Introduction to the Two Bays Project

by Barry Yates

Two Bays, One Environment - a shared biodiversity with a common focus, is a project part-financed by the European Community European Regional Development Fund through INTERREG II in the category of ‘Conservation and regeneration of the region’s heritage (conservation and promotion of natural parks and the countryside).’ The English lead partner is East Sussex County Council (ESCC) and the French lead partner is the Syndicat Mixte pour l’Aménagement de la Côte Picarde (SMACOPI).

The project encompasses areas in England and France, adjacent to, but separated by the English Channel / La Manche. The Baie de Somme ($50^{\circ}09'N\ 1^{\circ}27'E$) in Picardy, France, lies 90 km to the southeast of Rye Bay ($50^{\circ}56'N\ 0^{\circ}45'E$) in East Sussex, England (see map on front cover). Both of these bays have a wetland character with similar habitats and species (Yates and Triplet, 1998).

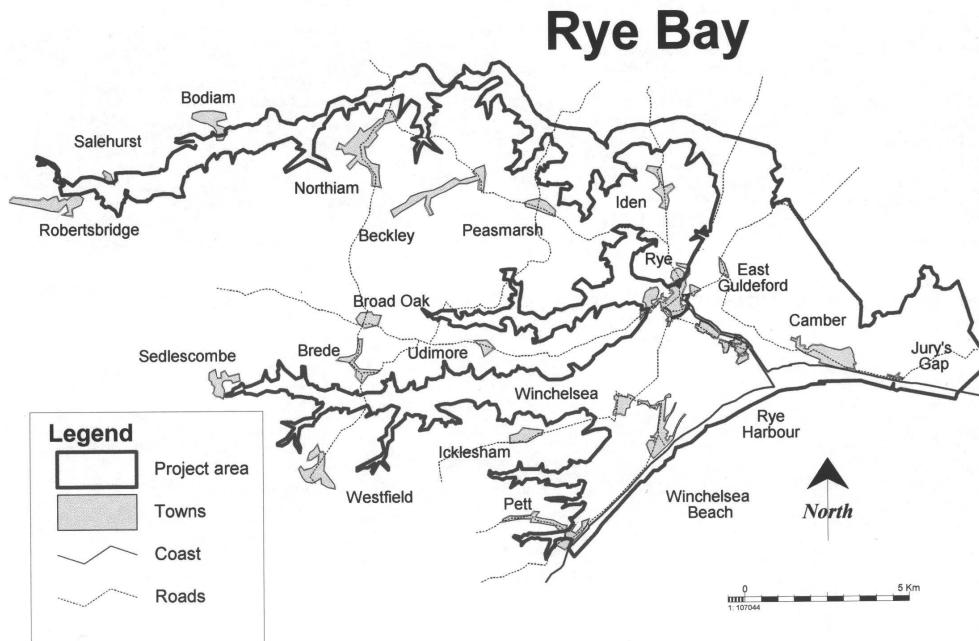

The project has four aims and this specialist report on Diptera, the two-winged flies, addresses aspects of each one:

1. **Study and record the wildlife** – this report summarises our current knowledge about the rarest of species and provides a basis for further study.
2. **Identify the main habitats present and how they can be enhanced** – this report highlights (where known) the specific habitat requirements of the rare species, which will facilitate suitable habitat management by site managers.
3. **Encourage farmers and landowners to manage areas for wildlife** – this report identifies the species that require careful consideration when considering habitat management. It is these species that site managers can be most proud of.
4. **Promote understanding of the wildlife importance of the Two Bays** – the rare species in this report can be a route to the wider appreciation of the special character of the Two Bays.

Rye Bay

The Rye Bay area, covering $91\ km^2$, corresponds to the East Sussex section of the Romney Marshes Natural Area. This area includes the valleys of the Rother, Tillingham and Brede, and the levels of Pett, East Guldeford and Broomhill. The project boundaries are the low water line along the shore, the ten metre contour line and the county boundary with Kent (see map below). Within Rye Bay there are few towns, villages and other settlements and the land use is dominated by agriculture, although in the summer there is increased pressure from tourism.

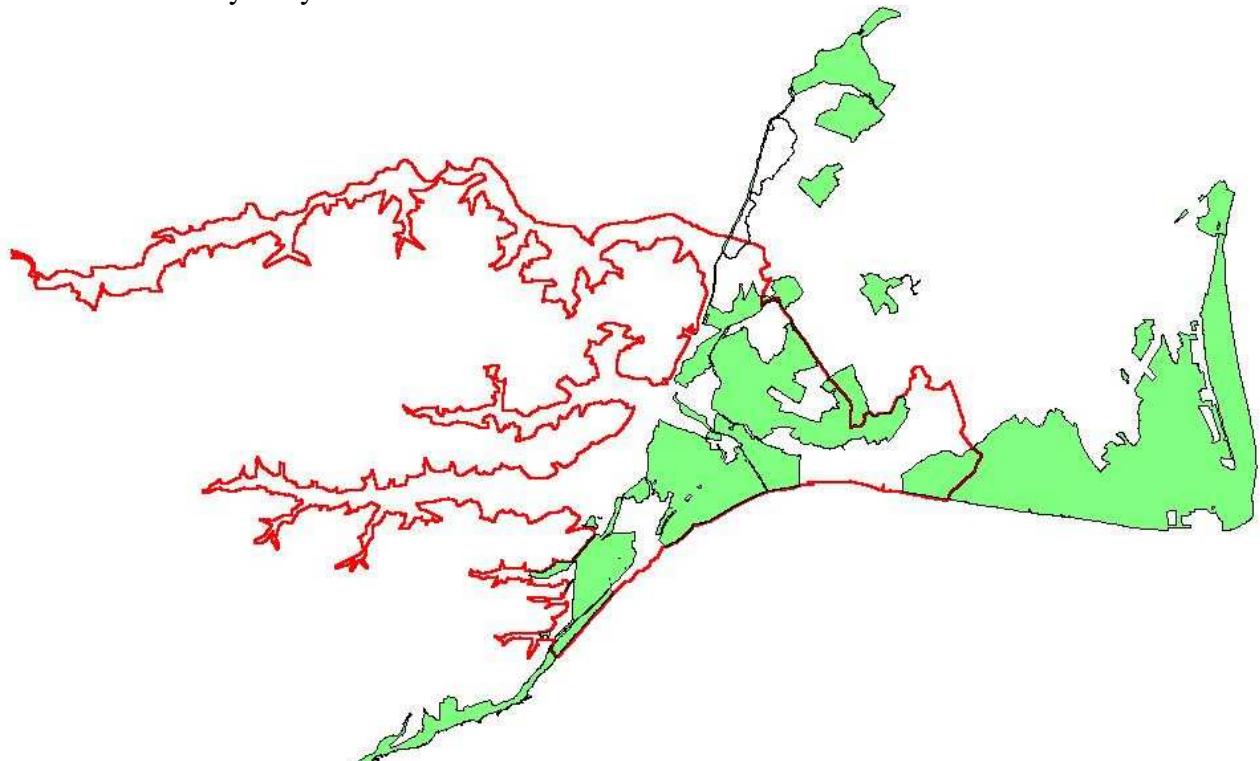

Fig. 1. Rye Bay Location Map

Within this Rye Bay there are large areas with wildlife designations:

- Eight Sites of Special Scientific Interest (SSSI) totalling 28.4 km.² in the Rye Bay area (see map below); all of - Rye Harbour SSSI, Pett Level SSSI, Camber and Rother Saltings SSSI, Winchelsea Cutting and Houghton Green Cliff SSSI, and part of - Walland Marsh SSSI, Dungeness SSSI and Hastings Cliff - Pett Beach SSSI.

