Microsoft Host Integration Server 2004

Microsoft Host Integration Server 2004 helps customers integrate IBM host applications, data sources, messaging, and security systems with new solutions developed using the Microsoft Windows Server System platform.

Host Integration Server 2004 features and technologies, including network integration, host access with enhanced security, and application integration, makes it possible for Windows developers to publish business processes in IBM mainframe and AS/400 applications as XML Web Services. This enables bringing their Host applications and processes into a Services Oriented Environment.

Introduction: What's New for 2004

This release of Microsoft® Host Integration Server 2004 offers many new and improved features. These features are highlighted below by product area.

Security Model

This release of Host Integration Server 2004 implements a new security model. The access control for the Host Integration Server 2004 components is based on two Windows security groups specified during setup. The Host Integration Server 2004 runtime group provides access to the Microsoft Windows® account under which all the services run. The Host Integration Server 2004 Admin group is used to provide access to users performing administrative tasks.

Setup and Configuration

Host Integration Server 2004 now installs with a new, Common Setup program used in other Microsoft e-Business products, such as Microsoft BizTalk® Server 2004.

In addition, the Resource Location Wizard has been replaced by a new Configuration Wizard, which allows you to configure all Host Integration Server 2004 services, databases, and subdomain information more efficiently, either during or after setup. A shortcut to the new Configuration Wizard is located in the Host Integration Server 2004 Start menu.

Transaction Integrator

One goal of Host Integration Server 2004 is to enable enterprise developers to move towards a services-oriented architecture (SOA) using the .NET Framework. Transaction Integrator (TI), formerly COM Transaction Integrator for CICS and IMS (COMTI), allows Microsoft Windows developers to publish business rules in mainframe CICS and IMS applications as XML Web services. The new TI Designer runs within Microsoft Visual Studio® .NET 2003, providing a more efficient developer experience. At the same time, TI has been extended to support AS/400 applications by offering a Report Program Generator (RPG) Import Wizard and distributed program call runtime across a TCP/IP network connection.

Host Integration Server 2004 includes innovative technologies, such as TI host-initiated processing (HIP) that offers TCP/IP and SNA listeners that allow a server computer running Windows to function as a peer to IBM mainframe and AS/400 computers. For example, CICS programmers can call into Windows COM+ or .NET server components, as if they were another CICS transaction program by using familiar programming models such as CICS distributed program link (DPL). HIP allows enterprises to more effectively move portions of their application logic or data onto the more cost-effective Windows and SQL Server platforms, while ensuring logical and secure bidirectional application communication.

Host Integration Server 2004 offers industry-standard technologies allowing the network administrator to move towards pure TCP/IP WANs and datacenters. Transaction Integrator supports the CICS enhanced TCP/IP listener and persistent TCP/IP connections.

The new TI allows computers running Windows to extend the functionality of existing IBM mainframe and IBM midrange AS/400 line-of-business (LOB) applications. In Host Integration Server 2004, TI offers both host-initiated processing (HIP) as well as the previously offered Windows-initiated processing (WIP). In Host Integration Server 2004, TI also supports AS/400 applications, as well as mainframe CICS and IMS applications, when integrated across a TCP/IP network connection. TI has been enhanced to offer support for the .NET Framework. Using the new TI Designer, which runs in the context of the Visual Studio .NET 2003 integrated development environment, Windows developers can use TI WIP for .NET to wrap existing LOB applications as XML Web service or .NET server components. In Host Integration Server 2004, the administrator can utilize the new TI Manager which combines TI WIP and HIP Microsoft Management Console (MMC) snap-ins into one view, allowing administrators to efficiently define and manage WIP and HIP component applications.

Finally, TI has a number of other new features, including:

- An alternative to explicit callback security by using the COMTIContext parameter to pass a user ID and password.
- Control of the TCP/IP CICS transaction request message (TRM) for interoperability with CICS using TCP/IP custom TRMs.
- Override of the remote environment (RE), program name, transaction name settings in a type library using the COMTIContext parameter.
- Support for persistent connections in WIP through client context. In Host Integration Server 2000, COMTI had to open and close a connection each time it made a method call to the mainframe. On the mainframe side, CICS had to start and stop a transaction program. In Host Integration Server 2004, persistent connections allow TI to open a connection for the first method in a group of methods, make all the method calls, and then close the connection. On the mainframe side, CICS starts an instance of the transaction program, keeps the instance active between method calls, and then stops the program after the last call.

- Support for CICS Enhanced Listener through the enhanced listener message (ELM) programming model. Host Integration Server 2004 takes advantage of the CICS Transaction Server 2.2 Enhanced Listener to provide client and server continuity and improved scalability for both the Transaction Integrator (TI) client and CICS environments through a more streamlined application level protocol exchange sequence. When you use the Enhanced Listener, TI bypasses the transport logic that waits for a TRM reply and immediately sends the application request data after the request header. TI then receives a single data stream and interprets the TRM reply prior to processing the application reply data.
- Windows Initiated and Host Initiated Single Sign-On (SSO)
- Arabic EBCDIC 420 bi-directional layout conversion
- Client Context provides an alternative to Explicit Call Back Security
- WIP Override RE via Client Context
- WIP Override Program Name via Client Context
- WIP Override Transaction Name via Client Context

The additional functionality provided by HIP and other forthcoming features prompted a renaming of the features and functionality that you may be familiar with in earlier versions of Host Integration Server:

- COM Transaction Integrator for CICS and IMS (COMTI) is now called Transaction Integrator (TI).
- COMTI Management Console is now called TI Manager.
- COMTI Component Builder is now called TI Designer.

Persistent Connections with the Mainframe

Using Custom TRMs and ELMs with COMTIContext

Security Integration

This release of Host Integration Server 2004 ships with Enterprise Single Sign-On (SSO), enabling single sign-on to end users for enterprise application integration (EAI) solutions. SSO is comprised of two main elements:

- Windows Initiated SSO maps Microsoft Windows accounts to back-end systems
- Host Initiated SSO allows host requests to access Windows accounts

SSO simplifies the management of user IDs and passwords, both for users and for administrators, by enabling users on host and Windows accounts to access systems more efficiently than before.

In addition, the new Password Sync adapters allow synchronization of passwords. A password sync adapter is an application you create that is registered within the configuration store.

Data Integration

New to this release are a .NET Framework-enabled Managed Provider for DB2 and a DB2 Network Protocol Client (DRDA AR), over which the ODBC, OLE DB, and Managed Provider communicate to the remote DB2 database server. The Data Access Tool and Data Source Wizard allow you to create and manage connection definitions to DB2 and host file systems, and make it easier to define the Host Column Descriptions used to access host data sets.

Additional new features include:

- Windows Initiated and Host Initiated Single Sign-On
- DB2 Distributed Transactions (two-phase commit) over TCP/IP
- DB2 Connection Pooling
- Arabic EBCDIC 420 bi-directional layout conversion
- DB2OLEDB support for multiple result sets on calls to DB2 stored procedures
- SNAOLEDB support access to VSAM data sets from SQL Server DTS
- UNICODE, Double-Byte, and Mixed-Byte character set support when accessing DB2
- Ability to import DB2 Connect configuration files
- Additional DB2 configuration properties such as DBMS Platform (optimizing data conversion across platforms), Default Qualifier (simplifying SQL syntax), and Quoted Prefix (ensuring better support for generic consumers such as SQL Server)

Network Integration

The new IP-DLC Link Service offers support for the industry-standard HPR/IP protocol, which IBM calls Enterprise Extender. This in turn provides SNA connectivity for applications using dependent and independent sessions over a routable IP network. The IP-DLC link service is an add-on feature to the existing SNA protocol node, transmitting each SNA packet across the IP network as a UDP datagram.

From an application perspective, such as a 3270 emulator or WinAPPC program, there is no change in functionality. However, the SNA network traffic from branch-deployed or centrally-deployed Host Integration Server computers can be routed across the IP network directly to an IBM mainframe system running OS/390 V2R10 or later and using an OSA or OSA Express compatible network adapter.

Secure Sockets Layer (SSL) and Transport-Level Services (TLS) allow a network administrator using the TN3270 Service to increase the overall security of the enterprise network when accessing mainframe terminal and printer resources, including authentication of access to mainframe sessions and encryption of data between client emulator and TN3270 server.

Although the Microsoft 3270 Client (emulator) does not support SSL or TLS, many third-party software vendors offer 3270 emulators that support this functionality, including Attachmate, IBM, NetManage, and WRQ.

Software Developers Kit

The Host Integration Server 2004 Programmer's Guide now installs with the core product documentation.

Online Documentation

The new, redesigned Host Integration Server 2004 documentation set is now entirely online. In addition to the documentation that ships with the product, you can download a fully updated documentation set over the Web on a quarterly basis. Some documents are included on your product CD; some documents are available only on the Web.

Perhaps the most important addition to the documentation is the focus on security. In keeping with the Microsoft Trustworthy Computing Initiative, the entire documentation set has been rewritten and now includes the following:

- The **Secure Deployment Guide** is a comprehensive source for the latest and most powerful deployment techniques to secure your Host Integration Server environment. This guide is required reading for Administrators, Programmers, and End Users.
- **Understanding Windows Security** offers a broad overview of computer security today, describes the STRIDE model for threat analysis, and lists the most common security threats and how to mitigate them.
- Numerous **Security Tips** placed throughout the conceptual, procedural, and developer material offer current best practices when and where you need them.
- General **prescriptive guidance** appears wherever appropriate in the documentation to help you increase system security, mitigate security threats, and decrease attack surfaces.

What’s New in this Documentation Update

This update of the Host Integration Server 2004 online documentation includes expanded material about the subjects below. This new material can be found in the Network Integration User's Guide.

Configuring IP-DLC Link Service for IBM Enterprise Extender

Host Integration Server 2004 offers an efficient means to integrate Systems Network Architecture (SNA) within data centers, across wide area networks (WANs) and in branch offices through a new link service, IP-DLC (Internet Protocol – Data Link Control), also known as IBM Enterprise Extender. The IP-DLC link service provides SNA connectivity for applications using dependent and independent sessions over a native IP network. This section will assist mainframe programmers and Host Integration Server 2004 administrators in configuring the IP-DLC link service.

Deploying Microsoft Host Integration Server 2004 in a TCP/IP Wide Area Network

This section describes how the IP-DLC (Internet Protocol–Data Link Control) link service of Microsoft Host Integration Server 2004 makes it possible to integrate vital mainframe data and business rules with new e-commerce solutions developed with Microsoft Windows-based programs. The IP-DLC link service of Host Integration Server 2004 enables you to connect directly to IBM mainframe computers through a pure TCP/IP wide area network or local area network. This section contains three detailed scenarios for deployment. Two of these scenarios describe migration from Host Integration Server 2000 to Host Integration Server 2004, and the third describes a new implementation based on Host Integration Server 2004.

Integrating Enterprise Business Processes with Microsoft Windows Using Host-Initiated Processing

This section uses the example of communication between a central data center and multiple branch offices to describe how the Host-Initiated Processing (HIP) feature of Microsoft Host Integration Server 2004 enables such communication. It assumes that the external (branch office) sources of data are likely to be based on Windows-based computing solutions, while the central data center likely relies on legacy data storage systems. HIP makes it possible to bring data from external sources into the legacy batch processing flow without disrupting pre-defined automated processing schedules.

Product Overview

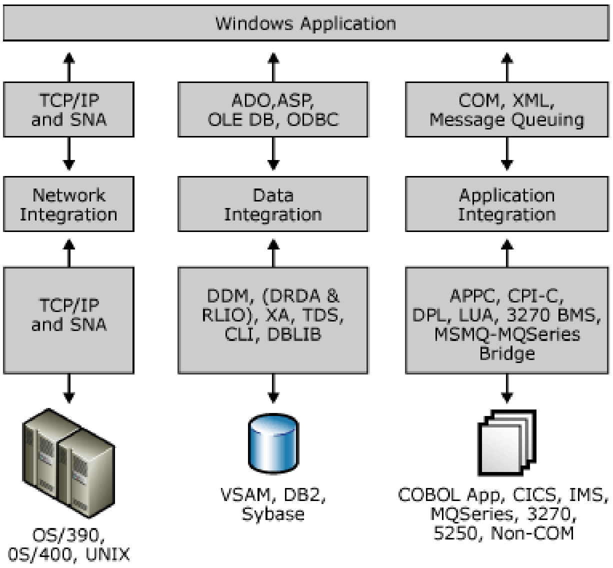
Microsoft Host Integration Server 2004 provides the key enabling technologies that allow customers to integrate their mission-critical host applications, data sources, messaging and security systems with new solutions developed using the Microsoft Windows® platform.

The following diagram shows an overview of the major features provided by Host Integration Server 2004.



Windows Application
TCP/IP and SNA
ADO,ASP, OLE DB, ODBC
COM, XML, Message Queuing
Network Integration
Data Integration
Application Integration
TCP/IP and SNA
DDM, (DRDA & RLIO), XA, TDS, CLI, DBLIB

OS/390, OS/400, UNIX
VSAM, DB2, Sybase
COBOL App, CICS, IMS, MQSeries, 3270, 5250, Non-COM

One goal of Host Integration Server 2004 is to enable enterprise developers to move towards a services-oriented architecture (SOA) using the .NET Framework. Transaction Integrator (formerly COMTI) allows Windows developers to publish business rules in mainframe CICS and IMS applications as XML Web Services. The new TI Designer runs within Visual Studio® .NET, providing a more efficient developer experience. At the same time, TI has been extended to support AS/400 applications by offering an RPG Import Wizard and distributed program call runtime across a TCP/IP network connection. To directly publish vital data stored in IBM DB2, Host Integration Server 2004 offers a Microsoft Managed Provider for DB2 that is based on an improved Microsoft network client for DB2.

Host Integration Server 2004 includes innovative technologies, such as TI Host-Initiated Processing (HIP) that offers TCP/IP and SNA listeners that allow a Windows Server computer to function as a peer to IBM mainframe and AS/400 computers. For example, CICS programmers can call into Windows COM+ or .NET server components, just as if they were another CICS transaction program, by using familiar programming models such as CICS DPL (distributed program link). HIP allows enterprises to more effectively move portions of their application logic or data onto the more cost-effective Windows Server and SQL Server platforms, while ensuring logical and secure bi-directional application communication.

Finally, Host Integration Server 2004 offers industry-standard technologies allowing the network administrator to move towards pure TCP/IP WANs and datacenters. Transaction Integrator supports the CICS enhanced TCP/IP listener and persistent TCP/IP connections. The DB2 data providers support reliable 2-phase commit distributed transactions over TCP/IP to DB2 running on most popular computing platforms. The new IP-DLC Link Service supports the industry-standard SNA over IP routing so that branch-deployed and centrally-deployed Host Integration Server computers can connect directly to z900 mainframes via high-speed IP networks. No longer do enterprises have to remotely administer branch cluster controllers, utilize expensive data link switching (DLSw) capable routers, or maintain costly front end processors (FEPs). With Host Integration Server 2004, enterprises can continue to consolidate their network infrastructure, while supporting the same level of SNA-compatible applications and services.

Transaction Integrator

Transaction Integrator (TI) enables you to integrate mainframe-based transaction programs (TPs) with component-based Microsoft Windows applications and enables the Microsoft Windows Server™ to function as a peer to IBM mainframe and AS/400 computers. These capabilities enable you to leverage existing COBOL and RPG applications for client/server or Web-service applications.

Running on Windows 2000 Server or Windows Server 2003, TI components appear as simple Automation or .NET servers that developers can easily add to their application. Behind the scenes, TI functions as a proxy that communicates with an application program running on IBM's Multiple Virtual Storage (MVS) or AS/400 operating systems. This means that you can invoke a legacy application on the host and return values to a Web-based client without rewriting the host application. You do not need any knowledge of COBOL or RPG programming to use Transaction Integrator.

Product Overview

Data Integration

Data services included with Host Integration Server 2004 enable you to interact with host data sources, including VSAM and DB2 systems.

> **Note** If you are using TCP/IP to connect to the mainframe or AS/400, you do not need to install or configure the Network Integration Services. You can use the Application and Data Integration Services over TCP/IP.

The following services are available:

- Managed Provider for DB2
- OLE DB Provider for AS/400
- OLE DB Provider for VSAM
- OLE DB Provider for DB2
- ODBC Driver for DB2

Managed Provider for DB2

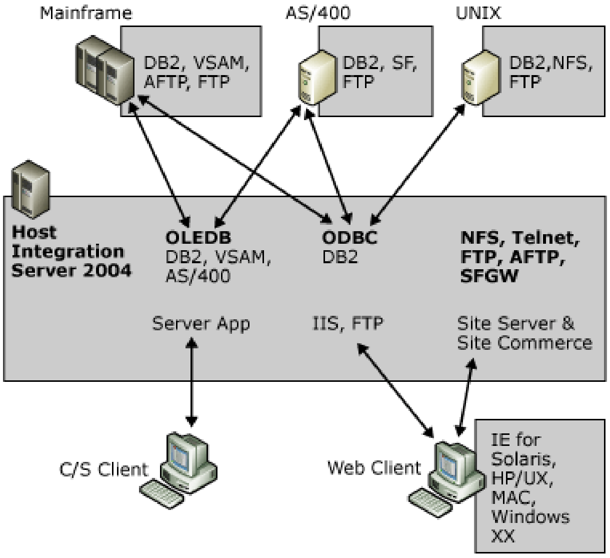
Host Integration Server 2004 includes a Managed Provider to access data from a loosely coupled data source; in this case, a DB2 database. The Managed Provider for DB2 uses two central .NET components to implement this capability: the ADO.NET DataSet and the Managed Provider for DB2 itself.

For more information, see the Managed Provider for DB2 Programmer's Guide.

OLE DB Provider for AS/400

The new Data Access Tool simplifies configuration and access to AS/400 systems.

The following diagram shows an overview of the OLE DB Provider for AS/400.



Mainframe
DB2, VSAM, AFTP, FTP
AS/400
DB2, SF, FTP
UNIX

ODBC Driver for DB2

Microsoft ODBC Driver for DB2 enables access over SNA LU 6.2 and TCP/IP networks to remote DB2 databases. This driver is implemented as an IBM Distributed Relational Database Architecture (DRDA) application requester that can connect to most DRDA-compliant DB2 systems, including MVS, VSE, VM, OS/400, AIX RS/6000, Sun Solaris, HP-UX, Digital/Compaq UNIX, OS/2, and Microsoft Windows 2000.

The driver can be used interactively or from an application program to issue SQL statements and execute DB2 stored procedures. Microsoft Excel users can import DB2 tables into worksheets and use Excel graphing tools to analyze the data. Microsoft Access users can import from and export to DB2. Using Microsoft Internet Information Server (IIS) on Windows 2000, developers can publish DB2-stored information to users through a Web browser interface.

The following diagram shows an overview of the ODBC Driver for DB2.

Network Integration

The new IP-DLC link service is a Host Integration Server 2004 feature that provides SNA connectivity for applications using dependent and independent sessions over a native IP network. It implements the HPR/IP protocol, which is also known as HPR over IP or Enterprise Extender. Each SNA packet is transmitted natively across the IP network as a UDP datagram.

Host Integration Server 2004 supports the following physical connection methods to your host system:

- 802.2 DLC (for supported OSA adapters)
- SDLC
- Channel (ESCON and Bus & Tag)

Physical connections to a host system are provided through the use of link services that support a variety of third-party adapters. A list of supported third-party adapters can be found in the online Help.

Host Integration Server 2004 supports the following standard SNA protocols for communications:

- LU 1 and LU 3 (for host printing)
- LU 2 (for 3270 displays)
- LU 6.2 (for APPC)
- LU 0
- LUA

Note If you are using TCP/IP to connect to the mainframe or AS/400, you do not need to install or configure the Network Integration Services. You can use the Application and Data Integration Services over TCP/IP.

Host Services

Host Integration Server 2004 provides a range of services that extend mainframe services to LAN users. These include the TN3270 Service for mainframe environments, the TN5250 Service for AS/400 environments, and Host Print Service and Host Integration (SNA) Remote Access Service for both mainframe and AS/400 environments.

Administrative Services

Host Integration Server 2004 provides network administrators with tools and services to monitor and manage host resources in your enterprise. These services are available for both the hierarchical and peer environments.

Accessing the Latest Documentation

A new, fully-updated documentation set is now available over the Web on a quarterly basis. Each quarterly release, which you download to your desktop, includes more in-depth information, updates, and new topics.

As the new documentation will replace your current set, you will need to close all instances of Host Integration Server 2004 Help for the update to install correctly. Downloading the new Help will not affect your Host Integration Server 2004 product installation or performance in any way.

You can download the latest documentation from the following location:

http://go.microsoft.com/fwlink/?LinkId=29507

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Documentation Roadmap

The Host Integration Server 2004 documentation has been expanded and reorganized to maximize usability. The text is fully searchable, and is organized into the groups below. This list contains documents that are included on your product CD, as well as documents that are available only on the Web.

- **Introduction: What's New for 2004** provides overview and What's New material.
- **Planning** contains important considerations for planning an effective deployment.
- **Secure Deployment Guide** contains information to help reduce the risk of attack on your system.
- **Installation and Configuration** guides you through setup and establishing a connection.
- **Operations** contains User's Guides for Transaction Integrator, Data Integration, Security Integration, Network Integration, and Messaging.
- **Technical Reference** contains reference material, user-interface help, and a glossary.
- **Programmer's Guide** provides conceptual material and programming considerations.
- **Programmer's Reference** contains reference material and tools for developers.
- **Samples** are sample code designed to help you learn and use Host Integration Server more effectively.

Planning

This section summarizes the key points of planning a Host Integration Server 2004 deployment.

This section contains:

- Planning Your Hardware
- Planning 3270 Connectivity
- Planning APPC Connectivity
- Planning for Transaction Integrator

Planning Your Hardware

Because Host Integration Server 2004 can be used in a wide variety of situations, there is no simple formula for the amount of processing power a specific computer needs. The information provided in this topic can help you evaluate your hardware requirements, including:

- A list of elements that reduce or increase demands on hardware. This helps you estimate the general level of your processing requirements. For example, a Host Integration Server 2004 computer can serve as many as 1500 to 2500 users. This indicates a need for large amounts of processing power, perhaps a Pentium processor with 64 or 128 megabytes (MB) of RAM. However, if your servers each support 500 users and most of those users connect briefly and at random times during the day, less processing power is needed.
- Ways to evaluate the current demand on an existing Host Integration Server 2004 computer, and the ability of the existing hardware to support that demand. This gives you a valuable baseline from which to work.

This section contains:

- Variables Affecting Hardware
- Estimating Hardware Demands
- Best Practices

Variables Affecting Hardware

Many factors affect the amount of memory and processing power required by a particular Host Integration Server 2004 computer. The major variables are:

- Number of clients served.

  This is the most important variable affecting hardware requirements. If you support large numbers of client computers, you need not only servers that have ample memory and processing capacity, but also fast, powerful LAN adapters. Such LAN adapters include their own processor and memory, and can use direct memory access (DMA). Without such adapters, the network interface can become the bottleneck when many clients are being supported. Similarly, SNA adapters must be powerful enough to keep pace with the communications load.

- Demand generated by the clients (constant, intermittent, heavy, light).
- Number of Host Integration Server 2004 computers configured to work together within a particular subdomain.

  This is affected by the configuration of the Host Integration Server 2004 installation: centralized, branch, or distributed. Host Integration Server 2004 computers in a centralized or a distributed configuration can provide load balancing; they can each take a share of the connection load. Server computers in a branch configuration are separated by wide area network (WAN) links, and cannot readily provide load balancing because of the communication delays involved.

- Use of data encryption between clients and servers.

  Data encryption is not dependent on the number of clients being served but on the number of messages that are encrypted. As the number of transactions per second increases, the load on the CPU increases. Using 128-bit encryption instead of 40-bit encryption also increases the load on the CPU.

- Additional network services (file sharing, database access, mail service, and so on) provided by each server computer.

  It is difficult to predict exactly how much processing power is required to run multiple server applications. In many cases, your own requirements to meet a certain level of response time or transaction rate will indicate the specific hardware requirements for your environment.

See Also

Estimating Hardware Demands

Best Practices

Estimating Hardware Demands

Use the information in the following table to estimate the amount of processing power required for your Host Integration Server 2004 computers.

Installation category	**Hardware guidelines**
Approximately 1500–5000 users for each server, with up to 15,000 sessions for each server	A multiprocessor system with at least 128 megabytes (MB) of RAM. Connections (such as DLC 802.2 or channel) that are fast enough to avoid bottlenecks (recommended). Multiple SNA adapters, except for channel. Multiple LAN adapters to avoid LAN bottlenecks. Optionally, dedicated Host Integration Server 2004 computers that do not provide file sharing or other LAN services (this depends on the load created by other LAN services).
Up to 600 users for each server (heavy use) or up to 1500 users for each server (light or intermittent use)	A Pentium computer, with at least 128 MB of RAM. Connections (such as DLC 802.2 or channel) that are fast enough to avoid bottlenecks (recommended). Multiple SNA adapters may be needed, except for channel connections. Multiple LAN adapters may be needed to avoid LAN bottlenecks. A more powerful CPU and more RAM may be needed if Host Integration Server 2004 computers must support significant additional loads, such as file sharing.
Up to 200 users for each server (heavy use) or up to 500 users for each server (light or intermittent use)	A Pentium computer, with at least 128 MB of RAM. A more powerful CPU and more RAM may be needed if Host Integration Server 2004 computers must support significant additional loads, such as file sharing.
Up to 25 users for each server	A Pentium computer, with at least 128 MB of RAM. A more powerful CPU and more RAM may be needed if Host Integration Server 2004 computers must support significant additional loads, such as file sharing.

See Also

Variables Affecting Hardware

Best Practices

Best Practices

Several rules of thumb can be applied when selecting your Host Integration Server 2004 hardware:

- Try to avoid memory paging.

  It is useful to increase the amount of physical memory in a Host Integration Server 2004 computer to avoid paging. This guideline is true for any Windows Server that performs communications-related functions.

- Increase memory when using Host Print service.

  When using Print service, you may need more memory on the Host Integration Server 2004 computer if large files or many print jobs are submitted. You also need adequate disk space to temporarily store the spooled print jobs.

- Use TCP/IP instead of Microsoft Networking.

  The Windows Sockets (Winsock) and TCP/IP combination uses less memory on the Host Integration Server 2004 computer than Microsoft Networking or other named socket solutions. TCP/IP also provides better performance than Microsoft Networking because of its lower network overhead.

Estimating Hardware Demands

Planning 3270 Connectivity

In the hierarchical SNA network model most frequently associated with a mainframe computer, you access centralized applications from remote terminals across a network.

This network model uses the information display protocol for IBM mainframe computers known as 3270. This protocol facilitates conversations between the mainframe and devices such as terminals, printers, and controllers. Through the definition and assignment of 3270 logical units (LUs), Host Integration Server 2004 provides access to these mainframe resources.

Once you establish the physical connection from the Host Integration Server 2004 computer to the mainframe, you need to determine the type of 3270 connectivity your users need. The topics in this section detail the networking services Host Integration Server 2004 can provide to your users and offers information on ways to set up these services.

This section contains:

- 3270 Access
- TN3270 Access
- Downstream Connections

3270 Access

Host Integration Server 2004 provides 3270 connectivity through 3270 logical units (LUs). A 3270 LU is known as a dependent LU because it requires a mainframe to function. Each 3270 LU defined within Host Integration Server 2004 is configured to use an existing connection to the mainframe system. Each 3270 LU corresponds to a matching LU resource allocated on the host computer, usually specified within VTAM. The 3270 LU definition in Host Integration Server 2004 is identified by a number that matches the number of the corresponding LU resource on the mainframe, and by a user-specified name.

The 3270 LU is further classified by the type of service provided over the connection. Like physical units (PUs) physical units, LU types are designated by numbers. For example, 3270 display data streams are known as LU 2 streams. Within Host Integration Server 2004, a 3270 LU can be configured as one of the following types:

- Display (LU 2)
- Printer (LU 1 or LU 3)
- Application (LUA)
- Downstream

Once configured, these LUs are accessed from an end-user applications using Host Integration Server 2004 client software that is installed on the client workstation. The client software manages communications between a 3270 application (like a terminal emulator) and the Host Integration Server 2004 computer. Applications designed for the Host Integration Server 2004 client API use the LUs defined within Host Integration Server 2004 to establish a communications link from the client personal computer to the mainframe via Host Integration Server 2004.

The link between the LU definition in Host Integration Server 2004 and the host LU resource is called a *session*. Sessions can be permanent and automatically started during initialization, or established on an as-needed basis. Concurrent sessions can share the same physical devices and communications links.

Providing Hot Backup and Load Balancing

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

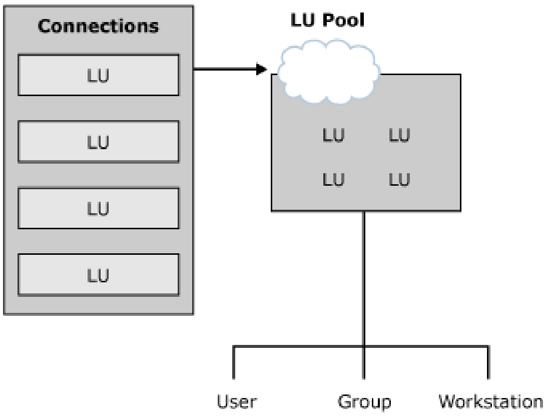
Deployment Strategies

This section describes deployment strategies that can be applied if you are providing 3270 connectivity services including:

- Using LU Pools
- Assigning LUs to Workstations
- Providing Hot Backup and Load Balancing

Using LU Pools

Although you can create individual LUs and assign them to users and groups, using LU pools to manage and deploy a large number of LUs is a more efficient method of administering these resources. LU pools are groupings of LUs that allow you to maximize access to these LUs. As shown in the following illustration, a user, an application, or a downstream system can access the LUs as long as any LU assigned to the pool is free. If any one of the pooled LUs ceases to function, another free LU in the pool is automatically used.



Creating and assigning LU pools

LU pools also allow groups of intermittent users to use a limited number of host resources more efficiently. Dedicating LUs to specific users who occasionally require host access wastes host resources. Using a pool, you can assign a smaller number of LUs to a group of users who require sporadic access. For example, if a group of 100 users require host access 25 percent of the time, assigning a pool of 25 LUs to the group may fulfill their needs.

See Also

Assigning LUs to Workstations

Providing Hot Backup and Load Balancing

Assigning LUs to Workstations

LUs and LU pools can also be assigned to workstations rather than users, effectively locking LUs to a specific machine. Assigning LUs to a workstation makes it easier for users to find and access different resources. For example, 200 hospital employees can share 50 workstations, each of which has a printer attached. Employees may want to access any of the 50 workstations and 50 printers. Instead of assigning 50 printer LUs to a pool and making the pool available to each user, each of the workstations can be added to Host Integration Server 2004 and a printer LU can be assigned to each workstation. Now, when a user logs onto any of the 50 workstations, the printer that is attached to the workstation will be available in the list of LUs.

To recover from situations where a particular host connection has failed, the Host Integration Server 2004 hot backup feature can be configured to allow for similarly configured resources to automatically fill in and support functions dependent on the failed connection. When a failure occurs, a user can simply reconnect to a given resource using an alternate connection or server without reconfiguring client software. Hot backup can be implemented across host connections on the same server, or across several servers in a domain using LU pools as shown in the preceding figure. Implementing fault-tolerant connections is a recommended strategy for enterprises of any size, and helps to provide reliable host access to your users.

Related to hot backup is a feature called load balancing. Load balancing evenly distributes sessions across multiple host connections and multiple servers using 3270 LU pooling. Instead of explicitly requesting specific LUs, users request the first available LU in a pool and Host Integration Server 2004 randomly assigns the user a free LU in the pool. Because each LU can be configured using different connections or servers, the server load can be spread out across all configured resources. Load balancing is implemented automatically when a pool is configured with LUs from multiple servers or connections.

Using LU Pools

Assigning LUs to Workstations

TN3270 Access

TN3270 is a type of Telnet service that allows access to mainframe computers over a TCP/IP network. Users can connect to mainframes using a TN3270 client and the TN3270 service provided with Host Integration Server 2004.

The TN3270 service supports these protocols:

- TN3270, for display sessions
- TN3287, for printer sessions
- TN3270E, for extended display and print sessions

The TN3270 service uses Host Integration Server 2004 features to provide mainframe access and to address issues such as security and redundancy when the data communications path between the client and server contains one or more nonsecured segments.

TN3270 Service

The TN3270 service communicates with Host Integration Server 2004 using the LUA (Logical Unit for Applications) API. Because of this, LUA-type connections and LUs must be configured on the server. Once configured, LUA LUs and LU pools can be assigned to the TN3270 service and made available for use by TN3270 clients requesting mainframe access.

Deploying Hot Backup and Load Balancing

Assigning LUs to an IP Address

Deployment Strategies

This section describes deployment strategies that can be applied if you are providing TN3270 connectivity services including:

- Setting Port Numbers
- Deploying Hot Backup and Load Balancing
- Assigning LUs to an IP Address

Setting Port Numbers

As with all TCP/IP services, TN3270 requires a free TCP port in which clients can locate the TN3270 service. By default, the TN3270 service defaults to port 23, the same port as standard Telnet services. Because no two services can share the same TCP port, it is recommended that you change the TN3270 service to use TCP port 24 or some other unused TCP port. When attempting to connect to the TN3270 service from a client application, you must also specify the new TCP port within the application connection settings.

Deploying Hot Backup and Load Balancing

Assigning LUs to an IP Address

Deploying Hot Backup and Load Balancing

A Windows domain can contain one or more Host Integration Server 2004 subdomains. Like 3270 LUs, LUA LUs from multiple servers in different subdomains can be assigned to the TN3270 service. This lets you distribute client sessions among the participating servers in the subdomain, thereby balancing the load.

Creating redundant connections to the mainframe and assigning them to a TN3270 service increases service availability. If one server goes down, a client can still access LUA LUs on a different server. Similarly, a single server can be configured with redundant host links to increase hot backup and bandwidth if no other Host Integration Server 2004 computers are available.

See Also

Setting Port Numbers

Assigning LUs to an IP Address

Assigning LUs to an IP Address

In the same way that you assign 3270 LUs to a user or workstation, you can restrict access to LUA LUs or pools by specifying an IP address or subnet mask for clients that must access the resource. If a workstation has a name that can be resolved using name resolution services like DHCP or WINS, the name can be associated with the resource instead.

Restricting access to clients with specific IP addresses or workstation names increases the security of the LUA resources.

Setting Port Numbers

Deploying Hot Backup and Load Balancing

Downstream Connections

In a hierarchical SNA environment, you configure 3270 communications between SNA nodes using SNA protocols. Usually those nodes are Host Integration Server 2004 computers and mainframes. A downstream system, however, is an SNA node that uses Host Integration Server 2004 as a physical unit (PU) gateway. To the downstream system, the Host Integration Server 2004 computer appears to be the actual mainframe providing the PUs and 3270 LUs. The following figure illustrates a downstream system.

LU
LU
Host Integration Server 2004
PU 2 Device Downstream System
Downstream Connections
Downstream LU
Downstream LU
Downstream Clients
PU
LU
LU
PU
LU
LU

A downstream system in this type of environment must be a PU 2 device, for instance, a cluster controller like an IBM 3745, or a client personal computer running a terminal emulator that emulates a PU 2 and acquires LU sessions from the Host Integration Server 2004 computer.

On the Host Integration Server 2004 computer, two connections are required to support downstream systems:

- A host connection between the server and the mainframe. This can be any standard physical connection method supported by the mainframe.
- A downstream connection between the server and the downstream system. This physical connection can be a DLC 802.2, SDLC, or X.25 connection.

Once configured, Host Integration Server 2004 can manage the downstream LUs in a manner similar to other LUs, including assigning them to LU pools.

Deployment Strategies

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Deployment Strategies

This type of configuration is useful in environments in which the downstream system may be unable to communicate directly with the mainframe because of hardware or network incompatibilities that the intermediate Host Integration Server 2004 computer can resolve.

Using Host Integration Server 2004 as a PU concentrator can also help reduce host configuration requirements. LUs from one or more physical units (PUs) can be shared with multiple downstream devices, alleviating the need to configure each downstream device in VTAM on the mainframe system. The result is more efficient use of host resources.

Downstream Connections

Planning APPC Connectivity

A peer-oriented SNA network, using the Advanced Program-to-Program Communications (APPC) protocol, relies on each device in the network to communicate directly with the others. Each computer depends primarily on its own intelligence and does not require constant access to a centrally located host computer.

APPC supports display and other application services across an SNA network. Although peer-oriented SNA networks are usually associated with an AS/400 host system, mainframe systems can also support peer-to-peer networking.

Once you establish the physical connection from Host Integration Server 2004 to the AS/400, you need to determine the types of APPC services required by your users. This section discusses the APPC services that Host Integration Server 2004 can provide to your users and tells how to set up these services.

This section contains:

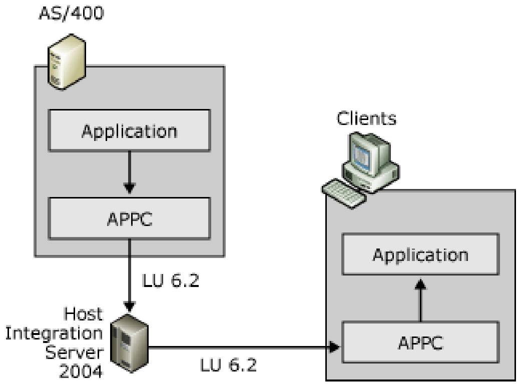
- Understanding Peer-to-Peer Networking
- APPC Applications
- APPC Deployment Strategies

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Understanding Peer-to-Peer Networking

Devices in peer-oriented SNA networks participate in Advanced-Peer-to-Peer Networking (APPN). Each device, known as a type 2.1 physical unit (PU 2.1), handles all network routing functions, as well as normal computing activities and applications.

LU 6.2 logical units are associated with PU 2.1 devices. Devices in an APPN network appear as LU 6.2 (also called APPC LU) entities. Programs that are executed on these devices are called transaction programs (TPs).

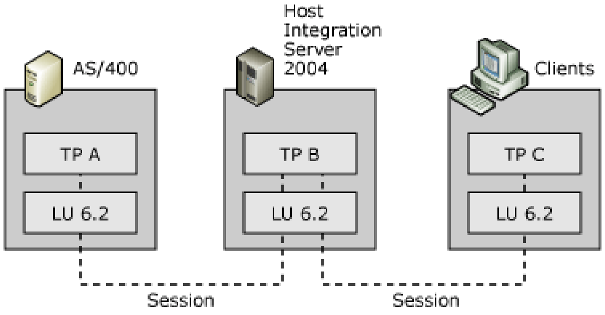


APPC enables TPs on different APPN systems to communicate directly with each other across an APPN network. In APPN networks, Host Integration Server 2004 provides support for the APPC protocol and emulates a PU 2.1 low-entry networking (LEN) node.

In the AS/400 environment, APPC is used for a variety of applications, including:

- 5250 access
- TN5250 access
- File transfer

TPs use LU 6.2 names to access other systems and other transaction programs as shown inthe following figure. With Host Integration Server 2004, a transaction program, such as a 5250 terminal emulator, can also use an APPC LU alias to access another TP. In this case, the LU alias maps to an LU name that is actually used to access the other system's TP.



APPC uses pairs of LUs to facilitate simultaneous, bi-directional communication between transaction programs. To achieve this, a local LU and a remote LU are defined on each device in the APPN network.

The perception of local and remote LUs is dependent on the system that you are configuring. When configuring Host Integration Server 2004, the local APPC LU corresponds to the Host Integration Server 2004 computer and the remote LU corresponds to the AS/400. Local LUs on one system communicate with remote LUs on another system. If you view the configuration from the AS/400 perspective, the Host Integration Server 2004 computer is the remote system and the AS/400 is the local system.

5250 Emulator
Database Access
File Transfer

When a client/server network TP, such as a 5250 terminal emulator, requests a conversation with a TP on the AS/400 (remote system), the server (local system) acts on behalf of the client request and negotiates an LU 6.2 - LU 6.2 session to the AS/400. The data sent or received from the AS/400 TP is handled by the server and sent to the client TP over the selected client/server protocol. This is illustrated in the preceding figure.

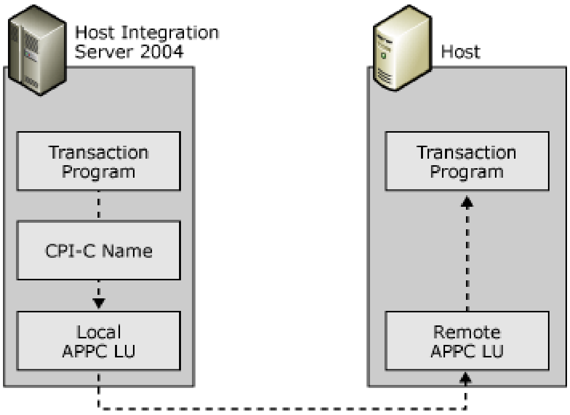
Understanding CPI-C

Understanding CPI-C

Common Programming Interface for Communications (CPI-C) is an application programming interface (API) that uses the LU 6.2 communications architecture. CPI-C comprises a set of C programming language routines that allow applications on computers to communicate with one another to accomplish a processing task, such as copying a file or accessing a remote database.

CPI-C programming provides a mechanism called client-side information that associates a set of parameters with a specified CPI-C symbolic destination name. The CPI-C program uses the symbolic destination name to initialize a conversation using APPC LUs that are associated with the CPI-C symbolic name.



Host Integration Server 2004 supports the CPI-C API and provides for configuration of CPI-C parameters. These parameters allow applications on the Host Integration Server 2004 systems to communicate with applications on any platform that supports APPC communications and CPI-C including mainframes, AS/400s, Windows systems, and UNIX systems.

TN5250 Access

TN5250 is a protocol that allows users to access AS/400 systems over a TCP/IP network using an appropriate TN5250 client terminal emulator. The TN5250 service provided with Host Integration Server 2004 enables any TN5250 client to connect to the AS/400 by means of Host Integration Server 2004 without installing or configuring TCP/IP on the AS/400. Full 5250 terminal emulation functions are supported by the service, as well as hot backup and security features similar to those provided with the TN3270 service.

APPC Applications

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

APPC Deployment Strategies

In most cases, deployment strategies are effective for APPC LUs, regardless of the application that the LUs support. This section describes the factors that you should consider when deploying APPC connections with Host Integration Server 2004. This section contains:

- Using Independent APPC LUs
- Using Dependent APPC LUs
- Choosing Modes
- Using LU Pools
- Configuring LUs
- Providing Hot Backup
- Choosing IP Settings

Using Independent APPC LUs

An independent LU can communicate directly with a peer system and does not need the support of a host computer. Independent APPC LUs, as used in AS/400 APPN networks, provide the ability to run multiple, concurrent, parallel sessions between a local and remote LU pair.

When configuring independent APPC LUs, you should note that when Host Integration Server 2004 is used to communicate with a transaction program (TP) on a mainframe over an independent APPC LU, the host system must be running VTAM version 3, release 2 (V3R2) or later. The version of Network Control Program (NCP) required on the mainframe depends on the type of front-end processor (FEP) used. For 3725 systems, NCP V4R3 or later is required. For 3745 systems, NCP V5R2 or later is required.

See Also

APPC Deployment Strategies

Using Dependent APPC LUs

A dependent local APPC LU requires the support of a mainframe in order to communicate with a remote TP. Dependent APPC LUs cannot be used to communicate with AS/400s. Unlike independent APPC LUs, dependent APPC LUs only allow a single session per LU.

Dependent APPC LUs are helpful when configuring Host Integration Server 2004 to communicate with a mainframe using a version of VTAM earlier than V3R2. Independent LUs are not supported in earlier VTAM versions. Support for dependent APPC LUs is provided with Host Integration Server 2004 for compatibility with older VTAM versions. If possible, use independent LUs.

When configuring APPC dependent LUs, you should specify the network name and LU name. Even though they are not required, they are used by software running on the Host Integration Server 2004 computer, such as the Windows Event Log. For example, if a remote APPC LU will be partnered with a dependent local APPC LU, naming the remote APPC LU helps to identify any events associated with the LU in the Windows Event Log.

See Also

APPC Deployment Strategies

Choosing Modes

Each LU-LU pair has a mode associated with it that determines session properties for that pair. For independent APPC LU sessions, the Parallel Session Limit parameter is of particular importance because this limit determines the number of simultaneous conversations that a session can support. If you plan to use a remote APPC LU that supports parallel sessions, it can only be used with a mode whose parallel session limit has a value greater than 1.

The following table lists the modes supplied with Host Integration Server 2004 and describes the scenarios in which each mode can be used.

Mode Name	Suitability
#BATCH	Batch-oriented sessions
#BATCHSC	Batch-oriented sessions that employ a minimal level of routing security
BLANK	Sessions using a default node name, encoded as eight blank EBCDIC spaces in a BIND APPC command
#INTER	Interactive sessions
#INTERSC	Interactive sessions that employ a minimal level of routing security
QPCSUPP	All sessions with an AS/400 computer
QSERVER	Database connectivity with an ODBC driver

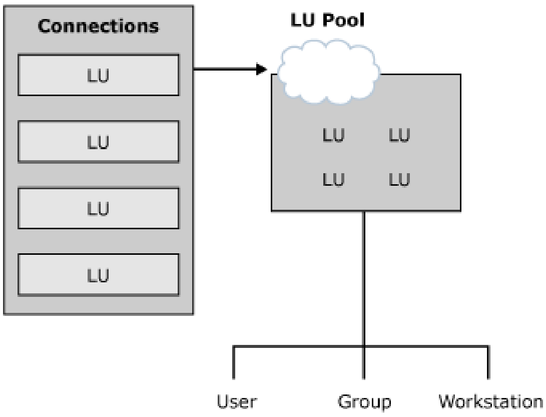
APPC Deployment Strategies

Using LU Pools

Although you can create individual LUs and assign them to users and groups, using LU pools to manage and deploy a large number of LUs lets you administer these resources more efficiently. An LU pool is a grouping of LUs that allows you to maximize access to these LUs as shown in the following figure. A user, an application, or a downstream system can access the LUs as long as any LU assigned to the pool is free. If any one of the pooled LUs ceases to function, another available LU in the LU pool is automatically used.



LU pools also allow groups of intermittent users to use a limited number of host resources more efficiently. Dedicating LUs to specific users who occasionally require host access wastes host resources. Using a pool, you can assign a smaller number of LUs to a group of users who require sporadic access. For example, if a group of 100 users require host access 25 percent of the time, assigning a pool of 25 LUs to the group may fulfill their needs.

See Also

APPC Deployment Strategies

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring LUs

When a user configures a 5250 emulator to access an AS/400, the emulator is configured with the local and remote APPC LU alias names. The LU alias names are mapped to LU names that are used for the conversation with the AS/400.

Host Integration Server 2004 allows you to define a default local and remote APPC LU for each user group accessing the AS/400. Setting default values relieves the user from having to remember APPC LU names; these values should be specified, if possible.

When creating local APPC LUs, it is recommended that you use the name of a user or group as the local LU alias. When the session from a particular user or group is active, the LU alias name is displayed in SNA Manager. Matching local LU alias names with user names allows you to tell which 5250 users are connected to the AS/400. This also makes it easy to keep track of which local LU a particular user should use.

