(Received 28 July 2016; accepted 28 September 2016)

Abstract *Potamogeton* is a cosmopolitan genus of 90–95 species in which numerous hybridization events have occurred worldwide. A plant recently collected from Argentina exhibited ambiguous morphology that does not match any species of the genus. We aimed to assess if the plant coexisting with another *Potamogeton* species is a product of reticulate evolution. A concatenated plastid DNA (*psbA-trnH*, *trnL* intron, and *trnL-trnF*) and nuclear ribosomal DNA (5S-NTS) data sets, primarily based on previous studies sample set mainly consisting of American and Asian species, were analyzed using Bayesian inference. Nuclear ribosomal ITS sequences were also obtained from five Argentina materials. We recovered similar topologies from both the plastid DNA and nuclear ribosomal 5S-NTS analyses in which most specimens are consistently placed. The specimen of primal interest from Argentina strongly clustered with co-occurring linear-leaved species in the 5S-NTS tree, but was genetically identical to broad-leaved ones in the plastid DNA analysis. The ITS sequence of the specimen was the same as that of the linear-leaved species and no polymorphisms were observed. Considering the discrepant phylogenetic positions between the trees and lack of ITS infra-individual variations, the origin of the specimen from Argentina is better explained by hybridization and subsequent introgression.

Key words: Alismatales, aquatic plants, Bayesian inference, hybridization, introgression, molecular phylogeny, plastid DNA, *Potamogeton*, topological conflicts, 5S-NTS.

Introduction

Potamogeton L. is one of the three genera of the aquatic plant family Potamogetonaceae. The number of the species varies depending on literature, but 90–95 species are in general accepted in the world (Haynes and Holm-Nielsen, 2003; WCSP, 2014). This cosmopolitan genus has its

center of species diversity in temperate regions of the northern hemisphere (Kaplan *et al.*, 2013), with nearly 70% of the world's species occurring in either Asia, Europe, or North America (Wiegleb and Kaplan, 1998). In contrast, the species in Southern South America, comprising Argentina, Chile, and Uruguay, has been scarcely studied. Following Tur (1982), Wiegleb and Kaplan

(1998), and Haynes and Holm-Nielsen (2003), nine well-recognized species were recorded in southern South America: i) *P. crispus* L. (cosmopolitan); ii) *P. ferrugineus* Hagstr. (South America); iii) *P. gayi* A.Benn. (South America); iv) *P. illinoensis* Morong (North and South America); v) *P. linguatus* Hagstr. (South America); vi) *P. montevidensis* A.Benn. (South America); vii) *P. polygonus* Cham. (South America); viii) *P. pusillus* L. (cosmopolitan); and ix) *P. spirilliformis* Hagstr. (South America). As reported in other regions, difficulties of morphological identification of *Potamogeton* species are known in South America. A plant recently collected from Argentina (Y. Ito YI1992 & *al.*; Fig 1; Appendix 1) exhibited ambiguous morphology that does not match any above-mentioned species of the genus (Fig. 1; Table 1).

Potamogeton is a genus in which numerous

hybridization events have occurred; therefore, it is recognized as a “classic” example of hybridization in aquatic plants (Les and Philbrick, 1993). In their morphology-based monographic work, Wieglob and Kaplan (1998) reported the number of hybrids that are approximately the same as the number of non-hybrid species. Subsequent molecular studies have detected and documented further cases of hybridization in *Potamogeton*, including ones that do not exhibit obvious morphological characteristics (Les *et al.*, 2009). A case of triple hybridization (a hybrid arisen from crosses of a primary hybrid with a third species) has been also reported in *Potamogeton* (Kaplan and Fehrer, 2007), implying that the genus has undergone rather complicated evolution. The aforementioned morphologically ambiguous plant from Argentina may be a product of hybridization, because it coexists with *P. pusillus*.

Fig. 1. Habitat of *Potamogeton* sp. YI1992_TNS in Córdoba, Argentina.