Fig. 2. The SSSIs of Rye Bay

- A Special Protection Area (SPA): Dungeness to Pett Level site 1209A (part in Rye Bay)
- A candidate Ramsar wetland site: Dungeness to Pett Level site 1209A (part in Rye Bay)
- A candidate Special Area of Conservation (SAC): Dungeness (part in Rye Bay)

- An Important Bird Area (IBA): Dungeness to Pett Level site 204 (part in Rye Bay)
- Six Sites of Nature Conservation Importance (SNCI): Brede Valley, Powdermill Reservoir, Mountsfield, Camber Sands, Dogs Hill Road, Pett Levels all designated in 1997.

And there are large areas managed with wildlife in mind, including:

- A Local Nature Reserve: Rye Harbour established in 1970.
- Two Sussex Wildlife Trust Reserves: Pett Pools and Castle Water established in 1992.
- A Wetland Trust Nature Reserve: Pannal Valley established in 1986.
- Three farms owned by the National Trust: Wickham Manor, Crutches Farm and Marsham Farm.
- Numerous private landowners in the Countryside Stewardship Scheme administered by the Ministry of Agriculture Fisheries and Food (MAFF).

Rye Bay has all of these designations and specially managed wildlife sites because of the variety and rarity of the habitats within it. These habitats include:

- **Intertidal** areas, which have important hidden wildlife as well as the more obvious flocks of gulls and wading birds.
- **Shingle** is the most important habitat around Rye because of its global rarity. For hundreds of years the power of the sea has formed great shingle ridges and still modifies the coast every day, sometimes dramatically. There are numerous rare and endangered plants and animals, which live on the new **bare shingle** such as the Sea Pea, the Little Tern and the flea beetle *Dibolia cynoglossi*. Older **vegetated shingle ridges** further inland are also very special habitats with special communities of plants and animals. The vegetation of these areas is maintained by sympathetic grazing.
- **Saltmarsh** is a habitat that was once extensive, but is now squeezed along the River Rother from Scots Float to the River Mouth. It has a unique character and is loved by artists, especially in the autumn when plants turn red and brown. Saltmarsh is home to the scarce Sea Heath and some breeding birds like Yellow Wagtail and Redshank.
- **Sand dunes** are areas that attract people, especially during sunny weather. They also are important for some plants such as Sea Spurge and many different solitary bees and wasps.
- **Grassland** in Rye Bay is no longer the traditional ‘wet grassland’ that it used to be. Efficient land drainage has created drier ground by managing a network of ditches. Botanical interest is mainly reduced to the ditches and more sandy areas.
- **Wetland** habitats are of great interest in Rye Bay, especially for bird life. For example, up to 600 Whimbrel roost at night on the Nature Reserve and feed in the grassland of Rye Bay during the day. Reedbeds form a special habitat for species such as Bittern and Reed Warbler. An important aspect of the wetlands is the gradient of salinity from salt water through to freshwater.

- **Open Water** has been created by the extraction of shingle, sand and clay. These areas of open water, like Pett Pools, Castle Water and Northpoint Pit are habitat for rare species such as Smew, Medicinal Leech and Saltmarsh Goosefoot.
- **Rivers** are the main arteries of the river valleys, providing the main drainage of the area. To improve this function they have been greatly modified and are heavily managed - the sea is excluded and the levels maintained.
- The old cliff line, such as at Cadborough Cliff has important micro-habitats such as **rock exposures** and **freshwater seepages**.

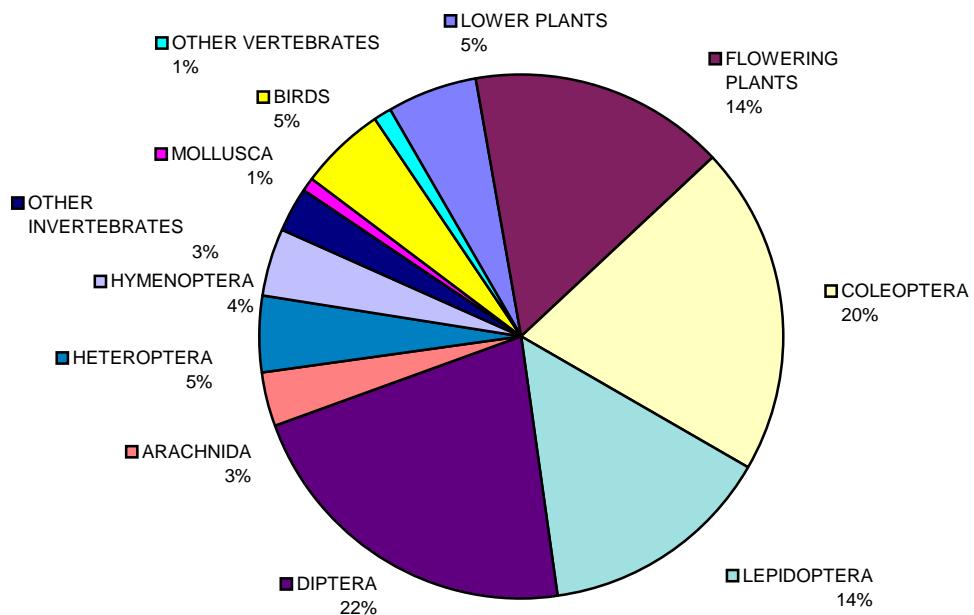

Rye Bay Wildlife

Following from the variety and diversity of habitats in Rye Bay, there is a great diversity of species, including a great many rarities – Rye Bay has a great biodiversity. Many species that are declining nationally still retain a stronghold in this area, for example the good populations of several farmland bird species, the Water Vole, the Medicinal Leech, the Marsh-mallow plant and moth, and many rare species of two-winged flies – the Diptera .

The Two Bays, One Environment project has brought together much of the existing wildlife records of the Rye Bay area and encouraged additional recording. Since the production of the first project report in August 1998 the total number of species recorded has increased from 4,617 to 6,095 by January 2000. The number of Diptera has, over the same period, increased from 477 to 1,317, representing 22% of recorded species – the single largest taxon.