To use this method, create a separate local APPC LU with an LU alias that matches the user name of each person or group being added to the SNA subdomain. After the LU is created, assign the LU to the user as the default local APPC LU along with a default remote APPC LU.

In Host Integration Server 2004, you can also specify an implicit incoming remote LU that defines the properties to use when Host Integration Server 2004 receives a request to start a session with a local LU, and the remote LU named in the request is not recognized by Host Integration Server 2004. You can also specify an implicit incoming mode that defines the session characteristics when a mode is not recognized by Host Integration Server 2004.

If you want to accept an incoming request that can arrive by many different remote LUs without explicitly defining each remote LU, you can specify implicit incoming remote LU pairs, along with their mode. When the implicit incoming remote LU and mode are specified, the remote LU does not need to be recognized by the server. As long as the local LU specified in the session request is recognized, the connection can be initiated.

See Also

APPC Deployment Strategies

Providing Hot Backup

In the AS/400 environment, Host Integration Server 2004 uses a combination of LU names and LU aliases over one or more servers to achieve transparent connections with hot backup to an AS/400.

Hot backup connections to an AS/400

A single Host Integration Server 2004 computer can use multiple connections to provide hot backup. To use this method, two or more APPC connections to the same AS/400 are configured and appropriate LUs are grouped into a pool. If one of the connections fails, the clients can reconnect to the AS/400 without reconfiguration.

Host Integration Server 2004 can also use multiple Host Integration Server 2004 computers as backups to one another. If one of the servers fails, the clients are shifted from the failed server to a working server. Use a combination of connections and servers with hot backup to maintain a high level of host availability in your enterprise.

See Also

APPC Deployment Strategies

Choosing IP Settings

IP settings assigned to the TN5250 definitions allow TN5250 clients to connect to the AS/400. By default, the TN5250 definition is not assigned an IP address or a subnet mask. This allows any TN5250 client to connect to the AS/400.

You can restrict access to the TN5250 service by specifying the IP address or subnet mask of the client workstation(s). When these values are specified, only clients whose IP and/or subnet mask match those specified in the TN5250 configuration are allowed access to the AS/400 through the TN5250 service. You can also specify the workstation name in place of the IP, and use a WINS, DHCP, or other name-resolution service to resolve a friendly name to an IP address.

Host Integration Server 2004 (SNA) Remote Access Service

Deployment Strategies

Host Integration Server 2004 (SNA) Remote Access Service

SNA Remote Access Service integrates the LU 6.2 transport of Host Integration Server 2004 with Windows Remote Access Service, allowing administrators to create virtual LAN connections between Windows systems across an existing SNA network. Using SNA Remote Access Service, the SNA network acts as a network backbone, passing network traffic between the Windows systems that are bridged with the host system.

The functions available with SNA Remote Access Service are the same as those for Remote Access Service over ISDN or X.25, except for the dial-back connection feature, which is not supported by SNA Remote Access Service. The SNA Remote Access Service supports the either the Windows Remote Access Service Server or Windows Remote Access Service client, depending on whether the machine to which SNA Remote Access Service is installed is a Host Integration Server 2004 client or server. In addition, a Windows Workstation computer running Host Integration Server 2004 client software and SNA Remote Access Service can dial out through the Host Integration Server 2004 computer that is also running SNA Remote Access Service.

SNA Remote Access Services is configured using local and remote APPC LUs that are assigned to clients using SNA Remote Access Service to connect to mainframe and AS/400 computers. After SNA Remote Access Service is installed, a SNA Remote Access Service port must be specified for each client or server connection that the computer will support. For example, to support one client and four server connections, a total of five ports must be specified. Each port must be added and configured before it can be used by SNA Remote Access Service.

See Also

Choosing IP Settings

Deployment Strategies

Since legacy SNA networks may include smaller-bandwidth links like SDLC, and LAN traffic typically generates more network traffic that can be effectively handled by slower connections, care should be taken to resolve bandwidth needs before deploying SNA Remote Access Service in your enterprise.

Before Windows Remote Access Service clients can connect through SNA Remote Access Service, Host Integration Server 2004 must be configured to provide the following items for each client system:

- A peer incoming connection
- A remote APPC LU for each client

Each Host Integration Server 2004 computer must also be configured with at least one local APPC LU that can be used by SNA Remote Access Service when communicating with the client system. One local LU is required for each SNA Remote Access Service port that is used. For each connection that you set up for use by SNA Remote Access Service, a corresponding remote APPC LU must be configured. This remote LU defines the local LU on the Remote Access Service client that will be used to connect to the server via SNA Remote Access Service. Once the LUs are configured, each remote user must be given permission to dial in to the server.

If you create a SNA Remote Access Service connection between a client and a server that are also connected by a LAN, you must disable the bindings between the Remote Access Server Service and the network adapter to prevent Windows Remote Access Service from attempting to insert the Remote Access Service client into the LAN. This scenario usually occurs when testing a Remote Access Service connection over a network.

After the APPC LUs are configured, the final step is to create a phone book entry for each connection. If you have configured more than one port for use by SNA Remote Access Service, you can create an additional set of phone book entries by associating the same connection with the additional Remote Access Service ports.

A common use of SNA Remote Access Service is to enable an administrator to manage Host Integration Server 2004 computers remotely via the SNA network itself. An administrator working at a Windows Workstation running SNA client software and SNA Remote Access Service can use the service to connect to and administer servers at branch locations connected to SNA network.

Choosing IP Settings

Planning for Transaction Integrator

Before installing and using Transaction Integrator (TI), determine whether your mainframe-based transaction programs (TPs) can be used with TI and whether any of them need modification. Answer the following three questions to find out whether TI can invoke your TP:

- Is the TP irretrievably terminal-oriented, or can you expose a request-response interface?
- What programming model does the TP need?
- Does the TP use data types that TI supports?

To use TI to invoke a mainframe-based transaction program (TP), you must separate the business logic from the presentation logic in the TP. TI uses the request-response model; it does not support conversational or pseudo-conversational transactions. The TP must support the so-called ping-pong request-reply mode.

Although TI does not support screen scraping, it does support eight other communication models. Some CICS and most IMS transactions that expose terminal interface can also be invoked using one of the eight supported models. For example, a CICS transaction might be terminal-oriented but still have the business logic partitioned in a separate link model transaction for load balancing or maintainability.

Communication Models

Data Types

Host and Automation Data

Communication Models

Transaction Integrator (TI) supports the following communication protocols for interacting with the host computer. These protocols are limited to single request/single response. However, the request and response can consist of multiple data segments in the case of unbounded recordsets.

- **CICS TCP Transaction Request Message Link**
  The host transaction must be IBM DPL-enabled. In other words, the mainframe transaction must be designed to be invoked by EXEC CICS LINK.
- **CICS TCP Transaction Request Message User Data**
  The host transaction must use explicit TCP SEND/RECEIVE.
- **CICS LU 6.2 Link**
  The host transaction must be IBM DPL-enabled (Distributed Program Link), that is, the mainframe transaction must be designed to be invoked by EXEC CICS LINK.
- **CICS LU 6.2 User Data**
  The host transaction must use explicit APPC SEND/RECEIVE.
- **IMS Connect**
  Enables you to use TCP/IP with your IMS-based TP without recompiling it. By using IMS Connect or OTMA, you can connect to existing IMS transactions without linking listeners to the TPs.
- **IMS Implicit**
  The IMS program must use implicit message queue and IMS library CBLADLI (rather than CBLTDLI).
- **IMS Explicit**
  The host transaction must use explicit TCP SEND/RECEIVE.
- **IMS LU 6.2 User Data**
  The IMS program must use an implicit message queue (the common design model).
- **OS/400 Distributed Program Calls**

About Security

As corporate networks become increasingly integrated with the Internet and other external networks, the threat of unauthorized access to your corporate resources grows significantly. When you plan your networking environment, you must strike a balance between protecting your resources and allowing users unobstructed access to data.

Following are some of the questions that must be answered as you prepare to secure your Host Integration Server 2004 environment:

- How can I authenticate users who require host resources?
- How can I control access to host resources?
- How can I control sensitive data flowing between workstations and host applications?
- How can I maintain security while connecting my host network to external sources like the Internet?
- How can I make host resources easier to access for authenticated users, yet maintain a secure and easy-to-administer host environment?

This section helps answer these questions and describes how to implement the security features to create a secure LAN-to-host environment.

Understanding Windows Security

File System Choices and Security

One of the keys to controlling security on Host Integration Server 2004 computers is the configuration file. To maintain good security with this file, be sure to install the Host Integration Server 2004 server software on an NTFS (NT File System) partition. With NTFS, you can assign permissions on a file-by-file basis. With the FAT (File Allocation Table) file system or HPFS (High Performance File System), this is not possible. Installing Host Integration Server 2004 software on an NTFS partition is especially important for the primary server because this computer contains the master copy of the configuration file used by all Host Integration Server 2004 computers in the subdomain.

If you must install Host Integration Server 2004 on a non-NTFS partition, you can limit a user's ability to view or change a Host Integration Server 2004 configuration file through the Host Integration Server 2004 SNA Manager, but you will not be able to set file permissions on the configuration file itself.

In addition, if you choose to install the software for one or more servers on a FAT or HPFS partition, you can set appropriate Read and Change permissions on the share, which gives servers access to the configuration file. (This is unnecessary for Host Integration Server 2004 software installed on an NTFS partition, because file permissions established through the Host Integration Server 2004 SNA Manager place tighter control on the configuration file than can be established by controlling the share.)

Securing Host Integration Server 2004 Files and Directories

If you install Host Integration Server 2004 onto an NTFS volume, you can control which SNA subdomain users can modify the Host Integration Server 2004 configuration file. A Host Integration Server 2004 administrator can control access to the configuration using the Host Integration Server 2004 SNA Manager. By specifying access permissions for users, you can control who has the ability to administer, change, or view a configuration.

When you install Host Integration Server 2004, you create a single directory tree that contains the files needed to configure and use Host Integration Server 2004. To control access to the configuration files in these shares, use the following guidelines:

- Create domain user accounts to run the SnaBase and SnaServer services. A domain user account is one that is allowed to log on to the network.
- Disable the Windows domain guest account.

At least one domain user or group must have Full Control permissions over all the shares, preferably a trusted group such as Administrators. If no user or group has Full Control permissions, the only person who can change the share permissions is the owner of the share. If necessary, this individual can change his or her permissions to Full Control as needed.

Understanding Windows Security

About Authentication

When Host Integration Server 2004 receives a request to access a host resource, such as an LU for a terminal session, the server must have some way to verify the request.

User validation is a fundamental security issue that you can address using one of two methods: Domain Authentication and Workstation Authentication. The method you choose depends upon the type of service being requested.

Domain Authentication

A *domain*, as it pertains to Windows, is a group of computers that share a network resource database and have a common security policy. A Windows domain contains a *primary domain controller* (PDC) computer that acts as the resource and user manager for the entire domain. One or more computers in the domain can be configured to act as a *backup domain controller* (BDC). The BDC can take over for the PDC should any problems arise. The remaining computers in the domain are user workstations or servers that provide resources to domain users.

Within a Windows domain, Host Integration Server 2004 computers are logically grouped into an entity called a *subdomain*. Each SNA subdomain can contain up to 15 Host Integration Server 2004 computers, and a Windows domain can contain an unlimited number of subdomains. It is common to have multiple domains that manage user accounts independently of one another.

The domain model provides two key advantages over peer-to-peer networks with regards to security:

- You can manage user accounts from a central location.
- You can set up one unified security system for all user accounts in the domain.

Host Integration Server 2004 relies on the PDC or BDC to provide authentication services to users requesting access to host resources. Only users who have been validated by the PDC or BDC can gain access to resources provided by servers in the subdomain.

You can use domain authentication to verify users who request resources provided by these services:

- 3270 or 5250 terminal access from workstations using Host Integration Server 2004 client software
- APPC, CPI-C, or LUA applications built using Host Integration Server 2004 APIs

See Also

About Authentication

Workstation Authentication

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Workstation Authentication

When you receive a request from a source that is external to the corporate network containing the SNA subdomain, or if you are not using a domain-type network, domain authentication is usually difficult to implement.

In this case, Host Integration Server 2004 performs workstation authentication on the following services:

- TN3270 terminal access
- TN5250 terminal access
- 3270 access from terminal emulators connecting through Host Integration Server 2004 client software

For these services, you can specify a list of allowed client workstation IP addresses for defined resources. When Host Integration Server 2004 receives a session request, it determines whether the requesting IP (or workstation name for TN3270E connections) matches that specified for the requested resource. Once verified, Host Integration Server 2004 allows the request to proceed.

> **Note** This type of authentication is not as secure as domain security because workstation names and the IP address are transmitted in clear text over the network.

About Authentication

Domain Authentication

Client Logon

The logon process conducted by a user on a client system performs the essential task of identifying the user to the Windows domain and to Host Integration Server 2004 computers in the domain. The way that Host Integration Server 2004 handles the logon process depends on the network software on the client system.

For any type of client computer, once the client's logon process for one Host Integration Server 2004 computer has been completed, additional servers can provide services without another interactive user logon. Servers can repeat the logon verification without the user being involved.

If you maintain tight security with the logon to a mainframe, it may make sense to keep access open-ended on the Host Integration Server 2004 computer.

Denying Access to Host Integration Server 2004

You can use one of two methods to deny a user or group the ability to use Host Integration Server 2004. Either remove the user or group from the list of those who have permissions, or assign No Access to the user or group.

When removing a user or group from the list of those who have been granted permissions, be sure to consider all groups to which a particular user belongs. To deny access to that user, either remove the applicable groups from the list of those with permissions, or remove the user account from these groups. Otherwise, the user can receive access through one of the groups (unless the second method, assigning No Access, is used).

You can deny all access to a user or group by assigning No Access, which overrides any other permissions that may apply to a user. For example, if a user belongs to a group that has Read permission, but the user has No Access, the user is not permitted administrative access. Likewise, if a user belongs to Group1 and Group2, and Group1 has Read permission while Group2 has No Access, the user is not permitted administrative access.

The following table provides recommendations for using the two methods of denying access.

Method of denying access	Recommended situations for use
Remove from list of those granted permissions	Use when you want to deny access to a medium or large group. If you then want to grant access to specific users in that group, add those users to the list of those with permissions. In contrast, if you assign No Access to a large group, none of the members of the group will be allowed access, even if explicit access is assigned to them through other accounts.
Assign No Access	Use when you want to deny access to an individual user or a small group. If you then want to grant access to other groups to which the affected users belong, you can do so. The No Access permission overrides the other permissions for the affected users. In contrast, if you attempt to deny an individual user access by removing the user from the list of those granted permissions, a group to which the user belongs might be left in the list. The permissions assigned to that group would be given to the user.

Understanding Windows Security

Security Audit

When you set up security auditing, you specify events for which the system will create event log entries.

You can monitor system events using the Host Integration Server 2004 SNA Manager. When you configure the properties, you can view a detailed problem analysis, significant system events or general information messages, or you can disable audit logging.

You can cause the system to create an entry every time a member of the Administrators group changes the configuration file. The entry would include the time, the user and process IDs, and other information.

When you set up auditing with Host Integration Server 2004, you are able to record not only access to the configuration file, but the running of Host Integration Server 2004 processes. However, using a file system other than NTFS limits the possibilities for auditing, just as it limits the possibilities for setting permissions. When Host Integration Server 2004 is not installed on NTFS, the only event that will actually result in log entries is the starting of the Host Integration Server 2004 SNA Manager. However, auditing information for this event is useful, if limited.

Auditing is an important way of collecting security-related information. However, there is a small performance overhead for each audit check the system performs. In addition, if you record a wide variety of events, the event log can grow very quickly. For these reasons, you may want to be selective when specifying events to be audited. You may want to focus on such events as Read Domain (Success), Write Domain (Success), and Manage Domain (Success). This list of events is a suggestion only. All the events offered for auditing through Host Integration Server 2004 can be useful, depending on the situation.

Among the events recorded when you enable auditing are the actions of Host Integration Server 2004 itself. For more information about event logs, the Event Viewer, and strategies for auditing, see your Windows documentation.

See Also

Understanding Windows Security

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Viewing and Interpreting Audited Events

Events audited by Host Integration Server 2004 are recorded on the server in which they occur. They are not stored centrally, in contrast with other records generated through Host Integration Server 2004.

The records generated through auditing are stored in the security section of the event log. In contrast, other Host Integration Server 2004 events are recorded in the application section of the log.

> **Note** When you view log entries for audited events related to Host Integration Server 2004, you will see a record of actions carried out by Host Integration Server 2004 itself, as well as actions carried out by users. The source of the actions carried out by Host Integration Server 2004 is the account under which the service is running.

The event details for some events will list an item called **Accesses** in the **Description** box. Unusual information may be shown here for events related to Host Integration Server 2004.

Use the following table for interpreting this information.

Information shown for Accesses (under Description)	Meaning
Unknown specific access (bit 0)	Read Domain access. This access applies when someone starts or attempts to start the Host Integration Server 2004 SNA Manager. (Host Integration Server 2004 must read the configuration file in order to function.)
Unknown specific access (bit 1)	Write Domain access. This access applies when someone starts the Host Integration Server 2004 SNA Manager in write mode — that is, when someone starts Host Integration Server 2004 and the primary Host Integration Server 2004 computer is available.
Unknown specific access (bit 2)	Manage Domain access. This access applies when someone starts or attempts to start the Host Integration Server 2004 SNA Manager.

Firewall Support Overview

Host Integration Server 2004 client computers and servers can interoperate with screening routers, where the client computer knows the address of the Host Integration Server 2004 computer. Host Integration Server 2004 client computers and servers can also interoperate with full-blown Internet firewalls, where the end user is not allowed to know the IP address of the Host Integration Server 2004 computers.

A firewall is a network security device that restricts access to network resources by allowing traffic only through specified port numbers. These port numbers are commonly defined in software components to allow Internet firewalls to filter packets based on port number, thereby denying or accepting their propagation to the private network. In many instances, the services of a firewall are provided in conjunction with a network router that bridges two network segments together.

Host Integration Server 2004 can be configured to use specific software port numbers, allowing administrators of Internet firewalls to filter packets based on port number. By assigning specific destination port numbers to Host Integration Server 2004 components, Host Integration Server 2004 can inter-operate with screening routers and full-blown firewalls.

If the Host Integration Server 2004 address is known, the client workstation configures the appropriate port and destination IP of the Host Integration Server 2004 computer in the client software, e.g. 1477 and 128.124.1.2. Alternatively, the Host Integration Server 2004 computer's service port numbers can be changed to the port number requested by the client.

You can configure destination port numbers in Host Integration Server 2004 for end-user and Administrator clients using TCP/IP, IPX/SPX.

Each network transport has the following three components for which you can assign destination ports.

DatagramPort
This port is used for datagram (mostly broadcast or multicast) traffic. Use the **Server Broadcasts** dialog box in the Host Integration Server 2004 SNA Manager to control which transport is used for server-to-server communication.

SnaBasePort
This is the port to which the server SnaBase listens for new client sponsor connections. Sponsor connections are used by the Host Integration Server 2004 client to learn about the SNA subdomain in which it participates.

SnaServerPort
This is the port where the SNASERVR.EXE waits for new application session requests.

If the Host Integration Server 2004 address is not known, the Host Integration Server 2004 IP transport replaces the real destination IP address with the address of a firewall. The firewall then maps the connection request to the actual Host Integration Server 2004 computer. This takes place when the transport opens a connection to a Host Integration Server 2004-based computer for application sessions or a sponsor connection.

Host Integration Server 2004 supports firewalls primarily on TCP/IP networks. It may also be possible to implement firewalls on IPX/SPX. For more information on configuring a firewall, consult your network documentation.

> **Note** The clients obtain the Host Integration Server 2004 ports through the sponsor connection. On IPX/SPX, the clients get the SnaBase ports from the NetWare bindery and VINES StreetTalk, respectively. There is no need to configure any port numbers on these two client network types.

It is also possible to create IP mappings which, by overriding service table entries, replace a specified IP address with a firewall address. To create a mapping, add an IPMapping key under the SnaTcp key, and then add a REG_SZ value for each mapping. An example is shown below:

```
IPMapping
xxx.xxx.x.xxx = yyy.yy.yy.yyy
```

With this mapping, any attempts at establishing a connection with xxx.xxx.x.xxx will instead connect to yyy.yy.yy.yyy.

For additional information on firewall support, including client-side registry settings and the use of DLS with firewalls, see the following Knowledge Base articles: Q139508, Q164590, Q224303, and Q215838.

Understanding Windows Security

Data Encryption

Data Encryption secures traffic between the client computer and Host Integration Server 2004 on a per-user basis. There is a client component and a server component. The data encryption is implemented transparently to any application that is written to the Host Integration Server 2004 APIs (application program interfaces). Any software, such as a third-party emulator, that is written to use the Host Integration Server 2004 client APIs will automatically benefit from the encryption.

Host Integration Server 2004 lets you encrypt data for client-to-server and server-to-server communications.

Client-to-server encryption prevents information from being sent in clear text between Host Integration Server 2004 client workstations and Host Integration Server 2004 computers. Data encryption enhances network security on the client-to-server communications path for all applications using Host Integration Server 2004 client connections, including 3270/5250 emulators and APPC logon IDs and passwords. Data encryption is enabled by default.

Server-to-server encryption can be used to provide secure communications across your network, the Internet, or any other wide area network. If a user enables data encryption, information transferred through Distributed Link Service (DLS) is automatically secure.

Data encryption is also supported in the distributed deployment of SNA Open Gateway Architecture (SOGA), which uses Host Integration Server 2004 to provide secure server-to-server communications across the Internet, intranets, and other WANs.

Host Integration Server 2004 lets you encrypt data for client-to-server and server-to-server communications.

Client-to-server encryption prevents information from being sent in clear text between Host Integration Server 2004 client workstations and Host Integration Server 2004 computers. Data encryption enhances network security on the client-to-server communications path for all applications using Host Integration Server 2004 client connections, including 3270/5250 emulators and APPC logon IDs and passwords. You can enable data encryption on a user-by-user basis using the Host Integration Server 2004 SNA Manager.

Server-to-server encryption can be used to provide secure communications across your network, the Internet, or any other wide area network. If a user enables data encryption, information transferred through the Distributed Link Service (DLS) is automatically secure.

Data encryption is enabled for Distributed Link Service by adding the domain user account under which Host Integration Server 2004 services such as SnaBase or SnaServer are running to the SNA subdomain. The actual encryption is implemented in the transport provider's layer of the Host Integration Server 2004 architecture. You can then enable data encryption settings for the user account, as described above.

Maximizing Product Security

In addition to the general guidelines elsewhere in this section, the following specific recommendations can help you increase the security of your Host Integration Server 2004 deployment. Since all of these actions are performed during deployment or configuration, procedures are located in the appropriate sections of this documentation.

> **Note** While these recommendations apply across the entire product, the Transaction Integrator Threat Mitigation section also offers information specifically for TI users.

The most effective action you can take is to utilize integrated security by using the Host Integration Server 2004 Single Sign-on (SSO) feature. It is especially important to use SSO because certain data used by the product is impossible or unwise to encrypt, making it potentially vulnerable. The SSO feature reduces or eliminates this vulnerability.

When accessing a SQL Server database:

- Since the Resync service will access this database -- and the database may service multiple, unsecured domains -- you should always use a local SQL Server database and never grant remote access to it.
- Use only Windows NT integrated security, and restrict access to only privileged Windows NT accounts.
- Use only Host Integration Server 2004 security groups which were created with the Host Integration Server 2004 Configuration Wizard.

When connecting via SNA Protocol:

- When connecting to an upstream Host Integration Server 2004 computer, use client/server encryption.
- When implementing SNA Open Gateway Architecture (SOGA) Distributed Link Service (DLS) across wide area networks, use server-to-server encryption.
- Locate upstream Host Integration Server 2004 computers within the data center using secure Token Ring, Ethernet, Bus and Tag Channel, or ESCON fiber channel attachments.

When connecting via TCP/IP protocol:

- Use upstream Windows software router computers or hardware routers to encrypt the TCP/IP traffic.
- Locate the upstream router within the data center using either secure Token Ring or Ethernet connections to the host.
- Since DRDA AR sometimes stores data in plain text:
- Use direct network connections over a private segment, with static IP or SNA addresses.
- Use IPSec where supported for IP communications between host and Windows servers.
- When connecting an SNA LU6.2 network to a mainframe or AS/400, with the Host Integration Server 2004 computer deployed as the SNA gateway to the a downstream Host Integration Server 2004 computer, use Host Integration Server 2004 server-to-server data encryption.
- For SNA LU6.2 network connections to mainframe, use the IP-DLC Link Service in conjunction with IPSec.
- Use encryption that is part of the Host Integration Server 2004 server-to-server and client-to-server connections.
- When connecting to a mainframe DB2 for z/OS, use IPSec on an IP-DLC, and also use NNS on the target system to utilize direct connections to DLUS and APPN Peer resources.
- When accessing DB2 DUW over the IP Resync Service:
- Increase the level of security access rights to the SQL Server database which stores the UOWID mapping tables.
- Use the (default) separate SQL Server database, as opposed to one shared with other applications.
- To protect unencrypted data and credentials in the com.cfg file:
- Implement IPSec.
- Deploy the Host Integration Server 2004 computer in an isolated network segment.
- Increase security settings on the host account used for session security.
- When using the TN3270 Server
- Stop and restart the TN3270 Server whenever a new CRL is downloaded. Otherwise, you will be using an out of date CRL, which could permit unwanted access to the host.

The following actions will increase server-to-host security, especially on an APPN Network or UDP sockets for HPR/IP Protocol Traffic:

- Deploy Host Integration Server 2004 in a secure network segment, and use encryption that is part of the Host Integration Server 2004 server-to-server and client-to-server connections.

- Use IPSec on the IP-DLC connection.
- Use NNS on the target system to utilize direct connections to DLUS and APPN Peer resources.
- Use a direct IP-DLC Connection to CS/390 (DLUS) and NNS, or a direct IP-DLC Connection to a peer APPN node.

Finally, as in the following recommendations, be vigilant about access to every file, connection, or other product component:

- In general, use System or User DSN's rather than file DSN's, as System and User DSN's are more secure.
- When using the OLE DB Provider for AS/400 and VSAM, store your HCD files in a secure local folder or share that can only be accessed by the developer and the runtime application.
- When using Transaction Integrator, place any objects going to CICS or IMS in a remote environment that requires Enterprise Single Sign-On.
- Be vigilant about your access control list (ACL). Although it is possible to install Host Integration Server 2004 and "inherit" a previous ACL, you should remove any existing ACLs and replace them with new ones.
- Store Printer Definition Tables (PDTs) and Printer Definition Files (PDFs) in a secure location to prevent their being replaced with a rogue file.
- Since trace files may contain non-encrypted data, always store them in a secure location, and delete them as soon as trace analysis is complete.
- Minimize unwanted access to the Resync Service by running it on the same computer as the application it services.
- Enable LUA Security for TN3270 access to the host, and then add the service account to the Configured Users folder. Among other things, this provides encryption if the TN3270 service uses LUs on another server.
- Enable LUA Security for TN5250 access to the host. This increases security by requiring explicit assignment of LUs to user records.
- When using the printing feature associated with the TN3270 Server, reconfigure the display and printer to use the same port. This is necessary because, since these two items are configured separately, they are often inadvertently configured to different ports, and subsequently different security settings.
- Always use IPSec when using the TN3270 or TN5250 Servers. Although data may be safe between the client and server without IPSec, that same data may become vulnerable between the server and the host. Using IPSec reduces the attack surface, ensures data encryption, and makes access available only to authorized users.

Securing Your Environment

Understanding Windows Security

Resource Security

This section describes accessing Host Integration Server 2004 resources, including Display LUs, Printer LUs, and LU pools.

This section contains:

- 3270 Terminal Access
- 5250 Terminal Access and APPC Access
- Securing the TN3270 and TN5250 Services

3270 Terminal Access

Users or groups who require access to 3270 sessions from workstations using Host Integration Server 2004 client applications must be members of the SNA subdomain. Therefore, they are also members of the Windows domain of which the subdomain is a part.

Once enrolled in the SNA subdomain, you can assign specific 3270 (LU type 2) resources to the appropriate accounts. The users can access only the specific resources you allocate to them.

The preferred method for maintaining security in your environment is by using domain security to authenticate users, and then limiting their access by assigning them only specified resources.

See Also

Resource Security

5250 Terminal Access and APPC Access

Users who want Advanced Program-to-Program Communications (APPC) access need not be defined in the SNA subdomain, but they must be members of a Windows domain.

For 5250 terminal access using a Host Integration Server 2004 client computer within the network, the AS/400 supplies the required security for logon to the AS/400.

For APPC access programmed into specific applications, you maintain security through the actual programmatic conversation, if required.

See Also

Resource Security

Securing the TN3270 and TN5250 Services

You can secure TN3270 and TN5250 services by specifying client workstation IP addresses that have permission to use the resources provided. In the case of TN3270E clients, you can specify a workstation name in place of the client IP address.

The method employed for verifying workstations can also be used to allow only specified IPs to request resources allocated to them.

See Also

Resource Security

Transaction Integrator Security

Security affects TI in two ways. First, TI components can be assigned security attributes in the same way as other COM+ components. This requires no TI development. Second, the TI run-time environment needs to deal with the security mechanisms of the remote environment (RE). TI provides two security options with an optional override for each:

- Package-level (also known as application-level)
- User-level
- Optional explicit-level override

When configured for user-level credentials, TI makes use of the APPC Privileged Proxy feature for single sign on. This requires that the user context that the APPC application (TI, in this case) is running under be a member of the **HSDomain_Proxy** group. (The **HSDomain_Proxy** group is one of the two groups created when the host security domain is created.) By default, the **HSDomain_Proxy** group contains the **Domain Admins** group. If TI is not running under the context of a user in the **Domain Admins** group, you will need to add the user to the **HSDomain_Proxy** group.

When deploying a TI component, the administrator must choose either package-level security or user-level security as the default. The optional explicit-level security override is a separate option that the administrator can enable or disable; the override applies regardless of which security option (package-level or user-level) is in place. If the explicit-level override is disabled, base applications will not be permitted to use the callback to provide user credentials. The administrator can also turn on the optional Already Verified settings.

This section contains:

- Application-Level Security
- User-Level Security
- Single Sign-On in Transaction Integrator

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Application-Level Security

When using application-level (or package-level) security, the TI run-time environment uses the single sign-on support in Host Integration Server 2004 to authenticate itself to the host by using the Windows® 2000 security identity of the COM+ application. The COM+ application containing the TI component must be configured in COM+ to run under a Windows account that maps to valid mainframe credentials.

When a TI component is deployed in a COM+ Application which itself is configured as a Library application or package (instead of a Server application or package) on the **Activation** tab of its property page, the choice of security level (Package-level or User-level) for a TI remote environment (RE) is ignored. A Library application (or package) runs in the Windows user credentials of the process that invoked it, and TI attempts to map this name to a corresponding host user ID.

Although the TI security level is ignored in Library COM+ applications, both of the following security options on the RE property page are accepted by both Library and Server COM+ applications:

- Allow application to override selected authentication
- Use Already Verified or Persistent Verification authentication

The Library application deployment model is supported by COM+. It offers better performance than the Server application deployment model in certain situations. TI supports both models. For example, Internet Information Services (IIS) documentation recommends that COM+ Automation servers that will be invoked from an active server page (ASP) be deployed in a COM+ Library application rather than a COM+ Server application. This way, IIS can control the level of multitasking on a system and kick off new Windows processes to support very high hit rates. By deploying in a Library Application, each IIS process gets its own set of TI components. Also, as a developer debugging a new application, you might prefer to debug a Library COM+ application instead of a Server COM+ application because the Library application simplifies debugging. All the breakpoints come up in one Windows process, and you can more easily see the flow of control.

To set the security level

1. Start TI Manager, and double-click **COM Transaction Integrator** for the computer.
2. Double-click **Remote Environments**.
3. Right-click the specific remote environment (RE) that you want to set, and then click the **Security** tab.
4. Select the **Set security on** check box.
5. Click **Authenticate with package credentials**, or click **Authenticate with User credentials**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

User-Level Security

If user-level security is enabled, the TI run-time environment provides the client identity to the single sign-on support of Host Integration Server 2004 before allocating the LU 6.2 conversation or connecting to the remote TCP/IP end point. This allows TI to use the client's identity (the identity of the client that invoked the COM+ component that resulted in the invocation of the TI component) to map to a mainframe credential by using the Host Integration Server 2004 single sign-on capability to authenticate itself with the mainframe.

When a TI component is deployed in a COM+ Application which itself is configured as a Library application or package (instead of a Server application or package) on the **Activation** tab of its property page, the choice of security level (Package-level or User-level) for a TI remote environment (RE) is ignored. A Library application (or package) runs in the Windows user credentials of the process that invoked it, and TI attempts to map this name to a corresponding host user ID.

Although the TI security level is ignored in Library COM+ applications, both of the following security options on the RE property page are accepted by both Library and Server COM+ applications:

- Allow application to override selected authentication
- Use Already Verified or Persistent Verification authentication

The Library application deployment model is supported by COM+. It offers better performance than the Server application deployment model in certain situations. TI supports both models. For example, Internet Information Services (IIS) documentation recommends that COM+ Automation servers that will be invoked from an active server page (ASP) be deployed in a COM+ Library application rather than a COM+ Server application. This way, IIS can control the level of multitasking on a system and kick off new Windows processes to support very high hit rates. By deploying in a Library Application, each IIS process gets its own set of TI components. Also, as a developer debugging a new application, you might prefer to debug a Library COM+ application instead of a Server COM+ application because the Library application simplifies debugging. All the breakpoints come up in one Windows process, and you can more easily see the flow of control.

Transaction Integrator Security

Single Sign-On in Transaction Integrator

Single sign-on (SSO) is a mechanism that enables a user to enter a user name and password once to access multiple applications. It provides users with simplified logon and maintenance of the many passwords needed to access Windows and back end systems and/or applications. It enables applications to integrate by automating the process of logging on to the host/backend system.

In general, there are three types of single sign-on services:

- **Common authentication single sign-on:** These services enable you to connect to multiple applications within your computer. Your credentials are requested and verified once when you log into the computer, and these credentials are used to determine what actions you can perform based on your permissions. An example of this type of single sign-on is Exchange Server, which uses Windows Integrated Security. Once the user has logged on to Windows, they do not need to provide additional credentials to access their email.
- **Internet single sign-on:** These services enable you to access resources over the internet by using a single set of user credentials. The user provides a set of credentials to log on to different websites that belong to different organizations. An example of this type of single sign-on is Microsoft® .NET Passport.
- **Intranet single sign-on:** These services enable you to connect to multiple heterogeneous applications and systems within the enterprise environment in your company. An example of this type of single sign-on is Enterprise Single Sign-On, which provides a framework for Windows applications to integrate with non-Windows applications to enable single sign-on.

SSO facilitates the translation of credentials by the Security Policy Wizard. SSO provides the means to define and manage the relationship between foreign host user ID and password credentials to Windows credentials. The basis for managing these relationships is the SSO Affiliated Application.

An Affiliated Application is a grouping of well defined host user identities under a logical entity that reflects the host administrator’s view of application processing systems in the non-Windows environments.

When SSO is handed a set of host credentials (user ID and password) along with a valid SSO Affiliated Application, SSO returns a Windows Access Token that represents the Windows credentials. HIP uses this Access Token when setting up the execution thread for methods on server object.

To facilitate this process, the Security Policy must know which SSO Affiliated Applications are to be queried in an attempt to gain access to the Windows credentials (access token) needed to execute methods on the server object. The wizard pane allows the user to select from a list of valid SSO Affiliated Applications and add them to the Security Policy being defined. The wizard pane also allows the user to remove SSO Affiliated Applications previously defined to the Security Policy.

About Programming Single Sign-On

Special Security Settings for TCP/IP

Two special security settings are available for the TCP/IP protocol for CICS and IMS:

- Link and Concurrent Server

  Mainframe authentication for the TCP/IP CICS MS Link and Concurrent server must have a user exit, EZACIC06, coded on the mainframe to validate the user ID and password supplied by TI. The user ID and password are part of the CICS transaction request message that is formatted by TI and used to initiate the TCP/IP server application in CICS. Refer to the IBM TCP/IP and CICS documentation for further detail.

- For TCP/IP IMS Explicit, IMS Implicit, and IMS Connect or OTMA

  Mainframe authentication for TCP/IP IMS Explicit, IMS Implicit, and IMS Connect or OTMA must have a user exit, IMSLSECX, coded on the mainframe to validate the user ID and password supplied by TI. The user ID and password are part of the IMS transaction request message that is formatted by TI and used to initiate the TCP/IP server application in IMS. Refer to the IBM TCP/IP and IMS documentation for further detail.

See Also

Transaction Integrator Security

Mainframe Authentication for CICS LINK

Resource-level authentication is recommended in the CICS region. Due to a restriction imposed by the IBM Distributed Program Link (DPL) protocol, a user ID and password transmitted from the workstation by TI are ignored and not used for transaction-level authentication. The target CICS region expects, under the circumstances, that authentication has been completed by the application that executes the IBM DPL; for example, a TI application on the PC. (Traditionally, the application that executes an IBM DPL has been another CICS region.) Instead, for transaction-level authentication, the target CICS region associates the default user ID for the region with the transaction ID of the CICS (mirror transaction) task and the user ID from the sender is ignored. Unless this is taken into consideration, attempts to secure the mirror transaction can cause an application malfunction because of the failure to authenticate.

Transaction Integrator Security

AS/400 Security

The support for AS/400 security is the same as for other Windows-initiated operations against the mainframe, with the following adjustments:

- No support for RACF, AFC/2, Kerberos, or Top Secret.
- Integrate with AS/400 native security system only.
- Support Single Sign-On via SSO.

Transaction Integrator Security

Limitations of User Access Level Sign On

When you sign on with only user access permissions, you have restricted capabilities for using Transaction Integrator. For TI Manager, user access:

- Allows you to view COM+ applications
- Does not allow you to open TI Manager
- Does not allow you to export a COM+ application.

For TI Designer, user access:

- Allows you to open TI Designer
- Allows you to create and save new type libraries
- Allows you to open and save existing type libraries.

Transaction Integrator Security

Transaction Integrator Threat Mitigation

Product security is a top priority across Microsoft. Beginning with the Windows Security Push in 2002, Microsoft has invested additional time and resources to developing secure code and detailed instructions for deploying and securing your computing environment. The increased attention to security issues has made Host Integration Server 2004 the most secure version in the history of the product. The Host Integration Server 2004 product team conducted a complete threat modeling analyses to identify and mitigate potential areas of concern. A threat model is a security-based analysis that helps you determine the highest-level security risks posed to a product or application and how attacks can manifest themselves.

Although Microsoft has mitigated all possible internal security threats to Host Integration Server 2004 , there are steps you should take to mitigate threats from elsewhere in your network environment. Threat modeling helps you evaluate the threats to the applications you are writing or running, and thereby reduce the overall risk to your computer system. For more information on threat model analysis, see Chapter 4 “Threat Modeling” in Michael Howard and David LeBlanc, *Writing Secure Code 2nd Edition*, Redmond, WA: Microsoft Press. 2003.

Howard and LeBlanc summarize six categories of possible security threats to your computing environment:

- **Spoofing identity**. Spoofing threats allow an attacker to pose as another user or allow a rogue server to pose as a valid server. An example of user identity spoofing is illegally accessing and then using another user’s authentication information, such as username and password.
- **Tampering with data**. Data tampering involves malicious modification of data. Examples include unauthorized changes made to persistent data, such as that held in a database, and the alteration of data as it flows between two computers over an open network, such as the Internet.
- **Repudiation**. Repudiation threats are associated with users who deny performing an action without other parties having any way to prove otherwise—for example, a user performing an illegal operation in a system that lacks the ability to trace the prohibited operations.
- **Information disclosure**. Information disclosure threats involve the exposure of information to individuals who are not supposed to have access to it—for example, a user’s ability to read a file that she was not granted access to and an intruder’s ability to read data in transit between two computers.
- **Denial of service**. Denial of service (DoS) attacks deny service to valid users— for example, by making a Web server temporarily unavailable or unusable. You must protect against certain types of DoS threats simply to improve system availability and reliability.
- **Elevation of privileges**. In this type of threat, an unprivileged user gains privileged access and thereby has sufficient access to compromise or destroy the entire system. Elevation of privilege threats include those situations in which an attacker has effectively penetrated all system defenses and become part of the trusted system itself, a dangerous situation indeed.

Howard and LeBlanc also point out that some threat types can interrelate. For example, it is possible for information disclosure threats to lead to spoofing threats if the user’s credentials are not secured. Similarly, elevation of privilege threats are by far the worst because if someone can become an administrator or root on the target computer, every other threat category becomes a reality. Conversely, spoofing threats might lead to a situation where escalation is no longer needed for an attacker to achieve his goal.

To mitigate threats that originate outside Transaction Integrator but which can negatively affect TI components and your application, Microsoft recommends that you:

- Protect the MSHIS60_HIP Database and SQL Server Stored Procedures
- Protect the TI DCGen COM+ Application and TCP/IP Listeners
- Protect the COM+ and .NET Servers
- Protect the Raw User Data
- Protect the HIP Listener
- Protect the Local File System, Database, and Registry
- Protect the Client Proxy
- Protect the Remoting Session
- Protect TI from Unauthorized Mainframe or AS/400 Access
- Protect the TI Runtime Environment
- Protect Mainframe Security Credentials from Being Overridden
- Protect the TI Runtime and Host Environments from Data Overflows

Protect the MSHIS60_HIP Database and SQL Server Stored Procedures

To prevent an attacker from spoofing their identity or tampering with the data or stored procedures in the HIP database, you should:

- Run the HIP Service in a valid Windows privileged account and use Windows integrated security to access the HIP SQL Server database.
- Allow only privileged accounts access to the HIP SQL Server database.
- Use a local SQL Server database and do not allow remote access.
- Use only Windows integrated security and restrict access to only privileged Windows accounts.

You can also help mitigate this threat with the following deployment scenarios:

- Service-based Security
- Host-initiated single sign-on (SSO).

You can learn more about this threat by reading about:

- How to secure remote access to SQL Server (for example, integrated Windows security).

Protect the TI DCGen COM+ Application and TCP/IP Listeners

To prevent an attacker from spoofing their identity, tampering with the data on the host, elevating their privileges, or denying service, you should:

- Use ASP.NET Admin to set the level of user or role-based security for Application Directory
- Tighten COM+ Application Security on the TI DCGen package
- Use TI Manager to set the security level for a remote environment
- Move the TI Designer-generated .dll to the remoting client computer.

You can also help mitigate this threat with the following deployment scenario:

- ASP.NET web client

You can learn more about this threat by reading about:

- ASP.NET application and IIS security
- Multiple levels of authorized users.

New Security Policy Wizard

Protect the COM+ and .NET Servers

To prevent an attacker from spoofing their identity, tampering with the data on the host, elevating their privileges, accessing restricted data, or denying service, you should:

- Use bounded recordsets
- Use static IP addresses on the host
- Run server components in-process with a HIP Service account.

You can also help mitigate this threat with the following deployment scenario:

- Send properly-formatted messages (for example, ELM, TRM, DPL, SNA, IP)
- Service-based security

See Also

Bounded Recordsets

Windows Service Configurations Screen

Protect the Raw User Data

To prevent an attacker from reading data packets on the network and either tampering with the data or disclosing the data, or to prevent an attacker from denying service, you should:

- Place the computer running Transaction Integrator (TI) and the host in a secure location.
- Use direct network connections over a private segment
- Use IPSec, where supported, for IP communications between host and Windows servers
- For SNA LU6.2 network connections to mainframe or AS/400 computers, use Host Integration Server 2004 server-to-server data encryption when deploying upstream an Host Integration Server 2004 computer as a SNA gateway to a downstream TI HIP computer
- For SNA LU6.2 network connections to mainframe, use Host Integration Server 2004 IP-DLC Link Service in conjunction with IPSec.

See Also

Configuring an IP-DLC Link Service

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Protect the HIP Listener

To prevent an attacker from spoofing their identity, tampering with the data, or denying service, you should run the HIP services in valid Windows privileged account.

1. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.
2. In the details pane, right-click **HIPService**, and then click **Properties**.
3. Click **This account**, and then specify a valid Windows privileged account.
4. Type the password for the user account in **Password** and in **Confirm password**, and then click **OK**. If you select the **Network Service** account, the password must be blank.

You can also help mitigate this threat with the following deployment scenario:

- Service-based security

See Also

Services Account Screen

Protect the Local File System, Database, and Registry

To prevent an attacker from spoofing their identity, accessing restricted data, or tampering with the data, you should:

- Place the computer running Transaction Integrator (TI) in a secure location.
- Confirm that the access permissions to TI programs, TI components, and the registry are set correctly.
- Use host-initiated single sign-on (SSO) in conjunction with valid host UID and PWD passed in the initial connection flows. You should not run the COM Server program in context of the default COM+ security context. Using both UID and PWD causes the HIP application to validate both items when calling SSO.
- Not use DCOM to remote calls from HIP Application server to a second Windows Server hosting COM+ server application.
- Use secure network connection (for example, CICS TRM over IPSec-protected TCP/IP network connection).

You can also help mitigate this threat with the following deployment scenarios:

- Service-based security
- Host-initiated SSO

You can learn more about this threat by reading about:

- How to secure remote access to SQL Server (for example, integrated Windows security)
- How to send a valid host user ID
- How to send a valid host password

Protect the Client Proxy

To prevent an attacker from tampering with a properly formatted message (for example, a TRM, DPL, SNA, or IP) sent by the client computer to the TI runtime or to prevent an attacker from sending a malformed message to the TI runtime, you should:

- Move the .NET assembly DLL generated by TI Designer to the remote client computer.

You can learn more about this threat by reading about:

- .NET remoting
- ASP .NET web clients.

See Also

Transaction Integrator Threat Mitigation

Protect the Remoting Session

To prevent an attacker from tampering with the remote session or denying service, you should:

- Use HTTPS between the remoting client and the server
- Use separate ASP.NET application contexts for various levels of privileged users, thereby preventing lower-privileged users from affecting sessions belonging to higher-privileged users.

You can also help mitigate this threat with the following deployment scenarios:

- ASP.NET web client.

You can learn more about this threat by reading about:

- Multiple levels of authorized users
- ASP.NET application and IIS security
- Properly-formatted TRM, DPL, SNA, IP, and other messages
- Valid host user ID and password
- Valid Windows user ID for single sign-on (SSO).

See Also

Transaction Integrator Threat Mitigation

Protect TI from Unauthorized Mainframe or AS/400 Access

To prevent an attacker from using the mainframe or AS/400 connection to access the server running Transaction Integrator, you should:

- Utilize direct network connections over private segment.
- Use IPSec, where supported, for IP communications between the host and Windows servers.
- For SNA LU6.2 network connections to mainframe or AS/400 computers, use Host Integration Server 2004 server-to-server data encryption when deploying upstream Host Integration Server 2004 computer as SNA gateway to downstream TI HIP computer.
- For SNA LU6.2 network connections to mainframe, use Host Integration Server 2004 IP-DLC Link Service in conjunction with IPSec.

