with limited homology to IL-10, namely IL-19, IL-20, IL-22, IL-24 and IL-26. The major sources of IL-22 are activated T cells, and IL-22 expression in other leukocyte populations such as monocytes, dendritic cells, NK cells and neutrophils is negligible. Recent studies have shown that Th17 cells are a source of IL-22[42,43]. We recently found that IL-22 expressing cells were increased in the inflamed mucosa of IBD patients[44]. In SEMFs, IL-22 upregulates the expression of inflammatory genes such as IL-6, IL-8, IL-11 and LIF *via* NF-κB, AP-1 and MAP-kinase dependent pathways[44]. Furthermore, the combination of IL-17A plus IL-22 showed an additive effect on transcription factor activation. These concerted responses were also observed as additive effects on cytokine mRNA expression and protein secretion. Thus, the cooperation between Th17 derived cytokines such as IL-17A and IL-22 may play an important role in the pathophysiology of IBD.

IL-31

IL-31 has a Th2 cell origin

IL-31 was cloned, and then found to be mainly produced by CD4+ T cells[45], in particular by skin-homing CD45RO+ (memory) T cells. Transgenic mice overexpressing IL-31 either with a lymphocyte-specific promoter or a ubiquitous promoter exhibit a skin phenotype closely resembling atopic dermatitis in human subjects[45]. In these mice, IL-31 seems to be preferentially produced by T cells skewed towards a Th2 phenotype; however, these Th1-skewed T cells also produce substantial amounts of IL-31[45]. IL-31 mRNA expression is widely detected in various organs, including the gastrointestinal tract[45].

IL-31 is most closely related to the family of IL-6-type cytokines known to be involved in many immunomodulatory functions, particularly the acute-phase response, but also in the proliferation of B and T cells[46]. A recent study indicated that IL-31 sustains the survival of hematopoietic stem cells, and contributes to effects on the cycling and numbers of hematopoietic stem cells

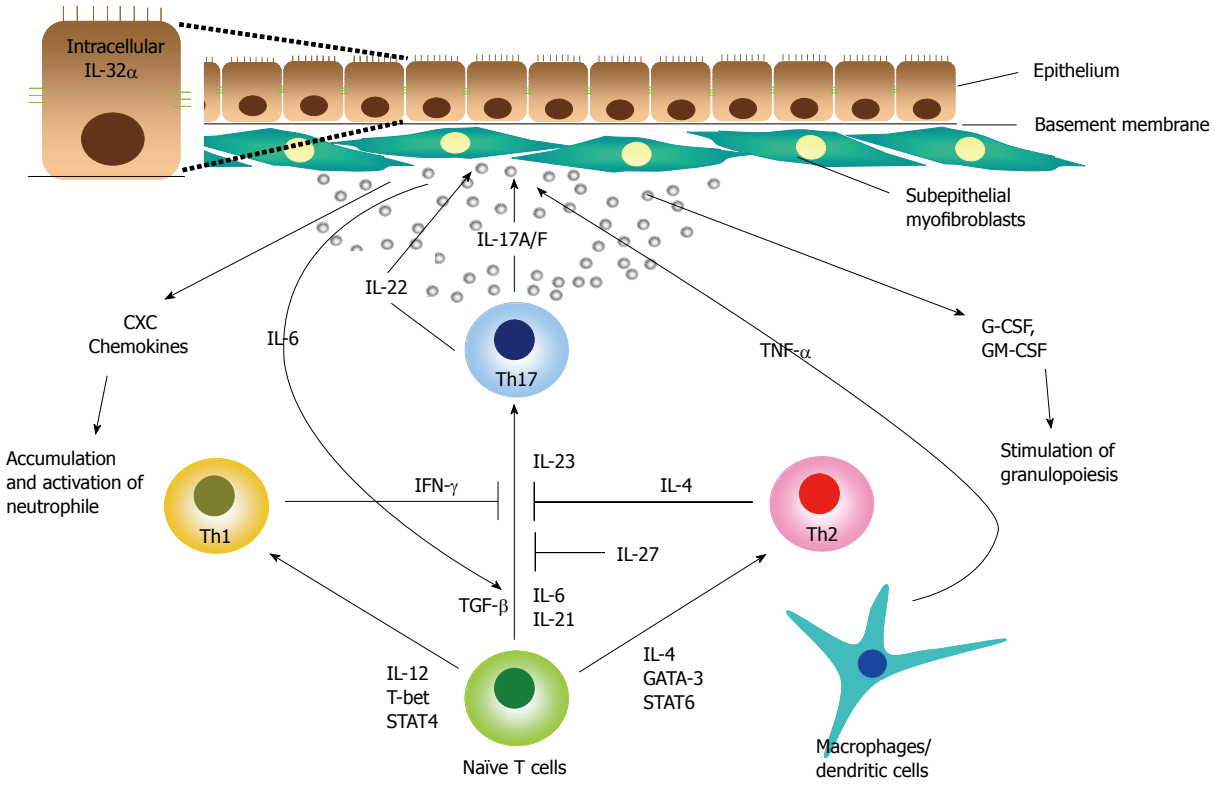

Figure 1 Mucosal cytokine network mediated by IL-17A/F and TNF-α. TGF-β induces the differentiation of Th17cells from naive CD4+ T cells in the presence of IL-6, and full differentiation to Th17 cells is dependent on IL-23. The transcriptional factors required for the development of Th1 (STAT4 and T-bet) and Th2 (STAT6) cells are not required for the induction of Th17/ThIL-17 cells. IFN-γ also suppresses the differentiation of Th17 cells. IL-4 inhibits the development of Th17 cells. One of the important roles of IL-17A/F is the augmentation of the TNF-α-induced secretion of IL-6, a crucial factor for Th17 cell development.

in vivo[47]. However, IL-31 is clearly distinct from the IL-6-type cytokines because it does not signal through glycoprotein-130 (GP-130), the common signaling receptor subunit. IL-31 uses an earlier described orphan receptor, the glycoprotein 130-like monocyte receptor or glycoprotein 130-like receptor (GPL)[48], in combination with the oncostatin M receptor (OSMR)[45], which is expressed on epithelial cells and keratinocytes[45,49].

IL-31 binds directly to the GPL, and OSMR mainly plays a role in delivering the signaling information into the cells. GPL and OSMR are widely expressed in various tissues, including the gastrointestinal tract. This suggests a role for IL-31 in the immune and inflammatory responses of the intestine. In response to IL-31, its receptor complex recruits the Jak1, Jak2, STAT-1, STAT-3 and STAT5 signaling pathways, as well as the PI3-kinase/AKT cascade[49]. SHP-2 and Shc adaptor molecules are also recruited, and contribute to an increased activation of the MAP kinase pathway in response to IL-31[49]. Despite the extensive study of intracellular signaling pathways activated by IL-31 stimulation, the cellular responses to IL-31 were barely investigated in any cell type.

IL-31 stimulates inflammatory responses in colon myofibroblasts

To define the role of IL-31 in the intestinal mucosa, we investigated how IL-31 modulates mRNA expression in human colonic SEMFs. An analysis of the cDNA microarrays indicated that IL-31 effectively induced the secretion of chemokines [CXCL8 (IL-8), CXCL1 (growth-related oncogene; GRO-α)], CCL7 (monocyte chemoattractant protein-3; MCP-3), CXCL3, CCL13, CCL15), proinflammatory cytokines (IL-6, IL-16 and IL-32), and matrix metalloproteinases (MMP-1, MMP-3, MMP-25 and MMP-7). The stimulatory effects of IL-31 were comparable to the effects of IL-17A. Furthermore, simultaneous stimulation with IL-31 and IL-17A showed additive effects on IL-6, IL-8, GRO-α, MCP-3, MMP-1 and MMP-3 secretion. Similar effects for IL-31 have been reported in bronchial epithelial cells[50]. In bronchial epithelial cells, IL-31 could significantly elevate both gene and protein expressions of epidermal growth factor (EGF), vascular endothelial growth factor (VEGF) and monocyte chemoattractant protein-1 (MCP-1/CCL2). The combination of IL-31 with either IL-4 or IL-13 further enhanced VEGF and CCL2 production. In these cells, IL-31 could activate p38 MAPK, extracellular signal-regulated kinase (ERK) and c-Jun N-terminal kinase (JNK).

As mentioned above, IL-31 is a Th2 type cytokine, and these findings indicate that Th2 cells may be involved in the immune and inflammatory responses of the intestinal mucosa through IL-31secretion. Since IL-31 and IL-17A stimulate the secretion of proinflammatory mediators in an additive manner, Th2-derived IL-31 and Th17-derived IL-17A cooperate in the pathophysiology of IBD.

IL-32

IL-32 cytokine family

IL-32 is a recently described cytokine produced by T lymphocytes, natural killer cells, monocytes, and epithelial cells[51,52]. IL-32 is a proinflammatory cytokine originally described as a transcript termed NK4, found in activated natural killer (NK) cells and T lymphocytes[53]. Although IL-32 was first reported as a transcript in IL-2 activated NK and T cells, it appears that the epithelial cells are the dominant and widespread source[54]. The gene encoding IL-32 is located on human chromosome 16p13.3, and is organized into eight exons[55]. There are four splice variants (IL-32α, IL-32β, IL-32δ and IL-32γ), and IL-32α is the most abundant transcript. Of particular importance, IL-32 is prominently induced by interferon (IFN)-γ in lung epithelial cells and monocytes[51]. IL-32 stimulates the secretion of proinflammatory cytokines and chemokines such as IL-1β, TNF-α, IL-6 and IL-8 by *via* the activation of NF-κB and p38 mitogen-activated protein kinases (MAPKs)[51,52]. IL-32 has been implicated in inflammatory disorders such as rheumatoid arthritis[54,56-58], mycobacterium tuberculosis infection[59,60], and IBD[61].

Intracellular accumulation of IL-32

The amino acid sequence derived from the initial NK4 cDNA contained a signal peptide without a transmembrane domain[53,54]. But, the transcript was never expressed as a recombinant protein, and was not sequenced. Activated human T cells generate IL-32 with a molecular weight of 25 kDa, which on Western blotting analysis is found in the lysates rather than the supernatants. Similar findings were reported for 293T cells transfected with either IL-32γ or IL-32β[62]. In human peripheral blood mononuclear cells stimulated with ConA, most of the IL-32 was found in the lysates[51]. On the other hand, the overexpression of IL-32α or IL-32β in COS cells resulted in secreted IL-32[51]. It remains unclear which isoforms are secreted from which particular cell type. Activated T cells and NK cells do not secrete IL-32, or alternatively, the secreted IL-32 is derived from apoptotic cells due to the presence of GAPDH in the same supernatants. These observations suggest that IL-32 is secreted only as a result of cell death[63]. Recently, we observed that in colon cancer cell lines, proinflammatory cytokines induce the intracellular accumulation of IL-32α, but does not induce secretion[61]. Similar results were also observed in myofibroblasts isolated from the normal human pancreas[64]. Goda *et al* suggest that there is a role for intracellular IL-32 with cell death, since attenuating intracellular IL-32 levels resulted in decreased cell death[62]. These results also support the concept that high levels of intracellular IL-32β may induce cell death. One hypothesis is that the proinflammatory activity of IL-32 may act upon its release through cell death (apoptosis).

Molecular mechanisms regulating IL-32α induction

Shioya *et al* demonstrated that stimulation with IL-1β, IFN-γ and TNF-α enhanced IL-32α mRNA expression in three colon cancer cell lines[61]. TNF-α was the strongest among them. These factors also induced the intracellular accumulation of IL-32α. Since transfection with the mutant form of IκBα inhibited the effects of both IL-1β and TNF-α on IL-32α mRNA expression, NF-κB must play a role in IL-1β- and TNF-α-induced IL-32α mRNA expression.

Nishida *et al* analyzed IL-32α expression in non-transformed myofibroblasts derived from the normal human pancreas[64]. IL-32α mRNA was weakly expressed without any stimulus, and its expression was markedly enhanced by IL-1β, IFN-γ and TNF-α. IL-1β, IFN-γ and TNF-α enhanced the intracellular accumulation of IL-32α protein. But, IL-32α was not detected in the supernatants. An inhibitor of phosphatidylinositol 3-kinase, (LY294002) significantly suppressed the IL-1β-, IFN-γ- and TNF-α-induced IL-32α mRNA expression, although MAPK inhibitors had no effect. Akt activation in response to these cytokines was confirmed by Western blotting analysis. Furthermore, LY294002 suppressed both IL-1β- and TNF-α-induced NF-κB activation, as well as IL-1β-, TNF-α- and IFN-γ-induced AP-1 activation. A blockade of NF-κB and AP-1 activation by an adenovirus expressing a stable mutant form of IκBα and a dominant negative mutant of c-Jun markedly suppressed the IL-1β-, IFN-γ- and/or TNF-α-induced IL-32α mRNA expression. Thus, they concluded that IL-32α mRNA expression was dependent on interactions between the PI3K/Akt-pathway and the NF-κB/AP-1 system.

IL-32α and IBD

Shioya *et al* performed an immunohistochemical analysis to evaluate the expression of IL-32α protein in the mucosa of IBD patients[61]. IL-32α was weakly immunoexpressed by epithelial cells in the normal colonic mucosa and samples of ischemic colitis. In contrast, the epithelial expression of IL-32α was markedly enhanced in the inflamed region of active UC and CD patients[61]. In particular, IL-32α expression tends to increase in samples from active CD patients. IL-32α expression was barely detectable in leukocytes. Thus, these observations indicate that epithelial cells are the major expression site for IL-32α in the intestinal mucosa, and that IL-32α expression is enhanced in the IBD mucosa.

Netea *et al* recently demonstrated that IL-32 augments the production of IL-1β and IL-6 induced by muramyl dipeptide (MDP), a peptidoglycan fraction of bacteria, by means of nucleotide-binding oligomerization domain proteins (NOD1 and NOD2) through a caspase-1-dependent mechanism[52]. NODs are a family of intracytoplasmic bacterial sensors, and the recognition of bacterial peptidoglycans subsequently induces NF-κB activation[65]. Mutations in *NOD2* have been implicated in the pathogenesis of CD[66,67], and CD patients homozygous for the frameshift 3020insC mutated allele have defective responses to MDP in terms of cytokine production[68,69]. Recently, it has been shown that *NOD2* mutations in CD patients potentiate NF-κB activity

and IL-1β processing[70]. Thus, these findings suggest a pivotal role for IL-32 in the pathophysiology of IBD, and in particular CD. Since IL-32α is a proinflammatory cytokine characterized by NF-κB and p38 MAPK activating activities[51,57] and because IL-32 acts synergistically with NOD ligands to induce proinflammatory cytokines[52], the overexpression of IL-32α in the IBD mucosa strongly suggests that it plays an important role in the inflammatory and antibacterial responses involved in the pathogenesis of IBD.

Recent studies have focused on the role of innate immunity in the pathogenesis of IBD[4]. The initial step of innate immunity is mediated by the recognition of pathogen-associated molecular patters (PAMPs) through Toll-like receptors (TLRs) and NOD proteins (NODs)[71]. TLRs are located mainly on cell-surface membranes, but NODs function as intracellular recognition systems[65,66]. In human monocytes, IL-32 acts synergistically with NOD specific peptidoglycans for the release of IL-1β and IL-6[52]. The synergistic effects of IL-32 and the NOD ligands on cytokine production is abolished in cells from CD patients bearing the NOD2 frameshift mutation 3020insC, indicating that this synergism between IL-32 plus MDP depends on NOD2[52]. Interactions between NOD-1 and IL-32 also potentiate proinflammatory cytokine production[52]. Furthermore, Berrebi *et al* previously reported the overexpression of NOD2 in infiltrated monocytes and epithelial cells in the IBD mucosa[72]. These observations suggest that overexpressed IL-32 may cause a specific and excessive stimulation of the NOD pathways, which leads to a marked amplification in IL-1β and IL-6 production in the IBD mucosa.

IL-32 was initially characterized as an inducer of TNF-α in circulating monocytes[51], and hence inflammatory responses in the affected mucosa of IBD patients may be amplified by the consecutive loop of IL-32-induced TNF-α secretion from monocytes and TNF-α-stimulated IL-32 secretion from epithelial cells. This loop may be further amplified by the Th1 cytokine IFN-γ. Previously, it has been reported that TNF-α and IFN-γ synergistically induced the release of NOD2[73], which supports the coupled regulation of IL-32α and NOD2. The coupled regulation of IL-32α with NOD2 may account for the rapid and efficient induction of innate immune responses at the intestinal mucosa. Furthermore, these data suggest that an amelioration of IBD symptoms by TNF-α-targeting therapies may be partially dependent on interference in the TNF-α-IL-32 loop.

The apoptosis of IECs is considered a normal biological function to eliminate damaged epithelial cells, and to restore epithelial cell growth, regulation, and epithelial integrity[74]. An overexpression of cytoplasmic IL-32α might account for the induction of apoptosis in damaged epithelial cells at the inflamed mucosa of IBD patients, leading to an efficient elimination and the rapid induction of mucosal repair. Apoptosis caused by accumulated IL-32 can be considered a host defense mechanism against invading microorganisms, in which damaged epithelial cells are efficiently eliminated along with the invading microorganisms, and thus any further invasion of the microorganisms can be blocked.

CONCLUSION

In this review, we have summarized the newly reported cytokines which may play significant roles in the pathophysiology of IBD. An augmentation of TNF-α effects by IL-17A/F and a possible amplifying cascade between TNF-α and epithelial-derived IL-32 are of particular interest. The clinical efficacy of TNF-α blocking may be associated with an interruption of these cascades. The discovery of new cytokines and the determination of their biological activities may support the development of a novel therapeutic strategy for the treatment of IBD patients.

Abstract

AIM: To examine the ability of cyclin-dependent kinase inhibitor (CDKI) roscovitine (Rosco) to enhance the antitumor effects of conventional chemotherapeutic agents acting by different mechanisms against human colorectal cancer.

METHODS: Human colorectal cancer cells were treated, individually and in combination, with Rosco, taxol, 5-Fluorouracil (5-FU), doxorubicin or vinblastine. The antiproliferative effects and the type of interaction of Rosco with tested chemotherapeutic drugs were determined. Cell cycle alterations were investigated by fluorescence-activated cell sorter FACS analysis. Apoptosis was determined by DNA fragmentation assay.

RESULTS: Rosco inhibited the proliferation of tumor cells in a time- and dose-dependent manner. The efficacies of all tested chemotherapeutic drugs were markedly enhanced 3.0-8.42 × 10^3 and 130-5.28 × 10^3 fold in combination with 5 and 10 μg/mL Rosco, respectively. The combination of Rosco and chemotherapeutic drugs inhibited the growth of human colorectal cancer cells in an additive or synergistic fashion, and in a time and dose dependent manner. Rosco induced apoptosis and synergized with tested chemotherapeutic drugs to induce efficient apoptosis in human colorectal cancer cells. Sequential, inverted sequential and simultaneous treatment of cancer cells with combinations of chemotherapeutic drugs and Rosco arrested the growth of human colorectal cancer cells at various phases of the cell cycle as follows: Taxol/Rosco (G_2/M- and S-phases), 5-FU/Rosco (S-phase), Dox/Rosco (S-phase) and Vinb/Rosco (G_2/M- and S-phases).

CONCLUSION: Since the efficacy of many anticancer drugs depends on their ability to induce apoptotic cell death, modulation of this parameter by cell cycle inhibitors may provide a novel chemo-preventive and chemotherapeutic strategy for human colorectal cancer.

INTRODUCTION

Colon cancer is the second leading cause of cancer death in the United States and is one of the most common cancers in Western countries[1]. Lack of improvement in overall survival and failure of the current systemic therapies have mandated that new approaches to this disease be explored.

A hallmark of neoplastic evolution and progression is deregulation of cell cycle control mechanisms. The key regulators of transition from one cell cycle phase to the next are the cyclin-dependent kinases (CDKs).

CDKs are serine/threonine kinases that regulate cell cycle progression in a highly coordinated manner[2]. A CDK enzyme complex becomes fully active after binding of its proper cyclin. Progression through cell cycle is mediated by the orchestrated activation and breakdown of CDK complexes[2].

A basis for selectivity of CDK-directed therapies against neoplastic cells might arise from the fact that alteration of CDK structure and function plays a key role in the pathogenesis of neoplasia[3]. At least one of the following changes is almost ubiquitously evident in human neoplasms: overexpression of cyclin D; amplification or structural alteration of CDK4; deletion or mutation of $p16^{INK4A}$; mutation of the CDK4 or 6/cyclin D substrate p^{Rb}; and loss of $p21^{WAF1/CIP1A}$ function through deletion or mutation of its transactivator P53. In relation to colon cancer, $p27^{KIP1}$ loss has been found to occur not by gene deletion or mutation, but by increased proteolysis of the CDK inhibitor (CDKI)[4]. Therefore, replacement of at least some of the missing capacity to inhibit cell cycle progression may restore some measure of cell cycle control. In contrast to their normal counterparts, transformed cells proliferate very rapidly due to the enhanced activity of the CDK[2]. Thus, inhibition of CDK/cyclin complexes offers a promising therapeutic strategy in the defense against cancer[5].

Many types of potential CDK modulators are conceivable. These include molecules that directly inhibit ATP or protein substrate binding; alter regulatory phosphorylations of the catalytic subunit; inhibit CDK catalytic subunit binding with its respective cyclin or other accessory proteins; mimic the action or increase the expression of endogenous CDK inhibitors, $p16^{INK4A}$ (or its homologues, $p15^{INK4B}$, $p18^{INK4C}$, and $p19^{INK4D}$), $p21^{WAF1}$, and $p27^{KIP1}$; interfere with the proper appearance and disappearance of cyclins; and finally alter normal signals for import of CDKs into the nucleus or localization to appropriate subcellular structures[6].

Pharmacological inhibitors of CDKs display selective anti-proliferative effects on cycling cells, especially malignant ones[7]. Depending on the selectivity profile of these novel drugs, growth inhibition in different phases of the cell cycle is observed[8]. Compounds targeting the activity of CDK4/6 block cells in early G_1, whereas selective inhibitors of CDK1/2 arrest cell cycle in G_1/S and G_2/M[8]. Interestingly, some inhibitors, especially those targeting the activity of CDK2, are able to selectively induce apoptosis in cancer cells[9,10].

CDKIs, representing a well-defined group of biologically active compounds, are structurally related to adenosine-5-triphosphate, ATP[7,8,11]. They antagonize binding of kinases to ATP. Differentially substituted adenines yielded a group of inhibitors such as roscovitine (Rosco), olomoucine and purvalanol[7]. These close analogs, characterized by increasing potency, differ in selectivity. Due to their selectivity and relative low direct cytotoxicity, CDKIs clearly provide useful anticancer drugs and offer an alternative to classic chemotherapeutics. In the present study, we have investigated whether Rosco could inhibit the growth of human colorectal cancer cells and increase their sensitivity to conventional chemotherapies.

MATERIALS AND METHODS

Cell culture and reagents

Human colorectal cancer cell lines (SW48, SW1116 and SW 837) were obtained from the American Type Culture Collection (ATCC, Rockville, Md., USA). Cells were cultured in Leibovitz's L-15 medium supplemented with 10% inactivated fetal bovine serum and 2 mmol/L glutamine. The L-15 medium formulation was devised for use in a free gas exchange with atmospheric air. CO_2 is detrimental to cells when using this medium for cultivation. All the other chemicals were purchased from Sigma Chemical Co.

Time and dose dependency of the antiproliferative effects induced in human colorectal cancer cells by treatment with Rosco

Human colorectal cancer cell lines (SW48, SW1116 and SW837) were plated (27×10^3 cells/well) into 96-well plates and incubated at 37℃ in a non-CO_2 incubator. Cells were treated with various concentrations of Rosco (0-40 μg/mL) or DMSO (0.3% final concentration) for various time periods beginning at 24 h after seeding the cells in culture. Control cells were untreated. Cell proliferation was determined at various time intervals (24-168 h) by 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay as previously described[12].

In vitro efficacy of single and combined treatment of Rosco and chemotherapeutic drugs on the growth of human colorectal cancer cells

Human colorectal cancer cell lines (SW48, SW1116 and SW837) were treated with taxol (10^{-11}-10^{-6} mol/L), doxorubicin (10^{-11}-10^{-6} mol/L), 5-fluorouracil (5-FU) (10^{-9}-10^{-4} mol/L), vinblastine (10^{-12}-10^{-7} mol/L) or combinations of the tested chemotherapeutic drug and Rosco (5 and 10 μg/mL) for 96 h. At the end of treatment, control and drug treated cells were scored for proliferation using the MTT assay.

Analysis of the type of interaction between Rosco and chemotherapeutic drugs in human colorectal cancer cells

Human colorectal cancer cell lines (SW48, SW1116 and SW837) were treated with Rosco (1, 10, 15, 20, 25 μg/mL) and chemotherapeutic drugs (0.5 IC_{50}-4 IC_{50}) individually and in combination. The effect of the combinations of Rosco and chemotherapeutic drugs on cell growth was determined as previously described[12,13] using the following formulae: $SF_{A+B} > (SF_A) \times (SF_B)$, antagonistic; $SF_{A+B} = (SF_A) \times (SF_B)$; additive; $SF_{A+B} < (SF_A) \times (SF_B)$, synergistic, where SF is the surviving fraction, and A and B indicate the agents used alone, while A + B refers to the agents used in combination.

Cell cycle analysis

Cell cycle phase distribution of human colorectal cancer

Table 1 IC_{50} and sensitization ratio of taxol and its combinations with Rosco towards human colorectal cancer cell lines

Treatment with taxol and combinations with Rosco	IC_{50} (mol/L)			Sensitization ratio[1]		
	SW48	SW1116	SW837	SW48	SW1116	SW837
Taxol	4.8×10^{-8}	1.2×10^{-7}	3.8×10^{-7}	-	-	-
Taxol + 5 μg/mL Rosco	7.4×10^{-10}	1.0×10^{-8}	5.4×10^{-8}	65	12	7
Taxol + 10 μg/mL Rosco	7.5×10^{-11}	8.1×10^{-10}	6.7×10^{-10}	6.4×10^{2}	1.5×10^{2}	5.7×10^{2}

[1]Sensitization ratio = IC_{50} (taxol)/IC_{50} (taxol + Rosco).

cells treated with Rosco, chemotherapeutic drugs and their combinations was determined by flow cytometry as previously described[12]. Human colorectal cancer cells (SW837, 5×10^5 cells/well in 24 well plates) were treated with taxol (12×10^{-8} mol/L, 72 h), doxorubicin (8×10^{-7} mol/L, 72 h), 5-FU (4.8×10^{-5} mol/L, 72 h), vinblastine (2.6×10^{-7} mol/L, 72 h), Rosco (15 μg/mL) and combinations of Rosco and chemotherapeutic drugs. The combinations were added in a sequential manner, drug (24 h) followed by Rosco (48 h); inverted sequential manner, Rosco (24 h) followed by drug (48 h) and simultaneous manner (72 h). The tested cells were collected by trypsinization, and then washed with cold phosphate-buffered saline, and counted using a cell counter. A sample of 3×10^6 cells/mL was processed using DNA-Prep kit (Beckman & Coulter, Fa., USA) and a DNA-Prep Epics workstation (Beckman & Coulter). During this process, the cell sample was treated with a cell membrane-permeabilizing agent and then with propidium and RNase enzyme. The sample was then incubated at room temperature for at least 15 min before analysis by aligned flow cytometry (Epics XL, Beckman & Coulter). The percentage of cells in different cell cycle phases was evaluated using the Phoenix statistical software package, advanced DNA cell cycle software (Phoenix Flow System, San Diego, Calif., USA).

DNA fragmentation analysis

DNA fragmentation assay was performed as previously described[14]. Briefly, colorectal cancer cells (5×10^5 cells/well, SW1116 and SW837) were treated with taxol (1.2×10^{-7} mol/L), doxorubicin (8×10^{-7} mol/L), 5-FU (4.8×10^{-5} mol/L), vinblastine (2.6×10^{-7} mol/L), Rosco (15 μg/mL) and the combinations of Rosco, and tested drugs for 72 h. The cell pellets were lysed with 100 μmol/L of hypotonic buffer (10 mmol/L Tris (pH 8.0), 20 mmol/L EDTA containing 0.5 % Triton X-100) for 30 min at 4℃. Following cell lysis, the intact chromatin (pellet) was separated from DNA fragments (supernatant) by centrifugation for 15 min at 12000 *g*. The supernatants containing DNA were precipitated overnight with 0.5 mol/L NaCl and 50% isopropyl alcohol at -20℃. Pellets were recovered by centrifugation at 12000 *g* for 10 min, air dried, resuspended in 30 μL of TE buffer supplemented with 1 mg/mL RNase I at 37℃ for 30 min, and then with 2 mg/mL of proteinase K for another 1 h. DNA samples were supplemented with 3 μL of sample buffer (0.25% bromophenol blue, 30% glyceric acid), and electrophorectically separated on a 1.5% agrose gel containing 0.1 μg/mL ethidium bromide at 80 V for 2 h. DNA fragments were visualized by ultraviolet transillumination.

Statistical analysis

Results are representative of two to three individual experiments. Errors are expressed as standard errors of the percentage of the means. Where appropriate, data were analyzed using ANOVA.

RESULTS

Inhibition of the proliferation of human colorectal cancer cells by Rosco

In this study, we initially investigated the effect of Rosco on the proliferation of human colorectal cancer cells using three human colorectal cancer cell lines (SW48, SW1116 and SW837). The results, shown in Figure 1, indicated that all cell lines tested were sensitive to micromolar range of Rosco, in a dose and time dependent manner. Rosco inhibited the growth of SW48 after 24-144 h of drug treatment. It affected the growth of the colorectal cancer cell line SW1116 slightly after 48 h of treatment. However, a dramatic inhibition of cell growth was observed after 72-144 h of treatment. Rosco slightly affected the growth of SW837 after 24 h of treatment. However, a marked inhibition was observed after 48-144 h of treatment with Rosco.

Modulation of taxol cytotoxicity on human colorectal cancer cells by combination with CDKI Rosco

The ability of Rosco to enhance the sensitivity of human colorectal cancer cells to taxol was assessed by treating human colorectal cancer cell lines SW48, SW1116 and SW837 with taxol (10^{-11}-10^{-6} mol/L) or taxol (10^{-11}-10^{-6} mol/L) and Rosco (5 or 10 μg/mL) for 96 h. The results summarized in Figure 2A and Table 1 clearly indicated that the combination of taxol and 5 μg/mL Rosco enhanced (65-fold) the anticancer activity of taxol on human colorectal cancer cell line SW48 (Table 1). The difference between SW48 growth inhibition produced by treatment with taxol alone [IC_{50} (taxol) = 4.8×10^{-8} mol/L] and that produced by treatment with the combination of taxol and 5 μg/mL Rosco [IC_{50} (taxol + 5 μg/mL Rosco) = 7.4×10^{-10} mol/L] (Table 1) was statistically non-significant ($P = 0.127$). The combination of taxol and 10 μg/mL Rosco greatly increased the sensitivity of human colorectal cancer cells to taxol (640-fold) compared to treatment with

Table 2 Analysis of the combined effects of taxol and Rosco on human colorectal cancer cell lines

Combined treatment of taxol and Rosco	Combination interaction at various durations of treatment in human colorectal cancer cells[1]

Taxol 4.0 IC_{50} + Rosco 25 μg/mL	ant	add	add	syn	ant	add	ant	ant	ant

[1]The data are based on the mean of absorbance measurements of 3 independent experiments. ant: Antagonistic; add: Additive; syn: Synergistic.

taxol alone (Table 1). The difference in SW48 growth inhibition produced by treatment with combination of taxol and 10 μg/mL Rosco (IC_{50} = 7.5 × 10^{-11} mol/L) and that produced by treatment with taxol alone (IC_{50} = 4.8 × 10^{-8} mol/L) (Table 1) was significant (P = 0.012).

The combination of taxol and 5 μg/mL Rosco had a higher growth inhibitory effect on SW1116 (12-fold) compared to treatment with taxol alone (Table 1). The difference in SW1116 growth inhibition produced by treatment with the combination of taxol and 5 μg/mL Rosco (IC_{50} = 1 × 10^{-8} mol/L), and that produced by treatment with taxol alone (1.2 × 10^{-7} mol/L) was non-significant (P = 0.256). On the other hand, the combination of taxol and 10 μg/mL Rosco markedly increased SW1116 growth inhibition (150-fold) compared to treatment with taxol alone (Table 1). The difference in SW1116 growth inhibition produced by the combination of taxol and 10 μg/mL Rosco (IC_{50} = 8.1 × 10^{-10} mol/L) and that produced by taxol alone (1.2 × 10^{-7} mol/L) was statistically significant (P = 0.03).

Treatment of SW837 cells with various concentrations of taxol inhibited their growth in a dose dependent manner with IC_{50} = 3.8 × 10^{-7} mol/L. The combination of taxol and 5 μg/mL Rosco produced higher SW837 growth inhibition (IC_{50} = 5.4 × 10^{-8} mol/L, sensitization ratio = 7-fold) than that produced by treatment with taxol alone (Table 1). This difference in SW837 growth inhibition was non-significant (P = 0.365). Treatment of SW837 with the combination of taxol and 10 μg/mL Rosco resulted in a more significant growth inhibition (IC50 = 6.7 × 10^{-10} mol/L, sensitization ratio = 570 and P = 0.045) compared to that produced by treatment with taxol alone (Figure 2, Table 1). The combinations of taxol and Rosco produced additive and/or synergistic effects depending upon the type of cell line used, relative concentrations of the mixed drugs and exposure time (Table 2).

Cell cycle analysis of human colorectal cancer cells treated with taxol, Rosco or their combinations added in sequential (taxol followed by Rosco), inverted sequential or simultaneous manner was determined by flow cytometry as described in Materials and Methods. Treatment of colorectal cancer cells with taxol or Rosco resulted in growth arrest at G_2/M phase, 24.9% and 16.6%, respectively, compared to 4.75% for untreated cells (Figure 1B). The combination of taxol and Rosco added in sequential manner growth arrested colorectal cancer cell in G_2/M (21.8%). Also, the same combination added in an inverted sequential manner growth arrested colorectal cancer cells in G_2/M (23.4%), meanwhile when the

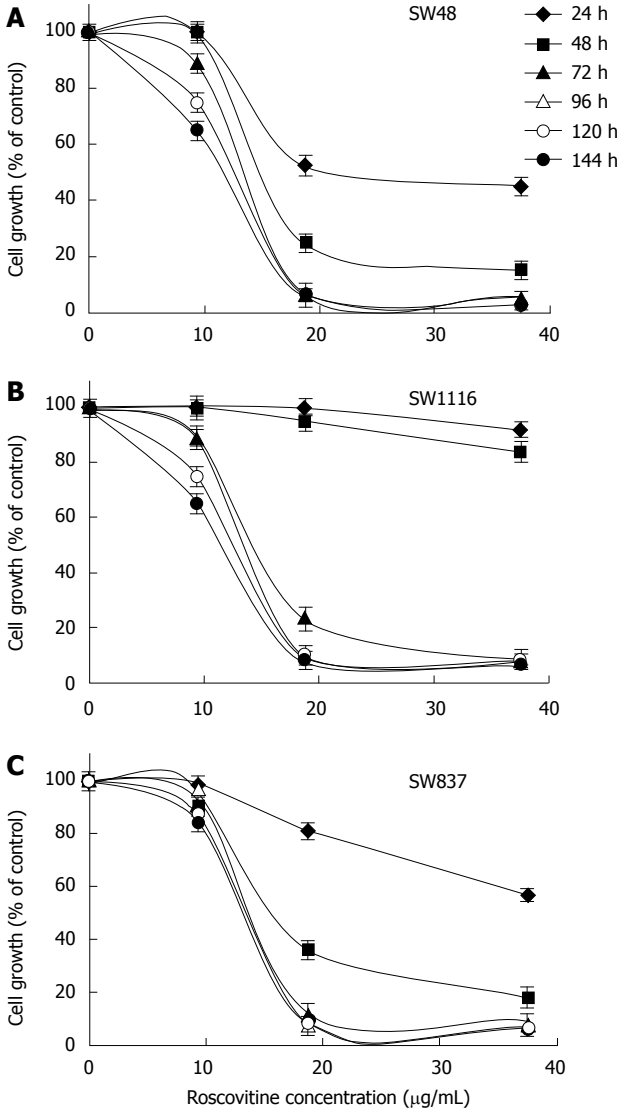

Figure 1 Time and dose dependent effect of roscovitine on the proliferation of human colorectal cancer cell lines. Human colorectal cancer cell lines SW48 (**A**), SW1116 (**B**) and SW837 (**C**) were plated (27 x 10^3 cells/well) into 96-well plates and incubated at 37℃ in a non-CO_2 incubator. Twenty four hours after starting the culture, the cells were treated with various concentrations of Rosco (0-40 μg /mL) or DMSO (0.3%, final concentration) for various time periods (24-144 h). Control (0.3% DMSO treated) and Rosco treated colorectal cancer cells were scored for proliferation using an MTT assay. Roscovitine concentrations 5 μg/mL and 10 μg/mL were used in the subsequent studies.

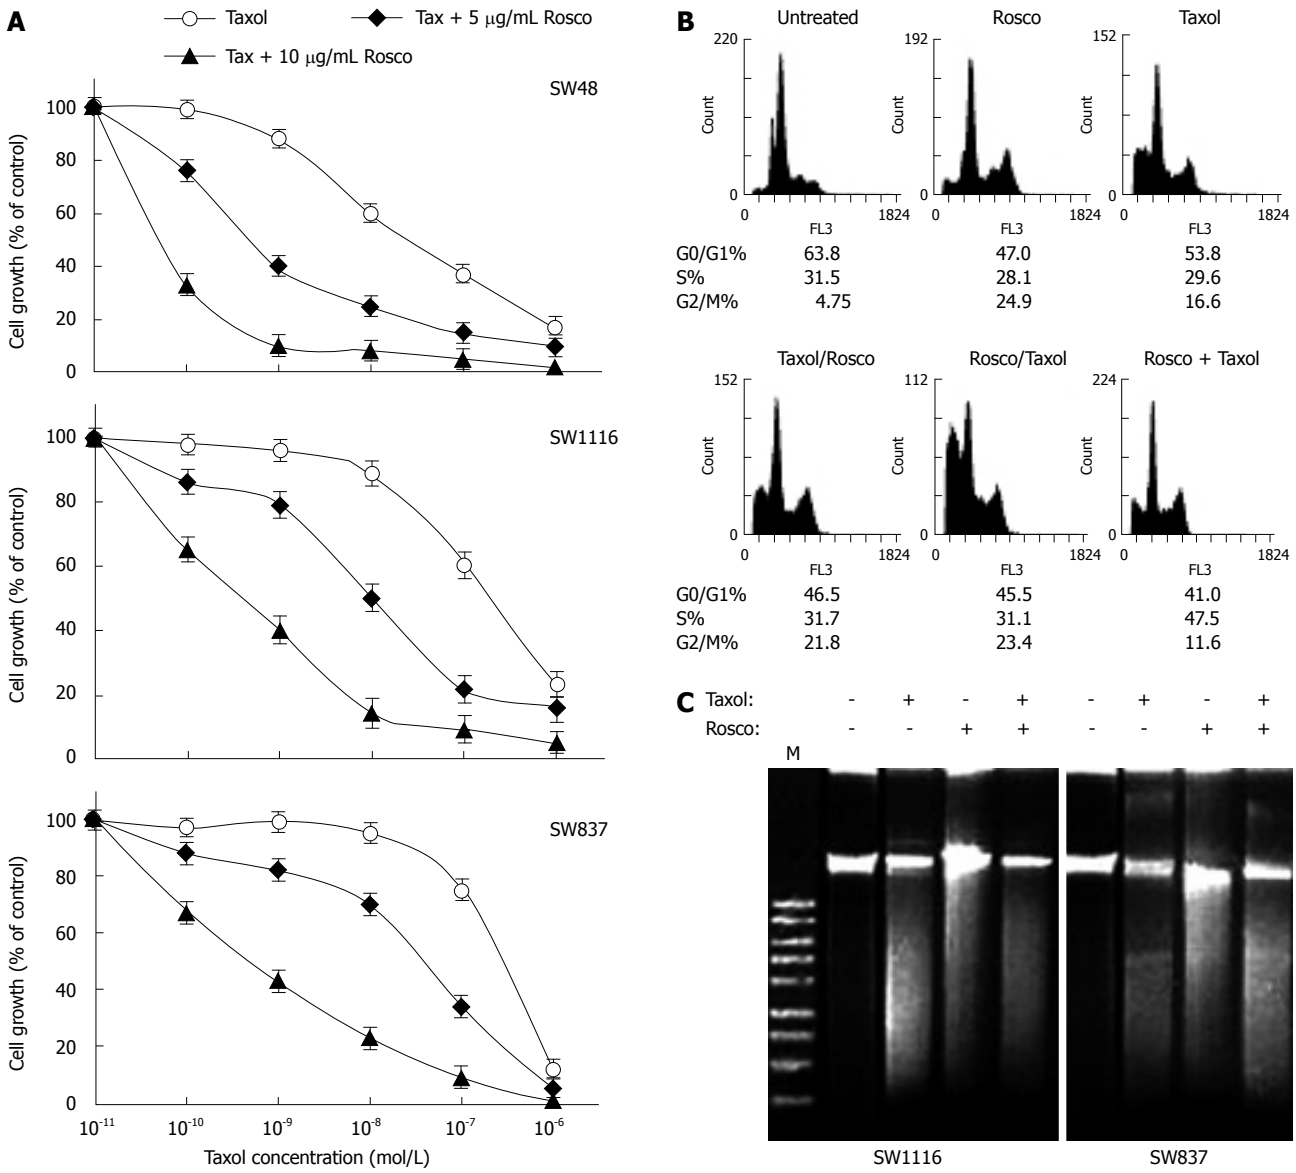

Figure 2 Potentiation of anticancer effect of taxol on human colorectal cancer cell lines by combination with cyclin dependent kinase inhibitor roscovitine. **A**: Human colorectal cancer cell lines were treated with taxol (10^{-11}-10^{-6} mol/L), or the combination of taxol (10^{-11}-10^{-6} mol/L) and Rosco (5 μg/mL or 10 μg/mL) for 96 h. At the end of treatment, control and drug treated cells were scored for proliferation using the MTT assay; **B**: Cell cycle phase distribution of human colorectal cancer cells (SW837, 5×10^5 cells/well) treated with taxol (12×10^{-8} mol/L, 72 h); Rosco (15 μg/mL, 72 h); sequential combination: taxol (12×10^{-8} mol/L, 24 h) followed by Rosco (15 μg/mL, 48 h); inverted sequential combination: Rosco (15 μg/mL, 24 h) followed by taxol (12×10^{-8} mol/L, 48 h) and simultaneous combination: taxol plus Rosco (12×10^{-8} mol/L, 15 μg/mL, 72 h) was evaluated by flow cytometry. The percentage of cells in different phases of the cycle was calculated by cell cycle analysis software, Multicycle (Phoenix Flow System, San Diego CA, USA); **C**: Human colorectal cancer cells, SW1116 and SW837 (5×10^5 cells/well), were treated with taxol (12×10^{-8} mol/L), Rosco (15 μg/mL), and the combination of taxol plus Rosco (12×10^{-8} mol/L + 15 μg/mL) for 72 h. DNA fragments were extracted and analyzed on 1% agrose gel.

same combination was used in a simultaneous manner, colorectal cancer cells were growth arrested in G_2/M (11.6%) and S (47.5%) phases, respectively, (Figure 2B). The effect of taxol, Rosco and their combination on inducing programmed cell death in human colorectal cancer cell lines SW1116 and SW837 was studied using DNA fragmentation analysis. The combination of taxol and Rosco induced apoptosis more efficiently compared to single treatment with taxol or Rosco (Figure 2C).

Modulation of 5-FU cytotoxicity on human colorectal cancer cells by combination *with the CDKI Rosco*

The anti-proliferative activities of 5-FU, Rosco and their combinations against human colorectal cancer cells are summarized in Figure 3. The combination of 5-FU (10^{-9}-10^{-4} mol/L) and Rosco (5 μg/mL) exerted a very potent anticancer effect ($P < 0.0001$) on SW48 with $IC_{50} = 5.7 \times 10^{-9}$ mol/L compared to $IC_{50} = 4.8 \times 10^{-5}$ mol/L when SW48 cells were treated with 5-FU alone (Figure 3A). These results indicate that Rosco (5 μg/mL) increased the sensitivity of SW48 to 5-FU by about 8.42×10^3-fold (Table 3). The same combination inhibited the growth of colorectal cancer cell lines SW1116 and SW837 with IC_{50} values equal to 6.7×10^{-6} mol/L and 1.8×10^{-6} mol/L compared to IC_{50} values equal to 2.5×10^{-5} mol/L and 4.8×10^{-5} mol/L obtained when these

5-FU	4.8×10^{-5}	2.5×10^{-5}	4.8×10^{-5}	-	-	-
5-FU + 5 μg/mL Rosco	5.7×10^{-9}	6.7×10^{-6}	1.8×10^{-6}	8.42×10^{3}	3.73	26.7
5-FU + 10 μg/mL Rosco	5.7×10^{-9}	1.0×10^{-7}	9.1×10^{-9}	8.42×10^{3}	250	5.28×10^{3}

[1]Sensitization ratio = IC_{50} (5-FU)/IC_{50} (5-FU + Rosco).

Table 4 Analysis of the combined effects of 5-FU and Rosco on human colorectal cancer cell lines

Combined treatment of 5-FU and Rosco	Combination interaction at various durations of treatment in human colorectal cancer cells[1]								
	SW48			SW1116			SW837		
	2 d	4 d	6 d	2 d	4 d	6 d	2 d	4 d	6 d
5-FU 0.5 IC_{50} + Rosco 1.0 μg/mL	ant	ant	ant	syn	syn	syn	ant	ant	add
5-FU 1.0 IC_{50} + Rosco 15 μg/mL	ant	ant	ant	syn	syn	syn	ant	syn	add
5-FU 2.0 IC_{50} + Rosco 20 μg/mL	ant	ant	ant	syn	add	add	add	ant	ant
5-FU 3.0 IC_{50} + Rosco 25 μg/mL	ant	ant	add	ant	ant	ant	add	ant	ant

[1]The data are based on the mean of absorbance measurements of 3 independent experiments; ant: Antagonistic; add: Additive; syn: Synergistic.

cells were treated with Rosco alone, respectively, (Figure 3A, Table 3). Rosco (5 μg/mL) increased the sensitivity of SW1116 and SW837 to 5-FU by about 3.73 and 26.7 fold, respectively. The increase in SW1116 and SW837 growth inhibition after treatment with this combination was found to be statistically non-significant $P = 0.519$ and $P = 0.122$, respectively, compared to single treatment with 5-FU.

The combination of 5-FU (10^{-9}-10^{-4} mol/L) and Rosco (10 μg/mL) exerted a marked growth inhibition on all the tested colorectal cancer cells SW48 ($P < 0.0001$), SW1116 ($P = 0.05$) and SW837 ($P = 0.005$) with IC_{50} values equal to 5.7×10^{-9} mol/L, 1.0×10^{-7} mol/L and 9.1×10^{-9} mol/L, respectively, compared to IC_{50} values of 4.8×10^{-5} mol/L, 2.5×10^{-5} mol/L, and 4.8×10^{-5} mol/L exerted on SW 48, SW1116 and SW837, respectively, when treated with 5-FU alone (Figure 3A, Table 3). The combination of 5-FU (10^{-9}-10^{-4} mol/L) and Rosco (10 μg/mL) increased the sensitivity of human colorectal cancer cell lines SW48, SW1116 and SW837 by 8.42×10^{3}, 250 and 5.28×10^{3} fold, respectively (Table 3). The combination of 5-FU and Rosco had synergistic effects on SW1116, additive effects on SW837 and antagonistic/additive effects on SW48 (Table 4). The type of interaction between the mixed drugs depends upon their relative concentrations, exposure time and the tested cell line.

The effect of this combination on human colorectal caner cell cycle was also evaluated. Treatment with Rosco alone growth inhibited colorectal cancer cells in G_2/M phase (24.9% *vs* 4.75% for untreated), while treatment with 5-FU alone growth arrested cancer cells in S-phase (51.9% *vs* 31.5% for untreated). However the combination of 5-FU and Rosco added in sequential, inverted sequential and simultaneous manners growth arrested human colorectal cancer cells in S-phase: 54.8%, 56.8% and 50.7%, respectively, compared to 51.5% in the S-phase for untreated (Figure 3B). The combination of 5-FU (4.8×10^{-5} mol/L) and Rosco (15 μg/mL) had synergistic or additive apoptotic effects on SW1116 and SW837 compared to single treatment with 5-FU or Rosco (Figure 3C).

Modulation of doxorubicin cytotoxicity on human colorectal cancer cells by combination with CDKI Rosco

Human colorectal cancer cells were treated with doxorubicin (10^{-11}-10^{-6} mol/L) or combinations of doxorubicin (10^{-11}-10^{-6} mol/L) and Rosco (5 or 10 μg/mL) for 96 h. The combination of doxorubicin and Rosco had a very potent anti-proliferative effect on the colorectal cancer cell line SW48 ($IC_{50} = 5.8 \times 10^{-11}$ mol/L, $P = 0.009$) compared to the effect of doxorubicin alone ($IC_{50} = 5.4 \times 10^{-8}$ mol/L) (Figure 4A, Table 5). The combination of doxorubicin and 5 μg/mL Rosco slightly increased the growth inhibition exerted on SW1116 and SW837 with IC_{50} values equal to 2×10^{-7} mol/L and 4.1×10^{-8} mol/L, respectively, compared to IC_{50} values equal to 6×10^{-7} mol/L and 4.1×10^{-7} mol/L obtained when SW1116 and SW837 were treated with doxorubicin alone, respectively, (Figure 3A, Table 5). The combination of doxorubicin and 5 μg/mL Rosco increased the sensitivity of SW1116 (3 fold) and SW837 (10 fold) to doxorubicin (Table 5). The difference in growth inhibition produced by treatment of SW1116 ($P = 0.543$) and SW837 ($P = 0.33$) with doxorubicin plus 5 μg/mL was statistically non-significant. The combination of doxorubicin and Rosco (10 μg/mL) produced very potent anti-proliferative effects on SW48 ($IC_{50} = 5.8 \times 10^{-11}$ mol/L, $P = 0.012$), SW1116 ($IC50 = 4.5 \times 10^{-9}$ mol/L, $P = 0.068$), and SW837 ($IC_{50} = 8.2 \times 10^{-10}$ mol/L, $P = 0.049$) compared to treatment with Rosco alone (Figure 4A, Table 5). The combination of doxorubicin and Rosco exhibited an additive effect on SW48, synergistic and additive effects on SW1116 and synergistic effect on SW837 in a time and

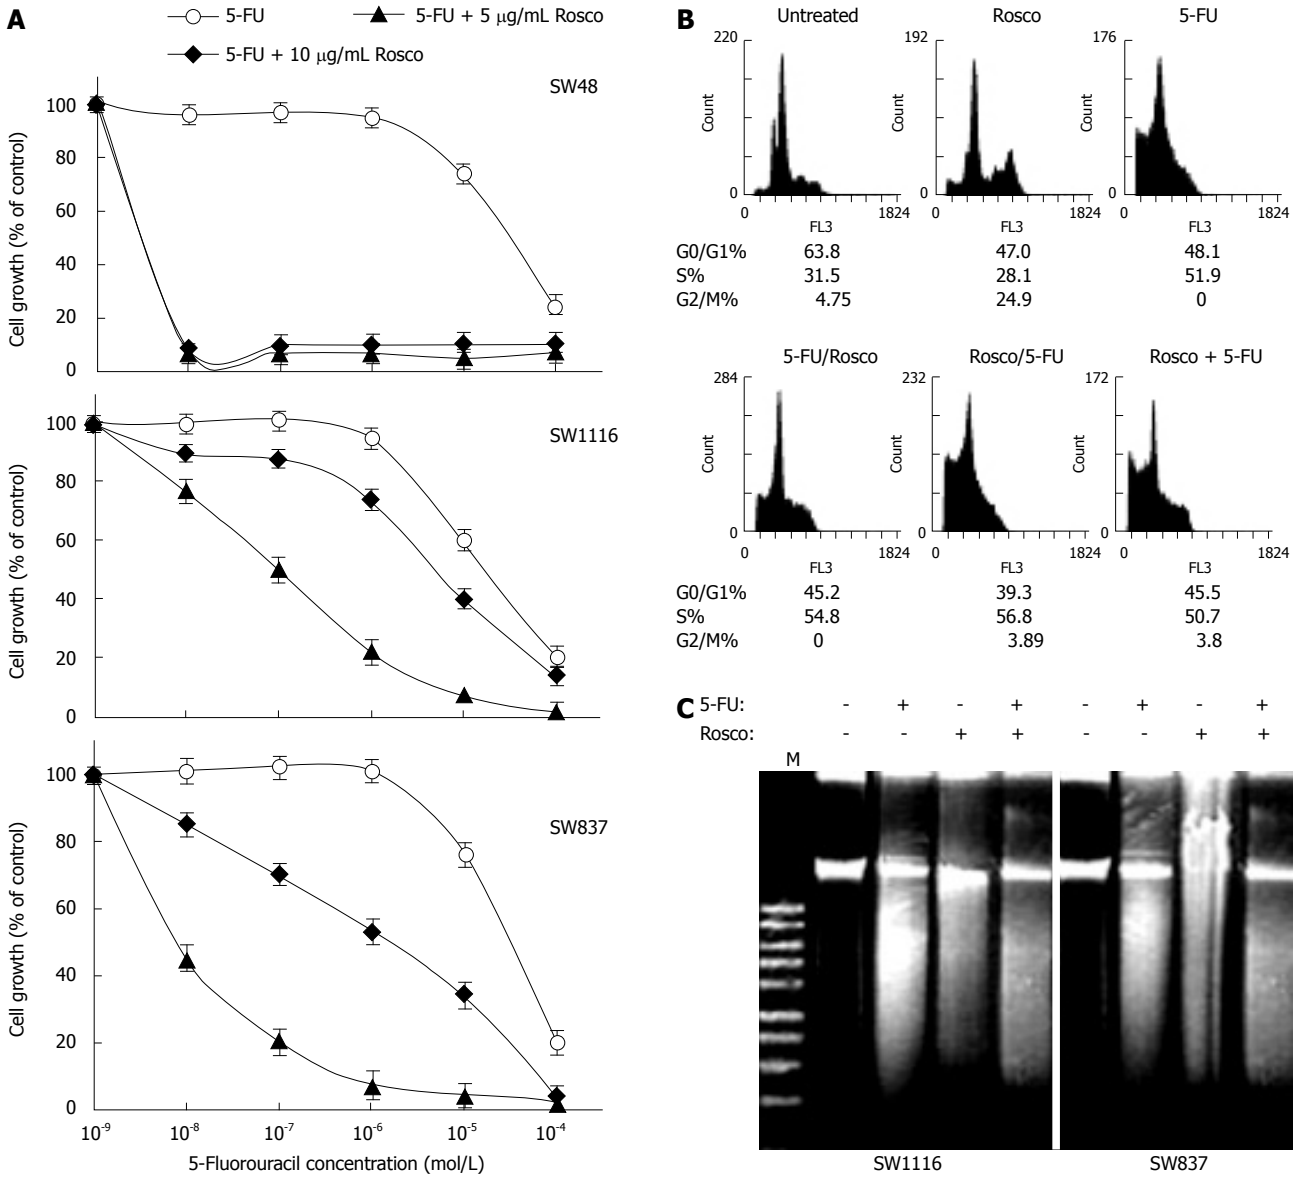

Figure 3 Potentiation of 5-FU anticancer effect on human colorectal cancer cell lines by combination with cyclin dependent kinase inhibitor roscovitine. **A**: Human colorectal cancer cell lines were treated with 5-FU (10^{-9}-10^{-4} mol/L), and the combination of 5-FU (10^{-9}-10^{-4} mol/L) and Rosco (5 μg/mL or 10 μg/mL) for 96 h. At the end of treatment, control and drug treated cells were scored for proliferation using the MTT assay; **B**: Cell cycle phase distribution of human colorectal cancer cells (SW837, 5×10^5 cells/well) treated with 5-FU (4.8×10^{-5} mol/L, 72 h); Rosco (15 μg/mL, 72 h); sequential combination: 5-FU (4.8×10^{-5} mol/L, 24 h) followed by Rosco (15 μg/mL, 48 h); inverted sequential combination: Rosco (15 μg/mL, 24 h) followed by 5-FU (4.8×10^{-5} mol/L, 48 h) and simultaneous combination: 5-FU plus Rosco (4.8×10^{-5} mol/L, 15 μg/mL, 72 h) was evaluated by flow cytometry. The percentage of cells in different phases of the cycle was calculated as described above; **C**: Human colorectal cancer cells, SW1116 and SW837 (5×10^5 cells/well), were treated with 5-FU (4.8×10^{-5} mol/L), Rosco (15 μg/L), and the combination of 5-FU plus Rosco (4.8×10^{-5} mol/L + 15 μg/mL) for 72 h. DNA fragments were extracted and analyzed on 1% agrose gel.

Table 5 IC_{50} and sensitization ratio of doxorubicin and combinations with Rosco towards human colorectal cancer cell lines

Treatment with doxorubicin and its combinations with Rosco	IC_{50} (mol/L)			Sensitization ratio[1]		
	SW48	SW1116	SW837	SW48	SW1116	SW837
Dox.	5.4×10^{-8}	6×10^{-7}	4.1×10^{-7}	-	-	-
Dox. + 5 μg/mL Rosco	5.8×10^{-11}	2×10^{-7}	4.1×10^{-8}	9.3×10^{2}	3	10
Dox. + 10 μg/mL Rosco	5.8×10^{-11}	4.5×10^{-9}	8.2×10^{-10}	9.3×10^{2}	1.3×10^{2}	5.0×10^{2}

[1]Sensitization ratio = IC_{50} (Dox.)/IC_{50} (Dox. + Rosco).

dose dependent manner (Table 6).

The effect of the combination on colorectal cancer cell cycle was also investigated. Treatment with Rosco growth arrested cancer cells in G_2/M (24.9% *vs* 4.75%

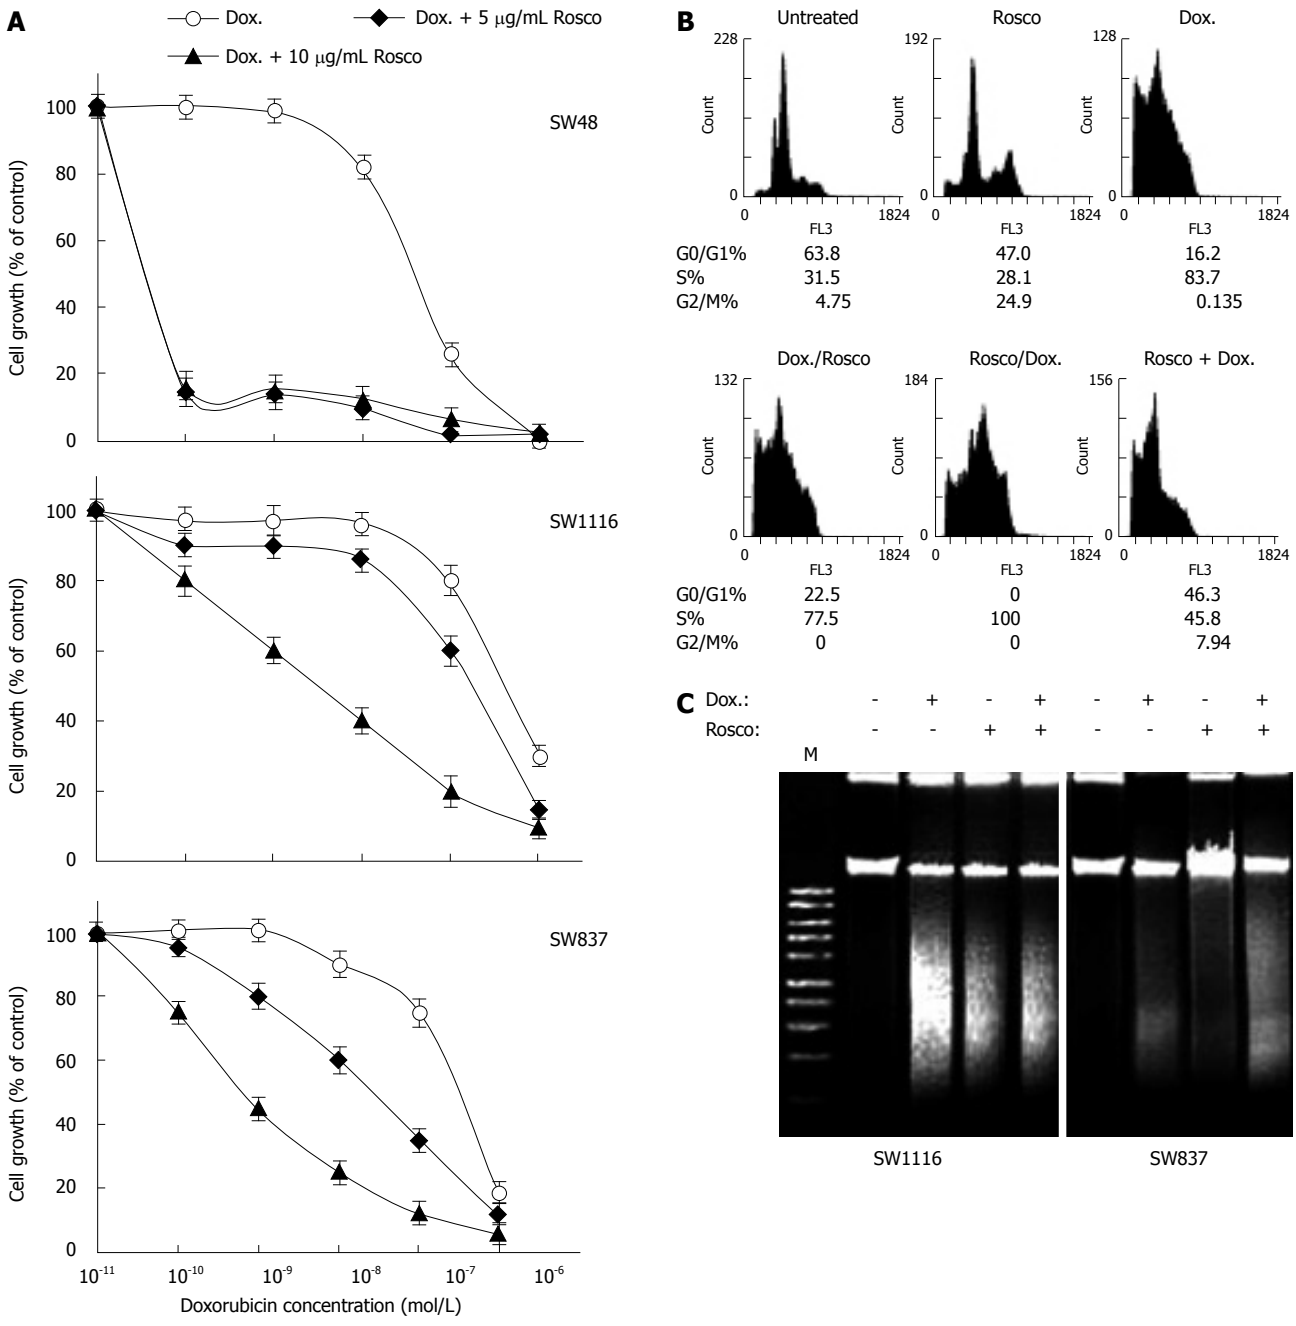

Figure 4 Potentiation of doxorubicin anticancer effect on human colorectal cancer cell lines by combination with cyclin dependent kinase inhibitor roscovitine. **A**: Human colorectal cancer cell lines were treated with doxorubicin (10^{-11}-10^{-6} mol/L), and the combination of doxorubicin (10^{-11}-10^{-6} mol/L) plus Rosco (5 μg/mL or 10 μg/mL) for 96 h. At the end of treatment, control and drug treated cells were scored for proliferation using an MTT assay; **B**: Cell cycle phase distribution of human colorectal cancer cells (SW837, 5 × 10^5 cells/well) treated with doxorubicin (8 × 10^{-7} mol/L, 72 h); Rosco (15 μg/mL, 72 h); sequential combination: doxorubicin (8 × 10^{-7} mol/L, 24 h) followed by Rosco (15 μg/mL, 48 h); inverted sequential combination: Rosco (15 μg/mL, 24 h) followed by doxorubicin (8 × 10^{-7} mol/L, 48 h) and simultaneous combination: doxorubicin plus Rosco (8 × 10^{-7} mol/L + 15 μg/mL, 72 h) was evaluated by flow cytometry. The percentage of cells in different phases of the cycle was calculated as previously described; **C**: Human colorectal cancer cells, SW1116 and SW837, (5 × 10^5 cells/well) were treated with doxorubicin (8 × 10^{-7} mol/L), Rosco (15 μg/mL), and the combination of doxorubicin plus Rosco (8 × 10^{-7} mol/L + 15 μg/mL) for 72 h. DNA fragments were extracted and analyzed on 1% agrose gel.

for untreated), while doxorubicin markedly growth arrested colorectal cancer cells in S-phase (83.7% *vs* 51.5% for untreated). The combination of doxorubicin and Rosco added to the culture in a sequential manner, i.e., doxorubicin followed by Rosco, growth arrested cancer cells in S-phase (77.5% *vs* 31.5% for untreated). The same combination added in an inverted sequential manner growth arrested cancer cells completely in S-phase (100% *vs* 31.5% for untreated). However, when the same combination was added in a simultaneous manner, the colorectal cancer cells were arrested in both S-phase (45.8% *vs* 31.5% for untreated) and G_2/M phase (7.94% *vs* 4.75% for untreated) (Figure 4B). The apoptosis inducing effect of the combination of doxorubicin (8 × 10^{-7} mol/L) and Rosco (15 μg/mL) was also tested. This combination enhanced apoptosis in SW1116 and SW837 compared to single treatment of doxorubicin and Rosco (Figure 4C).

Table 7 IC_{50} and sensitization ratio of vinblastine and its combinations with Rosco towards human colorectal cancer cell lines

Treatment with vinblastine and combinations with Rosco	IC_{50} (mol/L)			Sensitization ratio[1]		
	SW48	SW1116	SW837	SW48	SW1116	SW837
Vinb.	1×10^{-8}	6.3×10^{-7}	4.2×10^{-7}	-	-	-
Vinb. + 5 μg/mL Rosco	5.4×10^{-11}	7.5×10^{-8}	5.0×10^{-8}	1.9×10^{2}	8.4	8.4
Vinb. + 10 μg/mL Rosco	5.4×10^{-11}	7.9×10^{-10}	4.6×10^{-10}	1.9×10^{2}	8.0×10^{2}	9.1×10^{2}

[1]Sensitization ratio = IC_{50} (Vinb.)/IC_{50} (Vinb. + Rosco).

Modulation of vinblastine cytotoxicity on human colorectal cancer cells by combination with CDKI Rosco

The ability of cyclin dependent kinase inhibitor Rosco to sensitize human colorectal cancer cells to vinblastine was evaluated. Treatment of cancer cells with a combination of vinblastine (10^{-12}-10^{-7} mol/L) and Rosco (5 or 10 μg/mL) dramatically growth inhibited SW48 cells ($P = 0.023$ or $P = 0.019$) with $IC_{50} = 5.4 \times 10^{-11}$ mol/L compared to $IC_{50} = 1.0 \times 10^{-8}$ mol/L for the effect of vinblastine alone (Figure 5). These results clearly indicate that Rosco (5 or 10 μg/mL) sensitized SW48 cells to vinblastine anticancer activity by 190 fold (Table 7). Treatment of SW1116 with the combination of vinblastine and Rosco (5 μg/mL) produced a higher growth inhibition of SW1116 ($IC_{50} = 7.5 \times 10^{-8}$ mol/L, sensitization ratio = 8.4 fold) (Figure 5A, Table 7) compared to treatment with vinblastine alone ($IC_{50} = 6.3 \times 10^{-7}$ mol/L). The increase in the growth inhibition induced by mixing vinblastine with 5 μg/mL of Rosco was found to be statistically non-significant ($P = 0.216$). On the other hand, treatment of SW1116 with vinblastine and 10 μg/mL Rosco markedly enhanced the cytotoxicity of vinblastine ($IC_{50} = 7.9 \times 10^{-10}$ mol/L, $P = 0.013$) towards SW1116 demonstrating a great increase in the chemo-sensitization of SW1116 (8×10^{2}-fold) to vinblastine (Table 7). Similar results were obtained with the colorectal cancer cell line SW837. The combination of vinblastine and Rosco (5 μg/mL) slightly increased the growth inhibition of SW837 ($IC_{50} = 5 \times 10^{-8}$ mol/L, sensitization ratio = 8.4) compared to single treatment with vinblastine ($IC_{50} = 4.2 \times 10^{-7}$ mol/L) (Table 7). However, the combination of vinblastine and 10 μg/mL Rosco exerted significant growth inhibition of SW837 cells ($IC_{50} = 4.6 \times 10^{-10}$ mol/L, $P = 0.023$) compared to treatment with vinblastine alone ($IC_{50} = 4.2 \times 10^{-7}$ mol/L) demonstrating a marked increase in the sensitivity of SW837 (9.1×10^{2}-fold) to vinblastine.

The combination of vinblastine ($2IC_{50}$) and Rosco (15 μg/mL) had synergistic effect on SW48 after 4 d of combination treatment (Table 8). All the tested combinations had additive or synergistic effects on SW1116 after 2 d of treatment. The combination of vinblastine (IC_{50}) and Rosco (10 μg/mL) had additive and synergistic effects on SW1116 and SW837 after 4 and 6 d of treatment, respectively (Table 8).

The effects of single and combined treatment with vinblastine (2.6×10^{-7} mol/L) and Rosco (15 μg/mL) on colorectal cancer cell cycle distribution indicated that treatment of SW837 with Rosco growth inhibited colorectal cancer cells in G_2/M (24.9% *vs* 4.75% for untreated), while, vinblastine treatment markedly growth arrest these cells in G_2/M (71.9% *vs* 4.75% for untreated). The combination of vinblastine (2.6×10^{-7} mol/L) and Rosco (15 μg/mL) added in sequential manner (vinblastine followed by Rosco) greatly growth arrested SW837 cells in G_2/M (76.6% *vs* 4.75% for untreated). The same combination added in an inverted sequential manner markedly growth arrested the cells in G_2/M (85.7% *vs* 4.75% for untreated). The same combination added simultaneously to SW837 cells growth arrested these cells both in S- (44.6% *vs* 31.6% for untreated) and G_2/M-(19.3% *vs* 4.75% for untreated) phases (Figure 5B). The combination of vinblastine (2.6×10^{-7} mol/L) and Rosco (15 μg/mL) had a marked apoptotic effect on colorectal cancer cell lines SW1116 and SW837 compared to single treatments with vinblastine (2.6×10^{-7} mol/L) or Rosco (15 μg/mL) (Figure 5C).

DISCUSSION

The central finding of the present study is that the

cyclin dependent kinase inhibitor Rosco improved the therapeutic activity of several conventional chemotherapeutic drugs namely taxol, doxorubicin, 5-FU, and vinblastine that act by different mechanisms in human colorectal cancer cells. This finding is significant because chemotherapeutic drugs cause high toxicity to normal tissues during treatment of colorectal cancer as well as other cancers.

The adverse health effects of the conventional chemotherapeutic drugs, such as immunosuppression and cardiomyopathy, which severely increase in a dose-dependent manner, as well as development of primary or secondary drug resistance in tumor cells, limit their clinical success in cancer chemotherapy[15]. The increase in systemic toxicity and drug resistance, the major drawbacks of anticancer chemotherapeutic agents, has led to a new challenge in the field of cancer research. To overcome such problems, extensive research has been directed towards reducing systemic toxicity and increasing drug activity in cancer therapy[15,16]. In this regard, combination chemotherapy has received increasing attention in the search for compounds that could increase the therapeutic index of clinical anticancer drugs[17].

Deregulation of the cell cycle and oncogenic overexpression of several cell cycle related gene products in many human cancers provide new opportunities for anticancer drug discovery. Efforts to exploit these targets are progressing quite well, with inhibition of cyclin dependent kinase activity emerging as the most productive approach at present. This has resulted in the development of several small molecules, with specific and potent CDK inhibitory effects, which are now undergoing clinical trials in phases Ⅰ and Ⅱ, and the results awaited with expectation.

CDKs are essential players in the intracellular control of the cell cycle**.** Since CDKs and their regulatory partners are frequently deregulated and exhibit enhanced activity in human cancers, their inhibition by selectively acting drugs offers a new concept in the therapeutic strategy[5,18]. Recently, a number of pharmacological inhibitors of CDKs were developed, one efficient group of such compounds is based on the substitution of purines and pyrimidines. Substituted purines represent CDK inhibitors that are structurally most similar to ATP[7]. Among a series of C2, N6, N9-substituted adenines, Rosco displays high efficiency and selectivity towards some CDKs. Out of 25 kinases investigated, only a few were significantly inhibited by Rosco with IC_{50} values lower than 1 μmol/L. CDK2/cyclin B and CDK2/cyclin A were identified as the best targets[8]. Through its high selectivity, Rosco is predestinated to be a potent anti-mitotic drug. It acts not only as a cell cycle blocker[19-22], but seems also to induce apoptosis[11,22-24].

There is still a lack of systematic knowledge about the cytotoxic effects of Rosco on normal and malignant cells. The exact discrimination between inhibition of cell proliferation and impairment of cell *via*bility is necessary. Moreover, the pro- or anti-apoptotic action of Rosco on different cells is until now contradictory and has to be conscientiously examined. The consequences of Rosco-induced cell cycle arrest and apoptosis in colorectal cancer cells upon chemo-sensitization of such cells to conventional therapeutic drugs have not yet been investigated. In this study, we addressed the ability of Rosco to synergize with conventional chemotherapeutic drugs, acting by different mechanisms, to induce efficient apoptosis in human colorectal cancer cell lines.

In the present study, human colorectal cancer cells were shown to be sensitive to the antiproliferative and cytotoxic effects of Rosco with IC_{50} values: (11.56-25 μg/mL), (11.62-14.78 μg/mL) and (13.44-16.25 μg/mL) for SW48, SW1116 and SW837, respectively, after 24-144 h, 72-144 h and 48-144 h of Rosco treatment, respectively. These results are consistent with those reported for other cell types[8,25]. To explore whether inhibition of cell growth observed in the Rosco treated human colorectal cancer cells synergize with the conventional chemotherapeutic drugs acting by different mechanisms to induce efficient apoptosis of human colorectal cancer cells, we tested the efficacy of single and combined treatments with Rosco and taxol, doxorubicin, 5-FU or vinblastine on the growth of human colorectal cancer cells. Our results indicated that Rosco (5 and 10 μg/mL) markedly sensitized the tested human colorectal cancer cells to taxol (sensitization ratio = 7.0-6.4 × 10^2), doxorubicin (sensitization ratio = 3.0-9.3 × 10^2), 5-FU (sensitization ratio = 3.73-8.42 × 10^3) and vinblastine (sensitization ratio = 9-8 × 10^3) (Tables 1, 3, 5 and 7). The combination of Rosco and chemotherapeutic drugs inhibited the growth of human colorectal cancer cells in an additive or synergistic fashion, and in a time- and dose-dependent manner (Tables 2, 4, 6 and 8). Treatment of human colorectal cancer cells with Rosco, conventional chemotherapeutic drugs or the combination of Rosco and conventional chemotherapeutic drugs add-

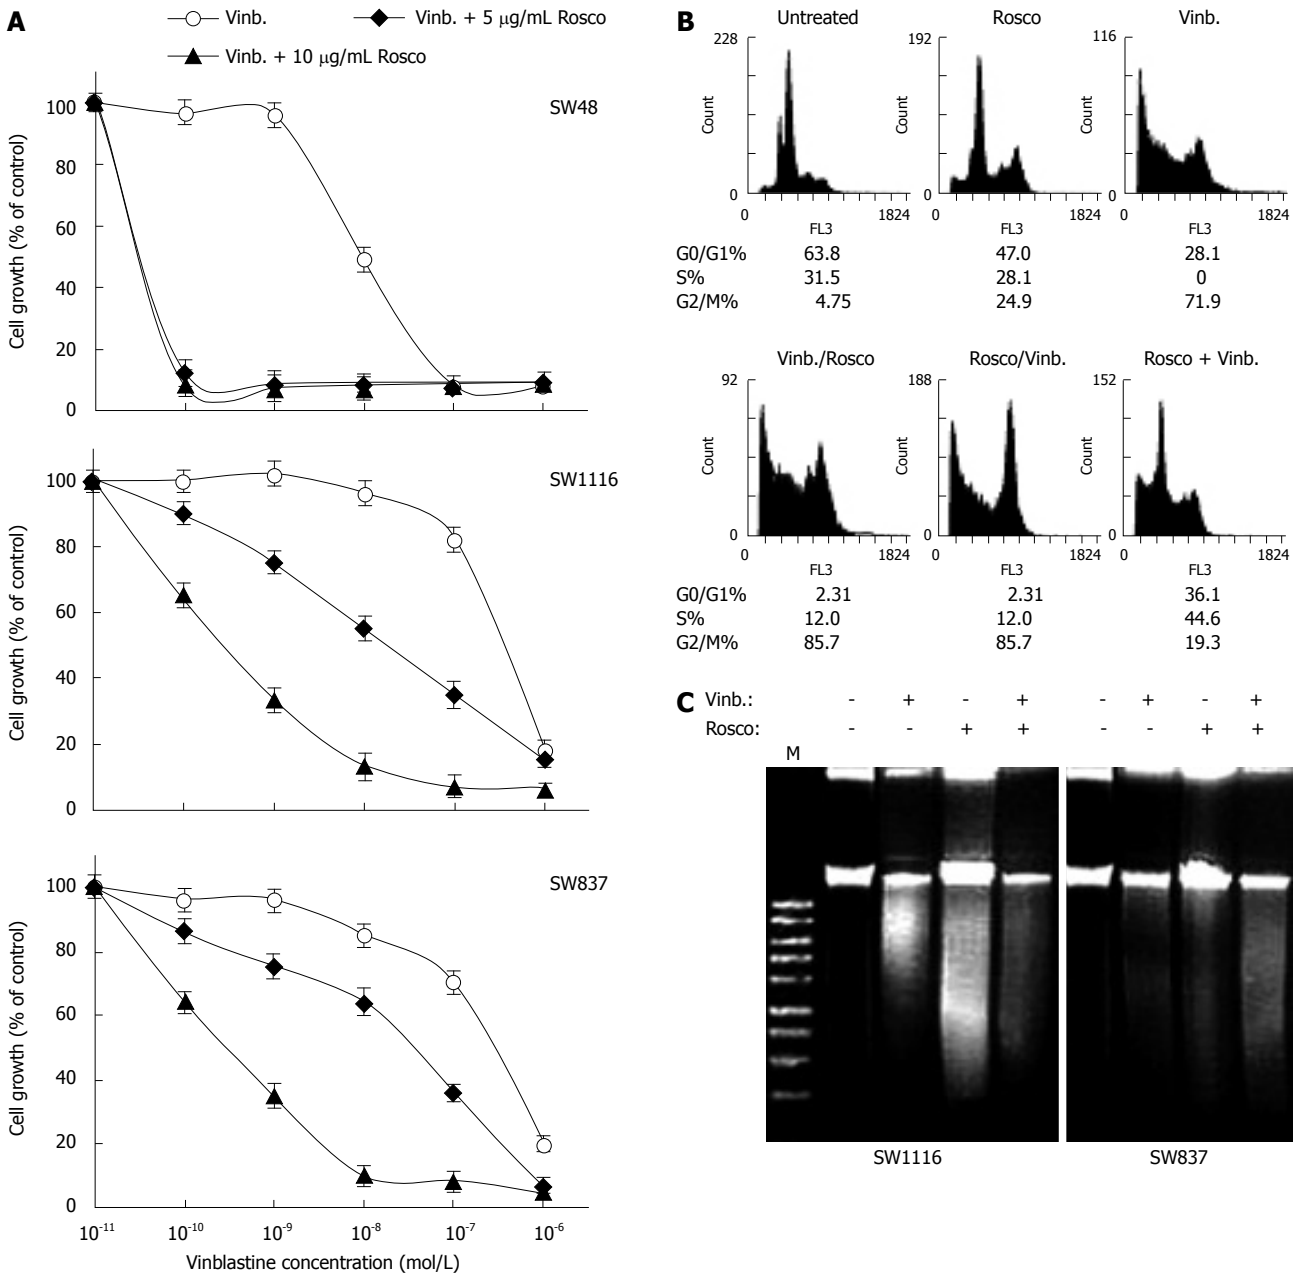

Figure 5 Potentiation of vinblastine anticancer effect on human colorectal cancer cell lines by combination with cyclin dependent kinase inhibitor roscovitine. **A**: Human colorectal cancer cell lines were treated with vinblastine (10^{-12}-10^{-7} mol/L) and the combination of vinblastine (10^{-12}-10^{-7} mol/L) plus Rosco (5 μg/mL or 10 μg/mL) for 96 h. At the end of treatment, control and drug-treated cells were scored for proliferation using an MTT assay; **B**: Cell cycle phase distribution of human colorectal cancer cells (SW837, 5 x 10^5 cells/well) treated with vinblastine (2.6 x 10^{-7} mol/L, 72 h); Rosco (15 μg/mL, 72 h); sequential combination: vinblastine (2.6 x 10^{-7} mol/L, 24 h) followed by Rosco (15 μg/mL, 48 h); inverted sequential combination: Rosco (15 μg/mL, 24 h) followed by vinblastine (2.6 x 10^{-7} mol/L, 48 h) and simultaneous combination: vinblastine plus Rosco (2.6 x 10^{-7} mol/L + 15 μg/mL, 72 h) was evaluated by flow cytometry. The percentage of cells in different phases of the cycle was calculated as described above; **C**: Human colorectal cancer cells, SW1116 and SW837, (5 x 10^5 cells/well) were treated with vinblastine (2.6 x 10^{-7} mol/L), Rosco (15 μg/mL) and the combination of vinblastine plus Rosco (2.6 x 10^{-7} mol/L + 15 μg/mL) for 72 h. DNA fragments were extracted and analyzed on 1% agrose gel.

ed in a sequential or inverted sequential manner growth arrested colorectal cancer cells in G_2/M- or S- phase of the cell cycle. While, simultaneous addition of Rosco and conventional chemotherapeutic drugs double blocked colorectal cancer cells in G_2/M- and S- phases of the cell cycle for all the tested drugs except for 5-FU, where, its combination with Rosco growth arrested colorectal cancer cells in S-phase. The growth arrest of colorectal cancer cells in G_2/M following Rosco treatment may facilitate the induction of apoptosis and sensitize the cells to conventional chemotherapeutic drugs.

Another notable observation from our morphological analysis was the extensive detachment of cells from the cell culture substratum after exposure to Rosco (data not shown). Recent evidence suggests that cellular attachment to the substratum is mediated by the interaction of integrins with ECM components such as fibronectin, collagen, and vitronectin[26]. Binding of integrins to these adhesion molecules results in the activation of focal adhesion kinase[27] accompanied by phosphorylation and recruit-

ment of a number of related cytoskeletal and signaling molecules, thereby transducing anchorage and survival messages to the nucleus[28,29]. Conversely, the uncoupling of integrins from ECM proteins leads to disruption of integrin-mediated signal transduction, inactivation of focal adhesion kinase, detachment of cells from the ECM, and apoptotic cell death[30]. Our data suggest that following Rosco treatment, human colorectal cancer cells detach from cell culture substratum, and die *via* apoptosis as indicated by the DNA fragmentation assay. This notion is consistent with previous reports demonstrating that cells deprived of matrix attachment underwent apoptosis[31]. Thus, the extensive detachment of cells from the cell culture substratum, and the apoptotic cell death observed in our experimental system may be due to the uncoupling of integrin-mediated signaling and/or disruption of cell-matrix interactions induced by Rosco. In addition to facilitating apoptosis, which will have its impact on chemosensitization of human colorectal cancer cells to conventional chemotherapeutic drugs, the loss of adhesion induced by this CDK inhibitor may deny cell anchorage and traction necessary for growth and migration and thus prevent colorectal cancer invasion and metastasis, the major cause of death in colorectal cancer patients. Because adhesion and invasion are crucial to the initiation of metastatic growth[32], additional studies on the effect of Rosco on cell adhesion to extracellular matrix components as well as the anti-invasive potential of the CDK inhibitor could be extremely rewarding. These studies are currently ongoing in our laboratory.

Rosco may prevent the assembly of actin fibers by modulating the expression and/or activity of Rho GTPases, which have been reported to be involved in the regulation of actin microfilament organization and other associated activities[33]. Disruption of actin microfilament architecture by Rosco has some biological implications. In view of the role played by actin microfilaments in various aspects of cellular physiology such as cell-cell interaction, proliferation, and secretion[33], it can be argued that all of these cellular activities could be affected in colorectal tumors following Rosco treatment.

Rosco strongly up-regulates wt p53 protein in cancer cells[19,20,22,34]. Since p53 protein plays a pivotal role in the regulation of cell cycle, the biological effect of Rosco cannot be restricted to the direct inhibition of distinct kinases. Considering the multiple p53 targets and functions, it is obvious that the Rosco-induced upregulation of p53 in cancer cells may essentially contribute to the cell cycle arrest, chromatin silencing and initiation as well as execution of apoptosis.

The role of CKDs in chemosensitization, and the potential downstream effectors of CDKs inhibition have been investigated by Crescenzi *et al*[5]. They showed that lung adenocarcinoma cell line H1299 treated with a nontoxic concentration of Rosco renders H1299 cells significantly more susceptible to doxorubicin or etoposide. In these cells, Rosco does not modulate senescence, but markedly reduces the capacity of H1299 cells to repair damage and resume proliferation after treatment. Combined treatment with Rosco and doxorubicin, or etoposide was found to enhance G_2-M accumulation, to increase the amount of γ-H2AX foci and to inhibit DNA repair. Two main repair pathways, homologous recombination and NHEJ, cooperate to repair DNA DSBs[35]. Crescenzi *et al*[5] investigated the ability of Rosco to modulate those two processes in doxorubicin-treated cells. They reported the ability of Rosco to negatively modulate DNA-PK activity in H1299 cells[5,36] and showed that Rosco significantly reduces the efficiency of recombination repair identifying a novel mechanism of action by which Rosco affects tumor cells that is inhibition of DNA DSBs repair.

The role of CDK2 and CDK1 kinases as targets for Rosco in tumor chemosensitization has also been investigated by Crescenzi *et al*[5]. In this study, experiments with inducible dn-K2 clones indicated that loss of Cdk2 and Cdk1 activity was responsible for the chemosensitizing effect of Rosco Overexpression of dn-K2 in H1299 cells potentiates doxorubicin-induced G_2-M arrest and inhibited recovery of the cells after treatment. It is worth noting that overexpression of dn-K2 results in both Cdk2 and Cdk1 inhibition[37]. Furthermore, analyses of homologous recombination in Hela cells transiently overexpressing either dn-K2 or dn-K1 or Cdk2 confirmed a role for Cdks in modulation of DNA repair processes[5]. A role for CDK in the control of DNA repair pathways has also been studied in the yeast cells[38,39]. Combined treatment of Rosco and DNA-damaging agents not only enhances drug-induced apoptosis, but also effectively hampers the recovery of mildly damaged tumor cells after treatment. Rosco, by hindering both homologous recombination and NHEJ repair processes, has the potential to inhibit recovery of mildly damaged tumor cells after chemotherapeutic drug treatment, and to increase the susceptibility of tumor cells to chemotherapy. Our results clearly indicated that Rosco synergizes with chemotherapeutic drugs to induce efficient apoptosis of human colorectal cancer cells. Important issues that need to be addressed in order to advance these agents to the clinical arena include the best drug administration schedule, testing various combinations with standard chemotherapeutic agents, the best tumor types to be targeted, and demonstration of CDK modulation of tumor samples from cancer patients.

COMMENTS

Background

Cyclin-dependent kinases (CDKs) are serine/threonine kinases that play a key role in regulating cell cycle progression. Aberrant expression or altered activity of distinct CDK complexes results in escape of cells from the cell cycle control and leads to malignant transformation. Therefore, inhibition of CDKs in malignant cells provides a new strategy in the fight against cancer. The present study examined the ability of roscovitine (Rosco), a CDK inhibitor (CDKI), to enhance the anticancer effects of chemotherapeutic drugs that act by different mechanisms on human colorectal cancer cells. The authors have also investigated whether Rosco differentially affects the cell cycle distribution of drug-treated human colorectal cancer cells.

Research frontiers

Extensive research has been directed towards reducing systemic toxicity and

increasing drug activity in cancer therapy. Combination chemotherapy has received increasing attention in the search for compounds that could increase the therapeutic index of clinical anticancer drugs. This study indicated that combinations of agents directed at different pathways or different steps of pathways involved in apoptosis can cause the cells to reach an apoptosis threshold resulting in synergistic apoptosis and increased therapeutic index of the anticancer drugs.

Innovations and breakthroughs

The central finding of this study is that the cyclin dependent kinase inhibitor Rosco improved the therapeutic activity of several conventional drugs namely taxol, 5-fluorouracil (5-FU), doxorubicin and vinblastine that act by different mechanisms. Also, Rosco differentially affected the cell cycle distribution of drug-treated colorectal cancer cells.

Applications

Chemotherapeutic drugs are highly toxic to normal tissues during treatment of colorectal cancer as well as other cancers. Rosco increases the sensitivity of several conventional chemotherapeutic drugs namely taxol, doxorubicin, 5-FU, and vinblastine. This finding is significant because increasing drug activity may reduce systemic toxicity in cancer therapy.

Terminology

CDKIs are a heterogeneous group of compounds that are able to inhibit CDKs involved in the cell cycle, transcription or neuronal functions. CDKIs are a chemically diverse, flat, hydrophobic heterocycles that compete with ATP. Rosco (CDKI) is structurally related to ATP, it blocks the cell cycle and induces apoptosis.

Peer review

A tremendous amount of *in vitro* work has been done looking at the anti colorectal cancer cell effect of Rosco, a novel CDK inhibitor, to enhance the antitumor effects of conventional chemotherapy agents. The approach is very well designed and the presentation of data is very detailed. It looks promising and may yield clinical benefits in the future.

Abstract

AIM: To investigate the combined effects of K-ras antisense oligodeoxynucleotide (K-ras ASODN) specific to GTT point mutation at codon 12 and type I insulin-like growth factor receptor (IGF-IR) antisense oligodeoxynucleotide (IGF-IR ASODN) on proliferation and apoptosis of human pancreatic cancer Patu8988 cells *in vitro* and *in vivo*.

METHODS: *K-ras* gene point mutation and its style at codon 12 of human pancreatic cancer cell line Patu8988 were detected by using polymerase chain reaction with special sequence primers (PCR-SSP) and sequence analysis. According to the mutation style, K-ras mutation ASODN specific to K-ras point mutation at codon 12 was designed and composed. After K-ras ASODN and IGF-IR ASODN treated on Patu8988 cells respectively or cooperatively, the proliferation and morphological change of Patu8988 cells were analyzed by 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay, colony forming assay and transmission electron microscopy; the expression of K-ras and IGF-IR mRNA and protein in the treated cells was measured by reverse-transcript polymerase chain reaction (RT-PCR) and flow cytometry respectively; apoptosis was determined by flow cytometry. The combined antitumor activity of K-ras ASODN and IGF-IR ASODN was evaluated in BALB/c nude mice bearing human pancreatic cancer inoculated with Patu8988 cells.

RESULTS: The results of PCR-SSP and sequence analysis showed that the human pancreatic cancer cell line Patu8988 had point mutation at codon 12, and the mutation style was GGT→GTT. 2-32 μg/mL K-ras ASODN and 2-32 μg/mL IGF-IR ASODN could inhibit Patu8988 cells' growth, induce apoptosis and decrease the expression of K-ras and IGF-IR mRNA and protein alone. However, there was much more effective inhibition of growth and induction of apoptosis by their combination than by each one alone. In tumor bearing mice, the combination of K-ras ASODN and IGF-IR ASODN showed a significant inhibitory effect on the growth of transplanted pancreatic cancer, resulting in a statistically significant difference compared with each alone.

CONCLUSION: It has been found that K-ras ASODN combined with IGF-IR ASODN could cooperatively inhibit the growth of Patu8988 cells, and induce their apoptosis *via* reinforcing specific down regulation of K-ras and IGF-IR mRNA and protein expression.

INTRODUCTION

Pancreatic cancer is the fatal cancer of the digestive system with the worst prognosis. The 5-year survival rate is approximately 1%-2%, and the median survival time after diagnosis ranges only 4-6 mo[1-3]. The reasons for poor prognosis include: (1) the difficulty of early diagnosis due to its anatomical location, and lack of specific early syndromes; (2) the high potential to infiltrate to the surrounding tissues and metastasize even in the early stage; and (3) the poor responsiveness to conventional treatments such as chemotherapy, radiotherapy and immunotherapy[4-6]. Surgery represents the only opportunity for possible cure, but it is restricted to early stage pancreatic cancer and most patients who undergo tumor resection show recurrence or distant metastases and die within a few years. At least, at the present time, an emphasis on early diagnosis alone may not be sufficient for significant improvement in the current poor prognosis of pancreatic cancer, which necessitates the search for novel treatment strategies to improve the prognosis.

Previous studies have demonstrated that a high percentage of pancreatic cancers harbors *K-ras* gene point mutation and overexpresses insulin-like growth factor receptor type 1 (IGF-IR)[7-11]. These alterations may together contribute to the progression and aggressiveness of pancreatic cancer from different pathways. Consequently, targeting expression of K-ras or IGF-IR has a potential value in pancreatic cancer therapy, and has led to the development of new therapeutic strategies based on the use of agents able to selectively inhibit targeted gene expression. In particular, antisense oligodeoxynucleotides (ASODNs) have proved their efficacy as targeted therapy, and are able to modulate target protein expression in pancreatic cancer studies[12-15]. In the practical application of the ASODN approach, many key problems need to be solved: selection of a single agent does not seem particularly promising because of the multigenic alterations of pancreatic cancer; finding a targeting site of *K-ras* mRNA or *IGF-IR* mRNA that is likely to be accessible to ASODNs; selection of an adaptable vector for mediating ASODNs; optimization of transfection concentration in a cell line, *etc*. Based on these considerations, we used polymerase chain reaction with special sequence primers (PCR-SSP) and sequence analysis to detect a K-ras point mutation at codon 12, and its mutation style on pancreatic cancer Patu8988 cells, designed and prepared ASODN (K-ras ASODN) specific for the K-ras point mutation at codon 12, and then combined it with strongest efficient IGF-IR ASODN designed by Resnicoff *et al*[16] to transfect pancreatic cancer Patu8988 cells with highly efficient vector Lipofectamine 2000. 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay, reverse-transcript polymerase chain reaction (RT-PCR), flow cytometry and transmission electron microscope were used to evaluate the effects of cell proliferation, apoptosis and target gene expression. Therapeutic efficacy of the combination treatment was also evaluated in xenografts.

MATERIALS AND METHODS

Cell culture

Human pancreatic cancer cell lines Patu8988 and BXPC-3 used in this study were preserved in our laboratory. The cells were grown in RPMI 1640 medium (Gibco, USA) supplemented with 10% heat-inactivated fetal bovine serum (Sijiqing, Hangzhou, China), 5 mmol/L HEPES, 100 U/mL penicillin and 100 U/mL streptomycin in 5% atmospheric CO_2 at 37℃. Cells were passaged every 3 d, checked routinely, and found to be free of contamination. When cells grew to 75% confluence, they were digested and used for *in vitro* and *in vivo* studies.

K-ras gene point mutation at condon 12 detected by PCR-SSP and sequence analysis

Genomic DNAs for Patu8988 cells and BXPC-3 cells were extracted according to the protocol. With regard to the sequences of K-ras cDNA in Genbank and the three high frequency mutation styles (CGT, GTT and GAT) at codon 12, three kinds of special sequence primers (SSP) for polymerase chain reaction were designed to detect *K-ras* gene point mutation at codon 12 for Patu8988 cells and BXPC-3 cells. Primers were as following: R1: 5'-GGTAGTTGGAGCTC-3'; R2: 5'-GTAGTTGGAGCTGT-3'; R3: 5'-GTAGTTGGAGCTGA-3'; R4: 5'-CTATTGTTGGATCATATTCG-3'. The pairing of R1-R4 amplified CGT mutation with a 89 base pair fragment; the pairing R2-R4 amplified GTT mutation with a 88 base pair fragment; the pairing R3-R4 amplified GAT mutation with a 88 base pair fragment. The amplification products were loaded on 8% acrylamide gels, and stained with ethidium bromide to detect mutation styles. In addition, *K-ras* gene was amplified from Patu8988 cells and BXPC-3 cells using RT-PCR, and the PCR products were directly sequenced.

Proliferation assay of Patu8988 cells treated with K-ras ASODN or IGF-IR ASODN alone

Based on the results of PCR-SSP and sequence analysis, the antisense phosphorothioate oligodeoxynucleotides 5'-TACGCCAACAGCTCCAAC-3' (K-ras ASODN) specific to the *K-ras* gene point mutation at codon 12 were designed and synthesized. The antisense phosphorothioate oligodeoxynucleotides 5'-TCCTCCGGAGCCAGACTT-3' (IGF-IR ASODN) specific to *IGF-IR* gene were synthesized according to the report from Resnicoff *et al*[16]. Exponentially growing Patu8988 cells at 1×10^5/well were seeded in 96-well microtiter plate, and treated with K-ras ASODN or IGF-IR ASODN mediated by Lipofectamine™ 2000 at concentration of 2-32 mg/L for 24 , 48, 72 and 96 h. The culture medium was changed every 24 h with fresh RPMI 1640 medium, which contained the same

concentration of K-ras ASODN or IGF-IR ASODN. The control cultures were left untreated at 37℃ for the same period of time, with triplicate wells for each concentration. After incubating for 24, 48, 72 and 96 h, 20 μL of 5 g/L MTT (Sigma, USA) in PBS was added to each well, followed by incubation for 4 h at 37℃. Formazan crystals were dissolved in DMSO for 15 min at 37℃. Absorbance was determined with an enzyme-linked immunosorbent assay reader at 570 nm. The cell proliferation curves were drawn according to the absorbance. The optimal concentration able to inhibit cell growth was selected for further experiments.

Proliferation assay of Patu8988 cells treated with combination of K-ras ASODN and IGF-IR ASODN

Patu8988 cells were seeded in a 96-well plate at a concentration of 1×10^5/well, and divided into three groups: (1) 16 mg/L K-ras ASODN group; (2) 16 mg/L IGF-IR ASODN group; (3)16 mg/L K-ras ASODN + 16 mg/L IGF-IR ASODN group. The cell cultures were measured for cell proliferation at different time points (0, 24, 48, 72 and 96 h after transfection) using MTT assay as described above. The cell proliferation curves were drawn according to the absorbance.

Apoptosis detection by annexin V-FITC/PI dual staining

Cells at the concentration of 1×10^5/mL were plated in 6-well plates, divided into three groups as described above. After being incubated for 48 h at 37℃, cells were harvested by trypsinization and rinsed with cold PBS twice. After centrifugation, cells were suspended by 250 μL conjugated buffer solution and then treated with 5 μL Annexin V-FITC and 10 μL propidium iodide (PI) for 15 min in the dark at room temperature. Finally, each sample was added into 300 μL of conjugated buffer solution and analyzed with flow cytometry. The experiments were performed in triplicate and the results were given as mean ± SE.

K-ras or IGF-IR protein expression detected by flow cytometry

Patu8988 cells, treated as described above, were removed from the plate by brief trypsinization with 0.25% trypsin, and then washed with PBS twice, stained with primary K-ras Ab or IGF-IR Ab, followed by FITC-conjugated goat anti-mouse IgG. After two rinses with PBS containing 2% FBS, these cells were analyzed with flow cytometry. Controls consisted of incubation with no antibodies or incubation with only the secondary antibody. The experiment was repeated three times.

K-ras or IGF-IR mRNA expression detected by semi-quantitive RT-PCR

Cells were plated in 6-well plates and performed as described above. Total cellular RNA was extracted by using Trizol Reagent (Invitrogen, USA) according to the manufacturer's instructions. The purity and concentration were determined by measuring the absorbance (A) at 260 nm and 280 nm (A_{260}/A_{280}). To generate first-strand cDNA, an oligo (dT) 18 was used as primer, and 2 μg RNA was reverse-transcribed in the light of MMLV First Strand cDNA Synthesis Kit (Fermentas, USA) protocols. Amplification of human β-actin served as an internal control. The primers used were 5'-GGACCTGACTGACTACCTC-3' (forward) and 5'-TCATACTCCTGCTTGCTG-3' (reverse). The amplification products were 540 bp. The primers for K-ras were 5'-CGCGGATCCATGACTGAATATAAACTTGTG-3' (forward) and 5'-CGCAAGCTTTTACATAATTACACACTTTGT-3' (reverse). The amplification products were 585 bp. The primers for IGF-IR were 5'-CCAAAACTGAAGCCGAGAAG-3' (forward) and 5'-TGCAGCTGTGGATATCGATG-3' (reverse). The amplification products were 300 bp. K-ras was amplified 35 cycles under the following conditions: denaturing at 94℃ for 5 min followed by 94℃ for 1 min, annealing at 51℃ for 30 s and extension at 72℃ for 1 min; the final extension was at 72℃ for 10 min. *IGF-IR* gene and β-*actin* were amplified 30 cycles under the following conditions: denaturing at 94℃ for 5 min followed by 94℃ for 1 min, annealing at 55℃ for 1 min and extension at 72℃ for 90 s; the final extension was at 72℃ for 10 min. PCR products were separated in 1.5% agarose gels, stained with ethidium bromide, and visualized by UV absorption. Densitometric scanning of the bands was performed, and the relative amount of each gene mRNA expression was estimated by normalization to the β-*actin* mRNA detected in the same sample.

Transmission electron microscopic examination

Patu8988 cells treated with the combination of K-ras ASODN and IGF-IR ASODN for 48 h were harvested, and washed in PBS. The cell pellets were prefixed in 2.5% glutaraldehyde, postfixed in 1% osmic acid, dehydrated in gradient acetone and embedded in the resin. Ultrathin sections were cut, stained with lead citrate and assessed for the morphological changes under transmission electron microscope.

Colony assays

Twenty Patu8988 cells treated with 16 mg/L K-ras ASODN, 16 mg/L IGF-IR ASODN or 16 mg/L K-ras ASODN + 16 mg/L IGF-IR ASODN were seeded in 6-well plate and cultured in 5% atmospheric CO_2 at 37℃ for 2 wk. The control was with the same volume of culture medium.

Treatment in vivo

To investigate whether the combination of K-ras ASODN with IGF-IR ASODN would alter the tumorigenicity of Patu8988, male 4-wk -old BALB/c nude mice were purchased from the Animal Center of Shanghai. 1×10^7 cells in 0.1 mL PBS were injected subcutaneously into the right flank of nude mice. Fourteen days later, 16 mice with about the same tumor size were divided into four groups randomly. Intratumoral injections were given with K-ras ASODN, IGF-IR ASODN or K-ras ASODN + IGF-IR

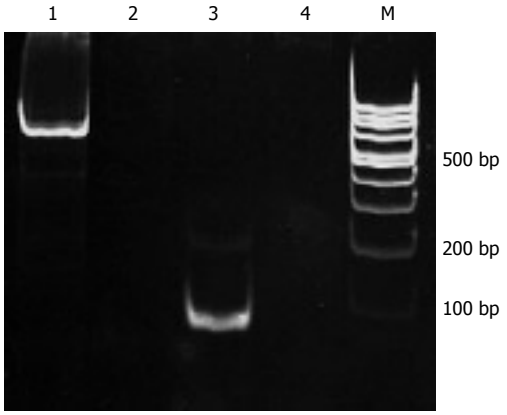

Figure 1 Detection of K-ras point mutation at 12 codon and its style in pancreatic cancer cell line Patu8988 by PCR-SSP. 1: β-actin; 2: R1-R4 pairing (CGT mutation); 3: R2-R4 pairing (GTT mutation); 4: R3-R4 pairing (GAT mutation); M: 100 bp DNA marker.

ASODN, and the control with 100 μL physiological saline. The injection was repeated every 48 h and 5 times in all. Tumor sizes were measured every 7 d and calculated by the formula: volume (mm^3) = $1/2(width)^2$ × length. After a 49-d follow-up period, mice were sacrificed. The tumors were removed, fixed by 4% polyformaldehyde, paraffin embedded and sectioned for immunohistochemical analysis.

Statistical analysis

All experiments were performed in triplicate and data were expressed as mean ± SD. Statistical analyses were conducted by one-factor analysis of variance and performed with SPSS 10.0 software. $P < 0.05$ was considered statistically significant.

RESULTS

K-ras point mutation at codon 12 of Patu8988 cell line

Detection of K-ras point mutation at codon 12 in the pancreatic cancer cell line Patu8988 is shown as Figure 1. The pairing R2-R4 had the amplification product of GTT mutation with an 88 bp fragment. But, the pairings of R1-R4 and R3-R4 had no amplification product of any mutation. Therefore, K-ras point mutation at codon 12 was found in pancreatic cancer cell line Patu8988, and the mutation style was GTT; no other mutation styles were found. For wild type pancreatic cancer cell line BXPC-3, no amplification products were found in pairings of R1-R4, R2-R4 and R3-R4. The direct sequencing results were consistent with the results from the PCR-SSP (Figure 2).

Inhibition of Patu8988 cell proliferation by K-ras ASODN and IGF-IR ASODN alone or combination

As shown in Figure 3A and B, when Patu8988 cells were exposed to K-ras ASODN and IGF-IR ASODN respectively, the growth of the cells was suppressed as compared to untreated cells ($P < 0.01$) except at the concentration of 2 mg/L. Moreover, when cells were exposed to different doses of K-ras ASODN

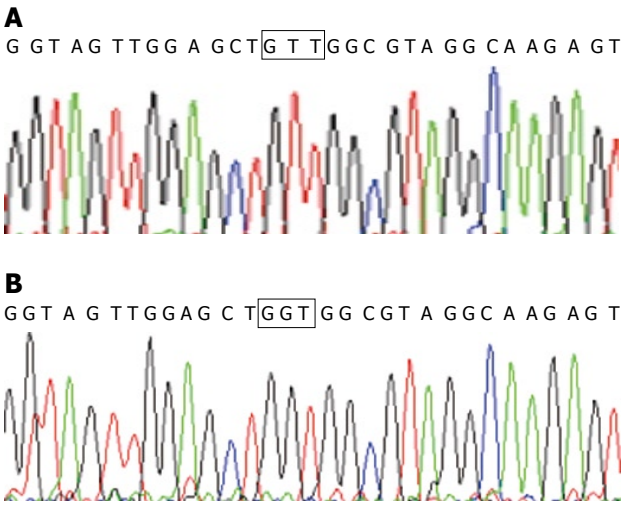

Figure 2 Sequence analysis of pancreatic cancer cell line Patu8988 (**A**) and BXCP-3 (**B**). Patu8988 had K-ras point mutation at codon 12 and its style was GGT→GTT (indicated in the square). BXCP-3 was a *K-ras* gene wild type cell line with normal GGT at codon 12; No other mutation styles were found.

and IGF-IR ASODN individually, growth inhibition was dose dependent: obvious inhibition was seen at the concentration of 16 mg/L, and the greatest effect was seen at a concentration of 32 mg/L. However, no statistical significance was found between 16 mg/L and 32 mg/L ($P > 0.05$). So, combination treatment with 16 mg/L K-ras ASODN and 16 mg/L IGF-IR ASODN was employed, and the ASODNs were transfected into Patu8988 cells for 24, 48, 72 and 96 h. Patu8988 cell growth was inhibited at a significantly higher rate in the combination treatment than that in K-ras ASODN or IGF-IR ASODN alone at different transfection times ($P < 0.01$) (Figure 3C). The inhibition peak was reached at 48 h. Subsequently, the inhibition ability wore off, and the tumor cells recovered proliferation. Further experiments were conducted to assess the combined effects on the expression of K-ras or IGF-IR mRNA and protein, apoptosis, clone formation and tumor growth inhibition *in vivo* with the combination treatment of 16 mg/L K-ras ASODN and 16 mg/L IGF-IR ASODN at 37℃ for 48 h.

Inhibition of colony formation by K-ras ASODN and IGF-IR ASODN alone or combination

Patu8988 cell proliferation treated in different groups was analyzed by soft agar colony formation assays. The average numbers of colonies in the control, K-ras ASODN, IGF-IR ASODN and combination group were 18.8, 11, 12 and 3, respectively. The Patu8988 cells in the combination groups formed significantly fewer colonies (6 fold decrease) in soft agar than those in the control groups did ($P < 0.05$ *vs* control). However, there were no statistical differences between K-ras ASODN groups and IGF-IR ASODN groups, although the number of colonies of IGF-IR ASODN groups was a little larger than those of K-ras ASODN groups ($P > 0.05$). At the same time, we noticed that the size of most of the colonies in the combination groups were much smaller than those in the control groups.

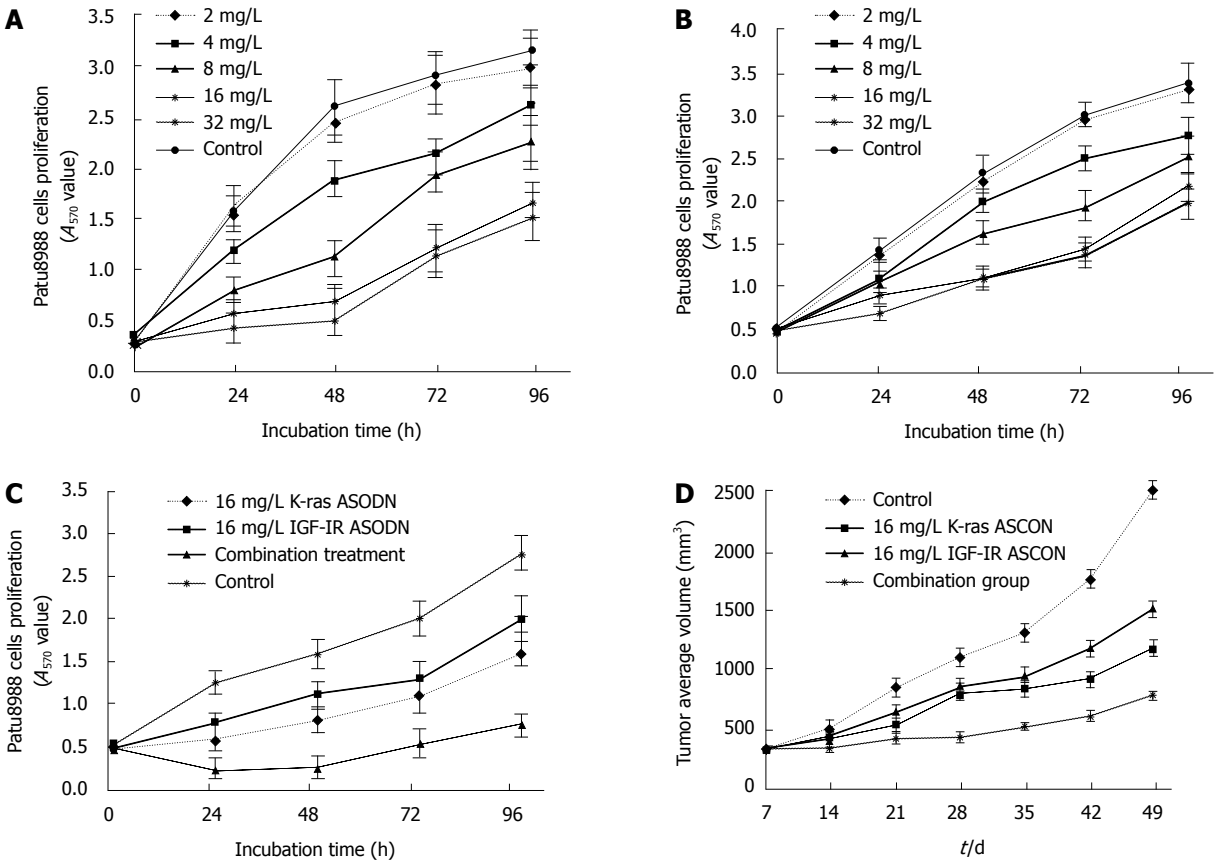

Figure 3 Each value represents the mean ± SD from triplicate determinations. **A**: Growth curves of Patu8988 cells treated with different concentrations of K-ras ASODN at different incubation times; **B**: Growth curves of Patu8988 cells treated with different concentrations of IGF-IR ASODN at different incubation times; **C**: Growth curves of Patu8988 cells treated with the combination treatment of 16 mg/L K-ras ASODN and 16 mg/L IGF-IR ASODN at different incubation times; **D**: The inhibition effect of the combination treatment with K-ras ASODN and IGF-IR ASODN on tumor growth in nude mice.

Table 1 Protein expression for K-ras and IGF-IR on Patu8988 cells detected by flow cytometry (%)

Groups	Positive rate	
	K-ras protein	IGF-IR protein
K-ras ASODN	25.95 ± 0.18[b]	85.25 ± 0.99
IGF-IR ASODN	69.18 ± 0.87	40.78 ± 1.42[b]
Combination	19.69 ± 1.15[b]	38.25 ± 1.22[b]
Control	76.15 ± 1.62	91.53 ± 1.62

All values are presented as mean ± SD of triplicate determinations. [b]$P < 0.01$ *vs* control group.

Apoptotic influence of Patu8988 cells treated with combination treatment of K-ras ASODN and IGF-IR ASODN

To further confirm the occurrence of apoptosis, we subjected the ASODNs-treated cells (48 h of ASODNs exposure) to annexin V-FITC/PI dual staining followed by flow cytometry analyses. The ratios of apoptosis cells were 21.54% ± 0.93%, 12.76% ± 0.74%, 8.43% ± 0.51% and 1.60% ± 0.19% in combination group, K-ras ASODN group, IGF-IR group and control group, respectively. Compared with the control group, statistically significant differences were observed ($P < 0.01$). The apoptotic rate of combination group was significantly higher than that of K-ras ASODN group alone or IGF-IR ASODN alone ($P < 0.05$). No difference existed between K-ras ASODN group and IGF-IR group ($P > 0.05$) (Figure 4).

K-ras and IGF-IR protein expression of Patu8988 cells detected by flow cytometry

Flow cytometry, results showed that the positive rate of K-ras protein was 76.15% ± 1.62% and 69.18% ± 0.87% in control group and IGF-ASODN group, respectively. No statistical difference was found between the two groups ($P > 0.05$). But, in K-ras ASODN group and the combination group, K-ras protein was significantly decreased by 25.95% ± 0.18% and 19.69% ± 1.15%, respectively, compared with that of control group ($P < 0.01$). Flow cytometric analysis by using IGF-IR antibody showed that there was high expression in K-ras ASODN group, and control group with a positive rate of 91.53% ± 1.62% and 85.25% ± 0.99%, respectively. But, in IGF-IR ASODN, and combination group, IGF-IR protein expression was reduced to 40.78% ± 1.42% and 38.25% ± 1.22%, respectively. Significant differences were found when compared with control group ($P < 0.01$). All above results revealed that antisense oligodeoxynucleotides can inhibit corresponding protein expression. But, K-ras ASODN can not obviously inhibit the expression of IGF-IR protein, and IGF-IR ASODN can not obviously inhibit the expression of K-ras protein (Table 1).

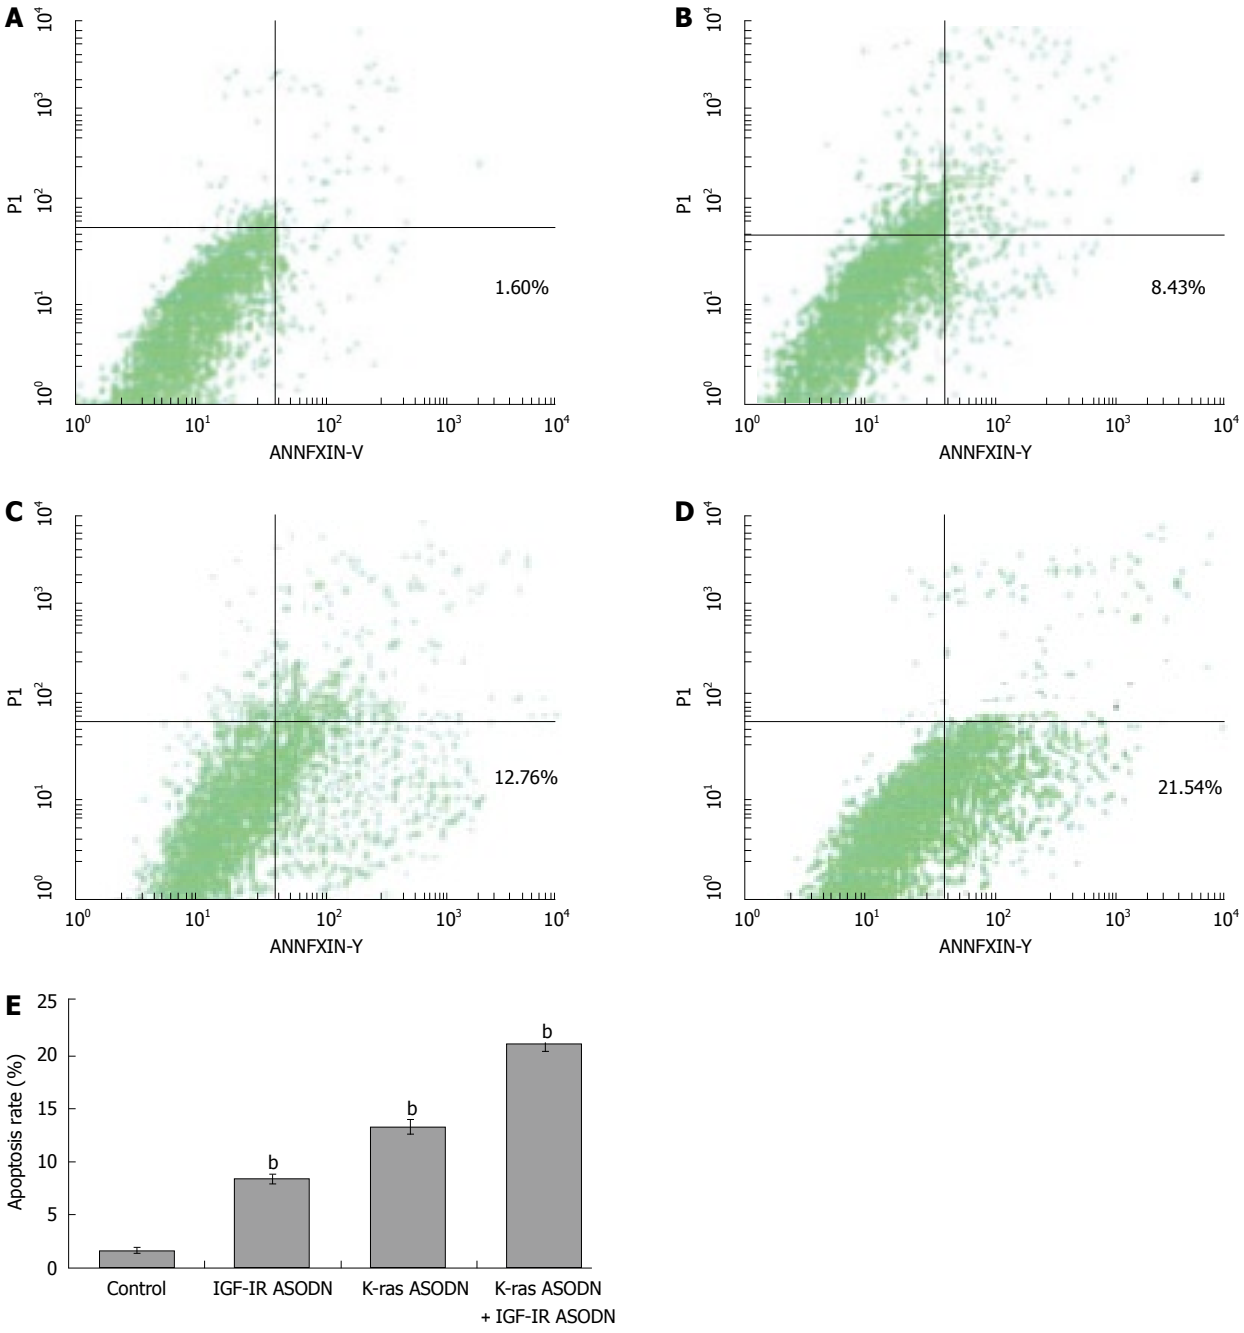

Figure 4 Apoptosis of Patu8988 cells detected by flow cytometry with Annexin V-FITC dual staining. **A**: Control group; **B**: IGF-IR ASODN group; **C**: K-ras ASODN group; **D**: K-ras ASODN + IGF-IR ASODN group; **E**: Apoptosis rate of Patu8988 cells for different groups. $^{b}P < 0.01$, *vs* control group. Each value represents the mean ± SD from triplicate determinations.

K-ras and IGF-IR mRNA expression of Patu8988 cells detected by RT-PCR

The mRNA expression intensities of *K-ras* gene and *IGF-IR* gene were analyzed by semiquantitive RT-PCR. The mRNA levels were normalized by internal control β-actin. At 48 h post-transfection, *K-ras* mRNA intensity levels were 0.389 ± 0.018 for IGF-IR ASODN group, 0.213 ± 0.027 for K-ras ASODN + IGF-IR ASODN group, 0.275 ± 0.023 for K-ras ASODN group and 0.391 ± 0.021 for control group. The statistical analysis showed that *K-ras* mRNAs of Patu8988 cells in K-ras ASODN group, and combination group were reduced significantly, compared with that of control group ($P < 0.05$). The inhibition rate reached 45.5% in the combination group. IFG-IR ASODN had no significant inhibitory effect on the expression of K-ras mRNA ($P > 0.05$, *vs* control) (Figure 5). As for *IGF-IR* gene, the relative mRNA levels were 0.642 ± 0.017 for *K-ras* ASODN, 0.355 ± 0.020 for the combination group, 0.387 ± 0.025 for IGF-IR ASODN group, and 0.630 ± 0.029 for control group. The statistical analysis showed that both IGF-IR ASODN group, and combination group could have a significant down-regulation effect on the mRNA expression of *IGF-IR* in Patu8988 cells ($P < 0.05$, *vs* control). The inhibition rate was 43.7% in the combination group. However, K-ras ASODN showed

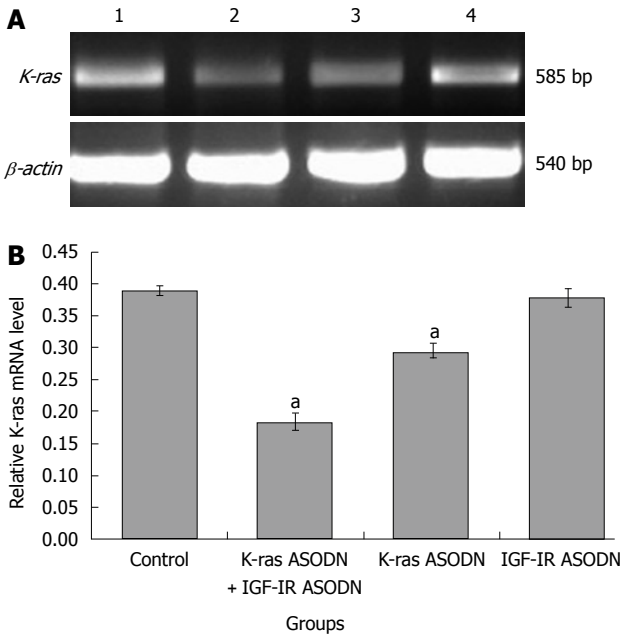

Figure 5 mRNA expression of *K-ras* gene in Patu8988 cells at 48 h post-transfection. **A**: RT-PCR analysis for *K-ras* gene in different groups. The *β-actin* gene was included as internal control. 1: IGF-IR ASODN group; 2: K-ras ASODN + IGF-IR ASODN; 3: K-ras ASODN group; 4: Control group; **B**: K-ras products quantified relative to the internal control β-actin. $^aP < 0.05$, *vs* control. Each value represents the mean ± SD from triplicate determinations.

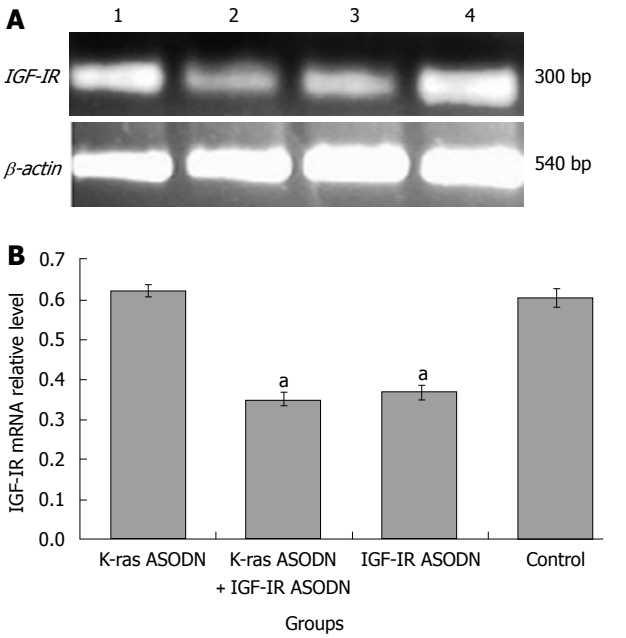

Figure 6 mRNA expression of *IGF-IR* gene in Patu8988 cells at 48 h post-transfection. **A**: RT-PCR analysis for *IGF-IR* gene in different groups. The β-*actin* gene was included as internal control. 1: K-ras ASODN group; 2: K-ras ASODN + IGF-IR ASODN; 3: IGF-IR ASODN group; 4: Control group; **B**: IGF-IR products quantified relative to the internal control β-actin. $^aP < 0.05$ *vs* control. Each value represents the mean ± SD from triplicate determinations.

no obvious inhibition for *IGF-IR* mRNA expression ($P > 0.05$ *vs* control) (Figure 6).

Inhibition of in vivo tumor growth by K-ras and IGF-IR downregulation

All nude mice were bearing pancreatic tumors from 7 to 10 d, and survived during the therapy with no red swelling, and disruption at the inoculation point. Before therapy, there were no significant difference for nude mice in weight and volume. As shown in Figure 3D, the tumor volume increased gradually in control group. The long diameter reached above 1.0 cm, and the volume reached 2230.0 ± 65.6 mm^3 on the 49th d after inoculation. The tumor growth in K-ras ASODN group, IGF-IR ASODN group and combined group was inhibited with significant difference when compared with control group ($P < 0.01$). The therapeutic effect in the combined group was greater than that of K-ras ASODN or IGF-IR ASODN alone ($P < 0.01$). These results indicated that combination group exerted a strong growth-suppressive effect on pancreatic cancer. However, between K-ras ASODN and IGF-IR ASODN group, there was no obvious difference ($P > 0.05$). The results of immunohistochemical showed that K-ras and IGF-IR protein expression decreased in tumor tissues (data not shown).

Morphologic change under transmission electron microscopy

Using transmission electron microscope, we saw that the normal Patu8988 cells had intact cell membranes and nuclear membranes, distributed nuclear chromosomes, distinct organelles, big nuclei and excessive nuclear division, which indicated that Patu8988 cells were highly malignant (Figure 7A). When Patu8988 cells were treated with K-ras ASODN combined with IGF-IR ASODN for 48 h, changes such as apoptosis, cell shrinkage, separation from neighboring cells, plasma condensation, plasma vacuolation, karyopyknosis, margination of condensed chromatin and membrane-bounded apoptotic bodies were observed (Figure 7B); some cells exhibited distinct deformation and disruption (Figure 7C).

DISCUSSION

The rapid development of molecular techniques has made it clear that tumorigenesis is actually a process of gene abnormalities. The strong invasiveness and rapid diffusive ability of pancreatic cancer are also closely associated with gene abnormalities. The study results of many years show that many genes' cooperation and many factors' participation contribute to the development of pancreatic cancer. Gene therapy brings hope for patients of pancreatic cancer. But, single gene therapy does not achieve ideal results. If two or more genes are combined to treat pancreatic cancer, in theory therapeutic effects will be better.

Since Almoguera *et al*[17] first reported that K-ras mutation occurred in patients with pancreatic cancer, 85%-95% patients with pancreatic cancer have been found to have K-ras mutation, and most of these were point mutations at codon 12. Among those point mutations, GAT, GTT and CGT mutation styles comprised more than 95% of the point mutations at

codon 12[18]. Therefore, K-ras point mutation at codon 12 is an early event for pancreatic cancer, which can be used as a target for early diagnosis and gene therapy[19,20]. *K-ras* gene mutation destroys the GTP enzyme activity of ras protein and makes K-ras active constantly, which makes K-ras protein unable to block signals for growth. Recently, K-ras antisense oligodeoxynucleotids (ASODNs) have been transfected into pancreatic cells in China and abroad. Wang *et al*[21] first detected and confirmed *K-ras* gene mutation type CGT in human pancreatic carcinoma cell line PC-2. Then, K-ras mutation ASODN specific to CGT at codon 12 was used to explore its inhibitory effects on target gene in cell line PC-2. The results show that ASODN specific to K-ras point mutation CGT had significant inhibitory effects on target gene expression in human pancreatic carcinoma cells *in vitro*. Nakada *et al*[22] used ASODN specific to K-ras point mutation GAT at codon 12 to transfect into human pancreatic cancer cell line PANC-1 (with GAT mutation at codon 12), and the invasive activity was investigated using *in vitro* chemoinvasion assay. The results show that K-ras mutation ASODN specific to GAT at codon 12 strongly inhibited the invasive activity of the cell line PANC-1, but not in that with a wild type K-ras (BxPC-3). So, ASODNs specific to mutated *K-ras* genes can inhibit the proliferation and invasiveness of human pancreatic cancer cell lines. Specific antisense therapy to the point mutation of K-ras might be a new anticancer strategy for pancreatic cancer. However, these studies also indicate that adopting K-ras ASODN alone could not eradicate all the tumor cells. For exploring more effective therapy methods, some scholars abroad recently started to explore therapeutic alliance with diverse antisense oligodeoxynucleotides to treat pancreatic cancer, such as simultaneous transfection with mda-7 ASODN and K-ras ASODN into pancreatic cancer *in vitro* and *in vivo*. The results of their studies showed that the therapeutic effects of combination methods were better than that of one alone[23,24].

IGF-IR is a receptor protein tyrosine kinase (RPTK) expressed in a wide variety of cell types including mesenchymal, epithelial, and hematopoietic cells. The receptor is a transmembrane heterotetramer consisting of two α-subunits and two β-subunits linked by disulfide bonds. The binding of IGF-I to its receptor results in receptor oligomerization, activation of PTK, inter-molecular receptor autophosphorylation and phosphorylation of cellular substrates that consequently lead to gene activation, DNA synthesis and cell proliferation. Overexpression of IGF-IR stimulated cells not only to transform toward malignance and sustain malignant phenotype, but also to promote tumor cells' anti-apoptosis, mitosis, proliferation and invasiveness. Min *et al*[10] reported that IGF-IR overexpressed in pancreatic cancer and down-regulation of IGF-IR expression using monoclonal antibodies or antisense oligodeoxynucleotides could inhibit tumor cell growth both *in vitro* and *in vivo*[25-27]. However, the inhibition ratio was not high[24].

Considering the important effects of *K-ras* gene point mutation at codon 12 in pancreatic cancer and the broad tumorigenesis of *IGF-IR* gene, our study explored the effects of Patu8988 cell proliferation, apoptosis and target gene expression using combined antisenses with K-ras ASODN against K-ras point mutation at codon 12 and IGF-IR ASODN against insulin-like growth factor-1. We noticed that different doses for K-ras ASODN or IGF-IR ASODN could inhibit Patu8988 cell growth. But, combinations could produce greater effects ($P < 0.01$). The results were also confirmed in animal experiments. Compared with the single method, combination could obviously induce Patu8988 cell apoptosis, and reduce protein and mRNA expression of K-ras and IGF-IR. In our study, the inhibition effects of K-ras ASODN were better than that of IGF-IR ASODN. Ras protein is not only one of the signal pathways of IGF-IR, but also the pathway for many other growth factors, such as VEGF. Therefore, mutated ras protein not only amplifies the IGF-IR signal, but also amplifies signals for many other growth factors to inhibit cell apoptosis, and also induces vascular growth and cell proliferation. IGF-IR ASODN can inhibit only IGF-IR signal. But, K-ras ASODN can inhibit signals for many factors. Therefore, the inhibition effects of K-ras ASODN was better than that of IGF-IR ASODN. So, combined therapy can inhibit signals on two sides. After being treated with K-ras ASODN and IGF-IR ASODN together, some cells appeared in the

form of apoptosis, some others in the shape of edema or deformation, which indicated that antisense not only induced apoptosis, but also promoted cell death directly.

