## Abstract

Riina, R. & Berry, P.E. 2010. Two new South American species of *Croton* (Euphorbiaceae) and their phylogenetic affinities. *Anales Jard. Bot.* Madrid 67(1): 23-27.

Two rarely collected species of *Croton* from South America are described and illustrated. *Croton chimboracensis* P.E. Berry & Riina is localized in western Andean Ecuador and is sister to *Croton* sect. *Adenophyllum* Griseb. *Croton abonari* Riina & P.E. Berry is known from a single location in Amazonian Brazil; it resembles both *C. sampatik* Müll. Arg. and members of *Croton* sect. *Cuneati* (G.L. Webster) Riina & P.E. Berry, but *C. abonari* can be easily distinguished from both groups by distinctive morphological characters.

**Keywords:** Amazon, Andes, *Croton abonari*, *C. chimboracensis*, Euphorbiaceae.

## Resumen

Riina, R. & Berry, P.E. 2010. Dos nuevas especies suramericanas de *Croton* (Euphorbiaceae) y sus afinidades filogenéticas. *Anales Jard. Bot.* Madrid 67(1): 23-27 (en inglés).

Se describen e ilustran dos especies raras de *Croton* de Suramérica. *Croton chimboracensis* P.E. Berry & Riina está localizada en los Andes occidentales de Ecuador y es hermana del clado de *Croton* sect. *Adenophyllum* Griseb. *Croton abonari* Riina & P.E. Berry se conoce de una sola localidad en la Amazonía de Brasil; es similar tanto a *C. sampatik* Müll. Arg. y a miembros de la sección *Cuneati* (G.L. Webster) Riina & P.E. Berry, pero *C. abonari* se puede diferenciar de ambos grupos por varios caracteres morfológicos distintivos.

**Palabras clave:** Amazonia, Andes, *Croton abonari*, *C. chimboracensis*, Euphorbiaceae.

## Introduction

As a result of recent and ongoing taxonomic and phylogenetic studies on *Croton*, our understanding of this large genus has increased substantially, especially in the Neotropics, where several new species have recently been described by our network of collaborators (Secco & al., 2001, 2005; Riina & al., 2007; Steinmann & Martínez-Gordillo, 2007; Carneiro-Torres & al., in press; Caruzo & al., 2008; Cordeiro & al., 2008; Lima & Pirani, 2008; Medeiros & al., 2009; Van Ee & Berry, 2009; Riina & al., 2010a, 2010b), and several more are currently in preparation. These new findings will not substantially change the number of species in the megadiverse genus *Croton*, since other published names are being synonymized at roughly the same rate (Caruzo & Cordeiro, 2007; Lima & Pirani, 2008; Van Ee & Berry, 2009; Riina & al., 2010b;

Carneiro-Torres & al., in press; Gomes & al., in press). In this paper we describe two new species from South America that appear to be rare based on the few collections known to date, but are clearly distinct from any known species.

## Materials and methods

We conducted a comparative morphological study of the new species using collections from several herbaria (GH, MICH, MO, NY, QCNE, US, WIS). Protoglosses and type specimens of similar *Croton* species were studied to clarify the delimitation of the new species. Standard morphological characters used by most previous taxonomic workers in *Croton* were used and described. All herbarium specimens were examined using a Olympus stereo microscope at  $\times 64$  to  $\times 400$  magnification. Information about

habit, habitat, and distribution was taken from specimen labels.