Fig. 3. Rye Bay Species

Total number of species = 6,095

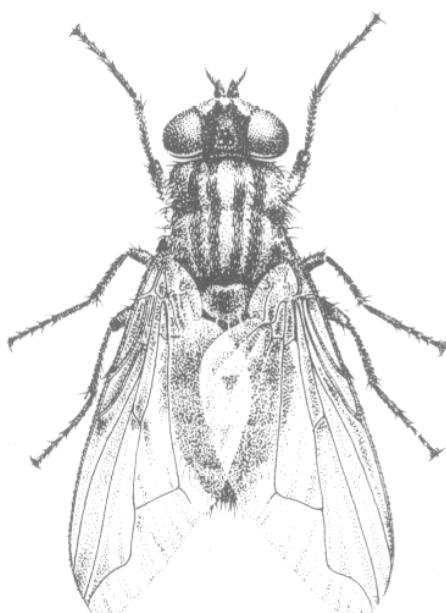

The number of records, species and their British status (according to Recorder 3.3) is summarised below;

Table 1: The British Status of the Species of Rye Bay.

	Common	Local	Notable	Rare	Total Species	Records
Diptera	941	283	72	21	1,317	4,941
All Species	4,246	1,139	475	235	6,095	147,777

Of the 6,095 species and 1,317 Diptera recorded so far, the most important are those considered to be rare. The rare category includes 21 Diptera species considered as Red Data Book species (RDB – see later section for detail), representing the species that are truly rare or endangered in Britain. This specialist report contains 17 Species Statements of RDB Diptera (the recent records of *Phaonia scutellata*, *Clusiodes geomyzina*, *Tabanus bovinus* and *Ectrepesthoneura colyeri* require some further clarification before species statements are produced). It is hoped that a series of these reports will be produced, so that they can together form an account of the species groups in Rye Bay and produce an important information resource.

The wildlife database is maintained on RECORDER and species records, distribution maps or summaries are available on request from the Two Bays, One Environment project at the address on the cover page.

The House Fly *Musca domestica*

Diptera of Rye Bay

by Patrick Roper

Most habitats contain an abundance of Diptera, the two-winged flies and, with its considerable habitat diversity, the Rye Bay area is particularly rich. These range from a few seashore species, to those associated with brackish and fresh water, with sand dunes, salttings, grassland, marsh and woodland. Many species are specialised and breed in animal dung, decaying wood, nests of birds, bees and wasps, fungi, soil, mud or carcasses. Some fly larvae are leaf miners or gall formers and others internal parasites of caterpillars, beetles, plant hoppers, ants, earthworms, snails, woodlice, toads, spiders, sheep, horses, cattle and other creatures.

Many flies are attractive to the general naturalist and walker. Most people with an interest in the countryside are aware of crane flies (Tipulidae), robber flies (Asilidae), bee flies (Bombylidae), soldier flies (Stratiomyidae), hover flies (Syrphidae) and the large numbers of Calypterate species like variously-coloured bluebottles and houseflies that jostle on the flat white umbels of hogweed all summer and ivy flowers in the autumn. Other flies may not be known by name but are an important part of the wild scene: the slowly gyrating swarms of Chironomidae in summer, or of winter gnats, the Trichoceridae, in the colder months.

A few flies draw attention to themselves by biting human beings for a blood meal. These include some (not all) mosquitoes, the biting midges and horse flies. Members of one family, the Hippoboscidae, live in the plumage of birds and the Nycteribiidae in the fur of bats as well as in their nests and roosts.

Flies are a very important source of food for birds, bats, fish, amphibians, and some other flies and invertebrates. Migrant insectivorous birds gathering in the bushy places along the coast, for example, are always likely to have a ready supply of midges and small crane flies that have bred in or near the various pools and gravel pits to fuel them for their travels.

Like other invertebrates, flies need an unpolluted substrate in which to develop. As adults they often require nectar, rotten fruit or prey in order to complete their life cycle and habitats rich in water, flowers and other invertebrates are often essential. For some higher plants flies are important pollinators and they help to distribute the spores of many kinds of fungi.

The richest habitats for Diptera in the Rye Bay area are the wetlands with a good growth of emergent vegetation providing the flowers with their nectar and pollen that many flies need during their adult lives. Of particular interest are the undredged, cattle or sheep grazed dykes, and the reed-fringed lakes, pools and canals. There are also many species associated with running water and there are different Diptera from the larger rivers, the streams and the woodland springs and ghylls. The sparse grass cover that develops on some sandy or shingly areas has its own characteristic species and is particularly favoured by the Chloropidae.

Woodland (in particular open marshy woodland in the rather few areas where it occurs) is often very rich, especially if trees have been left to decay naturally and fallen timber to lie undisturbed. If otter holts are reintroduced to the area they will provide habitats for a very wide range of saproxylic and dung/rotten fish breeding flies and other invertebrates, as well as for otters. A modest pile of decaying timber in a Sedlescombe garden produced over 260 species of Diptera during an experiment conducted in 1999 and this shows the importance of the dead wood habitat.

Like many British invertebrates, the majority of today's flies would have been present in Britain before the land bridge to the continent was broken. The Diptera of the Baie de Somme have had very little attention from recorders so far and only three species have been formally recorded (the hoverflies *Eristalis tenax* and *Helophilus pendulus* and the thistle gall fly *Urophora cardui*), but there is likely to be a similar suite of species to that found in the Rye Bay area with a few that have not managed to cross the Channel. Some of the larger Diptera are powerful fliers and undoubtedly able to migrate from and to mainland Europe. Little work has, however, been done on this apart from the regular recording of large summer influxes of species like the marmalade fly, *Episyrphus balteatus* and other hoverflies such as *Scaeva pyrastri*.

The generally warm, dry conditions in the Rye Bay area make it an excellent location for some of our more dramatic Diptera species. All five members of the genus *Volucella*, bee and wasp mimics are, for example, seen regularly in the area including the 'notable' *V. inanis*, *V. zonaria* and *V. inflata*. Local gardens and flowery waysides may have all three of these species on the wing together and *V. inanis* and *V. zonaria* can sometimes be seen lurking around the wasps' nests where they breed.

Diptera of particular conservation importance in the Rye Bay area include *Myopa fasciata*, *Thereva fulva*, *Odontomyia ornata*, *Sphaerophoria loewi*, *Pteromicra pectorosa*, *Atrichops crassipes* and *Anasimyia interpuncta*. These are described in detail later.

There are also several species that have not been allocated any of the 'Red Data Book' categories but are of particular interest in the Rye Bay area. They may be the only Sussex record, for example, or they may have been first recorded in Britain from this area. Some of the smaller and less well-known flies have only ever been found globally on very few occasions and there are several of these from Rye Bay. A good example is *Limnophyes punctipennis*, a very small yellow and black midge. Known from a very few sites in Europe and from the female only, this was found for the first time in Britain by the late Elizabeth Goldie-Smith, a local dipterist, on the Rye Harbour Nature Reserve on 30 April 1985.