Molecular phylogenetic analyses on *Potamogeton* have been independently conducted by different research groups based on their own unique sample and data sets that scarcely overlapped each other (e.g., Iida *et al.*, 2004; Lindqvist *et al.*, 2006; Wang *et al.*, 2007; Zhang *et al.*, 2008; Les *et al.*, 2009; Ito and Tanaka, 2013; Kaplan *et al.*, 2013). Therefore, it remains unclear which phylogeny is the most reliable one, as significant topological incongruences have occasionally been found among the studies (Ito and Tanaka, 2013). Lindqvist *et al.* (2006) provided a relatively well-resolved phylogeny of the genus, comprising broad-leaved and linear-leaved lineages based on the 5S non-transcribed spacer [hereinafter called 5S-NTS of the nuclear ribosomal DNA (nrDNA)], followed by Kaplan *et al.*'s (2013) 5S-NTS tree. Still, a question remains as to whether the same or similar topology can be recovered with a plastid DNA (hereinafter called ptDNA) data set because Lindqvist *et al.* (2006) failed to reconstruct a resolved phylogeny in their ptDNA analysis using two fast-evolving markers, *psbA-trnH* and *trnL* intron, and no analyses using ptDNA sequences were performed by Kaplan *et al.* (2013). However, Lindqvist *et al.*'s (2006) data set itself appears to be useful if 19 outgroups from the other genera of Potamogetonaceae and other distantly related monocots and non-monocot families, e.g., Arecaceae, Alismataceae, Juncaginaceae, and Magnoliaceae, are excluded from the analysis. Comparative data are available by Zhang *et al.* (2008, unpublished data), which using *trnT-trnL*, *trnL* intron, and *trnL-trnF*, recovered roughly the same broad-leaved and linear-leaved lineages (Zhang *et al.*, 2008).

To assess whether the unidentified *Potamogeton* (*Y. Ito YII992 & al.*) with ambiguous morphology from Argentina is a product of hybridization, we employed simultaneous molecular phylogenetic analyses of nrDNA and ptDNA based on data sets of Lindqvist *et al.* (2006) and Zhang *et al.* (2008) and comparable data from GenBank, which occasionally contains *trnL-trnF* from ptDNA (Kaplan and Fehrer, 2007; Zhang *et al.*,

2008). The data set of Lindqvist *et al.* (2006) is particularly relevant for our purpose because it mainly consisted of North American species that either are distributed in South America or apparently have South American relatives (Wieglob and Kaplan, 1998; Haynes and Holm-Nielsen, 2003). Topological incongruence between reconstructed phylogenetic trees were compared, with a particular focus on the taxa from Argentina. In addition, DNA sequences of the internal transcribed spacer (ITS) region of nrDNA were generated to seek another line of evidence of hybridization.

Materials and Methods

Taxon sampling

The data set for molecular phylogenetic analyses mainly consists of sequences deposited in GenBank: 41 samples (Lindqvist *et al.*, 2006); 26 (Zhang *et al.*, 2008, unpublished data); four (Kaplan and Fehrer, 2007; Kaplan *et al.*, 2013). Seventeen out of samples used in Lindqvist *et al.* (2006) that lack either ptDNA or 5S-NTS were not included in this study. Five samples from Argentina were added, which were *P. gayi* (one specimen), *P. pusillus* (three), and the unidentified *Potamogeton* sp. YI1992_TNS (one). The data set included 76 samples, which were equivalent to 46 species including one putative hybrid, *P. × haynesii* Hellq. & G.E.Crow (Appendix 1).

DNA extraction, PCR amplification, and sequencing

Total genomic DNA was extracted from the five newly collected *Potamogeton* specimens from Argentina following the method outlined in Ito *et al.* (2010) and their sequences of ptDNA and nrDNA regions were determined by PCR amplification and direct sequencing. The following primer pairs were used for PCR and sequencing: *psbAF* and *trnHR* (Sang *et al.*, 1997) for *psbA-trnH*; "c" and "d" (Taberlet *et al.*, 1991) for *trnL* intron; "e" and "f" (Taberlet *et al.*, 1991) for *trnL-trnF*; and *PI* and *PII* (Cox *et al.*, 1992) for 5S-NTS, and *ITS-4* and *ITS-5* for nrITS (Bald-