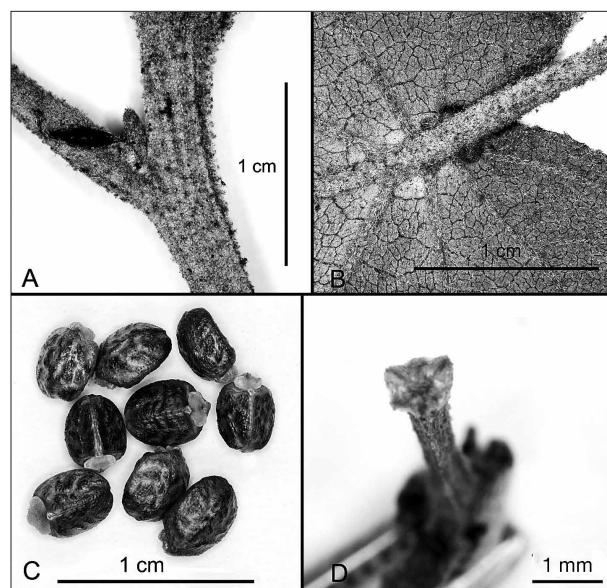

## Results and discussion

### *Croton chimbacensis* P.E. Berry & Riina, sp. nov.

Type: Ecuador. Chimborazo: Road from Alausí to Huigra, roadside thicket above Huigra, 02°16'28"S, 78°58'23"W, 1380 m, 11-III-2001, P.E. Berry, J. Caranqui & M. Cerna 7619 (holotype, MICH; isotypes, MO, QCNE, US, WIS). Figs. 1, 2.

*Croton ruizianus similis, sed staminibus minoribus (12-14), apicibus columellae applanatis non laevigatis, trichomatibusstellato-porrectis differt.*

Monoecious shrubs or small trees 1-5 m tall; young branches with a dense indumentum of stellate and multiradiate trichomes, producing a thick, orange sap when freshly cut. Stipules linear-lanceolate, 5-7 mm long, with a glandular tip, caducous. Leaves alternate, blades ovate to ovate-lanceolate, 5-12 × 4-10 cm, apex acute, base cordate or rounded, margin entire to finely

**Fig. 2.** *Croton chimbacensis*: **A**, stipule; **B**, petiolar glands, abaxial side of the leaf; **C**, seeds; **D**, distal end of the columella. Photos taken from the holotype.

**Fig. 1.** *Croton chimbacensis* P.E. Berry & Riina. Photo of the holotype, Berry & al. 7619 (MICH).

serrate, venation 3-5-plinerved, secondary veins 5-7, tertiary veins scalariform, primary and secondary veins raised on the abaxial surface, adaxial leaf indumentum of scattered sessile stellate and multiradiate trichomes not fully covering the surface, which is green underneath the indumentum, abaxial indumentum denser, completely covering the surface; petiolar glands 2-4, patelliform, sessile or subsessile, acropetiolar, visible on the abaxial side; petioles 2.5-7 cm long, densely covered by multiradiate trichomes. Inflorescences terminal or pseudo-axillary, erect, 15-20 cm long, rachis angular, densely covered by multiradiate trichomes; bracts ovate-lanceolate, 1.8-4.0 × 0.7-2.0 mm, sometimes glandular at the tip, caducous; cymules evenly spaced along the rachis, the basal ones pistillate or sometimes bisexual. Staminate flowers in small cymules along distal 2/3 of the rachis, pedicels 1-2 mm long at anthesis; sepals 5, imbricate, 1.5 × 1 mm, stellate abaxially, loosely villous adaxially; petals 5, imbricate, elliptic-oblong, glabrous on both surfaces but densely white-villous along the margins; stamens 12-14, filaments 2-3 mm long at anthesis, anthers 1 × 1 mm, oval-reniform. Pistillate flowers with pedicels 2-7 mm long, covered with sparse stellate and multiradiate trichomes; sepals 5, valvate to slightly imbricate, unequal, lanceolate to broadly ovate, 2-3 × 1.5-2.5 mm, abaxially with sparse stellate multiradiate trichomes concentrated on the central portion, adaxially glabrous; petals absent; ovary densely covered with multiradiate trichomes; styles 3, bifid (6 terminal tips), glabrous.