See Also

Introduction to the IP-DLC Link Service

Secure Deployment of the IP-DLC Link Service

Protect the TI Runtime Environment

To prevent an attacker from instantiating multiple Transaction Integrator (TI) components to launch a denial of service attack on the TI runtime environment, you should:

- Store all TI component type libraries and .NET assemblies in a secure directory.
- Confirm that the access permissions on all type libraries and .NET assemblies are set correctly.
- Confirm that the access permissions on the directory where the type libraries and .NET assemblies are stored are set correctly.

See Also

Transaction Integrator Threat Mitigation

Protect Mainframe Security Credentials from Being Overridden

To prevent an attacker from gaining control over security credentials used to access a mainframe host, you should:

- Use host-initiated single sign-on (SSO) in conjunction with valid host UID and PWD passed in the initial connection flows.
- Set the ClientContext to not allow security credentials to be overridden when using the **SelectionHint** property.

See Also

Use REOverride to Specify RE Programmatically

Protect the TI Runtime and Host Environments from Data Overflows

To prevent an attacker from using inbound, unbounded recordsets to launch a denial of service attack on either the Transaction Integrator (TI) runtime or host environment, you should:

- Store all TI component type libraries and .NET assemblies in a secure directory.
- Confirm that the access permissions on all type libraries and .NET assemblies are set correctly.
- Confirm that the access permissions on the directory where the type libraries and .NET assemblies are stored are set correctly.

- IP-DLC Link Service

SNA Open Gateway Architecture

Organizations with IBM mainframe or AS/400 computers are now consolidating their SNA-only and non-SNA networks into single TCP/IP-based wide area networks (WANs). In the past, two parallel networking systems have been deployed in most organizations: the traditional SNA network used to connect computers and hardware controllers with IBM mainframes and AS/400 computers, and local area networks (LANs) used primarily to access files and client/server applications running on local server computers.

Many organizations are seeking a single WAN solution that provides access to all desktops, servers, and host systems across a single networking protocol. At the same time, TCP/IP is emerging as the protocol of choice because of its versatility, openness, and ability to support Internet and intranet connections.

Many organizations cannot integrate their networks because of the need to ensure reliable and secure access to their existing IBM host systems—on which most organizations base their mission-critical daily operations.

SNA Open Gateway Architecture (SOGA) satisfies the requirement for reliable and secure host connectivity in the context of an integrated WAN. SOGA is a scalable framework for SNA enterprise connectivity, offering multiple options for integrating branch offices by means of routed inter-networks with IBM mainframe and AS/400 computers. This framework encompasses components from leading channel attachment and inter-networking vendors while deploying Host Integration Server 2004 computers in both traditional and innovative ways.

SOGA supports industry standards for SNA host access and presents flexible options for integrating host data across open WANs, such as those composed of Data Link Switching (DLSw), Frame Relay (RFC 1490), and Asynchronous Transfer Mode (ATM). Request for Comment (RFC) 1490 specifies methods of encapsulating TCP/IP and SNA within Frame Relay. The SOGA blueprint consists of three core elements:

- Flexible SNA gateway deployment models
- High-performance SNA gateway configurations
- Efficient wide area network utilization

Deploying Host Integration Server 2004

Deploying Host Integration Server 2004

Whether your enterprise consists of a single office or many branches spread throughout the world, SNA Open Gateway Architecture (SOGA) offers three flexible deployment models to implement Host Integration Server 2004 in your environment.

When planning your deployment strategy, ask the following questions:

- With what type of host systems do I need to connect?
- What kind of performance and host availability do my users expect?
- What kind of networking infrastructure is in place?

By answering these questions and using the information provided in this section, you can determine the best deployment strategy for your enterprise.

Connecting Servers

This section contains:

- About Connection Methods
- Choosing Server-to-Host Connections
- Choosing Network Protocols for Host Integration Server 2004
- Installing Host Integration Server 2004 Clients

After you have determined a suitable deployment model and subdomain configuration, you must choose how to connect Host Integration Server 2004 computers to the host system, to client workstations, and to other Host Integration Server 2004 computers.

This section explores how to choose:

- Connections between Host Integration Server 2004 computers and the host
- Network protocols for Host Integration Server 2004 computers and clients

To understand the connectivity options, you should first examine the different physical connections and network protocols that Host Integration Server 2004 supports.

See Also

- IP-DLC Link Service

About Connection Methods

This section contains:

- IP-DLC Link Service
- 802.2 Data Link Control (DLC)
- Synchronous Data Link Control (SDLC)
- Channel

Host Integration Server 2004 supports many different connection methods. However, not all may be available in your environment. When you choose a connection method, you should keep in mind:

- Deployment model you are implementing
- Host networking infrastructure that is in place
- Host systems to which you are connecting
- Expected usage level of host resources
- Level of performance and response expected by your users

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

802.2 Data Link Control (DLC)

Token Ring, Ethernet, and Fiber Distributed Data Interconnect (FDDI) connections use the IEEE 802.2 DLC protocol to connect to the host. In a mainframe environment, Host Integration Server 2004 usually connects to a front-end processor (FEP) or a communications controller, such as an IBM 3174. Occasionally, you can establish a connection to an adapter within a mainframe. With an AS/400 system, the connection goes directly to a network adapter in the AS/400 computer.

Token Ring connections are typically limited to 4 or 16 megabits per second (Mbps). Token Ring solutions are still found in some mainframe environments. In many scenarios, a Token Ring connection provides good performance at a reasonable cost in equipment.

Ethernet is a common connection type for local area networks (LANs) with workstations or computers. This connection type is also common in peer-type networks.

FDDI connections use fiber cabling to achieve connections reaching 100 Mbps or greater. The FDDI line communicates through an FEP that is channel-attached to the mainframe. This may limit the overall speed of communications. In many cases, this type of connection can provide a reasonably cost-effective solution if you require higher throughput and a channel solution is not possible.

DLC connections are well suited for the centralized and distributed deployment models, because both strategies implement Host Integration Server 2004 computers close to the host. You can also deploy data link control (DLC) in a branch model using routers or bridges that can route traffic between the branch offices and the central host system.

Host Integration Server 2004 supports DLC connections over any network adapter supported by Windows using the Windows-based DLC network transport driver.

About Connection Methods

Synchronous Data Link Control (SDLC)

Channel

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Synchronous Data Link Control (SDLC)

SDLC connections use a standard phone line (leased, public, point-to-point, or multidrop). An SDLC adapter within the Host Integration Server 2004 computer connects to a modem that uses the phone line to establish a connection with the host system. In a mainframe system, the SDLC connection uses a front end processor (FEP), a communications controller, or an integrated SDLC adapter. In an AS/400 system, the connection goes directly into the AS/400 computer.

SDLC throughput is limited by the medium used for the connection and the capabilities of the SDLC adapter in the Host Integration Server 2004 computer. The cost to implement SDLC grows significantly as faster line types are used. In general, SDLC connections are much slower than 802.2 connections. The following table lists the common line types and their speeds:

Line type	**Typical speed**
Analog (conventional phone line)	9600 to 19200 bits per second (BPS)
Digital Data System (DDS)	56 to 64 kilobits per second (Kbps)
Integrated Services Digital Network (ISDN)	56 to 128 Kbps
T1 carrier system	1.544 megabits per second (Mbps)
T3 carrier system	2.048 Mbps

SDLC connections are useful for wide-area connections between geographically disparate locations or when bandwidth and usage requirements are low. Because of these factors, SDLC is ideally suited for branch-type deployment strategies.

Host Integration Server 2004 supports SDLC connections using the link support included with Host Integration Server 2004 or through an SDLC link service available through various third-party vendors. Not all supported SDLC adapters support all link speeds listed in the previous table.

About Connection Methods

802.2 Data Link Control (DLC)

Channel

Channel

Channel connections provide direct channel attachment to a mainframe. There are two types of channel connections: older Bus & Tag channel connections, which can reach speeds of up to 4.5 megabytes per second (MBps), and newer ESCON connections, which can reach speeds approaching 17 MBps. Support for channel connections is limited to adapters supported natively through Host Integration Server 2004.

Enterprise System Connection (ESCON) channel attachments use standard fiber cable and increase throughput significantly.

ESCON is an ideal connection method in centralized or distributed deployments where high performance and responsiveness are required.

The following table summarizes all common connection methods that can be used with Host Integration Server 2004.

Method	Throughput	Characteristics
Token Ring	4 or 16 MBps	Midrange performance using data link control (DLC) protocol Supports multiple host connections using a single adapter Uncomplicated and inexpensive to implement Suitable for a wide range of purposes
Ethernet	10 GBps	Midrange performance using DLC protocol Supports multiple host connections using a single adapter Uncomplicated and inexpensive to implement Suitable for light to medium network traffic conditions
FDDI	100 MBps	High performance using DLC protocol Supports multiple host connections using a single adapter Relatively expensive to implement Suitable for higher-performance connections
SDLC	9600–19200 bits per second (BPS)	Low performance using SDLC protocol Supports 256 sessions over a single host connection Uncomplicated and inexpensive to implement Suitable for low-traffic WAN connections
Channel: Bus & Tag	4.5 MBps	High performance Supports a high number of host connections. More expensive Suitable for high-performance connections
Channel: ESCON	17 MBps	Highest performance Supports a high number of host connections More expensive Suitable for conditions where maximum throughput is required

Choosing Server-to-Host Connections

This section contains:

- Mainframe Connection Summary
- AS/400 Connection Summary

In Host Integration Server 2004 terms, a host connection is the data communications path between Host Integration Server 2004 and a host system. For a mainframe, the connection corresponds to a physical unit (PU) definition in Virtual Telecommunications Access Method (VTAM). On the AS/400 computer, the connection corresponds to an Advanced Program-to-Program Communications (APPC) controller definition.

For each physical adapter or connection, you install and configure an appropriate link service within Host Integration Server 2004. A link service is a Windows-based service or device driver that is used to control server-to-host communication adapters supported by Host Integration Server 2004. Once configured, the link service is available for use not only on the configured Host Integration Server 2004 computer, but also on any server in the subdomain using the Distributed Link Service (DLC) feature. See Distributed Link Service for more information.

After you configure the link services, you can configure the connections. Using a host connection, a client computer on a LAN can communicate with the mainframe system. For some link services, it is possible to define multiple connections over a single host link.

In SNA terms, a physical unit (PU) is the combination of a physical connection and the link service it uses. In an SNA network, Host Integration Server 2004 provides PU 2 or PU 2.1 functionality similar to that of an IBM cluster controller.

Several factors should be taken into account when determining a physical connection method to your mainframe:

- Performance requirements
- Expected server loads
- Existing network infrastructure
- Chosen Host Integration Server 2004 deployment model
- Cost

You should plan for enough future capacity to support additional connections to your host system. Ethernet connections are the best choice for an all-purpose connection to a host.

For some link services, multiple host connections are possible using a single adapter, most notably the IP-DLC link service. Host Integration Server 2004 supports up to 250 host connections per server. Up to four instances of Host Integration Server 2004 are supported on a single computer.

Mainframe Connection Summary

The hierarchical SNA network model provides access to a centralized processing resource from elements on the network. This model is most frequently associated with mainframe environments in which centralized applications are accessed from remote terminals across a network.

Devices in a hierarchical SNA network, such as terminals or cluster controllers, are called physical units (PUs). A number designates each class of device. For example, the mainframe is known as a PU 5 device.

Applications

Host Integration Server 2004 can directly connect to the mainframe if a high-performance connection is required. These physical connection methods are available:

- Open Systems Adapter, supporting Token Ring, Ethernet, and Fiber Distributed Data Interconnect (FDDI) connections
- Bus & Tag channel connection
- Enterprise System Connection (ESCON) channel connection

Connections to a front-end processor (FEP), which is a PU 4 device, are also supported. These types of connections may be easier to implement depending on your existing infrastructure and the physical proximity of the Host Integration Server 2004 to the mainframe. For an FEP, you can use one of the following connection methods:

- Token Ring
- Ethernet
- FDDI
- SDLC

In a hierarchical SNA network, Host Integration Server 2004 emulates a cluster controller and supports all standard protocols:

- LU 2, for 3270 terminal sessions
- LU 1 or 3, for SCS or 3270 printer sessions
- LU 6.2, for Advanced Program-to-Program Communications (APPC) and Common Programming Interface for Communications (CPI-C) applications
- LU 0, 1, 2, or 3, for logical unit application (LUA) RUI/RI general-purpose, customized applications

Any combination of these protocols can be used over a given physical connection.

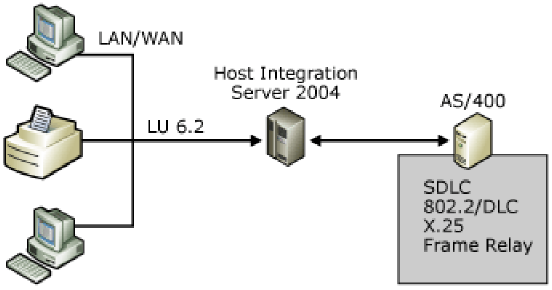
AS/400 Connection Summary

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

AS/400 Connection Summary

In the peer-oriented SNA network model, all computers on the network can communicate directly with each other. Advanced Peer-to-Peer Networking (APPN) is the architecture developed by IBM that enables distributed data processing. APPN defines how components communicate with each other, and the level of network-related services, like routing sessions, that are supplied by each computer in the network.



In an APPN network, Host Integration Server 2004 emulates a type 2.1 physical unit device (PU 2.1). Host Integration Server 2004 computers can connect to an AS/400 computer using several connection methods:

- Token Ring
- Ethernet
- FDDI
- SDLC

Frame relay or bridging solutions can also be implemented to transport SNA traffic over wide area network (WAN) connections in branch-based deployment models. Host Integration Server 2004 operates as an APPN low-entry networking (LEN) node and communicates with other APPN nodes using the Advanced Program-to-Program Communications (APPC) or LU 6.2 protocol.

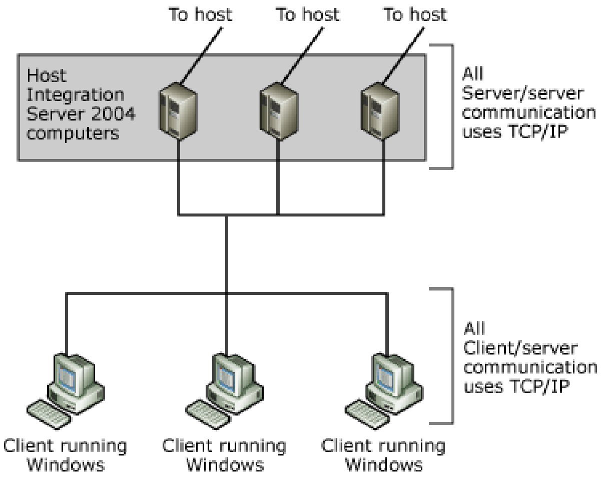
Choosing Network Protocols for Host Integration Server 2004

This section contains:

- Choosing Client/Server Network Protocols
- Choosing Server/Server Network Protocols

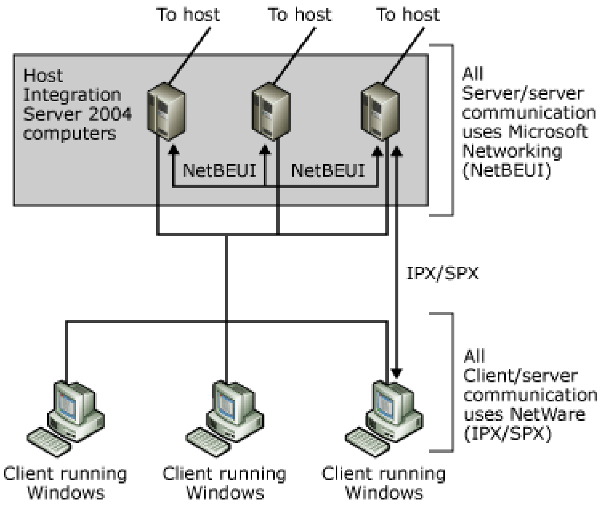
After you determine the server-to-host connection, you must choose the protocols to use for two additional Host Integration Server 2004 communication paths: client/server communication and server/server communication. You can use one protocol for both, or you can use a combination of different protocols, if all servers share at least one client/server protocol and use it for server/server communication.

Deploying a single protocol across your wide area network (WAN) is the easiest way to manage your communications. The following figure shows a network in which TCP/IP is used for all types of communication involving Host Integration Server 2004 computers and clients.



To host
To host
To host
Host Integration Server 2004 computers
All Server/server communication uses TCP/IP
All Client/server communication uses TCP/IP
Client running Windows
Client running Windows
Client running Windows

You may decide to gradually implement Host Integration Server 2004 throughout your enterprise, in which case you may need to use existing protocols for certain connections. The following figure shows a local area network (LAN) in which two protocols are used. For server/server communication, Microsoft Networking (Named Pipes) is used. For client/server communication, IPX/SPX is used.



To host
To host
To host
Host Integration Server 2004 computers
NetBEUI
NetBEUI
All Server/server communication uses Microsoft Networking (NetBEUI)
IPX/SPX
All Client/server communication uses NetWare (IPX/SPX)
Client running Windows
Client running Windows
Client running Windows

Similarly, other combinations of protocols can be used, if all the Host Integration Server 2004 computers share one protocol and use that protocol for server/server and client/server communication.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Choosing Client/Server Network Protocols

Host Integration Server 2004 client computers can communicate through a number of different local area APIs or network transports: Microsoft Networking (Named Pipes), IPX/SPX (sockets), or TCP/IP (sockets). The network software and the Host Integration Server 2004 software must be installed correctly on both clients and servers for them to handle different protocols correctly. Correct installation ensures two essential aspects of communication:

- Host Integration Server 2004 computers and client computers are visible to each other on the LAN. This results when the network software is installed correctly on all affected computers.
- Host Integration Server 2004 computers communicate with clients over the correct LAN protocol. Clients direct their communication to the correct subdomain name or (for some clients using Microsoft Networking (Named Pipes) or TCP/IP) to one or more correct server names.

TCP/IP is the standard network protocol for client/server applications. Its high performance and routing ability make it suitable for many wide area network (WAN) environments. In many cases, TCP/IP will be the best protocol choice for your network, especially if TCP/IP is already deployed to some degree in the LAN segment on which the Host Integration Server 2004 computers and clients reside.

Choosing Server/Server Network Protocols

Installing Host Integration Server 2004 Clients

Choosing Server/Server Network Protocols

Host Integration Server 2004 computers communicate with each other using mailslot messages or directed datagrams over a network. Host Integration Server 2004 allows you to make choices concerning these broadcasts.

You can select among the following protocols for server broadcasts: Microsoft Networking (Named Pipes), Novell NetWare (IPX/SPX), and TCP/IP.

> **Important** You must make sure that at least one protocol is available on all Host Integration Server 2004 computers in the subdomain, and that this protocol is used for server/server communication and client/server communication.
>
> For example, if all Host Integration Server 2004 computers in a subdomain use TCP/IP, but only some use IPX/SPX, the protocol used for server/server communication must be TCP/IP, and all servers must use TCP/IP for client/server communication as well.

Using multiple server/server transport protocols can add significantly to network overhead. This is because every server broadcast must be sent out through all protocols selected in the Host Integration Server 2004 management console.

For highest efficiency, select only one protocol for broadcasts between Host Integration Server 2004 computers. Remember that the protocol must be available on all Host Integration Server 2004 computers in the subdomain. Where multiple choices are available (multiple protocols are bound to the network adapters on all Host Integration Server 2004 computers), select a protocol other than Microsoft Networking (Named Pipes). This is recommended because of design requirements for mailslot broadcasts. When these broadcasts are sent over Microsoft Networking (Named Pipes), there is the local system cannot determine which protocol the receiving system will be using, so the broadcast is sent over all protocols bound to the local adapter. This causes multiple mailslot broadcasts by means of Microsoft Networking (Named Pipes) for adapters to which several protocols are bound. The multiple broadcasts cause an increase in network traffic.

In subdomains in which all Host Integration Server 2004 adapters can use multiple protocols, selecting one (and only one) of the following protocols is recommended: IPX/SPX or TCP/IP. You may be able to select extra protocols that do not exist in your network. However, selecting these has no effect.

The Host Integration Server 2004 management console also allows you to specify a parameter called Mean Time Between Server Broadcasts. For optimum efficiency, you should specify a value greater than or equal to 60 seconds (the default). The smaller this value, the less the efficiency, but the more likely the broadcasts will compensate for lost messages. It is recommended that you choose a value of 120 seconds or greater initially. If you encounter an increased number of lost messages, this value should be reduced until a low number of messages are lost.

Choosing Client/Server Network Protocols

Installing Host Integration Server 2004 Clients

Installing Host Integration Server 2004 Clients

Host Integration Server 2004 client software allows client workstations to communicate with Host Integration Server 2004 computers to access host resources. Client software is installed on each workstation using applications that communicate using any Host Integration Server 2004 programmatic interfaces. Client software is available for the following platforms:

- Microsoft® Windows Server™ 2003
- Windows® 2000 Server

The fastest Host Integration Server 2004 client/server network interface is TCP/IP, although you can use other local area network (LAN) protocols such as Microsoft Networking (Named Pipes) if your LAN supports them. If you select TCP/IP or Microsoft Network, the remote installation option is recommended. Selecting "local" requires the client workstation to be on the same TCP/IP subnet as the Host Integration Server 2004 computer, which is uncommon in routed IP networks.

> **Note** Host Integration Server 2004 client software is not required to use services such as TN3270 and TN5250. Applications, such a TN3270 emulator, communicate directly with these services using TCP/IP and do not use the Host Integration Server 2004 client/server interface.

Host Integration Server 2004 3270 Connectivity

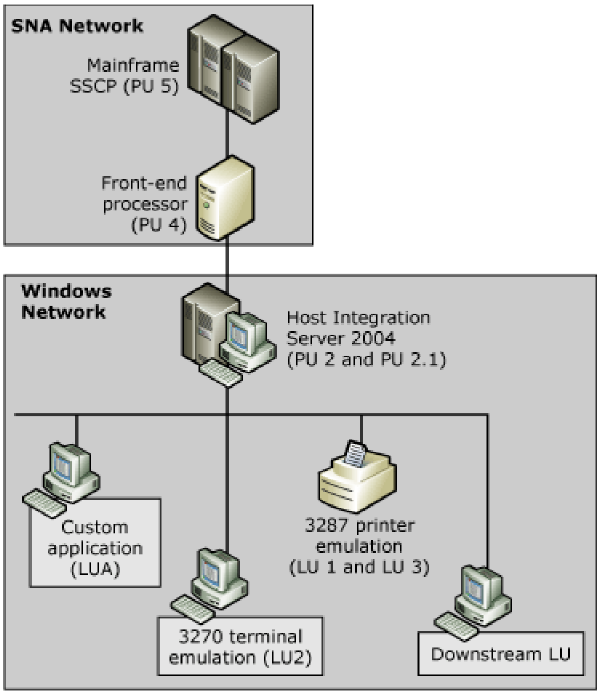
In the hierarchical SNA network model most frequently associated with a mainframe computer, you access centralized applications from remote terminals across a network. This network model uses the information display protocol for IBM mainframe computers known as 3270. This protocol facilitates conversations between the mainframe and devices such as terminals, printers, and controllers. Through the definition and assignment of 3270 logical units (LUs), Host Integration Server 2004 provides access to mainframe resources.

A 3270 LU is known as a dependent LU because it requires a mainframe to function. Each 3270 LU defined within Host Integration Server 2004 is configured to use an existing connection to the mainframe system. Each 3270 LU corresponds to a matching LU resource allocated on the host computer, usually specified within Virtual Telecommunications Access Method (VTAM). The 3270 LU definition in Host Integration Server 2004 is identified by a number that matches the number of the corresponding LU resource on the mainframe, and by a user specified name.

The 3270 LU is further classified by the type of service provided over the connection. Like physical units (PUs), numbers designate LU types. For example, 3270 display data streams are known as LU 2 streams. Within Host Integration Server 2004, a 3270 LU can be configured as one of the following types:

- Display (LU 2)
- Printer (LU 1 or LU 3)
- Application (LUA)
- Downstream

After the LUs are configured, they are accessed from client computers and applications using Host Integration Server 2004 client software that is installed on the client workstation. The client software manages communications between a 3270 application (like a terminal emulator) and the Host Integration Server 2004 computer. Applications designed for the Host Integration Server 2004 client API use the LUs defined within Host Integration Server 2004 to establish a communications link from the client workstation to the mainframe by means of Host Integration Server 2004.



SNA Network
Mainframe SSCP (PU 5)
Front-end processor (PU 4)
Windows Network
Host Integration Server 2004 (PU 2 and PU 2.1)
Custom application (LUA)
3287 printer emulation (LU 1 and LU 3)
3270 terminal emulation (LU2)
Downstream LU

The link between the LU definition in Host Integration Server 2004 and the host LU resource is called a session. Sessions can be permanent and automatically started during initialization, or established on an as-needed basis. Concurrent sessions can share the same physical devices and communications links.

A 3270 user communicating with a host uses a 3270 LU. The 3270 LU has a specific name (recognized by the host), is associated with a specific connection, and supports a specific use (either printing, or terminal emulation of a particular size). A collection of 3270 LUs that will be used by a group of users can be placed in an LU pool, so that whenever a user needs an LU, the next one in the pool will be made available. The connection, the 3270 LU, the 3270 LU pool, and the list of users (or groups) are the basic elements to configure when supporting 3270 users in a Host Integration Server 2004 installation.

LUA Access

Precedence of Accounts in Determining LU Access

Downstream Connections

LUA Access

Logical unit application (LUA) is an application programming interface (API) that allows you to write customized applications to communicate with the host. LUA LUs enable programmable control over the SNA messages that are sent between the communications software and the host. LUA LUs can be used to communicate with LU types 0, 1, 2, or 3 at the host as long as the application sends the appropriate SNA messages required by the host.

An LUA application uses a local LU, which uses Host Integration Server 2004 to communicate with the host system. When Host Integration Server 2004 connects to the host, there are three progressive sessions:

1. The PU-SSCP between the Host Integration Server 2004 physical unit (PU) and the system services control point (SSCP) on the host.
2. The SSCP-LU session between the LUA LU at the computer running the application and the SSCP.
3. The LU-LU session between the LUA LU at the computer running the application and the host LU.

The LU session's normal flow carries most of the data. The other flows are used only for control purposes.

The Host Integration Server 2004 configuration file contains information that is required for LUA applications to communicate. An LUA LU is configured to use a connection to the host by the link service that is installed. It is then given the LU number that matches that of an LU on the host.

The configuration may include LUA LU pools. A pool is a group of LUs with similar characteristics, and it allows an application to use any free LU from the pool. This feature can be used for allocating LUs on a first-come, first-served basis when there are more applications than LUs available, or for providing a choice of LUs on different connections, as well as providing hot backup and load balancing. For more information see Providing Hot Backup and Load Balancing.

The communications components to be configured include:

- A link service for communicating with the host.
- A connection to the host that uses the link service.
- A Host Integration Server 2004 service which owns the connection. This component is configured automatically.
- An LUA LU on a Host Integration Server 2004 service, configured to use the connections, with an LU number that matches an LU on the host.

You can perform the following actions with LUA LUs:

- Assign an LUA LU, or a range of LUA LUs, to a connection. A range of LUA LUs will allow multiple applications to use LUAs simultaneously. Configure the numbering for a new range of LUA LUs by specifying the lowest LU number and the number of LUs in the range.

  After creating a range of LUs, you can change the numbering of individual LUs in the range.

- Configure properties for a new LUA LU or a new range of LUA LUs. This includes specifying the LU name and LU number for the LUs.
- Group LUA LUs into one or more LUA LU pools. An LUA LU pool contains a number of LUs that are made available as a group to LUA applications. A given application can get LU access as long as one of the pooled LUs is available.
- View or modify an existing LUA LU, regardless of whether it was created as part of a range.
- Copy properties from one LU to another.
- Move an LU from one connection to another.
- Delete an LU.
- Move an LUA LU from one connection to another.

Check with the host administrator to determine the appropriate names and numbers for LUA LUs on your system. The LU Number for LUs on 802.2 or Synchronous Data Link Control (SDLC) connections should match the LOCADDR= parameter of the LU definition in VTAM or in the NCP Gen.

If the number you specify has already been assigned to an LU or an APPC LU-LU pair on the current connection, you must use a different number. The range for LU numbers is from 1 through 254.

The LU Name cannot be the same as any other LU name or pool name (except for APPC LU names) on the server.

If the High Priority LU is assigned to a pool, the priority setting of the pool overwrites the setting of the LU.

On an 802.2 or SDLC connection, you can configure multiple LUs at one time by configuring them as a consecutively numbered range. Multiple LUA LUs will allow multiple applications to access the host simultaneously. After configuring the range of LUs, you can modify the numbering and properties of individual LUs in the range.

See Also

Precedence of Accounts in Determining LU Access

Downstream Connections

Precedence of Accounts in Determining LU Access

When user and group account memberships overlap, the highest-priority account that contains a 3270 LU or pool determines the access the user gets. Accounts are prioritized as follows:

1. User accounts (highest priority)
2. Subdomain groups
3. Local groups
4. Well-known groups such as Everyone (lowest priority)

For example, if a 3270 LU called LU 1 is assigned to a user account (a high-priority account) called JOHND, and at the same time an LU called LU 2 is assigned to a local group (a low-priority account) of which JOHND is a member, JOHND will be given access to LU 1, not LU 2.

LUA Access

Downstream Connections

Downstream Connections

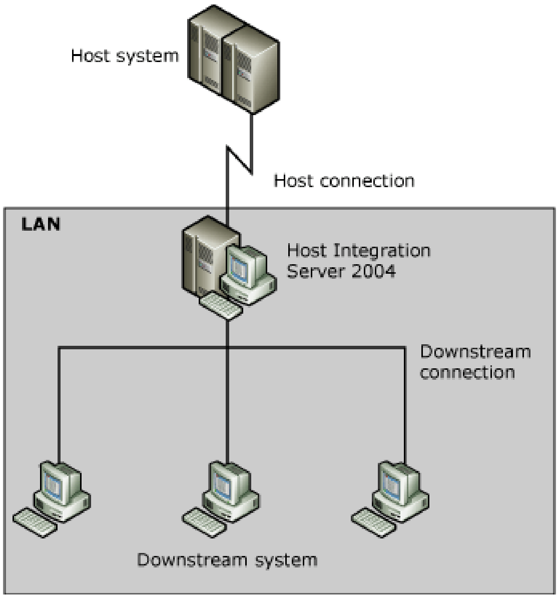
A downstream connection enables a remote computer without a direct connection to the host computer to pass information back and forth using Host Integration Server 2004 as the gateway. To the downstream system, there appears to be a direct connection to the host. Host Integration Server 2004 accomplishes this by passing information back and forth between the downstream system and the host.

Downstream connections and LUs enable Host Integration Server 2004 to support communication between 3270 nodes using SNA protocols. A downstream system is an SNA node (a Host Integration Server 2004 computer or mainframe) that uses Host Integration Server 2004 as a physical unit (PU) gateway. To the downstream system, the Host Integration Server 2004 computer appears to be the 3270 host providing the PUs and LUs. The downstream system may be unable to communicate directly with the 3270 host because of hardware or network incompatibilities that are supported by the intermediate Host Integration Server 2004 computer.

One method of reducing host configuration requirements is to concentrate PUs on the SNA gateway computer and pass the LUs to attached downstream physical units (DSPUs). LUs from one or more PUs can be shared with one or more downstream devices. This allows for more economical use of configured resources and alleviates the need to configure each downstream device in host Virtual Storage Access Method (VSAM).

Communication by means of a downstream connection and downstream LU in Host Integration Server 2004 is always dependent (controlled by a host). Independent communication, including APPC, is not available by means of downstream LUs on Host Integration Server 2004.

The following figure illustrates downstream connections.



The information that Host Integration Server 2004 passes from the downstream system to the host includes LU information. Therefore, Host Integration Server 2004 does not store detailed LU configuration information for downstream LUs. However, Host Integration Server 2004 does require all the usual connection information for the host and downstream connections.

Two connections are needed for a downstream system: a downstream connection (from the downstream system to Host Integration Server 2004) and an upstream connection, which is an ordinary host connection from Host Integration Server 2004 to the host.

You can configure the upstream connection as you would any other connection to the host. After that, you can configure the downstream connections. These must be 802.2 or SDLC.

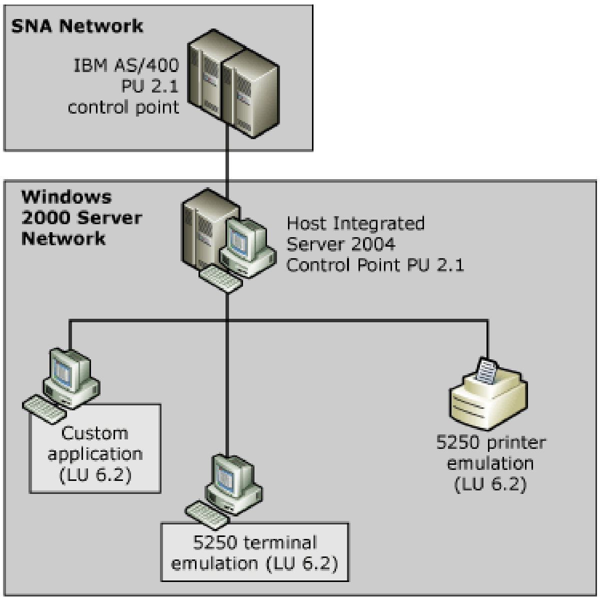
Precedence of Accounts in Determining LU Access

Host Integration Server 2004 5250 (AS/400) Connectivity

In the peer-oriented SNA network model, all computers on the network can communicate directly with each other. Advanced Peer-to-Peer Networking (APPN) enables distributed data processing, defines how components communicate with each other, and determines the level of network-related services that are supplied by each computer in the network. Although peer-oriented SNA networks are usually associated with an AS/400 host system, mainframe systems can also support peer-to-peer networking.

IBM AS/400 computers use the 52xx series of devices. In particular, 5250 describes the terminal display data stream. The Advanced Program-to-Program Communications (APPC) protocol is used to support 5250 terminals and other APPN network computers, devices, and programs to communicate with each other. Each device in an APPN network is known as a type 2.1 physical unit (PU 2.1). In addition, the APPC protocol defines associated logical units as APPC LUs (also called LU 6.2).



SNA Network
IBM AS/400
PU 2.1
control point
Windows 2000 Server Network
Host Integrated Server 2004 Control Point PU 2.1
Custom application (LU 6.2)
5250 terminal emulation (LU 6.2)
5250 printer emulation (LU 6.2)

In an APPN network, Host Integration Server 2004 computers emulate PU 2.1 devices and can connect to an AS/400 using several connection methods:

- Token Ring
- Ethernet
- Fast Ethernet
- FDDI
- SDLC

Frame relay or bridging solutions can also be implemented to transport SNA traffic over wide area network (WAN) connections in branch-based deployment models.

See Also

APPC

Connecting to an AS/400 Using 5250 Terminals

APPC

Advanced Program-to-Program Communications (APPC), or LU 6.2, provides a transport vehicle for programs on peer systems to communicate with each other over the SNA network. APPC is software that enables high-speed communications between programs on different computers.

APPC is a change from the terminal-to-host connections used in many 3270 systems. APPC moves to a distributed transaction programming environment by providing a common set of SNA protocols that brings compatibility at a program communications level.

APPC serves as translator between application programs and the network. When applications on one computer pass information to the APPC software, APPC translates the information and passes it to a network interface. APPC translates the information back into its original format and passes it to the corresponding partner application. APPC can be used across any of the standard types of connections supported by SNA and is not tied to any particular physical connection.

APPC generally uses a local APPC LU (LU 6.2) and one or more remote APPC LUs. A local APPC LU can be independent or dependent. In full peer-oriented APPN networks, typically implemented in an AS/400 environment or under the most modern evolution of mainframe technology, the independent APPC model applies. Dependent APPC is used in older mainframe networks, and its functions are reduced.

Local and remote APPC LUs work together in pairs. The local APPC LU is assigned to a server (unlike other LU types, which are assigned to connections). The remote APPC LU is assigned to the connection. Host Integration Server 2004 uses dynamic partnering to create any possible LU partnership on demand when local and remote LUs and modes recognize each other.

With dynamic APPC partnering, an administrator configures remote LUs, but does not need to partner them with local LUs. Host Integration Server 2004 will automatically partner the LUs when needed.

With dynamic APPC configuration, an administrator does not need to configure remote LUs. If a connection is designated to support dynamic APPC configuration, Host Integration Server 2004 will automatically define a remote LU and partner it with a local LU when needed.

Independent APPC provides the ability to run multiple, concurrent, parallel sessions between a single pair of LUs. Dependent APPC allows only a single session between a given pair of LUs.

Programs that use APPC are referred to as transaction programs (TPs). There are two types of TPs: those that can invoke a conversation, and those that can be invoked. A TP can provide any type of service: terminal emulation, data transfer, database query or update, and so on.

The characteristics that govern the interactions between TPs using an LU 6.2-LU 6.2 connection are determined by the mode associated with the connection. The mode can be associated in a fixed manner with a given LU, or it can be supplied by the invoking TP when a session is first initiated.

Host Integration Server 2004 5250 (AS/400) Connectivity

Connecting to an AS/400 Using 5250 Terminals

Connecting to an AS/400 Using 5250 Terminals

Host Integration Server 2004 computers provide access to AS/400 computers by emulating 5250 display terminals. A 5250 user communicating with an AS/400 must use a pair of APPC LUs (LU 6.2). This pair contains a local LU and a remote LU (as viewed by the Host Integration Server 2004 computer). Together, these two LUs (along with the mode that they use) contain the configuration information needed for establishing a session with the AS/400 computer.

A local APPC LU can be either independent or dependent. An independent local APPC LU can communicate directly with a peer system. A dependent APPC LU requires the support of a mainframe. These are described in more detail in later sections.

The 5250 user can share this pair of LUs with many other users at the same time, or the 5250 user can have exclusive possession of the LUs (depending on the Host Integration Server 2004 configuration). In addition, Host Integration Server 2004 computers can be configured so that users can start 5250 emulation sessions without knowing the names of LUs to request. This configuration is accomplished with the use of default LUs that are specified for each 5250 user or for groups of users.

Host Integration Server 2004 5250 (AS/400) Connectivity

APPC

Using Wizards

Using Wizards

You can configure 5250 terminal emulation using the wizard provided with Host Integration Server 2004. Available under the **Tools** menu, the wizard takes you through each step of configuring AS/400 connection properties, creating remote APPC LUs linked to your AS/400 computer, and, if necessary, creating local APPC LUs.

In addition to wizards, several features of Host Integration Server 2004 can simplify configuration for APPC:

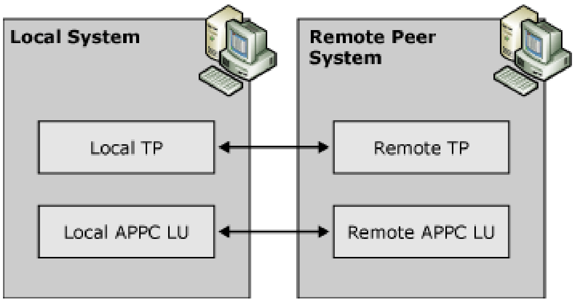
- Implicit Incoming Remote LU and Implicit Incoming Mode, which allow Host Integration Server 2004 to accept requests that arrive by unrecognized remote LUs and modes.
- Default Local APPC LU and the Default Remote APPC LU, which allow LU aliases to be associated with user or group names, simplifying the routing of incoming requests and the configuration of client systems.
- Default Outgoing Local APPC LU Pool, which allows LUs to be allocated dynamically to any invoking TP (transaction program) that does not specify a local LU.
- Single-System APPC, which allows two local APPC LUs residing on the same server to communicate with each other using defined parameters.

Independent APPC LUs

In APPC, an independent LU can communicate directly with a peer system and does not need the support of a host computer.

Independent APPC LUs provide the ability to run multiple, concurrent, parallel sessions between a single pair of LUs. Programs that use independent APPC LUs are referred to as transaction programs (TPs) and may provide any type of service: terminal emulation, data transfer, database query or update, and so on.

The following figure illustrates how an independent local APPC LU can communicate directly with a peer system.



Modes determine the interactions between TPs on an APPC-APPC connection. Modes can be assigned to an LU or supplied when the session is first established. For more information about modes, see APPC Mode Definition later in this section.

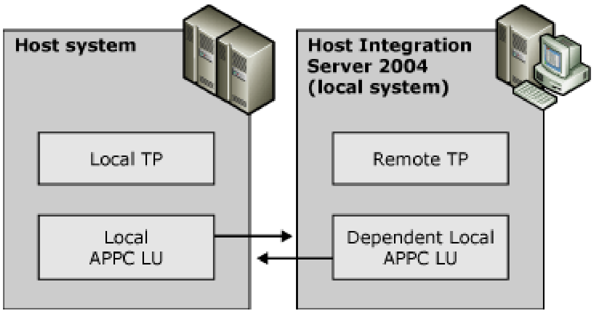
When configuring independent APPC LUs, note the following:

- If the independent local APPC LU communicates with a TP on a mainframe, the host system must be using VTAM version 3, release 2 or later with either NCP version 5, release 2 or later (3745 systems), or NCP version 4, release 3 or later (3725 systems).
- For independent LUs that communicate with a host, the LOCADDR parameter should be set to 0 in VTAM or in the NCP Gen.
- On connections used for independent APPC, the exchange identification (XID) type must be Format 3.
- The Network Name parameter is required. The default is the network name of Host Integration Server 2004.
- An LU Name parameter is required to identify local and remote APPC LUs to other components on the network. In contrast to 3270 LUs, independent APPC LUs do not need an LU number.
- If the remote APPC LU supports parallel sessions, it can only be used with a mode whose parallel session limit has a value greater than 1.

Dependent APPC LUs

A dependent local APPC LU requires the support of a mainframe to communicate with a remote TP. Dependent APPC LUs cannot be used to communicate with an AS/400 computer.

The next figure illustrates how a dependent APPC LU can communicate with the host.



Dependent local LUs have the following characteristics:

- Allow only a single session per LU.
- Use a connection configured with a Remote End of Host, not Peer.
- Only type of APPC LUs that Host Integration Server 2004 supports when communicating with a mainframe using a version of VTAM earlier than version 3, release 2.
- Require the mainframe VTAM to use a value of 1 or greater in the LOCADDR parameter in the NCP Gen.

The Network Name and LU Name are recommended but not required, because they are used only by local software such as the Microsoft® Windows® event log software. The default is the network name specified for the Host Integration Server 2004 computer. If a network name is not specified for the server, the default is APPN.

For a remote APPC LU that will be partnered with a dependent local APPC LU, the LU Name is recommended but not required. It identifies the LU to local software, such as the Windows event log software.

A number identifying the LU on its connection is required and should match the LOCADDR=parameter for the LU definition in VTAM or in the NCP Gen. Check the numbering for any non-APPC LUs on the connection that the remote APPC LU will use because this number must be unique.

The usual range for LU numbers is from 2 through 254.

A dependent APPC LU requires the support of a mainframe. During LU configuration, you need to select a host type of the connection to which the LU will be assigned. Also, the remote LU needs the same name as defined on the remote system services control point (SSCP). This name is required when using dependent APPC.

Configuring Dependent LUs

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring Dependent LUs

When you configure a dependent LU, make sure you do the following:

- Set up a single session for each dependent LU. (Only one session is allowed for each dependent LU.)
- Specify the remote end, using **Host**.
- Use VTAM 3.2 or later for host-to-APPC LU communication.

Set the host VTAM to a value of 1 or greater in the *LOCADDR*= parameter of the LU definition.

Dependent APPC LUs

APPC Mode Definition

A mode is associated with an LU-LU pair, and determines the session properties for that pair. One of the key mode properties is the Parallel Session Limit. This limit determines whether an LU-LU pair can perform only one interaction at a time or multiple concurrent interactions.

Parallel sessions are used only with independent APPC. If parallel sessions are to be allowed with an LU-LU pair, the local LU must be independent, and the remote LU in the pair must support parallel sessions.

If the LU-LU pair can have multiple parallel sessions, other mode properties, such as Minimum Contention-Winner Limit, determine to what extent each LU can initiate interactions.

The following table lists the modes provided with Host Integration Server 2004.

Mode name	To be used for
#BATCH	Batch-oriented sessions
#BATCHC	Batch-oriented sessions using compression
#BATCHSC	Batch-oriented sessions that employ a minimal level of routing security
BLANK	Sessions using a default mode name, encoded as eight blank EBCDIC spaces in BIND
#INTER	Interactive sessions
#INTERC	Interactive sessions using compression
#INTERSC	Interactive sessions that employ a minimal level of routing security
QPCSUPP	All sessions with an AS/400 computer
QSERVER	The ODBC drivers

The configuration parameters of the modes provided with Host Integration Server 2004 are shown in the following table.

Configuration parameter	#BATCH #BATCHSC and BLANK	#INTER and #INTERSC	QPCSUPP	QSERVER
Parallel Session Limit	8	8	64	8
Minimum Contention Winner Limit	4	4	32	4
Partner Contention Winner Limit	0	0	0	0
Automatic Activation Limit	0	0	0	0
High Priority Mode	No	Yes	Yes	Yes
Pacing Send Count	3	7	7	7
Pacing Receive Count	3	7	7	7
Max Send RU Size	1024	1024	1024	1024
Max Receive RU Size	1024	1024	1024	1024

The mode name and configuration parameters are used for both dependent and independent APPC LUs.

The Parallel Session Limit defines the number of sessions that can be activated. If the local APPC LU is dependent, specify 1 for the parallel session limit. Dependent local APPC LUs cannot have parallel sessions. Independent local APPC LUs can have from 1 through 1024 parallel sessions. The default is 1.

The Minimum Contention Winner Limit is the guaranteed number of sessions the local machine can initiate. The Partner Contention Winner Limit is the guaranteed number of sessions the remote machine can initiate. Each session can be established without permission from the partner LU. The sum of both must be less than or equal to the Parallel Session Limit. The range for each is from 0 through the Parallel Session Limit; the default is 0.

The Automatic Activation Limit specifies the number of Contention Winner sessions to be activated for the local LU whenever the connection for this mode is started. In a Contention Winner session, the LU can initiate conversations without permission from the partner LU. For a single-system APPC (communication between two local LUs), this field is meaningless. The range is from 0 through the Minimum Contention Winner limit.

High Priority Mode defines the priority of the data sent. This is beneficial for segregating batch data from interactive data. Batch data typically has a lower priority than interactive data.

Pacing Send Count and Pacing Receive Count allow you to specify the maximum number of frames without an SNA pacing response from either the local or remote APPC LU. For example, if you specify 0, the local APPC LU can send an unlimited number of frames without receiving a response. In this case, the remote APPC LU can negotiate and set a limit on the count. The range is from 0 through 63; the default is 4.

The request/response unit (RU) sets the size of the data message that can be sent or received. If an application needs to send a file that is larger than the specified size, it needs to break it up before sending the file. The minimum RU size on Host Integration Server 2004 is 256. The range for Max Send RU Size and Max Receive RU Size is from 256 through 16384; the default is 1024.

To add an APPC mode definition

1. In the SNA Manager tree, click **APPC Modes**.
2. On the **Action** menu, point to **New**, and click **Mode Definition**.
3. On each tab, configure the mode properties.
4. On the **Action** menu, click **Save configuration**.