win, 1992). The PCR amplification was conducted using TaKaRa Ex Taq polymerase (TaKaRa Bio, Japan), and PCR cycling conditions were 94°C for 60 s; then 30 cycles of 94°C for 45 s, 52°C for 30 s, 72°C for 60 s; and finally 72°C for 5 min. The PCR products were cleaned using illustra ExoProStar (GE Healthcare, Piscataway, USA) and then reacted using ABI Big Dye Terminator ver. 3.1 (Applied Biosystems, USA) with the same primers as those used for the PCR amplifications. DNA sequencing was performed with an ABI PRISM 3130xl DNA sequencer (Applied Biosystems). Automatic base calling was checked by eye using Genetyx-Win ver. 3 (Software Development Co., Japan). All sequences generated in the present study have been submitted to the DNA Data Bank of Japan (DDBJ), which is linked to GenBank, and their accession numbers and voucher specimen information are presented (Appendix 1).

Data analysis

We assembled two datasets from the 76 samples, which included the aforementioned five samples from Argentina: i) ptDNA (*psbA-trnH*, *trnL* intron, and *trnL-trnF*) and ii) nuclear 5S-NTS. Missing data found in ptDNA were retained because “it should generally be possible to accurately place incomplete taxa in phylogenies, if enough informative characters are sampled” (Wiens and Morrill, 2011); those are used as equivocal characters (N). Following Kaplan *et al.* (2013), one of the basal-most *Potamogeton* taxa in their ITS tree, namely *P. spirillus*, were chosen as an outgroup for addressing the intrageneric relationships, because this region was too variable to allow a reliable alignment with the other two genera. Sequences were aligned using MAFFT ver. 7.058 (Katoh and Standley, 2013) using “leave gappy regions” option and then inspected manually.

Phylogenetic inference was performed using Bayesian inference (BI; Yang and Rannala, 1997). Analyses were conducted with MrBayes ver. 3.2.2 (Ronquist and Huelsenbeck, 2003; Ronquist *et al.*, 2012) run on the CIPRES portal

(Miller *et al.*, 2010) after the best models had been determined in MrModeltest ver. 3.7 (Nylander, 2002); these models were GTR + I + G for ptDNA and GTR + G for 5S-NTS. For gap characters, the datatype = standard option of MrBayes was used. Analyses were run for 8,150,000 million and 460,000 million generations for the ptDNA and 5S-NTS data sets, respectively, until the average standard deviation of split frequencies dropped below 0.01, sampling every 1,000 generations and discarding the first 25% as burn-in. The convergence and effective sampling sizes (ESS) of all parameters were checked in Tracer ver. 1.6 (Rambaut *et al.*, 2014). All trees were visualized using FigTree ver. 1.3.1 (Rambaut, 2009). The data matrices and the MrBayes trees are available at Treebase (TB2:S18639).

Results

Molecular phylogeny

The ptDNA data set of *Potamogeton* included 1,391 aligned characters (*psbA-trnH*: 364 bp; *trnL* intron: 591 bp; *trnL-trnF*: 436 bp) and 17 indels, of which 146 characters including the binary-coded indels are polymorphic. The topology is resolved, yet the support values are mostly low (Fig. 2a).

The 5S-NTS data set of *Potamogeton* included 310 aligned characters and six indels, of which 275 characters including the binary-coded indels are polymorphic. We obtained a well-resolved tree, which topology followed that of the ptDNA tree (Fig. 2b).

Respective four groups, that belonged to linear-leaved and broad-leaved lineages detected in Lindqvist *et al.* (2006) and Kaplan *et al.* (2013), were recovered in either or both ptDNA and 5S-NTS trees; those are numbered from groups L1–L4 and groups B1–B4, respectively: group L1 (*P. diversifolius*–*P. spirillus*); group L2 (*P. compressus*–*P. gayi*–*P. obtusifolius*–*P. subsibiricus*–*P. trichoides*]; group L3 [*P. clystocarpus*–*P. foliosus*–*P. friesii*–*P. × haynesii*–*P. pusillus* (China)–*P. strictifolius*]; group L4 [*P. oxyphyllus*–*P. pusillus*