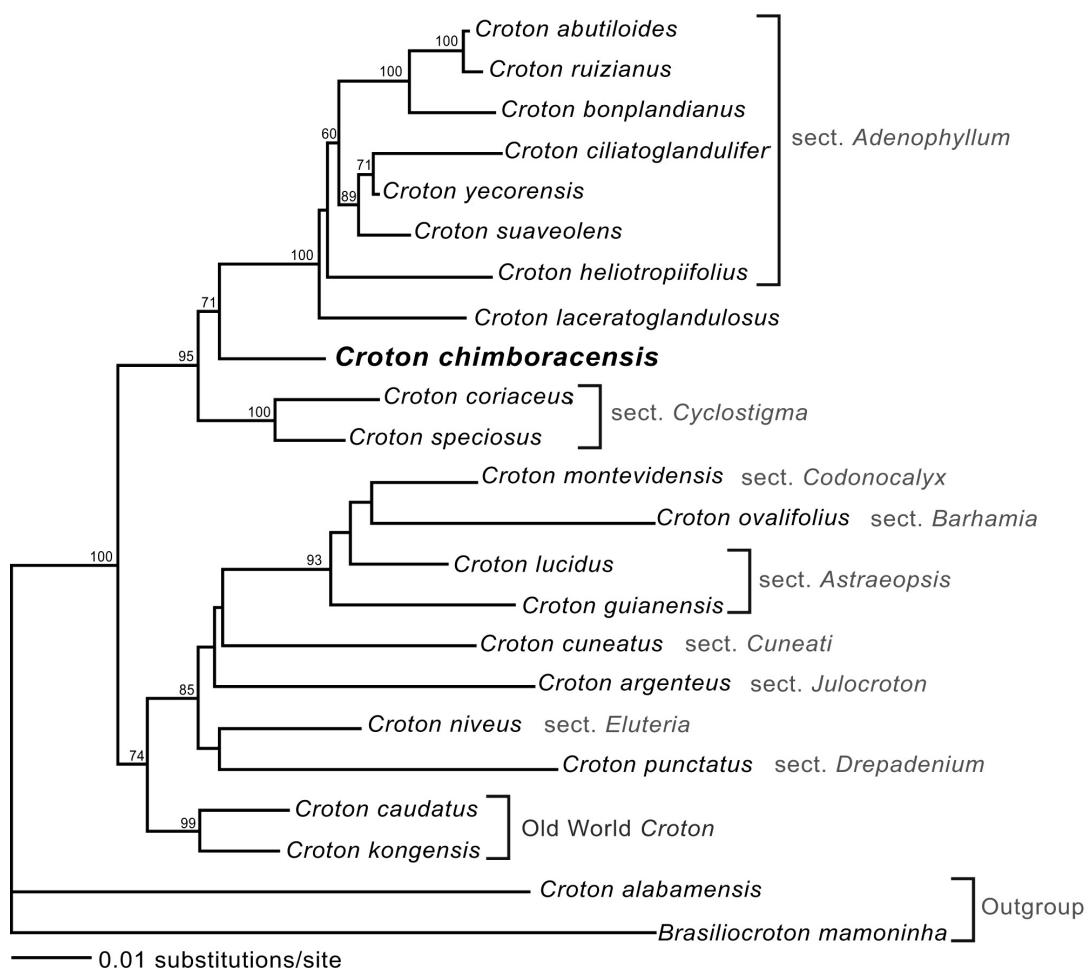

Capsules globose, 5–7 × 6–7 mm; columella 5–6 mm long, the tips ± flattened and rough; seeds obovoid, 3.8–4.9 × 3–3.1 mm, light gray, brown or blackish, rugose, with a trapezoidal caruncle, 1.9 × 1.5 mm.

In the first molecular phylogeny of *Croton* by Berry & al. (2005), and in a later work (Cordeiro & al., 2008), *C. chimboracensis* (which was listed as *Croton* sp. “Ecuador 7618”) appeared in a position sister to all sampled members of *C. sect. Cascarilla* Griseb. (Fig. 3), now recognized as *C. sect. Adenophyllum* Griseb. by van Ee & Berry (2010). Riina & al. (2009) identified the distal inflated lobes of the columella as a synapomorphy for this section (*C. sect. Cascarilla* in their work), but *C. chimboracensis* does not possess the characteristic inflated columella lobes of other members of the section, but more flattened lobes instead (Fig. 2D). Thus *C. chimboracensis* could repre-

sent a novel section in the genus, but until we obtain a broader sampling of species in and around *C. sect. Adenophyllum*, we prefer to leave it unplaced as to section. The US sheet of Hitchcock 20386 was annotated by Leon Croizat in 1939 as *C. ruizianus* var. *cordatus* Müll.Arg., but that taxon belongs unambiguously to *C. sect. Adenophyllum*, with its shorter stature (0.5–1.5 m), smooth, inflated, 3-lobed columella, more numerous stamens (30–42), and stellate-porrect trichomes. Based on van Ee & Berry (2010) we use the name *C. sect. Adenophyllum* Griseb. for what Webster (1993), Berry & al., (2005) and Riina & al. (2009) treated as *C. sect. Cascarilla* Griseb.