Implicit Incoming Remote LU and Implicit Incoming Mode

Default Local APPC LU and the Default Remote APPC LU

Default Outgoing Local APPC LU Pool

Single-System APPC

Implicit Incoming Remote LU and Implicit Incoming Mode

An implicit incoming remote LU is a remote APPC LU that defines the properties to use when Host Integration Server 2004 receives a request to start a session with a local LU and when the remote LU named in the request is not recognized by Host Integration Server 2004.

An implicit incoming mode is a mode that defines the properties to use when Host Integration Server 2004 receives a request to start a session and the mode named in the request is not recognized by Host Integration Server 2004.

An implicit incoming remote LU requires an implicit incoming mode. An implicit incoming mode must be configured for any remote LU that will be used as an implicit incoming remote LU. An implicit incoming mode can be (but does not have to be) configured for remote LUs that will only be used explicitly.

You may want to accept incoming requests that arrive by many different remote LUs without having to explicitly define each remote LU on a Host Integration Server 2004 computer. The Implicit Incoming Remote LU and Implicit Incoming Mode allow for flexible acceptance of requests. When these two items have been configured, and an incoming request is received by Host Integration Server 2004, the remote LU need not be recognized, as long as the local LU specified in the request is recognized. In such a situation, Host Integration Server 2004 uses the properties of the Implicit Incoming Remote LU and Implicit Incoming Mode for that LU-LU session.

For a session to be established, the incoming local LU name must be recognized by Host Integration Server 2004. Then the incoming remote LU must either be recognized explicitly or handled implicitly (if an implicit incoming remote LU has been configured). If the remote LU is recognized explicitly, but the mode is not recognized (as part of an LU-LU pair), Host Integration Server 2004 internally creates a new mode definition with the correct name using the properties of the implicit incoming mode. Alternatively, if the remote LU is handled implicitly, Host Integration Server 2004 also handles the mode implicitly, by internally creating a mode, as described.

To use an implicit incoming remote LU

1. In the SNA Manager tree, expand an SNA subdomain, expand the server you want to work with, expand **SNA service**, and then expand **Local APPC LUs**.
2. Right-click the first local LU that you want to configure, and click **Properties**.
3. Click the **Advanced** tab, and specify the **Implicit Incoming Remote LU** for incoming conversations, and then click **OK** to exit.
4. Using steps 2–4, configure each local LU that the remote system will call.
5. Expand **Remote APPC LUs**, right-click the remote LU that you want to configure, and then click **Properties**.
6. Click the **Options** tab, and select the **Implicit Incoming Mode**.
7. On the **Action** menu, click **Save configuration**.

   Note All incoming requests must specify a local LU name that is recognized by Host Integration Server 2004, even when using an implicit incoming remote LU and implicit incoming mode.

APPC Mode Definition

Default Local APPC LU and the Default Remote APPC LU

Default Outgoing Local APPC LU Pool

Single-System APPC

Default Local APPC LU and the Default Remote APPC LU

If a user or group uses transaction programs, 5250 emulators, or APPC applications, you can assign a default local APPC LU and a default remote APPC LU. These default LUs are accessed when the user or group member starts an APPC program (a TP, 5250 emulator, or APPC application) and the program does not specify LU aliases.

With Host Integration Server 2004, you can assign a default local APPC LU and a default remote APPC LU to each user or group. A user or group member can then start APPC programs (TPs, 5250 emulators, or APPC applications) that do not specify LU aliases. Host Integration Server 2004 will use the default local APPC LU and the default remote APPC LU assigned to that user or group.

There are two steps before assigning default APPC LUs to a user or group:

1. The user or group must have an account on the local area network.
2. The user or group must be added to the list used by Host Integration Server 2004.

If a user is assigned LUs through one or more accounts, such as group accounts and the user's individual account, one account determines the access for that user. The account that determines this access is the account found first when searching is performed in this order:

- User accounts (highest priority)
- Domain groups
- Local groups
- Well-known groups such as Everyone (lowest priority)

For example, suppose a user account (a high-priority account) called JOHND contains LOCLU1 as the default local APPC LU, but no default remote APPC LU. At the same time, suppose a local group (a low-priority account) of which JOHND is a member contains LOCLU2 as the default local APPC LU, and REMLU2 as the default remote APPC LU. For JOHND, the high-priority assignment, the default local APPC LU of LOCLU1 will be combined with the only other available assignment, the default remote APPC LU of REMLU2.

Implicit Incoming Remote LU and Implicit Incoming Mode

Default Outgoing Local APPC LU Pool

Single-System APPC

Default Outgoing Local APPC LU Pool

With Host Integration Server 2004, you can set up a pool of local APPC LUs that will be allocated dynamically for any invoking transaction program that does not specify a local LU. This feature is designed to coexist with the default local and remote LUs for users and groups, and does not override these settings.

Both of the default APPC LU features (the default outgoing local APPC LU pool and the default local and remote LUs for users and groups) allow client computers to start a session without specifying an LU name. This helps to simplify administration by eliminating APPC configuration for client computers.

If an application begins the invoking process but does not specify a local APPC LU, Host Integration Server 2004 first tries to determine the default local APPC LU of the associated user or group (the user or group logged on at the system where the application is running). If no such LU can be substituted, Host Integration Server 2004 attempts to assign an LU from the default pool of outgoing local APPC LUs. If no LUs are available from the default pool, the attempt to begin the invoking process is rejected.

The default outgoing local APPC LU pool differs from, and should not be confused with, 3270, LUA, and downstream pools.

Default Local APPC LU and the Default Remote APPC LU

Single-System APPC

Single-System APPC

Single-system APPC has two local APPC LUs residing on the same server. The LUs communicate with each other using defined parameters. You do not need to define a connection because the LUs are communicating with each other on the same system.

For a single-system APPC, you will need to assign two local APPC LUs to a server, not to a connection. Configuration of the local APPC LUs includes specifying the LU Alias, Network Name, and LU Name. Each of these labels identifies an LU to a particular set of software components.

If Common Programming Interface for Communications (CPI-C) is used, configure one or more CPI-C symbolic destination names. For more information, see CPI-C Access in the next section.

Single-system APPC is generally used for testing transaction programs. The basic steps for configuring single-system APPC are as follows.

To configure single-system APPC

1. Assign two local APPC LUs to a server.
2. Configure the local APPC LUs by specifying the LU Alias, Network Name, and LU Name.
3. If an appropriate mode has not already been configured, configure it.

   Note For single-system APPC, the Automatic Activation Limit specified in the mode is meaningless. Use one of the local LUs for the originator conversation and the other local LU for the destination conversation.

Default Outgoing Local APPC LU Pool

CPI-C Access

Common Programming Interface for Communications (CPI-C) provides a consistent application programming interface for network applications. CPI-C is a set of C-language routines that applications distributed across an SNA network can use to communicate as peers and exchange data to accomplish a processing task.

CPI-C programming provides a mechanism, called side information, that associates a set of parameters with a specified symbolic destination name. The CPI-C program then uses the symbolic destination name to initialize a conversation.

If you are using applications based on CPI-C, you configure one or more CPI-C symbolic destination names. A CPI-C symbolic destination name is a name assigned to a set of properties for a CPI-C conversation.

LU partners will need to recognize each other. This is accomplished using fully qualified names and LU aliases. The fully qualified name is a two-part name that identifies the remote LU. The first part of the fully qualified name is the network name and the second part is the remote LU name.

You will also need a mode name. For more information about modes, see the section APPC Mode Definition earlier in this section.

Conversation-level security requires a match between the user ID and password supplied by the invoking TP, and the user ID and password stored on the server where the remote TP resides. If the ID and password do not match, the session is not activated.

Transaction Programs

The part of an application that initiates or responds to APPC communications is called a transaction program (TP). TPs use APPC to exchange data with other TPs on a peer-to-peer basis.

Similar to a conversation when people talk with each other, the communication between two transaction programs is called a conversation. An application running on your computer can have many conversations active at one time, either with one other transaction program or with different transaction programs.

There are two types of TPs: TPs that can invoke (initiate a conversation with) other TPs, and TPs that can be invoked. A TP that can invoke another TP is called an invoking TP, and a TP that can be invoked is called an invokable TP.

If your Host Integration Server 2004 installation contains multiple systems (client computers or Host Integration Server 2004 computers), you can place invokable TPs on more than one system. When an invoking request is received in such an installation, there will (potentially) be a choice of systems on which to run the invokable TP. You can maintain specific control over this choice, or you can allow the choice to be made randomly by Host Integration Server 2004 (to distribute the load).

You can maintain specific control over this choice of system by setting up invokable TPs with unique names, or by setting up each invokable TP to run only with a specific, unique LU alias. With this arrangement, the information provided by the invoking TP (in the ALLOCATE verb) can specify the particular system on which the TP should run.

You can avoid controlling this choice of system, and allow the choice to be made randomly by Host Integration Server 2004, by setting the **DloadMatchLocalFirst** registry entry to **NO**, as described in the *Host Integration Server 2004 Administrator's Reference*. Then use invokable TPs that leave the local LU alias unspecified. When an incoming request is received, it is routed randomly, rather than preferentially, to the local Host Integration Server 2004 computer. In addition, no matter what LU alias is requested for the invokable TP, there cannot be a mismatch. Host Integration Server 2004 will start the TP, choosing randomly among the available systems.

Following are three of the possible ways that TPs can be arranged to run.

This section contains:

- TP Name Unique for Each TP
- TP Name Not Unique; Local LU Alias Unique
- TP Name Not Unique; Local LU Alias Unspecified
- Invoking Transaction Programs
- Invoking TPs and Host Integration Server 2004 Configuration
- Invokable Transaction Programs
- Invokable TPs and the Host Integration Server 2004 Configuration

TP Name Unique for Each TP

If you want to specify the system on which the invokable TP will run, you can use a unique TP name for each invokable TP. In this arrangement, the invoking TP identifies the invokable TP (and system) by naming the TP. This makes it unnecessary for an invokable TP to specify any LU alias in registry or environment variables.

TP Name Not Unique; Local LU Alias Unspecified

Invoking Transaction Programs

Invoking TPs and Host Integration Server 2004 Configuration

Invokable Transaction Programs

Invokable TPs and the Host Integration Server 2004 Configuration

TP Name Not Unique; Local LU Alias Unique

Instead of using a unique TP name to specify the system on which the invokable TP will run, you can give the same name to multiple invokable TPs, but associate each TP with a unique local LU alias. Configure each invokable TP (through registry or environment variables) to use a unique local LU alias. Then set up the invoking TPs so that each one is routed not only to the correct TP name but also to the correct partner LU alias for the intended invokable TP.

TP Name Unique for Each TP

TP Name Not Unique; Local LU Alias Unspecified

Invoking Transaction Programs

Invoking TPs and Host Integration Server 2004 Configuration

Invokable Transaction Programs

Invokable TPs and the Host Integration Server 2004 Configuration

TP Name Not Unique; Local LU Alias Unspecified

If it does not matter on which system an invokable TP runs, use the same name for multiple invokable TPs, but do not specify an LU alias in the registry or environment variables for the TPs. In such a situation, there are no associated aliases in the list of available invokable TP names on a Host Integration Server 2004 computer. Thus, a request received from an invoking TP cannot cause a mismatch on the LU alias, and will match according to the TP name.

If you set the **DloadMatchLocalFirst** registry entry to **NO**, as described in the *Microsoft Host Integration Server 2004 Reference*, the server randomly routes the request to one of the available TPs. This spreads the processing load among multiple systems, and provides hot backup (so that you can take systems online and offline without disrupting service).

Invokable TPs and the Host Integration Server 2004 Configuration

Invoking Transaction Programs

An invoking TP initiates a conversation with other TPs. An invoking TP can be located on any system on the SNA network.

An invoking TP identifies itself by issuing a TP_STARTED verb. TP_STARTED specifies the name of the invoking TP, and may specify the LU alias that the TP uses (or may leave the LU alias blank).

Next, the invoking TP initiates the invoking process by issuing an ALLOCATE verb. In ALLOCATE, the invoking TP specifies the name of the invokable TP, and may also specify the partner LU alias (the LU alias to be used by the invokable TP).

TP Name Not Unique; Local LU Alias Unspecified

Invoking TPs and Host Integration Server 2004 Configuration

Invokable Transaction Programs

Invokable TPs and the Host Integration Server 2004 Configuration

Invoking TPs and Host Integration Server 2004 Configuration

For Host Integration Server 2004 to support the beginning of the invoking process (to accept the TP_STARTED and ALLOCATE verbs issued by an invoking TP), the following parameters must be configured correctly:

- If the invoking TP specifies the LU alias that it uses (in TP_STARTED), that LU alias must match a local APPC LU alias on the supporting Host Integration Server 2004 computer.
- If the invoking TP leaves the LU alias blank in TP_STARTED, one of two methods for designating a default LU must be used on the supporting Host Integration Server 2004:
  - Assign a default local APPC LU to the user or group that starts the invoking TP (the user or group logged on at the system from which TP_STARTED is issued).

    – or –

  - Designate one or more LUs as members of the default outgoing local APPC LU pool.

  If the invoking TP leaves the LU alias blank in TP_STARTED, Host Integration Server 2004 first attempts to determine the default local APPC LU of the associated user or group, and then attempts to assign an available LU from the default outgoing local APPC LU pool. If these attempts fail, Host Integration Server 2004 rejects the TP_STARTED request.

- In most situations, the supporting Host Integration Server 2004 must contain an appropriate connection to another system (host or peer). Sometimes, for testing purposes, Host Integration Server 2004 contains two local LUs paired together (for invoking and invokable TPs that are in the same domain). In this situation, a connection to a host or peer is not necessary.
- If the invoking TP specifies the partner LU alias (in ALLOCATE), that LU alias must match a remote LU alias. In addition, that remote LU alias must be paired with the local LU alias specified in TP_STARTED. If the LU alias is left blank in ALLOCATE, a default remote APPC LU must be assigned to the user who started the invoking TP. If the default remote APPC LU is used, it must be paired with the local LU that will be used. Otherwise, the ALLOCATE verb fails.

The preceding parameters support the beginning of the invoking process. For the invoking process to successfully complete, additional parameters must be configured on another Host Integration Server 2004 computer, as described in the next section.

TP Name Not Unique; Local LU Alias Unspecified

Invoking Transaction Programs

Invokable Transaction Programs

Invokable TPs and the Host Integration Server 2004 Configuration

Invokable Transaction Programs

An invokable TP is a TP that can be invoked by another TP. Invokable TPs are written or configured to supply their names to Host Integration Server 2004 as a notification that they are available for incoming requests. Host Integration Server 2004 invokable TPs can be run on any Host Integration Server 2004 computer or on a Windows Server™ 2003 or Windows 2000 client.

There are two types of invokable TPs:

- **Operator-started invokable TPs**

  An operator-started invokable TP must be started by an operator before the TP can be invoked. When the operator-started invokable TP is started, it notifies Host Integration Server 2004 of its availability by issuing a RECEIVE_ALLOCATE verb. RECEIVE_ALLOCATE provides the name of the invokable TP.

- **Autostarted invokable TPs**

  An autostarted invokable TP can be started by Host Integration Server 2004 when needed. The TP must be registered on its local system, so that it can be identified to Host Integration Server 2004. (For details about how the TP is registered, see *Microsoft Host Integration Server 2004 APPC Applications* or *Microsoft Host Integration Server 2004 CPI-C Applications*.) The registered information defines the TP as autostarted, and must specify the TP name. The registered information may also specify the local LU alias that the invokable TP will use.

  If no local LU alias is registered with autostarted TPs, the resulting Host Integration Server 2004 configuration can be more flexible in responding to invoking requests.

  After an autostarted invokable TP is started by Host Integration Server 2004, the TP issues RECEIVE_ALLOCATE (just as an operator-started TP does). RECEIVE_ALLOCATE must provide the same TP name as was registered for the TP.

Each Host Integration Server 2004 maintains a list of invokable TP names and any LU aliases associated with the TP names. When a request comes in from an invoking TP, Host Integration Server 2004 compares the requested invokable TP name and the associated LU alias to the list of available invokable TPs (which may include associated LU aliases). For details about how this comparison is carried out, see *Microsoft Host Integration Server 2004 APPC Applications* or *Microsoft Host Integration Server 2004 CPI-C Applications*.

If a match is found, Host Integration Server 2004 signals the system containing the requested TP to connect to that Host Integration Server 2004 computer.

If no match is found, Host Integration Server 2004 rejects the incoming request.

Invoking Transaction Programs

Invoking TPs and Host Integration Server 2004 Configuration

Invokable TPs and the Host Integration Server 2004 Configuration

Invokable TPs and the Host Integration Server 2004 Configuration

For Host Integration Server 2004 to receive requests from an invoking TP on another system, and then route those requests to an invokable TP, certain parameters must be configured correctly:

- Host Integration Server 2004 must have a connection to the system from which the invoking TP's request is sent.
- Host Integration Server 2004 must have a remote LU capable of receiving the incoming request. This remote LU can be configured either explicitly or implicitly.

  When configured explicitly, there is an explicit match between a remote LU alias on Host Integration Server 2004 and the alias of the LU that conveys the invoking TP's request.

  When configured implicitly, an Implicit Incoming Remote LU (with its Implicit Incoming Mode) is used. Several items must work together. First, the LU alias specified in the incoming request (the LU alias requested for the invokable TP) must match a local LU alias on the server receiving the request. Second, the local LU on the server must have an Implicit Incoming Remote LU assigned to it. The properties of the Implicit Incoming Remote LU will be used for that LU-LU session. For more details about how an Implicit Incoming Remote LU works, see Implicit Incoming Remote LU and Implicit Incoming Mode, earlier in this section.

- Appropriate local LUs must be defined in the Host Integration Server 2004 configuration file.

APPC Security

Owners of APPC transaction programs may want to allow only a limited set of users to start the program. APPC provides a mechanism, called APPC conversation security, by which the client transaction program identifies its user to the server system.

There are three levels of security for client programs: None, Same, and Program:

- If the level of security is None, the client system sends no security information (user ID or password).
- If the level of security is set to Same, APPC tries to determine a user ID for the client program. If the server system requires a password and the client system permits APPC to retrieve one for the user ID, APPC will also send the password to the server system. If no user ID is available, or if the server requires a password but the client system does not allow APPC to retrieve the password, no security information is sent to the server. This is sometimes referred to as downgraded to security NONE.
- If the security level is set to Program, the client transaction program will override any security information that the local system may provide. The client program must supply both a user ID and a password. CPI-C programs may get the user ID and password by either prompting the user to enter the information or by checking the CPI-C side information. Not all systems allow this option.

If the client program uses SECURITY=SAME or SECURITY=PROGRAM, APPC on the server must check the user ID and password regardless of the server transaction's security requirements. This requirement can cause unexpected problems and is not recommended.

To configure session security for remote LUs

1. In the SNA Manager tree, expand an SNA subdomain, expand the server you want to work with, expand **SNA service**, and then expand **Remote APPC LUs**.
2. Right-click the LU that you want to configure, and click **Properties**.
3. Click the **Options** tab. Under **Session-Level Security**, select an option.
4. Click **OK**.
5. On the **Action** menu, click **Save configuration**.
6. To put the changes into effect, you must restart the server.

   Note Setting the security for remote LU sessions is optional.

Transaction Programs

Optimizing Communications

Servers used primarily for communications need to provide fast throughput, but they do not need to provide fast file access (as a file server would). Faster throughput will result if portions of memory are set aside for communications programs (such as Host Integration Server 2004 or Microsoft® SQL Server™).

Such dedicated memory includes nonpaged memory, or portions of memory that are never swapped to disk, but remain available for immediate use at all times. If more memory is dedicated to Host Integration Server 2004 or similar programs, less memory is available for file sharing.

Windows Server 2003 or Windows 2000 Server allow you to view or change network throughput options. However, Host Integration Server 2004 installation automatically sets the option to maximize throughput for network applications.

Servers used primarily for communications run many important background processes (processes not related to user actions in the current window). These servers generally do not need to run foreground processes at maximum speed. Host Integration Server 2004 throughput can be increased by making the operating system more responsive to background processes and less responsive to foreground processes.

A server that is less responsive to foreground processes will run local applications such as word-processing software, spreadsheets, or SNA Manager more slowly. Tasking is most appropriate for servers used primarily to support client systems, and not for servers used locally as desktop computers.

To optimize background processing for a computer running Windows Server 2003 or Windows 2000 Server

1. Click **Start**, point to **Settings**, click **Control Panel**, and then double-click **System**.
2. Select the **Advanced** tab.
3. In the **Performance** box, click **Performance Options**.
4. In the **Application response** box, **select Applications or Background services**.
5. Click **OK**, and then click **OK** again.

APPC Mode

A mode is associated with an LU-LU pair, and determines the session properties for that pair. One of the key mode properties is the Parallel Session Limit. This limit determines whether an LU-LU pair can perform only one interaction at a time or multiple concurrent interactions.

Parallel sessions are used only with independent APPC. If parallel sessions are to be allowed with an LU-LU pair, the local LU must be independent, and the remote LU in the pair must support parallel sessions.

If the LU-LU pair can have multiple parallel sessions, other mode properties, such as Minimum Contention-Winner Limit, determine to what extent each LU can initiate interactions.

The following table lists the modes provided with Host Integration Server 2004.

Mode name	To be used for
#BATCH	Batch-oriented sessions
#BATCHC	Batch-oriented sessions using compression
#BATCHSC	Batch-oriented sessions that employ a minimal level of routing security
BLANK	Sessions using a default mode name, encoded as eight blank EBCDIC spaces in BIND
#INTER	Interactive sessions
#INTERC	Interactive sessions using compression
#INTERSC	Interactive sessions that employ a minimal level of routing security
QPCSUPP	All sessions with an AS/400 computer
QSERVER	ODBC drivers

Notes Section

This section contains notes about AS/400 computers, local and remote names, time-outs for 802.2 connections, and adapter and adapter addresses.

Note About AS/400 Computers

To connect to an AS/400 computer, supply both local node and remote node parameters for the Network Name and the Control Point Name. These properties are configured in separate dialog boxes:

- **Local node (server) properties.** In the **Server Properties** dialog box of the computer running Host Integration Server 2004, type the **Control Point Name** and the **Network Name**. The server Network Name must correspond to the RMTNETID parameter in the AS/400 APPC controller description. (The default for the AS/400 computer network ID is typically APPN.) If this value is set to ***SAME**, refer to the Local Network ID parameter in the AS/400 Network Attributes screen (using the **dspneta** command). The server Control Point Name must match the RMTCPNAME parameter in the AS/400 APPC controller description. For 802.2 connections, the AS/400 computer can be configured to automatically create the APPC controller description when the computer running Host Integration Server 2004 first connects to the AS/400 computer, by setting the AUTOCRTCTL parameter to ***YES** in the AS/400 Token-Ring or Ethernet line description. However, for SDLC connections, the APPC controller description must be manually created.

  If you specify a CPNAME in **Connection Properties**, it overrides the CPNAME in the **Server Properties** dialog box. The CPNAME in **Server Properties** is the default and will be used unless it is changed in **Connections Properties**.

- **Remote node (connection) properties.** In the **Properties** dialog box for an 802.2 or SDLC connection, type the **Network Name** and **Control Point Name (CP name)** of the AS/400 computer into the **Network Name (Remote Node)** and **Control Point Name (Remote Node)** fields. The AS/400 Network Name and Local Control Point Name can be found on the AS/400 Network Attributes screen using the DSPNETA. For more information about these fields, click Help on the **Properties** dialog box for the connection.

  On an AS/400 computer, the Network Name is specified in the Local network ID parameter in the Network Attributes screen and in the RMTNETID parameter on the APPC controller description. For more information, see your APPN documentation.

Using Remote Node Identifiers

You can use several types of parameters to specify the remote node with which a connection should connect:

Remote address (802.2 connections only)

This parameter is required for 802.2 connections. For outgoing calls, it is used to specify the remote host, peer, or downstream system being called. This parameter is the **Remote Network Address**.

Network Name (Remote Node) and Control Point Name (Remote Node)

As a general guideline, use these parameters if the administrator of the remote host, peer, or downstream system uses them.

These two parameters work together; if either parameter is supplied, the other should also be supplied. These parameters are used only for Format 3 exchange identifications (XIDs), one of two types of exchange identification. Format 3 XIDs are generally used for APPC. If a connection does not use Format 3 XIDs, there is no need to specify these parameters. For information about how these parameters are checked on incoming calls (as identifiers for the remote system making the call), see Identifiers in Incoming XIDs.

See Also

Note About Local and Remote Names

Remote Node ID

As a general guideline, use this parameter if the administrator of the remote host, peer, or downstream system uses it. This parameter can be used in Format 0 XIDs or Format 3 XIDs, the two types of identification exchange. **Format 0 XID**s are generally used for 3270 communication and for LUA; **Format 3 XID**s are generally used for APPC. For information about how the Remote Node ID is checked on incoming calls (as an identifier for the remote system making the call), see Identifiers in Incoming XIDs.

See Also

- Guidelines for Identifiers for 802.2 Connections

- Guidelines for Identifiers for SDLC Connections
- Identifiers in Incoming XIDs

Note About Local and Remote Names

The **Network Name** and **Control Point Name** for the remote node are different from the **Network Name** and **Control Point Name** for the local node. The remote **Network Name** and **Control Point Name** are specified in the **Connection Properties** dialog box. The local **Network Name** and **Control Point Name** are specified in the **Server Properties** dialog box.

Configuring Multidrop Connections

In a multidrop connection, one primary computer communicates simultaneously with multiple secondary computers. Host Integration Server 2004 supports multidrop connections used for downstream systems on leased SDLC lines.

You can configure up to four multidrop connections on each line, with a computer running Host Integration Server 2004 as the primary server on each.

Configure each connection to be used in the multidrop configuration according to the instructions that follow.

To configure multidrop connections

1. Configure a link service for an SDLC line with the **Constant RTS** option not selected.
2. Configure each connection to be used in the multidrop configuration as follows:
    - In the **SDLC Properties** dialog box, select the same link service for each connection.
    - In the **SDLC Properties** dialog box, under **Remote End**, select **Downstream**.
    - Make all the parameters identical for each configuration, except for **Poll Address**, and possibly the **Local Node ID** and **Remote Node ID**. For these parameters, obtain values from the downstream system administrators. Make the **Poll Address** unique for each station.
3. For the primary connection in the multidrop configuration, on the SDLC page of the **SDLC Properties** dialog box, select the **Multidrop Primary** box.

For information about using the configuration dialog boxes, click **Help** in the **SDLC Properties** dialog box.

Note About Time-outs for 802.2

The time-outs for 802.2 (**t1**, **t2**, and **ti**) are derived from basic timer values that are set in the Windows registry. Host Integration Server 2004 is designed with the assumption that these registry values will not be changed after they have been set by the DLC (802.2) driver. If these registry values are changed, the choices displayed in the **Response Timeout**, **Receive ACK Timeout**, or **Inactivity Timeout** fields may no longer reflect the actual amounts of time that Host Integration Server 2004 waits.

Simplified Facility Data Example

The following simplified example shows how identifiers allow each facility request to be distinguished from the ones that follow:

40AAAA20BB

The example contains two requests. The first request begins with a 4, indicating that after the two-character identifier there are four characters (in this case, four occurrences of the A character). The second request follows, beginning with a 2, indicating that after the two-character identifier there are two characters (two occurrences of the B character).

Standard Facility Data Example

The facility data string in this example initiates a connection using 256-byte packets, a sending window of 7, a receive window of 4, and charges reversed. The facility requests that do this are as follows:

- 42 08 08 for Packet Size
- 43 04 07 for Window Size
- 01 01 for reverse charging

When these requests are concatenated, the following facility data string is created:

4208084304070101

Common Identifier Table

The following table shows commonly used identifiers for facility requests.

Facility	Identifier	Parameters	Meaning
Reverse charging	01	00 01	Reverse charging NOT requested Reverse charging requested
Packet Size	42	0r0s	r = Receive Packet Size s = Send Packet Size
			r and s can have the following values:
			6 for 64-byte packets 7 for 128-byte packets 8 for 256-byte packets 9 for 512-byte packets A for 1024-byte packets
Window Size	43	0r0s	r = Receive Window Size s = Send Window Size r and s can be from 1 through 7. They are usually set equal, making the send and receive windows the same size.

In this table, send and receive operate from the view of the initiator of the connection.

Note About Local Adapter Address

When communicating with the administrator of a remote host, peer, or downstream system, you may need to tell that administrator the address of your local adapter.

To determine the local address of an 802.2 adapter, at the command prompt, type:

net config server

In the resulting display, the address of the local adapter appears in the line labeled **Server is Active On**.

Primary Configuration Server

The primary configuration server is the Host Integration Server 2004 computer designated to contain the domain-wide configuration file. The configuration file reflects the Host Integration Server 2004 resources for the SNA subdomain, including all Host Integration Server 2004 computers, link services, LUs, 3270 users, and so on. There can be only one primary server in the subdomain.

Backup Configuration Server

The backup configuration server is a Host Integration Server 2004 computer on which the configuration file is replicated by Host Integration Server 2004. There can be more than one backup server in an SNA subdomain. Host Integration Server 2004 will load the copy of the configuration file located on a backup Host Integration Server 2004 computer if the primary Host Integration Server 2004 computer goes down. In this case, servers and connections can be started and stopped, but the configuration cannot be changed or saved.

Identifiers in Incoming XIDs

When deciding which type of remote node identifier to specify for a connection that accepts incoming calls, it may be helpful to understand how Host Integration Server 2004 uses exchange identifications (XIDs) from incoming calls.

When Host Integration Server 2004 receives an XID from an incoming call, it looks at the XID for some type of identifier of the remote system that made the call. It compares this identifier, in the order shown in the following list, against identifiers stored in the Host Integration Server 2004 configuration. If it finds a match, it accepts the call. If it finds that identifiers are left unspecified (in the configuration or the XID), and the connection is an SDLC connection, Host Integration Server 2004 accepts the call, pending further exchange of information. In other cases—when every comparison yields a mismatch, or when identifiers are left unspecified but the connection is 802.2—Host Integration Server 2004 rejects the incoming call.

Identifiers are compared in the following order:

1. If the incoming XID is Format 3, Host Integration Server 2004 examines the XID for a remote node Network Name and Control Point Name. If these parameters are present in both the Incoming XID and in the Host Integration Server 2004 configuration, and they match, the call is accepted. If the parameters are present and do not match, the call is rejected.
2. If the parameters were not available for the preceding step, Remote Node IDs are examined next. (Remote Node IDs may be used in either Format 0 or Format 3 XIDs.) If a Remote Node ID is present in both the Incoming XID and in the Host Integration Server 2004 configuration, and they match, the call is accepted. If the parameters are present and do not match, the call is rejected.
3. If the parameters were not available for the preceding steps, for 802.2 connections, remote addresses are examined:

   For 802.2 connections, the Remote Network Address in the Host Integration Server 2004 configuration is compared to the address from which the XID was received. If the addresses match, the call is accepted; if not, the call is rejected.

4. For 802.2 connections, if no match is found in any of the preceding steps, the incoming call is rejected.

   For SDLC connections, if no match is found in the preceding steps, but identifiers were left unspecified in the configuration or the XID, the call is accepted, pending further exchange of identifiers. However, if identifiers were not left unspecified and no identifiers match, the call is rejected.

Guidelines for Identifiers for 802.2 Connections

The following table lists guidelines for identifiers for 802.2 connections.

Conn. type	Allowed call directions	Guidelines for identifiers for remote node
802.2	Outgoing	Use Remote Network Address
802.2	Incoming	Match the identifiers used on the remote system: Remote node Network Name and Control Point Name or Remote Node ID or Remote Network Address
802.2	Both	Use a combination of outgoing plus incoming identifiers

Guidelines for Identifiers for SDLC Connections

The following table lists guidelines for identifiers for SDLC connections.

Conn. type	Allowed call directions	Guidelines for identifiers for remote node
SDLC	Outgoing	If Host Integration Server 2004 supplies the phone number to the modem, specify Dial Data (phone number of remote system)
SDLC	Incoming	Match the identifiers used on the remote system: Remote node Network Name and Control Point Name or Remote Node ID
SDLC	Both	Use a combination of outgoing plus incoming identifiers

Installation and Configuration

This section provides instructions for installing and configuring Microsoft® Host Integration Server 2004. This includes how to test and verify connections with the mainframe or AS/400 computer.

This section contains:

- Installation
- Making and Testing a Connection
- Configuring Your Enterprise

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Installation

This document contains information about the basic installation process for Host Integration Server 2004.

It is important to read the entire document before beginning installation, as it contains hardware and software requirements, correct installation procedures, and other information necessary for successful installation.

It is also important to read the Readme.htm before beginning installation. The Readme.htm is located on your product CD, and contains late-breaking information and known issues you should understand before installation.

This section contains:

- Hardware and Software Requirements
- New Security Model
- Installing the Product

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Hardware and Software Requirements

In the following sections, the version numbers listed are minimum requirements. Versions later than those listed here are supported unless otherwise noted.

Hardware prerequisites

The minimum hardware requirements for a complete installation of Host Integration Server 2004 are:

- 450 megahertz (MHz) or higher Intel Pentium-compatible CPU
- 512 megabytes (MB) of RAM
- 6-gigabyte (GB) hard disk
- CD-ROM or DVD-ROM drive
- Super VGA monitor (800 x 600) or higher resolution monitor with 256 color
- For TI Designer only: Display Super VGA (1024x768) or higher resolution with 256 colors
- Microsoft Mouse or compatible pointing device

Software prerequisites

Typical Installation

In order to install Host Integration Server 2004 you must be running one of the following operating systems:

- Windows 2000 Service Pack 4 or later, along with Update for Microsoft Windows 2000 KB821887 hotfix, which you can download from the following location:

  http://go.microsoft.com/fwlink/?LinkId=29480

- Windows XP Professional with Service Pack 1 or later
- Windows Server 2003

Custom Installation

If you choose to install only selected features of Host Integration Server 2004, the tables below outline which software prerequisites you will need.

Server Installation

Feature	Requirement	Location
Data Access Tool	.NET Framework v. 1.1	http://go.microsoft.com/fwlink/?LinkId=22828
Managed Provider for DB2	.NET Framework v. 1.1	http://go.microsoft.com/fwlink/?LinkId=22828
Transaction Integrator	.NET Framework v. 1.1	http://go.microsoft.com/fwlink/?LinkId=22828
TI Designer	.NET Framework v. 1.1 Visual Studio .NET 2003	http://go.microsoft.com/fwlink/?LinkId=22828 http://go.microsoft.com/fwlink/?LinkId=22837
TI Runtime	ASP.NET (only required when using TI WIP .NET components)	http://go.microsoft.com/fwlink/?LinkId=30968
TI Manager	ASP.NET (only required when using TI WIP .NET components)	http://go.microsoft.com/fwlink/?LinkId=30968
MSMQ-MQSeries Bridge	MSMQ with routing support	http://go.microsoft.com/fwlink/?LinkId=30969
Enterprise Single Sign-On	SQL Server 2000 with Service Pack 3a	http://go.microsoft.com/fwlink/?LinkId=22838 http://go.microsoft.com/fwlink/?LinkId=22839

Client Installation

Feature	Requirement	

Data Access Tool	.NET Framework v. 1.1	http://go.microsoft.com/fwlink/?LinkId=22828
Managed Provider for DB2	.NET Framework v. 1.1	http://go.microsoft.com/fwlink/?LinkId=22828
TI Designer	.NET Framework v. 1.1 Visual Studio .NET 2003	http://go.microsoft.com/fwlink/?LinkId=22828 http://go.microsoft.com/fwlink/?LinkId=22837

Configuration Wizard after Server setup

It is possible to install the Server software without running the Configuration Wizard, and then run the Configuration Wizard later. Eventually, however, you must run the Configuration Wizard. To do this, you will need the software listed in the table below. It can either be installed on the local Host Integration Server or a remote computer.

Feature	Requirement	
DB2 Distributed Transactions	SQL Server 2000 with Service Pack 3a	http://go.microsoft.com/fwlink/?LinkId=22838 http://go.microsoft.com/fwlink/?LinkId=22839
Transaction Integrator	SQL Server 2000 with Service Pack 3a	http://go.microsoft.com/fwlink/?LinkId=22838 http://go.microsoft.com/fwlink/?LinkId=22839

Special Considerations when installing Enterprise Single Sign-On

The following sections contain information regarding installation of the Enterprise Single Sign-On feature. Because of this feature's complex relationships to other features and systems, and because of its importance to system security, it is recommended that you read these sections carefully before installing Enterprise Single Sign-On.

Installing SSO and creating the Master Secret Server

Initial installation of Enterprise Single Sign-On must be done on the server that you will use as the Master Secret Server. This is also the only Master Secret Server allowed in the entire SSO system.

To install Enterprise Single Sign-On, run the Host Integration Server 2004 setup program and select **Custom Installation**. Under the **Security Integration** feature, select **Enterprise Single Sign-On** and continue installation.

After installation is complete, the **Configuration Wizard** launches. Since this is the Master Secret Server, when prompted with the question, Do you want to create a new SSO system or Join an existing SSO system? select **Create**. This will create the Master Secret Server and the SSO Credential Database.

> **Note** As soon as the configuration is complete, make sure you back up the Master Secret to a safe location. To do this, open a command prompt and navigate to the SSO directory located at Program Files\Common Files\Enterprise Single Sign-On, and run ssoconfig -backupsecret <backup file>.

It is recommended that you install only the Master Secret Server on this computer. It should not be used as a processing server.

Processing Servers for Enterprise Single Sign-On

In a multi-box environment, after the Master Secret Server and Credential database have been created, you can install Enterprise Single Sign-On on subsequent computers. These are typically the computers on which Host Integration Server 2004 is installed as well.

The initial installation process is the same as on the first computer. Configuration, however, becomes slightly different. Since the Master Secret Server and the SSO credential database are already in place, select **Join** when the Configuration Wizard asks, Do you want to create a new SSO system or Join an existing SSO system?

ENTSSO Administration install only

It is possible to install just the Enterprise Single Sign-On Administration feature. To do this, when you run the install program, select **Custom Installation**. Under the **Security Integration** feature, select only the **Enterprise SSO Administration** sub-feature.

Only SSO administrative components will be installed. The hardware and software requirements are the same as for a typical ESSO installation.

> **Note** While the SSO Administration feature in Host Integration Server 2004 is compatible with the server version of SSO in BizTalk Server 2004, the administrative components of Enterprise SSO in BizTalk Server 2004 are not compatible with the server version of Enterprise SSO in Host Integration Server 2004.

Installing the SSO administrative utility (ssomanage.exe) does not create shortcuts on the Start menu to access the command line utilities. To run the SSO administrative utilities after installation, you must open a command prompt and navigate to the SSO directory located at Program Files\Common Files\Enterprise Single Sign-On. You can use the ssomanage.exe to specify the SSO Server you want to use for management. To do this, open a command prompt and navigate to the SSO directory located at Program Files\Common Files\Enterprise Single Sign-On, and run ssomanage -serverall <SSO server name>.

SSO Client install

The stand-alone SSO client utility (ssoclient.exe) allows end users to configure their client mappings in the credential database. You can install the client utility from a self-extracting file (SSOClientInstall.exe) which is installed with the SSO administration feature.

To install the SSO client utility, you must be running one of the following operating systems on the client computer:

- Windows Server 2003
- Windows 2000 Server with Service Pack 4, or Windows XP Professional with Service Pack 1
- .NET Framework 1.1 (only necessary for the managed interoperability component of the SSO client utility)

Installing the SSO client utility does not create shortcuts on the Start menu to access the command line utilities. To run the SSO client utility after installation, you must open a command prompt and navigate to the SSO directory located at Program Files\Common Files\Enterprise Single Sign-On.

Password Synchronization

To install the password synchronization feature, run the install program and select **Custom Installation**. Under the **Security Integration** feature, select the **Enterprise Single Sign-On Password Synchronization** sub feature.

To addition to this, Password synchronization adapters are necessary to send and receive password changes to the external system. You can view a list of currently available adapters at the following location: http://go.microsoft.com/fwlink/?LinkId=30101

You can also contact support aliases to obtain information on these Password synchronization adapters.

There are 3 types of password synchronization sub-features supported in this release to simplify administration of the SSO credential database and to keep passwords across user directories in sync.

The first type is **Windows to External** (for example, Active Directory to RACF). A Windows user's password change is captured and sent to the Enterprise SSO Server assigned to receive password changes from domain controllers. This then forwards the password change to an external system and the mapping in the SSO credential database is kept in sync with the change made on the external system.

To capture password changes made in Active Directory, in addition to installing the ENTSSO Password Sync feature, components need to be installed on the domain controllers to capture password changes.

Both the Windows Password Capture component and Password Change Notification Service (PCNS) must be installed on all domain controllers from which you will be capturing passwords. You can find these components in the following location:

<HIS CD ROOT>\Platform\PCNS

Read the accompanying documentation (also located in the folder above) before you proceed with the installation on the domain controller.

The second type is **External to Windows - Full synchronization**. A password is captured on the External system and sent to the Enterprise Single Sign-On server assigned for Password Synchronization which then updates the password in the SSO credential database, and also updates the Windows user's password in Active Directory.

The third type is **External to Windows - Partial synchronization**. A password is captured on the External system and sent to the Enterprise Single Sign-On server assigned for Password Synchronization which then updates the password in the SSO credential database.

Upgrading from a previous version of SSO

If you are installing the Enterprise Single Sign-on feature and you already have a previous version deployed on your computer (for example, from Host Integration Server 2004 Beta, or Microsoft BizTalk® Server 2004), you must complete the steps below.

- Back up the SSODB to a secure location
- Back up the Master Secret Key on the Master Secret Server
- Update the Master Secret Server by running Host Integration Server 2004 setup, choosing **Custom Installation**, and then selecting **Enterprise Single Sign-On**. Select **Reuse** when the Configuration Wizard prompts you with the question: Do you want to reuse the existing configuration?

It is not necessary to update the other SSO Servers (non-Master Secret Servers) from your BizTalk Server 2004 installation. However, if you want the new Enterprise Single Sign-On features to be available on those servers, you must update them by using the same procedures outlined above.

If you have a Beta version of Enterprise SSO installed as part of a Host Integration Server 2004 Beta release, you can use the same mechanism to upgrade those servers.

> **Note** These considerations also apply if you are installing Microsoft BizTalk Server 2004 on a computer with an existing installation of Host Integration Server 2004 Enterprise Single Sign-On, and wish to update the servers.

Using Host Initiated SSO functionality in Enterprise Single Sign-On

Host Initiated Single Sign-On uses the protocol transition feature of Windows Server 2003 to perform Single Sign-On for the non-Windows user. This feature requires Windows Server 2003 and must be in a domain that has its **Domain Functional Level** set to **Windows Server 2003**.

Compatibility with earlier Host Integration Server products

SNA Server 2.0-SNA Server 3.0

Host Integration Server 2004 supports neither upgrade nor interoperability with SNA Server versions 2.0 – 3.0 inclusive.

SNA Server 4.0 and Host Integration Server 2000

Interoperability

Host Integration Server 2004 supports limited interoperability with SNA Server 4.0 and Host Integration Server 2000.

Host Integration Server 2004 clients will connect through SNA Server 4.0 servers and Host Integration Server 2000 servers.

SNA Server 4.0 clients will connect through Host Integration Server 2004 servers and Host Integration Server 2000 servers.

Neither SNA Server 4.0 servers nor Host Integration Server 2000 servers can act in the role of member or backup to a primary Host Integration Server 2004 server. Instead, you must upgrade the servers to Host Integration Server 2004 while running against the older SNA Server 4.0 or Host Integration Server 2000 primary server. Once all backup computers are upgraded to Host Integration Server 2004 , the remaining primary server computer can be upgraded to Host Integration Server 2004.

To deploy Host Integration Server 2004 as a backup in an existing Host Integration Server 2000 or SNA Server 4.0 domain, it is necessary to make the following configuration changes:

- Create a COMLOGS share pointing to <installdir>\system. Grant the service account and HIS Administrators group Read access. This share is used by the SNA Manager when creating link services on remote computers.
- Add any users who need to perform administrative tasks to the local Host Integration Server Administrators group on the Host Integration Server 2004 computer.
- Add any users who will create link services to the Local Administrators group on the computer where the link services will be created.
- Use the same service account for the Host Integration Server 2004 server that was used for the Host Integration Server 2000 or SNA Server 4.0 servers. This ensures that all components have the appropriate rights to perform their necessary functions.

> **Note** New features on Host Integration Server 2004 will not be available until all servers in the subdomain have been upgraded.

Upgrade

This release supports the upgrade of Host Integration Server 2000 Service Pack 1 and SNA Server 4.0 Service Pack 4.

Note that when you upgrade from SNA Server 4.0 to Host Integration Server 2004, it is necessary to reboot your computer. After the reboot has completed, you must then finish the installation by running the Configuration Wizard. The tables below outline possibilities in upgrading from previous versions.

Server Upgrades

This version	Can be upgraded to this version
SNA Server 4.0 SP4	HIS 2004 Enterprise Edition HIS 2004 Standard Edition HIS 2004 Evaluation Version HIS 2004 Developer Edition
HIS 2000 SP1	HIS 2004 Enterprise Edition HIS 2004 Standard Edition HIS 2004 Evaluation Version HIS 2004 Developer Edition
HIS 2004 Standard Edition	HIS 2004 Enterprise Edition
HIS 2004 Evaluation Version	HIS 2004 Standard Edition HIS 2004 Enterprise Edition

Client Upgrades

This version	Can be upgraded to this version
SNA Server 4.0 SP4 (Windows 9x)	HIS 2004 Client
SNA Server 4.0 SP4 (Windows NT)	HIS 2004 Client
HIS 2000 SP1 (End User)	HIS 2004 Client
HIS 2000 SP1 (Admin)	HIS 2004 Client

Build-to-Build Upgrades

For build-to-build upgrades, use the same backup and restore procedures as you would in preparing for Backup and Disaster Recovery. These procedures are listed below.

Back up your SNA Server configuration

1. Right click the SNA domain name in the SNA Manager and choose **Backup configuration…**.
2. Record the settings for the installed link services.

Back up your configuration using the Configuration Wizard

1. Re-run the Configuration Wizard from Start menu.
2. Proceed through the wizard screens to the Summary screen.
3. Choose **Save…**. to save your configuration.

Back up your Transaction Integrator configuration

1. Back up the HIP configuration by backing up the HIP database.
2. Backup the Remote Environments by saving a copy of the following registry key:

   ```
   HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Cedar
   ```

3. Export COM+ applications (Right-click application/Export…/Server Application).
4. Save Web Site or virtual directories individually to an XML file (Right-click Web Site or VD/All tasks/Save configuration to a file).
5. Back up the web site/virtual directory files/structure.

Back up your Data Integration Configuration

1. Backup any UDLs, HCDs or File DSNs. User and System DSNs can be converted to UDLs with the Data Access Tool and backed up.

Upgrade and restore your configuration

1. Launch the unattended setup using the XML file created in Step 3 of **Back up your configuration using the Configuration Wizard**.

   ```
   Setup.exe /Product HIS /InstallPlatform /L c:\HISInstall.log /S c:\ HISServerConfig.xml /INSTALLDIR C:\HIS
   ```

2. Restore the HIP database which you saved in Step 1 of **Back up your Transaction Integrator configuration**.
3. Launch the unattended configuration using the XML file created in Step 3 of **Back up your configuration using the Configuration Wizard**. This file will need to be updated with the service account password.