Our study shows that K-ras ASODN combined with IGF-ASODN obviously inhibited Patu8988 cell growth, and induced cell apoptosis and death. The mechanism may be associated with the inhibition of mRNA, and protein expression of K-ras and IGF-IR in Patu8988 cells. Cooperation with two synergistic antisense oligodeoxynucleotides could provide a new gene therapeutic strategy against pancreatic cancer. Meanwhile, the results of our study show that K-ras ASODN and IGF-IR ASODN inhibited tumor growth alone or in combination. However, a rapid cell proliferation tendency was seen in later stage of combined therapy. We speculated that this phenomenon might be associated with the degradation of ASODN in the late stage of treatment. We need to do further study to learn the relationship between dose-effect and time-effect. On the other hand, the development of pancreatic cancer involves many genes; we can not inhibit tumor growth completely by suppressing two genes of *K-ras* and *IGF-IR*, only partial.

COMMENTS

Background

Pancreatic carcinoma is the cancer that has the highest *K-ras* gene mutation rate. 95% of mutations happen at codon 12. Three major mutation types have been reported, including CGT, GAT and GTT. Antisense oligodeoxynucleotides (ASODNs) specific to CGT and GAT point mutations in human pancreatic cancer cell lines were reported; the ASODN against GTT point mutation in pancreatic cancer remains unclear. Some studies reported that type I insulin-like growth factor receptor (IGF-IR) is overexpressed in pancreatic cancer and down-regulation of IGF-IR expression using ASODNs could inhibit tumor cell growth. In this article, whether K-ras ASODN specific to GTT mutation in alliance with IGF-IR ASODN regulate Patu8988 proliferation, apoptosis, target gene expression *in vitro* and *in vivo* was investigated.

Research frontiers

In previous studies, antisense oligodeoxynucleotides (ASODNs) specific to CGT and GAT point mutation of *K-ras* gene were demonstrated to inhibit proliferation in pancreatic cancer.

Innovations and breakthroughs

It was found in the present study that K-ras ASODN combined with IGF-IR ASODN could cooperatively inhibit the growth of Patu8988 cells and induce their apoptosis via reinforcing specific down regulation of *K-ras* and *IGF-IR* mRNA and protein expression.

Applications

Cooperation with two synergistic antisense oligodeoxynucleotides could provide a new gene therapeutic strategy against pancreatic cancer.

Terminology

PCR-SSP is polymerase chain reaction with special sequence primers; K-ras ASODN is an antisense oligodeoxynucleotide against *K-ras* gene; IGF-IR ASODN is an antisense oligodeoxynucleotide against *IGF-IR* gene; GAT, CGT and GGT are three major point mutation types at codon 12 of *K-ras* gene.

Peer review

This is an interesting study that identifies molecular pathways that may be therapeutically targeted to inhibit pancreatic cancer growth.

Abstract

AIM: To investigate the role of phosphatidylinositol 3-kinase (PI 3-K)/Akt signaling pathway in the balance of HSC activation and apoptosis in rat hepatic stellate cells (HSC).

METHODS: An activated HSC cell line was used in this study. LY 294002, the PI 3-K/Akt signal pathway blocker was used to investigate the molecular events on apoptosis in HSC and to interpret the role of this pathway in HSC apoptosis. Immunocytochemistry, Western blot and reverse transcription polymerase chain reaction (RT-PCR) analysis were applied to detect the expression of PI 3-K, and simultaneously phosphorylated-Akt (p-Akt) and total-Akt were determined by Western blot. The HSC apoptosis was examined by annexin-V/propidium iodide double-labelled flow cytometry and transmission electron microscopy.

RESULTS: The apoptosis rates in LY 294002 (30.82% ± 2.90%) and LY 294002 + PDGF-BB (28.16% ± 2.58%) groups were significantly increased compared with those of control (9.02% ± 1.81%) and PDGF-BB (4.35% ± 1.18%). PDGF-BB augmented PI 3-K and p-Akt expression. LY 294002 significantly reduced the contents of PI 3-K and p-Akt. mRNA transcription evaluated by RT-PCR showed similar tendencies as protein expression.

CONCLUSION: Inhibition of PI 3-K/Akt signaling pathway induces apoptosis in HSC.

INTRODUCTION

The activation and proliferation of hepatic stellate cells (HSC) is a key event in fibrogenesis. On the other hand, HSC apoptosis results in fibrolysis and fibrotic regression[1-3]. Therefore, by understanding pro- and anti-apoptogenic factors, new therapeutic targets will be identified for the treatment of liver fibrosis. However, intracellular signals that regulate HSC apoptosis are still obscure. Our previous study has demonstrated that a cross talk between platelet-derived growth factor (PDGF), the most potent proliferative cytokines for HSC, and focal adhesive kinase (FAK), a nonreceptor tyrosine kinase, is involved in an integrin signaling pathway[4-6]. This interaction is essential for PDGF to induce HSC proliferation[7].

Phosphatidylinositol 3-kinase (PI 3-K)/Akt signaling molecules, which are downstream of FAK, are also activated by PDGF. The activated PI 3-K/Akt participate in regulation of HSC migration, proliferation, collagen secretion and adhesion[5]. PI 3-K is involved in regulating a number of cellular responses, such as cell growth, survival and migration. Akt, a serine/threonine kinase, is downstream of PI 3-K and an important anti-apoptotic factor. The purpose of the present study was to determine the effects and the molecular mechanisms whereby PI 3K/Akt influence apoptosis in HSC.

MATERIALS AND METHODS

Reagents and instruments

RPMI 1640 culture medium was obtained from Gibco (Invitrogen Corporation Carlsbad, California USA), fetal

bovine serum (FBS) from Sijiqing Company of Bio-products (Hangzhou, China) and LY 294002 from Sigma (Saint Louis, Missouri USA). Rat PDGF-BB was from Cytolab Biochemicals (Rehovot, Israel USA). Rabbit anti-phospho-Ser^{473} Akt polyclonal antibody and rabbit anti-PI 3-K p85α polyclonal antibody were from Santa Cruz Biotechnology (Santa Cruz, CA. USA). Rabbit anti-total Akt polyclonal antibody was purchased from Cell Signaling Biotechnology (Beverly, MA USA). RT-PCR amplification system was from Promega (Madison, WI USA). Annexin-V/Propidium iodide double-labelled flow cytometry kit was purchased from Baosai Company of Bio-products (Beijing, China). CO_2 incubator was from SANYO Company (Chatsworth, CA Japan). Flow cytometer type FACS-420 was purchased from Becton Dickinson Company (Franklin Lakes, NJ USA).

Cell line and cell culture

The activated HSC phenotype, from CCl_4 induced cirrhotic liver, was provided by Professor Greenwel (USA). This cell line is similar to that of primary cultured HSC except for absent expression of collagen type Ⅳ[8]. HSC was cultured in RPMI 1640 media supplemented with 10% FBS, penicillin (100 IU/mL)/streptomycin (100 μg/mL), and glutamine (4 mmol/L) in a 95% air and 5% CO_2 humidified atmosphere. Cell viability was determined by trypan blue exclusion staining. When exponential growing HSC populations were found to be nearly 100% confluence, HSC (2×10^5/mL) was incubated in serum free media for 24 h and then split into four groups: control, PDGF-BB (PDGF 20 ng/mL), PDGF-BB + LY 294002 group (LY 294002 50 μmol/L, PDGF-BB 20 ng/mL) and LY 294002 (LY 294002 50 μmol/L). Activated HSC was serum-starved for 24 h, and then treated as described above. One set of the cells was harvested for 4 h later for mRNA transcription and protein expression assay. The same set of cells was harvested 20 h later for electron microscopic examination, flow cytometric analysis and immunostaining.

Electron microscopic study

The cultured HSC of the four groups were collected, digested, washed with phosphate buffered solution (PBS), fixed with 4% glutaraldehyde for 2 h, and then fixed with osmium tetroxide for 1 h, stained with uranium acetate, embedded into 6.8# epoxide resin, after sectioning into ultra-thin slices, the cells were stained with lead citrate and examined under transmission electron microscopy.

Flow cytometric analysis

Four groups of HSC were collected, washed with pre-cooled PBS twice, fixed with cold 70% ethanol, digested with 50 μg/mL RNase at 37℃, and stained with 65 μg/mL propidium iodide at 4℃ for 1 h, and then the flow cytometric analysis was conducted. 10^4 cells were used in apoptotic analyses. Avian red blood cells were used as control. The variation coefficient (CV) of the assay was less than three percent. The data collected were analyzed in a computer (type HP-300 Consort 30), and analyzed with Histogram Statistics software.

RT-PCR

Total RNA from cultured HSC was extracted by the Trizol method. After RT (41℃, 45 min) and pre-denaturation (94℃, 2 min), PCR amplification was carried out for 35 cycles. The primers, as designed according to GenBank, were as follows: PI 3-K p85: sense 5'-CCCAGGAGCGGTACAGCAAAGAA-3', antisense 5'-TGGGGCAAATCCTCATCATCTTC-3'; β-actin: sense 5'-ACAGAGTACTTGCGCTCAGGAG-3', antisense 5'-GTCACCCACACTGTGCCCATCT-3'. The initial reaction mixture contained 1 μmol/L primers, AMV reverse transcriptase, RNA Tfl DNA polymerase and 25 mmol/L $MgSO_4$. Total volume was 50 μL. The amplicon lengths of the PCR products were: PI 3-K p85 355 bp and β-actin 585 bp. Denaturation (94℃ for 40 s), annealing (52℃ for 1 min), and extension (72℃ for 1.5 min). PCR products were analyzed by electrophoresis in a 1.5% agarose gel. β-actin amplification was used as internal control.

Immunostaining

Cultured cells were seeded onto glass coverslips and allowed to adhere for 20 h under routine culture conditions. After incubation, cells were washed twice with cold PBS, fixed and permeabilized by cold methanol for 8 min, and coverslips were then air-dried at room temperature. Immunostaining was performed using the SP kit according to the instructions of the manufacturer. Briefly, HSC was washed with washing buffer (0.2% Tween PBS), incubated with peroxidase-blocking reagent and normal goat serum. After rinsing, coverslips were incubated with primary antibodies (rabbit anti-phospho-Ser^{473}, Akt polyclonal antibody (1:100) and rabbit anti-PI 3-K p85α polyclonal antibody (1:50) at room temperature for 12 h. After rinsing primary antibody with washing buffer, horseradish peroxidase-conjugated goat anti-rabbit IgG antibody was added, and incubated at 37℃ for 30 min. Following rinsing with washing buffer, 3,3-diamino benzidine/enhancer (DAB) solution was added and incubated at room temperature for 5 min. After washing, the coverslips were counterstained with hematoxylin for 1 min, rinsed with water and dried for 10 min. The slides were dehydrated with 100% ethanol for 20 s twice, and finally with xylene for 20 s. The coverslips were mounted onto glass slices and viewed under microscopy.

Western blot analysis of PI 3-K, Akt and p-Akt

Cultured HSC was washed with PBS and lysed with protein sample buffer (50 mmol/L Tris-HCl pH 7.5, 150 mmol/L NaCl, 0.5% sodium deoxycholate, 1% NP-40, 0.1% SDS, 1 mmol/L EDTA, 1 mmol/L phenylmethyl sulfonylfluoride, and 2 mg/L leupeptin). The protein concentrations were measured using Coomassie brilliant blue chromatometry. Equal amounts (100 μg) of the denatured proteins per lane were loaded and separated on sodium dodecyl sulfate-10% polyacrylamide gels for p-Akt (Ser^{473}), Akt and β-actin, and 8% SDS-polyacrylamide gels for PI 3-K. After electrophoresis, proteins were

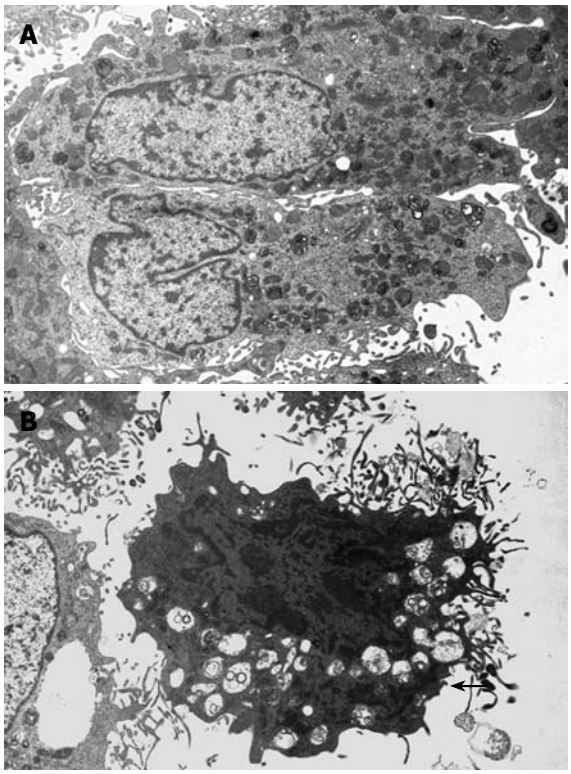

Figure 1 Transmission electron micrography of cultured HSC. **A**: Control HSC showing nuclear is intact and the mitochondria is smooth; **B**: LY 294002 treated HSC: Chromatins condensed, shrunk and aggregated along inside the nuclear membrane. The arrows points at the apoptotic bodies (× 5000).

transferred to nitrocellulose. The membranes were blocked for 12 h with 5% powdered skim milk in Tris-HCl-buffered saline containing 0.05% Tween 20 (TBS-T). After washed with TBS-T for three times, the membranes were incubated with horseradish peroxidase-conjugated goat anti-rabbit IgG antibody (1:3000). After washing 5 times, the blots were detected with the enhanced chemiluminescence method (ECL) assay.

Statistical analysis

Results were expressed as mean ± SD. Statistical analysis was performed by one-way ANOVA, and, when the *F* value was significant, by Student-Newman-Keuls test. *P* value less than 0.05 was considered statistically significant.

RESULTS

LY 294002 induces apoptosis in rat HSC

Under the transmission electron microscopy (Figure 1), the cells in LY 294002 and LY 294002 + PDGF-BB groups showed condensed chromatin, shrunk and aggregated along inside the nuclear membrane. The morphology of the cells showed spherical, petal or crescent shape, apoptotic bodies were found in some cells, while in control and PDGF-BB groups, HSC revealed normal silhouettes.

As listed in Table 1, the apoptotic rates in LY 294002 and LY 294002 + PDGF-BB groups were significantly increased compared with that of control group (30.82% ± 2.90%, 28.16% ± 2.58% and 9.02% ± 1.81%, respectively; $P < 0.01$). There was no significant difference between LY 294002 and LY 294002 + PDGF-BB groups ($P = 0.12$).

Table 1 Apoptosis induction of PDGF-activated HSC by LY 294002 (mean ± SD)

Groups	Apoptotic rate of HSC
Control	9.02 ± 1.81
PDGF-BB	4.35 ± 1.18[a]
PDGF-BB + LY 294002	28.16 ± 2.58[b]
LY 294002	30.82 ± 2.90[b]

[a]$P = 0.005$ *vs* control group; [b]$P < 0.0001$ *vs* control group.

Table 2 Protein expression of PI3K and p-Akt by immunocytochemistry (mean ± SD)

Groups	p-Akt (%)	PI3K (%)
Control	33.65 ± 1.90	35.82 ± 1.87
PDGF-BB	58.86 ± 1.89[a]	60.85 ± 1.75[a]
LY294002 + PDGF-BB	24.24 ± 0.84[a]	25.18 ± 1.05[a]

[a]$P < 0.0001$ *vs* control group.

PDGF-induced HSC activation abolished by LY 294002

PI 3-K assay: PDGF-BB could significantly increase PI 3-K expression in rat HSC. LY 294002 not only decreased the PI 3-K positive cells in control group, but also reduced PI 3-K content in PDGF-BB activated cells (Figure 2 and Table 2). These immunocytochemical results were supported by Western blots: the band density in PDGF-BB group was the strongest. LY 294002 not only decreased the PI 3-K expression in control cells, but also decreased the protein content in PDGF-BB activated cells (Figure 3). The effects of LY 294002 were reflected not only by the protein expression levels, but also by mRNA transcription (Figure 4).

Akt assay: Immunocytochemistry showed that p-Akt expression was parallel with PI 3-K: PDGF-BB stimulated p-Akt protein expression, while LY 294002 not only inhibited p-Akt concentration in control group, but also abolished PDGF stimulated p-Akt expression (Figure 2 and Table 2). Western blots showed the same pattern as immunocytochemistry for p-Akt. Noticeably, the total Akt levels assessed by Western blotting revealed no change in all four groups (Figure 5).

All the results above showed that PDGF activated the whole PI 3-K/Akt/p-Akt, pathway, while LY 294002 decreased the entire pathway activity not only in control cells, but also in PDGF stimulated circumstances.

DISCUSSION

It is activation of HSC that initiates liver fibrosis, and regardless of the etiology, is the final pathway is to activate HSC. The activated HSC is proliferative, fibrogenic,

and contractile myofibroblasts[5,9]. The proliferation and apoptosis of HSC keep balance in physiological situation. Once this equilibrium is broken under chronic injury, continuing HSC proliferation and collagen secretion will cause fibrosis[10]. Therefore, inhibiting the proliferation of HSC and inducing its apoptosis are two ways to delay or stop fibrogenesis. PI 3-K and Akt are two molecules that stimulate HSC proliferation[1,2].

PI 3-K is comprised of an 85-kDa regulatory subunit, and a catalytic 110-kDa subunit. Activated by growth factors such as PDGF and insulin-like growth factor (IGF), PI 3-K catalyzes the phosphorylation of phosphatidylinositol (PI) at the 3-OH position to generate phosphatidylinositol triphosphate (PIP3). Activated growth factor receptor migrates to the cellular membrane, and this results in PI 3-K activation, that later combines with its substrates. Akt, a serine/threonine kinase, is also known as protein kinase B (PKB). Three isoforms have been identified thus far in the mammalian cells: Akt1/PKBα, Akt2/PKBβ, and Akt3/PKBγ. The three isoforms have similar phosphorylation sites. One is in the N-terminal Thr^{308}. And the other in the COOH-terminal hydrophobic motif Ser^{473}. The phosphorylation of both sites is necessary for full activity. Activated PI 3-K/Akt signaling inhibits apoptosis, and stimulates cell proliferation, migration, survival as well as other biological behaviours[11].

Among the three PDGF isoforms, PDGF-AA, PDGF-BB and PDGF-AB, PDGF-BB has been identified as the most potent mitogen for HSC[7,12]. Liver

fibrosis is associated with an increase in PDGF protein expression and increased PDGF receptor expression. PDGF receptors have intrinsic tyrosine kinase activity and upon binding to its ligand, PDGF receptors can phosphorylate itself at tyrosine residues. In cultured human HSC, PDGF can activate PI 3-K which is necessary for both mitogenesis and chemotaxis[13-15]. This pathway is up-regulated during liver injury *in vivo*. Wortmannin and LY 294002, two specific PI 3-K inhibitors, can both dose-dependently block PI 3-K activity induced by PDGF and inhibit DNA synthesis[16].

Our immunocytochemistry in the present study found that PI 3-K and p-Akt were mainly in HSC cytoplasm. Immunocytochemistry, Western blot and RT-PCR demonstrated that PDGF-BB can significantly stimulate PI 3-K and p-Akt productions in both mRNA transcription (PI 3-K) and protein expression levels, LY 294002 not only reduced PI 3-K and p-Akt contents in control group, but also reduced PDGF stimulated PI 3-K expression and Akt phosphorylation. There was no significant difference between the groups of LY 294002 only and LY 294002 + PDGF. This means that LY 294002 can abolish the simulatory effect of PDGF. Our results also showed that there was no significant difference of total-Akt levels among four groups, indicating that instead of total Akt syntheses, LY 294002 mainly inhibits Akt phosphorylation. This *in vitro* study is consistent with the well-documented data which confirmed Akt phosphorylation being inhibited by LY 294002 in bile duct-ligated (BDL) animals. In addition, PDGF can induce Akt phosphorylation and LY 294002 blocks this phosphorylation.

The Akt family represents pivotal factors to promote cell survival, proliferation and inhibit apoptosis. Akt plays an important role in inhibiting apoptosis in variety of cells such as uterine leiomyoma cell lines, hematopoietic progenitor/stem cell lines, pancreatic beta cells and islet beta cells *etc*[17-20]. Our results showed that Akt also inhibited apoptosis in HSC. Following PI 3-K/Akt pathway inhibition, HSC revealed typical apoptotic morphous under transmission electron microscopy. Microvilli on the cell surface decreased，became short, and even disappeared. Cells shrank, cytoplasm condensed, ribosome and mitochondria aggregated. The chromatin condensed and shrank and aggregated along inside of the nuclear membrane to form of balls, petals and crescents. Sometimes，apoptotic bodies formed. The apoptosis rates of both LY 294002 treated groups were significantly increased compared with that of the control group and the PDGF group and thus, we conclude that PI 3-K/Akt inhibition enhances HSC apoptosis.

In summary, the data obtained have shown that inhibition of PI 3-K/Akt signaling pathway can induce apoptosis in rat HSC, even under strong mitogen stimulator (PDGF). The activation of HSC is essential for fibrogenesis, and PI 3-K/Akt signaling is indispensable to support HSC activation. Therefore, blocking the PI 3-K/Akt signaling pathway may provide a potential therapeutic benefit for liver fibrosis.

COMMENTS

Background

Hepatic fibrosis represents a reversible and dynamic process in response to a variety of chronic stimuli. Activation of the hepatic stellate cell (HSC), a perisinusoidal cell that resides in the liver in a quiescent state, is responsible for the increased synthesis and deposition of extracellular matrix (ECM) in the liver, and plays a critical role in fibrogenesis. The paradigms of HSC activation and apoptosis remain valuable frameworks for understanding pathways of hepatic fibrogenesis and fibrosis regression. HSC apoptosis results in fibrolysis and fibrotic regression. Therefore, by understanding the pro- and anti-apoptogenic factors, new therapeutic targets will be identified for the treatment of liver fibrosis. Phosphatidylinositol 3-kinase (PI 3-K)/Akt are components of the major intracellular signaling pathways elicited by platelet-derived growth factor (PDGF) in HSC. Intracellular signals that regulate HSC apoptosis are still obscure. Our previous study has demonstrated that a cross talk between PDGF, the most potent proliferative cytokines for the HSC, and focal adhesion kinase (FAK), a nonreceptor tyrosine kinase, is involved in integrin signaling pathway. This interaction is essential for PDGF to induce HSC proliferation.

Research frontiers

The activated HSC is primarily responsible for excessive deposition of ECM proteins and collagen deposition during liver fibrosis. Substantial insight is being gained into the molecular mechanisms responsible for apoptosis in the HSC. The activated HSC becomes responsive to both proliferative and fibrogenic cytokines. These cytokines activate both mitogen-activated protein kinase (MAPK) signaling, involving p38, and FAK-PI 3-K-Akt-p70 (S6K) signaling cascades. PI 3-K/Akt constitutes an important pathway regulating the signaling of multiple biological processes such as apoptosis, metabolism, cell proliferation and cell growth. Activating mutations, which have been reported for PI 3-K and Akt in tumors, are able to confer tumorigenic properties in several cellular systems. These regulate the proliferative response, activating cell cycle progression as well as collagen gene expression. It is anticipated that by understanding the molecular mechanisms responsible for HSC proliferation, apoptosis, and excess ECM production new therapeutic targets will be identified for the treatment of liver fibrosis.

Innovations and breakthroughs

HSC apoptosis results in fibrolysis and further on, fibrotic regression. Intracellular signals that regulate HSC apoptosis are still obscure. Our previous study has demonstrated that a cross talk between PDGF and FAK is involved in integrin signaling pathway. PI 3-K/Akt signaling molecules, which are downstream of FAK, are also activated by PDGF. Up to now, few studies have addressed the function of PI 3-K/Akt signal transduction pathways on the apoptosis of HSC. The present study determined the effects and the molecular mechanisms whereby PI 3K/Akt influences apoptosis in HSC, and showed that PDGF activated the whole PI 3-K/Akt/p-Akt, pathway, while LY 294002 decreased the entire pathway activity not only in control cells, but also in PDGF stimulated circumstances. PI 3K/Akt signal molecules will be new therapeutic targets for the treatment of liver fibrosis.

Applications

The present study has shown that inhibition of PI 3-K/Akt signaling pathway can induce apoptosis in rat HSC, even under strong mitogen stimulators (PDGF). The activation of HSC is essential for fibrogenesis, and PI 3-K/Akt signaling is indispensable to support HSC activation. Therefore, blocking the PI 3-K/Akt signaling pathway may provide a potential therapeutic benefit for liver fibrosis.

Peer review

The paper by Wang *et al* presents an interesting study of the role of PI 3-K/Akt in controlling apoptosis of hepatic stellate cells. The purpose of the present work was to determine whether inhibition of PI 3-K affected apoptosis in HSC. The methods used to measure expression of PI 3-K and phosphorylation of Akt as well as total Akt were acceptable, and the assessment of apoptosis in HSC also reliable. The results very clearly show that the apoptotic rate was markedly increased in presence of LY294002.

Abstract

AIM: To investigate the effects of ketamine anesthesia on the motility alterations and tissue injury caused by ischemia/reperfusion in rats.

METHODS: Thirty male Wistar rats weighing 200-250 g were used. Ischemia was induced by obstructing blood flow in 25% of the total small intestinal length (ileum) with a vascular clamp for 45 min, after which either 60 min or 24 h of reperfusion was allowed. Rats were either anesthetized with pentobarbital sodium (50 mg/kg) or ketamine (100 mg/kg). Control groups received sham surgery. After 60 min of reperfusion, the intestine was examined for morphological alterations, and after 24 h intestinal basic electrical rhythm (BER) frequency was calculated, and intestinal transit determined in all groups.

RESULTS: The intestinal mucosa in rats that were anesthetized with ketamine showed moderate alterations such as epithelial lifting, while ulceration and hemorrhage was observed in rats that received pentobarbital sodium after 60 min of reperfusion. Quantitative analysis of structural damage using the Chiu scale showed significantly less injury in rats that received ketamine than in rats that did not (2.35 ± 1.14 *vs* 4.58 ± 0.50, $P < 0.0001$). The distance traveled by a marker, expressed as percentage of total intestinal length, in rats that received pentobarbital sodium was 20% ± 2% in comparison with 25.9% ± 1.64% in rats that received ketamine ($P = 0.017$). BER was not statistically different between groups.

CONCLUSION: Our results show that ketamine anesthesia is associated with diminished intestinal injury and abolishes the intestinal transit delay induced by ischemia/reperfusion.

Key words: Ischemia/reperfusion; Ketamine; N-methyl-D-aspartate; Intestinal motility; Tissue damage

INTRODUCTION

Mesenteric ischemia is a clinical entity with a mortality rate between 60% and 100% that usually requires surgical resection of the necrotic intestinal segment[1]. Although there have been advancements in the treatment of ischemic injury, an ideal treatment has not been defined, and new options should be considered. A promising strategy is the use of anesthetic and sedative agents that might exert protective effects on the injured tissue. Ketamine is an agent that has been recommended for this purpose in clinical situations of sepsis, renal ischemia, cerebral ischemia and serious burn injuries[2-4].

The small intestine is very sensitive to ischemic insult[5]. Reperfusion causes additional damage through the release of free radicals, pro-inflammatory cytokines, leukotrienes and other related products[6]. Intestinal

ischemia/reperfusion (I/R) damages the intestinal mucosa and alters gastrointestinal motility[7]. The histological damage induced by I/R includes alterations in capillary permeability, mucosal barrier dysfunction, necrosis, epithelial shredding. The damage is reversed in a period of approximately 24 h[8].

The NMDA (N-methyl-D-Aspartate) receptor family is a heterogeneous group of excitatory ionotropic voltage and ligand gate dependent receptors. Ketamine is a parenteral anesthetic that non-competitively blocks the NMDA receptor[9]. It has been shown that ketamine protects various tissues from I/R injury, such as brain[10], myocardium[11] and skeletal muscle[12]. To the best of our knowledge, no previous studies have evaluated the effects of ketamine on intestinal motility impairment and tissue damage induced by I/R.

MATERIALS AND METHODS

Procedures

Animal procedures were performed in accordance with the proper use and care of laboratory animals. Experiments were performed on 30 male Wistar rats weighing 200-250 g. Animals were maintained under standard conditions, such as stable room temperature (24 ± 3℃), a 12 h light/12 h dark cycle, and access to commercial rat pellets and water *ad libitum*.

Animal models

Briefly, after anesthesia with pentobarbital sodium (Anestesal, Pfizer Inc, Mexico) or ketamine (Anesket, Pisa Agropecuaria, Hidalgo, Mexico), midline laparotomy was performed, and the small intestine was externalized and kept wrapped in humid sterile gauze to prevent dehydration. Rats were placed over a heating mat to maintain constant core temperature (37℃). Intestinal I/R was induced by selective clamping of the vascular supply of an ileum segment consisting of 25% of the total intestinal length with microvascular clamps for 45 min (ischemia) followed by either 60 min or 24 h reperfusion. Ischemia was confirmed by absence of pulsations as well as characteristic changes in intestinal coloration.

Thirty male Wistar rats were randomized into 3 groups (n = 10) depending on the type of anesthetic used. Each group was then divided into 2 subgroups. In subgroup A (n = 5), reperfusion lasted 60 min, and tissue was obtained for histological examination only, while in subgroup B (n = 5) it was extended to 24 h and the animals used to evaluate intestinal transit and intestinal electrical activity.

The control group (n = 10) animals were anesthetized with pentobarbital sodium (50 mg/kg) and sham-operated (only midline laparotomy and gut manipulation). In the SK group (n = 10) animals were anesthetized with pentobarbital sodium (50 mg/kg) and intestinal I/R was induced as described. In the KET group (n = 10) animals were anesthetized with ketamine (100 mg/kg) and intestinal I/R was induced as described.

Intestinal transit and basic electrical rhythm

In subgroup B, after 24 h of reperfusion, animals were anesthetized with pentobarbital sodium (50 mg/kg), mid line laparotomy was performed, and 3 subserosal bipolar electrodes were used to record the electrical activity of the ileum segment that had been subjected to I/R injury using a Power Lab 4/20T (ADInstruments, USA) equipped with 3 DC pre-amplifiers (ADInstruments, USA) to analyze and calculate intestinal Basic Electrical Rhythm (BER). Immediately after 30 min, 2 mL/kg of a non-absorbable charcoal solution marker was instilled through a canula into the proximal end of the ileum segment studied, and after another 30 min the intestine was removed, and the distance traveled by the marker was registered. The distance traveled by a marker was then expressed as percentage of total intestinal length from pylorus to cecum. This was used as an indicator of intestinal transit. Finally, tissue samples were obtained for morphologic examination.

Morphological examination

After the I/R procedure, rats were sacrificed by exsanguination from the aorta. Immediately, tissue samples were obtained and fixed in 10% neutral buffered formalin and embedded in paraffin, then 5 micrometer-thick sections were stained with hematoxylin and eosin and examined under light microscope by a blinded pathologist. The Chiu scale[13] of mucosal injury was used to evaluate the degree of histological alteration on 10 sections of 1 mm each to complete 1 cm per animal and then averaged. The scale consists of values from 0 to 5, where 0 normal mucosa; 1, development of sub epithelial (Gruenhagen's) spaces; 2, extension of the sub epithelial space with moderate epithelial lifting from the lamina propria; 3, extensive epithelial lifting with occasional denuded villi tips; 4, denuded villi with exposed lamina propria and dilated capillaries; and 5, disintegration of the lamina propria, hemorrhage, and ulceration.

Statistical analysis

Data were analyzed with SPSS 11.0 (SPSS Inc. Software, Chicago, Illinois, USA) statistical software using one-way analysis of variance (ANOVA) and with Tukey-Kramer test so as to determine comparison between groups, and differences between groups, respectively. All values were expressed as mean ± SD and $P < 0.05$ was considered statistically significant.

RESULTS

Morphological examination

Structural changes in intestinal mucosa in rats of group KET A (ketamine anesthesia) showed moderate alteration such as epithelial lifting, while ulceration, hemorrhage and villi disintegration was observed in rats of group SK A after 45 min of ischemia and 60 min of reperfusion (Figure 1). The results of the quantitative evaluation of structural damage using the Chiu scale were as follows: control A 0.7 ± 0.45, SK A 4.58 ± 0.50

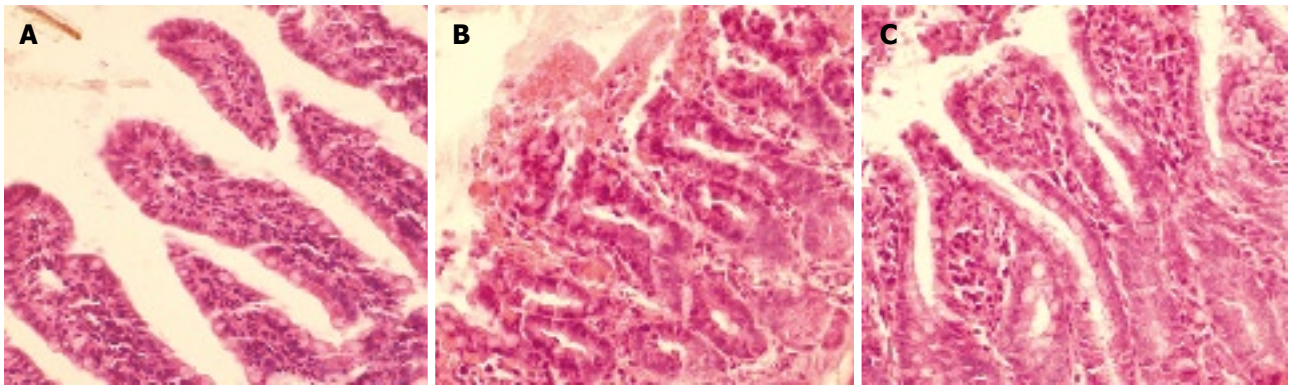

Figure 1 **A**: Control A group showing normal mucosa; **B**: SK A. Changes in intestinal mucosa structure following 45 min of ischemia and 60 min reperfusion; **C**: KET A. Less damage was observed (all x 40).

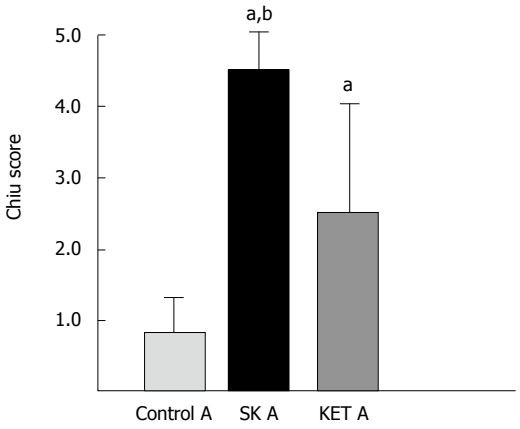

Figure 2 Bar diagram illustrating the Chiu score of mucosal injury after 60 min of reperfusion. Lower damage score was observed in a KET A group than in the SK A group. [a]$P < 0.0001$ *vs* control A; [b]$P < 0.0001$ *vs* KET A.

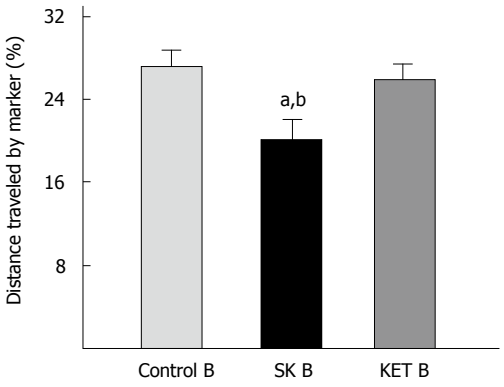

Figure 3 Bar diagram illustrating the distance travelled by the marker, expressed as a percentage of total intestinal length from pylorus to cecum. Intestinal I/R caused transit delay that was corrected by the administration of ketamine as anesthetic. [a]$P = 0.00019$ *vs* control B; [b]$P = 0.0004$ *vs* KET B.

and KET A 2.35 ± 1.14 (Figure 2). Damage in group KET A was significantly reduced in comparison with group SK A ($P < 0.0001$). However, the damage score in the KET A group did not reach control A group levels, indicating only moderate protection. The degree of mucosal damage after 24 h of reperfusion (subgroups KET B and SK B) was the same as in control rats and showed no statistical significance.

Intestinal transit and BER

The distance traveled by the marker, expressed as percentage of total intestinal length, in subgroup SK B was 20% ± 2% in comparison with subgroup KET B 25.9% ± 1.64%. In the control B group, the distance traveled was 27% ± 1.4% (Figure 3). Intestinal transit showed statistically significant delay in the SK subgroup compared with the other groups in this study ($P = 0.0004$). Group KET B showed no significant alteration in transit speed compared to the control B group. The frequency of the BER was not statistically different between any of the groups after 24 h reperfusion: Control B 11.5 ± 1.1/min; SK B 11.2 ± 0.5/min; KET B 11.75 ± 0.95/min.

DISCUSSION

The alterations on intestinal motility caused by I/R are directly related to the length of both ischemia and reperfusion[14]. The functional alterations caused by I/R have been previously identified[15]. These changes consist of reversible alterations in smooth muscle contractility and intestinal transit, as well as characteristic changes in electrical activity such as a decrease in BER frequency during ischemia[7,16]. Nitric oxide is one of the mediators thought to participate in the changes caused by I/R on intestinal motility in the rat[17].

The structural damage caused by ischemia is aggravated by the restitution of blood flow. The physiopathology of intestinal mucosal damage by I/R is not completely understood. But, it is believed that cytotoxic substances such as free radicals, nitric oxide, serotonin, complement, as well as neutrophil infiltration and nuclear transcription factors play important roles[18]. Macrophages have been also implicated in the initial damage caused by intestinal I/R[19]. I/R has also been shown to induce apoptosis[20]. Bacterial translocation and mucosal barrier dysfunction have been implicated in the damage caused by I/R in the gut[21]. This damage is also related to an increase in circulating levels of pro-inflammatory cytokines such as interleukin-6 and tumor necrosis factor alpha (TNF-alpha), liberated by the intestine itself[22].

Recently, anti-inflammatory properties of ketamine

have been described in various experimental models. Interleukin-1, 6, 8 and TNF-alpha levels are reduced after the administration of ketamine[23-25]. Neutrophil adhesion, migration, and free radical release is inhibited by ketamine[26,27], as is nitric oxide production by macrophages[28]. Further studies are needed to determine whether one of these effects is responsible for the mucosal protection against I/R that we observed in this study.

Glutamate is an excitatory neurotransmitter in the central nervous system, and it participates in the modulation of intestinal function through the enteric nervous system, where NMDA receptors have been found[29]. It has been shown that the glutamate system is involved in the pathogenesis of I/R in brain and intestine[30]. Glutamate release and NMDA receptor activation induces nitric oxide, and other free radicals that cause tissue injury[31]. Glutamate release during I/R could also cause toxicity in the enteric nervous system, which could cause motility alterations[32]. One recent study found that intestinal I/R causes myenteric plexus ganglion cell reduction and death[33]. This suggests that the NMDA receptor could be related to the functional alterations induced in the intestine by I/R. In one study, the NMDA antagonist MK-801 diminished nitric oxide production, and prevented the changes in the intestinal transit caused by intestinal ischemia/reperfusion[34]. We showed that ketamine, an NMDA receptor antagonist, also corrects the intestinal transit delay caused by intestinal I/R, but we did not find any changes in the frequency of the BER after 24 h of reperfusion. Further studies are needed in order to determine whether our results are explained by ketamine acting as an NMDA receptor antagonist in the gut.

Ketamine protects the intestine against other types of non-ischemic insults. Ketamine has been shown to protect the gut against endotoxemia induced injury in rats through diminished pro-inflammatory cytokine release[35]. Ketamine also decreased enterocyte apoptosis in a model of thermal burn induced intestinal injury[36]. However, this is the first study to demonstrate that ketamine anesthesia reduces I/R induced injury in intestinal mucosa.

COMMENTS

Background

In intestinal diseases associated with ischemia and reperfusion, intestinal tissue is damaged and intestinal function is altered. In this study, the aim was to investigate the effects of ketamine anesthesia in rats in which intestinal ischemia/reperfusion was induced.

Research frontiers

The authors suggest that ketamine anesthesia may have beneficial effects that prevent the tissue damage and functional alterations that follow from intestinal ischemia/reperfusion.

Innovations and breakthroughs

This study is the first to show that ketamine anesthesia can reduce the intestinal tissue damage induced by ischemia reperfusion.

Applications

Ketamine should be further studied and the possibility of using ketamine as anesthetic in cases of intestinal ischemia should be considered.

Peer review

Methods and results are clear, but in order for the authors to come to the conclusion that ketamine is functioning as an NMDA receptor antagonist the following experiment needs to be done: Compare the effect of pentobarbital plus a selective NMDA antagonist *vs.* ketamine plus a selective NMDA antagonist. If the authors' conclusion is correct the selective NMDA receptor antagonist should "nullify" the beneficial effect of ketamine.

Abstract

AIM: To examine whether the sedative effects assessed by psychomotor tests would depend on the cytochrome P450 (*CYP*) *2C19* genotypes after an infusion regimen of diazepam commonly used for gastrointestinal endoscopy in Japan.

METHODS: Fifteen healthy Japanese volunteers consisting of three different *CYP2C19* genotype groups underwent a critical flicker fusion test, an eye movement analysis and a postural sway test as a test for physical sedative effects, and a visual analog scale (VAS) symptom assessment method as a test for mental sedative effects during the 336 h period after the intravenous infusion of diazepam (5 mg).

RESULTS: The physical sedative effects assessed by the critical flicker test continued for 1 h (t values of 5 min, 30 min and 60 min later: 4.35, 5.00 and 3.19, respectively) and those by the moving radial area of a postural sway test continued for 3 h (t values of 5 h, 30 h, 60 min and 3 h later: -4.05, -3.42, -2.17 and -2.58, respectively), which changed significantly compared with the baseline level before infusion ($P < 0.05$). On the other hand, the mental sedative effects by the VAS method improved within 1 h. The *CYP2C19* genotype-dependent differences in the postinfusion sedative effects were not observed in any of the four psychomotor function tests.

CONCLUSION: With the psychomotor tests, the objective sedative effects of diazepam continued for 1 h to 3 h irrespective of *CYP2C19* genotype status and the subjective sedative symptoms improved within 1 h. Up to 3 h of clinical care appears to be required after the infusion of diazepam, although patients feel subjectively improved.

Key words: Diazepam; Sedation; cytochrome P450 (CYP) 2C19; Endoscopy; Complication; Critical flicker fusion test; Eye movement analysis; Postural sway test; Visual analog scale

INTRODUCTION

Gastrointestinal endoscopy is commonly performed for the screening and/or diagnosis of upper gastrointestinal disorders. Recent advances in gastrointestinal endoscopy are remarkable, and gastrointestinal endoscopy now plays an important role in the treatment of several upper gastrointestinal disorders (e.g. endoscopic mucosal resection of gastric cancer in the early stage and treatment of haemorrhage from peptic ulcer). However, gastrointestinal endoscopy is invasive and accompanied with distress of patients. Therefore, benzodiazepines, such as diazepam and midazolam, are commonly used as a premedication for gastrointestinal endoscopy[1,2]. The administration of benzodiazepines as premedications for endoscopy reduces distress of patients and results in a better patient acceptance and compliance for endoscopy[1,2]. However, use of benzodiazepines sometimes causes undesirable events; e.g. residual benzodiazepine after endoscopy may cause sustained distraction, which leads to some accidents. For the prevention of such undesirable accidents, the dose of benzodiazepines should, therefore, be minimized or optimized. However, a reduced dose of benzodiazepines sometimes results in an insufficient sedation for endoscopy, which is a dilemma for performing the safe and comfortable endoscopy.

Diazepam is metabolized by cytochrome P450 (CYP) 3A4 to temazepam, and by CYP3A4 and CYP2C19 to N-desmethyldiazepam[3,4]. There are genetic differences in the activity of CYP2C19[3,4]. The pharmacokinetics of diazepam significantly depend on *CYP2C19* genotype status[5-9], as observed in proton pump inhibitors, such as omeprazole and rabeprazole[10,11]. The *CYP2C19* genotypes are classified into the three groups: homozygous extensive metabolizers (EMs), heterozygous EMs, and poor metabolizers (PMs)[12-14]. In PMs, the plasma diazepam concentrations are markedly increased due to an impaired metabolism of diazepam in comparison with those in EMs[3-7]. However, whether the pharmacodynamic effects of an intravenous infusion of diazepam would differ between the CYP2C19 EMs and PMs remain, to our knowledge, unknown.

Psychomotor tests, such as a critical flicker fusion test, an eye movement analysis, a postural sway test and a visual analog scale (VAS) symptom assessment method are well known as psychometric markers and are commonly used to quantify the pharmacodynamic responses associated with an administration of benzodiazepine sedatives[15-17]. Indeed, plasma or serum diazepam concentrations were significantly correlated with psychomotor test scores[18,19].

In this study, we aimed to examine the objective and subjective sedative effects of an intravenous 5-mg dose of diazepam commonly used for gastrointestinal endoscopy in relation to *CYP2C19* genotypes.

MATERIALS AND METHODS

Subjects and CYP2C19 genotyping

Fifteen healthy Japanese volunteers whose *CYP2C19* genotypes had been determined by a PCR-RFLP method[20,21] were enrolled in this study (5 homozygous EMs, 5 heterozygous EMs and 5 PMs of *CYP2C19*) (Table 1). A written informed consent was obtained from each subject.

Study protocol

All subjects were given a single intravenous infusion of Diazepam (Cercine®, Takeda Pharmaceutical Co. Ltd., Osaka, Japan) 5 mg at 8:00 am, which was infused over 1 min. Four psychomotor tests, such as a critical flicker fusion test, an eye movement analysis, a postural sway test and a VAS symptom assessment method[15-17], were performed at the pre- and postinfusion time points of diazepam as follows: before the infusion and 5 min and 30 min, and 1 h, 3 h, 6 h, 10 h, 24 h, 72 h and 336 h postinfusion.

The critical flicker fusion test was measured by the discrimination of fused flickering red light (DF-1, Shibata Chemical, Tokyo, Japan). The value used for the fusion time was flickers per second. The results of an eye movement test used the saccadic latency (per second), which is time from the displacement of red light signal to the response of eye movement. The stimulated horizontal displacement of red lights at random intervals was recorded (DP1200A, Nihon Denki Sanei, Tokyo, Japan). The subjects responded to and followed a signal for 30 s as quickly as possible. The moving radial area (cm^2) for 60 s by a postural sway test was measured by a sway meter (G5500, Anima, Tokyo, Japan) for the 60 s period with eyes closed. The radial area was determined by calculating the radial distance to the center of pressure at each sampling interval from the geometric center of the stance. A VAS symptom assessment method consisted of questions of both the two parameters of mental sedation and physical sedation. Subjects had to mark on the 100 mm line to show the degree of their feeling.

All subjects were provided with three meals a day (breakfast at 7:30 am, lunch at 12:30 pm, and supper at 6:00 pm). Mineral water was allowed *ad libitum*. But, no other beverages including caffeine-containing and grapefruit juice-related products were permitted. None of them drank alcohol or had a smoking habit. None had taken any drugs for 1 mo before the study, nor did they take any during it. The subjects stayed in the translational research (TR) unit of Hamamatsu University School of Medicine during the first 24 h postinfusion period. Four psychomotor tests at 72 h and 336 h postinfusion were performed in the TR unit.

The protocol was approved in advance by the Human Institutional Review Board of the Hamamatsu University School of Medicine. Written informed consent was obtained from each subject before participation in the study.

Statistical analysis

The median values of four psychomotor tests and median percent changes from the baseline value (before Diazepam infusion) were determined. Statistically

Table 1 Demographic characteristics of healthy volunteers with different *CYP2C19* genotype status (n = 5)

	Homozygous EM	Heterozygous EM	PM	*P*
Genotype status	Wild-type/Wild-type (n = 5)	Wild-type/*CYP2C19* mutation in exon 5 (n = 3) Wild-type/*CYP2C19* mutation in exon 4 (n = 2)	*CYP2C19* mutation in exon 5/CYP2C19 mutation in exon 5 (n = 2) *CYP2C19* mutation in exon 4/CYP2C19 mutation in exon 4 (n = 1) *CYP2C19* mutation in exon 5/CYP2C19 mutation in exon 4 (n = 2)	
Male/Female	3/2	3/2	5/0	0.472
Age (yr)	24 (22-31)	29 (25-44)	23 (22-35)	0.093
Height (cm)	170 (154-174)	177 (155-181)	171 (169-180)	0.400
Body weight (kg)	62 (51-67)	67 (51-78)	65 (57-78)	0.424

Age and body weight are given as median (range). EM: Extensive metabolizer; PM: Poor metabolizer.

significant differences in the median pharmacodynamic parameters among the 3 different *CYP2C19* genotype groups at the pre- and postinfusion time points were determined by the Mann-Whitney *U*-test, when a significant difference was obtained by the Kruskal-Wallis test. Statistical differences with the median parameters between the different pre- and postinfusion time points in all of the subjects enrolled in this study were determined by using the Wilcoxon's signed rank test, when significant differences were obtained by the Friedmann's test. All *P* values were two-sided, and $P < 0.05$ was taken to indicate statistical significance.

RESULTS

There were no statistically significant differences in the demographic characteristics, such as age, body weight, height and sex ratio among the 3 different *CYP2C19* genotype groups (Table 1).

Objective sedative effects assessed by critical flicker fusion, postural sway and eye movement tests

Percent changes in the critical flicker fusion test, postural sway test, and eye movement test after an intravenous administration of 5 mg of diazepam as a function of *CYP2C19* genotype status are shown in Figure 1. Sedative effects with diazepam (5 mg) assessed by those methods did not significantly differ among the different *CYP2C19* genotype groups throughout the 336 h postinfusion period ($P > 0.05$) (Figure 1). For this reasoning, the data derived from the different *CYP2C19* genotypes were combined together in the following analyses.

In a critical flicker fusion test, the median percent changes from the baseline values (before diazepam infusion) and the postinfusion values at 5 and 30 min, and at 1 h significantly differed ($P = 0.0038$, 0.0018 and 0.0090, respectively) (Figure 2A). The median percent changes from the baseline values still appeared increased for longer than 3 h postinfusion, but not significantly (Figure 1A).

In the moving radial area of a postural sway test, the median values at 5 and 30 min, and 1 h and 3 h postinfusion were 167.9% (range; 100.3%-456.7%), and 153.2% (52.3%-391.0%), and 111.2% (75.6%-281.8%) and 130.8% (51.0%-337.1%), which were significantly greater than the baseline value ($P = 0.0007$, and 0.0018, and 0.0409 and 0.0125, respectively) (Figure 2B). These objective sedative assessment values required 3 h to 6 h postinfusion to return to the respective baseline levels (Figure 2).

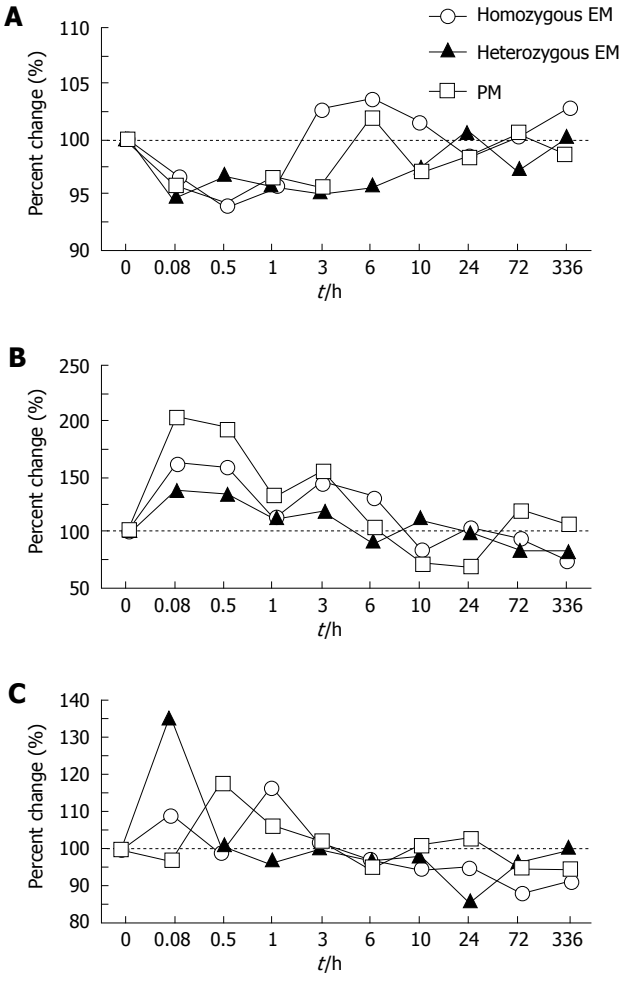

Figure 1 Median percent changes from the baseline value (before a diazepam 5 mg infusion) by a critical flicker fusion test (**A**), a postural sway test (**B**), and an eye movement test (**C**) in the 3 different *CYP2C19* genotype groups.

In the saccadic latency of an eye moving test, the median percent change from the baseline at 5 min postinfusion was 115.9% (81.9%-141.1%) ($P = 0.0171$) (Figure 2C).

The overall results indicated that the objective

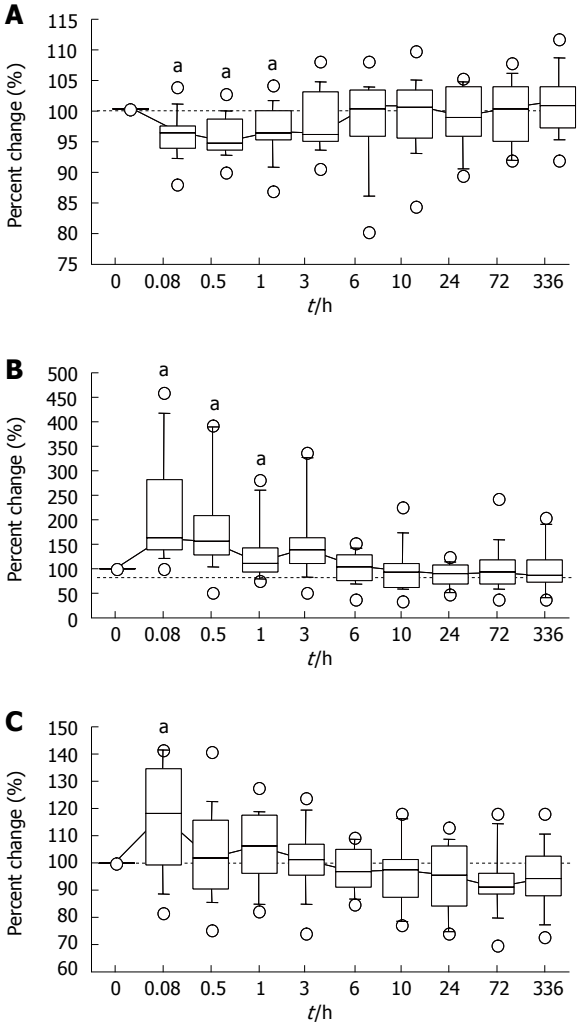

Figure 2 Median percent changes from the baseline value [before a diazepam (5-mg) infusion] by a critical flicker fusion test (**A**), a postural sway test (**B**), and an eye movement test (**C**) in all of the enrolled subjects. [a]$P < 0.05$ by using the Wilcoxon's signed rank test, when significant differences were obtained by the Friedmann's test.

sedative effects of diazepam assessed by the three methods continued for up to 3 h postinfusion.

Subjective sedative effects assessed by the VAS method

The sedative effects assessed by VAS method were fairly similar among the different *CYP2C19* genotype groups throughout the 336-h postinfusion period ($P > 0.05$) (Figure 3). The data of VAS method obtained from all of the subjects with different *CYP2C19* genotypes were, therefore, combined as mentioned above.

The median values by "alert to drowsy" of mental sedation parameter at 5 and 30 min postinfusion were significantly decreased compared with the baseline value ($P = 0.0098$ and 0.0047, respectively) (Figure 4A). This value returned to the level not different from the baseline of 1 h later (Figure 4A). In the "fuzzy to clear headed" of mental parameter, the median value at 5 min later was significantly lower ($P = 0.076$), but returned to the baseline at 30 min postinfusion (Figure 4B).

The median values of the "well-coordinated to clumsy" physical sedation parameter at 5 min and 30 min and 1 h after diazepam infusion were significantly increased compared with the baseline value ($P = 0.0031$, and 0.0038 and 0.0468, respectively) (Figure 4C). In the "lethargic to energetic" physical parameter, the median values at 5 min and 30 min postinfusion were significantly lower ($P = 0.0119$ and 0.0468, respectively), but returned to baseline level by 1 h postinfusion (Figure 4D).

These results assessed by the VAS symptom assessment method indicated that the subjective sedative effects of diazepam (5 mg) continued for less than 1 h postinfusion, although the objective sedative effects continued longer (for 1 h to 3 h postinfusion).

DISCUSSION

The development of an optimal infusion regimen of a premedication (e.g. diazepam) and an appropriate manual check at the endoscopy unit is necessary for a comfortable and safe gastrointestinal endoscopy. Although the proper premedication for gastrointestinal endoscopy should have a shorter onset of action, short elimination half-life, and faster time to recovery, diazepam is one of the first-line sedative drugs used as a premedication for gastrointestinal endoscopy in Japan. In this study, we demonstrated that the objective sedative effects by an intravenous infusion of diazepam (5 mg) continued for no less than 3 h with psychological tests, whereas the subjective sedative effects continued for no more than 1 h. Although the plasma diazepam concentrations of individuals with CYP2C19 PMs have been reported to be greater than those with homozygous EMs[5-9], we did not find any significantly different sedative effects of diazepam among the different *CYP2C19* genotype groups. Based upon these observations, we thought that patients who undergo an intravenous infusion of diazepam (5 mg) should be cared for at least 3 h postinfusion in the hospital irrespective of *CYP2C19* genotype status for the prevention of adverse events.

In the present study, the values of VAS method used for assessing the subjective symptom parameters demonstrated continuous sedative effects only during 30 min to 60 min after the infusion of diazepam (5 mg). After 1 h had passed from administration, the major parameters of the VAS assessment method returned to the respective baseline levels. However, the objective assessment by a critical flicker fusion test and a postural sway test revealed that the sedative effects of diazepam remained for approximately 3 h to 6 h postinfusion, indicating that a discrepancy exists between the subjective and objective sedative symptoms from 1 h to 6 h after the infusion of diazepam. Therefore, even if the patients feel improved or recovered from the sedation by diazepam at 1 h postinfusion, they may be at risk for some adverse effects, such as falling down and/or having driving errors. Then, we anticipate that the patients who undergo an intravenous infusion of diazepam (5 mg) should be checked for the prevention of possible sedative adverse effects during a 6 h postinfusion period at the endoscopy unit.

The sedative effects of diazepam are mediated *via* α1-$GABA_A$ receptors in the brain[22,23], and the minimum plasma concentration of diazepam to yield sedative

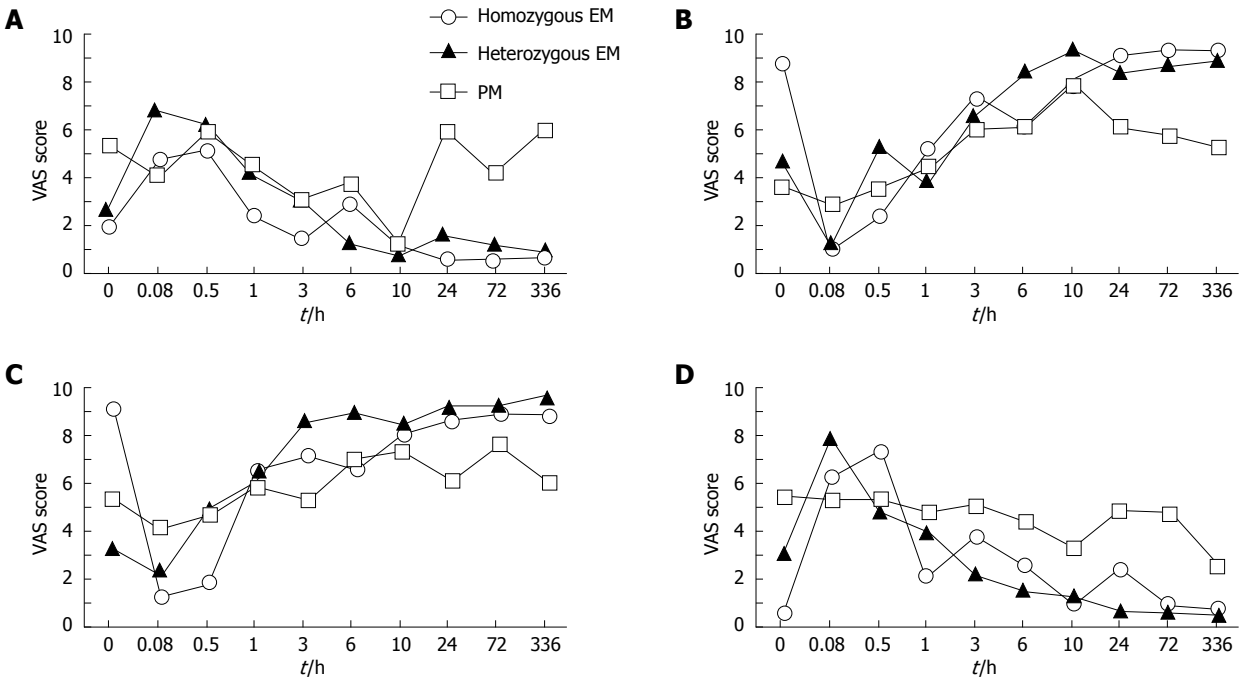

Figure 3 Median percent values for mental sedation, "alert to drowsy" (**A**), "fuzzy to clear-headed" (**B**), physical sedation, "lethargic to energetic" (**C**) and "well-coordinated to clumsy" (**D**) parameters by a VAS symptom assessment test in the 3 different *CYP2C19* genotype groups.

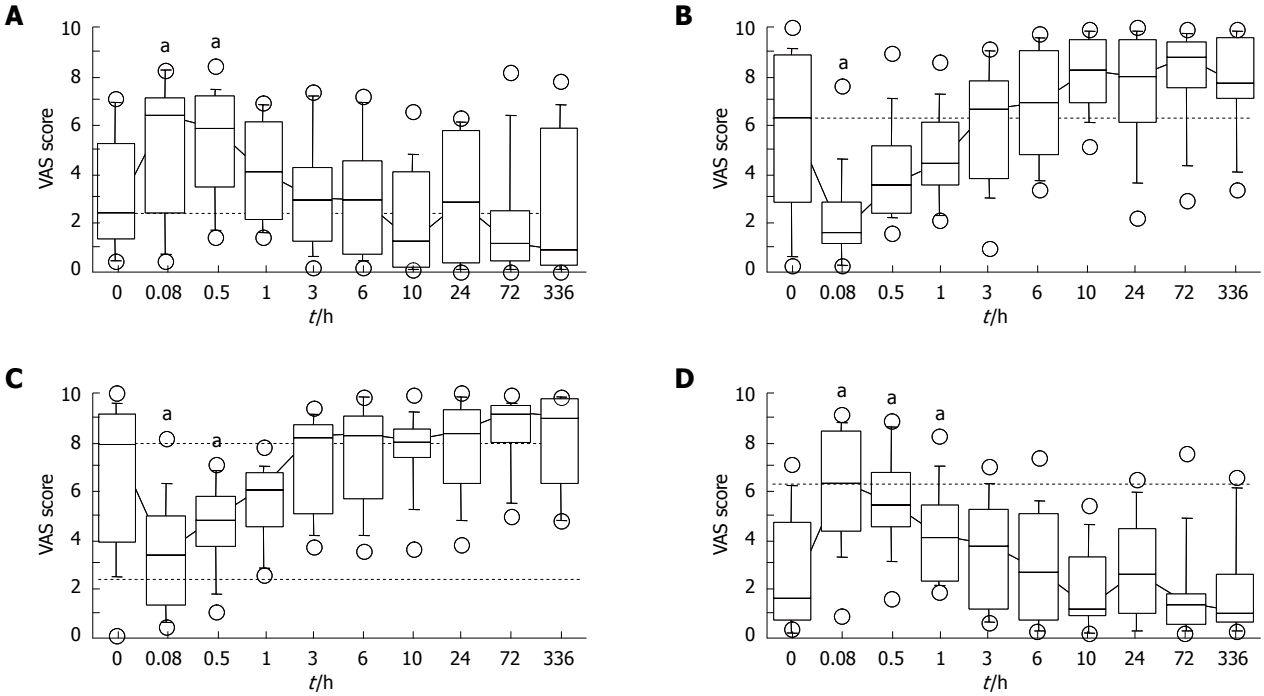

Figure 4 Median percent values for mental sedation "alert to drowsy" (**A**), "muzzy to clear-headed" (**B**), physical sedation "lethargic to energetic" (**C**) and "well-coordinated to clumsy" (**D**) parameters by a VAS symptom assessment test in all of the enrolled subjects. $^{a}P < 0.05$ by using the Wilcoxon's signed rank test, when significant differences were obtained by the Friedmann's test.

effects is more than 300 ng/mL to 400 ng/mL[18,19]. The pharmacokinetics of diazepam are affected by age[24,25], gender[26], obesity[26], liver disease[27] and *CYP2C19* genotype status[5-9]. The mean plasma elimination half-life of diazepam in PMs of CYP2C19 has been reported to be much longer than that in homozygous EMs: those values after a single oral dose of diazepam were 84.0 ± 13.7 h for PMs, 62.9 ± 9.8 h for heterozygous EMs and 20.0 ± 10.8 h for homozygous EMs[28]. However, plasma diazepam levels do not always correlate with the sedative effects[29,30]. Moreover, Kosuge *et al*[16] reported that influences of diazepam on psychomotor functions did not differ among the 3 different *CYP2C19* genotype groups, as observed in this study. Although we cannot offer appropriate explanations for the lack of difference in the pharmacodynamics of diazepam among the different

CYP2C19 genotype groups, several possible mechanisms can be raised as follows: first, the acute tolerance to diazepam may be developed, which is mediated by the dysfunction of the cortical GABA transmitter system, such as the decrease of glutaminic acid decarboxylase[31,32], reelin[33] and GABA membrane transporter[34], GABAA receptor up-regulation[35] and the decrease of dendritic spines[36]. Second, diazepam as well as its metabolites such as temazepam and N-desmethyldiazepam, have sedative effects[3,4]. Therefore, although the metabolic disposition of diazepam differs among the different *CYP2C19* genotype groups, the total amounts of diazepam plus its active metabolites would not differ among the different *CYP2C19* genotype groups, resulting in no statistical difference in the pharmacodynamics of diazepam. Third, our pharmacodynamic assessment methods may not have a sufficient power for the limited sample size (n = 15) in the psychomotor function status. Nevertheless, in a cimetidine-diazepam interaction study, only minimal changes were observed in the pharmacodynamic effects despite an increase in plasma diazepam concentration by about 60% during treatment with cimetidine[37]. Similarly, in a fluoxetine-diazepam interaction study[38], despite that the significant increment of plasma diazepam concentration occurred by about 50% with the co-administration of fluoxetine, no psychopharmacological changes were detected by the pharmacodynamic assessment methods similar to those we used. With the limitation of absent data on plasma concentrations of diazepam and its metabolites (e.g. desmethyldiazepam and temazepam) in this study, we are tempted to assume that the sedative effects assessed by the pharmacodynamic assessment methods we used would not differ among the different *CYP2C19* genotype groups when given an intravenous 5-mg infusion of diazepam as noted above.

Recently, when gastrointestinal endoscopy is performed for patients, midazolam and propofol are often used as a sedative drug. However, midazolam and propofol act quickly and potently, and therefore, advanced effects such as respiratory trouble occurs sometimes. However, the proper premedication for gastrointestinal endoscopy should have a shorter onset of action, short elimination half-life, and faster time to recovery. Therefore, we hope to evaluate the sedative effects of those drugs by using the psychopharmacological tests.

In conclusion, this study suggests that the psychopharmacological tests appear to be a useful tool for determining the optimal treatment with a benzodiazepine, such as diazepam, for gastrointestinal endoscopy. If patients undergo gastrointestinal endoscopy for sedation by an intravenous infusion of diazepam (5 mg), the sedative effects of patients should be monitored for preventing the possible adverse effects up to at least a 3-h postinfusion period in the endoscopy unit of the hospital, although patients appear to subjectively feel unimpaired or recovered.

COMMENTS

Background

Benzodiazepine is commonly used as a premedication for gastrointestinal endoscopy. However, use of benzodiazepine sometimes causes undesirable events, which leads to some accidents. For the prevention of such undesirable accidents, therefore, the dose of premedication should be minimized or optimized. For benzodiazepine, the pharmacokinetics of diazepam depends significantly on cytochrome P450 (*CYP*) *2C19* genotype status. However, whether the pharmacodynamic effects of an intravenous infusion would differ between the CYP2C19 EMs and PMs remain unknown. Moreover, there was no optimal protocol of diazepam use in the endoscopy unit.

Research frontiers

When patients receive gastrointestinal endoscopy, the development of optimal infusion regimens of sedative drug and care protocol in the endoscopy unit are required to prevent advanced effects in relation to *CYP2C19* genotypes.

Innovations and breakthroughs

There are many reports, which investigate the pharmacokinetics and pharmacodynamics of diazepam in pharmacological studies. The innovation of this study is to demonstrate the recommendation and attention of gastrointestinal endoscopy with diazepam (5 mg/body) as follows: An up to 3 h clinical care appears to be required after the infusion of diazepam irrespective of *CYP2C19* genotype status, although patients feel subjectively improved.

Applications

The physical sedative effects assessed by the critical flicker test continued for 1 h and those by the moving radial area of a postural sway test continued for 3 h, which significantly changed compared with the baseline level before infusion ($P < 0.05$). On the other hand, the mental sedative effects by the VAS method improved within 1 h. The *CYP2C19* genotype-dependent differences in the postinfusion sedative effects were not observed in any of the four psychomotor function tests. Therefore, up to 3-h of clinical care is required after the infusion of diazepam (5 mg) irrespective of *CYP2C19* genotype status, although patients feel markedly improved. Recently, many drugs, such as midazolam and propofol, were used at endoscopy as sedation drugs. Additional research, which compares with diazepam and other sedation drugs in efficacy and care time using the psychopharmacological tests, is required.

Terminology

The critical flicker fusion test: the measurement of the discrimination of fused flickering red light. The value used for the fusion time was flickers per second. The results of an eye movement test: the saccadic latency (per second), which is time from the displacement of red light signal to the response of eye movement. The subjects responded to and followed a signal for 30 s as quickly as possible. The postural sway test: the measurement of moving radial area (cm^2) for the 60 s period with eyes closed. The radial area was determined by calculating the radial distance to the center of pressure at each sampling interval from the geometric center of the stance.

Peer review

Authors examined whether the sedative effects assessed by psychomotor tests would depend on the *CYP2C19* genotypes after an infusion regimen of diazepam commonly used for gastrointestinal endoscopy in Japan. It's an interesting study, and the methodology is sound, and is a good objective assessment.

Abstract

AIM: To determine whether *Nigella sativa* prevents hepatic ischemia-reperfusion injury to the liver.
METHODS: Thirty rats were divided into three groups as sham (Group 1), control (Group 2), and *Nigella sativa* (NS) treatment group (Group 3). All rats underwent hepatic ischemia for 45 min followed by 60 min period of reperfusion. Rats were intraperitoneally infused with only 0.9% saline solution in group 2. Rats in group 3 received NS (0.2 mL/kg) intraperitoneally, before ischemia and before reperfusion. Blood samples and liver tissues were harvested from the rats, and then the rats were sacrificed. Serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), and lactate dehydrogenase (LDH) levels were determined. Total antioxidant capacity (TAC), catalase (CAT), total oxidative status (TOS), oxidative stress index (OSI) and myeloperoxidase (MPO) in hepatic tissue were measured. Also liver tissue histopathology was evaluated by light microscopy.
RESULTS: The levels of liver enzymes in group 3 were significantly lower than those in the group 2. TAC in liver tissue was significantly higher in group 3 than in group 2. TOS, OSI and MPO in hepatic tissue were significantly lower in group 3 than the group 2. Histological tissue damage was milder in the NS treatment group than that in the control group.
CONCLUSION: Our results suggest that *Nigella sativa* treatment protects the rat liver against to hepatic ischemia-reperfusion injury.

Key words: *Nigella sativa*; Ischemia reperfusion injury; Liver

INTRODUCTION

Ischemia followed by reperfusion (I/R) may cause metabolic and structural hepatic damage, and may be due to trauma, sepsis, liver transplantation[1] or hepatic pedicle clamping during liver surgery[2]. This remains a significant problem for surgical procedures, and also remains limitation of liver transplantation[3].

Oxygen free radicals, produced on reperfusion, play a critical role in the injury caused by ischemia-reperfusion[4]. Reactive oxygen radicals lead to an inflammatory response and tissue damage by activating some mediators. It can also directly damage cell components[5]. Several attempts to reduce these mechanisms have been reported in the literature. Protection against reperfusion injury can be induced by assorted treatments including administration of antioxidants and anti-inflammatory drugs[4,6-8].

Various therapeutic effects, such as antioxidant, anti-inflammatory, anticancer[9], antihistaminic[10], antibacterial effects[11] have been described for *Nigella sativa*. Additionally, it has been shown that *Nigella sativa* has protective effect against ischemia reperfusion injury to various organs[12-14]. Thymoquinone, the active constituent of *Nigella sativa* seeds, is a pharmacologically active quinone, which possesses several properties including analgesic and anti-inflammatory actions[15]. It has been reported that thymoquinone prevents oxidative injury in various *in vitro* and *in vivo* studies in rats[16,17]. It has been suggested that thymoquinone may act as an antioxidant agent and prevents membrane lipid peroxidation in tissues[18]. The mechanism of action is still largely unknown. But, it seems these effects may be related to inhibition of eicosanoid generation, namely thromboxane B2 and leucotrienes B4 (by inhibiting cyclooxygenase and 5-lipooxygenase, respectively), and membrane lipid peroxidation[13].

Moreover, it has been demonstrated that *Nigella sativa* can significantly prevent hepatotoxicity[19] and might have protective effects against nephrotoxicity induced by either disease or chemicals[13]. But, the exact mechanism is not clear. There are also several clinical studies. In one study, the prophylactic effect of boiled extract of *N. sativa* on asthmatic disease was examined[20]. Similarly, black seed oil was shown to be an effective adjuvant for the treatment of patients with allergic diseases[21]. In another clinical study, significant benefits of *Nigella sativa* extract in the treatment of acute tonsillopharyngitis was shown[22]. Also, it was shown that *Nigella sativa* has anti-epileptic effects in children with refractory seizures[23].

Therefore, it seems possible that the administration of *Nigella sativa* might protect the liver against the ischemia reperfusion injury; therefore, our aim was to confirm this hypothesis. We investigated alterations in the oxidant- antioxidant balance by measuring oxidant parameters such as total oxidative status (TOS), oxidative stress index (OSI) and myeloperoxidase (MPO), and antioxidant parameters, such as total antioxidant capacity (TAC) and catalase (CAT) in the liver tissue. Also we examined histopathological changes in the liver parenchyma.

MATERIALS AND METHODS

Thirty male Wistar-albino rats weighting 190 g to 250 g were used in this experimental study. All animals were maintained under standard conditions, and were fed water and rodent chow *ad libitum* and treated in compliance with the National Institutes of Health guidelines. Rats were deprived of food, but not water, for 24 h before surgery.

Animals were divided into three groups, sham group (Group 1), control group (Group 2), and *Nigella sativa* treatment group (Group 3). All rats were anesthetized with 0.2 mL/100 g of ketamine hydrochloride intraperitoneally. After the abdomen was shaved and disinfected, a midline incision was made and rats underwent either sham surgery or ischemia-reperfusion. Ischemia was carried out by exposing the afferent and efferent blood vessels and then clamping for 45 min with a microvascular "bulldog" clamp. Forty five minutes later, the ischemic liver was reperfused by opening the clamp, and reperfusion was achieved for 60 min. *Nigella sativa* was given to the rats in treatment group, before ischemia and before reperfusion at a dose of 0.2 mL/kg by intraperitoneal route. We chose the dose of this agent according to reported studies about I/R and *Nigella sativa*, as this dose has been shown to be effective in previous studies[24,25]. Rats in the control group were infused only with saline. At the end of the procedures, the rats were killed and blood and liver tissue samples were obtained. A portion of liver was stored at -80℃ for future analyses. Plasma alanine aminotransferase (ALT), aspartate aminotransferase (AST), and lactate dehydrogenase (LDH) activities were measured for evaluating the liver functions. To assess oxidative injury, TAC, TOS and OSI levels were determined.

OSI and MPO levels

The enzyme analyses of liver tissue were performed on the supernatant fractions of the tissue homogenates. The tissues were homogenized in 150 mmol/L ice-cold KCl to make a 10% homogenate, using a glass Teflon homogenizer. Then, the samples were sonicated on ice ten times for 5 s. The homogenates were centrifuged at 12 500 *g* for 30 min at 3℃, and the supernatant fractions were obtained.

Tissue samples for histological staining were obtained and fixed in 10% formalin-phosphate-buffered saline at 4℃ overnight. The samples were dehydrated and embedded in paraffin. Sections (7 μm) were cut and stained with hematoxylin and eosin. A pathologist evaluated the slides in a blinded manner.

Biochemical analyses

Plasma was used to measure AST, ALT and LDH as indicative parameters of hepatic function. The plasma activities of AST, ALT and LDH were estimated by commercially available kits using an autoanalyser (aeroset® Abbott Laboratories, Chicago, IL).

Measurement of the total antioxidant capacity

TAC of supernatant fractions was determined using a novel automated measurement method developed by Erel[26]. In this method, hydroxyl radical, which is the most potent biological radical, is produced. In the assay, ferrous ion solution, which is present in Reagent 1, is mixed with hydrogen peroxide, which is present in Reagent 2. The sequential produced radicals such as brown colored dianisidinyl radical cation, produced by the hydroxyl radical, are also potent radicals. Using this method, antioxidative effect of the sample against the potent-free radical reactions, which is initiated by the produced hydroxyl radical, is measured. The assay has excellent precision values, lower than 3%. The results are expressed as nmol Trolox Equiv./mg protein.

Measurement of total oxidant status

TOS of supernatant fractions was determined using a

novel automated measurement method, developed by Erel[27]. Oxidants present in the sample oxidize the ferrous ion-o-dianisidine complex to ferric ion. The oxidation reaction is enhanced by glycerol molecules, which are abundantly present in the reaction medium. The ferric ion makes a colored complex with xylenol orange in an acidic medium. The color intensity, which can be measured spectrophotometrically, is related to the total amount of oxidant molecules present in the sample. The assay is calibrated with hydrogen peroxide and the results are expressed in terms of nmol H_2O_2 Equiv./mg protein.

Oxidative stress index

Percent ratio of TOS level to TAC level was accepted as OSI. OSI value was calculated according to the following formula[28]: OSI (Arbitrary Unit) = TOS (nmol H_2O_2 Equiv./mg protein)/TAC (nmol Trolox Equiv./mg protein).

Determination of myeloperoxidase activity

The MPO (EC 1.11.1.7) activity was determined, using a 4-aminoantipyrine/phenol solution as the substrate for MPO-mediated oxidation by H_2O_2 and changes in absorbance at 510 nm were recorded[29]. One unit of MPO activity was defined as that which degraded 1 mol H_2O_2/min at 25℃. The results were expressed as mU/g protein.

Determination of catalase activity

Liver catalase activity was determined by Goth's colorimetric method, in which supernatant was incubated in H_2O_2 substrate, and the enzymatic reaction stopped by the addition of ammonium molybdate. The intensity of the yellow complex formed by molybdate and H_2O_2 was measured at 405 nm[30].

Histopathologic evaluation

Liver tissues were embedded in paraffin, cut into 3 to 5-μm sections, and mounted. After deparaffinization, the tissues were stained with hematoxylin and eosin (HE) for histological examination. Histological examination was performed by a pathologist.

Statistical analysis

For statistical analyses, nonparametric independent group comparisons were made. For multiple comparisons, the Kruskal-Wallis was used for comparisons between groups and the Mann-Whitney test used if any statistical significance was found. A level of 5% ($P < 0.05$) was considered statistically significant. Data were expressed as median and range.

RESULTS

Plasma ALT, AST, and LDH levels in the *Nigella sativa* treatment group were significantly lower than those in the control and sham groups ($P < 0.01$, $P < 0.01$ and $P < 0.05$, respectively, and $P < 0.01$ for all). They were significantly higher in the control group than those in the sham group ($P < 0.01$ for all). The results are summarized in Table 1.

Table 1 Clinical parameters, oxidative and antioxidative parameters in sham, I/R and I/R + NS rats (n = 10, mean ± SD)

	Sham	I/R	I/R + NS	*P*
Clinical parameters				
AST (U/L)	132 ± 22	952 ± 251[b]	571 ± 137[d,f]	0.001
ALT (U/L)	86 ± 17	695 ± 206[b]	321 ± 128[d,f]	0.001
LDH (U/L)	534 ± 181	4334 ± 760[b]	3113 ± 729[d,e]	0.001
TAC (nmol Trolox Eqv./mg protein)	2.96 ± 0.4	2.17 ± 0.6[a]	3.07 ± 0.2[e,1]	0.029
TOS (nmol H_2O_2 Eqv./mg protein)	10.4 ± 2.2	15.9 ± 2.0[b]	12.8 ± 3.1[1,2]	0.003
OSI (Arbitrary Unite)	3.54 ± 0.7	7.76 ± 1.9[b]	3.76 ± 0.6[1,2]	0.002
MPO (U/g protein)	9.4 ± 1.8	13.2 ± 1.7[b]	11.2 ± 2.2[f,1]	0.004
CAT (U/mg protein)	18.4 ± 3.9	10.1 ± 1.9[b]	18.3 ± 2.2[1,2]	0.004

AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; LDH: Lactate dehydrogenase; TAC: Total antioxidant capacity; TOS: Total oxidative status; OSI: Oxidative stress index; MPO: Myeloperoxidase; CAT: Catalase. [a]$P < 0.05$, [b]$P < 0.01$, Sham groups *vs* I/R groups; [d]$P < 0.01$, Sham groups *vs* I/R + NS groups; [e]$P < 0.05$, [f]$P < 0.01$, I/R groups *vs* I/R + NS groups. [1]$P > 0.05$, Sham groups *vs* I/R + NS groups; [2]$P < 0.001$, I/R groups *vs* I/R + NS groups.

TAC and CAT activities in liver tissue were significantly higher in Group 3 than those in Group 2 ($P < 0.05$ and $P < 0.001$, respectively). However, TAC and CAT activities in liver tissue were significantly lower in Group 2 than those in Group 1 ($P < 0.05$ and $P < 0.01$, respectively). TOS and OSI in hepatic tissue were significantly lower in Group 3 than those in Group 2 ($P < 0.001$ for both). Also MPO levels in hepatic tissue were significantly lower in Group 3 than those in Group 2 ($P < 0.01$). However, TAS, OSI and MPO levels in hepatic tissue were significantly higher in Group 2 than those in Group 1 ($P < 0.01$ for all). There were not statistically significant differences between the *Nigella sativa* treatment group and the sham group regarding to the oxidant and antioxidant parameters ($P > 0.05$). The results are summarized in Table 1.

In histopathological evaluation, there were no pathological changes in liver tissue of the sham group (Figure 1A). Liver specimens from rats after ischemia-reperfusion exhibited focal necrosis and infiltration of leukocytes (Figure 1B). *Nigella sativa* treatment significantly decreased these pathological changes (Figure 1C). Histological tissue damage was milder in the *Nigella sativa* treatment group than that in the control group.

Nigella sativa did not produce any adverse side effects in the doses tested in our study.

DISCUSSION

An excessive production of oxygen free radicals has been reported in ischemic reperfused liver, leading to tissue damage, and this is an unavoidable process in liver transplantation and in the surgical procedures in which the Pringle maneuver is used[4]. It has been shown in many studies that supplementation of free

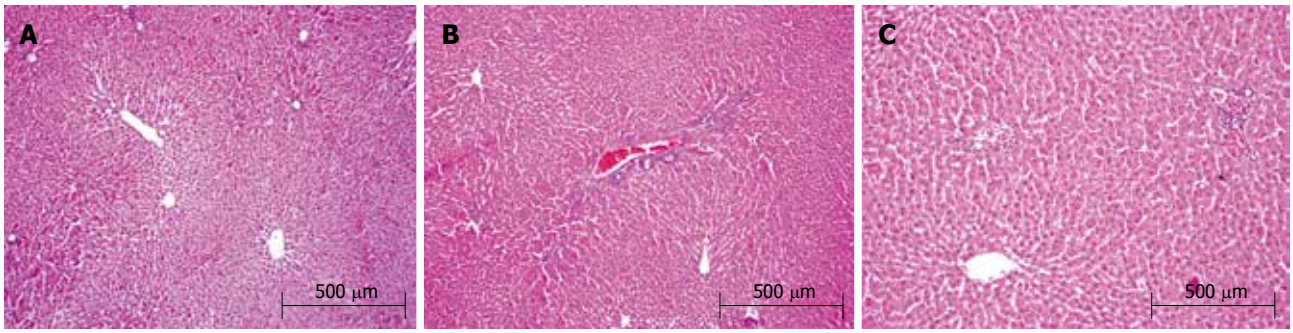

Figure 1 **A**: Normal liver tissue; **B**: Histopathological findings 60 min after reperfusion in the control group; **C**: Histopathological findings 60 min after reperfusion in the *Nigella sativa* treatment group.

radical scavengers is helpful in reducing hepatic ischemia reperfusion induced tissue damage[4,6,8]. *Nigella sativa* has been identified as a potent antioxidant acting as a free radical scavenger[9]. Therefore, it should not be surprising that *Nigella sativa* pretreatment has a protective effect on hepatic ischemia reperfusion injury in rats.

In some studies, to reduce the intestinal ischemia reperfusion injury, agents are administrated only before ischemia or reperfusion, and in some other studies both before ischemia and reperfusion. We preferred to administer both before ischemia and reperfusion as reported previously[31].

In the present study *Nigella sativa* treatment markedly attenuated ALT, AST and LDH activities which are associated with hepatic parenchymal injury. The increase of AST, ALT and LDH activities observed in control groups can be elucidated by lipid peroxidation leading to cytolysis, which is caused by the oxygen free radical formed during the reperfusion phase[32]. The decrease of AST, ALT, and LDH activities observed in the rats treated with *Nigella sativa*, when compared to the rats in control group, suggests a possible protective effect of *Nigella sativa* treatment in the hepatic ischemia/reperfusion condition.

Despite determination of either oxidants or antioxidant components alone may give information about oxidative stress, determination of oxidants along with antioxidants is more useful in this context[33]. So, we preferred to measure oxidants and antioxidant capacity simultaneously to assess oxidative stress more exactly. In the present study, we measured oxidative stress with OSI which was detected using both oxidative and antioxidative parameters. We evaluated TAC which reflects the antioxidative status and TOS to investigate oxidative status using a more recently developed measurement methods by Erel[27,28]. *Nigella sativa* treatment significantly reduced OSI and TOS levels, which show oxidative stress, and increased TAC levels, which show antioxidant capacity, in liver tissue. Oxidative stress activates mechanisms that lead to the synthesis of proinflammatory cytokines and cell adhesion molecules. Therefore, oxidative stress may contribute to an inflammatory response induced by endotoxemia after hepatic ischemia reperfusion. Our data confirm that liver ischemia reperfusion increases oxidative stress, an effect that not only produces direct tissue damage, but also modulates production of toxic cytokines leading to inflammation and leukocyte infiltration, consistent with previous studies. In addition to this, *Nigella sativa* treatment alleviated pathological structural changes.

Infiltration of neutrophils into tissues is commonly assessed by changes in activity of MPO, which is an enzyme found primarily in neutrophils. Increased MPO activity in the liver of rats after I/R suggests activation of an inflammatory response. In our study, we observed increased MPO activity in the liver tissue, and this may indicate that neutrophil accumulation and lipid peroxidation contributes to ischemia reperfusion-induced liver injury. Previously, it has been reported that the activated neutrophils located in the inflammatory foci and secreting MPO into the extracellular space can convert hydroperoxides into free radicals, triggering lipid peroxidation[34]. This is consistent with the results of our present study.

Catalase is an oxidoreductase enzyme, which transforms H_2O_2 into H_2O and O_2. It can protect cells from damage induced by ischemia reperfusion through scavenging reactive oxygen species[8]. The results of the present study showed that treatment with *Nigella sativa* can increase catalase activity, and this is consistent with its protective effect.

Although preliminary, our data indicate that *Nigella sativa* exhibits protective effects on liver tissue against ischemia reperfusion injury. The results of this present study may have clinical applications to the liver surgery associated with the Pringle maneuver and hepatic transplantation. However, more investigations are required to evaluate the protective effects of *Nigella sativa* on liver tissue damage in clinical and experimental models to verify this conclusion.

COMMENTS

Background

Hepatic ischemia-reperfusion (I/R) injury may occur in a variety of clinical settings such as trauma, sepsis, liver transplantation or hepatic pedicle clamping during a liver surgery and this remains a significant problem. Oxygen free radicals, produced on reperfusion have been shown to play a major role in hepatic I/R injury. Various therapeutic effects have been described for *Nigella sativa*. Additionally, it has been presented that *Nigella sativa* has protective effect against ischemia reperfusion injury to various organs. Therefore, it seems pos-

sible that the administration of *Nigella sativa* might protect the liver against the ischemia reperfusion injury and thus, we aimed to confirm this hypothesis.

Research frontiers

Tissue ischemia initiates a series of events that can ultimately lead to cellular dysfunction and necrosis. But, resumption of blood flow can paradoxically create more tissue injury, possibly because of the production of oxygen-derived cytotoxic products. It is important to reduce the oxidative stress mechanism and protect the liver tissue against the ischemia and reperfusion injury. This study demonstrated that *Nigella sativa* exhibits protective effects on liver tissue against ischemia reperfusion injury.

Innovations and breakthroughs

In previous studies, it has been demonstrated that *Nigella sativa* has protective effects against ischemia reperfusion injury on various organs. However, its protective effects on liver tissue against ischemia reperfusion injury are unclear.

Applications

It seems possible that the administration of *Nigella sativa* might protect the liver against the ischemia reperfusion injury which can occur due to a liver surgery, trauma or sepsis. Future studies will be required to verify the effectiveness of this substance.

Terminology

Reperfusion injury refers to damage to tissue caused when blood supply returns to the tissue after a period of ischemia. The absence of oxygen and nutrients from blood creates a condition in which the restoration of circulation results in inflammation and oxidative damage through the induction of oxidative stress rather than restoration of normal function.

Peer review

In the present study authors investigated the effects of *Nigella sativa*, an annual flowering plant, on hepatic ischemia-reperfusion injury. The late effects of *Nigella sativa* should be evaluated and survival experiments would be helpful.

Abstract

AIM: To evaluate the efficacy and safety of gemcitabine-oxaliplatin (GEMOX) combined with huachansu (cinobufagin) injection treatment in patients with locally advanced or metastatic gallbladder carcinoma (GBC), and to assess the quality of life (QOL) of such patients.

METHODS: Twenty-five patients with locally advanced or metastatic GBC were treated with intravenous gemcitabine (1000 mg/m^2) over 30 min on days 1 and 8, 2 h infusion of oxaliplatin (120 mg/m^2) on day 1, and 2-3 h infusion of huachansu (20 mL/m^2) on days -3-11, every 3-4 wk. Treatment was continued until occurrence of unacceptable toxicity or disease progression. QOL of patients was assessed by the EORTC QLQ-C30 at baseline, at the end of the first, third and sixth chemotherapy cycles, and 1 mo after the treatment.

RESULTS: Among the 25 patients with a median age of 64 years (range 42-78 years), 23 were evaluable in the study. A total of 137 cycles of therapy were performed and the median cycle was 5 (range 1-8) per patient. Out of the 23 patients whose response could be evaluated, 8 partial responses (PR) were observed (34.8%), while 7 patients (30.4%) demonstrated a stable disease (SD). The disease control rate was 65.2%. Progression of cancer was observed in 8 (34.8%) patients. The median progression-free and overall survival time was 5.8 mo (95% CI: 4.5-7.1 mo) and 10.5 mo, respectively. The therapy was well tolerated, with moderate myelosuppression as the main toxicity. Anemia grade 2 was seen in 16.0%, neutropenia grade 3 in 8.0% and thrombocytopenia grade 3 in 24.0% of patients, respectively. Non-hematologic toxicity ranged from mild to moderate. No death occurred due to toxicity. The QOL of patients was improved after chemotherapy, and the scores of QOL were increased by 10 to 20 points.

CONCLUSION: GEMOX combined with huachansu (cinobufagin) injection is well tolerated, effective, thus improving the QOL of patients with advanced GBC.

Efficacy and safety of gemcitabine-oxaliplatin combined with huachansu in patients with advanced gallbladder carcinoma. *World J Gastroenterol* 2008; 14(33): 5210-5216 Available from: URL: http://www.wjgnet.com/1007-9327/14/5210.asp DOI: http://dx.doi.org/10.3748/wjg.14.5210

INTRODUCTION

There is a marked worldwide geographic variation in gallbladder carcinoma (GBC) incidence, which correlates with the prevalence of cholelithiasis, and the highest prevalence of GBC is in Israel, Mexico, Chile, Japan, and America[1,2]. The incidence and mortality of GBC in China has had a tendency to increase in recent years[3].

The early symptoms of GBC are similar to those of other gallbladder diseases, such as gallstones or infection.

But, no characteristic symptoms could be observed at its early stage. In fact, early gallbladder cancer is discovered often when the gallbladder is removed as a treatment for gallstones. Otherwise, gallbladder cancer is often at its advanced stage at the time when it is diagnosed, and has a postoperative 5-year survival rate of less than 5%[4] with a high relapse rate.

Conventional surgery is considered the most effective treatment for GBC. But, many cases are inoperable at the time of its diagnosis. Chemotherapy has recently shown its effect on gallbladder cancer. The most commonly used chemotherapeutic agent is 5-fluorouracil (5-FU), which is often used alone or in combination with leucovorin. Several small trials of combined regimens for GBC, using 5-FU, cisplatin, mitomycin and/or leucovorin, have been reported to have mixed results. Other chemotherapeutic agents that are now in clinical trials include capecitabine, oxaliplatin[5], gemcitabine[6-8], erlotinib[9], *etc*. In addition, more and more people have paid their close attention to Chinese medicines for the prevention and treatment of cancer. Huachansu (cinobufagin) is just a widely used antitumor agent of traditional Chinese medicine in China[10,11].

Because the clinical data have demonstrated the effectiveness of gemcitabine on pancreatic cancer, and gallbladder shares a common embryological origin with the exocrine pancreas, we used gemcitabine-oxaliplatin (GEMOX) combined with huachansu injection (cinobufagin) in treatment of advanced GBC.

Since the prognosis of GBC patients is usually poor, it is important to maintain their health-related quality of life (HRQOL). The QOL of patients has been an important endpoint in assessment of GBC treatment. However, to our knowledge, only a few studies discussing QOL of patients with GBC, and there is no report on GEMOX and huachansu regimen for GBC patients. The aim of this study was to evaluate the efficacy and safety of GEMOX plus huachansu treatment of GBC, and to assess the QOL of GBC patients.

MATERIALS AND METHODS

Patients and eligibility criteria

From January 2003 to July 2005, of the 25 enrolled patients (10 males and 15 females) with locally advanced or metastatic GBC, 23 were assessable. The patients were required to have histologically confirmed diagnosis, measurable computed tomography (CT) scan or magnetic resonance imaging (MRI), Eastern Cooperative Oncology Group (ECOG) performance status (PS) 0-2, age < 78 years, a life expectancy > 3 mo. No patient underwent anticancer procedures within 1 mo before the present study. The laboratory criteria were leukocyte count $\geqslant 4.0 \times 10^9$/L, neutrophils $\geqslant 1.5 \times 10^9$/L, platelet count $\geqslant 100 \times 10^9$/L, aspartate aminotransferase (AST) and alanine aminotransferase (ALT) $\leqslant$ 2.5 × upper limit of normal (ULN), serum creatinine < 1.5 × ULN, serum bilirubin value < 2.5 × ULN. Basic CA19-9 level was recorded. Patients with active infections, unstable cardiovascular conditions, brain metastases, other malignancy or serious medical illnesses were excluded from this study. The pre-treatment characteristics are listed in Table 1.

Median	496
Range	7-10463

[1]Normal level.

Tumor size was assessed by CT scan or MRI within 3 wk prior to the first cycle, and baseline biological analysis was performed within 1 wk. A physical examination and complete blood cell count were performed 2-3 d before each cycle. Blood count was obtained each week to determine the level of myelosuppression. After every three cycles, a full clinical evaluation including performance status and physical examination was performed.

Treatment protocol

All patients received intravenous gemcitabine (1000 mg/m^2) over 30 min on days 1 and 8, 2 h oxaliplatin infusion (120 mg/m^2) on day 1 (oxaliplatin was discontinued if specific cumulative peripheral sensory neuropathy of NCI CTC grade 3 occurred), and 2-3 h huachansu infusion (20 mL/m^2) (0.5 g/mL) in 500 mL of 50 g/L glucose solution on days -3-11. Treatment was repeated every 3-4 wk until limiting toxicity or disease progression occurred, or further treatments were refused by patients. Biliary bypass or stenting was required in four patients before the treatment.

Follow-up

After two cycles of chemotherapy, patients were followed up every 4-6 wk till February 2007.

Assessment of efficacy

Tumor response was evaluated every three cycles by CT scan or MRI, using standard RECIST criteria[12]. Complete response (CR) was defined as a disappearance of all signs and symptoms of disease. Partial response (PR) was defined as a decrease > 30% of the sum of the largest diameters of target (measurable) lesions without appearance of new lesions or progression of non-target (evaluable) lesions. To be assigned a response status, changes in tumor measurement were confirmed by a repeated assessment performed no less than 4 wk after the criteria for response were first met. Stable disease (SD) was defined as no sufficient shrinkage to qualify partial response or less than a 20% increase in the sum of the largest diameters of target lesions without appearance of new lesions or progression of non-target lesions. Progressive disease (PD) was defined as a 20% increase in the sum of the largest diameters of target lesions or as appearance of new lesions or as progression of non-target lesions. Disease control was defined as the absence of tumor progression (i.e. complete and partial response and SD) for at least 2 mo. Progression-free survival (PFS) was determined from the first day of treatment until clinical progression or tumor progression assessed by CT scan. Overall survival (OS) was determined from the first day of treatment until the date of death. OS and PFS were analyzed using the Kaplan-Meier method. Toxicity was evaluated at each cycle according to the NCI CTC version 2.0.

Assessment of QOL

The validated traditional Chinese version of the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire-Core 30 (EORTC QLQ-C30) was used to measure the patients' QOL. Patients completed the EORTC QLQ-C30 at baseline, at the end of the first, third and sixth chemotherapeutic cycles, and 1 mo after completion of chemotherapy.

The QLQ-C30 is a 30-item standardized measure that includes a global QOL/ overall health status scale, five functioning scales (physical, role, emotional, cognitive, and social), three multi-item symptom scales (fatigue, pain, nausea and vomiting) and six single items (dyspnea, sleep disturbance, appetite loss, diarrhea, constipation, and financial impact). The raw scores obtained from the EORTC questionnaire were converted to scores ranging from 0 to 100 using linear transformation according to the scoring procedure. Higher scores on the functioning scales, and the overall health status indicate a higher functioning level and a better QOL. Higher scores on the symptom scales or single item scales represent a higher level of symptoms or problems.

QOL scores were determined in our study in the following domains: physical, role, emotional, cognitive and social function, global QOL/overall health status, fatigue, nausea and vomiting, and pain.

Statistical analysis

The objective response rate, progression-free survival, overall survival, toxicity and QOL were observed, and the 95% confidence interval (CI) was calculated using the method of Clopper and Pearson. Overall survival, progression-free survival, death or last follow-up was made using the Kaplan-Meier method using SPSS version 12.0 software. The life table method was used to evaluate the 1-year survival rate. Data were expressed as mean ± SD. QOL score analysis was done using the paired *t*-test for comparison between baseline and 1 mo after completing chemotherapy. $P < 0.05$ was considered statistically significant, whereas a mean difference of 10 or more points in QOL scales represents a clinically significant/relevant difference[13].

RESULTS

Response and survival

A total of 25 patients (10 males and 15 females) were included this trial and 23 were assessable. Twenty-one patients (84.0%) received GEMOX plus huachansu injection as the first-line and 4 (16.0%) as the second-line chemotherapy. A total of 137 cycles of therapy were performed, the median cycle was 5 (range 1-8) per patient. Up to February 2007, two patients were still alive. The median follow-up time was 11.5 (range, 2-33) mo. The one-year survival rate was 39.1%. There was no complete response. However, out of the 23 patients whose response could be evaluated, 8 (34.8%) went into PR, 7 (30.4%) demonstrated SD, 8 (34.8%) had progression of the disease. The disease control rate was 65.2%. The median progression-free and overall survival was 5.8 mo (95% CI: 4.5-7.1 mo) and 10.5 mo, respectively (Figure 1).

Four patients (16.0%) required biliary tract decompression by endoscopic or percutaneous stenting because of obstructive jaundice before chemotherapy.

Basic CA19-9 levels were recorded in all patients (median 496; range 7-10 463 kU/L), and 15 patients (60%) had elevated baseline levels. Serum CA19-9 levels were measured every 3-4 wk. The relative changes of CA19-9 during chemotherapy was negatively correlated with the baseline and progression-free survival ($P = 0.03$).

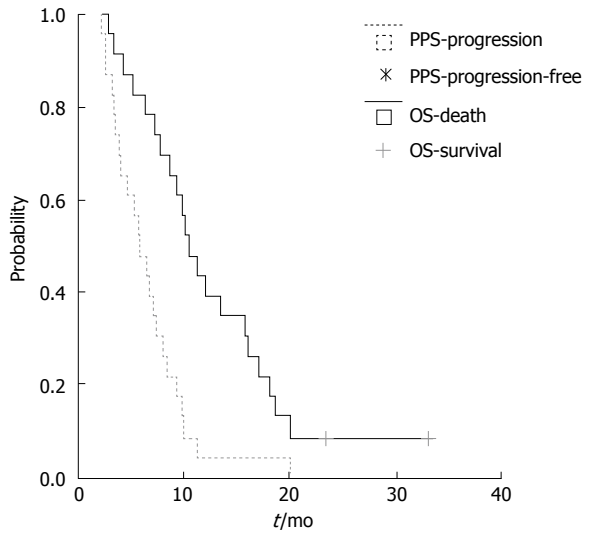

Figure 1 Kaplan-Meier curve of OS and PFS for patients treated with GEMOX plus huachansu. The median progression-free and median overall survival was 5.8 mo and 10.5 mo, respectively.

Toxicity

All patients were evaluable for toxicity. Gemcitabine in combination with oxaliplatin induced neutropenia, thrombocytopenia, nausea/vomiting, and peripheral neuropathy due their toxicity. It was observed by us that gemcitabine-based therapy was associated with a higher rate of thrombocytopenia among Chinese patients with cancer. Myelosuppression was the most frequent side-effect in our study. Anemia grade 2, neutropenia grade 3 and thrombocytopenia grade 3 were observed in 16%, 8% and 24% of patients, respectively. The nadir of thrombocytes appeared on days 6-12 [(51.0 ± 19.4) × 10^9/L, mean ± SD]. Recombinant human interleukin-11 (IL-11) was used to treat chemotherapy-induced thrombocytopenia. The platelet count returned to normal [(126.0 ± 18.2) × 10^9/L] after 3-8 d of IL-11 treatment at a dose of 25-50 μg/kg per day (Figure 2).

The symptoms induced by grade 1 non-hematologic toxicity included nausea/emesis (20.0%), diarrhea (4.0%), pain (8.0%), and peripheral neuropathy (64.0%). Sixteen patients (64.0%) felt anaesthesia of hands and feet, which was mild and did not interfere with their functions.

GEMOX combined with huachansu injection regimen was well tolerated (Table 2) with moderate myelosuppression as the main toxicity. No treatment-related death occurred.

QOL

The completion rate of QOL questionnaire declined from 96.0% at baseline to 73.9%, 1 mo after completion of chemotherapy. The mean score and standard deviation for the EORTC QLQ-C30 are presented in Table 3. An improvement of more than 10 points was found in the global QOL, physical, cognitive and emotional functioning, whereas symptoms such as pain decreased more than 18 points after chemotherapy. One month after the completion of treatment, physical functioning (PF) increased over baseline levels by approximately 12 points, and the global QOL score increased from 52.3 ± 20.0 at baseline to 65.3 ± 22.4, 1 mo after completion of chemotherapy. As compared with baseline, the patients reported fatigue that was worse immediately after the first cycle. However, fatigue then improved from the end of the first cycle to 1 mo after treatment. The five functional scales, global QOL, and multi-item symptom scales are shown in Figure 3. One month after treatment, the trend to improve the functioning, global QOL and symptoms was significant.

Table 2 Combined chemotherapy-related toxicities to patients *n* (%)

Toxicity	NCI-CTC grade			
	1	2	3	4
Leukopenia	9 (36.0)	5 (20.0)	2 (8.0)	0
Neutropenia	6 (24.0)	7 (28.0)	2 (8.0)	0
Anemia	2 (8.0)	4 (16.0)	0	0
Thrombocytopenia	7 (28.0)	5 (20.0)	6 (24.0)	2 (8.0)
Diarrhea	1 (4.0)	0	0	0
Nausea/emesis	5 (20.0)	0	0	0
Peripheral neuropathy	16 (64.0)	0	0	0
Pain	2 (8.0)	0	0	0

NCI-CTC: National Cancer Institute Common Toxicity Criteria. The combined treatment induced myelosuppression.

Table 3 Transformed scores for EORTC QLQ-C30 at different time points in patients treated with GEMOX and huachansu injection (mean ± SD)

Domain/Item	Baseline	First cycle	Third cycle	Sixth cycle	1 mo
Functioning					
Physical	65.4 ± 17.0	57.0 ± 20.3	64.4 ± 21.0	70.6 ± 18.3	77.5 ± 16.4[a]
Role	57.1 ± 26.3	55.0 ± 24.3	58.5 ± 26.2	60.4 ± 25.4	63.4 ± 27.2
Emotional	54.3 ± 33.0	47.2 ± 36.8	59.4 ± 39.1	70.5 ± 24.2	69.4 ± 30.1[a]
Cognitive	66.1 ± 24.6	68.1 ± 30.2	77.4 ± 26.3	79.1 ± 24.0	79.5 ± 21.7[a]
Social	47.2 ± 30.4	39.4 ± 33.6	44.1 ± 29.0	41.1 ± 30.7	48.2 ± 32.6
Global QOL	52.3 ± 20.0	41.4 ± 24.3	50.6 ± 29.7	55.4 ± 30.0	65.3 ± 22.4[a]
symptoms					
Fatigue	43.3 ± 31.2	51.2 ± 33.4	40.1 ± 27.4	42.1 ± 22.0	38.2 ± 28.6
Nausea and vomiting	7.6 ± 6.2	9.0 ± 5.1	7.4 ± 4.3	5.4 ± 2.5	3.2 ± 2.1[a]
Pain	44.5 ± 21.6	28.0 ± 18.3	25.5 ± 12.4	24.3 ± 9.1	26.0 ± 10.4[a]

Quality of life was assessed at baseline, at the end of the first, third and sixth chemotherapeutic cycles, and 1 mo after completion of chemotherapy. Scores of EORTC QLQ-C30 were converted to linear transformation ranging from 0 to 100. Higher scales for the functional and global QOL represent a better function. In contrast, higher scales for symptoms represent worse symptoms. [a]$P < 0.05$ *vs* baseline.

DISCUSSION

Due to the high mortality rate of GBC in China, we made this study to test the efficacy and safety of GEMOX combined with huachansu injection (cinobufagin) in patients with locally advanced or metastatic GBC and to assess the patients' QOL.

GBC, though rare, has a very poor prognosis. There is no generally accepted standard chemotherapy for

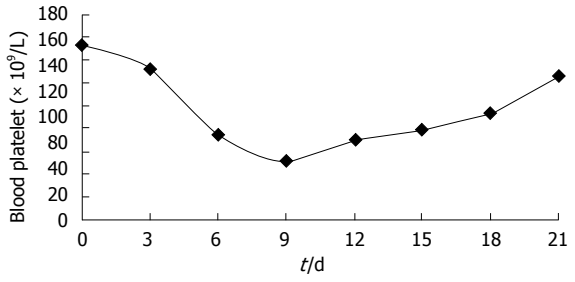

Figure 2 Peripheral blood platelet count after combined chemotherapy. The nadir of thrombocytes appeared on days 6-12.

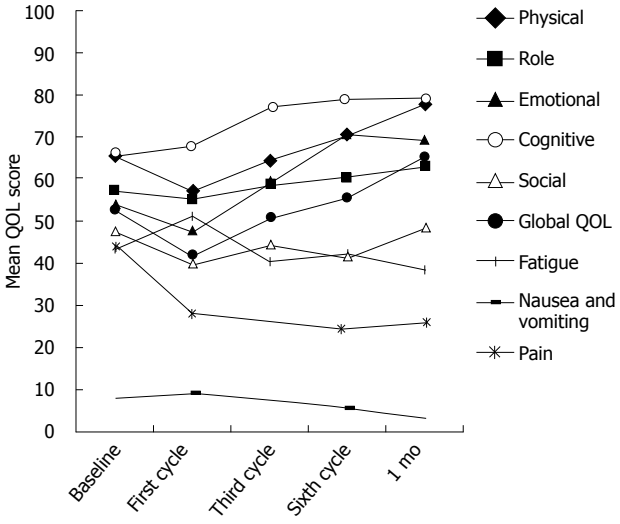

Figure 3 Functioning and symptom scales of the EORTC QLQ-30. First, third and sixth cycles: At the end of the first, third and sixth chemotherapeutic cycles; 1 mo: 1 mo after completion of chemotherapy. An improvement of more than 10 points was found in global QOL, physical and cognitive as well as emotional functioning, whereas symptoms such as pain were decreased by more than 18 points after completion of chemotherapy.

advanced, non-resectable cancer of the gallbladder or biliary tree. The median survival time of advanced GBC patients who receive best supportive care is approximately 6 mo[14].

Some new chemotherapeutic agents have been used in treatment of patients with advanced biliary tract cancer recently, such as gemcitabine, 5-fluorouracil[15-17], capecitabine[18], cisplatin[19,20], oxaliplatin or carboplatin. It was reported that gemcitabine is active against pancreatic and advanced biliary tract adenocarcinoma, and able to induce a response rate of 8.0%-60.0%[21,22].

Gallardo[23] conducted a phase Ⅱ trial with gemcitabine (1 000 mg/m^2 over 30 min weekly for 3 wk followed by a week of rest) in patients with locally advanced or metastatic GBC, and found that the overall response rate was 36.0%. The cancer remained stable in 6 (25.0%) patients, and progressed in 10 (40.0%) patients. The median survival time was 30 wk. In another phase Ⅱ trial with 24-h gemcitabine infusion weekly in patients with advanced gallbladder and biliary tract carcinoma, 18 patients were evaluated for response. One partial response was observed (6.0%), the disease control rate was 61.0%, the median time of tumor progression was 3.6 mo and the median overall survival time was 7.5 mo[24].

Andre *et al*[25] used GEMOX regimen to treat patients with advanced biliary tract adenocarcinoma, and found that the objective response was 36%, the median PFS time was 5.7 mo, the overall survival time was 15.4 mo in group A (PS 0-2), while the objective response was 22.0%, the median PFS time was 3.9 mo and the median OS time was 7.6 mo in group B (PS > 2).

Huachansu, one of the most widely studied traditional Chinese medicine, is a water soluble extract from *Bufo* toad skin, and can be sued in treatment of cancer, especially liver and pancreatic cancer. Some studies demonstrated that huachansu injection can improve the QOL of patients and has been used as a treatment of cancer in China[26-28]. It was reported that digitalis-like cinobufagin can protect prostate cancer cells from proliferation. The protein expression of active caspase 3 in LNCaP, DU145, and PC3 cells was increased after treated with combined cinobufagin and EGTA, the expression of Fas was increased, the expression of Bax was down-regulated in nuclei, and the protein expression of cytosolic cytochrom C was also increased after treatment with cinobufagin in these cell lines[29]. It has been shown that bufalin or cinobufagin increases Ca^{2+} and apoptosis in cancer cells, caspase 3 activities in DU145 and PC3 cells, and caspase 9 activities in LNCaP cells after a 24 h culture[30].

QOL is a multidimensional concept including physical, emotional, social, and daily-life functioning as well as disease symptoms and treatment from the patient's perspective. Improving QOL and disease-associated symptoms is increasingly important for patients with advanced GBC. QOL is now regarded as a biologically and clinically meaningful outcome that is as important as disease-free, and overall survival with regard to anticancer treatment. Huachansu injection was given 3 d before GEMOX in our study, and its effectiveness on pain relief appeared 1-2 d later (9/14 patients). The overall life quality of patients entered this trial improved 10 to 20 points. The patients undergoing GEMOX and huachansu regimen achieved better QOL outcomes. The partial response rate was 34.8%, and the disease control rate was 65.2%. The median progression-free and median overall survival was 5.8 mo and 10.5 mo, respectively. The patients tolerated the treatment well with moderate myelosuppression as the main toxicity. No treatment-related deaths occurred.

In conclusion, combined GEMOX and huachansu injection regimen can be used in treatment of GBC patients, especially those with advanced or metastatic GBC.

COMMENTS

Background

The difficulty in early diagnosis of gallbladder carcinoma (GBC) is its poor specificity in clinical and ambiguous early symptoms, thus affecting its prognosis. Some patients are found having GBC only when other diseases are diagnosed and treated. Surgery is the only curative treatment for gallbladder

cancer. However, because of frequent local and distant recurrence, radical surgery at its advanced stage is often unsuccessful. Thus, chemotherapy for patients with advanced GBC seems to be a better choice of treatment. However, no standard chemotherapy for GBC has yet been established.

Research frontiers

The increasing number of papers on chemotherapy for GBC emphasizes the need of a new standard beyond 5-FU. At present, clinical studies on the treatment of GBC with new chemotherapeutic agents are underway. Further clinical trials, especially large multi-institutional RCTs (phase Ⅲ studies) using novel agents such as gemcitabine, should be performed in order to establish a standard treatment for GBC.

Innovations and breakthroughs

In China, huachansu used in treatment of patients with lung cancer and hepatocellular carcinoma has achieved rather good results in suppressing the growth of cancer, alleviating of pain and fatigue, and improving the function of patients' immune system. Our findings provide certain possible evidence that combined gemcitabine-oxaliplatin (GEMOX) and huachansu chemotherapy may improve the survival and QOL of GBC patients.

Applications

The results of this study indicate that combined GEMOX and huachansu chemotherapy is an effective regimen for metastatic GBC. The patients can tolerate it well. Toxicities are mostly hematological and easily manageable. If this combined regimen could be applied in clinic practice, the patients would have a longer survival time.

Terminology

The World Health Organization (WHO) defines QOL as" an individual's perception of his or her position in life in the context of culture and value system in which he or she lives in relation to his or her goal, expectation, standard and concern. It is a broad-ranging concept affected in a complex way by the person's physical health, psychological state, independence, social relationships, and his or her relationship to salient feature of his or her environment." Studies showed that QOL is associated to the survival of cancer patients.

Peer review

This is an interesting study. The authors evaluated the efficacy and safety of combined GEMOX and huachansu injection (cinobufagin) treatment in patients with locally advanced or metastatic gallbladder carcinoma, and assessed the patients' QOL. The study was well designed.

Abstract

AIM: To determine whether efflux systems contribute to multidrug resistance of *H pylori*.

METHODS: A chloramphenicol-induced multidrug resistance model of six susceptible *H pylori* strains (5 isolates and *H pylori* NCTC11637) was developed. Multidrug-resistant (MDR) strains were selected and the minimal inhibitory concentration (MIC) of erythromycin, metronidazole, penicillin G, tetracycline, and ciprofloxacin in multidrug resistant strains and their parent strains was determined by agar dilution tests. The level of mRNA expression of *hefA* was assessed by fluorescence real-time quantitative PCR. A *H pylori* LZ1026 knockout mutant (Δ*H pylori* LZ1026) for (putative) efflux protein was constructed by inserting the kanamycin resistance cassette from pEGFP-N2 into *hefA*, and its susceptibility profiles to 10 antibiotics were evaluated.

RESULTS: The MIC of six multidrug-resistant strains (including 5 clinical isolates and *H pylori* NCTC11637) increased significantly (≥ 4-fold) compared with their parent strains. The expression level of *hefA* gene was significantly higher in the MDR strains than in their parent strains (P = 0.033). A *H pylori* LZ1026 mutant was successfully constructed and the Δ*H pylori* LZ1026 was more susceptible to four of the 10 antibiotics. All the 20 strains displayed transcripts for *hefA* that confirmed the *in vitro* expression of these genes.

CONCLUSION: The efflux pump gene *hefA* plays an important role in multidrug resistance of *H pylori*.

Key words: Efflux pump; *Helicobacter pylori*; Multidrug resistance; Fluorescence real-time quantitative PCR; Knockout mutant

INTRODUCTION

H pylori is a Gram-negative bacterium that colonizes human gastric mucosa[1] and plays an important role in the pathogenesis of chronic gastritis, peptic ulcer, gastric adenocarcinoma, and gastric mucosa-associated lymphoid tissue lymphoma[2,3]. Successful treatment usually requires two or three kinds of antibiotics in combination with a proton pump inhibitor. In recent years, the eradication rate of *H pylori* for standard therapies has decreased due to the increasing antimicrobial resistance[4,5]. Possible mechanisms of intrinsic drug resistance involve decreased drug uptake or increased drug efflux[6]. Efflux of compounds is a phenomenon commonly observed in bacteria[7-9]. Through this process, organisms are protected from possible toxic effects of metabolite accumulation or external compounds, and compound efflux results in a decreased susceptibility to a variety of antibiotics. Five families of multidrug efflux transporters have been described[10]. One of them, widespread in Gram-negative bacteria, is the resistance-nodulation-division (RND) family of efflux systems[11-13]. The RND family of efflux systems has three components: inner membrane efflux proteins (IEPs) which act with the other two components, a periplasmic efflux protein (PEP) which facilitates interaction with the other two components, and an outer membrane efflux protein (OEP) which

is the TolC (the outer membrane efflux protein in *Escherichia coli*) or a TolC homolog[14].

Bina JE and coworkers[15] have identified three RND efflux systems, namely *hefABC*, *hefDEF*, and *hefGHI*. Each of them is consisted a translocase, an accessory protein, and a TolC homolog. *hefA*, *hefD*, and *hefG* are the TolC homolog encoding the outer membrane efflux protein. In their study, the *hefGHI* operon was expressed only *in vivo*. Nevertheless, they could not establish a role of these efflux systems in antibiotic resistance. An unfortunate choice of compounds and a methodology that may not be sensitive enough to relatively small differences in susceptibilities between the mutant and parental strains may have impacted their study. van Amsterdam *et al*[16] identified 27 putative translocases in the *H pylori* 26695 genome, but only four putative *H pylori* OEPs or TolC homologs. Parallel translocases may function in a limited number of OEPs[17]. Thus, inactivation of a TolC-like protein may affect the functions of multiple translocases. They evaluated the susceptibility profiles of the inactivation of the four TolC homologs after insertion, but could not quantitate the operon expression levels of the efflux systems in multidrug resistant strains of *H pylori*. In view of the biological difference of the *H pylori* strains in Asia, Europe and North America[18], the present study was to determine whether efflux systems of *H pylori* contribute to antimicrobial susceptibility. A chloramphenicol-induced multidrug resistance model of 6 susceptible *H pylori* strains (5 isolates and *H pylori* NCTC11637) was developed by detecting the minimal inhibitory concentration (MIC) of the strains to metronidazole, tetracycline, erythromycin, penicillin G, and ciprofloxacin. The levels of mRNA expression of *hefA* in multidrug-resistance (MDR) strains and their parent strains were assessed by fluorescence real-time quantitative PCR. To further evaluate the role of *hefA* in multidrug resistance of *H pylori*, a clinical isolate of *H pylori* LZ1026 was selected, which represent the Chinese strains. A *H pylori* LZ1026 knockout mutant was constructed and its susceptibility profiles to 10 kinds of antibiotics were evaluated.

MATERIALS AND METHODS

Reagents

Chemical reagents were purchased from TaKaRa Biotechnology Co. Ltd (Dalian, China). Restriction enzymes, polymerases, T4 DNA ligase, Quant SYBR Green PCR Kits and other molecular biology reagents were purchased from Biosail Biotechnology Co. Ltd (Beijing, China), and used following their manufacturers' instructions. Amoxicillin, cefotaxime, ceftazidime, polymyxin B, nalidixic acid, clarithromycin, norfloxacin, gentamicin, metronidazole, tetracycline, erythromycin, chloramphenicol, and ciprofloxacin, penicillin G were purchased from the National Institute for the Control of Pharmaceutical and Biological Products (Beijing, China). Nucleic acid sequencing and synthesis were performed in SaiBaiSheng Biotechnology Co. Ltd (Beijing, China).

Bacterial strains, plasmid and culture conditions

H pylori LZ1026 and 20 other clinical isolates of *H pylori* were obtained from routine cultures of clinical gastric biopsies from patients with peptic ulcer or chronic active gastritis at the Second Affiliated Hospital of Zhengzhou University (Zhengzhou, China). *H pylori* NCTC11637 obtained from HeNan Key Laboratory of Molecular Medicine was used as a reference. Isolates were cultured on Brucella agar medium plates containing 7% lysed sheep blood at 37℃ under microaerobic conditions (50 mL/L O_2, 100 mL/L CO_2, 850 mL/L N_2) for 48-72 h. Identification of *H pylori* isolates was based on the results of Gram staining, cell morphology, and positive reaction for catalase, oxidase and urease activity. Putative multidrug efflux knockout mutant of *H pylori* LZ1026 was grown on sheep blood agar plates containing 25 μg of kanamycin (KAN) per mL and 100 μg of ampicillin (AMP) per mL. The vectors pBluescript Ⅱ SK (-)and pEGFP-N2 were from HeNan Key Laboratory of Molecular Medicine. *E.coli* DH5α was used for subcloning the hefA operon. *E.coli* were grown in Luria broth. For cloning in *E.coli*, 100 mg/mL AMP was used.

Induction of multiple antibiotic resistances of clinical isolates

Susceptible strains were isolated from gastric biopsy samples using multiple antibiotic resistance induction tests. Induction of chloramphenicol resistance of susceptible isolates was performed by selecting resistant colonies that arose in the agar plates containing 1/2 × MIC chloramphenicol. The resistant colonies were incubated for 48-72 h under microaerobic conditions to increase the concentration of chloramphenicol by one fold up to 128 × MIC. The strains were further incubated on fresh plates with no chloramphenicol for 4 generations, and then transfered onto plates containing 4 × MIC chloramphenicol[19].

Induced colonies were maintained on plates containing 4 × MIC of erythromycin, metronidazole, tetracycline, penicillin G or ciprofloxacin, respectively. The colonies were incubated for 48-72 h under microaerobic conditions. A four-fold increase in MIC of the multidrug resistant strains was considered significant[20]. Six multidrug resistant strains were selected.

Assessment of susceptibilities to antimicrobials

H pylori cells grown for 48 h on sheep blood agar plates were resuspended in phosphate-buffered saline. Suspensions of *H pylori* were adjusted to an optical density of 0.1 at 625 nm , and 1 μL of these suspensions containing approximately 10^5 CFU/mL, was spread on horse blood agar plates containing approximately 5 × 10^4 bacteria within 5 mm[21]. MICs of erythromycin, metronidazole, penicillin G, tetracycline, and ciprofloxacin in multidrug resistant strains and their parent isolates were determined with the conventional two-fold agar dilution tests. MICs of the kinds of 10 antibiotics against the *hefA* mutant strain of *H pylori* LZ1026 and its wild strain were also detected[22].

Real-time RT-PCR

RNA was isolated using the total RNA kit (SBS Genetech Co., Ltd Beijing, China) and reverse transcribed into cDNA. Complete removal of DNA was verified by direct PCR with the RNA as a template (Figure 1). *hefA*, *versus gyrB* (a housekeeping gene encoding for gyrase B), was utilized to study the relative expression of the *hefA* gene in 6 multidrug resistant strains, and their parent strains: *H pylori* 03154, *H pylori* 12025, *H pylori* 12021, *H pylori* 11032, *H pylori* 03174, NCTC11637. cDNA of *hefA* and *gyrB* was amplified using a 5700 sequence detector real time PCR machine (Perkin Elmer Company) in the presence of Real Master Mix (SYBR Green). The gene-specific primers used were designed based on the sequence alignments of the genes from *H pylori* 11637 in GenBank. The sequences of *hefA* (accession No: AF059041) are F: (5'-ACGCCTCGAGTAAAAGCG CAAGGGAATTTG-3') and R: (5'-ACGCTCTAG ATTCGCTAATTGGCCTAGCAT-3'). The PCR primers were predicted to amplify a 162-bp amplicon. Expression of the housekeeping gene *gyrB* (accession No: AB084049) was assessed in parallel with the primer pair *gyrB*: F: (5'-TTACTACGACTTATCCTGGGGCTA GCGCTG-3') and R: (5'-CCCCATCAATTTCCACAT TCTCCGC-3'). The PCR primers were predicted to amplify a 267-bp amplicon.

To plot standard curves for real-time PCR, cDNAs of the *hefA* and *gyrB* genes were cloned into the pMD19-T vector system (TaKaRa Biotechnology). The vector containing cDNAs of the *hefA* or *gyrB* genes with known molar concentrations was utilized. Single reactions were prepared for each cDNA along with each serial of dilution using the SYBR Green Master Mix (Stratagene). Each PCR also included a reverse transcription negative control to confirm the absence of genomic DNA, and a non template negative control to check the primer-dimer. Each reaction consisted of 20 μL, containing 2 μL of cDNA and 5 pmol of each primer. The cycling conditions were 1 cycle of denaturation at 95℃ for 1 min, followed by 35 three-segment cycles of amplification at 95℃ for 30 s, at 55℃ for 1 min, and at 68℃ for 30 s during which the fluorescence was automatically measured, and one three-segment cycle of product melting at 95℃ for 1 min, at 55℃ for 30 s, and at 95℃ for 30 s. The baseline adjustment method of the Gene Amp 5700 SDS (Perkin-Elmer) software was used to determine Ct (the threshold cycle) in each reaction. A melting curve was plotted for each primer pair to verify the presence of one gene-specific peak, and the absence of primer dimer. All samples were amplified in three independent reactions, and the mean was used for further analysis[23-25].

To assess whether the differences were actually statistically significant, an analysis of paired-samples *t* - test was utilized to study the degree of statistical significance of *hefA* gene expression between MDR and parent strains.

Mutagenesis of putative efflux operon

All standard DNA techniques, transformation of *E.coli*, and DNA analysis procedures were performed as previously described[26-28]. Plasmid DNA was isolated using a TIANprep Mini plasmid kit (TianGen Biotech Co. Ltd, Beijing, China). *H pylori* LZ1026 strain was isolated from a patient with peptic ulcer, and its internal portion (bp 277 to 1 574) of the *hefA* gene (reference from *H pylori* 11637 in GenBank accession number AF059041) was amplified. A restriction fragment, approximately 1298 bp, was purified and ligated into XbaI and XhoI-digested vector pBluescript Ⅱ SK(-). *H pylori* LZ1026 knockout mutant for (putative) efflux protein was constructed by inserting the KAN resistance cassette from vector pEGFP-N2 into *hefA*, resulting in an 859 bp deletion. This suicide plasmid was then introduced into *H pylori* LZ1026 by natural transformation, and transformants were selected by plating them on a selective medium containing 25 mg of kanamycin/mL. Insertion of the KAN resistance cassette at the desired location(s) in the *H pylori* putative efflux gene was confirmed by PCR. Each clone was sequenced by Biosia Biotechnology Company (Shanghai, China).

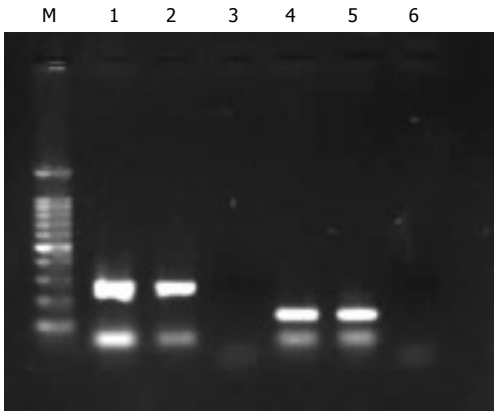

Figure 1 RT- PCR products of the *hefA* and *gyrB* genes. M: 100 bp DNA Marker; lanes 1 and 2: PCR products of *gyrB*; lanes 4 and 5: PCR products of *hefA*; lanes 3 and 6: PCR products with RNA as a template.

RESULTS

Phenotypic induction of hefA-mediated resistance of H pylori

To obtain the multidrug-resistant strains, a chloramphenicol-induced model was developed. Following one-fold concentration increase of chloramphenicol, the MICs of chloramphenicol-induced strains resistant to metronidazole, tetracycline, erythromycin, penicillin G, and ciprofloxacin were detected. The MICs of 6 multidrug-resistant strains (including 5 clinical isolates and *H pylori* NCTC11637) were significantly increased (≥ 4-fold) compared with their parent strains (Table 1).

Expression of hefA in multidrug resistant strains (MDR) and their parent isolates (PT)

The expression of *hefA* in multidrug resistant strains and their parent isolates was assessed by relative real-time RT-PCR. Each relative expression value was the mean of three replicas. The relative expression of *hefA versus gyrB*

03174	4.16	6.03
11637	4.41	9.56
Total (mean ± SD)	2.6356 ± 1.7245	5.8466 ± 2.9370

PT: Parent isolates; MDR: Multidrug resistant strains.

in 5 clinical isolates and *H pylori* 11637 was significantly higher in MDR (5.8466 ± 2.9370) than in PT (2.6356 ± 1.7245) (Table 2). The results reveal that the relative expression of *hefA* was higher in the induced multidrug resistant strains than in their wild isolates. The difference in *hefA* expression was statistically significant (P =0.033) (Figure 2).

Active efflux systems in H pylori

To further evaluate the role of efflux pump gene *hefA* of *H pylori* in multidrug resistance, a *H pylori* LZ1026 mutant was successfully constructed, and its disrupted *hefA* gene was uniquely different from that of the wild strain. A *hefA* gene fragment (about 1147 bp) of *H pylori* LZ1026 was sequenced and submitted to the GenBank (accession No. EU271683). Susceptibilities to wild-type strain of *H pylori* (*H pylori* LZ1026) and its isogenic mutant with putative RND outer membrane efflux protein were determined. The *hefA* (*H pilori* 0605, numbers refer to the loci in *H pylori* 26695) was genetically inactivated. MICs were determined by agar dilution tests. The *H pylori* mutant increased its susceptibility. The MIC of four of the 10 tested kinds of antibiotics (amoxicillin, cefotaxime, ceftazidime, polymyxin B, ciprofloxacin, nalidixic acid, clarithromycin, norfloxacin, chloramphenicol, and gentamicin,) was decreased at least 8-fold in the *H pylori* LZ1026 mutant, 8-fold in clarithromycin, 32-fold in cefotaxime, 16-fold in chloramphenicol, 8-fold in gentamicin. The MICs were decreased after treatment with different antibiotics, which is consistent with the hypothesis that the product of hefA participates in multidrug efflux.

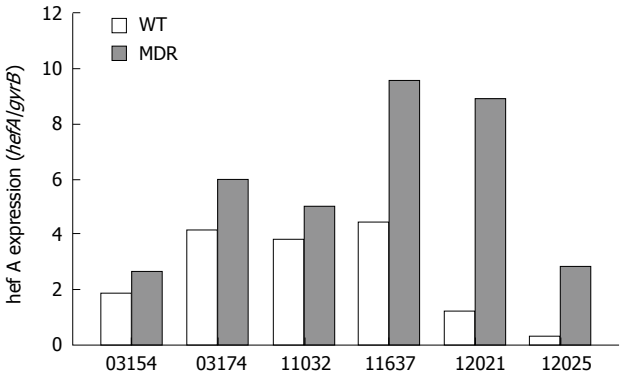

Figure 2 Expression of the *hefA* gene in PT and MDR strains.