#### Habitat and distribution

*Croton chimboracensis* is known only from Chimborazo Province in the western Andes of Ecuador, and it is restricted to a small area above the town of

**Fig. 3.** Maximum likelihood phylogram of combined ITS and *trnL-trnF* data, showing the phylogenetic position of *Croton chimboracensis* (bold) sister to all sampled members of *C. sect. Adenophyllum*. Numbers above branches are parsimony bootstrap percentages. The labels on the right (gray) refer to sections of *Croton*. Figure modified from Cordeiro & al. (2008) and reproduced here with permission from the *Botanical Journal of the Linnean Society* (Wiley-Blackwell).

Huigra. The species grows in secondary woody vegetation along roadsides at 1200-2550 m elevation.

#### Paratypes

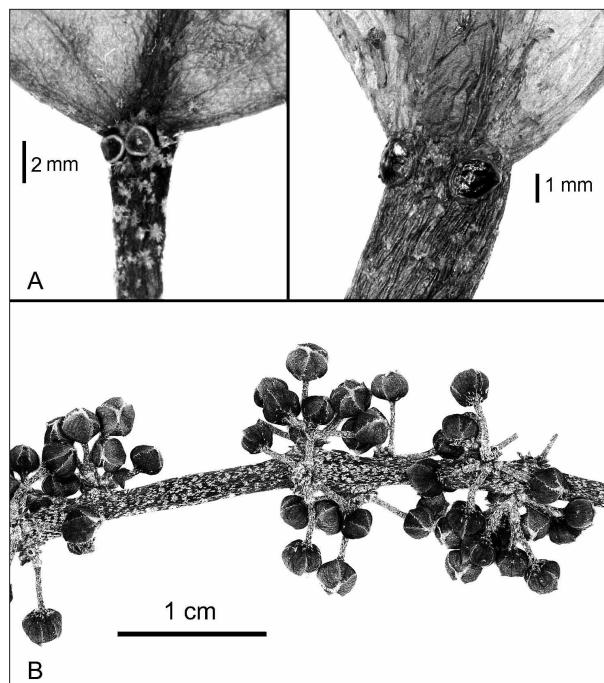

ECUADOR. Chimborazo: Road from Alausí to Huigra, roadside thicket above Huigra, 02°16'28", 78°58'23" W, 1300 m, 11-III-2001, P.E. Berry, J. Caranqui & M. Cerna 7618 (MICH, MO, WIS); Cañon of Rio Chanchan near Huigra, 4000-4500 ft. elev., 7-14-V-1945, W.H. Camp E-3199 (MO, NY); Huigra, 1200 m, 4, 16, 20, 27-VII-1923, A.S. Hitchcock 20386 (GH, NY, US); Sibambe, canyon of Río Chanchan, 2460-2550 m, 28-I-1945, F.R. Fosberg & M.A. Giler 22578 (US).

#### *Croton abonari* Riina & P.E. Berry, sp. nov.

Type: Brazil. Amazonas: Santo Antonio de Abonari, Manaus-Caracarai, Km 220, forest on terra firme, 26-XI-1976, G.T. Prance, R.J. Hill, L.F. Coelho, J.F. Ramos 24311 (holotype: NY; isotypes, MICH, US). Figs. 4, 5.

*Ad species sectionis Cuneati similis, sed glandulis petiolaribus adaxialibus, habitu non inundato differt.*

Monoecious trees ca. 6 m tall and 8 cm DBH; young branches glabrescent, with scattered stellate-

**Fig. 5.** *Croton abonari*: **A**, petiolar glands on a juvenile (left) and a mature leaf (right), adaxial leaf side; **B**, detail of the inflorescence (flowers in bud). Photos taken from the holotype.