   ```
   ConfigFramework.exe /L c:\ConfigFramework.Log /F /S c:\HISServerConfig.xml
   ```

4. Launch SNA Manager.
5. Re-create your link services using the information recorded in Step 2 of **Back up your SNA Server configuration**.
6. Right click the SNA domain name in the SNA Manager and choose **Restore configuration…**.
7. Start TI Manager. This will automatically recreate the HIP application from the database.
8. Restore TI and Data artifacts as appropriate.

Supported Host Platforms

SNA connectivity, 3270 terminal emulation, host print service, and SNA programming interfaces

- IBM z/OS, OS/390, MVS, VSE and VM

SNA connectivity, 5250 terminal emulation, host print service, and SNA programming interfaces

- IBM OS/400 V2R3 or later
- IBM AS/400 Advanced 36 System Support Program Release 7.5

IP-DLC Link Service

- IBM Communications Server for OS/390 V6 or later
- IBM OS/390 2R6 (with APAR OW36113) or later

Security Integration

- Computer Associates eTrust CA-ACF2 Security for z/OS and OS/390
- Computer Associates eTrust CA-Top Secret Security for z/OS and OS/390
- IBM RACF Security for z/OS and OS/390
- IBM AS/400 Security

OLE DB Provider for DB2, ODBC Driver for DB2, and Managed Provider for DB2

- IBM DB2 V6 and later for OS/390 and z/OS to support an SNA LU6.2 or TCP/IP network connection

- IBM OS/400 V5R1 and later to support an SNA LU6.2 or TCP/IP network connection
- IBM DB2 for Universal Database V7.1 and later for Windows and AIX operating systems to support a TCP/IP network connection

The following table provides a feature-by-feature view of the DB2 platforms and versions supported by Host Integration Server 2004.

Key Features for DB2	**DB2MVS**	**DB2400**	**DB2AIX**	**DB2NT**
Network Connections over SNA	V6	V5R1	n/a	n/a
Network Connections over IP	V6	V5R1	V7.1	V7.1
Distributed Transactions over SNA	V6	V5R1	n/a	n/a
Distributed Transactions over IP	V6	V5R1	V8.1	V8.1
Default Schema	V6	V5R1	V7.1	V7.1
Session Pooling	V6	V5R1	V7.1	V7.1
Single Sign-On (SNA and IP)	V6	V5R1	V7.1	V7.1
Client Application Name	V6	V5R1	V7.1	V7.1
Stored Procedure Multiple Results	V6	V5R1	V7.1	V7.1
Default Qualifier (CURRENT SCHEMA)	V6	V5R2	V7.1	V7.1
UNICODE Data	V7	V5R1	V7.1	V7.1
SQL Long Identifiers	V8	V5R1	V7.1	V7.1

OLE DB Provider for AS/400 and VSAM

- IBM Distributed File Manager (DFM) V1R2 and later to support an SNA LU6.2 network connection (DFM is a component of IBM Data Facility Storage Management Subsystem (DFSMS) for OS/390 and z/OS)
- IBM V5R1 and later to support an SNA LU6.2 or TCP/IP network connection
- IBM AS/400 Advanced 36 SSP (System Support Program) Release 7.5 to support an SNA LU6.2 network connection

Host File Transfer

- IBM Distributed File Manager (DFM) V1R2 and later to support an SNA LU6.2 network connection (DFM is a component of IBM Data Facility Storage Management Subsystem (DFSMS) for OS/390 and z/OS)
- IBM OS/400 V5R1 and later to support an SNA LU6.2 or TCP/IP network connection

AS/400 Data Queues

- IBM OS/400 V5R1 and later to support an SNA LU6.2 network connection

Transaction Integrator

- IBM CICS (Customer Information Control System) for MVS V3R3 or later to support an SNA LU6.2 network connection
- IBM CICS Transaction Server for VSE/ESA V2R1 or later to support an SNA LU6.2 network connection
- IBM CICS Transaction Server for OS/390 Version 1 or later to support an SNA LU6.2 or TCP/IP network connection
- IBM CICS Transaction Server for z/OS Version 2 or later to support an SNA LU6.2 or TCP/IP network connection
- IBM CICS Transaction Server for z/OS Version 2 Release 2 or later to support an Enhanced Listener for TCP/IP network connection
- IBM IMS (Information Management System) Version 4 to support an SNA LU6.2 network connection
- IBM IMS Version 5 to support an SNA LU6.2 network connection
- IBM IMS Version 6 or later to support reliable 2PC transactions across an SNA LU6.2 network connection
- IBM IMS Version 6 to support an SNA LU6.2 or TCP/IP network connection
- IBM IMS Version 7 to support an SNA LU6.2 or TCP/IP network connection
- IBM IMS Version 8 to support an SNA LU6.2 or TCP/IP network connection
- IBM OS/400 Version 4 Release 1 or later to support a TCP/IP network connection.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

New Security Model

Host Integration Server 2004 includes a new security model that greatly reduces the rights required for the service account compared to previous versions of the product. After upgrading a previous version of the product, the following user rights assignment and group membership can be removed from the service account.

User rights assignment

Act as part of the operating system (SE_TCB_NAME)

Group Membership

Local Administrators

Installing the Product

The following sections contain installation information for Host Integration Server 2004.

Important notes about installation

- In this release, the installation program may not provide complete information on whether you have installed all of the software prerequisites. It is important to read the previous section, Hardware and Software Requirements, carefully and make sure all prerequisites are complete before running the install program.
- This release supports limited interoperability with previous versions of Host Integration Server and SNA Server.
- You must install this release on a computer with no previous versions (retail or Beta) of either Host Integration Server or SNA Server.
- If you uninstall the product and then reinstall, all previous administration configuration will be lost.
- To install the Client package on a local account, you must be an administrator. To install the Client package on a domain account, you can be either an administrator or a non-administrator.

Accessing the latest product documentation

A new, fully-updated documentation set is now available over the Web on a quarterly basis. Each quarterly release, which you download to your desktop, includes more in-depth information, updates, and new topics. As the new documentation will replace your current set, you will need to close all instances of Host Integration Server 2004 Help for the update to install correctly. Downloading the new Help will not affect your Host Integration Server 2004 product installation or performance in any way.

You can download the latest documentation from the following location:

http://go.microsoft.com/fwlink/?LinkId=29507

Standard Edition and Enterprise Editions

Host Integration Server 2004 is available in Standard and Enterprise editions. The Enterprise edition has the same capabilities as the Standard edition, with the addition of the following features:

Application Integration

- Transaction Integration
- Transaction Integration Designer

Message Integration

- MSMQ-MQSeries Bridge

You can use the SNAVER utility to quickly determine which version and edition of Host Integration Server 2004 is installed on the servers in your organization.

To check version and edition information

1. Click **Start**, and then click **Run...**
2. Type "snaver" and click **OK**. Your version and edition will be displayed.

To Install Host Integration Server 2004

1. In Windows Explorer, navigate to the installation folder in which you extracted the setup files.
2. Double-click **setup.exe**. The Host Integration Server 2004 Autorun panel will appear.
3. Click **Install Host Integration Server 2004** to begin installation. The Host Integration Server 2004 **Installation Wizard** appears and guides you through the rest of the installation process.
4. Click **Finish** when you are done.

To Uninstall Host Integration Server 2004 using Add/Remove Programs

1. Click **Start**, point to **Settings**, and then click **Control Panel**.
2. In Control Panel, open **Add/Remove Programs**, select **Microsoft Host Integration Server 2004** and click **Change/Remove**. The Microsoft Host Integration Server 2004 Add/Remove Application dialog box appears.
3. Click **Remove**, and then click **Next**. The **Uninstall Wizard** appears and automatically begins the uninstall process.
4. When the wizard has completed the process, click **Finish**.

Note Uninstalling Host Integration Server 2004 does not uninstall Single Sign-On. To uninstall Single Sign-On, see Uninstalling Single Sign-On below.

Unattended install

Unattended installation is useful for installing Host Integration Server 2004 on a large number of computers to ensure that they are all configured in exactly the same way. It is also useful if you need to change or update the existing configuration of a large number of computers.

You perform an unattended installation by creating a “model” installation on one computer, which you then apply to the other computers.

To perform unattended installations

1. Using the standard, Windows-based installation program, perform a full installation on a single computer. Since the installation parameters you choose will be saved as a model, make the selections you want to use on the other installations.
2. When setup is complete, run the **Configuration Wizard** on the same computer. As in Step 1, make the selections you want to use on the other installations. Stop when you reach the **Summary Page**.
3. At the **Configuration Wizard Summary Page**, click **Save**. The wizard will create a configuration file called **HISServerConfig.xml**.
4. Finish and close the **Configuration Wizard**.
5. If you need to, open **HISServerConfig.xml** in a browser and make any necessary changes.
6. On the appropriate server computer, open a command prompt and run the **Unattended Installation** command (see below). Where the command calls for the configuration file, use the name and location of the **HISServerConfig.xml** file created in Steps 1-5. You can also use the options listed below.

Commands

Use the following commands and options for unattended install.

```
Setup.exe /Product HIS /InstallPlatform /L c:\HISInstall.log /S c:\ HISServerConfig.xml /INSTALLDIR C:\HIS
```

```
ConfigFramework.exe /L c:\ConfigFramework.Log /F /S c:\HISServerConfig.xml
```

Options

/InstallPlatform

Using this flag will cause the installation program to install any platform prerequisites.

/Product [HIS | HISC]

Using this flag will install either Host Integration Server 2004 (HIS), or Host Integration Server 2004 Client (HISC).

/L c:\HISInstall.log

Using this flag will determine the log file location that is created during setup.

/S C:\HISServerConfig.xml

Using this flag will specify the configuration file (list of features) that is used on installation. The file "HISServerConfig.xml" contains information about which features to install and how they should be configured. Sample copies of these files are located in the Support\Unattended_Installs directory of the install folder. This file can also be created during setup by selecting the **Save** button in the summary panel of the Configuration Wizard.

/INSTALLDIR C:\HIS

This option tells setup where to install the product (for example C:\HIS or "C:\Program Files\Microsoft Host Integration Server\")

Unattended uninstall

Use following command for unattended uninstall:

```
Setup.exe /l C:\UninstallLog.txt /REMOVE ALL /Product HIS
```

Uninstalling Enterprise Single Sign-On

Uninstall

Uninstalling Host Integration Server will not uninstall Enterprise Single Sign-On. To uninstall this feature, use the following procedure:

1. On the **Start** menu, point to **Settings**, and then click **Control Panel**.
2. Double-click **Add/Remove Programs**.
3. In the **Add/Remove Programs** dialog box, click **Microsoft Enterprise Single Sign-On**, and click **Remove**.
4. Click **Yes** when prompted to confirm removal of Microsoft Enterprise SSO.

    Note If you have BizTalk Server Runtime, Development, or Administration features installed, or Host Integration Server Administration features installed, you will not be able to uninstall the SSO Runtime or Administration components until all dependencies are removed.

Unattended Uninstall

> **Note** You will need the original installation media to perform unattended uninstalls of Single Sign-On Server or Client versions.

Use the following commands for unattended uninstall:

HIS 2004 Server

MSIEXEC /X <Drive>\Platform\SSO\SSO.msi\SSO.MSI

HIS 2004 Client

MSIEXEC /X <Drive>\Platform\SSO\CLIENT\SSOClient.msi

> **Note** If you have BizTalk Server Runtime, Development, or Administration features installed, or Host Integration Server Administration features installed, you will not be able to uninstall the SSO Runtime or Administration components until all dependencies are removed.

Making and Testing a Connection

This section provides the procedures used to make successful connections. Several steps are required to connect your host system to Microsoft® Host Integration Server 2004.

One way to remember the four steps required to make a successful connection is with the acronym **LCLUA** that stands for **L**-Link Service, **C**-Connection, **LU**-LUs and **A**-Adding and Assigning Users.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

For information about configuring Host Integration Server 2004 for your enterprise environment, see Configuring Your Enterprise.

This section contains:

- Important Connection Information
- Important Configuration Information
- Step 1 (L) Creating and Configuring Link Services
- Step 2 (C) Creating and Configuring Connections
- Step 3 (LU) Creating and Configuring 3270 LUs
- Step 4 (A) Adding and Assigning Users
- Testing the Connection

IP-DLC Link Service

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

About Making a Connection

Complete the following steps to give users and groups access to the mainframe environment, install connections, and verify the installation.

(For information on the new IP-DLC Link Service, see IP-DLC Link Service.)

Install Host Integration Server 2004, which includes:

- Verify Host connection information
- Verify Microsoft Windows Server™ 2003 or Windows® 2000 Server configuration information
- Verify Host Integration Server 2004 SNA service configuration information
- Install Host Integration Server 2004
- Install appropriate link services

Configure Host Integration Server 2004, which includes:

- Step 1 (L) Creating and Configuring Link Services
- Step 2 (C) Creating and Configuring Connections
- Step 3 (LU) Creating and Configuring 3270 LUs
- Step 4 (A) Adding and Assigning Users

Test Host Integration Server 2004, which includes:

- Testing Connections with the 3270 Client
- Testing Connections with the 5250 Client

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Items to Consider for a Successful Connection

For a connection to be established successfully, a number of software settings and hardware characteristics must work together.

The following table outlines items to consider when configuring a connection with Host Integration Server 2004.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

Element	Considerations
Host configuration settings must match the connection and server settings on the Host Integration Server 2004 computer.	**Mainframe node ID settings**: For most mainframes, IDBLK and IDNUM in the physical unit (PU) definition must match the two parts of the Remote Node ID on the Host Integration Server 2004 connection. **AS/400 name settings**: For the AS/400 computer, local and remote control point names (CP names) and network names must be matched with corresponding Host Integration Server 2004 settings **Addresses**: For 802.2, X.25, or channel connections, you must match the host settings with equivalent settings on the Host Integration Server 2004 connection. **BTU length**: For the mainframe, the BTU length is set through MAXDATA in the PU definition. For the AS/400 computer, this is set through MAXFRAME. These should equal the Max BTU Length on the Host Integration Server 2004 connection. **Other settings**: With SDLC, the NRZ/NRZI settings on the host must match those on the Host Integration Server 2004 connection.
For SDLC and X.25 **Communications hardware**: line, modem (if applicable), and adapter characteristics must match the link service and connection settings on the Host Integration Server 2004 computer.	**Speed and duplexing**: For SDLC and X.25, note the speed and duplexing capabilities of the line, modem (or DCE), and adapter, to be sure that they will not be exceeded by the settings in the Host Integration Server 2004 link service and connection. Settings for fast transmission or for full duplexing cause greater demands on hardware. The hardware element with the smallest capacity limits the capacity of the entire system.

IP-DLC Link Service

Using SNA Manager

SNA Manager provides an interface for configuration and operation of Host Integration Server 2004 components. SNA Manager allows flexibility in viewing and managing SNA server subdomains, computers, link services, connections, logical units (LUs), sessions, and users. It integrates the administration of TN3720 service, TN5250 service, Host Print service, Shared Folder Gateway service, and Host Security Integration.

You can view all Host Integration Server 2004 computers in an SNA server subdomain and manage multiple subdomains at the same time. This allows for central configuration and administration of all servers in an enterprise. You can remotely configure and manage Host Integration Server 2004 computers across all popular protocols, including TCP/IP, IPX/SPX, and Microsoft Networking.

SNA Manager can be installed on any computer running Windows Server 2003 or Windows 2000 Server, enabling management of the entire Host Integration Server 2004 network from a single computer. In addition, SNA Manager allows more than one administrator to simultaneously view and manage the same SNA server subdomain.

SNA Manager provides a hierarchical, tree-like view of an SNA server subdomain and all its resources.

In the console tree, the subdomain is presented as a hierarchical collection of resources. At the top of the hierarchy is the subdomain itself, which contains Servers, LU Pools, Configured Users, Workstations APPC Modes, CPI-C Symbolic Names, and Host Security Domains. You can view as much of the subdomain detail as needed by opening and closing folders.

When you click an item in the console tree, the details pane shows resources available to the item. Double-clicking an item that does not contain other objects displays the properties of the item.

Shortcut menus (available by right-clicking an object) allow selection of the appropriate command for a particular object. For example, if you select a server and right-click, a shortcut menu allows you to stop the service, control all other services, insert new resources, and view and configure the properties.

SNA Manager lets you administer more than one SNA subdomain by displaying each domain in a separate window with its own hierarchical arrangement of resources.

SNA Manager also simplifies administrative tasks by providing wizards to step you through many of the more complicated tasks, such as configuring AS/400 connectivity, configuring 3270 display LUs, and creating a range of LUs.

Opening a Subdomain

Configuring Server Properties

Configuring SNA Service Properties

Opening a Subdomain

Before you can configure Host Integration Server 2004 components, you must open a subdomain.

The **Start Subdomain** dialog box can be used to change SNA subdomains including:

- Local SNA Subdomain
- Remote SNA Subdomain
- Offline Configuration

To open a subdomain

1. Start SNA Manager.
2. In SNA Manager, right-click **SNA Manager** (top level), and select **Open Subdomain**. The **Start SNA Manager for** dialog box appears.
3. Select the appropriate settings for your subdomain, and click **Finish**.

Configuring Server Properties

The **Server Configuration** dialog box can be used to change Host Integration Server 2004 properties, including:

- Server Name
- Subdomain Name
- Active Directory OU Name
- Server Role - Primary or Backup
- Restart - MngAgent and SnaBase

To configure server properties

1. Start SNA Manager.
2. In SNA Manager, right-click the server, and select **Properties**.
3. To change the server name, click **Change** near the top of the **Server Configuration** tab. Note that the server must be offline before you can change the name.
4. To set the Group Identity (Subdomain name and Active Directory), Server Role (Primary or Backup), or Network Transports (TCP/IP is default), click **Change** near the bottom of the **Server Configuration** tab.
5. Make the appropriate changes to your configuration, and then click **OK**.
6. You must save your configuration to keep the properties you set. Right-click the server, and click **Save Configuration**.

Using SNA Manager

Opening a Subdomain

Configuring Server Properties

Step 1 (L) Creating and Configuring Link Services

This section details creating and configuring link services. The maximum number of 802.2 link services that one Host Integration Server 2004 computer can support is:

- 64 per network adapter (limited by SAP)
- 255 per SNA server (limited by index from 0x01 to 0xFF)

However, SNA Manager allows only 64 link services per Host Integration Server 2004 computer, no matter how many adapters are installed on the server. To configure the number higher than this, use the utility Linkcfg.exe.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

To create and configure link services, see the following topics:

- Creating Link Services
    - Creating the DLC 802.2 Link Service
    - Creating the 3270 Demonstration
    - Creating the 5250 Demonstration
    - Creating the LU1 Print Demonstration
    - Creating the LU3 Print Demonstration
- Configuring Link Services
    - Configuring the DLC 802.2 Link Service
    - Configuring the 3270 Demonstration
    - Configuring the 5250 Demonstration
    - Configuring the LU1 Print Demonstration
    - Configuring the LU3 Print Demonstration

Creating Link Services

By default, when Host Integration Server 2004 is installed, all the software files required by all standard link services are copied to the server, but the link services themselves are not installed or configured.

The following sections contain procedures detailing how to create link services using SNA Manager. This section contains:

- Creating the DLC 802.2 Link Service
- Creating the 3270 Demonstration
- Creating the 5250 Demonstration
- Creating the LU1 Print Demonstration
- Creating the LU3 Print Demonstration

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Creating the DLC 802.2 Link Service

The following procedure details creating a new DLC 802.2 link service.

To create the DLC 802.2. link service

1. Start SNA Manager.
2. In SNA Manager, right-click the server on which to add the link service, point to **New**, and then click **Link Service**.
3. Select the **DLC 802.2 Link Service**, and click **Add**.
4. Configure the following link service information (if required):
   - Title
   - Adapter
   - Local Service Access Point (SAP)
   - Use Fixed SAP option
   - Allow Link Server to be Distributed option
5. Click **OK**.

   The **Insert Link Service** box will continue to be displayed, allowing you to insert additional link services as needed.
6. After you have finished adding the needed link services, click **Finish**.
7. Right-click **Link Services**, and then click **Save configuration**.

   > **Note** When the link services have been inserted, SNA Manager displays them in the **Link Services** folder.

Creating the 5250 Demonstration

Creating the LU1 Print Demonstration

Creating the LU3 Print Demonstration

Creating the 3270 Demonstration

The following procedure details creating the Continuous 3270 Demonstration.

To create the 3270 demonstration

1. Start SNA Manager.
2. In SNA Manager, right-click the server on which to add the link service, point to **New**, and then click **Link Service**.
3. Select **DEMO SDLC Link Service**, and click **Add**.
4. Verify the script file is for the **3270 Continuous Demo** and click **OK**.

   The **Insert Link Service** box will continue to be displayed, allowing you to insert additional link services as needed.

5. After you have finished adding the needed link services, click **Finish**.
6. Right-click **Link Services**, and then click **Save configuration**.

> **Note** When the link services have been inserted, SNA Manager displays them in the **Link Services** folder.

1. In SNA Manager, right-click the server on which to add the link service, point to **New**, and then click **Link Service**.
2. Select **DEMO SDLC Link Service**, and click **Add**.
3. Verify the script file is for the **LU1 Print Demo** and click **OK**.

   The **Insert Link Service** box will continue to be displayed, allowing you to insert additional link services as needed.

4. After you have finished adding the needed link services, click **Finish**.
5. Right-click **Link Services**, and then click **Save configuration**.

> **Note** When the link services have been inserted, SNA Manager displays them in the **Link Services** folder.

Configuring Link Services

By default, when Host Integration Server 2004 is installed, all the software files required by all standard link services are copied to the server. After the link services are installed, they must be configured for your host environment.

The following sections contain procedures detailing how to configure link services.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

This section contains:

- Configuring the DLC 802.2 Link Service
- Configuring the 3270 Demonstration
- Configuring the 5250 Demonstration
- Configuring the LU1 Print Demonstration
- Configuring the LU3 Print Demonstration

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring the DLC 802.2 Link Service

Use the following procedure to configure the DLC 802.2 link service.

To configure the DLC 80.2. link service

1. In SNA Manager, expand the server, and then click **Link Service**.
2. Right-click the DLC 802.2 **(SNADLC1)** link service, and click **Properties**.
3. In **Properties**, click **Configure**.
4. Make configuration changes, and click **OK**.
5. Click **OK** to close the **Properties** dialog box.

Step 2 (C) Creating and Configuring Connections

This section details creating and configuring connections.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

This section contains:

- Creating Connections
    - Creating a 3270 Connection Using a Wizard
    - Creating a 3270 Connection Manually
    - Creating a 5250 Connection Using a Wizard
    - Creating a 5250 Connection Manually
    - Creating a 5250 Local APPC LU
    - Creating a 5250 Remote APPC LU
- Configuring Connections
    - Configuring a 3270 Connection
    - Configuring a 5250 Connection
    - Configuring a 5250 Local APPC LU
    - Configuring a 5250 Remote APPC LU

Creating Connections

With Host Integration Server 2004, you can create connections with wizards or manually. Host Integration Server 2004 provides you with three wizards to aid you in installing and configuring connections to your host environment (HE).

These tools step you through configuring connection properties, creating 3270 display LUs and an LU pool, and assigning the LUs to the LU pool.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

This section contains:

Mainframe (3270) environments:

- Creating a 3270 Connection Using a Wizard
- Creating a 3270 Connection Manually

AS/400 (5250) environments:

- Creating a 5250 Connection Using a Wizard
- Creating a 5250 Connection Manually
- Creating a 5250 Local APPC LU
- Creating a 5250 Remote APPC LU

Creating a 3270 Connection Using a Wizard

The following procedure details using a wizard to create a 3270 connection. The 3270 Continuous link service will be used as an example.

To create a 3270 connection using a wizard

1. In SNA Manager, right-click the server on which to add a connection.
2. Point to **All Tasks**, and then select the **3270 Wizard** option.
3. Click **Next** on the **Welcome** screen.
4. Select the computer where SNA service resides, and click **Next**.
5. Enter a **Name** for the connection, **DM3270**, and click **Next**.
6. Select the appropriate link service, **SNADEMO1**, and click **Next**.
7. Accept the default Local Node ID information, and click **Next**.
8. Accept the default PU address information, and click **Next**.
9. Accept the default LU information, and click **Next**.
10. Click **Add** to add a member (user).
11. Select a member, click **Add**, and then click **OK**.
12. Click **Next**.
13. Click **Finish** to complete the wizard.
14. Click **OK** on the final wizard information page.
15. When the wizard completes, right-click **SNA Service**, and click **Save configuration**.
16. Stop and then start SNA service.

Creating a 3270 Connection Manually

The following procedure details creating a 3270 connection manually.

To create a 3270 connection manually

1. In SNA Manager, expand the server on which to create the connection, and then expand **SNA Service**.
2. Right-click **Connections**, point to **New**, and then click the type of connection (802.2) to be created.
3. Configure the **Connection Properties**. You are required to specify which link service to use for the connection, as well as the name of the connection and additional information. The choices you make depend on the purpose of the connection.

   The following information must be configured correctly to make a connection:

   - General Tab
   - Address Tab
   - System Identification Tab
   - DLC 802.2 Tab
4. Click **OK**.
5. Right-click **SNA Service**, and then click **Save configuration**.
6. Stop and then start SNA service.

   To display this dialog box after the connection has been created, double-click the connection in the tree view, or select the connection, and click **Properties** in the **View** menu.

Configuring Connections

If you run a wizard to create your connections, most of the configuration information will be added with the criteria you entered when the wizard runs. The AS/400 Wizard, the Mainframe APPC/LU6.2 Wizard, and the 3270 Wizard step you through configuring connection properties, creating 3270 display LUs and an LU pool, and assigning the LUs to the LU pool.

If you need to configure a connection manually, you may need to verify the host connection information before you can proceed. For more information, see Verify Host Connection Information.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

This section contains:

Mainframe (3270) environments:

- Configuring a 3270 Connection

AS/400 (5250) environments:

- Configuring a 5250 Connection
- Configuring a 5250 Local APPC LU
- Configuring a 5250 Remote APPC LU

Configuring a 3270 Connection

The following procedure details configuring a 3270 connection.

To configure a 3270 connection

1. In SNA Manager, expand the server on which to configure the connection, and then expand **SNA Service**.
2. Expand **Connections**, right-click the 3270 (**DM3270**) connection, and then click **Properties**.

   Connection Properties lets you specify which link service to use for the connection, as well as the name of the connection and additional information. The choices you make depend on the purpose of the connection.

3. After you have made your configuration changes, click **OK**.
4. Right-click **SNA Service**, and then click **Save configuration**.
5. Stop and then start SNA service.

Step 3 (LU) Creating and Configuring 3270 LUs

This section details information regarding creating and configuring LUs.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

This section contains:

- Creating LUs
    - Creating a 3270 Display LU
    - Creating a 3270 Printer LU
    - Creating a 3270 Application LU (LUA)
    - Creating a 3270 Downstream LU
    - Creating a Local APPC LU
    - Creating a Remote APPC LU
- Configuring LUs
    - Configuring a 3270 Display LU
    - Configuring a 3270 Printer LU
    - Configuring a 3270 Application LU (LUA)
    - Configuring a 3270 Downstream LU
    - Configuring a Local APPC LU
    - Configuring a Remote APPC LU

Creating LUs

After configuring the connection, you can create the 3270 LUs. The LUs can be display (terminal emulation) LUs, printer LUs, application LUs (LUAs), or downstream LUs.

Each 3270 LU is configured based on the type of connection used. If the connection is channel, 802.2, X.25, or SDLC, the LUs need an LU number, which identifies the LU on its connection. This number should match the LOCADDR= parameter of the LU definition in Virtual Telecommunications Access Method (VTAM) or in the Network Control Program (NCP) GEN. Up to 254 LUs can be configured for each connection, and they can be consecutively configured as a range of LUs.

You can create LUs one at a time or in a consecutively numbered range. When creating a range of LUs, all the LUs are given the same properties. You can modify individual LUs after creating them.

This section contains:

- Creating a 3270 Display LU
- Creating a 3270 Printer LU
- Creating a 3270 Application LU (LUA)
- Creating a 3270 Downstream LU
- Creating a Local APPC LU
- Creating a Remote APPC LU

Creating a 3270 Display LU

The following procedure details how to create a display LU.

To create a 3270 display LU

1. In SNA Manager, expand **Servers**, expand **SNA Service**, and then expand **Connections**.
2. Right-click the appropriate connection, **DM3270**, point to **New**, and then click **Display LU**.

   You can define LUs in this **Properties** dialog box. Keep the default for the **LU Number** box as 2. Two is the first available number, because one is reserved for the host.

   The LU number is meaningful to the connection. You can add a user-friendly name in the **LU Name** box.

3. Type the LU Name, **LU 2**. Leave the other boxes as they are.
4. Click the **Display Model** tab and choose **2 (24 X 80)** as the display station model. Because models can change without notification, click **Model can be overridden**.
5. Click the **Associated Printer** tab. When configuring an LU, these boxes are generally left blank.
6. Click **OK**.

Creating a 3270 Printer LU

The following procedure details how to create a printer LU.

To create a 3270 printer LU

1. In SNA Manager, expand **Servers**, expand **SNA Service**, and then expand **Connections**.
2. Right-click the appropriate connection, **DM3270**, point to **New**, and then click **Printer LU**.

   You can define LUs in this **Properties** dialog box. Keep the default for the **LU Number** box as 3. Three is the first available number, because two was used in the previous example and one is reserved for the host.

   The LU number is meaningful to the connection. You can add a user-friendly name in the **LU Name** box.

3. Type the LU Name, **LU 4**. (You might have expected LU 3, but LU 3 is reserved for the LU3 demo.) Leave the other boxes as they are.
4. Type a comment (optional).
5. If you are using compression, select the **Use Compression** box.
6. If the workstation is secured, select the **User Workstation Secured** box.
7. Click **OK**.

Creating a 3270 Downstream LU

Creating a Local APPC LU

Configuring LUs

This section provides information detailing configuring LUs.

This section contains:

- Configuring a 3270 Display LU
- Configuring a 3270 Printer LU
- Configuring a 3270 Application LU (LUA)
- Configuring a 3270 Downstream LU
- Configuring a Local APPC LU
- Configuring a Remote APPC LU

Configuring a 3270 Display LU

The following procedure details how to configure a display LU.

To configure a 3270 display LU

1. In SNA Manager, expand **Servers**, expand **SNA Service**, and then expand **Connections**.
2. Right-click the appropriate connection, **DM3270**. You should see the available LUs in the details pane.
3. Click the **Display LU**, **LU 2**, and then click **Properties**.
4. Make appropriate configuration changes, and then click **OK**.

Configuring a 3270 Printer LU

The following procedure details how to configure a printer LU.

To configure an 3270 printer LU

1. In SNA Manager, expand **Servers**, expand **SNA Service**, and then expand **Connections**.
2. Right-click the appropriate connection, **DM3270**. You should see the available LUs in the details pane.
3. Click the **Printer LU**, **LU 3**, and then click **Properties**.
4. Make appropriate configuration changes, and then click **OK**.

Step 4 (A) Adding and Assigning Users

This section describes adding users and assigning LUs to configured users.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

This section contains:

- Adding Users
- Assigning LUs to Configured Users
- Assigning Remote APPC LUs to Configured Users

Adding Users

Although Host Integration Server 2004 utilizes the User accounts of the Windows Server 2003 or Windows 2000 Active Directory® directory service, users must be configured to use Host Integration Server 2004 resources such as LUs.

To add new users

1. In SNA Manager, expand the SNA subdomain where the users reside.
2. Right-click **Configured Users**, point to **New**, and then click **User**.
3. Select a user (or group) from the list, and click **OK**.

See Also

IP-DLC Link Service

Assigning LUs to Configured Users

Assigning Remote APPC LUs to Configured Users

Assigning LUs to Configured Users

Although Host Integration Server 2004 utilizes the User accounts of the Windows Server 2003 or Windows 2000 Active Directory directory service, users must be configured to use Host Integration Server 2004 resources such as LUs.

To assign LUs to configured users

1. In SNA Manager, expand the SNA subdomain where the users reside.
2. Expand **Configured Users**. Select a user, and then right-click **Assign LUs**.
3. Select an LU, and then click **OK**.

The list of LUs that a particular user can access depends on how the user connects to Host Integration Server 2004. If Active Directory is used, a user can access any LUs assigned directly to the user account and can also access any LUs assigned to any of the groups the user is a member of. If not using Active Directory, a user can only access LUs assigned directly to the user, or if no LUs are assigned to the user account, then the user can access LUs assigned to exactly one group. The groups are checked in the following order: global groups, local groups, well known groups. There is no ordering within a group.

Adding Users

Assigning Remote APPC LUs to Configured Users

Assigning Remote APPC LUs to Configured Users

Although Host Integration Server 2004 utilizes the User accounts of the Windows Server 2003 or Windows 2000 Active Directory directory service, users must be configured to use Host Integration Server 2004 resources such as LUs.

To assign remote APPC LUs to a configured user

1. In SNA Manager, expand the SNA subdomain where the users reside.
2. Select **Servers**, expand **Servers**, select a server, expand it, and then expand **Remote APPC LUs**.
3. Select an LU, right-click it, and assign it to a user.
4. Select the user, and click **OK**.

Adding Users

Assigning LUs to Configured Users

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Testing the Connection

The topics in this section detail testing, including running and configuring, the 3270 and 5250 Client applications.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

This section contains:

- Testing Connections with the 3270 Client
  - Running the 3270 Client
  - Configuring the 3270 Client
  - Running the 3270 Client Demonstration
- Testing Connections with the 5250 Client
  - Running the 5250 Client
  - Configuring the 5250 Client
  - Running the 5250 Client Demonstration

Testing Connections with the 3270 Client

The 3270 Client can be used to access your mainframe (3270) environment.

This section contains:

- Running the 3270 Client
- Configuring the 3270 Client
- Running the 3270 Client Demonstration

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Running the 3270 Client

The following procedure details running the 3270 Client application.

To run the 3270 client

1. Start **SNA Manager**.
2. On the **Tools** menu, click **3270 Client**. This launches the Host Integration Server 2004 3270 Client application.
3. Next, configure the 3270 Client application. For details, see Configuring the 3270 Client.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring the 3270 Client

The following procedure details configuring the 3270 Client application.

The 3270 continuous demo will be used for this procedure.

To configure the 3270 client

1. Start SNA Manager.
2. On the **Tools** menu, click **3270 Client**.
3. On the **Session** menu, click **Session Configuration**.
4. Select the correct LU or pool name, **DM3270**, and then click **OK**.
5. Next, run the 3270 demonstration. For details, see Running the 3270 Client Demonstration.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Running the 3270 Client Demonstration

The following procedure details running the 3270 continuous demonstration.

To run the 3270 client demonstration

1. Start SNA Manager.
2. On the **Tools** menu, click **3270 Client**.
3. On the **Session** menu, click **Connect**, which connects you to the 3270 demonstration script.
4. Return to SNA Manager. The status of the DM3270 connection should show **Active**.

IP-DLC Link Service

Testing Connections with the 3270 Client

Testing Connections with the 5250 Client

The 5250 Client can be used to access your AS/400 environment. The following topics detail running and configuring the 5250 Client application.

This section contains:

- Running the 5250 Client
- Configuring the 5250 Client
- Running the 5250 Client Demonstration

Running the 5250 Client

The following procedure details running the 3270 Client application.

To run the 5250 client

1. Start SNA Manager.
2. Right-click **SNA Service**, and click **Start**.
3. On the **Tools** menu, click **5250 Client**. This launches the Host Integration Server 2004 3270 Client application.
4. Next, configure the 5250 Client application. For details, see Configuring the 5250 Client.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring the 5250 Client

The following procedure details configuring the 5250 Client application.

The 5250 (AS/400) demo will be used for this procedure.

To configure the 5250 client

1. Start SNA Manager.
2. On the **Tools** menu, click **5250 Client**.
3. On the **Session** menu, click **Session Configuration**.
4. Select the correct LU or pool name, **DM5250**, and then click **OK**.
5. Next, run the 5250 demonstration. For details, see Running the 5250 Client Demonstration.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Running the 5250 Client Demonstration

The following procedure details running the 5250 demonstration.

To run the 5250 client demonstration

1. Start SNA Manager.
2. On the **Tools** menu, click **5250 Client**.
3. On the **Session** menu, click **Connect**, which connects you to the 5250 (AS/400) demonstration script.
4. Return to SNA Manager. The status of the DM5250 connection should show **Active**.

Testing Connections with the 5250 Client

Configuring Your Enterprise

While the section Making and Testing a Connection provided the basic steps to configure a link service, make a connection, create logical units (LUs), and log on to a host computer, this section follows a similar format and provides the concepts and procedures for configuring Host Integration Server 2004 in your enterprise.

For information about the new IP-DLC Link Service, see IP-DLC Link Service.

This section contains:

- Creating and Configuring Link Services
- Creating and Configuring Connections
- Creating and Configuring LUs
- Configuring APPC LUs for TPs or 5250 Emulation
- Managing Users

Creating and Configuring Link Services

By default, when Host Integration Server 2004 is installed, all the software files required by all standard link services are copied to the server, but the link services themselves are not installed or configured.

For information about the new IP-DLC Link Service, see IP-DLC Link Service.

The following procedures detail how to create link services using SNA Manager:

- Creating DLC 802.2 Link Service
- Creating the 3270 Demonstration
- Creating the 5250 Demonstration
- Creating the LU1 Print Demonstration
- Creating the LU3 Print Demonstration

The following procedures detail how to configure link services using SNA Manager:

- Configuring the DLC 802.2 Link Service
- Configuring the 3270 Demonstration
- Configuring the 5250 Demonstration
- Configuring the LU1 Print Demonstration
- Configuring the LU3 Print Demonstration

Creating and Configuring Connections

You can create connections between Host Integration Server 2004 and your host computer with wizards or manually. Host Integration Server 2004 provides three wizards to help you install and configure connections to your host environment (HE).

The AS/400 Wizard, the Mainframe APPC/LU 6.2 Wizard, and the 3270 Wizard step you through configuring connection properties, creating 3270 display LUs and an LU pool, and assigning the LUs to the LU pool.

For information about the new IP-DLC Link Service, see IP-DLC Link Service.

The following procedures detail how to create connections:

Mainframe (3270) environments:

- Creating a 3270 Connection Using a Wizard
- Creating a 3270 Connection Manually

AS/400 (5250) environments:

- Creating a 5250 Connection Using a Wizard
- Creating a 5250 Connection Manually
- Creating a 5250 Local APPC LU
- Creating a 5250 Remote APPC LU

If you use a wizard to create your connections, most of the configuration information is added along with the criteria you entered when the wizard runs.

If you need to configure a connection manually, you may need to verify some of your connection information. For more information, see Important Connection Information.

Creating and Configuring LUs

After you configure the connection, you can create the 3270 LUs. The LUs can be display LUs (terminal emulation), printer LUs, application LUs (LUAs), or downstream LUs.

Each 3270 LU is configured based on the type of connection used. If the connection is channel, 802.2, X.25, or Synchronous Data Link Control (SDLC), the LUs need an LU number, which identifies the LU on its connection. This number should match the LOCADDR= parameter of the LU definition in Virtual Telecommunications Access Method (VTAM) or in the Network Control Program (NET) Gen. Up to 254 LUs can be configured for each connection, and they can be consecutively configured as a range of LUs.

You can create LUs one at a time or in a consecutively numbered range. When you create a range of LUs, all the LUs are given the same properties. You can modify individual LUs after creating them.

For information about the new IP-DLC Link Service, see IP-DLC Link Service.

For procedures about creating LUs, see the following:

- Creating a 3270 Display LU
- Creating a 3270 Printer LU
- Creating a 3270 Application LU (LUA)
- Creating a 3270 Downstream LU
- Creating a Local APPC LU
- Creating a Remote APPC LU

For procedures about configuring LUs, see the following:

- Configuring a Range of 3270 LUs
- Assigning LUs to Workstations
- Associating 3270 Printer LUs with 3270 Display LUs
- Configuring Downstream Connections
- Configuring APPC LUs for TPs or 5250 Emulation
- Precedence of Accounts in Determining Default LUs

To modify a 3270 LU

1. In SNA Manager, ensure that the appropriate service is inactive by right-clicking **SNA service**, and then click **Stop**.
2. Double-click **Connections**, and then double-click the connection that contains the LU you want to view.
3. Right-click the LU whose properties you want to view, and then click **Properties**. Click the appropriate tab to view or modify the LU properties.
4. Click **Save Configuration** on the **Action** menu if you made changes, and then restart the affected service.

   Note Restarting the server disconnects all users. Try to schedule configuration changes when they least affect users.

Configuring a Range of 3270 LUs

You can create a consecutively numbered range of LUs. To do so, you will need to identify the base LU name—limited to eight characters—on which the numbered range of names will be built.

After identifying the base LU name, you can create the LUs by identifying the number of LUs in the range and the number the range will start with. Host Integration Server 2004 will create LUs using the sequential numbering scheme.

To configure a range of 3270 LUs

1. In SNA Manager, ensure that the appropriate service is inactive by right-clicking **SNA service**, and then click **Stop**.
2. Right-click the connection to which you want to assign the LUs. Point to **All Tasks**, and then click the **Range of LUs**.
3. Fill in the LU Creation Wizard, and click **Finish** when done.
4. On the **Action** menu, click **Save Configuration**.
5. On the **Action** menu, click **Refresh**.

    Note When you create a range of LUs, all the LUs are given the same properties. You can modify individual LUs after creating them.

Creating and Configuring LUs

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Creating LU Pools

Although you can create individual LUs and assign them to users and groups, using LU pools to manage and deploy a large number of LUs is a more efficient method of administering these resources.

LU pools are groupings of 3270, LUA, or downstream LUs that allow you to maximize access to LUs. A user, LUA application, or downstream system using the pool can get LU access as long as one of the pooled LUs is available. If some of the pooled LUs are not functioning, the user, LUA application, or downstream system will not be affected, as long as another LU in the pool is available.

LU pools allow groups of intermittent users to use resources efficiently. For example, ten 3270 users who only need intermittent access may find that a pool of five 3270 LUs is adequate for their needs.

If a user needs access to multiple LU sessions, you can assign one LU or LU pool for each session that the user needs. A pool can be assigned multiple times to the same user.

To encourage efficient use of LUs, you can change the order in which they appear in lists seen by the user. For example, you can place an LU at the top of the list, so the user is likely to try that LU first.

In this security mode, if a user is assigned LUs through one or more accounts (such as group and individual accounts), the LUs accumulate, allowing the user to access all LUs assigned to that user.

For example, a 3270 LU called LU 1 is assigned to a user account (a high-priority account) called JOHND. At the same time, an LU named LU 2 is assigned to a local group (a low-priority account) of which JOHND is a member. JOHND will be given access to both LU 1 and LU 2.

You can place LUs in pools by using the drag-and-drop feature. After configuring the LU pool properties (pool name, pool type, and 3270 display model), you can select the LUs to be added and then drag them to the named pool.

An LU can be removed from an LU pool by simply deleting it from the pool.

The following procedures will help you manage your LU pools:

- To create LU pools
- To assign a 3270 LU to a connection
- To assign LUs and LU pools to users and groups
- To view LUs or pools assigned to users
- To add 3270 LUs to a pool
- To add a workstation and assign LUs
- To remove an LU from a pool

To create LU pools

1. In SNA Manager, right-click the **Pools** folder, point to **New**, and then click **3270 Display LU Pool**.
2. In **Pool Properties**, enter a name for your pool, up to eight characters in length. A comment is optional.
3. Leave the check box cleared, and click **OK**.
4. The new pool appears in the **Pools** folder.

To assign a 3270 LU to a connection

1. In SNA Manager, expand SNA service for the server you are working with, and then expand **Connections**.
2. Right-click the connection where you want to add the LU, point to **New**, and click the type of 3270 LU you want to assign.
3. In the **3270 LU Properties** box, enter the LU Name. The LU number is system-assigned.
4. Click **OK** to exit.
5. On the **Action** menu, click **Save Configuration**.

To assign LUs and LU pools to users and groups

1. In SNA Manager, right-click the LU or LU pool, click **Assign to User**, and then select the users you want to assign.
2. Click **OK**.
3. Verify that the state of the server is active and that the connections are available (either **OnDemand** or **Active**). If the server is not active, right-click the server in SNA Manager, and then click **Start**.

To view LUs or pools assigned to users

1. In SNA Manager, double-click **Configured Users**. Then click the user or group that you want to view. The details pane shows the LUs and pools assigned to that user or group, plus other details, such as status and LU number.
2. To view local or remote APPC LUs assigned to a user or group, right-click the targeted user or group, and click **Properties** under **Configured Users**. Click the **APPC Defaults** tab. When you are done viewing, click **Cancel**.

To add 3270 LUs to a pool

1. In SNA Manager, expand **Servers**, and then expand the server you are working with.
2. Expand **Connections**, and then click the connection that contains the needed 3270 LUs.
3. In the right pane, right-click the 3270 LU that you want to assign and click **Assign Pool**.
4. In the dialog box, click the pool to which you want to assign the LU, and then click **OK**.
5. Repeat steps 2 and 3 for each LU that you want to assign to a pool.
6. On the **Action** menu, click **Save Configuration**.

   Note To verify that the LUs are in the correct pool, make sure the **Pools** node is expanded, double-click the name of the affected pool, and view its LUs in the details pane.

   Both the LUs and the LU pool must be of the same type (3270).

To add a workstation and assign LUs

1. In SNA Manager, right-click **Workstations**, point to **New**, and then click **Workstation**.
2. Fill in the **Workstation Properties** dialog box.
3. Click **OK** to add the new workstation.
4. To assign LUs to the workstation, double-click **Connections**, and then double-click the connection that contains the needed LUs.
5. Right-click the LU that you want to assign, and click **Assign to Workstation**.
6. In the dialog box, click the workstation, and then click **OK**.
7. On the **Action** menu, click **Save Configuration**.

   Note All workstation users must be members of the same SNA subdomain. You can avoid having to add each user to the subdomain by assigning the **Everyone** group to the subdomain and assigning no LUs to the group.

To remove an LU from a pool

1. In SNA Manager, click **Pools**.
2. Right-click the LU that you want to remove, and then click **Delete**.
3. In the **Confirmation** dialog box, click **Yes** to delete the LU.
4. On the **Action** menu, click **Save Configuration**.
5. On the **Action** menu, click **Refresh**.

   Note An empty pool provides no LU access.

See Also

Creating and Configuring LUs

Assigning LUs to Workstations

You can assign LUs to a workstation rather than a user, which makes it possible to lock LUs to a particular workstation. Assigning an LU to a workstation makes it easier for users to find and access different resources. For example, it makes it easier for a user at a workstation to use a printer located near the workstation, instead of one assigned to the user.

With this feature, you can insert a workstation object and define it by specifying parameters such as IP address, workstation name, and others. You can then assign 3270 display and printer LUs to the workstation. These LUs will be accessible to any users connecting from those workstations. The LUs do not need to be specifically assigned to the user.

For example, 200 hospital users share 50 workstations and 50 printers. Users may want to use any of the 50 workstations and 50 printers. They can log on to any of the 50 workstations and print using the printer attached to that workstation. Instead of assigning all 50 printers to 200 user accounts, the administrator can add the 50 workstations to Host Integration Server 2004 and assign a printer LU to each workstation. When a user logs on to any of the 50 workstations, the printer attached to that workstation will be available in the list of LUs.