Transcribed gene encoding TolC homolog in vitro

Transcription of the gene *hefA* encoding a homolog of *E.coli* TolC outer membrane protein was assessed by RT-PCR with cDNA obtained from 20 different *H pylori* isolates. All the 20 strains displayed transcripts of *hefA* that confirmed the *in vitro* expression of these genes (data not shown).

DISCUSSION

Treatment of *H pylori* infection usually requires administration of two or more kinds of antibiotics concurrently. However, it may ultimately not be sufficient due to increased antibiotic resistance. Indeed, bacterial resistance to antibiotics hampers treatment of *H pylori* infections. Besides chromosomally-encoded drug resistance, intrinsic resistance to toxic compounds through increased export might be of importance in multidrug resistance of *H pylori*. Efflux systems have been identified in *H pylori*[15,16], yet the possibility that these systems are implicated in multidrug resistance has not been established previously[15]. In this study, the *hefA* gene was chosen from three TolC homologs: *hefA*, *hefD* and *hefG*, which encode the outer membrane efflux protein in *H pylori*. It was demonstrated earlier that the *hefD* and *hefG* genes are only poorly expressed *in vitro* and only RND efflux systems are known to have a wide variety of antibiotic substrates[15,22].

In the present study, because it was laborious to select the multidrug resistant strains from clinical isolates of *H pylori*, we developed a chloramphenicol-induced multidrug resistant model of *H pylori*, for the first time to our knowledge. Using this model, six multidrug resistant strains were elicited successfully, and their MICs of metronidazole, tetracycline, erythromycin, penicillin G, and ciprofloxacin were significantly increased (≥ 4-fold) compared with their parent strains, except that the MIC of erythromycin was mildly increased in 4 wild strains, indicating a difference in substrate specificity with other bacteria[29,30]. In contrast, they could only dampen the

function of a group of efflux systems by constructing mutant strain. But, they could not quantitate the operon expression levels in the efflux systems[16]. In this study, the relative real-time RT-PCR was introduced to assess the expression level of the *hefA* gene encoding the outer membrane efflux protein in 5 clinical isolates and *H pylori*11637, suggesting that the relative expression of *hefA* is higher in induced multidrug resistant strains than in their wild susceptible isolates. This is consistent with the hypothesis that the expression of RND efflux systems in many bacteria is regulated by environmental stimuli, including the presence of antibiotics and antimicrobial compounds, growth stage, and stress factors[7-9]. By inserting the KAN resistance cassette into *hefA*, we also constructed a *H pylori* mutant strain (Δ*H pylori* LZ1026). By detecting the susceptibility to 10 kinds of antimicrobials with a more sensitive method of two-fold agar dilution tests, we showed that similar to other gram-negative organisms, the *H pylori hefA* mutant increased its susceptibility to antibiotics, which is consistent with the findings in a previous study[22], confirming that high expression of the *hefA* plays an important role in MDR of *H pylori*. Since *H pylori* contain an active multidrug efflux mechanism, compound efflux needs to be taken into account when determining resistance mechanisms in *H pylori*.

ACKNOWLEDGMENTS

The authors thank Zhi-Gang Huang for excellent technical assistance and providing plasmid pBluescript Ⅱ SK(-) and pEGFP-N2. This research was accomplished at the HeNan Key Laboratory of Molecular Medicine.

COMMENTS

Background

In recent years, the eradication rates of *H pylori* for standard therapies have decreased due to increasing antimicrobial resistance. Multidrug resistant *H pylori* strains have already been discovered. Possible mechanisms underlying multidrug resistant *H pylori* strains are involved in decreased drug uptake or increased drug efflux. Efflux of compounds is a phenomenon commonly observed in bacteria, and compound efflux decreases the susceptibility of *H pylori* strains to a variety of antibiotics. The contribution of efflux proteins to antibiotic resistance of *H pylori* strains is not well established.

Research frontiers

With the increasing antimicrobial resistance to *H pylori*, multidrug resistant *H pylori* strains have been discovered. Researches on the mechanisms of antibiotic resistance of *H pylori* have becoming a medical research hotspot. The mechanism underlying multidrug resistance of *H pylori* is still unclear.

Innovations and breakthroughs

The contribution of efflux proteins to antibiotic resistance of *H pylori*, strains is not well established. In view of the biological difference of *H pylori* strains in Asia, Europe and North America, *H pylori* strains were isolated from Chinese people in the present study. The study was to determine whether efflux systems in *H pylori* strains contribute to their antimicrobial susceptibility. A chloramphenicol-induced multidrug resistant model of *H pylori* strains was developed. The level of mRNA expression of *hefA* in multidrug-resistant (MDR) strains and their parent strains were assessed by fluorescence real-time quantitative PCR. A *H pylori* LZ1026 knockout mutant was constructed and its susceptibility profiles to 10 kinds of antibiotics were evaluated.

Applications

This study confirmed that high expression of the *hefA* plays an important role in MDR of *H pylori*. Since *H pylori* contain an active multidrug efflux mechanism, compound efflux needs to be taken into account when determining resistance mechanisms in *H pylori*.

Terminology

Efflux pump is chromosomally located or acquired by bacteria, which can either be activated by environmental signals or by a mutation in a regulatory gene. Two major categories exist: one is energized by proton motive force and the other is dependent on ATP. The pumps may have limited or broad substrates, the so-called multiple drug resistant pumps themselves form a number of related families.

Peer review

The authors studied the significance of efflux pump gene hefA in multidrug resistance of *H pylori*. The study is interesting and well designed.

Abstract

A 76-year-old diabetic man underwent cholecystectomy for gangrenous calculous cholecystitis. His postoperative course was complicated by the development of Candida albicans esophagitis necessitating antifungal therapy, and total parenteral nutrition (TPN) for 15 d. Seven weeks after cholecystectomy, he presented with cholangitis. Endoscopic retrograde cholangiopancreatography (ERCP) demonstrated extrahepatic filling defects. Despite endoscopic extraction of a biliary cast, cholestasis remained unchanged. Oral administration of ursodeoxycholic acid (UDCA), 750 mg/d, resulted in normalization of liver function tests. We, therefore, propose for the first time, combined endoscopic plus UDCA treatment for the management of biliary cast syndrome.

Key words: Biliary cast; Ursodeoxycholic acid; Endoscopic retrograde cholangiopancreatography

Katsinelos P, Kountouras J, Chatzimavroudis G, Zavos C, Pilpilidis I, Paroutoglou G. Combined endoscopic and ursodeoxycholic acid treatment of biliary cast syndrome in a non-transplant patient. *World J Gastroenterol* 2008; 14(33): 5223-5225 Available from: URL: http://www.wjgnet.com/1007-9327/14/5223.asp DOI: http://dx.doi.org/10.3748/wjg.14.5223

INTRODUCTION

Though uncommon, biliary casts are most frequently described in liver transplant patients[1-4]. The etiology of cast development is not fully known, but it is likely to be multifactorial with biliary sludge being a prerequisite for cast formation. Bile duct damage and ischemia, hemolysis, cholangitis, fasting, total parenteral nutrition (TPN) and recent surgery are thought to be implicated in cast, pathogenesis *via* sludge development[3,4].

We describe a diabetic man who developed a biliary cast after cholecystectomy. The patient underwent endoscopic retrograde cholangiopancreatography (ERCP) with extraction of an extrahepatic biliary cast. But, his cholestasis remained unchanged. Oral administration of ursodeoxycholic acid (UDCA) resulted in normalization of liver function tests.

CASE REPORT

A 76-year-old diabetic patient underwent emergent cholecystectomy for gangrenous calculous cholecystitis. He had a protracted postoperative course complicated with Candida esophagitis treated with 200 mg fluconazole, twice per day and TPN for 15 d during which dyslipidemia was present. His cholesterol level was 503 mg/dL (< 200 mg/dL) and triglyceride was 967 mg/dL (< 200 mg/dL). Seven weeks later, he presented with abdominal pain, chills and a fever of 38.5℃. On admission, clinical examination revealed right upper quadrant tenderness and jaundice. Laboratory data (normal values in parentheses) showed 7.8 mg/dL total bilirubin (< 1.2 mg/dL), 986 IU/L alkaline phosphatase (< 40 IU/L), 519 IU/L γ-glutamyl transpeptidase (< 40 IU/L), 189 IU/L ALT (< 40 IU/L), 167 IU/L AST (< 40 IU/L), 484 mg/dL cholesterol, 878 mg/dL

Figure 1 ERCP image revealing the dilated biliary tract with a tubular filling defect in the common bile duct until the junction of right and left hepatic ducts.

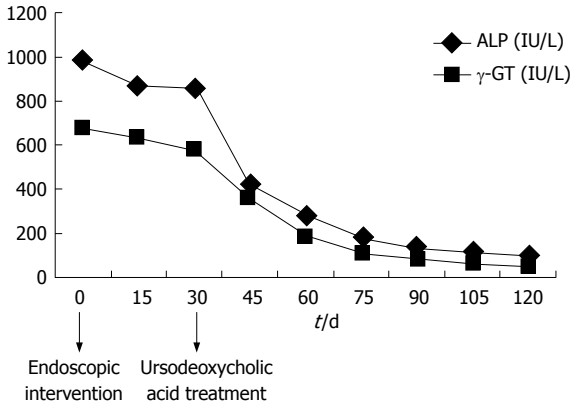

Figure 3 Effect of UDCA on cholestatic enzymes.

triglycerides and 18 000 cells/mm^3 white blood cell count (< 10 000 cells/mm^3).

Abdominal ultrasound and computed tomography demonstrated biliary tract dilatation without apparent lesion. At ERCP, a common bile duct tubular filling defect was found (Figure 1). Endoscopic sphincterotomy was performed, followed by basket retrieval of a cast of extrahepatic biliary tract (Figure 2). No residual cast in the visualized intrahepatic bile ducts was demonstrated. Cholangitis resolved, but cholestasis remained unchanged in the next month. UDCA (750 mg/d) was administered and a gradual improvement in cholestasis was observed with normalization of cholestatic enzymes after a 3-mo treatment period (Figure 3). After a 6-mo treatment period, a repeated ERCP showed a normal biliary tract. The patient's condition was excellent with normal liver function tests 6 mo after cessation of UDCA treatment when we wrote this paper.

DISCUSSION

The biliary cast syndrome describes the presence of casts causing obstruction with its resultant sequelae of biliary infection, hepatocyte damage secondary to bile stasis and ductal damage, all contributing to cholangiopathy. The diagnosis is suspected in liver-transplant patients presenting with abnormal liver-associated enzymes of a cholestatic pattern, evidence of ductal dilatation on abdominal imaging studies or clinical evidence of obstruction, such as cholangitis or jaundice[1-4] and is usually confirmed by ERCP.

To the best of our knowledge, there are only three reports of a total biliary cast in the non-transplant situation. D'Haens *et al*[5] described an elderly lady with extensive cast formation that developed after initial recovery from emergency cholecystectomy. Despite multiple attempts at endoscopic removal, post-mortem findings confirmed the presence of diffuse bile casts and acute suppurative cholangitis. The authors suggest that, in the absence of a gallbladder, the increased bile pigment load may have initiated biliary cast formation. In the second report, Byrne *et al*[6] described a patient with a history of traumatic head injury requiring admission to the intensive care unit, who developed a biliary cast. Despite endoscopic and surgical attempts at cast removal from large bile ducts, liver transplantation was ultimately performed for biliary cast formation. In a recent report, Gleeson *et al*[7] described 2 patients with biliary cast syndrome in a non liver transplant setting. In the first case, biliary cast syndrome developed in a patient with no preexisting liver pathology. But, probably hepatic infarction induced by antiphospholipid antibody syndrome triggered the ischemic event leading to extrahepatic cast formation. In the second case, the etiology of cast formation was multifactorial, including fasting-related gallbladder hypocontractility, parenteral nutrition, biliary infection and possible ischemia due to hypotension-induced sepsis.

Biochemical analysis of biliary casts in liver-transplant patients showed that bilirubin seemed to be the main component (10%-50%) of casts and comprised conjugated free and oxidized varieties. Bile acids comprised 10%-15% of the cast sample and cholesterol represented about 5%-10%[4]. The chemical composition of biliary casts in non-transplant patients is unknown due to its rarity. However, in both reported non-transplant patients[5,6] and in our case, the biliary cast developed after difficult abdominal surgery in two patients, and severe head injury in one patient. They all had a long postoperative course with TPN. Our patient had similar characteristics (fasting, parenteral nutrition, biliary infection) with the second patient in Gleeson *et al*'s report[7], while the underlying mechanism of biliary cast syndrome in the first patient was hepatic ischemia due

to antiphospholipid antibody syndrome. The similarities and differences of all reported non transplant patients with biliary cast syndrome underscore its multifactorial pathogenesis. It is known that sick patients, particularly abdominal surgical and neurosurgical patients, in intensive care units have been shown to develop biliary sludge frequently and rapidly[8,9]. Fasting promotes gallbladder hypocontractility due to insufficient secretion of cholecystokinin and may, in part, explain the abdominal surgical patient group preference[8,9]. Other risk factors for sludge formation include TPN, pregnancy and acquired immunodeficiency syndrome[10,11].

The persistent cholestasis of our patient, despite removal of the extrahepatic biliary cast, is explained by the fact that development of cast was extensive and included the small intrahepatic ducts resulting in obstructive cholangiopathy. It is known that prolonged obstruction of the intra-and/or extrahepatic biliary tree due to stones or sludge, predisposes to caliber irregularities of the biliary system and also toxic effects of bile on hepatocytes with cholangitis further to contribute to cholestatic liver damage[10].

We suppose that the mechanism by which the UDCA resolved our patient's cholestasis is the dissolution of biliary cast of small intrahepatic bile ducts because its main component is cholesterol. The presence of diabetes associated with a high level of cholesterol and combined with long-postoperative TPN contributes to hypersaturation of bile with cholesterol, and initiates biliary cast formation. Stone or sludge dissolution by UDCA is a complex physiochemical process, affecting mainly the cholesterol and phospholipid ionophase and enhancing cholesterol solubilization[12,13]. It would be interesting if chromatography had been performed to reveal the components of our patient's biliary cast and confirm our hypothesis.

The beneficial effect of UDCA on biliary cast-associated cholestatic liver damage may be related to its hepatocytoprotective action, improvement in biliary acid secretion and immunomodulatory properties which reduce immune-related liver damage[14,15]. Mechanisms underlying the beneficial therapeutic effects of UDCA on cholestatic liver diseases include: (1) protection of injured cholangiocytes against toxic effects of bile acids, (2) stimulation of impaired biliary secretion, (3) stimulation of detoxification of hydrophobic bile acids, and (4) inhibition of apoptosis of hepatocytes. However, it is not clear which of these mechanisms by which UDCA exerts its beneficial effects on cholestatic liver diseases. Most likely, such effects depend on the specific cholestatic liver disease and its stage[16]. Knowing that biliary infection, bile duct damage and ischemia, fasting, hemolysis and abdominal surgery are all factors that may be implicated in biliary cast syndrome[17], it would be interesting to use UDCA as a prophylactic in patients at risk of developing biliary cast syndrome. However, the rarity of this complication makes such a study practically impossible.

In conclusion, administration of UDCA, if cholestasis remains unchanged after endoscopic removal of extrahepatic biliary cast, is a very promising treatment modality for biliary cast syndrome.

Abstract

A number of new, novel strategies for managing constipation in the elderly have emerged over the past few years. Prucalopride is one such new agent that is highly efficacious in managing chronic constipation. In fact, Camilleri *et al* in a recent study reported that the average number of bowel movements increased by at least one in nearly 47% of the patients who were administered a dose of 4 mg. Lubiprostone is another new agent recently approved by the FDA that shows efficacy in managing the symptoms of constipation. Neostigmine has also been successfully used for the management of recalcitrant constipation. Most of these studies have used subcutaneous neostigmine. Symbiotic yogurt containing components, such as Bifidobacterium and fructoligosaccharide, have also been recently shown to be highly effective in improving symptoms of constipation. Elderly patients especially those in hospices and nursing homes are often on opiods for pain management. Constipation secondary to opioid use is extremely common in nursing homes. Subcutaneous methylnaltrexone has recently been shown to be highly effective in the management of opioid-related constipation, and was recently approved by the FDA. Sacral nerve stimulation is another emerging strategy. A recent analysis by Mowatt *et al* supports the efficacy of this technique. Botulinum toxin is another agent that has already been successfully used for the management of chronic, refractory constipation in children and may be very effective for elderly constipation. Further larger studies are needed to confirm the findings noted in these studies. Constipation is clearly a major issue in the elderly and these new, emerging strategies will hopefully improve the quality of life and relieve the symptoms of constipation in this population.

TO THE EDITOR

The recent article by McCrea *et al* about the pathophysiology of constipation was highly enlightening[1]. Interestingly, a number of new, novel strategies for managing constipation in the elderly have emerged over the past few years.

Prucalopride is one such new agent that is highly efficacious in managing chronic constipation. In fact, Camilleri *et al* in a recent study reported that the average number of bowel movements increased by at least one in nearly 47% of the patients who were administered a dose of 4 mg[2]. Lubiprostone is another new agent recently approved by the FDA that shows efficacy in managing the symptoms of constipation. Lubiprostone is most efficacious when administered in a daily dose of 16 mg[3]. Neostigmine has also been successfully used for the management of recalcitrant constipation. Most of these studies have used subcutaneous neostigmine administered in cancer patients[4]. Symbiotic yogurt containing components, such as Bifidobacterium and fructoligosaccharide, have also been recently shown to be highly effective in improving symptoms of constipation[5].

Elderly patients especially those in hospices and nursing homes are often on opioids for pain management. Constipation secondary to opioid use is extremely common in nursing homes. Subcutaneous methylnaltrexone has recently been shown to be highly effective in the management of opioid related constipation and was recently approved by the FDA[6,7]. Sacral nerve stimulation is another emerging strategy[8]. A recent analysis by Mowatt *et al* supports the efficacy of this technique[9]. Botulinum toxin is another agent that

has already been successfully used for the management of chronic, refractory constipation in children and may be effective in elderly constipation[10].

Further larger studies are needed to confirm the findings noted in these studies. Constipation is clearly a major issue in the elderly, and these new, emerging strategies will hopefully improve the quality of life and relieve the symptoms of constipation in this population.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

World Journal of Gastroenterology ISSN 1007-9327

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903
Ocean International Center, Building D
No. 62 Dongsihuan Zhonglu
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

It has now become clear that only about 40% or less of patients with heartburn and/or regurgitation have esophagitis, and that the majority of them lack visible distal esophageal mucosa breaks. These subjects are referred to as non-erosive gastroesophageal reflux disease (NERD) patients. It has been estimated that in the Western world at least one tenth of the general population has at least weekly heartburn. This proportion seems to be lower in Asia, while prevalence is rapidly increasing. Although it would be extremely useful to have prospective information regarding the fate of such patients, the natural history of NERD is largely unknown, and very few studies in the literature have addressed this issue. These studies are for the greater part old, not well conducted, and suffer from methodological drawbacks including ill-defined entry criteria. However, a review of these studies indicates that a consistent minority of NERD patients may develop erosive disease at an approximate rate of about 10% per year.

Key words: Gastroesophageal reflux disease; Non-erosive gastroesophageal reflux disease; Esophagitis; Proton pump inhibitor

Peer reviewer: Tomohiko Shimatani, Assistant Professor, Department of General Medicine, Hiroshima University Hospital, 1-2-3 Kasumi, Minami-ku, Hiroshima 7348551, Japan

INTRODUCTION

The recently published Montreal Criteria, dealing with a global classification of gastroesophageal reflux disease (GERD), define heartburn as a burning sensation in the retrosternal area (behind the breastbone) (level of agreement = 100%), claim gastroesophageal reflux (GER) as the most common cause of heartburn (level of agreement = 100%), but admit that heartburn can have a number of non-reflux related causes (level of agreement 98%) and that the prevalence of these is unknown[1]. Moreover, these criteria state that the typical reflux syndrome can be diagnosed on the basis of the presence of characteristic symptoms, i.e. heartburn and regurgitation, without diagnostic testing (level of agreement = 100%). The epidemiology of heartburn shows a clear geographical variation; in North America heartburn occurring at least weekly ranges between 13.2% and 27%; it is slightly lower in Europe ranging between 7.7% and 15%, whereas the prevalence remains definitely lower of in Asia (3.1%)[2].

It is now clear that only about 40% of patients with heartburn and/or regurgitation have visible distal esophageal mucosal breaks caused by gastroesophageal reflux[3,4]. The remaining approximately 60% suffer from non-erosive reflux disease (NERD) or, according with the Montreal criteria, a typical reflux syndrome[2], i.e. the presence of heartburn and/or regurgitation without esophageal injury.

This negative etiologic definition is not satisfactory: it has been suggested that this may lead to a rather heterogeneous group of patients, including both patients with and without pathological esophageal acid exposure[5]. Thus, subcategorization of NERD relies primarily on the results of 24-h esophageal pH monitoring. Patients with GER symptoms and abnormal esophageal acid exposure during 24-h esophageal pH monitoring can be classified as NERD; additionally, even patients with a normal esophageal acid exposure but a positive symptom-reflux association may be defined as NERD. The remainder patient may be defined as

having "functional heartburn"[5]. Recently, the Rome Ⅲ Committee added that functional heartburn patients also have to demonstrate a negative response to standard course of proton pump inhibitor (PPI) treatment[6].

Since these definitions appear to be useful only at a research setting, and not at a primary care level, in this review we will describe the epidemiology and natural history of NERD patients solely defined on the basis of their symptoms and the absence of endoscopic injury.

EPIDEMIOLOGY

By far, the best study available up to now is the Kalixanda study[3]. The aim of this study was to estimate the prevalence of, and to identify risk factors for gastroesophageal reflux symptoms and esophagitis in the adult population of two Swedish municipalities, Kalix and Haparanda ("the Kalixanda study"), with roughly 30 000 inhabitants, chosen because the distribution of age and gender in this area was similar to the national average in Sweden. In the two communities, upper endoscopies were provided by both primary and secondary care physicians and by two endoscopy units involved in the study. By using the computerized Swedish national population register, consisting of all citizens in order of date of birth, the adult population living in the two municipalities was identified and defined as the target population (n = 21 610). Subsequently, a systematic sample (every seventh) of the target population (13.9% of the target population) was enrolled as the study population (n = 3000), and one-third of them were submitted to an esophago-gastroduodenoscopy (EGD) on a voluntary basis, and this formed the study population, i.e. 1000 individuals in random order, representing 4.6% of the target population. The primary symptom analysis in this study was based on the presence of troublesome heartburn and/or acid regurgitation over the past 3 mo.

Four hundred subjects (40%, CI = 37.0-43.0) reported at the time of the EGD visit that they had been bothered by troublesome heartburn and/or acid regurgitation over the past 3 mo. There was no statistically significant difference in prevalence between the sexes, except in the oldest age group, where women had more symptoms ($P < 0.01$).

Weekly symptoms were reported by 200 (20%, CI = 17.5-22.5, mean age 52.4, 45% M) and daily symptoms by 59 individuals (5.9%, CI = 4.4-7.4, mean age 52.8, 44.1% M). There was no statistically significant difference in age or gender between these two groups. Erosive esophagitis (EE) was found in 155 subjects (15.5%, CI = 13.2-17.7) with a mean age of 52.6 years and was most prevalent in men (22%) especially in the youngest age group (32%), and most often mild esophagitis (L-A grade A or B in 95.5% of cases) was diagnosed. The esophagus was macroscopically normal in 769 subjects (76.9%, CI = 74.3-79.5) in the EGD study sample. These subjects had a mean age of 53.5 years and 340 of them (44.1%) were men. This group also includes 123 individuals who had a hiatus hernia as the only finding. Overall, a hiatus hernia was observed in 239 individuals (23.9%, CI = 21.2-26.5) with a mean age of 55.6 years, 54.4% being men. Thus, in this study, 40% of subjects reported typical GER symptoms during the last 3 mo (half of them on a weekly basis), and of these 15.5% had esophagitis whereas 76.9% had absence of esophagitis (NERD) at upper endoscopy. Globally, about 10% of the study population had erosive esophagitis (n = 98), whereas almost 27% of the sample had typical GER symptoms but no esophagitis (n = 271); if only cases with weekly symptoms were considered, the rate cuts down to 12.5% (n = 125).

In a preliminary report of an Italian endoscopic study, the Loiano-Monghidoro project, conducted on 892 adult subjects belonging to the general population, the prevalence of esophagitis was 8.2%, and 24.8% of those had no symptoms[4]. The prevalence of at least weekly heartburn in the same population was 21.5%.

Therefore, from these two population studies, we can estimate that in Europe at least one tenth of the general population has at least weekly heartburn.

NATURAL HISTORY

Evaluating the natural history of NERD is useful for a number of reasons[7], this knowledge may help (1) to discern the percentage of the population that will progress from non-erosive to erosive disease and possibly to its complications, such as stricture, Barrett's oesophagus, and esophageal adenocarcinoma, or from exclusively esophageal to supraesophageal manifestations, (2) to define, assess, and validate productivity of risk factors for such complicated forms of the disease, (3) to determine if medical or other therapies are able to positively modify the natural course of the disease, and (4) to determine the need for maintenance therapy to prevent complications and persistent symptoms in such patients.

Until recently, patients with NERD were considered to suffer from a milder disease[8], i.e. requiring less intensive/prolonged treatment and possibly characterized by a better long-term prognosis. This concept was subsequently proven to be incorrect, since the impairment in disease-related quality of life (HRQoL), for example, appears to be similar in GERD patients with or without endoscopic esophagitis and is related in both instances to symptom severity[9]. Also, the symptomatic acute response to PPI drugs in patients with or without endoscopic mucosal damage seems not to be different, and in fact might be worse in NERD[10,11]. Finally, after discontinuation of acute treatment, symptomatic relapse within 6 months appears to affect a similarly high proportion of both GERD groups[12].

We reported one of the first natural history studies of symptomatic GERD patients without endoscopic esophagitis but with a pathological esophageal pH-metry[13]. In that study we showed that 5 of 33 such patients treated with antacids or prokinetic agents developed endoscopic esophagitis within 6 mo, and that the extent of esophageal acid exposure at entry was not

predictive for this complication. In a subsequent study[14], we extended the observation of the original patient group up to a median duration of 10 years. The first interesting observation regarding this patient sample is that almost all patients that we were able to trace (28/29) are affected by GERD symptoms when anti-secretory drugs are discontinued, and therefore the majority (75%) were on such therapy due to GERD symptoms. Secondly, a very high proportion (89%) of our patients in whom repeat endoscopy was performed (n = 18) showed an erosive esophagitis. Thus, a considerable proportion of the original patient cohort indeed showed a *progression* from non-erosive to erosive disease.

Schindlbeck *et al*[15], in a study investigating the fate of GERD patients with and without esophagitis, reported on 16 patients with pH-documented GERD and no esophagitis 3 years after the diagnosis. During this period, four patients (25%) developed reflux esophagitis, while the majority of the patient population, which also included patients with esophagitis at entry, was still taking medications on a daily basis because of their GERD symptoms. Symptoms were rated to be equal or worse than at entry by 70% of patients in the absence of treatment.

In a Finnish study, 57 consecutive referrals with symptoms of GERD were treated by modification of lifestyle/antacids[16]. Initial assessment included endoscopy and esophageal pH recording, and patients were then followed up for a median of 19.5 years. Of the 30 patients with no evidence of erosive esophagitis at presentation, five (17%) developed grade 1 esophagitis according to Savary-Miller classification. In the study by McDougall *et al*[17], 71% of the 17 patients with a pH-metry documented NERD complained of frequent heartburn 3 to 4.5 years after initial diagnosis, 59% were on daily acid suppressive therapy, and 24% of those patients who had repeat endoscopy developed esophagitis. Again, a progression from non-erosive to erosive GERD was observed, at least in a proportion of patients.

More recently, we have performed a study on patients with typical GERD symptoms presenting to our laboratory to undergo 24-h esophageal pH-monitoring. We have analyzed patients (n = 35) with a pathological investigation, defined as a 24-h % of GER exceeding 5.0% of the total recording time, and with a negative upper GI endoscopy. These NERD patients have been interviewed by mean of a structured questionnaire on average three years after the initial diagnosis, in order to assess the presence and severity of GERD symptoms, the therapy (if any) received during this period of follow-up, and the results of any subsequent endoscopic examination performed.

The results of this retrospective survey show that 14% of those NERD patients who underwent repeat endoscopy developed erosive esophagitis during the 3-year follow-up, despite the fact that almost all of them received effective symptomatic treatment, i.e. H2-RA or PPI therapy[18].

Finally, in a recent multicenter trial[19] conducted on 588 patients with NERD and assessing the effectiveness of continuous *vs* on demand PPI maintenance therapy, it was observed that a proportion as high as 5% of patients treated "on-demand" developed erosive changes within 6 mo of study, as compared with 0% in the continuous treatment arm.

A study has been conducted in a cohort of 3894 patients with predominant heartburn, with or without esophagitis, (1717 NERD, 1512 Los Angeles grade A/B and 278 LA grade C/D, and 387 had Barrett's esophagus) under routine clinical care in Germany, Austria, and Switzerland (ProGERD study)[20]. After initial treatment with esomeprazole, they were followed up for two years, regardless of their response. Medical therapy or endoscopy was initiated at the discretion of their primary care physician, in line with routine care. At two years, endoscopy with biopsy was performed according to the protocol. The results were as follows: 25% of patients who had NERD at baseline progressed to LA A/B and 0.6% to LA C/D. At 2 years, 22% of patients had been off medication for at least 3 mo. The conclusions of the authors were that GERD does not seem to be a categorical disease. Progression and regression (the latter likely due to therapy) between grades was observed in this large cohort of patients under routine clinical care.

Another recent study has examined the possible progression in 47 subjects with symptomatic GERD without endoscopic evidence of esophagitis, out of a group of 497 patients undergoing upper GI endoscopy for various reasons[21]; all those patients (47 + 450) were endoscopically assessed annually for 5 years. Esophagitis developed in 36.2% of patients with NERD, as compared with 11.3% in the control group, with a hazard ratio of developing esophagitis in the former group of 3.07. The authors concluded that the condition of symptomatic GERD carries a high risk of developing esophagitis, which increases steadily with time and was more frequent in those NERD patients with hiatus hernia, who smoke and drink alcohol, and who are without *H pylori* infection[21].

All these studies indicate that some patients with NERD may indeed develop erosive disease, at an approximate rate of about 10% per year. If this rate remains stable with time, a substantial proportion of patients with NERD may develop ERD within 10 years, which is a rate close to what we observed in our 10-year follow-up study of NERD patients[14].

These conclusions are in accordance with results of a recently published systematic review of 22 publications on the endoscopic assessment of erosive or non-erosive GERD over periods larger than 12 months[22]. In this review, authors conclude that the observed progression rate from NERD to ERD ranges in the literature from 0% to 30%. The variability may be related to the duration of follow-up and other factors as *H pylori* infection.

CONCLUSION

NERD is a heterogeneous condition, presently defined on the basis of the presence of typical GERD symptoms and the absence of esophageal damage as

judged by upper endoscopy. This definition is for various reasons unsatisfactory. The prevalence of at least weekly heartburn in the general population in Europe can be estimated to range from 10% to 20%.

A consistent proportion of this group will develop an erosive esophagitis (progression), even under routine therapeutic care, with a rate probably around 10% per year within a 10-year frame.

Abstract

Despite significant advances over the last decade, mucosal lesions of the small bowel are poorly detected by imaging studies such as CT scan, MRI-enteroclysis and contrast-enhanced abdominal ultrasound. Capsule endoscopy (CE) has dramatically changed the diagnostic approach to intestinal diseases. Moreover, the use of CE can be extended to include other conditions. However, it is difficult to assess the positive influence of CE on patient outcomes in conditions involving a small number of patients, or in critically ill and difficult to examine patients. CE has the advantage of diagnosing intestinal lesions and of directing the use of double balloon enteroscopy (DBE) in order to obtain biopsy specimens. Moreover, CE allows repeated assessment in chronic conditions, especially to detect relapse of an infectious disease.

Key words: Capsule endoscopy; Non-steroidal anti-inflammatory drugs-enteropathy; Intestinal diseases

INTRODUCTION

Since it was introduced by Iddan and Meron in 2000[1], capsule endoscopy (CE) has dramatically changed the diagnostic approach to intestinal diseases. Despite significant advances over the last decade, mucosal lesions of the small bowel are poorly detected by techniques such as CT scan, MRI-enteroclysis and contrast-enhanced abdominal ultrasound[2]. The diagnostic superiority of CE over these methods is related to its ability to provide a complete examination of the small bowel mucosa. On the other hand, the drawback of CE is the inability to obtain biopsies. However, this deficiency has been overcome with the use of double balloon enteroscopy, which permits obtaining biopsies from lesions detected by CE[3].

Therefore, the diagnostic approach to conditions such as obscure GI bleeding, Crohn's disease and coeliac sprue has been dramatically altered by CE[4-6]. Moreover, the use of CE has resulted in significant advances in the understanding and diagnosis of several gastrointestinal diseases including assessment of the effect of medications on the small bowel, intestinal lesions secondary to systemic diseases, and some rare conditions[7].

In this review, the role of CE will be discussed in the following conditions: (Ⅰ) Intestinal consequences of medications such as non-steroidal anti-inflammatory drugs (NSAIDs). (Ⅱ) Rare conditions mainly involving the small bowel. (1) Primary lymphangiectasia such as Waldmann's disease. (2) Common variable immunodeficiency disorder. (3) Familial polyposis syndromes with small bowel involvement. (Ⅲ) Immunological disorders with small bowel involvement. (1) Acute and chronic graft versus host disease. (2) Hypobetalipoproteinaemia. (Ⅳ) General diseases with intestinal lesions, such as vasculitides. (Ⅴ) Infectious intestinal diseases such as Whipple's disease and CMV infection in immunosuppressed patients.

For each of these conditions, the clinical and biological characteristics will be discussed when needed, to understand the role of CE in diagnosis. The typical endoscopic patterns observed with CE will be described, and the use of CE will be integrated in a global diagnostic approach.

CE FOR THE EVALUATION OF INTESTINAL TOXICITY OF MEDICATIONS: THE EXAMPLE OF NSAID-RELATED ENTEROPATHY

CE is a simple and efficient tool to detect intestinal lesions due to NSAIDs

Background: NSAIDs account for 5%-10% of all drug prescriptions in developed countries and about 25% of the reported side effects caused by all classes of medications, including gastroduodenal ulcers seen in 10%-30% patients with intestinal lesions[8]. The prevalence of severe side effects involving the small bowel and colon is 0.89 per 100 patient-years with naproxen, and 0.41 with rofecoxib, corresponding to 39.4% and 42.0%, respectively, of all the severe gastrointestinal side effects[9]. NSAIDs alter the intestinal permeability, about 12 hours after intake and result in mucosal inflammation within 10 days. A variety of endoscopic lesions have been described, ranging from asymptomatic enteropathy to severe lesions such as ulcers, perforation, stenosis (Figure 1), diaphragms and villous atrophy. CE may be able to help detect these lesions and clarify their pathophysiology.

Description of the lesions: One of the most interesting studies was reported by Maiden *et al*[10], who evaluated the number and the type of intestinal lesions induced by NSAIDs in 40 healthy volunteers between the ages of 21 and 61 years, using CE and fecal calprotectin. The fecal calprotectin test and CE were performed before and after a 2-week course of treatment with diclofenac (75 mg) and omeprazole (20 mg twice a day). The CE recordings were read by three independent investigators, and the lesions were regarded as significant if indicated by at least two of them. The lesions were classified into six categories: (1) reddened folds; (2) denuded area with loss of villous architecture; (3) petechiae; (4) mucosal breaks; (5) presence of blood without a lesion being visualized; and (6) other findings, mainly lymphangiectasia and angiodysplasia. Before treatment, lymphangiectasia and arteriovenous malformations were observed in three patients each. After treatment with nonsteroidal anti-inflammatory drugs (NSAIDs), lesions were seen in 27 patients, 15 of whom had more than one lesion: 16 mucosal breaks (40%), including two cases of bleeding; 14 reddened folds (35%); 13 petechiae and red spots (33%); eight denuded areas (20%), including two patients with mucosal breaks; and three patients with blood in the intestinal lumen (8%). After 2 weeks, the fecal calprotectin level increased significantly in 30 subjects (+ 75-82 μg; $P < 0.0001$) but this increase did not correlate with the number of lesions detected by CE. The authors concluded that short-term NSAID treatment was associated with a high level of intestinal inflammation, and an increased frequency of intestinal lesions.

CE helps understanding the pathophysiology of NSAIDs-enteropathy

NSAID-related lesions were located equally in the proximal and distal parts of the small bowel. The study by Maiden *et al*[10] was interesting, as it showed that significant lesions can occur even after a short course of NSAID treatment in healthy individuals. However, the study had several methodological limitations: (1) The interpretation of CE images was often difficult[11] and the clinical relevance of lesions detected by CE was not always established, since such lesions could be found in the absence of any treatment in healthy individuals[12]. (2) Other causes of intestinal lesions such as chronic ischemia were not excluded. (3) A standardized terminology allowing a consistent description of the lesions and comparisons between different studies was lacking[11]. Moreover, DBE provides a direct access to intestinal lesions detected by CE and biopsy specimens can be obtained. Therefore, our understanding of the pathophysiology of early lesions induced by NSAIDs is likely to improve.

Table 1 Intestinal diseases with lesions similar to Crohn's disease, ranked by order of frequency

	Frequency
Crohn's disease	++++
Drug-related injuries (NSAIDs)	+++
Mesenteric ischaemia	++
Coeliac disease (jejunitis)	++
Cryptogenic multifocal ulcerous stenosing enteritis	+
Radiation enteritis	+
Lymphoma, ulcerated cancer	+
Vasculitides (lupus, polyarthritis, PAN)	+
Behçet's disease	+/-
Eosinophilic enteritis	+/-
Infections (CMV, Whipple, yersinia *etc*)	+/-

CE to evaluate the benefit of medications preventing the toxic intestinal effects of NSAIDs

Shunji and Nakamura showed in a randomized trial on 16 patients that rebaminide significantly decreased the prevalence of diclofenac-induced small intestinal mucosal injury[13]. These results need to be confirmed in larger studies. On the other hand, the etiological diagnosis of intestinal lesions observed by CE is often difficult. The distinction of lesions related to NSAIDs or those seen in Crohn's disease is particularly difficult, as recently shown by Voderholzer who reported a rate of misdiagnosed lesions in as many as 25% of the 40 patients with 146 intestinal lesions detected by CE[14].

Table 1 shows how difficult the differential diagnosis is of intestinal erosions and ulcers, since they may be related to a number of pathological conditions and diseases. Therefore, DBE with biopsy of the lesions will often be necessary to obtain a correct diagnosis.

RARE DIGESTIVE DISEASES WITH SMALL BOWEL INVOLVEMENT

Waldmann's disease (Figure 2)

Intestinal lymphangiectasia appears on CE recordings as whitish areas, often diffusely spread over the intestinal mucosa. The endoscopic appearance of

Figure 1 Intestinal stenosis caused by NSAIDs. Capsule endoscopy shows narrowed segment, surrounded by an ulcerated but non-inflammatory mucosa.

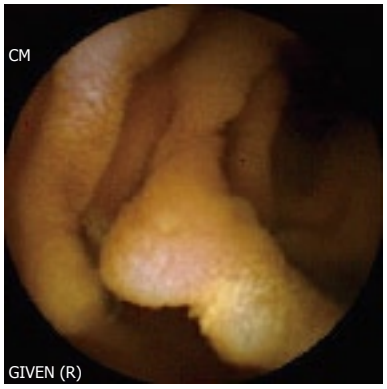

Figure 2 Waldmann's disease. The presence of dilated lymphatic vessels in the submucosa gives a whitish appearance to the mucosa. If lymphangiectasia becomes more prominent, it may protrude into the lumen.

lymphangiectasia is the result of an accumulation of chylomicrons in the dilated lymphatic vessels, varying in size from a few millimeter white spots to large white nodular areas. Lymphangiectasia may be diffuse or may involve a localized segment of the small bowel. Clinically, lymphangiectasia is classified as primary, secondary or functional. Functional lymphangiectasia are not clinically relevant and it is often encountered in patients with functional digestive disorders. Secondary lymphangiectasia is a consequence of intestinal or extra-intestinal diseases causing compression of the gut. By contrast, Waldmann's disease is primary idiopathic lymphangiectasia, which results in an exudative enteropathy. This condition may present as a diffuse disease or may involve only a localized segment of the small bowel. Localized lymphangiectasia can be treated surgically, by resection of the pathological segment. However, diffuse disease requires medical treatment (diet containing medium chain fatty acids). DBE shows thickened mucosal folds without villous atrophy in the duodenum, jejunum and ileum. Small size nodules (spots) may be observed as well as large confluent areas[15]. CT scan may show thickening of the mucosal folds.

Immunoglobulin deficiency: The example of common variable immunodeficiency disorder (CVID, Figure 3)

This condition is characterized by hypogammaglobulinaemia, recurrent bacterial infections, mainly pulmonary, and is frequently associated with autoimmune and neoplastic disorders. Table 2 summarizes the clinical features. CE shows small (millimetre size) nodular lesions spread diffusely over the intestinal mucosa. In some cases, the lesions are polypoidal, of variable sizes[16]. DBE shows similar findings and may also demonstrate areas of atrophic mucosa, in the event of an associated infection. The nodules correspond to hypertrophic lymphoid follicles, without plasma cells.

Figure 3 Common variable immunodeficiency disorder. The characteristic lesions include polypoidal and nodular lesions of variable size, which are disseminated over the intestinal mucosa.

Table 2 Common variable immunodeficiency disorder: Clinical manifestations

Gastrointestinal signs	Extra-intestinal signs
Giardia lamblia infection	Recurrent respiratory tract infections
Small bowel bacterial overgrowth	Increased risk of lymphomas
Viral and infectious diarrhoea	Increased risk of gastric cancer
Coeliac disease	
Frequent nodular lymphoid hyperplasia, not premalignant	

In most instances, the lesions (either nodules or polyps) are disseminated throughout the gut. There is an increased risk of intestinal lymphoma in these patients. CE allows regular surveillance of the small bowel. When CE reveals a change in the endoscopic findings, DBE with biopsy should be performed or the patient should refered to a surgeon for intestinal resection.

Familial polyposis syndromes

Background: CE is very effective in detecting intestinal tumours. Intestinal tumours account for 3% to 6% of all digestive neoplasms, less than 2% of which are malignant. The data collected since the introduction of CE, shows a higher frequency of intestinal tumours, between 6.3% and 12.3% in patients investigated for obscure digestive bleeding by CE[17]. Since the use of CE permits earlier diagnosis, the clinical course of intestinal tumours has changed. These tumours are now seen as ulcerated, haemorrhagic lesions, before the occurrence of obstructive signs. Therefore, one may assume that CE can be used for the detection of intestinal tumours in patients with familial polyposis syndromes. There are

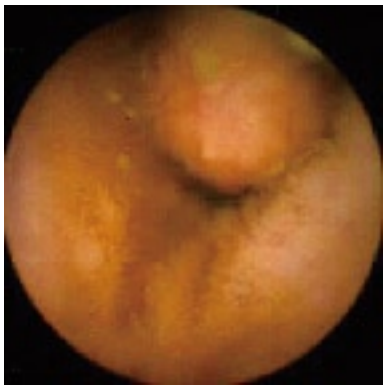

Figure 4 Peutz-Jeghers syndrome. Presence of a large polyp in the ileum, in a young patient with Peutz-Jeghers syndrome. The polyp was ulcerated and required endoscopic resection.

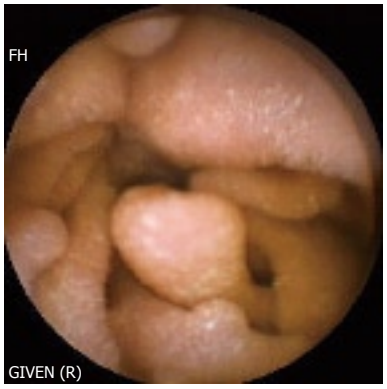

Figure 5 Familial adenomatous polyposis. Multiple polyps of regular shape are present in the ileum.

two conditions that are of particular concern: Peutz-Jeghers syndrome and familial adenomatous polyposis syndrome.

Peutz-Jeghers syndrome (Figure 4): In patients with Peutz-Jeghers syndrome, the prevalence of small bowel cancer is particularly high. Intussusception of the polyps may cause intestinal obstruction, while ulcerated lesions may be responsible for acute or chronic gastrointestinal bleeding. CE can detect polyps in the entire length of the small intestines, with a higher diagnostic yield compared to CT scan and MRI with enteroclysis, particularly for lesions < 1 cm in diameter[18]. The role of CE has recently been established in the initial work-up, as well as for the follow-up of patients with Peutz-Jeghers syndrome[18]. However, it is difficult to determine the size of the polyps on capsule recordings, which is an important factor in selecting patients for removal by DBE. It should be noted that polyps selected for removal are of a large size, and those at high risk of ulceration, malignancy and intussusception.

Familial adenomatous polyposis syndrome (FAP, Figure 5): There is currently no established indication for small bowel CE in the initial work-up of patients with FAP. By contrast, CE may be indicated in FAP patients with multiple duodenal polyps (Spiegelmann Ⅲ or Ⅳ)

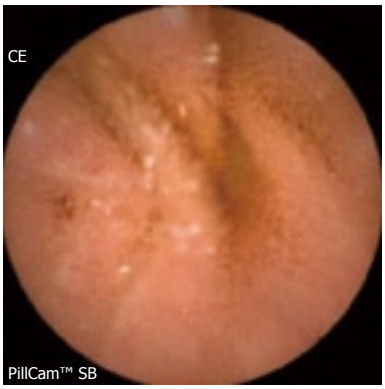

Figure 6 Acute Graft versus Host Disease (GVHD). The lesions correspond to Stage Ⅲ disease, manifesting as diffuse erythema and oedema of the mucosa, with a few erosions.

as these patients have more frequent intestinal polyps[19]. Moreover, polyps larger than 10 mm in diameter should be removed because of the risk of malignancy, either by DBE or intra-operative enteroscopy. On the other hand, examination of the duodenum, in particular the area of the papilla is often difficult with CE because of the rapid transit of the capsule through this segment. Therefore, assessment of the duodenum with a lateral viewing endoscope is the preferred approach.

Capsule endoscopy should be used with caution in familial polyposis syndromes, since many of these patients have undergone multiple abdominal surgeries which may delay capsule progression or even cause its retention.

B-cell lymphoma: Finally, in this section on rare intestinal tumours, it is important to mention the role of CE in the investigation of patients with suspected B-cell lymphoma. CE not only allows the diagnosis of such tumours but also helps to evaluate the extent of the intestinal disease[20]. CE is also useful in evaluating the response to chemotherapy.

IMMUNOLOGICAL DIGESTIVE DISORDERS (PHOTO N° 9 ET 10) (MALADIE DE BORDIGONI)

Acute gastrointestinal graft versus host disease (GVHD) after bone marrow transplantation (Figure 6)

Bone marrow transplantation is widely used for the treatment of a number of haematological diseases. Acute GVHD is a severe complication that requires quick initiation of treatment with immunosuppressive drugs. The small bowel is often involved in acute GVHD, with the development of hematochezia, diarrhoea, abdominal pain, nausea and vomiting. The diagnosis is difficult and GVHD must be distinguished from other conditions sharing a similar clinical picture such as cytomegalovirus enteritis and *Clostridium difficile* infection.

The diagnosis is easier in the presence of multi-system disease, especially when the skin lesions can be biopsied. In patients without skin involvement, an endoscopic

work-up is needed, with esogastroduodenoscopy and ileocolonoscopy. Until recently, esogastroduodenoscopy was regarded as the gold standard for the examination of the duodenum, with findings of mucosal oedema, denuded mucosa, erosions, erythema and bleeding ulcers. These lesions are classified into 4 grades, grade Ⅰ refers to focal erythema, grade Ⅱ diffuse erythema and oedema, grade Ⅲ severe oedema and friable mucosa with erosions, and grade Ⅳ presence of exudate, ulcers and active bleeding[21].

The clinical usefulness of CE in acute GVHD was demonstrated in two studies. Neumann *et al*[22] evaluated 14 patients with clinical signs of acute GVHD after bone marrow transplantation, and observed typical intestinal lesions with histological confirmation on biopsy obtained by endoscopy, performed subsequently. This study also showed that the lesions involved the entire length of the small bowel and were more intense in the ileum compared to in the jejunum. The most important finding was the very high negative predictive value of CE since patients with a negative CE did not develop acute GVHD during the 2-month follow-up period after CE. These findings were confirmed by Aghai *et al*[23] in a study on a larger cohort of patients.

Although it is worth mentioning that CE is well tolerated by such critically ill patients, certain limitations should be noted. In some patients, the capsule may be retained in the stomach. The Rapidview system can be used to monitor the progression of the capsule[24]. In the event of delayed gastric clearance, erythromycin may be administered. Moreover, it should be emphasized that in some patients, CE was normal but these patients had acute GVHD[25].

Despite the limited data available in the literature, CE should now be regarded as an alternative to esogastroduodenoscopy in the workup of patients with suspected GVHD, particularly in critically ill patients requiring quick therapeutic decisions. Indeed, CE appears to be as effective as esogastroduodenoscopy with biopsy for the diagnosis of acute GVHD[25-27].

Hypobetalipoproteinemia (Figure 7)

Background: Hypobetalipoproteinemia is an autosomal dominant disorder caused by a mutation or deletion in the *apoB* gene which produces a truncated apolipoprotein B. The plasma concentrations of the two forms of apolipoprotein B, that is, Apo B-100 synthesized by the liver and Apo-B48 synthesized by the intestine, are undetectable. The biological and clinical picture is similar to that of abetalipoproteinemia. Heterozygous hypobetalipoproteinemia is present in 0.1%-0.8% of the general population, while homozygous hypobetalipoproteinemia is rare. The prognosis of Apo B-related disorders depends mainly on the consequences of the malabsorption syndrome, and on the progression of neurological alterations caused by the deficiency of soluble vitamin E[28].

Diagnostic procedure: Laboratory tests show hypocholesterolemia, acanthocytosis and undetectable ApoB lipoprotein. CT scan shows massive and diffuse infiltration of the liver. CE demonstrates diffuse whitish pattern of the intestinal mucosa with occasional yellow areas seen in the entire length of the small bowel, but without any villous atrophy. Enteroscopy, formerly performed with push enteroscopes and currently with DBE shows a similar pattern as CE and moreover, biopsy specimens can be obtained. These lesions are produced by the accumulation of fat vesicles in the enterocytes in the jejunum and ileum, without causing villous atrophy[29]. Immunohistchemistry shows migration of truncated Apo-B and the absence of normal Apo-B hypobetalipoproteinemia.

INTESTINAL EXPRESSION OF VASCULITIDES

Background

General considerations: Systemic diseases include several very heterogeneous pathological conditions which share some common features: (1) symptoms suggesting the involvement of multiple organs, (2) specific immunological and biological alterations, (3) a tendency to chronicity, and (4) clinical response to immunosuppressive therapy. Systemic diseases are divided into two main categories[30,31]: connective tissue or collagenous diseases with predominant abnormal production or deregulated synthesis of collagen, and vasculitides with predominant inflammation of the blood vessels resulting in abnormal vascular permeability, thrombosis and tissue ischaemia. These conditions share some pathophysiological mechanisms such as abnormal production of proteins or cytokines, and abnormal humoral or cellular immunity that results in muscular inflammation, atrophy and fragmentation. In the end, the vascular endothelial changes become predominant and are responsible for the muscular, neurological and digestive abnormalities.

Digestive manifestations of vasculitides and systemic diseases include a number of clinical conditions (Table 3)[32]. The development of GI symptoms raises three main questions: Do the digestive symptoms correspond to the initial manifestation of the condition or to a new acute phase of the disease? Are the digestive symptoms secondary to a complication of the treatment? Is the observed complication a component of the primary disease? To answer these questions, the clinician may use diagnostic techniques such as CT scan, biological and immunological tests, and CE. The use of CE will be illustrated by a few examples.

Specific characteristics of diseases

Behçet's disease: Behçet's disease is a systemic inflammatory condition, with 10% to 25% patients developing GI manifestations. The symptoms consist mainly of abdominal pain, diarrhoea and acute or chronic bleeding. CE may show erosions and aphthous ulcers in the small bowel, as reported by Fylejk in a series of 20 patients[33]. Intestinal lesions may be present

Table 3 Frequency of digestive manifestations of vasculitides and connective tissue diseases (adapted from Muller-Ladner[32])

Disease	Frequency of digestive manifestations
Primary vasculitides	
Periarteritis nodosa.	30%-50%
Churg-Strauss Syndrome	25%-50%
Behçet's disease	Up to 30%
Takayasu's arteritis	Up to 15%
Wegenre's disease (granulomatosis)	5%-10%
Lymphomatous granulomatosis	1.5%
Horton's disease	1%
Henoch-Schönlein purpura	50%-90%
Secondary vasculitides	
Systemic lupus erythematosus	Up to 50%
Rheumatoid arthritis	Up to 10%
Connective tissue disorders	
Systemic sclerosis	75%-90%
Systemic lupus erythematosus (except vascular lesions)	25%

Figure 7 Hypobetalipoproteinemia. The endoscopic picture is characterized by a diffuse whitish pattern of the mucosa due to the accumulation of fat vesicles in the enterocytes. The size of the intestinal villi is normal.

in symptomatic and asymptomatic patients, and do not show a specific endoscopic pattern.

Churg et Strauss disease (Figure 8): Churg et Strauss disease is a systemic disease characterized by eosinophilia and NTE manifestations suggesting an allergenic reaction. The small bowel is involved in nearly 50% patients, presenting with gastrointestinal bleeding, diarrhoea and abdominal pain. Intestinal ulcers are not uncommon and often manifest as bleeding or perforation. Sanchez *et al*[34] have shown that the ulcers detected by CE are deep, involve the jejunum and ileum, and respond well to immunosuppressive treatment. Therefore, CE is also useful in evaluating the response to treatment.

Henoch-Schönlein purpura: The clinical picture of Henoch-Schönlein purpura is characterized by the occurrence of purpuric lesions, abdominal pain, polyarthralgia and renal failure. The disease is a consequence of the deposition of IgA in the blood vessels. CE may reveal intestinal involvement, with

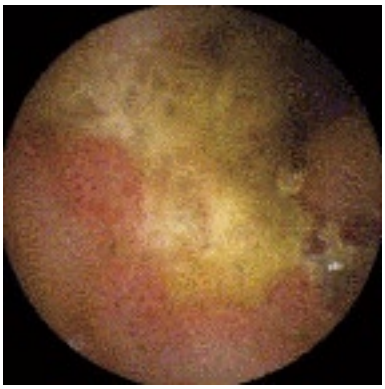

Figure 8 Churg and Strauss disease. A large ulcer is present in the ileum.

findings of oedematous mucosa, multiple ulcers, fibrin deposits and bleeding. Lesions observed by CE are often diffuse, involving the jejunum and ileum. If the clinical picture suggests Henoch-Schönlein purpura, the presence of intestinal lesions at CE should be regarded as diagnostic, and further endoscopic assessment is not required[35].

Antral vascular ectasia associated with vasculitides: Antral vascular ectasia are a common cause of bleeding and anaemia, particularly in patients with liver cirrhosis and portal hypertension. However, portal hypertension is not observed in nearly 70% patients. In these patients, the condition is related to immunological disorders such as systemic sclerosis and rheumatoid arthritis, renal failure and diabetes. Antral vascular ectasia can be diagnosed by CE with a typical endoscopic pattern of "watermelon stomach". Thus, CE is useful not only in diagnosing the cause of anaemia but also for the follow-up of patients treated with endoscopic haemostasis[36].

INFECTIOUS INTESTINAL DISEASES AND VIRAL INFECTIONS IN IMMUNODEFICIENT PATIENTS

Background

The clinical manifestation of intestinal infection is usually an acute episode of diarrhoea, which resolves spontaneously, and endoscopic assessment is not indicated in most patients. By contrast, patients with persistent diarrhoea or malabsorption require further workup. Recently, there has been an increase in the incidence of certain viral infections in patients with immunodeficiency due to HIV infection or those on immunosuppressive therapy. Endoscopy is the main diagnostic procedure as it allows examination of the mucosa, and biopsy specimens can be obtained for identification of the causal virus. Biopsies are frequently performed during esogastroduodenoscopy and ileo-colonoscopy. These procedures have a limited range of examination, since a large part of the small bowel is excluded. CE is a very useful complement to these investigations, as it allows assessment of the intestinal

Figure 9 Cytomegalovirus infection in a heart transplant patient. The disease is characterized by the presence of bleeding ulcers and erosions.

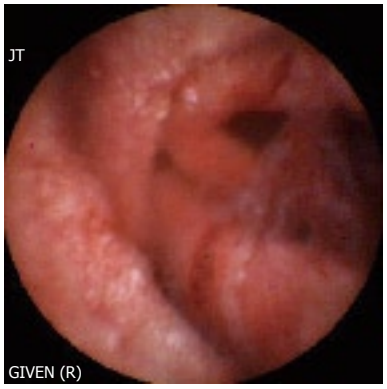

Figure 10 Whipple's disease. The endoscopic picture shows an oedematous and friable mucosa with erosions and serpiginous ulcers. The lesions may involve the entire length of the small bowel.

mucosa with a high diagnostic yield, and can have a direct impact on the management of such patients[37]. Moreover, lesions detected by CE can be subsequently biopsied during DBE.

Infectious diseases in immunodeficient patients (Figure 9)

CE can detect ulcers involving the intestinal mucosa in patients with viral, fungal or bacterial infections. Cytomegalovirus infection can be diagnosed by the presence of one or two large jejunal ulcers in immunodeficient patients, as for example in transplant patients. These ulcers may bleed and are the source of haematochezia when located in the distal ileum or the colon[38]. Fungal infection in HIV patients, such as histoplasmosis is characterized by the presence of multiple deep ulcerations accompanied with submucosal nodules protruding into the lumen. The diagnosis is confirmed by the detection of the pathogenic agent on biopsies obtained during enteroscopy[39]. In patients with tuberculosis, CE may reveal deep ulcers, often appearing as serpiginous. The lesions are difficult to differentiate from those of Crohn's disease. The pathological examination of the biopsies may show a typical granuloma. Studies using CE have shown that the lesions may not be restricted to the ileum but are also seen in the jejunum[40].

Whipple's disease, an example of diffuse intestinal infection (Figure 10)

Whipple's disease is a multisystem infectious condition caused by *Tropheryma whippelii*. GI symptoms are often present and the diagnosis is made by demonstrating the presence of the infectious agent on duodenal biopsy. The most typical endoscopic finding is the presence of an oedematous, friable and haemorrhagic mucosa with multiple erosions and serpiginous ulcers. CE has shown that the intestinal lesions are diffuse, involving the jejunum and ileum. This is explained by the fact that previous investigative techniques allowed only limited access to the intestinal mucosa, i.e. before CE and DBE became available[41]. Moreover, CE is also a useful non-invasive method to determine the response to treatment, which has to be maintained for at least two years, and occasionally five years in order to avoid relapse, especially of the neurological manifestations[42].

CONCLUSION

Since it was introduced in 2000, the use of CE in several clinical situations has been validated. However, the indications for CE can be extended to other diseases, although an assessment of a positive influence of CE on patient outcomes is difficult obtain in conditions which occur either in a small number of patients, or in critically ill and difficult to examine patients. Clearly, CE has the advantage of detecting lesions in the small intestine and directing DBE to the correct location in order to obtain biopsies. Moreover, repeated assessment can be made in chronic conditions, especially to detect the response to treatment.

Abstract

Until recently, diagnosis and management of small-bowel tumors were delayed by the difficulty of access to the small bowel and the poor diagnostic capabilities of the available diagnostic techniques. An array of new methods has recently been developed, increasing the possibility of detecting these tumors at an earlier stage. Capsule endoscopy (CE) appears to be an ideal tool to recognize the presence of neoplastic lesions along this organ, since it is non-invasive and enables the entire small bowel to be visualized. High-quality images of the small-bowel mucosa may be captured and small and flat lesions recognized, without exposure to radiation. Recent studies on a large population of patients undergoing CE have reported small-bowel tumor frequency only slightly above that reported in previous surgical series (range, 1.6%-2.4%) and have also confirmed that the main clinical indication to CE in patients with small-bowel tumors is obscure gastrointestinal (GI) bleeding. The majority of tumors identified by CE are malignant; many were unsuspected and not found by other methods. However, it remains difficult to identify pathology and tumor type based on the lesion's endoscopic appearance. Despite its limitations, CE provides crucial information leading in most cases to changes in subsequent patient management. Whether the use of CE in combination with other new diagnostic (MRI or multidetector CT enterography) and therapeutic (Push-and-pull enteroscopy) techniques will lead to earlier diagnosis and treatment of these neoplasms, ultimately resulting in a survival advantage and in cost savings, remains to be determined through carefully-designed studies.

Key words: Capsule endoscopy; Enteroscopy; Obscure gastrointestinal bleeding; Small-bowel tumors; Polyposis syndromes

INTRODUCTION

Tumors of the small intestine present a unique challenge to the clinicians across medical specialties. Although the small bowel represents 75% of the length and 90% of the overall mucosal surface of the alimentary tract and despite its anatomic location between two regions of high cancer risk, the small bowel is generally considered as a rare location for the development of neoplasms, accounting for only 1%-3% of all primary gastrointestinal (GI) tumors[1-3].

The overall age-adjusted incidence of small-bowel cancers estimated in population based studies in Western countries ranges between 0.9 and 1.4 (Table 1)[1,4-9]; malignant tumors account for about one half of all new cases of small-bowel tumors reported[10]. The incidence rate of small-bowel cancer varies among populations: cancer rates are high among the Maori of New Zealand (about 4 cases per 100 000 per year) and among ethnic Hawaiians, and low in India, Romania, and other parts of Eastern Europe[1]. Some recently published studies reported an increasing incidence of these neoplasms over the last 20 years (Figure 1)[1,9].

Because small-bowel tumors are relatively rare compared with other neoplasms of the gastrointestinal tract, several factors have been proposed to explain or understand this disparity: (1) a quick transit allowing only short contact of possible carcinogens from food

SEER: Surveillance epidemiology and end result.

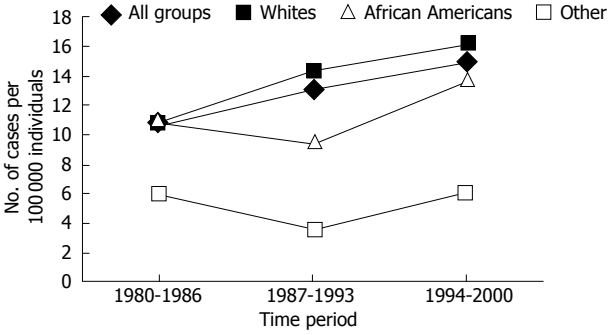

Figure 1 Incidence of small-bowel tumors per race in the Connecticut tumor registry per periods of 7 years since 1980 to 2000[5].

with the intestinal mucosa; (2) the intestinal content is mixed together with a great volume of intestinal juices decreasing the concentration of irritating agents; (3) a decrease in mechanical and/or chemical inflammation of the mucosa because of the liquidity and alkaline pH of the small-bowel contents; (4) the high concentration of lymphatic tissue and of immunoglobulin exerts an effective immune surveillance; (5) the low bacteria concentration in the small intestine processing the intestinal content produces a low amount of carcinogens; (6) the rapid turnover of epithelial cells should decrease the potential growth and development of neoplastic cells[1,10,11].

Genetics could also play a role in some particular subgroups of patients; subjects affected by familiar adenomatous polyposis, hereditary non-polypoid colorectal cancer, Crohn's disease, celiac disease, Peutz-Jeghers syndrome, and several other diseases must be surveyed for the risk of small intestine tumor[9,12]. A relevant role of genetics has also been described in patients with sporadic gastrointestinal stromal tumors (GISTs) in which four different regions (exon 9, exon 11, exon 13, and exon 17) of the *KIT* gene have found to be mutated[13].

Approximately 40 different histological types of small intestinal tumors have been identified[14]. Among malignant tumors, about 30%-50% are adenocarcinomas, 25%-30% are carcinoids, and 15%-20% are lymphomas. A recently published study, including 1260 cases of small-bowel tumor, showed that they seem to be frequently located in the ileum (about 30% of cases) or in the duodenum (about 25% of cases)[9]; the sites at highest risk for malignant neoplasms have been reported to be the duodenum for adenocarcinomas and the ileum for carcinoids and lymphomas[1]. One reason why adenocarcinomas tend to arise in the duodenum may implicate bile or its metabolites in the etiology of the neoplasm at this site[15]. However, among patients with Crohn's disease, which generally affects the ileum rather than the more proximal small bowel, adenocarcinomas tend to occur in the terminal ileum[1].

Secondary neoplastic involvement of the small intestine has been reported to be more frequent than primary small intestinal neoplasms. Primary tumors of the colon, ovary, uterus, and stomach can involve the small bowel (by direct invasion or by intraperitoneal spread) whereas primaries from breast, lung, and melanoma metastasize to the small bowel by the hematogenous route[16]. SB metastases from melanoma have been described in 1.5%-4.4% of patients[17,18] with previously removed skin melanoma and in 58% of post-mortem specimens[17].

In the majority of cases, the diagnosis of small-bowel tumors is delayed. This could be due to several factors: (Ⅰ) Small-bowel tumors grow slowly, extraluminally, remaining asymptomatic for years or presenting insidiously with non-specific complaints such as abdominal pain, diarrhea, iron deficiency anemia, bleeding, extra intestinal symptoms (flushing, paraneoplastic syndromes)[19]. Obstruction is also a common presentation; indeed, small-bowel tumors are the third most common cause of small-bowel obstruction in the United States[20]. (Ⅱ) The rare incidence of small-bowel tumors may contribute to the relatively low index of clinical suspicion for their presence.(Ⅲ) Routine laboratory tests and other diagnostic tests may frequently be inconclusive; as a consequence, diagnostic laparoscopy or exploratory laparotomy may be indicated not only to deliver an effective treatment but also to reach a definitive diagnosis.

Since the introduction in clinical practice of capsule endoscopy, several case reports describing primary and secondary tumors affecting the small bowel have been published. More recently, a few retrospective studies collecting series of patients in which this technology was able to show the presence of a small-bowel tumor have also been published.

SMALL-BOWEL TUMORS: DIAGNOSTIC TOOLS

Historically the small bowel has been considered a difficult organ to evaluate. For many years, visualization of the small-bowel mucosa and the diagnosis of small-bowel tumors were feasible only in a surgical setting and this organ has been considered a sort of "black box". This situation derived both from the anatomical characteristics of the small bowel and the limitations of available techniques. The length of the small intestine,

the distance between the organ and external orifices (mouth and anus), its sinuousness, its ability to produce huge amounts of fluids and the continuous contractions long hampered accurate inspection of the small-bowel mucosa.

Traditional radiological techniques, including small-bowel follow-through and small-bowel enteroclysis, allow an indirect evaluation of the entire small bowel, however the difficulty to place a specific catheter in the right position (enteroclysis), the low pressure and the dilution of the contrast medium (small-bowel follow-through) contribute to a high miss rate for small and/or flat lesions. Conventional cross-sectional imaging techniques, such as computed tomography (CT) and magnetic resonance imaging (MRI), can be helpful in identifying large small-bowel masses or extraintestinal disease, but are unable to provide precise data about the intestinal wall. Endoscopy has the advantage of visualizing intestinal mucosa directly and, above all, of carrying out targeted biopsies. Upper GI endoscopy, when performed to the ligament of Treitz, is suited for identifying duodenal tumors; however, lesions located distally pose a unique diagnostic challenge. Push enteroscopy (PE) is an effective diagnostic and therapeutic procedure which entails the oral insertion of a dedicated enteroscope; however, it only allows thorough examination of the distal duodenum and proximal jejunum to approximately 50-100 cm beyond the ligament of Treitz. Because of its ability to examine the entire small intestine, sonde enteroscopy has been utilized to diagnose small-bowel tumors[21]. However, this technically-challenging procedure has been today completely abandoned. Intraoperative enteroscopy (IOE) is the most complete, but also the most invasive means of examining the small bowel. It is a difficult, time-consuming technique, often traumatic to the bowel, with a substantial risk of complications and even mortality.

The development and the introduction in the clinical practice of the capsule endoscopy (CE) has revolutionized the field of small-bowel imaging, not only opening up this sort of "Pandora's box", but also stimulating the development of other imaging techniques aimed at studying the small bowel.

Magnetic resonance enteroclysis (MRI-enteroclysis) combines the advantages of cross-sectional resonance with those of volume challenge of conventional enteroclysis in the detection and characterization of small-bowel wall abnormalities, such as initial neoplasms. Small-bowel tumors usually exhibit moderate signal intensity on true-FISP images, as opposed to the high signal intensity of the distended lumen and the mesenteric fat. Post-gadolinium 3D FLASH with fat saturation may be the most important sequence for the identification and characterization of small-bowel tumors by their enhancement pattern. The degree of prestenotic dilatation, the peritoneal extension of the neoplasm and associated lymphadenopathy is well visualized in all MRI-enteroclysis sequences[22,23]. The multidetector row computed tomography (MRCT) has the potential to provide high-resolution images and a precise delineation of pathology. The multiplanar reformatted images obtained using MRCT have spatial resolution similar to that of the axial plane without any loss of information. These advantages of MDCT imaging lead to a more accurate demonstration of the site of the tumor and possible complications of underlying small-bowel tumors including small-bowel obstruction, intussusception, perforation and bleeding[24]. The administration of methyl-cellulose as a neutral luminal contrast material in a 4%-15% water-soluble solution or a diluted (1%) barium solution as positive luminal contrast in patients undergoing MRCT results in a computed tomography enteroclysis (CT-enteroclysis). As previously described for MRI-enteroclysis, this technique combines the advantages of enteral volume challenge and the ability of cross-sectional imaging to depict extra intestinal manifestations of the disease[25]. Both MRI enteroclysis and CT-enteroclysis require the placement of a specific catheter into the third part of the duodenum (fluoroscopic monitored), administration of medications (anti-motility agents and sedative medications) and small-bowel preparation with laxatives (PEG-based solutions, 2 to 4 L)[24]. Up to now, there are only few, but promising, publications about the role of these three techniques in the diagnostic algorithm of small-bowel tumors.

In the attempt to design a new scope that would allow a large part of the small-bowel mucosa to be visualized, overcoming the limits of PE and IOE, Yamamoto *et al*[25] developed a new method of push-and-pull enteroscopy (PPE) using a double-balloon technique. PPE affords inspection of the entire small bowel, combining the oral and anal approaches, with the advantage of enabling biopsies and endoscopic interventions to be performed in all parts of the small bowel without laparotomy. It is, however, invasive, time-consuming, and requires conscious sedation[26].

CAPSULE ENDOSCOPY IN THE DIAGNOSIS OF SMALL-BOWEL TUMORS

In a recently published paper, the hypothesis of an increased incidence of small-bowel tumors in recent years was put forward, based on the increasing number of cases diagnosed by means a non-invasive methods such as CE and small-bowel ultrasound[11]. In fact, compared with previously mentioned diagnostic techniques for the study of the small bowel, CE seems to be an ideal tool to recognize the presence of neoplastic lesions along the small bowel. The potential of CE for the diagnosis of small-bowel tumors, as well as for the surveillance of subjects at increased risk of developing them, depends largely on the technical characteristics of this diagnostic device. CE is a non-invasive tool, well accepted by patients, who can allow the visualization of the entire small bowel; high-quality images of the small-bowel mucosa may be captured and small and flat lesions recognized, without exposure to radiation.

In fact, since the introduction of CE in clinical

Table 2 Summary of CE studies for small-bowel tumors

practice, some studies have been published[27-32] reporting a frequency of small-bowel tumors higher than previously expected, ranging between 3.6% and 9%. All these studies were retrospective; each of them collected about 350-500 patients undergoing CE, described the frequency of small-bowel tumors in a highly selected group of patients with symptoms (obscure GI bleeding in the majority of cases) and sometimes the diagnosis was based only on the endoscopic images (one study[30] reported 35% of lesions described as tumor without histological confirmation). Two recent studies, coming from the USA and Europe, only published in abstract form[33,34], examined a large population of patients undergoing CE (respectively, 1000[33] and more than 5000[34]) in whom the definitive diagnosis was confirmed by means of tissue sampling (Table 2). They reported a small-bowel tumor frequency only slightly above that reported in previous surgical series, ranging from 1.6% to 2.4%, and also confirmed that the main clinical indication to CE in patients with small-bowel tumors is obscure GI bleeding (in about 90% of cases). Other indications for CE in these two studies were: chronic diarrhea, abdominal pain, para-neoplastic syndromes or, in a small group of patients, presence of conditions increasing the risk to develop a small-bowel tumor (such as refractory celiac disease, familial adenomatous polyposis or Peutz-Jeghers syndrome). In some rare cases CE was also used to confirm the presence of a tumor previously suspected by other imaging modalities. Although Cobrin *et al*[28] underlined that in their study the percentage of patients with tumor was greater among patients younger than 50 years, the median age of patients enrolled the above mentioned large studies ranged between 59[34] and 67 years[33] (Table 2).

Confirming data previously reported in surgical series[9,10] the majority of tumors identified by CE (from 63%[29] to 86%[33]) are malignant neoplasms and the most frequent histological types are adenocarcinomas and carcinoids (in about 20% of cases each[28,29,32]), while GISTs represent the most frequently identified benign neoplasm. Of note, this tumor accounted for more than one third of all collected cases in the large multi-center European study[34]. As far as small-bowel metastases are concerned, these lesions mainly (about 1/3 of cases[34]) derived from previously removed skin melanomas[35], but there are also some papers reporting lesions derived from colorectal cancers[29], from hepatocellular carcinoma or from rare tumors such as seminomas[34].

Small-bowel tumors appear at CE as masses or polyps in about 70%-80% of cases[28-34] and as ulcers (sometimes actively bleeding) or stenoses in 20%-30% of cases (Figure 2). Unfortunately, it is very difficult to identify pathology and tumor type based on the capsule endoscopic appearance of lesions[36]. These tumors are mostly located in the jejunum, 40%-60% of cases, in the ileum, 25%-40% of cases, and less frequently in the duodenum, in 15%-20% of cases[28-34]. The location of the majority of lesions in the mid-small bowel could be a partial explanation of the extensive (and mainly negative) diagnostic work-up performed in patients enrolled in all these studies. Each patient underwent a mean of 2%-4.6%[29,32] examinations before CE while, focusing only on exams addressed to evaluate the small bowel (particularly small-bowel series and/or small-bowel follow-through and/or PE and/or CT-enteroclysis), the mean number of examinations performed per patient ranged between 1 and 2[28,29,32]. Despite the extensive number of examinations performed before CE, this technique was found to have a positive impact on diagnosis (defined as the capability to identify a neoplasm not shown by other diagnostic techniques or as the ability to provide crucial information leading to change the subsequent patient management) in about 65%-80% of cases[31,34]. Urbain *et al*[31], trying to evaluate the impact of CE on the therapeutic choices of malignant small-bowel tumors, found that CE may influence directly the therapeutic work-up in about 55% of cases by providing

information about size, location and appearance of the lesion.

Because the early diagnosis and treatment of cancer usually affects outcome, some authors[28,29] suggest that the capability of CE to discover small-bowel tumors at an early stage may have an impact on prognosis for patients with these lesions. All the papers previously mentioned reported that in patients with small-bowel neoplasm identified by CE, surgery alone or surgery plus chemotherapy is the treatment of choice in about 85%-90% of the cases[28-30,33,34] but, to date, there is only one published paper describing the follow-up of these patients. Bailey *et al*[29] reported that surgical treatment was performed in 88% of patients with small-bowel tumor, in half of the cases with curative aim. None of the patients who underwent a curative resection developed tumor recurrence at follow-up (range, 26-51 mo). These authors also reported that none of the patients with benign tumors discovered by CE and treated according to CE findings had recurrence of either overt or occult obscure GI bleeding at follow-up (3-51 mo).

CAPSULE ENDOSCOPY FOR SPECIFIC SMALL-BOWEL TUMORS

Thanks to its capability to identify a small-bowel lesion in most patients with a prior negative diagnostic work-up, several case reports, but also some small series, aimed at evaluating the possible role of the CE in the diagnosis of specific tumors in particular clinical conditions, have been published over the last few years.

Van Tuyl *et al*[37], in a prospective descriptive study, evaluated 20 patients with liver metastases, mesenteric metastases or both, originated from a neuroendocrine tumor (NET) with unknown primary location. All these patients had undergone several examinations including small-bowel enteroclysis, abdominal CT, pentetreotide scintigraphy and laboratory tests. In this particular subset of patients, CE showed a diagnostic yield (60%) significantly higher than enteroclysis and CT scan. Pentetreotide scintigraphy had an even higher diagnostic yield than CE, but without differentiation between intestinal and mesenteric localization. In this study, the absence of findings at CE in patients with abnormalities at nuclear imaging was interpreted to be related to the presence of NET restricted to the mesentery or to a false-negative CE. On the ground of these data, the authors suggested that patients with a metastatic NET and an unknown primary tumor should undergo CE. Conversely, in a small retrospective study of 8 patients[38], CE detected NETs of the small bowel with high specificity, but slightly lower sensitivity than did CT enteroclysis. It was concluded that CE should not be used as a routine method for diagnosing NET in the small bowel.

As far as small-bowel metastases are concerned, Prakoso and Selby[35] performed a retrospective analysis of a prospective database identifying 13 patients with previous or recurrent malignant melanoma referred for CE. The indication for CE were overt GI bleeding in three patients, anemia in six, abnormal imaging in two, abdominal pain in one, and one patient had positive fecal occult blood test. In these patients, CE was able not only to show small-bowel metastases (in 5 patients), but also to provide a different possible explanation of symptoms in three other patients (NSAID-related ulcers, artero-venous malformation or aphtoid lesions). The authors concluded that since the optimal investigation for the detection of small-bowel metastases in patients with melanoma has still to be determined, CE can be considered an ideal method to do so because it appears to be more sensitive than small-bowel follow-through and CT scan.

Flieger *et al*[39] explored the potential contribution of CE to the diagnosis and staging of gastrointestinal lymphomas describing capsule endoscopic features of these tumors. They studied with CE a total of 27 consecutive patients with newly diagnosed gastrointestinal lymphoma: 20 patients with histologically confirmed gastric lymphoma and seven patients with intestinal lymphoma. All seven patients with primary intestinal lymphomas were found to have pathological findings at CE (ulcerations, nodules or villous atrophy), while 5 of the 20 patients with gastric lymphoma had pathological findings in the small bowel (including abnormal villi, white nodules or villous atrophy). In this study, the authors found that CE is able to identify pathological intestinal findings in patients with gastrointestinal lymphoma more frequently than previously thought and suggest that knowledge of small-bowel involvement can lead to changes in the therapeutic strategy in individual cases.

Lymphomatous polyposis (LP), first described by Cornes in 1961[40,41], is a rare condition; however, since the introduction of CE and PPE in clinical practice, a few reports[42,43] have been published on this topic. LP is defined as polypoid mucosal involvement of long segments of the GI tract by neoplastic lymphoid cells[40]. For many years LP has been considered the macroscopic appearance of the mantle cell lymphoma, but it has recently been suggested that it can be also the macroscopic manifestation of mucosa-associated lymphoid tissue (MALT) lymphoma and follicular B cell lymphoma[44]. In patients with LP, CE is a valuable tool because it may recognize the presence of nodules, evaluate the extent of the small-bowel involvement and drive further investigations (i.e. the decision about the PPE approach).

Another peculiar clinical condition is represented by patients with refractory celiac disease. It is known that these patients have an increased risk to develop small-bowel neoplasms, mainly enteropathy associated T-cell lymphoma (EATL). However, in this particular subgroup of patients CE is aimed at identifying not only a malignant neoplasm, but also some other possible complications such as ulcerative jejunitis. To date, two papers have been published on this topic[45,46] showing that CE is a useful tool in the assessment of complicated

celiac disease, especially in patients with refractory celiac disease type Ⅱ[45].

CAPSULE ENDOSCOPY: RISKS AND LIMITATIONS IN PATIENTS WITH SMALL-BOWEL TUMORS

Several papers[47-49] described risks and limitations related to the use of CE in everyday clinical practice. Some limitations can be present in any procedure performed regardless of the clinical indication ("general limitations"); these limitations are mainly related to the technical characteristics of the device or to the anatomical structure of the small bowel, for example, due to the duration of battery life (about 8 h), the capsule allows an evaluation of the entire small bowel only in 75%-85%[47,49] of cases. In addition, sometimes the presence of fecal debris, particularly in the distal small bowel, can hamper the accurate visualization of the small-bowel mucosa.

Among general limitations, capsule retention is certainly the more feared one because it can significantly modify the subsequent management of the patient. It is generally recognized that the frequency of capsule retention is mostly dependent on the clinical indication to CE (Table 3), ranging between 0% in healthy subjects to 21% in patients with intestinal obstruction[50,51]. Patients with small-bowel tumors, which frequently appear as lesions protruding into the small-bowel lumen or as stenoses, in both cases capable of narrowing the lumen of the small bowel, have a high probability to develop capsule retention. However, although capsule retention at the site of the lesion has been described in 10%[29,34] to 25%[33] of these patients (Table 2), most authors consider this situation as a minor complication. In fact, although some case reports describing possible acute obstructions due to capsule retained at the site of the tumor[52,53] exist, none of the 15 patients with capsule retention described in large published series[29,33,34] developed acute small-bowel obstruction. In these patients the subsequent surgical intervention, allowing capsule retrieval, was planned basically to treat the tumor (or because of symptoms persistence) rather than to retrieve the capsule. We must also keep in mind that surgical intervention aimed to retrieve the capsule can be done in a laparoscopic way[54] and that PPE can also allow capsule retrieval when surgical intervention is contraindicated or not feasible[55]. In addition, the recently developed Patency capsule[56] (given imaging, Yoqneam, Israel) can be used in selected patients as a screening method to prevent capsule retention.

The capsule can also have some problems in sizing lesions because of the shape of its dome, its magnification capability, the lack of air insufflation and of remote orientation. This issue has recently been highlighted in papers addressed to study patients with small-bowel inherited polyposis syndromes[57,58] in which the authors found that MRI seems to be more accurate and reliable than CE in the estimation of location and size of polyps[58]. The ingestion of "reference granules" of mesalazine 15-20 min before CE has recently been proposed to increase the accuracy of the procedure[59].

Table 3 Frequency of capsule retention in patients undergoing capsule endoscopy (modified from Pennazio[50])

Clinical indication	Frequency of capsule retention (%)
Healthy volunteers	0
Obscure GI bleeding	1.5
Suspected Crohn's disease	1.4
Known Crohn's disease	4-13
Small-bowel tumor	10-25
Suspected small-bowel obstruction	21

Another general limitation, that can be critical in the field of small-bowel tumors, is the accurate localization of the lesion along the small bowel. To estimate the location of a lesion we can correlate the time when the lesion appears to the small-bowel transit time divided in three equal thirds[60], or we can refer to the localization system[61]; both these systems are time-consuming, depend on some reference points established by the reader, are not suitable when the capsule does not reach the ileo-cecal valve during examination time and the localization software is reliable only considering a two dimension plan. Despite all these obvious limitations, in one large study[33] the capsule was able to correctly estimate the location of the lesion in a surprisingly high percentage of patients (about 85%).

Unfortunately, in the field of small-bowel neoplasms, in addition to these general limitations there are some other related to the intrinsic characteristics of these lesions ("tumor-related limitations").

Several studies[30,62-64] reported patients with negative CE in whom further examinations showed small-bowel tumors (false negative capsule endoscopy). Lewis *et al*[63], analyzing data from an industry-maintained trial database, found that in about 1.5% of patients with small-bowel tumors CE was completely negative. These authors estimated that the miss rate of CE in neoplastic diseases can reach 18.9%. Although this percentage is substantially lower than that reported in the same paper for other diagnostic techniques (63.2%) it remains still alarming, especially if one keeps in mind the clinical relevance of these missing findings. Obviously, there are several reasons contributing to that miss rate, but probably the crucial one is related, in this particular subset of patients, to the fact that sometime it is arduous, on the ground of CE findings, to discriminate masses from bulges. A bulge is defined as a round smooth, large base protrusion in the lumen having an ill defined edge on the surrounding mucosa; it can be a prominent normal fold or the luminal expression of intestinal loop angulation and stiffness, and sometimes it can be virtually indistinguishable from a small submucosal tumor. Some visual clues may help distinguishing masses from bulges (i.e. changes in mucosal characteristics, presence of bridging folds, of transit abnormalities, of repetitive images, and of synchronous lesions), but unfortunately all these are indirect indicators and often

are completely lacking.

Pasha *et al*[33] described 51 patients with polypoid lesions revealed at CE that were not confirmed at further examinations (false positive capsule endoscopy). This problem, highlighted also in other studies[30], can significantly influence the subsequent management; in fact a positive CE requires further invasive examinations (PPE or surgical interventions). For this reason, the final interpretation of a finding identified by CE must be done taking into account not only the endoscopic images, but also the patient's clinical history and other diagnostic examinations performed.

CAPSULE ENDOSCOPY IN INHERITED POLYPOSIS SYNDROMES

On the ground of its own technical characteristics (i.e. high-quality endoscopic images of the whole small bowel, no need for radiations) and of the patients' acceptance, CE has also been proposed in patients with inherited polyposis syndromes for both surveillance over time and in case of symptomatic disease.

In Peutz-Jeghers syndrome (PJS) the polyps are chiefly located in the small bowel (Figure 3) and may give rise to complications in the form of intussusception, bleeding and obstruction of the intestine, depending on the number and size of the polyps present, as well as to small-bowel malignancy. Several studies have explored the possible diagnostic role of CE in these patients[57,58,65,66] showing that this tool seems to be superior to small-bowel follow-through[57]. Unfortunately, the same studies also underlined that CE (as discussed above) is not reliable for accurate sizing of polyps. At the present time, it is suggested that CE should be performed at diagnosis in all patients with PJS, as the primary surveillance modality every 2-3 years from the age of 10, and as part of the investigation of patients with symptoms[50]. Additional information to evaluate the size and location of polyps, which is useful for planning the appropriate therapeutic strategy, can be provided by CT/MRI[57,58]. The coupling of CE with PPE and polypectomy may offer an ideal follow-up and treatment method for these patients, possibly avoiding surgery[67].

The role of CE is less clear in familial adenomatous polyposis (FAP). CE may miss duodenal/periampullary polyps due to a quick passage of the device in the descending duodenum. In a recently published prospective study, Wong *et al*[68] compared CE with push enteroscopy and with lower GI endoscopy in 32 patients with FAP. They showed that, in a defined segment of the small bowel, CE diagnosed significantly fewer small-bowel polyps than standard endoscopy, showed only fair agreement with PE in determining polyp counts, and was fairly inaccurate in determining the size of the largest polyp and also in detecting large polyps. For these reasons, CE is not presently recommended when the diagnosis of FAP is well established, but it may be considered as a part of surveillance for patients with severe duodenal polyposis (Spigelman stage Ⅲ-Ⅳ; Figure 4)[65,66]. Moreover, in FAP patients with known mesenteric desmoids, caution is recommended before performing CE for the possible risk of capsule retention.

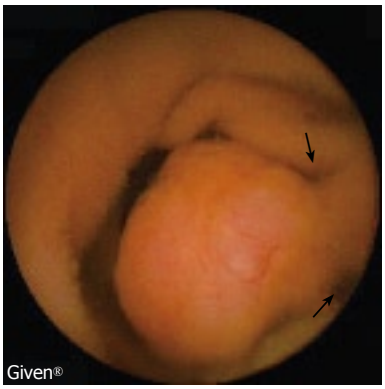

Figure 3 Small sessile, plaque-like, polyp (arrows) in the distal duodenum in a patient with familial adenomatous polyposis.

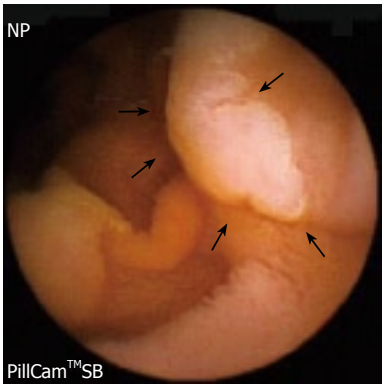

Figure 4 Pedunculated jejunal polyp (arrows denote stalk) in a patient with Peutz-Jeghers syndrome.

CONCLUSION

Small-bowel tumors are a small, but significant proportion of GI neoplasms. Using new diagnostic modalities, their frequency has been shown to be slightly superior than previously thought. Until recently, diagnosis and management of these tumors were delayed by the difficulty of access to the small bowel and the poor diagnostic capabilities of the available diagnostic techniques. An array of new methods has recently been developed, increasing the possibility of detecting these tumors at an earlier stage. Despite its limitations, CE plays a pivotal role in this setting. Whether the use of CE in combination with other new diagnostic (MRI or multidetector CT enterography) and therapeutic (PPE) techniques will lead to earlier diagnosis and treatment of these neoplasms, ultimately resulting in a survival advantage and in cost savings, remains to be determined through carefully-designed studies.

Abstract

Capsule endoscopy is now considered as the first imaging tool for small bowel examination. Recently, new capsule endoscopy applications have been developed, such as esophageal capsule endoscopy and colon capsule endoscopy. Esophageal capsule endoscopy in patients with suspected esophageal disorders is feasible and safe, and could be also an alternative procedure in those patients refusing upper endoscopy. Although large-scale studies are needed to confirm its utility in GERD and cirrhotic patients, current results are encouraging and open a new era in esophageal examination.

Key words: Capsule endoscopy; Esophagus; Gastroesophageal reflux disease; Varices; Esophagoscopy; PillCam ESO

INTRODUCTION

Since its introduction by Iddan *et al*[1], capsule endoscopy (CE) has acquired a well-established role in the investigation of suspected small bowel (SB) diseases. In fact, over 500 000 CE-procedures have been performed worldwide. Demands for CE are hoped to increase because of its proven superiority to conventional techniques for small bowel examination[2-11] and emerging indications, such as esophageal capsule endoscopy (ECE) and colon capsule endoscopy. Currently, upper endoscopy (EGD) is considered by most authors as the best method to explore the esophagus. However, because of the discomfort of intubation, conscious sedation is usually required resulting in increased costs, risks and patients acceptability[12-14]. In fact, because of these concerns, some patients are reluctant to undergo EGD even when it is indicated. So, it seems that there is a need for an alternative, simple and less invasive diagnostic tool for the evaluation of patients with known or suspected esophageal disorders. The esophageal capsule (PillCam™ ESO), which was approved by the FDA in November 2004, allows direct visualization of the esophagus without the need of sedation. Advantages include also its invasiveness and painless nature, the ability to pursue normal daily activities after the procedure and patients acceptability. Clinical data on its use and current indications, although quite limited, have opened a promising era for esophageal endoscopic examination.

PILLCAM™ ESO

The PillCam™ ESO (Given Imaging Ltd. Yoqneam, Israel) is an ingestible and disposable capsule measuring 11 mm × 26 mm (similar to PillCam™ SB) that acquires video images from both ends at a combined rate of 14 frames per second (7 from each side of the capsule) during its natural passage through the esophagus (Figure 1). The battery expires in 20-30 min approximately, resulting in more than 15 000 images captured per procedure, which are usually enough to explore the entire esophagus and sometimes, part of the stomach. The images, transmitted via digital radio frequency communication channel to the data recorder unit located outside the body, are captured by an antenna array located on the upper chest and the abdominal wall of the patient. Upon completion of the procedure, the images are transmitted to the Rapid® Workstation for processing and interpretation, which takes only a few minutes. Recently, a new complementary tool has been developed by Given Imaging: the RAPID® Access

Figure 1 PillCam™ ESO.

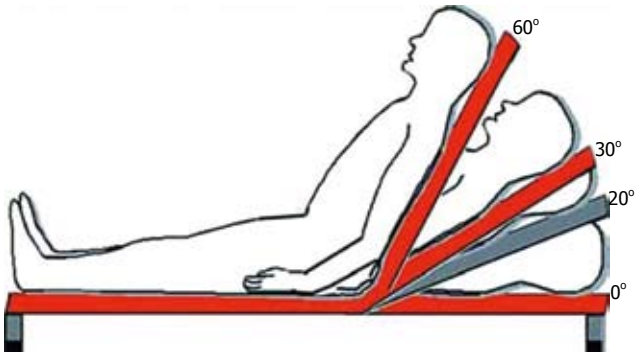

Figure 2 Ingestion protocol.

RT. During the ECE-procedure, the RAPID® Access RT allows real time visualization of capsule images. This is extremely useful in certain circumstances as the physician can intervene to optimize the procedure by changing patient position or administering medications such as laxatives depending on the images obtained in real time.

PROCEDURE

ECE is a quite simplex procedure, which can take only 4-5 min to physicians. This procedure requires implementation of a specific ingestion procedure to assure effective coverage of the esophagus (Figure 2). After a 6 h fast and before capsule ingestion, the patient is asked to drink swiftly a small amount of water (100 mL) in a standing position to clear saliva from the esophagus. Then, the capsule is swallowed in the supine position helped by a small sip of water (10 mL) if required. The patient must remain in this position for 2 min and then must be rose to an inclination of 30 degrees. The patient must remain in this position for 2 min and then the inclination must be increased to 60 degrees. One minute later, the patient is asked to drink a small sip of water (10 mL) and then, allowed to sit upright and to drink again 10 mL of water. In this moment, the patient is allowed to get up and walk in the waiting room for 15-20 min. During procedure in bed, the patient is instructed not to talk. Once the batteries have expired, the procedure is over and downloading

Figure 3 **A**: PillCam™ ESO image of erosive esophagitis; **B**: Upper endoscopy image of distal esophagus in the same patient.

process begins (4-5 min). Recently, an article published by Gralnek *et al*[15] has evaluated a new simplified ingestion procedure (SIP) in healthy volunteers who swallowed the capsule in the right supine position. Although esophageal transit time was shorter in comparison with the original ingestion procedure (mean: 38 s *vs* 225 s, respectively; $P < 0.001$), results showed that the SIP provides significantly improved visualization of the Z-line (visualization of $\geqslant$ 2 quadrants of the Z-line in 100% *vs* 75% of the cases; $P = 0.025$). Therefore, the authors recommend testing the proposed SIP in patients undergoing ECE.

ECE IN GERD PATIENTS (TABLE 1, FIGURES 3 AND 4)

Persistent heartburn is one of the most frequent gastrointestinal symptoms in western countries. Symptomatic GERD affects at least 5%-7% of the global population and in western countries, up to 30% of the population is affected by this disorder[16-18]. Complications of GERD include erosive esophagitis, ulcers, strictures or Barrett's (BE) esophagus. Up to 30% of subjects with GERD are found to have esophagitis while ulcers or strictures occur in 5% of patients[19]. Barrett's esophagus, which carries a risk of 0.5% per patient-years of esophageal adenocarcinoma, may occur in up to 10% of patients with chronic GERD[20]. Therefore, international guidelines recommend screening EGD in all GERD patients. However, as demonstrated, its cost and invasiveness limits its utilization in many patients[21].

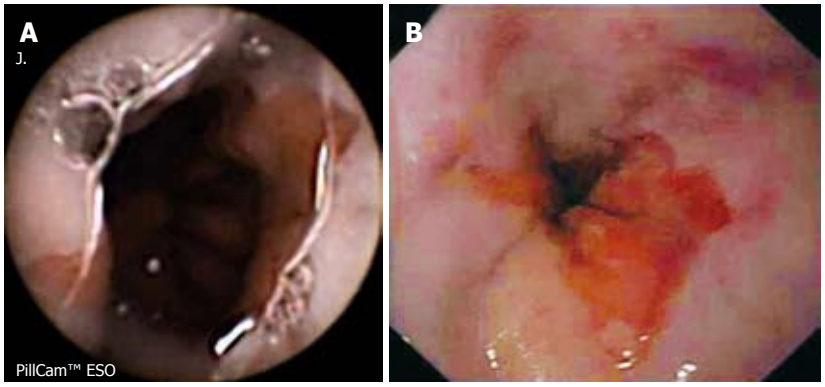

Figure 4 **A**: PillCam™ ESO image of short segment Barrett´s esophagus; **B**: Subsequent upper endoscopy image which confirms capsule findings.

In 2003, Neu *et al*[22] published the first article regarding ECE. Using SB capsules (single camera at a frame rate of 2/s), they evaluated the accuracy of capsule endoscopy in 8 patients with known esophagitis. All patients swallowed the capsule in the supine position. The capsule detected only 3 of 8 (37.5%) patients with esophagitis and an adequate visualization of 50% and 100% of the Z-line circumference was achieved in 12.5% and 37.5% of the patients, respectively. They also evaluated the quality of images obtained by the capsule in 58 patients examined for suspected small bowel pathology with poor results (0% of 100% of the Z-line circumference visualization), due to the short esophageal transit time (these patients swallowed the capsule in standing position). They concluded that distal esophageal assessment by SB capsules was not feasible.

Few months later, Ramirez *et al*[23] used SB capsules attached to strings allowing capsule control up and down the esophagus. Fifty patients with Barrett's esophagus were enrolled in this study. The mean recording time in this study was much longer than in the previous study by Neu *et al* (7.9 min *vs* 3 s). All 50 patients with BE were detected by the capsule. The majority of patients (92%) preferred string-capsule endoscopy to EGD because usually, none or minimal discomfort was associated with capsule ingestion. They concluded that string esophageal capsule endoscopy is feasible, safe and highly acceptable by patients with esophageal disorders.

In 2004, Eliakim *et al*[24] published a pilot study of ECE using specifically-designed capsules for esophageal examination (double camera at a frame rate of 4 per second). They compared the diagnostic yield of ECE to EGD (used as gold standard) in 17 patients with suspected esophageal disorders. All patients swallowed the capsule in supine position to avoid rapid esophageal transit of the capsule. All patients with positive findings at EGD (12/17) were detected by the capsule. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were 100%, 80%, 92% and 100%, respectively. Of 15 patients asked, 12 (80%) preferred the capsule experience to EGD which was performed under sedation with Midazolam 2.5-5 mg. They concluded that ECE with the new device proposed is an accurate, convenient, safe and well-tolerated method for patients with esophageal disorders. These results were encouraging but the small sample size of this pilot study was an obstacle to elaborate solid conclusions. Then, largescale studies seemed to be necessary.

A similar study conducted at 7 sites in 2005[25] evaluated the new developed PillCam™ ESO (double camera at a frame rate of 4 per second) compared to EGD in 106 patients (93 with GERD and 13 with BE). All patients swallowed the capsule in the supine position. Sensitivity, specificity, PPV and NPV for esophagitis were 89%, 99%, 97% and 94%, respectively, and 97%, 99%, 97% and 99%, respectively, for BE. ECE was preferred over EGD by all patients. These results were consistent with those obtained by Eliakim *et al*[24] in 2004. They concluded that ECE was a convenient and sensitive method for visualization of esophageal mucosal pathology and may provide an effective method to evaluate patients for esophageal disease.

However, some experiences have shown that the speed of the capsule in the proximal esophagus can reach up to 20 cm per second. It means that using the

Table 2 ECE in portal hypertension: Results in published studies

Author	Yr	*n*	Indication	Capsule	Ingestion	S	E	PPV	NPV
Ramirez[40]	2005	30	Varices	String SB	Standing	96%	100%	100%	83.3%
Eisen[41]	2006	32	Varices	ESO 14-fps	Supine	100%	89%	(-)	(-)
Eisen[41]	2006	32	PHG	ESO 14-fps	Supine	100%	77%	(-)	(-)

4-frame per second capsule, only one image could be taken per 10 cm length in some instances. Koslowsky *et al*[26] speculated in 2006 that the diagnostic yield of the ECE might be improved by using a 14-frame per second capsule. Fifty patients (42 suffering from GERD symptoms and 8 with confirmed BE) were included in this study and all of them swallowed the capsule in the supine position: 25 underwent ECE with the 4-frame per second capsule and 25 underwent ECE with the 14-frame per second capsule. Using EGD as gold standard, the 4-frame per second capsule sensitivity, specificity, PPV and NPV were 81%, 61%, 74% and 79%, respectively, and the 14-frame per second capsule sensitivity, specificity, PPV and NPV were 100% ($P < 0.02$), 74%, 100% and 77%, respectively. The upper esophageal sphincter and the entire esophagus were assessed by the 4-fps capsule in 25% and 12% of the cases, respectively, and in 81% ($P < 0.01$) and 76% ($P < 0.01$) of the cases by the 14-fps capsule, respectively. They concluded that ECE using the 14-fps capsule has a greater sensitivity and allows better visualization of the entire esophagus than the 4-fps capsule.

Recently, two prospective, blinded and well-designed studies have compared the diagnostic accuracy of ECE using the 14-fps capsule *vs* EGD in both GERD and BE. Sharma *et al*[27] included 100 patients with GERD and BE. Ninety-four of these patients swallowed the capsule in the supine position. Results reported showed a higher diagnostic accuracy for BE than for erosive esophagitis. The sensitivity, specificity, PPV and NPV for BE in GERD patients were 67%, 87%, 60% and 90%, respectively, and for known Barrett's esophagus in patients undergoing surveillance were 79%, 78%, 94% and 44%, respectively. The diagnostic accuracy of ECE for long Barrett's segment esophagus (LSBE) was greater than for short Barrett's segments esophagus (SSBE). For erosive esophagitis, the sensitivity was 50%, the specificity 90%, the PPV 56% and the NPV 88%. These results were quite different than those obtained in previous studies. These differences might be attributed in part, to the diagnostic skills of examiners and to the ingestion protocol in the supine position. Anyway, the authors require for the future an improvement in technology and learning curve assessments. The other study, published at the same time by Lin *et al*[28], included 96 patients with chronic gastroesophageal reflux and BE undergoing surveillance. Again, the selected ingestion protocol was in the supine position. ECE sensitivity, specificity, PPV and NPV for BE were 67%, 84%, 22% and 98%, respectively. There were no differences between SSDE and LSBE detection. These results were similar to the study by Sharma *et al*[27] but again, quite different to those showed in previous studies with the 4-fps capsule. The authors attributed these differences to the patient adjudication process in previous studies (unblinded investigators). They conclude that ECE is not, at present, suitable as a primary screening tool for BE but may be used in patients unwilling to undergo EGD. Precisely, one study by Sanchez-Yague *et al*[29] published in 2006, reviewed 30 cases of ECE in patients refusing conventional endoscopy. They demonstrated that ECE is an adequate alternative diagnostic method for the study of patients with suspected esophageal diseases.

ECE IN PATIENTS WITH PORTAL HYPERTENSION (TABLE 2, FIGURES 5 AND 6)

The presence of esophageal varices is one of the most common complications of portal hypertension in cirrhotic patients. Although they are present in about 50% of the patients when cirrhosis is diagnosed, most of these patients develop varices during their lifetime[30,31]. Severe upper gastrointestinal bleeding as a complication of portal hypertension occurs in about 30%-40% of cirrhotic patients and in most cases because of the presence of esophageal varices[32,33]. Despite recent improvements in the diagnosis and treatment of esophagogastric variceal haemorrhage, the mortality rate of first variceal haemorrhage remains high (20%-35%)[33-36]. The risk of bleeding is related to the hepatic venous pressure, the Child- Pugh class and the endoscopic appearance of the varices[37]. Therefore, one of the challenges is to identify those cirrhotic patients who have esophageal varices and are also at risk of bleeding. Recently, the Baveno Ⅲ Consensus Conference on portal hypertension recommended that all cirrhotic patients should be screened by means of upper endoscopy for esophageal varices when liver cirrhosis is diagnosed, at 2-3 years intervals in compensated patients without varices and at 1-2 years intervals in compensated patients with previous small varices[38]. However, sedation during EGD in cirrhotic patients carries increased risks of cardiopulmonary complications because they are more susceptible to oversedation than those with normal liver function[12,39].

At the moment, three published studies have evaluated the role of ECE in portal hypertension. The first study was published in 2005 by Ramirez *et al*[40] who used the string-capsule endoscopy to evaluate portal

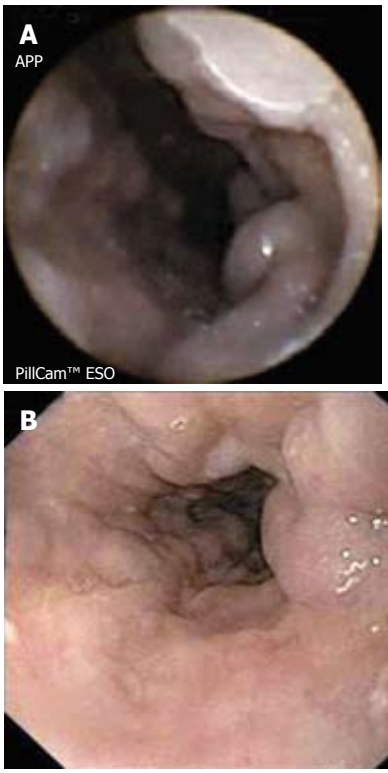

Figure 5 **A**: PillCam ESO™ image showing esophageal varices; **B**: Upper endoscopy image of distal esophagus in the same patient.

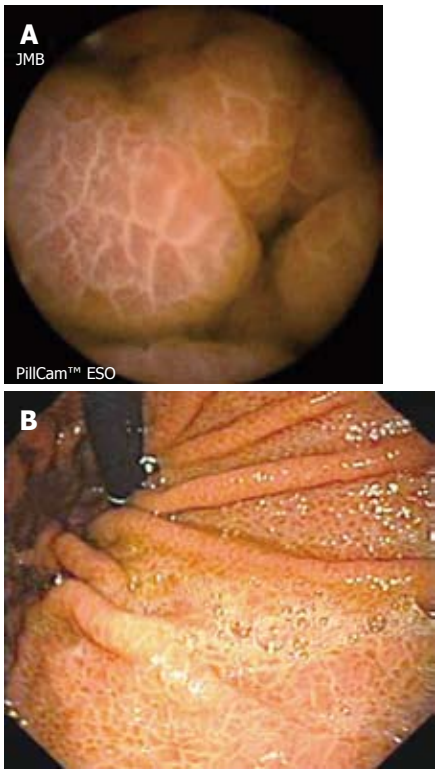

Figure 6 **A**: PillCam ESO™ image of the gastric wall showing portal hypertension gastropathy; **B**: Subsequent upper endoscopy image which confirms capsule findings.

hypertension in 30 cirrhotic patients. They reported an overall accuracy of 96.7% for varices (sensitivity of 96%, specificity of 100%, PPV of 100% and NPV of 83.3%, respectively) and all patients preferred string-capsule endoscopy to EGD.

On the other hand, two comparative studies have been recently published. Both of them used the new 14-fps capsule, which were swallowed in the supine position, and compared ECE *vs* EGD for portal hypertension in cirrhotic patients. Eisen *et al*[41] included 32 cirrhotic patients who were undergoing EGD for varices screening or surveillance. They reported a sensitivity of 100%, specificity of 89%, positive likelihood ratio of 9.1 and negative likelihood ratio of 0.0 for esophageal varices detection in comparison with EGD. There was complete agreement in the grading of varices in 65% of the cases and in 95% of the cases within one grade. They also evaluated the accuracy of the capsule to detect portal hypertension gastropathy (PHG). Sensitivity, specificity, positive likelihood ratio and negative likelihood ratio for PHG were 100%, 77%, 4.3 and 0.0, respectively. This pilot study led to a multicenter study with more than 300 patients included which is now finished but not yet published. The other comparative study by Lapalus *et al*[42], simultaneously published, included 21 cirrhotic patients who were undergoing unsedated EGD for varices screening. Results showed that ECE accurately assessed the presence of esophageal varices in 85% of the cases and correctly indicated a need for primary prophylaxis in 100% of the cases. All patients preferred ECE to unsedated EGD which was performed with a small-diameter upper gastrointestinal endoscope.

CONCLUSION

Capsule endoscopy has opened a new era in small bowel examination. Its indications are now well-defined and currently, wireless capsule endoscopy is considered as the first-line imaging tool for the diagnosis of small bowel diseases. ECE has been shown to be feasible, safe (no ECE-related complications have been reported with the PillCam™ ESO) and a good alternative technique in patients refusing conventional endoscopy. Although results reported in both GERD and cirrhotic patients are encouraging, great differences in terms of accuracy (particularly in GERD patients) have been found in published studies. These differences have been attributed to study designs, the lack of adequate experience and inconvenience of ingestion protocols. In summary, more large-scale studies evaluating the new 14-fps capsule, adequate ECE-experience and new modified ingestion protocols are still needed.

Abstract

Obscure gastrointestinal bleeding (OGIB) is defined as bleeding of an unknown origin that persists or recurs after negative initial upper and lower endoscopies. Several techniques, such as endoscopy, arteriography, scintigraphy and barium radiology are helpful for recognizing the bleeding source; nevertheless, in about 5%-10% of cases the bleeding lesion cannot be determined. The development of videocapsule endoscopy (VCE) has permitted a direct visualization of the small intestine mucosa. We will analyze those techniques in more detail. The diagnostic yield of CE for OGIB varies from 38% to 93%, being in the higher range in those cases with obscure-overt bleeding.

INTRODUCTION

Obscure gastrointestinal bleeding (OGIB) is defined as bleeding of an unknown origin that persists or recurs after negative initial upper and lower endoscopies[1]. It can be subclassified as either obscure-occult, detected only by positive fecal occult blood tests (FOBT) and/or iron deficiency anemia (IDA), or obscure-overt with recurrent or persistent visible episodes of bleeding[2].

Approximately 5% of all gastrointestinal bleeding[3] are of obscure origin, and the most frequent causes are found among these: esophagitis, Cameron ulcers, Dieulafoy lesions, angiodysplasias, GAVE, portal hypertensive gastropathy, small bowel neoplasms, hemobilia, Meckel diverticulum, Crohn's disease, medication-induced mucosal lesions and a few others[2].

Several techniques, such as endoscopy, arteriography, scintigraphy and barium radiology, are helpful for recognizing the bleeding source; nevertheless, in about 5%-10% of cases the bleeding lesion cannot be determined[4]. Before 2001, the study of OGIB was deficient as the small bowel could not be reviewed reliably in its whole, but the development of videocapsule endoscopy (VCE) has permitted a direct visualization of the small intestine mucosa.

DIAGNOSTIC TECHNIQUES

Capsule endoscopy (CE)

Capsule endoscopy (CE) is a disposable 26 mm × 11 mm plastic capsule (Figure 1) consisting of an optical dome, 4 light-emitting electrodes, a sensor, 2 batteries and a micro transmitter. It acquires and transmits 2 frames per second (until the battery expires after 7 h ± 1 h[5]) to a sensor array attached to the patient[2]. Image features include a 140-degree field of view, 1:8 magnification, 1 to 30 mm depth of field and a minimum size for detection of about 0.1 mm[5].

It is passively propelled by peristalsis and it captures images of the entire length of the small intestine. The main limitations are the lack of air insufflation, the unavailability of rinsing, taking biopsies or/and treating lesions[2].

The incidence of capsule retention accounts of less than 1%[2] and is generally related to the presence of endoluminal narrowing. For that reason, and intending to predict the risk of retention, patients with high suspicion of bowel narrowing (history of NSAID's intake, Crohn's Disease, occlusive symptoms or ischemic bowel disease) should undergo capsule endoscopy exploration after performing other techniques such as CT scan, small

Figure 1 Hand holding a small bowel PillCam.

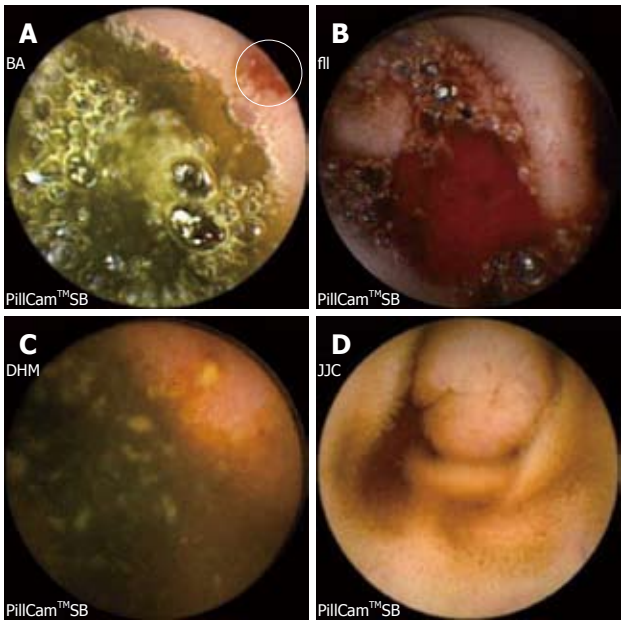

Figure 2 Lesions in the small bowel suspicious of being responsible for bleeding that can be found on CE: Angioectasia (**A**); Active bleeding (**B**); Ileal ulceration (**C**); Polypoid lesion (**D**).

bowel series or M2A patency capsule.

The diagnostic yield of CE for OGIB varies from 38% to 93%[5], being in the higher range in those cases with obscure-overt bleeding[3]. The ability to exclude bleeding lesions is between 82.6% and 100%[2]; nevertheless, in up to 35% of cases the capsule doesn't reach the cecum, probably due to slow gastric transit[2]. The most commonly detected lesions in the small bowel suspicious of being responsible for bleeding, that can be found on CE, are: angioectasia (Figure 2A), fresh blood (Figure 2B), ulceration (Figure 2C), polypoid or tumoral lesions (Figure 2D) and varices[5], and it seems that there is no significant difference in the diagnostic yield of CE in obscure-overt and obscure-occult bleeding[5,6]. One of the difficulties while reading the CE is to determine what has to be considered a positive finding with clinical significance, and a consensus still has to be reached[3]. In general, nonspecific mucosal changes (red spots in Figure 3, white spots, *etc*) are not considered positive

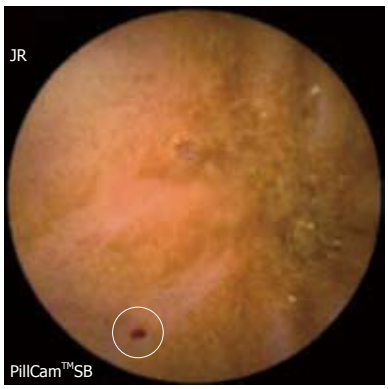

Figure 3 Red spot, with no relevant clinical significance.

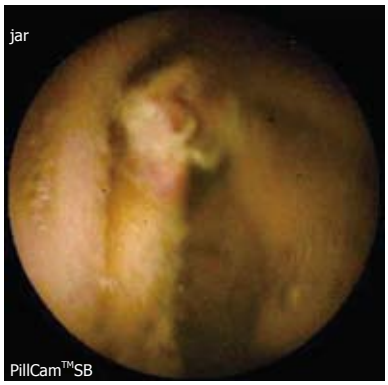

Figure 4 Ulcerated polyp.

findings; while angioectasias, tumors (Figure 4), masses or mucosal breaks should be included as positive findings.

This wide range of diagnostic yield can be related to several reasons, and one that has been suggested is the performance of CE within 15 days which can improve it (91% *vs* 34%, $P < 0.001$)[4]. Despite this improvement, some bleedings are still from an unknown origin. It has been suggested that a repeated CE can come across new findings in about 75% of cases, leading to changes in patient management in 62.5%[7] of cases. One of the main reasons to repeat a CE is the limited visualization that happens in about 44% of cases[7]. Recurrent bleeding is another reason for repeating CE. It can be helpful if the lesion responsible for bleeding is present intermittently or there was no bleeding source recognized in the first CE[7].

However, not only is it important to have a high diagnostic yield, but also to know if patient outcomes are improved after performing a CE. Carey *et al* considered measures of patient outcome the number of hospitalizations, units of blood transfused and the number of tests or procedures related to GI bleeding. Considering these measures, patient outcome appeared to improve after CE[3].

Lai *et al*[8] reported, in 2006, the results of a long-term follow-up of patients with obscure gastrointestinal bleeding. In 63.3% of cases, CE was able to determine the bleeding source and 32.7% of patients presented re-bleeding within the follow-up (median follow-up period: 19 mo)[8]. Patients with angiodysplasia were more susceptible to re-bleed (58.3% of cases were due to this condition), followed by patients with active

bleeding during the CE procedure with no identified bleeding source (53.8%)[8]. They found that the probability of re-bleeding was significantly higher in patients with positive CE than in those with negative CE ($P = 0.003$)[8].

Repeat upper endoscopy and colonoscopy

Between 35% to 75% of patients can be under-diagnosed at the initial endoscopic study[2]. Missed lesions occur due to their size, location, presence of clots or the absence of active bleeding while the endoscopy is being performed. Other possible causes are anemia, volume contraction, the effect of sedatives, as they can result in paleness of vascular lesions, and the timing of the endoscopy, as it is more probably to identify the bleeding source if the endoscopy is performed within 48 hours of the acute event[2].

It has been recommended to repeat upper and lower endoscopy ("second-look endoscopy")[2], nevertheless, about 5% to 10% of patients will remain undiagnosed.

Push enteroscopy

Enteroscopy consists of a peroral insertion into the jejunum of a long endoscope, using either a pediatric colonoscope or an enteroscope, and with or without the use of an overtube in order to avoid gastric looping[2]. This technique allows the examination of 15 to 160 cm beyond the ligament of Treitz[5] and it is generally considered the next diagnostic step after upper and lower negative endoscopic studies.

In 38%-75% of cases, the lesion causing OGIB can be identified with this technique[2,5]. However, in 28% to 75% of cases, it is reachable with a gastroscope[5]. Common findings are angiodysplasias (20%-46%), peptic ulcer disease, benign and malignant jejunal tumors, diverticulum, esophagitis and varices[2]. A meta-analysis has been published showing that the yield of CE for all findings is 63% *vs* 28% for Push Enteroscopy, with an incremental yield of 35%, $P < 0.00001$[9]. Yield of clinically significant findings is 56% for CE *vs* 26% for Push Enteroscopy[9].

Small bowel series and enteroclysis

Before the development of CE, a radiologic study of the small bowel was mandatory for the study of OGIB. The diagnostic yield is about 6%[2,5], and the most common missing lesions include angioectasia, ulcers and erosions[5]. The diagnostic yield can be improved (diagnostic yield of 10%-20%)[5] by performing enteroclysis. This technique consists in the introduction of a catheter into the small intestine followed by the injection of barium and methylcellulose. The barium coats the intestine and the methylcellulose distends the lumen to give a double contrast exam that allows for fluoroscopic visualization of the entire small bowel. The sensitivity of enteroclysis for small bowel tumors is higher than small bowel series[5].

A recent meta-analysis has shown that the diagnostic yield for all findings for CE is 67%, compared with an 8% for small bowel series. Diagnostic yield for significant findings is 42% for CE *vs* 6% for small bowel radiography[9].

Bleeding scanning with technetium-99-labeled RBC and angiography

This test can be useful if active bleeding is present as it may detect the source of hemorrhage if the bleeding rate ranges from 0.1 to 0.4 mL/min. Angiography can also be performed for diagnosis, as it is able to detect bleeding rates over 0.5 mL/min[2]. If the bleeding scanning is positive, an angiography should be performed to detect bleeding lesions and treat them if possible[2]. The diagnostic yield of these techniques varies from 44% to 68%[2].

Computed tomographic angiography (CTA)

Angiographic images can be obtained, not only by routine angiographic techniques, but also by CT scan. CTA is noninvasive and potentially useful for the diagnosis of GI bleeding, as it avoids the risks of standard angiography[10]. The CTA is able to identify the bleeding source in 24% of patients[10]. As has been recently published, CE is able to identify the bleeding source in a higher proportion of patients than CTA (72% *vs* 24%)[10].

Intraoperative enteroscopy (IE)

IE is the final diagnostic procedure for OGIB. It consists of performing an enteroscopy with the help of the surgeon, who helps by pushing the bowel over the enteroscope as the endoscopist examines it. The insertion can be done transoral or directly through a small enterotomy, but the last is more likely to achieve a complete examination of the small bowel. One of the drawbacks of this technique is that the manipulation of the bowel can create artifacts, which can be considered as bleeding sources although they are really not[2]. The direct effect of this handicap is that the examination of the mucosa has to be done while the intubation and not while the withdrawal of the endoscope. IE can achieve a diagnostic yield of a 70 to 93 which is comparable to CE[9].

Double balloon enteroscopy (DBE)

DBE is a novel endoscopic technique that allows for visualization of the entire small bowel, tissue sampling and therapeutic interventions. It consists of an enteroscope with 2 latex balloons, one attached to the endoscope and the other attached to an overtube. The procedure is performed by inflating and deflating the balloons, allowing the deep intubation through the small bowel. The route of insertion (perorally or transanally) selected depends on the patients' symptoms (hematochezia, melena *etc*).

A potential bleeding cause can be found in 75.7% of patients[11] and approximately a quarter of patients might need both anterograde and retrograde approaches[11]. DBE can change patient management in about 83.5% of cases, with an average therapeutic endoscopic intervention of 15.7%[11]. Hadithi *et al*[12] have published that CE is able to detect the presence of a possible

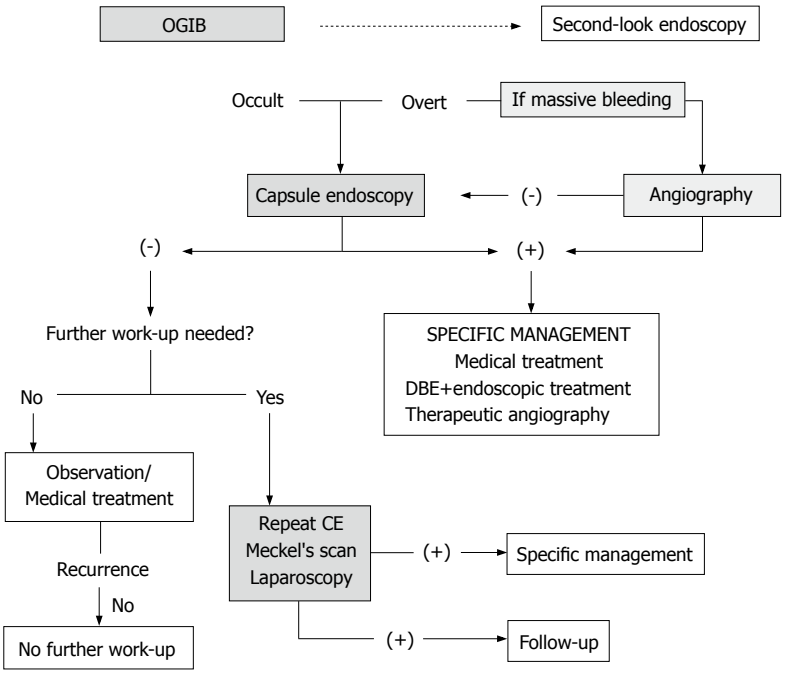

Figure 5 Suggested algorithm for OGIB.

bleeding source in a higher proportion of patients than DBE (80% *vs* 60%).

CONCLUSION

As explained before, there are some diagnostic techniques that can be used for the study of OGIB. With so many different tools, it is important to establish which should be performed first, not only taking into account the diagnostic yield but also the cost effectiveness of each one. Finally the suggested algorithm for OGIB by the International Consensus on Capsule Endoscopy is shown in Figure 5.

Abstract

Wireless capsule endoscopy has become the first imaging tool for small bowel examination. Recently, new capsule endoscopy applications have been developed, such as esophageal capsule endoscopy and colon capsule endoscopy. Clinical trials results have shown that colon capsule endoscopy is feasible, accurate and safe in patients suffering from colonic diseases. It could be a good alternative in patients refusing conventional colonoscopy or when it is contraindicated. Upcoming studies are needed to demonstrate its utility for colon cancer screening and other indications such us ulcerative colitis. Comparative studies including both conventional and virtual colonoscopy are also required.

INTRODUCTION

Colorectal cancer (CRC) is the second most frequent cause of cancer-related death in western countries -skin tumors excluded-, after lung cancer in men and breast cancer in women. One out of three patients suffering from CRC will not survive[1]. Nevertheless, it can be considered as a preventable and curable condition. Firstly a preventable condition because in most cases, it develops from colonic adenomas. In fact, colonic adenomas are found in 11% to 40% of average risk population[2-4]. And secondly, a curable condition, because the 5-year survival rate in early stages can reach 90%[1]. For these reasons, conventional colonoscopy is suggested to be the optimal technique to be used for CRC screening programs in high-risk population, allowing a 90% decrease in CRC incidence[5]. However, it has to be considered that no more than 25% of compliance has been achieved in screening programs[5]. This low compliance can be explained by the drawbacks of conventional colonoscopy, such as being painful, patient's embarrassment or the need of sedation. Non-invasive techniques for colonoscopy, such as CT colonography[6-8] and Colon Capsule Endoscopy[9-11] are currently being evaluated as alternatives to conventional colonoscopy in order to improve the compliance to screening programs.

PILLCAM™ COLON CAPSULE

A large number of clinical trials have been performed testing different capsule designs in healthy volunteers. Finally, Given Imaging Ltd. has developed the final prototype for colon examination, which is called PillCam™ Colon. The PillCam™ Colon capsule has some differences from those used to study the small bowel and the esophagus. It measures 31 mm in length (4 mm longer than the PillCam™ ESO and SB) and 11 mm in diameter (the same as PillCam™ ESO and SB).

Figure 1 shows some morphologic differences between the three capsules commercially available. The PillCam™ Colon capsule has also some technical improvements, such as being equipped with cameras on both ends taking 4 images per second (2 images per camera). Each camera contains an automatic lighting control and has improved optics, which capture more

Figure 1 PillCam™ SB, ESO and Colon.

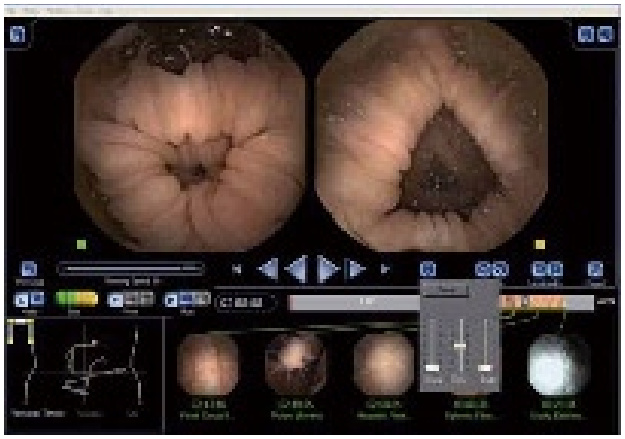

Figure 2 New Software for Colon Capsule reading: RAPID® 5 Scientific Edition.

than twice the coverage area and depth of field of PillCam™ SB resulting in a superior observation field. Other specific features are the presence of a longer battery (lasts 9-10 h on average), which can also "hibernate" minutes to hours after ingestion in order to conserve power before the capsule enters into the colon.

The accessory devices (sensor arrays and Data Recorder) are similar to those ones used by the PillCam™ ESO and SB. The RAPID® software used for images visualization during first clinical trials is a scientific version very similar to RAPID® 4, which includes (Ⅰ) a larger image display (round-rectangular shape), (Ⅱ) a complementary capsule localization system and an (Ⅲ) image enhancement (IE) features (Figure 2). The localization display is similar to the one already in use for the small bowel, but it also includes a schematic diagram of the colon that helps the physician to identify the location of findings, i.e., right, transverse and left colon segments once the main anatomic landmarks (first cecal image, the hepatic flexure, the splenic flexure and the body exit) have been selected. Moreover, this software allows the physician to enhance the appearance of the image by changing their color, brightness and sharpness.

[1]If the capsule was excreted, the regimen was discontinued; [2]Only if the capsule has exit the stomach.

RAPID® Access RT by Given Imaging allows real time visualization of capsule images. This is extremely useful in certain circumstances as the physician can intervene to optimize the procedure by changing patient position or administering medications such as laxatives depending on the images obtained in real time. In the PillCam™ Colon procedure, the importance of the real time viewer is that -as we will see later in more detail- 2 h post PillCam™ Colon Capsule ingestion, the patient has to drink a small amount of Sodium Phosphate. It is well known that Sodium Phosphate can delay gastric emptying time; therefore before giving it to the patient, it is recommended to check if the capsule has left the stomach, which can be easily done with the real time viewer.

PROCEDURE AND CLEANLINESS

The procedure of bowel cleansing until capsule ingestion is similar to that used for traditional colonoscopy. It usually begins one day before capsule ingestion, with the administration of laxatives to the patient. Patients are usually asked to maintain a low fiber diet 2 d before capsule ingestion. After the capsule has been ingested additional laxative and prokinetic agents are provided to the patient in order to (Ⅰ) maintain the cleanliness of the colon throughout the transit of the capsule and (Ⅱ) enhance capsule propulsion and excretion within 9-10 h post ingestion. The laxative and prokinetic agents are commercially available, and are provided within their permitted dose. Detailed information of the prep and procedure regimen used in recent trials[9-11] is shown in Table 1.

First results using the same prep as conventional colonoscopy showed low capsule excretion rates (about

20%) which meant low rates of complete colonoscopies. Changes in prep regimens were then introduced (see Table 1) and higher excretion rates were reported by Eliakim *et al*[9], Schoofs *et al*[10] and Lewis *et al*[11] (78%, 84% and 90%, respectively). Moreover, the colon cleansing level reported by Eliakim *et al*[9] and Schoofs *et al*[10] was good to excellent in 84.4% and 88% of the patients, respectively. Recently, an undergoing European multicenter study published in abstract form[12] has reported a capsule excretion rate of 93% and good to excellent colon cleansing level in 71% of the patients. All these results are consistent with those obtained by conventional colonoscopy. As the goal of colon capsule endoscopy is to improve patient compliance to CRC screening, other simplified ingestion regimens including Moviprep® as the main laxative product or capsule procedures during the night are currently under evaluation.

LESIONS DETECTION

The long term primary objective of the PillCam™ Colon capsule is the average risk population undergoing CRC screening. In order to evaluate the accuracy of the new capsule device, it is being tested in those patients with known or suspected lesions (i.e. polyps or tumors). At the moment, encouraging results has been reported. Two European feasibility studies[9,10] including a total of 132 patients and one American study[11] published in abstract form including 25 patients, have recently evaluated the role of the PillCam™ Colon capsule in detecting colonic lesions. In all of these studies, conventional colonoscopy was considered the gold standard and the American[11] study included also the virtual colonoscopy as an additional comparative procedure. Preliminary results from these studies are resumed in Table 2. The European studies showed a capsule sensitivity (S) for polyps of any size of 69% and 76%, specificity (E) of 81% and 64%, positive predictive value (PPV) of 74% and 83% and negative predictive value (NPV) of 78% and 54%, respectively. Those polyps greater than 6 mm or 3 polyps of 3 mm were considered significant lesions. The accuracy of the colon capsule for significant lesions was very similar as well as for inflammatory lesions (i.e. diverticula, ulcerative colitis, *etc*). These results are consistent with those obtained in the American study

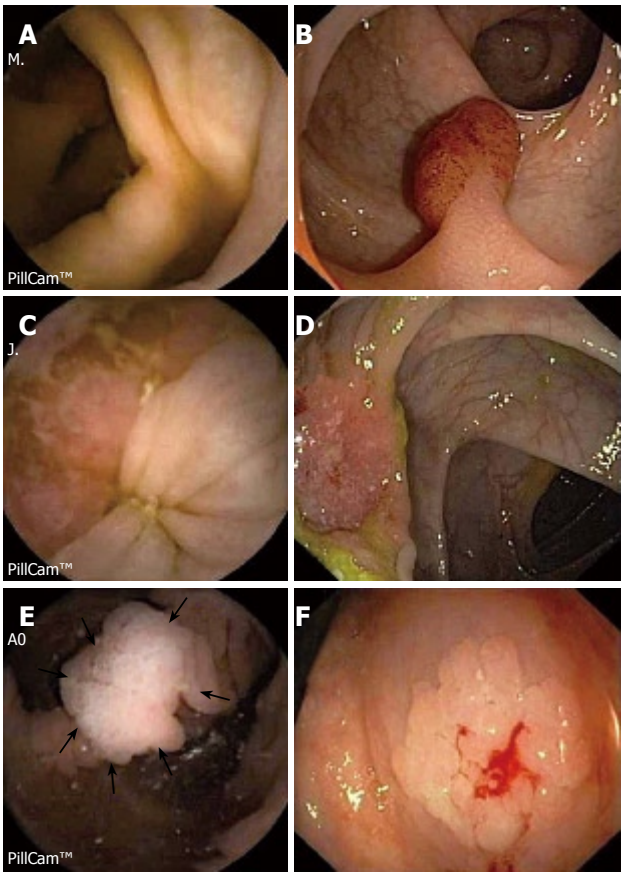

Figure 3 Images captured by the Pillcam™ Colon and conventional colonoscopy. **A** and **B**: Pedunculated polyp in the sigmoid colon; **C** and **D**: Ulcerated tumor in the transverse colon; **E** and **F**: Flat adenoma in the ascending colon.

which also showed that conventional colonoscopy was more accurate than colon capsule endoscopy and virtual colonoscopy (81%, 63% and 54%, respectively). In the European multicenter study[12], S, E, PPV and NPV for significant lesions were 66%, 82%, 72% and 77%, respectively; S, E, PPV and NPV for polyps > 6 mm were 64%, 84%, 60% and 86%, respectively and S, E, PPV and NPV for polyps > 10 mm were 60%, 98%, 83% and 93%, respectively. These results are very similar to those obtained by previous studies. On the other hand, the Z line is clearly visualized in 60% of cases by the capsule, even if the capsule is ingested in the standing position[10]. It means that patients undergoing CRC screening by PillCam™ Colon capsule endoscopy could be also screened for Barrett´s esophagus. Figure 3 shows some images from PillCam™ Colon capsule endoscopy.