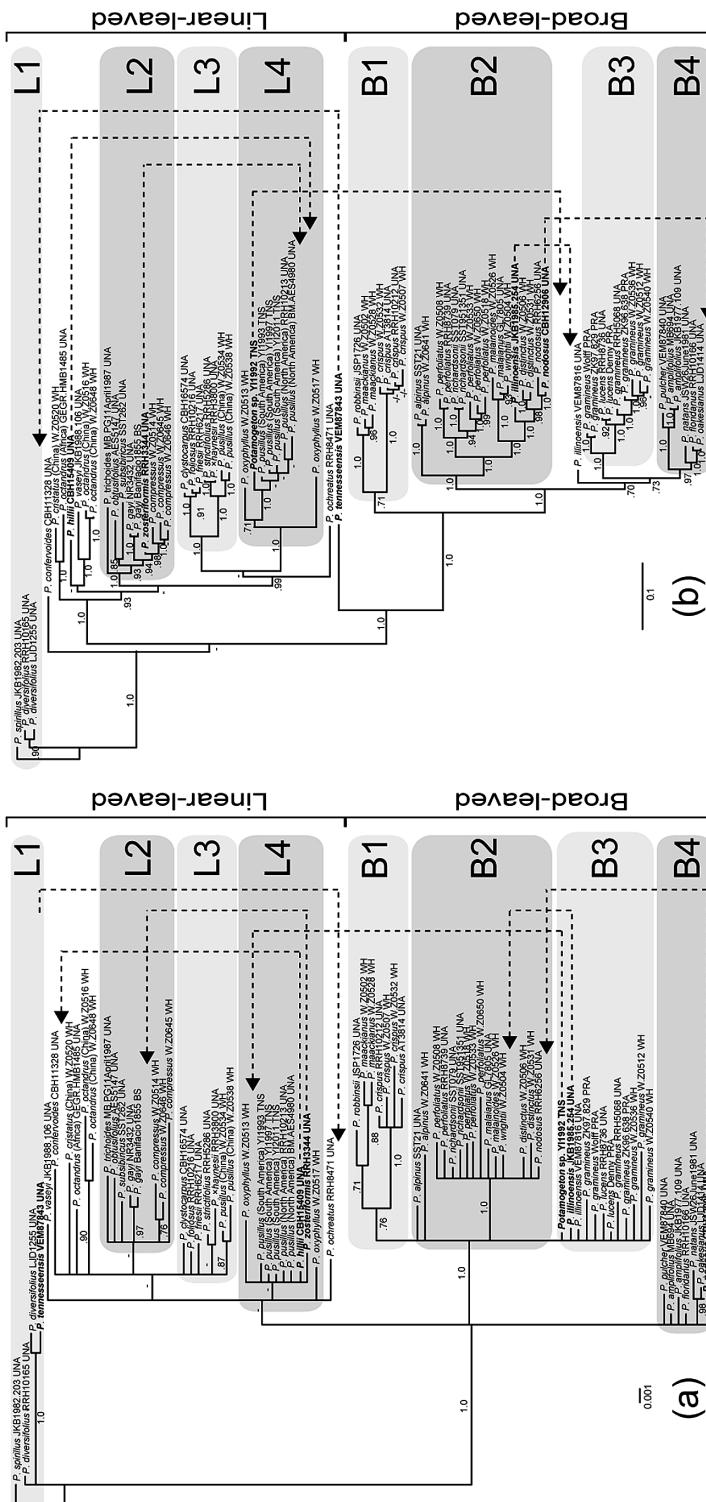

Fig. 2. MrBayes trees for *Potanogenon* based on a) the concatenated plastid DNA (*psba-trnH*, *trnL*, and *trnL-trnF*) and b) the nuclear 5S-NTS data sets. Letters refer to groups noted in the text. The six accessions of which phylogenetic positions are inconsistent between the data sets are emphasized in bold, for which the corresponding phylogenetic positions in the other analysis are indicated by dotted arrows. Numbers above or below the branches indicate Bayesian posterior probabilities (PP). Clades with PP < 0.7 are indicated by hyphens.