You can also configure a workstation so that it will only allow the use of those LUs assigned to the workstation, regardless of the user who is logged on. You can assign LUs to workstations in the same manner that LUs are assigned to users.

For example, if the workstation is flagged for restricted access, a user cannot gain unauthorized access to other LUs regardless of the user ID and password that is used. This feature enhances network security.

To assign LUs to workstations

1. In the Host Integration Server 2004 console tree, right-click **Workstations**, point to **New**, and then click **Workstation**.
2. Fill in the **Workstation Properties** dialog box.
3. Click **OK** to add the new workstation.
4. To assign LUs to the workstation, click **Connections**, and then click the connection that contains the LUs.
5. Right-click the LU that you want to assign, and click **Assign to Workstation**.
6. Click the workstation, and click **OK**.
7. On the **Action** menu, click **Save Configuration**.

   Note All workstation users must be members of the same SNA subdomain. You can avoid having to add each user to the subdomain by assigning the **Everyone** group to the subdomain and assigning no LUs to the group.

Associating 3270 Printer LUs with 3270 Display LUs

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Associating 3270 Printer LUs with 3270 Display LUs

Users who have host applications with direct relationships between display LUs and printer LUs can associate printers with the LUs.

You can associate a printer LU with a display LU. This feature is designed to support specialized host applications that have hard-coded associations between display LUs and printer LUs. When a 3270 display LU is configured to have an associated printer and then subsequently assigned to a user or group, users will see both the display LU and a special printer LU named ASSOCPRT. When users connect to the display LU, they can then open the ASSOCPRT LU, which Host Integration Server 2004 maps to the defined associated printer LU.

You can also add display LUs with associated printer LUs to LU pools. The LU pools can then be assigned to users and groups.

When multiple display LUs are assigned to users, the order in which the resources are opened is important. If all of the display LUs have associated printers, the user should alternate opening displays and ASSOCPRTs. If some of the display LUs do not have associated printers, use a naming convention so the user can determine the display LUs that have associated printers from those that do not.

To associate printer LUs to display LUs

1. In the Host Integration Server 2004 console tree, click **Pools**.
2. Right-click the display LU that you want to associate with a printer, and click **Properties**.
3. Click the **Associated Printer** tab.
4. In the **Associated Printer LU** box, select the printer that you want to associate, and then click **OK**.
5. Repeat steps 2 through 4 for each display LU that you want to associate with a printer LU.
6. On the **Action** menu, click **Save Configuration**.

   Note Printer LUs are available to any users or groups that have been assigned the corresponding display LUs.

   Associated printer LUs are assigned a generic placeholder name of ASSOCPRT.

Assigning LUs to Workstations

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring Downstream Connections

You can configure Host Integration Server 2004 to enable downstream LUs to communicate with the host. Following are the general procedures:

1. Gather needed information about the host and downstream systems, including information about identifiers, such as addresses and exchange identification (XID), and information about Max BTU Length.
2. Configure the host connection as you would configure any other host connection. When specifying the remote end for the connection, select **Host System**.
3. Select the host connection and assign and configure one or more new downstream LUs.
4. Optionally, you can put downstream LUs into a pool to maximize their availability.
5. Configure the downstream connection. When specifying the remote end for the connection, select **Downstream**.

   The downstream connection can be an 802.2, SDLC, or X.25 connection. It cannot be a channel connection.

6. Select the downstream connection and associate the downstream LUs (from step 3) and LU pools (from step 4) with that connection.
7. If necessary, reorder the downstream LU numbers; that is, the LU numbers used by the downstream system.

   A downstream LU has two LU numbers: one recognized by the downstream system and one recognized by the host. These numbers need not match.

To put configuration changes into effect, save the configuration file and restart the server (if you have added a link service or connection).

> **Note** It is recommended that you manually separate the sessions of your downstream pools if you are upgrading from SNA Server 4.0 or later. If this is not done, you may experience incorrect behavior from Host Integration Server 2004 when attempting to connect downstream client computers.

After creating the downstream LUs, you must associate them with the downstream connection they will use. Downstream LUs do not stand alone and need to be mapped to the upstream LU. Associating the LUs with the upstream connection maps the correct downstream LUs to the correct upstream LUs.

Downstream LUs have two parameters:

- The LU number, which identifies the LU to the host.
- The downstream LU number, which identifies an LU or LU pool to the downstream system.

The LU number and the downstream LU number need not match, and probably will not match. The downstream LU number should match the LU number on the downstream system.

Check with the host administrator for the correct value of the LU number. It should match the LOCADDR= parameter of the LU definition in VTAM or in the NCP Gen. If the number you specify has already been assigned to an LU or an APPC LU-LU pair on the current connection, you must change the number. The range for LU numbers is 1 through 254.

Host Integration Server 2004 assigns a downstream LU number to each LU or LU pool assigned to the downstream connection. Host Integration Server 2004 assigns downstream LU numbers starting with 2 and ascending sequentially. Therefore, one way to change downstream LU numbers is to reorder the list of LUs for the downstream connection. Another way to change downstream LU numbers is to use empty LU pools to take up unwanted numbers, leaving the correct (larger) numbers for other LU pools or LUs.

> **Note** The LU numbers generated for an LU range are sequential. If the numbers assigned by your host administrator are not sequential, you can modify the numbers of individual LUs after they have been created.

You can move one or more downstream LUs to a different host connection, regardless of whether the LUs were created as part of a range. Although downstream LUs can be associated with multiple downstream connections, they can be assigned to only one host connection.

You can configure multiple LUs simultaneously by configuring them as a consecutively numbered range. After configuring the range of LUs, you can modify the numbering of individual LUs in the range.

To configure a downstream connection

1. In the Host Integration Server 2004 console tree, expand **Servers**, expand the server you are working with.
2. Right-click **Connections**, point to **New**, and click either **802.2**, **SDLC**, or **X.25**.

3. Fill in the **Connection Properties** dialog box, type a name for the new downstream connection, select a link service, and type a comment.
4. Under **Remote End**, select **Downstream**.
5. Under **Allowed Directions**, select an option. For SDLC downstream connections, select **Outgoing Calls**.
6. If you selected **Outgoing Calls**, under **Activation**, select either **On Server Startup** or **By Administrator**.
7. Click the other tabs to specify other connection parameters between the downstream system and Host Integration Server 2004. Click **OK** to exit.
8. On the **Action** menu, click **Save Configuration**.
9. To put the configuration changes into effect, you must restart the server.

   Note Restarting the server disconnects all users. Try to schedule configuration changes when they least affect users.

   Two connections are needed for a downstream system: a downstream connection (from the downstream system to the computer running Host Integration Server 2004) and an ordinary host connection (from the computer running SNA Server to the host).

   Activation does not affect incoming calls. A connection that accepts incoming calls begins to listen for these calls when the server node is started.

To assign a downstream LU to a host

1. Before you begin, verify that you have configured the host connection that the downstream LU will use.
2. Ensure that the server is inactive. If necessary, right-click the appropriate server node, and click **Stop**.
3. Double-click **SNA service**, and then double-click **Connections**.
4. Right-click the host connection to which you want to assign a downstream LU, point to **New**, and then click **Downstream LU**.
5. Enter the LU name. Click **OK** to exit.
6. On the **Action** menu, click **Save Configuration**.

   Note After you assign a new downstream LU to a host, you must also associate that LU with a downstream connection.

   A downstream LU pool must contain LUs from a single server. Downstream LUs cannot access pooled downstream LUs from multiple servers.

To view or modify a downstream LU

1. Right-click the LU whose properties you want to view, and click **Properties**.
2. In the **Properties** dialog box, do one of the following:
   - View the properties and click **Cancel**.
   - Modify the properties and click **OK**.
3. If you made changes, on the **Action** menu, click **Save Configuration**.
4. Stop and restart **SNA service**.

To assign a downstream LU

1. In the Host Integration Server 2004 console tree, expand **Servers**, expand the server you are working with, and then click **Connections**.
2. Right-click the host connection to which you want to assign the downstream LU, point to **New**, and click **Downstream LU**.
3. Fill in the **Connection Properties** dialog box, and click **OK**.
4. On the **Action** menu, click **Save Configuration**.

To associate a downstream LU with a downstream connection

1. Verify that the server is inactive. If necessary, right-click the service node and click **Stop**.
2. In the Host Integration Server 2004 console tree, select the downstream LUs from the host connection.

   To select several adjacent items, click the first item you want, hold down SHIFT, and click the last item.

   To select several nonadjacent items, hold down CTRL as you click the items that you want.

3. Drag the LUs from the host connection to the downstream connection.
4. On the **Action** menu, click **Save Configuration**.

    Important If a downstream system needs access to multiple LU sessions, assign one LU or LU pool for each session needed. You can assign a pool multiple times to the same downstream connection.

    Note Before you can associate downstream LUs with a downstream connection, you must define the host connection, downstream connection, and the LUs.

    Note Downstream LU pools must contain LUs from a single server. Downstream LUs cannot access pooled downstream LUs from multiple servers.

See Also

Creating and Configuring LUs

Reordering Downstream LUs

An administrator might create a downstream LU called DOWNLU3, and then realize that two additional LUs are needed. After creating the LUs, with the names DOWNLU2 and DOWNLU4, the LUs would be associated with the listed LU numbers.

LU name	**Downstream LU number**
DOWNLU3	2
DOWNLU2	3
DOWNLU4	4

To change the downstream numbers so that they match the digits in the LU names, DOWNLU2 could be reordered so that it is placed before DOWNLU3.

LU name	**Downstream LU number**
DOWNLU2	2
DOWNLU3	3
DOWNLU4	4

To reorder the numbering of downstream LUs

1. Verify that the server is inactive. If necessary, right-click the server node, and click **Stop**.
2. In the Host Integration Server 2004 console tree, select the downstream connection with which the LUs are associated.
3. Select one or more LUs and pools that you want to move up in the list.

   To select several adjacent items, click the first item you want, hold down SHIFT, and click the last item.

   To select several nonadjacent items, hold down CTRL as you click the items that you want.

1. To move LUs up or down in the list, click the up or down arrow buttons on the Host Integration Server 2004 toolbar.
2. To put configuration changes into effect, restart the server.

To create a downstream pool

1. Right-click **Pools**, point to **New**, and then click **Downstream LU Pool**.
2. Type a pool name and, if desired, a comment. This name identifies the pool on SNA Server, not on the host or downstream system.
3. To add LUs to the new downstream pool, double-click **Connections**, and then double-click the connection that has the LUs you want to work with.
4. Verify that the **Pools** node is fully expanded, and drag the first LU into the pool.
5. To add more LUs to the pool, drag each LU from its place in the **Connections** folder to its downstream LU pool.
6. On the **Action** menu, click **Save**.

   Note Downstream LU pools must contain LUs from a single server. Downstream LUs cannot access pooled downstream LUs from multiple servers.

Creating and Configuring LUs

Configuring APPC LUs for TPs or 5250 Emulation

The following is an overview of the procedures to add and configure APPC LUs:

1. Assign the local APPC LU to a server.
2. Configure the local APPC LUs:
    - For an independent LU, specify the LU Alias, Network Name, and LU Name. Depending on system configuration, you may need to specify other information.
    - For a dependent LU, specify LU Alias, LU Number, and LU Name. Depending on system configuration, you may need to specify other information.
3. Create a remote APPC LU on a connection and configure the remote APPC LU:
    - For a remote LU to be used with an independent local LU, specify the LU Alias, Network Name, and LU Name. Depending on system configuration, you may need to specify other information. For communication with an AS/400 computer, make the remote LU name the same as the name of the AS/400 computer.
    - For a remote LU to be used with a dependent local LU, specify the LU Alias, Network Name, LU Name, and Uninterpreted LU Name. Depending on system configuration, you may need to specify other information.
4. Optionally, configure session security for the remote LU.
5. You must configure an appropriate mode if it has not already been done.
6. Optionally, assign a default local APPC LU and a default remote APPC LU to users and groups.
7. If you are using Common Programming Interface for Communications (CPI-C), configure one or more CPI-C symbolic destination names.
8. If you are using the display verb, you may want to change the default connection that Host Integration Server 2004 uses for the verb. To ensure that all changes take effect, restart the server.

    Note APPC LUs are used for transaction programs (TPs) or for 5250 emulation. APPC LUs used with TPs are generally for communication between TPs on different systems, not communication between TPs on a single system.

To add local and remote APPC LUs

1. In the Host Integration Server 2004 console tree, double-click **SNA service**, and then click **Local APPC LUs**.
2. On the **Action** menu, point to **New**, and click **Local LU**.
3. Configure the properties for the local LU, and then click **OK**.
4. To add the remote LU, click **Remote APPC LUs**.
5. On the **Action** menu, point to **New**, and click **Remote LU**.
6. Configure the properties for the remote LU, and click **OK**.
7. On the **Action** menu, click **Save Configuration**.

    Note APPC uses both local and remote LUs. These LUs need to be properly configured before Host Integration Server 2004 can communicate with the AS/400 computer.

    The option, **Member of Outgoing Local APPC LU Pool**, differs from other types of LU pools, such as the 3270, LUA, and downstream LU pools.

    Configuring session security for remote LUs is optional.

To configure incoming APPC sessions

1. Verify that you have configured a remote LU to represent the incoming host or that you have configured one remote LU for each host.
2. In the Host Integration Server 2004 console tree, double-click **Local APPC LUs**, and then click the local LU that you want to configure.
3. On the **Action** menu, click **Properties**.
4. Click the **Advanced** tab, specify the **Implicit Incoming Remote LU**, which is the name of the incoming host, and then click **OK**.
5. Repeat steps 2–4 for each local APPC LU that you want to configure.
6. On the **Action** menu, click **Save Configuration**.

Note All incoming requests must specify a local LU name that is recognized by Host Integration Server 2004, even when using an Implicit Incoming Remote LU and Implicit Incoming Mode.

To assign default APPC LUs to users or groups

1. In the Host Integration Server 2004 console tree, double-click **Configured Users**, and click the user or group that you want to configure.
2. On the **Action** menu, click **Properties**.
3. Click the **APPC Defaults** tab.
4. In the **Local APPC LU** box, select a default local APPC LU.
5. In the **Remote APPC LU** box, select a default remote APPC LU, and then click **OK**.
6. On the **Action** menu, click **Save Configuration**.

Precedence of Accounts in Determining Default LUs

When user and group account memberships overlap, the highest-priority account that contains a default local APPC LU determines that LU for the user, and the highest-priority account that contains a default remote APPC LU determines that LU for the user. Accounts are prioritized as follows:

1. User accounts (highest priority)
2. Subdomain groups
3. Local groups
4. Well-known groups such as Everyone (lowest priority)

For example, suppose a user account (a high-priority account) called JOHND contains LOCLU1 as the default local APPC LU, but no default remote APPC LU. At the same time, suppose a local group (a low-priority account) of which JOHND is a member contains LOCLU2 as the default local APPC LU, and REMLU2 as the default remote APPC LU. For JOHND, the high-priority assignment, a default local APPC LU of LOCLU1, will be combined with the only other available assignment, a default remote APPC LU of REMLU2.

To assign or edit CPI-C information

1. In the Host Integration Server 2004 console tree, click **CPI-C Symbolic Names**.
2. On the **Action** menu, point to **New**, and click **CPI-C Symbolic Name**.
3. Fill in the **Properties** dialog box, and click **OK**.
4. On the **Action** menu, click **Save Configuration**.

   Note If you are using applications based on Common Programming Interface for Communications (CPI-C), use this procedure to configure the CPI-C symbolic destination name.

To configure the default display verb

1. In SNA Manager, select the subdomain that you want to configure.
2. On the **Action** menu, click **Properties**.
3. Click the **Display Verb** tab.
4. Select the default connection for the display verb, and click **OK**.
5. On the **Action** menu, click **Save Configuration**.

   Note When the display verb does not specify a connection, Host Integration Server 2004 uses the connection that you specify in this procedure. If you do not specify a default display verb connection, Host Integration Server 2004 randomly selects a connection for the verb to use.

To configure hot backup for 5250 LUs

Configuring hot backup involves setting up a system environment in which one resource can automatically fill in if another fails. In such a configuration, resources are interchangeable.

1. Configure one connection to the AS/400 computer for each computer that runs Host Integration Server 2004 and supports the 5250 protocol.
2. Create a local LU on each server, specifying the following:
   - For **LU 6.2 Type**, select **Independent**.
   - For **LU Alias**, specify the same string on each server.
   - For **LU Name**, specify a unique string on each server. This is required to avoid device name conflicts across servers.
3. Create a remote LU on each server and give all the remote LUs the same LU name and alias, (which must match the Control Point Name of the AS/400 computer).

   Be sure that the **Supports Parallel Sessions** box is selected for these LUs.
4. Make the local and remote LUs available to users and groups, by doing one of the following:
   - For each group or user that uses 5250, select the appropriate default local APPC LU and the appropriate default remote APPC LU.
   - To keep this process simple, use or create a group that includes all 5250 users, and assign the appropriate default LUs

to that group.

- For the 5250 emulator, have users specify the local and remote LUs when configuring a session on the emulator.

Note To achieve hot backup, Host Integration Server 2004 chooses a server to connect with the AS/400 computer based on availability. This distributes the load more evenly.

To configure hot backup for 5250 users, you must configure multiple servers and pairs of LUs that can all handle sessions to the intended AS/400 computer.

For better protection against failure, use multiple servers, and not multiple connections on the same server.

To configure a server with multiple connections to the same AS/400 computer

1. In the Host Integration Server 2004 console tree, double-click **Connections**.
2. Click the first connection that you want to configure.
3. On the **Action** menu, click **Properties**.
4. Click the **System Identification** tab, and fill in the properties for the local and remote node.
5. Click **OK** to exit the dialog box.
6. Repeat steps 2 through 5 for each connection to the same AS/400 computer.
7. On the **Action** menu, click **Save Configuration**.
8. After you configure a connection, you must stop and restart the server.

Important Each connection to the same AS/400 computer must use a separate link service.

Note This procedure makes the fully qualified network name unique for each connection.

The settings that you specify in this procedure override the fully qualified network name configured in the properties for the server.

To configure a connection for dynamic definition of remote APPC LUs

1. Select the connection that you want to configure.
2. On the **Action** menu, click **Properties**.
3. On the **General** tab in the **Properties** dialog box, select **Supports Dynamic Remote APPC LU Definition**, and click **OK**.
4. On the **Action** menu, click **Save Configuration**.

Configuring APPC LUs for TPs or 5250 Emulation

Managing Users

Although Host Integration Server 2004 utilizes the User accounts of the Microsoft® Windows Server™ 2003 or Windows® 2000 Active Directory® directory service, users must be configured to use Host Integration Server 2004 resources such as LUs.

To create users

1. In SNA Manager, expand the SNA subdomain where the users reside.
2. Right-click **Configured Users**, point to **New**, and then click **User**.
3. Select a user (or group) from the list, and click **OK**.

To view active 3270 users

1. In SNA Manager, expand **Servers**, and then expand the server you are working with.
2. Click **Active Users**. The results pane shows the active 3270 users and provides details such as **User Name**, **Client**, and **Server**.

Application Integration User's Guide

Transaction Integrator (TI) is the synchronous COM+ or .NET application integration solution in Microsoft® Host Integration Server 2004. TI enables you to integrate mainframe-based transaction programs (TPs) and AS/400 transactions with component-based Windows Server System™ applications under the following conditions:

- A synchronous or transactional solution is needed
- Both the client and server systems are running at the time the call is made

If you need an application integration solution that does not require the client and server systems to be running at the time the call is made, use an asynchronous messaging solution such as the MSMQ-MQSeries Bridge instead of TI. In an asynchronous solution, the middle-tier queuing system is running at the time the client issues a request message, the server retrieves the message and sends back the reply, and then the client receives the reply back from the middle tier.

With TI, you can integrate existing mainframe-based TPs with Windows-based COM, distributed COM (DCOM), or .NET applications. You might not even have to modify your TP if you have separated the business logic from the presentation logic. The wizards in TI guide you through the modification process, step by step.

With TI, you can preserve existing CICS and IMS TPs as you move to a three-tier client/server or Web-to-host computing environment. By using TI to invoke mainframe transactions, you can program in the visual object-oriented environments and programming languages that you know while you maintain access to host transactions.

TI supports both SNA connectivity and TCP/IP connectivity without requiring a host footprint or costly host transaction rewrites. You can choose SNA connectivity if you need two-phase commit (2PC), or choose TCP/IP connectivity if you need direct throughput. IBM has not implemented 2PC for the TCP/IP protocol, but for those cases where 2PC is not necessary, TCP/IP can give you direct connectivity.

True integration of online transaction processing (OLTP) with COM- or .NET-compliant systems means the integration of CICS and IMS with Windows-based solutions. CICS and IMS are widely used in the mainframe arena to create distributed OLTP solutions such as customer tracking and order entry. TI integrates CICS and IMS with COM by creating COM interfaces or .NET interfaces to the CICS and IMS transactions and then running the CICS and IMS transactions on the mainframe from Windows.

A TI component in a COM+ application works in concert with the TI run-time environment, Microsoft Distributed Transaction Coordinator (MS DTC), and the associated remote environment (RE) to drive a CICS or IMS TP. Together, they accomplish these tasks:

- Activate the host (mainframe) TP.
- Pass the parameters specified by the TI component to the TP.
- Run the TP.
- Return the results to the TI component.

Once you deploy a TI component (a type library .tlb file) in a COM+ application, that COM+ application becomes a TI *Automation server*. When a client application invokes a method in that TI Automation server, Windows automatically starts the TI run-time environment in the associated remote environment to invoke the mainframe transaction that is associated with that TI method. Component Services in Windows 2000 automatically handles any class factory, early or late binding, or other internal operations needed. The invoked mainframe transaction can call other transactions on the mainframe before it returns the result to the COM-based client application through the TI Automation server.

Introduction to Host-Initiated Processing

This section features an example of communication between a central data center and multiple branch offices. It shows how the Host-Initiated Processing (HIP) feature of Microsoft® Host Integration Server 2004 enables such communication.

An important goal of a successful enterprise organization is to reduce costs and increase profitability. One approach to achieving this goal is to improve operating efficiency and streamline the production process. A common obstacle to achieving this goal is the cost of integrating legacy data-storage systems with newer desktop systems often used at remote sites.

A typical enterprise organization might run its daily operations using mission-critical applications composed of customized COBOL programs running in an IBM MVS environment either as scheduled batch jobs or as online programs in CICS and IMS transaction programs. Such an organization faces the challenge of bringing data from external sources into the legacy batch processing flow without disrupting predefined automated processing schedules.

These external sources are likely to be based on new Windows®-based computing solutions—for example Microsoft SQL Server™ and Microsoft BizTalk® Server—that offer qualities such as performance, scalability, and reliability. Taking advantage of emerging Windows-based technologies and integrating them with legacy business processes can be daunting for most IT departments, because the organization must invest in costly and complex development programs to build applications to achieve that integration.

Microsoft Host Integration Server 2004 offers a variety of tools that help you effectively and rapidly implement new integration solutions. The Host-Initiated Processing (HIP) feature enables you to build applications that integrate resources like SQL Server databases, BizTalk orchestration schedules, BizTalk messaging, and Microsoft Exchange Server with enterprise application processes that drive data acquisition from those Windows-based resources.

HIP is composed of three core features:

- **Transaction Integrator Designer.** You use Transaction Integrator Designer to build and deploy integrated business processes that are initiated from IBM legacy batch processing jobs or CICS and IMS transaction manager environments so that they can easily and seamlessly access services and resources in the Microsoft Windows environment (for example, COM+, the NET Framework, BizTalk Server).
- **Transaction Integrator Manager.** You use Transaction Integrator Manager to configure endpoints, associate resources with requests, and define security and access rules. With TI Manager, you can easily integrate IBM client application programs and Windows services and resources.
- **HIP Service.** The HIP Service is a run-time service that manages the Windows communications endpoint for accepting requests from programs in an IBM environment, presenting the requests to a Windows resource, and returning the resulting information from the resource to the requesting IBM application program.

The example presented in this section shows how you can use HIP to integrate processes between legacy and Windows-based applications.

This section contains:

- A Typical Banking System Using Legacy Processes
- How HIP Can Help to Streamline the Processes

A Typical Banking System Using Legacy Processes

Enterprise organizations using IBM operating environments like MVS, CICS, and IMS need solutions for automatically incorporating data from remote sites and for integrating this information into existing business processing systems. Enterprise organizations also need to release knowledge workers from constraints imposed by the data center's schedules, resources, and computing capacity, especially when the processes are periodically run under control of an automated scheduling system.

The following three situations exemplify these needs:

- Legacy batch processing systems need to routinely pull information from one or more remote sites.
- Existing batch processing systems or online transaction programs need to push periodic updates to remote sites.
- Online transaction programs need to report, log, or notify knowledge workers of sales or business activity.

A typical enterprise organization uses large IBM mainframe systems running MVS or z/OS in a centralized data center, and small and mid-range systems running OS/400, MVS, or z/OS at remote sites.

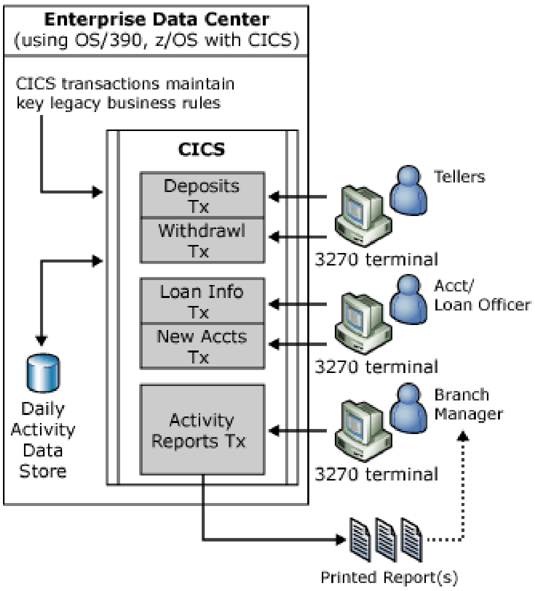
The following topics describe typical enterprise environment operations within a banking system, and how knowledge workers interact with that system.

This section contains:

- Legacy Online Activity
- Legacy Off-Peak Batch Processing
- Legacy Batch Processing Systems Updating Branch Offices
- Legacy Systems Handling Notification Requests

Legacy Online Activity

The following diagram shows an enterprise environment in which a central data center maintains the data store and legacy business rules in online processing systems. Daily transactions are collected and maintained in a data store for subsequent processing during off-peak hours. Businesses that typically operate under these rules include banks, insurance companies, and subscription fulfillment firms.



Enterprise Data Center
(using OS/390, z/OS with CICS)
CICS transactions maintain key legacy business rules
CICS
Deposits Tx
Withdrawl Tx
Loan Info Tx
New Accts Tx
Activity Reports Tx
Daily Activity Data Store
Tellers
3270 terminal
Acct/ Loan Officer
3270 terminal
Branch Manager
3270 terminal
Printed Report(s)

The activities illustrated are:

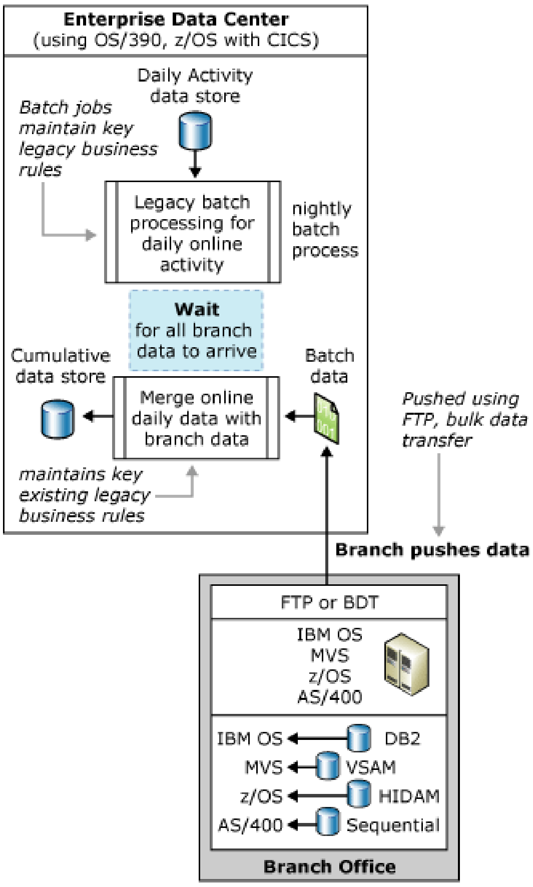
- Online bank teller activity occurs throughout business hours, using standard IBM 3270 terminal devices.
- Online account and loan officer activity occurs throughout business hours, using standard IBM 3270 terminal devices.
- Data is captured for later processing during off-peak hours. Legacy business rules are applied to the daily data captured during online entry.
- The branch manager requests periodic reports. These requests are made from standard IBM 3270 terminal devices to a CICS transaction. The reports are typically printed to an IBM 3270 printer at the remote location.
- The report is generated by the CICS transaction and sent to a standard IBM 3270 printer at the remote site. The branch manager can then review the printed report material.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Legacy Off-Peak Batch Processing

The following diagram continues the banking application scenario by showing the central data center that maintains the data store and legacy business rules in the batch processing system. The central data center uses the daily transaction activity from online processing and merges additional business data from branch offices.

When all daily activity is available, merging and final processing can continue. The final processing must be complete before the organization opens for business the next day. This makes the business processes very time-sensitive.



Enterprise Data Center
(using OS/390, z/OS with CICS)
Daily Activity data store
Batch jobs maintain key legacy business rules
Legacy batch processing for daily online activity
nightly batch process
Wait for all branch data to arrive
Cumulative data store

FTP or BDT
IBM OS
MVS
z/OS
AS/400
IBM OS
DB2
MVS
VSAM
z/OS
HIDAM
AS/400
Sequential
Branch Office

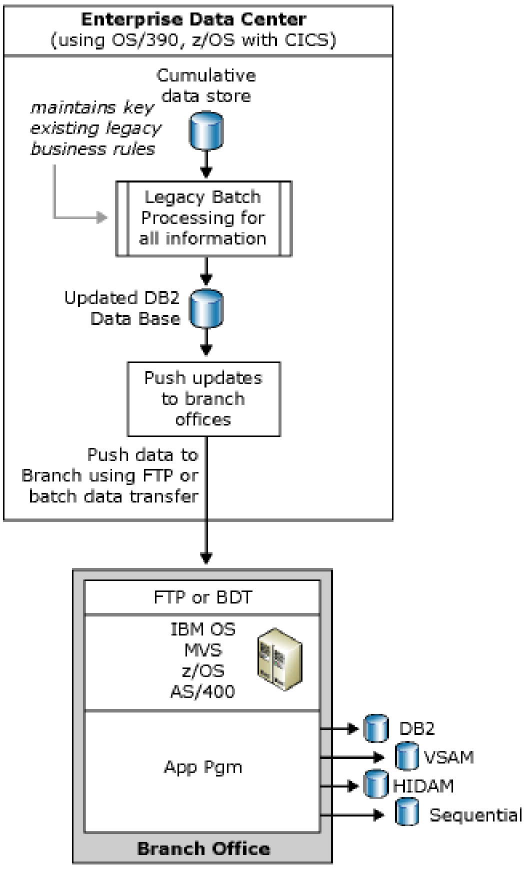
The activities illustrated are:

- Data is collected from online activity processed during off-peak hours. Validation is performed by batch jobs that correlate and apply legacy business rules to this raw transaction data.
- The central data center includes the data from remote sites in the processing stream.
- The data center processing schedule is delayed until all the branch offices have delivered their daily data, typically through bulk data transfers (BDT), File Transfer Protocol (FTP), or file drop procedures. The length of the delay can be affected by geographic locations of the branch offices, staffing, and availability of the processing systems at the branch offices.
- Each branch office typically delivers its daily activity data through BDT, FTP, or file drop procedures that are manually initiated.
- After all branch office data is available to the central processing system, the validated online activity data from the central data center and the remote site data are merged to produce a cumulative image of the daily activity.

Legacy Batch Processing Systems Updating Branch Offices

The following diagram continues the banking application scenario by showing business processes that occur after the cumulative data is available at the central data center.

Before the organization opens for business the following day, the data center must apply business rules to the cumulative data and must make the online systems available for the next day. Delays in this process can be expensive and can damage trust on the part of the branch offices.



Enterprise Data Center
(using OS/390, z/OS with CICS)
Cumulative data store
maintains key existing legacy business rules
Legacy Batch Processing for all information
Updated DB2 Data Base
Push updates to branch offices
Push data to Branch using FTP or batch data transfer
FTP or BDT
IBM OS
MVS
z/OS
AS/400
App Pgm
DB2
VSAM
HIDAM
Sequential
Branch Office

The activities illustrated are:

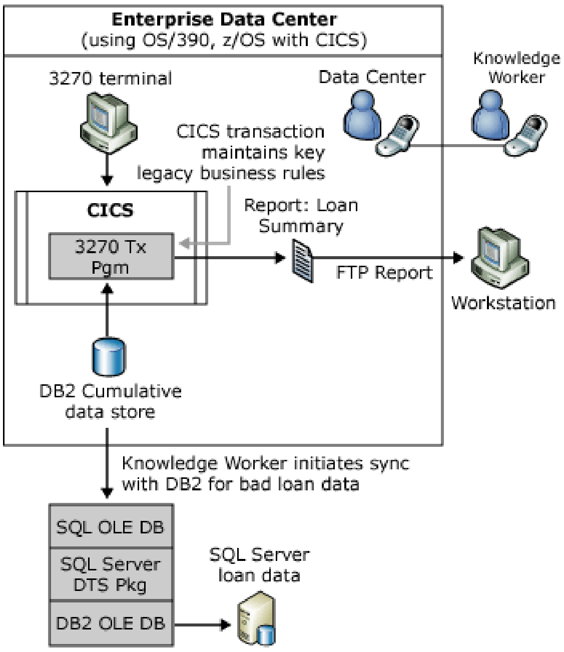
- The cumulative data store is made available for continued processing. Legacy business rules are applied to the data through batch processing.
- Legacy business processes eventually update the central data center’s data repository.
- The final batch processing step is to distribute the information to the branch offices. This process is accomplished by techniques similar to those that initially receive the data from the remote sites (BDT, FTP, or file drop).
- There can be logistics problems (from the central data center’s perspective) in getting the branch office data stores updated with accurate and timely information. The process can be affected by the reliability of the branch office operations staff and availability of their processing systems. If any one of the branch offices does not successfully receive and update the data stores, the business as a whole is adversely affected.
- Each branch office must receive the information and update its local data store.

Legacy Systems Handling Notification Requests

Additional workloads can be placed on the central data center's processing capacity when knowledge workers request special information that is maintained in the central data center's repositories. This information could be raw data, preprocessed data, or summarized reports.

In legacy processing systems there can be long delays between the time a request is made and the time the information can be delivered to the knowledge worker. These delays are typically due to limited central data center resources used to analyze the request and present the data, or to limited processing capacity for handling special requests.

The following diagram continues the banking application scenario by showing a typical delivery of information (such as sales forecasts, financial updates, or budget changes) to knowledge workers throughout the organization. A knowledge worker can request some of this information on an as-needed or periodic basis.



Enterprise Data Center
(using OS/390, z/OS with CICS)
3270 terminal
Data Center
Knowledge Worker
CICS transaction maintains key legacy business rules
CICS
3270 Tx Pgm
Report: Loan Summary
FTP Report
Workstation
DB2 Cumulative data store
Knowledge Worker initiates sync with DB2 for bad loan data
SQL OLE DB
SQL Server DTS Pkg
DB2 OLE DB
SQL Server loan data

The activities illustrated are:

- A knowledge worker calls the data center and makes a special request.
- The data center accepts the call, identifies the calling individual, and determines the nature of the request.
- The data center starts an online transaction to satisfy the request.
- The online transaction produces the requested information.
- Reports are sent to the requesting knowledge worker.
- The knowledge worker begins a manual process to synchronize the data repository in the IBM environment (DB2) with the local repository (SQL Server). This allows the knowledge worker to produce custom reports that help improve the corporate processes (such as bad loans, mortgages, or overdraft accounts).

How HIP Can Help to Streamline the Processes

The challenge for most organizations is to design and implement a comprehensive solution that is reliable and that seamlessly fits into the data center's established legacy processing procedures and schedules. Technical issues surrounding this challenge include:

- Building customized reliable data transfer application programs and procedures.
- Allowing remote sites to use new emerging technologies (Windows, SQL Server, BizTalk Server, the .NET Framework, COM+) to improve operating efficiency while maintaining compatibility with legacy data center processing procedures.
- Moving away from the manual scheduling procedure of legacy procedures to automated scheduling and automatic execution of new procedures associated with local or remote sites.

The Host-Initiated Processing (HIP) feature of Host Integration Server 2004 delivers a simple solution that enterprise organizations need to bridge the gap between old and new technologies. HIP is highly scalable, high performing, robust, and easily administered for integrating legacy processing procedures with the Windows Server System™ environment.

The following topics describe how the use of HIP and .the NET Framework can assist with integration in the banking application scenario.

This section contains

- Integration Objectives
- Providing Data Center and Remote Site Independence
- Using Host-Initiated Processing

Integration Objectives

This scenario integrates legacy enterprise business processing systems and rules that are maintained in a centralized data center with remote site operations. Its objectives are:

- Use Microsoft technologies to improve site cost effectiveness, efficiency, and operations while allowing the central data center to maintain its investment in legacy business rules captured in the COBOL application programs.
- Provide seamless integration of existing data center processing procedures with new business systems written for Microsoft environments.
- Provide access to Microsoft Windows services through standard IBM operating systems, transaction manager facilities, and data sources that are familiar to individuals working in those IBM environments.
- Allow the central data center to use less costly human resources to develop portions of the solution, reserving more expensive personnel resources to maintain the legacy systems and lend support to integration with new business rules on Microsoft server platforms.

The next section describes how these objectives can be applied to assist an enterprise customer to improve business operations.

Providing Data Center and Remote Site Independence

The organization’s central data center is the reliable and secure place to maintain the corporate data. However, it can be time-consuming and costly for the data center staff to satisfy special requests for data and information. Remote sites are often better equipped for such tasks.

However, in cases where the remote sites are running small IBM systems (for example, OS/400, OS/390, or z/OS), the cost to maintain, enhance, and customize the application systems running there can be staggering. These costs include hardware, operating system software, and application systems. Perhaps the most costly are the human resources necessary to work on these legacy systems. Few knowledgeable COBOL programmers are available. People who can effectively and efficiently maintain MVS operating systems are rare, as are those who are competent in CICS and IMS system generation and maintenance.

In the IBM operating environment, it is difficult to react quickly to customer needs. Using Microsoft technologies to run day-to-day business at remote sites enables those sites to improve their operating efficiency and to gain flexibility. In turn, this enables them to provide a personal level of contact and support for their customers.

Integration of data between the data center and remote sites using Microsoft technologies must be seamless and efficient. After this is accomplished, the data center benefits from not dealing with special requests for information, and the remote sites gain the flexibility to manage local business operations in a manner that benefits customer relations.

Using Host-Initiated Processing

Inserting host-initiated processing into the legacy business processing model can streamline the data center operations with little impact on the legacy system processing architecture.

The banking scenario described earlier can be made more efficient and cost effective by:

- Replacing legacy remote site operating environments with streamlined systems based on Microsoft technologies (Windows Server™ 2003, the .NET Framework, COM+, SQL Server, and BizTalk Server).
- Allowing the knowledge worker to use the Transaction Integrator feature to subscribe to data and information that is maintained by the central data center and updated on a periodic basis.
- Using the Host-Initiated Processing (HIP) feature to systematically pull data from remote sites.
- Using HIP to systematically update remote site data stores.
- Using HIP to notify knowledge workers about information availability.
- Using HIP to automatically deliver or synchronize custom data with knowledge workers.

The following topics describe a similar banking system that takes advantage of the capabilities of the Host Integration Server 2004 HIP feature.

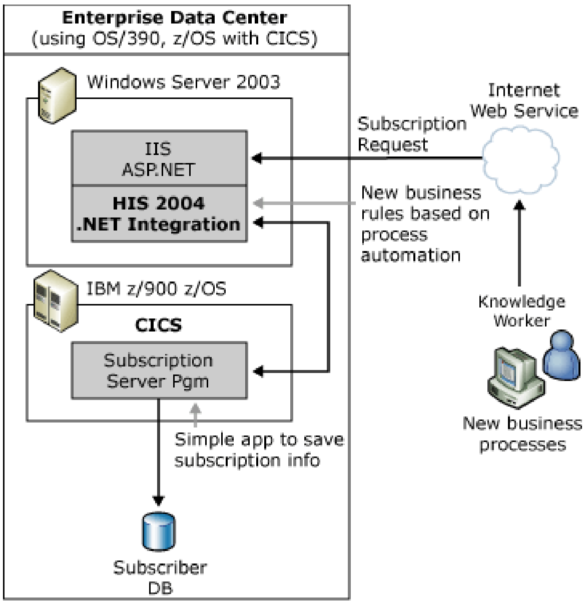
This section contains:

- Subscribing to Data Center Services
- Updated Online Activity
- Automated Accumulation of Business Data
- Distributing Information by Pushing Updates
- Distributing Information by Pulling Updates

Subscribing to Data Center Services

It is time and resource intensive for a knowledge worker to repeatedly request data or information from a data center. The .NET Framework application integration feature of Host Integration Server 2004 enables the knowledge worker to use Microsoft technologies to make such a request just one time. After the request is made, the central data center can periodically deliver the information to the knowledge worker any time that it is available.

The following diagram shows the banking scenario using .NET Framework application integration.



Enterprise Data Center
(using OS/390, z/OS with CICS)
Windows Server 2003
IIS
ASP.NET
HIS 2004
.NET Integration
IBM z/900 z/OS
CICS
Subscription
Server Pgm
Simple app to save subscription info
Subscriber DB
Internet Web Service
Subscription Request
New business rules based on process automation
Knowledge Worker
New business processes

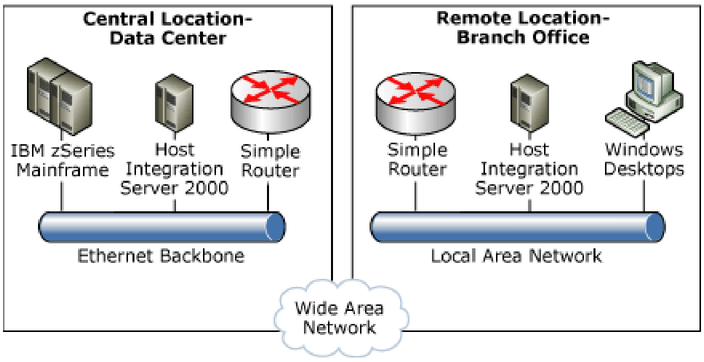
The activities illustrated are:

- The knowledge worker uses Microsoft technologies to manage customer relationships and business processes at the remote site.
- The knowledge worker uses the .NET Framework and the Host Integration Server 2004 .NET Integration Web Service to build new business rules and to subscribe to the central data center for periodic custom information updates and other notifications.
- The new business rules are based on the .NET Framework and on Web services that are part of the Host Integration Server 2004 .NET Integration feature.
- The Host Integration Server 2004 .NET object executes a CICS subscription transaction that records the subscription request.
- The request is recorded to a subscriber database for later use in the existing business processing system.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Updated Online Activity

The following diagram shows the updated banking application scenario. This enhanced online transaction processing system uses HIP to automatically deliver report data to a Web site so that branch managers and knowledge workers can access the information using robust new technologies that provide high availability.



Central Location-
Data Center
IBM zSeries Mainframe
Host Integration Server 2000
Simple Router
Ethernet Backbone
Remote Location-
Branch Office
Simple Router
Host Integration Server 2000
Windows Desktops
Local Area Network
Wide Area Network

The activities illustrated are:

- Online bank teller activity occurs throughout business hours, using standard IBM 3270 terminal devices.
- Online account and loan officer activity occurs throughout business hours, using standard IBM 3270 terminal devices.
- Data is captured for later processing during off-peak hours. Legacy business rules are applied to the daily data captured during the online entry.
- Based on subscription information provided at an earlier time, an online transaction constructs a report or raw data that is automatically delivered, using HIP, to a predefined Web site or Web service.
- A knowledge worker can generate custom reports to meet customer needs. A branch manager can either view the requested reports through an easy-to-use Web service or view the raw data on the Web site. The availability of the data on the Web site is now independent of the central data center's schedule.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

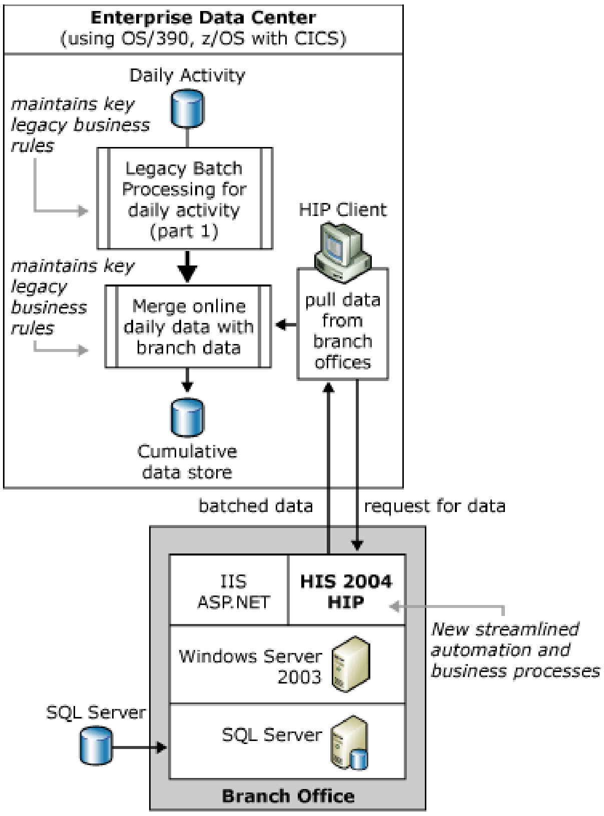
Automated Accumulation of Business Data

While the knowledge worker drives the process of subscribing to the central data center for updates, the central data center should control the process of accumulating daily data from the remote sites. The central data center's control of the data acquisition process removes barriers to timely processing of all data by the organization as a whole.

Remote sites have different needs. They need to have their daily data available from the central data center when they need it, which is typically outside the normal business hours for the remote site.

The remote sites also need to have the freedom and flexibility to develop new business rules that improve their customer partnerships. The use of Microsoft technologies such as SQL Server, BizTalk Server, the .NET Framework, and Web services can help the remote sites achieve their specialized and responsive needs.

The HIP feature brings together these disparate processing models by providing a way to easily insert steps into legacy batch processing systems to retrieve data from an intelligent remote site and seamlessly present the data to an existing business process.