SAFETY

The capsule colonoscopy seems to be a safe procedure. Capsule or laxatives-related complications during procedures has nor been reported by first feasibility studies[9-11]. On the other hand, 2 of 126 patients (1.6%) were unable to swallow the capsule in the study by Eliakim *et al*[9]. However, in these patients, the capsule can be easily introduced into the stomach or duodenum by means of the capsule deliver system (US Endoscopy).

COST-EFFECTIVENESS

As demonstrated by several studies, patients' compliance for CRC screening is still much lower that for other common neoplastic diseases such as breast and prostate cancer. Therefore, alternative procedures such as colon capsule endoscopy or CT colonography, which may increase patients´ compliance, are welcome. In fact, colon capsule endoscopy is an attractive non-invasive method for CRC screening, especially for those patients who are non-compliant to current screening procedures. Whether colon capsule endoscopy will be cost-effective has not been widely evaluated. However, a recent paper by Hassan *et al*[13] based on a mathematical Markov model concludes that colon capsule endoscopy may be cost-effective compared with colonoscopy if a 30% patients´ compliance increase is achieved. Moreover, as polyp detection by capsule endoscopy is expected to be more accurate in the future, it may be cost-effective even if compliance rates achieved remains lower than 30%.

CONCLUSION

Based on current available studies, PillCam™ Colon capsule colonoscopy is a feasible, effective and safe procedure that allows the visualization of the entire colon in most of the cases. It may be complementary to conventional colonoscopy and could be an appropriate exam for those patients who have received incomplete colonoscopy, contraindicated or are unwilling to undergo conventional colonoscopy. Further studies are needed to confirm these results and the possibilities of this new modality for endoscopic examination of the colon and for CRC screening. As colon capsule endoscopy has still some limitations (cannot insufflate air, clean or take biopsies), future capsule prototypes seem to be necessary. Moreover, it is anticipated that future procedures with modified regimens that may be performed at home, possibly over the weekend, can offer a unique method and further enhance patient compliance.

Abstract

Small bowel strictures can be missed by current diagnostic methods. The Patency capsule is a new non-endoscopic dissolvable capsule which has as an objective of checking the patency of digestive tract, in a non-invasive manner. The available clinical trials have demonstrated that the Patency© capsule is a good tool for assessment of the functional patency of the small bowel, and it allows identification of those patients who can safely undergo a capsule endoscopy, despite clinical and radiographic evidence of small-bowel obstruction. Some cases of intestinal occlusion have been reported with the Patency© capsule, four of them needed surgery. So, a new capsule with two timer plugs (Agile© capsule) has been recently developed in order to minimize the risk of occlusion. This new device stars its dissolution process earlier (30 h after ingestion) and its two timer plugs have been designed to begin the disintegration even when the device is blocked in a tight stricture.

Key words: Capsule endoscopy; Patency capsule; Agile capsule; Small bowel strictures

INTRODUCTION AND DEVICE DESCRIPTION

Since Iddan *et al*[1] reported the new wireless endoscopy system the capsule endoscopy (CE) has become one of the most significant technical innovations of Gastroenterology in recent years. Regarding the complications of the techniques, some incidental cases of impaction in a Meckel´s diverticulum[2], a Zenker´s diverticulum[3], or in the cricopharyngeal muscle[4], as well as aspiration of the capsule[5-7], solved without complications, have been reported. However, the most frequent side effect is undoubtedly the non-natural excretion (NNE) of the capsule due to a stricture or a tumor in the small bowel. The retrospective analysis of some series indicates that the incidence of NNE depends on the indication for the capsule exam: 0% in healthy controls[8], 1.4% in obscure gastrointestinal bleeding[9-13], 1.48% in suspected Crohn´s disease[14-17], 5%-13% in known Crohn´s disease[17-19] and 21% in suspected small bowel obstruction[20].

In the vast majority of cases, capsule retention, regardless of its cause, is asymptomatic, being evidenced by the absence of excretion and confirmed by means of radiology. On the other hand, capsule retention frequently allows for the identification of the bowel pathology which caused the symptoms in the patient and which could not have been diagnosed by means of standard methods, furthermore facilitating the location of the stricture or the tumor for the surgeon after "milking" the capsule through the bowel. For these reasons, many authors have described NNE as a "therapeutic complication" of the CE[21-23]. However, although this consideration is valid for patients with tumors or those with stricture due to NSAIDs, radiotherapy or previous abdominal surgery, it may not be valid in patients with stenoses secondary to Crohn's disease. Unlike the previously mentioned groups, in patients with Crohn's disease, surgery is not curative and may present more complications, thus in this case, NNE of the capsule can become more an "undesirable circumstance" than a "therapeutic complication". The same can be said of those patients showing high surgical risk or who would not be willing to undergo surgery in the event that NNE occurs.

Current imaging techniques can show long or medium stenoses, with great reduction of the lumen size; however, short stenoses usually cannot be detected by standard methods. This fact explains that in most

of the reported cases of non-natural excretion (NNE) of the capsule, the previous performance of the usual radiological studies was not capable of diagnosing the intestinal strictures which the capsule clearly showed[9,11-13,19-21]. It is, therefore, proven that the lack of findings in radiological techniques does not rule out the existence of a bowel stenosis.

The manufacturing company of the PillCamSB has recently developed a new system (Given® M2A Patency System) which has as an objective of checking the patency of digestive tract, in a non-invasive manner. The Patency Capsule (PC) consists of a small identification tag (RFID), detectable by radiofrequency, which is surrounded by an absorbable material with a small amount of barium, all this covered by an external cover (Figure 1). PC has the same dimensions (11.4 mm × 26.4 mm) and the same shape as the standard capsule. PC is designed to remain intact in the gastrointestinal tract for about 80 h. After this period, if still within the body, it spontaneously disintegrates, except for the identification tag, whose small size (3 mm × 13 mm) allows it to pass through a stenosis of a very reduced lumen size. The persistence of the PC inside the organism can be verified by means of radiology, or with a radiofrequency emitting external detector device locating the identification tag.

CLINICAL TRIALS WITH PATENCY CAPSULE

Clinical experience with PC is still limited. A prospective, multi-center trial was designed to assess the clinical usefulness and safety of the PC capsule in patients with intestinal strictures suspected from clinical and/or radiological data. The global data of this trial have not been published, but the results of four of these centers have been reported (Table 1)[24-27]. In the series reported by Spada *et al*[24], 30 out of 34 (88.2%) patients with known or suspected small bowel stricture retrieved the capsule in the stool. After the excretion, the PC was intact in 20 cases (median transit time 22 h), and disintegrated in 10 patients (median transit time 53 h). Ten patients underwent video capsule endoscopy following the patency capsule examination. In all of these the video capsule passed through the small-bowel stricture without complication. The rate of patients with the PC excreted intact was similar in the seria of Boivin *et al*[25] (16/22, 73%), Delvaux *et al*[26] (16/22, 73%), Signorelli *et al*[27] (26/32, 81%). In our center, the percentage of cases with PC excreted intact was significant lower (13/29, 45%), probably because of patient selection[28]. In all the seria, the patency system scanner showed a good agreement (94%-100%) with fluoroscopy findings in identifying the presence of the tag in the body and may be used to detect the presence of the patency capsule without the need for radiology.

All these authors conclude that PC was unable to detect the presence of a small bowel stricture as previously defined by radiological techniques, but it added crucial information on the functional patency of the stenoses, and this information could allow a distinction between rigid fibrotic strictures and flexible ones. Boivin *et al*[25] found that passage of an intact capsule that is

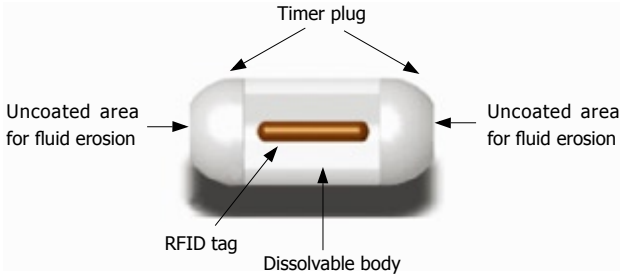

Figure 2 Schematic drawing of AGILE® patency Capsule.

accompanied by severe pain, similar to disintegration of the capsule with or without pain, seems indicative of a clinically relevant small-bowel stricture and is associated with a high probability of surgery. This observation seems to be confirmed by a recent retrospective analysis of 42 patients who underwent PC with known or suspected small bowel stricture[29]. In this study, the rate of patients who need to be operated in a period of three months was significantly higher in those with a delayed excretion, with the capsule excreted deformed, or with pain during the procedure. Moreover, in patients where painless natural expulsion of the intact PC occurred, CE could be applied without problems despite radiographic evidence of small-bowel strictures. This is an important finding since it might open the path to CE for about 60% of patients where video capsule investigation would otherwise be denied on grounds of history and radiological findings.

Abdominal pain during the procedure seems to be the main complication of PC (Table 2), observed in almost 20% of the cases reported to date. Probably, this pain is secondary to symptomatic intestinal occlusion, and it resolves spontaneously when the disintegration process concludes. However, at least four cases of occlusion did not respond adequately to conservative treatment and needed surgery. According to Gay *et al*[30], the problem could be that when the PC entrapped in a very tight stenosis it might not have been in contact with fluids and, therefore, only started to dissolve 48 h later, after moving back to the enlarged intestinal loop where it encountered fluids. Another possible factor is proposed by Gay *et al*[30]; PC is mainly made of lactose and the presence of lactase, an enzyme produced by intestinal mucosal cells, may be of importance in initiating the dissolution process. As lactase is mainly produced in the jejunum, one may also assume the enzyme is massively destroyed before the intestinal content reaches the ileum and that in the cases of occlusion, the enzyme could not have interacted with the capsule material. These authors[26,31] conclude that the start of dissolution at 40 h after ingestion is too slow to prevent episodes of intestinal occlusion, and so, it should be used cautiously under clinical surveillance in patients with Crohn´s disease.

THE AGILE© PATENCY CAPSULE

In order to reduce the risk of obstruction, a new dissolvable capsule with two timer plugs, one at each end, has been recently developed (Figure 2). With these

two timer plugs, the dissolution process starts earlier (30 h), and the contact with intestinal fluids is ensured even if the device is blocked in a tight stricture[32]. The new capsule, named Agile© Patency Capsule, has been evaluated in a multicenter clinical trial[33] designed to assess its safety in patients with known strictures and its ability to help physicians identify which patients may safely undergo CE. In this study, the intestinal tract was considered to be sufficiently patent if the capsule was excreted intact, or if the capsule was not detected by the scanner at 30 h after ingestion. If patency was established, then the patient underwent CE. Fifty-nine out (56%) of the 106 included patients excreted the Agile© capsule intact and subsequently underwent CE. There were no cases of retention of the video capsule and no Agile© capsules were found to have dissolved before 30 h after ingestion. Significant findings on CE were found in 24 patients (41%). A total of 17 (17/106) subjects had an adverse event, of these, 11 (11/106) consisted of abdominal pain. The pain resolved with conservative management within 48 h in all except for a patient with Crohn´s disease who need surgery (1/106). This patient developed obstruction after ingestion of the AGILE capsule and underwent surgery with resection of the terminal ileum and proximal colon, no remnants of the capsule were found at surgery. The physicians involved felt that the capsule did not lead to the obstruction. All of the other adverse events resolved within 48 h with conservative management.

In summary, the AGILE Patency capsule seems to be a useful, non-invasive tool to identify which patients with suspected strictures could safely ingest the standard video capsule. It has been designed to minimize the risk of intestinal occlusion.

Abstract

AIM: To investigate the potential role of Active Chinese mistletoe lectin-55 (ACML-55) in tumor immune surveillance.

METHODS: In this study, an experimental model was established by hypodermic inoculating the colon cancer cell line CT26 (5×10^5 cells) into BALB/c mice. The experimental treatment was orally administered with ACML-55 or PBS, followed by the inoculation of colon cancer cell line CT26. Intracellular cytokine staining was used to detect IFN-γ production by tumor antigen specific CD8+ T cells. FACS analysis was employed to profile composition and activation of CD4+, CD8+, γδ T and NK cells.

RESULTS: Our results showed, compared to PBS treated mice, ACML-55 treatment significantly delayed colon cancer development in colon cancer -bearing Balb/c mice *in vivo*. Treatment with ACML-55 enhanced both Ag specific activation and proliferation of CD4+ and CD8+ T cells, and increased the number of tumor Ag specific CD8+ T cells. It was more important to increase the frequency of tumor Ag specific IFN-γ producing-CD8+ T cells. Interestingly, ACML-55 treatment also showed increased cell number of NK, and γδT cells, indicating the role of ACML-55 in activation of innate lymphocytes.

CONCLUSION: Our results demonstrate that ACML-55 therapy can enhance function in immune surveillance in colon cancer-bearing mice through regulating both innate and adaptive immune responses.

INTRODUCTION

Mistletoe (Viscum album) is a semiparasitic plant with many unusual properties. It was used as a kind of herbal remedy in the ancient Chinese Pharmacopoeia and has been used in traditional Chinese medicine for diseases, such as gonorrhea, syphilis, hypertension and rheumatism for thousands of years. The aqueous extract of European Mistletoe (EM) has been used in conventional cancer therapy for decades[1]. Therapeutic efficacy is mostly attributed to the mistletoe lectins

(ML) ML-Ⅰ, ML-Ⅱ, ML-Ⅲ, that belong to the "toxic lectin family" and represent ribosome deactivating proteins class Ⅱ. They consist of one N-glycosidase (A chain) and one galactoside binding lectin (B chain) linked by a disulfide bridge. The lectins ML-Ⅰ and ML-Ⅲ preferentially bind to galactoside or N-acetylgalactosamine groups while ML-Ⅱ can bind to both carbohydrates[2].

EM has recently been found to act through several distinct bioactivities as a potent immune modulator. First, EM exerts its broad immunostimulatory activity by activating different types of cells[3-5] *in vivo* and *in vitro*. Incubation of lymphocytes with EM could result in anti-tumoral cytotoxic T lymphocytes bearing phosphorylated mistletoe ligands[6,7]. Second, EM favors bridging of natural killer tumor cell conjugates, enhancing its efficiency of killing[8-10]. Third, it has been found that EM could activate immune responses by modulating the complex network of cytokines that regulate leukocyte functions. EM caused increased secretion of tumor necrosis factor (TNF)-α, interleukin (IL)-1, and IL-6 from isolated human mononuclear cells *in vitro*[11,12]. Finally, EM has also been described as an inducer of cell apoptosis. In the presence of EM, human mononuclear cells and many cell lines underwent apoptosis[1,13].

While the EM has been studied intensively, less is known about the Chinese mistletoe as an anti-cancer drug. In our prior study, a mistletoe lectin was purified from Chinese mistletoe and the effect of the active Chinese mistletoe mectin-55 (ACML-55) on human γδ T cell cytotoxicity, apoptosis and modulation of the cytokine network was reported[14,15]. Although these investigations suggest that ACML-55 may modulate the immune response against tumor development, the precise mechanism by which ACML-55 regulates the immune function has not been studied systematically. In this study, we demonstrate that ACML-55 enhances tumor immune surveillance against colon cancer formation by regulating both innate and adaptive immune responses. Our results suggest that ACML-55 may be a useful complementary therapy for treating colon cancer.

MATERIALS AND METHODS

Mice

BALB/c mice were purchased from Shanghai Experimental Animal Center, Chinese Academy of Science and were used at 6-8 wk of age in all experiments. All mice were maintained under specific pathogen-free conditions at Shanghai Jiao Tong University School of Medicine.

Administration of ACML-55

ACML-55 was dissolved in PBS at final concentration of 2 g/L. Mice were treated with ACML-55 or PBS orally (200 μL/mouse) once a day for 2 wk. Oral administration was achieved by gavage to ensure all mice received the entire dose.

Reagents

Recombinant murine IL-2 was purchased from R&D Systems (Minneapolis, MN, USA). Anti-mouse antibodies (CD3, NK1.1, CD4, CD8, CD62L, CD44, anti-αβ, anti-γδ and IFN-γ) used for phenotypic and cytokine analysis were purchased from BD Biosciences (San Jose, CA, USA).

Preparation of mistletoe lectins

Mistletoe lectins were isolated from extract of Chinese mistletoe, a subspecies of V. album according to previously described methods[14] with our own modifications. Briefly, the air-dried mistletoe (3 kg), collected from Sichuan province, China, was crushed and purified twice with 20 L methanol/water (1:1, V/V). The homogenate was filtered through a nylon cloth. After filtration, with its volume reduced to 2 liters, the aqueous phase was successively partitioned with cyclohexane, dichloromethane and ethyl acetate. Ethanol was added to the concentrated aqueous phase to a final concentration of 85% (V/V). A precipitate was obtained and separated from the supernatant by centrifugation (8000 *g*, 20 min). The supernatant was concentrated and ethanol was added to 85% (V/V). After centrifugation, the precipitate was collected and combined with the former precipitate. The final yield of ML extract was 100 g from 3 kg mistletoe. All the precipitate was dissolved in 100 mL phosphate buffer (10 mmol/L, pH 6.5) and the stock solution of mistletoe extract was stored at -80℃.

Purification of mistletoe lectins

To obtain the pure Chinese mistletoe protein, extract was further purified by CM-Sepharose column chromatography[14]. The aqueous layer (1 mL) was applied to a column of CM-Sepharose (1.5 cm × 20 cm) equilibrated with 10 mmol/L phosphate buffer (pH 6.5). After washing with 10 mmol/L phosphate buffer (pH 6.5) and 100 mmol/L NaCl in the same buffer at a rate of 0.5 mL/min, a peak eluted with 500 mmol/L NaCl in the same buffer was dialyzed with PBS (pH 7.4). The fractions containing hemagglutinating protein were collected and then applied to a column of Con A column (1.5 cm × 20 cm) equilibrated with 10 mmol/L PBS (pH 7.4). The column was washed with PBS (pH 7.4) and eluted with 300 mmol/L glucose in the same buffer. Fractions were subject to sodium dodecyl sulphate (SDS)-electrophoresis and fractions containing 55 kDa protein were pooled, dialyzed against water and freeze-dried.

SDS-polyacrylamide gel electrophoresis (PAGE)

The molecular mass and purity of ACML-55 was determined by SDS-PAGE. Twelve percent polyacrylamide gel was used as resolving gel and 5% was used as stacking gel. To further denature the proteins by reducing disulfide linkages, the samples were heated at 100ºC for 3 min in the presence of a reducing agent,

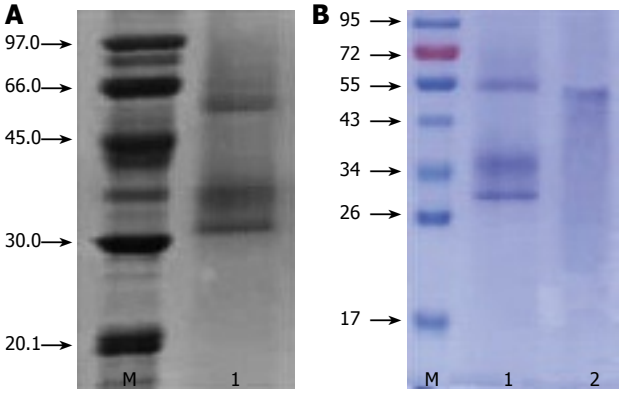

Figure 1 **A**: SDS-PAGE profiles of ACML-55. ACML-55 was determined by SDS-PAGE; ACML-55. **B**: ACML-55 was also determined by SDS-PAGE. ACML-55. ACML-55 in presence (lane 1) and absence (lane 2) of reducing agent.

then electrophoresed using electrophoresis system at 200 V for 75 min and lastly the gel was stained with Coomassie brilliant R-250 to show bands.

Tumor models

Colon cancer cell line CT26 and OVA-expressing EG7 cell line were purchased from ATCC (Manassas, VA, USA). For tumor induction, colon cancer cell line CT26 cells (5×10^5 cells/mouse) were injected subcutaneously, and tumor growth was monitored and recorded daily for over 3 wk as described in our previous studies[15]. For some experiments, EG7 tumor cells were also administered intraperitoneally (1.0×10^6 tumor cells/mouse).

IFN-γ production of tumor antigen specific CD8+ T cells

Mice were treated with ACML-55 or PBS for 2 wk as described above. These treated mice ($n = 5$ for each group) were immunized with 200 μg of CT26 tumor lysate emulsified in CFA in the hind footpad, as described in previous studies[16]. On day 7 post-immunization, draining lymph node cells were harvested, lymphocytes were cultured with comptumor air ratio RPMI-1640 containing 200 μg/mL CT26 tumor lysate for 24 h, with brefeldin A added for the last 3 h. Cells were then used for intracellular cytokine staining as described below.

Intracellular cytokine staining

Cultured draining lymph node cells were stained with FITC-anti-CD8 antibody followed by fixation with 2% formaldehyde and permeabilization with 0.5% saponin (w/v) for intracellular IFN-γ staining, using PE-anti-IFN-γ as described previously[17]. PE-conjugated rat IgG2a (BD Pharmingen) was used as an isotype control. Gating was performed on CD8+ T cells and the percentage of IFN-γ+ cells was reported.

Detecting tumor antigen specific CD8+ T cells

Both ACML-55 treated mice ($n = 4$) and control mice ($n = 4$) were inoculated intraperitoneally with 1.0×10^6 EG7 tumor cells. On day 10, splenocytes from these mice were isolated and stained with FITC-anti-CD8 and PE-tetramer antibodies for OVA. Percentage of tetramer positive CD8+ T cells was shown by FACS analysis.

Analysis of cell composition and activation

Both ACML-55 treated mice ($n = 4$) and control mice ($n = 4$) were inoculated intraperitoneally with 5×10^5 CT26 cells. On day 10, splenocytes from these mice were isolated and stained with one of the following antibody combinations: FITC-anit-CD3 and PE-anti-NK1.1; FITC-anti-γδ and PE-anti-αβ; PE-anti-CD62L, CyChrome- anti-CD44, FITC-anti-CD8a and APC-anti-CD4. Percentages of different cell subpopulations were shown by FACS analysis.

Statistical analysis

Statistical significance was evaluated by two tailed unpaired Student's test or non-parametric analysis if SDs were significantly different between two compared groups using InStat 2.03 for Macintosh software (Graph Pad Software). The incidence of tumor development was compared and analyzed using the log rank test, performed by Graph Pad Prism Version 3.0a for Macintosh (Graph Pad Software). $P < 0.05$ was used to denote statistical significance.

RESULTS

SDS-PAGE

Chinese ML extractions were analyzed by SDS-PAGE. In the presence of the reducing agent, it showed an estimated 55 kDa band consisting of two bands of a 30 kDa A chain and a 34 kDa B Chain (Figure 1).

Oral administration of ACML-55 enhances tumor immunesurveillance

Based on the findings that EM reduces the metastasis of rat mammary adenocarcinomas and its ability to modulate immune functions[18,12], we hypothesized that ACML-55 might enhance tumor immune surveillance. To assess the effect of ACML-55 on tumor development, ACML-55 or PBS was administered to sex- and age-matched BALB/c mice by gavage daily for 2 wk, followed by subcutaneous inoculation of CT26 cells (5×10^5 cells/mouse). Tumor growth was observed and recorded daily as previously described[16,19]. Compared to control group (PBS treated), ACML-55 treated mice showed delayed tumor development (Figure 2A) as well as reduced tumor size (Figrue 2B). ACML-55 treated mice were much more resistant to tumor cell growth upon subcutaneous tumor inoculation (Figrue 2C). The results indicate that ACML-55 significantly enhances tumor surveillance.

ACML-55 increases tumor specific activation of CD4+ and CD8+ T cells

To define the underlying molecular mechanisms of ACML-55 mediated anti-tumor immune response, we first tested the effect of ACML-55 on the adaptive immune response. Sex- and age- matched BALB/c mice

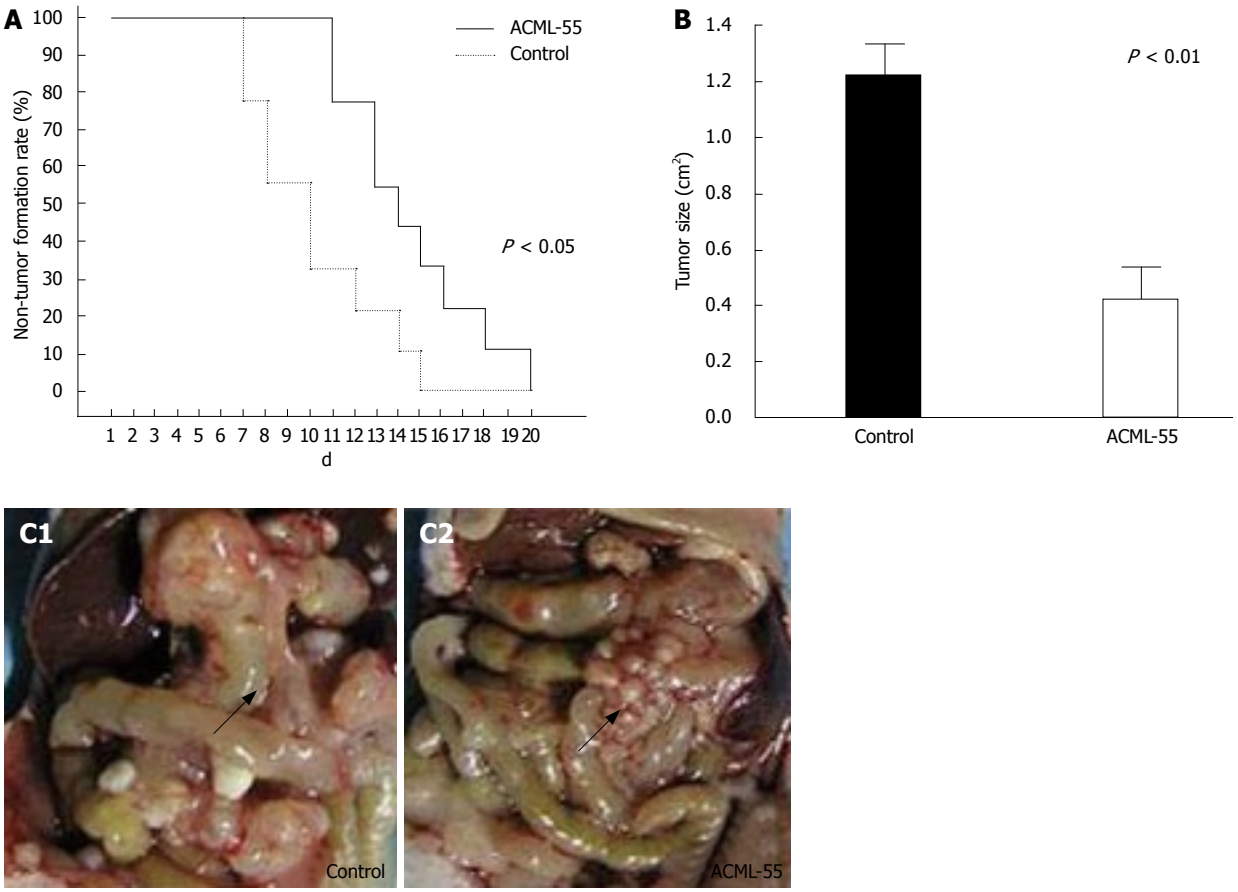

Figure 2 ACML-55 enhances tumor surveillance. **A**: ACML-55 treatment delays CT26 melanoma tumor formation. Sex- and age-matched BALB/c mice were administered orally either with 2 mg/mL (200 μL/mouse) ACML-55 or equivalent volume of PBS (control) daily for fifteen days (n = 20 for each group), followed by subcutaneous inoculation of CT26 melanoma tumor cells (5 × 10^5/mouse) on day 7 after the initiation of ACML-55 or PBS treatment. Tumor growth was recorded daily. Tumor size > 5 mm × 5 mm was considered positive. Data represents three independent experiments (P < 0.01). **B**: ACML-55 treatment inhibits tumor growth. The mean tumor size from ACML-55 and PBS-treated mice at day 20 is shown in this figure (P < 0.01). **C**: ACML-55 treatment significantly reduces intraperitoneal tumor formation. BALB/c mice were treated with ACML-55 or PBS followed by CT26 tumor cell inoculation intraperitoneally (n = 20 for each group) as described above, and tumor growth was monitored. A representative example of tumor formation is provided. Arrows point to intraperitoneal tumor.

were given ACML-55 or PBS daily for 2 wk, followed by intraperitoneal inoculation with EG7 tumor cells (EG7 tumor cells expressing OVA, 1.0 × 10^6 cell/mouse)[20]. On day 10 post-inoculation, harvested splenocytes were used for analysis of CD4+ and CD8+ T cell activation using specific activation markers. ACML-55 treatment significantly increased the number of activated CD4+ and CD8+ T cells. According to our findings, the percentage of $CD62L^{low}$ $CD44^{high}$ population in the spleen for each T cell subset was significantly higher in ACML-55 treated mice compared to those treated with PBS [14.29 ± 4.3 *vs* 7.63 ± 2.95 for CD4+ T cells, and 6.79 ± 1.41 *vs* 3.95 ± 1.97 for CD8+ T cells (Figure 3A), P = 0.0008 for CD4 and P = 0.0002 for CD8]. Representative data of the FACS profile for CD4+ and CD8+ T cells from ACML-55 or PBS treated mice are represented in Figure 3B.

ACML-55 promotes IFN-γ production in CD8+ T cells

IFN-γ has been shown previously to be a critical cytokine in tumor immunosurveillance[21]. To define the effect of ACML-55 on tumor antigen specific IFN-γ production, ACML-55 or PBS was administered to sex- and age- matched BALB/c mice (n = 6 for each group) as mentioned above for 2 wk, and then immunized in the hind footpad with CT26 tumor lysate in CFA. Eight days post-immunization, lymphocytes from the draining lymph nodes were isolated, cultured with 200 μg/mL tumor lysate for 24 h, with brefeldin A added during the last 3 h of culture. These cells were then fixed and permeabilized with 0.5% saponin for intracellular cytokine staining. The percentage of IFN-γ producing CD8+ T cells from ACML-55 treated mice (mean ± SD) was significantly higher than that of PBS treated mice (10.05 ± 2.3 and 2.30 ± 1.013, respectively, P = 0.0001; Figure 4A). An example of FACS analysis is represented in Figure 4B. In the same cultures, the percentage of IFN-γ producing CD4+ T cells from ACML-55 treated mice was also higher than those from PBS treated mice, although it did not reach significance (data not shown). ACML-55 treatment did not enhance the percentage of IFN-γ producing CD8+ T cells responding to control tumor lysate (different tumor cell line, data not shown). Our results demonstrate that ACML-55 not only enhances activation and proliferation of T cells, but also increases their capacity to produce

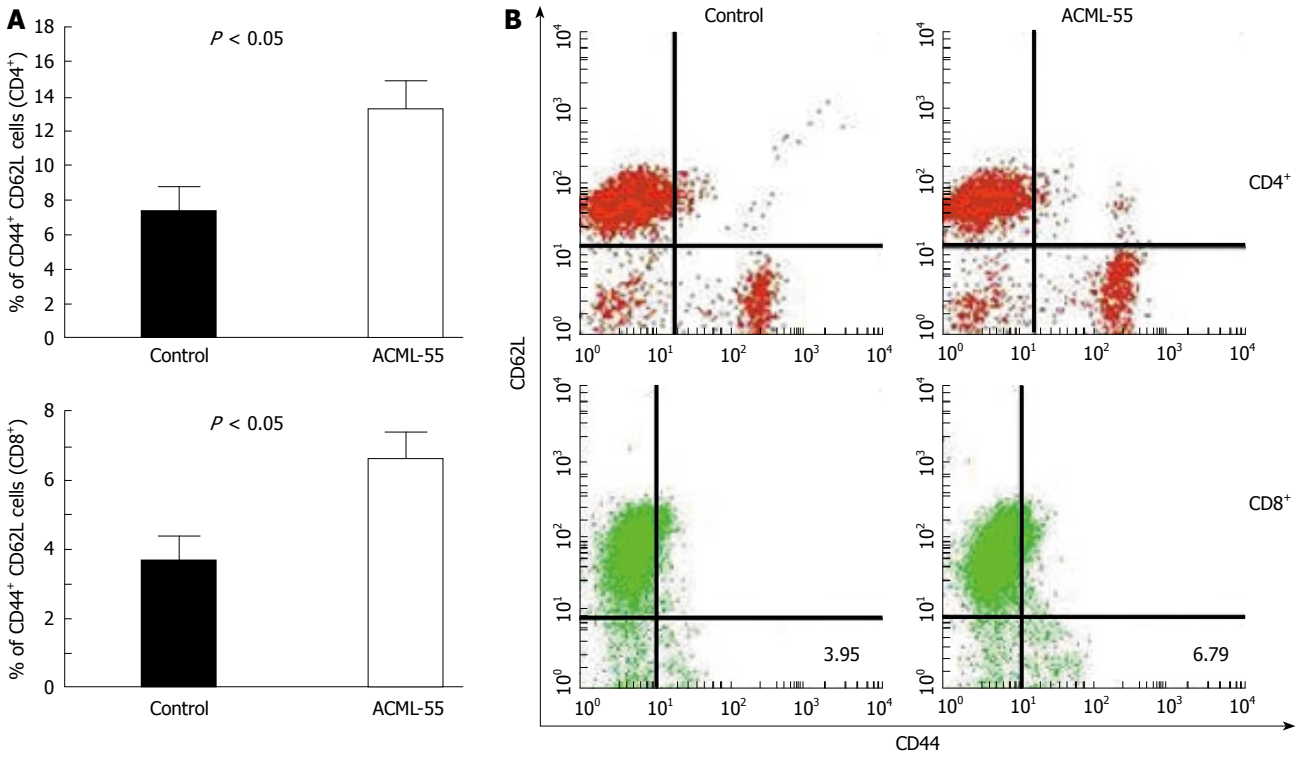

Figure 3 ACML-55 enhances CD4+ and CD8+ T cell activation. Sex- and age- matched BALB/c mice were administered orally with 2 mg/mL (200 μL/mouse) ACML-55 or equivalent volume of PBS daily for 15 days (n = 5 for each group), and on day 7, received an intraperitoneal inoculation with EG7 tumor cells (1×10^6 cells/mouse). Ten days postinoculation, splenoctyes were stained with antibodies against different surface molecules and analyzed by FACS. **A**: The percentage of activated CD4+ and CD8+ T cells (mean ± SD) is shown ($P < 0.05$); **B**: An example of the FACS profile for CD4+ and CD8+T cells is given.

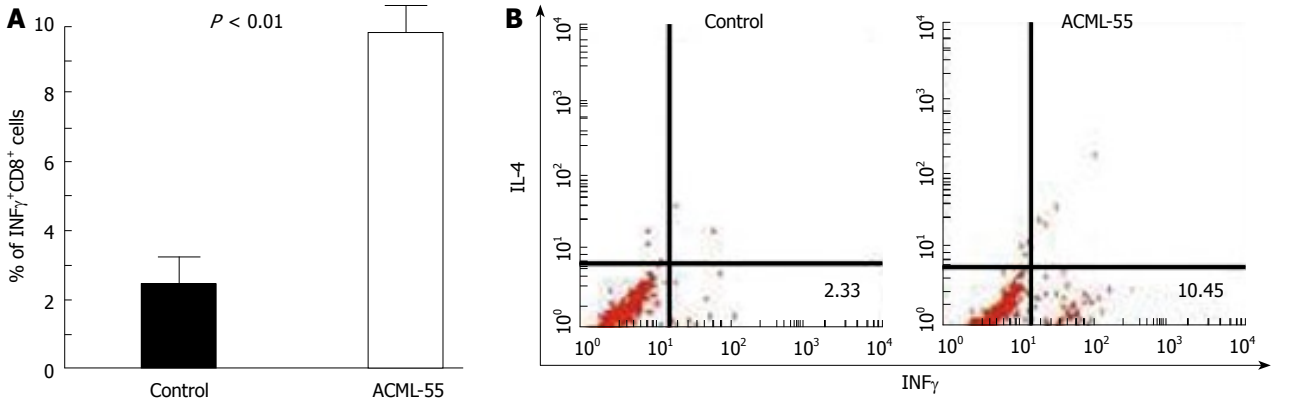

Figure 4 ACML-55 increases the number of IFN-γ+CD8+ T cells. Sex- and age- matched BALB/c mice were administered orally with 2 mg/mL (200 μL/mouse) ACML-55 or equivalent volume of PBS daily (n = 5 for each group) for fourteen days, followed by immunization with 200 μg of CT26 tumor lysate emulsified in CFA. After seven days, lymphocytes recovered from draining lymph nodes of immunized mice were cultured with 200 μg/mL of tumor lysate for 24 h, with the addition of brefeldin A to the culture for the remaining 3 h. Cells were then fixed with 2% formaldehyde and permeabilized with 0.5% saponin for intracellular IFN-γ staining. **A**: The percentage of IFN-γ producing cells (mean ± SD) from CD8+ T cells is shown; **B**: An example of intracellular cytokine staining upon gating on CD8+ T cells is shown.

IFN-γ cytokine.

ACML-55 increases the number of both NK and γδ T cells

Both NK cells and γδ T cells play a critical role in tumor immune surveillance. To test the effect of ACML-55 on these cell types, sex- and age- matched BALB/c mice were treated with ACML-55 or PBS (n = 6 for each group) as above for 2 wk, and the percentages of NK and γδ T cells in the spleen were analyzed by flow cytometry. Treatment with ACML-55 significantly increased the numbers of splenic NK cells and γδ T cells, with the percentage (mean ± SD) of NK1.1+ cells in ACML-55 treated mice *vs* control being 6.28 ± 0.90 *vs* 3.48 ± 0.77, and the percentage of CD3+ γδ+ cells for ACML-55 *vs* control being 6.51 ± 0.59 *vs* 3.85 ± 0.59, (Figure 5A, P = 0.0001). A representative result of FACS analysis for CD3 and NK1.1 as well as αβ/γδ T cell staining is presented in Figure 5B. Splenocytes from ACML-55 or PBS treated mice were cultured with anti-CD3 and anti-CD28 antibodies in the presence of brefeldin A for 6 h, and the percentage of IFN-γ + γδ+ T cells was analyzed by intracellular cytokine staining after gating TCR γδ positive cells. The results showed there is no significant difference in the percentage of

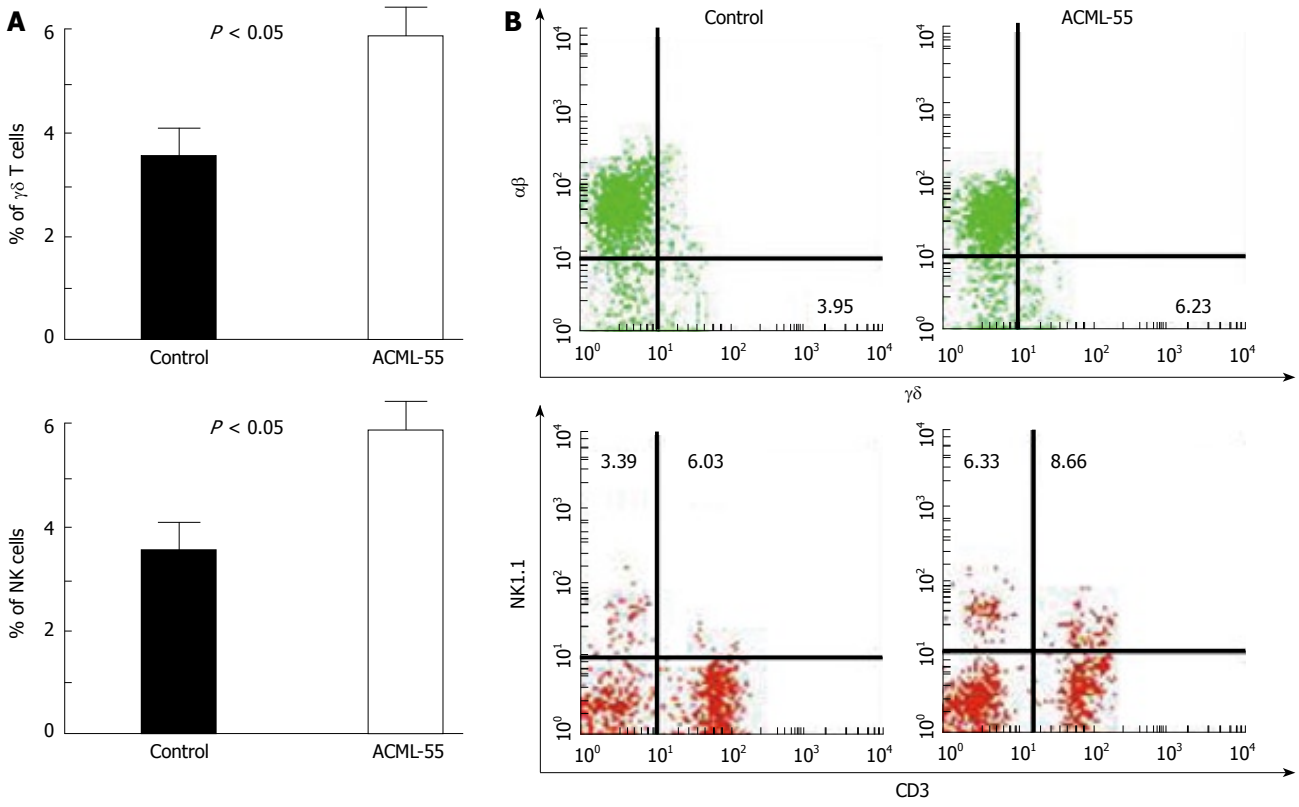

Figure 5 ACML-55 treatment increases the number of NK and γδ T cells. Sex- and age- matched BALB/c mice were administered orally with 2 mg/mL (200 μL/mouse) ACML-55 or equivalent volume of PBS daily (n = 5 for each group) for fourteen days, followed by inoculation with CT26 tumor cells intraperitoneally. Ten days post-inoculation, splenocytes were used for analysis of NK, NKT, αβ, and γδ T cells. **A**: The percentage of NK and γδ T cells (mean ± SD) is shown (P < 0.05); **B**: An example of the FACS analysis is given.

IFN-γ producing γδ T cells between two groups (data not shown). NKT cells (CD3+ NK1.1+) were also higher in ACML-55 treated mice compared to controls, although it did not reach significance. These results indicate that ACML-55 may enhance the antitumor immune response not only through modulating the adaptive immune response, but also working on innate immunity.

DISCUSSION

Extracts from European mistletoe are used widely in the treatment of cancer, but the mechanism of antitumor properties has not yet been clearly elucidated. Consumers often use EM as a complementary therapy for cancer treatment, and in some cases as an alternative to conventional cancer treatment[22,23]. Although Korean mistletoe, a subspecies of European mistletoe, has been used as a medicinal herb and shown to be cytotoxic against tumor cells as well[24], there are fewer systemic controlled studies to define the effect of EM in tumor immunity. In this study, we demonstrate that ACML-55 enhances tumor immune surveillance against both melanoma and lymphoma by regulating both innate and adaptive immune responses. We first illustrated that oral administration of ACML-55 prior to tumor inoculation could significantly delay the tumor growth and reduce tumor size (Figure 2A and B).The anti-tumor effect of ACML-55 is not limited to melanoma.

It has been shown that lymphocytes and IFN-γ both are essential components of tumor immune surveillance[25,26]. Different subsets of lymphocytes contribute to anti-tumor immune responses at different stages. CD4+ and CD8+ T cells are critical elements for the adaptive anti-tumor immune response. CD4+ T cells, especially Th1 subsets, produce IFN-γ to facilitate innate and adaptive immune responses[27]. These cells are also in favor of CD8+ T cells to develop memory response, whereas CD8+ T cells provide cytokines (IFN-γ and TNF-α) and cytotoxicity to exert their function to kill tumor cells directly. To explain the molecular mechanisms through which ACML-55 could mediate anti-tumor immune response, we sought to determine whether ACML-55 modulates the adaptive immune response. Our results indicate that ACML-55 treatment enhances activation and proliferation of both CD4+ and CD8+ T cells (Figure 3A and B). Moreover, administration of ACML-55 significantly increases the frequency of tumor antigen specific CD8+ T cells and their ability to produce higher level of IFN-γ (Figure 4A and 3B). Finally, ACML-55 treatment can make antigen specific CD8+ T cells expand more actively. The increasing number of CD8+ T cells partially contributes to the tumor resistance of ACML-55 treated mice. However, it is unclear how ACML-55 enhances the function of these T cells. It is possible that the mixture of polysaccharides in ACML-55 may activate the innate immune response

through undefined signaling pathways, such as Toll-like receptors and the downstream NF-κB pathway, which in turn helps to regulate the adaptive immune response. Consistently, it has been reported that ACML-55 enhances IL-12 production from macrophages[10] and increases nitric oxide concentration[12]. Further studies are needed to clarify the underlying mechanisms that mediate the effect of ACML-55 on the adaptive immune response.

A potential target of ACML-55 modulation within the innate immune system may be γδ T cells. These cells belong to a unique subset of T cells. They recognize protein or peptide independent of antigen presentation and function as innate like cells[28]. Our earlier studies have demonstrated that γδT cells predominantly produce IFN-γ upon activation[12,29] and play a critical role in tumor immune surveillance by providing an early source of IFN-γ[14]. Interestingly, ACML-55 treatment significantly increases the number of γδ T cells compared to those of PBS-treated mice (Figure 5). Since ACML-55 was given orally, it is possible that the effective components in ACML-55 might directly encounter γδ T cells lining the epithelial layer of the intestine resulting in their activation. In addition to γδ T cells, it has been well established that NK cells play an essential role in tumor immune surveillance. Interestingly, we found that treatment with ACML-55 also upregulates the number of NK cells upon tumor inoculation. Although the changes of NK T cells did not reach significance, the trend is clear. These results indicate that ACML-55 has multiple effects on the immune system.

Given the findings that ACML-55 could efficiently enhance several immune parameters (CD4+, CD8+ and γδ T cells), which were shown previously to be positive for tumor immune surveillance, it is likely that ACML-55 mediates its potential effects on tumor surveillance, at least in part, by upregulation these particular parameters. Future studies using different T cell subset from deficient mice will help to illuminate these questions.

In summary, we have presented clear picture that, as an active lectin from Chinese mistletoe, ACML-55 enhances tumor immune surveillance by regulating both the innate and the adaptive immune responses. Further studies are needed to define the molecular mechanisms mediating the effect of ACML-55 in tumor immunity.

COMMENTS

Background

Mistletoe is a semiparasitic plant with many unusual properties. In our prior study, a mistletoe lectin was purified from Chinese mistletoe and the effect of the active Chinese mistletoe lectin-55 (ACML-55) on human γδ T cell cytotoxicity, apoptosis and modulation of the cytokine network was reported. Although these investigations suggest that ACML-55 may modulate the immune response against tumor development, the precise mechanism by which ACML-55 regulates the immune function has not been studied systematically.

Research frontiers

In this study, an experimental model was established by hypodermically inoculating the colon cancer cell line CT26 into Balb/c mice. Intracellular cytokine staining used to detect tumor antigen specific CD8+ T cell IFN-γ production. The FACS profile for CD4+ and CD8+ T cells and NK or γδ T Cells composition and activation.

Innovations and breakthroughs

This study is investigates the potential effect of active Chinese mistletoe lectin-55 to enhance colon cancer immune surveillance through regulating both innate and adaptive immune responses.

Applications

The results demonstrate that ACML-55 can enhance colon cancer immune surveillance through regulating both innate and adaptive immune responses and also suggest that ACML-55 may be a useful complementary therapy for treating colon cancer.

Peer review

The study investigates the potential effect of ACML-55 to enhance colon cancer immune surveillance through regulating both innate and adaptive immune responses. Its scientific contents can reflect the advanced levels of basic research and the first report on Chinese mistletoe lectin-55.

Abstract

AIM: To evaluate gallstone incidence and risk factors in a large population-based study.

METHODS: Gallstone incidence and risk factors, were evaluated by structured questionnaire and physical examination, respectively, in 9611 of 11 109 (86.5%) subjects who were gallstone-free at the cross-sectional study.

RESULTS: Six centers throughout Italy enrolled 9611 subjects (5477 males, 4134 females, aged 30-79 years), 9517 of whom were included into analysis: 424 subjects (4.4%) had gallstones and 61 (0.6%) had been cholecystectomized yielding a cumulative incidence of 0.67% per year (0.66% in males, 0.81% in females). Increasing age, a high body mass index (BMI), a history of diabetes, peptic ulcer and angina, and low cholesterol and high triglyceride levels were identified as risk factors in men while, in females, the only risk factors were increasing age and a high BMI. Increasing age and pain in the right hypochondrium in men and increasing age in females were identified as predictors of gallstones. Pain in the epigastrium/right hypochondrium was the only symptom related to gallstones; furthermore, some characteristics of pain (forcing to rest, not relieved by bowel movements) were significantly associated with gallstones. No correlation was found between gallstone characteristics and clinical manifestations, while increasing age in men and increasing age and BMI in females were predictors of pain.

CONCLUSION: Increasing age and BMI represent true risk factors for gallstone disease (GD); pain in the right hypochondrium and/or epigastrium is confirmed as the only symptom related to gallstones.

Key words: Gallstone disease; Ultrasonography; Epidemiology; Prevalence; Incidence; Abdominal pain; Cholecystectomy; Body mass index

INTRODUCTION

Gallstone disease (GD) is a very common gastrointestinal disorder, presents mainly in the Western world[1,2]. Although this disease has a low mortality rate, its economic and health impact is significant due to its high morbidity. In fact, GD is one of the most common abdominal conditions for which patients in developed countries are admitted to hospitals[3], and this frequency has increased in Western countries since the 1950s[4]. GD is considered "a surgical disease"

since only a cholecystectomy is capable of definitively curing the disease[5]. However, since the introduction of laparoscopic cholecystectomy in the early 90s, which is considered a safe treatment for GD[6], a possible unjustified increase in surgical procedures has been observed[7]. Therefore, there is the need for more knowledge of the epidemiological characteristics of GD in order to better identify therapeutic strategies.

The availability of ultrasonography (US) as an accurate tool for gallstone diagnosis has allowed the evaluation of gallstone prevalence by means of epidemiological surveys of the general population, both in Eastern and Western countries[8,9]. Furthermore, these studies, as well as case-control studies, have allowed the identification of the factors most frequently associated with GD, i.e. increasing age, female sex, familial history of GD, number of pregnancies, obesity, or type 2 diabetes[10].

However, only a few prospective US surveys, mainly in Europe[11-14], have been carried out which aimed measuring the gallstone incidence rate and risk factors for the disease. The knowledge of disease risk factors is crucial to carrying out primary or secondary preventive programs.

The Multicenter Italian Study on Epidemiology of Cholelithiasis (the MICOL project) is a population-based cross-sectional study which began in 1985 and extended since 1998 and it was designed to obtain an overview of the distribution of GD in Italy according to different regions and ages[15]. Results on prevalence distribution, associated factors, and clinical manifestations have been extensively reported in previous articles[15-17].

This article reports the incidence rate and risk factors for GD which were evaluated in six units belonging to the MICOL project.

MATERIALS AND METHODS

Study design

The MICOL project is a population-based, cross-sectional study carried out in 8 Italian regions by different operative units. Complete details on the study protocol have been published elsewhere[15]. The project plan includes 2 cross-sectional surveys; the first began in 1985 and was completed in 1988 and the second survey was carried out on the same subjects 10 years later in order to estimate the incidence of GD as well as its natural history. Seven of the original operative units were able to complete the second survey.

Subjects

After 10 years, all participants in the first survey were invited to a follow-up examination. Preliminarily, using the electoral lists, subjects who had died or moved were identified. The remaining subjects received a standardized invitation for a general health examination and an US examination of the upper abdomen. Subjects who did not respond were invited again; those who refused to participate or those who did not respond at all were contacted by telephone.

Screening protocol

The re-examination took place between 1995 and 1998. Subjects who were found to have had gallstones or a previous cholecystectomy for gallstones at the first survey were studied separately, the major aim of this re-examination being evaluation of the natural history of gallstones.

Similarly to what had been carried out in the first survey[15], the screening protocol included upper abdominal US, physical examination, fasting blood specimen collection, and administration of a precoded questionnaire. This questionnaire inquired about family and personal history, dietary habits, past and current use of medications, and the presence of comorbidities (diabetes, chronic heart disease, liver cirrhosis, peptic ulcer); the questionnaire also included a specific section aimed at assessing the occurrence/presence of abdominal symptoms (details of the structure of the questionnaire as well as details on its items have been published elsewhere[17]). The questionnaire was administered by trained interviewers selected from the medical staff of each operative unit. Upper abdominal US was performed thereafter by independent physicians.

Statistical analysis

The incidence rate for new-onset gallstones was determined from baseline to the second examination, after adjustment for age and gender. Logistic regression analysis was carried out providing risk factors and Odd Ratios (OR) for developing gallstones; Cox proportional hazard regression was used to calculate hazard ratios.

According to previous results regarding associated factors obtained from the gallstone prevalence study[15] and from available literature data[8,10,18], different factors were evaluated by means of logistic regression analysis as possible risk factors for GD including age, gender, educational level, family history of gallstones, body mass index (BMI) (measured both at the prevalence and the incidence studies), number of pregnancies, history of diets, diabetes, peptic ulcer, inflammatory bowel disease, liver cirrhosis, smoking, coffee drinking, and serum levels of total cholesterol, HDL-cholesterol, and triglycerides.

To identify the possible role of the disease status on clinical presentation, patients were subsequently classified into 4 groups according to their disease status: gallstone-free subjects (GF), patients with gallstones not previously diagnosed (GNDP), patients with previously diagnosed gallstones (GPD), and patients with a history of cholecystectomy for gallstones (CC).

Logistic regression models were created for the latter 3 groups, using the gallstone-free subjects as the comparison group.

As a consequence of the results of the logistic regression models, patients referring pain located at the right hypochondrium or epigastrium were selected and further evaluated.

A multivariate analysis was subsequently carried out using logistic regression and, for each gallstone group, a model was created using the gallstone-free subjects

as the comparison group. SPSS (ver.9.0 for windows) statistical software was used. A probability of $P < 0.05$ was considered significant.

RESULTS

Subjects

Out of the 12709 potentially enrolled subjects belonging to the seven participating units, 502 died and 1098 transferred. Among the dead subjects, one case of gallbladder cancer was observed, which translates in a mortality rate for this cause of 2.5/10000 per year.

Of the 11109 enrolled subjects, 9611 (5477 males, 4134 females, aged 30-79 years) were evaluated (86.5%). The attendance rate was different in different age classes, greater in younger than in older subjects (83% in the 40-60 years old group and 74% in the > 60 years old group) while no difference was documented between the sexes (78% in males, 89% in females). The mean follow-up period was 8 years.

On the basis of US diagnosis, 9517 (5428 males, 4089 females) were suitable for analysis since, in 94 cases, the US diagnosis was biliary sludge (35 cases) or gallbladder polyps (40 cases); in 19 cases, the US diagnosis was uncertain. These 94 cases were excluded from the study, since no definitive data are available in literature regarding these aspects as true gallstones[5,10,11].

Four hundred and twenty-four subjects (206 males, 218 females) (4.4%) were found to have gallstones and 61 (26 males, 35 females) (0.6%) had been cholecystectomized for gallstones during the follow-up period.

The cumulative incidence rate of GD thus was 0.67% per year [0.66% per year in males, 0.81% per year in females (Table 1)]. Table 1 also shows the incidence rate among the different operative units.

Table 2 reports the morphological characteristics of gallstones; incident gallstones were more frequently small in size (77.9% less than 1.5 cm); no difference was observed between males and females in terms of gallstone number or size.

According to the disease status evaluation, of the 9517 subjects enrolled in the study, 9032 (94.5%) were GF; 312 (3.3%) were GNPD, 112 (1.2%) were GPD, and 61 (0.6%) were CC.

Risk factors and predictors for GD

Risk factors for GD: The results of the logistic regression analysis carried out to identify the risk factors for GD are shown in Table 3.

Among the factors considered, in males, increasing age ($P < 0.0001$), a high BMI ($P < 0.006$), a history of diabetes ($P < 0.01$) and of peptic ulcer ($P < 0.01$), low levels of total ($P < 0.03$) and HDL ($P < 0.04$) cholesterol, and high levels of triglycerides ($P < 0.007$) were identified as risk factors.

In females, only increasing age ($P < 0.00001$) and a high BMI ($P < 0.0001$) were identified as risk factors for GD.

When evaluating the risk factor distribution according to the classification of the patient's clinical status (Table 4), no differences were observed in terms of age, BMI, and biochemical parameters while the presence of comorbidities increased among the three groups; in particular in males, diabetes, peptic ulcer, and myocardial infarction while, in females, peptic ulcer and myocardial infarction.

Predictors of GD: The evaluation of predictive factors for the presence of GD (Table 5) in patients with abdominal pain indicated that these were increasing age ($P < 0.04$) and pain in the right hypochondrium ($P < 0.03$) in males with gallstones and only increasing age

($P < 0.0001$) in females with gallstones; in cholecystectomized male patients, the only factor was increasing age ($P < 0.02$) while, in cholecystectomized females, pain in the right hypochondrium ($P < 0.01$) and the epigastrium ($P < 0.002$) were the predictive factors.

Considering only the effect of comorbidities, the evaluation of predictive factors for the presence of GD indicated that, in males with gallstones, these factors were increasing age ($P < 0.0001$), the presence of diabetes ($P < 0.001$), peptic ulcer ($P < 0.04$), and liver cirrhosis ($P < 0.002$) while, in females with gallstones, only increasing age ($P < 0.0001$) (Table 6) was a predictor of GD; in cholecystectomized male patients peptic ulcer ($P < 0.004$) and liver cirrhosis ($P < 0.0001$) were predictors while, in female patients, only peptic ulcer ($P < 0.004$) appeared as a predictor of the disease.

Clinical manifestation of GD

The distributions of abdominal symptoms in the four groups are reported in Table 7. No differences among the groups were documented in terms of frequency for non-specific symptoms, with the exception of nausea, while pain in the epigastrium and the right hypochondrium were related to GD and varied according to the disease categories.

In Table 8, the characteristics of abdominal pain in the considered groups are reported: some characteristics resulted significantly associated with GD, showing a progressive increase in the ORs throughout the disease categories; pain necessitating rest, pain not relieved by bowel movements and the presence of clinical signs of gallstone complications (jaundice, fever, dark urine).

Predictive factors for biliary pain

No correlation was found between US gallstone characteristics (number and size) and their presence or clinical manifestation.

In males with GD, increasing age was the only predictor of biliary pain (mainly pain in the right hypochondrium) while, in females, BMI was also related to pain (mainly pain in the epigastrium). No correlation was found between comorbidities and GD.

Table 7 Distribution of symptoms (and unadjusted ORs) in gallstone-free subjects, patients with gallstones not previously diagnosed, patients with a previous diagnosis of gallstones, and patients with a history of cholecystectomy for gallstones

Symptoms (%) OR (95% CI)	Gallstone-free subjects (n = 9001)	Gallstones not previously diagnosed (n = 312)	Gallstones previously diagnosed (n = 112)	Cholecystectomized (n = 61)

DISCUSSION

The present study evaluated incidence and risk factors for GD in a large population from various Italian regions, thus providing a more detailed picture of the epidemiological characteristics of this disease. Incidence was higher in females than in males and increased with age. In our population, the risk factors for GD in males were increasing age, BMI, concomitant diseases such as diabetes, liver cirrhosis, peptic ulcer, coronary disease, HDL and total cholesterol, and high levels of triglycerides while, in females, only increasing age and BMI. Increasing age, pain in the right hypochondrium/epigastrium, and the presence of concomitant diseases are predictors of GD. Pain in the right hypochondrium or epigastrium was the only symptom associated with GD; symptom severity increased as a function of the natural history of the disease. Increasing age in men and aging and BMI in females were the only predictive factors for the eventual presence of symptoms.

GD is a very common gastrointestinal disorder mainly in the Western world[1,2]; although this disease has a low mortality rate, its economic and health impact is significant due to its high morbidity. In fact, GD is one of the most common abdominal conditions for which patients are admitted to hospitals in developed countries[3]. Knowledge of disease epidemiology is therefore crucial in managing this disorder, not only for planning preventive programs, but also for the identification of the best therapeutic strategy. Several US-based surveys have been carried out in Europe[19-23] and in North[24,25] and South[26] America as well as in Asia[27,28], indicating prevalence rates for GD ranging from 5.9%[20] to 21.9%[22]. However, few studies[11-14] have been carried out to evaluate incidence and risk factors of GD, mainly due to the difficulties in following up large populations for several years. The MICOL study was designed to obtain a general overview of GD in Italy, investigating GD in terms of prevalence, incidence, risk factors, and natural history[15]. In the present study, a large general population was evaluated with the objective of identifying gallstone incidence and risk factors as well as the morphological and clinical characteristics of newly developed gallstones. Incidence was higher than that measured in previous Italian studies[12-14]; these differences could be related to the small population sample evaluated in the earlier studies. Furthermore, prevalence was also higher than in Denmark (4.5% and 5.8%, in males and females, respectively)[11]. Differences in research design may justify these differences even it is not possible to exclude the role of environmental factors.

In the present study, the response rate was higher (79%) than that reported in other GD incidence surveys performed in the north (63.7)[12] and in the centre (73.5%)[14] of Italy and similar to that observed in Denmark (82.8%)[11] and in southern Italy (87.7%)[13]; this percentage indicates a high adherence of the target population to the epidemiological study.

The participation rate was also higher in the present incidence study (79%) than in the previous study evaluating GD prevalence (64.4%)[15]; this difference could be related to a possible self-selection of patients or to an effect of dilution in the prevalence study since, in that study, 14 units participated while, in the present study, only 7 units were able to adhere to the protocol.

Table 8 Distribution of pain characteristics (and unadjusted ORs) in subjects reporting abdominal pain

Characteristics of Pain	Gallstone-free subjects	Gallstones not previously diagnosed (*n* = 312)	Gallstones previously diagnosed (*n* = 112)	Cholecystectomized (*n* = 61)
Radiation

OR (95% CI)		2.02 (1.07-3.82)	1.76 (0.99-3.10)	5.35 (2.07-13.76)
Clinical signs of gallstone complications				
Yes (%)	29.9	36.4	47.7	69.4
No (%)	70.1	63.6	52.3	30.7
OR (95% CI)		1.31 (0.69-2.46)	2.13 (1.16-3.94)	5.28 (2.56-10.9)

[1]The category "< ½ h" has been taken as baseline.

We documented variability between the different units in terms of incidence; this difference could be related to the role of environmental factors (life style, dietary habit, *etc*.) even if we were unable to identify any possible difference between the different operative units.

Gender, increasing age, and BMI were confirmed as true risk factors for GD; in males, low levels of cholesterol, high levels of triglycerides, and the presence of co-morbidities such as diabetes, peptic ulcer, angina, and liver cirrhosis represented additional risk factors. These results further confirm the importance of environmental factors in gallstone development, possibly related to an unhealthy life style. In fact, recent epidemiological studies have suggested that GD may be included in those disorders which characterize the metabolic syndrome[29,30]. In particular, a close relationship between obesity and cardiovascular disease (two of the more characteristic features of the metabolic syndrome) and GD has been identified[31,32].

We did not confirm a family history of gallstones, dieting, the number of pregnancies, and the use of contraceptive pills, which were found to be significantly associated with GD in the prevalence study as risk factors[16]. We are unable to interpret the significance of this result; however, the data available on some risk factors for GD are frequently conflicting[8,10]. The prospective cohort design of the present study and the use of US as the diagnostic tool have reduced the possibility of a recall and other information bias; furthermore, the high response rate makes selection bias unlikely.

An important result of the present study is related to the clinical manifestation of incident gallstones. In fact, we have confirmed the observation made in the prevalence study[15,17] that pain in the right hypochondrium and/or epigastrium is the only symptom significantly associated with gallstones while the so-called "non-specific biliary symptoms", i.e. dyspeptic symptoms, showed the same frequency in gallstone-free subjects and GD patients.

We have also confirmed our previous observation[17] concerning the usefulness of splitting the subjects

enrolled in the study into 4 categories reproducing the different stages of GD (absence of disease, silent disease, overt disease, severe disease); in fact, the frequency and severity of the clinical symptoms and the signs of GD increased throughout the 3 disease categories.

Furthermore, for those characteristics that are an expression of the degree of pain severity (pain forcing to rest, presence of clinical signs of gallstone complications) they progressively increased from silent gallstones to symptomatic gallstones to cholecystectomized patients for gallstones, suggesting that the natural history of GD moves from a silent to a clinically evident stage; this is also true for newly developed gallstones. This information may be useful in choosing the best therapeutic strategy in gallstone patients since surgical treatment is indicated only in true symptomatic gallstone patients[5,33].

Finally, we were unable to identify any predictive factor for the presence of biliary pain in terms of gallstone characteristics (number and size), while increasing age in males and a high BMI in females were related to the presence of biliary pain. These results are in agreement with some[34], but in disagreement with others[35,36].

In conclusion, this study provides data on the gallstone incidence and risk factors for GD in a large free-living population; the incidence rate is higher in females and it increases with age. Increasing age and BMI represent true risk factors for GD; pain in the right hypochondrium and/or epigastrium is confirmed as the only symptom related to GD; pain, as well as its characteristics of disease severity, increases in severity and frequency throughout the different stages of GD (from silent to severe disease). This information may help physicians in clinical decision making.

COMMENTS

Background

Gallstone incidence and risk factors are poorly understood and the relationship between gallstone presence and its clinical manifestations is debated.

Research frontiers

Gallstone incidence, risk factors, and clinical manifestations.

Innovations and breakthroughs

The present paper provides important information on gallstone incidence and risk factors and clearly identifies the clinical manifestations of the disease.

Applications

The results of the present paper can be useful for the early recognition of gallstones and for deciding the most appropriate therapeutic management according to the clinical presentation. Furthermore, preventive strategies can be identified and planned according to these results.

Peer review

This manuscript is a multicenter Italian study giving information about the incidence of gallstone disease in Italy. The results of this study can provide information for the comparison of Italian population results with the other nations' results.

Abstract

AIM: To assess whether in ulcerative colitis (UC) patients with ileo-rectal anastomosis (IRA), ileal lesions may develop in the neo-terminal-ileum and their possible relation with phenotypic changes towards colonic epithelium.

METHODS: A total of 19 patients with IRA under regular follow up were enrolled, including 11 UC and 8 controls (6 Crohn's disease, CD; 1 familial adenomatous polyposis, FAP; 1 colon cancer, colon K). Ileal lesions were identified by ileoscopy with biopsies taken from the ileum (involved and uninvolved) and from the rectal stump. Staining included HE and immunohistochemistry using monoclonal antibodies against colonic epithelial protein CEP (Das-1) and human tropomyosin isoform 5, hTM5 (CG3). Possible relation between development of colonic metaplasia and ileal lesions was investigated.

RESULTS: Stenosing adenocarcinoma of the rectal stump was detected in 1 UC patient. The neo-terminal ileum was therefore investigated in 10/11 UC patients. Ileal ulcers were detected in 7/10 UC, associated with colonic metaplasia in 4/7 (57.1%) and Das-1 and CG3 reactivity in 3/4 UC. In controls, recurrence occurred in 4/6 CD, associated with colonic metaplasia in 3/4 and reactivity with Das-1 and CG3 in 2/3.

CONCLUSION: Present findings suggest that in UC, ileal lesions associated with changes towards colonic epithelium may develop also after IRA. Changes of the ileal content after colectomy may contribute to the development of colonic metaplasia, leading to ileal lesions both in the pouch and in the neo-terminal ileum after IRA.

Key words: Ulcerative colitis; Ileo-rectal anastomosis; Ileal lesions; Colonic metaplasia

INTRODUCTION

Inflammatory changes of the distal ileum in ulcerative colitis (UC) may be observed in backwash ileitis[1-3] and after total proctocolectomy with ileal pouch ("pouchitis")[4-8]. Chronic inflammation of the ileal pouch has been described not only in patients with UC[9-13], but also after total proctocolectomy for other conditions, including Familial Adenomatous Polyposis (FAP). The frequency of pouchitis is more frequent in UC (60%-70% at 1 years)[14-16] than in FAP (< 50% at 1 years), thus suggesting that the underlying UC may be involved in the pathogenesis of pouchitis[8,14,17]. Common bacterial flora also appears to play a major role in

pouchitis, as suggested by both experimental and clinical evidences, supporting the efficacy of probiotics in subsiding symptoms of pouchitis in UC[18-22]. Although the etiology of pouchitis is unknown, the development of changes of the ileal mucosa lining the pouch, including flattening, reduced number and/or complete villar atrophy has been involved in UC[4,23,24]. These changes of the ileum, becoming similar to the colonic epithelium ("colonic metaplasia") have been reported more frequently associated with pouchitis. Changes of the resident bacterial flora after proctocolectomy have therefore been involved in the development of both colonic metaplasia and pouchitis.

Proctocolectomy represented the procedure of choice in severe UC over the past 30 years[25], and permanent ileostomy[26,27] is still a valid option in an elderly patient in whom either an ileal pouch or an ileo-rectal anastomosis (IRA) is contraindicated. Nowadays, colectomy with IRA[28-30] must be compared with the more recent sphincter saving procedure, namely restorative proctocolectomy. Ravitch and Sabiston[31] are rightly given the credit for the development of total colectomy and ileo-anal pouch, representing the preferred surgical option in referral IBD surgical unit[32].

IRA for UC determines the persistence of the diseased rectal stump requiring local treatment and cancer surveillance, thus being rarely performed in UC, due to technical feasibility or clinical requirements. It is conceivable that not only after ileal pouch, but also after IRA, the neo-terminal ileum may develop inflammatory changes.

In order to investigate this issue, we aimed to assess whether inflammatory changes of the ileum in UC may also be observed after IRA. We also explored whether these changes of the neo-terminal ileum are associated with the development of colonic metaplasia of the ileum itself. For this purpose, colonic metaplasia of the ileum was investigated in biopsy samples taken from the neo-terminal ileum of patients with IRA for UC, by both conventional histological assessment and immunohistochemistry, using monoclonal antibodies (MoAb) against colonic epithelial antigens (CEP and hTM5)[23,33-36]. In one UC patient, ileal lesions were also assessed by wireless capsule endoscopy (WCE). As controls, a small group of patients with IRA for Crohn's disease (CD), FAP or colon cancer (colon K) were also investigated as patients with IRA for UC.

MATERIALS AND METHODS

Patients

A total of 19 patients with IRA in regular follow up at the University "Tor Vergata" of Rome, Italy, were studied. Clinical characteristics of each patient are reported in Table 1. The study population included patients with IRA for UC (n = 11), and, as control group, 6 patients with IRA for CD, 1 for FAP and 1 for adenocarcinoma of the sigmoid colon (colon K). In all UC patients and controls the diagnosis was confirmed by macroscopic and histological analysis of the surgical specimen. Clinical history, endoscopic, surgical and histological findings were reviewed for the possibility that endoscopic findings after surgery would suggest possible changes of previous diagnosis (i.e. ileal lesions in UC). The study group included 11 UC patients (5 M; median age 46; range 25-63), with a median UC duration of 7 years (range 1-20), a median time interval from surgery of 4 years (range 1-12). Indication for surgery was adenocarcinoma in the rectal stump (n = 1), medical intractability (n = 8), toxic megacolon (n = 2). Among the 8 controls, there were 6 patients with CD (3 M, median age 51, range 22-83), with a median CD duration of 3 years (range 0-24), a median time interval from surgery of 4 years (range 1-20). Indication was stenosis of the sigmoid colon (n = 2), recto-vaginal fistula (n = 1), obstruction (n = 1), pelvic abscess (n = 1), refractory CD (n = 1). Control group also included 2 patients with IRA for FAP (F, age 57) (n = 1) and adenocarcinoma of the sigmoid colon (F, age 68) (n = 1).

Study protocol

Endoscopy: Endoscopy was performed according to clinical criteria, including possible treatment changes, cancer surveillance, or recurrence assessment (in CD). According to these criteria, 9 IBD patients underwent repeated endoscopic assessments of the rectum and ileum, in a median follow up of 4 years (range 1-20). The numbers of endoscopic assessment were: 21 in the 11 UC, 12 in the 6 CD, and 1 in the only FAP and colon cancer patients. Persistence or healing of the ileal lesions was searched in patients undergoing repeated endoscopies. All endoscopies were performed by the same gastroenterologist (LB), with pictures taken from

Figure 1 Endoscopic view of the rectal stump from one UC patient (TR) showing a hard and ulcerated mass inducing stenosis of the anastomosis, not passed by the colonoscope. Histological analysis of the lesion detected an adenocarcinoma of the rectal stump.

the rectum, anastomosis and neo-terminal ileum. In UC, the endoscopic degree of inflammation was graded according to the Mayo score (0-4)[37]. The presence and degree of ileal lesions visualized by the endoscope was searched and described as: erosions, aphthoid or deep ulcers, strictures and/or stenosis. The extent of the lesions (cm), the number of ulcerations (few or diffuse: < 5 or $\geqslant 5$) and macroscopic aspect of the ileum between ulcers were also reported. In CD, endoscopic recurrence was graded according to Rutgeerts *et al* (from 0 to 4)[38].

Histology: In all patients biopsies ($n = 2$) were taken from the neo-terminal ileum (uninvolved and involved area), anastomosis and rectal stump. In all patients, at least 10 cm of the neo-terminal ileum were visualized. When considering all biopsy samples taken during repeated endoscopies, 90 biopsy samples (180 biopsies) were taken from the ileum, anastomotic area and rectum. In UC, biopsies were taken from the neo-terminal ileum (macroscopically uninvolved $n = 17$, involved $n = 12$), anastomosis ($n = 3$) and rectum ($n = 18$). In controls, biopsies were taken: in CD from the ileum (uninvolved $n = 8$; involved $n = 8$), anastomosis ($n = 6$) and rectal stump ($n = 11$), in FAP ($n = 1$) and colon cancer patients ($n = 1$) from the uninvolved $n = 2$ or involved $n = 1$ ileum, anastomosis ($n = 2$) and rectum ($n = 2$). Biopsy samples were kept in 10% formalin. Paraffin blocks were used for routine histology by HE staining and for immunohistochemistry by immunoperoxidase staining. Histological assessment was made by one single histopathologist (GP), in order to: (1) Confirm the diagnosis of UC or CD; (2) Assess the presence and degree of inflammation; (3) Detect dysplasia/neoplasia in the rectal stump; (4) Detect changes of the epithelium lining the ileum towards colonic epithelium. Inflammatory changes were assessed according to conventional criteria[4,23,39]. Histologic elements of inflammatory and colonic metaplasia were assessed according to Fruin *et al*[24], including: (1) An inflammatory score considering histological characteristics of the villi epithelia, crypt epithelia, stroma and ulceration (A score: range 0-28); (2) Colonic metaplasia score considering characteristics of villous atrophy and crypt hyperplasia (B score: range 0-6).

Immunohistochemistry: In order to detect possible ileal changes towards colonic epithelium, the expression of colonic antigens was assessed by immunoperoxidase using 2 MoAbs against human tropomyosin isoform 5 (hTM5) (CG3) and against the > 200 kDa colonic epithelial antigen (Das-1)[33-36]. Sections were stained as reported previously[33-36].

Clinical assessment: Clinical assessment was made according to the Mayo score in UC[37] and to the CD Activity Index (CDAI) in CD[40].

WCE: In one compliant UC patient, the presence and extent of the lesions in the neo-terminal ileum was also investigated by WCE. WCE examination was performed using the Given M2A capsule (Given Imaging, Yoqneam, Israel[41,42]) as described[43], by using bowel preparation with PEG (2 L). Exclusion criteria included: low compliance, diverticula, blind loop, pace-maker, neurological disorders, intestinal strictures. WCE images were assessed by one gastroenterologist. The detection of the following lesions was reported: erosions, ulcers, strictures or stenosis. Any other lesion was also reported.

The study was approved by the Local Ethic committee.

RESULTS

UC patients

In one UC patient, an anastomotic stricture that could not be passed by the endoscope was detected. A hard and ulcerated area was present in the rectal stump, compatible with adenocarcinoma, confirmed by histology (Figure 1). The ileum was therefore visualized in 10/11 patients. Figure 2A shows the percentage of UC patients with endoscopic lesions in the neo-terminal ileum, together with changes towards colonic epithelium, as detected by both conventional histology and staining using CG3 and Das-1 MoAbs. As indicated, ileal lesions were detected at first endoscopy in 7/10 patients. Histological analysis of the macroscopically involved ileum detected changes towards colonic epithelium in 4/7 patients. CG3 and Das-1 MoAbs staining were observed in ileal samples from 3 out of these 4 patients. The endoscopic and histological views of the neo-terminal ileum and rectal stump from 2 UC patients with lesions associated or not with changes towards colonic epithelium are shown in Figures 3 and 4, respectively.

Clinical assessment: At first endoscopy, UC was clinically active (Mayo score) in 5 and inactive in 6 patients.

Endoscopy: As the neo-terminal ileum was not visualized in 1 UC patient due to an adenocarcinoma of

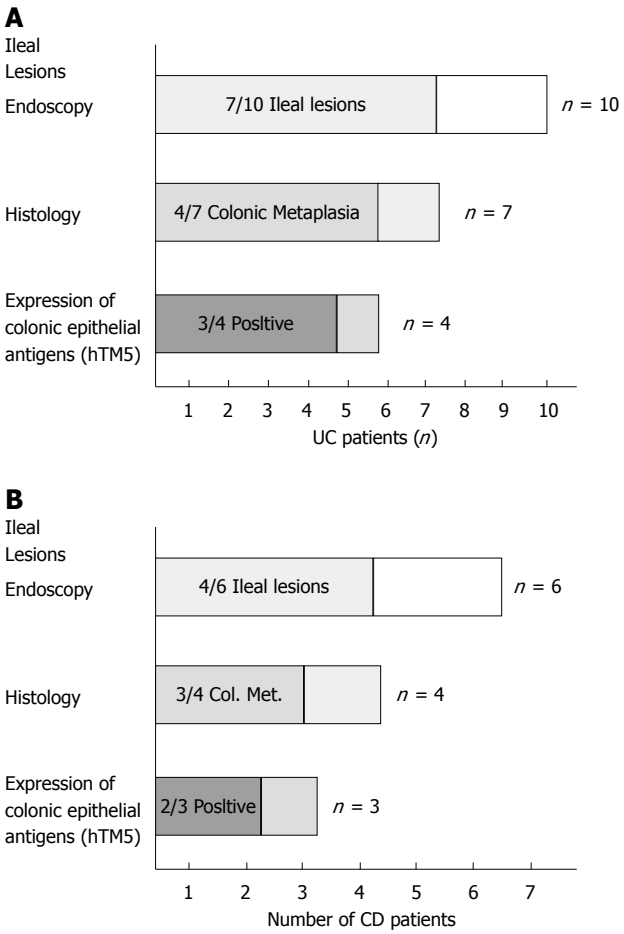

Figure 2 Histograms indications. **A**: The number of UC patients after IRA showing: Lesions in the neo-terminal ileum as assessed by endoscopy; Histological findings compatible with colonic metaplasia; Expression of hTM5-related colon epithelial antigens; **B**: The number of CD patients with IRA showing ileal recurrence at endoscopy, inflammatory changes at histology (including those compatible with colonic metaplasia) and expression of hTM5-related colonic epithelial antigens.

the rectal stump (Figure 1), the ileum was visualized in 10/11 patients. Among these 10 patients, macroscopic lesions were detected in the rectal stump in 8, in the anastomosis in 6, in the ileum in 7. Rectal lesions in the 8 patients included erosions (n = 2) and ulcers (n = 6). In 2/6 patients with anastomotic lesions, a stricture that could be passed by the endoscope was observed. Table 2 shows the endoscopic and histological findings in each of the 11 UC patients studied. Among the 10 patients, 7 showed macroscopic lesions in the ileum proximal to the IRA at first endoscopy. Lesions were localized within 15 cm above the anastomosis in all patients, including ulcers, sporadic (< 5) in 5 (apthoid, n = 3; deep, n = 2) and diffuse (> 5) in 2 UC. In all 7 patients, ileal lesions were surrounded by macroscopically uninvolved areas, while the rectal stump showed typical UC lesions. All 6 UC with anastomotic lesions also showed ileal lesions, while 1 patient with ileal lesions showed a normal anastomosis.

Histology: HE staining. Adenocarcinoma of the rectal stump was detected in 1 patient (Figure 1) and inflammatory changes in the remaining 10. In the macroscopically uninvolved ileum, biopsies were taken from 7/10 UC, showing inflammatory changes (n = 2), lamina propria oedema (n = 3) or no lesions (n = 2) (Table 2). In the macroscopically involved ileum, histology detected inflammation in all 7 UC (acute and chronic inflammation n = 3; villous atrophy n = 4). The anastomotic area showed inflammation in 3/6 UC.

Assessment of changes of the ileal epithelium toward colonic epithelium. Changes towards colonic epithelium are observed in the macroscopically uninvolved ileum from 7/10 UC, showing an inflammatory infiltrate in 3 (A1, n = 1; A2, n = 2), no inflammation in 4 and colonic metaplasia in 1 (B2) (Table 2). Changes toward colonic epithelium were found in the 7/10 UC with ileal lesions, showing inflammatory changes in 4 (A12, n = 1; A10, n = 1; A6, n = 2). Ileal changes towards colonic epithelium have been detected in the 4/7 UC with ileal lesions (A12, n = 1; A4, n = 1; A3, n = 1; A2, n = 1).

Figures 3A to C and 4A to C show the endoscopic, histologic and immunohistochemistry analysis of biopsy samples taken from 4 additional UC patients with IRA.

Immunohistochemistry: Expression of hTM5-related antigens was seen in the uninvolved ileum from 6/10 UC, showing CG3 staining in all 6 and Das-1 staining in 5/6 UC. The involved ileum showed CG3 staining in 5/6 UC and Das-1 staining in 3/6 UC.

Longitudinal study: Endoscopy. Among the 7 patients with ileal lesions, 6 underwent repeated endoscopies (n = 5 in 1; n = 2 in 4; n = 3 in 1). Ileal lesions were detected at all endoscopies in 3/6 UC, at first but not at second endoscopy in 2, healing at third endoscopy in 1 UC. Figure 5 shows the endoscopic, histologic and immunohistochemical analysis of the rectum, involved and uninvolved ileum from one UC patient at 3 consecutive endoscopies.

Histology. Ileal lesions at endoscopy were confirmed by histology in all UC patients. One patient showed ileal changes toward colonic epithelium at all endoscopies (Figure 3).

Immunohistochemistry. In UC, biopsy samples were taken during repeated endoscopies from the uninvolved (n = 11) and involved ileum (n = 10). In the uninvolved ileum, 10/11 biopsies showed CG3 staining (strong in 4) and 8/11 Das-1 staining (glandular n = 5; epithelial cells n = 3). In the involved ileum 9/10 biopsies showed CG3 staining (glandular n = 2; epithelial cells n = 7, strong in 3) and 6/10 showed Das-1 staining (glandular n = 5; epithelial cells, n = 1).

WCE. In the only UC patient studied by WCE, this procedure confirmed the endoscopic findings, showing multiple erosions and ulcers covered by fibrin in the distal 10 cm of the neo-terminal ileum (Figure 3D). These lesions appeared focal, being surrounded by macroscopically uninvolved mucosa. No other lesions, active bleeding or strictures were detected by WCE in the entire small bowel.

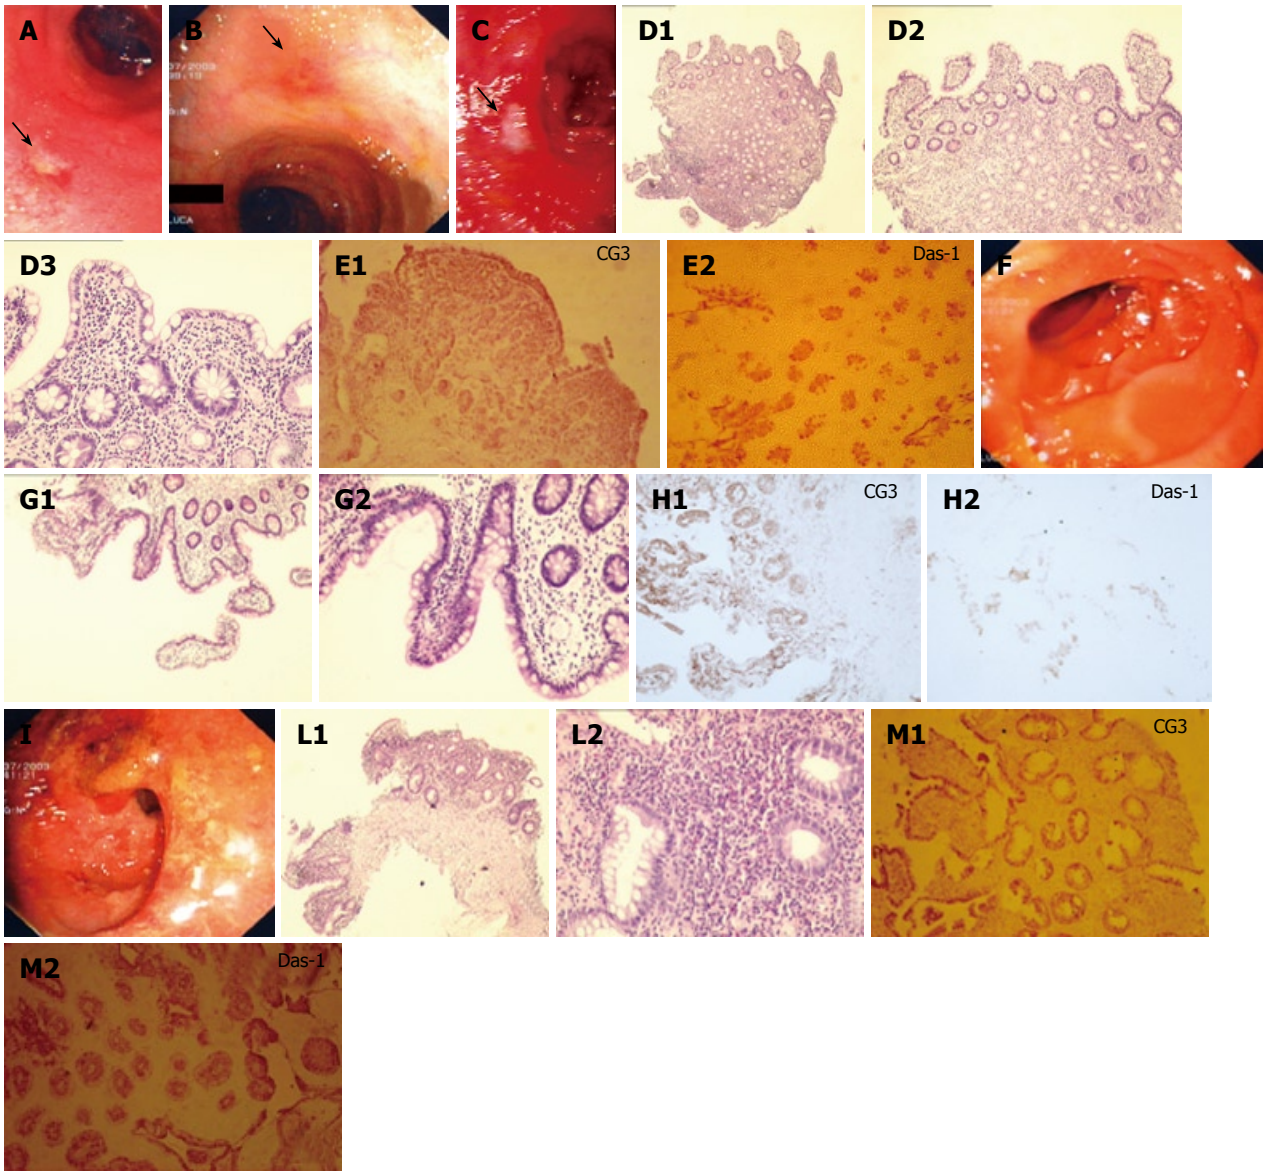

Figure 3 Endoscopic view, histological analysis and immunohistochemistry against CG3 and Das-1 MoAbs of biopsy samples taken from the neo-terminal ileum and rectal stump from a second UC patient (DLE) with IRA. **A-C**: Endoscopic views of the neo-terminal ileum at 3 endoscopies, showing focal erosions and ulcers at all times; **D**: Histological analysis of ileal biopsy samples, compatible with changes towards colonic epithelium, including villous atrophy; **E**: Immunostochemistry showing staining against CG3 (**E1**) and Das-1 (**E2**) MoAbs in the same ileal samples. **F-H**: Endoscopic view (**F**), histological (**G1, G2**) and immunohistochemical analysis against CG3(**H1**) and Das-1 MoAbs (**H2**) of the uninvolved ileum, showing no inflammation or colonic metaplasia. **I-M**: Endoscopic view (**I**), histological (**L1, L2**) and immunohistochemical analysis using CG3(**M1**) and Das-1 MoAbs (**M2**) of the rectal stump, showing typical UC lesions and staining against hTM5-related antigens.

Controls with IRA

CD patients: Figure 2B shows the percentage of CD patients with ileal recurrence detected by endoscopy and histology, together with changes towards colonic epithelium assessed by histology and immunohistochemistry. Recurrence was detected in 4 out of 6 patients: histology detected changes towards colonic epithelium in 3 out of these 4 patients, associated with the expression of colonic epithelial antigens in 2 out of 3 patients.

Clinical assessment. At first endoscopy, disease was active in 3 (CDAI > 150) and inactive in 3 patients.

Endoscopy. Lesions were detected in the rectum in 2/6 patients, in the anastomosis in 5/6 and in the ileum in 4/6 patients. Lesions included CD recurrence of grade 0 (n = 2), 2 (n = 2), 3 (n = 1) or 4 (n = 1) (Figures 6 and 7).

Histology. (1) HE staining: In rectal samples, inflammatory changes were detected in 3/6 CD. The macroscopically uninvolved ileum from 4/6 patients showed changes towards colonic metaplasia (n = 1), inflammation and villous atrophy (n = 2) or no lesions (n = 1) (Figures 6 and 7). Among the 4 patients with ileal recurrence, inflammation was detected in 3 (with villous atrophy in 2) and colonic metaplasia in 1. The anastomosis showed inflammation in 3 (glandular hyperplasia n = 1, villous atrophy n = 1, colonic metaplasia n = 1). (2) Assessment of changes of the ileal epithelium toward colonic epithelium: In 4/6 CD, biopsy samples were taken from the macroscopically uninvolved ileum, showing inflammation in 3/4 (A2, n = 1; A4, n = 2) and changes towards colonic metaplasia

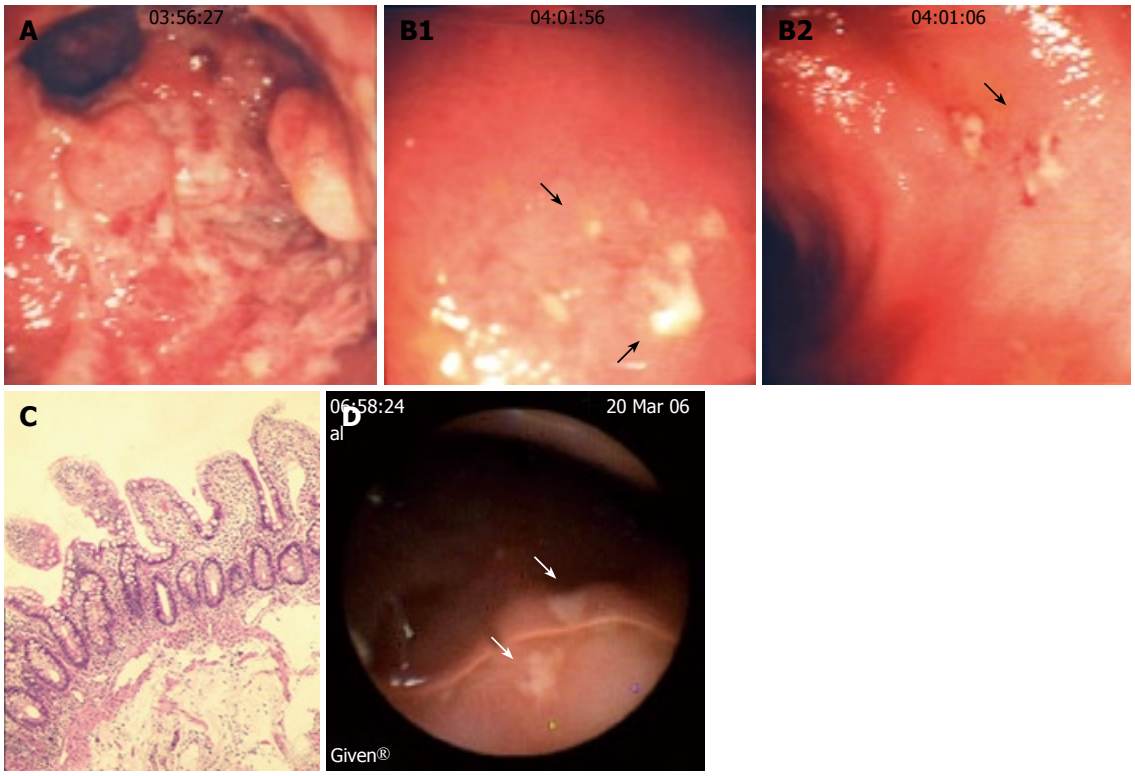

Figure 4 Endoscopic view, histological analysis and WCE images of the rectum and neo-terminal ileum from a third UC patient (LRA) with IRA. **A**: Endoscopic view of the rectal stump showing erosions and pseudopolyps; **B**: Endoscopic views of the ileum showing small focal ulcers above the anastomosis; **C**: Ileal biopsy sample from the same patient showing no villous atrophy or colonic metaplasia by histology; **D**: WCE images showing in the neo-terminal ileum above the anastomosis, 2 ulcers covered by fibrin (arrows) surrounded by macroscopically normal ileum.

in 2/4 (B2, *n* = 1; B4, *n* = 1) (Table 3). Ileal lesions at endoscopy were confirmed by histology in all 4 CD (A2, *n* = 1; A8, *n* = 1; A10, *n* = 1; A12, *n* = 1) showing colonic metaplasia in 3/4 patients (B3, *n* = 1; B4, *n* = 2). (3) Immunohistochemistry: hTM5-related antigens expression in the uninvolved ileum was searched in 2 CD, showing staining against CG3 in both and against Das-1 in 1 patient. Biopsies from the involved ileum

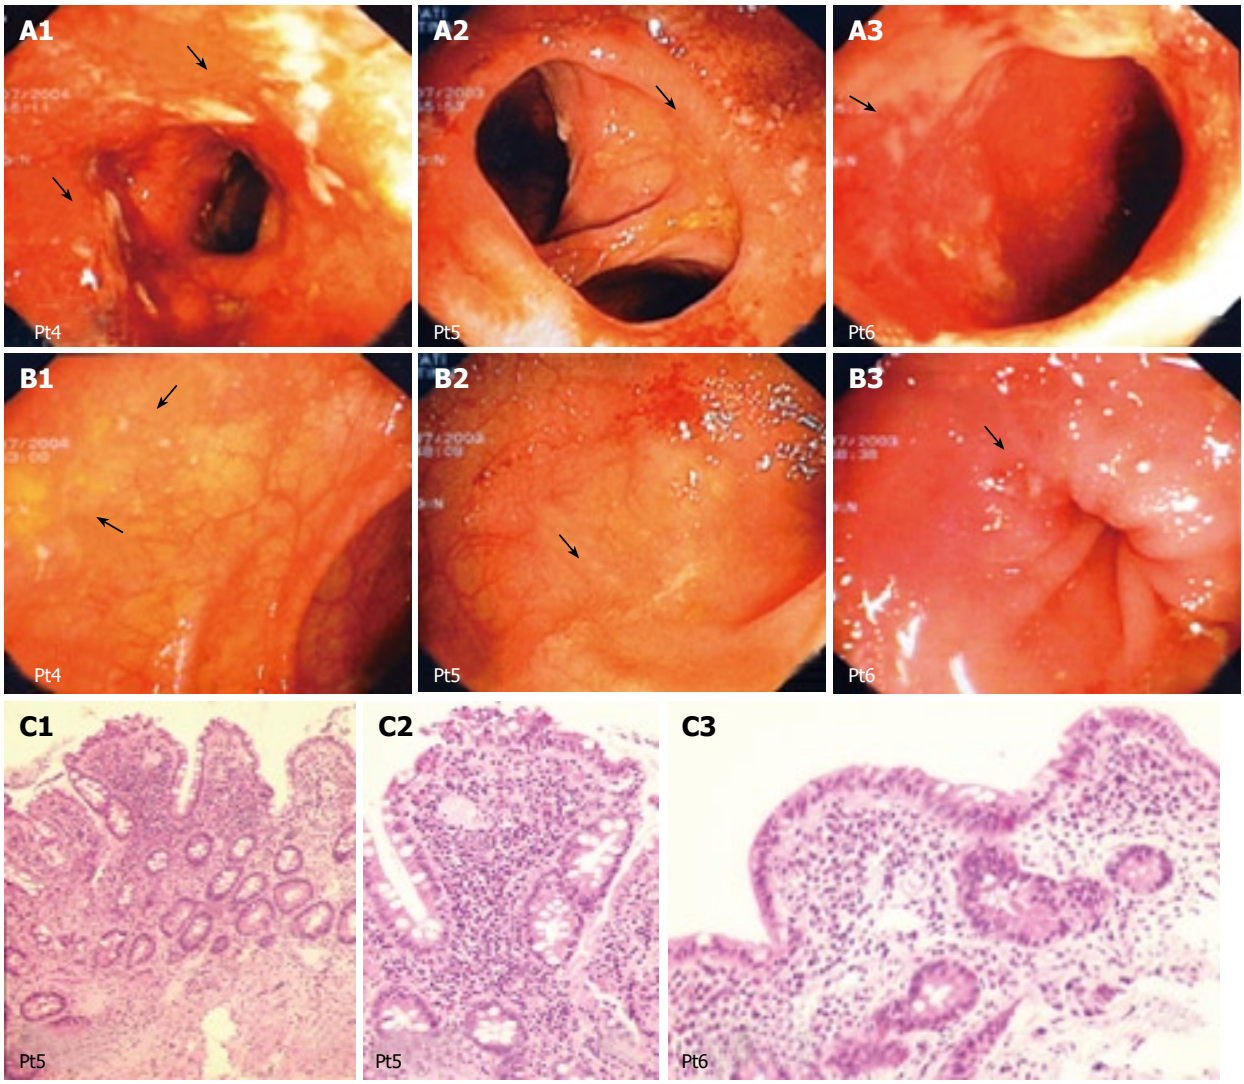

Figure 5 Endoscopic view and histological analysis of the anastomosis and neo-terminal ileum from 3 UC patients with IRA. **A**: Endoscopic views of the anastomosis from 3 UC patients showing focal small ulcers; **B**: Endoscopic views of the neo-terminal ileum from the same 3 UC patients, scattered ulcerations surrounded by macroscopically uninvolved ileum; **C**: Histological analysis of biopsy samples taken from the involved neo-terminal ileum from patients 5 and 6, showing changes towards colonic metaplasia.

were taken from 3 CD, showing CG3 staining in all 3, and Das-1 staining in 2/3 patients.

Longitudinal study: Endoscopy: Repeated endoscopies (n = 4 in 1; n = 3 in 2) were performed in 3/6 patients, showing persistent lesions. Histology: In 5/6 patients, ileal inflammatory changes were detected at all endoscopies. Immunohistochemistry: The only patient with repeated immunohistochemical analysis showed persistent CG3 positivity and Das-1 negativity.

Patient with FAP

Endoscopy: One anastomotic ulcer was detected. Histology: Inflammation were detected only in the anastomosis (A = 0; B = 2).

Patient resected for colon cancer

Endoscopy: No lesions were detected. Histology: Mild inflammation was detected in the rectum only.

DISCUSSION

In UC, inflammatory changes of the ileum in UC may be observed in pouchitis[4-8] and in backwash ileitis[1-3]. In pouchitis, ileal lesions have been related to the development of changes of the epithelium towards colonic epithelium ("colonic metaplasia")[4,23,24]. Although the etiology of pouchitis remains unknown, the resident bacterial flora is involved in the pathogenesis of this condition[15,18,19,21,22]. In particular, the efficacy "*in vivo*" of probiotic preparations in UC patients with pouchitis suggests a pathogenetic role for changes of the resident bacterial flora after proctocolectomy[18,19,21]. As proctocolectomy is required for both ileal pouch and IRA, we aimed to assess whether UC patients may develop inflammatory changes of the ileum not only in the ileal pouch, but also above the IRA. We also explored whether these changes are associated with the development of colonic metaplasia of the epithelium lining the ileum. Ileal changes have been examined by

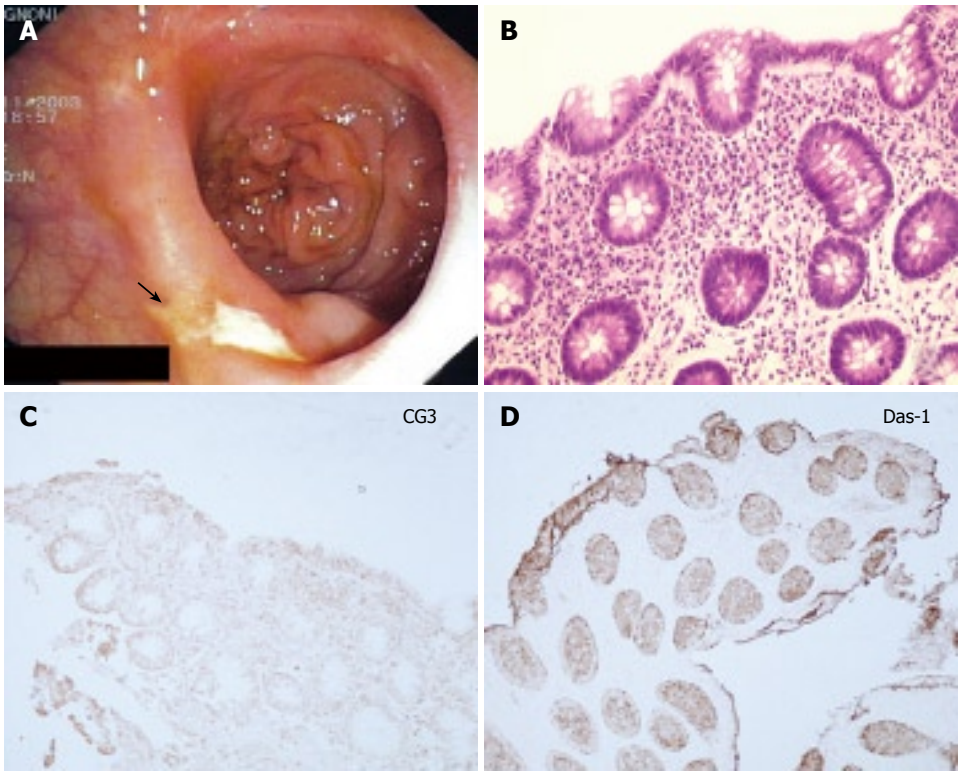

Figure 6 Endoscopic view (**A**), histological (**B**) and immunohistochemical analysis using CG3 (**C**) and Das-1 MoAbs (**D**) of the neo-terminal ileum form one CD patient. histology and immunohistochemistry using MoAbs against the major cytoskeletal microfilament protein, tropomyosin isoform 5 (hTM5) in colon epithelium[33-36]. Evidence indicates that bacterial-host interactions may induce the expression of cryptic cytoskeletal proteins on human cells surface[23,44]. Cytoskeletal proteins include a family of intracytoplasmatic proteins (α-actinin, talin, ezrin, villin, F-actin, myosin Ⅱ, calpactin, gelsolin, laminin, tropomyosin), modulating the structure, shape, and motility of several cell types, including human colonic epithelial cells[45]. The enteropathogenic Escherichia coli binds to enterocytes by injecting a translocated intimin receptor in the host cells membrane, linking to the intimin receptor of the bacterium itself. This binding is followed by a rearrangement of the cytoskeletal proteins within the cytoplasm of the enterocytes (α-actinin, talin, ezrin, villin, F-actin, myosin Ⅱ, TMs), thus forming pedestals linking the bacterium

itself to colonic epithelial cells[44,45]. These observations prompted us to also assess whether hTM5 may be expressed on the epithelial cells lining the neo-terminal ileum in UC patients with IRA, due to changes of the ileum towards colonic epithelium after colectomy and the possible relation between the development of colonic metaplasia and ileal lesions. Our findings from a limited number of patients with IBD suggest that ileal lesions may be observed after IRA, although more frequently in UC (7 out of 10 patients). The presence of scattered erosions and ulcers in the neo-terminal ileum above the anastomosis was confirmed by WCE images, acquired as described[41-43], from the only patient performing this procedure. Despite the focal inflammation of the ileum, histological analysis of the surgical colonic specimen confirmed the diagnosis of UC in all 7 patients. Ileal lesions were associated with epithelial changes towards colonic epithelium in 4 out of these 7 patients, associated with the expression of hTM5-related antigens in 3 out of these 4 patients. The same findings were not detected in any of the 7 UC patients with no ileal lesions. Surprisingly, colonic metaplasia and the expression of colonic epithelial antigens were also observed in some of the few tested patients with IRA for CD. Although "colonization" of the ileum after total colectomy for any indication has been described, its possible relation with the development of ileal lesions is unknown. The score from Fruin *et al*[24] was used for assessing colonic metaplasia, as for pouchitis. Major limits of our study include the low number of patients and the cross-sectional study plan, not allowing comparisons before versus after surgery. Although it is said that colectomy cures UC, this study underscores the fact that surgery is not the final answer due to the high incidence of pouchitis and other functional problems experience by these patients. Of particular concern is the asymptomatic neoplasia that can arise in the residual rectal stump required for these surgical procedures, which was seen in one of the study patients.

Although not conclusive, our findings suggest that lesions may be observed in the neo-terminal ileum of UC and CD patients following IRA. These changes are towards colonic epithelium phenotype and with the expression of colonic epithelial antigens in some patients. Longitudinal studies are ongoing for further characterization of the molecular mechanisms leading to ileal changes in UC. Present findings suggest that changes of the ileal content after colectomy may contribute to the development of colonic type of metaplasia, leading to ileal lesions both in the pouch and in the neo-terminal ileum after IRA.

COMMENTS

Background

Inflammatory changes of the distal ileum in ulcerative colitis (UC) may be observed in backwash ileitis and after total proctocolectomy with ileal pouch ("pouchitis"). Although total proctocolectomy with ileal pouch currently represents the most frequently performed surgical procedure in UC, colectomy with ileo-rectal anastomosis (IRA) is still in these patients. The persistence of the diseased rectal stump after IRA requires endoscopical surveillance. Ileal inflammation may be observed in UC patients with pouchitis, being related to changes of the ileal epithelium towards colonic epithelium ("colonic metaplasia"). Whether the ileum above IRA in patients with IRA for UC may develop inflammatory changes as observed in pouchitis is unknown and this observation may be useful for proper follow up of patients after surgery.

Research frontiers

The etiology of pouchitis in patients with UC is unknown. However, the development of changes of the ileal mucosa lining the pouch, including flattening, reduced number and/or complete villar atrophy has been involved in the pathogenesis of pouchitis. These changes of the ileum, becoming similar

to the colonic epithelium ("colonic metaplasia") have been reported more frequently associated with pouchitis. Changes of the resident bacterial flora after proctocolectomy therefore have been involved in the development of both colonic metaplasia and pouchitis. It is conceivable that after total colectomy for UC and related changes of the common bacterial flora, ileal lesions may develop not only after ileal pouch, but also after IRA.

Innovations and breakthroughs

The present study showed that In UC, ileal lesions associated with changes towards colonic epithelium may develop after IRA. Changes of the ileal content after colectomy may contribute to the development of colonic metaplasia, leading to ileal lesions also after IRA.

Applications

Results from our study suggest that patients with IRA for UC need endoscopical assessment not only for cancer surveillance but also for assessing the possible development of ileal lesions above anastomosis. Present findings also add new insights regarding the natural history of UC after IRA.

Terminology

Tropomyosin isoform 5 (hTM5) is a cytoskeletal microfilament protein present in the epithelium from human colon, but not from the ileum. Mucosal and circulating antibodies against hTM5 have been demonstrated in patients with UC. Evidences indicate that bacterial-host interactions may induce the expression of cryptic cytoskeletal proteins on human cells surface. Cytoskeletal proteins include a family of intracytoplasmatic proteins (α-actinin, talin, ezrin, villin, F-actin, myosin Ⅱ, calpactin, gelsolin, laminin, tropomyosin), modulating the structure, shape, and motility of several cell types, including human colonic epithelial cells.

Peer review

This is a clinical and immunohistochemical study supporting the need of continued endoscopical follow up of UC patients after IRA.

Abstract

AIM: To provide a specific review and meta-analysis of the available evidence for continuous wound infusion of local anaesthetic agents following midline laparotomy for major colorectal surgery.

METHODS: Medline, Embase, trial registries, conference proceedings and article reference lists were searched to identify randomised, controlled trials of continuous wound infusion of local anaesthetic agents following colorectal surgery. The primary outcomes were opioid consumption, pain visual analogue scores (VASs), return to bowel function and length of hospital stay. Weighted mean difference were calculated for continuous outcomes.

RESULTS: Five trials containing 542 laparotomy wounds were eligible for inclusion. There was a significant decrease in post-operative pain VAS at rest on day 3 (weighted mean difference: -0.43; 95% CI: -0.81 to -0.04; P = 0.03) but not on post-operative day 1 and 2. Local anaesthetic infusion was associated with a significant reduction in pain VAS on movement on all three post-operative days (day 1 weighted mean difference: -1.14; 95% CI: -2.24 to -0.041; P = 0.04, day 2 weighted mean difference: -0.97, 95% CI: -1.91 to -0.029; P = 0.04, day 3 weighted mean difference: -0.61; 95% CI: 1.01 to -0.20; P = 0.0038). Local anaesthetic wound infusion was associated with a significant decrease in total opioid consumption (weighted mean difference: -40.13; 95% CI: -76.74 to -3.53; P = 0.03). There was no significant decrease in length of stay (weighted mean difference: -20.87; 95% CI: -46.96 to 5.21; P = 0.12) or return of bowel function (weighted mean difference: -9.40; 95% CI: -33.98 to 15.17; P = 0.45).

CONCLUSION: The results of this systematic review and meta-analysis suggest that local anaesthetic wound infusion following laparotomy for major colorectal surgery is a promising technique but do not provide conclusive evidence of benefit. Further research is required including cost-effectiveness analysis.

Key words: Colorectal surgery; Laparotomy; Local anaesthesia; Infusion; Wound healing

INTRODUCTION

Open surgery comprising colonic resection and primary bowel anastomosis accounts for up to a third of elective general surgical admissions[1]. The control of pain following these operations represents a major challenge as highly complex nociceptive pathways are involved[2-4]. Pain control following abdominal laparotomy and bowel anastomosis is therefore not amenable to

pharmacological monotherapy and modern analgesic strategies following major colorectal surgery involve the combination of many agents including parenteral opiates, nonsteroidal anti-inflammatory drugs (NSAIDs), paracetamol and epidural infusion techniques[5].

Unfortunately, there is no ideal analgesic regimen - all current techniques have disadvantages in the form of important side-effects, cost, patient compliance, procedural complications and delays in discharge[6]. Suboptimal post-operative pain control is of great clinical consequence and has been associated with cardiovascular and respiratory complications and increased gastrointestinal paralysis[5].

A recent systematic review[7] has revealed the promise of continuous wound infusion of local anaesthetic agents to provide improved pain control following thoracic[8-10], abdominal[11-13], gynaecological[14-16], and orthopaedic[17-19] operations, but there is a need for a more focused review of the evidence specific to colorectal laparotomy.

MATERIALS AND METHODS

An electronic search was performed using the Embase and Medline databases from 1966 until 2007. The search terms "postoperative pain", "postoperative analgesia", "local anesthetics", "continuous", "infusion", "perfusion", "irrigation", "patient-controlled", and MeSH headings "Colorectal Surgery" (MeSH), "Laparotomy" (MeSH), were used in combination with the Boolean operators AND or OR. Two authors independently performed electronic searches in March 2008. The electronic search was supplemented by a hand search of published abstracts from meetings of the Surgical Research Society, the Society of Academic and Research Surgery, the American Society of Anesthesiologists, the Anaesthetic Research Society and the Association of Surgeons of Great Britain and Ireland from 1980 to 2007. The reference lists of articles obtained were also searched to identify further relevant citations. Finally, the search included the Current Controlled Trials Register (www.controlled-trials.com) and the Cochrane Database of Controlled Trials.

Abstracts of the citations identified by the search were then scrutinised by two observers (SRW and AK) in order to determine eligibility for inclusion in the meta-analysis. Studies were included if they met each of the following criteria: randomised controlled trial, patients undergoing midline laparotomy for colorectal surgery, randomisation to groups with or without continuous wound infusion of local anaesthetic.

The primary outcome measure for the meta-analysis was the opioid consumption in each arm. Data from eligible trials were entered into a computerized spreadsheet for analysis. The quality of each trial was assessed using the Jadad scoring system[20]. The statistical analysis was performed using Statsdirect 2.5.7 (Statsdirect Ltd., UK). Weighted mean difference were calculated for the effect of local anaesthetic infusion on opioid consumption and linear analogue pain scores on post-operative days 1, 2 and 3. Further pooled outcome measures were duration of hospital stay and time to return of bowel function. All pooled outcome measures were determined using random-effects models as described by Der Simonian and Laird[21]. Heterogeneity amongst the trials was assessed by Cochran's Q statistic, a null hypothesis test in which $P < 0.05$ is taken to indicate the presence of significant heterogeneity. The Egger test was used to assess the funnel plot for significant asymmetry, indicating possible publication or other biases.

RESULTS

The initial search identified 590 papers. After screening, 5 randomised controlled trials were identified[22-26]. The five trials included 542 laparotomy wounds, of which 259 were randomised to infusion of local anaesthetic agents.

Outcome measures

Opioid consumption: Four of the five trials reported total opioid consumption with or without local anaesthetic wound infusions[22-25] (Figure 1A). Local anaesthetic wound infusion was associated with a significant decrease in total opioid consumption (weighted mean difference: -40.13; 95% CI: -76.74 to -3.53; $P = 0.03$). This outcome measure was associated with significant statistical heterogeneity (Cochran's Q = 45.31, $P = 0.02$) but not significant bias (Egger Test = -4.69, $P = 0.27$).

Four of the five trials reported separate data for opioid consumption with or without local anaesthetic wound infusion on post-operative day 1[22,23,25,26] (Figure 1B). Local anaesthetic wound infusion was associated with a significant decrease in opioid consumption on post-operative day 1 (weighted mean difference: -8.34; 95% CI: -16.38 to -0.31; $P = 0.04$). There was significant statistical heterogeneity (Cochran's Q = 9.98, $P = 0.019$) but not significant bias (Egger test: -2.11, $P = 0.48$).

Three trials reported opioid consumption on post-operative days 2 and 3[22,23,26] (Table 1). There was no significant effect on opioid consumption (d 2 weighted mean difference: -9.49; 95% CI: -20.37 to 1.39; $P = 0.087$; day 3 weighted mean difference: -4.80; 95% CI: -11.72 to 2.13; $P = 0.17$). Two trials did not report this outcome measure rendering calculation of statistical heterogeneity or bias impossible.

Visual analogue pain scores at rest

Four of the five trials reported visual analogue scores (VASs) of pain on post-operative days 1, 2 and 3[22-24,26]. Post-operative pain was reduced with local anaesthetic infusion on d 1 and 2 but the difference was not significant (Table 1) (d 1 weighted mean difference: -0.18; 95% CI: -1.31 to 0.95; $P = 0.75$ and d 2 weighted mean difference: -0.20; 95% CI: -1.06 to 0.66; $P = 0.65$). However, these outcome measures were associated with significant statistical heterogeneity (Cochran's Q 18.15 and 15.42, $P < 0.05$). The use of local anaesthetic wound infusions was associated with a significant decrease in post-operative pain at rest on d 3 (Figure 1C) (weighted mean

Table 1 Results of meta-analyses

Outcome measure	Weighted mean difference	95% CI	*P*	Heterogeneity	Bias
Opioid consumption					
Total	-40.13	-76.74 to -3.53	0.03	$P = 0.02$	$P = 0.27$
Postoperative day 1	-8.34	-16.38 to -0.31	0.04	$P = 0.019$	$P = 0.48$
Postoperative day 2	-9.41	-20.37 to 1.39	0.087	NA	NA
Postoperative day 3	-4.8	-11.72 to 2.13	0.17	NA	NA
Visual analogue pain score at rest					
Postoperative day 1	-0.18	-1.31 to 0.95	0.75	$P < 0.05$	$P = 0.80$
Postoperative day 2	-0.20	-1.06 to 0.66	0.65	$P < 0.05$	$P = 0.47$
Postoperative day 3	-0.43	-0.81 to -0.044	0.029	NA	$P = 0.63$
Visual analogue pain score on coughing or movement					
Postoperative day 1	-1.14	-2.24 to -0.041	0.04	NA	NA
Postoperative day 2	-0.97	-1.91 to -0.029	0.04	NA	NA
Postoperative day 3	-0.61	1.01 to -0.20	0.0038	NA	NA
Duration of hospital stay	-20.87	-46.94 to 5.21	0.12	$P = 0.016$	$P = 0.30$
Time to return of bowel function	-9.4	-33.98 to 15.17	0.45	NA	NA

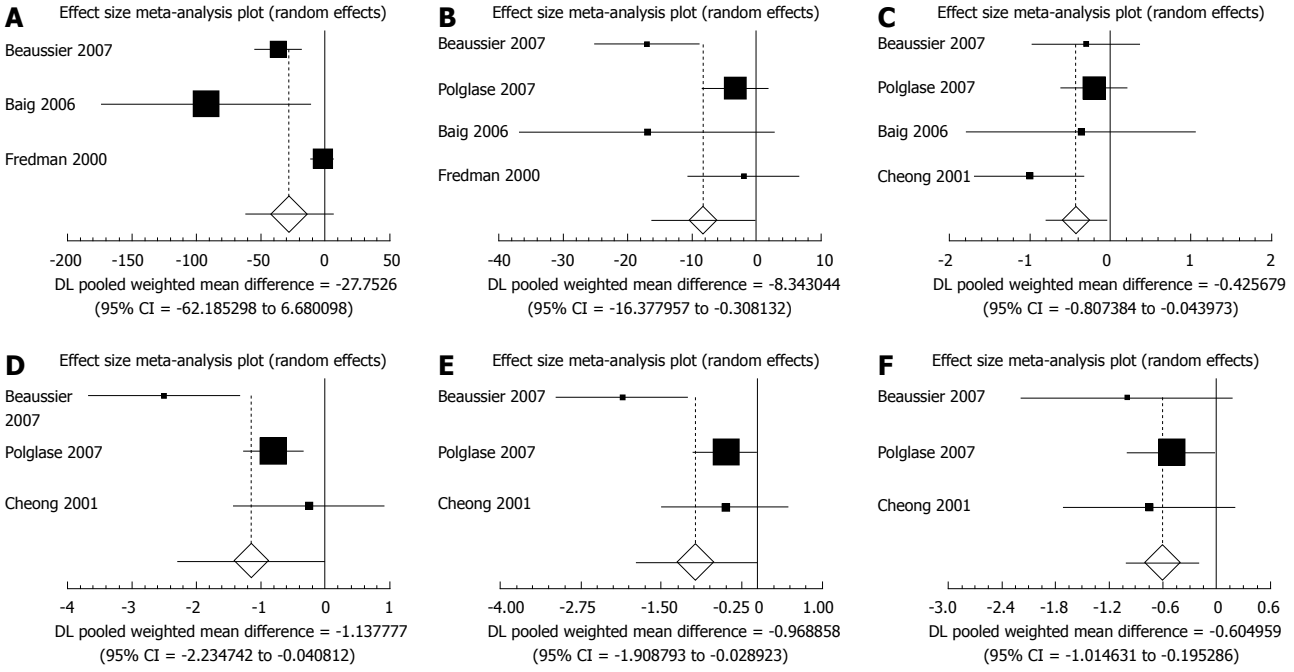

Figure 1 **A**: Forest plot for total postoperative opioid consumption with or without continuous wound infusion of local anaesthetic agent; **B**: Forest plot for opioid consumption on postoperative d 1 with or without continuous wound infusion of local anaesthetic agent; **C**: Forest plot for pain VAS at rest on postoperative d 3 with or without continuous wound infusion of local anaesthetic agent; **D**: Forest plot for pain VAS on coughing or movement on postoperative d 1 with or without continuous wound infusion of local anaesthetic agent; **E**: Forest plot for pain VAS on coughing or movement on postoperative d 2 with or without continuous wound infusion of local anaesthetic agent; **F**: Forest plot for pain VAS on coughing or movement on postoperative d 3 with or without continuous wound infusion of local anaesthetic agent.

difference: -0.43; 95% CI: -0.81 to -0.044; $P = 0.0288$). There was no evidence of bias for days 1, 2 or 3 (day 1 Egger test 0.99, $P = 0.80$; day 2 Egger test 2.75, $P = 0.47$; day 3 Egger test -1.00, $P = 0.63$).

Visual analogue pain scores on coughing or movement

Three of the five trials reported pain VAS on coughing or movement, grouped for this analysis as a composite endpoint[23,24,26]. Local Anaesthetic infusion was associated with a significant reduction in pain VAS on all three post-operative days (Figures 1D to F) (day 1 weighted mean difference: -1.14; 95% CI: -2.24 to -0.041; $P = 0.04$, day 2 weighted mean difference: -0.97, 95% CI: -1.91 to -0.029; $P = 0.04$, day 3 weighted mean difference: -0.61; 95% CI: 1.01 to -0.20; $P = 0.0038$). Two trials did not report this pain on movement, rendering calculation of statistical heterogeneity or bias impossible.

Duration of hospital stay

All five trials reported length of stay. There was no significant decrease in length of stay (Table 1) (weighted mean difference: -20.87; 95% CI: -46.96 to 5.21; $P = 0.12$). This outcome measure was associated with significant statistical heterogeneity (Cochran's Q: 12.20, $P = 0.016$) without significant bias (Egger test: -1.12, $P = 0.30$).

Time to return of bowel function

Mean time to production of faeces was reported by three trials[22-24]. There was no significant effect of local anaesthetic wound infusion (Table 1) (weighted mean difference: -9.40; 95% CI: -33.98 to 15.17; $P = 0.45$). Two trials did not report this outcome measure rendering calculation of statistical heterogeneity or bias impossible.

DISCUSSION

The results of our meta-analysis suggest that wound infusions are a promising adjunct to existing analgesic regimens following laparotomy for major colorectal surgery. The results do not, however, provide conclusive evidence of significant benefit conferred by this technique and it is doubtful whether the data gathered are sufficient to support generalisation of this conclusion to routine practice. The number of eligible trials (5) and total abdominal wounds (542) is small, and meta-analyses on small samples may be vulnerable to confounding if one or two of the eligible trials demonstrate a strong trend for or against the intervention under investigation.

For the purpose of this meta-analysis, the outcome measure "opioid consumption" was chosen to reflect opioid-sparing effect provided by local anaesthetic infusions. However, the significant statistical heterogeneity associated with this outcome measure reflects a variety of background analgesic regimens used in both control and treatment groups. Polglase *et al* utilized a multimodal analgesic regimen whereas the other trials studied used only patient controlled opioid analgesia to provide background analgesia. This degree of methodological heterogeneity between the trials may have influenced the meta-analysis.

Analysis of pain VAS may also have been affected by methodological heterogeneity between the trials studied. Furthermore, pain VAS is a non-parametric variable whereas the meta-analysis models used assume parametric distribution of the variables under study. The variable "length of stay" reflects a composite endpoint that may have been affected by several factors other than the presence of local anaesthetic infusions, and therefore it is not possible to draw causative inferences from the results of this pooled outcome measure with great validity. It was not possible to obtain sufficient data for all the trials under study to provide a reliable analysis of return to bowel function.

An economic analysis of local anaesthetic wound infusions is also needed - it seems likely that a greater amount of data is needed to clarify any trends in postoperative complications that may support the use of these infusions. Further large randomised controlled trials are required to investigate the promise of local anaesthetic wound infusions in major colorectal surgery, using standardized local anaesthetic agents, background analgesic regimens, experimental protocols, discharge criteria and anatomical site for wound infusion delivery.

In conclusion, Although suboptimal postoperative pain control is associated with cardiovascular, respiratory and gastrointestinal complications, many multimodal regimens for analgesia following major colorectal laparotomy provide inadequate pain relief. Although the number of trials available for meta-analysis is small, the available data demonstrate potential benefit in terms of reduction in opioid consumption following laparotomy for major colorectal surgery. Further large-scale studies will be needed to ascertain if any clear benefit or harm is conferred by the prophylactic use of local anaesthetic wound infusions in major colorectal surgery. Future research on this topic should also address the inaccuracies introduced by the methodological heterogeneity previously addressed in available trials, and provide a cost-effectiveness analysis of the use of continuous wound infusions in colorectal surgery.

COMMENTS

Background

Pain control following abdominal laparotomy and bowel anastomosis in colorectal surgery is a complex challenge not amenable to pharmacological monotherapy. Modern multimodal analgesic regimens may provide suboptimal postoperative pain control, which is associated with cardiovascular and respiratory complications and increased gastrointestinal paralysis.

Research frontiers

Continuous wound infusions of local anaesthetic agents have been suggested to provide improved pain control following a broad range of surgical incisions, both alone and as part of a multimodal analgesic regimen.

Innovations and breakthroughs

There is a need for a focused and quantitative review of the evidence for the analgesic benefit of continuous wound infusion of local anaesthetics specific to colorectal laparotomy, which is provided by this meta-analysis.

Applications

The meta-analysis demonstrates potential benefit in terms of reduction in opioid consumption following laparotomy for major colorectal surgery. The review highlights the need for future research on this topic and identifies that such future research should address the inaccuracies introduced by the methodological heterogeneity identified in available trials, and provides a cost-effectiveness analysis of the use of continuous wound infusions in colorectal surgery.

Terminology

Visual analogue scale (VAS) is a validated research tool used to quantitatively assess the subjective experience of patients' pain perception.

Peer review

The authors present a systematic analysis of local anaesthetics in wounds after open colorectal surgery. This is an area that has not been addressed by systematic analysis previously. It is a well-done and timely review.

Abstract

AIM: To determine if the presence *H pylori* or its virulence affect toll-like receptor 4 (TLR4) and TLR5 mRNA expression levels.

METHODS: For the *in vivo* assays, gastric biopsies were obtained from 40 patients and *H pylori* status was determined. For the *in vitro* assays, human gastric adenocarcinoma mucosal cells (AGS) were cultured in the presence or absence of twelve selected *H pylori* strains. *H pylori* strains isolated from culture-positive patients and selected strains were genotyped for *cagA* and *vacA*. The cDNA was obtained from mRNA extracted from biopsies and from infected AGS cells. TLR4 and TLR5 mRNA levels were examined by real-time PCR.

RESULTS: The presence of *H pylori* did not affect the mRNA levels of TLR4 or TLR5 in gastric biopsies. The mRNA levels of both receptors were not influenced by the *vacA* status ($P > 0.05$ for both receptors) and there were no differences in TLR4 or TLR5 mRNA levels among the different clinical presentations/histological findings ($P > 0.05$). In the *in vitro* assay, the mRNA levels of TLR4 or TLR5 in AGS cells were not influenced by the *vacAs1* status or the clinical condition associated with the strains ($P > 0.05$ for both TLR4 and TLR5).

CONCLUSION: The results of this study show that the mRNA levels of TLR4 and TLR5 in gastric cells, both *in vivo* and *in vitro*, are independent of *H pylori* colonization and suggest that *vacA* may not be a significant player in the first step of innate immune recognition mediated by TLR4 or TLR5.

Key words: *H pylori*; Toll-like receptor 4; Toll-like receptor 5; AGS cells; mRNA

INTRODUCTION

H pylori is a Gram-negative, flagellated bacterium that colonizes the gastric mucosa of approximately two-thirds of the world's population and is the primary cause of peptic ulcers and gastric adenocarcinoma. The complex interactions between different *H pylori* strains, the host immune system or environmental factors (or combinations thereof) are responsible for the significant variability in disease presentation associated with *H pylori* infection[1].

Vacuolating cytotoxin (VacA) and the CagA protein are the two major virulence markers usually associated with *H pylori* pathogenicity. VacA induces the formation of intracellular vacuoles in epithelial cell lines. Aside from its direct cell-damaging effect *in vitro*, VacA also plays a major role in inducing cytoskeletal changes, apoptosis and suppression of epithelial cell prolifera-

tion[2]. The *vac*A gene is present in all *H pylori* strains and contains at least two variable domains. The s-region, which encodes the signal peptide, exists as either an s1 or s2 isoform. The *vacA* s1 genotype has been linked to increased disease severity[2,3].

Some *H pylori* strains contain a pathogenicity island, which carries a number of virulence factors, including *cagA*, which is considered to be a marker for this island. A type Ⅳ secretory system translocates the CagA protein into host epithelial cells where it is phosphorylated by host-cell kinases[4]. *H pylori cagA*-positive strains have been associated with more severe inflammation of the gastric mucosa and more severe disease manifestations[1,2].

Toll-like receptors (TLRs) are a family of mammalian homologs of the *Drosophila* Toll proteins and, in mammalian systems, TLR4 confers responsiveness to Gram-negative lipopolysaccharide (LPS), while TLR5 recognizes flagellin[5]. Previous studies have shown that gastric epithelia express both TLR4 and TLR5[6-9]. Here, we studied the mRNA levels of TLR4 and TLR5 in gastric epithelial cells to determine if distinctive changes in the levels of mRNA could be affected by the presence of toxigenic and non-toxigenic (in particular *vacA*+ strains) *H pylori* strains.

MATERIALS AND METHODS

Study population, RNA isolation, and H pylori status

Forty patients (mean age, 58.3 years; age range, 18-81 years; F/M, 25/15) with indications of upper gastroduodenal endoscopy were included and the study was approved by the local ethics committee. Eighteen biopsy specimens were obtained from each patient. Total RNA was extracted from four of the biopsies from each patient (two from the antrum and two from the corpus) using Trizol® reagent (Invitrogen, Carlsbad, CA, USA) according to manufacturer's instructions. Eight biopsies were used for histological evaluation; two from the lesser curvature, two from the greater curvature, two from the incisura angularis, and two from the prepyloric region. Biopsies were fixed, paraffin embedded and examined histologically after hematoxylin-eosin staining.

Patients' *H pylori* status was determined by histology, the rapid urease test performed by an in-house validated test on two biopsies (one from the antrum and one from the corpus)[10], and culture analysis performed by standard methods on four biopsies (two from the antrum and two from the corpus)[11]. Bacterial genomic DNA was extracted from *H pylori* strains and typing for *cagA* and *vacA* was performed using primers previously described[3,12]. Patients were considered *H pylori*-positive when at least two of the diagnostic tests were positive.

Infection of AGS cells and RNA isolation

From our collection, we selected 12 strains that were isolated from patients with gastritis, distal gastric cancer, and peptic ulcer disease (4 from each pathologic/histologic finding). All strains were genotyped for *vacA* and *cagA* as described above. Human gastric epithelial AGS CRL-1739 cells were grown in RPMI 1640 supplemented with 10% FBS. *H pylori* bacteria were added at a multiplicity of infection (MOI) of 100:1, followed by a phosphate buffered saline (PBS) pH 7.4 wash to remove non-adherent bacteria. After 24 h, total RNA was isolated using the RNA tissue kit (Gentra Systems, Minneapolis, MN). The *H pylori* J99 ATCC 700824 strain was used as a control in all experiments.