(North and South America)]; group B1 (*P. crispus*–*P. maackianus*–*P. robbinsii*); group B2 [*P. alpinus*–*P. distinctus*–*P. malaianus*–*P. malainoides*–*P. nodosus* (RRH6256 UNA)–*P. perfoliatus*–*P. richardsonii*–*P. wrightii*]; group B3 [*P. gramineus*–*P. illinoensis* (VEM87816 UNA)–*P. lucens*]; group B4 (*P. amplifolius*–*P. floridanus*–*P. oakesianus*–*P. natans*–*P. pulcher*).

Of samples from Argentina, *Potamogeton* sp. YI1992_TNS was positioned significantly differently between ptDNA and 5S-NTS trees (group B3 in ptDNA; group L4 in 5S-NTS; Fig. 2).

Nuclear DNA (ITS) sequence comparisons

ITS sequences obtained from the five specimens from Argentina were 713 bp in length. No intra-individual variation were found in any of the specimens, except the 1-bp intra-individual variation observed in *Potamogeton pusillus* YI1997. No sequence differences were found between *P. pusillus* and *Potamogeton* sp. YI1992_TNS, from which *P. gayi* is distinguishable by two nucleotide substitutions.

Discussion

The present study reconstructed phylogenies of *Potamogeton* based on ptDNA and nuclear 5S-NTS of nrDNA data sets, in which six accessions show significant inconsistency between the trees (Fig. 2). Such topological incongruences resulting from ptDNA and nrDNA markers are often reported in phylogenetic studies (Wendel and Doyle, 1998; Degnan and Rosenberg, 2009). Although some causes of phylogenetic incongruence, e.g. gene choice and incomplete lineage sorting, are suggested, hybridization and introgression are likely to be attributed to the topological conflicts in *Potamogeton*, as is concluded by Hamzeh and Dayanandan (2004), Fehrer *et al.* (2007), Tipperry and Les (2011), Ito *et al.* (2013), Ren *et al.* (2015), Soto-Trejo *et al.* (2015). The six specimens discrepantly resolved between the trees may indicate such reticulate evolution. Here, out of the six accessions, we discussed only for *Potamogeton* sp. YI1992_TNS, that was

collected by ourselves.

Potamogeton sp. (Y. Ito YI1992 & al.) has ptDNA close to those of broad-leaved species, such as *P. illinoensis* and *P. lucens* (group B3; Fig. 2a) and nrDNA identical or closely related to that of the co-occurring linear-leaved *P. pusillus* (group L3; Fig. 2b). Considering the incongruence of phylogenetic position and the lack of ITS intra-individual polymorphisms, which has been used as a line of evidence to identify *Potamogeton* hybrids (e.g. Kaplan and Fehrer 2007, Du *et al.*, 2010), not simple hybridization but introgression following multiple hybridizations between linear-leaved and broad-leaved species better explain the origin of *Potamogeton* sp. YI1992_TNS. With the empirically confirmed maternal inheritance of chloroplast DNA in *Potamogeton* (Kaplan and Fehrer, 2006), hybridization between a paternal *P. pusillus* and a maternal broad-leaved *Potamogeton* species is likely. The maternal parent is most probably *P. illinoensis* because this American species is also distributed in Argentina (Haynes and Holm-Nielsen, 2003), where it once may have occurred with *P. pusillus* (which yet co-exists in the river in Córdoba, Argentina) and have repeatedly hybridized with its pollen, termed “cytoplasmic introgression” (Rieseberg, 1997).

Conclusions

We performed simultaneous molecular phylogenetic analyses of *Potamogeton* based on previous studies' data sets and our newly collected samples. The topological comparison between ptDNA and 5S-NTS clearly exhibited significant incongruences. A single accessions from Argentina that was inconsistently positioned between the trees may be a product of hybridization or introgression. Future phylogenetic researches may aim at i) improving the support values by adding more valuable ptDNA regions, ii) seeking alternative nrDNA markers, such as low-copy nuclear DNA loci, and iii) applying alternative methods such as AFLP and RADseq.

Acknowledgment

The authors thank N.B. Deginani (SI) for her help with examining specimens, C. Ishii (Tsukuba) for help with DNA sequencing, J. Viljoen (Cape) for his kind advice on molecular phylogenetic analyses, Y. Ito (Kunming) for assistance with preparing the appendix, P. B. Pelser (CANU), J. Li (Kunming), and J. Murata, H. Ikeda, T.