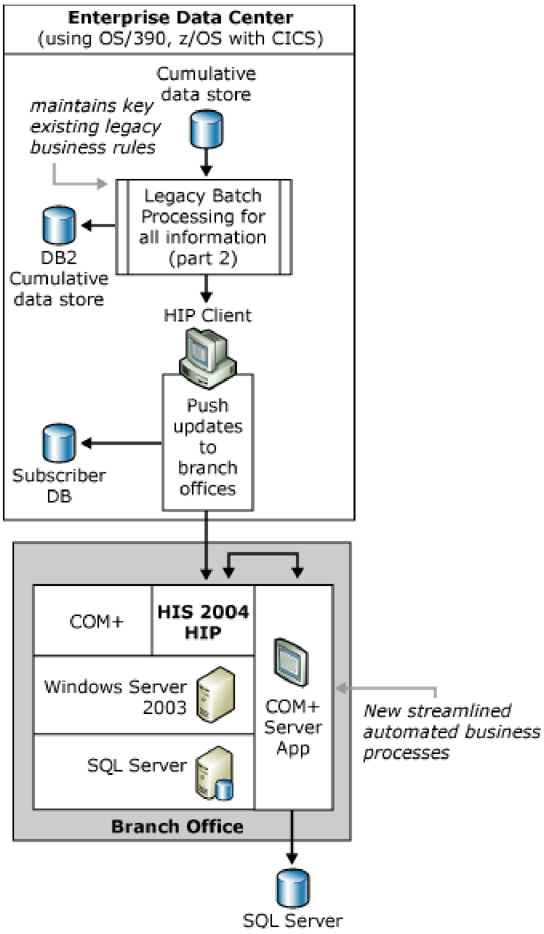
Enterprise Data Center
(using OS/390, z/OS with CICS)
Daily Activity
maintains key legacy business rules
Legacy Batch Processing for daily activity (part 1)
HIP Client
maintains key legacy business rules
Merge online daily data with branch data
pull data from branch offices
Cumulative data store
batched data
request for data
IIS ASP.NET
HIS 2004 HIP
New streamlined automation and business processes
Windows Server 2003
SQL Server
SQL Server
Branch Office

The activities illustrated are:

- The daily online activity data is presented to the batch processing system that is run during off-peak hours. Validation, correlation, and the merging of business rules are applied to this data in preparation for subsequent processing.
- A step (an application program), which acts as a HIP client, is inserted into the legacy batch processing system to retrieve data from each remote site. This application program can be written in a language that is familiar to people who work in IBM environments (for example, COBOL). This step in the legacy batch processing system contacts each site and retrieves the daily data.
- The central data center processing does not have to "wait" for the remote site to deliver the data.
- The remote site does not have to be attended.
- The HIP client accepts the request, activates the COM+ or .NET object, and returns data in a form that is native to the legacy IBM operating environment (for example, COBOL copybook data constructs). This information is then presented to the existing batch processing system, usually in the form of a sequential file.
- The daily data from the central data center and the remote sites is merged into a cumulative data store that is maintained at the central data center.

Distributing Information by Pushing Updates

The following diagram shows subsequent business processes performed on the cumulative data collected by the central data center. Before the organization opens for business the following day, the data center must apply its business rules against the cumulative data and make the online systems available for the next day of business.



Enterprise Data Center
(using OS/390, z/OS with CICS)
Cumulative data store
maintains key existing legacy business rules
Legacy Batch Processing for all information (part 2)
DB2 Cumulative data store
HIP Client
Push updates to branch offices
Subscriber DB
COM+
HIS 2004 HIP
Windows Server 2003
SQL Server
COM+ Server App
New streamlined automated business processes
Branch Office
SQL Server

The activities illustrated are:

- The cumulative data store is available for continued processing at the central data center. Legacy business rules are applied to the data and the central data store is updated.
- A batch processing step uses the information that was previously entered into the subscription database to distribute the updates to the remote sites.

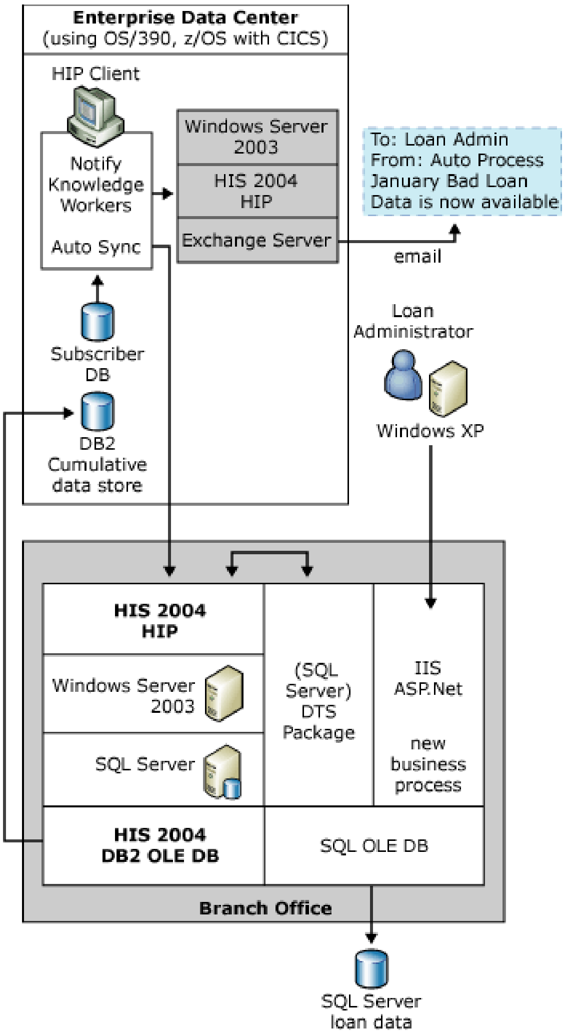
The batch processing step eliminates the need for manual or attended operations at the remote site by using HIP to automatically push the updates to the Windows environments.

Each remote site uses a HIP server application to automatically receive the updates and apply them to the local data store.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Distributing Information by Pulling Updates

The following diagram shows a process by which SQL Server uses notification messages to inform knowledge workers that product processing or requested data is available and to initiate the data synchronization process between central and remote site repositories.



Enterprise Data Center
(using OS/390, z/OS with CICS)
HIP Client
Notify Knowledge Workers
Auto Sync
Subscriber DB
DB2 Cumulative data store
Windows Server 2003
HIS 2004 HIP
Exchange Server
To: Loan Admin
From: Auto Process
January Bad Loan
Data is now available
email
Loan Administrator
Windows XP
HIS 2004 HIP
Windows Server 2003
SQL Server
(SQL Server) DTS Package
IIS ASP.Net
new business process
HIS 2004 DB2 OLE DB
SQL OLE DB
Branch Office
SQL Server loan data

The activities illustrated are:

- HIP is used to start two concurrent processes. This batch processing step sends a notification e-mail message to knowledge workers who previously subscribed to such messages. It also initiates the automatic synchronization of the updated DB2 data store on the IBM mainframe with the remote site SQL Server repository.
- The HIP client delivers a message, generated from a COBOL program, to a Windows COM or .NET object through HIP. This object interprets the message and delivers a message through Exchange Server to notify a set of knowledge workers that specific business processes have been completed.
- At the same time, the HIP client initiates a Data Transformation Services (DTS) package in COM+ that uses the HIS DB2OLEDB and SQLOLEDB providers to automatically retrieve data from DB2 and update the SQL repository.
- Finally, the knowledge worker uses Web services to access the information in the updated SQL repository, independent of the central data center's schedule and availability.

Installing Transaction Integrator

Transaction Integrator (TI) is installed and configured as part of the Host Integration Server 2004 Server Installation Wizard. You can install and configure TI at the time you first install Host Integration Server 2004 Server, or you can use the Host Integration Server 2004 Installation Wizard to add TI at a later time. The HIS 2004 Server Installation Wizard installs everything you need, including program files, Help files, the CedarBank sample application, and other tools. The main hardware and software requirements for TI are the same as for Host Integration Server 2004.

To install Transaction Integrator

1. Launch Host Integration Server 2004 Server setup and accept all defaults until you reach the **Custom Installation** page.
2. On the **Custom Installation** page, expand the **Application Integration** node.
3. Select **Transaction Integrator** and any other options.
4. Click **Next**, and then follow the directions on screen.

See Also

Installation

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Remotely Administering Transaction Integrator

Transaction Integrator (TI) does not support remote installation or configuration, and it does not support remote administration of Windows-initiated processing (WIP) except through use of the Windows Remote Desktop. TI does support remote administration of host-initiated processing through the use of TI Manager and the Remote Desktop. TI also supports the use of remote SQL Server databases.

Remote Installation and Configuration

TI must be installed and configured locally, and TI does not support remote installation or configuration. The only way to install TI Manager and the TI runtime is by using the **Host Integration Server 2004 Installation Wizard**, and selecting Application Integration on the options page. You cannot install TI Manager or the TI runtime programmatically.

Remote Administration of Windows-Initiated Processing

You can administer Windows-initiated processing only from the local computer, and TI does not support remote administration for WIP. Each computer that has TI installed and configured and that is used for WIP is administratively separate from any other computer that also has TI installed. If you need to administer WIP when you are away from the local computer, then you must use the Windows Remote Desktop feature to access TI Manager and the TI runtime.

Remote Administration of Host-Initiated Processing

You can administer the host-initiated processing remotely, but only from a computer that also has TI installed on it and uses the same HIP configuration database. For example, if three servers each have TI installed on them and all three are configured to use the same HIP database, then you can remotely administer any of the three servers from either of the other two servers. You cannot remotely administer the TI runtime from another server that has TI installed but uses a different HIP configuration database. For example, if you have a fourth server also has TI installed but uses a different HIP configuration database from the three servers in the previous example, you cannot remotely administer the TI runtime on any of the three other servers. Neither can you remotely administer the fourth server from any of the other three servers.

If you need to administer HIP when you are away from a computer that is configured to use the same HIP configuration database, then you must use the Windows Remote Desktop feature to access TI Manager and the TI runtime.

Use of Remote Databases

You can also configure TI to use a remote SQL Server database. The SQL Server database is used to store TI host-initiated processing (HIP) configuration data. Use the **Microsoft Host Integration Server 2004 Configuration Wizard** to specify the database server to use.

To configure a remote database

1. Click Start, then point to **Programs** and **Microsoft Host Integrator Server 2004**, and then click **Configuration Wizard**.
2. Follow the directions on the screen.
3. One the **Database configurations** wizard page, select **Transaction Integrator Configuration Database**.
4. Click **Edit**.
5. In the **Transaction Integrator Configuration Database Properties** dialog box, select the remote server and database to be used.
6. Click **OK**, and then click **Next**.
7. Continue to follow the directions on the screen.

After you click **Finish** in the Wizard, TI installs the HIP database on the designated remote server.

Installation

The Transaction Integrator Manager Console

Transaction Integrator is administered through the Transaction Integrator (TI) Manager management console. The Microsoft Management Console (MMC) is a framework for hosting administrative tools called snap-ins. In general, a console can contain tools, folders or other containers, World Wide Web pages, and other administrative items. These items are displayed in the left pane of the console, called a console tree. The MMC provides a single user interface for integrating various Microsoft and third-party management tools. You can create custom consoles combining your choice of the various registered snap-ins; for example, you might put the SNA Manager and Transaction Integrator snap-ins together in a single console.

The TI Manager management console consists of a left pane that displays the console tree and a right pane that displays the properties of the objects in the left pane. The topmost node in the console tree is the **Console Root**, and as you add snap-ins to the MMC they appear under the **Console Root**.

When you first open TI Manager, the console root has three major nodes (or snap-ins):

- **Transaction Integrator**. The **Transaction Integrator** node is the entry point to the TI Manager administrative tool.
- **Component Services**. The **Component Services** node is the entry point to the Component Services administrative tool. The Component Services administrative tool enables you to configure and administer COM components and COM+ applications, including installing and configuring COM+ applications, setting security at the application level, and creating and maintaining COM+ partitions. The Component Services administrative tool is designed both for system administrators and for application developers. For example, developers can configure routine component and application behavior, such as participation in transactions and object pooling.
- **Internet Information Services**. The **Internet Information Services** (IIS) node appears in the console only if IIS is installed on the computer. The Internet Information Services node is the entry point to the IIS administrative tool.

The **Transaction Integrator** node contains two major subnodes:

- **Host-Initiated Processing**. You can use the **Host-Initiated Processing** node to view the major elements used in host-initiated processing (HIP) environment.
- **Windows-Initiated Processing**. You can use the **Windows-Initiated Processing** node to view the major elements used in Windows-initiated processing (WIP) environment.

Windows-Initiated Processing Node

Using Host-Initiated Processing

The following topics explain how to use Host-Initiated Processing.

This section contains:

- Creating a Local Environment
- Creating a Host Environment
- Creating a Security Policy
- Defining New Objects
- Creating an Object View
- Modifying Objects
- Creating a New Application

Creating a Local Environment

A local environment (LE) is a set of end points that the HIP runtime uses to listen for incoming requests from the host. If communications with the host uses the TCP/IP network protocol, then the endpoints are either port numbers or service names. If communications with the host uses the SNA network protocol, the endpoint is the local LU alias.

Use the **New Local Environment Wizard** to create a new local environment.

See Also

Using Host-Initiated Processing

Creating a Host Environment

A host environment (HE) defines the network and hardware characteristics of the non-Windows host that will be initiating requests to the Windows platform. For example, a host that uses the TCP/IP protocol to initiate requests to Windows will be identified to host-initiated processing (HIP) through an HE that contains the IP address of the host and the code page that the host uses to represent its data.

You can use the **New Host Environment Wizard** to create a new host environment.

See Also

Using Host-Initiated Processing

Creating a Security Policy

Security policy definitions are created and managed from within the **Security Policies** node. When the HIP Console is first started the **Security Policies** node is empty. The **Security Policies** node contains definitions for how Windows security credentials are established prior to the execution of the server object. The source of the security credentials can be:

- Based on User IDs and Passwords delivered to HIP by the client application program
- Based on User IDs and Passwords delivered to HIP by well defined host protocol standards (SNA attach header: FMH5)
- Default host based User ID and Password
- Windows credentials that eh HIP Application runs under

When host based credentials are used, the windows credentials are obtained through the use of the single sign-on (SSO) feature. This feature translates, in a secure manner, host based User ID, Password and SSO Affiliated Application ID to a SID that is representative of the Window credentials.

The execution of the server object is then executed with the translated security credentials.

You can create a new security policy using the **Security Policy Wizard**.

Defining New Objects

Objects in the host-initiated processing (HIP) environment represent the Windows Server that will be started after a request is received from a host. The object is defined by a Transaction Integrator Metadata (TIM) file that is generated by the development-time tool in Microsoft Visual Studio .NET 2003.

See Also

Using Host-Initiated Processing

Creating an Object View

Object views in HIP allow different ways to look at and manage Windows Server objects in the HIP environment. During the definition of an object view, all methods or a subset of the Object's methods can be defined in the view. This provides a level of security by limiting the number of methods available for execution.

When a Host environment is associated with an object view the level of security is elevated. With the HE association, only certain hosts are able to execute specific methods of an Object.

When the object view is finally associated with a local environment, the security is enhanced further by restricting the execution of a method on an object to a request from a specific host that made a request to a specific transport endpoint on the Windows platform.

You can create new object views using the New Object View Wizard. The **New Object View Wizard** helps you construct the following administrative entities:

- A view of an object
- One or more methods in the object to be defined on the view
- A local environment association
- Host environment association
- Method resolution information

See Also

Using Host-Initiated Processing

Modifying Objects

After an object has been created and assigned to an application within the host-initiated processing environment, you must be careful when making changes to the object or its TIM file.

To safely modify a TIM file for an existing object

1. In the TI Manager console tree, right click the object to be changed, and then click **Delete**.
2. Exit TI Manager.
3. Modify the TIM file and save it.
4. Start TI Manager.
5. In the TI Manager console tree, right-click **Objects**, point to **New**, and then click **Object**.
6. Follow the instructions in the **Object Wizard** to re-create the object.
7. In the TI Manager console tree, right-click the re-created object, point to **New**, and then click **View**.
8. Follow the instructions in the **New Object View Wizard** to re-create the object views.

Creating a New Application

HIP applications represent the execution environment for Windows Server objects that are initiated or driven from host requests. The HIP application execution environment is hosted in and synonymous with a Windows service.

A HIP application can host more than one server object. A HIP application can also have more than one listening endpoint associated with it.

Application definitions are created and managed from within the Computers node on a specific computer. When the HIP console is first started the **Computers** node has only a single computer defined. That single computer is the computer where the HIP administrative console is running. When the Console is first started, no applications are defined on that computer.

You can add a new application to the TI Manager without specifying the local environment, host environment, objects, and object views used by the application.

Using Host-Initiated Processing

Using Windows-Initiated Processing

The following topics explain how to use Windows-Initiated Processing over TCP/IP and over SNA.

This section contains:

- Run TI Over TCP/IP
- Run TI Over SNA (APPC/LU 6.2)

Run TI Over TCP/IP

You can install and run TI over TCP/IP without installing or using any of the SNA services of Host Integration Server 2004.

Use the following procedure to run a TI application over TCP/IP.

1. Configure the mainframe (CICS or IMS) for TCP/IP, and establish a connection with your Windows-based Host Integration Server 2004 Server computer. For more information, see Configure CICS for TCP/IP or Configure IMS for TCP/IP.
2. Install the COBOL programs within the CICS or IMS region that receives TI-initiated calls.
3. Define an appropriate TCP/IP remote environment for the CICS or IMS region that receives TI-initiated calls.
4. Build the TI component with a method for each transaction in the TP.
5. Deploy the TI component in a COM+ application to create a TI Automation server.
6. Run the client application that calls the new TI Automation server to automate the TP.

You can test this out by using the CedarBank sample application. For more information, see the *Sample Application Tutorial for HIS 2004 Transaction Integrator*.

Define a TCP/IP Remote Environment

Configure CICS for TCP/IP

CICS TCP/IP Platform Requirements

TCP/IP version 3R2

CICS version 3.3 or later

Connections to CICS using TCP/IP

CICS uses the IBM-supplied Concurrent Listener (program EZACIC02, transaction ID CSKL) to establish an interaction with TCP/IP. The Listener is a transaction that automatically starts when CICS TCP/IP is started and enabled. When the Listener starts, it obtains a socket on which it can "listen" for connection requests from TCP/IP. The Listener binds the socket to a specified port, and then waits for a client request on that port. TCP/IP maintains a relationship of a port number to a CICS job. When a client makes a request on a port associated with CICS, TCP/IP forwards the connection request to the Listener in that CICS job.

For additional details about the CICS MS LINK communication model, see "CICS MS LINK (TCP/IP)"

TCP/IP-to-CICS Configuration

A TCP/IP port number is associated with a CICS region in the TCP/IP profile data set (hlq.PROFILE.TCPIP). The port statement is used to define this relationship. For example, a port statement that associates port 3000 with CICS region CICSRG is:

```
3000 TCP CICSRG
```

CICS-to-TCP/IP Configuration

The following sample host definition shows configuration parameters for CICS-to-TCP using the EZAC transaction:

```
EZAC,DEFINE
ENTER ONE OF THE FOLLOWING
CICS         ===> yes                  Enter Yes|No

SECEXIT      ===>                      Name of Security Exit
```

Before attempting to use the TCP/IP connection:

- Verify that you have a TCP address space running on the host. (You should be able to PING the host at its IP address or DNS name.) Record the IP address; you will need to know it later when you use TI Manager to define a TCP/IP remote environment for the CICS region.
- Check that the CICS region supports TCP/IP, and that the IBM-supplied Listener (program EZACIC02, transaction ID CSKL) is defined. These procedures are described in chapter 5 of *TCP/IP V3R2 for MVS: CICS TCP/IP Socket Interface Guide* (IBM Document #SC31-7131). Note that this is a CICS TS version 1.2 document, but the configuration is supported in CICS version 4.1, as well.
- Determine the IP port number of the Listener (EZAC DISPLAY LISTENER); you will need to know it when you use TI Manager to define a TCP/IP remote environment for the CICS region.
- Start the IBM-supplied Listener (EZAO START) and check the CICS view of the Listener status (execute the CEMT INQUIRE TASK command, and verify that CSKL is running).

Configure IMS for TCP/IP

IMS TCP/IP Platform Requirements

TCP/IP version 3R2

IMS version 4 or later

Connections to IMS using TCP/IP

IMS uses a Listener (program EZAIMSLN) to establish an interaction with TCP/IP. The Listener in an IMS Batch Message Processing (BMP) helps facilitate the connection process. When the Listener starts, it obtains a socket on which it can "listen" for connection requests from TCP/IP. The Listener binds the socket to a specified port, and then waits for a client request on that port.

TCP/IP maintains a relationship of a port number to an IMS Listener BMP. When a client makes a request on a port associated with IMS, TCP/IP forwards the connection request to the Listener in that BMP.

Implicit mode

Implicit mode uses the IMS Assist Module to translate conventional IMS communication into corresponding socket calls. The Implicit mode is dependent on the IBM-supplied default Listener (EZAIMSLN) that runs in a BMP region.

The host server application model processes input data using the IMS message queue. The Listener puts the TRANID and the input data into the queue. The IMS control region schedules the transaction in a Message Processing Region. The Transaction Program reads the request from the queue using GU and GN commands. All response data is delivered to the client by way of the ISRT command. The IBM-supplied Assist Module delivers the data directly to the client through socket API calls.

The Assist Module uses the DBLADLI API for Implicit mode. Host applications are written using CBLADLI or CBLTDLI APIs. If you want existing IMS applications to use Implicit Mode TCP/IP, you must change to the CBLADLI API and recompile the program.

Explicit mode

The IMS Explicit (TCP/IP) model requires the installation, within IMS, of the IBM-supplied default Listener (EZAIMSLN) that runs in a BMP region. This host server application model processes data without using the IMS message queue. The Listener places only a single segment (the Transaction Initiation Message) into the message queue. The IMS control region schedules the execution of the transaction into a Message Processing Region. The transaction then communicates directly with the client through socket API calls.

All IMS host server programs must be administered by IMS as no-response transactions.

For additional details about the IMS communication models, see "IMS Implicit (TCP/IP)" and "IMS Explicit (TCP/IP)."

TCP/IP-to-IMS Configuration

A TCP/IP port number is associated with an IMS Batch Processing Region (BPR) in the TCP/IP profile data set (hlq.PROFILE.TCPIP). The port statement is used to define this relationship. For example, a port statement associating port 3000 with an IMS batch region with a job name of WNWIBR1 is:

```
3000 TCP WNWIBPR1
```

IMS-to-TCP/IP Configuration

You can start an IMS Message Processing Program by specifying the program name of the IBM-supplied Listener program (EZAIMSLN). The Listener reads a configuration file identified by the DD statement "LSTNCFG." This configuration data set contains one or more of the following startup parameter statements (one set for each transaction defined for at least one Command Region):

- TCPIP statement
- LISTENER statement
- TRANSACTION statement

The TCPIP statement identifies the job name for the TCP/IP address space that manages the connection for the Listener.

The LISTENER statement specifies the port number that the Listener will use. This statement also specifies other port-related parameters, such as backlog, timeout values, and so on.

The TRANSACTION statement defines a list of transactions that the Listener can start. It also defines whether the Implicit or

Explicit connection mode is used.

The Listener uses the three previously listed parameter statements to inform TCP/IP which port to use and which transactions are accessible through TCP/IP.

Here is a sample of an IMS-to-TCP/IP host definition:

```
TCPIP ADDRSPC=WNWTCP31
LISTENER PORT=4000 BACKLOG=50
TRANSACTION NAME=TRANIMPL TYPE=IMPLICIT
TRANSACTION NAME=TRANEXPL TYPE=EXPLICIT
```

Run TI Over TCP/IP

Define a TCP/IP Remote Environment

The following tables shows how you can define a TCP/IP remote environment (RE) to fit each of the five mainframe-based programming models even though there are only two TI RE types.

TI Remote Environment Type	Mainframe Programming Model
CICS and IMS using TCP/IP	CICS Concurrent Server (TCP/IP)
CICS and IMS using TCP/IP	CICS MS Link (TCP/IP)
CICS and IMS using TCP/IP	IMS Implicit (TCP/IP)
CICS and IMS using TCP/IP	IMS Explicit (TCP/IP)
IMS Connect or OTMA	IMS Connect or OTMA (TCP/IP)

Use TI Manager to define either TCP/IP RE.

Run TI Over SNA (APPC/LU 6.2)

If you have a distributed network, use TI over an SNA (APPC/LU 6.2) network connection in order to take advantage of its support for two-phase commit (2PC) in ACID (atomic, consistent, isolated, and durable) transaction processing. To support ACID transactions, your COBOL transaction program (TP) must support Sync Level 2. The TCP/IP protocol has no default support for 2PC, so TCP/IP is not appropriate in a distributed network.

To run a TI application over an SNA network

1. Configure the mainframe (CICS or IMS) for SNA, and establish a connection with your Windows-based Host Integration Server 2004 Server computer.
2. Install the COBOL transaction programs within the CICS or IMS region that receives TI-initiated calls.
3. Define an appropriate SNA remote environment for the CICS or IMS region that receives TI-initiated calls.
4. Build the TI component with a method for each transaction in the TP.
5. Deploy the TI component in a COM+ application to create a TI Automation server.
6. Run the client application that calls the new TI Automation server to automate the TP.

You can test this out by using the CedarBank sample application. For more information, see the *Sample Application Tutorial for HIS 2004 Transaction Integrator*.

Test an Application Using Capture and Playback

Once you have developed a client application that generates TI requests, you can capture either actual or simulated activity between your application and a mainframe transaction program (TP). Captured messages are stored in a recording (.rcd) file. Once you have created the recording, you can play it back to provide responses to your application as though a mainframe program were executing and returning output parameters and a return value. Captured messages do not have to be played back in the order they were recorded. The .rcd file is more like a database of stored responses. Using Capture and Playback allows you to reduce the costs and overhead of connecting to the mainframe as you develop your application.

You can create a recording file either by capturing live from the mainframe or by capturing responses that you typed into the TI Test Console.

- **Capture from the mainframe**
  The Capture mechanism is used to record activity between a TI client and a mainframe server. Later, you can use this recording (.rcd) file as the source for information needed to respond to incoming client requests. This scenario requires mainframe connectivity, and a mainframe server application in order to create the initial recording.
- **Capture from the TI Test Console**
  The TI Test Console extends the Capture/Playback facility by allowing the recording to be created without a live connection to a mainframe transaction program (TP). On the TI Test Console user interface, you can see the input parameters of a remote request and type in values for output parameters. This gives you the ability to develop a test environment for TI Automation server applications, prior to the development of the mainframe code to respond to the requests.

Recording files are available in the CedarBank sample application for all eight possible environments. Use the CedarBank sample client application to practice using Diagnostic Capture and Diagnostic Playback remote environments (REs) as testing tools. For more information, see the *Sample Application Tutorial for HIS 2004 Transaction Integrator*.

> **Note** To use the TI Test Console, you must set the application or package identity in a COM+ application to **Interactive User**.

Capture Mainframe Transaction Program Responses

Capture TI Test Console Responses

Define a Diagnostic Capture Remote Environment

Define a Diagnostic Playback Remote Environment

Play Back Captured Responses

Define a Diagnostic Capture Remote Environment

You can define a specialized remote environment (RE) called a Diagnostic Capture RE to record mainframe or TI Test Console responses to TI requests. The responses are captured and stored in an .rcd file. The responses come from the Diagnostic Capture RE's *target,* which can be either the TI Test Console (the default) or from the mainframe transaction program (TP) over a live connection.

When you play back a recording (.rcd) file, it will give the recorded responses when the TI run-time environment makes a recorded request. For information on how to play back the recording, see Play Back Captured Responses.

Use the following procedures to define a Diagnostic Capture RE and set it to record responses coming from TI Test Console or from the mainframe TP:

- To define a Diagnostic Capture RE
- To change the default target from TI Test Console to the mainframe

To define a Diagnostic Capture RE

1. Start TI Manager.
2. In the console tree, double-click **COM Transaction Integrator**, and then click **Remote Environments**.
3. On the **Action** menu, point to **New**, and then click **Remote Environment**.
4. Click **Diagnostic Capture**, and then click **OK**.
5. Click the type of RE that your TI component uses, and click **Next**.
6. Type a name for the recording (.rcd) file to be created by the capture session. The name for a recording file can be a maximum of 255 characters. The default extension for the recording file is .rcd. If you want to store the .rcd file in a specific location, precede the name you enter with the path to that location.

   To use an existing .rcd file, click **Browse** to locate the file. When you run your application against an existing recording file, new data is appended to the file. If your application makes requests that were previously captured in the file, the new responses to these requests will overwrite the old responses.

7. Type a name for this new instance of a Diagnostic Capture RE (or accept the default). The name can be a maximum of 255 characters. Optionally, type a comment to describe any distinguishing characteristics of this Diagnostic Capture RE, and then click **Next**.
8. Click **Finish**.
9. If you are using capture and playback with a .NET application:
   a. Open the Capture RE file properties, and then select the security tab
   b. On the security tab, add everyone, and then set the permissions to all access. Failure to do this might cause TI runtime to return the following error (1300) Transaction Integrator was unable to allocate a state machine to process the method call (progress=3, hr=0x8000ffff).

The default target that provides responses to TI run-time environment requests is the TI Test Console. If you intend to create a recording file from a mainframe connection, change the default by specifying the RE that hosts the TP whose responses you want to record.

To change the default target from TI Test Console to the mainframe

1. Start TI Manager.
2. Double-click **COM Transaction Integrator**, double-click **Remote Environments**, and then click the Diagnostic Capture RE that you want to modify.
3. On the **Action** menu, click **Properties**, and then click the **Target** tab.
4. Click **Use responses from the following Remote Environment**.
5. Click the drop-down box, and click the RE that you want to respond to TI requests.
6. Click **OK**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Define a Diagnostic Playback Remote Environment

You can define a specialized remote environment (RE) called a Diagnostic Playback RE to play back previously recorded mainframe or TI Test Console responses to TI requests. You must have recorded the responses in a recording (.rcd) file previously by using a Diagnostic Capture RE.

Typically, you will play back recorded responses when you are testing a TI Automation server (a TI component in a COM+ application), and there is no live connection to the mainframe from the computer that you are using.

For complete information about how to play back a recording, see Play Back Captured Responses.

To define a Diagnostic Playback RE

1. Start TI Manager.
2. In the console tree, double-click **COM Transaction Integrator**, and then click **Remote Environments**.
3. On the **Action** menu, point to **New**, and then click **Remote Environment**.
4. In the **Add Remote Environment** dialog box, click **Diagnostic Playback**, and then click **OK**.
5. Click the type of RE that your TI component is designed to use, and then click **Next**.
6. Click **Browse** to locate the recording file that you want to play back, and then click **Next**.

   Alternatively, you can type the name of the file. If the recording file is stored in a location other than the default location, you must include the path when you type the file name.

7. Type a name for the new RE (or accept the default). The name can be a maximum of 255 characters. Optionally, comment to describe any distinguishing characteristics of this Diagnostic Playback RE, and then click **Next**.
8. Click **Finish**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Capture Mainframe Transaction Program Responses

Once you have developed a client application that generates TI requests, you can capture activity between your application and a mainframe transaction program (TP). Captured request/response pairs are stored in a recording (.rcd) file. Once you have created the recording, you can play it back to provide responses to your application as though a mainframe program were executing and returning output parameters and a return value.

To capture (or play back) mainframe responses, you need to create a Diagnostic Capture (or Diagnostic Playback) remote environment (RE) instance. By using the Diagnostic Capture and Diagnostic Playback REs, you can minimize the costs and overhead of connecting to the mainframe as you develop your application.

To capture mainframe responses in a recording (.rcd) file and subsequently play back the recording file, define the following three RE instances:

- An active RE that your application is designed to use
- A Diagnostic Capture RE used to create the recording file
- A Diagnostic Playback RE used to play back the recording file

To record mainframe responses, move your COM+ application's TI components from the active RE to the Diagnostic Capture RE. Then when a client application calls the COM+ application that holds those components, the TI run-time environment will save all mainframe (or TI Test Console) responses in the .rcd file.

To play back the recording, move the TI components from the Diagnostic Capture RE to the Diagnostic Playback RE. Then when a client application calls the COM+ application that holds those components, the TI run-time environment will use the mainframe responses that were previously captured and stored in the .rcd file.

When you finish testing your TI components, return them to their original RE.

When you create a Diagnostic Capture RE, you will see that the default capture target is the TI Test Console. If you create a recording file from a live mainframe connection, you must first change the default setting in the Capture Remote Environments property page Target tab to Use responses from the following Remote Environment. Then specify a corresponding RE that hosts the transaction program responses you want to record. You can specify this RE on the Target tab of the Diagnostic Capture RE's properties dialog box.

You can add to an existing recording by setting the recording file of a Diagnostic Capture RE to the existing file. The target can be either a mainframe RE or the Test Console. Either one will generate responses that will be returned to the application and added to the recording. When you run your application against an existing recording file, new data is appended to the file. If your application makes requests that were previously captured in the file, the new responses overwrite the old responses. You should exercise caution when using the Test Console with an existing recording file. This caution is noted here because recording files that are created or modified with the Test Console are more likely to contain less data or less accurate data than recording files that are created through an active connection with the mainframe.

See the "Define a Diagnostic Capture Remote Environment" topic in this guide to learn how to capture responses from the mainframe.

Test an Application Using Capture and Playback

Capture TI Test Console Responses

The TI Test Console extends the TI Capture/Playback facility by allowing you to respond to a remote request without connecting to a mainframe. The TI Test Console is a user interface that you can use to type in responses.

To get the TI Test Console to pop up, move a TI component from an SNA (APPC/LU 6.2) or TCP/IP remote environment (RE) to a Diagnostic Capture RE that has been targeted to the TI Test Console. Then when you run a client application that calls the TI Automation server containing that TI component, the TI Test Console will pop up, and you can enter a return value to be sent back to the client application.

For this to work, you must have both of these:

- A TI Automation server (a TI component in a COM+ application)
- A client application that calls the methods of the TI Automation server

However, you do not need a mainframe transaction program to service the TI requests.

TI Test Console User Interface

The TI Test Console consists of a menu bar, a console tree, and a details pane. The menu bar gives you commands for setting output parameters, completing responses, and locating help. The commands on the Edit menu reflect the properties of an item selected in the console tree. These properties were set when you created the TI component in Visual Studio.

The console tree lists the parameters of the method call and fully expands complex items to their elemental levels. The details pane gives the details about the properties of the method parameters. For example, selecting a recordset in the console tree causes information on the members of the recordset to appear in the details pane. If an elemental item is selected in the console tree, the details pane gives the details for that elemental item. An elemental item is one that cannot be further expanded, such as integers, the first element of an array of strings, a Long member of a recordset, or a user-defined type.

If the TI Test Console is the target of a Diagnostic Capture RE associated with a TI component in a COM+ application, you can type in the responses that will be recorded in the .rcd file. In this case, the TI Test Console pops up automatically to accept your input, and after you finish sending the response, the TI Test Console disappears automatically.

TI Test Console works with Diagnostic Capture REs only, not with Diagnostic Playback REs. In other words, you can use the TI Test Console to record responses that can later be played back in a Diagnostic Playback RE, but you cannot use TI Test Console to issue responses "live" to respond to TI Automation server requests.

You can use the TI Test Console to generate recorded interactive responses to TI Automation server requests. When a request is received, the TI Test Console displays the method's parameters in an explorer-like interface. The input values contain the values received with the request, and the output values are given initial default settings.

The menu bar provides a number of commands that allow the output parameters of the request to be set. When you have set all the output parameter values, click Terminate, and then click OK. This sends the responses back to the client application. All requests that complete successfully are added to the recording file associated with the Diagnostic Capture RE. The TI Test Console then exits until it receives another request.

> **Note** When you test your application, the Test Console appears only on the Host Integration Server 2004 Server computer where the TI run-time environment is installed.

Initial Output Value Settings in TI Test Console

The following table shows the default values that TI Test Console uses for the various parameter types.

VT_TYPE	Type Name	Default Value
VT_I2	Integer	0
VT_I4	Long	0
VT_R4	Single	0
VT_R8	Double	0
VT_CY	Currency	0
VT_DATE	Date	Current date and time
VT_BOOL	Boolean	0 (False)
VT_UI1	Byte	0
VT_DECIMAL	Decimal	0

VT_BSTR	String(n)	Empty string

Defaults for OCCURS DEPENDING ON Values

TI Test Console gives output-only OCCURS DEPENDING ON values an initial value of 1, and it initially sets input/output OCCURS DEPENDING ON values to their value on input if this value does not violate any of the bounds set in the type library for associated parameters. If the DEPENDING ON value exceeds any bounds, TI Test Console initially sets the OCCURS DEPENDING ON parameter to the largest legitimate value.

Defaults for Output Row Size

TI Test Console initially sets the number of output-only variably sized recordset output rows to 1, and it initially sets the number of input/output variably sized recordset output rows to the number of rows on input.

Defaults for Output Array Size

TI Test Console initially sets the number of output-only variably sized array output elements to 1 and the number of input/output variably sized array output elements to the number of array elements on input.

Defaults for Output String Size

TI Test Console initially sets the output-only variably sized string length to 1 and the input/output variably sized array string length to the string length on input.

Using TI Test Console

You can use the TI Test Console to make a recording file or enter responses live.

To use TI Test Console to make a recording (.rcd) file

1. In TI **Manager**, define a Diagnostic Capture RE for the TI component that you want to test. Accept the default value of **Use responses created from the Test Console**.
2. Move the TI component that you want to test to the new Diagnostic Capture RE.
3. Run the client application that calls the TI Automation server that contains the TI component that you want to test.
4. Enter the output values that you want to record when the TI Test Console pops into view.

To use TI Test Console to enter responses live

1. In TI **Manager**, define a Diagnostic Capture RE for the TI component that you want to test. Accept the default value of **Use responses created from the Test Console**.
2. Move the TI component that you want to test to the new Diagnostic Capture RE.
3. Run the client application that calls the TI Automation server that contains the TI component that you want to test.
4. Enter the output values that you want to send when the TI Test Console pops into view.

Test an Application Using Capture and Playback

Play Back Captured Responses

Once you have created a recording file either "live" from the mainframe or by using TI Test Console, you can play back the recording to:

- Test or demonstrate your application without connecting to the mainframe or requiring interactive intervention.
- Allow others to use your TI components without mainframe connectivity.

When you play back a recording, the TI run-time environment uses the recording file (.rcd file) to respond to the TI Automation server's requests in the same way that a mainframe would respond. To play back a recording (.rcd file), you need to create and use a Diagnostic Playback remote environment (RE) by using the following procedure.

> **Note** The recording file has no implicit ordering. During playback, the sequence of requests does not need to match that used during capture. Matches are determined by looking at each request independently.

To play back a recording (.rcd) file

1. Start TI **Manager**, and double-click **COM Transaction Integrator** in the console tree.
2. Right-click **Remote Environments**, point to **New**, and click **Remote Environment**.
3. In the **Add Remote Environment** dialog box, click **Diagnostic Playback**, and then click **OK** to start the **Playback Remote Environment Wizard**.
4. In the **Playback Remote Environment Wizard**, specify the actual type of RE that your TI components will use, the name of the recording (.rcd) file that you want to play back, and the name for the Diagnostic Playback RE.
5. Verify that none of the TI components support transactions. To do this, double-click **Component Services** (or **Microsoft Transaction Server**) in the console tree, and then navigate down to the COM+ application that contains the TI components that you want to use. For each TI component, right-click the component name. Then click **Properties**, click the **Transactions** tab, and click **Disabled** or **Not Supported** under **Transaction Support**. TI components that use a recording (.rcd) file cannot support ACID transactions because there is no real connection to the mainframe.
6. Move the TI components to the Diagnostic Playback RE that you just defined. To do this, double-click **COM Transaction Integrator** in the console tree. Then double-click **Remote Environments**, double-click the current remote environment, right-click each TI component, click **Move**, and then click the new RE in the **Move Component** dialog box.
7. Run the client application to call the TI Automation server.

Data Integration User's Guide

New to this release are a .NET Framework-enabled Managed Provider for DB2 and a DB2 Network Protocol Client (DRDA AR), over which the ODBC, OLE DB, and Managed Provider communicate to the remote DB2 database server.

The Data Integration User's Guide contains information about the Data Access Tool (DAT). The DAT provides a single mechanism to help configure network, security, and database information. The DAT also helps you create packages on the DB2 system.

This section contains:

- Using the Managed Provider
- Determining Which Provider to Use
- Data Access Tool
- About Data Access

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Using the Managed Provider

For information about using the Managed Provider, see the following topics in the Host Integration Server 2004 Developer’s Guide.

- Managed Provider Programmer's Guide
- Managed Provider for DB2 Programmer's Reference

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Determining Which Provider to Use

Microsoft® Host Integration Server offers two different types of providers with which to access data: a traditional COM-based OLE DB provider, and an ADO .NET provider. Both providers have their advantages, which you should consider carefully when determining which provider to use.

Reasons to Use the .NET Provider

The reasons to use the .NET Providers will be familiar to many who have programmed with .NET technologies: using the .NET providers improves your ability to manage and reuse your code base, access distributed and disconnected systems, and to increase security.

- Improved support for the disconnected business model

  ADO provides limited support for disconnected access using the **Recordset**. ADO.NET introduces a new object, the **DataSet**, which serves as a common, in-memory representation of relational data. The **DataSet** is, by design, disconnected at all times. Because it holds no persistent connection to outside resources, the **DataSet** is ideal for packaging, exchanging, caching, persisting, and loading data.

- Provider support

  Host Integration Server 2004 supports .NET database access using two optimized providers: the Managed Provider for DB2, and the OLE DB Provider for DB2 using ADO.NET. In addition, ADO.NET includes general provider support for SQL, OLE DB, and ODBC. Therefore, a .NET solution may work better for you than a COM-based solution if you are accessing these types of databases.

- XML integration

  In addition to persisting and loading both data and its relational structure as XML, ADO.NET relies on XML for remoting data between tiers or clients. The generic XML representation that ADO.NET uses provides a convenient method for transmitting data across any network, including those with restrictive security perimeters. For example, ADO.NET XML data objects are easier to transmit through firewalls, whereas most firewalls are set up to block the COM marshalling commands used by an OLE DB provider. ADO.NET also uses XML tools to perform validation, hierarchical queries, and data transformations on relational data.

- Consistent programming interface

  ADO constructs, such as the **Recordset**, do not employ familiar programming constructs but instead are modeled to be database-oriented. For example, cursors, which are used to navigate and retrieve data, function differently than other data constructs such as arrays and collections. In ADO .NET, however, in-memory data can be exposed through common .NET Framework structures, including arrays and collections, providing you with common access methods when working with relational data.

- Improved UI controls

  .NET data controls, such as the **DataGrid**, **Datalist**, and **DropDownList** controls, are generally easier to use and maintain the code base for than their predecessors. Such controls can change the face of your application, improving the look and feel, and increasing overall developer productivity.

- Increased native support

  Recent products by Microsoft are incorporating native support for the .NET Framework. For example, Microsoft BizTalk® Server has native orchestration and messaging support for the .NET framework, and therefore has been optimized to work efficiently with .NET data providers.

- Explicit control of data access behavior

  The design of ADO includes implicit behaviors that may not always be required in an application and that may therefore limit performance. ADO.NET provides well-defined, factored components with predictable behavior, performance, and semantics that enable you to address common scenarios in a highly optimized manner.

Reasons to Use the COM Provider

As with the .NET providers, the main reasons to use the COM providers will be familiar to many who have examined the issue for other technologies: COM providers have been integrated with current and legacy technologies, use less system resources than the

.NET equivalent, and do not require conversions or upgrades in order to implement.

- Speed and efficiency

  Like most COM-based technologies, the OLE DB provider tends to run with a smaller footprint and at greater speeds while using less network resources than the equivalent .NET provider does. While this is often countered with the increased ease in which .NET applications can be implemented and maintained, the OLE DB providers are more effective in situations where speed and bandwidth efficiency is a prime consideration.

- Scalability

  As a consequence of the previous point, an optimized OLE DB provider will scale more efficiently than the equivalent .NET provider will. Therefore, in a large-scale enterprise dealing with thousands of transactions per second over a wide-area network, you will most likely be better served using a COM-based connection.

- Architecture restrictions

  ADO .NET is optimized for a disconnected business model, where data is stored locally in discrete chunks. However, architectures designed with uninterrupted connections in mind will have little reason to take advantage of this feature.

  For example, an enterprise whose primary clients use server-side cursors to access data on a mainframe over a landline would not need to use the disconnected business features built into ADO.NET.

- Provider and driver support

  Host Integration Server 2004 supports several different options for data access. The OLE DB Provider for DB2 allows you to access a DB2 database; the OLE DB Provider for Host Files allows you to access the file system. While a .NET solution would grant you access to DB2, there is no equivalent .NET provider for accessing the file system.

  In addition, Host Integration Server 2004 supports an ODBC driver for DB2. In contrast, ADO.NET supports a general-purpose ODBC provider. Like a COM-based provider, the ODBC driver for DB2 is faster and has a smaller footprint than the equivalent .NET provider has. While not technically a COM-based solution, the ODBC driver is mentioned here as another possible reason for using a technology other than .NET.

- Product compatibility

  Some commonly used products are compatible only COM-based technologies and not with the .NET Framework. Specifically, SQL Server 2000 consumers utilize OLE DB and not ADO or ADO .NET. Similarly, Office XP consumers utilize ODBC and ADO. Therefore, when writing applications that interface with these products, you should also use the OLE DB Provider.

- Native support

  Many applications natively support COM access, and are therefore more efficient when accessing data through OLE DB than the .NET equivalent. Specifically, BizTalk Server Orchestration has native support for COM, which more effectively supports writing custom Receive Functions and AICs using the OLE DB Provider for DB2.

- Conversion overhead

  You may be working in an environment in which you have an existing code base that is not completely compatible with the .NET Framework. In order to use the .NET providers, you would have to translate your application into a language compatible with .NET, such as Microsoft Visual Basic® .NET. As doing so is a non-trivial task, it may pose a greater resource drain than you are willing to accept at this time.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Data Access Tool

The Data Access Tool (DAT) is a new feature in Host Integration Server 2004 designed to streamline the process of creating and managing connections to data sources on host environments. Whereas this used to be divided into multiple feature sets and programs, the DAT provides a single mechanism to guide you through configuring network, security, and database information, and creating packages on the DB2 system.

The DAT consists of two items:

The **Data Source Browser** displays all data sources in familiar MMC format for configuration and management.

The **Data Source Wizard** guides you step by step through the configuration process. The wizard dynamically adapts to both DB2 and File System data sources, and displays the appropriate screens.

Note The Data Access Tool and DB2 data providers create DB2 packages for use by all DB2 users, by setting the execute privilege on the DB2 packages to PUBLIC. It is recommended that you revoke execute privileges to PUBLIC on these packages, and then grant execute to selected DB2 users or groups.

This section contains:

- Editing a Configuration
- Displaying an Initialization String
- Testing a Connection
- Creating Packages
- Running a Sample Query
- Converting Data Sources
- Adding a Table
- Creating a New Data Source or Data Description
- Opening a File
- Importing a File
- Other Tasks

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Editing a Configuration

Editing the configuration brings up the editor for the specific data source. In other words, OLE DB data sources trigger the Universal Data Links page, and ODBC data sources trigger the Data Access Tool Wizard.

To edit a configuration

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Edit Data Source**. The **Data Source** property page will appear. When you are finished editing, click **OK**.

Data Access Tool

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Displaying an Initialization String

This option displays the native initialization string, for example, an OLE DB connection string or an ODBC connection string, in the output window. This string can be copied from the output window and pasted into another text-based window.