Table 1 Distribution of *H pylori* infection status and the *H pylori* genotype

	***H pylori* genotype (*n* = 20 strains)**		
Diagnosis	*vacA s1*	*vacA s2*	*cagA*
Gastritis	5/15	10/15	15/15
Intestinal metaplasia	4/4	0/4	4/4
Antral ulcer	0/1	1/1	1/1
Atrophic gastritis	0/0	0/0	0/0

Reverse transcription and real-time PCR

Five micrograms of RNA were reverse-transcribed using SuperScript Ⅲ (Invitrogen) in a 20 μL reaction volume using oligo dT primers. The resulting cDNA was real-time-amplified in a final volume of 25 μL. The mix contained 1 U of Hot-Start *Taq* DNA polymerase (Invitrogen), 1 × reaction buffer, 200 μmol/L of each deoxynucleoside triphosphate (dNTPs), 3 mmol/L $MgCl_2$, 0.3 μmol/L of each primer and 0.25 × SYBR Green (Molecular Probes, Eugene OR). PCR was performed in glass capillaries using a Light Cycler instrument (Roche Applied Science, Indianapolis, IN). All reactions were performed in duplicate, and the thermal cycling conditions were 1 min at 94℃, followed by 35 cycles of 94℃ for 10 s, 59℃ for 10 s and 72℃ for 10 s with a ramp of 5℃/s. Real time PCR for glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was performed as described previously[7]. The relative amounts of the PCR products were calculated as the ratio of each TLR mRNA to GAPDH mRNA.

Statistical analysis

Comparisons were performed using a non-paired Student's *t* test. Analyses were carried out using the Statistics software 7.0 (Melbourne, Australia).

RESULTS

H pylori infection status and histological findings in the study population

The majority, 57.5 % (*n* = 23), of the patients examined were *H pylori* positive (F/M, 14/9; 22-81 years; 53.8 ± 20.3). Of the 40 patients in the study, 29 had gastritis confirmed by histology, 5 had intestinal metaplasia (IM) and 4 had antral ulcers. Only two patients had atrophic gastritis. All of the *H pylori* strains that were isolated were *cagA*-positive (Table 1).

TLR4 and TLR5 mRNA levels in gastric biopsies

We plotted the TLR/GADPH ratios for both TLR4

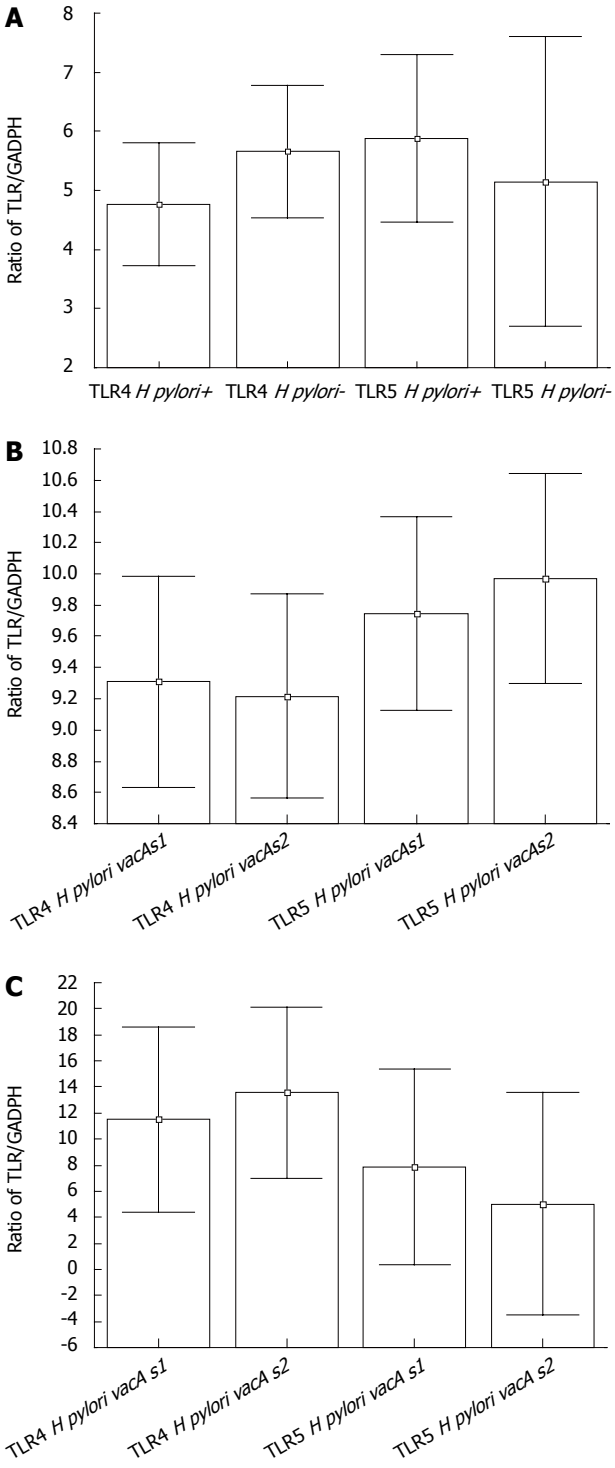

Figure 1 **A**: Mean (95% CI) ratio of TLR/GADPH mRNA levels for both TLR 4 and TLR5 in *H pylori*-positive and *H pylori*-negative patients; **B**: Mean (95%CI) TLR/GADPH mRNA ratios for both TLR 4 and TLR5 in patients infected with either *H pylori vacAs1* or *H pylori vacA s2* ($P > 0.05$ for both analysis); **C**: Mean (95% CI) TLR/GADPH mRNA ratios for both TLR 4 and TLR5 expression in AGS cells infected with *H pylori vacAs1* or *H pylori vacA s2*. All is $P > 0.05$.

and TLR5 in both infected and non-infected patients (Figure 1A). The presence of *H pylori* did not affect the mRNA levels of either Toll receptor. We did a similar analysis comparing patients infected with either *H pylori vacAs1* or *H pylori vacAs2* (Figure 1B). These data demonstrated that the mRNA levels of TLR4 and TLR5 were not influenced by the *vacA* status ($P > 0.05$ for both receptors). There were no differences in TLR4 or TLR5 mRNA levels between patients with different clinical presentations/histological findings ($P > 0.05$, data not shown). We were not able extract conclusions with respect to *cagA*, because all strains were *cagA* positive.

mRNA levels of TLR4 and TLR5 in AGS cells

Eleven (91.7%) of the selected strains were *cagA*-positive and there was an equal *vacA* s1 and s2 distribution between the strains examined. There were no differences in the mRNA levels of TLR4 or TLR5 regarding the *vacAs1* status or the clinical condition associated with the infecting strains ($P > 0.05$ for both TLR4 and TLR5, Figure 1C).

DISCUSSION

Several studies have addressed the mRNA levels and protein expression of TLR4 and TLR5 in gastrointestinal cells or in AGS cells[6-9,13]. In this study, we examined the mRNA levels of TLR4 and TLR5 in gastric epithelial cells (biopsies and AGS cells) in order to determine if significant changes in mRNA levels could be related to the presence of *H pylori* or differences between the virulence of the strains. Our examination of gastric biopsies from infected and non-infected patients showed that there were no quantitative differences in the mRNA levels of these receptors regardless of whether *H pylori* was present or of the patient's *H pylori vacA* status.

Gastritis is thought to precede the development of IM, antral ulcer or atrophic gastritis[1,2]. In this study, we included biopsies from 40 patients and among them, 29 had gastritis, 5 had IM, 4 had antral ulcers, and 2 had atrophic gastritis. When we compared the mRNA levels of both receptors between patients with gastritis and with each clinical condition/histological findings, we were unable to identify differences, suggesting that mRNA levels for both receptors may not be influenced by the infection process, or at least not at the time points selected for analysis.

Our analysis of TLR4 and TLR5 mRNA levels in AGS cells in the presence or absence of *H pylori* showed that the amounts of TLR4 and TLR5 mRNA in human gastric epithelial cells were independent of *H pylori vacA* status. In the *in vitro* assay, the analysis showed no differences in the amounts of TLR4 and TLR5 mRNA linked to different clinical conditions related to the *H pylori* strains selected.

Our results do not exclude the possibility of differential expression between TLR4 and TLR5 receptors since mRNA levels do not accurately reflect protein expression. In this study, we used quantitative real-time PCR, which is the most commonly used technique for studying mRNA expression levels[14]. This technique has some advantages, such as accuracy, sensitivity and reproducibility. Also, it allows for high throughput analyses and can be performed on very small samples. However, some problems associated with this

technique must be addressed, such as the effects of different amounts of starting material, especially when analyzing biopsies. To deal with this variation, an internal control (housekeeping gene) must be simultaneously amplified with the gene of interest for normalization purposes[15]. In this study, even though we included analysis of GADPH as an internal control we could not assume that protein expression levels of both receptors were equal based on the levels of detected mRNA.

An additional caveat was that the *in vivo* mRNA analysis of pooled biopsies from forty patients minimized the ability to identify biopsy-to-biopsy or patient-to-patient differences. Since RNA was extracted from all four antrum and corpus biopsies in the same vial, different gene expression profiles associated with different tissues would not have been detected. By analyzing four combined biopsies, it was possible that mRNA differences between corpus and antrum mucosal samples could have been missed. However, in the *in vitro* assay the mRNA levels obtained following infections with 12 different *H pylori* strains showed no differences in TLR expression. Although this is a uniform tissue, the observation that at least different *H pylori* strains did not affect TLR mRNA levels suggested that the same results would be observed in biopsy samples.

Some investigators have suggested that the subcellular distribution of receptors, rather than TLR expression level, could be relevant in the pathogenesis of inflammatory diseases because the expression of these receptors seems to be constitutive[7]. Our results are consistent with this view. Nonetheless, a study examining the cellular distribution of expression in relation to *H pylori vacA* status would be an interesting issue to address.

Schmausser *et al*[9], reported that gastric epithelium with intestinal metaplasia and dysplasia expressed TLR4 and TLR5. They demonstrated that 17 out of 22 patients strongly expressed TLR4 (77.27%) and all 22 patients with gastric carcinoma expressed TLR5. Our study confirmed the presence of TLR4 and TLR5 mRNA, which preceded the expression of both receptors.

It is likely that evaluating the roles of other Toll-like receptors would help elucidate differences in disease manifestation and severity of diseases caused by *H pylori* infections. Valuable information regarding the recognition of whole *H pylori* or its LPS by TLR2 has been reported. Smith *et al*[16] demonstrated that gastric epithelial cells recognized and responded to *H pylori* infection, at least in part, via TLR2 and that *H pylori* LPS was a TLR2 agonist.

Additionally, Mandell *et al*[17] demonstrated that cytokine responses to whole *H pylori* were mediated by TLR2. Based on these investigations, more work examining the role of TLR2 in relation to the *H pylori vacA* status is needed. The results of this study show that the TLR4 and TLR5 mRNA levels in gastric cells both *in vivo* and *in vitro* are independent of *H pylori* and suggest that *vacA* may not be involved in the first steps of innate immune-recognition of *H pylori*.

COMMENTS

Background

H pylori is the primary cause of peptic ulcers and gastric adenocarcinoma. The variability of clinical manifestations is associated with bacterial, host immune responses and environmental factors.

Research frontiers

Gastric epithelia express toll-like receptor 4 (TLR4) and TLR5. We studied the mRNA levels of TLR4 and TLR5 in gastric epithelial cells to determine if distinctive changes in mRNA levels could be influenced by the presence of toxigenic *H pylori* strains.

Innovations and breakthroughs

In this study, *we* analyzed the mRNA levels of both TLR4 and TLR5 in gastric biopsies from infected and non-infected patients and in AGS cells infected with *H pylori*. We correlated these results with the *vacA* status of the strains. There were no quantitative differences in the mRNA levels of these receptors regardless of *H pylori* presence or the *H pylori vacA* status both in gastric biopsies and in AGS cells.

Applications

The mRNA levels of TLR4 and TLR5 in gastric cells both *in vivo* and *in vitro* are independent of *H pylori* or their *vacA* status.

Peer review

The results show that the mRNA levels of TLR4 and TLR5 in gastric cells are not influenced by *H pylori vacA* status and suggest that *vacA* may not be a significant player in the first step of innate immune recognition mediated by TLR4 or TLR5. It seems innovative and very interesting.

Abstract

AIM: To evaluate the chemoradiotherapy for locally advanced pancreatic cancer utilizing low dose gemcitabine as a radiation sensitizer administered twice weekly.

METHODS: We performed a retrospective analysis of chemoradiotherapy utilizing gemcitabine administered twice weekly at a dose of 40 mg/m^2. After that, maintenance systemic chemotherapy with gemcitabine, at a dose of 1000 mg/m^2, was administered weekly for 3 wk with 1-wk rest until disease progression or unacceptable toxicity developed.

RESULTS: Eighteen patients with locally advanced unresectable pancreatic cancer were enrolled. Three of those patients could not continue with the therapy; one patient had interstitial pneumonia during radiation therapy and two other patients showed liver metastasis or peritoneal metastasis during an early stage of the therapy. The median survival was 15.0 mo and the overall 1-year survival rate was 60%, while the median progression-free survival was 8.0 mo. The subgroup which showed the reduction of tumor development, more than 50% showed a tendency for a better prognosis; however, other parameters including age, gender and performance status did not correlate with survival. The median survival of the groups that died of liver metastasis and peritoneal metastasis were 13.0 mo and 27.7 mo, respectively.

CONCLUSION: Chemoradiotherapy with low-dose gemcitabine administered twice weekly could be effective to patients with locally advanced pancreatic cancer; however, patients developing liver metastases had a worse prognosis. Another chemoradiotherapy strategy might be needed for those patients, such as administrating one or two cycles of chemotherapy initially, followed by chemoradiotherapy for the cases with no distant metastases.

Key words: Advanced pancreatic cancer; Chemoradiotherapy; Gemcitabine; Radiosensitizer; Tumor marker

INTRODUCTION

Pancreatic cancer is one of the leading causes of cancer death in the world and in most patients the tumor is surgically unresectable at the time of diagnosis[1]. Even in the patient with complete surgical resection, both distant and local patterns of recurrence are common[2]. In approximately 50% of resected pancreatic tumors, the surgical margins are involved with tumor cells, so it can be assumed that most patients are harboring occult metastases at the time of diagnosis[3]. Recently, studies for adjuvant chemotherapy or chemoradiotherapy, and those for neoadjuvant chemotherapy or chemoradiotherapy have been investigated[3-6].

For patients with locally advanced pancreatic cancer, chemoradiotherapy has been accepted as a standard treatment[7]. The results of previous randomized trials

have indicated that external-beam radiation therapy and 5-fluorouracil (5-FU) therapy results in a significantly longer survival time than radiotherapy[8] or chemotherapy alone[9]. Gemcitabine, a deoxycytidine analog that functions as an antimetabolite, has been approved for use in patients with advanced pancreatic cancer[10,11]. In a randomized study, gemcitabine improved survival in inoperable pancreatic cancer in comparison with 5-FU[12]. Gemcitabine has also been shown to exert an effect in 5-FU-refractory pancreatic cancer[13]. Gemcitabine has also been shown to be a potent radiosensitizer, both *in vivo* and *in vitro*[14]. The vast majority of the reported phase I-Ⅲ clinical trials have used gemcitabine as a single agent given weekly in a single dose[7,15,16] (i.e. 250 mg/m^2).

Several preclinical data, including animal studies[17], would suggest that maximum radiation sensitization with gemcitabine is observed at a lower dose administered twice weekly[15,17]. Blackstock *et al*[14,15] and Magnino *et al*[18] reported on a phase Ⅱ study of chemoradiotherapy in which the patient's were treated with gemcitabine twice weekly at 40 mg/m^2 and 50 mg/m^2, respectively, associated with radiotherapy. Therefore, in the present study, we analyzed the results of retrospective analysis of chemoradiotherapy for locally advanced pancreatic cancer, utilizing gemcitabine as a radiation sensitizer administered twice weekly at a dose of 40 mg/m^2, followed by maintenance systemic chemotherapy with gemcitabine.

MATERIALS AND METHODS

Eligibility criteria included (1) locally advanced unresectable pancreatic cancer confirmed histologically or by imaging techniques including systemic computed tomography; (2) 20-74 years of age; (3) ECOG performance status of 0-2; (4) adequate hematological function, and adequate renal function, and (5) no prior anti-cancer treatment. A total dose of 40-50.4 Gy was delivered using 1.8-2.0 Gy daily fractions. Treatment planning was determined by a three-dimensional treatment planner. The targeted irradiation volume included the tumor, possible surrounding edema, and 1-cm margin. Gemcitabine, at a dose of 40 mg/m^2, was administered as a 30-min intravenous infusion twice weekly (80 mg/m^2 per week) for 4-5 wk. Gemcitabine was given within 2 h before radiation treatment. At 2 wk after the completion of chemoradiotherapy, maintenance systemic chemotherapy of gemcitabine at a dose of 1000 mg/m^2 was administered as a 30-min intravenous infusion weekly for 3 wk with 1-wk rest until disease progression or unacceptable toxicity. Both radiation therapy and chemotherapy were suspended for grade 3 hematological toxicities or grade 2 non-hematological toxicities (according to the National Cancer Institute Common Toxicity Criteria) during the treatment course, and treatment was resumed when toxicity was resolved. The objective tumor response, as defined by the WHO criteria, was assessed every 2 mo or 3 mo by computed tomography scan or earlier if clinically indicated.

The Kaplan-Meier method was used to estimate the distribution of overall survival and progression free survival. Progression free survival was calculated from the first day of treatment until there was evidence of clinical progression, tumor progression assessed by computed tomography scan measurement or death. Overall survival was calculated from the first day of treatment until the date of death. In this study, there is no control arm to treat the locally advanced pancreatic cancer.

Table 1 Patient characteristics

Number of patients completing the protocol	15
Gender	
Male	9 (60%)
Female	6 (40%)
Age (yr)	
Mean (range)	62.2 (50-73)
Tumor location	
Head	7 (46.7%)
Head-Body	1 (6.6%)
Body-Tail	7 (46.7%)
Total radiation dose	
40.0 Gy	12 (80%)
50.0 Gy	1 (6.6%)
50.4 Gy	2 (13.4%)
Response	
Complete response	1 (6.6%)
Partial response	4 (26.7%)
Stable disease	9 (60 %)
Progressive disease	1 (6.6%)
Cause of death	
Liver metastasis	10 (66.7%)
Peritoneal metastasis	3 (20%)

RESULTS

Clinical data

Eighteen patients were enrolled in this study. Three of those patients could not continue with the therapy under this protocol; one patient had interstitial pneumonia during radiation therapy and two other patients showed liver metastasis or peritoneal metastasis in an early stage of this protocol. Fifteen patients, including nine males and six females, completed therapy as planned and patient characteristics are shown in Table 1. The mean age was 62.2 years old (range, 50-73). The mean diameter of the tumor was 4.8-cm and the tumor was located in the pancreatic head in seven patients. Twelve patients received radiotherapy at a total of 40-Gy, two patients at a total dose of 50-Gy and one patient with 50.4-Gy. In general, therapy was well tolerated, one patient suffered AGML and another patient had an eruption. All the patients showed elevation of tumor markers, including CA19-9, Span-1 and DUPAN-2, at the enrollment for this study.

Survival

Regarding overall response, there was one complete response, 4 partial responses, 9 stable diseases and one progressive disease; the response rate was 33%. No patients could undergo tumor resection even after the completion of chemoradiotherapy, because of infiltration

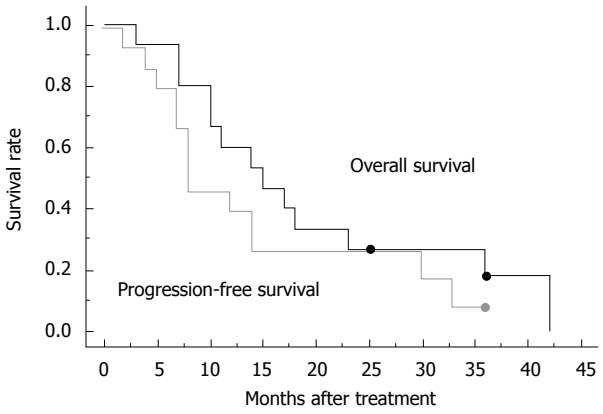

Figure 1 Overall survival curve and progression-free survival curve for 15 patients who received chemoradiotherapy under this study protocol. Dot indicates censored cases.

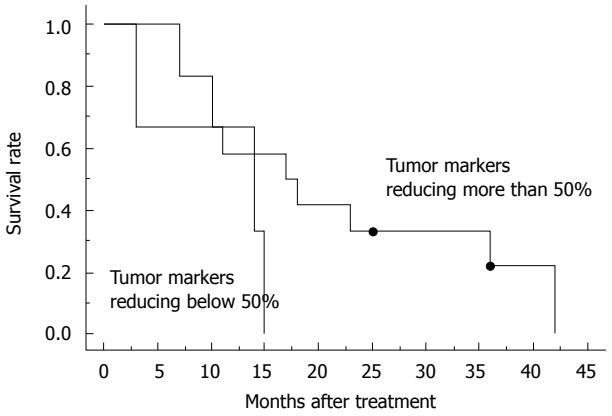

Figure 2 Overall survival curve for patients with tumor markers reducing more than 50% compared to that of pretreatment (n = 12) and those reducing below 50% (n = 3). Dot indicates censored cases.

of the adjacent large vessels. The median survival was 15.0 mo and the overall 1-year survival rate was 60%, while the median progression-free survival was 8.0 mo, estimated by the Kaplan-Meier method (Figure 1). In 80% of the patients, the level of tumor marker, including CA19-9, Span-1 and DUPAN-2, was reduced more than 50% compared to that of pretreatment. The subgroup where the tumor marker was reduced more than 50% had a tendency for a better prognosis (Figure 2), compared to the group with reduced tumor marker below 50% of pretreatment. Blackstock *et al*[15] postulated previously that the extended median survival observed in the CA19-9 responding patients might reflect the impact of the improved local control. However, a recent study demonstrated that pretreatment serum CA19-9 concentration was an independent prognostic factor for survival for advanced pancreatic cancer, but a decrease in concentration during chemotherapy was not significantly associated with lengthened survival compared with those who did not have a corresponding decrease[19]; therefore, the importance of decreasing in serum tumor marker concentration during therapy requires further discussion. In the subgroup with a tumor size less than 4-cm in diameter, median progression-free survival was 14.0 mo,

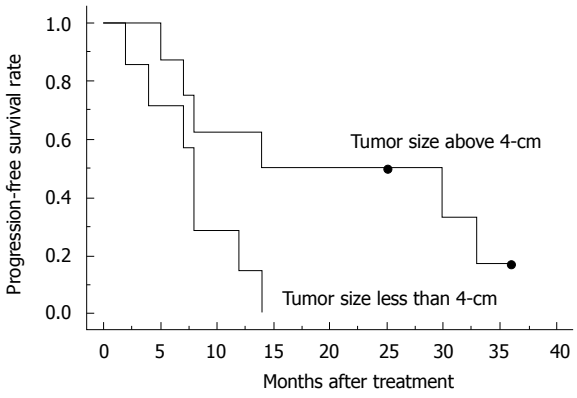

Figure 3 Progression free-survival curve for patients with tumor size less than 4-cm (n = 6) and those with a size above 4-cm (n = 9). Dot indicates censored cases.

which was better than those above 4-cm in diameter (8.0 mo, Figure 3). Other parameters, including age, gender and performance status, did not correlate with survival. The major causes of death were liver metastasis and peritoneal metastasis. The median survival of the groups that died of liver metastasis and peritoneal metastasis were 13.0 mo and 27.7 mo, respectively.

DISCUSSION

A recent retrospective comparison of the toxicity and efficacy of concurrent gemcitabine-based chemoradiotherapy with that of 5-FU based chemoradiotherapy for the patients with unresectable pancreatic cancer[20], showed a significantly higher toxicity rate in patients treated with gemcitabine and similar median survival times between the two arms. Investigators in Taiwan[21] reported favorable results for chemoradiotherapy with concurrent gemcitabine administration (600 mg/m^2 once a week); however, this needs further confirmation by larger multi-institutional clinical trials.

Although this study, using a twice weekly gemcitabine infusion schedule for locally advanced pancreatic cancer was not a controlled study, the results of the median survival time, median disease free survival time and overall 1-year survival rate was found to be preferable compared to previous studies[7-9,15]. Okusaka *et al*[7] presented data of a phase Ⅱ study for locally advanced pancreatic cancer treated with external-beam radiation (50.4 Gy) and weekly gemcitabine (250 mg/m^2 once a week) followed by maintenance chemotherapy using gemcitabine. The median survival time, median progression-free survival time and 1-year survival rate was 9.5 mo, 4.4 mo and 28%, respectively[7]. An expanded retrospective review of patients receiving gemcitabine-based chemoradiotherapy at the M. D. Anderson Cancer Center reflected the difficulties combining the systemic toxicities of 200-500 mg/m^2 doses of gemcitabine with the local-regional toxicities associated with chemoradiotherapy to the upper abdomen[22]. Furthermore, in the original GITSG trial of radiation and 5-FU based chemotherapy, 18% and 21% of the patients randomized into the

40-Gy and the 60-Gy treatment arms, respectively, were unable to complete all planned radiation[8]. For those patients completing the chemoradiotherapy, almost one-third were unable to initiate the planned maintenance 5-FU chemotherapy[8]. In this study, 15 of 18 patients could complete the planned protocol which might have come from the treatment with gemcitabine administered *via* a twice weekly infusion with radiation therapy and that most patients received radiation therapy at a total dose of 40-Gy. This might have resulted in the successful initiation in the maintenance of gemcitabine chemotherapy and to obtain a feasible survival rate in this trial. Some investigators did not propose maintenance chemotherapy after chemoradiotherapy[1]. Several studies of chemoradiotherapy used a therapeutic sequence with prior chemoradiotherapy and then chemotherapy until disease progression, but increased toxicity of chemotherapy after chemoradiotherapy limits this strategy[23,24], which might partially contribute to the total dose of radiation.

Two of the three patients enrolled initially who did not continue with the therapy under this protocol showed liver metastasis or peritoneal metastasis in the early stage of this protocol. Blackstock *et al*[15] pointed out in their study that the radiation sensitizing properties of twice weekly gemcitabine were important for improving the local control, and did not impact the survival for patients harboring micrometastatic disease at the initiation treatment. Hugutet *et al*[1] discussed that, an important concern about administrating chemoradiotherapy as first-line treatment in patients with locally advanced pancreatic cancer was that approximately 30% of them had occult metastatic disease at diagnosis and thus, they would clearly not benefit from this locoregional treatment. Furthermore, another investigator demonstrated that a fraction of patients with locally advanced pancreatic cancer developed metastases within a few weeks and died very quickly despite the type of treatment[25]. In this study, the patients who developed liver metastasis had a worse prognosis, which might owe to the miss-diagnosis of the staging of the disease at the initiation of the therapy, because of failure to detect micrometastasis by conventional imaging modalities. In this situation, we might need another strategy for the chemoradiotherapy for locally advanced pancreatic cancer, such as one in which the patients receive one or two cycles of systemic chemotherapy using gemcitabine at a dose of 1000 mg/m^2 weekly for 3 wk with 1-wk rest, and then re-evaluated the staging of the disease, initiating the chemoradiotherapy under the protocol in this study. A recent study suggested that after control of disease by initial chemotherapy for at least 3 mo using combination of leucovorin, fluorouracil and gemcitabine, or gemcitabine and oxaliplatin, chemoradiotherapy with 5-FU, could significantly improve survival in patients with locally advanced pancreatic cancer compared with chemotherapy alone[1].

In conclusion, chemoradiotherapy with low-dose gemcitabine given twice weekly could be effective to patients with locally advanced pancreatic cancer; however, patients developing liver metastases had a worse prognosis. We might need another strategy for the chemoradiotherapy for those patients. Further investigations are required in the near future.

COMMENTS

Background

Pancreatic cancer is the fifth most common cause of cancer death in Japan. The prognosis is extremely poor because it is difficult to detect this disease in the early stage and also the postoperative incidence of recurrence is still high. We do not have any effective treatment for inoperable patients. Recently, chemoradiotherapy has been regarded as one of the standard therapies for locally advanced pancreatic cancer and it has improved the survival and presented a clinical benefit.

Research frontiers

In the early 1980s, fluorouracil-based concomitant chemoradiotherapy was shown to be better than radiotherapy alone for patients with locally advanced pancreatic cancer. Gemcitabine has improved the outcome of patients with advanced disease by improving survival with a clinical benefit. Gemcitabine also has been shown to be a potent radiosensitizer, both *in vivo* and *in vitro*. The vast majority of the reported phase Ⅰ-Ⅲ clinical trials have used gemcitabine as a single agent given weekly in a single dose (i.e. 250 mg/m^2), and there is no consensus of the protocol of the administration of gemcitabine.

Innovations and breakthroughs

Several preclinical data, including animal studies, would suggest that maximum radiation sensitization with gemcitabine is observed at a lower dose administered twice weekly. In this study, we show that we could obtain the feasible results of survival compared to previous studies using our protocol. There existed some patients who could not continue the therapy, because of developing metastases. One reason could be the failure to detect micrometastasis by conventional imaging modalities at the beginning of chemoradiotherapy.

Applications

Chemoradiotherapy, with low-dose gemcitabine given twice weekly, could be effective to patients with locally advanced pancreatic cancer. To improve this survival data, we may need stricter selection of the cases suitable for this chemoradiotherapy; however, using conventional imaging modalities, it seems to be hard to diagnose the micrometastasis, especially in the liver before this chemoradiotherapy. Another strategy that may be useful is where patients receive one or two cycles of systemic chemotherapy using gemcitabine at a dose of 1000 mg/m^2 weekly for 3 wk with 1-wk rest, and then be re-evaluated for the staging of the disease, and then initiating the chemoradiotherapy under the protocol in this study.

Peer review

This is a nicely written paper that looks at the use of gemcitabine as a radiation sensitizer for pancreatic cancer. They report on twice-weekly doses. This dose contributes new information to the literature.

Abstract

AIM: To investigate the therapeutic usefulness of leukocytapheresis (LCAP; Cellsoba) in steroid-naive patients with moderately active ulcerative colitis (UC).

METHODS: Eighteen steroid-naive patients with moderately active UC received one LCAP session every week for five consecutive weeks.

RESULTS: The remission rate 8 weeks after the last LCAP session was 61.1% (11/18). All three patients with deep ulcers showed worsening after LCAP. For the remaining 15 patients, who had erosions or geographic ulcers, the average clinical activity index (CAI) score dropped significantly from 9.4 to 3.8 eight weeks after the last LCAP session (t = 4.89, P = 0.001). The average C-reactive protein (CRP) levels before and after LCAP were 1.2 mg/dL and 1.0 mg/dL, respectively. Of the patients with erosions, geographic ulcers, and deep ulcers, 100% (9/9), 33.3% (2/6), and 0% (0/3) were in remission 8 weeks after the last LCAP session, respectively (χ^2 = 7.65, P < 0.005). Forty-eight weeks after the last LCAP session, the remission rates for patients with erosions and geographic ulcers were 44.4% (4/9) and 16.7% (1/6), respectively. Only one patient suffered a mild adverse event after LCAP (nausea).

CONCLUSION: LCAP is a useful and safe therapy for steroid-naive UC patients with moderate disease activity. Moreover, the efficacy of the treatment can be predicted on the basis of endoscopic findings.

Key words: Ulcerative colitis; Steroid-naive; Leukocytapheresis; Efficacy; Endoscopic findings

INTRODUCTION

Although the etiology of ulcerative colitis (UC) is still unknown, it is believed that an immune abnormality may be involved in its development[1,2]. It is characterized by chronic over-activation of the colonic mucosal immune system. Consequently, if remission cannot be achieved by salazosulfapyridine or mesalazine treatment, the second line of treatment has conventionally been to administer steroids[2-6]. However, steroid administration can increase susceptibility to infections, diabetes mellitus and osteoporosis. Recently, it was reported that steroid-refractory or steroid-dependent patients with UC can be effectively treated by cytapheresis[7-10]. To determine whether leukocytapheresis (LCAP) may also be useful with other UC patients, we administered LCAP to 18 steroid-naive UC patients. We also assessed whether the efficacy of LCAP can be predicted on the basis of endoscopic findings.

MATERIALS AND METHODS

From January 2005 to April 2007, 33 UC patients were treated with LCAP at our hospital. All patients were

Table 1 Steroid-naïve UC patient characteristics (mean ± SD)

examined by colonoscopy before treatment and UC was diagnosed on the basis of established endoscopic and histological criteria[11]. At the time of diagnosis, infectious colitis (*Salmonella, Campylobacter, Vibrio, Yersinia* and *Shigella spp.*) was ruled out by stool culture and *Clostridium difficile* toxin testing. Moreover, we excluded Crohn's disease, ischemic colitis, radiation colitis and intestinal Behçet disease. None of patients were receiving drugs, including non-steroidal anti-inflammatory drugs or antibiotics. Patients with severe cardiovascular disease, severe cerebral disease, severe anemia (hemoglobin; less than 8 g/dL) and hypotension (less than 80 mmHg) were excluded. Of the 33 patients, 15 had severe activity and were treated with steroids along with LCAP. These patients were excluded from the study. The remaining 18 steroid-naive patients had moderate activity, as defined by a Lichtiger's clinical activity index (CAI) score[12] of < 12. These patients were enrolled in the study. Their characteristics are summarized in Table 1.

For all patients, LCAP sessions were performed once a week for five consecutive weeks by using Cellsorba (Asahi Medical Co., Ltd, Tokyo, Japan). Leukocyte removal in LCAP is effective because of its adherence to fibers in the filter. The throughput was 2-3 L of whole blood and the flow rate was 30-50 mL/min for approximately 60 min. The access and return lines were connected to cubital veins. Heparin was used as an anticoagulant for the extracorporeal circulation.

Patients were 46.1 ± 18.4 years old; there were 11 males and 7 females. Their duration of disease was 6.0 ± 8.5 years. With regard to their clinical course, four patients presented the "first attack" type, six the "relapse-remitting" type, and eight the "chronic continuous" type. We defined patients presenting with an activity phase lasting for 6 mo or longer from the first attack as belonging to the "chronic continuous" type. Fifteen patients had total colitis, two had left-sided colitis and one had proctitis. We performed endoscopy before and after LCAP. For the present study, we classified the patients into three groups on the basis of the endoscopic findings before LCAP treatment, namely, those with erosions, geographic ulcers, or deep ulcers (Figure 1). Nine patients had erosions in the large intestine, six had geographic ulcers, and three had deep ulcers. All patients were concomitantly treated with mesalazine (2250 mg/d) for at least 4 weeks prior to the initiation of LCAP therapy. There was no change in the dosage of mesalazine. Immunomodulators such as azathioprine, 6-mercaptopurine and cyclosporine were never administered.

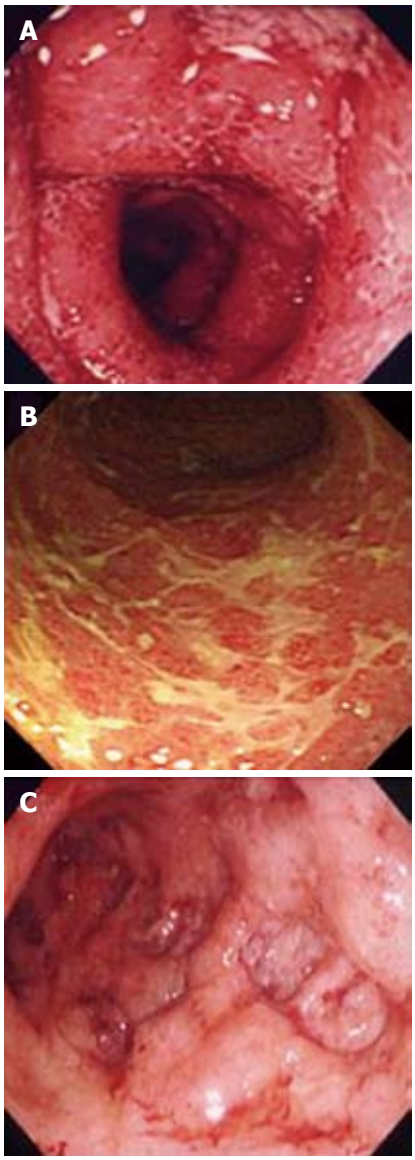

Figure 1 The patients were divided before LCAP into three groups according to whether their endoscopic findings revealed erosions (**A**), geographic ulcers (**B**), or deep ulcers (**C**). Representative findings are shown.

Disease activity was evaluated before and after LCAP by measuring the CAI. A CAI less than 4 indicates remission. Relapses were also identified when the patient needed another therapy, such as steroid or cyclosporine treatment and/or LCAP.

The endpoint of this study was to determine the factor related to remission by LCAP.

Statistical analysis

The Wilcoxon test was used to compare CAI scores

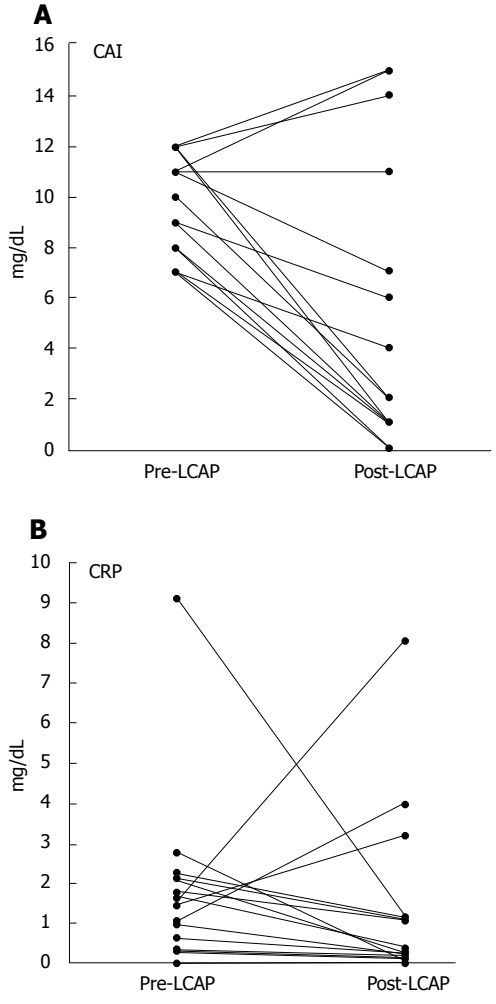

Figure 2 Change in average CAI score (**A**) and CRP levels (**B**) 8 wk after the last LCAP session. The data of the three patients with deep ulcers whose conditions worsened during LCAP are not included. The average CAI dropped from 9.4 ± 1.9 to 3.8 ± 4.8 (P = 0.001) while the average CRP levels before and after LCAP were 1.2 ± 0.8 mg/dL and 1.0 ± 2.0 mg/dL, respectively, and did not differ significantly.

and C-reactive protein (CRP) levels before and after treatment. The Mann-Whitney U-test was used to compare the age, duration of disease, pre-CAI, post-CAI, pre-CRP and post-CRP levels of two groups, while the χ^2 test was used to test the effect of sex. χ^2 test was used to compare the clinical course, extent of disease and endoscopic findings of two groups. $P < 0.05$ was considered to indicate statistical significance. Results were presented as mean ± SD.

RESULTS

Efficacy of LCAP

For all 18 patients, the remission rates 8 and 48 wk after the last LCAP session were 61.1% (11/18) and 27.7% (5/18), respectively. At 48 wk after remission, the relapse rate was 54.5% (6/11), and the duration to relapse was 8.7 ± 4.2 mo. Three patients with deep ulcers worsened during LCAP and required additional treatments such as steroids. However, the remaining 15 patients showed a significant drop in the CAI score from 9.4 ± 1.9 to 3.8 ± 4.8 eight weeks after the last LCAP session (P = 0.001) (Figure 2). The CRP levels before (1.2 ± 0.8 mg/dL) and after (1.0 ± 2.0 mg/dL) LCAP did not differ significantly (Figure 2). When the endoscopic findings obtained before LCAP were considered, we found that all nine patients with erosions had entered remission (100%) 8 wk after the last LCAP session. However, only two of six (33%) and none of three of the patients with geographic ulcers and deep ulcers, respectively, had entered remission at this time point ($P < 0.005$) (Table 2). The remission rates dropped over time as of the patients with erosions and geographic ulcers who were in remission at the 8-wk timepoint, 44.4% (4/9) and 16.7% (1/6) remained in remission 48 wk after LCAP.

LCAP: Leukocytapheresis; CAI: Clinical activity index; CRP: C-reactive protein levels (mg/dL).

Clinical characteristics of the patients who entered remission

Table 2 shows how the responders compare to the non-responders 8 wk after LCAP. These two groups did not differ significantly in patient characteristics (i.e., sex, age, duration of disease, pre-CAI levels and pre-CRP levels). However, all first attack and relapse-remitting type patients entered remission while seven of the eight chronic continuous type patients did not ($P < 0.001$). Whether there was total colitis, left-sided colitis, or proctitis was not significantly associated with the ability of the patient to enter remission after LCAP. As indicated above, with regard to the endoscopic findings, all patients with erosions entered remission after LCAP but it was more difficult to induce remission in patients with geographic ulcers or deep ulcers ($P < 0.005$).

Clinical characteristic of the patients who entered remission and then relapsed

Of the 11 patients who entered remission 8 wk after LCAP, six relapsed. Table 3 summarizes the

Table 3 Comparison of the remission and relapse groups 48 wk after the last LCAP session (mean ± SD)

characteristics of the five patients who remained in remission 48 wk after LCAP and the six relapsed patients. The two groups only differed significantly in terms of the post-CAI scores ($P < 0.05$). None of the other parameters, namely, the clinical course, extent of disease, or endoscopic findings, correlated with relapse.

Course of the cases who worsened during LCAP

Table 4 summarizes the courses of the three cases with deep ulcers that worsened during LCAP. As a result, two cases were given steroids and one case received cyclosporine. Two patients became infected with cytomegalovirus and received ganciclovir. After a transient improvement, two patients relapsed and underwent surgery. The remaining patient, who developed interstitial pneumonitis, died of aspiration pneumonitis. Aspiration pneumonitis developed 3 mo after LCAP, and therefore the two events were probably unrelated to each other. We think that interstitial pneumonitis was a cause of the development of aspiration pneumonitis.

Adverse effects

None of the patients experienced any severe adverse effects from LCAP. Only one patient reported a mild adverse event (nausea). However, this patient did not suffer from the same problem after subsequent LCAP sessions.

DISCUSSION

When UC patients fail to enter remission after salazosulfapyridine or mesalazine treatment, the conventional second-line therapy involves administration of steroids[13,14]. However, steroids can cause severe side effects in some patients[15,16]. When patients with severe

Table 4 Course of cases whose condition worsened during LCAP

activity fail to respond to steroids, they must undergo a colectomy, although cyclosporine can sometimes induce remission in these cases[17-20]. In 1995, Sawada *et al*[21] introduced LCAP therapy for patients with UC. This therapy is now a widely used treatment option for UC[22,23]. LCAP is a method where the blood is passed though a leukocyte removal filter before being returned to the body. On average, 1.6×10^{10} leukocytes are removed during one session. These leukocytes include granulocytes, lymphocytes and monocytes. Almost 100% of granulocytes and monocytes and 60% of lymphocytes are removed by removal filter[24,25]. It has been reported that 73.3% of steroid-refractory patients with UC enter remission after LCAP[26]. It is likely that this treatment is effective because it reduces the number of leukocytes available for transmigration and infiltration into the colonic mucosa.

In this study, we found that 61.1% of steroid-naive UC patients (11/18) had entered remission 8 wk after the last LCAP session. At this time point, the average CAI score had dropped significantly from 9.4 ± 1.9 to 3.8 ± 4.8 ($P = 0.001$) (the three cases who worsened during LCAP were excluded from this calculation). Since steroids can induce remission in 45% to 90% of salazosulfapyridine or mesalazine non-responders[15,27-29], it appears that LCAP is as efficacious as steroids as a second-line treatment. Given the low rate of adverse events suffered by patients treated with LCAP, we propose that patients with moderately active UC should be treated with LCAP before steroids are considered. It should be noted, however, that 54.5% of the patients in remission (6/11) relapsed 48 wk after the last LCAP session, and that the average duration to relapse was 8.7 mo. Thus, while LCAP is useful for inducing remission in steroid-naive UC patients, it does not maintain remission.

Analysis of the endoscopic findings of the patients revealed that while all nine patients with erosions had entered remission 8 wk after the last LCAP session, only two of six (33%) and none of three patients with geographic ulcers and deep ulcers, respectively, entered remission. Indeed, the three cases with deep ulcers worsened during LCAP and had to be given steroids (2 cases) or cyclosporine (1 case). Two of these cases became infected with cytomegalovirus and were administered ganciclovir. These observations suggest that patients with geographic ulcers and deep ulcers tend to be refractory to LCAP, particularly the latter. Indeed,

LCAP may not improve the situation for patients with deep ulcers given their higher risk of developing cytomegalovirus infections[30]. Such patients should perhaps be treated with an intensive therapy such as cyclosporine at a more early stage[31]. However, since all patients with erosion entered remission 8 wk after LCAP and many (44.4%) remained in remission at the 48-wk time point, LCAP is strongly recommended for patients with erosion.

The post-CAI was the only factor that predicted a relapse. In other words, if the post-CAI could be maintained at < 1 by LCAP, it may be possible to maintain long duration remission.

In conclusion, LCAP is a useful and safe therapy for steroid-naive UC patients with moderate activity. Moreover, endoscopic findings help to predict the efficacy of this treatment.

COMMENTS

Background

An immune dysfunction is believed to be involved in the development of ulcerative colitis (UC). For a long time, steroids have represented the second line therapy for the induction to remission in UC, if remission cannot be achieved by salazosulfapyridine or mesalazine treatment. However, steroid administration can cause several side effects. Leukocytapheresis (LCAP) have been reported to be effective for steroid-refractory or steroid-dependent patients with UC; however, the data of LCAP for steroid-naïve patient with UC is limited.

Research frontiers

To determine whether LCAP may also be useful in steroid-naive UC patients, these authors administered LCAP to steroid-naive UC patients. They also assessed whether the efficacy of LCAP can be predicted on the basis of endoscopic findings.

Innovations and breakthroughs

The authors found that 61.1% of steroid-naive UC patients (11/18) had entered remission 8 wk after the last LCAP session. Since steroids can induce remission in 45% to 90% of salazosulfapyridine or mesalazine non-responders, it appears that LCAP is as efficacious as steroids as a second-line treatment. Analysis of the endoscopic findings of the patients revealed that the remission rate of the patients with erosion was extremely high after LCAP, compared to the extremely low rate observed in patients with geographic ulcers and deep ulcers. None of the patients experienced any severe adverse effects from LCAP.

Applications

Given the low rate of adverse events suffered by patients treated with LCAP, authors propose that patients with moderately active UC should be treated with LCAP before steroids are considered.

Terminology

LCAP is a treatment procedure where leukocytes are removed through their adherence to fibers in the filter.

Peer review

LCAP is a useful and safe therapy for steroid-naive UC patients with moderate activity. Moreover, endoscopic findings help to predict the efficacy of this treatment. This is an interesting study.

Abstract

AIM: To study halothane hepatitis (HH) in Iran and its associated risk factors.

METHODS: We retrospectively studied files of all cases diagnosed with HH referred to three referral hospitals and four private centers in Iran from April 1994 to September 2006. Information on age at surgery, gender, medications history, obesity, history of previous exposure, previous reaction to halothane, familial history, type of surgery, perioperative hypoxia or sepsis, morbidity and mortality were recorded and analyzed.

RESULTS: A total of 59 cases were identified. Forty-eight (81%) were women. The median age at the time of surgery was 44 years (range, 18 to 80 years). Sixty percent of patients were above 40-year-old. Obesity was observed in 22.2%. Previous history of exposures to halothane was noted in 61% of which 50% had history of post-exposure reaction. Coronary artery bypass graft (CABG), cholecystectomy, and cosmetic surgeries (mainly weight reduction) were the most frequent surgeries. The mortality rate was 12.2%. In patients developing encephalopathy, it was as high as 50%.

CONCLUSION: HH remains an important cause of morbidity and mortality in centers still using this anesthetic. However, a large percentage of these cases could have been avoided. To lessen occurrence of further cases of HH, the authors suggest that in female patients having a history of surgery (or delivery) with general anesthesia, the use of halothane should be absolutely avoided. Utilization of proper substitutes in adults' anesthesia is advocated.

Key words: Anesthesia; Inhalation; Halothane; Hepatitis; Drug-induced

INTRODUCTION

Halothane was first introduced to clinical practice in 1956 and was immediately recognized as a great advance in anesthesia[1]. First reports of postoperative liver necrosis with halothane began to appear in 1958[2,3] followed by further anecdotal reports[4-7]. By 1963, 7 years after the introduction of halothane, at least 350 cases of "halothane hepatitis" (HH) had been reported[8]. These reports led to the National Halothane Study, which estimated fatal hepatic necrosis following halothane anesthesia to be approximately 1 in 35 000 in the US[9]. Other retrospective studies confirmed that halothane was associated with severe liver dysfunction, with an incidence ranging from 1 in 6000 to 1 in 35 000[10].

Two major types of hepatotoxicity are associated with halothane administration: type I (mild) and type Ⅱ (fulminant). Type Ⅱ hepatotoxicity is associated with massive centrilobular liver cell necrosis that leads to fulminant liver failure and is clinically characterized by fever, jaundice, and grossly elevated serum transaminase levels. It appears to be immune mediated and initiated by oxidative halothane metabolism by cytochrome P450 to an intermediate compound. This compound binds to trifluoroacetylate proteins in the hepatic endoplasmic reticulum, thought to occur in genetically predisposed

individuals[11]. In this study, type Ⅱ hepatotoxicity was regarded as HH.

Concerns about its hepatotoxicity have virtually eliminated the use of halothane for adults in the United States and many other countries. Halothane was eventually replaced by safer newer volatile anesthetics such as isoflurane[12,13]. But in other countries with different medicolegal climates, halothane is still widely used because of its relatively low cost[11]. There are reports of HH from South Africa[14], Tunisia[15], Kenya[16], India[17], and Spain[18]. Halothane is being used as the main anesthetic in more than 80% of hospitals of Iran[19]. Unfortunately, increasing numbers of HH are being reported in Iran. In this retrospective study, we review cases reported within a 12-year period from 7 centers in Iran.

MATERIALS AND METHODS

Cases were recruited from three referral hospitals (Namazi Hospital of Shiraz University of Medical Sciences, Shariati Hospital of Tehran University of Medical Sciences, Mehr General Hospital of Tehran) and four referral GI clinics in Tehran, from April 1994 to September 2006.

There is no definite test for the diagnosis of HH and it is basically a diagnosis of exclusion. In our study, the diagnosis of HH was confirmed if the patient met the following criteria; clinical findings (jaundice, malaise), paraclinical findings (marked elevation of ALT, AST, total and direct bilirubin), recent exposure to halothane, exclusion of other causes of liver damage (viral hepatitis, *etc*) and confirmation by at least one gastroenterologist as fulminant HH.

Charts were reviewed to determine the age at surgery, weight, gender, medication history (including P450 inducing drugs), preoperative obesity (BMI $\geqslant$ 30), history of recurrent exposure to halothane, history of previous reaction to halothane (unexplained post-operative fever, jaundice, abnormal liver enzymes following earlier halothane anesthetics), positive family history (defined as reactions to halothane in first degree relatives), type of surgery, perioperative hypoxia, interval between anesthesia with halothane and symptoms heralding or attesting hepatitis, postoperative sepsis, morbidity and mortality.

Data were presented as simple count and percent, median and range, or mean ± SD and were compared by Fisher's exact test. Statistical calculations were performed using SPSS version 15.0. $P < 0.05$ was considered significant.

The study was approved by the institutional review board and ethics committee of the Digestive Disease Research Center (DDRC) of Tehran University of Medical Sciences.

RESULTS

Fifty-nine cases of HH were identified, 48 women (81%), 11 men (19%). The median age at the time of surgery was 44 years (range, 18 to 80 years). Sixty percent of patients were above 40 years old. The age distribution of patients is given in Figure 1.

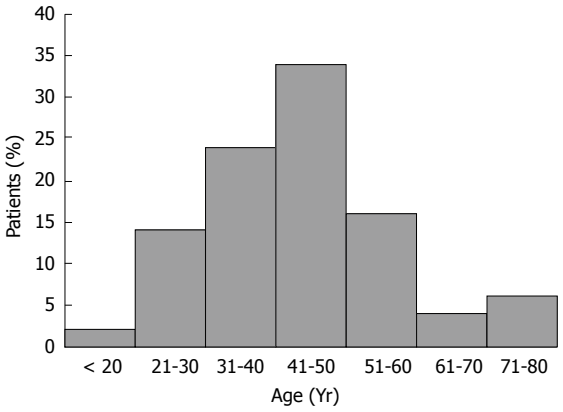

Figure 1 The age distribution of patients with HH.

Table 1 Characteristics and laboratory test results of 59 patients with HH

Variable	*n*	%
Characteristics		
Female gender	48	81.4
Obesity	6	22.2
Recurrent exposure history	22	61.2
Post-exposure reaction history	10	17
Encephalopathy	8	14.5
Requiring ICU care	7	12.5
Mortality	6	12.2
Laboratory test results		
ALT rise	48	100
AST rise	47	97.9
Total bilirubin rise	41	97.6
Direct bilirubin rise	37	100
Alkaline phosphates rise	35	100
PT rise	21	61.8

Percentages are relative to patients for whom data was available.

The mean of interval between anesthesia and hepatitis symptoms was 15.2 ± 13.6 d. The mean weight of patients was 76.1 ± 18.7 kg and 22.2% of patients were obese. Data on clinical findings, morbidity, and mortality are given in Table 1. No cases had previous history of liver disease or sepsis. One case had documented perioperative hypoxia, another one had a positive family history of HH, and two others had positive drug history (Phenobarbital). Table 1 shows the results of routine laboratory investigations including biochemistry and coagulation tests.

Coronary artery bypass graft (CABG), cholecystectomy and cosmetic operations (mainly weight reducing surgeries including partial gastrectomy and liposuction) were the most common operations. Information about different types of surgery is given in Table 2. The mortality rate was 12.2%. In patients who developed encephalopathy, it was as high as 50%. The mortality rate in male patients was higher than females (20% *vs* 12%), although this did not reach statistical significance.

Table 2 Surgery types and the percentage of cases of HH regarding each type of surgery

Variable	*n*	%
Cholecystectomy	5	8.5
CABG surgery	4	6.8
Aesthetic surgeries		
Partial gastrectomy	1	1.7
Liposuction	1	1.7
Face lifting	1	1.7
Mandible reconstruction	1	1.7
Others	3	3.4
General Surgeries		
Intra-abdominal surgeries	2	3.4
Extra-abdominal surgeries	4	6.8
Obstetrics & Gynecologic surgeries		
Cesarean section	2	3.4
Others	9	
Eye surgeries	3	5.1
Orthopedic surgeries	2	3.4
Urologic surgeries	2	3.4
Other types of surgery	5	8.5

Percentages are relative to patients for whom data was available.

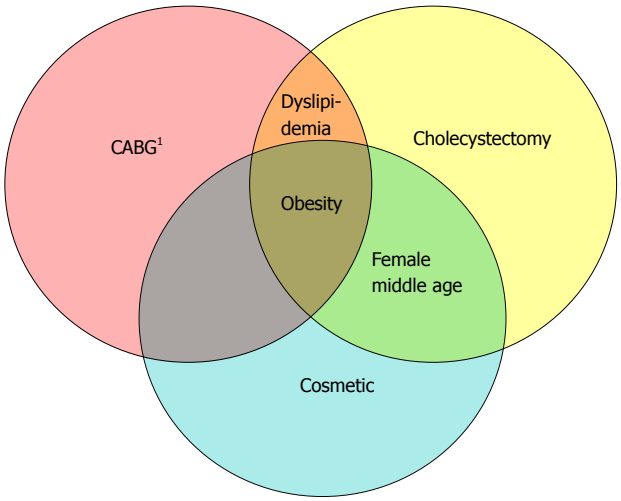

Figure 2 Common risk factors between three most common surgeries among patients with HH. [1]Coronary Artery Bypass Graft Surgery.

DISCUSSION

Because of the retrospective nature of the study, confirmation of the diagnosis with antibodies to halothane-altered protein antigens was not possible.

It has been shown that HH is more frequent in females, male-to-female ratio ranging from 1:1.6[11] to 1:2[20,21]. In our series, this ratio was 1:4.3. Additionally, it has been revealed that middle-aged patients have a greater propensity to develop liver damage than the young or elderly[11, 21-24]. Over 70% of patients are more than 40 years old with peak age of 50-60[10]. We also observed a greater prevalence among middle-aged patients, yet it appears that the patients in our series are younger compared to other series[14]. The younger age of our patients could be due to the fact that the most common surgery in our series, cholecystectomy, is frequently performed in young to middle-aged women. Obesity appears to be the common factor between most frequent operations associated with HH in our series. CABG, cholecystectomy and weight reducing-cosmetic surgeries are all linked with obesity (Figure 2). It has been showed that hepatic dysfunction is more common in obese than in non-obese patients[23-25]. As halothane accumulates in adipose tissue, this could delay its excretion and, theoretically, prolong exposure to potentially reactive halothane metabolites, resulting in increased risk in obese patients. In addition, obese patients metabolize halothane more extensively than do non-obese patients[26], further predisposing them to liver injury.

Other possible relationships between the most common surgeries are shown in Figure 2. Female gender and middle age are common risk factors for gall stone formation, cholecystitis, and coronary artery disease[27-30]. Dyslipidemia is also a risk factor for coronary artery disease and plays an important role in the pathogenesis of gallstones[27,28]. Furthermore, hypoperfusion is the possible explanation of hepatic injury in CABG and cholecystectomy surgeries. Imbalance between oxygen supply and demand predisposes the patient to halothane-induced liver damage[10,31]. Halothane has been shown to decrease both portal blood flow and hepatic arterial blood flow[32-35]. Furthermore, surgical manipulation of the splanchnic bed may reduce hepatic blood flow[36]. It has been demonstrated that CABG is accompanied with splanchnic hypoperfusion and hypoxia[37,38]. The ischemia is probably caused by hypoperfusion due to low cardiac output, hypotension due to blood loss, and intra-abdominal atheroemboli. As a result, ischemia may be the common mechanism of predisposing the patients to the HH in CABG and cholecystectomy surgeries.

Multiple exposures to halothane are the single greatest risk factor for HH[11]. The association between hepatotoxicity and repeated exposure to halothane might be explained by the fact that halothane anesthesia itself induces drug metabolizing enzymes[39-41]. The risk of HH is increased greatly when repeated halothane anesthetics are given over a short period[11,22,42,43], especially at intervals of < 6 wk[11]. In the present study, previous history of exposure to halothane was noted in 22 of 36 (61.1%) and obvious post-exposure reaction history in 10 of 22 (45.5%). Considering the fact that guidelines clearly elucidated that patients with previous reaction to halothane are among the high-risk groups[44] and should have not received halothane again, in addition to the results of this study, it is concluded that a large percentage of these cases could have been avoided. To lessen further occurrence of cases of HH, we suggest that the use of halothane in patients who are at risk of HH should be absolutely avoided. This group of patients consists of female patients having a history of post-anesthesia reactions following exposure to halogenated anesthetics. On the other hand, the item of "post-exposure reaction history" is often quite difficult to obtain with a reasonable certainty; therefore, its usefulness in preventing HH should be weak. As a result, a second set of criteria, which is female gender patients with a history of surgery (or delivery) with general anesthesia, is recommended. This is likely easier

to obtain and can be simply defined pre-operatively by the anesthesiologist *via* reviewing the "anesthesia sheet" of the previous general anesthesia. Strict adherence to this set of criteria will reduce, but not totally prevent, further cases from occurring in countries still utilizing halothane in adults' anesthesia.

Furthermore, the incidence of liver injury was greater in subjects treated with phenobarbitone before halothane anesthesia than in those not taking enzyme inducing medication[11,45]. There were two cases of chronic Phenobarbital use in our series among the 16 for which data was available.

Susceptibility to HH may be heritable and positive family history must be taken into consideration[11,46]. We had one case with positive family history of HH out of 7 cases that had data.

Type Ⅱ hepatotoxicity has a mortality rate of approximately 50%, which rises to 80% when hepatic encephalopathy is present[10,11,31,47]. Our data confirms this since the mortality was 50% in our patients with encephalopathy. Such patients have a very poor prognosis and should be referred to specialist centers where orthotopic liver transplantation is available[48]. Patients who survive the acute illness usually make a complete recovery[11]. Considering that none of our patients underwent liver transplantation, our mortality rate is considerably lower than other reports[14]. Improved intensive care, faster diagnosis and initiation of medical care may be involved. In consistence with former reports[22,24,49], mortality in male patients was higher than females in our series (20% *vs* 12.1%), although it did not reach statistical significance.

Although halothane is rarely associated with fulminant hepatic failure[48], it occupies the fifth place of suspected hepatic adverse drug reactions with a fatal outcome received by the WHO Collaborating Centre for International Drug Monitoring in Uppsala Sweden from 1968 to 2003[50]. Consequently, its usage was restricted in adults' anesthesia; however, it is still widely used in many countries, including Iran, mainly due to economic reasons[11].

Guidelines have been developed to reduce the probability of a patient developing HH; still, adverse reactions continue to occur. Even though it was clearly noted in guidelines that patients thought to be sensitized to halothane must never be re-exposed to the drug, we found ten cases of known previous reaction that were re-exposed to halothane. Based on the results of this study, to lessen further cases of HH to occur, the authors suggest that in female patients having a history of surgery (or delivery) with general anesthesia, the use of halothane should be absolutely avoided. However, the most effective preventive tool is to avoid the use of halothane in adults' anesthesia. Utilization of proper substitutes is advocated.

ACKNOWLEDGMENTS

This study was the postdoctoral project of Dr. Payam Eghtesadi-Araghi and supported by a grant from Digestive Disease Research Center of Tehran University of Medical Sciences. The authors wish to thank Professor Malekzadeh, Dr. Merat, Dr. Nasseri-Moghaddam, Dr. Ganji, and Dr. Mortezaei for their invaluable assistance.

COMMENTS

Background

Halothane is a volatile anesthetic, which was first introduced to clinical practice in 1956. After several years, concerns about its hepatotoxicity have virtually eliminated the use of halothane for adults in the United States and many other countries. It was replaced by safer newer volatile anesthetics such as isoflurane. However, in some countries with different medicolegal climates, halothane is still widely used because of its relatively low cost. In Iran, halothane is being used as the main anesthetic in more than 80% of hospitals. Unfortunately, increasing numbers of halothane hepatitis (HH) are being reported in Iran.

Research frontiers

Although the use of halothane was restricted in many countries, there are reports of HH occurring in South Africa, Tunisia, Kenya, India, and Spain in recent years.

Innovations and breakthroughs

In previous studies, guidelines have been developed to reduce the probability of a patient developing HH; however, the results of this study revealed that they are largely ignored in Iran. Furthermore, the results showed that a large percentage of these cases could have been avoided. In this study, we aimed to suggest a set of criteria that can easily define the high risk group of patients pre-operatively.

Applications

To reduce, but not totally prevent, further cases of HH from occurring in countries still utilizing halothane in adults' anesthesia, the authors suggest that the use of halothane should be absolutely avoided in female patients with a history of surgery (or delivery) with general anesthesia. However, the most effective preventive tool is to avoid the use of halothane in adults' anesthesia. Utilization of proper substitutes is advocated.

Terminology

Two major types of hepatotoxicity are associated with halothane administration: type Ⅰ (mild) and type Ⅱ (fulminant). Type Ⅱ hepatotoxicity is associated with massive centrilobular liver cell necrosis that leads to fulminant liver failure and is clinically characterized by fever, jaundice, and grossly elevated serum transaminase levels. In this study, type Ⅱ hepatotoxicity was regarded as HH.

Peer review

This series of 59 cases of HH collected in 12 years in a country with health security conditions lower than those found in the US or Western Europe is of high medical interest for the Iranian population and populations of other countries in the Middle East and, most likely, also in Africa and Asia. Therefore, the topic of the present paper is quite pertinent and extremely interesting for many physicians around the world.

Abstract

AIM: To study the seroprevalence of antibody to hepatitis B core antigen (anti-HBc) in healthy blood donors negative for HBsAg and to evaluate whether anti-HBc detection could be adopted in India as a screening assay for HBV in addition to HBsAg.

METHODS: A total of 1700 serum samples collected from HBsAg-negative healthy blood donors were tested for the presence of anti-HBc antibody (IgM + IgG). All samples reactive for anti-HBc antibody were then investigated for presence of anti-HBs and for liver function tests (LFTs). One hundred serum samples reactive for anti-HBc were tested for HBV DNA by PCR method.

RESULTS: Out of 1700 samples tested, 142 (8.4%) blood samples were found to be reactive for anti-HBc. It was significantly lower in voluntary (6.9%) as compared to replacement donors (10.4%, P = 0.011). Seventy-two (50.7%) anti-HBc reactive samples were also reactive for anti-HBs with levels > 10 mIU/mL and 70 (49.3%) samples were non-reactive for anti-HBs, these units were labeled as anti-HBc-only. These 142 anti-HBc reactive units were also tested for liver function test. HBV DNA was detected in only 1 of 100 samples tested.

CONCLUSION: Keeping in view that 8%-18% of donor population in India is anti-HBc reactive, inclusion of anti-HBc testing will lead to high discard rate. Anti-HBs as proposed previously does not seem to predict clearance of the virus. Cost effectiveness of introducing universal anti-HBc screening and discarding large number of blood units *versus* considering ID NAT (Individual donor nuclic acid testing) needs to be assessed.

Anti-HBc screening in Indian blood donors: Still an unresolved issue. *World J Gastroenterol* 2008; 14(34): 5327-5330 Available from: URL: http://www.wjgnet.com/1007-9327/14/5327.asp DOI: http://dx.doi.org/10.3748/wjg.14.5327

INTRODUCTION

Hepatitis B virus (HBV) infection is a serious global health problem affecting two billion people worldwide, and 350 million people suffer from chronic HBV infection[1]. Despite mandatory screening for HBsAg by ELISA for over 20 years, transfusion-associated HBV (TAHBV) continues to be a major problem in India, more so in patients receiving repeated transfusions[2]. The incidence of transfusion-associated hepatitis (TAH) after cardiac surgery (4 + 2.4 units transfusion) was estimated at 6.9%, of which TAHBV constituted 20%[2]. The incidence of TAHBV in patients receiving multiple transfusions, such as thalassemia, ranged from 17.9% in the first year to 69.2% by the third year. Patients on renal dialysis showed similar rates of infection with HBV[2]. It has been demonstrated that some HBsAg-negative individuals and those reactive for anti-HBc continue to replicate HBV[3,4]. Thus the absence of HBsAg in the blood of apparently healthy individuals may not be sufficient to ensure lack of circulating HBV. Blood containing anti-HBc with or without detectable presence of HBsAg might be infectious; therefore, routine blood donor screening for anti-HBc has been implemented

in some countries resulting in a decrease in the risk of post-transfusion HBV infection[5].

These findings suggest that recovery from acute hepatitis B virus infection may not result in complete virus elimination, but rather the immune system keeps the virus at a very low level called occult hepatitis B infection. Occult hepatitis B infection (OBI) is defined as the presence of HBV DNA in blood or tissues without detectable HBsAg, with or without antibody to hepatitis B core antigen (anti-HBc) or hepatitis B surface antigen (anti-HBs)[6]. Such occult hepatitis B infection may be detected in (1) individuals with resolving HBV infection reactive for both anti-HBc and anti-HBs, (2) "anti-HBc-only" carriers in a window period of infection who are seronegative for HBsAg, and (3) carriers in whom HBsAg is not detectable due to presence of escape mutants[7].

As of today, some countries have retained or adopted anti-HBc testing to decrease HBV transfusion risk, while others have not. Anti-HBc testing is still not mandatory in blood banks in India and only HBsAg testing by ELISA is used as screening test for HBV[8]. In this study, we aimed to evaluate whether anti-HBc detection could be adopted in India as a screening assay for HBV in addition to HBsAg to improve the safety of blood transfusion.

MATERIALS AND METHODS

Materials

This study was conducted by the Department of Transfusion Medicine in collaboration with Department of Hepatology, PGIMER, Chandigarh, India from July 2005 to December 2006, after obtaining an approval from the Ethics Committee of the Institute. Seventeen hundred HBsAg ELISA non-reactive blood donors were included, 998 of them were voluntary donors and 702 were replacement donors. These samples were then tested for anti-HBc (IgM + IgG), anti-HBs, LFTs and HBV DNA in the following sequence: (1) Blood units non-reactive for HBsAg and reactive for anti-HBc were tested for antibody to surface antigen (anti-HBs) and for liver function tests (LFTs); (2) the blood units non-reactive for HBsAg but reactive for anti-HBc with or without anti-HBs were tested for HBV DNA by PCR method.

Serological tests

HBsAg was tested by using commercial ELISA kit SURASE B-96 (TMB) (GBC, Taiwan, ROC); anti-HBc antibodies were tested using commercial ELISA kit HBcAb two-step incubation (MBS-SRL, Milano, Italy); anti-HBs antibodies were tested using commercial ELISA kit MONOLISA anti-HBs 3.0 (BIORAD).

HBV DNA detection

The DNA from serum was extracted using QiaAmp (Qiagen, Hilden, Germany), followed by in-house nested PCR, amplifying two different regions of the HBV genome using two sets of primers shown in Table 1. The procedure was standardized by positive control obtained from National Institute of Virology Pune, India.

Table 1 Primers used for HBV PCR

First PCR		
GP1	5'-YCCTGCTGGTGGCTCCAGTTC-3': sense	nt 3144-3164
GP2	5'-AAGCCANACARTGGGGGAAAGC-3': antisense	nt 583-604
Second PCR (nt 120-604)		
GP3	5'-GTCTAGACTCGTGGTGGACTTCTCTC-3': sense	nt 120-145
GP4	5'-AAGCCANACARTGGGGGAAAGC-3': antisense	nt 583-604

First PCR was carried out in 20 μL volume containing 1 × Taq buffer [100 mmol/L Tris HCL (pH 8.4), 25 mmol/L $MgCl_2$ and 500 mmol/L KCL], 20 pmol of reverse and forward primers (Table 1), 1 unit of Taq polymerase and 200 ng viral DNA. Thirty-five amplification cycles were performed in PCR machine (Stratagene, La Jolla, USA). Each cycle consisted of denaturation at 94℃ for 30 s, annealing at 55℃ for 30 s and extension at 72℃ for 30 s. A second PCR was performed using the first PCR product as a template using the primers GP-3 and GP-4 which amplified a 485-bp product.

For the detection of PCR product, the second PCR product was run on 20 g/L agarose in TBE buffer containing 0.5 μg/mL ethidium bromide at 50 V for about 1 h and finally visualized under a UV transilluminator (UVP, Upland, USA) and then photographed. A 100-bp DNA ladder (MBI Fermentas, Opelstrasse, Germany) was also run in parallel and the predicted size of the PCR product, which was found to be 485 bp.

Biochemical tests

Liver function tests, including serum bilirubin, alanine aminotransferase (ALT), aspartate aminotransferase (AST), were carried out by enzymatic method.

RESULTS

A total of 1700 HBsAg non-reactive blood donors (998 voluntary and 702 replacement donors) were screened for anti-HBc (IgM + IgG) using competitive ELISA, of them 142 turned out to be reactive, giving an overall seropositivity of 8.4%. It was markedly lower in voluntary (6.9%) as compared to replacement donors (10.4%, $P = 0.011$). Donors with age 18-30 years had minimum seropositivity (6.1%) with 50% donors contributing from this group. No significant difference was found in the seropositivity of first time *versus* repeat donors, male *versus* female donors and student *versuss* non-student donors, although the seropositivity was slightly less in female donors and student donors.

The anti-HBc reactive donors were tested for anti-HBs. Seventy-two (50.7%) anti-HBc reactive samples were also positive for anti-HBs with levels > 10 mIU/mL and 70 (49.3%) samples were non-reactive for anti-HBs, these units were labeled as anti-HBc-only. The anti-HBc-only reactivity was significantly lower in voluntary (34/998, 3.4%) than in replacement donors (36/702, 5.1%; $P = 0.38$) (Table 2). The anti-HBc reactive units were also tested for LFTs. All the samples had normal

Table 2 Prevalence of anti-HBc and anti-HBs in study population

Donor category	Number	Anti-HBc total	Anti-HBc-only	Anti-HBc and anti-HBs
Voluntary (%)	998 (58.7)	69 (6.9)	34 (3.4)	35 (3.5)
Replacement (%)	702 (41.3)	73 (10.4)	36 (5.1)	37 (5.3)
Total (%)	1700	142 (8.4)	70 (4.1)	72 (4.2)
P value		0.011	0.038	0.03

serum bilirubin levels, and 25 (18%) samples showed enzyme elevation. Out of these 25 samples with elevated enzyme levels, 14 (56%) were positive for anti-HBc-only and 11 (44%) were positive for anti-HBc + anti-HBs ($P = 0.460$).

One hundred samples from these 142 anti-HBc reactive (45 anti-HBc-only and 55 anti-HBc with anti-HBs) samples were tested for HBV DNA by using PCR. Only one sample was positive for HBV DNA. This sample had an anti-HBs level > 150 mIU/mL, LFTs for this sample were within normal limits. This was a 22-year-old male repeat replacement blood donor.

DISCUSSION

Despite mandatory screening of donor blood for HBsAg, transfusion-associated HBV (TAHBV) continues to be a major problem in India, more so in patients receiving repeated transfusions[2].

Literature worldwide shows presence of anti-HBc in HBsAg-negative blood donors. The incidence of anti-HBc in blood donors varies from 0.07% to 18%, and 0.3%-38% of these donors show presence of HBV DNA in their blood, depending on the type of blood donors and the endemicity of disease in the study population[2,4,6,9-12].

This study was conducted on 1700 HBsAg ELISA non-reactive blood donors. The study population belonged to Chandigarh and states of Punjab, Haryana, Himachal Pradesh, Jammu and Kashmir. The present study showed 8.4% anti-HBc positivity. Prevalence of anti-HBc was 6.9% in voluntary donors and 10.4% in replacement donors. A study reported from New Delhi (Northern India) by Chaudhuri *et al*[2] revealed that the prevalence of anti-HBc was 10.82% with distribution of 6.92% in voluntary donors and 12.53% in replacement donors. In contrast, a study from West Bengal (Eastern India) by Bhattacharya *et al*[7] showed an anti-HBc positivity as high as 18.3% in voluntary blood donors. Prevalence of anti-HBc reported by Behzad-Behbahani *et al*[10] in Iran was 6.55%, in this study only voluntary donors were included. High prevalence of anti-HBc (17.28%) was reported by Bhatti *et al*[6] from Pakistan, and all the donors in this study were replacement donors. The prevalence of anti-HBc in Europe and North America is quite low, an anti-HBc prevalence of 0.07% in the UK and 1.5% in Germany has been reported[6]. A study from Japan[4] reported anti-HBc prevalence of as 1.1%. The enormous variation in global seroprevalence of anti-HBc among blood donors is a reflection of difference in the type of blood donors and HBV endemicity of the study population. The low seroprevalence in US, UK and German blood donors may be due to 100% voluntary donor base, stringent donor screening, high literacy rates and self exclusion by high- risk donors. In our study, a significantly low seropositivity (6.1%) was seen in donors with age 18-30 years as compared to donors with age 31-40 years (11.6%, $P = 0.003$). Donors with age 18-30 years were 50% of the study population and were largely composed of young college students. The results are comparable with study from our department in 2004 by Sharma *et al*[13] that student donors have significantly lower incidence of all the markers for transfusion-transmitted infections. Therefore, efforts should be made to increase and retain these young motivated voluntary donors to maintain safe blood supply.

Our study revealed similar prevalence of anti-HBc positivity in first time donors (8.4%) and repeat donors (8.3%, $P = 0.94$), suggesting that lack of education among both our donor groups regarding minor modes of HBV transmission like tattooing, ear/nose piercing, sharing of shaving kits or a visit to a road side barber. It highlights the uniformity of donor behavior between the two groups. Our study is in accordance with recent three studies by Retrovirus Epidemiology Donor Study (REDS)[14-16] groups which showed that the incidence rate of viral infection is not lower in repeat blood donors than first time donors and abbreviated screening for repeat blood donors is not advisable.

Prevalence of anti-HBc-only was 4.1% in our study, out of which 3.2% was in voluntary and 5.1% in the replacement donors ($P = 0.038$). In a study from New Delhi (Northern India)[2], the reported prevalence of anti-HBc-only was 4.2%, out of which 2.72% was in voluntary and 4.85% in replacement donors[2]. Similarly, a study from Iran[10] reported anti-HBc-only prevalence of 2.3%.

Anti-HBc reactive samples were tested for LFTs. All the samples had normal serum bilirubin levels, and 25 (18%) samples showed elevation of liver enzymes. Elevated levels of liver enzymes in our donors indicates underlying hepatitis or some kind of liver injury which can be ruled out by additional investigations, such as hepatic ultrasound, liver biopsy and genetic testing which were not an objective of the present study.

HBV DNA was detected in 1 of 100 anti-HBc reactive donors tested. None of the anti-HBc-only samples were positive for HBV DNA. One sample was positive for HBV DNA and sample also contained anti-HBs levels > 150 mIU/mL, LFTs for this sample were within normal limits. Other studies from india[2,7] reported HBV DNA positivity of 20.87% in New Delhi (Northern India) and 21% in West Bengal (Eastern India). HBV DNA was detected among 12.2% of anti-HBc reactive donors in Iran, 2.8% in Lebanon, 2.9% in Pakistan[7]. A study from Japan[4] reported that HBV DNA was detected in 19 (38%) of 50 anti-HBc reactive samples. The viral load in these samples is usually low and their detection requires sensitive DNA amplification techniques.

In our study, low incidence of HBV DNA in anti-HBc reactive samples may be due to limitation of sensitivity of HBV DNA amplification technique. Another reason of low HBV DNA positivity in our study could be due to type of blood donors and the endemicity of disease in the study population, in our study 50% of donors were between 18-30 years, largely belong to young college students. This group being better educated can understand and cooperate in answering to the risk factors in acquiring HBV infection during pre-donation questionnaire. Another study from Chandigarh (Northwestern India) by Duseja *et al*[17] showed 0% prevalence of HBV DNA in 100 adult healthy blood donors, non-reactive for HBsAg.

Keeping in view that 8% to 18% of donor population in India is anti-HBc reactive, inclusion of anti-HBc testing will lead to high discard rate. Anti-HBs as proposed previously does not seem to predict clearance of the virus as the single donor, who tested reactive for HBV DNA in our study, had high anti-HBs titers. Cost effectiveness of introducing universal anti-HBc screening and discarding large number of blood units *versus* considering ID NAT (Individual donor nuclic acid testing) needs to be assessed. Awareness and education of donors is required regarding minor modes of HBV transmission, modification of the donor questionnaire to eliminate all donors with a history of jaundice in adult life and more stringent one-to-one donor screening to elicit such information should be implemented.

COMMENTS

Background

Despite mandatory screening of donor blood for HBsAg, transfusion-associated HBV (TAHBV) continues to be a major problem in India, more so in patients receiving repeated transfusions.

Research frontiers

The present study was undertaken to assess the seroprevalence of antibody to hepatitis B core antigen (anti-HBc) in serum samples of healthy blood donors negative for HBsAg and to evaluate whether anti-HBc detection could be adopted in India as a screening assay for HBV in addition to HBsAg.

Innovations and breakthroughs

There is high prevalence of anti-HBc in Indian blood donors. Voluntary donors have lower incidence of anti-HBc than replacement donors. Anti-HBs does not seem to predict clearance of the virus in the blood donors.

Applications

Keeping in view that 8%-18% of donor population in India is anti-HBc reactive, inclusion of anti-HBc testing will lead to high discard rate. Cost effectiveness of introducing universal anti-HBc screening and discarding large number of blood units *versus* considering ID NAT needs to be assessed.

Peer review

This is an important and timely paper assessing the role of anti-HBc testing to detect occult HBV infectivity for addressing the important issue of TAHBV in Indian blood donors. The research was done at PGIMER Chandigarh, India, one of the premier institutes in the country. This paper deserves publication.

Abstract

AIM: To identify the characteristics of morphology, location and collateral circulation involved in paraesophageal varices (para-EV) of portal hypertension patients with 64-row multidetector computed tomography (MDCT).

METHODS: Fifty-two of 501 patients with portal hypertensive cirrhosis accompanied with esophageal varices were selected for 64-row MDCT examination after the observation of para-EV. The CT protocol included unenhanced, arterial and portal phases with a slice thickness of 0.625 mm and a scanning field of 2 cm above the bifurcation to the lower edge of kidney. The CT portal venography (CTPV) was reformatted on AW4.3 workstation. The characteristics of origination, location, morphology and collateral circulation in para-EV were observed.

RESULTS: Among the 52 cases of para-EV, 50 showed the originations from the posterior branch of left gastric vein, while the others from the anterior branch. Fifty cases demonstrated their locations close to the esophageal-gastric junction, and the other two cases were extended to the inferior bifurcation of the trachea. The circuitous pattern was observed in 16 cases, while reticulated pattern was seen in 36 cases. Collateral circulation identified 4 cases of single periesophageal varices (peri-EV) communication, 3 cases of single hemiazygous vein, one case of single inferior vena cava, 41 cases of mixed type (collateral communications of at least 2 of above mentioned types) and 3 cases of undetermined communications. Among all the cases, 43 patients showed the communications between para-EV and peri-EV, while hemiazygous vein (43 cases) and inferior vena cava (5 cases) were also involved.

CONCLUSION: Sixty-four-row multidetector computed tomography portal venography could display the location, morphology, origin, and collateral types of para-EV, which provides important and referable information for clinical management and disease prognosis.

INTRODUCTION

Esophageal varice is a common collateral circulation manifestation in portal hypertension, and may cause a severe complication if ruptured[1-3]. Endoscopic therapy is an effective approach that is being applied worldwide[4,5], although the recurrences have been reported in many cases[6]. Some authors reported that the existence of perforating veins, the communicating branches between periesophageal varices (peri-EV) and paraesophageal varices (para-EV), and their blood flow found by endoscopic color Doppler ultrasonography (ECDUS) affected the recurrences of hemorrhage caused by rupturing[7]. However, ECDUS is an invasive technique, requires specialized equipment

and technology, and is incapable of demonstrating the drainage types and morphologic features of esophageal varices. Multidetector computed tomography portal venography (MDCTPV) has been used widely in collateral circulation studies of esophageal and gastric varices[8-11]. The drainage veins of esophageal varices can be clearly displayed on MDCTPV[10]. Our study focuses on the utilization of MDCTPV in observing para-EV drainage types to provide referable information for clinical management selection and prognosis evaluation.

MATERIALS AND METHODS

Patient population

A total of 501 portal hypertensive cirrhotic patients with esophageal varices were investigated from April 2007 to May 2008. Among them, 52 patients with presence of para-EV were selected for this study, including 35 male and 17 female, aged 21-71 years, averaging 45.2 years. There were 27 cases of hepatitis B, 3 hepatitis C, 16 alcoholic, 2 primary biliary and 4 cases of cryptogenic cirrhosis. Based on Child's grading, 9 cases were Grade A, 28 cases Grade B and 15 cases of Grade C. Among the 52 patients, 50 were accompanied with gastric varices. Fifty patients were not treated with esophageal varice ligation (EVL), esophageal varice sclerotherapy (EVS) or any other endoscopic therapies, while 1 case received post-EVL therapy and 1 case received post-EVS therapy. Liver cirrhosis was confirmed in all patients through general consideration from clinical histories, laboratory findings, as well as CT, sonography or MRI examinations. Informed consent for CT scans and the use of contrast media were obtained from all patients before scanning procedures.

Imaging acquisition

A GE VCT 64-row MDCT scanner was applied to perform unenhanced, arterial and portal vein phase enhanced scans on all patients. The scanning range covers from 2 cm above the tracheal bifurcation to the lower edge of the kidney. One hundred mL of non-ionic contrast medium (Omnipaque 350) was introduced with an infusion rate of 4.0 mL/s. The arterial phase scanning time delay was determined with Smart technology, and portal phase scanning was initiated at 25 s after the beginning of arterial phase. Slice thickness was set at 5.0 mm, and reconstitution thickness was 0.625 mm.

Image analysis

Post-processing methods: vertebrae, costal bones and other structures with bony densities were removed using GE AW4.3 workstation, and then maximum intensity projection (MIP), multi-planner reformation (MPR) technique were applied to reveal the origin, location, morphology and communicating veins of para-EV. The 3D structures of esophageal varices were displayed with volume rendering (VR) technique.

Observation item and indications

Origin of para-EV: The relationship between para-EV and anterior or posterior branches of the left gastric vein were examined and determined.

Morphology and location of para-EV: The morphological patterns of para-EV were categorized into circuitous pattern and reticulated pattern, in which circuitous pattern was denoted as para-EV linear, near-parallel pathways, while reticulated pattern was denoted as prominent para-EV winding and distortion, forming meshwork or loops. In case of the presence of both circuitous and reticulated patterns, the categorization was determined according to their diameter ratios and then was defined as "mainly circuitous pattern" or "mainly reticulated pattern". Large-diameter vessels with a ratio of over 1 were defined as dominant type. The para-EV was divided into 3 sections according to the extent, including the upper section located at a level superior to the tracheal bifurcation; the middle section located at or near the tracheal bifurcation level, and the lower section located at the abdominal as well as the lower thoracic segment of the esophageal periphery.

Communicating veins of para-EV: The communications between para-EV and peri-EV, hemiazygous vein, subphrenic vein, inferior vena cava and other vessels were investigated. The criteria set for CTPV judgment on the communication of para-EV and its collaterals were as follows: (1) Para-EV was directly conjoint with the above-mentioned vessels; (2) Para-EV and the vessels mentioned above were conjoint with their peripheral circuitous and reticulated blood vessels, respectively.

RESULTS

Origination of para-EV

There were 50 patients with their varices originating from the posterior branch of the left gastric vein (50/52, 96.15%) (Figure 1A) while the varices of the other 2 patients originated from the anterior branch of the left gastric vein (2/52, 3.85%), in which the posterior branch of the left gastric vein was absent and the anterior branch of left gastric vein routes up and enters the fundus through the gastroesophageal junction to form gastric fundal varices. The latter routes up to form peri-EV, then penetrate through esophageal wall to form para-EV.

Morphology and location of para-EV

Sixteen cases of circuitous morphological pattern (16/52, 36.54%) (Figure 1B) and 36 cases of reticulated morphological pattern (36/52, 63.46%) (Figure 1C) were observed. The locations of para-EV were identified as follows: 50 cases in lower section (50/52, 96.15%) (Figure 1C), 2 cases in middle section (2/52, 3.85%), and none in upper section.

Communicating veins of para-EV

Among the 52 cases, 3 showed undetermined communicating vessels (3/52, 5.77%) with 1 of circuitous morphological pattern, while the others were of reticulated

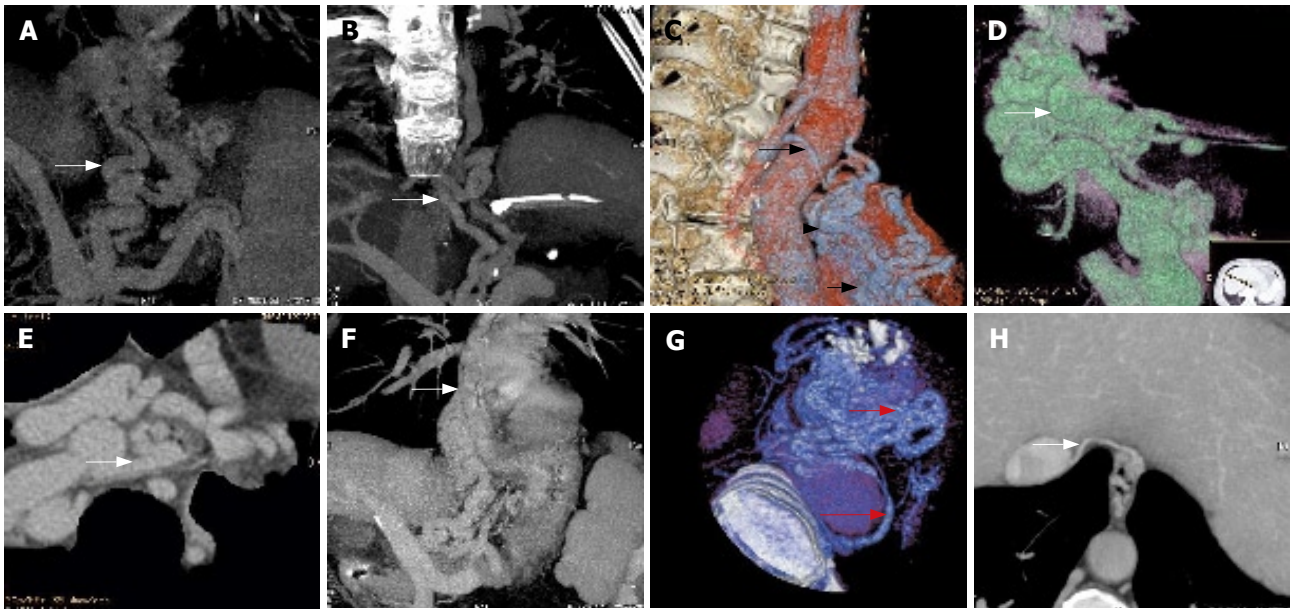

Figure 1 **A:** Para-EV originated from the posterior branch of the left gastric varices (arrow); **B:** Circuitous morphological para-EV (arrow); **C:** Para-EV in reticulatous pattern (short arrow), located at lower section of the esophagus (arrowhead), communicating to hemiazygous vein (long arrow); **D:** Para-EV communicating to peri-EV (arrow); **E:** Para-EV communicating to peri-EV directly (arrow); **F:** Para-EV communicating to peri-EV with peripheral circuitous appearance (arrow); **G:** Para-EV communicating to peri-EV (short arrow) and the hemiazygous vein (long arrow); **H:** Para-EV communicating to the subphrenic vein (arrow).

Hemi: Hemiazygos vein; Sub: Subphrenic vein; Reti: Reticular; Cir: Circuitous.

morphological pattern. In the other 49 cases, 43 cases involved the peri-EV (43/49, 87.76%) (Figure 1D-G), and a similar number of patients also demonstrated the hemiazygous vein (Figure 1B, C and G). Inferior vena cava was included in 5 cases (5/49, 10.20%) (Figure 1H).

The specific communicating patterns found in this study were listed as follows (Table 1): 8 cases with single communication, 41 with mixed communications and, in 3 cases, the drainage veins of the para-EV remained uncertain. Among the 8 cases of single communication, the para-EV connecting to peri-EV (Figure 1E and F) with reticulated shape was found in 4 cases (4/49, 8.16%), connecting to Hemiazygos vein of circuitous appearance in 3 cases (3/49, 5.77%), and to the subphrenic vein draining circuitously in 1 case (1/49, 1.92%).

In the 41 cases of mixed type, the para-EV was found connecting to peri-EV and hemiazygous vein in 37 cases (37/49, 71.15%) (Figure 1G), with circuitous shape in 8 cases and reticulated in 29 cases. Three cases presented para-EV communicating to subphrenic vein: 1 to peri-EV (1/49, 1.92%) and 2 to Hemiazygos vein circuitously (2/49, 3.84%). In 1 case (1/49, 1.92%), all the drainage mentioned above was observed with reticulated appearance. The para-EV was circuitous in 1 case and reticular in 2 cases of uncertain drainage.

DISCUSSION

The prevalence rate of esophageal varices is high in patients with liver cirrhosis, and the mortality rate is very high imposed by massive hemorrhage due to rupture[2,12]. It is reported that more than 70% of portal hypertension patients with a variceal bleeding history may suffer from recurrent bleeding[13]. The esophageal varice was divided into three groups: peri-EV, para-EV and perforating veins[14]. The factors associated with the rupture of esophageal varices included the extent and collateral circulation of peri-EV and para-EV[15,16]. Therefore, the acquisition of reliable images for the above mentioned factors will provide valuable information for further treatment implementation and prognosis of the patients.

Angiography is one of the earliest investigations applied in hemodynamic evaluation of portal hypertension-induced esophageal varices by displaying esophageal varices and their drainage vessels through arterial portography[17]. However, the invasive procedure and the incapability to differentiate peri-EV and para-EV prevent it to be applied in a general clinical setting.

Color Doppler ultrasound has been widely used to investigate the relationship between EV and hemodynamics associated with portal hypertension and liver cirrhosis. But it could not show the para-EV and peri-EV clearly[18].

Endoscopy is a more popular approach for the observation of morphological patterns, extension and severity of esophageal submucotic varices with the limitations to intramural and para-EV[19].

ECDUS is gradually becoming a useful tool for esophageal varicose inspection, which is able to display peri-EV, para-EV, perforating veins and the blood flow directions of perforating veins[7,14,20]. However, it is unable to clearly display the pathway and collaterals of para-EV. On the other hand, endoscopic sonography is costly, and also an invasive procedure that requires a skillful operator, which limited its application in clinical settings.

MDCTPV has already been a matured investigation technique used to examine esophageal and gastric varices. It is competent in displaying the types of morphological pattern, origin and collateral circulations of esophageal and gastric varices[10,11]. Sixty-four-row MDCT consists of thin slice of 0.625 mm, and a high spatial resolution, which makes it capable of displaying the communicating patterns of para-EV and peri-EV. Among the 52 cases in our study, this pattern of collateral circulation was shown in 49 (94.23%) cases. Generally, it is a non-invasive technique, and hence, it can be used to evaluate para-EV conveniently. However, displaying of this sort of collaterals is relatively rough and unsatisfactory in detail if compared with EUS. In addition, it is incapable to assess the blood flow directions of paraesophageal-periesophageal collateral circulation due to the characters of CTPV.

According to our study, vast majority of para-EV originate from the posterior branch of left gastric vein, and only 2 cases originated from the anterior branch of left gastric vein. The latter is highly associated with gastric fundal varices. A previous report suggested that[21], in cases of coexisting gastric fundal varices and esophageal varices in lower esophageal segment, the extent of esophageal varices could be aggravated after imposing obliteration therapy for gastric fundal varices. In our study, there was one patient who experienced alleviation of gastric varices with aggravated para-EV and peri-EV after receiving gastroesophageal varices treatment. The origination of para-EV may be related directly to its anatomical formation.

In our study, para-EV was found more abundant near the superior part of the gastroesophageal junction, which is also the lower esophageal segment (96.15%) than in the middle segment (3.85%). There was no para-EV involved in the upper segment. This suggests that para-EV usually occurs in the middle and lower esophageal segment and drains into the vena cava system through collateral vessels. The involved drainage vessels that we have noted were peri-EV, hemiazygous veins and subphrenic veins.

The communicating branches of para-EV and hemiazygous vein manifest as drainage "detour" veins bypassing along the anterior descending aorta to the hemiazygous vein, and subsequently drain into the superior vena cava. Ibukuro *et al*[22] described the above anatomic changes as preaortic vein using CT and CTAP application. This "detour" is a commonly seen drainage route, and has an occurrence rate of 87.76%.

The hemodynamics of para-EV communicating peri-EV is relatively complicated. The communicating vessels of para-EV and peri-EV are mostly situated close to the top of the cardia level. Sato *et al*[7] observed the presence of perforating veins between peri-EV and para-EV with Levovist ECDUS, and meanwhile, he found the bidirectional blood flow of peri-EV and para-EV, which included the directions from para-EV to peri-EV and from peri-EV to para-EV, as well as mixed type that presented both blood flow directions. This may explain why previous para-EV studies about the recurrence risk of post-esophageal varices treatment remain controversial[20,23,24].

Para-EV can still drain into the inferior vena cava through the subphrenic vein, or directly communicate with the inferior vena cava. The subphrenic veins are the bilateral vessels which end up at inferior vena cava at the diaphragm level[25]. The communication between para-EV and subphrenic veins shown on CTPV was consistent to the precaval route and morphological pattern as reported by Ibukuro *et al*[25] from their CTAP and autopsy findings.

The degree of varices will be more severe if the morphological patterns of para-EV are reticulated. Under such condition, para-EV and peri-EV are individually communicated, or may be accompanied with hemiazygous vein drainage. They will mostly drain into the hemiazygous veins or subphrenic veins if the collaterals of para-EV are circuitous. Explanations about this correlation and its pathological significance require further studies.

Even though CTPV is incapable of displaying the blood flow directions of para-EV, it has a certain guidance value for EUS application. If para-EV is detected on CTPV, EUS should be further implemented to confirm the presence of specific communicating branches between peri-EV and para-EV as well as the location and hemodynamic characteristics of their communicating branches so as to provide relevant referable information for treatment selections.

COMMENTS

Background

The existence of para-EV and perforating veins and the direction of their blood flow can affect the recurrence of hemorrhage caused by rupturing.

Research frontiers

The morphology, location and collateral circulation characteristics of para-EV in portal hypertensive patients were studied with 64-row multidetector computer tomography portal venography (MDCTPV), which is a non-invasive method.

Innovations and breakthroughs

In majority cases of this study, the collateral circulation pattern of para-EV and the morphological characteristics of para-EV were revealed thanks to the high spatial resolution images of the advanced MDCT and the appropriate image post-processing.

Applications

MDCTPV is a noninvasive method to display the morphological characteristics of para-EV, which is useful in clinical management and disease prognosis.

Terminology

Paraesophageal varices are the varices that exist outside the esophagus. Peri-

EV is the varices that exist in the esophageal wall or the submucotic varices. Perforating vein is the communicating branch between peri-EV and para-EV. The subphrenic vein is the bilateral vessel that ends up at inferior vena cava at the diaphragm level. CTPV is the abbreviation of CT portal venography.

Peer review

This is a good review with excellent images. MDCTPV is a convenient method to display the morphological and collateral circulations of the para-EV. It is of important value in the selection of clinical therapy and evaluation of prognosis.

Abstract

AIM: To integrate results from different studies in examining the effectiveness of music in reducing the procedure time and the amount of sedation used during colonoscopic procedure.

METHODS: An electronic search in various databases was performed to identify related articles. Study quality was evaluated by the Jadad's scale. The random effect model was used to pool the effect from individual trials and the Cohen Q-statistic was used to determine heterogeneity. Egger's regression was used to detect publication bias.

RESULTS: Eight studies with 722 subjects were included in this meta-analysis. The combined mean difference for the time taken for the colonoscopy procedure between the music and control groups was -2.84 with 95% CI (-5.61 to -0.08), implying a short time for the music group. The combined mean difference for the use of sedation was -0.46 with 95%CI (-0.91 to -0.01), showing a significant reduction in the use of sedation in the music group. Heterogeneity was observed in both analyses but no publication bias was detected.

CONCLUSION: Listening to music is effective in reducing procedure time and amount of sedation during colonoscopy and should be promoted.

Key words: Colonoscopy; Colon cancer; Meta-analysis; Music therapy; Screening

INTRODUCTION

In 2005, colorectal cancer was the fourth most frequent cancer type worldwide for both sexes and colon cancer accounted for about 655 000 deaths per year[1]. Most colon cancers develop from polyps that grow abnormally in the colon. If polyps grow unnoticed and are not removed, they may become cancerous. Indeed, colorectal cancer is among the most preventable and curable cancers and with early detection 75%-90% of them can be prevented[2]. The aim of screening is to find precancerous polyps so they can be removed before they become cancerous. Screening for colon cancer has been shown to be effective in reducing mortality[3].

Colonoscopy is now the recommended method for screening colon cancer[4]. During a colonoscopy procedure, physicians insert a colonoscope into the rectum of a patient from the anus and slowly guide it into the colon for direct visualization and diagnosis[5]. As can be imagined, it is not a comfortable experience. In fact, many people refuse to undergo colonoscopy because of discomfort and anxiety[6], some feel out of control with what would be happening during the procedure and were fearful of looking foolish[7]. Even those who agree to undergo a colonoscopy feel frightened and anxious before the procedure[8]. After it, they express it was an unpleasant and stressful experience[9]. Therefore, most physicians prefer to

perform colonoscopy with conscious sedation[10] although some still start the procedure without sedation, particularly in non-anxious patients[11].

Since the use of sedation is risky-it may contribute to the occurrence of cardiovascular events and is associated with the risk of cardio-respiratory complication[12,13] especially for elderly patients[14]-pand costly, non-pharmacological methods for alleviating patients' discomfort and anxiety have been developed and music therapy is one of them. The use of music therapy to promote relaxation has a long history in medicine[15,16]. The ancient Chinese medical reference, Yellow Emperor's Classics of Internal Medicine, mentioned the use of music for treatment[17], while ancient Indian treatises, like Samaveda, stated the therapeutic utility of music[18]. Earlier studies show the effectiveness of music on patients with acute myocardial infarctions[19] and receiving intensive medical/surgical care[20]. The effects of music on different screening procedures were examined during the early 1990s. For example, Fullhart[21] and Palakanis[6] studied anxiety in patients undergoing flexible sigmoidoscopy and Bampton[22] assessed the role of relaxation music on patient tolerance of gastrointestinal endoscopic procedures. Since then, more and more studies have examined the effect of music during colonoscopy, but no conclusion has yet been reached about its effectiveness. Recently, a meta-analysis[23] focusing on the general endoscopic procedure was published and the authors reported significantly lower anxiety levels and shorter procedure times. The aim of this meta-analysis is to integrate results from different studies in examining the effectiveness of music in reducing procedure time and amount of sedation used during colonoscopy.

MATERIALS AND METHODS

Search strategies

We identified studies to evaluate the effect of listening to music during colonoscopy. The electronic search was conducted on six databases, namely, AMED-Allied and Complementary Medicine (1985 to 2007), ACP journal club (1991 to 2007), CINAHL (1982 to March 2007), Cochrane Central Register of Controlled trials (up to 1st quarter of 2007), EMBASE (1980 to March 2007), and MEDLINE (1966 to March 2007). Only two sets of keywords, i.e. Colonoscopy and Music/Music, were used to include as many articles as possible. We also attempted to identify any potential unpublished studies such as theses and dissertations using the above keywords through the ProQuest Dissertations and Theses database, and the web using Internet search engines, Google and Yahoo, with thesis or dissertation as additional keywords. Reference lists of the collected papers were also checked for any potential articles.

Inclusion criteria

Only randomized controlled studies reported in English were included. At least one of the comparison groups included listening to music during colonoscopy as part of the intervention.

Data extraction

For each eligible study, we extracted information on author/s, year of publication, age distribution, gender proportion, other demographic data, intervention, outcome measures, and results. The data extraction form was modified from the data extraction form of van Tulder[24]. Two investigators (WT and EW) of the study independently extracted the data, which was then summarized by one of them. Agreement was reached on the extracted data before proceeding to data analysis.

Methodological quality

The methodological quality of the included studies was assessed using the Jadad's scale[25]. The quality variables recorded in the criteria list included the procedure of patient allocation, information regarding withdrawals and dropouts, blinding of patients, and outcome assessment. A maximum of five points can be obtained using the scale. However, as blinding of patients is difficult while assessing behavioral interventions[26], only blinding of outcome assessors was considered in the scale. Furthermore, as withdrawals and attrition of patients were unlikely in such a short period, such item in the Jadad's scale was also ignored. Therefore, the maximum points obtainable for each study became four. Besides the Jadad's scale, one additional question was extracted from van Tulder[24] for assessing the comparability of the two comparison groups.

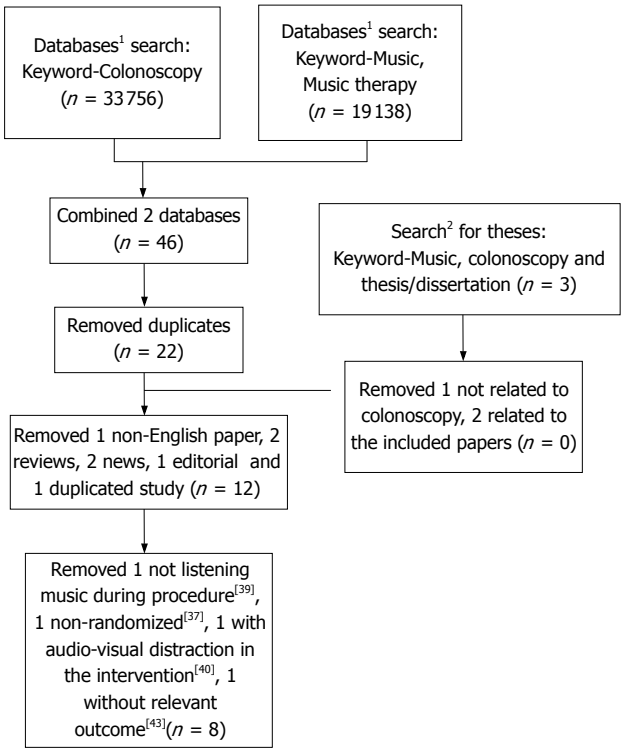
Statistical analysis

Random-effect models were used to combine the outcome effect, i.e. the (standardized) difference between treated and control groups, for each study[27]. Heterogeneity was examined using the Q-test and I^2[27]. All analyses were conducted using RevMan[27]. Publication bias was examined by funnel plot and Egger's regression[28].

RESULTS

Search strategies

The electronic search was conducted in May 2007 and 19 records were found. The title and abstracts of these papers were examined and it was found that one was written in Portuguese[29], one was a systematic review focus on pain[30], one was a discussion paper on the use of sedation[31], one was an editorial[32], and two were news[33,34]. One paper[35] occurred twice in our search as the surname of the first author was recorded differently in two electronic databases (EBASE and MEDLINE), so one was removed. Hence, only 12 studies[35-46] were included and the full articles were obtained for further examination. A study[37] was found to be a non-randomized study



[1]Databases included CINAHL (1982 to 2007 March), Cochrane Central Register of Controlled trials (up to 1st quarter of 2007), EMBASE (1980 to 2007 March) and MEDLINE (1966 to 2006 January); [2]Search in ProQuest Dissertations and Theses database (1861 to 2007) and through search engine yahoo and google (only the first 20 pages of results were checked for detail).

Figure 1 Flowchart of the search history.

and was excluded and another study[43] not examining the procedure time nor the amount of sedation was also excluded. One study[39] required their subjects in the intervention group to listen to music before the colonoscopy procedure on a voluntary basis. The author was contacted to see how many subjects in the intervention group listened to music during the procedure. Although the author implied that most of the subjects continued to listen to music during the procedure, the study was excluded because not all participants in the intervention group listened to music during the procedure. Another study[40] provided audiovisual distraction to patients instead on listening to music alone and the effect may have been enhanced; therefore, it was also excluded from the analysis.

As to the search of potential theses or dissertations, one doctoral dissertation[47] and two master theses[48,49] were identified and their abstracts were obtained. However, one[48] was not related to colonoscopy and the others[47,49] related to the papers from previous search[40,45]. A flowchart is provided to show the search history (Figure 1).

A total of 722 subjects were involved in 8 studies (Table 1), four from Europe[35,36,42,44], two from the US[36,45], and three from Asia[38,41,46]. Two studies[38,45] provided different types of music for their patients to choose from. Four studies broadcasted the music through headphones/earphones[35,38,41,45], three broadcasted as background music[36,42,44], and one did not specify the media method[46]. Seven studies mentioned that all colonoscopy procedures were conducted by an experienced colonoscopist[42,46] or a group of experienced colonoscopists[35,36,38,41] for both comparison groups.

Quality of studies

All of the included studies were randomized controlled studies and only five of them reported the method of randomization[35,36,38,41,42]. No information on attrition was reported in any study probably because most of the procedures were completed in a relatively short period of time. Incomplete procedures were reported in two studies but no significant incomplete rates were detected[35,41]. Although it would be impossible to blind the subjects, outcomes assessor was blinded in two studies[35,38] by requesting the patients in the control group to take the earphones. Six studies[35,36,41,42,45,46] showed that baseline characteristics between control and treatment groups were comparable. One study did not provide the test statistics[44] and one did not report the baseline characteristics[38] (Table 2). Overall, five studies[35,36,38,41,42] got 2 points (half) or above in our modified Jadad's scale.

Procedure time (Figure 2)

The total time taken for the procedure between music and control groups was measured in seven studies[35,36,38,41,44-46]. Six of them[36,38,41,44-46] showed a reduction of time in the music group but only in one case was this significant[44]. Since two studies[36,38] did not provide the means or standard deviations, the corresponding authors of the studies were contacted to obtain this information. Authors from both studies[36,38] generously provided the means and standard deviations of the respective parameters and therefore their results could be included in the analysis. The combined mean difference between the treated and control groups was -2.84 with 95% CI (-5.61 to -0.08). The Q-value and the I^2 were 13.46 ($P = 0.04$) and 55%, suggesting possible heterogeneity among the studies. Publication bias was not detected using Egger's regression method ($P = 0.9133$).

Sedation (Figure 2)

Six studies[36,38,41,42,44,45] examined the use of sedation, i.e. midazolam in mg, and four[38,41,42,45] showed a reduction in the music group. Sedation was given or added based on patients' request[38,41,44] or colonoscopists' decision[36,42]. The means and standard deviations of the 2 studies[36,38] were requested from the authors. The combined mean difference for the six trials was -0.46 with 95% CI (-0.91 to -0.01), showing a marginally significant reduction of the use of sedation in the

Table 1 Characteristics of each of the included studies

Study	Design	Baseline characteristic	Comparison group	Outcome
Andrada *et al* (2004)[35]	RCT	Intervention- 31 males 32 females, mean age: 46 (14.22) Control- 28 males 27 females, mean age: 49 (13.88)	Intervention- Listening music until the end of procedure (classical tracts) Control- Usual colonoscopy screening	Blood pressure, capillary and oxygen saturation, heart rate level of anxiety
Bechtold *et al* (2006)[36]	RCT	Intervention- 41 males and 44 females, age: 58.5 Control- 42 males 39 females, age: 54.1	Intervention- Playing music upon the entrance the patient (same music for all patients) Control- 50 mg of meperidine and 1 or 2 mg of midazolam	Dose consumed, time to time, reach cecum, total procedure insertion difficulty scale, experience scale, pain scale, want music next time
Harikumar *et al* (2006)[38]	RCT	Intervention- 38 (male + female), age 15 - 60 Control- 40 (male + female), age 15-60	Intervention- Listening music (popular film songs based on classical rages, classical music, devotional songs, folk songs, soft instrumental music, and bioacoustics Control- 2 mg intravenous boluses of midazolam on demand; Colonoscopic procedure performed by endoscopists with experience of performing at least 200 full-length colonoscopic procedure	Pain score, discomfort score, procedure time, recovery time, dose consumed
Lee *et al* (2002)[41]	RCT	Intervention 1- 33 male 22 female Inter-quartile age range: 46-68 mean age: 54 Intervention 2- 29 male 26 female, Inter-quartile age range: 39-67 mean age: 47 Intervention 3- 27 males 28 females, Inter-quartile age range: 40-65 mean age: 51	Intervention 1- Patient-controlled sedation Intervention 2- Patient-controlled sedation+ music1 Intervention 3- Music1 Could request intravenous administration of diazemuls (0.1 mg/kg) and meperidine (0.5 mg/kg) Nasal oxygen (2 L/min) to all patients in the study 1Type of music: classical, jazz, popular (Chinese and English) and Chinese opera Examination performed endoscopists having more than 300 similar procedures before	Dose of propofol, pain score, satisfactory score, willingness to repeat the same mode of sedation.
Ovayolu *et al* (2006)[42]	RCT	Intervention- 14 males 16 females, age: 20-39 (n = 10), 40-59 (n = 11), 60 or above (n = 9) Control- 14 males 16 females, age: 20-39 (n = 5), 40-59 (n = 11), 60 or above (n = 14)	Intervention- Listening music (classical Turkish music, a slow and relaxing music) Control- Usual colonoscopy screening; procedure performed by an expert endoscopist with experience of performing at least 200 full-length procedure previously	Dose of sedation consumed, anxiety score, pain score, VAS score, willingness to the procedure score and satisfaction score.
Schimann *et al* (2002)[44]	RCT	Intervention- 25 males 34 females, mean age: 52.3 (13.9), Control- 33 males 27 females, mean age: 55.8 (13.5)	Intervention- Music from radio Control- Conventional procedure	Request of sedation (midazolam), oxygen supplement, procedure time
Smolen *et al* (2002)[45]	RCT	Intervention- 10 male 6 females, mean age: 58.83 (13.64) Control- 7 males 9 females, mean age: 61.06 (9.48)	Intervention- Listening music (classical, jazz, pop rock and easy listening) Control- Undergo standard colonoscopy procedure including explanation of the procedure by the nurse; receive a standard pre-procedure sedation consisting of a slow intravenous injection of 1 mg of midazolam in combination with 50 mg of meperidine	Sedation, anxiety and heart rate
Uedo *et al* (2004)[46]	RCT	Intervention- 7 males 7 females, mean age: 54 (6) Control- 11 males 4 females, mean age: 54 (8)	Intervention- Listen the music (easy listening style) from the beginning and during procedure Control- Usual procedure for undergoing colonoscopy, no anxiolytic medications, no antisecretory agents	Salivart cortisol levels

Table 2 Quality assessment by Jadad's scale and baseline comparison

music group. The Q-test and I^2 were respectively 34.83 ($P < 0.001$) and 86% suggesting strong heterogeneity. Publication bias was not detected using Egger's regression method ($P = 0.1150$).

DISCUSSION

Colon cancer is the fourth leading cause of death among all cancers[1] but remains one of the most preventable and curable cancers if detected early[2]. Screening for colon cancer has been shown to be an effective method of reducing the risk of mortality, but the compliance rate is still low probably due to the unpleasant feeling of patients during the procedure[9]. Non-pharmacological methods for alleviating patients discomfort and anxiety have been developed and, in the early 1990s, Palakanis[6] demonstrated that listening to music before and during sigmoidoscopy was effective in reducing one's anxiety. Colonoscopy has been the recommended procedure for screening colon cancer[4] and more studies have been conducted in examining the effect of listening to music during this procedure.

Our results show that listening to music during the colonoscopy would effectively reduce the mean procedure time and the amount of sedation used. One possible explanation for the reduction of sedation is that patients in the music group are more relaxed and with less anxiety. Therefore, the physician can complete the procedure in a shorter period of time and use less sedation[45]. The reduction of procedure time implies a reduction of the anxious, frightening, and unpleasant time spent while undergoing the procedure and may be useful in enhancing the compliance rate.

It was reported that conscious sedation with midazolam contributed to the occurrence of cardiovascular events during colonoscopy[12] and was associated with the risk of cardio-respiratory complication[14]. Avoidance of sedation may provide a quicker patient discharge, less need for monitoring, and overall cost savings[50]. Our results also found a significant reduction in anxiety score, but only weak evidence was observed for pain score, blood pressure, and mean recovery time.

Besides the above-mentioned beneficial effects to patients, two advantages of listening to music during colonoscopy are cheapness and ease of implementation[51]. Although cassette players and compact disc players were used in most of the included studies, digital players, like MP3 players, may be a better choice in the future[52]. With advanced technology, a thumb-sized MP3 player can store hundreds of songs at a much lower cost. Therefore, more choices can be given to patients, which is important as personal preference has a strong impact on one's responses to music[53].

No harmful effects from listening to music were reported in any study in the meta-analysis and other references that we read. Only one shortcoming about patients listening to music through headphone/earphone was the isolation of verbal communication between patients and the medical staff during the procedure. However, broadcasting the music as background music might disturb the staff conducting the procedure probably because an imposed choice of musical selection can be annoying to the listener[53].

Recently, a meta-analysis was published on a similar topic[23] but there are several differences between that study and the present one. First of all, colonoscopy was the focus of this paper. Second, this study's search strategy was more comprehensive, meaning that more databases were included and theses/dissertations were also identified. Third, besides the numerically combined results, the characteristics of all included studies were presented and discussed in the text or in the table.

Although our findings confirm the effectiveness of listening to music during the colonoscopy procedure, several areas are worth further investigation. These include the choice of music, the mode of broadcasting music (earphone, background, or both), the possibility of using placebo to the patients in the control group, the possibility of blinding to the colonoscopist/s or medical staff involved in the procedure, the interaction of the medical staff to background music as well as the effect of playing audiovisual materials. Finally, it was suggested that the role of music should be considered whenever applicable[54].

Our results confirm that patient listening to music during colonoscopy is an effective way in reducing

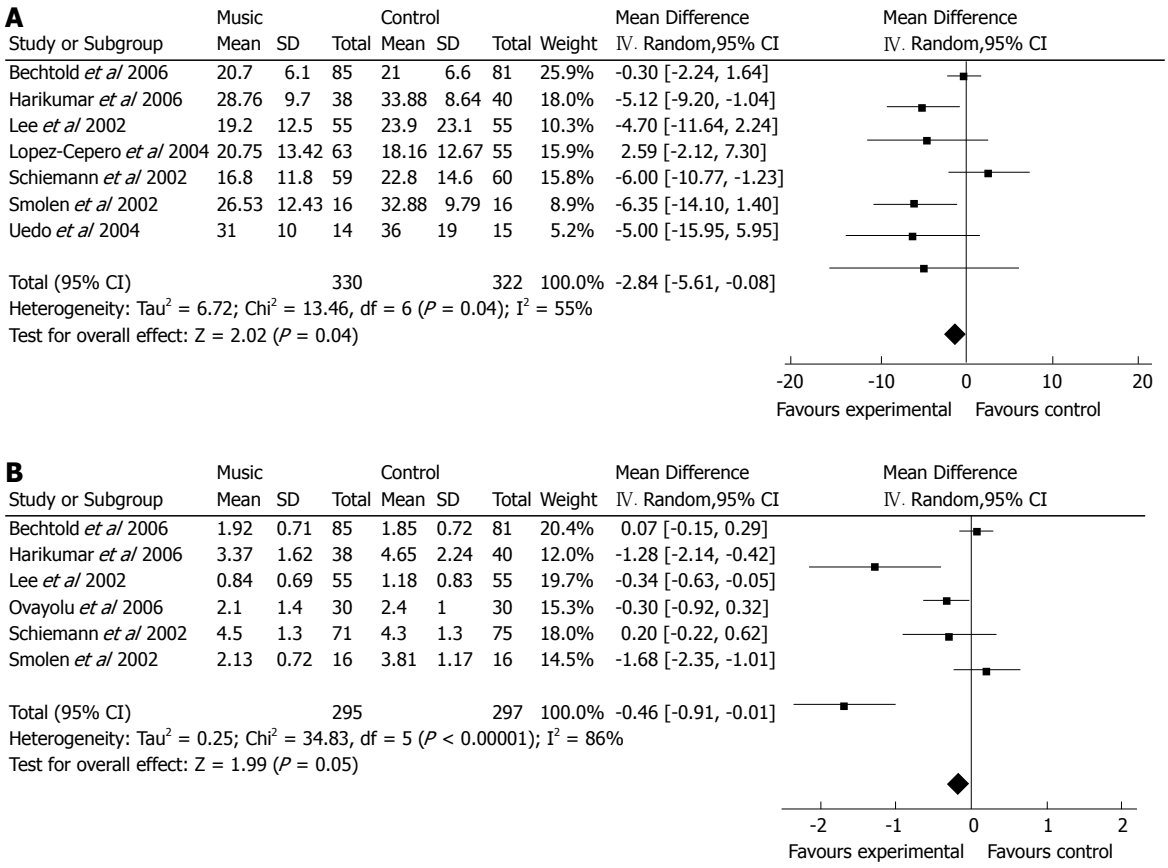

Figure 2 **A**: Forrest plot of the effect of music in procedure time; **B**: Forrest plot of the effect of music in sedation.

procedure time, anxiety, and the amount of sedation. More importantly, no harmful effects were observed for all the studies. Therefore, listening to music during colonoscopy should be recommended.

ACKNOWLEDGMENTS

The authors would like to thank Prof. Mattew Bechtold, Prof. Nair Harikumar, Prof. Ann Hayes and Prof. John Marshall for providing the information in their studies.

COMMENTS

Background

Colonoscopy is the recommended method for screening colon cancer but many people are unwilling to receive it because of fearing the pain, anxiety and other reasons. The use of music in medical research has long history and the beneficial effects of listening music during colonoscopy have been widely reported.

Research frontiers

A meta-analysis was conducted to integrate results from different studies in examining the effectiveness of music in reducing the procedure time and the amount of sedation during colonoscopy.

Innovations and breakthroughs

Our results show that listening to music during colonoscopy may effectively reduce the mean procedure time and the amount of sedation used.

Applications

Listening to music during colonoscopy should be promoted because of its beneficial effect and negligible cost.

Peer review

This is a research on a kind of a complementary and alternative medicine, a "music therapy".

Abstract

AIM: To investigate the effects of exogenously mutated p27^{kip1} (p27) on proliferation and apoptosis of human cholangiocarcinoma cell line, QBC$_{939}$ *in vivo*.

METHODS: Adenoviral vectors were used to transfect mutated p27 cDNA into human QBC$_{939}$ cell line. Expression of *p27* was detected by RT-PCR. Western blot. Cell growth, morphological change, cell cycle, apoptosis and cloning formation were determined by MTT assay and flow cytometry.

RESULTS: The expression of p27 protein and mRNA was increased significantly in QBC$_{939}$ cell line transfected with Ad-p27mt. The transfer of Ad-p27mt could significantly inhibit the growth of QBC$_{939}$ cells, decrease the cloning formation rate and induce apoptosis. *p27* over expression caused cell cycle arrest at G_0/G_1 phase 72 h after infection with Ad-p27mt.

CONCLUSION: *p27* may cause cell cycle arrest at G_0/G_1 phase and subsequently lead to apoptosis. Recombinant adenovirus expressing mutant p27 may be potentially useful in gene therapy for cholangiocarcinoma.

Key words: Adenovirus; Cholangiocarcinoma; Gene therapy; Cell cycle; Apoptosis

INTRODUCTION

It is well known that cell cycle progression is governed by cyclin-dependent kinases (CDKs). P27^{kip1} (p27), a key inhibitor of CDKs, can directly inhibit the entry of cell cycle from G_1 phase into S phase. A major mechanism underlying the regulation of p27 is proteolysis by the ubiquitin–proteasome pathway. Phosphorylation of p27 on threonine 187 (T187) by Cdk2 creates a binding site for a Skp2-containing E3 ubiquitin-protein ligase, SCF. Ubiquitylation of p27 by SCF results in degradation of p27 by the proteasome.

In this study, a replication-deficient adenovirus vector encoding a mutated p27 at the Thr-187/pyrophosphorylation site was constructed and transfected into the cultured human cholangiocarcinoma cell line QBC$_{939}$, in order to investigate the effects of adenovirus-mediated p27 on proliferation and apoptosis of cholangiocarcinoma cells.

MATERIALS AND METHODS

Materials

Human cholangiocarcinoma cell line QBC$_{939}$ was kindly donated by Professor Wang Shu-Guang of the Hepatobiliary Department of Xinan Hospital, Third Military Medical University. Tetramethyl-azo-zole-cyan (MTT) and iodized-dine (PI) were purchased from Sigma Ltd. Human-source rat anti-p27 monoclonal antibody was purchased from Beijing Zhongshan Ltd. Sense and anti-sense primers of p27 were synthesized by Shanghai Sangon Bioengineering and Technology Service Co. Ltd. Recombinant adenovirus vehicle Ad-p27mt and adenovirus control vehicle Ad-LacZ were kindly donated by Professor Xu Shao-Yong at Digestive Medical Department and Doctor Wang Jia-Ning at

Cardiovascular Department, Yunyang Medical College. CO_2 gas incubator(Binder, Germany), inverted phase contrast microscope (Olympus, Japan), FACsort flow cytometry (USA BD Ltd.) were used in this study. Cells used in experiments were divided into control group (QBC_{939} group), Ad-LacZ group and Ad-p27mt group.

Cell culture and transfection

Human cholangiocarcinoma cell line QBC_{939} was incubated in 10% FCS-containing RPMI 1640 culture medium at 37℃ at an atmosphere containing 50mL/L CO_2, and infected with Ad-LacZ or with Ad-p27mtatant at multiplicity of infection (MOI) of 50 as the density reached to 40%-50%.

Transduction efficacy of recombinant adenovirus

Ad-LacZ was used to infect QBC_{939} cholangiocarcinoma cells when the MOI was set at 25, 50, 100 and 200. X-gal staining was performed after 48 h culture. Blue-staining cells were counted and the percentage was calculated to confirm recombinant adenovirus infection efficacy. Results demonstrated that as MOI ⩾ 50, recombinant adenovirus was able to implement an approximately 100% transduction efficacy rate on the two types of cells.

Cell growth inhibition test (MTT assay)

Cells (4000-6000 cells/well) were inoculated in 96-well plates. The culture fluid was discarded after 48h of grouping, and 150 μL /well (0.5 mg/mL) MTT solution was supplemented at 37℃ for 4 h followed by 150 μL/well DMSO, and shaken for 10 min. Absorbance (A) value was detected with an autokinetic enzyme scaling meter at 492 nm wavelength. Cell growth suppressive rate = (1-A value of experimental group/A value of the same titre QBC_{939} group) × 100%.

Clone formation

The cells infected with Ad-LacZ or with Ad-p27mutant at a MOI of 50 were transferred into a 12-well plate (500 cells/well) in triplicate and cultured for 3, 6, 9, and 12 d, respectively, then fixed with methanol and stained with 0.4% crystal violet. Clones containing at least 50 cells were counted under inverse microscope. Clone formation ratio (%) = cell clone amounts/500 × 100%.

Extraction of total RNA and RT-PCR

Total cellular RNA was extracted from QBC_{939} cells transfected with Ad-p27mt and Ad-LacZ for 48 h using the Trizol method. PCR was performed after reverse transcription. The sequences of P27mt gene are upstream primer: 5'-CCTAGAGGGCAAGTACGAG TG-3', downstream primer: 5'-GAAGAATCGTCGG TTGCAGGTCGCT-3'. Reaction parameters were pre-degenerated at 95℃ for 5 min, degenerated at 94℃ for 30 s, 39 cycles of annealing at 56.3℃ for 35 s, extension at 72℃ for 35 s, a final extension at 72℃ for 10 min. Electrophoresis was performed for the PCR products on a 2% agarose gel.

Western blot

Cellular protein disposed for 72 h was extracted with the same method as described above. The proteins electro-transferred onto nitrocellulose membranes and blocked by confining liquid were bound to p27 monoclonal antibody and secondary antibody, and colored by enhanced chemiluminescence (ECL).

Table 1 In different testing groups QBC_{939} cells

Group	Cell clone count (ratio, cell clone amounts/500)			
	3 d after transfect	6 d after transfect	9 d after transfect	12 d after transfect
Ad-p27mt group	9 (1.8)	14 (2.8)	15 (3.0)	21 (4.2)
Ad-LacZ group (n = 3)	16 (3.2)	27 (5.4)	49 (9.8)	56 (11.2)
QBC_{939} group (n = 3)	18 (3.6)	31 (6.2)	46 (9.2)	62 (12.4)

F = 10.361, P = 0.011 (cell clone ratio, Ad-p27m *vs* AdLacZ group).

Cell cycle and apoptosis counting analysis by flow cytometry

Cells of each group (above 10^6 cells in each group) were harvested at different time points. RNA enzyme was added at 37℃ and reacted for 1 h after cells were fixed in 70% alcohol at 4℃ for 24 h (final concentration 50 μg/mL). After 20-30 min of PI solution (concentration 100 μg/mL) staining, cells were counted by monochromatic fluorescence flow cytometry to observe the apoptosis rate.

Statistical analysis

All data were expressed as mean ± SD. The data were analyzed with SPSS 10.0 software. Variance analysis SNK method was employed in comparison of multi-groups. $P < 0.05$ was considered statistically significant.

RESULTS

Titre of recombinant adenovirus

Ultraviolet spectrophotometry showed that the titre of recombinant adenovirus after multiplication, amplification, and purification was up to 7.95×10^{12} CFU/mL.

Transduction efficacy of recombinant adenovirus

Ad-LacZ was used to infect QBC_{939} cholangiocarcinoma cells. The multiplicity of infection (MOI) was 25, 50, 100 and 200. X-gal staining was performed after 48 h culture. Blue-staining cells were counted and the percentage was calculated to confirm the recombinant adenovirus infection efficacy. Results demonstrated that as MOI ⩾ 50, recombinant adenovirus was able to implement an approximately transduction efficacy rate of 100% in the two types of cells.

Growth suppression of QBC_{939} cells by introduction of mutated p27 gene

Clone formation test: The number and ratio of cellular clones in different groups are shown in Table 1 and Figure 1. The transfer of Ad-p27mt significantly inhibited the growth of QBC_{939} cells, decreased the clone formation, which was significantly different from the Ad-LacZ-infected and uninfected groups (F = 10.361, P = 0.011) with no statistical difference.

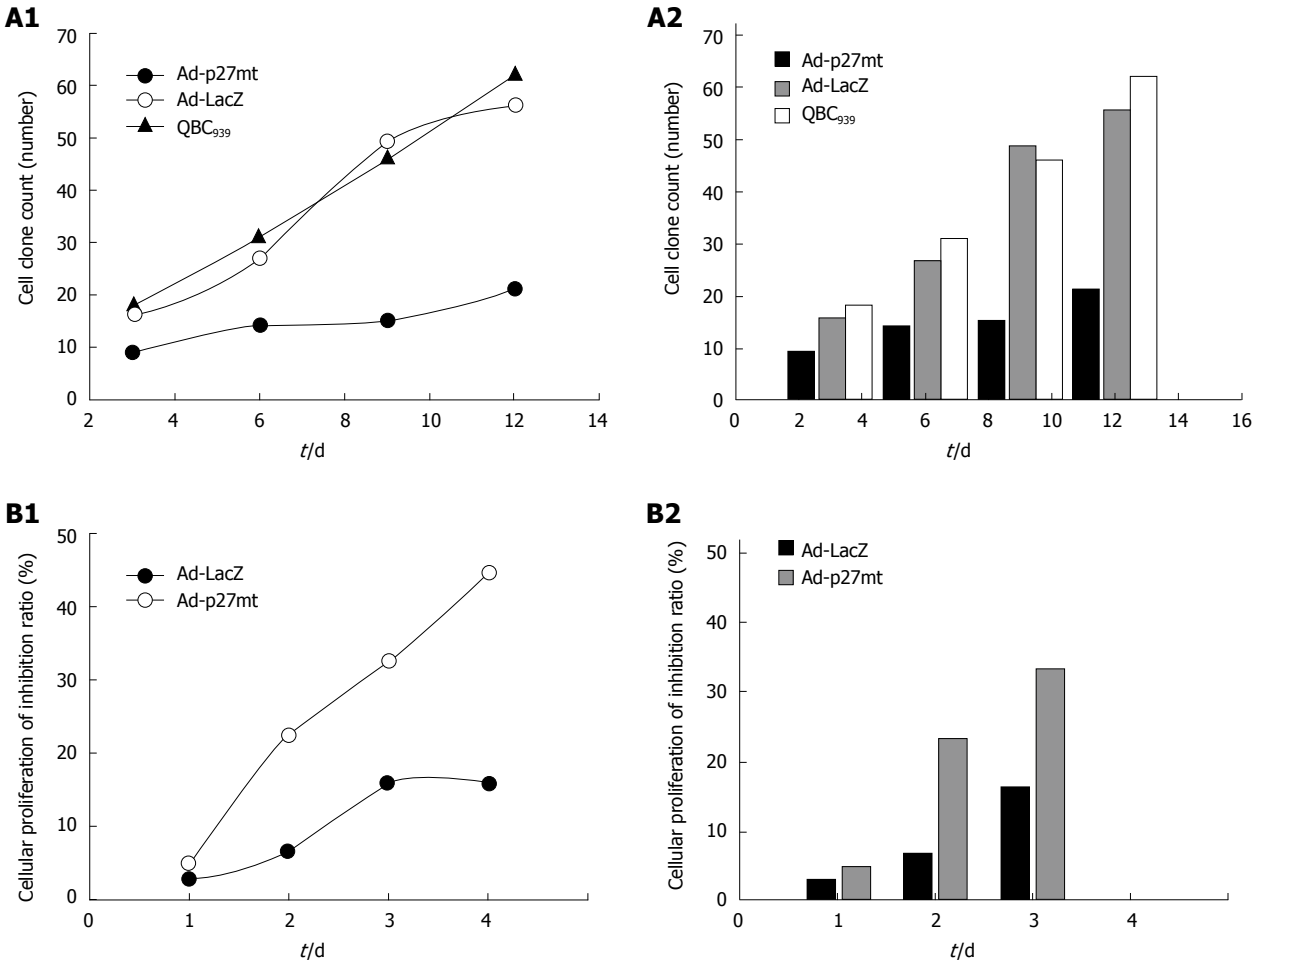

Figure 1 Clone formation test and MTT assay showing effect of Ad-p27mt and Ad-LacZ on growth curve of QBC_{939} cells (**A1**, **B1**) and on the proliferation of QBC_{939} cells (**A2**, **B2**).