**Fig. 4.** *Croton abonari* Riina & P.E. Berry. Photo of the holotype, Prance & al. 24311 (NY).

appressed or stellate-lepidote trichomes. Stipules deciduous. Leaves alternate, blades oblong-ovate, 8-20 × 4-8 cm, apex cuspidate with an abrupt acuminate tip, base acute to rounded, margin irregularly and loosely dentate, with ovoid glands at the tip of each tooth and discoid sessile glands in the sinuses, both leaf surfaces glabrous or with very few stellate or stellate-lepidote trichomes on the main vein, lamina, or along the margins; venation pinnate, secondary veins 9-11, primary and secondary veins raised on abaxial and adaxial surfaces; petiolar glands patelliform, sessile, acropetiolar, positioned on the adaxial surface of the petiole; petioles 1.5-6.5 cm long, terete, sparsely stellate or appressed stellate-lepidote. Inflorescences terminal, usually clustered, erect, 15-18 cm long, rachis angular, densely stellate-multiradiate or appressed stellate-lepidote; bracts at the base of the inflorescence linear-lanceolate, 3-5 × 0.9-1.1 mm, cymule bracts variable in size and shape, from linear-lanceolate to broadly ovate with dentate margins; basal cymules bisexual. Staminate flowers numerous, 10-15, in dense cymules along most of the rachis, pedicels 2.3-4 mm long; sepals 5, valvate to slightly imbricate, broadly ovate to obovate (apical part wider), 2.9-3.2 × 1.8-2.1 mm, glabrous on both surfaces, margin and apex pilose; petals 5, narrowly ovate, 2-2.2 × 0.8-0.9 mm, glabrous on both surfaces, margin and apex lanate, re-

ceptacle pilose, stamens 16, filaments basally hirsute, 1.5-2 mm long (in bud), anthers  $1.0\text{-}1.2 \times 0.6\text{-}0.8$  mm. Pistillate flowers (in bud) subsessile; sepals 5, valvate to slightly imbricate; petals reduced to a filament with an apical gland; style branching uncertain (undeveloped in flower buds). Fruits and seeds unknown.

This new species has some characters in common with members of *Croton* sect. *Cuneati* (G.L. Webster) Riina & P.E. Berry, such as the sinus glands on the leaf margin, stellate-lepidote trichomes, and the inflorescences in terminal or subterminal, apical clusters. *Croton abonari* differs from other members of *C. sect. Cuneati* in the adaxial position of the acropetiolar glands, which are usually abaxial in all the species of the section, in the cuspidate leaf apex, and in the much less dense indumentum on leaves and branches. Only one species in *C. sect. Cuneati* is glabrous, *C. malambo*, but it is restricted to dry coastal vegetation of northwestern Venezuela and northern Colombia. Unfortunately, the specimens of *C. abonari* lack seeds, which are morphologically quite distinct in species of *C. sect. Cuneati* (Riina & al., 2010b). In addition, all lowland species of *C. sect. Cuneati* grow in riparian or flooded forests (except *C. malambo*), whereas *C. abonari* has been reported from low elevation terra firme forests. *Croton abonari* also resembles *C. sampatik* Müll. Arg., another Amazonian tree species in the Sampatik clade sensu Riina & al. (2009), in features such as number of stamens (16), and the morphology and position of the petiolar glands. The two species differ in the type of marginal glands, which are stipitate in *C. sampatik* and sessile in *C. abonari*, and the leaf apex, which is cuspidate in *C. abonari*, and acute and not cuspidate in *C. sampatik*. Mature pistillate flowers, fruits and seeds, in addition to molecular data, will be needed to determine with confidence the phylogenetic position of *C. abonari* within the Neotropical members of *Croton*.

#### Habitat and distribution

*Croton abonari* is so far only known from the type locality in Amazonas State, Brazil, where it grows in terra firme forests (rainforests that are not inundated by flooded rivers).

#### Acknowledgments

We thank Bruno Manara for his revision of the Latin diagnoses and Jacquelyn Kallunki and Benjamin van Ee for their help in locating herbarium specimens at NY and GH. Heather Higgins (MICH) kindly scanned the herbarium specimens for the illustrations.
