ovigerous female [Carapace length (CL): 15mm; Rostrum length (RL): 28mm] was reddish in colour with dark red ring formation in posterior abdomen. The telson was found damaged. The eggs were spherical in shape with pale green colour. Voucher specimen was deposited in the National Designated Repository, ICAR-CMFRI, Kochi with Accession Number ED2.4.3.8.

The morphometric characters recorded were as follows: Rostrum extending beyond the antennal scale, dorsally armed with 6 teeth, including 3 on carapace posterior to level of orbital margin, armed ventrally with 35 teeth; abdomen with strong, recurved posteromesial tooth but without median dorsal carina on 3rd somite, 4th somite with pleuron rounded, 3rd maxilliped with epipod; pereopods with

Voucher specimen of *Plesionika reflexa*

well-developed epipods on anterior pairs, 2nd pair sub equal, 3rd pair extending beyond the antennal scale by a length of dactylus, none of pereopods are extremely slender or thread like. This species is closely related to *Plesionika ensis* (A.Milne-Edwards, 1881). In *Plesionika reflexa*, the posteromesial tooth on the third abdominal somite shows a tendency to recurve, whereas same has not been noticed in *P.ensis*.