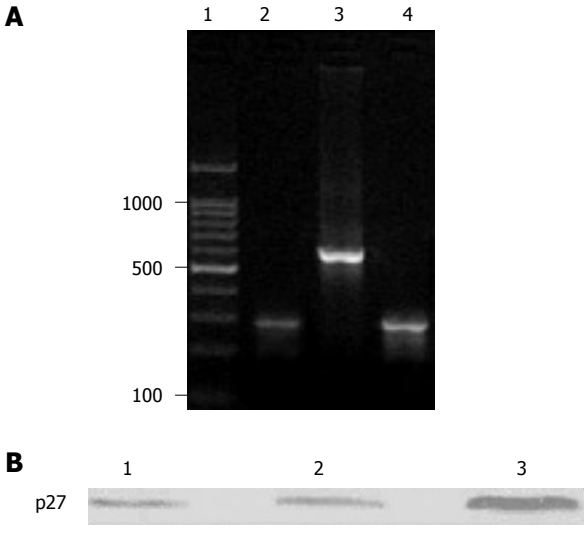

Figure 2 *p27* expression at mRNA (**A**) and protein level (**B**). Lane 1: Marker; Lane 2: QBC_{939}; Lane 3: β-actin; Lane 4: QBC_{939}/Ad-p27mt in Figure 2A; Lane 1: QBC_{939}; Lane 2: QBC_{939}/Ad-LacZ; Lane 3: QBC_{939}/Ad-p27mt in Figure 2B.

MTT assay for cell growth and viability: MTT assays also indicated that the proliferation of QBC_{939} cells was significantly inhibited after Adp27 infection, with its inhibitory effect peaked at 72 h. The transfer of Ad-p27mt could significantly inhibit the growth of QBC_{939} cells and decrease clone formation. After 24, 48 and 72 h of Adp27 infection, the average CD value was remarkably lower in Adp27-infected group than in Ad LacZ-infected and uninfected groups, revealing that introduction of exogenously mutated p27 gene *via* a recombinant adenovirus vector could significantly suppress the growth of QBC_{939} cells in a non time-dependent manner within 72 h.

Expression of p27 in cholangiocarcinoma QBC_{939} cells at mRNA level

Gel electrophoresis for the RT- PCR products displayed that the expression of *p27* was decreased in normal control group, but the expression of QBC_{939} cells was significantly elevated with a distinct 275bp objective gene strap (Figure 2A).

Expression of p27 in cholangiocarcinoma QBC_{939} cells at protein level

The expression of *p27* was significantly increased in Ad-p27mt-tranfected QBC_{939} cells. However, the expression of *p27* could be detected in a small number of Ad-LacZ-tranfected QBC_{939} cells (endogenous) and in the control group (Figure 2B).

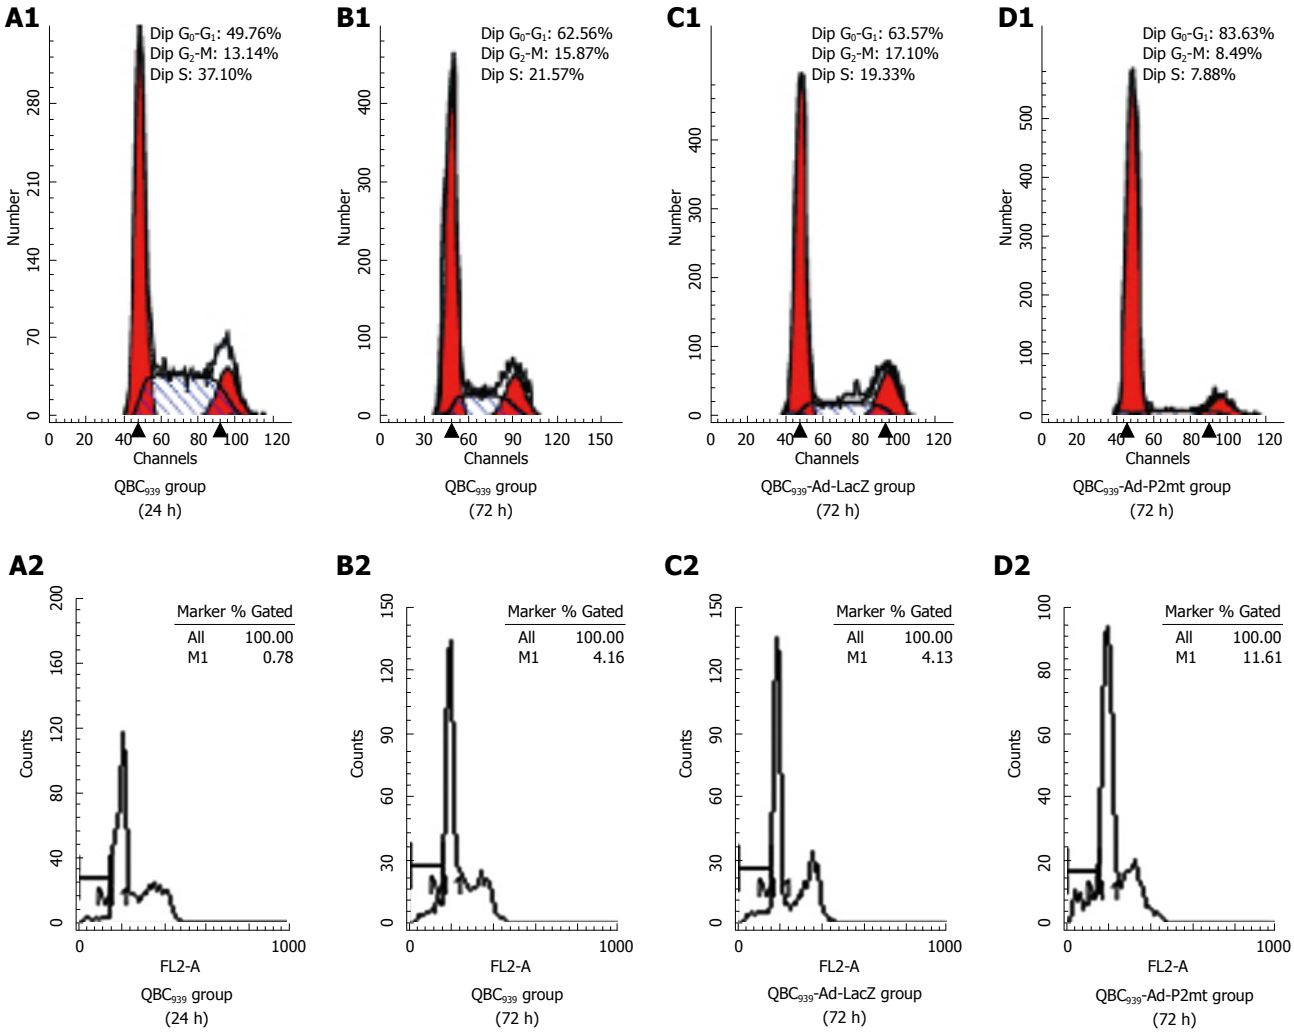

Figure 3 Impact of exogenous *p27* gene on QBC_{939} cell cycle and apoptosis.

Table 2 Influence of gene transfect on QBC_{939} cells at G_0/G_1 phase and apoptosis in different testing groups (mean ± SD)

Group	G_0/G_1 (%)/apoptosis (%)		
	24 h after transfect	48 h after transfect	72 h after transfect
Ad-p27mt group (n = 3)	61.02 ± 1.03/ 0.81 ± 0.052	73.32 ± 2.99/ 5.27 ± 0.030	83.63 ± 2.10/ 11.61 ± 1.23
Ad-LacZgroup (n = 3)	54.91 ± 2.32/ 0.76 ± 0.031	62.56 ± 2.71/ 1.28 ± 0.043	63.57 ± 2.32/ 4.16 ± 0.230
QBC_{939} group (n = 3)	49.76 ± 1.97/ 0.78 ± 0.041	56.95 ± 1.06/ 1.10 ± 0.071	62.56 ± 2.88/ 4.13 ± 0.454

F = 15.954, P = 0.012 (G_0/G_1 cell ratio, Ad-p27m *vs* AdLacZ group); F = 3.236, P > 0.05 (apoptosis rates, Ad-p27m *vs* AdLacZ group).

Impact of exogenous p27 gene on QBC_{939} cell cycle and apoptosis

A high expression level of exogenous p27 protein in QBC_{939} cells evoked a strong cell cycle arrest at G_0/G_1 phase in a time-dependent manner within 72 h. The cell ratio was stabilized at about 83.63% ± 2.10% in a non time-dependent manner after 72 h, which was significantly different from that in the Ad-LacZ-infected and uninfected groups (F = 15.954, P = 0.012; Table 2 and Figure 3). The apoptosis rate was 11.61% ± 1.23% when the cells were infected with Ad-p27mt for 72 h. The sub-G_1 apoptosis was more significant in Ad-p27mt group than in AdLacZ and control groups (Table 2 and Figure 3). All results were obtained from experiments performed in triplicate.

DISCUSSION

Cholangiocarcinoma remains one of the most difficult tumors to treat in clinical practice. Currently, there is no effective chemotherapy for this disease. Surgery offers the only opportunity to cure it. However, the majority of patients fail to qualify for such a treatment. Therefore, new therapeutic modalities are needed. Gene therapy is regard as one of the most important and potential new modalities for this disease.

The CDK inhibitor *p27* plays a major role in controlling the cell cycle, which negatively regulates the transition from the G_1 into the S phase. Moreover, p27^{kip1} is also a tumor suppressor. Loss of p27 function weakens the control of G_1/S checkpoint, thus accelerating cell cycle progression and predisposing cells to malignant transformation[1,2]. Ganoth *et al*[3]

and Troncone *et al*[4] reported that the degradation of *p27* is mainly regulated by post-translational ubiquitin-proteasome-mediated proteolysis of phosphorylation in threonine (Thr) 187. In order to inhibit the degradation of *p27* and restore the function of G_1/S checkpoint, we transfected mutated p27 into cholangiocarcinoma QBC_{939} cell line, which has a mutation of Thr-187/Pro-188 (ACGCCC) to Met-187/Ile-188(ATGATC).

Western blot analysis showed that 72 h after infection with Ad-p27mt, *p27* in the CBC_{939} cells expressed a strong band, whereas Ad-LacZ-infected QBC_{939} cells showed a faint p27 protein product in the uninfected groups, suggesting that tansgenes can be successfully induced and expressed. The elevated level of *p27* expression demonstrated that mutated p27 was resistant to degradation and more stable than wild p27, indicating that phosphorylation of threonine (Thr) 187 can trigger degradation of wild p27. The transfer of Ad-p27mt significantly inhibited the proliferation of QBC_{939} cells, decreased clone formation, strongly induced cell cycle arrest and apoptosis at G_1/S phase within 72 h after infection, which is consistent with the previous findings[5].

It has been well documented that over expression of wild p27 *via* adenoviral gene transfer on p27-deficient tumor cells could strongly inhibit cell cycle arrest and even lead to significantly apoptosis in disparate types of human cancers, such as spongiocytoma, lung cancer, leukaemia. It is a common phenomenon that recombinant adenovirus-mediated p27 can eliminate carcinoma cells through apoptosis. Although there was no significant difference in apoptosis between Adp27mt- and AdLacZ-infected cells, uninfected cells at any time point, our data show that 72 h after infection with Adp27mt, the typical sub-G_1 apoptotic peak could be observed by flow cytometry, which was more apparent than in AdLacZ-infected and uninfected cells. Although the precise mechanism by which *p27* induces apoptosis is unclear, transfer of *p27* is associated with a moderate level of apoptosis as shown by FACS analysis. Since QBC_{939} cells have mutated p53, the mechanism underlying apoptosis induced by transfer of *p27* must be p53-independent. Further investigation is needed on how *p27* regulates and induces apoptosis.

In conclusion, Ad-p27mt at Thr-187 can be used as a novel, potent, tumor-suppressing gene therapy tool in the treatment of cholangiocarcinoma.

ACKNOWLEDGMENTS

The authors thank Doctors Chen YJ and Wang WY for their long, concerted, and fruitful efforts, Professor Wang SG for kindly donation of human cholangiocarcinoma cell line QBC_{939}, Professors Xu SY and Wang JN for their recombinant adenovirus vehicle Ad-p27mt and adenovirus control vehicle Ad-LacZ, Professor Zou SQ for his useful suggestions, and a great debt of gratitude to its organizer, Professor Zou SQ.

COMMENTS

Background

As a cyclin-dependent kinase inhibitor, $p27^{Kip1}$ (*p27*) regulates cell cycle progression by transcriptional, translational and proteolytic mechanisms. G_1/S cell cycle progression requires p27 proteolysis, which is triggered by its phosphorylation of threonine (Thr) 187. Increased *p27* causes proliferating cells to exit from the cell cycle, while decreased *p27* is required for quiescent cells to resume cell division. Low levels of *p27* are associated with excessive cell proliferation in pathological conditions such as inflammation and cancers. High levels of *p27* are observed in such conditions of diminished cell proliferation as in late stages of arterial wound repair in atherosclerosis. Interestingly, in many types of tumors such as gastric, prostate and breast carcinomas, the expression of *p27* gene is down-regulated. Loss of *p27* expression may result in tumor development and/or progression.

Research frontiers

The research involved cell morphologyoncology, cell morphology, molecular biology and gene therapy for cholangiocarcinoma.

Innovations and breakthroughs

It is well know that the degradation of *p27* is mainly regulated by post-translational ubiquitin-proteasome-mediated proteolysis during phosphorylation of threonine (Thr) 187. In order to inhibit the degradation of *p27* and restore the function of G_1/S checkpoint, we transfected mutated p27 into cholangiocarcinoma QBC_{939} cell line, which can mutate from Thr-187/Pro-188 (ACGCCC) to Met-187/Ile-188(ATGATC). The recombinant adenoviral vector cannot replicate in target cells because it lacks the E1 gene, thus only expressing the inserted gene. Because the foreign gene fragment is not incorporated into the genome of target cells, the danger of mutations affecting treatment is reduced. Meanwhile, adenoviral vectors are stable and easy to purify. This technique can effectively affect both proliferating and quiescent cells *ex vivo*. The potential for gene therapy by using the recombinant adenovirus is worthy of extensive attention. The results of our study suggest that adenovirus-mediated p27 gene transfection can be used as a novel gene therapy for cholangiocarcinoma.

Applications

The prognosis of cholangiocarcinoma is extremely poor although aggressive multidisciplinary cancer therapies have been used in clinical practice. Thus, it is imperative to develop new and effective treatment modalities for cholangiocarcinoma, such as gene therapy.

Peer review

The authors showed that transfection of a human cholangiocarcinoma cell line (QBC_{939}) could cause cell cycle arrest and apoptosis, which are of interest in developing new treatment modalities for cholangiocarcinoma. The methods used were well described. The results are of scientific interest.

Abstract

We present a case report of a patient with a suspicious ileal carcinoid tumour. Clinical examination as well as computer tomography (CT) scan suggested a tumour. Octeotride scan showed uptake in the same bowel loop reported as pathological in CT. The patient underwent surgery and biopsy which reported Crohn's disease (CD). The interest in the case is due to the fact that this is, to the best of our knowledge, the second report of Crohn's disease as a cause of false positive octeotride scan. Unfortunately, no somatostatin receptors could be found in the sample, so further studies should be performed.

Key words: Crohn's disease; Carcinoid tumour; Octreoscan; Somatostatin receptor scintigraphy; ^{111}In-DTPA- octreotido

INTRODUCTION

Somatostatin receptors (SS-Rs) are membrane glycoproteins spreading over a large number of body tissues and can be found in normal and pathological conditions[1]. Many benign and malignant tumours over express SS-R in their membranes especially in neuroendocrine tumours (NETs) but there are other benign conditions showing an increase number of SS-Rs, such as granulomatous or inflammatory disease[2].

Octeotride is an analogue whose molecule is a shortened version of somatostatin's, from 8 to 14 aminoacides, sharing its active nuclei and allowing the ^{111}Indium-DPTA molecule to bind to the N-terminal (d-phe).

Thus, ^{111}In- DTPA-D- Phe1- octreótido (^{111}In-DTPAOC) is the labelled form of octreotide. There are 5 subtypes of SS-R, and somatostatin shows a high affinity for all of them. However, octeotride has a high affinity for only SS-R 2 subtype and a low affinity for SS-R 3 and SS-R 5 subtypes. Therefore, pathological conditions over expressing these receptors are able to be imaged in ^{111}In- DTPAOC scans.

The sensitivity of ^{111}In- DTPAOC in detecting these pathological conditions is variable being very high in carcinoid tumour (86%)[3]. Uptake in other tissues can lead to false-positive findings when studying suspected NETs. Only one case of Crohn's disease (CD) has been recently reported as a cause of false positive scan[4].

We report a case of a false positive ^{111}In- DTPAOC scintigraphy in a patient with CD mimicking an ileal carcinoid tumour. A discussion about SS-R potential alterations in CD was included.

CASE REPORT

A 40-year-old man was admitted to our outpatient clinic with an 8-mo history of dull abdominal pain and weight loss of 20 kg, but no other gastrointestinal symptoms. In terms of past medical or surgery history, the patient denied of smoking or other diseases. Physical examination only revealed a painful site in the right lower quadrant of the abdomen and a body temperature of 37.3℃. Laboratory test only revealed an increased erythrocyte sedimentation rate of 35 mm/h (normal range: 0-25 mm/h) and C-reactive protein rate of 2.37 mg/dL (normal range: 0-0.5 mg/dL). A computer tomography (CT) scan was performed (Figure 1) and showed thickening of the ileum distal wall and the presence of a 4 cm solid mass with irregular border adjacent to the affected ileum, conditioning retraction, with prominent mesenteric lymph nodes. All these findings suggested a carcinoid tumour.

Figure 1 CT-scan showing thickening of the distal ileum (long arrow) with an adjacent solid mass (short arrow), suggesting a carcinoid tumour.

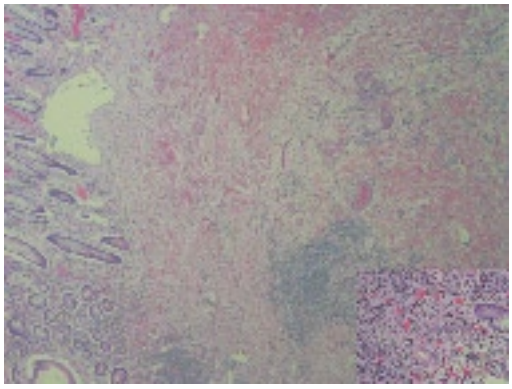

Figure 3 CD showing marked transmural inflammatory changes (involving the walls of veins and arteries): edema, lymphatic dilatation, hyperplasia of the muscularis mucosae, fibrosis ("obliterative muscularization"), and epithelioid granuloma.

Further explorations were performed. Colonoscopy with ileoscopy (at least 15 cm of the distal ileum was explored) showed an irregular ileal mucosa with erythema, irregular nodular areas and marked stiffness, suggesting an infiltrative process. Ten ileal biopsies were taken and showed unspecific inflammatory changes without evidence of malignancy, granulomas or histological features suggestive of carcinoid tumour or CD. A 24-h urine collection for 5-hydroxyindolacetic acid (5-HIAA) showed a normal result of 3.3 mg/24 h (normal range < 10 mg/24 h).

Due to the low sensitivity of the 24-h 5-HIAA test and the high suspicion of carcinoid tumour, an ^{111}In-DTPAOC scan was performed. The patient was injected with 3mCi ^{111}In- DTPAOC. Total body images were obtained at 4 and 24 h, and an abdominal SPECT was also performed at 14 h. The images showed pathological uptake in central and right pelvic fossae at 4 and 24 h (Figure 2). SPECT showed a C-shape uptake in the sagittal plane that matches with the thickened loop on CT. No uptake was observed in the solid mass. The scan was reported as a highly suspicious carcinoid tumour.

With all these results, laparoscopy with curative intention was performed. An inflammatory mass involving the distal ileon was found at surgery, and a distal small bowel resection and right hemicolectomy with lateral anastomosis were performed. Histological analysis

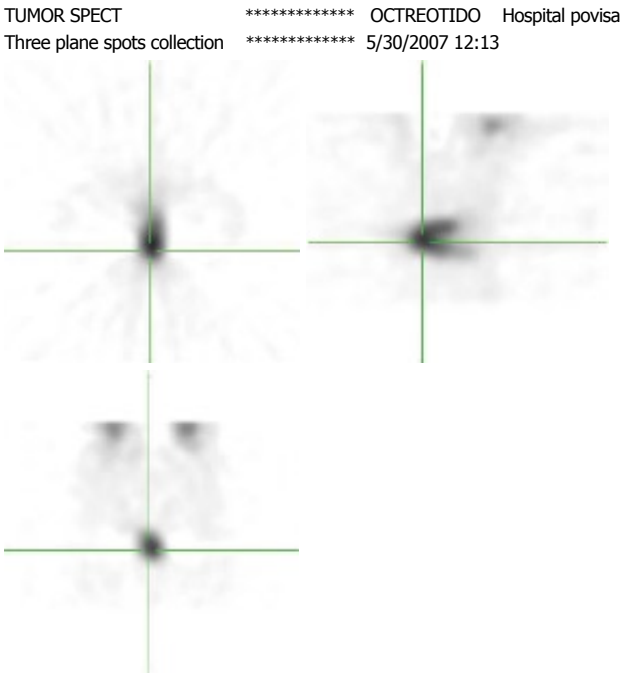

Figure 2 Octeotride-SPECT images showing pathological uptake in the ileal thickened loop at CT-scan.

of macroscopically-affected segments and specimens of non-macroscopically-involved segments was carried out. Thickened serosa and shortened mesentery could be grossly observed in the involved terminal ileum (20 cm), resulting in a corrugated bowel contour in the terminal portion of the small bowel. These changes could probably mimic the impression on CT-scan to an abdominal mass. The mesenteric lymph nodes were enlarged measuring 8 mm in the larger diameter. The detailed macroscopic examination failed to show any tumour mass. Photo of gross specimen neither was nor included. Other gross findings of significance included stricture formation, fissuring, cobblestone appearance (discontinuous involvement with transmural spread) with an intervening normal or edematous mucosa. The main microscopic features were ulceration, fissure, non caseating sarcoid-like granuloma and lymphoid aggregates. The regional lymph nodes showed sinusal dilatation and lymphoid hyperplasia. Chromogranin stain was not performed.

Intestinal tissue sections were routinely fixed in 10% neutral formalin and embedded in paraffin. Immunohistochemical staining for Dako® polyclonal antibodies against human somatostatin protein was performed with the standard avidin-biotin method. The slide-mounted tissue sections were allowed to reach room temperature and incubated for 60 min at a solution of 1:900, using saponic to antigenic recuperation. Somatostatin immunohistochemical expression was undetectable in the veins or arteries of inflamed and non inflamed control intestinal tissue sections. No concordance was reached in immunohistochemistry/scintigraphy somatostatin receptor. No areas of dysplasia or carcinoma were identified.

In the absence of features other than the typical appearance of CD, the pathologic diagnosis of Crohn's ileitis was made (Figure 3).

After surgery, azathioprine was started for prevention of postoperative recurrence. The patient underwent a complete clinical recovery and 6 mo later he was asymptomatic. A surveillance/follow-up colonoscopy did not show any abnormality and inflammatory signs of recurrence.

DISCUSSION

There are many cases of carcinoid tumour misdiagnosed as CD only discovered when treatment is not effective or surgery is performed. It was reported that approximately 2.3% of patients with ileal carcinoid are first diagnosed and treated as CD[5]. However, the reverse is a very uncommon situation.

In our case, the clinic features as well as the image of CT-scan strongly suggested a carcinoid tumour. In order to confirm the suspected disease, ^{111}In- DTPAOC scan was performed and showed a C-shape uptake in the bowel loop that corresponded to that reported as pathologic in CT, but there was no uptake in the solid mass. The patient underwent surgery and the final pathologic report was CD. The mass that did not show uptake was reported as inflammatory.

^{111}In- DTPAOC is a radio-labelled octreotide analogue that binds to SS-R expressed in cell membranes. Many benign and malignant diseases overexpress SS-R and thus, can be imaged with this radioligand[6]. Carcinoid tumour, one of the malignant tumours, shows more uptakes in the bowel loop due to its high density of SS-R. Reported values for the detection of known carcinoid tumour localizations vary from 80% to nearly 100%[1]. Uptake is related to SS-R density and even tumours smaller than 1 cm in diameter can be detected. This is the reason why somatostatin receptor scintigraphy (SRS) plays a central role in locating and assessing the primary gastroenteropancreatic NET[7] and has a marked effect in the clinical management of these malignancies[8,9]. However, 12% of SRS examinations result in false-positive localization of NET, understanding a false-positive as an uptake not related with the tested pathology. Renal parapelvic cysts, accessory spleens, ventral hernias, thyroid or breast disease are the most frequent cases of false positive localizations[10]. SS-R is over expressed in activated peripheric lymphocytes and macrophages in granulomatous and inflammatory diseases, allowing obtaining images[11,12].

In normal bowel, SS-R is expressed in gastrointestinal mucosa, peripheral nervous system and lymphoid tissue. Several tumours, such as carcinoid tumour, express SS-R in peritumoral veins[13]. In intestinal inflammatory disease, a high density of SS-R is detected by autoradiography in intestinal intramural veins but not in normal tissues. SS-R is seen in small muscular veins of submucosa, tunica muscularis and subserosa, and the thickness of veins is labelled. These veins are histologically normal and seldom have a minimal lymphocyte infiltration although label intensity does not seem to depend on them as the surrounding tissues are infiltrated with these cells and do not show labelling[14-16].

Usually no ^{111}In- DTPAOC uptake is found in inflammatory bowel disease. There is only one recent report of ^{111}In- DTPAOC uptake in Crohn's disease in literature although there is no evidence that SS-R is determined[4]. In our case, the samples were studied to assess the existence of SS-R. Immunohistochemical staining of somatostatin receptors was performed and somatostatin immunohistochemical expression was undetectable in the veins or arteries of inflamed and non inflamed control intestines.

Unfortunately, SS-R could not be found in the tissues studied, so we could not explain this abnormal uptake. No concordance was reached in immunohistochemistry/ scintigraphy somatostatin receptor, possibly as a consequence of somatostatin receptor heterogeneity. Further studies should be made to assess the possible causes of uptake in CD.

However, there are several reports of small carcinoid tumours (a few millimetres in diameter) found in patients with CD, suggesting a correlation between the pathogenesis of both disorders[17]. It has been theorized that inflammation creates a favourable environment for the development of carcinoid tumour, although most of the carcinoid tumours reported are found in non-inflamed bowel. Other theories include the hyperstimulation of enteroendocrine cells by inflammation[18] and the role of proinflammatory cytokines such as PTHrP or IL-6[19].

We would like to encourage physicians to be aware of CD as a cause of false positive results when performing ^{111}In- DTPAOC scans.

Abstract

A case of inflammatory myoglandular polyp (IMGP) causing hematochezia is reported. The patient was a 33-year-old man who visited our hospital for further evaluation of hematochezia. Colonoscopy revealed a red, hard, spherical peduncular polyp with erosion and mucous exudation, about 20 mm in diameter, in the descending colon. Excluding the polyp, there was no lesion in the colorectum. Endoscopic polypectomy was performed. Histological examination of the specimen revealed inflammatory granulation tissue in the lamina propria, proliferation of smooth muscle, and hyperplastic glands with variable cystic changes. This polyp was diagnosed as an IMGP. The symptom of hematochezia was resolved after endoscopic resection. Our case shows that treatment is necessary for IMGP if intestinal bleeding occurs and endoscopists should be aware of the endoscopic characteristics of IMGP.

Key words: Inflammatory myoglandular polyp; Colonoscopy; Endoscopic polypectomy; Gastrointestinal bleeding

INTRODUCTION

Inflammatory myoglandular polyp (IMGP) is characterized by inflammatory granulation tissue in the lamina propria[1], proliferation of smooth muscle[2], and hyperplastic glands with variable cystic changes[3-7]. Only a small number of cases have been reported and the pathogenesis and natural history remain unclear[8-12]. Herein, we describe a relatively rare case of inflammatory myoglandular polyp causing hematochezia.

CASE REPORT

A 33-year-old man presented with the symptom of hematochezia. He was in good health with no specific family or past medical history. His body temperature was 36.7℃, blood pressure was 148/82 mmHg, and radial pulse rate was 70 beats/min and regular. He had neither anemia nor jaundice. Neurological examination revealed no abnormal findings. Abdominal palpation revealed tenderness in the left lower quadrant. Routine hematological examination and biochemical tests were within normal limits. Colonoscopy revealed a red, hard, spherical peduncular polyp with erosion and mucous exudation, about 20 mm in diameter, in the descending colon (Figure 1). With conventional colonoscopy, the lesion did not show type Ⅲ or Ⅳ pit pattern although magnifying colonoscopy was not performed. We speculated that this polyp was non-neoplastic. It was suspected to be an inflammatory polyp from endoscopic findings although it should be distinguished from a juvenile polyp. An air contrast barium enema also revealed a pedunculated polyp in the descending colon (Figure 2). Excluding the polyp, there was no lesion in the colorectum. We speculated that the polyp in the descending colon was the causative lesion of hematochezia. Endoscopic polypectomy was performed. At polypectomy, polyp erosion was healed (Figure 3). Histological examination of the specimen revealed inflammatory granulation tissue in the lamina propria, proliferation of smooth muscle, and hyperplastic glands with variable cystic changes (Figure 4). The lesion was diagnosed as an IMGP. After endoscopic polypectomy, the symptom of hematochezia was resolved.

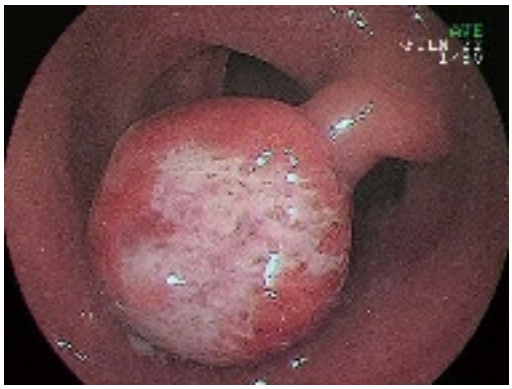

Figure 1 Endoscopy showing a red, hard and spherical peduncular polyp, about 20 mm in diameter, in the descending colon.

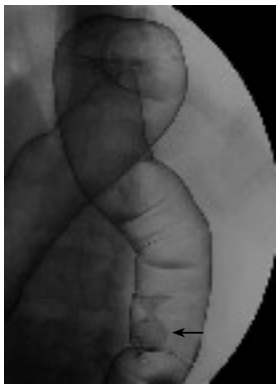

Figure 2 Double contrast radiograph of descending colon showing an about 20 mm peduncular polyp.

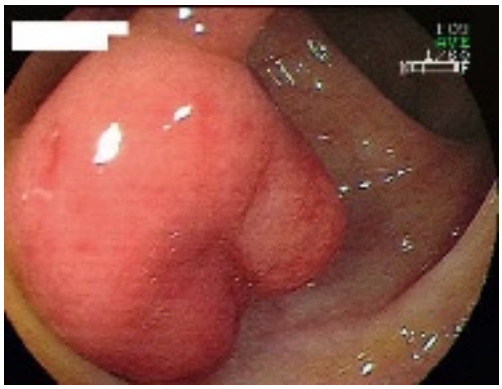

Figure 3 The second colonoscopy showing a healed polyp.

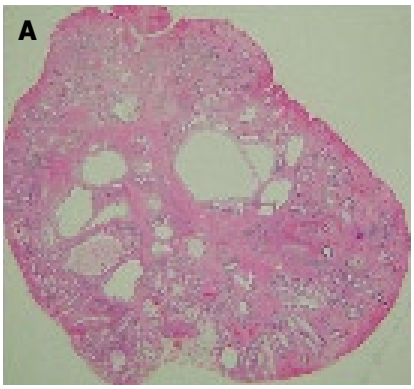

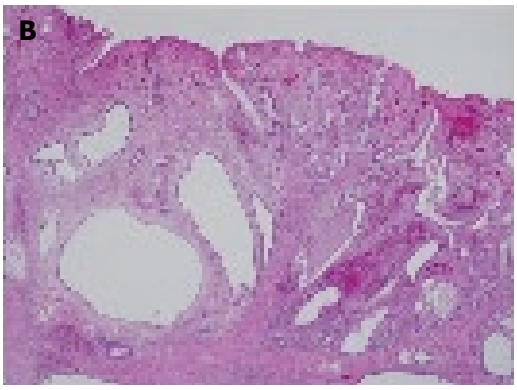

Figure 4 Microscopic findings of the polypectomy specimen. Low-power view of a cross section showing a stalked polyp containing numerous cystically dilated glands (**A**) and inflammatory granulation tissue in the lamina propria mucosae and proliferation of smooth muscle (**B**).

DISCUSSION

IMGP is a non-neoplastic colorectal polyp, first described by Nakamura *et al*[1]. IMGP is solitary, pedunculated and rarely, covered by a fibrin cap, and follows a benign course. Also, IMGP has no association with inflammatory bowel diseases and is located not only in the rectosigmoid, but also in the descending and transverse colon[3]. In the present case, it was located in the descending colon. Although the pathogenesis of IMGP remains unknown, Nakamura[1] proposed that chronic trauma from intestinal peristalsis may contribute to the pathogenesis of IMGP.

Only a small number of IMGP cases have been reported. According to Fujino *et al*[8], a review of the literature revealed 48 cases of IMGP in the large intestine up to 2001. However, recent advances in diagnostic techniques, especially the widespread use of colonoscopy for colorectal tumors, have enabled us to identify small and asymptomatic polyps, and reports on IMGP of the colon have been increasing[9,10]. Fujino *et al*[8] described that the macroscopic appearance is the pedunculated type in 83.3% of cases. In that report, the sites of IMGP in the large intestine were studied and 47 of 48 cases (97.9%) had lesions in the rectum to transverse colon. Thus, IMGPs of the large intestine are predominantly in the distal colon[8,9]. IMGPs in the colon are usually asymptomatic and often detected incidentally on barium enema or endoscopy[8-10]. Another review of the literature revealed that the main clinical feature of colorectal IMGPs is hematochezia[10,11]. Endoscopic characteristic findings include (1) pedunculated or semipedunculated, (2) red and (3) smooth, spherical and hyperemic surface with patchy mucous exudation and erosion[8,9]. In the present case, the endoscopic findings of the polyp were compatible with those of IMGP.

As to therapy, IMGP of the large intestine can best be removed endoscopically, because it is thought to be clinically and histologically benign. Most Japanese cases have been treated with polypectomy or endoscopic mucosal resection (EMR)[5,7-11]. If we could confirm the histological diagnosis of small colonic IMGPs by endoscopic biopsy, endoscopic resection of IMGP might be unnecessary because IMGP follows a benign course.

However, the diagnosis of colorectal IMGPs could seldom be made by endoscopic biopsy and the final diagnosis of colonic IMGP depends on the pathological findings of EMR or endoscopic polypectomy specimens. Endoscopic or surgical treatment is necessary if gastrointestinal bleeding[9] or colonic intussusception occurs. Local excision of the polyp is curative. Kayhan *et al*[12] have reported a case of large IMGP (> 6 cm) that was too large to be removed endoscopically, and was thus treated with surgical resection. We consider that the percentage of patients with colonic IMGP who undergo surgical resection will decrease and endoscopic resection will increase in the future because of recent advances in diagnostic technologies such as improved endoscopic images.

In conclusion, we report a case of IMGP causing hematochezia. IMGP should generally be taken into consideration as a differential diagnosis of peduncular polyp of the colon. IMGP of the large intestine is not fatal and patients remain asymptomatic in their daily lives except for gastrointestinal bleeding or bowel obstruction. Therefore, it is likely that there are many latent patients with IMGP who might be incidentally discovered in the future. Endoscopists should be aware of that IMGP may exhibit the aforementioned endoscopic characteristics and may cause hematochezia. The causes of IMGP are still obscure, and further accumulation of cases may disclose their pathogenesis.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialities, and thus eventually improving the clinical practice and healthcare for patients.

Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology* and *Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com/wjg. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903
Ocean International Center, Building D
No. 62 Dongsihuan Zhonglu
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

Acute mesenteric ischemia (AMI) is a highly-lethal surgical emergency. Several pathophysiologic events (arterial obstruction, venous thrombosis and diffuse vasospasm) lead to a sudden decrease in mesenteric blood flow. Ischemia/reperfusion syndrome of the intestine is responsible for systemic abnormalities, leading to multi-organ failure and death. Early diagnosis is difficult because the clinical presentation is subtle, and the biological and radiological diagnostic tools lack sensitivity and specificity. Therapeutic options vary from conservative resuscitation, medical treatment, endovascular techniques and surgical resection and revascularization. A high index of suspicion is required for diagnosis, and prompt treatment is the only hope of reducing the mortality rate. Studies are in progress to provide more accurate diagnostic tools for early diagnosis. AMI can complicate the post-operative course of patients following cardio-pulmonary bypass (CPB). Several factors contribute to the systemic hypo-perfusion state, which is the most frequent pathophysiologic event. In this particular setting, the clinical presentation of AMI can be misleading, while the laboratory and radiological diagnostic tests often produce inconclusive results. The management strategies are controversial, but early treatment is critical for saving lives. Based on the experience of our team, we consider prompt exploratory laparotomy, irrespective of the results of the diagnostic tests, is the only way to provide objective assessment and adequate treatment, leading to dramatic reduction in the mortality rate.

Key words: Acute mesenteric ischemia; Non-occlusive; Cardio-pulmonary bypass; Laparotomy; Prognosis; Mortality

INTRODUCTION

Acute mesenteric ischemia (AMI) is a life-threatening surgical emergency in which the outcome is closely dependent on the elapsed time to diagnosis and treatment. The diagnosis is typically difficult and delayed due to non-specific results of biological and radiological tests. Since prompt treatment is the key to a better outcome, AMI remains a challenging condition because of controversial algorithms and numerous therapeutic options.

When AMI occurs after a cardio-pulmonary bypass (CPB) procedure, the condition has a more subtle clinical presentation, is more difficult to diagnose and treat, leading to a higher mortality rate.

This report is an updated review of AMI with respect to the pathophysiologic events, diagnostic tests, therapeutic options, mortality rate and promising new areas of research. A separate section is dedicated to AMI in CPB patients and focuses on the main differences in the diagnosis, management and outcome.

AMI IN STANDARD CONTEXT

Definitions

AMI is caused by a sudden decrease in the blood flow to the bowel and abdominal viscera. Important features of AMI include: bacterial translocation, systemic

inflammatory response syndrome and reperfusion injury, which exacerbate the ischemic damage of the intestinal microcirculation and negatively impact the outcome. Although rare, the incidence of AMI is increasing, in parallel with the aging population[1].

Pathophysiology

AMI is the result of four distinct pathophysiologic mechanisms: arterial embolus, arterial thrombosis, splanchnic vasoconstriction, known as non-occlusive mesenteric ischemia (NOMI) and venous thrombosis.

Arterial embolus is the most common cause, responsible for almost half of all cases[2,3]. The source of the embolus is usually the heart, and the affected vessel is the superior mesenteric artery in 50% of cases. In general, the obstruction occurs at the mid to distal bifurcation points of the blood vessel[1,4].

Arterial thrombus is the underlying cause in approximately 30% of patients[2,3], with rupture of an atherosclerotic plaque in the mesenteric arteries. The site of the occlusion tends to occur at the origin of the blood vessels. The patients can tolerate major visceral artery obstruction because of the slow progressive nature of atherosclerosis, with the development of collaterals. Nearly 75% of patients have pre-existing chronic mesenteric ischemia[5], and acute bowel ischemia or infarction only ensues if the last remaining visceral artery or an important collateral artery occludes. The extent of bowel ischemia or infarction is typically greater than that seen with embolism.

In NOMI, diffuse vasospasm of the mesenteric and other visceral arteries occurs as a result of a sustained hypoperfusion state[6,7]. No vascular occlusion is usually demonstrated because pulsatile blood flow is present in larger arteries[8]. There are several predisposing factors, which are often interrelated, such as heart failure, arterial hypotension, elevated sympathetic activity, hypovolemia, sepsis, use of vasopressors and pre-existing atherosclerotic lesions[7]. Catecholamines and medications such as digitalis[9], by interfering with the auto-regulation of mesenteric circulation, can also cause vasospasm[10].

Mesenteric venous thrombosis accounts for approximately 10% of all AMI cases[2] and involves the superior mesenteric vein in over 90% of patients. Mesenteric venous thrombosis is usually secondary to an underlying coagulopathy, while in 10% the cause is idiopathic[11-15]. Patients should be screened for genetic thrombophilias. Compromised venous return leads to interstitial swelling in the bowel wall, with subsequent arterial flow disturbances and eventual necrosis. The etiologic factors responsible for venous thrombosis include portal hypertension, intra-abdominal sepsis, cirrhosis, pancreatitis, malignancy and trauma.

Other rare causes of mesenteric ischemia are aortic dissection, lupus, vasculitis, median ligament syndrome, ergot administration and post laparoscopic cholecystectomy[16]. In young patients, arterial occlusion due to inherited coagulopathy is exceedingly rare and only isolated cases have been reported[17].

The clinical features of AMI originate from factors such as the site of involvement, systemic inflammatory response triggered by damage to the microcirculation, and reperfusion injury.

At the cellular level, ischemia causes mitochondrial dysfunction, loss of ion transfer regulation, and intracellular acidosis. Alterations in membrane permeability, and the release of free radicals and degradative enzymes leads to cell death and tissue necrosis[18]. In the ischemic tissue, numerous cells including neutrophils, endothelium, monocytes and platelets are activated. Proinflammatory substances are produced such as tumor necrosis factor, interleukines, platelet-activating factor and leukotrienes. Subsequently, the injury is due to leukocyte adhesion, platelet aggregation[19] and nitric oxide production impairment[20]. The activated neutrophils release superoxide substances such as superoxide O_2, peroxide H_2O_2 and hydroxyl radicals OH[21], along with neutrophil enzymes, which result in further damage to the surrounding tissues.

Ischemic/reperfusion double-hit injury consists of an initial hypoxic episode followed by the subsequent reperfusion injury due to reestablishment of forward flow[10]. Superoxide molecules, neutrophil enzymes and pro-inflammatory substances are carried in the bloodstream, causing distant organ damage. Moreover, reperfusion causes swelling of the corresponding organs since capillary permeability is considerably increased during ischemia[22]. Finally, damage to the intestinal micro-vessels and the disruption of the intestinal mucosal barrier results in leakage of water and bacteria, with resulting endotoxemia[23] and bacteremia[24,25]. Ultimately, multi-organ failure ensues and involves the liver[18], heart[26], kidneys[27] and lungs[28]. Acute pulmonary edema resulting from mesenteric ischemia/reperfusion is caused by an increase in pulmonary microvascular permeability to fluids and proteins, as well as smooth muscle dysfunction[29,30].

Clinical presentation

Abdominal pain is the primary symptom. The pain is characteristically out of proportion to the clinical findings. It is described as colicky and is most severe in the paraumbilical region. Other symptoms are present inconstantly and include nausea (93%), vomiting (80%) and diarrhea (48%)[31]. Physical examination is unremarkable unless peritonitis has developed. During the late stages, abdominal distension and guarding, as well as systemic complications may be encountered.

Laboratory tests

Soon after onset but prior to the development of mesenteric infarction, the sensitivity of laboratory tests in detecting mesenteric ischemia is poor[32]. Even at the time when ischemia is confirmed at laparotomy, elevation of serum lactate, amylase, creatine kinase and C-reactive protein (CRP), as well as leucocytes may be absent[31]. At present, no laboratory test is available for accurately establishing or eliminating the diagnosis[33,34]. One study

reported that hemoconcentration and hyperamylasemia were independent predictive factors of massive ischemic infarction[35].

Imaging studies

It is important to remember that when intestinal ischemia is clinically suspected, diagnostic imaging studies should be performed if peritoneal signs are absent.

Plain abdominal radiographs are of little help in the diagnosis of mesenteric ischemia. The presence of dilated loops is non-specific[36,37], and thickened bowel loops, "ground-glass" appearance suggesting ascites, or "thumbprinting" caused by submucosal edema or hemorrhage are seen in less than 40% patients. Twenty-five percent patients with bowel infarction have negative plain radiographs of the abdomen[38].

Barium enema has no place in the diagnosis of AMI since it may increase intra-luminal pressure and reduce perfusion to the bowel wall, causing translocation of bacteria and potentially, perforation. In addition, the presence of barium may compromise subsequent diagnostic tests, such as computed tomography (CT) and angiography[32].

Magnetic resonance imaging has shown promising results in detecting mesenteric ischemia but remains a slow-processing technique that seems to be inadequate in an emergent situation such as AMI[39,40].

Mesenteric duplex sonography is a highly user-dependent modality that can only confirm diminished blood flow in the trunks of the mesenteric blood vessels. Mesenteric duplex scanning identifies stenosis of the superior mesenteric and celiac arteries by the mean of elevated peak systolic velocities. A velocity > 275 cm/s is indicative of >70% stenosis with a sensitivity of 92% and a negative predictive value of 99%[41]. Doppler sonography is useful in diagnosing chronic mesenteric arterial occlusive disease but has limited role in AMI[42-45]. Other applications for duplex sonography are detection of reversible celiac flux alteration such as in median ligament syndrome, and follow-up of mesenteric bypass grafts and stents[41]. The new technique of contrast-enhanced ultrasonography is a promisingly non-invasive tool for the diagnosis of bowel ischemia[46].

Angiography is the gold standard diagnostic test in acute mesenteric artery occlusion[47], providing both anatomical visualization of the vessels and therapeutic options[48]. The sensitivity and specificity are 74% to 100% and 100%, respectively[49]. When used in the absence of peritonitis signs, angiography has been shown to improve the survival rate[50,51]. Mesenteric angiography can usually identify the underlying pathophysiologic event, by differentiating between embolic and thrombotic occlusion[52]. NOMI characteristically shows narrowing and multiple irregularities of the major SMA tributaries recognized as the "string of sausages" sign. Mesenteric venous thrombosis is characterized by a generalized slowing of arterial flow (up to 20 s) in conjunction with a lack of opacification of the corresponding mesenteric or portal venous outflow tracts. However, angiography is an invasive, time consuming and potentially nephrotoxic procedure. Its routine use is controversial in emergency situations[53] and therefore, it is employed only in selected patients.

Since CT is a fast, widely available non-invasive modality, it is considered as the initial imaging test[54]. It is useful in detecting intestinal signs suggestive of ischemia, as well as vascular abnormalities such as occlusion and stenosis. It is also useful in assessing other causes of acute abdominal pain. Still, the CT findings of mesenteric ischemia and infarction are not pathognomonic, and a direct correlation between CT findings and the final diagnosis is not accurate[55]. Overall, the sensitivity and specificity of contrast-enhanced CT for mesenteric ischemia are 64% and 92%, respectively[31,56,57]. Because of these drawbacks, the American Gastrointestinal Association[49] concluded that CT is of limited use in the diagnosis of AMI and that unremarkable CT findings in the context of a high suspicion of mesenteric ischemia should prompt an angiography without delay. An exception to this rule is when superior mesenteric vein thrombosis is suspected; a situation where CT scan remains the test of choice with sensitivity rate in the range of 90%[14,50].

Recently, the multi-detector row CT has emerged as a widely established non-invasive technique that not only delineates the blood vessels, but also shows an anatomical three dimensional relationship with the surrounding tissues, and allows evaluation of tissue perfusion[58]. The sensitivity and specificity rates are 92%-96% and 94%-100%, respectively[31,59,60], with positive and negative predictive values of 90% and 98%, respectively[61]. Moreover, when a cardiac source of mesenteric emboli is suspected, scanning of the heart provides a method for concomitant detection of the source of the embolus[62].

Therapeutic approaches

Therapeutic decisions are taken based on four main considerations: the presence or absence of peritonitis, the presence or absence of irreversible ischemia or infarcted segments of the intestine, the general condition of the patient, and the pathophysiologic phenomenon responsible for the event.

Once a diagnosis of AMI is made, treatment should be initiated without delay. This should include active resuscitation and treatment of the underlying condition, along with efforts directed toward reducing the associated vasospasm. Broad-spectrum antibiotics and intravenous heparin at therapeutic doses should be initiated as early as possible. If the diagnosis was established through angiography, intra-arterial infusion of papaverine, a phosphodiesterase inhibitor, is recommended for NOMI and for occlusive arterial AMI, since arterial vasospasm persists even after successful treatment of the precipitating event[1,3]. When angiography is not performed, intravenous glucagon may help reduce the vasospasm[52].

In the setting of a hemodynamically stable patient, with no signs of peritonitis, conservative medical

management may be attempted. For embolus- and thrombus-induced events, thrombolytic agents such as streptokinase, urokinase or recombinant tissue plasminogen activator are effective treatments[63-66]. Thrombolytic therapy seems to be most successful in distal clots, when used within 12 h after the onset of symptoms[66]. Ultimately, primary endovascular techniques and surgical resection may prevent mesenteric infarction when performed promptly in hemodynamically stable patients with arterial mesenteric ischemia[67]. For NOMI, especially when diagnosed by angiography, selective intra-arterial infusion of papaverine at the usual dose of 30 to 60 mg/h, is an adequate treatment[1,52,53]. It reduces the mortality rate from 70% to 50%-55%[68]. Early treatment with continuous intravenous high dose prostaglandin E(1)[69] or a prostacyclin analogue[70] have shown promising results in the treatment of NOMI. As for venous mesenteric ischemia, the standard treatment is anticoagulation, while venous thrombectomy has not improved the outcome and is controversial[71,72]. Heparin should be initiated as soon as the diagnosis is established, and is associated with reduction in the recurrence rate and mortality[13,14]. Another appropriate therapeutic modality is thrombolysis[73-75].

At any time during evaluation, should signs of peritonitis develop, the patient should undergo exploratory laparotomy without delay. First, the intestine is assessed for viability. Visual evaluation of the bowel relies on arterial pulsations and intestinal peristalsis and colour, although these findings are not specific[52]. Another technique is the use of sodium fluorescein, which is injected intravenously; it is detected with a Wood's lamp in the presence of hypoxic damage. Both retrospective analysis and randomized trials have shown that this technique is more reliable than clinical evaluation of mesenteric viability[76-78]. When compared with histological results, intraoperative laser Doppler flowmetry has been shown to be 100% accurate in assessing bowel viability[79]. Doppler ultrasound can be used intraoperatively but does not provide a quick assessment of the entire length of the intestine and thus does not carry any advantage over clinical judgment[80].

In patients with arterial occlusive AMI, when sufficient bowel is potentially viable, revascularization prior to resection of the infarcted bowel may improve the survival[2]. Although surgical revascularization is the standard procedure[81], embolectomy, thrombectomy, endarterectomy[38], as well as endovascular techniques such as antegrade percutaneous stenting[82], and open retrograde stenting[83-85] provide attractive alternatives with good short-term outcome. A high stent restenosis rate is the drawback of these techniques, requiring close follow-up of the patients[85,86]. Contraindications to revascularization include obvious infarction of the bowel supplied by the affected artery, patient's instability precluding further resection, and mesenteric vein thrombosis[53,87].

Surgical bowel resection must include all of the clearly non viable and infarcted portions of the bowel. Primary anastomosis can be performed if perfusion is adequate. A second-look laparotomy is scheduled within 12 to 24 h, if large portions or multiple segments of intestine of questionable viability were left behind[88], provided that complete resection should not result in a short bowel syndrome. Although widely approved[1,3], some authors question its routine use, and limit second-look laparotomy to individual cases[89].

Alternatively, second-look laparoscopy has emerged as a minimally-invasive, technically simple procedure that can provide diagnostic and therapeutic advantages[90] despite the fact that the evaluation is limited to the serosa and that mucosal lesions can be missed[91]. As a result, the value of second-look laparotomy in preventing morbidity is uncertain[90,92-94].

Outcome

Despite advances in the identification of mortality risk factors and greater therapeutic options, the overall mortality associated with AMI is as high today as it was several decades ago[31,95], ranging from 60% to 90%[49,96-99]. When specific etiologies are considered separately, arterial thrombosis has the highest mortality rate of 70% to 100%[3,98,100] in part because of the extensive ischemia-infarction of the bowel, and the need for more complex surgical revascularization. The mortality associated with NOMI is also within this range[98], whereas arterial embolism and venous thrombosis have much better prognosis, with mortality rates of 0% to 50%[15,98,101] and 20%[5], respectively. The peri-operative factors predicting mortality after mesenteric ischemia have been extensively studied[7,99]. Of the various factors examined, age > 70 (where diagnosis is more frequently overlooked), and prolonged duration of symptoms were independent predictors of mortality[97,102-104]. It cannot be overemphasized that a high index of suspicion, prompt diagnosis and aggressive early treatment are the only surgeon-dependent factors that have a positive influence on the outcome.

Perspectives for the future

A number of biochemical and genetic studies are in progress, designed to elucidate the pathophysiologic changes in an ischemic/reperfused intestine. Several molecules have been identified which attenuate intestinal injury and reduce the production of proinflammatory cytokines[105-110]. Intra-luminal infusion of hyperoxygenated solution during ischemia may improve the functional and structural status of the enterocyte mitochondria associated with ischemia/reperfusion syndrome[111]. Most therapies have to be initiated prior to the onset of ischemia, making their clinical application difficult to foresee.

Since the prognosis is closely related to delay in the treatment, and since the diagnostic tools currently available are not very accurate, great effort is being focused on identifying more accurate methods of early diagnosis. Serum assays such as D-dimers[112-114], alcohol dehydrogenase[115], glutathione S-transferase[116] and cobalt-albumin binding[117], and measurement of pH and potassium in peritoneal irrigation fluid[118], as well

as liver tissue oxygenation index[119] are good examples of current research. Seidel *et al* showed that mesenteric electrical activity may detect mesenteric ischemia with a high degree of sensitivity and specificity[120]. However, promising studies in animals remain to be validated under clinical conditions.

Experimental studies in which laparoscopy was combined with ultraviolet light and IV injection of fluoresceine showed that this technique may be useful in detecting mesenteric ischemia and viability of the intestine at an early stage[121,122]. Moreover, trans-serosal pulse oximetry may help determine bowel viability and resection extension prior to laparotomy[123].

AMI AFTER CPB

Incidence and frequency

Abdominal complications after CPB for cardiac surgery are seen in < 1% of patients[124-132] but carry a high mortality of 14.1%[131]. AMI represents 10%-67% of these complications[129,133,134], and is the most lethal, with a case-fatality rate of 70% to 100%[129,131,132,135,136].

Pathophysiology

AMI occurring after CPB, is due to NOMI in the vast majority of cases[137-139]. The various contributory factors are: low cardiac output (frequent in this category of patients), use of vasopressors and underlying atherosclerotic disease. It is well established that CPB is responsible for mesenteric endothelial dysfunction and microcirculation disturbances even under stable hemodynamic conditions. An increase in the contractile response to alpha1-adrenergic agonist and an early release of pro-inflammatory substances has been observed after CPB[140-142]. Nevertheless, the effect of pulseless extracorporeal circulation on bowel hypoperfusion is still under debate[143,144], and off-pump coronary artery bypass does not prevent subsequent mesenteric ischemia[134,145,146]. The physiologic changes in intestinal perfusion during cardiac surgery remain to be elucidated. It has been observed that there is significant mesenteric hypoperfusion followed by hyperemic response[147] after off-pump cardiac surgery along with an increase in the resistive and pulsatility indexes[148]. Moreover, studies focusing on the identification of predisposing factors for mesenteric ischemia after CPB[135,124-126], have produced different, and even opposite results. Rare cases of embolic acute arterial infarction can be prevented when a calcified aorta is detected on pre-operative CT scan[149].

Clinical presentation

In the context of CPB, patients are usually sedated and mechanically ventilated for a few days. Consequently, symptoms are not reported and the physical examination is equivocal due to masked, late-appearing, or missing clinical signs[125,139,150]. This accounts for the delay in diagnosis, and the disease may progress to a late, even irreversible stage by the time clinical signs become obvious (i.e. cyanosis). Finally, extracorporeal circulation induces a systemic inflammatory response with vasodilatation, such that hemodynamic instability can no longer be interpreted as a clue to an underlying mesenteric ischemia. A high index of suspicion in detecting subtle clinical evidence of AMI is the key to reducing the delay in diagnosis.

Laboratory tests

Pulseless perfusion during extracorporeal circulation causes systemic hypoperfusion, as illustrated by major derangements in the biochemical tests. These abnormalities are difficult to distinguish from those related to an underlying AMI. Moreover, laboratory test abnormalities are observed inconstantly in AMI. Even if unexplained metabolic acidosis with elevation of lactate level is considered as an early sign[151], several studies have shown that serum lactate may remain normal in the presence of extensive mesenteric infarction[139]. As indicated by Edwards *et al*[130], neither routine clinical investigations nor biological tests (such as leucocytosis, and elevation in serum creatinine, creatine kinase, hepatic or pancreatic enzymes) are discriminatory for mesenteric ischemia when the diagnosis is clinically suspected.

Imaging

When AMI is suspected after CPB, imaging studies should be such that they provide a rapid and accurate diagnosis, while being safe and avoid further morbidity in an already fragile patient. Traditional radiologic studies are not accurate for the diagnosis of AMI (as stated above) and are not recommended. Abdominal ultrasound is a non-invasive technique but remains highly operator-dependent. Its accuracy decreases significantly in emergent situations, especially in the presence of ileus and dilated bowel loops, which have a negative impact on image quality. Multi-detector abdominal CT scan theoretically provides good diagnostic results in AMI, but its specificity and sensitivity after CPB are reduced dramatically; accurate diagnosis correlates with laparotomy findings in < 50% of patients[139]. This is in part due to the limitation in the use of intravenous contrast because of borderline renal function and frequent presence of diabetes in these patients. This consideration applies also to angiography that remains the gold standard diagnostic tool in peripheral splanchnic disease[152], despite its invasive nature and time-consumption.

Therapeutic options

An early diagnosis and prompt treatment based on a high index of suspicion are the only hope for reducing the mortality and improving the outcome[153,154]. The initial treatment consists of hemodynamic support, but if these measures fail, prompt intervention is mandatory. Some experts believe that surgery within the first 6 h has a positive impact on the prognosis[151]. Since most mesenteric ischemic episodes after CPB are due to NOMI, some authors argue in favour of selective angiography as the initial test, as it provides the potential for both diagnosis and therapy. Intra-arterial infusion

of papaverine[155] or tolazoline with heparin[125] are both effective treatments.

Perspectives for the future

AMI occurring in the post CPB period remains a challenging surgical emergency, characterized by extremely high mortality and a controversial management approach. As stated above, clinical assessment as well as laboratory and radiological tests are typically unreliable in establishing the diagnosis.

In view of these considerations, we have adopted a uniform treatment strategy. When a diagnosis of AMI after CPB was suspected, exploratory laparotomy was carried out, irrespective of the results of the diagnostic tests. We performed a retrospective analysis on 1634 consecutive patients undergoing CPB for coronary artery bypass alone or combined with valvular surgery, between January 1st, 2000 and July 31st, 2007. A total of thirteen patients were suspected to have mesenteric ischemia, based on clinical and/or laboratory and/or radiological findings. All patients underwent exploratory laparotomy and were divided into two groups (Group 1 and Group 2) depending upon whether or not ischemic bowel was present. There was no difference in the clinical findings, laboratory tests and radiological results between the two groups. The mean delay in laparotomy was 13.7 h and 51.4 h in Group 1 and Group 2, respectively; the difference was statistically significant. Mortality rates in Group 1 and Group 2 were 42.8% and 50%, respectively. Based on these findings, we concluded that in the context of post-CPB AMI, diagnostic tests do not provide any information of practical value, but instead consume valuable time. By performing early exploratory laparotomy, we were able to reduce the mortality rate considerably. Since all of our patients had NOMI, no revascularization was required and resection of the irreversibly ischemic and infarcted segments of the bowel helped in preventing the vicious circle leading to multi-organ failure and death.

CONCLUSION

Although AMI has been known for several decades, it remains a highly lethal emergency, characterized by numerous controversies. The pathophysiologic process has not been completely resolved, the clinical presentation is often subtle and misleading, and despite the introduction of new technologies the diagnostic tools are often inaccurate. A high index of suspicion and prompt treatment are the only means to reduce mortality.

AMI in cardiac patients undergoing CPB is an extremely challenging surgical emergency. The role of clinical evaluation becomes even more relevant since the laboratory and radiological tests are no longer effective. In this context, prompt laparotomy is the only method of providing objective assessment and targeted treatment. Using this approach we achieved considerable improvement in the mortality rate. Although promising, this practice needs to be confirmed in a larger series of patients.

Abstract

Drink tests are advocated as an inexpensive, nonivasive technique to assess gastric function in patients with a variety of upper digestive symptoms. Many patients with dyspeptic complaints will achieve satiation or develop symptoms at ingested volumes below those typically required to achieve these endpoints in controls. Substantial variation in test performance exists and a greater degree of standardization is required. Additionally, it remains unclear exactly what drink tests measure as correlations with measures of gastric sensation, accomodation and emptying are modest at best. Finally, results of drink tests do not guide therpay. At present, these tests are best reserved for research studies and are not advocated for use in clinical practice.

Key words: Drink test; Dyspepsia; Gastroparesis

OVERVIEW AND RATIONALE

Drink tests were originally developed as a noninvasive means to assess upper digestive sensation and, perhaps, gastric accommodation. These tests are most commonly performed in patients with symptoms of functional dyspepsia or gastroparesis and many patients with these conditions will achieve satiation or develop dyspeptic symptoms at ingested volumes below those typically required to achieve these endpoints in controls. Drink tests are well tolerated, inexpensive and easy to perform. They are variously performed using either water or nutrient-containing solutions administered at different rates. This variability in test performance has limited our understanding of the exact physiologic parameters measured by the test. Drink tests are often used in clinical studies evaluating patients with functional dyspepsia or gastroparesis. Although patients often report satiation or develop symptoms at substantially smaller ingested volumes than controls, it remains unclear exactly what physiologic processes are assessed by the drink test. Additionally, results of drink tests do not guide therapy. As such, these tests are probably best reserved for research studies and are not advocated for use in clinical practice.

Drink tests and symptoms

Drink tests were originally developed as a symptom provocative technique for patients with dyspeptic complaints. Patients with dyspepsia will generally drink less and report more symptoms than do healthy subjects. Symptom reporting is influenced to a large degree by the endpoint of the drink test. For example, the 5-min water load test asks subjects to drink room temperature water *ad libitum* over a 5 min period until they become full[1]. Patients rate symptoms of fullness, nausea and bloating at the end of the drink test and then again 20 min and 30 min after the conclusion of the test. Not surprisingly, scores for the endpoint of fullness do not differ as greatly between patients with functional dyspepsia and controls while patients with functional dyspepsia do report significantly greater scores for symptoms of bloating and nausea (Figure 1)[2]. Compared with controls, symptoms induced by the drink test are more likely to persist in patients with functional dyspepsia compared with controls.

Boeckxstaens *et al*[3] have evaluated symptom responses to both water and Nutridrink consumed at a rate of 100 mL/min in healthy subjects and patients with functional dyspepsia. After each 100 mL, symptoms of satiety, epigastric bloating, nausea, and pain were scored on a scale from 0 (no sensation) to 5 (discomfort). The test was ended when a score of 5 was reached for at least one of the symptoms and the maximal ingested volume calculated. Subjects also rated these symptoms

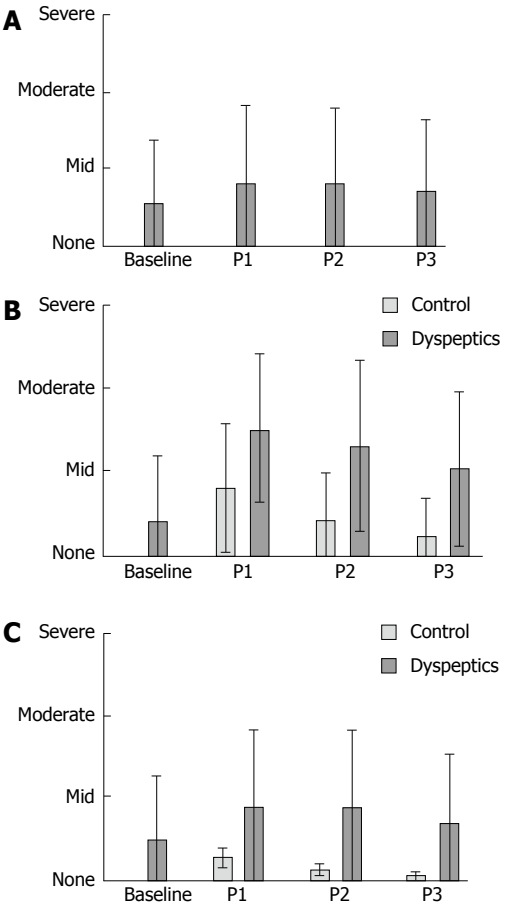

Figure 1 Symptoms before and after a 5-min water load test in controls and patients with functional dyspepsia. Patients with dyspepsia were significantly more symptomatic in terms of nausea (**A**), fullness (**B**), and bloating (**C**) both at baseline and after the water load test. Symptom scores at all time points were significantly different between the two groups. P1: 10 min after WL5; P2: 20 min after WL5; P3: 30 min after WL5. Data are expressed as mean ± SD. Adapted from Jones *et al*[2].

1 and 2 h after the end of the drink test. Again, patients with functional dyspepsia reported greater and more persistent symptoms during the drink test than did controls. Nutridrink was more symptom-provoking than water. Importantly, subjects in this study also underwent gastric barostat testing and were classified as having either normal physiology, visceral hypersensitivity or impaired accommodation. Symptom scores during drink tests were not influenced by the results of the barostat study.

While patients with functional dyspepsia will often achieve satiation at lower drink test volumes than controls and will report greater symptoms during the test, specific dyspeptic symptoms are not associated with an abnormal drink test. Jones and Maganti[4] evaluated the relationship between 15 common dyspeptic symptoms and volume to fullness as measured by a 5-min water load test. The only symptom significantly correlated with volume to fullness was nausea which showed a weak inverse correlation with nausea severity (r = -0.3, P = 0.05). Similarly, Boeckxstaens *et al*[5] reported that while patients with functional dyspepsia were more likely to report more symptoms during drink testing, no specific symptom was more likely to be associated with an abnormal drink test. Finally, Kindt *et al*[6] recently reported that maximal drink test volume was inversely associated with dyspeptic symptom scores prior to the study. For specific dyspeptic symptoms, only early satiety was significantly associated with the endpoint of the first satiety drinking test (r = 0.25, P = 0.02).

Psychiatric comorbidity is common in functional dyspepsia. In healthy subjects, experimentally induced anxiety is associated with decreased gastric compliance and meal-induced accommodation as well as increased symptom scores during a standard nutrient drink challenge[7]. However, in patients with functional dyspepsia, correlations between drink test volumes and general psychiatric distress (measured using either the SCL-90R or the Psychological General Well Being Scale) have been modest at best[2,4]. We do often encounter patients who report fullness at volumes that clearly defy physiologic parameters (< 50 mL), suggesting that central factors clearly influence test results. Finally, patients with functional dyspepsia, compared with controls, patients with gastroparesis or patients with gastroesophageal reflux often demonstrate poor self-efficacy and are less capable of estimating the volume required to produce fullness (Figure 2)[2].

Drink tests and accommodation

Assessment of gastric sensation and accommodation is most rigorously measured using a barostat. This is a cumbersome, expensive device that is decidedly patient unfriendly. Logically, it would seem that incrementally distending the stomach by drinking could achieve a result similar to incrementally distending the stomach using a balloon on the end of a catheter. Indeed, Tack *et al*[8] have reported a good correlation between barostat-measured accommodation and total calories consumed during a nutrient drink test administered at 15 mL/min. For both patients with functional dyspepsia and controls, the correlation was 0.76 (P < 0.001) and the nutrient drink test was calculated to have a sensitivity of 92% and a specificity of 86% in predicting impaired gastric accommodation.

Not all authors have agreed with these findings. Boeckxstaens *et al*[5] found no correlation between drinking capacity and fundal accommodation to a meal. These authors used both water and nutrient drink tests to evaluate subjects. The sensitivity of the water load test and nutrient drink test to detect impaired accommodation was 73% and 81%, respectively. The discrepant results between these two studies may reflect the methods used. Tack *et al*[8] had subjects ingest Nutridrink at a rate of 15 mL/min while Boeckxstaens *et al*[5] had subjects consume Nutridrink or water at 100 mL/min.

Accommodation can also be assessed using single-photon emission computed tomography (SPECT). Using a nutrient drink test administered at a rate of 120 mL/4 min, Gonenne *et al*[9] found that after controlling for covariates in a convenience sample of controls and patients with functional dyspepsia, the maximal tolerated nutrient drink test volume explained

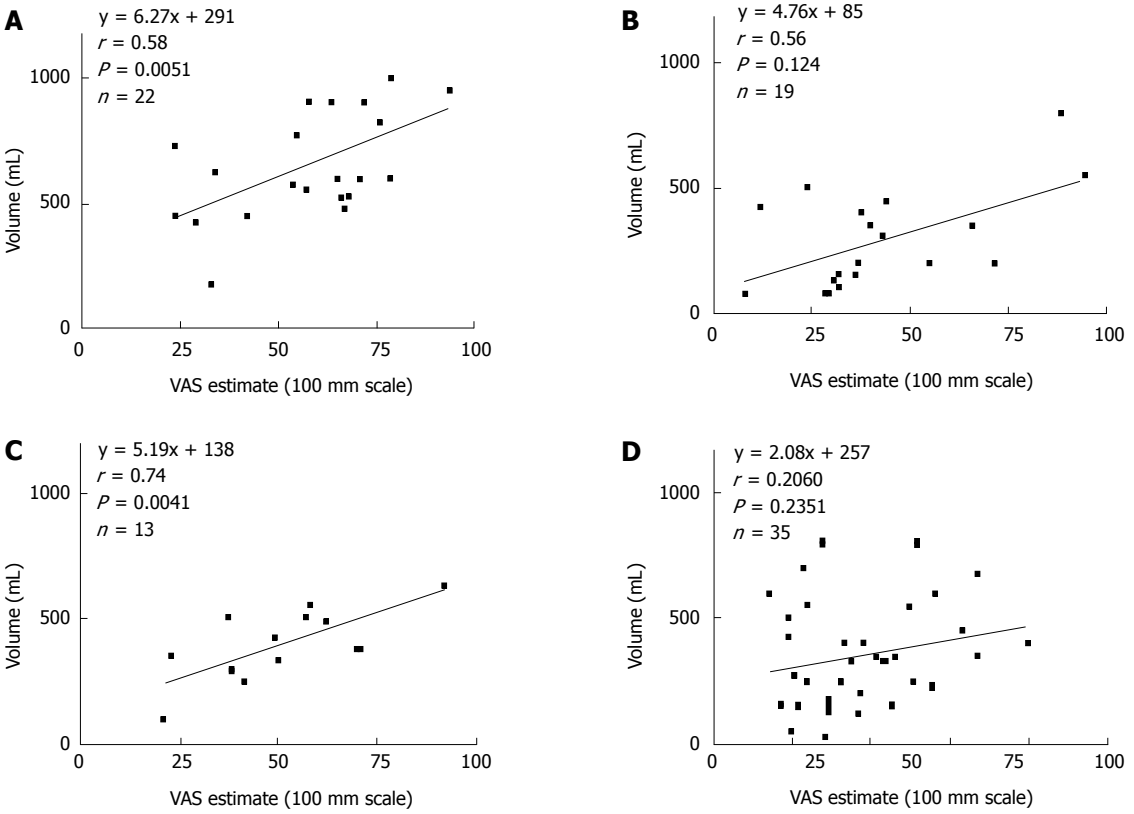

Figure 2 Drink test self-efficacy. Controls (**A**), and patients with either gastroparesis (**B**) or gastroesophageal reflux disease (**C**) are able to accurately estimate drinking capacity, while patients with functional dyspeptics (**D**) cannot. VAS: Visual analog scale. Adapted from Jones *et al*[2].

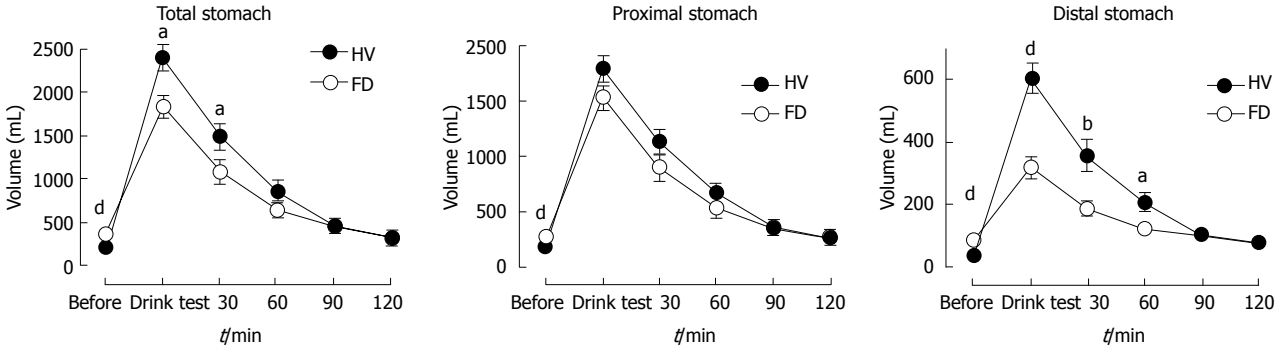

Figure 3 Volumes measured by gastric volume scintigraphy for total, proximal and distal stomach volume over time. Patients with functional dyspepsia had higher fasting volumes but reduced maximal tolerated volumes during drink test and reduced lower distal stomach volumes ($^{a}P < 0.05$, $^{b}P < 0.01$, $^{d}P < 0.001$; Mann-Whitney *U*-test). Adapted from van der Elzen *et al*[10]. HV: Healthy volumes; FD: Functional dyspepsia.

only 13% and 3% of the variations in fasting and postprandial volumes measured by SPECT.

Recently, van den Elzen *et al*[10] have shown that drinking capacity may be more related to distal rather than proximal stomach function. Compared to controls, patients with functional dyspepsia ingested significantly less water ($P < 0.001$) and had reduced filling of the distal stomach ($P < 0.001$) after the drink test (Figure 3).

Drink tests and gastric emptying

Only a few studies have examined the relationship between gastric emptying and maximal tolerated volume and that relationship appears modest at best. Cuomo *et al*[11] reported that in females with functional dyspepsia, the correlation between maximal tolerated drink test volume and the fractional rate of gastric emptying was 0.48 ($P = 0.0003$, Figure 4). Tack *et al*[8] also reported a weak but significant correlation between maximal tolerated volume for the nutrient drink test and the half time of gastric emptying for a solid meal when pooled controls and patients with functional dyspepsia were studied ($r = -0.40$, $P = 0.001$). The correlation was not statistically significant when only evaluating patients with functional dyspepsia. Jones *et al*[2] did not find a correlation between volume to fullness using a 5-min

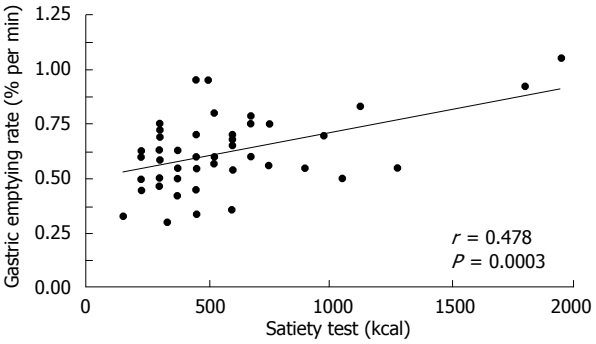

Figure 4 Correlation between nutrient drink test (kcal) and gastric emptying rate (% per min of gastric content) in the dyspeptic patients. Adapted from Cuomo *et al*[11].

water load test and T_{lag} (r = 0.1532, P = 0.4549) or $T_{1/2}$ (r = 0.1489, P = 0.4679) using a stable isotope gastric emptying breath test.

COMPARISONS BETWEEN DRINK TESTS

Drink tests are performed using either water or nutrient-containing beverages which are consumed at various rates. No method has proven superior although nutrient drink tests appear to be performed more often in clinical research. Presently, there is a need for a consensus on drink test methodology so that observations made by various investigators will be uniformly interpretable. Limited data exist regarding the performance characteristics of drink tests. Males ingest greater volumes than females but there appears to be less of an influence with respect to age and BMI[2,5,6,8].

Results of drink tests are reproducible at least in the short term. For healthy subjects, the correlations between 5-min water load tests at baseline and repeated 2 wk and 2 mo later were 0.78 (P < 0.0001) and 0.33 (P = 0.16)[2]. Cuomo *et al*[11] repeated a nutrient drink test between 2 d and 5 d in 10 controls and 5 patients with functional dyspepsia. The resulting inter-day variation of kcal ingested was 4.7% ± 1.5%.

Water loading at different rates produces comparable results in healthy subjects. The correlation between volumes to fullness for the 5-min water load and 100 mL/min water load was 0.79 (P < 0.0001)[2]. For the same subjects, the correlation between the 5-min water load and a 5-min nutrient drink test was 0.20 (P = 0.48). Boeckxstaens *et al*[5] found a significant correlation between the maximal volume ingested in the water test and the nutrient drink test. The correlation was greatest among controls (r = 0.67, P = 0.0001) and weakest among patients with functional dyspepsia (r = 0.57, P = 0.0001).

Using a 15 mL/min Nutridrink test, Kindt *et al*[6] demonstrated excellent test-retest reliability for a group that included 34 controls and 78 patients with FD (r = 0.88, P < 0.0001). During repeat testing, controls tended to consume higher volumes while patients with functional dyspepsia showed less variability.

PUBLISHED VALUES AND RANGES FOR DRINK TESTS

For the 5-min water load test, the mean volume required to produce fullness in a group of 73 controls was 648 ± 204 mL[2]. Males (703 ± 217 mL) drank more than females (611 ± 188 mL), but the difference was not statistically significant (t = 1.907; P = 0.0605). No healthy subject consumed < 300 mL of water and that volume was proposed as a cut-off for an abnormal test. A subsequent study demonstrated that the 300 mL cut-off value for the 5-min water load test discriminated controls from patients with functional dyspepsia with a sensitivity of 98% and a specificity of 46%[12].

For healthy subjects, the mean volume to fullness for the 100 mL/min water load test in controls has been reported as 1128 ± 355 mL[2]. In the same population, the mean volume to fullness for the 5-min nutrient drink test was 688 ± 187 mL. The nutrient drink test was performed using Boost™ (Mead Johnson Nutritionals, Evansville, Indiana) which contains 1.1 kcal/mL and is 70% carbohydrate, 15% fat, and 16% protein. Boost differs somewhat from Nutridrink™ (N.V. Nutricia, Zoetermeer, Netherlands) which contains 1.5 kcal/mL and is 39% fat. Boost™ is comparable to Ensure™ (Abbott Laboratories, Abbott Park, Ill.) which contains 1.06 kcal/mL and is 65% carbohydrate, 20% fat, and 15% protein. These test meals have not been directly compared but Tack *et al*[8] have shown that with increasing caloric density, maximum satiety occurs at progressively higher caloric intakes while satiety scores according to ingested volumes do not differ significantly. This suggests that volume may be a greater stimulus than caloric density. No study has assessed the influence of caloric composition or palatability.

Boeckxstaens *et al*[5] have reported normal values for both Nutridrink and water load administered at 100 mL/min. Males consumed significantly more water (2084 ± 181 mL *vs* 1367 ± 97 mL, P = 0.0001) and Nutridrink (1405 ± 81 mL *vs* 946 ± 74 mL, P = 0.002) than females. Using the 10th percentile as the lower limit of the normal range, volumes < 1100 mL of water for men and < 800 mL of water for women were considered abnormal. Similarly, volumes < 800 mL of Nutridrink for men and < 600 mL for women were considered abnormal. The difference in results for the 100 mL/min water load tests between these two studies likely reflects the fact that Jones *et al*[2] had subjects stop drinking when they first experienced fullness while Boeckxstaens *et al*[5] had patients continue to drink until they developed very severe or uncomfortable sensations of symptoms of satiety, epigastric bloating, nausea or pain.

Using a Nutridrink test administered at a rate of 15 mL/min to healthy volunteers, Tack *et al*[8] reported that maximum satiety occurred after ingestion of 1005 ± 35 mL (mean ± SE) with a lower limit of normal of 653 mL. This observation was supported by a more recent observation from the same group[2]. In this study, controls reported maximum satiety after ingestion of 937 ± 428 mL. Increasing drink test

volumes were associated with male sex and increasing age[6]. Moreover, Chial *et al*[13] used a nutrient drink test adopted from the methodology of Tack *et al*[8]. Subjects consumed 120 mL of Ensure™ every 4 min until full, and the average volume of nutrient drink ingested (mean ± SE) was 1181 ± 50 mL. There was a weak but significant correlation ($r = 0.29$, $P = 0.02$) between volume to fullness and body mass index.

Indications for drink tests

Given that it is unclear exactly what drink tests measure, and that the test remains poorly standardized, the role of drink tests in clinical practice remains to be established[14,15]. The test has most often been employed in clinical research studies evaluating patients with functional dyspepsia. Water loading is also performed as a provocative maneuver during the performance of electrogastrography[1].

Performing a drink test

Patients should be studied in the morning after an overnight fast. While certain medications can alter digestive sensation, accommodation or gastric emptying, we do not routinely stop motility or sensory modifying medications for clinical studies.

The 5-min water load test is performed by having subjects drink room temperature tap water *ad libitum* over a 5-min period until reaching the point of fullness. Water is consumed from an unmarked flask that is taken from the subject and refilled after each drink. The volume required to refill the flask to the initial level is recorded, and the total volume consumed is calculated by summing these volumes. In this way, the flask is "bottomless" and the subject blinded as to the actual volume of water consumed. During the test, patients rate symptoms of fullness, bloating, and nausea using a 4-point Likert scale for each symptom. Scores are recorded at baseline and then every 10 min for a 30-min period after completion of the test. Individual symptoms can therefore receive a total score ranging from 0-12, and the total WL symptom score has a range of 0-36.

Nutrient drink tests can be performed in a several ways. The simplest method is that used by Chial *et al*[13], in which subjects consume 120 mL of Ensure™ every 4 min until full. Ensure is administered in a paper cup that is refilled every 4 min. At 5 min intervals, participants score fullness using a rating scale that combines verbal descriptors on a scale graded 0-5 [0: no symptoms; 1: first sensation of fullness (threshold); 2: mild; 3: moderate; 4: severe; 5: maximum or unbearable fullness]. Participants are told to stop when a score of 5 is obtained. Postprandial symptoms were measured 30 min after completing the test with participants scoring symptoms of bloating, fullness, nausea and pain using a visual analogue scale (VAS) with 100 mm lines and the words "unnoticeable" and "unbearable" as anchors. The sum of the four 100-mm VAS scales for each symptom provides an aggregate symptom score.

The nutrient drink test used by Boeckxstaens *et al*[5] had subjects who consumed Nutridrink™ at a rate of 100 mL/min. Nutridrink™ is given in beakers or paper cups filled with 100 mL aliquots. After each 100 mL, symptoms of satiety, epigastric bloating, nausea, and pain are scored on a 5-point Likert scale (0: no sensation; 1: very mild; 2: mild; 3: moderate; 4: severe; 5: very severe or discomfort). When a score of 5 is reached for any symptom, the test ends and the maximal ingested volume is calculated.

Reporting and interpreting test results

Drink test results are reported as the maximal ingested volume. Occasionally, a patient may experience emesis during the test. If emesis occurs, the volume of emesis should be recorded and subtracted from the total ingested volume. Along with the maximal ingested volume, individual and cumulative symptom scores can be reported.

While the utility of drink tests remains to be determined, we find the test most helpful when it is either normal or glaringly abnormal. In the former scenario, the patient can be reassured that gastric function is likely to be intact. The latter scenario is more subjective. Often patients will report maximal fullness after the consumption of physiologically insignificant volumes (< 50 mL). We have not found results from the water load test to be correlated with measures of psychiatric distress or somatization but maximal ingested volumes are positively correlated with quality of life[2,12]. Others have reported that maximal ingested volumes are reduced in patients with depression[16]. While drink tests are not intended as surrogates for assessing psychosocial factors or quality of life, maximal fullness at extremely low volumes may suggest that extra-gastric or central factors are playing an important role in symptom generation, perpetuation or tolerance.

Since the physiologic parameters that determine maximal ingested volumes are not well known at present, drink test results cannot be reasonably used to guide therapy. Few studies have assessed the impact of commonly used treatments for functional dyspepsia on drink test results. A brief, randomized controlled trial found that 14 d of therapy with nortriptyline, mirtazapine or placebo did not alter either maximal ingested volumes or symptom scores[17]. A similar study also found no effect on maximal ingested volume or symptoms in healthy subjects treated with either citalopram, desipramine or placebo for 11 d[18]. In contrast, in healthy subjects, the kappa-opioid agonist asimadoline has been shown to increase maximal tolerated volumes without altering gastric emptying[19].

A small trial randomized patients with functional dyspepsia to biofeedback (breathing exercises using software for vagal biofeedback) or an educational control group[20]. Drinking capacity and quality of life improved significantly more in the biofeedback group than in the control group without any significant change in baseline autonomic activity or intra-gastric volume.

Combining an incomplete understanding of relevant pathophysiologic alterations that might be measured by drink tests with limited data regarding effects of

therapy on drink test volumes leads us to conclude that drink tests are of limited utility in guiding clinical management. Until our understanding in this area has evolved, drink tests should not routinely be performed in clinical practice.

CONCLUSION

Drink tests are often used in clinical studies evaluating patients with functional dyspepsia or gastroparesis. Although patients often report satiation or develop symptoms at substantially smaller ingested volumes than controls, it remains unclear exactly what physiologic processes are assessed by the drink test. Additionally, results of drink tests do not guide therapy. As such, these tests are probably best reserved for research studies and are not advocated for use in clinical practice.

Abstract

Gastro-entero-pancreatic (GEP) neuroendocrine tumors (NETs) are rare neoplasms, although their prevalence has increased substantially over the past three decades. Moreover, there has been an increased clinical recognition and characterization of these neoplasms. They show extremely variable biological behavior and clinical course. Most NETs have endocrine function and secrete peptides and neuroamines that cause distinct clinical syndromes, including carcinoid syndrome; however, many are clinically silent until late presentation with mass effects. Investigation and management should be individualized for each patient, taking into account the likely natural history of the tumor and general health of the patient. Management strategies include surgery for cure or palliation, and a variety of other cytoreductive techniques, and medical treatment including chemotherapy, and biotherapy to control symptoms due to hormone release and tumor growth, with somatostatin analogues (SSAs) and alpha-interferon. New biological agents and somatostatin-tagged radionuclides are under investigation. Advances in the therapy and development of centers of excellence which coordinate multicenter studies, are needed to improve diagnosis, treatment and therefore survival of patients with GEP NETs.

Key words: Gastro-entero-pancreatic neuroendocrine tumors; Carcinoids; Entero-endocrine tumors; Pancreatic tumors; Medical treatment; Molecular targeted therapy

INTRODUCTION

Neuroendocrine tumors (NETs) of the gastro-entero-pancreatic (GEP) system are rare and originate from the diffused endocrine system, located in the gastro-intestinal (GI) tract (carcinoids) and in the pancreas (insular tumors), with extremely varying clinical pictures. GEP NETs represent about 2% of all the GI tumors[1], but their prevalence has increased substantially over the past three decades, only in part as a consequence of increased awareness and improved diagnostic techniques[2]. The most recent estimates suggest a global clinical incidence of 2.5-5 cases/100 000 per year[2,3], with an autoptical incidence 2-5 times higher than the clinical one, and a slight predominance in females[4,5].

The term carcinoid (from the German *Karzinoide*) was introduced in 1907 by Oberndorfer to identify some ileal tumors, originating from the enterochromaffin cells (EC) that produce serotonin, characterized by a better prognosis in comparison with adenocarcinomas. Later the term was used to describe NETs, both of the gut and extra-intestinal sites (pancreas, lung and bronchus, liver, thymus), even though the term NET should always be used specifying the tumor's origin site, in order to avoid misunderstanding. The term carcinoid should be used to indicate the serotonin-secreting tumors[6].

The diffused endocrine system of the GEP tract is the widest of the whole organism, with at least 16 different types of endocrine cells that produce more than 50 peptides or amines[2,6,7]. GEP NETs arise within the GI tract, but NETs can also occur elsewhere such as in the bronchus and lung (bronchial epithelium), hypophysis, thyroid, parathyroids, thymus, adrenal cortex and medulla, and paraganglia. GEP NETs can preserve and amplify the activity of the origin cells

characterized by secretion of a number of peptides and neurotransmitters, which can lead to the development of typical clinical syndromes by the so called "functioning" tumors, or they can be biologically inactive ("non-functioning" tumors)[1,2,8] for several reasons (defect of hormonal synthesis/secretion, rapid hormone degradation, synthesis of precursors/inactive hormones, co-secretion of antagonist hormones).

GEP NETs are usually sporadic, but they may also be multiple and may occur in some genetic syndromes such as multiple endocrine neoplasia (MEN) type 1, von Hippel-Lindau syndrome, neurofibromatosis type 1 and tuberous sclerosis[2,9,10]. Their frequency in these syndromes varies from very low (< 1%) for carcinoid to high (80%-100%) for pancreatic endocrine tumors (insulinomas 5%-20%, gastrinomas 25%-30%, non-functioning > 50%)[6].

CLASSIFICATION

As GEP NETs represent a heterogeneous group of tumors, their classification is still a critical point. In the past, GEP NETs were classified according to their embryonic origin and, according to the classification of William and Sandler[11], three distinct groups have been identified: (1) carcinoids derived from the proximal GI tract (foregut), located in the stomach, proximal duodenum, biliary tract and pancreas fed by the celiac tripod; (2) carcinoids derived from intermediate GI tract (midgut), located in the distal duodenum, small intestine, appendix and right colon, fed from the superior mesenteric artery; (3) carcinoids of the distal intestine (hindgut) localized into the descending colon, sigmoid colon and rectum, fed from the inferior mesenteric artery.

The most recent WHO classification[12] (Table 1) categorized all GEP NETs on the basis of clinical-pathological criteria as follow: (1) well-differentiated endocrine tumors, with benign or uncertain behaviour; (2) well-differentiated endocrine carcinomas, with a low-grade malignant behaviour; (3) poorly differentiated endocrine carcinomas (small cells carcinomas), with a high-grade malignant behaviour; (4) mixed endocrine-exocrine carcinomas, with characteristics of both endocrine and exocrine tumors. Each category includes functioning and non-functioning tumors.

However this classification has prognostic limits and a suboptimal reproducibility among pathologists hence TNM classification is being developed for NETs[13,14]. Table 2 provides examples of TNM classification for pancreatic NETs and carcinoids.

CLINICAL FEATURES

Clinical manifestations of GEP NETs are very heterogeneous: indeed, they can either remain asymptomatic for years, or can occur with obstructive symptoms, such as abdominal pain, nausea, vomiting, cholestasis, or can present with metastases, found accidentally, or can occur with typical syndromes due to hormonal hypersecretion. In most cases, because of vagueness of symptoms, the diagnosis is delayed (3-10 years on average), with an increased risk of developing metastases.

Gastrointestinal NETs (carcinoids)

NETs of the small intestine according to the Surveillance, Epidemiology, and End Results (SEER) database have an incidence of 0.15-0.5 cases/100 000 per year[15]. They are usually asymptomatic or characterized by obstructive symptoms, due to the local fibrotic reaction or, rarely, to the mass itself, until liver metastases appear[6]. At this stage, the typical clinical picture is the carcinoid syndrome that occurs in 18% of patients with ileal carcinoid[2,16] and is characterized by flushing, diarrhea, abdominal pain; less frequent events are lacrymation, profuse sweating, telangiectasias, cardiac fibrosis, and cutaneous manifestations pellagra-like due to lack of niacin (Table 3). Carcinoid syndrome is caused by the release of serotonin, which is no longer metabolized in the liver, and other substances, such as tachykinins, prostaglandins, and bradykinins[2,17].

Gastric carcinoids, that account for 4.6% of all carcinoids[15], originate from gastric EC-like mucosal cells, are mostly asymptomatic and occasionally found in the course of gastroscopies[6]; rarely they can cause an atypical carcinoid syndrome (flushing of greater duration than typical, of a red colour, with scialorrea, sweating, tearing, hypotension and itching)[16-18]. These carcinoids are divided into 3 groups: those that occur in chronic hypergastrinemic conditions, such as the type 1, associated with chronic atrophic gastritis, and type 2, associated with Zollinger Ellison syndrome in MEN-1, while type 3 is not associated with hypergastrinemia and is frequently malignant, with distant metastases.

Appendiceal endocrine tumors are often small and are found incidentally during appendectomies, with a frequency of 3-9/1.000 appendectomies and are usually benign[6,19-21]. Colonic carcinoids account for 8.6% of all carcinoids. They are often large and, among the intestinal carcinoids, have the worst prognosis[6,22].

Rectal carcinoids may present as an incidental finding on sigmoidoscopy or colonoscopy (1:2.500). They are typically small, non-functioning and distant metastases are rarely present at diagnosis (probably due to the early diagnosis)[6,22].

Carcinoids have previously been reported to be associated with secondary non-carcinoid malignancies, with rates as high as 46%-55%, more frequently located in the lung, breast, prostate and colon[23,24].

Pancreatic NETs

Endocrine tumors of the pancreas can occur with typical syndromes due to hormonal hypersecretion, such as insulinoma, gastrinoma, VIP-oma, glucagonoma and somatostatinoma (Table 4), but in a percentage of 40%-50% they are non-functioning or secrete peptide with a low biological impact, such as pancreatic polypeptide (PP) and neurotensin. Moreover a metastatic disease can be present at the time of diagnosis in approximately 50% of the cases[1,2,6,8].

Table 1 WHO classification[12]

Site	Well differentiated endocrine tumor		Well-differentiated endocrine carcinoma	Poorly-differentiated endocrine carcinoma
	BB	UB		
Pancreas	< 2 cm	⩾ 2 cm	Local invasion	Small cells
	< 2 mitoses[1]	> 2 mitoses	2-10 mitoses	> 10 mitoses
	< 2% Ki-67	> 2% Ki-67	> 5% Ki-67	> 15% Ki-67
	No vascular invasion	Vascular invasion	Vascular invasion ± metastases	Vascular/perineural invasion
Stomach	Mucosa/Submucosa	Mucosa/Submucosa	Invasion of muscolaris propria ± metastases	Small cells
	⩽ 1 cm	> 1 cm		
	No vascular invasion	Vascular invasion		
Duodenum/	Mucosa/Submucosa	Mucosa/Submucosa	Invasion of muscolaris propria ± metastases	Small cells
Jejunum	⩽ 1 cm	> 1 cm		
	No vascular invasion	Vascular invasion

Criteria for carcinoids of the appendix and colon rectum differ only for the tumor size.

Insulinoma and gastrinoma are the most frequent pancreatic NETs. The incidence of insulinomas is 2-4 new cases/1 000 000 per year, whereas that of gastrinoma is 0.5-4 new cases/1 000 000 per year[8,25].

Insulinoma are usually (90%) benign tumors, most are small (> 90% are < 2 cm) and single, 6%-13% are multiple, and 4%-6% are associated with MEN-1. Clinically they are characterized by fasting hypoglycemia and neuroglycopenic symptoms. Moreover the release of catecholamines induced by hypoglycemia produces symptoms such as sweating, tremor and palpitation. Diagnostic procedures are given in Table 4.

Gastrinoma is a NET secreting gastrin. The chronic hypergastrinemia results in marked gastric acid hypersecretion that ultimately causes peptic ulcer disease, often refractory and severe, diarrhea and gastroesophageal reflux disease (Zollinger Ellison Syndrome, ZES).

At the time of diagnosis 50%-60% of gastrinomas are malignant. The tumor is preferentially located in the pancreas (24%-53%) and in the duodenum (13%-49%). Approximately 20% of gastrinomas are part of MEN-1. The diagnosis requires the demonstration of hypergastrinemia with hyperchlorhydria (Table 4).

Table 3 Carcinoid syndrome

Clinical features	Incidence (%)	Characteristics	Mediators
Flushing	90	Foregut tumors: prolonged fit, red-purple, localized to face and trunk. Midgut tumors: quick fit, pink-red.	Serotonin, histamine, P substance, prostaglandins
Diarrhea	70	Secretory	Serotonin, histamine, VIP, prostaglandins, gastrin
Abdominal pain	40	Long lasting	Obstruction, hepatomegaly, intestinal ischemia, fibrosis
Profuse sweating	15		Serotonin, histamine
Telangiectasias	25	Face	Unknown cause
Heart disease	30 (right)	Valvulopathies (tricuspid valve, pulmonary valve). Right heart failure. Dyspnea	P substance, serotonin
	10 (left)		
Pellagra	5	Dermatitis	Deficit of niacin

Table 4 Clinical features of the main endocrine pancreatic tumors

Tumor (syndrome)	Clinical features and diagnostic tests	MEN-1 (%)	Metastases (%)	SnSRS (%)
Insulinoma	Spontaneous or fasting hypoglycemia (Whipple's triad) Positive fasting test (hypoglycemia with hyperinsulinism)	8-10	10	50
Gastrinoma (Zollinger-Ellison syndrome)	Peptic ulcers, diarrhea, GERD, BAO > 15 mEq/h Positive secretin test (serum gastrinemia > 200 ng/L within 10 min from secretin venous infusion, 2 U/kg per min)	30	60	80
VIP-oma (Verner Morrison syndrome)	Severe watery diarrhea (> 1L/die), hypokalemia, hypochlorhydria	Rare	70	80
Glucagonoma	Necrolytic migratory erythema, diabetes, weight loss, anemia, hypoaminoacidemia, venous thrombosis	Rare	60	80
Somatostatinoma	Diarrhea, steatorrhea, weight loss, diabetes, cholelithiasis	Not associated	84	80
CRH/ACTH-oma	Cushing's syndrome	-	90	-
GHRH-oma	Acromegaly	-	-	-

SnSRS: Sensitivity of ^{111}In-Pentetreotide scintigraphy (Octreoscan®).

VIP-omas are NET that secretes VIP, which causes a distinct syndrome (Verner Morrison syndrome) characterized by large volume watery diarrhea, hypokalemia and dehydration. Pancreatic VIP-omas are rare (3%-8% of all pancreatic NETS)[8,25]. They are usually large (72% are > 5 cm) and malignant at the time of diagnosis (64%-92%). Extra-pancreatic VIP-omas may occur in pediatric patients and are neurogenic tumors (ganglioneuromas, ganglioneuroblastomas, neuroblastomas and pheochromocytomas).

Glucagonomas are rare (1/20 000 000 per year)[8,25,26]. They are usually large tumors at diagnosis with a size of 5-10 cm and from 50% to 82% are metastatic. The most common presenting feature is necrolytic migratory erythema, associated with glucose intolerance or diabetes, anemia, weight loss, depression, diarrhea and thromboembolism.

Somatostatinomas are rare tumors of either the pancreas or the upper small intestine, usually duodenum, near the ampulla of Vater. Somatosatinomas can be part of neurofibromatosis 1. Pancreatic tumors are usually large and metastatic (70%-92%) at diagnosis. The clinical symptoms include: diabetes, cholelithiasis, diarrhea with steatorrhea, hypochloridria, abdominal pain, weight loss and anemia.

Other rare tumors include CRH/ACTH-omas, GRF-omas, calcitoninomas and neurotensinomas[26]. Non functioning tumors constitute 30%-50% of all pancreatic NETs and differentiation from pancreatic adenocarcinomas is extremely important because prognosis is clearly different. The tumors are usually large, can be multifocal when are part of MEN-1 and malignancy rate varies from 62% to 92%[25].

DIAGNOSIS

Hormonal dosages

Several circulating or urinary tumor markers can be used for the diagnosis and follow-up of GEP NETs.

Among the generic markers, chromogranin A (CgA), a glycoprotein contained in secretion granules of neuroendocrine cells, has become the most important circulating tumor marker for the diagnosis and follow-up of NETs[27,28]. Elevated circulating levels of CgA are found in about 60%-80% of GEP NETs, both functioning and non-functioning[29], even if other non-neoplastic conditions, such as renal insufficiency, atrophic chronic gastritis, therapy with proton pump inhibitors[30,31] can determine false-positive results, reducing its specificity. Other generic markers include neuron-specific enolase (NSE), PP and human chorionic gonadotropin, with lower diagnostic accuracy than CgA[6,32].

5-hydroxyindoleacetic acid (5-HIAA) is the specific marker for carcinoids producing serotonin[2,6,18,32]; it is a metabolite of serotonin that can be determined in 24 h urines. The sensibility of the urinary 5-HIAA is about 65%-75%, while its specificity between 90%-100%[6].

Certain foods and drugs will affect the urinary excretion of 5-HIAA if they are taken in the 3-5 d before collection

of the urine sample. Bananas, avocados, aubergines, pineapples, plums, walnuts, cough syrup, paracetamol, fluorouracil, methysergide, levodopa, aspirin, 5-aminosalicylic acid (5-ASA), naproxen and caffeine may cause false-positive results. Adrenocorticotrophic hormone (ACTH), glucocorticoids, heparin, isoniazid, methyldopa and phenothiazines may give false-negative results[6].

For functioning NETs, the dosage of the specific hormone that causes the characteristic syndrome represents the specific tumor marker[1,6,8]. In particular in patients with suspected insulinoma, glycemia, insulin, peptide C and pro-insulin must be tested. Further biochemical tests include the prolonged fast (48-72 h), which is the gold standard for establishing the diagnosis of insulinoma. Indeed, 98% of patients with insulinoma will develop symptomatic hypoglycemia within 72 h.

In Zollinger Ellison syndrome, serum gastrin and basal gastric acid output should be evaluated[33,34]. If the gastrin is $\geqslant$ 1000 ng/L and gastric pH $<$ 2.5, the diagnosis is established. The secretin test is the provocative test of choice in patients with gastrin levels $<$ 1000 ng/L (Table 4). Plasma vasointestinal polypeptide (VIP) determination is used to diagnose VIP-oma in the suspicion of Verner-Morrison syndrome, plasma glucagon for glucagonoma, and serum somatostatin for somatostatinoma[1,6,8].

Imaging

Different integrated techniques can be used for diagnosis[1,2,6,35]. Imaging has an important role in localizing the primary tumor, identifying sites of metastatic disease and assessing response to treatment. The gastric and intestinal tumors are usually well studied with endoscopic techniques and endoscopic ultrasound. The tumors of the small intestine may require, besides enforcement of traditional radiological techniques (small bowel barium studies), the use of the most current techniques for studying small bowel (double balloon enteroscopy, video endoscopic capsule). Both for carcinoid and pancreatic tumors, computer tomograghy (CT) and magnetic resonance imaging (MRI) are important in defining the extent of metastatic disease and assessing response to treatment. Both techniques appear to have similar sensitivities for detection of these tumors, ranging from 30% to 94%[35]. Endoscopic ultrasound has an important role in the preoperative assessment of the pancreas where a small functioning tumor or the possibility of multiple tumors is suspected. This technique is very successful in expert hands, with sensitivities as high as 79%-100% being reported[35].

Functional imaging modalities, such as somatostatin receptor scintigraphy (SRS, Octreoscan®), have great impact on patient management by providing tools for better staging of the disease, visualization of occult tumor, and evaluation of eligibility for somatostatin analogue (SSA) treatment. In fact NETs generally express somatostatin receptors and by administering a radiolabelled SSA, the tumor is highlighted by the scintigraphic investigation. The SRS is a highly specific examination with sensitivity, for tumors of more than 1 cm, approximately of 80%-90% (with the exception of insulinoma that expresses somatostatin receptors in only 50% of cases)[1,2,6,36,37]. SRS also detects distant metastases with a sensitivity that can reach 96%[2,6]. It should be also noted that a positive SRS may lead to a possible systemic SSAs treatment or radionuclide therapy. On the other hand, even more sensitive techniques are being developed, based on methods combining PET-CT using [^{18}F] levodopa, 5HTP [^{11}C] or [^{68}Ga] linked to a SSA (^{68}Ga-DOTA-octreotide-PET)[36].

On the contrary, PET with conventional fluoro-deoxy-glucose has not proven advantageous for NET imaging, because of GEP NETs' low metabolic activity, with the exception of tumors with high proliferative activity and low differentiation[36].

Finally angiographic techniques, with the possible establishment of hormonal gradients, are currently used only in special cases and adequately equipped centers.

Pathology

Histopathological examination is the main criterion of the WHO classification[12] (Table 1), which takes into account: tumor size, number of mitosis, presence of cellular atypias, proliferative index, angioinvasion. Immunohistochemistry is also one of the most important techniques for the study of NETs. Several antibodies are available both against general endocrine markers such as NSE, sinaptofisin and CgA, and against specific hormones.

It is also important to discriminate well-differentiated forms from poorly-differentiated carcinomas using malignancy markers. With this aim, the immunohistochemical expression of Ki67 seems as important as the determination of the mitotic index, expressed as the number of mitoses/10 high power fields[6,38].

TREATMENT

Surgical treatment

If possible, radical surgery is the cornerstone of the treatment of primitive GEP NETs. If there is loco-regional or liver metastases a debulking surgery can be performed in patients in whom 90% of the tumor is removable. It is suggested to perform a palliative surgery in the following clinical situations: (1) on the primary tumor with non-operable liver metastases (particularly in functioning tumors) because symptoms correlate with neoplastic mass; (2) if the primary tumor is localized in the small bowel, as it can lead to bowel obstruction; (3) in the case whereby surgery allow a subsequent multimodal treatment.

A combination of several therapies can be performed for liver metastases, such as surgical resection, (chemo) embolization, radiofrequency ablation and, in selected cases, orthotopic liver transplantation may be considered[16,39,40]. Although there are few studies that compare different treatment options on liver metastases, it would seem that different treatments improve survival

Table 5 Results of studies of molecularly targeted agents in patients with neuroendocrine tumours[54,55]

Agent	Response rate (%)	PFS rate (%)/Duration
VEGF monoclonal antibody		
Bevacizumab[56]	18	95 at 18 wk
mTOR inhibitor		
RAD001 (everolimus)	13	71 at 24 wk
Temsirolimus[57]	5.6	50 at 6 mo
VEGF TKI		
Sunitinib	10	Median, 42 wk
Vatalanib	In progress	(time to progression)
Sorafenib	In progress	
Pazopanib	In progress	
PDGFR/Kit/Abl inhibitor		
Imatinib[58]	4	Median, 5.9 mo
EGFR inhibitor		
Gefitinib	4	61 (carcinoids) and 31 (pancreatic tumor) at 6 mo
Other		
Bortezomib[59]	0	Median, 3 mo (Time to treatment failure)

PFS: Progression free survival.

rate at 5 years globally from 30% for the untreated tumor to 50%-70%[39,40].

Medical therapy

Medical treatment of NETs is different depending on whether the tumor is a well-differentiated or a poorly differentiated one. Functioning tumors are usually well differentiated and the first target of therapy is the control of symptoms. As these tumors are generally slow in growth, with a relatively long life expectancy, it is essential to ensure patients a good quality of life.

Treatment of gastrinomas is based on the use of proton pump inhibitors at an appropriate dosage (omeprazole and lansoprazole 40-60 up to 120 mg/d)[41,42]. Insulinomas are treated with diazoxide associated with hydrochlorothiazide; if this therapy is ineffective calcium channel blockers, beta blockers and glucocorticoids can be used[43]. For other well-differentiated cancers therapy is based on the use of SSAs, interferon and, more recently, targeted therapy[44,45].

Somatostatin is a hormone that inhibits the secretion of various hormones and peptides; somatostatin receptors are present in most well-differentiated GEP NETs (70%-95% of tumors), with the exception of insulinoma. SSAs allow control of hormonal-related symptoms and should be used both in a preoperative setting and in inoperable tumors[44]. They are sometimes used as antiproliferative agents, even if clinical studies have given disappointing results with regard to tumor regression and tumor shrinkage is demonstrated in less than 10% of the patients at standard dosage, although about 50% of patients can show stabilization of tumor size[46]. A possible positive effect on tumor volume regression with high-dose SSAs has yet to be demonstrated. Two different SSAs, octreotide and lanreotide, are used clinically. These analogues bind principally to the receptor subtypes 2 and 5. Recently pasireotide, a somatostatin analog with high affinity for all types of somatostatin receptors, has been introduced and has been shown to be effective in patients who do not respond to the currently available SSAs octreotide and lanreotide[47]. However, its use is still restricted to clinical studies. Altogether, SSAs are safe, easy to use, and well tolerated by patients experiencing only mild and infrequent side effects, among which are diarrhea, abdominal pain, steatorrhea, and cholelithiasis[48].

In addition, alpha interferon, such as monotherapy or in combination with SSAs, can be used to inhibit hormone hypersecretion and to stabilize the disease, with variable response rates. There has been biochemical response in 40%-60% of patients, symptomatic improvement in 40%-70% of patients, and significant tumor shrinkage in a median of 10%-15% of patients[48,49]. Interferon is used for the same indications as are SSAs in NETs of the gut, except for carcinoid crisis. Side-effects are generally mild, flu-like syndrome, fatigue, weight loss, polyneuropathy, myositis, thrombocytopenia, anemia, leukopenia, hepatotoxicity and neutralizing antibodies.

Poorly differentiated tumors are generally treated with different chemotherapy schedules. The role of chemotherapy in the treatment of GEP NETs is still uncertain, as variable response rates in different studies have been reported. While well-differentiated tumors are not responsive to chemotherapy (based on streptozotocin, doxorubicin, dacarbazine and 5-flurouracile variously associated with each other)[6,50] with only about 10% of carcinoids having a positive response, the best response rates (40%-70%) have been reported in some studies for anaplastic cancer, using different schemes based on cisplatin and etoposide, although there is no unequivocal evidence of survival improvement[51-53]. Furthermore, randomized controlled trials on chemotherapy *versus* biological treatment (SSAs with/without interferon) are still lacking.

GEP NETs can over express some molecules, such as epidermal growth factor receptor (EGFR), vascular endothelial growth factor (VEGF) and its receptor (VEGFR) or insulin-like growth factor receptor (IGFR), that can be targeted by some new drugs under assessment in early clinical trial (see Table 5)[54-59]. Other molecular therapies currently under investigation include the Raf-kinase inhibitor sorafenib and the inhibitor of the mTOR pathway, everolimus (RAD001)[54,55].

Peptide receptor radionuclide therapy (PRRT)

Another therapeutic approach is PRRT, which uses somatostatin analogs to convey radioactivity within the tumor itself (using generally ^{90}Ittrium, ^{177}Lutetium or ^{111}Indium), through somatostatin receptors[60,61]. PRRT can be considered in patients with inoperable GEP NETs and positive nuclear medicine imaging. According to some studies a stabilization of the disease can be reached in 50%-70% of cases[62-64] and control of symptoms in 70%[60]. Data in the literature, which however are not based on randomized, comparative studies, seem to favor [^{177}Lu-DOTA, Tyr] octreotate as

the most suitable peptide and radionuclide for PRRT[65]. Currently, tolerated dose is defined by the dose tolerated by the critical organs, kidney and bone marrow; it is likely that the dose can be modified in the future by more sophisticated, individually tailored dosimetry models, and by the introduction of new protective agents, different treatment schedules and radionuclides. This treatment has to be carried out in centers properly equipped and is to be reserved for selected cases.

Abstract

Helicobacter pylori (*H pylori*) infection is the main cause of gastritis, gastroduodenal ulcer disease, and gastric cancer. After more than 20 years of experience in *H pylori* treatment, in my opinion, the ideal regimen to treat this infection is still to be found. Currently, apart from having to know first-line eradication regimens well, we must also be prepared to face treatment failures. Therefore, in designing a treatment strategy we should not focus on the results of primary therapy alone, but also on the final (overall) eradication rate. The choice of a "rescue" treatment depends on which treatment is used initially. If a clarithromycin-based regimen was used initially, a subsequent metronidazole-based treatment (quadruple therapy) may be used afterwards, and then a levofloxacin-based combination would be a third "rescue" option. Alternatively, it has recently been suggested that levofloxacin-based rescue therapy constitutes an encouraging second-line strategy, representing an alternative to quadruple therapy in patients with previous PPI-clarithromycin-amoxicillin failure, with the advantage of efficacy, simplicity and safety. In this case, a quadruple regimen may be reserved as a third-line rescue option. Finally, rifabutin-based rescue therapy constitutes an encouraging empirical fourth-line strategy after multiple previous eradication failures with key antibiotics such as amoxicillin, clarithromycin, metronidazole, tetracycline, and levofloxacin. Even after two consecutive failures, several studies have demonstrated that *H pylori* eradication can finally be achieved in almost all patients if several rescue therapies are consecutively given. Therefore, the attitude in *H pylori* eradication therapy failure, even after two or more unsuccessful attempts, should be to fight and not to surrender.

Key words: *Helicobacter pylori*; Rescue; Salvage; Rifabutin; Levofloxacin

INTRODUCTION

Helicobacter pylori (*H pylori*) infection is the main cause of gastritis, gastroduodenal ulcer disease, and gastric cancer. After more than 20 years of experience in *H pylori* treatment, in my opinion, the ideal regimen to treat this infection is still to be found. Consensus conferences have recommended therapeutic regimens that achieve *H pylori* cure rates higher than 80% on an intention-to-treat basis[1-3]. However, several large clinical trials and meta-analyses have shown that the most commonly used first-line therapies-including proton pump inhibitors (PPIs) plus two antibiotics-may fail in up to 20% of patients[4,5], and in the clinical routine setting, the treatment failure rate might be even higher. Moreover, during the last few years, the efficacy of PPI-based regimens seems to be decreasing, and several studies have reported intention-to-treat eradication rates lower than 75%[6-14] and even lower than 50%[15,16]. Antibiotic resistance to clarithromycin has been identified as one of the major factors affecting our ability to cure *H pylori* infection, and the rate of resistance to this antibiotic seems to be increasing in many geographical areas[17,18].

Reports dealing with retreatment of *H pylori* after failure are difficult to analyze for several reasons[19]. Firstly, patients who fail with their first-line treatment

probably include a higher percentage of individuals who are unreliable tablet takers, others have resistant organisms and there is the "constitutional" group, where failure will be inevitable. On the other hand, some patients submitted for rescue therapy have already had more than one previous treatment for *H pylori*, and this circumstance is not always clarified in the protocols. Furthermore, the original primary treatments vary among the different studies, not only with respect to the antibiotic type, but also with respect to the dose and duration of the regimen. Finally, only a few studies have directly compared, in the same protocol, two or more second therapies[20,21].

Several rescue therapies have been recommended, but they still fail to eradicate *H pylori* in more than 20% of cases[20], and these patients constitute a therapeutic dilemma[21]. Patients who are not cured with two consecutive treatments, including clarithromycin and metronidazole, will have at least single, and usually double, resistance[18]. Furthermore, bismuth salts are not available worldwide anymore and, therefore, management of first-line eradication failures is becoming challenging. Currently, a standard third-line therapy is lacking, and European guidelines recommend a culture for these patients to select a third-line treatment according to microbial sensitivity to antibiotics[2,3]. However, cultures are often carried out only in research centers, and the use of this procedure as "routine practice" in patients who failed several treatments seems not to be feasible[20-22]. Therefore, the evaluation of drugs without cross-resistance to nitroimidazole or macrolides as components of retreatment combination therapies would be worthwhile.

All these issues are important at the present time, but they will be even more relevant in the near future, as therapy for *H pylori* infection is becoming more and more frequently prescribed. Therefore, the evaluation of second or third rescue regimens for these problematic cases seems to be worthwhile. In designing a treatment strategy, we should not focus on the results of primary therapy alone; an adequate strategy for treating this infection should use several therapies which, if consecutively prescribed, come as close to the 100% cure rate as possible[20,21,23,24].

The aim of the present manuscript will be to review the experience dealing with "non-responders" to *H pylori* eradication therapy. As, at present, the current most prescribed first-line regimens include a combination of PPI plus two antibiotics, the present review will focus only on rescue regimens when these triple combinations fail. Bibliographical searches were performed in the PubMed (Internet) database including studies available until March 2008, looking for the following words (all fields): pylori AND (retreatment OR re-treatment OR rescue OR failure OR salvage OR second-line OR third-line OR fourth-line). References of reviews on *H pylori* eradication treatment, and from the articles selected for the study, were also examined in search of articles meeting inclusion criteria (that is, dealing with *H pylori* rescue therapies).

IS IT NECESSARY TO PERFORM CULTURE AFTER FAILURE OF THE FIRST ERADICATION TREATMENT?

Pretreatment antibiotic resistance is the most important factor in nonresponse to initial treatment[25-29]. Thus, the choice of a second-line treatment depends on which treatment was used initially, as it would appear that retreatment with the same regimen cannot be recommended[30]. If a clarithromycin-based regimen was used, a metronidazole-based treatment (or at least a clarithromycin-free regimen) should be used afterwards, and *vice versa*[31]. This recommendation is based on the observation that acquired bacterial resistance to metronidazole or clarithromycin results primarily from the previous treatment failure[26,32,33], and therefore rescue therapies should avoid these antibiotics and use different combinations.

An antimicrobial susceptibility test for *H pylori* before second-line treatment is sometimes performed, although whether the test is truly necessary remains unknown. Some authors have evaluated the efficacy of susceptibility-guided *vs* empiric retreatment for *H pylori* after a treatment failure. In the study by Yahav *et al*[34], patients in whom at least one treatment regimen for *H pylori* eradication had failed underwent gastric biopsy and culture, and were retreated according to the *in vitro* susceptibility results. Findings were compared with those of control patients (where culture was unavailable). Susceptibility-guided retreatment was associated with better eradication rates (86%) than empiric treatment (63%). However, several methodological drawbacks exist in this study. Firstly, more than 50% of the patients received first-line eradication treatment with both clarithromycin and metronidazole (instead of including clarithromycin and amoxicillin), which is not the generally recommended combination; consequently, no logical empirical treatment remained afterwards (levofloxacin-based regimens were not available at that time). In this respect, when only the eradication rates in control (culture unavailable) patients treated with a first regimen of PPI-amoxicillin-clarithromycin followed by a second *empiric* quadruple regimen were considered (the generally recommended first and second-line strategies), the success figures were not significantly different from those reported in patients receiving susceptibility-guided retreatment. Secondly, because this study was nonrandomized, there might have been heterogeneity among the two groups with respect to the treatment regimens prescribed by the treating physicians. Finally, this study was limited by the lack of susceptibility data for the controls, which restricted the ability to analyze the reasons why empiric therapy did not work as well as the susceptibility-guided protocol.

In a French multicenter study[35], patients in whom one previous *H pylori* eradication therapy (mainly with PPI-amoxicillin-clarithromycin) had failed were randomized to receive one of three empirical triple therapy regimens or a strategy based on antibiotic susceptibility. The empirical regimens

were PPI-amoxicillin-clarithromycin (for 7 d or 14 d) or PPI-amoxicillin-metronidazole (for 14 d). In the susceptibility-based strategy, patients with clarithromycin-susceptible strains received PPI-amoxicillin-clarithromycin, whilst the others received PPI-amoxicillin-metronidazole. The eradication rates for empirical therapies were low, while the cure rate was higher (74%) for the susceptibility-based treatment. If the *H pylori* strain was clarithromycin-susceptible (which occurred in approximately 1/3 of the cases), a high success rate was obtained with the PPI-clarithromycin-amoxicillin rescue regimen. The study, however, was done in France, where bismuth is banned, so that the use of quadruple therapy with a PPI, bismuth, tetracycline, and metronidazole as recommended by the updated Maastricht Consensus Report[3], was not tested. In fact, as will be reviewed later, several studies have obtained relatively good results with this quadruple regimen empirically prescribed, with a mean eradication rate of 77%, which is similar to the 74% achieved for the susceptibility-based treatment in the present study. Thus, in this study, instead of not readministering any of the antibiotics against which *H pylori* had probably become resistant, the authors insist on prescribing again clarithromycin (or metronidazole) for the second-line treatment. Furthermore, statistically significant differences were not demonstrated when comparing the efficacy of the empirical PPI-amoxicillin-metronidazole and the susceptibility-based strategy, suggesting that the metronidazole-based combination may be an effective empirical alternative after failure of a clarithromycin-based combination.

In the updated Maastricht Consensus Report[3], it was recommended that culture and antimicrobial sensitivity testing should be routinely performed only after two treatment failures with different antibiotics. According to this statement, some studies have suggested that an antimicrobial susceptibility test for *H pylori* before administering second-line treatment is not necessary. In this respect, in the study by Avidan *et al*[36], after failure of first-line eradication treatment, half of the patients were randomly assigned to treatment with a different PPI-based triple regimen regardless of the culture obtained, and the other half was assigned to treatment with PPI and two antibacterial agents chosen according to a susceptibility test; the authors found that the culture results did not influence the treatment protocol employed. Similarly, in the study by Miwa *et al*[37], patients with *H pylori* infection for whom first-line treatment with a PPI-amoxicillin-clarithromycin regimen had failed were randomly assigned to two groups: those having or not having the susceptibility test before retreatment. For those patients in the susceptibility-test group, the authors used what they considered the best regimen based on susceptibility testing; while for those patients in the group with no susceptibility testing, PPI-amoxicillin-metronidazole was prescribed. The cure rates in the groups with and without susceptibility testing were not different.

SECOND-LINE *H PYLORI* RESCUE THERAPY AFTER FAILURE OF ONE ERADICATION TREATMENT

Rescue regimen after PPI-clarithromycin-amoxicillin failure

PPI, amoxicillin and metronidazole: After failure of a combination of PPI, amoxicillin and clarithromycin, a theoretically correct alternative would be the use, as second option, of other PPI-based triple therapy including amoxicillin (which does not induce resistance) and metronidazole (an antibiotic not used in the first trial), and several authors have reported encouraging results with this strategy[37-44]. However, in our experience, when this therapy has been administered twice-daily for one week, eradication rates lower than 50% have been obtained[45]; the subsequent use of higher (three times per day) antibiotic doses was followed only by a mild increase in eradication rate (58%), which was still unacceptable[45]. However, if ranitidine bismuth citrate (RBC) is used instead of PPI, also plus amoxicillin and nitroimidazole, encouraging results have been reported (81% cure rate), although in this protocol antibiotics were administered for 14 d instead of 7 d[46]. In this same study, the readministration of clarithromycin, even when co-prescribed with RBC, was associated with poor eradication rates. In the same way, Nagahara *et al*[47] studied a group of patients who, after failure of first-line PPI-clarithromycin-amoxicillin therapy, had received second-line therapy with the same regimen (for 14 d) or had received PPI-amoxicillin-metronidazole (for 10 d). The eradication rates for second-line therapy with the same regimen (thus readministering clarithromycin) was only 53%, while it was 81% with PPI-amoxicillin-metronidazole. These observations underlie the idea that antibiotics, and specifically clarithromycin, should not be readministered in successive treatments.

Quadruple therapy: Another alternative, the use of a quadruple regimen (i.e. PPI, bismuth, tetracycline and metronidazole), has been generally used as an optimal second-line therapy after PPI-clarithromycin-amoxicillin failure, and has been the recommended rescue regimen in several guidelines[3,48-50]. Several studies have obtained relatively good results with this quadruple regimen, and the results are summarized in Table 1[45,51-71]. Thus, the weighted mean eradication rate with this rescue therapy, calculated from the studies included in the table, is 77%. In this combination regimen, PPI should be prescribed in the usual dose for twice a day, colloidal bismuth subcitrate 120 mg four times per day, tetracycline 500 mg four times per day, and metronidazole is probably best prescribed at high doses (i.e. 500 mg three times per day). The study with the lowest efficacy[57] administered metronidazole at low doses (250 mg four times per day). Limited experience suggests that quadruple therapy may also be effective when the first (failed) regimen included RBC instead of PPI. Thus, Beales *et al*[72] reported that four of the five patients

Eradication rates by intention-to-treat analysis when available. *H pylori* eradication rate (weighted mean) with quadruple therapy is 77%.

initially failing RBC-clarithromycin-amoxicillin therapy were successfully treated with quadruple therapy. Seven-day treatment duration seems to be sufficient when quadruple therapy is used after a failed first regimen, as quite similar eradication rates with 7, 10 and 14 d have been reported (mean figures, calculated from Table 1, of 74%, 72% and 81%, respectively). Furthermore, in a recent retrospective study, patients who failed the standard triple therapy (PPI, amoxicillin, clarithromycin) received 1 or 2 wk quadruple therapy, and the eradication rate was similar between the two regimens[54]. These results are in agreement with those reported previously with quadruple therapy as a first-line regimen, where 1-wk therapy appeared sufficient, and prolonging treatment did not increase efficacy[73]. Finally, although PPIs are generally prescribed as the antisecretors in quadruple therapy, some authors have shown, in a randomized study, that omeprazole 20 mg *b.i.d.* and ranitidine 300 mg *b.i.d.* were equally effective as antisecretory agents combined in a second-line quadruple eradication regimen after failure with previous regimens without metronidazole[62]. Nevertheless, these regimens were administered over 14 d and, therefore, it remains to be demonstrated whether the equivalence between both antisecretors-PPIs and H_2-blockers- is also observable with 7 d regimens.

The question may be suggested whether treatment with PPI-clarithromycin-amoxicillin followed by rescue with quadruple therapy if initial failure occurs is preferable to the inverse strategy. To analyze this interesting aspect, Gomollón *et al*[74] randomized consecutive patients to one of two strategies: (1) treatment during 7 d with quadruple therapy, and if failure occurs then second-line treatment with omeprazole-clarithromycin-amoxicillin during 7 d; and (2) initial treatment with omeprazole-clarithromycin-amoxicillin and if failure occurs then treatment with quadruple therapy. Direct and indirect costs were estimated, and a cost-effectiveness analysis using a decision-tree model was undertaken after real clinical data. Eradication was obtained (intention-to-treat) in 73% with the first strategy, *versus* 92% with the second strategy. Furthermore, cost per case eradicated was lower in the second group (320 *versus* 296 euros). However, in a similar but more recent study, Marko *et al*[61] assessed the usefulness and the cost-effectiveness of these two treatment strategies, performing a decision analysis. The effectiveness of "triple first" and "quadruple first" strategies was similar, although the latter seemed slightly more cost-effective.

RBC, tetracycline and metronidazole: More recently, it has been reported that replacing the PPI and the bismuth compound of the quadruple therapy by RBC also achieves good results as a rescue regimen[57,75-80]. RBC is a compound that has, on the one hand, the antisecretory activity of ranitidine, and, on the other hand, the mucosal protective and anti-*H pylori* effects of certain other bismuth salts[81-83]. To date, several studies have evaluated 7-14 d RBC-based second-line regimens after PPI-based triple therapy failures, achieving encouraging results, with eradication rates of 67%[77], 68%[79], 76%[84], 82%[75], 83%[57], 86%[80], and 96%[76]. Furthermore, one randomized study has demonstrated that triple RBC-based therapy, when prescribed to patients with previous PPI-clarithromycin-amoxicillin failure, achieved an even higher efficacy than quadruple therapy, with additional advantages of a lower number of drugs and a simpler dose scheme[57]. Nevertheless, the eradication rate with a quadruple regimen in this last study was remarkably low, which was explained by the low dose of metronidazole prescribed. The favorable results obtained with RBC in the aforementioned studies were explained, at least in part, by the fact that RBC-based therapies may overcome the impact of metronidazole resistant and clarithromycin resistant strains on *H pylori* eradication treatment[18,81-83]. In summary, due to the aforementioned encouraging results, quadruple therapy (as well as RBC-based regimens) may be considered as the preferred regimen after initial treatment failure with PPI-clarithromycin-amoxicillin[3,20,78,85]. However, bismuth salts, including RBC, are no longer available worldwide, and some National Guidelines have been changed accordingly[86].

PPI, amoxicillin and levofloxacin: As previously mentioned, after failure of a combination of a PPI-based triple regimen, the use of the quadruple therapy has been generally recommended as the optimal second-line therapy based on the relatively good results reported

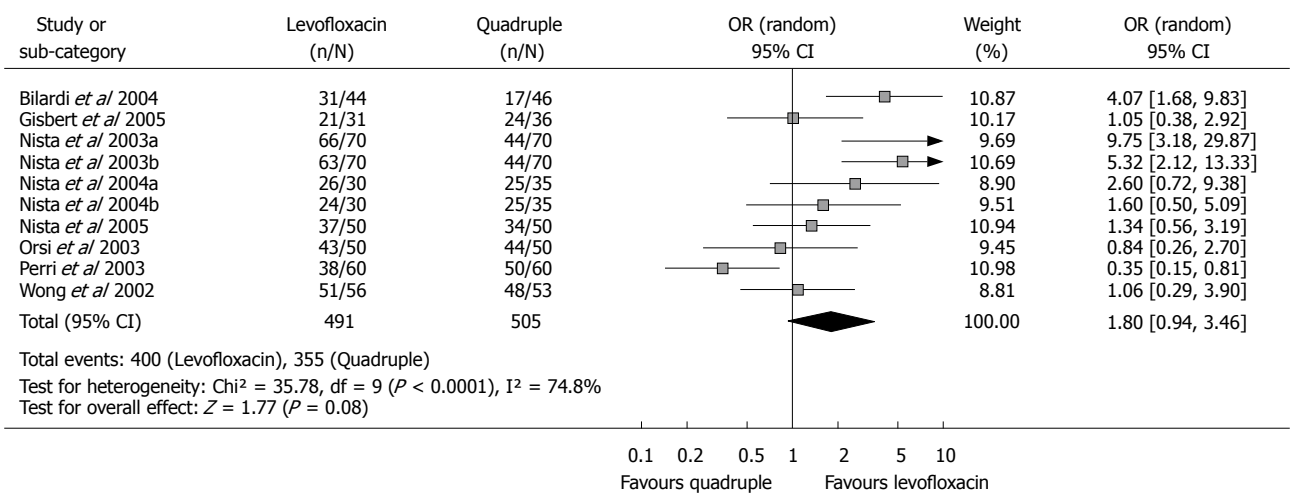

Figure 1 Meta-analysis comparing *H pylori* eradication efficacy with levofloxacin-based triple regimens *versus* quadruple therapy, as second-line "rescue" regimen after failure of a proton pump inhibitor-amoxicillin-clarithromycin.

by several authors[3,20,78,85]. However, this quadruple regimen requires the administration of 4 drugs with a complex scheme (bismuth and tetracycline usually prescribed every 6 h, and metronidazole every 8 h) and is associated with a relatively high incidence of adverse effects[20]. Furthermore, this quadruple regimen still fails to eradicate *H pylori* in approximately 20% to 30% of the patients, and these cases constitute a therapeutic dilemma, as patients who are not cured with two consecutive treatments including clarithromycin and metronidazole will usually have double resistance[20].

Levofloxacin is a fluoroquinolone antibacterial agent with a broad spectrum of activity against Gram-positive and Gram-negative bacteria and atypical respiratory pathogens[87]. Recently, some studies have evaluated the efficacy of new fluoroquinolones, such as levofloxacin, that could prove to be a valid alternative to standard antibiotics, not only as first-line therapies, but more interestingly, as second-line regimens[21,88-90]. In this respect, levofloxacin-based second-line therapies represent an encouraging strategy for eradication failures, as some studies have demonstrated that levofloxacin has, *in vitro*, remarkable activity against *H pylori*[91], and that primary resistances to such an antibiotic are (still) relatively infrequent (when compared with metronidazole or clarithromycin)[92-96]. A recent *in vitro* study also showed a synergistic effect of quinolone antimicrobial agents and PPIs on strains of *H pylori*[97]. Furthermore, it has been shown *in vitro* that levofloxacin retains its activity when *H pylori* strains are resistant to clarithromycin and metronidazole[95,98,99]. These favorable results have been confirmed *in vivo*, indicating that most of the patients with both metronidazole and clarithromycin resistance are cured with the levofloxacin-based regimen[52,94,100].

A combination of a PPI, amoxicillin and levofloxacin, as a first-line regimen, has been associated with favorable results, with mean eradication rates of about 90%[95,101-106]. Subsequently, other authors studied this same regimen in patients with one previous eradication failure, also reporting exciting results, with *H pylori* cure rates ranging from 60% to 94%[52,64,65,67,70,98, 100,106-111]. A recent systematic review showed a mean eradication rate with levofloxacin-based rescue regimens (combined with amoxicillin and a PPI in most studies) of 80%, which represents a relatively high figure when considering that this regimen was evaluated as a rescue therapy[89]. This systematic review found higher *H pylori* cure rates with a 10-d rather than a 7-d regimen, both in general (81% *vs* 73%) and also with the levofloxacin-amoxicillin-PPI combination in particular (80% *vs* 68%), suggesting that the longer (10-d) therapeutic scheme should be chosen.