Many invertebrates, and flies are no exception, are often found in one small corner of a much larger habitat all of which appears perfectly suitable for the species. The factors involved are seldom clear and may never be elucidated. However, it is important to remember this when undertaking habitat management work and to try and avoid too much undesirable disturbance in places where rarities are known to occur. Most records are kept as six figure map references, but for rare and endangered species more precise locations are important so that site management does not destroy some of the things it is setting out to conserve. With the advent of GPS (Geographical Positioning System) equipment and a growth in the number of, and input from, specialist recorders the risks should diminish and our knowledge of the flora and fauna and their interrelationships increase.

Diptera Species Statements

Amiota basdeni (Fonseca) (Drosophilidae - a fruit fly)

1. Description

A small fruit fly associated with decaying wood and fungi. It was described by Fonseca in 1965 and has been very rarely recorded in Britain with only a handful of locations in the South East. The genus has had a number of European species added in recent years and caution needs to be exercised in the determination of all *Amiota* species until more is known about them.

Amiota basdeni has distinctive round white spots on its shoulders and white tarsi (as do some other members of the genus). This is not uncommon in insects that live in dark places and presumably helps the sexes identify each other.

2. Current status

In Britain the species is classified as provisional RDB2. Although rarely recorded and certainly much scarcer than many of its congeners, *A. basdeni* is probably widespread in suitable habitats and more records will no doubt accrue with the growing interest in saproxylic invertebrates.

In Rye Bay it has been recorded from a garden in Sedlescombe where several examples were trapped over a pile of decaying timber in the summer of 1999 by Roper.

There are no records for the Baie de Somme.

3. Current factors affecting status

The species is clearly associated with dead and decaying wood and the more of this that can be left in situ in woodland habitats, the more the species is likely to benefit.

4. Current action

Wherever possible landowners and statutory agencies are being encouraged to conserve decaying wood and to appreciate its value for wildlife better.

5. Objective for the species

Maintain and increase its populations in appropriate locations

6. Proposed action

Establish and maintain standing and fallen dead wood wherever possible. Encourage the management of dead wood for wildlife among landowners and statutory agencies with an interest.

***Thereva fulva* (Meigen)**
(Therevidae - a stiletto fly)

1. Description

An active, hairy brown fly that favours scrubby places in areas of fixed sand.

2. Current status

In Britain it is described as provisional RDB3. Outside East Sussex it has been recorded mainly from North Kent and South Wales. It is a species that has declined greatly this century.

In Rye Bay, although only recorded once, by Clemons in June 1996, it is probably resident on the north side of Castle Water and in other suitable areas.

There are no records from the Baie de Somme.

3. Current factors affecting status

Clearly areas of open, but stable, sand with bushes and other scrubby vegetation are essential. This is the kind of temporary habitat that would have been constantly developing and disappearing in the past and it is important that the species has new areas to which to move as well as maintaining appropriate conditions in existing areas.

Small populations of species with specialised habitat requirements are particularly vulnerable to predators and parasites unless populations are continually re-establishing themselves in new locations.

4. Current action

Management of existing habitat

5. Objective for the species

Maintain and increase its abundance in appropriate locations

6. Proposed action

Manage existing areas of stable sand and scrub and, if possible, create, or encourage the creation of, new areas.

***Aphrosylus mitis* (Verrall)**
(a dolichopodid fly - Dolichopodidae)

1. Description

A small, raptorial fly of the coast that preys on other smaller invertebrates. The males have enlarged, silvery palpi that reflect the light like tiny headlamps and, no doubt, act as signals to females and other males.

2. Current status

This species has been recorded from suitable habitats in Suffolk, Essex, Hampshire and Kent (including, in the latter case, the Walland Marsh adjoining the Rye Bay area). It has also been found inland in Wiltshire, Cambridgeshire and London, though these are considered as possibly stray examples.

In Britain the species is classified as provisional RDB2

In the Rye Bay area it has been recorded from the Lime Kiln saltmarsh area at Rye Harbour.

There are no records for the Baie de Somme.

3. Current factors affecting status

The species is thought to be declining due to agricultural improvement of saltmarshes, coastal defence works and associated destruction of larval habitat.

4. Current action

Conservation of salt marsh and coastal habitats at Rye Harbour.

5. Objective for the species

Maintain and increase its populations in appropriate locations.

6. Proposed action

Discover where it might be breeding, monitor the population and continue to conserve its habitat.

***Myopa fasciata* Meigen (Conopidae – a fly)**

1. Description

A brown, rather hunched fly whose larva are parasitoids of aculeate hymenoptera (probably mainly, or entirely, mining bees of the genus *Andrena*). Many of the records from other parts of Britain are from heathland areas and at Rye Bay it is probably occupying a different habitat (as in the case of the Silver-studded Blue butterfly elsewhere). This could be of significance in its conservation.

2. Current status

In Britain it is described as provisional RDB3. A rare and declining species confined to south east England with only a few British records since 1960, though possibly under-recorded in some areas.

In Rye Bay it has only been recorded once, in 1910.

There are no records from the Baie de Somme.

3. Current factors affecting status

The species is an obligate parasitoid of bees, probably mining bees, and therefore factors that encourage its host species are likely to help *M. fasciata*. Mining bees need friable soil such as loose sand, sunny banks, the root platforms of wind thrown trees and so on.

4. Current action

Try to obtain further records and see if breeding areas can be discovered and which mining bees it is using as hosts

5. Objective for the species

Maintain and increase numbers by working out an action plan for host(s) and parasitoid

6. Proposed action

Initially this will mean dipterists and hymenopterists working together (as they already do at Rye Bay). It is worth bearing in mind that the species may be more abundant in the Baie de Somme and that it might be easier to do this research there. This could be achieved by e-mail liaison with Baie de Somme entomologists.

***Odinia maculata* (Meigen)**
(Odiniidae – a fly)

1. Description

A small fly with marked wings that is associated with sap runs caused by boring beetles and damaged trees, particularly those used by goat moth larvae, *Cossus cossus*.

2. Current status

In Britain it is described as provisional RDB3. Recorded from only half a dozen localities in Britain, all in southern England.

In the Rye Bay area it has been recorded twice, by J. E. Collin in 1952 from Guestling and by Roper (det. Skidmore) in 1961 from Bush Barn Farm (now Almonds), Robertsbridge (the goat moth was also recorded from this locality in the mid-1950s)

There are no records from the Baie de Somme.

3. Current factors affecting status

Availability of suitable trees for breeding.

4. Current action

None specifically proposed, though goat moth trees, if identified, should be very carefully conserved as they are attractive to a wide range of rare invertebrates other than goat moths.

5. Objective for the species

Identify and conserve habitat if further examples turn up.

6. Proposed action

Look out for up to date records and attempt to locate and conserve breeding sites.