Furthermore, two recent meta-analyses have suggested that after *H pylori* eradication failure, a levofloxacin-based rescue regimen is more effective than the generally recommended quadruple therapy[88,89]. In one of these meta-analyses[89], higher *H pylori* cure rates with the levofloxacin-based triple regimens than with the quadruple combinations were found (81% *vs* 70%), but with borderline statistical significance (Figure 1). Nevertheless, results were heterogeneous, mainly due to the discordant results of the study by Perri *et al*[67], who reported a cure rate of only 63% with the levofloxacin-regimen, which is the lowest reported in the literature, and is a figure that contrasts with the mean eradication rate of 80% calculated in a systematic review[89]. Nevertheless, when that single outlier study[67] was excluded from the meta-analysis, the difference between cure rates with both regimens reached statistical significance and heterogeneity markedly decreased. Furthermore, when only high-quality studies were considered, the advantage of the levofloxacin regimen over the quadruple regimen increased (88% *vs* 64%), also achieving statistical significance, and heterogeneity among studies almost disappeared[89].

As previously mentioned, the quadruple regimen requires the administration of a complex scheme[20]. On the contrary, levofloxacin-based regimens (with amoxicillin and PPIs administered twice daily, and levofloxacin every 12 or 24 h) represents an encouraging alternative to quadruple therapy, with the advantage of simplicity. Furthermore, the quadruple regimen is associated with a relatively high incidence of adverse

effects[20]. In contrast, levofloxacin is generally well tolerated, and most adverse events associated with its use are mild to moderate in severity and transient[87]. The most frequent adverse effects affect the gastrointestinal tract[87]. Occasional cases of tendinitis and tendon rupture have been reported in the literature with levofloxacin therapy[52,87]. However, data derived from more than 15 million prescriptions in the US indicated the rate is fewer than 4 per million prescriptions[112]. In the aforementioned systematic review[89], adverse effects were reported, overall, by 18% of the patients treated with levofloxacin-based therapies, and these adverse effects were severe (defined so by the authors or explaining treatment discontinuation) in only 3% of the cases. Furthermore, the incidence of adverse effects was not different when levofloxacin-amoxicillin-PPI was administered for 7 d or 10 d, supporting the aforementioned recommendation of prescribing the more effective 10-d regimen. Moreover, two meta-analyses have demonstrated a lower incidence of adverse effects with levofloxacin-based treatments than with the quadruple combinations[88,89].

Unfortunately, it has been shown that resistance to quinolones is easily acquired, and in countries with a high consumption of these drugs, the resistance rate is increasing and is already relatively high[94,103,107,113-123]. More importantly, it has been demonstrated that the presence of levofloxacin resistance significantly reduce the eradication rate following a therapy with this antibiotic[94,103,121,124]. Therefore, it has been suggested to reserve levofloxacin for rescue treatment to avoid the increase of the resistance phenomenon.

Rescue regimen after PPI-amoxicillin-nitroimidazole failure

After PPI-amoxicillin-nitroimidazole failure, retreatment with PPI-amoxicillin-clarithromycin has proved to be very effective, and it seems to be a logical strategy, as while amoxicillin is maintained (which does not induce resistance), clarithromycin is substituted for metronidazole. Furthermore, the absence of cross-resistance among nitroimidazoles and clarithromycin favors this position. With this therapy, some authors[45] have achieved *H pylori* eradication in 85% of cases, while others have reported success rates of 86%[125] or even 100%[126]. In favor of this strategy is the study by Magaret *et al*[127], who studied a group of 48 patients after failure of previous *H pylori* therapy with a metronidazole-containing regimen, and randomized them to either lansoprazole, amoxicillin and clarithromycin twice daily for 14 d, which is the logical approach with triple therapy not repeating metronidazole, or to lansoprazole, bismuth, metronidazole and tetracycline for 14 d, which is the quadruple therapy repeating metronidazole. Intention-to-treat efficacies were 75% for a triple regimen and 71% for a quadruple. Although this difference did not reach statistical significance, the small sample size of this study does not preclude the possibility of a small but clinically significant difference in efficacy between the regimens. Finally, preliminary studies have suggested that RBC may be used instead of PPI in this triple second-line strategy (i.e., RBC-clarithromycin-amoxicillin), with similar or even better results[72].

Rescue regimen after PPI-clarithromycin-nitroimidazole failure

As previously mentioned, acquired bacterial resistance to metronidazole or clarithromycin results primarily from the previous treatment failure[26,32], and therefore the first choice probably should not be a regimen that combines these two antibiotics in the same regimen[23,24,128]. Although this regimen is very effective[4], patients who are not cured will probably have double resistance[26,129], and no logical empirical treatment remains afterwards (although, more recently, the levofloxacin-based regimens may represent an option). Thus, some authors have demonstrated that initial regimens containing both clarithromycin and nitroimidazole are associated with significantly worse results overall, with lower eradication rates after logically chosen second-line therapy and sensitivity-directed third-line therapy; these poor results were due to the emergence of multiple resistant strains as evidenced by the results of culture testing after the second failed course[72]. In summary, due to problems with resistance it could be suggested that both key antibiotics-clarithromycin and metronidazole- should not be used together until a valid empirical back up regimen is available[23].

Nevertheless, if culture is not performed after failure of PPI-clarithromycin-metronidazole, and hence antibiotic susceptibility is unknown, several rescue options may be suggested. Firstly, omeprazole plus amoxicillin, with a high dose of both the antibiotic and the antisecretor, could, in theory, be recommended[128,130]; however, we must remember that this "old-fashioned" dual combination has achieved disappointing results in many countries. Therefore, a second antibiotic should be added, and at this point a difficult decision appears, as both antibiotics used in the first trial (clarithromycin and metronidazole) are capable of inducing secondary resistance to *H pylori*, playing a negative role in future efficacy[25-29,131]. Nevertheless, the following possibilities exist:

Readministering metronidazole: Due to the fact that metronidazole resistance is frequent and clinically relevant[25-28], if this antibiotic is readministered, it should be used within a bismuth-based quadruple regimen (thus PPI might reduce the negative effect of metronidazole resistance[28,58,132,133]). With this regimen, eradication rates up to 80% have been achieved[45]. RBC, which may overcome the impact of resistance to metronidazole[81], may also play a role in this regimen. Thus, some authors have reported an 88% cure rate with a 2-wk regimen or RBC-tetracycline-tinidazole in patients who had previously failed a clarithromycin-tinidazole based triple therapy[76].

Readministering clarithromycin: Several studies have underlined the relevance of clarithromycin

resistance[25-27,29], and advise against readministering this antibiotic. Therefore, a further option which has been proposed, is to add (for example to PPI-amoxicillin-clarithromycin) a fourth medication (such as bismuth) with a bactericidal effect against *H pylori*, with which a 70% eradication rate has been achieved[45].

Readministering no antibiotic: A final alternative, obviously, consists of no readministering of either metronidazole or clarithromycin. Although only published in abstract form, one study has prescribed RBC, tetracycline and amoxicillin for 2 wk and has reported eradication in 89% of the cases which had previously failed PPI, clarithromycin and tinidazole[134]. These encouraging results may be due, at least in part, to the use of RBC instead of bismuth in this regimen, as "classic" triple therapy with bismuth, tetracycline and amoxicillin have been previously considered relatively ineffective. Finally, although not specifically evaluated in PPI-clarithromycin-metronidazole failures, rifabutin or levofloxacin-based regimens (e.g. PPI, amoxicillin and either levofloxacin or rifabutin) could play a role in this difficult situation.

IS IT NECESSARY TO PERFORM CULTURE AFTER FAILURE OF THE SECOND ERADICATION TREATMENT?

As previously mentioned, it has been generally recommended that performing culture after a first eradication failure is not necessary, and therefore assessing *H pylori* sensitivity to antibiotics only after failure of the second treatment may be suggested in clinical practice[3,23,48,135]. However, the utility of the culture (with consequent antibiotic susceptibility testing) and the moment when it must be performed after eradication failure are both controversial[21]. It is evident that, as pretreatment, antibiotic resistance is the most important factor in nonresponse to initial treatment[25-29], and knowledge of the organism's antibiotic susceptibility may represent an aid in selecting the therapy regimen. However, performing culture systematically after the second eradication failure also has some limitations, which are summarized as follows:

(1) Culture implies, obviously, the performance of endoscopic exploration, which has several disadvantages: it is not free of risk, and, since endoscopy centers have been meeting increasing demand, culture usually involves prolonged waiting times.

(2) *H pylori* culture is expensive, due to the cost of the procedure itself, but mainly the costs of the associated endoscopy, which is necessary to obtain biopsy samples.

(3) Culture is time-consuming, as *H pylori* is a rather "fastidious" bacterium at culture, especially when a low bacterial load is present, as generally occurs after eradication failure[22].

(4) Culture is not always available on a routine basis.

(5) The sensitivity of bacterial culture is not 100%, and therefore the antimicrobial susceptibility cannot be obtained in all cases[136]. Indeed, even in the optimal conditions usually encountered in therapeutic trials- when both gastroenterologist and microbiologist are thoroughly motivated- a culture sensitivity of "only" approximately 90% has been achieved in patients not previously treated[22]. Furthermore, in several studies enrolling patients who had failed one or more eradication treatments, the bacterium was isolated in less than 80% of cases[22]. Therefore, an even lower probability of isolating the bacterium is to be expected in routine clinical practice. This indicates that, even in the hands of experts, antimicrobial sensitivity would not be obtained in several eradication failure patients, who had undergone an upper endoscopy solely for bacterial culture[22].

(6) Antibiotic susceptibility testing in clinical practice yields useful information only regarding a few antibiotics. Antibiotics effective and generally used against *H pylori* are mainly the following four: amoxicillin, clarithromycin, metronidazole, and tetracycline. Resistance to amoxicillin has been estimated to be less than 1% in most studies[18,22]. Hence, its role in clinical practice may even be marginalized. Similarly, resistance to tetracycline is also very low, or even absent, in most countries[18,22]. Therefore, it may even be assumed that antibiotic susceptibility testing in clinical practice yields useful information only regarding the latter two antibiotics, namely clarithromycin and metronidazole[22].

(7) *In vitro* antibiotic susceptibility does not necessarily lead to eradication *in vivo*. Even knowing the susceptibility of *H pylori*, eradication rates do not achieve 100%, as the results observed *in vivo* by following *in vitro* susceptibility to anti-*H pylori* antibiotics are often disappointing[137]. Some discrepancies between antibiotic susceptibility and *H pylori* eradication may occur, due for example, to the possibility of co-infection with different *H pylori* strains[138]. Thus, a variable proportion of non-eradicated patients is made of subjects who harbor strains sensitive to the administered drugs, and in these patients the reasons for treatment failure are unclear[139]. For example, Gomollón *et al*[140] reported how third-line treatment often (in 50% of the cases) failed to eradicate *H pylori* infection, in spite of giving a 14-d, full-dose, quadruple culture-guided combination, showing that *in vitro* susceptibility did not predict eradication success. In the same way, Vicente *et al*[141] determined the effectiveness of a third, culture-guided, treatment of *H pylori* infection after two unsuccessful attempts. Patients received a two-week quadruple culture-guided therapy, and overall eradication was achieved in only 60% of the patients. In fact, paradoxically, the lowest eradication rate was obtained in patients with *H pylori* strains sensitive to all antibiotics. In summary, it seems that despite the use of culture-guided combinations of drugs, a third treatment is frequently unsuccessful, indicating that other factors, different from *in vitro* antibiotic susceptibility, influence eradication rates. On the other hand, the reverse situation is also possible, as *H pylori* eradication may, nonetheless, be achieved in the presence of metronidazole- or clarithromycin-

resistant strains, even with a drug combination including these antibiotics. Therefore, *in vitro* resistance to either clarithromycin or metronidazole could be overcome *in vivo* in a significant proportion of patients by prescribing the same antibiotics[22].

(8) When a repeat (rescue) therapy must be selected, we have several data that will aid us in suspecting resistance to a particular antibiotic, without the necessity of a culture, based on the observation that acquired bacterial resistance to metronidazole or clarithromycin results primarily from previous treatment failure[26,32]. Thus, when a therapy with clarithromycin fails, resistance to this antibiotic appears in most cases, and the same is true when a nitroimidazole is the antibiotic first used[18,29,131,142]. Even if resistance to these antibiotics does not appear, it remains uncertain whether their readministration is adequate, as they were not efficacious (for unknown reasons) for the first time. Some studies suggest that retreatment of *H pylori* infection with the same combination is still a choice when the status of bacterial resistance to antibiotics is unknown, however, full doses and a longer treatment duration must be used and a poor eradication rate has usually been reported[143]. Therefore, the position in the case of therapy failure would be clear: do not readminister any of the antibiotics against which *H pylori* has probably become resistant[1,49].

(9) Finally, relatively high eradication rates have been obtained with *empirical* third-line treatment after two consecutive failures in several studies[76,144-156].

However, limited experience suggests that endoscopy with culture and susceptibility testing may be appropriate after failure of two eradication therapies; in this situation, a non-randomized retrospective study suggests that third-line therapy directed by the results of sensitivity testing improve eradication compared to further empirical antibiotics, demonstrating that the success rate of sensitivity-directed therapy is superior to PPI-amoxicillin-rifabutin triple therapy, and therefore suggesting that endoscopy and sensitivity testing at this point may be worthwhile rather than more widespread use of rifabutin-based regimens[72]. Cammarota *et al*[122] assessed the efficacy of a third-line, culture-guided treatment approach for the eradication of *H pylori*. After the first two eradication attempts, all patients were resistant to metronidazole, and 95% were resistant to clarithromycin. Consequently, most patients (89 out of 94) received a quadruple regimen including PPI, bismuth, tetracycline and amoxicillin, and *H pylori* eradication was obtained in 90% of the cases. Although the authors concluded that a culture-guided, third-line therapeutic approach is effective for the eradication of *H pylori*, it would seem more appropriate to conclude, in fact, that the tetracycline- and amoxicillin-based quadruple regimen may be a good *empirical* third-line rescue treatment option (as to choose such a regimen, which implies not readministering metronidazole or clarithromycin, it would not be necessary to know antibiotic susceptibilities).

In summary, when critically reviewing the role of culture in the management of *H pylori* infection in clinical practice it may be concluded, in coincidence with other authors, that *H pylori* culture is an invasive, time-consuming method, offering quite low sensitivity, requiring significant cost, and which, in practice, tests very few antibiotics, with a questionable contribution to the management of non-responder patients[22,157]. Obviously, the importance of *H pylori* culture remains unaltered both in epidemiological and pharmacological research fields. However, whether patients should undergo an upper endoscopy for bacterial culture after second-line therapy failure remains a debatable matter, and the role of culture in clinical practice requires a critical reappraisal[22,157]. As it has been brilliantly expressed by Zullo *et al*, regrettably, gastroenterologists need to accept that gastric biopsy culture is not as simple as filling a sample bottle![22]

Nevertheless, it is recommended that those prescribing *H pylori* eradication therapies continually assess their success rate and adjust the relevant local practices and policies in line with the results and local bacterial resistance patterns. Thus, it would be recommendable that culture should be routinely performed after eradication failure in some specialized centers with special interest in *H pylori* research and treatment, with the intention to study the incidence of resistances after failures and also to evaluate the influence of such resistances on the efficacy of rescue regimens[158]. Data coming from this experience on *H pylori* resistance will be used as a reference for the corresponding population. This preventive approach has been recommended to avoid an increase in refractory *H pylori* infection in the future[158].

EMPIRICAL THIRD-LINE *H PYLORI* RESCUE THERAPY AFTER FAILURE OF TWO ERADICATION TREATMENTS

If it is decided, finally, not to perform culture before the administration of a third-line rescue treatment after failure of the first two trials (generally including clarithromycin and metronidazole), different possibilities for *empirical* treatment may be suggested. As eradication regimens may be less efficacious for retreatment, as compared to their efficacy when used as primary treatment, it may be suggested that the course of the rescue therapy should be extended to 10-14 d, at least when rescue therapy fails and third-line regimens are therefore prescribed[159]. As several studies have underlined the relevance of metronidazole[25-28] and clarithromycin[25-27,29] resistance, these two antibiotics should not be readministered, and several regimens have been evaluated in this scenario.

Amoxicillin ± tetracycline-based regimens

In a recent study, patients with at least one treatment failure who were infected with *H pylori* resistant to both metronidazole and clarithromycin, were treated with high doses of omeprazole (4 × 40 mg) and amoxicillin (4 × 750 mg) for 14 d, and the infection was cured

Table 2 Rifabutin-based "rescue" therapies (rifabutin-amoxicillin-proton pump inhibitor) in patients with previously failed eradication treatments and/or resistance to clarithromycin and nitroimidazoles

Author	Number of patients	Drugs and doses	Duration of treatment (d)	Eradication rate (%)
Beales *et al*[72]	10	Rifabutin 300 mg *o.d.* Amoxicillin 1 g *b.i.d.* Omeprazole 20 mg *b.i.d.*	14	60
Bock *et al*[152]	25	Rifabutin 150 mg *b.i.d.* Amoxicillin 1 g *b.i.d.* Lansoprazole 30 mg *b.i.d.*	7	72
Borody *et al*[169]	67	Rifabutin 150 mg *b.i.d.* Amoxicillin 1-1.5 g *t.i.d.* Pantoprazole 60 mg *t.i.d*	12	90
Canducci *et al*[153]	10	Rifabutin 300 mg *o.d.* Amoxicillin 1 g *b.i.d.* Omeprazole 20 mg *b.i.d.*	10	70
Gisbert *et al*[149]	14	Rifabutin 150 mg *b.i.d.* Amoxicillin 1 g *b.i.d.* Omeprazole 20 mg *b.i.d.*	14	79
Gisbert *et al*[155]	20	Rifabutin 150 mg *b.i.d.* Amoxicillin 1 g *b.i.d.* Omeprazole 20 mg *b.i.d.*	10	45
Gonzalez Carro[170]	92	Rifabutin 150 mg *b.i.d.* Amoxicillin 1 g *b.i.d.* Pantoprazole 40 mg *b.i.d*	10	61
Miehlke *et al*[130]	73	Rifabutin 150 mg *b.i.d.* Amoxicillin 1 g *b.i.d.* Esomeprazole 20 mg *b.i.d.*	7	74
Navarro-Jarabo *et al*[63]	45	Rifabutin 150 mg *b.i.d.* Amoxicillin 1 g *b.i.d.* Omeprazole 20 mg *b.i.d.*	7	44
Perri *et al*[151]	41	Rifabutin 300 mg *o.d.* Amoxicillin 1 g *b.i.d.* Pantoprazole 40 mg *b.i.d.*	7	71
Toracchio *et al*[171]	65	Rifabutin 150 mg *b.i.d.* Amoxicillin 1 g *b.i.d.* Pantoprazole 40 mg *b.i.d.*	10	78
Van der Poorten *et al*[172]	44	Rifabutin 150 mg *b.i.d.* Amoxicillin 1 g *b.i.d.* PPI *b.i.d.*	10	68

PPI: Proton pump inhibitor (omeprazole, pantoprazole, rabeprazole or esomeprazole) at the usual dose. Eradication rates by intention-to-treat analysis when available. *H pylori* eradication rate (weighted mean) with rifabutin-based "rescue" therapy is 69%.

in 76% of the cases[160]. This study suggests that, although the "old-fashioned" dual combination of omeprazole plus amoxicillin is generally considered quite ineffective as a first-line regimen, it may be associated with relatively good results if prescribed at high doses, even for *H pylori* resistant to both metronidazole and clarithromycin, in patients who experienced previous treatment failures. Another possibility to avoid retreatment with clarithromycin or metronidazole is to prescribe a quadruple combination of PPI, bismuth, tetracycline and amoxicillin (instead of metronidazole), which has been used by some authors with favorable results[161]. Nevertheless, this regimen has been tested only as second-line (and not third-line) therapy, and only after failure of PPI-clarithromycin-amoxicillin (and not after metronidazole-based therapy), emphasizing that the experience should be extended to patients with two previous eradication failures containing both clarithromycin and metronidazole. Finally, as previously mentioned, one study prescribed RBC, tetracycline and amoxicillin for 2 wk and achieved eradication in 89% of the cases which had previously failed PPI, clarithromycin and tinidazole[134].

Levofloxacin-based rescue regimens

It has been suggested that levofloxacin-based therapies may also represent an alternative when two (or more) consecutive eradication treatments have failed to eradicate the infection[52,94,118,147,154,155,162-164]. As an example, a recent study by Zullo *et al*[147] aimed to evaluate the efficacy of a levofloxacin-amoxicillin-PPI combination in patients who previously had failed two or more therapeutic attempts, and they found the eradication rate was 83% (intention-to-treat analysis). More recently, Gisbert *et al*[155] evaluated, in a multicenter study including 100 patients, the efficacy of a third-line levofloxacin-based regimen in patients with two consecutive *H pylori* eradication failures. An intention-to-treat eradication rate was 66%, which represents a relatively high figure when considering that this regimen was evaluated as a third-line therapy. Other alternative rescue therapies, different from levofloxacin-based regimens, have been suggested. Rifabutin-based rescue therapy, as will be reviewed in the following section, also constitutes a possible strategy after previous eradication failures, although it has been recently shown that a 10 d triple levofloxacin-based regimen is more effective than the same combination with rifabutin as a rescue regimen[155]. In summary, levofloxacin-based rescue therapy constitutes an encouraging empirical third-line strategy after multiple previous *H pylori* eradication failures with key antibiotics (such as amoxicillin, clarithromycin, metronidazole and tetracycline).

Rifabutin-based rescue regimens

As previously mentioned, the evaluation of drugs without cross-resistance to nitroimidazole or macrolides as components of retreatment combination therapies seem to be worthwhile. *H pylori* has been proved to be highly susceptible *in vitro* to rifabutin, a rifamycin derivate of the established tuberculostatic drug[165-167]. Moreover, rifabutin is chemically stable at a wide pH range and its antibacterial activity is likely not to be hampered by the acidic environment of the stomach[168]. Furthermore, selection of resistant *H pylori* strains has been low in experimental conditions. Thus, until now, no rifabutin resistant strain has been isolated from patients who were either treated or untreated for *H pylori* infection[166].

As summarized Table 2, rifabutin-based rescue therapy constitutes an encouraging strategy after multiple previous eradication failures[63,72,130,149,151-153,155,169-172]. As an example, Perri *et al*[151,173] used a 1-wk regimen of PPI, amoxicillin and rifabutin in patients who were still *H pylori* infected after two or more courses of PPI-based triple therapies, and achieved an eradication rate of 71% by intention-to-treat analysis. Gisbert *et al*[149], in a prospective multicenter study, included patients in whom a first eradication trial with PPI, clarithromycin and amoxicil-

lin and a second trial with PPI, bismuth, tetracycline and metronidazole had failed. A third 14 d eradication regimen with rifabutin, amoxicillin and a PPI was effective in 79% of the patients (intention-to-treat analysis). However, these encouraging results were not confirmed in a more recent study by these same authors[155]. In the largest study on rifabutin[170], 92 consecutive patients diagnosed with *H pylori* infection resistant to two previous treatment regimens were treated with a PPI, rifabutin and amoxicillin for 10 d and the intention-to-treat eradication rate was 61%. In summary, the weighted mean eradication rate with rifabutin-based rescue therapy, calculated from the studies included in the Table 2, is 69%.

These findings suggest that new rifabutin-based combinations are effective for *H pylori* strains resistant to antibiotics, and specifically to clarithromycin or metronidazole[174]. Furthermore, rifabutin-based therapies have been compared with the widely used "classic" quadruple therapy. Perri *et al*[66] performed a randomized study where three groups of patients were treated for 10 d with pantoprazole, amoxicillin, and rifabutin 150 mg *o.d.*, or 300 mg *o.d.*, and quadruple therapy. On intention-to-treat analysis, eradication rates were 67% in the rifabutin 150 mg and quadruple groups, and higher (87%) in the rifabutin 300 mg group. Finally, in this comparative study, side-effects were less frequent in rifabutin-treated patients than in those on quadruple therapy[66].

Several concerns still remain, however, regarding rifabutin treatment. Firstly, this drug is very expensive. Secondly, severe leucopoenia and trombocytopenia have been reported in one patient treated with rifabutin, with myelotoxicity demonstrated by bone marrow aspirate[153]. Although blood cell count returned to normal at day 15 after discontinuation of therapy, physicians should be aware of the risk of major side-effects arising during a rifabutin-based regimen[149,155]. Finally, there is some concern about wide-spread use of rifabutin, a member of a class of established antimycobacterial drugs, in patients with *H pylori* infection. Because multiresistant strains of *Mycobacterium tuberculosis* increase in numbers, indications for these drugs should be chosen very carefully to avoid further acceleration of development of resistance[152]. At present, therefore, rifabutin should be considered only as the last option (e.g. restricted to infected patients even after several eradication regimens including, among them, levofloxacin).

Furazolidone-based rescue regimens

Furazolidone is an antimicrobial drug that belongs to synthetic nitrofurans and is active against a broad spectrum of gram-negative and gram-positive bacteria and protozoa. This antibiotic has demonstrated a high antimicrobial activity against *H pylori* if given as a single drug[175], and the majority of first-line furazolidone-based combination therapies revealed eradication rates above 80%[92]. Primary resistance to furazolidone is virtually absent[158,176,177], and its potential to develop resistance is as low as for bismuth compounds or amoxicillin[178]. Moreover, this drug has no cross-resistance potential to metronidazole[176]. Triple therapy in which furazolidone is used instead of metronidazole achieves high eradication rates, even in populations with a high prevalence of nitroimidazole resistance[179-182]. In this respect, a recent study has evaluated furazolidone-based triple therapy (combined with bismuth and tetracycline) in the eradication of *H pylori* resistant to metronidazole, with favorable results (86% eradication rate)[183]. A few years ago, some authors tested a quadruple combination of furazolidone, bismuth, tetracycline and PPI as a second-line eradication therapy, and reported encouraging results[184]. More recently, Treiber *et al*[145] investigated whether this quadruple regimen containing furazolidone could be effective as a third-line therapy in patients with *H pylori* treatment failure after first-line (clarithromycin-metronidazole ± amoxicillin) and second-line (PPI-bismuth-tetracycline-metronidazole) regimens, and *H pylori* infection was cured in up to 90% of the cases. Furthermore, a 7 d triple-regimen comprising furazolidone, amoxicillin and a PPI achieved an eradication rate of 60% in 10 patients who failed first-line, second-line and even rifabutin-based triple therapy[185].

A recent systematic review and meta-analysis of the effect of furazolidone- and nitrofurantoin-based regimens in the eradication of *H pylori* infection has been performed[186]. The pooled eradication rate of primary PPI-based regimens containing furazolidone was 76%. Second-line schedules containing furazolidone obtained eradication rates of 76%. Finally, third-line rescue therapies were effective in 65% of the cases. In summary, a quadruple regimen including furazolidone, bismuth, tetracycline and PPI seems to represent a promising alternative after two consecutive failures with regimens including both metronidazole and clarithromycin.

CUMULATIVE ERADICATION RATES WITH THREE (OR MORE) CONSECUTIVE ERADICATION TREATMENTS

In patients with conditions where the indication for *H pylori* eradication is definitively accepted, as is the case of peptic ulcer disease (or gastric MALT lymphoma), rescue treatment after first-line failure is clearly advisable. Furthermore, if the second therapy fails, a third or even a fourth regimen should be prescribed, as infected patients continue to have high risk of ulcer recurrence and ulcer complications and are in an obviously disadvantageous situation in view of the enormous benefits that follow *H pylori* eradication in peptic ulcer disease: increased ulcer healing, less ulcer recurrence, and less ulcer bleeding. However, multiple repeated antibiotic treatment of patients where benefits of *H pylori* eradication has not been so clearly established, such as those with functional dyspepsia[174,187], may not be completely justified.

Some authors have evaluated, in the same study,

different regimens after failure of two eradication treatments, which provide interesting information about cumulative, and not only absolute, eradication rates[21]. For example, in the study by Gasbarrini *et al*[188], a total of 2606 patients were administered a PPI, tinidazole and clarithromycin for 1 wk. Patients with continuing infection were then given a second 1-wk course of amoxicillin, clarithromycin and RBC. Finally, patients still infected after the second course underwent upper gastrointestinal endoscopy with *H pylori* culture, and then received a 1-wk quadruple scheme established on antibiotic sensitivity. Eradication rates after the first, second and third treatment, were, respectively, 79%, 77%, and 52%. This algorithm led to overall per-protocol eradication rates of 99%. Chan *et al*[146] prescribed quadruple therapy to a group of patients who had failed to respond to RBC-based regimens (as first regimen) and PPI-clarithromycin-amoxicillin combination (as second regimen), and achieved successful eradication in 83% of the cases receiving a quadruple regimen, finally achieving a 99% cumulative eradication rate. Beales *et al*[72] evaluated 469 patients receiving eradication therapy in routine clinical practice. Second-line therapy was chosen empirically, using whichever of clarithromycin or metronidazole was not used initially. All patients requiring third-line therapy underwent endoscopy, choice of therapy being guided by sensitivities. Overall success after one, two and three courses of therapy were 73%, 94% and 98%, respectively. Zullo *et al*[76] reported 83% cure rate in patients who had previously failed two courses of clarithromycin-amoxicillin and clarithromycin-tinidazole based triple therapies. Gomollón *et al*[140] studied the effectiveness of third-line treatment of *H pylori* infection with two-week quadruple, culture-guided regimens. The combination of omeprazole, tetracycline, bismuth and clarithromycin showed an eradication rate of only 36%, but if amoxicillin was used the rate was 67%. In the study by Vicente *et al*[141], after two unsuccessful attempts at eradication, all patients underwent endoscopy and culture, and patients received a quadruple culture-guided therapy. Cumulative *H pylori* eradication rate with this strategy was as high as 99.6%. Treiber *et al*[145] investigated whether a quadruple regimen containing furazolidone could be effective as a third-line therapy in patients with two previous *H pylori* treatment failures. Cure of *H pylori* was achieved in 90% of the patients nonresponsive to a second eradication trial, which gave a final eradication rate of 99%. In the study by Qasim *et al*[185], 3280 patients received standard first-line eradication therapy, which was successful in 77% of the cases. Second-line therapy (bismuth-based quadruple) or triple therapy (altering constituent antibiotics) was successful in 56% of treated patients. Subsequent eradication attempts using rifabutin-based regimen was successful in 38% of patients, giving a cumulative eradication rate of 94%. Gisbert *et al*[150] included consecutive patients in whom two eradication regimens had failed to eradicate *H pylori*, prescribed empirical third-line rescue regimens, and achieved *H pylori* eradication in 71% of the cases (intention-to-treat analysis). Based on these results, with estimated efficacy of 85%, 75% and 71%, respectively with first, second and third regimens, *H pylori* eradication could finally be achieved in 99% of the patients. Finally, Gisbert *et al*[156] evaluated the efficacy of different rescue therapies empirically prescribed during 10 years to 500 patients in whom at least one eradication regimen had failed to cure *H pylori* infection. Antibiotic susceptibility was unknown (therefore rescue regimens were chosen empirically). Overall, *H pylori* cure rates with the second and third-line rescue regimens were 70% and 74%, giving a cumulative eradication rate as high as 98%.

Therefore, a wider perspective of the benefits of retreating *H pylori* infection can be obtained if cumulative eradication rates with successive treatments are taken into account. Thus, as represented in Figure 2, it can be concluded that *H pylori* eradication can finally be achieved in almost 100% of the patients if three rescue therapies are consecutively given[72,76,140,141,144-146,150,156,185,188].

Furthermore, these encouraging (cumulative) results have been obtained when more than three consecutive treatments have been prescribed[21]. As an example, Seppälä *et al*[144] reported a cumulative eradication rate of 93% (intention-to-treat analysis) and even 100% (per-protocol analysis) after four empirical retreatments. We have recently confirmed that a levofloxacin-based regimen can also be administered with good results after three previous eradication failures with antibiotics, such as amoxicillin, clarithromycin, metronidazole, tetracycline, and even rifabutin[163]. Thus, we prospectively evaluated 10 patients with three consecutive *H pylori* eradication failures (1st treatment with PPI-clarithromycin-amoxicillin, 2nd treatment with RBC-tetracycline-metronidazole, and 3rd treatment with PPI-amoxicillin-rifabutin). A fourth eradication regimen with 10 d levofloxacin, amoxicillin and PPI was prescribed, and intention-to-treat eradication rates were 70%. When we reviewed our experience with different rescue therapies empirically prescribed during 10 years to 500 patients, the cumulative *H pylori* eradication rate with 4 successive treatments was 99.5%[156].

Finally, reports of "ineradicable" *H pylori* infection after more than four eradicating treatments failed have been recently published. Dore *et al*[148] prescribed a quadruple combination of PPI, bismuth, tetracycline, and metronidazole to patients who had failed two or more treatment courses of *H pylori* eradication therapy (33 patients had failed prior treatment twice, 19 had failed three times, and 16 had failed four or more times); despite this *a priori* difficult task, *H pylori* eradication was finally achieved in 93% of the patients. Tucci *et al*[189] reported their experience of 13 patients with at least 5 eradication failures and *H pylori* strains resistant to both clarithromycin and nitroimidazoles. The treatment was organized into three sequential schedules employing partially different drug combinations (to face the various resistant strains), suspension formulations were preferred to tablets (to improve the dispersal of the drugs into the stomach), antibiotics were administered after meals and

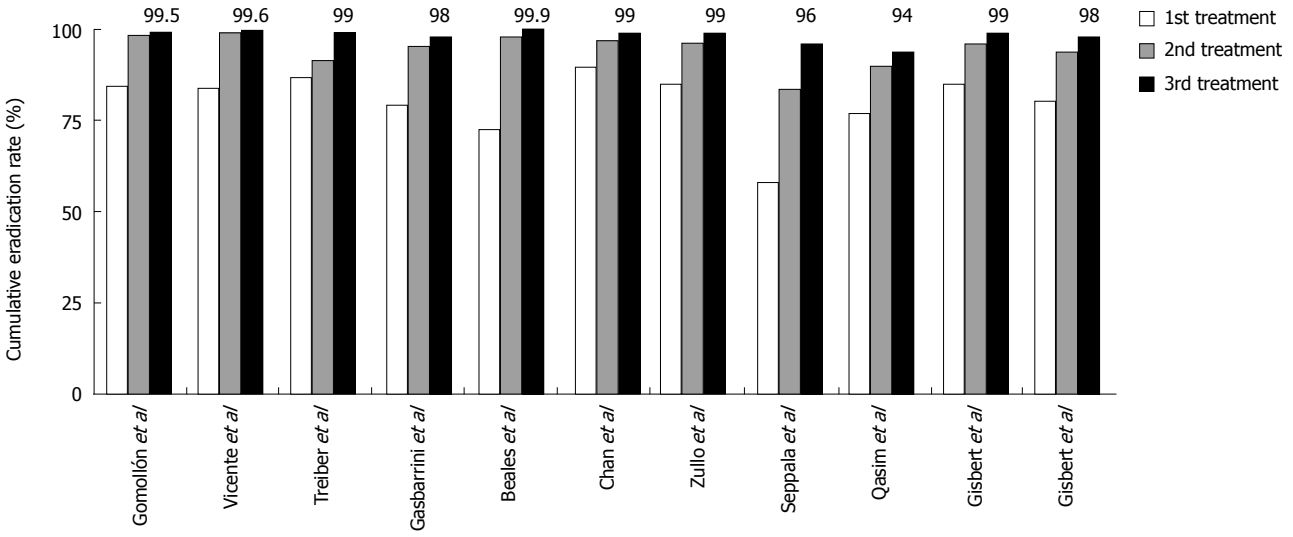

Figure 2 Cumulative *H pylori* eradication rates with three consecutive eradication treatments.

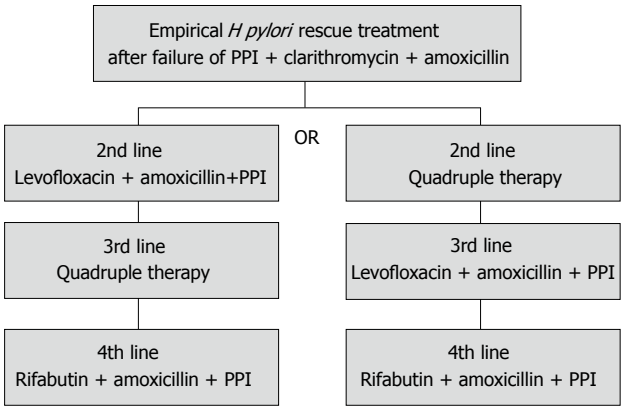

Figure 3 Choice of a empirical retreatment regimen, without culture and antimicrobial sensitivity testing, after failure of proton pump inhibitor (PPI), amoxicillin and clarithromycin combination. Quadruple therapy: Combination of PPI, bismuth, tetracycline and nitroimidazole (metronidazole or tinidazole).

a variation on a standard diet exceeding the normal fat composition was given (to increase the time of contact of the antimicrobials with gastric mucosa), and patients were invited to lie down after the meals, changing their position every 5 min (to facilitate the penetration of drugs amid the anfractuosities of fundic mucosa). With this particular therapy, eradication was successful in 70% of the patients. In another example of "ineradicable" *H pylori* infection, levofloxacin-amoxicillin combination was successfully employed in a patient with a clarithromycin- and metronidazole-resistant strain, who previously failed eight consecutive therapeutic attempts[162].

CONCLUSION

Even with the current most effective treatment regimens, ⩾ 20% of patients will fail to eradicate *H pylori* infection. This issue seems important at the present time, as therapy for *H pylori* infection is becoming more and more frequently prescribed. Currently, apart from having to know first-line eradication regimens well, we must also be prepared to face treatment failures. Therefore, in designing a treatment strategy we should not focus on the results of primary therapy alone, but also on the final (overall) eradication rate.

The choice of a rescue treatment depends on which treatment is used initially. If a first-line clarithromycin-based regimen was used, a second-line metronidazole-based treatment (such as the quadruple therapy) may be used afterwards, and then a levofloxacin-based combination would be a third-line rescue option. Alternatively, it has recently been suggested that levofloxacin-based rescue therapy constitutes an encouraging second-line strategy, representing an alternative to quadruple therapy in patients with previous PPI-clarithromycin-amoxicillin failure, with the advantage of efficacy, simplicity and safety. In this case, quadruple regimen may be reserved as a third-line rescue option. Finally, rifabutin-based rescue therapy constitutes an encouraging empirical fourth-line strategy after multiple previous eradication failures with key antibiotics such as amoxicillin, clarithromycin, metronidazole, tetracycline, and levofloxacin (Figure 3).

Even after two consecutive failures, several studies have demonstrated that *H pylori* eradication can finally be achieved in almost all patients if several rescue therapies are consecutively given. As a final conclusion, therefore, the attitude in *H pylori* eradication therapy failure, even after two or more unsuccessful attempts, should be to fight and not to surrender[190].

Abstract

AIM: To investigate the effect and mechanism of action of erlotinib, an epidermal growth factor receptor (EGFR) small molecule tyrosine kinase inhibitor (TKI), in the human pancreatic cancer cell line BxPC-3 both *in vitro* and *in vivo*.

METHODS: *In vitro*, human pancreatic cancer cell line BxPC-3 was exposed to varying concentrations of erlotinib, and its effects on proliferation, cell cycle distribution, apoptosis and the expression of pro- and antiapoptotic factors such as bcl-2, bcl-xl, bax and bak, and the expression of vascular endothelial cell growth factor (VEGF) were measured with 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay, flow cytometric analysis, terminal deoxynucleotidyl transferase-mediated nick end labeling assay (TUNEL), and reverse transcription-polymerase chain reaction (RT-PCR). Potential effect of erlotinib on angiogenesis was examined by tube formation assay. Tumor growth suppression was observed in xenografted nude mice with pancreatic cancer *in vivo*. Immunohistochemical (IHC) staining for EGFR and factor Ⅷ-related antigen was undertaken to detect the microvessel density and VEGF expression in tumor tissue in xenograft nude mice.

RESULTS: Erlotinib, as a single agent, repressed BxPC-3 cell growth in a dose-dependent manner, triggered G_1 arrest and induced cell apoptosis, and suppressed capillary formation of endothelium *in vitro*. Expressions of VEGF were significantly down-regulated at a high concentration of 200 μmol/L, however, the expressions of bcl-2 and bcl-xl were decreased at 50 μmol/L. *In vivo*, Erlotinib-treated mice demonstrated a reduced tumor volume, weight and microvessel density as compared to the control. IHC staining showed decreased expression of EGFR and RT-PCR had lower VEGF expression in treated mice.

CONCLUSION: The *in vitro* and *in vivo* findings provide evidence that BxPC-3 cells are inhibited with erlotinib treatment. Inhibition of EGFR may be a promising adjuvant chemotherapy strategy in pancreatic cancer treatment.

INTRODUCTION

Pancreatic cancer is one of the most lethal human cancers and continues to be a major unsolved health problem[1,2]. Recently, several orally bioavailable compounds aimed at specific molecular targets have been developed in hopes of improving survival in this dismal disease. Tumor development and progression depend on cellular changes like overexpression of oncogenic tyrosine kinase receptors. Many gastrointestinal tumors, including pancreatic cancer, have been shown to overexpress the epidermal growth factor receptor (EGFR)[3,4]. The overexpression of the EGFR and its ligands correlates with rapidly progressive disease and resistance to chemotherapy.

EGFR is a 170-kDa transmembrane protein with intrinsic tyrosine kinase activity. Stimulation of the EGFR results in activation of multiple intracellular signaling cascades that increase cellular proliferation and prevent programmed cell death[5]. Multiple therapeutic strategies designed to manipulate this receptor have been developed, including specific antibodies and low molecular EGFR tyrosine kinase inhibitors (TKIs). Erlotinib is a small molecule TKI that efficiently blocks EGFR. Preliminary results of a phase Ⅲ trial of gemcitabine with or without erlotinib in pancreatic cancer revealed a modest improvement in survival with the addition of erlotinib. Treatment with anti-EGFR agents is used as a potential therapeutic strategy for pancreatic cancer, but the mechanisms are not yet precisely understood.

The aim of this study was to investigate the growth inhibitory effects of erlotinib in pancreatic cancer cells *in vitro* and *in vivo*, to determine the mechanisms involved and to examine the effects of erlotinib on the regulation of angiogenesis.

MATERIALS AND METHODS

Cell culture and reagents

Human pancreatic cancer cell lines BxPC-3, obtained from Shanghai Institute of Biochemistry and Cell Biology, and ECV 304, a cell line derived from human umbilical vein endothelial cells from ATCC were maintained in RPMI-1640 (Gibco) medium supplemented with 10% fetal calf serum in a humidified atmosphere containing 5% CO_2 at 37℃. The EGFR-selective TKI erlotinib was provided by DeBioChem (Nanjing, China). The agent was dissolved in DMSO (Sigma) or carboxymethylcellulose sodium at appropriate concentrations for *in vitro* or *in vivo* studies, respectively.

Reverse transcription-polymerase chain reaction (RT-PCR) analysis

Total cellular RNA was extracted with TRIzol (Life Technologies, INC) following the manufacturer's instructions. Reverse transcription was performed starting with 2 μg of total RNA, using oligo (dT) primer and other reagents, and procedures contained in the MMulv RT-PCR kit (Promega) to form cDNA. cDNA (2 μL), 2 μL of 50 pmol/L of each primer, 10 mmol/L dNTP Mix 1 μL, 1 μL of Taq DNA polymerase (Sangon, China) were used for PCR analysis. The PCR amplification cycles consisted of denaturation at 94℃ for 5 min, 35 cycles of denaturation at 94℃ for 60 s, annealing [54℃ for *bcl-2*, *bcl-xl*, *bax*, *bak*, vascular endothelial cell growth factor (VEGF), 56℃ for GAPDH] for 60 s, extension at 72℃ for 60 s, and a final elongation at 72℃ for 10 min. The PCR products were separated on a 1.5% agarose gel, stained with 0.5 mg/mL ethidium bromide, and visualized by UV light. The primer sequences are listed in Table 1.

Tube formation assay

A well established method was used for the process of *in vitro* angiogenesis assay[6] with a kit from Chemicon (Temecula, California, USA). A 96-well tissue culture plate was coated with Matrigel (50 μL/well). After matrix solution gelled, ECV304 cells were premixed with RPMI-1640 (control), erlotinib (100 μmol/L) and then seed at a concentration of 1×10^4 per well onto the surface of the polymerized gel. Four wells were used for each treatment. After 18 h of incubation at 37℃ and 5% CO_2, the status of capillary tube formation by ECV304 cells was recorded using a CCD camera attached to an inverted light microscope (40 × objective lens).

Cell viability assay

The viability of BxPC-3 cells treated with erlotinib was determined by the standard 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. BxPC-3 cells were plated (5×10^3 per well) in 96-well plates and incubated overnight at 37℃. Erlotinib was dissolved in DMSO and added to the cell culture medium at a concentration not exceeding 0.1% (v/v). The effects of erlotinib on cell proliferation were studied at various concentrations (0, 1, 5, 10, 50 and 100 μmol/L) and at different time points (24, 48, 72 and 96 h) with a certain concentration (50 μmol/L). The MTT assay was done in quadruplicate for each drug concentration used. At appropriate intervals, 100 μg MTT solution was added to each well and incubated for 4 h at 37℃, 5% CO_2. The supernatant was removed, and 150 μL of DMSO was then added. Plates were then read at 490 nm wavelength using a microplate reader (BIO-RAD550, USA). Percentage of inhibition was determined by comparing the cell density in the drug-treated cells with that in the untreated cell controls in the same incubation period [percentage of inhibition = (1-cell density of a treated group)/cell density of the control group]. All experiments were repeated three times.

Cell cycle analysis and apoptosis assays

The effects of EGFR TKIs erlotinib on both cell cycle and apoptosis in BxPC-3 cells were analyzed using flow cytometry. Cells were plated into 12-well plates and the following day, erlotinib (50 μmol/L) was added and kept for 48 h. Cell floating in the medium combined with adherent layer were trypsinized and fixed with 2 mL of Citrate buffer for 1 h. Cells were then incubated with RNase A (1500 μL) and stained with propidium iodide (1500 μL). Samples were immediately analyzed by flow cytometry for cell cycle and apoptosis assays. Immunocytochemical (ICC) detection of apoptotic cells was carried out with terminal deoxynucleotidyl transferase-mediated nick end labeling assay (TUNEL), in which residues of digoxigenin-labeled dUTP were catalytically incorporated into the DNA by terminal deoxynucleotidyl transferase Ⅱ. After treatment with erlotinib (50 μmol/L) for 48 h, slides were fixed and washed thrice in 0.01 mol/L PBS, the following procedures were performed according to the manufacturer instructions (Boster, Wuhan, China). The positive particles of DAB staining were viewed under microscope (Olympus Japan). The number of apoptotic cells was viewed and counted

Table 1 PCR primers

under microscope (40 × objective lens, Olympus Japan) and expressed as the Apoptotic Index (AI = number of apoptotic body/1000 cells).

Development of nude mice xenografts of pancreatic cancer

BALB/C nu/nu female mice, aged 4-6 wk, weighing about 20 g, were maintained pathogen free at the Shanghai Experimental Animals Centre of Chinese Academy of Sciences. BxPC-3 cells (1×10^7, suspended in 200 μL of PBS) were implanted *s.c.* in the hind flank of each mouse. Once palpable tumors were established, animals were randomly divided into two groups so that all groups had similar starting mean tumor volumes of 100-150 mm^3. The mice in each group were orally gavaged with the vehicle control (0.5% CMC-Na, $n = 6$) and erlotinib (100 mg/kg, $n = 6$) for 4 wk. The tumor size was measured with a linear caliper twice a week up to 4 wk, and the volume was estimated using the equation $V = (a \times b^2)/2$, where a is the large dimension and b the perpendicular diameter. After all the mice were sacrificed, part of the tissue was fixed in formalin and embedded in paraffin, and some parts were frozen in liquid nitrogen. Hematoxylin and eosin staining confirmed the presence of tumors. Total mRNA was prepared and RT-PCR analyses were performed as described previously.

Immunohistochemistry (IHC) of tumor xenografts

To assess EGFR expression and microvessel density (MVD) in xenograft tumors, rabbit polyclonal anti-EGFR antibody (diluted to 1:100, Boster, Wuhan) and rabbit polyclonal factor Ⅷ antibody (Boster, Wuhan) were used in IHC. Paraffin-embedded tissue sections (4 μm) were dried, deparaffinized, and rehydrated. Endogenous peroxidase was blocked with 3% hydrogenperoxide in ion free water for 30 min. After nonspecific binding sites were blocked with 10% goat serum, slides were incubated at 4℃ overnight with 1:100 dilution of primary antibody directed against EGFR and factor VIII followed by a 30-min incubation in a Horseradish peroxidase (HRP)-conjugated sheep anti-rabbit IgG secondary antibody. Sections were rinsed with PBS and developed with the DAB kit (Boster, Wuhan) and then counterstained with haematoxylin. Each slide was scanned at a low power (× 100) and the area with a higher number of new vessels was identified (hotspot). This region was then scanned at × 400 magnification. For individual tumors, microvessel count was scored by averaging the five field counts[7].

Statistical analysis

Quantitative results were expressed as mean ± SEM. Statistical analysis was performed using a two-tailed unpaired *t* test (between two groups) or a one way analysis of variance (ANOVA) (among three or more groups) with the computer software SAS 8.02. $P < 0.05$ was considered statistically significant.

RESULTS

Growth inhibition of BxPC-3 pancreatic cancer cells by erlotinib

Overall cell growth of BxPC-3 pancreatic cancer cells treated with erlotinib at different concentrations ranging from 1 to 100 μmol/L was determined by MTT assay. The results showed that erlotinib inhibited cell growth in a dose-dependent manner and significant growth inhibition was demonstrated at 72 h ($P < 0.01$). A similar result was obtained after erlotinib treatment for 96 h. We also treated BxPC-3 cells with erlotinib at 24 and 48 h. The results showed a trend toward growth inhibition, but it was not statistically significant among different concentrations ($P > 0.05$). Cell proliferation was again determined by MTT at 24, 48, 72 and 96 h. No significant difference in cell growth was noted between 24 h and 48 h, 72 h and 96 h at a concentration of 50 μmol/L. Percentage of survival cells is illustrated in Figure 1.

Effect of erlotinib treatment on cell cycle progression and apoptosis in BxPC-3 cells

To elucidate potential mechanisms of erlotinib-induced growth inhibition previously shown by MTT assay, we examined the distribution of cell cycle and apoptotic cells by flow cytometry and TUNEL. The concentration of the drug was 50 μmol/L which inhibited BxPC-3 cell growth by approximately 53.5% after 3 d of exposure. The results showed that erlotinib led to the accumulation of BxPC-3

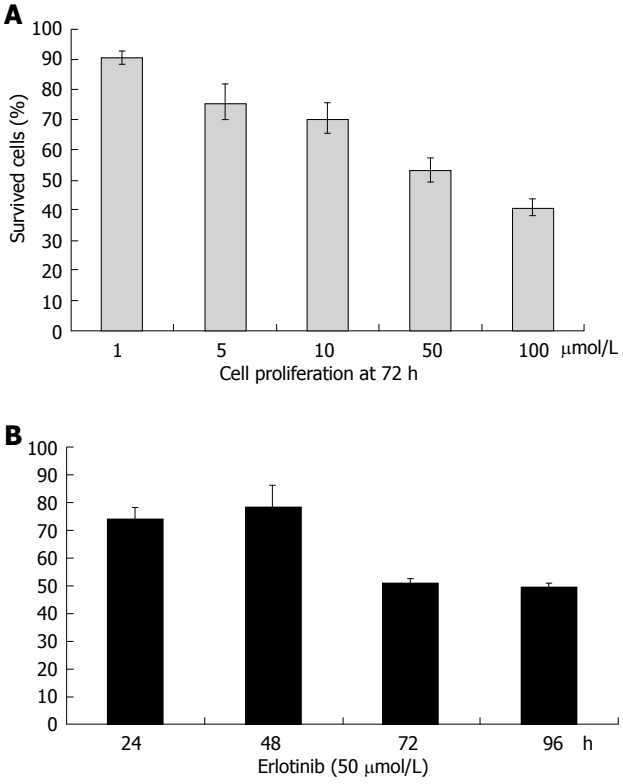

Figure 1 **A**: Growth percentage of BxPC-3 cell line after 72 h of exposure to erlotinib at varying concentrations ranging from 1-100 μmol/L. BxPC cell proliferation was significantly suppressed by erlotinib at different concentrations; **B**: Growth percentage of BxPC-3 cell line after exposure to erlotinib at a concentration of 50 μmol/L at different time points.

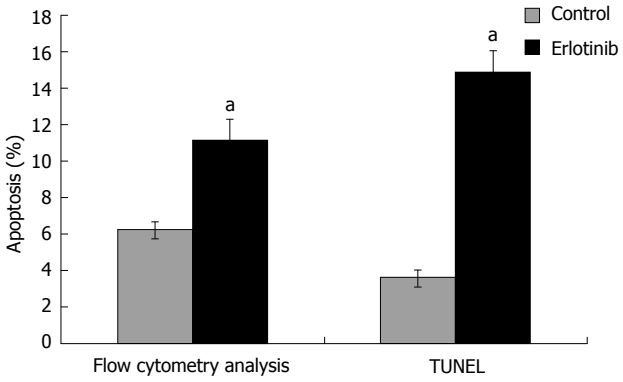

Figure 2 Induction of apoptosis in BxPC-3 cell line. There was a significant apoptosis in erlotinib treated group both in flow cytometry analysis and TUNEL assay after 48 h treatment ($^aP < 0.05$).

cells in G_0/G_1 phase, thereby decreasing the proportion of cells in the S phase (Table 2). To assess the effects of erlotinib on induction of cell apoptosis of pancreatic cancer cells, we performed a PI apoptosis and TUNEL assay after 48 h. Flow cytometric analysis showed an induction of apoptosis (11%) compared with the control (6%) ($P < 0.05$), which was further confirmed by TUNEL (AI 14.86 ± 1.20 to 3.60 ± 0.45) ($P < 0.05$) (Figure 2). The cell cycle alterations and cell apoptosis increase indicated that cell cycle arrest and increase in apoptosis are one of the mechanisms responsible for the antiproliferative action of erlotinib in BxPC-3 cells *in vitro*.

Table 2 Cell cycle analysis (%, mean ± SD)

Group	G_0/G_1	S	G_2/M
Control	63.31 ± 0.99	25.28 ± 0.88	11.40 ± 1.68
Erlotinib	73.40 ± 1.34[b]	14.15 ± 0.99[b]	12.44 ± 1.95

$^bP < 0.01$ *vs* control group.

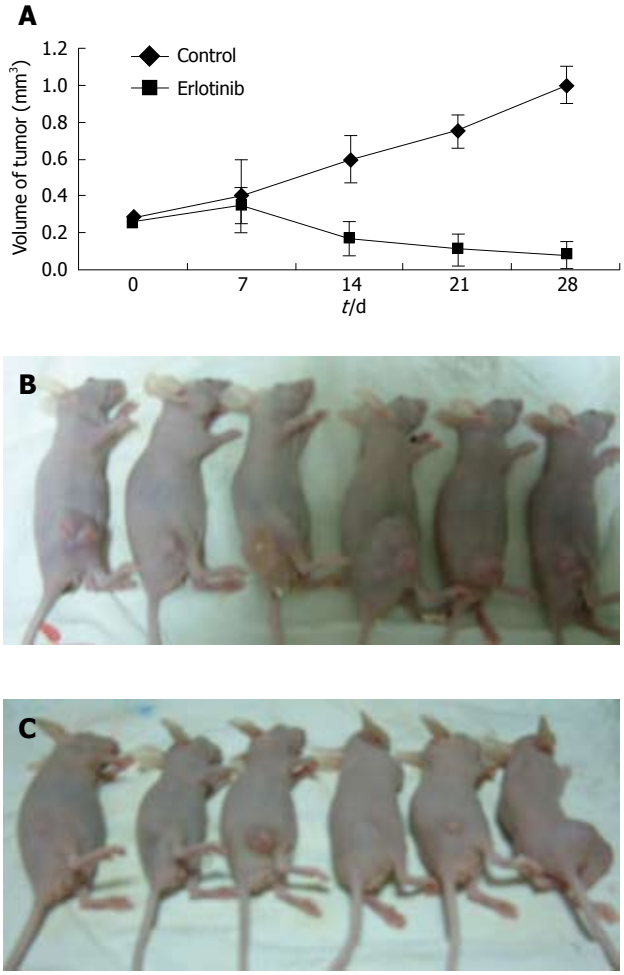

Figure 3 **A**: Effect of erlotinib on mean tumor volume in the BxPC-3 xenograft model. Mice were implanted with BxPC-3 cells. When palpable tumors were established, animals were randomly divided into two groups. The animals were continuously gavaged with the agents for 4 wk as described in Matericals and Methods. Tumor size was measured twice per week. Values are means, $n = 6$. **B**: Mice of control group; **C**: Mice of erlotinb group.

Effect of treatment with erlotinib on the growth of mouse xenografts

A nude mouse model of pancreatic cancer was used for the *in vivo* portion of the study to assess the *in vivo* antitumor activity of erlotinib. Heterotopic murine pancreatic carcinoma was successfully established in the flank of BALB/C nude mice. Erlotinib at a dose of 100 mg/kg per day was administered to mice bearing established BxPC-3 tumors. The results indicated that erlotinib significantly inhibited tumor growth. As shown in Figure 3, at day 14, the control group of mice showed an increased tumor volume by 114.3% of the initial tumor while the group treated with erlotinib showed a decreased tumor volume by 34.6%. At the end of the

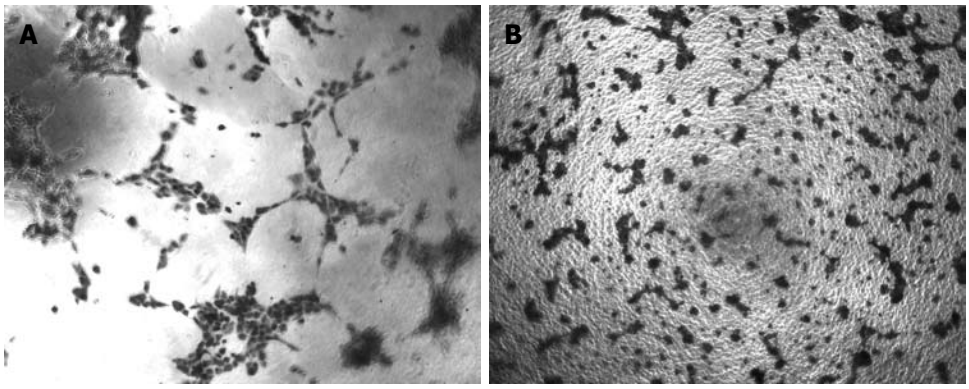

Figure 4 Effects of erlotinib on capillary formation by ECV304 were examined *in vitro*. **A**: When cultured on ECMatrix, ECV304 cells rapidly aligned with hollow tube-like structures; **B**: ECV304 cells were treated with erlotinib (100 μmol/L), and significant inhibition of tube formation was achieved compared with the control.

study in the BxPC-3 xenograft (day 28), the growth inhibition rate was 74.5% ($P < 0.05$) in the erlotinib treated group.

In vitro angiogenesis

EGFR TKIs have been reported to inhibit angiogenesis of pancreatic carcinoma. To determine whether erlotinib suppressed tumor vessel formation *in vitro*, we examined the effects of erlotinib on the ability of ECV304 to form capillary tube structures. ECMatrix is a solid gel of basement proteins prepared from the Engelbreth Holm-Swarm (EHS) mouse tumor and consists of laminin, collagen type Ⅳ, heparin sulphate proteoglycans, entactin, and nidogen. It also contains various growth and proteolytic enzymes that occur normally in EHS tumors. When cultured on ECMatrix, ECV304 cells rapidly aligned and formed tube-like structures (Figure 4A), however, the length of the tubes in the erlotinib treated cells was markedly reduced compared with the control which demonstrated that erlotinib significantly inhibited ECV304 tube formation (Figure 4B).

In vivo inhibition of EGFR and MVD after treatment with erlotinib

The EGFR expression pattern in the BxPC-3 tumors was examined by IHC staining. IHC analysis confirmed that the tumor xenograft tissues maintained both cell membrane and cytoplasmic EGFR expression. The expression of EGFR was decreased in the erlotinib treated groups (2.45 ± 0.81) compared with the control (10.65 ± 1.26) ($P < 0.05$). MVD was also assessed by immunostaining with factor Ⅷ-related antigen in the most intense areas of neovascularization. Representative images of the two groups are shown in Figure 5. MVD of erlotinib treated tumors (1.86 ± 0.43) was significantly lower than that of the control (5.98 ± 1.27) ($P < 0.05$).

Modulation of apoptosis-associated gene and VEGF expression in BxPC-3 cells and xenografts treated with erlotinib

The effect of erlotinib on the expression of EGFR, apoptosis-associated factors such as *bcl-2*, *bak*, *bax*, *bcl-xl* and *VEGF* mRNA was determined by RT-PCR. BxPC-3 cells were treated with erlotinib at different concentrations ranging from 5-200 μmol/L for 48 h. The results showed that the expression of *EGFR* and *VEGF* mRNA in the BxPC-3 cell line seemed to be down-regulated, the highest suppression was detected at the highest concentration used, 200 μmol/L. Densitometric analysis revealed the relative expression of VEGF at 200 μmol/L concentration of erlotinib (1.2% ± 0.68%) was significantly lower than that of the control (2.67% ± 0.13%) ($P < 0.05$). Apoptosis-associated gene including *bcl-xl* and *bcl-2* was suppressed by erlotinib in a concentration dependent manner; however, bax appeared to be up-regulated following erlotinib treatment at various concentrations; but it did not apparently affect bak expression. In the tumor xenograft tissues, the expression of *VEGF* mRNA was significantly lower (almost disappeared) in the erlotinib-treated group compared with that in the control ($P < 0.01$) (Figure 6).

DISCUSSION

Treatment options of pancreatic adenocarcinoma are unsatisfactory, and the prognosis of patients with pancreatic cancer is poor. Considering that the cure rate for these patients with surgery alone is low[8], development of potentially effective treatment is urgently needed. Many features of the pancreatic malignant phenotype are associated with the signaling networks that involve the EGFR. EGF and its receptor, EGFR, are over-expression in many human pancreatic cancers[9,10]. Recently, there is increasing evidence demonstrating the therapeutic potential of EGFR blockade in the management of pancreatic cancer and other malignancies[11-13]. EGFR inhibitors have shown activity in clinical trials in pancreatic, colorectal and non-small cell lung cancers[14-16]. Erlotinib is an orally available low-molecular-weight quinazolinamine that acts as a potent and reversible inhibitor of EGFR-TK activity. Single agent activity was observed in patients with non-small cell lung cancer, head and neck carcinoma and ovarian cancer[17-20]. A randomized phase Ⅲ placebo-controlled trial has shown that the combination of gemcitabine and erlotinib is associated with a modest but statistically significant survival benefit compared with gemcitabine and placebo and this represents an EGFR-targeted agent conferred benefit in addition to chemotherapy[21]. In this study, we evaluated the efficacy of erlotinib, as a single agent, on pancreatic cancer cells grown *in vitro* and *in vivo*

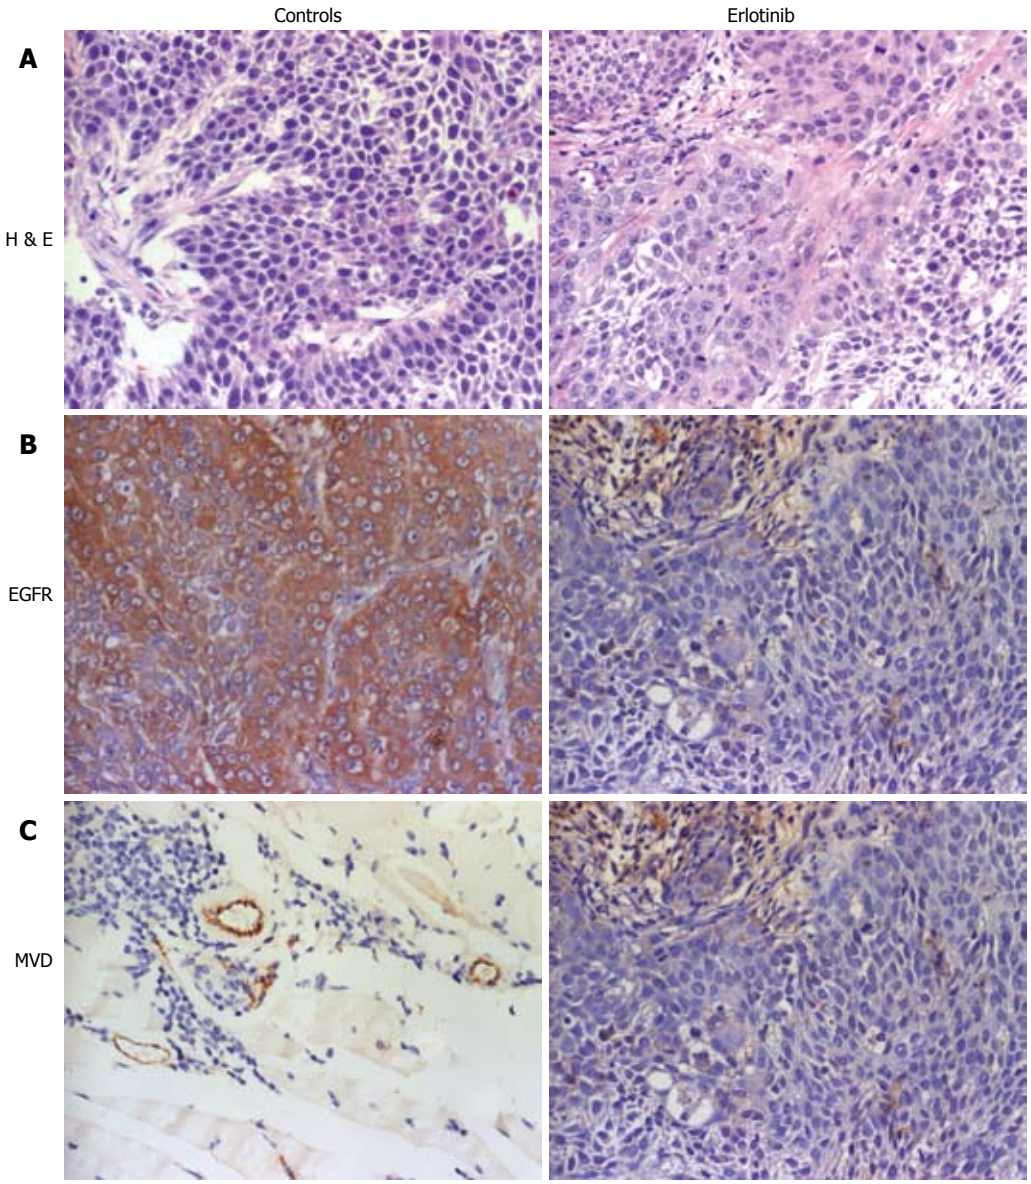

Figure 5 Expression of EGFR and the blood vessel endothelial cells in different treatment group in BxPC-3 mouse xenograft tissues. IHC was used to determine expression levels of EGFR and evaluate tumor microvessel density. **A**: HE staining for each sample (x 400); **B**: Expression of EGFR in treatment group was decreased compared with the control (x 400); **C**: Microvessel density of erlotinib treated group was lower than that of the control group.

using a nude mice xenograft model and explored the mechanisms involved as well. *In vitro* results showed an inhibition efficiency of 53.5% by erlotinib at the concentration of 50 μmol/L in the growth of cultured BxPC-3 pancreatic carcinoma cells as determined by MTT assay. The cell viability of BxPC-3 pancreatic cells was 53.5% with erlotinib treatment at a 50 μmol/L concentration by the MTT assay *in vitro*. There was no difference between 50 μmol/L and 100 μmol/L concentrations of erlotinib when cells were treated for 48 h (data not shown). We performed cell cycle analyses to characterize the underlying mechanisms of erlotinib's mode of action. Upon erlotinib treatment for 48 h, the proportion of cells in the G_0/G_1 phase increased to 73.4%, being significantly higher than that of the control. The antineoplastic effect of erlotinib is not solely due to cell cycle arrest. Induction of apoptosis by EGFR-TK inhibition has recently been reported[22,23]. In our study, we also observed cell apoptosis induced by erlotinib following cell cycle arrest. As we know, Bcl-2 members are crucial regulators of apoptotic cell death. We also checked the expression of anti-apoptotic factors such as bcl-2, bcl-xl as well as pro-apoptotic factors bax and bak. Erlotinib induced a moderate decrease in the expression of bcl-2 and bcl-xl at a concentration of $\geqslant$ 50 μmol/L. Our study *in vitro* provides evidence that the growth of BxPC-3 cells can be suppressed by erlotinib and at least two mechanisms are involved, i.e. cell cycle arrest and apoptosis. We used a nude mouse xenograft model to further evaluate the antitumor efficacy of erlotinib in pancreatic cancer *in vivo*. Erlotinib was very effective in suppressing the growth of BxPC-3 tumors in a subcutaneous tumor model. Tumor inhibition of approximately 74.5% was observed after 4 wk of treatment with erlotinib at a dose of 100 mg/kg per day. IHC staining of sections of subcutaneously implanted tumors showed constitutively high EGFR expression, however, the mice treated with 100 mg/kg erlotinib daily showed lower levels of EGFR. These results showed that erlotinib as monotherapy has strong antitumor activity in human BxPC-3 xenograft models expressing EGF receptors.

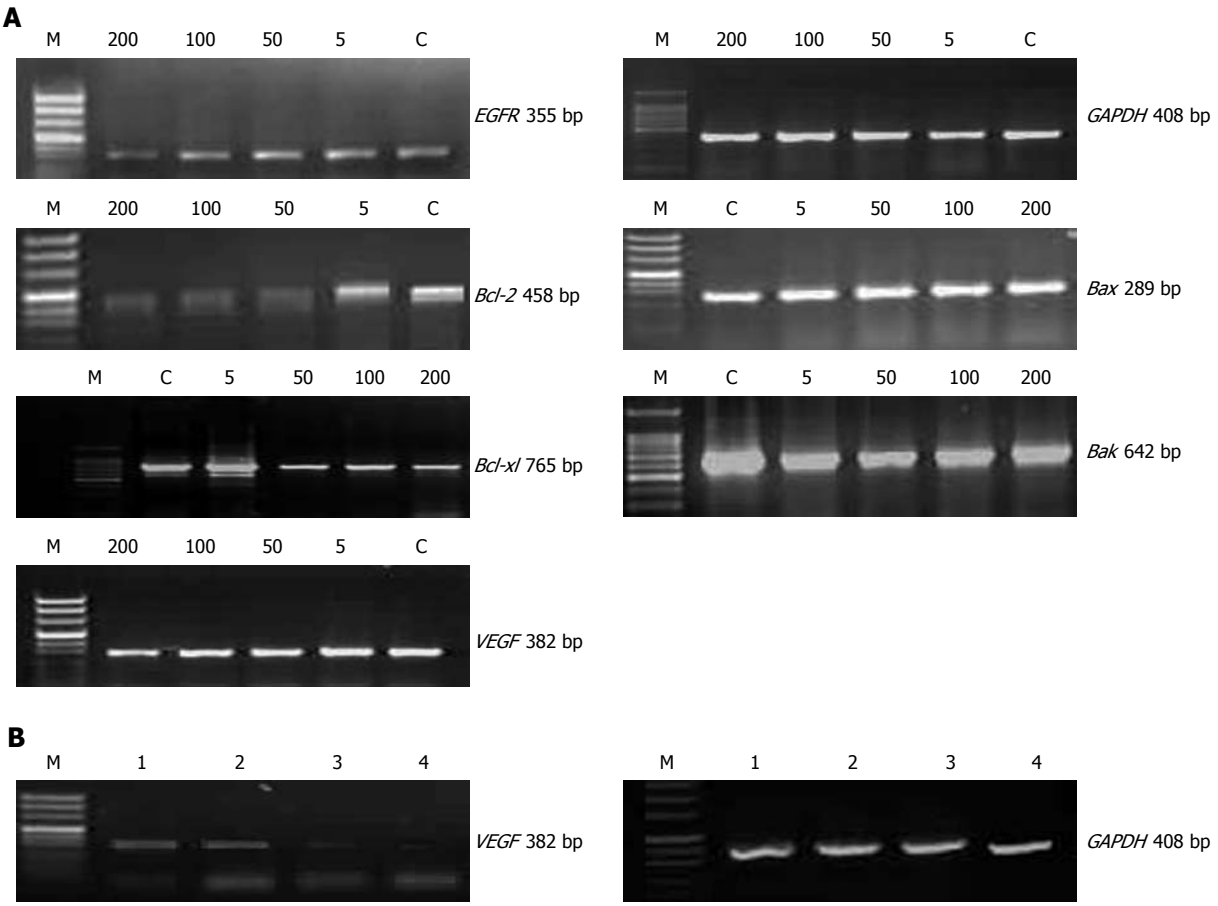

Figure 6 Expressions of *EGFR*, *Bcl-2*, *Bcl-xl*, *Bax*, *Bak* and *VEGF* mRNA in BxPC-3 cells treated with different concentrations (μmol/L) of erlotinib for 48 h and xenograft tissues were detected by RT-PCR. **A**: Effects of erlotinib on the expressions of EGFR, apoptosis-associated factors and *VEGF*. Lane M: DNA marker; Lane C: Control; other lanes: Different concentrations of erlotinib. **B**: Effects of erlotinib (100 mg/kg daily) on expression of VEGF in tumor tissues. Lane M: DNA marker; Lane 1, 2: Control group; Lane 3, 4: Treatment group. RT-PCR for *GAPDH* was performed in parallel and showed an equal amount of total RNA in the sample.

Numerous lines of evidence have shown that angiogenesis plays a significant clinicopathological role in tumors. Although pancreatic cancer is not a grossly vascular tumor, it often exhibits enhanced foli of endothelial cell proliferation. Moreover, several studies have reported a positive correlation between blood vessel density and disease progression in cases of pancreatic cancer, supporting the important role of angiogenesis in this disease[24-26]. EGFR signaling has previously been shown to play a role in angiogenesis[27]. In this study, we used the expression of VEGF, the MVD and tube formation assay to investigate the effects of erlotinib on angiogenesis both *in vitro* and *in vivo*. At the molecular level, VEGF is believed to be critical for pancreatic cancer angiogenesis[28]. Erlotinib exhibited a moderate decrease in VEGF expression *in vitro*, especially at a high concentration (200 μmol/L). Similarly, in xenograft tissues, there were marked reductions in the amounts of VEGF present in the treated group as compared with the control. As a unique tool, an *in vitro* capillary formation assay has been used to verify specific antiangiogenic activities of many agents with a good correlation to blood vessel formation *in vivo*[29]. Using this method, we observed that erlotinib as a single agent inhibited capillary tube formation by ECV304. Our immunohistochemical analysis of tumor specimens revealed that the treatment of mice with erlotinib produced a significant decrease in the number of tumor-associated blood vessels (MVD). The decrease in MVD could be attributable to a decrease in endothelial cell proliferation, as we proved *in vitro*.

In summary, our study showed that blockade of the EGFR signaling pathway by erlotinib has provided significant treatment in the BxPC-3 cell line *in vitro* and in nude mice and it may have a potential for the treatment of human pancreatic carcinoma. However, it is apparent that the use of a single signal transduction inhibitor cannot antagonize all the potentially relevant survival pathways in pancreatic cancers. As an adjuvant use in chemotherapy, targeting EGFR pathway seems to be a promising approach in the prevention and/or treatment of pancreatic cancer.

We thank Shanghai Institute of Biochemistry and Cell Biology for providing technical assistance.

COMMENTS

Background

The activity of the epidermal growth factor receptor (EGFR), a tyrosine kinase

receptor of the ErbB family, is abnormally elevated in most human solid tumors, including pancreatic cancer, and is associated with progression and poor prognosis. There are two main categories of therapeutic strategy for targeting the EGFR pathway, specific anti-EGFR monoclonal antibodies and EGFR tyrosine kinase inhibitors (TKIs). Blockage of EGFR activity may lead to growth inhibition in pancreatic cancer.

Research frontiers

Molecularly targeted therapies have recently expanded the options available for patients with gastrointestinal tumors. Low weight EGFR TKIs such as erlotinib may play an important role in the treatment of human pancreatic carcinoma. Administration of erlotinib inhibites the BxPC-3 human pancreatic cancer cell line growth and induces antiangiogenic effect both *in vitro* and *in vivo*.

Innovations and breakthroughs

Small-molecule inhibitors of the EGFR tyrosine kinase, such as erlotinib, have shown promise in phase Ⅲ trials in non-small-cell lung cancer (NSCLC). But the anticancer mechanism has not been clearly elucidated especially in gastrointestinal tumors, including pancreatic cancer. The results indicate that the blockade of EGFR may provide a rationale for translating this therapeutic strategy into a clinical setting in some pancreatic cancer patients.

Applications

This study showed that blockade of the EGFR signaling pathway by erlotinib suppressed the BxPC-3 human pancreatic cancer cell line growth and induced antiangiogenic effects both *in vitro* and *in vivo*. As an adjuvant used in chemotherapy, targeting the EGFR pathway seems to be a promising approach in the prevention and or treatment of pancreatic cancer.

Terminology

The epidermal growth factor (EGF) receptor (or ErbB1) and the related ErbB4 are transmembrane receptor protein tyrosine kinases which bind extracellular ligands of the EGF family. ErbB2 and ErbB3 are "co-receptors" structurally related to ErbB1/ ErbB4, but ErbB2 is an "orphan" receptor and ErbB3 lacks tyrosine kinase activity. They transduced biological signals from the extracellular to the intracellular compartment. These families of ligands and receptors have been firmly linked to proliferative signaling and oncogenesis.

Peer review

In this paper, the effect of erlotinib on the proliferation and apoptosis of the human pancreatic cancer cell line BxPC-3 was studied. A dose-dependent inhibition of BxPC-3 cell growth *in vitro*, with a block of G_1-S transition, and rise in apoptosis were observed in erlotinib-treated cells. A decrease in tumor volume and microvessel density was also found in erlotinib-treated nude mice carrying BxPC-3 cell xerographs. This is a very interesting manuscript with some minor points needing further addressing.

Abstract

AIM: To investigate the biological impact of hepatitis B virus X- hepatitis C virus core (HBV X-HCV C) fusion gene on hepatoma cells.

METHODS: The recombinant adenoviruses Ad-XC, Ad-X and Ad-C expressing HBV X-HCV C fusion gene, *HBV X* gene and *HCV C* gene were constructed, respectively. Hepatoma cells were infected with different recombinant adenoviruses. MTT, colony-forming experiment, FCM, TUNEL assay were performed to observe the biological impact of the HBV X-HCV C fusion gene on liver cells.

RESULTS: MTT showed that the Ad-XC group cells grew faster than the other group cells. Colony-forming experiment showed that the colony-forming rate for the Ad-XC group cells was significantly higher than that for the other group cells. FCM analysis showed that Ad-XC/Ad-X/Ad-C infection enhanced the progression of G1→S phase in the HepG2 cell cycle. The apoptosis index of the Ad-XC, Ad-X, Ad-C group cells was significantly lower than that of the Ad0 and control group cells. Semi-quantitative RT-PCR showed that the expression level of c-myc was the highest in Ad-XC infected cells. Tumor formation was found at the injected site of mice inoculated with Ad-XC-infected LO2 cells, but not in control mice.

CONCLUSION: Ad-XC, Ad-X and Ad-C facilitate the proliferation activity of HepG2 cells and inhibit their apoptosis *in vitro*. The effect of Ad-XC is significantly stronger than that of Ad-X and Ad-C. Up-regulation of c-myc may be one of the mechanisms underlying the synergism of *HBV X* and *HCV C* genes on hepatocarcinogenesis in athymic nude mice.

Key words: Hepatitis B virus X gene; Hepatitis C virus core gene; Hepatocellular carcinoma; Proliferation; Apoptosis

INTRODUCTION

Hepatocellular carcinoma (HCC) is the second most common cancer in China. Many etiological factors are related with HCC development. Chronic infection with hepatitis B virus (HBV) or hepatitis C virus (HCV) and prolonged dietary exposure to aflatoxin are responsible for about 80% of all HCCs in human beings. Chronic HBV and HCV infection often results in cirrhosis and enhances the probability of developing HCC. The underlying mechanisms leading to malignant transformation of infected cells, however, remain unclear. Based on epidemic data, super-infection with HBV and HCV is associated with the increased frequency in the development of HCC, but the relative mechanism remains elusive. It has been reported that both *HBV X* gene and *HCV core* (*HCV C*) gene play an important role in hepatocarcinogenesis. The fact that *HBV X* and *HCV C* genes induce HCC in transgenic mice offers more evidence for the relationship between these genes and HCC.

Imbalance between proliferation and apoptosis may contribute to hepatocarcinogenesis. HBV X and HCV C proteins are multiple-functional proteins, and can deregulate cell cycle check points, transactivate or activate cellular and viral genes, which are involved in transcription regulation, signal transduction pathway, cell cycle regulation, *etc*. Therefore, they may deregulate cell cycle and apoptosis and may have a common target

point. However, if there is synergism of HBV X and HCV C proteins on hepatocarcinogenesis still remains unclear. In the present study, recombinant adenoviruses expressing HBV X-HCV C fusion protein, HBV X protein and HCV C protein were constructed, and their effect on the biological behavior and expression of c-myc in hepatocytes were investigated.

MATERIALS AND METHODS

Materials

Pyrobest™ DNA polymerase, S*al* I , E*co*RV, H*ind*Ⅲ and T4 DNA ligase were purchased from TaKaRa Company (Dalian, China). Plasmid pecob6 was constructed by professor Ren Hong in our institute, plasmid pcDNA3.1/HCV-C was constructed by Dr. Wei-xian Chen in our institute. Lipofectamine was purchased from Invitrogen Company (California, USA). P*ac* I and P*me* I were from New England Biolabs (Beijing, China). Primers were synthesized by Shanghai Sangon Company (Shanghai, China). AdEasy system was a gift from professor Tong-Chuan He, University of Chicago Medical Center. DH5α was kept in our laboratory. Fetal bovine serum and calf serum were purchased from Hyclone (Utah, USA). RPMI 1640 was provided by GIBCO (New York, USA). 293 cells, LO2 and HepG2 cells were purchased from Shanghai Cytobiology Research institute of Chinese Academy of Science (Shanghai, China). BALB/c nude mice were from Shanghai Experimental Animal Centre of Chinese Academy of Science. Mouse anti-human hepatitis B virus X-protein monoclonal antibody was purchased from CHEMICON (California, USA). Monoclonal antibody to hepatitis C virus core protein was purchased from BIODESIGN (Maine, USA).

Construction, identification and amplification of recombinant adenoviruses

The recombinant adenoviruses Ad-XC, Ad-X and Ad-C containing *HBV X-HCV C* fusion gene, *HBV X* gene and *HCV C* gene, were constructed using the AdEasy system[1]. *HBV X* and *HCV C* genes were amplified by PCR from pecob6 or pcDNA3.1-HCV C. Using gene SOEing method[2], *HBV X* and *HCV C* genes were fused through a linker coding for a sequence rich in glycine. The sequences of gene primers used in this study are listed in Table 1. The fragment was bi-mold-cut with S*al* I and E*co*RV and inserted into two spots of S*al* I and E*co*RV of the pAdTrack-CMV. The recombinant shuttle plasmid was confirmed by PCR, double restriction nuclease digestion and sequencing. Mini preparations were performed using the conventional alkaline lysis method. The linearized shuttle plasmid was co-transformed with adenoviral backbone plasmid pAdEasy-1 to *E. coli* BJ5183 by electroporation. The cloned candidate was further tested by restriction nuclease digestion with P*ac* I and PCR. After digested with P*ac* I , the recombinant adenoviral plasmid was transfected into 293 cells for package. Generation of recombinant adenoviruses was monitored by GFP expression. Transfected cells were collected 12-15 d after transfection by scraping cells off flasks and pelleting them with 1 mL PBS. After three cycles of freezing and rapid thawing at 37℃, 10 μL proteinase K was added into 5 μL of viral lysate at 55℃ for 1 h and boiled for 5 min and 2 μL of which was used as a model to identify the correct recombinant adenovirues (*HBV X*, *HCV C* and *HBV X-HCV C* fusion gene). The upstream sequence of adenovirus primer is 5'-CTGTGGACCGTGAGGATA-3', the downstream sequence of adenovirus primer of adenovirus primer is 5'-TGTTGGGCATAGATTGTT-3' (Table 1). PCR system contained 2 μL viral DNA, 2 μL 10 μmol/L primer, 5 μL 10 × PCR buffer, 3 μL $MgCl_2$, 4 μL 2 mmol/L dNTP and 1 μL Taq enzyme. Water was added until the final volume of PCR reached 50 μL. Thirty-five cycles of PCR were carried out, each consisting of 94℃ for 30 s, 51℃ for 40 s, 72℃ for 40 s, and a final extension at 72℃ for 10 min. Electrophoresis on 1.0% agarose gel was performed. The identified positive recombinant adenoviruses were amplified in 293 cells for further experiment. The virus titer was tested with GFP expression and limited dilution method.

Infective efficiency of recombinant adenoviruses

Two hundred and ninety three, NIH3T3 and HepG2 cells were seeded in six-well plates in the appropriate medium at a density of 2×10^5 cells/well, infected with various adenoviruses at a multiplicity of infection (MOI) from 5 to 100, and incubated at 37℃ for 48 h. The number of cells expressing GFP was recorded under an inversion difference fluorescence microscope.

The percentage of cells with GFP expression was calculated.

Infection with recombinant adenoviruses and expression of fusion protein

The human liver cancer cell line HepG2 was incubated in an atmosphere containing 50 mL/L CO_2 at 37℃. When the density reached 90%, the experimental groups were infected with Ad-XC, Ad-X, Ad-C or Ad0, respectively, at different MOI. During the process, the culture fluid was shaken every 30 min, 4 h later. Another 6 mL 10% NCS RPMI 1640 was added. The control group was a non-virus group. After HepG2 cells were incubated for 48 h, total protein was extracted using RIPA. The expression of HBV X-HCV C fusion protein, HBV X and HCV C protein was detected by Western blot.

MTT assay

HepG2 cells (1.5×10^3 cells/well) were plated in 96-well plates (16 wells for each group) and infected with various MOI of Ad0, Ad-C, Ad-X or Ad-XC, respectively. Cell proliferation was determined by MTT assay. After 1-7 d, 20 μL of MTT solution (5 mg/mL) was added to each well. After incubation for 4 h at 37℃, MTT was removed and 200 μL dimethyl sulfoxide (Sigma) was added. The mixture was shaken and the crystals were fully dissolved for about 10 min. The A value of each well was detected at a test wavelength of 490 nm. Cell growth curve was plotted according to the A values.

Colony-forming experiment

HepG2 cells of five groups were digested into a single-cell suspension and inoculated into a six-well plate. Each well was inoculated with 1.0×10^3 cells. The cells were incubated for 12 d and fixed with methanol, stained with Giemsa stain fluid. Then the number of colonies with more than 50 cells was recorded. The experiment was repeated five times.

Flow cytometry

When the density of HepG2 cells reached 90%, the experimental groups were infected with Ad-XC, Ad-X, Ad-C and Ad0, respectively. Forty-eight hours after infection, the cells were collected (using trypsin digestion) and centrifuged at 1000 r/min for 5 min. The upper clear fluid was discarded, PBS was added to adjust the cell density to 10^6/mL. One hundred microliters of cell suspension was put into a tube, into which 200 μL DNA-PREPTMLPR was added and mixed. Two microliters of DNA-PREPTM stain reagent (PI stain) was added and mixed after 30 s. After 30 min, the cell cycle was detected by flow cytometry (FCM).

Cell apoptosis assay

Cell apoptosis was estimated by TUNEL staining. HepG2 cells were planted into 24-well plates at a density of 1×10^5 cells/well and infected with Ad-XC, Ad-X, Ad-C and Ad0 respectively. At the same time, 1 mL TNF-α (100 ng/mL) was added into each well. After incubation at 37℃ for 48 h, the cells were fixed with 4% paraformaldehyde and chilled in ice bath for 4 min with permeabilization solution (0.1% Triton X-100 in 0.1% sodium citrate). Then, 50 μL of TUNEL mixture was added, incubated in a humidified chamber at 37℃ for 90 min. The TUNEL mixture was removed, 50 μL POD was added and incubated for another 40 min. The cells were rinsed with PBS, stained with DAB, and detected by optic microscopy.

Effect of Ad-XC infection on c-myc mRNA expression in HepG2 cells

Expression of c-myc mRNA in each group was assayed by semi-quantitative RT-PCR. β-actin was used as an internal control. Total RNA was extracted with TRIZOL reagent. RT-PCR was performed using an access RT-PCR system (Promega). The reaction volume was 50 μL containing 10 μL AMV/Tf1 buffer, 2 μL $MgSO_4$, 1 μL dNTP, 1 μL target gene sense and anti-sense primers, 1 μL β-actin primer pair, 1 μL AMV reverse transcriptase, 1 μL Tf1 DNA polymerase, 2 μg RNA and nuclease-free water. The sequences of gene primers are listed in Table 1. Thirty cycles of amplification were performed, each consisting of denaturation at 94℃ for 45 s, annealing at 58℃ for 30 s, extension at 37℃ for 1 min, an initial denaturation at 45℃ 45 min and at 94℃ for 2 min, and a final extension at 72℃ for 10 min. About 5 μL PCR products were separated by electrophoresis on 10 g/L agarose gel and detected by ultraviolet radiography. The densities of bands were analyzed using a Bio imaging system, the ratio of c-myc density to β-actin density was represented as the relative expression level of mRNA. The semi-quantitative detection was analyzed five times.

Nude mice experiment

LO2 cells were infected with Ad0 or Ad-XC. The infected cells were collected and resuspended in 200 μL PBS after 48 h. Three BALB/c nude mice were subcutaneously inoculated with the infected LO2 cells randomly (Ad0, $n = 1$; Ad-XC, $n = 2$). Tumors were observed every 2 d for 6 wk.

Statistical analysis

All data were expressed as mean ± SE. The significance for the difference between groups was assessed with SPSS 12.0 by one-way ANOVA. $P < 0.05$ was considered statistically significant.

RESULTS

Identification of recombinant adenoviruses by PCR co-amplification method

The PCR product depending on the viral DNA model was evaluated by 1.0% agarose electrophoresis. The recombinant adenoviruses that could amplify 465 bp HBV X cDNA fragment/576 bp HCV C cDNA fragment/HBV X-HCV C fusion gene fragment and a 759 bp virus gene frame fragment at the same time were obtained (Figure 1). Recombinant adenoviruses

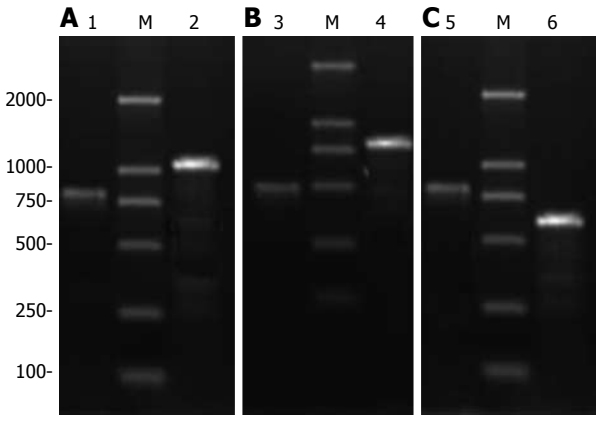

Figure 1 PCR verifying recombinant adenoviruses of Ad-XC (**A**), Ad-X (**B**), and Ad-C (**C**). M: DL2000; lanes 1, 4 and 5: PAdEasy-1; lane 2: HBV X-HCV C fusion gene; lane 3: X gene; lane 6: C gene.

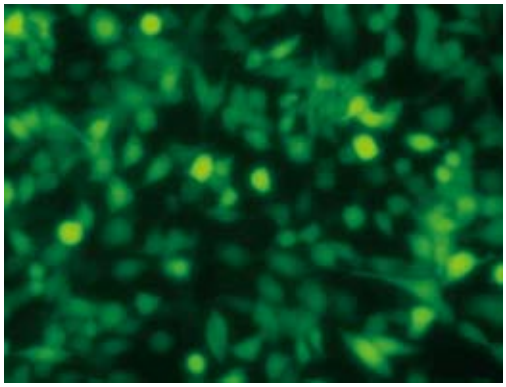

Figure 2 HepG2 cells infected with recombinant adenoviruses (x 200).

containing HBV X cDNA fragment, HCV C cDNA fragment and HBV X-HCV C fusion gene fragment, respectively, were produced.

Titer and transfection rate of recombinant adenoviruses

The titer of amplified recombinant adenoviruses Ad-XC, Ad-X, Ad-C and Ad0 was 1.9×10^9 pfu/mL, 2.0×10^9 pfu/mL, 2.2×10^9 pfu/mL, 1.7×10^9 pfu/mL, respectively. When the MOI was 20 or greater, the infection rate of HepG2 cells reached 100% (Figure 2).

Expression of different proteins in HepG2 cells

Forty-eight hours after infection, Western blot revealed the expression of HBV X-HCV C fusion protein, HBV X and HCV C proteins in HepG2 cells infected with recombinant adenovirus (Figure 3).

Effect of recombinant adenoviruses on growth curve of HepG2 cells

The expression of HBV X-HCV C fusion gene, *HBV X* and *HCV C* genes improved cell proliferation significantly compared with that of control HepG2 cells. The A values were higher in HepG2 cells infected with Ad-XC, Ad-X and Ad-C than in control HepG2 cells (Figure 4). These results indicate that HBV X-HCV C fusion gene, HBV X and HCV C genes, especially Ad-XC, stimulated the metabolic activity and the viability of HepG2 cells.

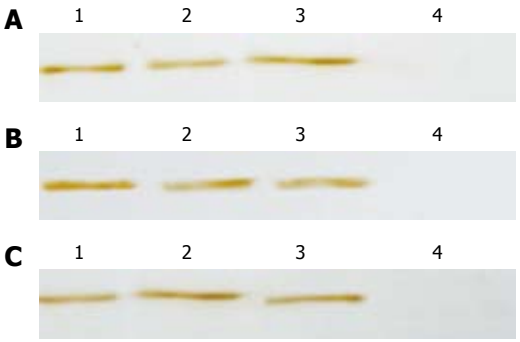

Figure 3 Western blotting displaying expression of fusion protein (**A**), HBV X protein (**B**), and HCV C protein (**C**). Lanes 1-3: Infected HepG2 cells; lane 4: Uninfected HepG2 cells.

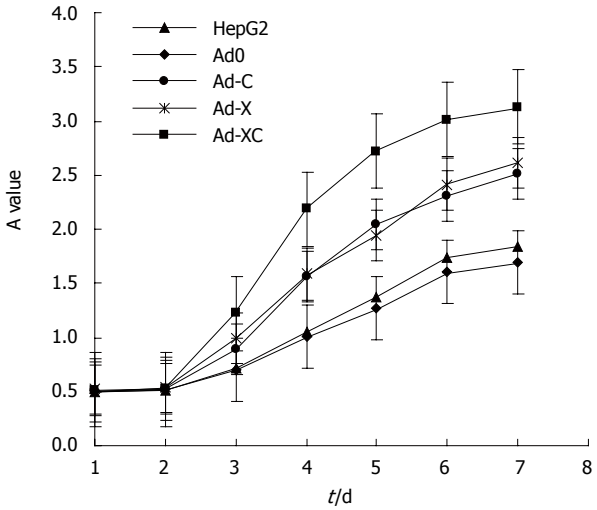

Figure 4 Growth status change in HepG2 cells after infection.

Table 2 Cell cycle of HepG2 cells infected with recombinant adenovirus (%, mean ± SE)

	G_0/G_1	S	G_2/M
HepG2	71.57 ± 0.79	19.18 ± 0.77	9.25 ± 0.76
Ad0	72.94 ± 1.84	18.38 ± 0.9	8.68 ± 1.12
Ad-C	50.21 ± 1.37	32.15 ± 0.15[b]	17.65 ± 1.22[b]
Ad-X	48.17 ± 1.13	33.19 ± 1.47[b]	18.64 ± 0.56[b]
Ad-XC	36.49 ± 0.84	42.06 ± 0.24[a,b]	21.45 ± 0.89[a,b]

[a]$P < 0.005$ *vs* Ad-C and Ad-X cells; [b]$P < 0.001$ *vs* HepG2 and Ad0 cells.

Effect of recombinant adenoviruses on colony-forming ability of HepG2 cells

The colony-forming rate of Ad-XC infected HepG2 cells was 82.2% ± 6.1%, significantly higher than that of the Ad-X, Ad-C, Ad0 infected HepG2 cells and control cells (53% ± 4.1%, 49% ± 7.1%, 27.6% ± 5.1%, 30.2% ± 4.4%, respectively, $P < 0.0001$, $n = 5$).

Effect of recombinant adenoviruses on cell cycle

Cell cycles from FCM are listed in Table 2. Compared

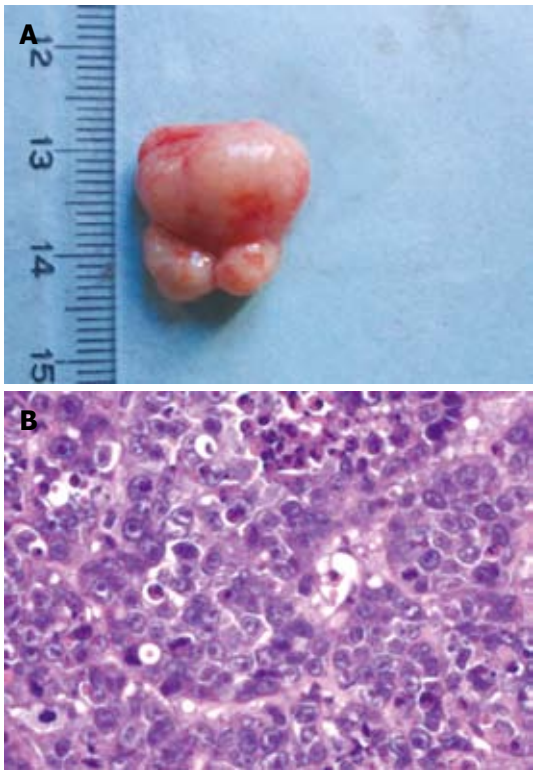

Figure 5 Surgical specimens of tumor tissue (**A**) and histological examination (**B**) showing a 1.5 cm tumor (HE staining, × 400).

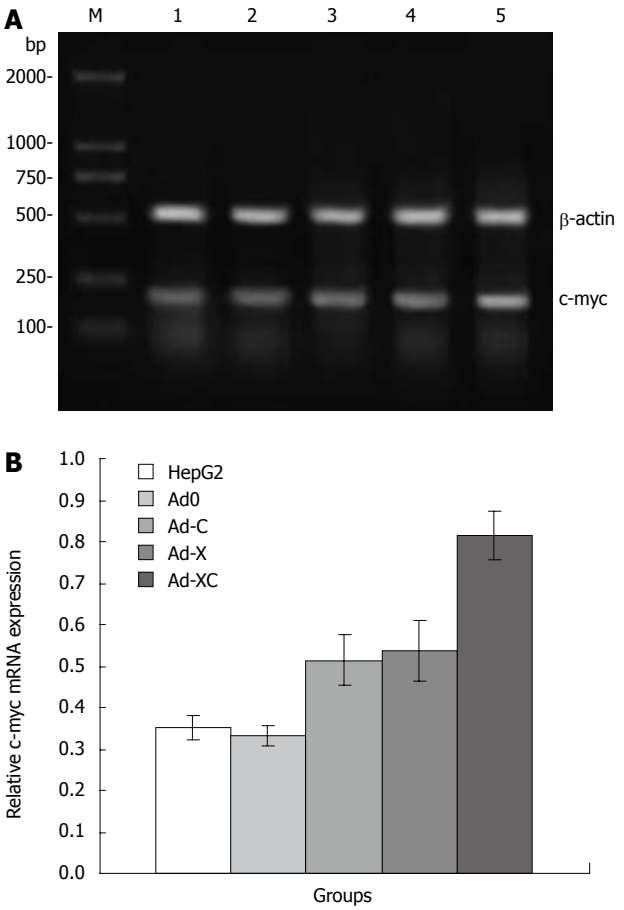

Figure 6 RT-PCR revealing mRNA expression of c-myc (**A**) and relative mRNA expression level of c-myc (**B**) in HepG2 cells. M: DL2000; lanes 1-5: HepG2, Ad0, Ad-C, Ad-X and Ad-XC cells ($P < 0.05$, Ad-XC group *vs* other groups).

with Ad0 and non-virus group cells, the number of cells in G_0/G_1 phase was decreased, but increased in Ad-XC, Ad-X, Ad-C groups at S phase, indicating that proliferation of the cells was active. A significant difference was observed in cell proliferation between the Ad-XC group and other groups ($P < 0.0001$, $n = 3$).

Cell apoptosis assay

TUNEL showed that the apoptosis rate of HepG2, Ad0, Ad-C, Ad-X and Ad-XC cells was 20.7% ± 0.6%, 21.8% ± 0.9%, 12.6% ± 0.8%, 11.7% ± 0.9% and 5.1% ± 0.8%, respectively. The apoptosis rate of the experimental group decreased obviously in comparison to the control group. The apoptosis rate of Ad-XC was the lowest. The apoptosis rate of these five groups of cells differed sharply when compared to each other ($P < 0.0001$, $n = 3$).

Nude mice experiment

Tumor formation was observed at the injection site of mice inoculated with Ad-XC infected LO2 cells (Figure 5), but not in control mice.

Effect of Ad-XC infection on c-myc mRNA expression in HepG2 cells

The mRNA level of c-myc in Ad-XC cells was the highest (Figure 6), indicating that transient expression of *HBV X-HCV C* fusion gene obviously induced expression of c-myc in HepG2 cells.

DISCUSSION

HCC is one of the most common malignant tumors in the world. Chronic hepatitis B and C are responsible for the great majority of cases of HCC worldwide. Both HBV and HCV are parenterally transmitted and superinfection is not uncommon in intravenous drug users and in countries with a high prevalence of HBV[3]. The risk of developing HCC in subjects with both HBV and HCV infections has been investigated in two meta-analyses[4,5], showing that there is a synergistic hepatocarcinogenic interaction between HBV and HCV infections and that the increased risk is super-additive but not multiplicative.

It was reported that transgenic mice with hepatitis B and C have the oncogenic potential of *HBV X* and *HCV C* genes in the liver[6,7]. It was also reported that HBV X and HCV C proteins have an oncogenic potential[8-14], but the involvement of their synergisms in hepatocarcinogenesis remains unclear. HBV X and HCV C proteins additively repress the universal cyclin-dependent kinase inhibitor p21 gene at the transcription level and additively stimulate cell growth, suggesting that additive repression of p21 is important to understand the cooperative development of HCC due to these two proteins[15]. When HBV X and HCV C proteins transform mouse fibroblast NIH3T3 cells in cooperation, they additively stimulate cell growth, especially in the absence of serum growth factors. Cells expressing these two viral proteins exhibit a higher tumorigenicity, as demonstrated in athymic nude mice[16]. HBV X protein

increases liver pathogenesis in HCV transgenic mice by a mechanism involving an imbalance between hepatocyte death and regeneration[17]. In the present study, Ad-XC, Ad-X and Ad-C could facilitate the proliferation activity of HepG2 cells and inhibit their apoptosis *in vitro*. The effect of Ad-XC was significantly stronger than that of Ad-X and Ad-C, suggesting a more than additive but less than multiplicative effect of *HBV X* and *HCV C* genes on hepatocarcinogenesis as demonstrated in athymic nude mice[16].

The increased expression of oncogene is thought to be a major cause for tumor formation/progression. C-myc, an oncogene located on 8q24, may be important in hepatocarcinogenesis. The expression level of c-myc in the cells transiently transfected with the HBV X gene was much higher than that in the control cells[18]. c-myc protein expression above its basal level significantly increased c-myc stability, as revealed by its prolonged intracellular half-life in HepG2 expressing HCV core protein, suggesting that HCV core protein may promote cell cycle progression in HepG2 cells by increasing the stability of c-myc oncoprotein[19]. The present study aimed to evaluate the expression level of c-myc in cells infected with different recombinant adenoviruses by RT-PCR. The highest expression level of c-myc was observed in Ad-XC infected cells, suggesting that up-regulation of c-myc expression may be one of the mechanisms underlying the synergism of *HBV X* and *HCV C* genes in hepatocarcinogenesis.

In conclusion, HBV X and HCV C genes have a synergism in hepatocarcinogenesis. The reasons for the interaction are uncertain, although the increased c-myc expression in the presence of both genes with tumor promoting effects, including the enhanced up-regulation of c-myc expression, may play a role in hepatocarcinogenesis. Interaction between hepatocarcinogenic effects of the two genes remains to be investigated.

COMMENTS

Background

Chronic hepatic B virus (HBV) and hepatic C virus (HCV) infection often results in cirrhosis and enhances the risk of developing HCC. The underlying mechanism leading to malignant transformation of infected cells, however, remains unclear. Based on epidemic data, Super-infection with HBV and HCV is associated with an increased frequency in the development of HCC, but the relative mechanism remains to be elucidated. It was reported that both HBV X and HCV core (HCV C) genes play an important role in hepatocarcinogenesis.

Research frontiers

The fact that HBV X and HCV C genes induce HCC in transgenic mice offers more evidence for the relationship between these genes and HCC. However, whether there is a synergism of HBV X and HCV C proteins on hepatocarcinogenesis is still unclear.

Innovations and breakthroughs

In the present study, recombinant adenoviruses expressing HBV X-HCV C fusion protein were constructed, and their effects on biological behavior and c-myc expression level in hepatocytes were investigated.

Applications

HBV X and HCV C genes may have a synergism in hepatocarcinogenesis. The reasons for the interaction are uncertain, although increased c-myc expression in the presence of both genes with tumor promoting effects, including the enhanced up-regulation of c-myc expression, may play a role in hepatocarcinogenesis. Interaction between hepatocarcinogenic effects of the two genes remains to be investigated.

Peer review

This is an elegant, well designed study investigating the combined effect of adenoviruses expressing HBV-X and HCV-C genes on the proliferation and apoptosis of HepG2 cells. The major finding of the study was that the combined effect of the two genes on cell proliferation and apoptosis was superior over that of HBV-X or HCV-C gene alone. The authors also stressed that the underlying mechanism may be, at least, partly explained by the increased c-myc expression.

Abstract

AIM: To assess the predictive value of the insulin-like growth factor 2 (*Igf2*) methylation profile for the occurrence of Hepatocellular Carcinoma (HCC) in hepatitis C (HCV) cirrhosis.

METHODS: Patients with: (1) biopsy-proven compensated HCV cirrhosis; (2) available baseline frozen liver sample; (3) absence of detectable HCC; (4) regular screening for HCC; (5) informed consent for genetic analysis were studied. After DNA extraction from liver samples and bisulfite treatment, unbiased PCR and DHPLC analysis were performed for methylation analysis at the *Igf2* locus. The predictive value of the *Igf2* methylation profile for HCC was assessed by Kaplan-Meier and Cox methods.

RESULTS: Among 94 included patients, 20 developed an HCC during follow-up (6.9 ± 3.2 years). The methylation profile was hypomethylated, intermediate and hypermethylated in 13, 64 and 17 cases, respectively. In univariate analysis, two baseline parameters were associated with the occurrence of HCC: age (P = 0.01) and prothrombin (P = 0.04). The test of linear tendency between the three ordered levels of *Igf2* methylation and probability of HCC occurrence was significant (Log Rank, P = 0.043; Breslow, P = 0.037; Tarone-Ware, P = 0.039).

CONCLUSION: These results suggest that hypomethylation at the *Igf2* locus in the liver could be predictive for HCC occurrence in HCV cirrhosis.

Key words: Liver cancer; Cirrhosis; Insulin-growth factor 2, DNA methylation

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most frequent malignant neoplasms worldwide[1], and its incidence has increased in the past decade in Europe and the USA[2-5]. In Western countries, HCC mostly develops in the presence of cirrhosis. Chronic Hepatitis C virus (HCV) infection plays an important role in the increased incidence of HCC in the western world[6] where HCC is presently the leading cause of death

of patients with HCV related cirrhosis[7]. In these patients, the annual incidence of HCC varies from 2% to 6%[8-13]. The main predictive factors of HCC in patients with HCV-cirrhosis are age over 50[14-17], male gender[12,14,15,17], increased serum alpha-fetoprotein (AFP) baseline levels[12,18,19], symptoms of portal hypertension, such as thrombopenia[17,18] or esophageal varices[17,19], obesity[20,21] and diabetes[22,23]. Identification of molecular abnormalities associated with an increased risk of HCC is particularly important to improve knowledge of both the pathways of liver carcinogenesis and the outcomes.

Insulin-like growth factor 2 (IGF2) is a fetal growth peptide produced by the liver which is structurally and functionally closely related to insulin[24]. It is over expressed in a wide variety of neoplasms[25,26] and is involved in experimental liver carcinogenesis. *In vitro*, a pathophysiological link between IGF2 over expression and hepatocyte proliferation was demonstrated by Lin *et al*[27], who found high concentrations of IGF2 in human hepatoma cell lines HuH7 and HepG2 and showed that antisense oligonucleotides complementary to *Igf2* mRNA reduced both *Igf2* mRNA and protein, in association with decreased cell proliferative activity. *In vivo*, Rogler *et al*[28] reported an increased frequency of HCC in *Igf2* transgenic mice and serum IGF2 has been recently proposed as a marker for human HCC to improve the diagnostic accuracy and sensitivity in patients with low serum AFP level[29].

Various epigenetic alterations have been reported in human cancers, including global DNA hypomethylation, gene hypomethylation and promoter hypermethylation, and *Igf2* loss of imprinting[30]. The *Igf2* gene is controlled by genomic imprinting, a non-Mendelian inherited epigenetic process that leads to the silencing of either a maternal or paternal allele[31,32]. In the liver, unlike in other tissues, its expression is monoallelic (maternally imprinted) during the fetal period and becomes biallelic thereafter. Early observations showed over expression of the *Igf2* gene in liver tumors and preneoplastic hepatic foci in different animal models as well as in human HCC[33,34]. This over expression is associated with re-expression of the fetal pattern of *Igf2* transcripts and restoration of monoallelic *Igf2* expression in preneoplastic hepatic foci[35] as well as in HCC[36], and with re-expression of monoallelic fetal promoters P2-P4[37] and loss of activity of the adult biallelic promoter P1[38]. One key factor of these epigenetic changes is the alteration of the genomic methylation pattern within regulatory Differentially Methylated Regions (DMRs) of imprinted genes, which inappropriately leads to loss of imprinting in the *Igf2* gene[39] and to transcriptional activation of the normally silent maternal allele. Hypomethylation at the *Igf2* locus has been found in many type of cancers, including ovarian, lung and colon[40]. In a previous study analyzing the methylation status of *Igf2* DMR2 in 71 liver samples from mostly viral HCC compared to 6 normal liver samples, we observed a hypomethylated profile at the *Igf2* locus in 89% of cases of HCC in contrast with the pattern observed in normal livers[41]. In addition, Cui *et al*[42] showed that hypomethylation of the *Igf2* gene in peripheral blood lymphocytes (PBL) is associated with a predisposition to colorectal cancer, suggesting that the epigenetic alteration of *Igf2* could be an early event in colorectal carcinogenesis.

The aim of the present study was to investigate whether hypomethylation at the *Igf2* locus in the liver is a predisposing factor for HCC in patients with HCV-related cirrhosis. Thus, we analyzed the methylation status of the *Igf2* gene spanning the 11p15 imprinted domain in patients with compensated HCV-related cirrhosis who were prospectively followed-up with periodic HCC screening.

MATERIALS AND METHODS

Patients

Ninety-four patients were retrospectively selected for this study among all patients hospitalized for liver biopsy between January, 1989 and December, 2000 in our department, based on the following criteria: (1) compensated (Child-Pugh A) HCV-related cirrhosis with presence of serum HCV RNA; (2) absence of viral co-infection by hepatitis B virus or human immunodeficiency virus; (3) regular follow-up until death with periodic HCC screening by liver ultrasonography and test of serum AFP levels every 6 mo at least; (4) absence of detectable HCC at enrollment; (5) available baseline frozen (-80℃) liver biopsy specimen for genetic study; (6) informed consent for genetic analysis obtained from the patient according to French guidelines.

Baseline demographic, clinical, biological and histological data (at time of liver biopsy) were recorded. All patients were prospectively followed-up. Complete physical examination, standard biochemical tests, serum AFP determination and abdominal ultrasonography were repeated every 6 mo. When a focal liver lesion or increased AFP levels were detected, tomodensitometry and, whenever possible, fine needle guided liver biopsy were performed. Diagnostic criteria for HCC were: (1) histological and (2) clinical, in patients with AFP value greater than 400 ng/mL and evidence of focal liver lesion at imaging techniques. After 2002, the HCC diagnosis was based on the guidelines of the European Association for the Study of the Liver[43].

Twenty-five histopathologically normal liver samples were also studied as control cases.

DNA extraction, bisulfite treatment of DNA and methylation analysis

DNA from frozen liver biopsies was extracted and treated with sodium bisulfite. Unbiased PCR amplification and Denaturing High Performance Liquid Chromatography (DHPLC) analysis were

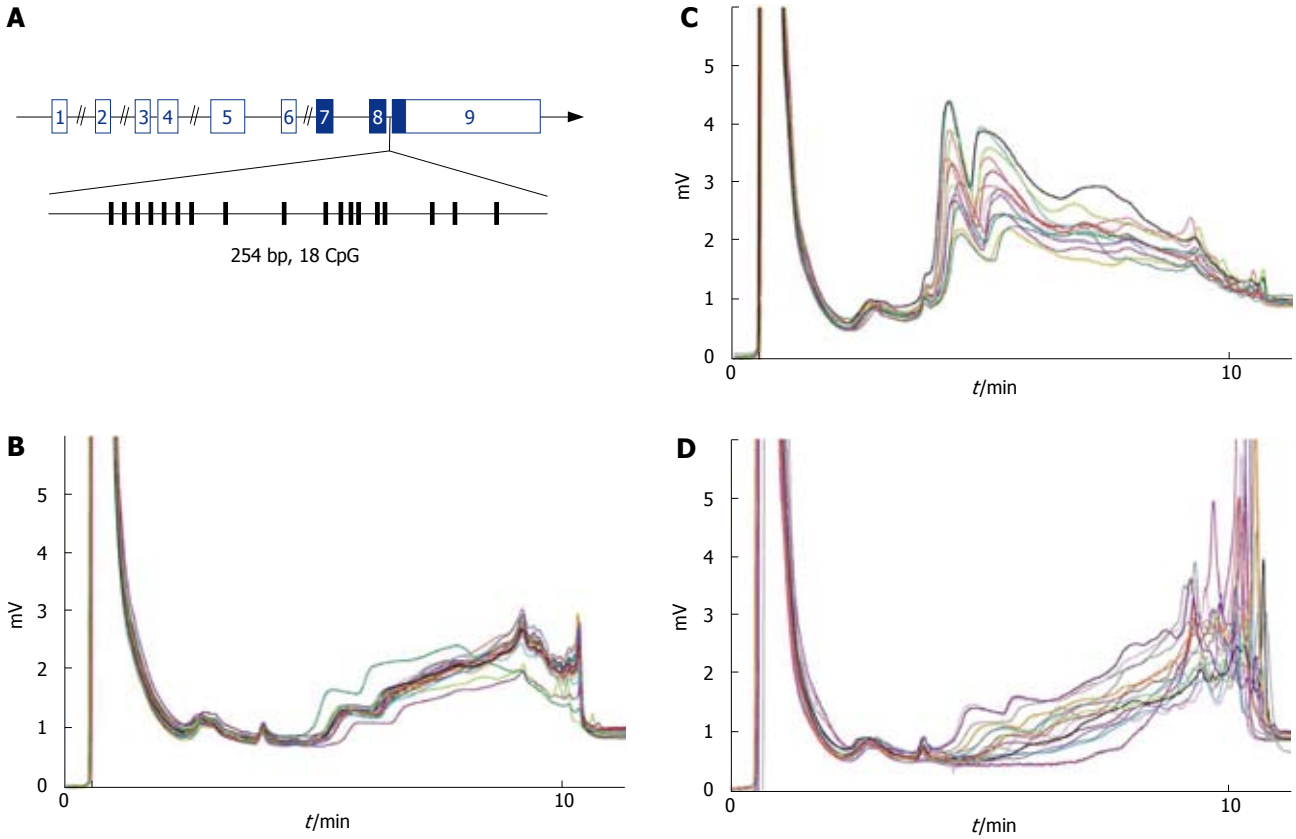

Figure 1 Methylation analysis of *Igf2* DMR2 in normal and HCV related cirrhosis livers. **A**: Exon-intron structure of *Igf2* gene. Exons are shown as numbered boxes (plain are coding). The 254bp fragment of *Igf2* DMR2 amplified for methylation analysis is enlarged below. Vertical lines indicate CpG positions. **B**: DHLPLC chromatograms of PCR products from normal liver samples. Twenty-two out of 25 are superimposable, and this major profile was used to assess hypermethylated profiles (ie more methylated than normal liver). **C** and **D**: DHPLC chromatograms of PCR products from HCV-related cirrhosis. Among 94 samples, 13 (**C**) and 17 (**D**) samples show respectively hypomethylated and hypermethylated profiles.

used for methylation analysis at the DMR of exon 8 and 9 of the *Igf2* imprinted gene (Figure 1A), as previously reported[42]. We amplified a DNA fragment encompassing 18 CpGs of the *Igf2* gene (Accession number AC005809; nt 43058-43312; 254 bp) by nested-PCR using the following primers: forward external 5'-GTTAAGAGGTTTTAGAGGTTATAGG-3', reverse external 5'-CCTTCCAAAACCTAACCTAAAAACA-3', forward internal 5'-GGGAAAGGGGTTTAGGAT-TTTTAT-3', reverse internal 5'-ATAATTTACTCCCCC-TTCAACCTC-3'. PCRs were performed in 3 mmol/L $MgCl_2$, 0.2 mmol/L dNTP, 0.5 μmol/L of each primer and 1.25 U of AmpliTaq Gold® DNA polymerase (Perkin Elmer, Norwalk, CT) under the following conditions: 94℃ for 10 min followed by 40 cycles of 94℃ for 45 s, 62℃ for 45 s, 72℃ for 1 min and a final extension step of 10 min at 72℃. After the first round of DNA amplification, a 1 μL aliquot of the PCR solution was used for the nested PCR.

Methylation profiles were studied by a newly developed DHPLC-based method, as previously described[44]. Briefly, DHPLC scanning was performed on an automated DHPLC instrument (WAVE®, Hitachi model D-7000. Chromatography Data Station Software, Transgenomic LTD Cheshire, UK); the column used was a DNAsep® Cartridge (Transgenomic, Santa Clara, CA) and the running temperature experimentally evaluated was 57℃. In a second step, methylation profiles of PCR products from liver biopsies were analyzed in comparison with PCR products from reference 100% methylated and 0% methylated control alleles, and with PCR product from normal liver biopsies. Fifteen microliter aliquots of the PCR products were eluted within a linear acetonitrile gradient. Because of the difference in retention times, the methylation patterns could be assessed by DHPLC independently of sequencing information by overlaying the DHPLC profiles with those of reference fragments. Methylation profiles were objectively classified in three categories as follows: samples displaying a higher proportion of methylated alleles than normal liver were considered as hypermethylated (M); samples which showed less methylation than normal liver were sorted according to the maximal absorbances of their first (4 min < retention time < 5 min, demethylated alleles) and last (10 min < retention time < 11 min, methylated alleles) elution specific peaks, by calculating R = [Abs (first peak) - Abs (baseline)]/[Abs (last peaks) - Abs (baseline)]; samples with R>2 (high proportion of demethylated alleles) were considered hypomethylated (U), the others being intermediate (UM). Reproducibility of the method was checked by double testing of randomly chosen

Continuous values are used for quantitative parameters. HR: Hazard ratio; CI: Confidence interval; HCC: Hepatocellular carcinoma; BMI: Body mass index; ALAT: Alanine amino-transferase; GGT: Gamma glutamyl transferase; ULN: Upper limit of normal; AFP: Alpha-foetoprotein; IGF2: Insulin-growth factor 2. [1]Performed in 63 patients.

samples. To rule out interpretation bias, clinical database including outcome of the patients, especially in relation to the occurrence of HCC, was kept by clinicians (NG, PN, JCT, MB) and not available for molecular biologists (PC, AK, AM, JC).

IGF2 serum quantification

Frozen serum collected at enrollment and stored at -25℃ was available in 63 (67%) of the 94 included patients. In these patients, serum IGF2 was quantified using an enzymatic amplified "two step" sandwich-type immunoassay (active IGF2 ELISA, Diagnostic Systems Laboratories, Webster, USA). Each sample was duplicated and tested blindly.

Statistical analysis

Data were expressed as mean ± SEM and percentages. All means were compared using the Mann-Whitney rank-sum test or the Kruskal-Wallis nonparametric analysis of variance. Furthermore, continuous variables were transformed into binary information according to median and cut-off points. Associations were tested in 2 × 2 cross tabulations using the Fisher's exact test. In case of larger cross tabulations, and as appropriate according to the validity conditions, liaisons were tested by the Pearson's Chi-square, or by computing either the exact probability value or the Monte Carlo estimate of the exact probability value. The basic non parametric Kaplan-Meier method[45] was used to search for heterogeneity of time-dependent cumulative probabilities of HCC according to levels of methylation and a linear trend between HCC probability and ordered methylation levels. From then on and practically, we used a series of tests, the Log Rank (Mantel-Cox) test, the Breslow test (Generalized Wilcoxon), and Tarone-Ware test in the two situations in which we attempted to test the heterogeneity of HCC occurrence or a linear trend between HCC probability and ordered methylation levels[46]. As regards to heterogeneity of risk according to *Igf2* levels, the Cox regression[47] was used for the estimation of the Hazard Ratios and 95% CI intervals. The 0.05 probability level was used for all statistical significance. Statistical analyses were performed using SPSS software (SPSS 10.05, SPSS Inc., Chicago, IL) and STATXACT (StatXact, CYTEL Software Corporation, Cambridge, MA).

In Table 1, the expression HR = 1.05 (1.01-1.09) is linguistically awkward, henceforth, 1.05 indicates that with each extra year in age the estimated hazard is 1.05 times that for subjects one year younger. Another way to express this variation is to convert it into a percentage difference in hazard by using the expression 100 × (HR - 1). Then, 100 × (1.05 - 1) = 5% tells us that the HR of HCC is 5% higher for each additional year of age.

RESULTS

Characterization and interpretation of methylation profiles

Methylation profiles of normal liver samples were highly

Table 2 Baseline characteristics according to the methylation profile at the *Igf2* locus (U, UM, and M, respectively, for hypomethylated, normal and hypermethylated patterns) in patients with Child-Pugh A hepatitis C-related cirrhosis

Quantitative variables are expressed as means (SD). BMI: Body mass index; ALAT: Alanine amino-transferase; ULN: Upper limit of normal; AFP: Alpha-foetoprotein; IGF2: Insulin growth factor 2; OV: Esophageal varices; HCV: hepatitis C virus. [1]Performed in 63 patients, [2]known in 78 patients (11, 52, 15 patients respectively in U, UM and M groups).

similar (Figure 1B) and 22 of 25 were superimposable. Among 94 tested patients, 13 (14%) were considered as hypomethylated (U), 64 (68%) as intermediate (UM) and 17 (18%) as hypermethylated (M) (Figure 1C). All double tested samples showed similar results in both experiments (data not shown).

Baseline patient characteristics

The main characteristics of patients at enrollment were not significantly different according to the methylation profile at the *Igf2* locus as shown in Table 2. All patients but 2 were Caucasians (1 from Africa with M profile and 1 from Asia with UM profile). In addition, the proportion of patients who received antiviral treatment during the study (72.7% in U, 58.8% in UM and 61.7% in M; $P = 0.738$), the proportion of sustained responders (22.2% in U, 31.4% in UM and 40.0% in M; $P = 0.707$), the mean follow-up (5.20 ± 3.63 years in U, 7.21 ± 3.09 years in UM, 7.22 ± 3.04 years in M; $P = 0.198$), were not statistically different between the three groups.

IGF2 serum quantification

Each IGF2 serum level measurement was duplicated and results were reproducible in 98% of cases. The mean serum value was 279.6 ng/mL (range, 36-640) without any significant difference between patients with U, UM or M methylation profiles at the *Igf2* locus (Table 2).

Predictive value for HCC

During a mean follow-up of 6.9 ± 3.2 years, 20 patients developed an HCC (4, 15 and 1 cases, in patients with U, UM and M methylation profile, respectively). The cumulative incidence of HCC at 10 years reaches 30.8% in patients with a U profile, 23.4% in patients with a UM profile, and 24.7% in patients with either a U or a UM profile in contrast with 5.9% only in patients with a M profile.

In the Cox analysis testing successively each of the 17 baseline studied variables, two were predictive for the occurrence of HCC: age at liver biopsy ($P = 0.01$; HR, 1.05; 95% CI, 1.01-1.09) and prothrombin time ($P = 0.04$, HR, 0.97; 95% CI, 0.95-1.00; Table 1). Moreover, a clear trend ($0.05 < P < 0.1$) was observed for 5 baseline variables: bilirubin, esophageal varices, Knodell score, serum IGF2 level and liver *Igf2* hypomethylation.

When patients with a U profile were compared in a paired way to those with M profile, the Log-Rank test was significant ($P = 0.047$). Moreover, the test for linear tendency between the 3 ordered levels of *Igf2* methylation and cumulative probability of HCC occurrence was significant (Log Rank, $P = 0.043$; Breslow, $P = 0.037$; Tarone-Ware, $P = 0.039$; Figure 2).

DISCUSSION

A growing body of evidence underlines that both DNA hypomethylation, leading to genomic instability, and regional CpG hypermethylation, leading to silence tumor suppressor gene, are dominant events during HCC development[48]. Calvisi *et al* recently showed that the extent of genome-wide hypomethylation progressively increased from non-neoplastic surrounding liver to fully malignant HCC[49], indicating that genomic hypomethylation is an important prognostic factor in HCC and opens the possibility of using molecular targets for chemoprevention or

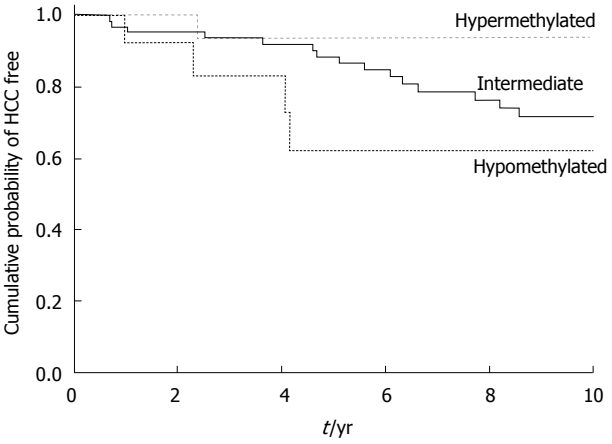

Figure 2 Occurrence of hepatocellular carcinoma at 10 years according to the methylation profile at the *Igf2* gene in 94 patients with Child-Pugh A hepatitis C-related cirrhosis (Kaplan-Meier method). Test of heterogeneity of HCC distributions: (log-rank test) $P = 0.13$. Test of the linear trend between levels of *Igf2* methylation and corresponding survival functions: Breslow (Generalized Wilcoxon) $P = 0.037$.

treatment of HCC. Regarding *Igf2* locus, we have observed hypomethylation at *Igf2* exon 8-9 in 90% (28/31) of HCV associated HCC, in contrast to the normal methylation pattern of two other genes located in the same area, the 11p15 locus[41]. This indicates that alterations in the IGF2 pathway are a pivotal event in hepatocarcinogenesis, at least in patients with HCV-related cirrhosis.

Our results suggest a possible link between *Igf2* hypomethylation in the liver of caucasians with uncomplicated and compensated HCV cirrhosis and the further occurrence of HCC. We observed a significant increased cumulative incidence of HCC at 10 years in patients with a hypomethylated pattern compared with those with a hypermethylated profile (30.8% *versus* 5.9%, $P = 0.047$) and a significant linear tendency between the ordered levels of *Igf2* methylation and the probability of HCC occurrence. The other variables identified in our patients were 2 well-known predictive factors for the occurrence of HCC: age[14-17] and prothrombin time related to liver failure[12,16-18] (Table 1). Due to a low number of patients, we could not show significant link with other known predictive factors (esophageal varices and bilirubin serum levels $0.05 < P < 0.08$). Conversely, as previous studies in patients with HCV-cirrhosis, we did not identify male gender[16,19], high AFP serum level[14,17], low platelet count[14,16,19] and diabetes[21] as predictive factors for the occurrence of HCC. These results, observed in Caucasians, may be different in other ethnic groups. However, IGF2 overexpression in HCC, which is mainly due to aberrant activation of the epigenetically regulated *Igf2* promoters, seems to be independent of ethnic origins. In addition to hypermethylation of promoters of several tumor suppressing genes found even in premalignant conditions, *Igf2* hypomethylation could thus contribute to the multistep process leading to malignant transformation[50].

This link between *Igf2* methylation and HCC occurrence should be validated in an external independent cohort. It may be underestimated in this study for several reasons. First, although the cumulative incidence was as high as previously reported in HCV-cirrhosis, the relative number of patients who further developed HCC ($n = 20$) is low. Secondly, being given cirrhotic liver heterogeneity and the small size of liver samples obtained by fine needle percutaneous biopsy, the extent of *Igf2* hypomethylation could have been underestimated. In addition, as samples were not microdissected, we analyzed not only hepatocytes, but also a variable amount of other minority hepatic cell types, such as sinusoidal cells and Kupffer cells, which may not share the same methylation pattern. Lastly, *Igf2* hypomethylation could be a late event in hepatocarcinogenesis, present to a low extent in uncomplicated cirrhosis and occurring later with the onset of liver failure and/or portal hypertension.

If there is a true link, whether these altered methylation patterns at *Igf2* locus lead to significant changes in expression profile and the function of genetic networks, or whether these changes just indicate severe epigenetic disturbances, remains to be investigated. A link between increased IGF2 expression and HCV infection has already been reported, showing that IGF2 over expression is significantly associated with HCV replication in patients with HCV-related cirrhosis[51]. The persistent process of hepatocyte damage and regeneration in HCV chronic hepatitis could provoke uncontrolled growth of hepatocytes and lead to malignant transformations due to disruption of growth regulation or mitogenic factors. However, whether HCV plays a direct or indirect role in IGF2 deregulation remains unknown. One could wonder if the link between Igf2 and HCC could be mediated by diabetes and metabolic syndrome. Indeed, epidemiological association between diabetes mellitus and HCC has been corroborated by molecular studies related to IGF1 or Igf Binding Protein 3. However, conversely to IGF1, IGF2 is mainly a fetal protein and its insulin-like metabolic effects in the post-natal period remains uncertain[52].

In these experiments, epigenetic changes in *Igf2*, potentially leading to re-expression of its fetal pattern, could be considered in parallel with AFP over expression as the hallmark of some fetal characteristics in the cirrhotic liver. The lack of correlation between the *Igf2* intron 8-9 methylation profile and IGF2 serum levels may be explained by an IGF2 local over expression leading to an autocrine effect, as previously suggested by Cariani *et al*[53].

Our observation that hypomethylation at the *Igf2* exon 8-9 is present in 14% of patients (13/94) with uncomplicated HCV-related cirrhosis and associated with a trend of overrisk of cancer are comparable to recent studies in the field of colorectal cancer[42,54]. Cui

et al[42] observed *Igf2* hypomethylation in normal colonic mucosa in 30% of patients with colorectal cancer in contrast to 10% in healthy patients. Moreover, *Igf2* hypomethylation is present in mesoderm-derived PBL and abnormal methylation profiles in this tissue are also highly correlated with both familial and personal histories of colorectal cancer. The prevalence of abnormal methylation patterns in PBL increases from 6.5% in patients with no personal history of colorectal cancer to 23% and 28%, respectively in patients with a personal history of adenoma or a family history of colorectal cancer, and to 56% in patients with colorectal cancer. These facts support a possible role of epigenetic changes of *Igf2* in the early steps of colorectal carcinogenesis. The most obvious unanswered question is whether the *Igf2* hypomethylation profile in PBL could be constitutive, resulting from inherited genetic mutations, or due to environmental events leading to epigenetic alterations. To try to answer this question in the field of HCC, further studies are ongoing in the PBL of a large cohort of patients with HCV-related cirrhosis screened for HCC and in healthy controls. If the results are comparable to those in patients with colorectal cancer, this may have clinical implications for defining high risk patients for HCC eligible for intensive screening and/or to reduce their risk with the use of dietary and/or therapeutic agents developed to reverse the epigenetic alterations such as methylated-oligonucleotides[55-57].

COMMENTS

Background

Hepatocellular carcinoma (HCC) is considered the fifth most frequent malignant neoplasm worldwide. In high incidence areas, it is strongly associated with viral hepatitis B and C and liver cirrhosis. Identification of molecular abnormalities associated with an increased risk of HCC is particularly important to improve knowledge of both the pathways of liver carcinogenesis and the outcomes.