***Graphogaster brunnescens* (Villeneuve)
(a parasitic fly - Tachinidae)**

1. Description

A brownish fly, like a small house-fly. The larvae are parasitoids of various micro-lepidoptera species.

2. Current status

This species has been recorded from Wiltshire, Gloucestershire, Kent and northern Scotland.

In Britain the species is classified as RDB3

In the Rye Bay area it has been recorded from a garden in Sedlescombe

There are no records for the Baie de Somme.

3. Current factors affecting status

Although apparently scarce, the species parasitises a wide range of smaller moth caterpillars and probably does best in open, flower-rich scrubland and chemical-free country gardens.

4. Current action

Conservation of the general habitat wherever practical and appropriate.

5. Objective for the species

Maintain and increase its populations in appropriate locations.

6. Proposed action

Discover where it might be breeding, monitor the population and continue to conserve its habitat.

***Phaonia bitincta* (Rondani) (Muscidae - a muscid fly)**

1. Description

A rarely recorded yellow Muscid . Many *Phaonia* spp. have larvae that live under bark or in saprophytic fungi where they are predatory on other invertebrates. Adults visit flowers of ivy and other plants. Both records from the Rye Bay area are in October so *P. bitincta* may have a primarily late flight period so that it has been overlooked by recorders

2. Current status

In Britain it is described as provisional RDB3. Only four confirmed records from southern England outside the Rye Bay area.

It has been taken twice in a garden in Sedlescombe in October 1992 and October 1999 by Roper, once at flowers of *x Fatshedera lizei* and once from an emergence trap over a pile of decaying logs.

There are no records from the Baie de Somme.

3. Current factors affecting status

Not known. Many of the under-bark breeding *Phaonia* are abundant so there must be some particular limiting factor in the case of this species.

4. Current action

None specifically proposed other than conservation and proper management of dead and decaying timber.

5. Objective for the species

Identify and conserve habitat if further examples turn up.

6. Proposed action

Gather more data on the species and its requirements.

***Spilogona scutulata* (Schnabl & Dziedzicki)**
(Muscidae - a muscid fly)

1. Description

A rare fly about which rather little is known except that it is thought to breed in moss at the edges of lakes, streams and rivers where the larvae are probably predacious on other invertebrates. It is a drab coloured insect like a small housefly and difficult to separate from its congeners.

2. Current status

In Britain it is described as provisional RDB3. Fonseca (1968) gives only two other British records: from Westmorland in 1929 and Hampshire in 1936. While there have probably been further records since then, this gives an indication of the species' scarcity.

It has been recorded once from the Rye Bay area, at Castle Water by Clemons in September 1996.

There are no records from the Baie de Somme.

3. Current factors affecting status

Not known.

4. Current action

None specifically proposed other than conservation and proper management of the wetland areas where it probably breeds. It may well be one of the many species that is vulnerable to over-enthusiastic dyke and ditch clearance.

5. Objective for the species

Identify and conserve habitat if further examples turn up.

6. Proposed action

Gather more data on the species and its requirements.

***Mycetophila autumnalis* (Lundstroem) (a fungus gnat – Mycetophilidae)**

1. Description

A small yellow and brown insect associated with fungi. It was added to the British list by Chandler in 1977 and has been rarely recorded, though there are few entomologists studying this group and it is probably more widespread than records suggest.

2. Current status

Although rarely recorded and certainly much scarcer than many of its congeners, *M. autumnalis* is probably widespread in suitable habitats and more records will no doubt accrue with the growing interest in saproxylic invertebrates.

In Britain the species is classified as provisional RDB3

In the Rye Bay area it has been recorded from a garden in Sedlescombe where two examples were trapped over a pile of decaying timber in May and July 1999 by Roper.

There are no records for the Baie de Somme.

3. Current factors affecting status

The species is clearly associated with dead and decaying wood and the more of this that can be left in situ in woodland habitats, the more the species is likely to benefit.

4. Current action

Wherever possible landowners and statutory agencies are being encouraged to conserve decaying wood and to appreciate its value for wildlife better.

5. Objective for the species

Maintain and increase its populations in appropriate locations

6. Proposed action

Encourage the management of dead wood for wildlife among landowners and statutory agencies with an interest.

Establish and manage standing and fallen dead wood wherever possible.

Stratiomys longicornis (Scopoli) (a soldier fly - Stratiomyidae)

1. Description

A densely hairy soldier fly with grey triangles on the abdomen. It is associated with brackish water habitats and is rather rarely recorded perhaps partly due to a very short flight season. The larvae develop in standing water in saline coastal marshes and saltmarsh pools. The adults occur on low vegetation and flowers, usually near the larval habitats (Shirt, 1987)

2. Current status

This species has been recorded from suitable habitats in Suffolk, Essex, Hampshire and Kent (including, in the latter case, the Walland Marsh adjoining the Rye Bay area). It has also been found inland in Wiltshire, Cambridgeshire and London, though these are considered as possibly stray examples.

In Britain the species is classified as provisional RDB2

In the Rye Bay area it has been recorded once from Rye Harbour saltmarsh, 10 July 1999.

There are no records for the Baie de Somme.

3. Current factors affecting status

The species is thought to be declining due to agricultural improvement of saltmarshes, coastal defence works and associated destruction of larval habitat.

4. Current action

Conservation of salt marsh and brackish water habitats at Rye Harbour.

5. Objective for the species

Maintain and increase its populations in appropriate locations.

6. Proposed action

Discover where it might be breeding, monitor the population and continue to conserve and, if possible, extend the salt marsh or brackish water habitat.

***Odontomyia ornata* (Linnaeus) (Stratiomyidae – soldier flies)**

1. Description

An attractive greenish and black soldier fly that has a liking for flowers of hemlock water dropwort, *Oenanthe crocata*. It breeds in wetland areas such as grazing marshes and the larvae develop in the shallow water of dykes, lakes and slow-flowing rivers.

2. Current status

In Britain it is described as RDB2. It is also listed as a significant species in the Low Weald and Pevensey Natural Area by English Nature (1997). There are a few places where the fly is locally frequent such as areas of grazing marsh in Somerset and Gwent and there are scattered records from elsewhere in south and east Britain, mostly near the coast. With eight records, the Rye Bay area must be considered one of its strongholds.

It has been recorded eight times (since 1986) from the Rye Bay area, mostly Pett Level, but also from Cadborough Cliff near Rye.

There are no records from the Baie de Somme.

3. Current factors affecting status

The species is regarded as declining. It is vulnerable to dyke and river dredging and pollution.

4. Current action

Continued conservation and proper management of the wetland areas where it breeds and encouragement of floral diversity for the benefit of the adult flies.

5. Objective for the species

Increase the size of the local populations and the range of the species in the Rye Bay area.

6. Proposed action

Secure and manage habitat in the areas where it occurs and encourage the conservation of other suitable sites throughout the area. *O. ornata* is one of the easier Diptera rarities to monitor and this should be considered as part of any conservation programme in order to evaluate the actions being taken.

***Sphaerophoria loewi* (Zetterstedt) (Syrphidae – hoverflies)**

1. Description

A small, yellow and black hoverfly difficult to distinguish in the field from some of its commoner congeners. It frequents brackish marsh with areas of sea club rush, *Scirpus maritimus* and reed (*Phragmites*) where the larvae feed on aphids.

2. Current status

In Britain it is described as RDB2. A rarely recorded species with a disjunct distribution. Most records are from coastal areas in southern England, but there is also a record from Elgin in Scotland.

It has been recorded once from the Rye Bay area, at Pett Pools by P.Hodge in 1987.

There are no records from the Baie de Somme.

3. Current factors affecting status

Scarcity of areas of brackish water with emergent vegetation of the right type and well stocked with aphids. Some places where the species breeds may be liable to inundation by the sea and it is important that there are several sites in different parts of the Rye Bay area to ensure that not all colonies are simultaneously destroyed.

4. Current action

Continued conservation and proper management of the wetland areas where it breeds and encouragement of floral diversity for the benefit of the adult flies.

5. Objective for the species

Increase the size of the local populations and the range of the species in the Rye Bay area.

6. Proposed action

Monitor the areas where it occurs to ensure that the vegetation is doing well and try to increase the number of such areas.

***Pteromicra pectorosa* (Hendel) (Sciomyzidae – snail-killing flies)**

1. Description

A brownish fly found in wetlands near shallow, often temporary, pools. The larvae are parasitoids of freshwater snails though in the wild in Europe the species it uses have not yet been determined.

2. Current status

In Britain it is described as RDB2. Rare in Britain though, as suitable habitat is not uncommon and the female can lay over 700 eggs, the reasons for this are not clear. It is widespread in Europe and North America

It has been recorded once from the Rye Bay area, at Castle Water by L.Clemons in June 1996.

There are no records from the Baie de Somme.

3. Current factors affecting status

Not clear apart from a general reduction in habitat. It seems to prefer temporary pools and, like other wetland species, is probably sensitive to pollution, land-drainage and over-enthusiastic dredging.

4. Current action

Try to obtain more records of the species and establish where it is breeding.

5. Objective for the species

Increase the size of the local populations and the range of the species in the Rye Bay area.

6. Proposed action

Conserve and manage likely breeding areas.

***Parydroptera discomyzina* (Collin)**
(Ephydriidae – shore flies)

1. Description

A small shore fly associated with salt marshes and saline mud.

2. Current status

In Britain it is described as RDB2. Described by Collin in 1913 from specimens taken at Rye and at Southwold, Suffolk. Ismay took further examples at Rye in 1980 and it has also been taken (1993) at Iwade, Kent. These appear to be the only British records.

It has been recorded twice from the Rye Bay area, both by J.W.Ismay in 1950.

There are no records from the Baie de Somme.

3. Current factors affecting status

Reduction of habitat. Salt marsh is now far less extensive at Rye Harbour than it was earlier in the century and is diminishing elsewhere.

4. Current action

Continued conservation and proper management of the areas where it breeds.

5. Objective for the species

Monitor local populations if possible and try to ensure that the conditions it prefers are maintained.

6. Proposed action

Monitor the areas where it occurs and, if possible and appropriate, increase this area.

As with many rare invertebrates, it is important to try and establish very precise (GPS) locations, dates and weather conditions for the adults so that sites can be visited annually and further behavioural and population data obtained. Many species only occur in one corner of an apparently otherwise suitable habitat, which can make them particularly vulnerable.

***Atrichops crassipes* (Meigen)**
(Rhagionidae – a snipe fly)

1. Description

A black (male) or black and yellow (female) fly resembling a small ichneumon with the habit of sometimes congregating in trees near rivers. It is a particular speciality of the river Rother. The aquatic larvae develop in aquatic vegetation where they are probably carnivorous.

2. Current status

In Britain it is described as RDB3. There are scattered records from southern England and Wales. It was first recorded from the East Sussex Rother at Witherenden between 1900 and 1904, then in 1991 (Drake) and in 1998 at Salehurst in the Rye Bay area (Hodge).

It has been recorded once from the Rye Bay area, in the Rother valley near Salehurst by P.Hodge in June 1997.

There are no records from the Baie de Somme.

3. Current factors affecting status

Degradation of riverine habitat through lowering of water levels and diminution of aquatic vegetation.

4. Current action

None at present.

5. Objective for the species

Monitor local populations and try to ensure that the conditions it prefers are maintained.

6. Proposed action

Once the areas where the species occurs are more precisely known steps can be taken to try and conserve its habitat more effectively.

***Anasimyia interpuncta* (Harris) (Syrphidae - hoverfly)**

1. Description

A rare and vulnerable hoverfly found in fens and marshes, especially where they flood in winter, and along the margins of ditches and ponds. It is an early-flying species with a particular fondness for the flowers of marsh marigold, *Caltha palustris*. It is thought to breed in the waterlogged debris beneath beds of *Glyceria*.

2. Current status

In Britain it is described as RDB3. There are three main centres of distribution: the Cambridgeshire Fens, the Norfolk Broads and the Thames Estuary, but it has been recorded several times in the Rye Bay area and is almost certainly resident.

It has been recorded three times from the Rye Bay area, from Pett Level and Pewis Marsh by P. Hodge in 1987 and 1989.

There are no records from the Baie de Somme.

3. Current factors affecting status

The species seems to need extensive areas of marsh that floods in winter and the *Glyceria* beds beneath which the aquatic larvae breed. The loss of such areas are the main factors affecting its abundance.

4. Current action

Continued conservation and proper management of the low-lying wetland areas in the Rye Bay area.

5. Objective for the species

Increase population size by conserving and, where practical and appropriate, extending habitat.

6. Proposed action

Monitor the areas where it occurs so that opportunities can be more readily identified.

***Myopites inulaedyssentericae* (Blot) (Tephritidae – a picture-winged fly)**

1. Description

A yellowish grey fly with patterned wings that breeds in the flower heads of fleabane, *Pulicaria dysenterica*, and elecampane, *Inula helenium*.

2. Current status

In Britain it is described as RDB3. A rather rarely recorded species usually found near the coast in southern England. It appears to be widespread though scarce the Rye Bay area.

It has been recorded four times from the Rye Bay area, mainly in the Brede Valley, but also from Castle Water, since 1996.

There are no records from the Baie de Somme.

3. Current factors affecting status

Reduction in extent of the rough meadows and waysides where its food plants grow. The species no doubt prefers to develop in undisturbed stands of its foodplant, but most are cut before the end of the summer or in the autumn.

4. Current action

County and local verge cutting policies may be helping the species as may be the retention of wider headlands and rough, flowery meadowland. Where populations are known to occur, a sensible policy is always to leave some fleabane standing until the adults emerge the following year.

5. Objective for the species

Maintain local populations, and stands of its main foodplant, *Pulicaria dysenterica*.