Research frontiers

Insulin-like growth factor 2 (IGF2) is a fetal growth peptide produced by the liver, which is over expressed in a wide variety of neoplasms including HCC and is involved in experimental liver carcinogenesis. In a previous work analyzing the methylation status of *Igf2* in 71 HCC liver samples, we observed an hypomethylated profile in 89% of HCC.

Innovation and breakthroughs

Not only can *Igf2* hypomethylation be observed in HCC liver samples, but also in premalignant hepatitis C cirrhotic livers. In this case, *Igf2* hypomethylation is associated with a higher risk of HCC occurrence than *Igf2* hypermethylation.

Applications

Studies examining the Igf2 methylation status in hepatitis C cirrhotic liver could help identify patients with a high risk and patients with a low risk of HCC occurrence.

Peer review

This is a well designed study with interesting results. These results suggest that hypomethylation at the *Igf2* locus in the liver could be predictive for HCC occurrence in HCV cirrhosis.

Abstract

AIM: To study the secretory inhibitor of platelet microbicidal protein (SIPMP) phenotypes of faecal anaerobic isolates from patients with diarrhea.

METHODS: Faecal isolates of anaerobic bacteria (*B. fragilis*, n = 42; *B. longum*, n = 70; *A. israelii*, n = 21; *E. lentum*, n = 12) from children with diarrhea were tested. SIPMP production was tested by inhibition of platelet microbicidal protein (PMP) bioactivity against *B. subtilis* and was expressed as percentage of inhibition of PMP bactericidal activity.

RESULTS: Among anaerobic isolates 80% of *B. longum* strains, 85.7% of *A. israelii* strains, 50% of *E. lentum* strains and 92.86% of *B. fragilis* strains were SIPMP-positive. The isolated anaerobic organisms demonstrated SIPMP production at a mean level of 13.8% ± 0.7%, 14.7% ± 1.8%, 3.9% ± 0.9% (P < 0.05) and 26.8% ± 7.5% (P < 0.05) for bifidobacteria, *A. israelii*, *E. lentum* and *B. fragilis,* respectively.

CONCLUSION: Data from the present study may have significant implications in understanding the pathogenesis of microecological disorders in the intestine, as well as for future improvement in the prevention and therapy of anaerobe-associated infections.

Distribution of secretory inhibitor of platelet microbicidal protein among anaerobic bacteria isolated from stool of children with diarrhea. *World J Gastroenterol* 2008; 14(35): 5428-5431 Available from: URL: http://www.wjgnet.com/1007-9327/14/5428.asp DOI: http://dx.doi.org/10.3748/wjg.14.5428

INTRODUCTION

Anaerobic microorganisms are important constituents of human intestinal microbiota[1]. Enzymes produced by these bacteria provide nutrients for growth, participate in the pathogenesis of infections involving these bacteria, *etc.* Infections caused by anaerobic bacteria are increasingly being recognized as a major problem in clinical medicine[2,3]. The commensal anaerobic bacterial flora of the colon may undergo changes during diarrhea, owing to colonization of the intestine by pathogens and to rapid intestinal transit[4]. As it is difficult to establish exactly the significance of various anaerobic microorganisms in the pathogenesis of infections, it is imperative to delineate both microbial and host factors that contribute to its development. Identifying such a factor(s) produced by anaerobes is important for understanding and possibly modulating interactions between these bacteria and the host.

The intestinal mucosa forms a primary barrier providing both barrier function and immediate effective recognition of bacterial products invading the mucosa. This is of great importance for the prevention of permanent and chronic inflammation as a reaction to the commensal intestinal flora and the multitude of antigens present in the intestinal lumen[5].

The major role of endogenous cationic antimicrobial peptides in preventing the onset of infection has been emphasized recently[6,7]. In mammals, these peptides have evolved to have a central function in the host defense properties of granulocytic leukocytes, mucosal surfaces, skin and other epithelia[7]. Antibacterial protection of intestinal mucosa is provided in part by Paneth cell-derived antibacterial peptides[8-10]. Such peptides have also been found by several authors in human platelets

and are designated platelet microbicidal proteins (PMPs)[11,12]. These peptides are secreted at sites of infection and exert microbicidal activity against many pathogens[11]. Bukharin *et al* showed that an enhanced level of PMP in coprofiltrates of patients is associated with *Salmonella* gastroenteritis[13]. However, we suspect that successful pathogens (especially anaerobes) would have involved mechanisms to resist or degrade the inhibitory and microbicidal activities presented by the host. For example, in a recent publication[14], we reported the detection of an extracellular staphylococcal product, designated secretory inhibitor of platelet microbicidal protein (SIPMP), which causes local inhibition of the bactericidal action of PMP in the fluid phase. We also demonstrated that SIPMP represents a hitherto unrecognized determinant of staphylococcal pathogenicity and SIPMP production is associated with a prostatitis source.

At the same time, it is surprising that no extracellular product of anaerobic microorganisms with remarkable anti-PMP potential has been described. Thus, in this communication we report on *in vitro* detection of SIPMP phenotypes of faecal anaerobic isolates from patients with diarrhea.

MATERIALS AND METHODS

Clinical isolates were obtained from diarrhea stool samples collected from April to December 2000 in Orenburg Regional Child Hospital. A total of 145 strains of anaerobic bacteria (*B. fragilis*, $n = 42$; *B. longum*, $n = 70$; *A. israelii*, $n = 21$; *E. lentum*, $n = 12$) were kindly provided by Natalia Elagina (Department of Dysbiosis, Institute of Cellular and Intracellular Symbiosis). Bacteria were isolated from children with diarrhea (ranging from 10 mo old to 6 year old) and identified at the Anaerobe Laboratory, Department of Dysbiosis, Institute of Cellular and Intracellular Symbiosis, Russian Academy of Sciences, Orenburg.

PMP was prepared and standardized as described previsiously[12].

SIPMP production was performed by viable counting according to the recently proposed procedures[14]. Strains were grown in brain heart infusion broth (BHI, Oxoid), supplemented with yeast extract (0.5%) under anaerobiosis conditions (90% N_2/10% CO_2), at 37℃, for 48 h and cell-free supernatants were obtained by centrifugation. Bacterial supernatants were sterilized by filtration *via* 0.45 μm pore-size membranes (Millipore). Each culture supernatant (0.6 mL) (an equal volume of BHI was loaded in the control tubes) was combined with 0.3 mL of PMP at 3.0 μg/mL and incubated at 37℃. After 1 h, 100 μL *B. subtilis* suspension at 10^4 CFU/mL was added to each of the tubes. The tubes were incubated on a rotary shaker (300 r/min) at 37℃. After 1 h, aliquots of 200 μL were plated on blood agar plates. Colonies were counted after incubating overnight at 37℃ and numbers of surviving microorganisms were calculated. The SIPMP production as expressed in percentage of inhibition of PMP bactericidal activity and calculated by using the formula: % inhibition = (No. - Nk1) × 100/(Nk2 - Nk1), where No. was the number of surviving *B. subtilis* cells in the presence of bacterial supernatant and PMP, Nk1 was the number of surviving *B. subtilis* cells in the presence of PMP alone, and Nk2 was the number of surviving *B. subtilis* cells in BHI.

All of the experiments were carried out in triplicate and mean values and SEM were calculated. The differences between groups of microorganisms were assessed by using Student's *t*-test. $P \leqslant 0.05$ was considered significant.

Table 1 SIPMP production of fecal isolates of anaerobic bacteria *n* (%)

Organism	No. of SIPMP-producing strains (total/%) with different levels of SIPMP[1]			
	0	0.1-10.0	10.1-20.0	> 20
B. longum ($n = 70$)	14 (20)	0 (0)	56 (80)	0 (0)
A. israelii ($n = 21$)	3 (14.3)	0 (0)	18 (85.7)	0 (0)
E. lentum ($n = 12$)	6 (50)	6 (50)	0 (0)	0 (0)
B. fragilis ($n = 42$)	3 (7.14)	0 (0)	2 (4.76)	37 (88.1)

[1]SIPMP was expressed in percentage of inhibition of PMP bactericidal activity.

RESULTS

For exclusion the cooperative inhibitory effect of PMP and culture supernatants on *B. subtilis*, each culture supernatant was combined with *B. subtilis* suspension. After coincubation for 1 h, aliquots were plated on blood agar plates. Colonies were counted after incubating overnight at 37℃ and numbers of surviving microorganisms were calculated. None of the supernatants tested inhibited growth of *B. subtilis* cells. The stability of SIPMP was tested by subjecting culture supernatants to boiling for 30 min. This treatment completely destroyed the biological activity of SIPMP. Among anaerobic isolates 80% of *B. longum* strains, 85.7% of *A. israelii* strains, 50% of *E. lentum* strains and 92.86% of *B. fragilis* strains were SIPMP-positive (Table 1). The extracellular products of bacteria reduced the PMP-induced killing of *B. subtilis*. The isolated anaerobic organisms demonstrated SIPMP production at a mean level of 13.8% ± 0.7%, 14.7% ± 1.8%, 3.9% ± 0.9% ($P < 0.05$) and 26.8% ± 7.5% ($P < 0.05$) for bifidobacteria, *A. israelii*, *E. lentum* and *B. fragilis* respectively.

DISCUSSION

At local sites of microbial infections, epithelial cells, platelets, neutrophils, or macrophages release large amounts of different bactericidal peptides[7]. However, most infections are the result of contamination of host tissues with anaerobic flora from the gut[15] despite the presence of multiple antibacterial peptides in intestinal cells and mucus[7,16,17]. There is an urgent need to understand the virulence properties of anaerobic

organisms that may take part in their resistance to cationic antimicrobial peptides; identifying such a factor(s) would be helpful in devising effective treatment strategies.

In the present work, we detected an extracellular bacterial product of anaerobic microorganisms with remarkable anti-PMP potential which, to our knowledge, has not been described before. We anticipate that SIPMP serves to protect invading bacteria by inducing local consumption of PMP in the fluid phase. The strategy underlying this process would be straightforward and effective. We believe that SIPMP represents a widespread and hitherto unrecognized determinant of bacterial pathogenicity. Similarly, in a study of distribution of streptococcal inhibitor of complement variants in pharyngitis and invasive isolates by Hoe *et al*[18], 62% of group A streptococci from patients with pharyngitis produced this extracellular protein. Collectively, our study and the results of several studies[19-21] suggest that the inactivation of components of innate immunity may be important for bacterial pathogens to induce and perpetuate infections of different localization by surviving or avoiding microbicidal proteins mediated clearance. Bacteria-derived proteases may contribute to mucosal surface destruction, and are likely to impair host defense by degrading antimicrobial peptides[22]. It was confirmed by the fact that the lowest level of SIPMP production was observed with the non-protease producing species *E. lentum*. On the other hand, proteases of anaerobic microorganisms caused platelet aggregation with followed by release of a number of antibacterial proteins[11,23].

In contrast to *B. fragilis*, normal microflora have low levels of SIPMP. Hypothetically, the constituents of normal flora must have basal levels of resistance to the antimicrobial host defense factors. It is possible that low levels of inactivation of PMP activity by normal organisms are sufficient to protect them from PMP-dependent killing, thus providing stability of intestinal microflora. We believe that SIPMP is the stable characteristic and the same strains express more SIPMP in case of infection. On the other hand, our results suggest that the normal microflora was replaced by other organisms with pronounced pathogenic properties in patients with persistent infection[24].

At the same time, in the presence of infections, properties of normal microflora probably could change. The constituents of normal microflora, receiving signs of pathogenicity, are capable of causing diseases, as has been shown for lactobacilli and staphylococci[24,25].

The predominantly anaerobic microbiota of the distal ileum and colon contain an extraordinarily complex variety of metabolically active bacteria that intimately interact with the host's epithelial cells and mucosal immune system[26]. Crohn's disease, ulcerative colitis, and pouchitis are the result of continuous microbial antigenic stimulation of pathogenic immune responses as a consequence of host genetic defects in mucosal barrier function, innate bacterial killing, or immunoregulation. Identification of these host and microbial alterations in individual patients should lead to selective targeted interventions that correct underlying abnormalities and induce sustained and predictable therapeutic responses[27]. New treatment strategies aim at neutralization of such pathogenic properties of microorganisms as pronounced resistance to the cationic antimicrobial peptides and/or ability to inhibit the antimicrobial host defense factors and thereby improve the quality of life in patients[28-30].

Data from the present study may have significant implications in understanding the pathogenesis of microecological disorders in intestine, as well as for future improvement in the prevention of and therapy for anaerobe-associated infections. However, the exact mechanism of PMP inhibition in anaerobic bacteria remains to be determined, as does its molecular characteristics, occurrence and possible significance *in vivo*.

COMMENTS

Background

Anaerobic microorganisms are important constituents of human intestinal microbiota. Infections caused by anaerobic bacteria are increasingly being recognized as a major problem in clinical medicine. The commensal anaerobic bacterial flora of the colon may undergo changes during diarrhea, owing to colonization of the intestine by pathogens and to rapid intestinal transit. The major role of endogenous cationic antimicrobial peptides in preventing the onset of infection has been emphasized recently. Such peptides have been found in platelets and are designated platelet microbicidal proteins (PMPs). It is shown that an enhanced level of PMP in coprofiltrates of patients is associated with *Salmonella* gastroenteritis. Here we made an attempt to *in vitro* detection of secretory inhibitor of platelet microbicidal protein (SIPMP) phenotypes of faecal anaerobic isolates from patients with diarrhea.

Research frontiers

The article focuses on inhibition of PMP by extracellular bacterial products of faecal anaerobic microorganisms isolated from stool of children with diarrhea. Among anaerobic isolates 80% of *B. longum* strains, 85.7% of *A. israelii* strains, 50% of *E. lentum* strains and 92.86% of *B. fragilis* strains were SIPMP-positive. The isolated anaerobic organisms demonstrated SIPMP production at a mean level of 13.8% ± 0.7%, 14.7% ± 1.8%, 3.9% ± 0.9% ($P < 0.05$) and 26.8% ± 7.5% ($P < 0.05$) for bifidobacteria, *A. israelii*, *E. lentum* and *B. fragilis*, respectively.

Innovations and breakthroughs

In the present work, the authors detected an extracellular bacterial product of anaerobic microorganisms with remarkable anti-PMP potential that has not been described before. SIPMP represents a widespread and hitherto unrecognized determinant of bacterial pathogenicity.

Applications

Data from the present study may have significant implications in understanding the pathogenesis of microecological disorders in intestine, as well as for future improvement in the prevention and therapy of anaerobe-associated infections.

Terminology

PMP is a group of small cationic peptides isolated from rabbit and human platelets after stimulation by acid or thrombin; the secretory inhibitor of PMP is an extracellular bacterial product with anti-PMP activity.

Peer review

In this manuscript, the authors reported the detection of SIPMP phenotypes of faecal anaerobic isolates from patients with diarrhea. The study was well performed and interesting.

Abstract

AIM: To evaluate the role of pentavalent Tc-99m dimercaptosuccinic acid [Tc-99m (V) DMSA] in the diagnosis of ischemic colitis.

METHODS: Fourteen patients with endoscopically and histologically confirmed ischemic colitis were included in the study. Tc-99m (V) DMSA scintigraphy was performed within 2 d after colonoscopy. Images were considered positive when an area of increased activity was observed in the region of interest and negative when no abnormal tracer uptake was detected.

RESULTS: In 3 out of the 14 patients, Tc-99m (V) DMSA images showed moderate activity in the bowel. The scintigraphic results corresponded with the endoscopic findings. In the other 11 patients, no abnormal tracer uptake was detected in the abdomen.

CONCLUSION: Besides the limited number of patients, Tc-99m (V) DMSA could not be considered as a useful imaging modality for the evaluation of ischemic colitis.

INTRODUCTION

Ischemic colitis (IC) initially was described by Boley *et al* in 1963[1] and represents the most common form of gastrointestinal ischemia[2]. It is presented either as an occlusive or a nonocclusive form, usually seen in the elderly population with associated co-morbid factors[2-4]. Its pathophysiologic characteristic is the sudden loss of blood flow and the extent of damage is proportional to the degree and the duration of tissue hypoxia[5,6]. Moreover the disruption of the mucosal barrier may lead to inflow of intraluminal bacteria and toxins from the gut[3]. The clinical spectrum ranges from transient self-limited ischemia with brief episodes of abdominal pain and rectal bleeding to fulminant transmural necrosis, perforation and death[5,6]. The histological findings include mucosal necrosis and ulcerations, submucosal edema and haemorrhage or transmural infarction[2,3,5].

The identification of colonic ischemia is highly dependent upon clinical suspicion[2,7]. Although invasive, colonoscopy and colonic biopsies have become the standard for diagnosing ischemic colitis[6,8].

The radionuclide imaging in IC is an area under investigation. Since mucosal inflammatory changes often coexist with bowel ischemia, radiotracers used to localise inflammation could probably play an important role in the diagnosis of IC. A few reports of the scintigraphic findings using radionuclide labelled leukocytes have been published[9-12]. Moreover, recently pentavalent Tc-99m dimercaptosuccinic acid [Tc-99m (V) DMSA] has been successfully used in the identification of intestinal inflammation[13-15]. To our knowledge, its role in the diagnosis of intestinal ischemia has not been yet reported in the literature.

The aim of the present study was to determine

whether Tc-99m (V) DMSA scintigraphy could provide an alternative non-invasive imaging modality in the diagnosis of IC.

MATERIALS AND METHODS

Patients

We examined fourteen patients, (5 males and 9 females, mean age 70.6 years) with clinically, endoscopically and histologically confirmed IC. All patients included were admitted at the Department of Gastroenterology of the University Hospital Heraklion, Crete, Greece, within two days after the onset of symptoms. The patients were non-surgically treated and non-received medical therapy that would interfere with scintigraphic results. Half of the patients reported daily tobacco use. Endoscopic assessment was performed the day following the hospital admission in all cases.

Concerning the disease type, transient IC was the most frequent presenting in 9 patients (62.4%) followed by reversible ischemic colopathy in 3 patients (21.4%), chronic ulcerative IC in 1 patient (7.1%) and ischemic colonic stricture in 1 patient (7.1%).

The lesions were distributed depending on their locations: splenic flexure in 8 patients (57.1%), rectosigmoid in 3 patients (21.4%), right colon in 2 patients (14.2% and extensive IC in 1 patient (7.1%)

All patients were subjected to standard laboratory tests such as red and white blood cell counts, haemoglobin and hematocrit level, platelet count, albumin level, erythrocyte sedimentation rate and C-reactive protein level. Colonoscopy with biopsies was performed in all patients. The endoscopic findings for each bowel segment were evaluated by blinded specialists.

The study was approved by the ethics committee and patients were provided with an informed consent.

Scintigraphic imaging

Tc-99m (V) DMSA scintigraphy was performed in fourteen patients with IC. In all patients scintigraphy was performed within 2 d after colonoscopy, in order to avoid any variation in disease activity. Imaging was performed after intravenous administration of 555 MBq (15 mCi) of Tc-99m (V) DMSA. A gamma-camera (Millenium; GE Medical Systems, Milwaukee, Wis) equipped with a low energy all purpose collimator was used. With the patient in the supine position, planar views of the abdomen were obtained 4 hours after radiotracer injection. Before scanning patients were asked to void their bladders to avoid false results.

The bowel was divided to five segments: small bowel (A), ascending colon (B), transverse colon (C), descending colon (D) and rectosigmoid (E). Images were considered positive when an area of increased uptake was observed and negative when no abnormal tracer uptake was detected in any of the five segments. In the event of a positive result, semi quantitative measurements were included with reference to the uptake in the iliac crest and was graded as: 0: No uptake in the region of interest, 1: Faint uptake less than the iliac crest bone marrow, 2: Moderate uptake similar to that of the iliac crest, 3: Severe uptake greater than the iliac crest bone marrow.

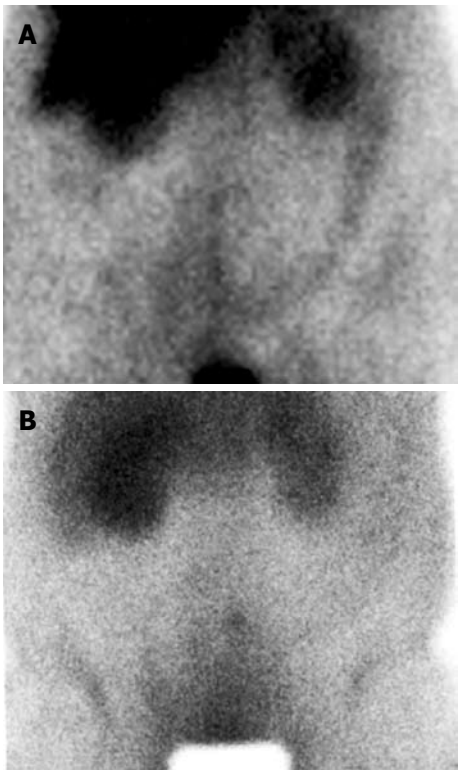

Figure 1 Anterior Tc-99m (V) DMSA scintigram in a patient with ischemic colitis: Moderate uptake of the radiotracer in the splenic flexure and the descending colon (**A**) and no uptake of the radiotracer in the bowel (**B**).

Scintigrams were blindly evaluated by three nuclear medicine physicians (MIS, SIK, NSK) and the results were compared with endoscopic and clinical data.

RESULTS

No patients showed adverse events during or after scintigraphy. A total of fourteen patients were included in this study. In all patients, endoscopy revealed characteristic findings suggestive of IC, which was histologically confirmed. In three out of the fourteen patients, the Tc-99m (V) DMSA scintigraphy demonstrated moderate uptake in the bowel (Figure 1A). Compared to endoscopic findings, radionuclide images were in agreement with the segments concerned. In the other eleven patients, Tc-99m (V) DMSA revealed no increased uptake in the bowel at all (Figure 1B).

Positive cases included one case with localization in the splenic flexure, one with ischemic rectosigmoiditis and one with extensive IC. Concerning the disease type among positive cases there were two cases with transient IC and one with chronic ulcerative IC. The small number of cases does not permit further statistical analysis.

The calculated sensitivity was only 21.4%. Owing to the low sensitivity and the false-negative results the study was stopped.

DISCUSSION

The most important finding in our study was that the majority of the patients with IC, who underwent Tc-99m (V) DMSA scintigraphy, yielded false- negative results. Only three of them showed increased tracer uptake in the regions of interest which corresponded with the findings at colonoscopy.

The pathophysiologic basis of IC is the sudden loss of blood supply. Localized low flow states involve mostly the splenic flexure and the rectosigmoid junction while systemic low flow states involve mostly the right colon, follow a relatively benign course and may affect younger patients[4,5,7,8].

Colonic ischemia may be precipitated by several conditions, such as shock, colon cancer, surgical intervention on the aorta or the mesenteric vessels, autoimmune disease, coagulopathies, long-distance running, constipation, illicit drug use and medications[2,4,6]. Recent studies have suggested a role of prothrombotic disorders in the development of IC[16,17].

No test specific for IC has yet been developed. The diagnosis of IC depends on the clinical evaluation of the patient in association with the biochemical, radiological, endoscopic and histologic assessment[18]. Most laboratory tests will be normal usually, yet in the event of abnormal results they have been found nonspecific[3,5,8].

Radiological evidence includes a wide spectrum of findings, which are frequently nonspecific, insensitive, and often they cannot easily differentiate ischemic from other forms of colitis[5,7,8].

Endoscopic assessment is the most sensitive and specific method of evaluating the colon for ischemic injury. The visual inspection and the ability to biopsy the mucosa allow the clinician in the majority of cases to make a firm diagnosis[6,8].

CT imaging has been employed in the evaluation of patients with abdominal pain of unknown etiology. Besides its limitations, it may be used to detect abnormalities and suggest the diagnosis, exclude other serious medical conditions and narrow the differential diagnosis[19-21].

Non-invasive Doppler sonography has been used as well. Although a high specificity has been reported, it is limited by overlying bowel gas, operator dependent quality and poor sensitivity for low flow vessel disease[3,5,8].

More recently, scintigraphic methods have been used in the diagnosis of IC. In-111 or Tc-99m labeled leukocyte scintigraphy has been studied and demonstrated successful imaging of bowel infarction, yet the localization mechanism still remains unclear. It is suggested that the presence of polymorphonuclear leukocytes in the inflammatory response to tissue ischemia, as a result of reperfusion injury may play the primary role[9-12]. However, the time-consuming preparation procedure, the handling and the reinjection of blood constitute shortcomings of radiotracer labeled leukocyte imaging.

Tc-99m (V) DMSA is a low-molecular weight complex that has been used successfully in the scintigraphic diagnosis of inflammation[22,23]. The suggested mechanisms of uptake by inflammatory lesions is either the infiltration into the interstitial space caused by increased capillary permeability or its similar behavior to phosphate ion since it seems to accumulate in areas where calcification is present[22,23].

Its role in the evaluation of intestinal inflammation has been already reported[13,14], moreover when compared to Tc-99m HMPAO labeled leukocytes, it seems to provide a useful, non-invasive, practical, easy to prepare and accurate alternative method for the assessment of disease activity in patients with IBD[15].

Based on the simultaneous presence of inflammatory response to tissue ischemia, we assumed that Tc-99m (V) DMSA could localize successfully the ischemic bowel and assist in the detection and diagnosis of IC.

The results of our study stand in contrast with the aforesaid assumption. The expected abnormally increased uptake was detected only in three out of the fourteen patients with IC while all other cases yielded false-negative scintigraphic results which were probably due to the presence of a milder degree of inflammatory response compared to the positive ones. It is possible that in the false negative cases of our study there was mainly a transient mucosal congestion and the chronic inflammation was not sufficient to provide successful bowel uptake of the radiotracer.

In conclusion, our data suggest that Tc-99m (V) DMSA has no possible role in the detection and diagnosis of IC.

COMMENTS

Background

Pentavalent Tc-99m dimercaptosuccinic acid [Tc-99m (V) DMSA] has been proved advantageous in the imaging of various inflammatory lesions, intestinal inflammation included.

Research frontiers

Tc-99m (V) DMSA could successfully localize the ischemic bowel and assist in the diagnosis of IC due to the simultaneous presence of inflammatory response to tissue ischemia.

Innovations and breakthroughs

We examined fourteen patients, (5 males and 9 females, mean age 70.6 years) with clinically, endoscopically and histologically confirmed IC. In all patients scintigraphy was performed within 2 d after colonoscopy, in order to avoid any variation in disease activity. In three out of the fourteen patients, the Tc-99m (V) DMSA scintigraphy demonstrated moderate uptake in the bowel however in the other eleven patients, Tc-99m (V) DMSA revealed no increased uptake in the bowel at all (false negative results).

Applications

Despite the fact that Tc-99m (V) DMSA scintigraphy has been used successfully in the evaluation of intestinal inflammation it seems to have no role in the diagnosis of ischemic colitis.

Peer review

The present study is relevant as it emphasizes the role of radionuclide imaging in IC and the focus of interest in future studies.

Abstract

AIM: To investigate the effectiveness of direct hemoperfusion with polymyxin B-immobilized fibers (DHP-PMX therapy) on warm ischemia-reperfusion (I/R) injury of the small intestine.

METHODS: The proximal jejunum and distal ileum of mongrel dogs were resected. Warm ischemia was performed by clamping the superior mesenteric artery (SMA) and vein (SMV) for 2 h. Blood flow to the proximal small intestine was restored 1 h after reperfusion, and the distal small intestine was used as a stoma. The experiment was discontinued 6 h after reperfusion. The dogs were divided into two groups: the DHP-PMX group (n = 6, DHP-PMX was performed for 180 min; from 10 min prior to reperfusion to 170 min after reperfusion) and the control group (n = 5). The rate pressure product (RPP), SMA blood flow, mucosal tissue blood flow, and intramucosal pH (pHi) were compared between the two groups. The serum interleukin (IL)-10 levels measured 170 min after reperfusion were also compared.

RESULTS: The RPP at 6 h after reperfusion was significantly higher in the PMX group than in the control group (12 174 ± 1832 mmHg/min *vs* 8929 ± 1797 mmHg/min, $P < 0.05$). The recovery rates of the SMA blood flow at 1 and 6 h after reperfusion were significantly better in the PMX group than in the control group (61% ± 7% *vs* 44% ± 4%, $P < 0.05$, and 59% ± 5% *vs* 35% ± 5%, $P < 0.05$, respectively). The recovery rate of the mucosal tissue blood flow and the pHi levels at 6 h after reperfusion were significantly higher in the PMX group (61% ± 8% *vs* 31% ± 3%, $P < 0.05$ and 7.91 ± 0.06 *vs* 7.69 ± 0.08, $P < 0.05$, respectively). In addition, the serum IL-10 levels just before DHP-PMX removal were significantly higher in the PMX group than in the control group (1 569 ± 253 pg/mL *vs* 211 ± 40 pg/mL, $P < 0.05$).

CONCLUSION: DHP-PMX therapy reduced warm I/R injury of the small intestine. IL-10 may play a role in inhibiting I/R injury during DHP-PMX therapy.

Key words: Ischemia-reperfusion injury; Interleukin-10; Polymyxin B-immobilized hemoperfusion cartridge; PMX

INTRODUCTION

The small intestinal villi are extremely sensitive to ischemia-reperfusion (I/R) injury, and many microcirculatory disturbances contribute to structural and functional changes[1]. I/R injury of the small intestine is consequently a critical problem that is important in situations such as the interruption of blood flow to the intestines due to abdominal aortic aneurysm surgery, small intestinal transplantation, surgery involving cardiopulmonary bypass, strangulated hernias, and neonatal necrotizing enterocolitis[2]. Intestinal I/R injury produces injury in both the intestines and distant organs including the lungs, kidneys, and liver[3]; therefore, it is associated with

high rates of morbidity and mortality in both surgical and trauma patients[4].

A polymyxin B-immobilized fiber column (PMX cartridge, Toraymyxin; Toray Industries, Tokyo, Japan), which was developed in Japan in 1994, is an extracorporeal hemoperfusion device that uses polymyxin-B fixed to α-chloroacetamide-methyl polystyrene-derived fibers packed in the cartridge. Direct hemoperfusion with PMX (DHP-PMX) therapy can remove circulating endotoxins and reduce various cytokines, even in patients with high levels of plasma cytokines[5]. DHP-PMX has been used for the treatment of endotoxemia[6] and reported to lower inflammatory cytokine and plasminogen activator inhibitor-1 (PAI-1) levels immediately[7]. DHP-PMX therapy has also been attempted for severe sepsis secondary to intra-abdominal infection[8], acute lung injury, and acute respiratory distress syndrome caused by sepsis[9], and its effectiveness has been reported. Recently, we hypothesized that DHP-PMX therapy could reduce I/R injury and demonstrated the usefulness of this therapy on pulmonary warm I/R injury in a canine model[10].

In this study, we evaluated the effectiveness of DHP-PMX on warm I/R injury of the small intestine using a canine model.

MATERIALS AND METHODS

Animals

Eleven adult mongrel dogs of both sexes, weighing 7.5-15.5 kg, were used in this study. The dogs were fasted but had free access to water for 24 h prior to the experiment. All of the animals were cared for in accordance with the guidelines set forth in the Guide for the Care and Use of Laboratory Animals published by the National Institutes of Health (NIH publication 85-23; revised 1985). This study was also approved by the Animal Care and Experimentation Committee, Gunma University, Showa Campus, Japan.

Surgical procedures

After intramuscular administration of ketamine hydrochloride (2 mg/kg), the animals were anesthetized. Endotracheal intubation was performed, and the animals were ventilated with a respirator (Servo Ventilator 900C; Siemens-Elema, Solna, Sweden). The inspired O_2 concentration (FIO_2) was set at 1.0 during the experiment. Mechanical ventilation was performed with a tidal volume of 20 mL/kg and a rate of 10 breaths/min. General anesthesia was maintained with the inhalation of 1% to 2% isoflurane, and muscular relaxation was obtained with additional pancuronium bromide (0.1 mg/kg) every 20 min. The surgery was performed under sterile conditions. A polyethylene catheter was positioned in the abdominal aorta through the right femoral artery and connected to a pressure transducer to record arterial pressure. Another polyethylene catheter was inserted into the right femoral vein to use as a venous infusion line. The infusion rate for the lactated Ringer's solution was set at 30 mL/kg per h for 6 h after reperfusion. Laparotomy was performed *via* a midline incision after the blood pressure and respiration parameters stabilized. The small intestine was isolated with the vascular pedicle, and both the superior mesenteric artery (SMA) and the superior mesenteric vein (SMV) were dissected from the surrounding lymph nodes, plexuses, and tissues. The proximal jejunum and distal ileum were resected to interrupt the intramural blood flow. Warm ischemia was induced by clamping the SMA and SMV for 2 h. Proximal intestinal continuity was restored with an end-to-end anastomosis 1 h after the reperfusion. The resected distal intestine was used as a stoma to measure the tissue blood flow and pHi. During the 6-h experimental period, the abdominal cavity was closed and opened temporarily for each measurement. The experiment was discontinued 6 h after the reperfusion. Catecholamines were not used at any point during the experiment.

Experimental groups

The experimental study was composed of two groups: the DHP-PMX group (n = 6) and the control group (n = 5). The animals were randomly assigned to either the DHP-PMX group or the control group. In the DHP-PMX group, a double-lumen catheter was inserted into the portal vein through the left gastric vein, and DHP with PMX was performed with a flow rate of 80 mL/min for 180 min (from 10 min prior to reperfusion to 170 min after reperfusion) using that catheter. DHP was not performed in the control group.

Arterial blood pressure and heart rate (HR)

The arterial blood pressure and HR were directly monitored through a catheter connected to a transducer (Spectramed TA 1017; San-ei Co., Tokyo, Japan). The rate pressure product (HR × systolic pressure, RPP) was also calculated.

SMA blood flow

The SMA blood flow was measured prior to ischemia and at 1, 3, and 6 h after reperfusion using an electromagnetic blood flow meter (Model MFV-3100; Nihonkohden Co., Ltd., Tokyo, Japan). The SMA blood flow was expressed as the percentage of the level that was determined prior to ischemia.

Tissue blood flow measurements

The tissue blood flow was measured in the small bowel mucosa using a laser Doppler flow meter (ALF 21; Advance Co., Ltd., Tokyo, Japan) prior to ischemia and at 1, 3, and 6 h after reperfusion. Each measurement was made at three points by inserting a probe through the stoma and placing it against the antimesenteric side of the bowel lumen. The laser probe reading reflects tissue blood flow within about 1.0 mm of the surface of the bowel wall. Tissue blood flow was calculated as the mean of the three measurements and expressed as the percentage of the level determined prior to ischemia.

Intramucosal pH (pHi) measurements

pHi was measured prior to ischemia and at 1, 3, and 6 h

after reperfusion. This method has been described previously[11]. In brief, a tonometer (Trip; Tonometrics, Helsinki, Finland) was inserted into the small bowel lumen through the stoma. Within 40 min, the PCO_2 of the saline in the balloon placed at the tip of the tonometer had equilibrated with the intraluminal PCO_2, which reflects the mucosal PCO_2 of the bowel. The HCO_3^- concentration in the bowel wall was assumed to be the same as the HCO_3^- concentration in the arterial blood. The saline PCO_2 and HCO_3^- concentration in the artery were determined with a blood gas analyzer (Stat Profile M; Nova Biomedical Co., Waltham, MA) and were used to calculate the pHi using the Henderson-Hasselbach equation: pHi = 6.1 + log[arterial HCO_3^-/(0.03 × saline PCO_2)].

Measuring serum interleukin-10 (IL-10) levels

Arterial blood samples were collected 170 min after reperfusion (that is just before DHP-PMX removal) for measuring serum IL-10 levels using a commercial sandwich ELISA (Predicta ELISA kit; Genzyme Corp., Cambridge, MA) according to the manufacturer's instructions. In each experiment, a standard curve was obtained with serial dilutions using linear regression analysis of specific samples *versus* expected concentrations. Interleukin measurements were done in duplicate.

Statistical analysis

All results are expressed as the mean ± SEM. The significance of the differences was determined using analysis of variance (ANOVA) or Mann-Whitney *U*-test. $P < 0.05$ was considered to be statistically significant.

RESULTS

All 11 mongrel dogs were successfully observed for 6 h after reperfusion without any complications.

The changes in RPP

The changes in the RPP are shown in Figure 1A. The RPPs gradually decreased with time in the control group. Those in the PMX group also decreased gradually; however, it had improved at 6 h after reperfusion and was significantly different compared to the control group ($P < 0.05$).

The changes in SMA blood flow

The recovery rates of the SMA blood flow expressed as a percentage of the baseline control value obtained before I/R injury are shown in Figure 1B. The SMA blood flow remarkably decreased 1 h after reperfusion in both groups. Additionally, the SMA blood flow gradually decreased until 6 h after reperfusion in the control group. The changes in SMA blood flow in the PMX group, however, were consistently higher after reperfusion than those in the control group, especially with significant ($P < 0.05$) differences at 1 and 6 h after reperfusion (Figure 1B).

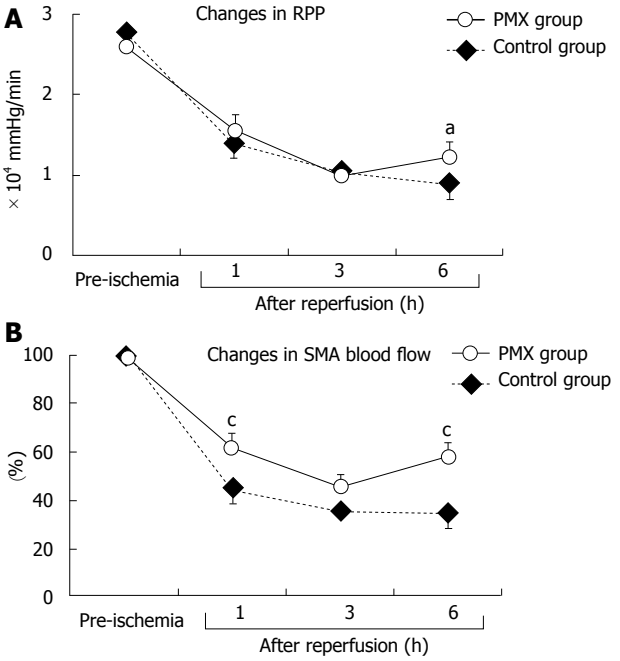

Figure 1 **A**: The changes in the RPP (HR × systolic pressure), $^aP < 0.05$; **B**: The changes in the recovery rates of SMA blood flow, $^cP < 0.05$.

The changes in mucosal tissue blood flow

The recovery rates of the mucosal tissue blood flow expressed as a percentage of the baseline control value obtained before I/R injury are shown in Figure 2A. In both groups, the mucosal tissue blood flow decreased gradually with time except at 6 h after reperfusion in the PMX group. The decreases in the mucosal tissue blood flow after reperfusion were smaller in the PMX group than in the control group. At 6 h after reperfusion, the mucosal tissue blood flow rate was significantly higher in the PMX group than in the control group after reperfusion.

The changes in pHi

As shown in Figure 2B, the changes in pHi also decreased remarkably in both groups. No significant differences in pHi levels were observed at 1 and 3 h after reperfusion in both groups; however, the pHi level in the PMX group was significantly higher ($P < 0.05$) than in the control group at 6 h after reperfusion.

Serum IL-10 levels

The serum IL-10 levels 170 min after reperfusion (that is just before DHP-PMX removal) in both groups are shown in Figure 3. As shown in Figure 3, the serum IL-10 level was significantly ($P < 0.05$) higher in the PMX group than in the control group.

DISCUSSION

Polymyxin B binds to endotoxin, an outer membrane component of gram-negative bacteria that is thought to be an important pathogenic trigger for the production of inflammatory mediators. Several preclinical studies have demonstrated that hemoperfusion or plasmapheresis

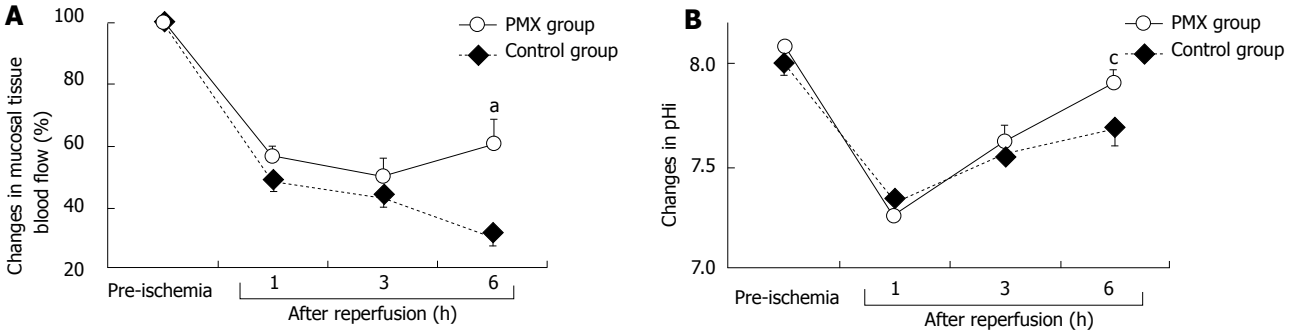

Figure 2 **A**: The changes in the recovery rates of mucosal tissue blood flow, $^{a}P < 0.05$; **B**: The changes in pHi, $^{c}P < 0.05$.

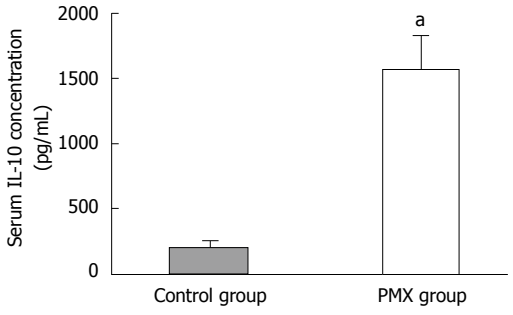

Figure 3 Serum IL-10 levels measured just before DHP-PMX removal, $^{a}P < 0.05$.

over immobilized polymyxin B can remove endotoxin from the blood[12-14]. Recently, some studies reported improved hemodynamic status[15] and improved survival[16] in patients with sepsis treated with PMX, and DHP-PMX therapy is effective for patients with septic shock who are infected not only by gram-negative bacteria but also by gram-positive bacteria without endotoxin release[17]. Therefore, DHP-PMX therapy has been conventionally used in patients with severe sepsis or septic shock, and its clinical effect has been confirmed. In addition, some authors have discussed the mechanism of DHP-PMX action. Kushi *et al* reported that the adsorption of pathogenic bacteria prevented the release of inflammatory cytokines and lessened the stimulation of vascular endothelial cells to lower PAI-1 level rather than directly inhibiting PAI-1 production by DHP-PMX therapy[18]. Tani *et al* speculated that a reduction in plasma endotoxins by endotoxin adsorption contributed to the cessation of cytokine gene expression and the excretion of cytokines[7]. Additionally, improvement in the PaO_2/FiO_2 ratio in patients with acute lung injury or acute respiratory distress syndrome caused by sepsis has been related to DHP-PMX therapy and decreases in blood neutrophil elastase (NE) and IL-8 levels[9]. We hypothesized that DHP-PMX therapy might be valuable in various inflammatory situations. Consequently, we evaluated the usefulness of DHP-PMX therapy on normothermic cardiopulmonary bypass in a pig model[19] and on pulmonary warm I/R injury in a canine model[10], and obtained satisfactory results. In the present study, we investigated the effectiveness of DHP-PMX therapy on small intestinal warm I/R injury in a canine model because intestinal I/R injury produces injury in both the intestines and distant organs including the lungs, kidneys, and liver[3] and is therefore associated with high rates of morbidity and mortality in both surgical and trauma patients[4].

As a result, the RPP was significantly ($P < 0.05$) better in the PMX group than in the control group at 6 h after reperfusion. The SMA and the mucosal tissue blood flow in the control group gradually decreased after reperfusion. Those parameters in the PMX group, however, had improved at 6 h after reperfusion and were significantly ($P < 0.05$) different compared to those parameters in the control group. The pHi level had also improved at 6 h after reperfusion and was significantly ($P < 0.05$) different from that in the control group. Our results showed the effectiveness of DHP-PMX therapy on small intestinal warm I/R injury.

IL-10 is a 35-kDa cytokine that regulates immune and inflammatory responses[20]. Systemic inflammatory response syndrome (SIRS) following major abdominal surgery is characterized by complex alterations in cytokine concentrations, and the balance between tumor necrosis factor (TNF)-α and IL-10 may be related to the occurrence of postoperative complications[21]. Wu *et al* reported that small intestinal ischemia reperfusion increased mucosal inflammatory modulator IL-6 concentration and inhibited anti-inflammatory cytokine IL-10 synthesis[22]. In addition, endogenous IL-10 exerts an anti-inflammatory role during reperfusion injury, possibly by regulating early stress-related genetic response, adhesion molecule expression, neutrophil recruitment, and subsequent cytokine and oxidant generation[23]. Malleo *et al* demonstrated that the absence of endogenous IL-10 enhanced organ dysfunction and mortality associated with multiple organ dysfunction syndrome in mice[24]. In this study, we focused on the serum IL-10 levels after reperfusion, and those in both groups were measured and compared. As a result, the serum IL-10 level measured 170 min (that is just before DHP-PMX removal) in the PMX group was significantly higher than in the control group. In addition, RPP, the recovery rates of SMA blood flow, the mucosal tissue blood flow, and the pHi levels after reperfusion were significantly better in the PMX group than in the control group. Therefore, we suggest that the IL-10 level is associated with the inhibition of small intestinal I/R injury using DHP-PMX therapy.

The authors of a recent study suggested that the absorption of anandamide by PMX might abolish

the diverse negative effects of anandamide such as hypotension, immunosuppression, and cytotoxicity[25]. Taking these results into consideration, the possibility exists that treatment with PMX not only removes endotoxin, but also reduces inflammatory reactions through the inhibition of various inflammatory cascades and has an effective role on I/R injury. Further studies that include the role of endotoxin and alterations of inflammatory factors such as cytokines and chemokines with DHP-PMX therapy are necessary.

In conclusion, DHP-PMX therapy may reduce warm I/R injury in the small intestine, and IL-10 could play an important role in this mechanism.

ACKNOWLEDGMENTS

We thank Toray Medical Co. for supplying the endotoxin adsorption cartridge (Toraymyxin).

COMMENTS

Background

Ischemia-reperfusion (I/R) injury of the small intestine is consequently a critical problem that is important in situations such as the interruption of blood flow to the intestines due to abdominal aortic aneurysm surgery, small intestinal transplantation, surgery involving cardiopulmonary bypass, strangulated hernias, and neonatal necrotizing enterocolitis. Intestinal I/R injury produces injury in both the intestines and distant organs including the lungs, kidneys, and liver, therefore, it is associated with high rates of morbidity and mortality in both surgical and trauma patients.

Research frontiers

A polymyxin B-immobilized fiber column (PMX cartridge, Toraymyxin), which was developed in Japan in 1994, is an extracorporeal hemoperfusion device that uses polymyxin-B fixed to α-chloroacetamide-methyl polystyrene-derived fibers packed in the cartridge. Direct hemoperfusion with PMX (DHP-PMX) therapy can remove circulating endotoxins and reduce various cytokines, even in patients with high levels of plasma cytokines.

Innovations and breakthroughs

DHP-PMX has been used for the treatment of endotoxemia and reported to lower inflammatory cytokine and plasminogen activator inhibitor-1 levels immediately. DHP-PMX therapy has also been attempted for severe sepsis secondary to intra-abdominal infection, acute lung injury, and acute respiratory distress syndrome caused by sepsis, and its effectiveness has been reported. Recently, we hypothesized that DHP-PMX therapy could reduce I/R injury and demonstrated the usefulness of this therapy on pulmonary warm I/R injury in a canine model.

Applications

DHP-PMX therapy may reduce warm I/R injury in the small intestine, and IL-10 could play an important role in this mechanism.

Terminology

The possibility exists that treatment with PMX not only removes endotoxin, but also reduces inflammatory reactions through the inhibition of various inflammatory cascades and has an effective role on I/R injury.

Peer review

The authors demonstrated that DHP with a polymyxin B-immobilized cartridge reduced reperfusion injury in the small intestine. This study was well designed and well investigated.

Abstract

AIM: To clarify whether insulin resistance and metabolic syndrome are risk factors for erosive esophagitis.

METHODS: A case-control study was performed using the database of the Kangbuk Samsung Hospital Medical Screening Center.

RESULTS: A total of 1679 cases of erosive esophagitis and 3358 randomly selected controls were included. Metabolic syndrome was diagnosed in 21% of the cases and 12% of the controls ($P < 0.001$). Multiple logistic regressions confirmed the association between erosive esophagitis and metabolic syndrome (Odds ratio, 1.25; 95% CI, 1.04-1.49). Among the components of metabolic syndrome, increased waist circumference, elevated serum triglyceride levels and hypertension were significant risk factors for erosive esophagitis (all $P < 0.01$). Furthermore, increased insulin resistance (Odds ratio, 0.91; 95% CI, 0.85-0.98) and fatty liver, as diagnosed by ultrasonography (Odds ratio, 1.39; 95% CI, 1.20-1.60), were also related to erosive esophagitis even after adjustment for a series of confounding factors.

CONCLUSION: Metabolic syndrome and increased insulin resistance are associated with an increased risk of developing erosive esophagitis.

Key words: Metabolic syndrome; Erosive esophagitis; Insulin resistance; Fatty liver

INTRODUCTION

Metabolic syndrome is a cluster of metabolic abnormalities defined as the presence of an increased waist circumference and two of the following components: high blood pressure, hypertriglyceridemia, low levels of high density lipoprotein (HDL)-cholesterol, or diabetes/hyperglycemia. This syndrome helps to identify individuals at high risk for both cardiovascular disease and diabetes mellitus (DM); therefore, metabolic syndrome has become one of the major health problems worldwide.

Gastroesophageal reflux disease (GERD) and obesity are two of the most common diseases in Korea and the incidences of both have been increasing rapidly. Recently, GERD was shown to affect approximately 3.4%-3.8% of the Korean population[1,2] and in 1995 the prevalence of being overweight [body mass index (BMI) = 25-30 kg/m^2] or obese (BMI > 30 kg/m^2) was, respectively, reported as 11.7% and 2.1% in males, and 18.0% and 2.5% in females; in 2000 the prevalence of being overweight or obese was 33.1% and 3.2% in males, and 32.2% and 4.5% in females, respectively[3].

Several studies have shown the relationship between obesity, erosive esophagitis, and GERD symptoms[4-8]. Also, a recent study demonstrated that metabolic syndrome was associated with reflux esophagitis[9]. However, literature on whether metabolic syndrome and insulin resistance are risk factors for GERD is scant.

In this study, we therefore intended to determine whether metabolic syndrome and insulin resistance are associated with erosive esophagitis in a Korean population.

MATERIALS AND METHODS

Study population and selection of study participants

We conducted a cross-sectional case-control study. The study population consisted of subjects who visited the Medical Screening Center at Kangbuk Samsung Hospital from January to December 2006. Exclusion criteria

consisted of a history of prior gastric surgery, benign gastric or duodenal ulcer, gastric cancer or current proton pump inhibitor medication therapy.

Of the 83032 patients visited the Medical Screening Center, 44718 patients underwent upper gastrointestinal (UGI) endoscopic examination. However, only 28949 patients completed a questionnaire pertaining to their symptoms (heart burn and regurgitation) and provided weights, heights, and waist circumferences. The mean age of the participants was 45 ± 9.6 years and 11375 (39%) were females. After application of the exclusion criteria, 1679 (5.8%) subjects were included as patients with erosive esophagitis. Two controls for each case patient (3358 subjects) were randomly selected from the subjects with normal UGI endoscopic findings and no reflux symptoms.

Questionnaire

All participants completed a self-administered validated questionnaire that identified reflux symptoms, such as irritating heartburn and/or acid regurgitation experienced during the preceding year[6]. In addition, the questionnaire included questions about current smoking and other medical or surgical histories.

Measurement

BMI and metabolic syndrome components, such as waist circumference, lipid profile, blood pressure and fasting glucose level, were measured in all study participants. BMI was calculated as the ratio of weight (kg) to the square of height (kg/m^2) and abdominal obesity was defined as a waist circumference ≥ 80 cm in females and ≥ 90 cm in males[10]. Measurements were made at the World Health Organization (WHO) recommended site (the midpoint between the lower border of the rib cage and the iliac crest) by trained personnel[11]. The mean blood pressure was checked more than twice in the supine position with a sphygmomanometer after 10 min of rest. All blood testing was done after more than 12 h of fasting. Total cholesterol, triglycerides (TG), HDL-C and low-density lipoprotein (LDL)-C were measured with an automatic analyzer (Advia 1650, German). Total C and TG were analyzed by an enzymatic calorimetric test. A selective inhibition method was used in HDL-C measurement and a homogenous enzymatic calorimetric test was used in LDL-C measurement. Fasting glucose was measured by the hexokinase method with an automatic analyzer (Advia 1650) and fasting insulin was assayed *via* an immunoradiometric assay (Biosource, Belgium). The intraassay variation coefficients were 2.1%-4.5% and the interassay variation coefficients for the quality controls were 4.7%-12.2%. The degree of insulin resistance was evaluated by homeostasis model assessment (HOMA-IR) according to the following formula: (fasting insulin in μU/mL × fasting glucose in mmol/L)/22.5[12]. An experienced radiologist who was blind to the laboratory data performed ultrasonographic liver examinations. Fatty liver was defined as a bright liver on ultrasonography (USG). The diagnosis of bright liver was based on abnormally intense and high level echoes arising from the hepatic parenchyma with amplitudes similar to those of echoes arising from the diaphragm.

Participants were diagnosed with metabolic syndrome if they had an increased waist circumference and two of the following components: (1) high blood pressure (≥ 130 mmHg systolic or ≥ 85 mmHg diastolic), (2) hypertriglyceridemia (≥ 150 mg/dL), (3) low levels of HDL-C (≤ 40 mg/dL in males or ≤ 50 mg/dL in females), or (4) DM/hyperglycemia[10].

Upper gastrointestinal endoscopy

Standard endoscopic examination of the esophagus, stomach, and duodenum was performed in all subjects. The severity of erosive esophagitis was graded from A-D according to the LA classification[13]. We considered LA-A to be the cutoff for erosive esophagitis. We also considered a hiatal hernia to be present if diaphragmatic indentation was seen > 2 cm distal to the Z-line and the proximal margins of the gastric mucosal folds, which were observed with considerable air insufflation during inspiration. Distance was measured using the centimeter markings on the endoscope[14].

Statistical analyses

Statistical analysis was done using the χ^2 test for comparison of discrete variables and the *t*-test for comparison of continuous variables. The continuous variables measured in this study were expressed as the mean ± SD. Multivariate analysis was conducted using logistic regression. To examine the risks of potential confounders, including metabolic syndrome for erosive esophagitis, multivariate models included adjustments for age, gender, smoking, alcohol, and metabolic syndrome as categorical factors. For each variable, the odds ratio (OR) and 95% confidence interval (CI) were given. A two-tailed *P* value of < 0.05 was considered statistically significant.

RESULTS

Of the 28949 subjects, 1679 (5.8%) were confirmed to have erosive esophagitis; 1326 (78.9%) cases were classified as LA-A, 328 (19.5%) as LA-B, and 25 (1.6%) as LA-C or LA-D. The mean age was 45.19 ± 9.3 years and 86% of the subjects were men. The study characteristics are mentioned in Table 1. We found a significant increase in the mean BMI, waist circumference, systolic and diastolic blood pressure, fasting blood glucose, HbAlc, TG and HOMA in patients with erosive esophagitis as compared to the controls. Also, patients with erosive esophagitis were more likely to be male, obese, current smokers, regular consumers of alcohol, and more likely to have metabolic syndrome and fatty liver (as diagnosed by abdominal ultrasonography) and less than a college education.

Table 2 shows the results from the multivariate analysis examination of the association between erosive esophagitis and various risk factors. Male gender, current smoking, metabolic syndrome, reflux symptoms, regular

FBS: Fasting blood sugar; TG: Triglycerides; HDL-C: High-density lipoprotein-cholesterol. [1]Unadjusted; [2]Adjusted for gender, current smoking, hiatal hernia, reflux symptoms, alcohol use, fatty liver on abdominal USG, and HOMA.

alcohol use, HOMA and fatty liver (as diagnosed by abdominal ultrasonography) were significant independent risk factors for erosive esophagitis. Among the individual components of metabolic syndrome, increased waist circumference, hypertension, increased levels of TG, and low levels of HDL-C were significantly associated with erosive esophagitis. However, after adjusting for gender, smoking, hiatal hernia, reflux symptoms, regular alcohol use, HOMA and fatty liver (as diagnosed by abdominal ultrasonography), increased waist circumference, increased levels of TG, and hypertension were strongly associated with the development of erosive esophagitis (Table 3).

We also attempted to determine the relationship between the severity of erosive esophagitis, according to the LA classification, and various risk factors. Male gender, current smoking, regular alcohol use, hiatal hernia, metabolic syndrome, reflux symptoms, HOMA and fatty liver (as diagnosed by abdominal ultrasonography) were significantly associated with the severity of erosive esophagitis (Table 4). Among the individual components of metabolic syndrome, increased waist circumference and increased levels of TG were predictive factors for the severity of erosive esophagitis (Table 5).

DISCUSSION

This cross-sectional study in a Korean population showed that metabolic syndrome was strongly associated with the development and severity of erosive esophagitis. Also, insulin resistance, independent of metabolic syndrome, was another significant risk factor for erosive esophagitis.

Recently, the prevalence of metabolic syndrome has rapidly increased in Korea. According to the International Diabetes Federation (IDF) criteria, the age-adjusted prevalence of metabolic syndrome in males was 10.9% in 1997 and 23.3% in 2003. In females, the age-adjusted prevalence of metabolic syndrome was 42.2% in 1997 and 43.4% in 2003[15]. In the current study,

[1]Adjusted for gender, current smoking, hiatal hernia, reflux symptoms, alcohol use, fatty liver on abdominal USG, and HOMA.

the prevalence of metabolic syndrome was lower than previously reported, especially for females. A possible explanation for this difference is that the participants in this study were much younger than those in previous studies. Because the prevalence of metabolic syndrome increases with age[16,17], younger subjects are more likely to have a lower prevalence of metabolic syndrome than older subjects. Additionally, the higher educational level and economic status of the subjects could be another reason for the lower than expected prevalence of metabolic syndrome. Higher income was protective against metabolic syndrome[18] and females in the lower economic group were more likely to be at risk for metabolic syndrome when compared with females in the higher economic group[19,20].

With the increased prevalence of metabolic syndrome, GERD has also become more prevalent in Korea. The overall prevalence of erosive esophagitis was 3.4% in 2001[21] and 6.6% in 2006[6]. In terms of reflux symptoms, 2.5% of adults experienced heartburn and reflux symptoms in 2000[22]. In contrast, 7.1% reported that GERD symptoms were present at least once a week in 2007[1]. This increase may be due to extended life expectancy, greater intake of Westernized food[2], and/or increasing rates of obesity[6]. Moreover, an increase in alcohol consumption[23,24] and a decrease in *Helicobacter pylori (H pylori)* infections[25] could be possible reasons for the increase in erosive esophagitis in Korea.

This study demonstrated that metabolic syndrome and insulin resistance were also risk factors for erosive esophagitis. A recent study verified that elevated triglyceride levels, a component of metabolic syndrome, is an independent predictor for reflux esophagitis and suggested that humoral compounds might alter the lower esophageal sphincter pressure or affect esophageal clearance of refluxate[9]. In fact, human adipose tissue is a major site of IL-6 secretion[26]. IL-6 stimulates hepatic triglyceride secretion in rats[27] and plays an important role in insulin resistance in humans[28]. Moreover, IL-6 reduces esophageal circular muscle contraction[29]. Therefore, cytokines may play important roles in the pathogenesis of reflux esophagitis. However, given that very complex relationships exist among the risk factors for erosive esophagitis[23,30,31], we should be careful when interpreting the clinical significance of these relationships.

An interesting finding of this study was that among the individual components of metabolic syndrome, an elevated level of serum TG was a significant predictive factor not only for the presence of erosive esophagitis, but also for the severity of erosive esophagitis. This result is consistent with a recent study about metabolic syndrome and erosive esophagitis[9] as well as previous studies[32,33]; however, other reports did not find such a relationship between elevated serum TG and erosive esophagitis[34,35]. There are several possible explanations for this association. First, in view of the results of this study, insulin resistance and fatty liver may be responsible for increased serum TG levels because liver fat is a significant correlate of fasting glucose and triglyceride levels[36]. Also, hypertriglyceridemia is associated with increased insulin resistance[37]. Second, considering that *H pylori* infection has been suggested to be a protective factor for erosive esophagitis[38,39] and chronic *H pylori* infections can modify the serum lipid profile, including the increment of total C and TG[40,41], elevated serum TG levels could be just an epiphenomenon accompanying *H pylori* infection. Further studies are needed in order to

verify that point.

There were several limitations to our study. First, *H pylori* infections were not included in the multivariate analysis. *H pylori* infections in this study were diagnosed by histologic analysis of biopsy specimens. However, most of the subjects did not undergo the historical examination for *H pylori* because tissue biopsies were performed only when suspicious lesions were found by UGI endoscopic examination. Therefore, the prevalence of *H pylori* infection was lower in our subjects in comparison with the normal population. Nevertheless, patients undergoing a biopsy were randomly allocated to each comparison group; thus the rate of positive *H pylori* infection in patients with erosive esophagitis was significantly lower than in patients without erosive esophagitis, which is consistent with the result of a previous study[38]. Moreover, the result that metabolic syndrome was a significant risk factor for erosive esophagitis was still persistent after multivariate analysis, including *H pylori* infection ($P < 0.05$). Second, there is a possibility of selection bias because only one-half of the subjects who visited the health care center underwent UGI endoscopy and only a portion of them responded to the questionnaire regarding their symptoms. However, although subjects with reflux symptoms were more likely to participate in this study, the prevalence of patients with reflux symptoms was consistent with that of a recent study[1] and when the limited effects of reflux symptoms on erosive esophagitis are considered, this bias did not seem to affect the primary results of this study.

In conclusion, our study demonstrates that metabolic syndrome is an independent risk factor for erosive esophagitis. In addition, metabolic syndrome is significantly associated with the severity of erosive esophagitis. Therefore, we should take into account not only acid suppression, but also metabolic factors when consulting with patients who have erosive esophagitis.

COMMENTS

Background

Gastroesophageal reflux disease (GERD) and obesity are two of the most common diseases in Korea and the incidences of both have been increasing rapidly.

Research frontiers

Several studies have reported the relationship between obesity, erosive esophagitis, and GERD symptoms. A recent study demonstrated that metabolic syndrome was associated with reflux esophagitis. However, literature on whether metabolic syndrome and insulin resistance, suggested causes of metabolic syndrome, are risk factors for GERD remains scant.

Innovations and breakthroughs

One of the major findings of this study was that metabolic syndrome was strongly associated with the development and severity of erosive esophagitis. Moreover, insulin resistance, independent of metabolic syndrome, was a significant risk factor for erosive esophagitis.

Applications

This study should help to identify patients with particular risk for erosive esophagitis. An early identification of patients at risk for erosive esophagitis would allow more timely treatment and symptom relief.

Peer review

The present study showed a significant correlation between metabolic syndrome and erosive esophagitis and may be helpful for identifying the cause of erosive esophagitis. This study is interesting and valuable.

Abstract

AIM: To characterize the clinical, serologic and virologic features of hepatitis B virus (HBV) infection in Iranian patients with different stages of liver disease.

METHODS: Sixty two patients comprising of 12 inactive carriers, 30 chronic hepatitis patients, 13 patients with liver cirrhosis and 7 patients with hepatocellular carcinoma (HCC) were enrolled in the study. The HBV S, C and basal core promoter (BCP) regions were amplified and sequenced, and the clinical, serologic, phylogenetic and virologic characteristics were investigated.

RESULTS: The study group consisted of 16 HBeAg-positive and 46 HBeAg-negative patients. Anti-HBe-positive patients were older and had higher levels of ALT, ASL and bilirubin compared to HBeAg-positive patients. Phylogenetic analysis revealed that all patients were infected with genotype D (mostly *ayw2*). The G1896A precore (PC) mutant was detected in 58.1% patients. HBeAg-negative patients showed a higher rate of PC mutant compared to HBeAg-positive patients (χ^2 = 9.682, P = 0.003). The majority of patients with HCC were HBeAg-negative and were infected with PC mutant variants. There was no significant difference in the occurrence of BCP mutation between the two groups, while the rate of BCP plus PC mutants was higher in HBeAg-negative patients (χ^2 = 4.308, P = 0.04). In the HBV S region, the genetic variability was low, and the marked substitution was P120T/S, with a rate of 9.7% (n = 6).

CONCLUSION: In conclusion, HBV/D is the predominant genotype in Iran, and the nucleotide variability in the BCP and PC regions may play a role in HBV disease outcome in HBeAg-negative patients.

Key words: Hepatitis B virus; Clinical and virologic features; Genetic variability; Phylogenetic analysis

INTRODUCTION

Hepatitis B virus (HBV) infection is one of the most important infectious diseases worldwide and is a major global health problem. Approximately one million people die annually because of acute and chronic HBV infection despite the availability of effective vaccines and effective antiviral medications[1]. HBV replicates *via* the reverse transcriptase enzyme system which lacks proofreading ability; therefore, new virions

possess diverse genetic variability[2]. Different selection pressures such as host immunity (endogenous pressure), and vaccine or antiviral agents (exogenous pressure) influence the production of HBV quasispecies in infected individuals. It has been demonstrated that mutations in the HBV genome not only impact the replication fitness of the virus (phonotypical effect) but can also influence the disease outcome, as well as the response to treatment (clinical effect)[3]. Mutations in the HBV surface (*S*), precore (*PC*) and basal core promoter (*BCP*) genes are observed frequently in HBV infected patients, and studies show that these mutations are associated with the clinical outcomes of HBV disease[4-6]. The most clinically relevant mutations in the S region arise in the immunologic "a determinant" domain, and neutralizing antibodies (anti-HBs) are targeted against this epitope[7]. The most frequent and clinically important mutations in the PC and BCP regions are G1896A and A1762T/G1764A, respectively; which are often detected in HBeAg-negative chronic HBV infected patients[5]. Moreover, it has recently been documented that HBV genotypes may also contribute to the clinical features, disease outcome, and response to antiviral therapy[8].

Iran is located in the Middle East, and has an intermediate-to-low prevalence of the HBV infection[9]. The prevalence of HBV infection in Iran is around 2% and it appears that after the implementation of the HBV National Vaccination Programme (started in 1993), the HBV infection rate in young children has diminished significantly[9-11]. There are very few reports on the molecular epidemiology of HBV in Iran[12-14]. Recently, a study on the clinical and serological findings of HBV infection in Iran was published[15], however, there are no reports on the association of the clinical, serologic, virologic (HBV genetic variability) and phylogenetic features of HBV infection. In the present study, we have attempted to determine the HBV genetic variability, and its association with clinical outcome in HBV infected patients at different stages of liver disease.

MATERIALS AND METHODS

Patients

Sixty two HBsAg-positive patients who were referred to the Tehran Hepatitis Centre (2004-2006), were enrolled in a cross-sectional study. The study population consisted of 79% males (n = 49) and 21% (n = 13) females. The mean ± SD age was 37.3 ± 12.3 years (range: 15-64 years, median 36 years). All patients were interviewed and examined by gastroenterologists to evaluate the clinical findings and the results of the investigative workup (liver histology, ultrasonography, and laboratory tests such as serologic, biochemical and virological tests) in order to determine the clinical status of the patient. We followed the American Association for the Study of Liver Disease (AASLD) practice guidelines with regard to the diagnostic criteria. Briefly, inactive carriers had persistent HBV infection without significant necro-inflammatory disease. Chronic hepatitis was defined as HBsAg positivity with or without the presence of HBeAg and a high HBV DNA (> 100 000 copies/mL) level determined by the Amplicor HBV monitor, persistent or intermittent elevation in the serum ALT levels, and compatible liver biopsy. Liver cirrhosis and hepatocellular carcinoma (HCC) were confirmed by liver biopsy. Informed consent was obtained from the patients before collecting blood samples. Sera from the patients was frozen at -20℃ in aliquots, until used for virological examination.

Serologic, virologic and biochemical parameters

All patients were tested for HBV serological markers (HBsAg, anti-HBs, total anti-HBc, HBeAg, and anti-HBe), hepatitis D virus (HDV), hepatitis C virus (anti-HCV) and human immunodeficiency virus (anti-HIV) using commercial kits (DIA PRO Diagnostic Bioprobes, Srl., Italy). Coinfected patients with HIV, HDV and HCV were excluded from the study. Liver function tests such as serum albumin, total bilirubin, ALT, AST and ALP were measured by an auto-analyzer[16]. HBV DNA viral load was determined using the Cobas Amplicor HBV Monitor test (Roche Applied Science, Mannheim, Germany).

Detection of S and BCP/C mutations

HBV DNA was extracted using a nano-particle magnetic beads kit (BILATEC AG, Viernheim, Germany) according to the manufacturer's instructions. The HBV S/pol and BCP/C regions were amplified as previously described[17]. Negative serum samples from subjects with no HBV markers served periodically as a negative control. The PCR amplicons were purified using the AccuPrep™ Gel Purification Kit (Bioneer Inc, Alameda, CA), sequenced bi-directionally with inner primers using the BigDye Terminator v3.1 cycle sequencing kit (Applied Biosystems, Foster City, CA) and the data were collected by an ABI PRISM 3130XL Genetic Analyzer (Applied Biosystems).

Phylogenetic and sequence analysis

Phylogenetic and molecular evolutionary analyses were conducted using MEGA version 3.1[18], as well as BioEdit, version 7.0.4.1 as described previously[14]. Briefly, sequences of BCP/C plus S regions (approximately 1000-bp) were block aligned by the CLUSTAL X program and corrected visually; the Kimura two-parameter algorithm was used for genetic distance calculation. A phylogenetic tree was generated by the neighbour-joining method, and bootstrap re-sampling and reconstruction was carried out 1000 × to confirm the reliability of the phylogenetic tree.

Statistical analysis

The data were statistically analyzed using the SPSS software, version 11.0 (SPSS, Inc., Chicago, IL). $P < 0.05$ was considered significant.

RESULTS

Clinical and demographic data

Based on the clinical and laboratory findings the

Table 1 Clinical, serological, virological and biochemical features of patients infected with HBV (mean ± SD)

Clinica-status	Number (%)	Sex		Age (yr)	HBs Ag+	Anti HBs+	Anti HBc+	HBe Ag+	Anti HBe+	ALT (IU/L)	AST (IU/L)	Alk (U/L)	T-Bil (mg/dL)	Albumin (g/dL)	HBV DNA (log copies /mL)

patients were divided into four categories: 19.4% patients (n = 12) were inactive HBsAg carriers, 48.4% (n = 30) had chronic hepatitis B infection, 21.0% (n = 13) were diagnosed with cirrhosis, and 11.3% (n = 7) had HCC. The clinical and laboratory findings (serologic, biochemical and virologic) are summarized in Table 1. The clinical features of HBeAg-positive patients and anti-HBe-positive patients are shown in Table 2. Based on the HBeAg serology status, 16 patients were HBeAg-positive and 46 patients were anti-HBe-positive. There was no significant difference in age, ALT, AST, and bilirubin levels (biochemical parameters), and HBV viral load between HBeAg-positive and HBeAg-negative groups; however, a significant difference in the gender distribution was observed (χ^2 = 10.96, P = 0.003) (Table 2). All chronic hepatitis B patients with HCC were HBeAg-negative and were older than the other groups.

HBV genotype and subtype

The phylogenetic tree was constructed using the block alignment of HBV S plus BCP/C gene sequences (62 HBV isolates from this study) along with different HBV genotype (A to H) sequences retrieved from the GenBank[19] as reference genes. The phylogenetic tree revealed that all Iranian isolates were branched with other genotype D of HBV reference isolates with a high bootstrap value, 99%, 1000 × replicates (Figure 1). Thus, all Iranian patients were infected with only genotype D. To assess the HBV subtype, the amino acid mapping on the HBV *S* gene protein was performed. Based on the presence of Arg[122], Thr[125], Pro[127], and Lys[160] residues, 98.4% (n = 61) and 1.6% (n = 1) of isolated HBV were subtyped as *ayw2* and *ayw3*, respectively.

Characteristics of nucleotide substitution in the S and BCP/C regions

Amino acid sequences of a portion of the S region of all 62 isolates of the study patients were compared with the amino acid sequences of the reference genes. Amino acid mapping revealed that the S region was relatively conserved; however, an important substitution of P120T/S was observed. P120T/S substitutions were detected in 9.7% of chronic hepatitis and cirrhotic patients (n = 6). No G145R substitution was identified in the isolates; whereas, some substitutions such as P127T, T131I, Y134H, D144N and I152T were observed in the immunologic domain of the "a determinant" region.

With regard to the mutations in the BCP and C regions (Table 3), a high rate of G1896A PC mutant variants (58.1%, 36/62) was detected in the isolates. The rate of precore mutant isolates was significantly higher (χ^2 = 9.682, P = 0.003) in HBeAg-negative patients (69.5%, n = 32) compared to HBeAg-positive patients (25%, n = 4). In the HBV precore region, mutation of G1899A (Gly-to-Asp, at codon 29) was found in 37.1% isolates (n = 23), and was mostly detected in patients with cirrhosis (61.5%), and HCC (42.8%). All isolates had T1585 which is specific for genotype D.

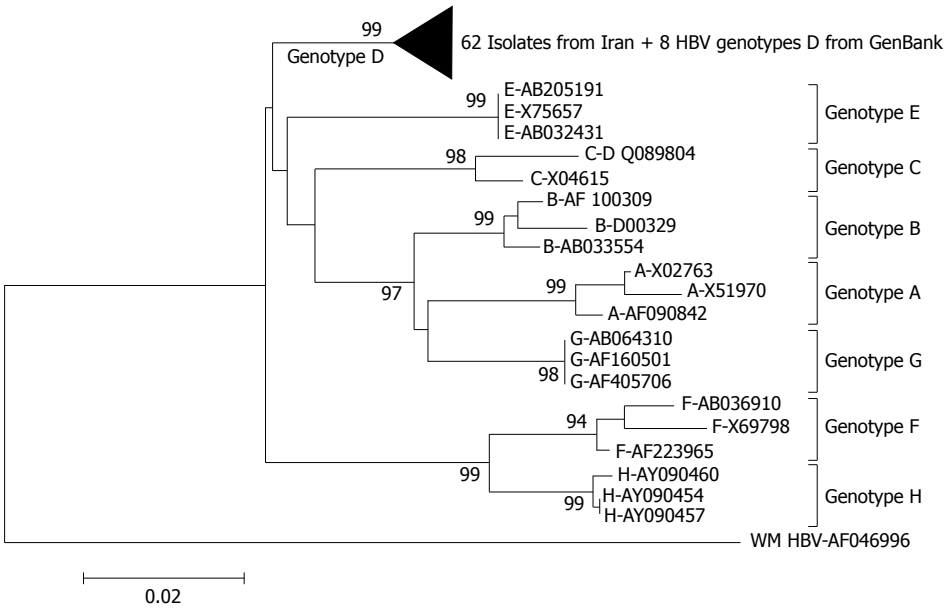

Figure 1 Neighbour joining phylogenetic analysis based on the block-alignment of the S/BCP/C gene regions (approximately 1000-bp) of 62 HBV isolates from Iran and other HBV genotypes form GenBank as reference genes. Bootstrap values indicate 1000-fold replicates. Due to clarity, the 62 isolates from Iran and 8 reference genes of HBV genotype D were collapsed. Woolly monkey HBV was used as an out-group.

BCP double mutation (T1762/A1764) was observed in 37.1% isolates (n = 23); whereas, T1762 and A1764 were also found alone. There was no significant difference in the rate of BCP double mutation between HBeAg-positive and HBeAg-negative patients. The occurrence of precore mutant plus BCP double mutation was detected in 28.2% of HBeAg-negative patients (n = 13); and in 12.5% (n = 2) HBeAg-positive individuals. The G1862T mutation was observed in 4.8% of chronic hepatitis patients (n = 3). This mutation, in which valine (Val) was replaced by phenylalanine (Phe) at position 17 in the PC region, was observed only in HBeAg-negative patients.

DISCUSSION

In the present study, we examined the clinical, serologic, virologic and phylogenetic features in patients with different clinical stages of HBV-related liver disease (inactive HBsAg carriers, chronic hepatitis B, chronic hepatitis B with cirrhosis and HCC). We believe this is the first such study from Iran. Our previous studies on the molecular analysis of HBV, revealed the presence of genotype D in Iran[14,20]. As expected, the present study also showed that genotype D with *ayw2* subtype was present in all 62 patients studied. Genotype D has been reported globally[21]; but has a high prevalence in the Mediterranean area and in the Middle East[22].

The relationship between HBV genotype(s), and the outcome of liver disease, and the response to treatment has been well documented, and has an important impact on public health[8,23]. For example, several studies have shown differences in disease progression between genotype B and C in Asian patients. HBV genotype C is associated with more severe cirrhosis and HCC, and poorer response to interferon therapy[24,25]. Moreover, it has been observed that genotypes can influence HBV replication. For example, HBeAg-negative patients harbouring genotype B had lower viral replication efficiency[25]. Since HBV genotype D was the only predominant genotype in the present study, a comparison between different genotypes was not possible. Non D HBV genotypes are not seen in Iran; whereas, different subtypes of genotype D have been reported[26].

In the present study, amino acid mapping of the *S* gene showed a high rate of homology between the sequences. It has been shown that amino acid substitutions within the "a determinant" domain in the HBV *S* region may lead to conformational changes in the S protein. Some of these changes may create important medical and public health problems including vaccine escape, failure of hepatitis B immune globulin (HBIG) to protect liver transplant patients and babies born to HBV carrier mothers, and failure to detect HBV carriers with certain diagnostic tests[7,27]. In this study, the P120T/S was the most important substitution. This substitution was located at the outside of the "a determinant" immunologic domain. The P120T/S was detected in six isolates. As previously reported, the P120T/S substitution may cause problems with diagnostic assays, and may also cause vaccine escape and poor response to HBIG therapy[27,28].

The G1896A PC mutation truncates the HBeAg protein product by creating a stop codon at position 28 within the precore mRNA. Therefore, patients with HBV variants carrying the A1896 mutant in the genome are usually HBeAg-negative. The G1896A PC mutant may be detected in 20%-95% of HBeAg-negative patients worldwide[3], and is highly predominant in the Mediterranean area where HBV genotype D has a high rate of infection[29]. In a previous study, the rate of HBV precore mutant variants in Iran was reported to be 54%[14]; in the present study, the rate was 58.1%. We observed that patients with a precore mutant variant were older and had a higher rate of AST and ALT elevation (but not statistically significant) compared to patients without this variant, suggesting that this variant occurs in patients with a longer history of HBV infection and worse liver disease. In this study, 85.7%

of patients with HCC (n = 6) carried A1896 variants; whereas, this rate was less in the other study groups. These results are in accordance with previous reports[6,30]. The precore mutant variants have also been reported in HBeAg-positive patients, ranging from 0%-80%[6,31]. In our study, two patients with cirrhosis were infected with the HBV A1896 variants despite HBeAg positivity.

The BCP T1762/A1764 double mutations located at the HBV X gene diminishes HBeAg production, and is associated with more active liver disease[2,32]. In the present study, BCP double mutation T1762/A1764 was detected in 37.1% of patients; but there was no association between these mutations and the status of liver disease (P = 0.7). Moreover, no significant difference (P = 0.9) was observed between the frequency of BCP double mutation in patients with HBeAg-positive and HBeAg-negative phenotypes. By contrast, other studies have shown a relationship between BCP double mutations and the clinical manifestations of HBV infection[6,30]. Moreover, the T1764/G1766 double mutation in the BCP region was detected in 14.5% of isolates (n = 9) (Table 2). However, this study utilized a relatively small study population, and the results suggest that mutations in the PC region were related to more severe liver disease. More studies in larger populations are required to better understand these associations.

In conclusion, the present study has shown that genotype D (predominantly subtype *ayw2*) is the only genotype in Iranian patients. Moreover, a high rate of the precore mutation and BCP double mutation was detected in our study.

ACKNOWLEDGMENTS

We are grateful to Abbas Padeganeh for his comments and critical reading of the manuscript.

COMMENTS

Background

Heterogeneity of hepatitis B virus (HBV) genome and its mutations may influence the outcome of liver disease as well as the response to antiviral treatment. Considering this fact, we studied the clinical, virologic and phylogenetic features of HBV infection in four groups of patients: inactive carriers, chronic hepatitis, cirrhosis and hepatocellular carcinoma.

Research frontiers

The present study revealed an association between certain HBV mutations and the outcome of liver disease, and the response to treatment.

Innovations and breakthroughs

This is the first report on the association between different clinical presentations of HBV infection and mutations in three regions of the HBV genome: basal core promoter (BCP)/Precore, P and S.

Peer review

The present study is relatively small, but it provides useful information on HBV characteristics in Iranian patients with chronic HBV infection.

Abstract

AIM: To identify the two polymorphisms of microsomal triglyceride transfer protein (*MTP*) gene in the Chinese population and to explore their correlation with both hepatitis B virus (HBV) self-limited infection and persistent infection.

METHODS: A total of 316 subjects with self-limited HBV infection and 316 patients with persistent HBV infection (195 subjects without familial history), matched with age and sex, from the Chinese Han population were enrolled in this study. Polymorphisms of MTP at the promoter region -493 and at H297Q were determined by the allele specific polymerase chain reaction (PCR).

RESULTS: The ratio of males to females was 2.13:1 for each group and the average age in the self-limited and chronic infection groups was 38.36 and 38.28 years, respectively. None of the allelic distributions deviated significantly from that predicted by the Hardy-Weinberg equilibrium. There was a linkage disequilibrium between H297Q and -493G/T (D' = 0.77). As the χ^2 test was used, the genotype distribution of *MTP*-493G/T demonstrated a significant difference between the self-limited infection group and the entire chronic group or the chronic patients with no family history (χ^2 = 8.543, P = 0.015 and χ^2 = 7.199, P = 0.019). The allele distribution at the *MTP*-493 position also demonstrated a significant difference between the study groups without family history (χ^2 = 6.212, P = 0.013). The T allele emerged as a possible protective factor which may influence the outcomes of HBV infection (OR: 0.59; 95% CI: 0.389-0.897).

CONCLUSION: The polymorphism of the *MTP* gene, T allele at -493, may be involved in determining the HBV infection outcomes, of which the mechanism needs to be further investigated.

Key words: Hepatitis B virus; Microsomal triglyceride transfer protein; Single nucleotide polymorphism; Self-limited HBV infection; Chronic hepatitis B; Clinical outcomes

INTRODUCTION

Hepatitis B virus (HBV) is the most common cause of acute and chronic liver disease worldwide, especially in several areas of Asia and Africa. Most infected individuals can clear the virus, while only 5%-10% develop chronic hepatitis and remain in a persistent viral state[1,2]. The reasons for viral persistence are poorly understood, but host genetic factors are likely to influence the disease outcome[3].

Molecular genetics methods have increased our

ability to discover variations in the human genome and to correlate them with disease. Single nucleotide polymorphisms (SNPs) are used to characterize gene variations. Genetic associations can provide clues to fundamental questions about the pathogenesis of diseases and lead to new therapeutic avenues[4]. For chronic hepatitis B, this approach may help determine the basis for viral persistence and the development of end-stage complications such as cirrhosis or hepatocellular carcinoma. Initial genetic studies of viral hepatitis focused on human leukocyte antigen (*HLA*) associations[5] and polymorphisms in the promoter or coding region of several genes, such as interleukin-10 (*IL*-10), interferon-γ (*IFN*-γ), vitamin-D receptor (*VDR*), *etc*[6-10], and demonstrate some relationships with the outcome of HBV infection.

The liver is the major organ for the production of plasma lipoproteins, their uptake from plasma and their catabolism[11]. The production of apolipoprotein B (apoB)-containing lipoproteins by the liver is required for the assembly and secretion of very low-density lipoproteins (VLDLs) and low-density lipoproteins (LDLs)[12-16]. The microsomal triglyceride transfer protein (MTP) also plays a key role in apoB secretion by catalyzing the transfer of lipids to the nascent apoB molecule as it is co-translationally translocated across the endoplasmic reticulum membrane[17,18]. Recent studies have shown that the polymorphism at *MTP*-493 is responsible for a change in the *MTP* gene at the transcription level, and that this is prone to influence the intrahepatic triglyceride content[19-21].

Hepatic steatosis frequently occurs during chronic hepatitis B and C. In a transgenic mouse model, hepatitis C virus (HCV) core protein has been shown to inhibit the MTP activity and to modify the hepatic VLDL assembly and secretion[22]. However, no data are available to demonstrate the functional polymorphism of *MTP*-493T/G in HBV-infected patients. The aim of this pilot study was to identify the two polymorphisms of the *MTP* gene in the Chinese population by SNP and to explore their correlation with both HBV self-limited infection and persistent infection.

PATIENTS AND METHODS

Human subjects

In China, 90% of Chinese people are Han and the other 10% derive from 55 minority populations. We enrolled 632 Han Chinese subjects from Ruijin Hospital of Shanghai Jiaotong University Medical School. Among them, 316 had persistent HBV infection (including 195 patients with no family history of chronic hepatitis B) and 316 had previously self-limited HBV infection with no family history. Age and sex were matched between these groups.

The diagnostic criteria for persistent HBV infection were based on the presence of hepatitis B surface antigen (HBsAg) and anti-core IgG-antibody (Anti-HBc), and the absence of anti-hepatitis B surface antibody (Anti-HBs) for more than 6 mo. The mean time from the presumed onset of HBV infection was defined as the first documented seropositivity for HBsAg with or without elevated serum liver enzyme.

Self-limited hepatitis B virus infection was defined as being positive for anti-HBs and anti-HBc, in the absence of previous HBV vaccination, and a negative family history of chronic hepatitis B. Serum HBV-DNA was analyzed to exclude patients with occult HBV infection.

Subjects negative for all HBV markers were not included in the study as these subjects were unlikely to have been exposed to HBV. If they had been exposed to the virus, it would be impossible to predict their outcome.

Patients with concurrent hepatitis A, C, D, E or human immunodeficiency virus (HIV) infection were excluded from the study. Patients with liver disease caused by other factors, such as excess alcohol consumption and autoimmune hepatitis, were also excluded from the study. Our study conforms to the ethical guideline of the 2004 Declaration of Helsinki.

Serological test

Five milliliters of whole blood samples was collected from each subject, the sera were stored at -20℃. Serology for HBsAg, anti-HBs, HBeAg, anti-HBe and anti-HBc was conducted in accordance with the manufacturer's protocol (Axsym, Abbott).

Genomic DNA extraction

Genomic DNA was isolated using a genomic DNA purification kit (PUREGENE) according to its manufacturer's instructions. DNA samples were quantified with a biophotometer (Eppendorf) and subjected to allele specific real-time polymerase chain reaction (PCR).

Genotyping of gene polymorphisms

Polymorphisms of MTP, including *MTP*-493G/T and H297Q were analyzed. We used the Allele Specific PCR Primer Design Program provided by Roche to design primers (Table 1).

All amplifications were performed on ABI-7000 (real-time PCR) with a 50 μL reaction mixture containing 30 ng of genomic DNA, 0.2 μmol/L per primer, PCR buffer, 0.2 μmol/L of each dNTP (Promega), 4% DMSO (Fisherbrand), 2.4% glycerine, 5 units of Delta Z05 DNA polymerase (Roche), 1 × SYB green (Cambrex). Each genotyping contains 2 amplifications, with one common primer and two specific primers, respectively. To genotype the polymorphisms at the promoter region-493 and at the coding region of MTP at amino acid position 297, primers *MTP*-493-1, *MTP*-493-2, *MTP*-493-cp and MTP H297Q-1, MTP H297Q-2, MTP H297Q-cp were used to analyze the *MTP*-493 G/T and MTP H297Q polymorphisms, respectively (Table 1). Amplification was performed with activation and denaturation at 94℃ and at 95℃ and an annealing temperature of 60℃, respectively.

Genotypes were determined by the difference in cycling numbers (ΔCT) of 2 amplification curbs with the same genomic DNA and the melting curbs, according to the manufacturer's (Roche) instructions.

Statistical analysis

The frequencies of *MTP*-493G/T and *MTP* H297Q alleles were compared between the chronic infection and self-limited infection groups by the χ^2 test. Hardy-Weinberg equilibrium was tested by comparing the expected and observed genotype frequencies using the χ^2 test. To analyze the linkage disequilibrium (LD), pair wise LD was analyzed between two loci on MTP by evaluating the measurement of D'. The difference between the probabilities of observing the alleles independently in the population is: $f(D) = f(A_1B_1) - f(A_1)f(B_1)$, where A and B refer to two genetic markers and *f* is their frequency. D' is obtained from D/Dmax and a value of 0.0 suggests independent assortment, whereas 1.0 means that copies of an allele occur exclusively with one of the possible alleles of the other marker. Analysis of D' was performed using HAPLOVIEW 3.0. The odds ratio with a 95% confidence interval, *P* values and Mantel-Haenszel test were calculated using SAS 8.0 to explore the SNP which may independently influence the outcome of HBV infection.

Table 2 General characteristics of 632 subjects

	Self-limited HBV infection (*n* = 316)	Chronic hepatitis B (*n* = 316)	
		With family history (*n* = 121)	No family history (*n* = 195)
Male	215	80 (25.3%)	135 (42.7%)
Female	105	41 (13.0%)	60 (19.0%)
Age (yr)	38.28 ± 11.44	36.93 ± 12.28	39.12 ± 10.84
Age range (yr)	9-75	9-69	16-75
ALT level (× ULN)	Normal	3.62 ± 3.48	3.12 ± 2.62
HBV-DNA level (Log)	Undetectable	5.45 ± 2.34	

RESULTS

Demographic characteristics of subjects

In the 2 groups matched for age and sex, the male to female ratio was 2.13:1 (215:101) in each group. The distribution of age in the chronic hepatitis B and self-limited groups, calculated by SAS respectively, was normal ($P = 0.07$ and 0.182). The mean age of subjects in the two groups was 38.28 years and 38.36 years, respectively, with no significant deviation (STDEV was 11.44 and 11.12). In the chronic hepatitis B subgroups, 121 patients (80 males and 41 females) had a family history while 195 (135 males and 60 females) had no family history of liver disease. Serum alanine aminotransferase (ALT) levels in the self-limited group were normal, and 3 times higher than the upper normal limit in the chronic hepatitis B group. Serum HBV-DNA was detectable in each study subject but undetectable (< 3 $\log_{10}$) in the self-limited group, whereas it was positive in the chronic hepatitis B group (5.45 ± 2.34 $\log_{10}$).

The general characteristics of our study subjects are summarized in Table 2.

Allele frequencies and linkage disequilibrium

The polymorphisms of *MTP* H297Q and *MTP*-493G/T were analyzed in 632 subjects of the Chinese Han population in Shanghai. The T minor allele frequency of promoter polymorphisms-493 in the *MTP* gene was 0.123, whereas the G frequency of missense polymorphism H297Q was 0.668. The 2 SNPs of the *MTP* gene showed a statistically significant linkage disequilibrium (D' = 0.77, $P < 0.05$). None of the allelic distributions deviated significantly from that predicted by the Hardy-Weinberg equilibrium (calculated by SAS, Chi-Square $P > 0.05$).

Association of SNP genotypes with outcomes of HBV infection

The genotype distribution of *MTP*, depending on the outcome of HBV infection, is shown in Table 3. The genotype frequencies of *MTP* H297Q, CC, CG and GG were 0.104, 0.468 and 0.428 in the self-limited group while 0.104, 0.443 and 0.453 in the chronic group, respectively. The frequencies of the TT, TG and GG genotypes of *MTP*-493G/T were 0.013, 0.253 and 0.734 in the self-limited group, and 0.025, 0.165 and 0.810 in the chronic group, respectively. The χ^2 test was used to analyze the association of genotype distribution with HBV infection outcomes. The distribution of *MTP*-493G/T was significantly different between the self-limited and chronic hepatitis B groups, both before and after adjustment for family history ($\chi^2 = 8.543$, $P = 0.015$; $\chi^2 = 7.199$, $P = 0.019$). The genotype distributions of *MTP* H297Q demonstrated no significant difference between the two groups and subgroups (i.e. with and without family history).

A significant difference was demonstrated in the allele distribution of *MTP*-493G/T between the self-limited and chronic hepatitis B groups without familial history ($\chi^2 = 6.212$, $P = 0.013$, Table 4). As calculated by Mantel-Haenszel, the T allele emerged as a potential protective factor positively influencing the HBV infection outcomes in the self-limiting group compared with the chronic hepatitis B group without family history ($P = 0.013$, OR = 0.59 < 1).

DISCUSSION

Several studies suggested that HBV-associated chronic hepatitis, liver cirrhosis and hepatocellular carcinoma (HCC) are more common in men than in women[24-26], showing that the relative risk for chronic HBV infection is increased in men when compared to that in women. In China, most HBV infections occur during the neonatal or perinatal period, following materno-foetal transmission where the mothers are HBeAg-positive

and the infants subsequently become chronic HBV carriers. The predominant mode of HBV spread is intra-familial from mothers to infants or siblings to siblings[25]. This should mean an equal exposure rate of males and females to HBV. The mechanism underlying such a male predominance is unknown. As age and sex were matched when the subjects were enrolled in our study, there was no significant difference in sex and age ($P > 0.05$). We also studied the family history of 632 subjects, in which all of the self-limited subjects and 195 chronic hepatitis B patients had no family history of the disease.

The majority of published studies on HBV persistence correlate to the role of the major histo-compati-bility complex (MHC) in determining the infection outcomes. The most convincing evidence refers to the association between HBV carriage and MHC class Ⅱ and Ⅰ molecules, such as human leukocyte antigen allele *DRB1*1302*[27-29] and allele A*0301[30], which are associated with viral clearance, whilst B*08 is associated with persistent infection[30]. Non-MHC genes have also proved interesting and successful candidates for association studies of hepatitis B viral infection. It was reported that SNPs in the *VDR*[31,32] and *TNF-α* genes, at position-857[33] as TT, are associated with the clearance of HBV in Gambians and the Chinese population, respectively. Two studies showed that the *TNF-α* SNP at position-238 may be associated with persistent infection[33,34]. Several population-based studies also revealed that *IFN-γ* with its +847 and CA repeat allele[35], cytotoxic T-lymphocyte antigen 4 (*CTLA4*) with its -318[36] and *IL-18* with its -607 and -137[37], interferon alpha receptor 1 with its -568C and -408T[38], CC chemokine receptor 5 (*CCR5*) with its 59029G and 59353, heterozygosity of *CCR5* delta 32[31,39], and mannose binding lectin (*MBL*)[40,41] are all associated with chronic HBV infection or HBV clearance.

MTP catalyzes the transport of triglyceride, cholesteryl ester, and phospholipids on phospholipid surfaces[42]. The large subunit of the human *MTP* gene is situated on chromosome 4q22-q24[43]. It has a key function in intracellular apolipoprotein (apo) B lipidation and secretion of VLDL[44]. Abundant MTP has been found on the luminal side of the endoplasmic reticulum and in the liver, intestine, and heart[45]. In the present study, we investigated the two polymorphisms of *MTP*; one is located at -493 of the promoter, the other at the 297th amino acid of the coding region. The polymorphism of *MTP*-493 G-to-T substitution affects the promoter activity of the *MTP* gene[19,20]. It was recently reported that the G allele, which decreases the *MTP* gene transcription, increases intrahepatic triglyceride content[21]. The T allele is associated with an increased expression of the MTP gene[19]. There is linkage disequilibrium between the 2 SNPs[46]. In our study, the genotype of *MTP*-493G/T distribution was significantly different between the two study groups, with different outcomes of HBV infection ($P = 0.015$). This significant difference was observed in allele distribution after adjustment for sex, age and family history ($P = 0.013$), indicating that the T allele may be one of the protective factors against HBV infection, especially against postnatal infection (OR: 0.59 < 1; 95% CI: 0.389-0.897).

A recent study showed that hepatitis C, as a metabolic disease, is associated with liver steatosis involving accumulation of intracytoplasmic lipid droplets[47].

The function of MTP is to lipidate the growing apoB polypeptide chain during translation, allowing apoB to fold correctly and assemble a lipoprotein with a neutral lipid core before secretion[48,49]. It appears to be obligatory for hepatic secretion of apoB[50,51]. It has been shown that the G allele in *MTP*-493 G/T influences the transcriptional activity and is associated with low plasma levels of LDL cholesterol in healthy middle-aged men, and the T allele is associated with an increased expression of the *MTP* gene *in vitro*, and may enhance hepatic secretion of larger VLDL[19]. It was reported that TT and TG in *MTP*-493 increase the *MTP* gene expression and hepatic secretion of VLDL. However, one French study demonstrated that the functional G/T *MTP* polymorphism does not play a role in the development of steatosis in chronic hepatitis C[52].

Brozovic S[53] recently showed that CD1d, a MHC class I-related molecule that functions in glycolipid antigen presentation to distinct subsets of T cells that express natural killer receptors and an invariant T-cell receptor-α chain (invariant NKT cells), is regulated by MTP in hepatocytes. MTP deletion affects the ability of hepatocytes CD1d to activate invariant NKT cells.

In self-limited infections, HBV-DNA falls by more than 90% within 2-3 wk following the viral replication peak and before the peak of antigen-specific CD8 response and liver damage[54]. The role of NK cells in the initial viral containment is confirmed by the observation that the NK cell peak in the circulation of patients infected with HBV precedes the decline of HBV replication[55]. This maximal elevation of the NK cell frequency is then followed by the peak of HBV-specific CD8 cells a few weeks later[55]. Experiments of T cell depletion with anti-CD4 or anti-CD8 antibodies injected into infected chimpanzees showed that NK and NKT cells can contribute substantially to early viral containment[56]. MTP may influence the outcomes of HBV infection by a mechanism mediated by CD1d regulation and NKT cells' activation during the early period of infection.

In summary, the 2 SNPs in MTP have linkage disequilibrium and the T at *MTP*-493G/T may be associated with the clearance of HBV leading to self-limited infection. This might be mediated by CD1d regulation and activation of NKT cells during the early period of infection. The mechanism needs to be further investigated. With the development of SNP detection technology, more SNPs in different genes are likely to be found to be associated with HBV infection. The combination of several SNPs can serve as a predictor for the HBV infection outcomes, leading to new therapeutic methods for HBV infection.

ACKNOWLEDGMENTS

The authors thank Dr. Alexendre Alcais and Dr. Emmanuelle Jouanguy, Faculte de Medecine Necker Paris France for their statistical analysis and helpful discussion.

COMMENTS

Background

Most infected individuals infected with hepatitis B virus (HBV) can clear the virus, while only 5%-10% develop chronic hepatitis and remain in a persistent viral state. The reasons for viral persistence are poorly understood, but host genetic factors are likely to influence the disease outcome.

Research frontiers

This study looked for the potential host genetic factors which may influence the outcomes of HBV infection.

Innovations and breakthroughs

The results show, for the first time, that single nucleotide polymorphisms (SNPs) of microsomal triglyceride transfer protein (*MTP*)-493G/T, which is responsible for MTP transcription level, might be involved in determining the outcomes of HBV infection.

Applications

Based on the results of our study, further investigation should be focused on the mechanism underlying the association between MTP-dependent lipid metabolism and HBV infection, which may lead to new therapeutic methods.

Peer review

The manuscript reports results of an interesting clinical trial. The authors analyzed the polymorphisms of *MTP*-493 at 297 positions in correlation with self-limited and persistent HBV infection in 632 Han Chinese patients. Such an analysis is of importance. The study is well designed and the paper is written in rather good English.

Abstract

AIM: To systematically investigate if cGMP/cGMP-dependent protein kinase G (PKG) signaling pathway may participate in dendroaspis natriuretic peptide (DNP)-induced relaxation of gastric circular smooth muscle.

METHODS: The content of cGMP in guinea pig gastric antral smooth muscle tissue and perfusion solution were measured using radioimmunoassay; spontaneous contraction of gastric antral circular muscles recorded using a 4-channel physiograph; and Ca^{2+}-activated K^+ currents ($I_{K(Ca)}$) and spontaneous transient outward currents (STOCs) in isolated gastric antral myocytes were recorded using the whole-cell patch clamp technique.

RESULTS: DNP markedly enhanced cGMP levels in gastric antral smooth muscle tissue and in the perfusion medium. DNP induced relaxation in gastric antral circular smooth muscle, which was inhibited by KT5823, a cGMP-dependent PKG inhibitor. DNP increased $I_{K(Ca)}$. This effect was almost completely blocked by KT5823, and partially blocked by LY83583, an inhibitor of guanylate cyclase to change the production of cGMP. DNP also increased STOCs. The effect of DNP on STOCs was abolished in the presence of KT5823, but not affected by KT-5720, a PKA-specific inhibitor.

CONCLUSION: DNP activates $I_{K(Ca)}$ and relaxes guinea-pig gastric antral circular smooth muscle *via* the cGMP/PKG-dependent singling axis instead of cAMP/PKA pathway.

INTRODUCTION

Natriuretic peptides (NP) include atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP), C-type natriuretic peptide (CNP), dendroaspis natriuretic peptide (DNP) and urodilatin[1]. DNP is a recently isolated peptide that contains 38 amino residues and shares structural and functional properties with the other members of the natriuretic peptide family[2]. Studies about its physiologic functions mainly focus on cardiovascular[3-5], genital[6], and urinary systems[7]. Evolutionary studies[8] have suggested the presence of DNP-like immunoreactivity

in rat colon, and the DNP-like molecule may control colonic motility as a local regulator. Interestingly, we found that DNP inhibits spontaneous contraction in gastric circular smooth muscle[9]. NPs are similar to nitric oxide (NO), which play important physiological functions by affecting the activity of cGMP and cAMP. Sabbatini *et al* reported[10] that CNP enhances amylase release by reducing cAMP in the exocrine pancreas. Borán *et al*[11] showed that ANP could play a beneficial role in the resolution of neuroinflammation by removing dead cells and decreasing levels of proinflammatory mediators in microglia *via* the cGMP-dependent protein kinase G (PKG) signaling pathway. ANP stimulates lipolysis in human adipocyte through a cGMP signaling pathway[12]. However, Wen *et al*[13] found that CNP activates the pGC-cGMP- phosphodiesterases 3 (PDE3)-cAMP signaling to play a role in hyperthyroid beating of rabbit atria. It is indicated that NP exerts its physiological function by a different pathway. In our previous study, we simply observed that cGMP participates in DNP-induced relaxing of circular smooth muscle, by using a pharmacologic approach. Thus, the aim of this study was to systematically investigate if the cGMP-PKG or cAMP signaling pathway may participate in DNP-induced relaxation using pharmacologic, radioimmunoassay and patch-clamp technique in gastric circular smooth muscle of guinea pigs.

MATERIALS AND METHODS

Preparation of muscle strips

Guinea pigs of either sex, weighing 250-350 g, were purchased from the Experimental Animal Center, Dalian Medical University. The guinea pigs were housed in plastic cages containing corn-chip bedding with free access to food and water for 1 d before they were used for experiments. The care and use of the animals were followed strictly in accordance with the National Institutions of Health Guide for the Care and Use of Laboratory Animals. Guinea pigs were euthanized by a lethal intravenous dose of pentobarbital sodium (50 mg/kg). The abdomen of each guinea pig was opened along the midline, and the stomach was removed and placed in pre-oxygenated Tyrode's solution at room temperature. After the mucous layer was removed, strips (approximately 2.0 mm × 15.0 mm) of gastric antral circular muscles were prepared. The muscle strips were placed in a bath chamber (2 mL volume). One end of the strip was fixed on the lid of the chamber through a glass claw, and the other end was attached to an isometric force transducer (TD-112S, Nihon Kohden-Kogyo Japan). The chamber was constantly perfused with pre-oxygenated Tyrode's solution at 1 mL/min. The temperature was maintained at 37.0 ± 0.5℃ with a water bath thermostat (WC/09-05, Chongqing, China). The muscle strips were allowed to incubate for at least 40 min before the experiments were started.

Isolated cell preparation and electrophysiological recording

The longitudinal layer of muscle was dissected from the other muscle layers using fine scissors and then cut into small segments (1 mm × 4 mm). These segments were kept in modified Kraft-Bruhe (K-B) medium at 4℃ for 15 min. They were then incubated at 36℃ in 4 mL of digestion medium [Ca-free physiologic salt solution (Ca-free PSS)] containing 0.1% collagenase Ⅱ, 0.1% dithioerythritol, 0.15% trypsin inhibitor, and 0.2% BSA for 25-35 min. The digested muscle segments were transferred into the modified K-B medium, and the single cells were dispersed by gentle disruption with a wide-bore, fire-polished glass pipette. The isolated gastric myocytes were kept in modified K-B medium at 4℃ prior to use. Isolated cells were transferred to a 0.1 mL chamber on the stage of an inverted microscope (IX-70 Olympus, Tokyo, Japan) and allowed to settle for 10-15 min. The cells were continuously perfused with an isosmotic PSS at a rate of 0.9-1.0 mL/min. An 8-channel perfusion system (L/M-sps-8, List Electronics, Berlin, Germany) was used to exchange different solutions. The Ca^{2+}-activated K^+ currents ($I_{K(ca)}$) were recorded using the conventional whole-cell patch-clamp technique. Patch-clamp pipettes were manufactured from borosilicate glass capillaries (GC 150T-7.5, Clark Electromedical Instruments, London, UK) using a 2-stage puller (PP-83, Narishige, Tokyo, Japan). The resistance of the patch pipette was 3-5 MΩ when filled with pipette solution. Liquid junction potentials were canceled prior to the seal formation. Whole-cell currents were recorded using an Axopatch 1-D patch-clamp amplifier (Axon Instruments, Foster City California, USA), and data were filtered at 1 KHz. Command pulses, data acquisition, and storage were applied using the IBM-compatible, 486-grade computer and pCLAMP 6.02 software (Axon Foster City, California, USA). Spontaneous transient outward currents (STOCs) were recorded simultaneously by an EPC-10-HEAKA amplifier (HEAKA Instruments, Berlin, Germany). All experiments were performed at room temperature (20-25℃).

Radioimmunoassay

Radioimmunoassay was performed as described elsewhere[14].

Drugs and solutions

Tyrode solution contained (in mmol/L): NaCl 147, KCl 4, $MgCl_2{\cdot}6H_2O$ 1.05, $CaCl_2{\cdot}2H_2O$ 0.42, $Na_2PO_4{\cdot}2H_2O$ 1.81, and 5.5 mmol/L glucose. Ca^{2+}-free PSS was composed of (in mmol/L): NaCl 134.8, KCl 4.5, glucose 5, and N-(2-hydroxyethyl) piperazine-N-(2-ethanesulphonic acid) (HEPES; pH was adjusted to 7.4 with Tris (hydroxymethyl aminomethane). Modified K-B solution contained (in mmol/L): *L*-glutamate 50, KCl 50, taurine 20, KH_2PO_4 20, $MgCl_2{\cdot}6H_2O$ 3, glucose 10, HEPES 10, and egtazic acid 0.5 (pH 7.40 with KOH). PSS contained (in mmol/L): NaCl 134.8, KCl 4.5, $MgCl_2{\cdot}6H_2O$ 1, $CaCl_2{\cdot}2H_2O$ 2, glucose 5, HEPES 10, and sucrose 110 (pH 7.4 with Tris). In order to eliminate delayed rectifier K^+ currents ($I_{K(V)}$), external solution contained 4-aminopyridine (10 mmol/L), a selective inhibitor of $I_{K(V)}$. The pipette solution for recording $I_{K(Ca)}$

contained (in mmol/L): K^+-aspartic acid 110, Mg-ATP 5, HEPES 5, $MgCl_2{\cdot}6H_2O$ 1.0, KCl 20, egtazic acid 0.1, di-tris-creatine phosphate 2.5, and disodium-creatine phosphate 2.5 (pH 7.3 with KOH). Tetraethylammonium (TEA), DNP, LY83583, zaprinast, KT5823 and KT5720 were made up as stock solutions. All chemicals in this experiment were purchased from Sigma (St Louis, MO, USA).

Statistical analysis

All data was expressed as mean ± SD. Statistical significance was evaluated using Student *t*-test. Differences were considered to be significant when $P < 0.05$.

RESULTS

Effect of DNP on cGMP production

Our previous pharmacological study[15] suggests that DNP obviously inhibits spontaneous contraction in gastric antral circular smooth muscle through the cGMP-dependent signaling pathway. To directly confirm the involvement of cGMP on the effect of DNP, in the present study, we measured the content of cGMP in the smooth muscle tissue and in the perfusion solution using radioimmunoassay. The result indicated that cGMP in the smooth muscle tissue and perfusion solution was markedly increased after addition of 10 nmol/L DNP (Figure 1A and B). Pretreatment with 10 nmol/L LY83583 significantly diminished DNP-induced increase in the content of cGMP (Figure 1A and B).

Effect of cGMP-dependent protein kinase on DNP-induced relaxation

Because cGMP activates PKG, we tested the effect of KT-5823 (1 μmol/L), a membrane-permeable PKG-specific inhibitor, on DNP-induced relaxation in the gastric antral circular smooth muscle to determine the potential involvement of PKG. The result indicated that KT-5823 could markedly diminish, although not completely abolish the inhibitory effect of DNP on spontaneous contraction (Figure 1C).

Effect of cGMP on DNP-induced increase of $I_{K(ca)}$

Considering our previous finding that DNP relaxed smooth muscle by increasing $I_{K(ca)}$[15], here we further investigated the relationship between cGMP and DNP-induced increase of $I_{K(ca)}$, and found that the effect of DNP on $I_{K(ca)}$ was observed in the presence of LY83583, an inhibitor of guanylate cyclase to change the production of cGMP. LY83583 (10 nmol/L) significantly blocked DNP-induced increase of $I_{K(ca).}$ The percentage of DNP-induced increase was diminished from 63.24% ± 4.32% to 28.53% ± 3.31% at 60 mV (Figure 2).

Effect of cGMP-dependent protein kinase on DNP-induced increase of $I_{K(ca)}$

To extend our understanding of the role of DNP in the regulation of $I_{K(ca)}$ through the cGMP/PKG pathway, the effect of KT-5823 (a membrane-permeable PKG-specific inhibitor) on channel activity was tested. As the results show in Figure 3, the addition of KT-5823 (1 μmol/L) completely inhibited DNP-induced increase of $I_{K(ca)}$. This data suggests the involvement of PKG-mediated phosphorylation in DNP-mediated regulation of $I_{K(ca)}$.

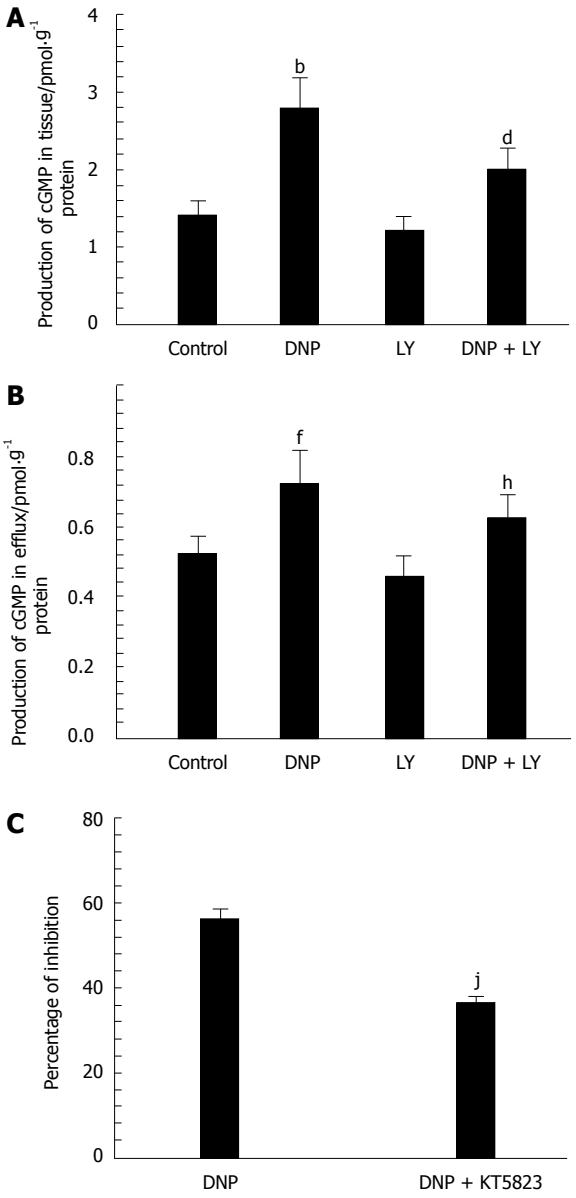

Figure 1 **A**: Effect of 10 nmol/L LY83583 on cGMP production of in tissue ($n = 8$), $^bP < 0.01$ *vs* control group, $^dP < 0.01$ *vs* DNP group; **B**: Effect of 10 nmol/L LY83583 on cGMP production of in efflux ($n = 8$), $^fP < 0.01$ *vs* control group, $^hP < 0.01$ *vs* DNP group; **C**: Effect of a membrane-permeable PKG-specific inhibitor (KT5823) on DNP-induced inhibition of spontaneous contraction in gastric antral circular smooth muscle ($n = 8$), $^jP < 0.01$ *vs* DNP group.

Effect of cGMP-dependent protein kinase on DNP-induced increase in STOCs

STOCs, which can be activated by extracellular Ca^{2+} influx and intracellular Ca^{2+} release, were recorded at -20 mV. The currents were sensitive to TEA (a nonselective K^+ channel blocker) and CHTX (a selective Ca^{2+}-activated K^+ channel blocker). As described in our previous study, DNP increased STOCs in gastric circular myocytes. To

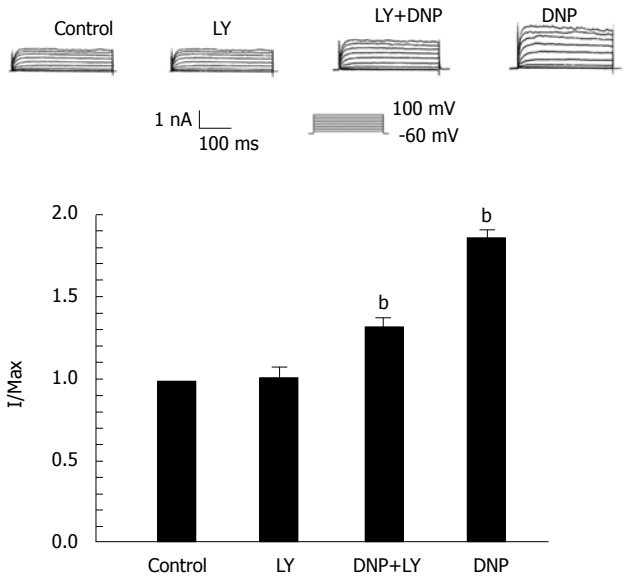

Figure 2 Effect of LY83583 on DNP-induced increase of $I_{K(Ca)}$, $^{b}P < 0.01$ *vs* control group.

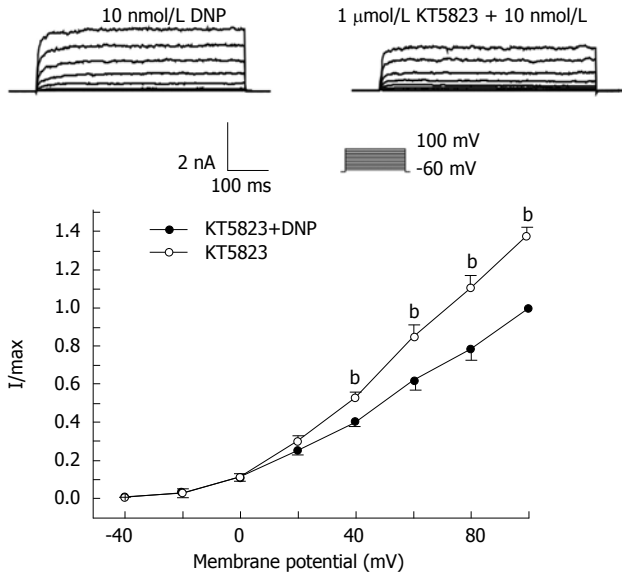

Figure 3 Effect of a membrane-permeable PKG-specific inhibitor, KT-5823, on DNP-induced increase of $I_{K(Ca)}$ (n = 8), $^{b}P < 0.01$ *vs* control group.

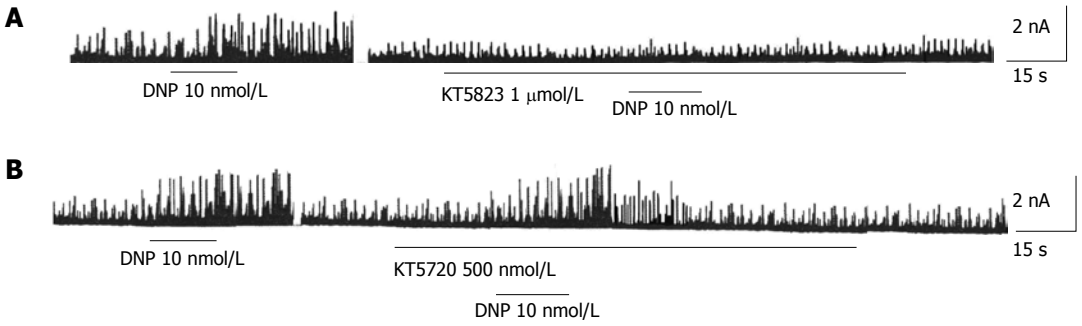

Figure 4 **A**: Effect of a membrane-permeable PKG-specific inhibitor, KT-5823, on STOCs (n = 10); **B**: Effect of KT-5720 (500 nmol/L), a PKA-specific inhibitor, on STOCs (n = 10).

further investigate the relationship between cGMP/PKG pathway and DNP-induced increase in STOCs, we examined the effect of KT5823 on DNP-induced increase in STOCs. The result indicated that KT5823 almost completely abolished DNP-induced increase of STOCs (Figure 4A). However, KT-5720 (500 nmol/L), a PKA-specific inhibitor, could not suppress DNP-induced increase in STOCs (Figure 4B).

DISCUSSION

In the present study, the patch clamp technique, radioimmunoassay and specific pharmacological inhibitors were used to determine involvement of the pGC-cGMP-PKG pathway in DNP-mediated relaxation in guinea-pig gastric antral circular smooth muscle.

In this study, we found that cGMP in the smooth muscle tissue and perfusion solution both were markedly increased after the addition of DNP. The effect of DNP was diminished after treatment with LY83583, an inhibitor of guanylate cyclase to change the production of cGMP. These data indicate that DNP may inhibit spontaneous contraction by increasing cGMP levels. Consistent with this view, KT5823, a PKG inhibitor, markedly diminished the inhibitory effect of DNP on spontaneous contraction. In an attempt to understand how DNP relaxes smooth muscle by affecting the cGMP-dependant pathway, patch clamp experiments were carried out. We observed that KT5823 inhibited DNP-induced increase of $I_{K(ca)}$, and almost completely abolished the DNP-induced increase of STOCs. However, KT-5720 (500 nmol/L), a PKA-specific inhibitor, had no effect on DNP-induced increase in STOCs.

NPs, similar to NO, can increase the generation of cGMP and cAMP, and play important physiological functions in a variety of cell types. In smooth muscle cells, NPs exhibited an inhibitory effect on motility *via* the cGMP pathway. For example, ANP increases intracellular cGMP levels and mediates the role of endothelium- and cardiac-derived NO in regulating sympathetic control functions of the heart and the microvasculature in conscious rats by affecting cGMP-dependent release of catecholamines[16]. Additionally, Kedia *et al*[17] observed that CNP is involved in the cGMP-dependent control of the normal function of human prostatic smooth muscle. Our previous study also found that CNP inhibited spontaneous contraction

by increasing cGMP in gastric antral circular smooth muscle[18]. All these previous reports are consistent with our current findings that DNP-induced relaxation is related to cGMP in gastric circular smooth muscle.

It has been reported that intracellular cGMP may not only result in activation of PKG, but also inhibits activity of PDE3[19]. The latter action would lead to an increase in cAMP, and hence may stimulate another cyclic nucleotide-dependent protein kinase, PKA. NPs exert some physiological functions by affecting PKA. Birukova *et al*[20] have found that Epac/Rap and PKA are novel mechanisms of ANP-induced Rac-mediated pulmonary endothelial barrier protection. However, our present study indicates that DNP-induced increase of $I_{K(ca)}$ and STOCs were significantly blocked by LY83583 and KT-5823. DNP stimulated STOCs even in the presence of a PKA-specific inhibitor (KT-5720), suggesting that the DNP-induced increase of STOCs was due to stimulation of PKG, rather than PKA. The direct effect of cGMP on the activity of ion channels has been reported previously. Yao *et al*[21] showed that a cGMP-gated K^+ channel is expressed in the kidney. Nakamura *et al*[22] revealed that protein kinase G activates inwardly rectifying K^+ channels in cultured human proximal tubule cells. Hirsch *et al*[23] demonstrated the existence of cGMP-regulated K^+ channels that were inhibited by cGMP without PKG-mediated phosphorylation. In our current study, however, DNP-induced relaxation in gastric antral myocytes was inhibited by KT5823. This indicates that PKG-mediated phosphorylation participates in DNP-induced relaxation. Consistent with our data, a previous report has shown that CNP can inhibit L-type Ca^{2+} channel currents, and the inhibitory effect is mediated by pGC-cGMP-PKG-dependent signal pathway in gastric antral myocytes of guinea pigs[24]. However, it should be pointed out that the results of our current study can not determine whether a direct or indirect activation of Ca^{2+}-activated K^+ channels by PKG participates in DNP-induced relaxation of in gastric antral smooth muscle cells. As such, further experiments are necessary to decode this intriguing question.

Taken together, it can be concluded that DNP relaxes gastric circular smooth muscle by activating Ca^{2+}-activated K^+ channels, mediated by a pGC-cGMP-PKG-dependent signal pathway. cAMP did not participate in the process.

COMMENTS

Background

Dendroaspis natriuretic peptide (DNP) is a recently isolated peptide that contains 38 amino residues and shares structural and functional properties with the other members of the natriuretic peptide (NP) family. Studies about its physiologic functions mainly focus on cardiovascular, nervous, and urinary systems. In a previous study, these authors found that DNP inhibited spontaneous contraction in gastric circular smooth muscle. NP plays important physiological functions by affecting the activity of cGMP and cAMP. However, it is unclear whether cGMP or cAMP participates in regulating DNP-induced inhibition of gastric motility.

Research frontiers

Studies about the physiologic functions of DNP mainly focus on cardiovascular, nervous, and urinary systems. There are few reports about the relationship between DNP and gastrointestinal functions. Studies have demonstrated that the DNP system is present in the rat colon and regulates colonic motility as a local regulator. The relationship between DNP and gastrointestinal function has become a focus of study. A previous study has indicated that DNP inhibits gastric motility, which is the first report about DNP regulating gastric motility. However, the mechanism on how DNP regulates gastric motility is still unclear and is the focus of the author's study.

Innovations and breakthroughs

The author's of this paper have shown that, for the fist time, DNP activates $I_{K(Ca)}$ and relaxes guinea-pig gastric antral circular smooth muscle *via* the cGMP/PKG-dependent signaling axis, instead of the cAMP/PKA pathway. The combined use of pharmacologic, radioimmunoassy and patch-clamp techniques can sufficiently demonstrate the mechanism involved in DNP regulation of gastric motility.

Applications

This work enhanced the understanding of the mechanism on how DNP regulates gastric motility.

Peer review

This is a very interesting study. The authors demonstrated that DNP activates $I_{K(Ca)}$ and relaxes guinea-pig gastric antral circular smooth muscle *via* the cGMP/PKG-dependent signaling axis instead of the cAMP/PKA pathway. This study is well designed, and the analysis is reasonable.

Abstract

We present three cases of patients (at the age of 56 years, 49 years and 74 years respectively) with severe acute pancreatitis (SAP), complicated by intra-abdominal compartment syndrome (ACS) and respiratory insufficiency with limitations of mechanical ventilation. The respiratory situation of the patients was significantly improved after decompression laparotomy (DL) and lung protective ventilation was re-achieved. ACS was discussed followed by a short review of the literature. Our cases show that DL may help patients with SAP to recover from severe respiratory failure.

Key words: Severe acute pancreatitis; Intra-abdominal compartment syndrome; Decompression laparotomy; Intensive care Unit; Respiratory failure

INTRODUCTION

Severe acute pancreatitis (SAP) is associated with organ failure leading to a mortality rate of 10%-20% that is often related to respiratory failure. Approximately one third of SAP patients develop respiratory complications[1,2]. In the majority of cases, this lung injury is characterized by an increased permeability of pulmonary microvasculature and subsequent leakage of protein-rich exudates into the alveolar spaces[1]. Furthermore, concomitant diseases, such as intra-abdominal hypertension (IAH) defined by intra-abdominal pressure (IAP) greater than 12 mmHg[3], may result in restrictive ventilation disorders and deteriorate the pulmonary situation.

Surgical debridement was the preferred treatment to control necrotizing pancreatitis in the past. However, management of necrotizing pancreatitis has changed since the last decade. The first approach now tends to be non-surgical and relies on conservative strategies including early transfer of patients to intensive care units at specialized centres. Indication for necrosectomy is still given in cases of infected necrosis as well as intestinal infarction, perforation or bleeding, but there is a clear trend towards surgical treatment as late and as rare as possible[2]. In contrast, more and more studies are published promoting decompression laparotomy (DL) for SAP patients developing abdominal compartment syndrome (ACS) defined by IAP greater than 20 mmHg associated with new organ failure[3-7]. This procedure can not only prevent critical decrement of intestinal and renal perfusion, but may lead to improvement in the respiratory situation.

We present three patients with SAP and abdominal compartment syndrome, who developed respiratory insufficiency with limitations of mechanical ventilation associated with high peak pressure levels, low tidal volumes and poor Horowitz-indices (pO_2/FiO_2; HI). The three patients showed a benefit from decompression laparotomy so that ventilation with adequate oxygenation could be re-achieved. Surgery was performed at the Intensive Care Unit of our hospital without transportation of the patients to the operating room.

Intensive Care Unit of our hospital because of necrotizing pancreatitis. One week prior to admission, he underwent an ambulant gastroduodenoscopy in the referring hospital and resection of pancreatic papilla minor due to misinterpretation as a polyp. Following endoscopy, progredient upper abdominal pain developed with rising serum lipase and CRP levels. Diagnostic procedures including abdominal sonography, CT-scan and endoscopic-retrograde-cholangio-pancreaticography (ERCP) confirmed pancreatitis. At admission, intubation was performed followed by mechanical ventilation because of respiratory insufficiency (Figure 1A). In the next days, fluid resuscitation was performed, and increasing peak inspiratory and mean airway pressures were needed to achieve sufficient oxygenation. Meanwhile, IAP determined by an indwelling transurethral bladder catheter increased. On day 4, criteria for an ACS were fulfilled (Figure 1B). Simultaneously, Horowitz index decreased (75 mmHg) with 100% oxygen, a positive end expiratory pressure of 20 mmHg and a peak inspiratory airway pressure of 39 mmHg. Sonography revealed an elevation of the diaphragm without any movement. On day five, we decided to perform decompression laparotomy to improve pulmonary gas exchange. A median laparotomy of approximately 30 cm was performed. The abdominal cavity was closed with absorbable Vicryl®-Mesh. Postoperative oxygenation improved with decreasing ventilation pressures and chest wall compliance. Nevertheless the respiratory situation deteriorated again with low oxygenation values and hypercapnia, while IAP equally rose. A pumpless extracorporeal lung assist system (ILA®) was installed on day eight, resulting in a marked decrease in pCO_2, but the Horowitz index did not improve. Since the IAP values increased again (> 20 mmHg), the laparotomy was extended from xiphoid process to symphysis, thereby leading to a significant improvement in the respiratory situation. Again, the abdominal cavity was closed with Vicryl®-Mesh. During the next days, CT scan-guided retroperitoneal drainage was performed for debridement of pancreatic necrosis. As a result, IAP further decreased (Figure 1B). The patient was successfully weaned, therapy with ILA® system could be quickly terminated and the abdomen healed by secondary wound healing.

Patient 2

A 49-year-old man with morbid obesity (172 cm, 150 kg, BMI = 50.7 kg/m^2) presented in the Emergency Department of our hospital for colicky abdominal pain. His past medical history included a limited cardiac function due to ischemic heart disease and recurrent ventricular tachycardia. Laboratory and radiological findings as well as endoscopy revealed biliary pancreatitis. Three days after admission, his respiratory situation worsened and he was transferred to the Intensive Care Unit. Mechanical ventilation had to be initiated. On the second day of intensive care treatment, intra-abdominal inflammation, massive fluid resuscitation (fluid intake about 10 L/d, urine output 1 L/d the first day, up to 7 L/d the next days) and pre-existing obesity led to ACS with a measured IAP above 25 mmHg. Limitations of ventilation therapy with decreased lung and chest compliance prompted us to perform decompression laparotomy. IAP, APP, Horowitz index as well as compliance values significantly improved after surgical therapy and lung protective ventilation could be re-achieved. Secondary wound healing of the open abdomen was improved after vacuum-assisted closure (VAC) therapy (Figure 2B). Unfortunately, the patient developed cardiovascular complications and died of fulminant lung bleeding two weeks later.

Patient 3

A 74-year-old woman was admitted with post-ERCP pancreatitis after an ERCP was performed for symptomatic cholecystolithiasis. She was transferred to our hospital from another hospital due to aggravation of her condition with rising inflammation parameters. On the day of admission, she had to be intubated, mechanical ventilation was started and fluid resuscitation was performed. Within 3 d the HI dramatically dropped with simultaneously increasing peak pressure levels (Figure 3). Under 100% oxygen ventilation, inverse ventilation ratio (2:1), peak pressure of 45 mmHg and positive end-expiratory pressure (PEEP) of 22 mmHg, and PO_2 of 70 mmHg could be achieved. Clinically, she presented with massive abdominal tenderness. IAP-values above 20 mmHg were measured

and decompression laparotomy was performed due to respiratory failure. Immediately after the intervention, her respiratory situation improved significantly. During the next days, interventional CT-guided drainage therapy was performed and led to a further decrease in intra-abdominal pressure. Weaning was successful and spontaneouse breathing was re-achieved after dilatation tracheotomy and prolonged respiratory therapy due to septic complications. Three months after recovery, the abdominal laparotomy wound was closed along with elective cholecystectomy.

DISCUSSION

We present three cases of patients with SAP developing ACS leading to severe limitations of respiratory therapy. In each of these patients, decompression laparotomy caused immediate improvement in pulmonary function and led to definite survival in two cases.

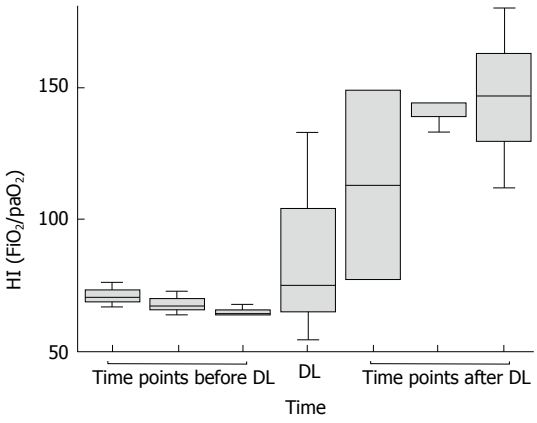

Figure 3 Development of Horowitz-indices (HI). In the Box blots, the HI 3, 2 and 1 d before, at and 1, 2 and 3 d after DL of all 3 patients is shown. The line refers to the median, whereas the boxes refer to the interquartile ranges. The whiskers represent the 5th and 95th percentiles, respectively.

Approximately 30%-40% of SAP patients develop ACS because of pancreatic-retroperitoneal inflammation, edema of peripancreatic tissue, fluid formation or abdominal distension, subsequently leading to intestinal ischemia with ileus and renal failure[5]. Besides, additional fluid resuscitation is known to further increase IAP. It was reported that ACS generally affects cardiac, pulmonary and renal function, and contributes to multi-organ dysfunction with a mortality rate ranging 10%-50% within two weeks[6,8-11]. The degree of IAP in patients with SAP seems to correlate with the degree of organ dysfunction, the severity of disease, the length of intensive care unit stay and mortality[6,8-11].

Pulmonary side effects mediated by IAH, such as atelectasis, edema, decreased oxygen transport and increased intrapulmonary shunt fraction, are caused by compression of pulmonary parenchyma. IAP is transmitted to the thorax through the elevated diaphragm and causes pulmonary parenchyma compression. The abdominal pressure on lung parenchyma is aggravated in mechanically ventilated patients due to high positive airway pressure, thereby leading to an elevated risk of alveolar barotraumas[12]. Furthermore, a study in ACS trauma patients demonstrated an increased rate of pulmonary infections[13].