6. Proposed action

Monitor the areas where it occurs and try to safeguard stands of its foodplant.

There are a few places in the Rye Bay area where *Inula helenium* grows as a garden escape and these plants can be monitored to see if *M. inulaedyssentericae* is breeding in the flower heads.

The Complete List of Diptera of Rye Bay

SPECIFIC NAME	ENGLISH NAME	FAMILY	BRITISH STATUS	RECORDS
<i>Trichocera annulata</i>	a winter gnat	Trichoceridae	Common	27

<i>Lucilia illustris</i>	a blue bottle or green bottle	Calliphoridae	Common	1
<i>Lucilia richardsi</i>	a blue bottle or green bottle	Calliphoridae	Unknown	1
<i>Lucilia sericata</i>	a blue bottle or green bottle	Calliphoridae	Common	2
<i>Pollenia rudis</i>	a blue bottle or green bottle	Calliphoridae	Common	2
<i>Pollenia varia</i>	a blue bottle or green bottle	Calliphoridae	Common	1
<i>Pollenia vespillo</i>	a blue bottle or green bottle	Calliphoridae	Local	2
<i>Protocalliphora azurea</i>	a blue bottle or green bottle	Calliphoridae	Unknown	1
<i>Norellisoma lituratum</i>	a dung fly	Scathophagidae	Local	1
<i>Norellisoma spinimanum</i>	a dung fly	Scathophagidae	Common	1
<i>Cordilura ciliata</i>	a dung fly	Scathophagidae	Local	4
<i>Scathophaga decipiens</i>	a dung fly	Scathophagidae	Notable/Nb	1
<i>Scathophaga furcata</i>	a dung fly	Scathophagidae	Common	2
<i>Scathophaga litorea</i>	a dung fly	Scathophagidae	Local	1
<i>Scathophaga lutaria</i>	a dung fly	Scathophagidae	Common	3
<i>Scathophaga stercoraria</i>	a dung fly	Scathophagidae	Common	25
<i>Fucellia maritima</i>	a fly	Anthomyiidae	Unknown	1
<i>Pegohylemyia fugax</i>	a fly	Anthomyiidae	Common	1
<i>Lasiomma nitidicauda</i>	a fly	Anthomyiidae	Unknown	1
<i>Hydromyia divisa</i>	a fly	Anthomyiidae	Common	1
<i>Anthomyia pluvialis</i>	a fly	Anthomyiidae	Unknown	4
<i>Anthomyia litorata</i>	a fly	Anthomyiidae	Common	1
<i>Leucophora cinerea</i>	a fly	Anthomyiidae	Unknown	1
<i>Delia brassicae</i>	a fly	Anthomyiidae	Common	1
<i>Delia florilega</i>	a fly	Anthomyiidae	Common	2
<i>Delia interflua</i>	a fly	Anthomyiidae	Unknown	1
<i>Delia platura</i>	a fly	Anthomyiidae	Common	2
<i>Hylemya nigrimana</i>	a fly	Anthomyiidae	Local	3
<i>Hylemya vagans</i>	a fly	Anthomyiidae	Common	1
<i>Adia cinerella</i>	a fly	Anthomyiidae	Common	3
<i>Egle muscaria</i>	a fly	Anthomyiidae	Unknown	1
<i>Egle rhinotmeta</i>	a fly	Anthomyiidae	Unknown	2
<i>Nupedia debilis</i>	a fly	Anthomyiidae	Unknown	1
<i>Mycophaga testacea</i>	a fly	Anthomyiidae	Common	1
<i>Fannia aequilineata</i>	a lesser house fly	Fanniidae	Local	1
<i>Fannia armata</i>	a lesser house fly	Fanniidae	Common	1

<i>Fannia canicularis</i>	a lesser house fly	Fanniidae	Common	2
<i>Fannia coracina</i>	a lesser house fly	Fanniidae	Unknown	1
<i>Fannia genualis</i>	a lesser house fly	Fanniidae	Local	2
<i>Fannia glaucescens</i>	a lesser house fly	Fanniidae	Unknown	1
<i>Fannia immutica</i>	a lesser house fly	Fanniidae	Notable/Nb	1
<i>Fannia manicata</i>	a lesser house fly	Fanniidae	Common	3
<i>Fannia nidica</i>	a lesser house fly	Fanniidae	Notable/Nb	1
<i>Fannia nigra</i>	a lesser house fly	Fanniidae	Notable/Nb	1
<i>Fannia pallitibia</i>	a lesser house fly	Fanniidae	Local	2
<i>Fannia polychaeta</i>	a lesser house fly	Fanniidae	Common	1
<i>Fannia scalaris</i>	a lesser house fly	Fanniidae	Unknown	1
<i>Fannia sociella</i>	a lesser house fly	Fanniidae	Common	2
<i>Polietes lardaria</i>	a muscid fly	Muscidae	Common	1
<i>Mesembrina meridiana</i>	a muscid fly	Muscidae	Common	6
<i>Eudasyphe cyanella</i>	a muscid fly	Muscidae	Common	2
<i>Morellia aenescens</i>	a muscid fly	Muscidae	Common	1
<i>Musca domestica</i>	House Fly	Muscidae	Common	1
<i>Musca autumnalis</i>	Face Fly	Muscidae	Common	3
<i>Azelia cilipes</i>	a muscid fly	Muscidae	Common	1
<i>Azelia nebulosa</i>	a muscid fly	Muscidae	Common	4
<i>Thricops diaphanus</i>	a muscid fly	Muscidae	Common	1
<i>Thricops longipes</i>	a muscid fly	Muscidae	Unknown	1
<i>Hydrotaea ignava</i>	a muscid fly	Muscidae	Local	1
<i>Hydrotaea albipunctata</i>	a muscid fly	Muscidae	Common	1
<i>Hydrotaea armipes</i>	a muscid fly	Muscidae	Common	1
<i>Hydrotaea cinerea</i>	a muscid fly	Muscidae	Notable/Nb	1
<i>Hydrotaea cyrtoneurina</i>	a muscid fly	Muscidae	Local	1
<i>Hydrotaea dentipes</i>	a muscid fly	Muscidae	Common	3
<i>Hydrotaea pilipes</i>	a muscid fly	Muscidae	Notable/Nb	1
<i>Muscina levida</i>	a muscid fly	Muscidae	Common	1
<i>Phaonia angelicae</i>	a muscid fly	Muscidae	Common	2
<i>Phaonia bitincta</i>	a muscid fly	Muscidae	pRDB3	3
<i>Phaonia errans</i>	a muscid fly	Muscidae	Common	2
<i>Phaonia fuscata</i>	a muscid fly	Muscidae	Local	1
<i>Phaonia magnicornis</i>	a muscid fly	Muscidae	Local	1
<i>Phaonia pallida</i>	a muscid fly	Muscidae	Common	1
<i>Phaonia palpata</i>	a muscid fly	Muscidae	Common	1
<i>Phaonia rufiventris</i>	a muscid fly	Muscidae	Common	4
<i>Phaonia scutellata</i>	a muscid fly	Muscidae	Appendix (extinct)	1
<i>Phaonia tuguriorum</i>	a muscid fly	Muscidae	Common	5
<i>Phaonia subventa</i>	a muscid fly	Muscidae	Common	7
<i>Phaonia valida</i>	a muscid fly	Muscidae	Common	4
<i>Phaonia mystica</i>	a muscid fly	Muscidae	Local	1
<i>Helina reversio</i>	a muscid fly	Muscidae	Common	4
<i>Helina obscurata</i>	a muscid fly	Muscidae	Local	1
<i>Hebecnema vespertina</i>	a muscid fly	Muscidae	Common	3
<i>Hebecnema nigricolor</i>	a muscid fly	Muscidae	Common	2
<i>Hebecnema nigra</i>	a muscid fly	Muscidae	Common	1
<i>Mydaea corni</i>	a muscid fly	Muscidae	Common	1
<i>Mydaea urbana</i>	a muscid fly	Muscidae	Common	2
<i>Graphomya maculata</i>	a muscid fly	Muscidae	Common	8
<i>Spilogona scutulata</i>	a muscid fly	Muscidae	pRDB3	1
<i>Villeneuvia aestuum</i>	a muscid fly	Muscidae	Local	1
<i>Limnophora tigrina</i>	a muscid fly	Muscidae	Local	2
<i>Lispe tentaculata</i>	a muscid fly	Muscidae	Common	1
<i>Caricea erythroceria</i>	a muscid fly	Muscidae	Common	1
<i>Schoenomyza litorella</i>	a muscid fly	Muscidae	Common	1

Dexiopsis ruficornis	a muscid fly	Muscidae	Local	1
Coenosia agromyzina	a muscid fly	Muscidae	Unknown	1
Coenosia infantula	a muscid fly	Muscidae	Unknown	1
Coenosia albicornis	a muscid fly	Muscidae	Common	1
Coenosia pumila	a muscid fly	Muscidae	Common	3
Coenosia tigrina	a muscid fly	Muscidae	Common	4
Stomoxys calcitrans	Stable Fly	Muscidae	Common	1
Ornithomya avicularia	a flat fly	Hippoboscidae	Common	1
Ornithomya fringillina	a flat fly	Hippoboscidae	Common	2
Crataerina hirundinis	a flat fly	Hippoboscidae	Common	1
Crataerina pallida	a flat fly	Hippoboscidae	Common	1

Status Definitions And Criteria For Invertebrates

Criteria for the selection of species into the **Red Data Book** categories follow Shirt (1987), with minor modifications that are *italicised*. Categories RDB K (insufficiently known) and RDB I (indeterminate) are based on the criteria used by Wells, Pyle & Collins (1983). Criteria for the selection of Nationally Notable species follow Eversham (1983).

STATUS CATEGORIES

Red Data Book category 1 (RDB 1) - Endangered

Definition.

Taxa in danger of extinction in *Great Britain* and whose survival is unlikely if the causal factors continue operating.

Included are those taxa whose numbers have been reduced to a critical level or whose habitats have been so dramatically reduced that they are deemed to be in immediate danger of extinction. Also included are *some* taxa that are *possibly* extinct.

Criteria.

Species which are known *or believed to occur* as only a single population within one 10 km square of the National Grid.

Species which only occur in habitats known to be especially vulnerable.

Species which have shown a rapid or continuous decline over the last twenty years and are now *estimated* to exist in five or fewer 10 km squares

Species which are *possibly* extinct *but have been recorded this century* and if rediscovered would need protection.

Red Data Book category 2 (RDB 2) - Vulnerable

Definition.

Taxa *believed* likely to move into the endangered category in the near future if the causal factors continue operating.

Included are taxa of which most or all of the populations are decreasing because of *over-exploitation*, extensive destruction of habitat or other environmental disturbance; taxa with populations that have been seriously depleted and whose ultimate security is not yet assured; and taxa with populations that are still abundant but are under threat from serious adverse factors throughout their range.

Criteria.

Species declining throughout their range.

Species in vulnerable habitats.

Red Data Book category 3 (RDB 3) - Rare

Definition.

Taxa with small populations *in Great Britain* that are not at present endangered or vulnerable, but are at risk.

These taxa are usually localised within restricted geographical areas or habitats or are thinly scattered over a more extensive range.

Criterion.

Species which are estimated to exist in only fifteen or fewer 10 km squares. *This criterion may be relaxed where populations are likely to exist in over fifteen 10 km squares but occupy small areas of especially vulnerable habitat*

Red Data Book category 4 (RDB 4) - Out of Danger

Definition.

Taxa formerly meeting the criteria of one of the above categories, but which are now considered relatively secure because effective conservation measures have been taken or the previous threat to their survival *in Great Britain* has been removed.

Red Data Book category 5 (RDB 5) - Endemic

Definition.

Taxa which are not known to occur naturally outside *Great Britain*. Taxa within this category may also be in any of the other RDB categories *or not threatened at all*.

Red Data Book Appendix (RDB app.) - Extinct

Definition.

Taxa which were formerly native to Great Britain but have not been recorded since 1900.

Red Data Book category I (RDB I) - Indeterminate

Definition.

Taxa *considered* to be Endangered Vulnerable or Rare in Great Britain but where there is not enough information to say which of the three categories (RDB 1 to 3) is appropriate.

Red Data Book category K (RDB K) - Insufficiently Known

Definition.

Taxa in Great Britain that are suspected *but* not definitely known, to belong to any of *the* above categories, because of lack of information.

Criteria.

Taxa recently discovered or recognised in Great Britain which may prove to be more widespread in the future.

Taxa with very few or perhaps only a single known locality but which belong to poorly recorded or taxonomically difficult groups.

Species known from very few localities but which occur in inaccessible habitats or habitats which are seldom sampled.

Species with very few or perhaps only a single known locality and of questionable native status, but not clearly failing into the category of recent colonist, vagrant or introduction.

Nationally Scarce Category A - Notable A (Na)

Definition.

Taxa which do not fall within RDB categories but which are none-the-less uncommon in Great Britain and are thought to occur in 30 or fewer 10 km squares of the National Grid or, for less well recorded groups, within seven or fewer vice-counties.

Nationally Scarce Category B - Notable B (Nb)

Definition.

Taxa which do not fall within RDB categories but which are none-the-less uncommon in Great Britain and are thought to occur in between 31 and 100 10 km squares of the National Grid or for less well recorded groups, between eight and twenty vice-counties.

Nationally Scarce - Notable (N)

Definition.

Taxa which do not fall within RDB categories but which are none-the-less uncommon in Great Britain and are thought to occur in between 16 to 100 10 km squares of the National Grid. Species within this category are often too poorly known for their status to be more precisely estimated.