To display an initialization string

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Display Connection String**. The connection string appears for viewing or copying.

Data Access Tool

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Testing a Connection

This command tests the connection to the data source and displays information about it, such as the host platform and version. In a connection between an AS/400 and a DB2, a typical result of this operation might look like the following:

```
Successfully connected to data source 'My_SOURCE'.
Server class: DB2/400
Server version: 05.01.0000
```

Certain operations may require the user to enter a user name and password. If this is the case, the **Password** dialog box will appear.

To test a connection

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Test Connection**.

Data Access Tool

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Creating Packages

The create package command creates Host Integration Server packages on a DB2 system. As the process runs, status messages are displayed in the results pane. As seen on an AS/400, the result of this operation is:

```
Connected to data source 'MY_SOURCE_IP'.
AUTOCOMMITTED package has been created.
READ COMMITTED package has been created.
READ UNCOMMITTED package has been created.
SERIALIZABLE package has been created.
REPEATABLE READ package has been created.
The package creation process has completed successfully.
```

To create packages

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Create Packages**. The **Create Packages** dialog box will appear.

Data Access Tool

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Running a Sample Query

This command performs a sample query against the host data source. The query retrieves a list of tables from the system catalogs using the default schema property configured in the data source. The data is displayed in the results pane as two tabs: an **Output** tab and a **Grid** tab.

To run a sample query

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Sample Query**.

See Also

Data Access Tool

Converting Data Sources

Converting data sources allows you to convert a DB2 data source from one provider type to another. Only acceptable provider type conversion will be displayed. For example, converting from DB2 OLE DB to DB2 OLE DB is not enabled.

To convert a data source

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Convert To**, and then select a provider from the list.

See Also

Data Access Tool

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Adding a Table

This command displays the **Table** dialog box. You can also access this dialog box by selecting a table and clicking **Properties** from the context-sensitive menu.

To add a table

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Add Table**. The **Table** property page will appear.
3. Enter the appropriate information in the **Table** property page. For more information about these properties, click the **Help** button.
4. When you are finished, click **OK**.

Creating a New Data Source or Data Description

Clicking **New Data Source** initiates the Data Source Wizard. Clicking **New Data Description** creates an empty data description file and adds it to the tree view.

To create a new data source or data description

1. In the **Data Source Browser** window, click the **File** menu.
2. Click **New**, and then click **Data Source** or **Data Description**.

See Also

Data Access Tool

Opening a File

Use this command to choose a .udl or .dsn file through a standard **File Open** dialog box. The command will open the data source using the Data Source Wizard.

To open a file

1. In the **Data Source Browser** window, click the **File** menu.
2. Click **Open Data Source**. The **File Open** dialog box appears.
3. **Browse** to the appropriate data source and click **Open**.

See Also

Data Access Tool

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Importing a File

This command enables you to import a file that contains the information in a DB2 Connect exported file (TCP/IP only). The values in the file are parsed and displayed in the Data Source Wizard.

To import a file

1. In the **Data Source Browser** window, click the **File** menu.
2. Click **Import**, and then click the appropriate file.

About Data Access

Data services included with Microsoft® Host Integration Server 2004 enable you to interact with vital data sources, including host file systems and DB2 databases.These services are available for both the hierarchical and peer environments.

This section contains:

- OLE DB Provider for AS/400 and VSAM
- OLE DB Provider for DB2
- ODBC Driver for DB2
- File Transfer

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

OLE DB Provider for AS/400 and VSAM

To use Microsoft OLE DB Provider for AS/400 and VSAM with an OLE DB consumer application, you must either create a universal data link (.udl) file and call this from your application, or call the provider using a connection string that includes the provider name. Microsoft Data Access Components (MDAC) includes Microsoft Data Link, a generic method for managing and loading connections to OLE DB data sources. Microsoft Data Link also supports finding and storing connections to OLE DB data sources.

For additional information about using .udl files or connection strings, see Creating a Connection String for a .udl File or Configuring Data Descriptions in the Programmer's Guide..

> **Note** The SNAOLEDB provider runtime and Data Access Tool both support a full path to the HCD files. To maximize security, you should store HCD files in a secure local folder or share that only the developer and the runtime application can access.

Adding or Configuring a Data Link for Windows

Configuring a Data Source for OLE DB Provider for AS/400 and VSAM

Browsing OLE DB Data Sources

Data Description for AS/400 and VSAM

With the Microsoft OLE DB Provider for AS/400 and VSAM you can directly access record-level data in mainframe VSAM, Partitioned Data Sets (PDS), and midrange OS/400 files from within an application that uses OLE. The Object Linking and Embedding Database (OLE DB) is a standard set of interfaces that provides heterogeneous access to disparate sources of information located anywhere — file systems, e-mail folders, and databases. The OLE DB Provider for AS/400 and VSAM combines the universal data access of OLE DB with the record-level input/output (RLIO) protocol of the IBM Distributed Data Management (DDM) architecture.

In addition to describing tables used by the Microsoft OLE DB Provider for AS/400 and VSAM, tables can be described for the File Transfer utility. To indicate that the File Transfer Utility should use a given table, click the **Properties** page for the specific table, and then select the **Use Table for File Transfer** check box. Leaving this box clear indicates that the table is to be used by the Microsoft OLE DB Provider for AS/400 and VSAM.

In addition to the sample applications provided on the Host Integration Server 2004 CD-ROM, many of the sample programs that ship as part of the Microsoft Data Access Components (MDAC) SDK can be used with the OLE DB Provider for AS/400 and VSAM. To use the OLE DB Provider for AS/400 and VSAM, you must specify **SNAOLEDB** for the provider name.

For more information about using the Host Data Description utility, see Host CCSID and Data Description in the OLE DB Providers Programmer's Guides..

OLE DB Provider for DB2

To use the Microsoft OLE DB Provider for DB2 with an OLE DB consumer application, you must either create a universal data link (.udl) file and call it from your application, or call the provider using a connection string that includes the provider name. Microsoft Data Access Components (MDAC) version 2.0 and later includes Microsoft Data Link, a generic method for managing and loading connections to OLE DB data sources. Microsoft Data Link also supports finding and storing connections to OLE DB data sources.

For additional information about using .udl files or connection strings, see OLE DB Provider for DB2 Programmer's Guide in the OLE DB Providers Programmer's Guides

For information on File Transfer utility, see the utility’s online Help or the *Developer's Guide*.

Packages for DB2

Microsoft OLE DB Provider for DB2 and Microsoft ODBC Driver for DB2 are implemented as IBM Distributed Relational Database Architecture (DRDA) Application Requesters. These features use DB2 packages to issue dynamic SQL statements and call DB2 stored procedures. The provider and driver create packages dynamically in the location to which the user points using the Package Collection attribute in the data source definition.

To launch the Create Package utility

- On the **Start** menu, click **Host Integration Server**, click **Data Integration**, and then select **Packages for DB2**.

See Also

OLE DB Provider for AS/400 and VSAM

Create Package Utility

Microsoft OLE DB Provider for DB2 and Microsoft ODBC Driver for DB2 are implemented as IBM Distributed Relational Database Architecture (DRDA) application requesters. These features use DB2 packages to issue dynamic SQL statements and call DB2 stored procedures. The provider and driver create packages dynamically in the location to which the user points using the Package Collection attribute in the data source definition.

By default, the provider will automatically create one package in the target collection, if one does not exist, at the time the user issues their first SQL statement (or calls SQL catalog to fetch schema information). The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the User ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level associated with the transaction isolation level property and parameter. If no transaction isolation level is specified, then the default for mainframe DB2 is CS and for other platforms the default is NC.

A problem can arise in multiuser environments. For example, if User A specifies a Package Collection value that represents a DB2 collection used by multiple users, but User A does not have authority to GRANT execute rights to the packages to other users (for example, PUBLIC), then the package is created for use only by User A. This means that User B may be unable to access the required package. The solution is for an administrative user, with package administrative rights (for example, PACKADM authority in DB2 for OS/390), to create a set of packages for use by all users.

Host Integration Server 2004 offers the Create Packages for DB2 utility, which an administrator can use to create packages. This utility can be run using a privileged User ID to create packages in collections accessed by multiple users. The utilities will create the following sets of packages and grant EXECUTE privilege to PUBLIC for all:

- AUTOCOMMIT package (MSNC001)
- READ_UNCOMMITTED package (MSUR001)
- REPEATABLE_READ package, (MSRR001)
- READ_COMMITTED package, (MSCS001)
- SERIALIZABLE or REPEATABLE_READ package (MSRS001)

Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, DB2/400 QSYS.SYSPACKAGE, and DB2 UDB SYSIBM.SYSPACKAGE catalog tables.

> **Note** When upgrading to Host Integration Server 2004 from Microsoft SNA Server 4.0 Service Pack 2 or Service Pack 3, it is necessary to re-create any existing packages by running the CrtPkg utility.

Support for Isolation Levels Using the ODBC Driver for DB2

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

ODBC Driver for DB2

Microsoft ODBC Driver for DB2 enables access over SNA LU 6.2 and TCP/IP networks to remote DB2 databases. This driver is implemented as an IBM Distributed Relational Database Architecture (DRDA) application requester that can connect to most DRDA-compliant DB2 systems, including MVS, OS/390, OS/400, AIX RS/6000, and Microsoft Windows.

The driver can be used interactively or from an application program to issue SQL statements and execute DB2 stored procedures. From Microsoft Excel, users can import DB2 tables into worksheets and use Excel graphing tools to analyze the data. From Microsoft Access, users can import from and export to DB2. Using Microsoft Internet Information Services (IIS), developers can publish DB2-stored information to users through a Web browser interface.

Host Integration Server 2004 offers the Create Packages for DB2 utility, which an administrator can use to create packages. This utility can be run using a privileged User ID to create packages in collections accessed by multiple users. The utilities create the following sets of packages and grant EXECUTE privilege to PUBLIC for all:

- AUTOCOMMIT package (MSNC001)
- READ_UNCOMMITTED package (MSUR001)
- REPEATABLE_READ package, (MSRR001)
- READ_COMMITTED package, (MSCS001)
- SERIALIZABLE or REPEATABLE_READ package (MSRS001)

For a table that maps the DB2 isolation levels to the ANSI isolation levels, see the following topics:

- Support for Isolation Levels Using the OLE DB Provider for DB2
- Support for Isolation Levels Using the ODBC Driver for DB2

Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, DB2/400 QSYS.SYSPACKAGE, and DB2 UDB SYSIBM.SYSPACKAGE catalog tables.

> **Note** When upgrading to Host Integration Server 2004 from Microsoft SNA Server 4.0 Service Pack 2 or Service Pack 3, it is necessary to re-create any existing packages by running the CrtPkg utility.

File Transfer

Host File Transfer provides a user with the ability to move a file between the local computer and a host system.

This section contains:

Host File Transfer

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Host File Transfer

Host File Transfer provides a user with the ability to move a file between the local computer and a host system. Host Integration Server 2004 provides this service by means of a single ActiveX® control. This extends the ability for the client application to perform file transfer operations from a large number of client development environments.

For an example of the proper usage of the File Transfer ActiveX® control, see the following SDK sample:

SDK/Samples/FileTransfer/TestConnectVB/TestConnect.exe.

Samples in this directory may also be used as fully functional utilities.

Network Integration User's Guide

The topics in this section provide an overview of network communication in a Microsoft® Host Integration Server 2004 environment and describe the services you can use to manage it.

This section contains:

- IP-DLC Link Service provides steps for configuring and using the IP-DLC Link Service.
- SNA Service provides an overview of Host Integration Server 2004 data communications and connections.
- Host Print Service provides steps for configuring a print service in your environment.
- TN Service provides an overview of this Telnet-based service.
- Active Directory Services provides an overview of the Microsoft® Active Directory® directory service for Host Integration Server 2004.
- Host Configuration lists the configuration requirements for a host computer.
- Applications and Tools describes the use of tracing and performance utilities.

IP-DLC Link Service

This section describes the configuration and use of the IP-DLC Link Service.

This section contains:

Introduction to the IP-DLC Link Service

Managing IP-DLC Link Services

Secure Deployment of the IP-DLC Link Service

Configuring IP-DLC

Introduction to the IP-DLC Link Service

This section describes the overall architecture of the Host Integration Server 2004 system with IP-DLC link service functionality.

IP-DLC is a Host Integration Server 2004 feature that provides SNA connectivity for applications using dependent and independent sessions over a native IP network. It implements the HPR/IP protocol, which is also known as HPR over IP or Enterprise Extender. Each SNA packet is transmitted natively across the IP network as a UDP datagram.

This section contains:

- System Overview
- Supported Features
- Scalability
- Key Limitations
- IP-DLC Link Service Concepts and Terminology

System Overview

This topic outlines key points of the Host Integration Server 2004 implementation of the IP-DLC link service.

Key features of the IP-DLC link service include:

- The IP-DLC link service is configured and managed by the Host Integration Server 2004 administrator as for any other link service.
- To provide the support required for transporting dependent LU sessions across an APPN network, the IP-DLC link service runs the DLUR feature as defined by the SNA/APPN DLUR Architecture Reference. This provides dependent LU session support to a CS/390 host running the matching DLUS feature.
- The IP-DLC link service operates as a Branch Network Node (BrNN) as defined in the SNA/APPN Branch Extender Architecture Reference. When large numbers of Host Integration Server systems are connected to a mainframe, the Branch Network Node configuration ensures that the overhead of topology and network search traffic on the Host Integration Server 2004 and mainframe links is minimal—comparable to using Host Integration Server 2004 without the IP-DLC link service.
- Multiple IP-DLC link services can be configured, one for each local IP address on the Host Integration Server 2004 system.
- Multiple IP-DLC connections are supported for each IP-DLC link service. There is one IP-DLC connection for each PU local to Host Integration Server 2004.
- Remote independent LUs are associated with an IP-DLC link service instead of a connection. All remote independent LUs accessible through an IP-DLC link service are associated with the single peer connection for the IP-DLC link service. All independent LU traffic is routed by the APPN network and may traverse any active HPR/IP link.

See Also

Supported Features

Scalability

Key Limitations

IP-DLC Link Service Concepts and Terminology

Supported Features

This topic lists the features that are supported over the IP-DLC link service.

Base SNA Features

The following existing Host Integration Server 2004 SNA features are supported over the IP-DLC link service:

- LU types 0, 1, 2, 3 and 6.2 (dependent and independent)
- LUA, FMI, APPC, and CPI-C APIs
- Dynamically Defined Dependent LUs (DDDLUs)
- Dynamic addition of local LUs, remote LUs, and connections
- Incoming and outgoing calls
- Connection Activation at Server startup, on demand or by administrator
- SNA data compression
- PU concentration with the upstream link over IP-DLC
- NetView RUNCMD/Alerts (note that the IP-DLC link service does not generate alerts)

Because the preceding SNA features are supported, it follows that the following applications are also supported over the IP-DLC link service:

- Host Integration Server 2004-compatible 3270 emulators
- Host Integration Server 2004-compatible 5250 emulators
- APPC - 3270 Session Viewer (including the LU-LU Test feature)
- Host Print Service
- Data Integration Services
- Local and remote administration
- TN3270 server
- TN5250 server
- MSMQ-MQSeries Bridge
- Transaction Integrator

Fault Tolerance Features

Note that because the IP-DLC link service uses the APPN and HPR/IP protocols, it is automatically able to take advantage of the following fault tolerance features:

- Ability to reroute sessions around a failure in the network provided that an alternative route exists.
- Ability for mainframe applications to be moved to a different processor with little or no impact to users when system or application failures occur on the mainframe.

Load Balancing Features

Load balancing for a single IP-DLC link service, with a single local IP address, over multiple adapter cards can be achieved using NIC Teaming at the MAC layer. The IP-DLC link service handles frames arriving out of sequence.

Security Features

Because the IP-DLC link service uses UDP/IP, the Windows IPSec feature can be used to provide end-to-end data security over the IP-DLC link service. Windows handles configuration of IPSec independently. No specific configuration is required for the IP-DLC link service.

Diagnostic Features

The diagnostics provided by the IP-DLC link service are used through the Host Integration Server 2004 Tracer Initiator and Trace Viewer facilities.

Scalability

Key Limitations

IP-DLC Link Service Concepts and Terminology

Scalability

The IP-DLC link service supports the Host Integration Server 2004 capacity of 30,000 simultaneous host sessions per server.

Note Four nodes are required to achieve 30,000 simultaneous host sessions and a single node supports a maximum of 15,000 simultaneous host sessions.

System Overview

Supported Features

Key Limitations

IP-DLC Link Service Concepts and Terminology

Key Limitations

The key limitations with the IP-DLC link service implementation are as follows:

- The IP-DLC link service cannot be run as a distributed link service (DLS).
- The PU Passthrough and Downstream connections are not supported over IP-DLC connections. It is not possible to have a one-to-one correspondence between upstream and downstream messages where the upstream connection is an IP-DLC connection.
- Each IP-DLC link service must use a different CP name from the SNA node service.
- Each IP-DLC link service requires a unique local IP address. If multiple IP-DLC link services are required, each must have its own unique local IP address.
- A single IP-DLC link service cannot be shared by multiple SNA node services. Each SNA node service must use a different IP-DLC link service for IP-DLC connectivity.

Key Limitations

IP-DLC Link Service Concepts and Terminology

The following is a brief introduction to the terminology and concepts that are referred to in this section, including APPN and HPR.

Session

A session is a logical connection between two network accessible units (NAUs). The most common example of an NAU is a logical unit (LU) (for more information, see Logical Unit (LU) later in this topic).

Physical Unit (PU)

The component that manages and monitors the resources (such as attached links and adjacent link stations) associated with a node. This term applies to non-APPN nodes only.

Logical Unit (LU)

A logical unit (LU) is a port through which an application or end user accesses the SNA network to communicate with another application or end user. An LU may be capable of supporting many sessions with other LUs.

There are two types of LUs:

- Dependent LUs require assistance from a mainframe to establish a session with another LU. These are also sometimes referred to as old LUs.
- Independent LUs can establish a session with another LU without the assistance of a mainframe.

APPN

Advanced Peer-to-Peer Networking (APPN) is a network architecture that supports distributed network control. It makes networks easier to configure and use, provides centralized network management, and supports flexible connectivity.

APPN Nodes

APPN nodes include systems of various sizes, such as mainframes using CS/390, Solaris servers running DCLs SNAP-IX, PCs running IBM Communications Server for Windows NT/2000 and IBM AS/400.

In an APPN network, nodes can be one of the following types:

- Network Nodes (NN)
- End Nodes (EN)
- Branch Network Nodes (BrNN)
- Low-entry networking nodes (LEN nodes)

Each node in an APPN network is connected to at least one other node in the APPN network. Where supported, CP-CP (Control Point to Control Point) sessions are established over these connections to adjacent nodes (nodes in the same network that can establish direct connections without going through a third node). CP-CP sessions are used to exchange network topology information, request the location of network resources, and manage sessions. All of the nodes in an APPN network share a common network name.

Network Node

A Network Node provides distributed directory and routing services for all LUs in its domain, where its domain is all directly attached End Nodes and LEN nodes that are using the services of the Network Node. The Network Node is referred to as the Network Node Server (NNS) for those directly attached End Nodes and LEN nodes.

A Network Node provides the following services:

- LU-LU session services for its local LUs.
- Directory searches and route selection for all LUs in its domain.
- Intermediate session routing for sessions between LUs on different nodes.
- Routing for Management Services (MS) data, such as alerts, between a served End Node or LEN node and an MS focal point.

End Node

An End Node is an end point in an APPN network. It maintains directory information only for local resources. An APPN End Node can independently establish sessions between local LUs and LUs on adjacent nodes. For sessions with LUs on nodes not directly connected to the End Node, an End Node requests routing and directory information from its Network Node Server using CP-CP sessions.

End Nodes can register their local LUs with their Network Node Server. This capability means the network operator at the Network Node Server does not have to predefine the names of all LUs on the attached End Nodes to which the Network Node provides services.

An End Node can be attached to multiple network nodes, but it can have CP-CP sessions active with only one Network Node at a time: its Network Node Server. The other Network Nodes can be used only to provide intermediate routing for the end node or as substitute Network Node servers if the main Network Node Server becomes unavailable.

An End Node can also have a direct connection to another End Node or LEN node, but CP-CP sessions are never established between the two nodes.

LEN Node

A LEN Node is a type 2.1 node that uses independent LU 6.2 protocols, but does not support CP-CP sessions. It can be connected to a Network Node or End Node but does not support APPN functions. The existing SNA node of Host Integration Server is a LEN node.

A Network Node can provide routing services for an attached LEN node, enabling the LEN node to participate in an APPN network without requiring links to be defined between the LEN node and all of the nodes in the APPN network.

LUs in the APPN network with which the LEN node may want to establish sessions must be defined to the LEN node as if they reside on the LEN node's Network Node server. The LEN node establishes sessions with LUs defined to be contacted through its Network Node Server. The Network Node routes the session through the APPN network to the node in the network where the LU actually resides.

LUs on the LEN node must be predefined to the Network Node that serves the LEN node. LU resources on LEN nodes (unlike those on End Nodes) cannot be registered on the Network Node Server by the LEN node.

When a LEN node's only link is to an End Node, the LEN node can communicate only with LUs on the End Node through the direct link between the two nodes. This is because an End Node cannot provide intermediate routing.

Branch Network Node

The Branch Network Node (BrNN) combines the functions of a Network Node and an End Node. As the name implies, a BrNN can be used to subdivide a network into a backbone network and attached branch networks. The BrNN provides the following functions:

- To the backbone network, the BrNN appears as an End Node, connected to its Network Node Server (NNS) in the backbone network.
- The nodes in the backbone network are not aware of the nodes within the branch, reducing the amount of topology information that must be stored.
- Because the BrNN appears as an End Node, it does not receive topology information from the backbone network (topology information is transmitted only between Network Nodes) reducing the amount of network overhead traffic flowing into the branch network.The BrNN registers all resources in the branch with its NNS as though they were located on the BrNN itself. This means that the nodes in the backbone network can locate resources in the branch without having to be aware of the separate nodes in the branch.
- To the branch network, the BrNN appears as a Network Node, acting as the NNS for End Nodes and LEN Nodes in the branch.

High Performance Routing

High Performance Routing (HPR) is an extension of the APPN architecture. HPR provides the following functions:

- Rapid Transport Protocol (RTP) minimizes processing cycles and storage requirements for routing network layer packets through intermediate nodes on a session route.
- Automatic network routing (ANR) enables APPN networks to automatically reroute sessions if a portion of the originally computed route fails.

Dependent LU Requester/Server

Dependent LU Requester (DLUR) function enables sessions for dependent LUs to reside on remote nodes across an APPN network, instead of requiring a direct connection to the host.

DLUR works in conjunction with Dependent LU Server (DLUS) at the host. Together, they route sessions across the network from dependent LUs in the APPN network to the DLUS host. The route to the host can span multiple nodes and can take advantage of APPN's network management, dynamic resource location, and route calculation facilities.

If the local node is a Network Node, dependent LUs on downstream computers can also use pass-through DLUR, in the same way that LUs internal to the node do, to access the host across the network.

Key Limitations

Managing IP-DLC Link Services

This section gives procedures for creating, configuring, viewing, and deleting IP-DLC link services.

This section contains:

- Creating an IP-DLC Link Service
- Configuring an IP-DLC Link Service
- Viewing Link Services
- Viewing Link Service Properties
- Deleting Link Services
- Link Service and the LnkCfg Utility

Creating an IP-DLC Link Service

You create and configure an IP-DLC link service as you would create any other link service.

To create an IP-DLC link service

1. In the SNA Manager, locate the computer on which you want to create the IP-DLC link service.
2. Right-click the **Link Services** folder under that computer.
3. On the context menu, click **New/Link Service.** The **Insert Link Service** dialog box appears.
4. From the list of available link services, select **IP-DLC Link Service**.
5. Click **Add** to load the **IP-DLC Link Service** properties dialog box.
6. To configure the new link service, follow the steps for Configuring an IP-DLC Link Service.

See Also

Managing IP-DLC Link Services

Viewing Link Services

As with other link services, you can view IP-DLC link services in the list view of the **Link Services** folder.

To view link services

1. In the scope pane of the Microsoft Host Integration Server 2004 MMC snap-in, locate the computer with the link services that you want to view.
2. Expand the list for that computer.
3. Select the **Link Services** folder. The link services for that computer will appear in the right pane.

See Also

Managing IP-DLC Link Services

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Viewing Link Service Properties

As with other link services, you can view IP-DLC link service properties by using the context menu in the list view of the **Link Services** folder.

To view link service properties

1. In the scope pane of the Microsoft Host Integration Server 2004 MMC snap-in, locate the computer with the link services that you want to view.
2. Expand the list for that computer.
3. Select the **Link Services** folder. The link services for that computer will appear in the right pane.
4. Right-click the appropriate link service, and then click **Properties**. The **Link Service Properties** page will appear.
5. Click **Configure**. The properties for this IP-DLC link service appear, and can be viewed or edited.

See Also

Managing IP-DLC Link Services

Deleting Link Services

As with other link services, you can delete an IP-DLC link service in the MMC snap-in.

Note When you delete a link service, all related connections will no longer be associated with any link service. A user might associate such a connection with any other IP-DLC link service that is associated with the node. Deleting a node associated with a link service will break association between these items.

To delete a link service

1. In the scope pane of the Microsoft Host Integration Server 2004 MMC snap-in, locate the computer with the link services that you want to delete.
2. Expand the list for that computer.
3. Right-click the appropriate link service, and then click **Delete**.

Link Service and the LnkCfg Utility

LnkCfg is a useful command-line utility for deploying and managing link services. The format of the command line for configuring the link service is specified as follows.

LINKCFG LINKSVC "Title"

/SERVER:servername

/LSTYPE:"IP-DLC Link Service"

/PRIMARYNNS:NNSServer

/BACKUPNNS:NNSServer

[/LOCALADDRESS:ipaddress] or [/ADAPTER:adaptername]

/NETWORKNAME:networkname

/CPNAME:name

/NODEID:“xxx.xxxxx”

/LENNODE:lennode

The following table describes the command-line parameters.

Property	**Description**	**Content**
"Title"	Title of the link service.	1-128 characters.
/SERVER:servername	Name of the server.	Valid server name.
/PRIMARYNNS:NNSServer	Primary network node server.	DNS name or IP address.
/BACKUPNNS:NNSServer	Backup network node server.	DNS name or IP address.
/ADAPTER:adaptername	Name of the local adapter. /ADAPTER and /LOCALADDRESS arguments should not be used together.	Name of the physical or logical adapter on the computer.
/LOCALADDRESS:ipaddress	Local address. /ADAPTER and /LOCALADDRESS arguments should not be used together.	Valid IP address or server name.
/NETWORKNAME:networkname	Network name of the Branch Network Node implemented by the link service.	1-8 characters SNA Type A string.
/CPNAME:name	Control point name of the Branch Network Node implemented by the link service.	1-8 characters SNA Type A string.
/NODEID:“xxx.xxxxx”	Identity of the Branch Network Node implemented by the link service.	String in format HHH.HHHHH where H is a hexadecimal digit.
/LENNODE:lennode	Name of the associated LEN node.	Name of a LEN node deployed on the local computer.

Connections and the SnaCfg Utility

SnaCfg is a useful command-line utility for deploying and managing SNA Server configurations.

The following table describes the command-line parameters.

Property	Description	Validation
/conntype:type	Connection type.	IP-DLC.
/RemoteAddress:adr	Address of the remote DLUS service. This property is not accessible through the user interface. It provides a way of establishing a direct connection with DLUS rather than routing the connection through the NNS.	Valid IP address or DNS name.
/PrimNetworkName:name	Network name of the primary DLUS server.	1–8 characters, SNA Type A string.
/PrimCPName:name	Control point name of the primary DLUS server.	1–8 characters, SNA Type A string.
/BackupNetworkName:name	Network name of the backup DLUS server.	1–8 characters, SNA Type A string.
/BackupCPName:name	Control point name of the backup DLUS server.	1–8 characters, SNA Type A string.
/DLURRetryType:N	DLUR retry type.	0 indicates none 1 indicates infinite 2 indicates limited
/DLURRetryLimit:N	DLUR retry limit. This parameter is invalid unless the DLUR retry type is set to limited.	1–65534
/DLURRetryDelay:N	Delay after a DLUR retry. This parameter is invalid unless the DLUR retry type is set to limited.	1–65535
/RetryLimit:N	Number of the connection retries.	0 indicates unlimited 1–65534 number of retries
/RetryDelay:N	Delay after a connection retry.	0–327670, must be a factor of 5.
/XIDFormat:N	XID type.	Set to: 1 – "Format 3"
/RemoteNetName:name	This value is always set to the network name of the IP-DLC link service.	Must be left blank for a new connection.
/RemoteCPName:name	This value is always set to the control point name of the IP-DLC link service.	Must be left blank for a new connection.

Creating an IP-DLC Connection

Viewing Connections

Defining Dependent LUs

Secure Deployment of the IP-DLC Link Service

Secure Deployment of the IP-DLC Link Service

The IP-DLC link service takes advantage of the entire Microsoft Host Integration Server 2004 secure deployment feature set, especially the following:

- A typical IP-DLC link service deployment scenario may use Internet Protocol security (IPSec), a firewall, or a virtual private network (VPN) as a security barrier between the Host Integration Server computer and the remote node. (A VPN is advisable if the HPR/IP link spans an insecure IP network.)
- Incoming frames from IP addresses that are not already defined in Host Integration Server are rejected. This isolates the main SNA node service from such attack.
- The IP-DLC link service checks the length of incoming datagrams before copying the data into internal data areas, and discards any that are too long.
- All configuration data—whether from registry entries, COM.cfg, or the SNA node service—is validated for correct value when first accessed. Particular consideration is given to validating lengths to avoid buffer overruns. If any errors are found, the IP-DLC link service logs an event and terminates.

Defining Dependent LUs

Connections and the SnaCfg Utility

Configuring IP-DLC

Host Integration Server 2004 offers an efficient means to integrate legacy Systems Network Architecture (SNA) networks with PC based data centers.

Host Integration Server has supported SNA as it has evolved beyond traditional subarea networks. Advanced Peer-to-Peer Networking (APPN) was an enhancement to SNA that brought the ability to move logical units and change routing without coordinated system definition. High Performance Routing (HPR) is an extension of the APPN architecture; it provides the following functions:

- Rapid Transport Protocol (RTP) minimizes processing cycles and storage requirements for routing network layer packets through intermediate nodes on a session route.
- Automatic Network Routing (ANR) enables APPN networks to automatically reroute sessions if a portion of the originally computed route fails.

Host Integration Server 2004 and IP-DLC

Internet Protocol - Data Link Control (IP-DLC) is another evolution of SNA, providing a means for the efficient transport of SNA data across an IP network. IP-DLC, also known as Enterprise Extender (EE) is an industry-standard solution defined by Internet Engineering Task Force (IETF) (RFC 2353). With IP-DLC, the RTP endpoint views its interface with the Universal Datagram Protocol (UDP) layer of the stack as just another data link control, and treats the connection across the IP network the same as it would any SNA connection.

This purpose of this section is to assist mainframe programmers and Host Integration Server 2004 administrators in configuring for IP-DLC. It also serves as a reference for Host Integration Server 2004, to be used in conjunction with online help in diagnosing and troubleshooting connectivity and configuration issues.

This section contains:

- Mainframe IP-DLC Configuration
- Host Integration Server 2004 Configuration
- Supported Features and Limitations
- Supported Configurations
- Troubleshooting
- Example Full Qryipdlc Log
- Automated Configuration

Mainframe IP-DLC Configuration

This section describes how to configure IP-DLC support on an IBM mainframe running the OS/390 or z/OS operating system. IP-DLC is also known as IBM Enterprise Extender.

To support IP-DLC on OS/390, you need OS/390 (version 2.7 or later) or z/OS.

Host Requirements

- IBM Enterprise Extender solution
- OS/390 (V2R7 or higher) or z/OS
- Communication Server for OS/390 V6 or higher

Network Adapter Requirements

- OSA or OSA Express
- Modes
  - SNA and TCP/IP (non-QDIO)
  - TCP/IP only (QDIO)

Configuring the OS/390 VTAM and TCP/IP Components:

1. Switch on the HPR support and CP-CP session support start options in SYS1.VTAMLST(ATCSTR00).
2. Define an External Communications Adapter (XCA) major node for HPR/IP.
3. Enable Virtual Telecommunications Access Method (VTAM) to be a TCP/IP application.
4. Configure switched major nodes for physical units (PUs) SYS1.VTAMST(member)

Each of these configuration steps is described briefly in the following sections. For more detailed explanations on configuring Enterprise Extender as well as additional examples from the VTAM and TCP/IP configuration files (including a switched major node definition for some of the PUs), see the following IBM documentation:

- OS/390 eNetwork Communications Server SNA Resource Definition Reference (SC31-8565-02)
- OS/390 eNetwork Communications Server IP Configuration (SC31-8513-02)**http://www.1.ibm.com/servers/eserver/zseries/library/techpapers/enterprise_extender.html**

The HPR and CP-CPs Session start options are set as follows:

To configure the. HPR and CP-CP Session Start Options(SYS1.VTAMLST(ATCSTR00))

- Add the following line to the start options in SYS1.VTAMLST(ATCSTR00):

  HPR=RTP,CPCP=YES

A typical ATCSTR00 file is displayed below:

```
CONFIG=00,SUPP=NOSUP,
SSCPID=06,NOPROMPT,
HOSTSA=1,SACONNS=YES,
SSCPNAME=P390,HOSTPU=P390$PU,
NETID=APPN,
NODETYPE=NN,CPCP=YES,
DYNLU=YES,CDSERVR=YES,HPR=RTP,CDRDYN=YES,CONNTYPE=APPN,DYNADJCP=YES,
CMPVTAM=4,BN=YES,
DIRTIME=90000S,
CRPLBUF=(208,,15,,1,16),
IOBUF=(400,508,19,,1,20),
LFBUF=(104,,0,,1,1),
LPBUF=(64,,0,,1,1),
SFBUF=(163,,0,,1,1)
*/*
*/* LIB: SYS1.VTAMLST(ATCSTR00)
*/* GDE: CBIPO COMMUNICATIONS
*/* DOC: THIS MEMBER CONTAINS THE ACF/VTAM DEFAULT
*/*      START OPTIONS ON THE MODEL INSTALLATION SYSTEM.
*/*
```

A new dataset member containing an IP-DLC XCA major node definition must be added to SYS1.VTAMLST

To add the XCA major node (SYS1.VTAMLST(member)):

1. Open SYS1.VTAMLST. An example of SYS1.VTAMLST is displayed below:

```
*/* SYS1.VTAMLST(XCAE40EE)
*/* ---------------------------------------------------------------
*/*
*/* ENTERPRISE EXTENDER OVER TOKEN RING ADAPTER1 (E40)
*/*
*/* ---------------------------------------------------------------
*/*
XCAE40EE VBUILD TYPE=XCA
*/*
XPE40EE PORT MEDIUM=HPRIP, -
VNNAME=EEJEB, -
VNGROUP=EEGRPJ, -
LIVTIME=15, -
SRQTIME=15, -
SRQRETRY=9, -
SAPADDR=04
*/*
EEGRPJ GROUP ANSWER=ON, -
AUTOGEN=(64,L,P), -
CALL=INOUT, -
DIAL=YES, -
DYNPU=YES, -
DYNPUPFX=$E, -
ISTATUS=ACTIVE
*/*
```

1. It may be possible to add the new dataset member to the list of nodes that are activated during VTAM startup (SYS1.VTAMLST(ATCCON00). However, in order to do so, the TCP/IP stack first requires initialization. If, when adding the dataset member to the VTAM, startup fails, try adding it to the VTAM application startup list (SYS1.PARMLIB(VTAMAPPL) by appending the following lines:

```
v net,act,id=xcae40ee (id= should be the XCA member name)
Pause 120
```

The **Pause** command is specified in seconds and should be coded with enough time to let TCP/IP initialize on the target platform.

An example of a VTAMAPPL file is displayed below:

```
CommandPrefix=None   /* This is the default value */
/*-----------------------------------------------------------------*/
/* Automatically Start Several VTAM Applications                   */
/*-----------------------------------------------------------------*/
Pause 10      /* Wait for sys to get up first  */
S vlf,sub=mstr
Pause 10      /* Wait for sys to get up first  */
S lla,sub=mstr
S Tcas        /* Time Sharing Option */
/*S rmf*/         /* RMF                 */
S tcpip
/*s irlmproc*/
Pause 10      /* Wait for sys to get up first  */
/* s imwebsrv */
/* s nfss  */
Pause 10      /* Wait extended for TCAS        */
s sdsf
s cicsa
```

```
Pause 135     /* Wait extended for TCAS        */
v net,act,id=xcae40ee
Pause 120
$S LOGON(1)
Pause 30
$s LINE(*)
Pause 30
$s RMT(*)
Pause 60

Pause 60
S NVDM
Pause 60
F NVDM,START
/*-START DB2*/
D T                            /* Display Ending time                   */
* Comment lines may also start with a single asterisk.
* Remember - blank lines are a BIG no-no.
*CommandPrefix=)   /* Require all Vtamappl commands to start with ")" */
*@ *--------------------------*
*@ * IPL startup is complete! *
*@ * >>> Have a nice day! <<< *
*@ *--------------------------*
```

To configure VTAM to TCP/IP (TCPIP.PROFILE.TCPIP):

1. The TCP/IP profile file must be updated. Add an IUTSAMEH device and link as shown below so that VTAM can access the TCP/IP stack:

```
DEVICE IUTSAMEH MPCPTP AUTORESTART
LINK samehlnk MPCPTP IUTSAMEH
```

1. Add a VIPA device and link for IP-DLC as shown below:

```
DEVICE VIPADEV2 VIRT 0
LINK P390IP VIRT 0 VIPADEV2
```

1. Add the VIPA link to the head of the **HOME** list as shown below:

```
HOME
172.1.1.1 P390IP
```

An example of a TCPIP.PROFILE.TCPIP file is as displayed below:

```
; TCPIP.PROFILE.TCPIP
; ===================

;
; You can specify DATASETPREFIX in the PROFILE.TCPIP and
; TCPIP.DATA data sets. If this statement is used in a profile or
; configuration data set that is allocated to a client or a server, then
; that client or server dynamically allocates additional required data
; sets using the value specified for DATASETPREFIX as the data set name
; prefix.  The DATASETPREFIX parameter can be up to 26 characters long,
; and the parameter must NOT end with a period.
;
```

```
; For more information please see "Understanding TCP/IP Data Set
; Names" in the Customization and Administration Guide.

Switched Major Nodes for PUs SYS1.VTAMST(member)

It is possible to define each PU to VTAM in a switched major node, however, the recommended method is to configure the VTAM user exit ISTEXCCS to dynamically define PUs as connections made over IP-DLC.

These PU definitions are not specific to IP-DLC and can be used by PUs to connect over any External Communications Adapter (XCA).

1. Follow the example below to to configure the VTAM user exit ISTEXCCS to dynamically define PUs as connections made over IP-DLC

```
*/* SYS1.DYNXID.VTAMLST(WSICSW01)

```

Verifying IP-DLC (Enterprise Extender)

Once IP-DLC has been configured, it must be verified. After IP-DLC activation, issue the following three commands to verify Enterprise Extender is running:

- D TCPIP,TCPIP,NETSTAT,DEV
- D NET,ID=XCAEE
- D NET,ID=PUTO65,E

D TCPIP, TCPIP, NETSTAT, DEV shows the status of Virtual IP Adapter (VIPA) and IUTSAMEH (VTAM) DEVICE is used for Enterprise Extender.

To issue the D TCPIP,TCPIP,NETSTAT,DEV command:

1. Issue the following command:

```
D TCPIP,TCPIP,NETSTAT,DEV
```

1. The returned data should resemble the following:

```
DEVNAME: VIPA DEVTYPE: VIPA
DEVSTATUS: READY
LNKNAME: VLINK LNKTYPE: VIPA LNKSTATUS: READY
NETNUM: 0 QUESIZE: 0
DEVNAME: IUTSAMEH DEVTYPE: MPC
DEVSTATUS: READY
LNKNAME: EELINK LNKTYPE: MPC LNKSTATUS: READY
NETNUM: 0 QUESIZE: 0
```

1. Confirm that the Virtual IP Adapter and IUTSAMEH (VTAM) have a link status of "READY".

D NET,ID=XCAEE,E shows a display of XCAEE (XCA majnode) used for Enterprise Extender.

To issue the D NET,ID=XCAEE,Ecommand:

1. Issue the following command:

```
D NET,ID=XCAEE,E
```

1. The returned data should resemble the following:

```
IST097I DISPLAY ACCEPTED
IST075I NAME = XCAEE, TYPE = XCA MAJOR NODE 222
IST486I STATUS= ACTIV, DESIRED STATE= ACTIV
IST1679I MEDIUM = HPRIP
IST1685I TCP/IP JOB NAME = TCPIPD
IST1680I LOCAL IP ADDRESS 172.168.1.2 (VIPA1)
IST1656I VTAMTOPO = REPORT, NODE REPORTED - YES
IST170I LINES:
IST232I L0000000 ACTIV
IST232I L0000001 ACTIV
IST232I L0000002 ACTIV
IST232I L0000003 ACTIV
IST314I END
```

1. Ensure the status of the XCA major node is set to ACTIV and that the following has been configured:

```
HPRIP Medium=HPRIP (as opposed to CSMACD, ATM, or RING).
TCPIPD This is the TCP/IP job name.
172.168.1.2 This is the local VIPA.
```

D NET,ID=PU3270,E shows a display of the Physical Unit used for Enterprise Extender.

To issue the D NET,ID=PU3270,Ecommand

1. Issue the following command:

```
D NET,ID=PU3270,E
```

1. The returned data should resemble the following:

```
IST097I DISPLAY ACCEPTED
IST075I NAME = PU33270, TYPE = PU_T2.1 643
IST486I STATUS= ACTIV, DESIRED STATE= ACTIV
IST1043I CP NAME = HISERVER, CP NETID = APPN, DYNAMIC LU = YES

```

1. Confirm that the following is true:

   PU_T2.1

   The link station is a PU type 2.1, APPN connection between the NNs.

   TGN CP-CP

   The link station is in the APPN topology database CP-CP

   HPR=RTP.

   The level of HPR supported is RTP and the status of the connection.

   LOCAL IP ADDRESS

   172.168.1.2 is the VIPA address of the TCP/IP stack being used by this VTAM.

   REMOTE IP ADDRESS

172.168.1.3 is the VIPA address of the remote NN.

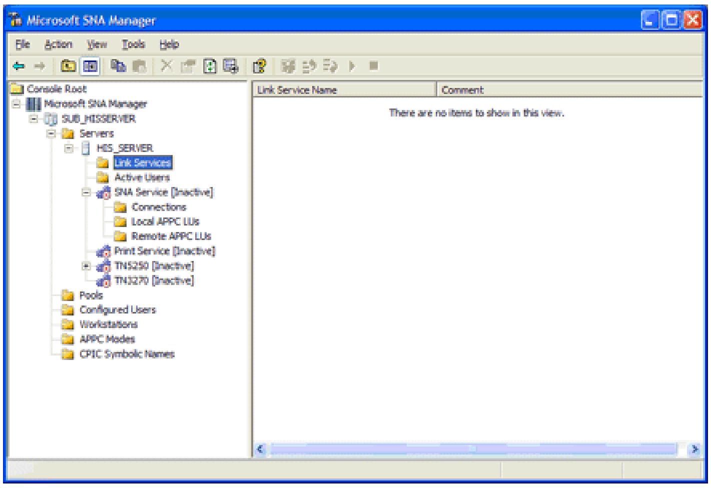
Host Integration Server 2004 Configuration

Host Integration Server 2004 is typically configured through SNA Manager. However, there are automated methods for configuring IP-DLC link service and Connections.

Follow the instructions below to create an IP-DLC Link Service:

To configure the Link Service:

1. Click **Start**, click **Programs**, click **Microsoft Host Integration Server**, and then click **SNA Manager**. The following dialog box will appear.

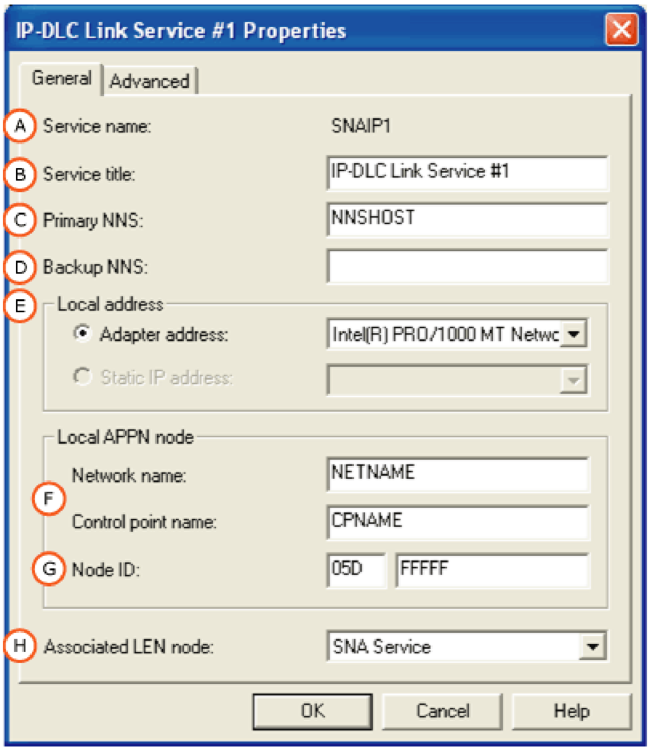


Microsoft SNA Manager
File Action View Tools Help
Console Root
Microsoft SNA Manager
SUB_HISSERVER
Servers
HIS_SERVER
Link Services
Active Users
SNA Service [Inactive]
Connections
Local APPC LUs
Remote APPC LUs
Print Service [Inactive]
TN5250 [Inactive]
TN3270 [Inactive]
Pools
Configured Users
Workstations
APPC Modes
CPIC Symbolic Names
Link Service Name
Comment

There are no items to show in this view.

2. Right-click **Link Services**, click **New**, and then **Link Service**.
3. Select **IP-DLC Link Service**, then click **Add**. The Link Service Properties dialog will appear.

Use the following illustration as a guideline to configure the IP-DLC Link Service.



IP-DLC Link Service #1 Properties
General

Help

Service name: SNAIP1

Service title: IP-DLC Link Service #1

Primary NNS: NNSHOST

Backup NNS:

Local address

● Adapter address: Intel(R) PRO/1000 MT Netwc

○ Static IP address:

Local APPN node

Network name: NETNAME

Control point name: CPNAME

Node ID: 05D FFFFF

Associated LEN node: SNA Service

Title	Description
A: Service Name	Name of the link service to be configured. For a new link service, the name is predefined as SNAIP#, where # is the ordinal number of the link service.
B: Service title:	A user friendly description up to 128 characters. Default value is IP-DLC Link Service #N, where N is the ordinal number of the link service.
C: Primary NNS:	Enter the IP address, host name, or fully qualified name of the Primary Network Node Server.

D: Backup NNS:	Enter the IP address, host name, or fully qualified name of the Backup Network Node Server. Note: Primary and Backup NNS values can be determined by using /D NET,VTAMOPTS command and locating the IPADDR= parameter.
E: Local Address	Assigns the link service to an IP address. Every link service must be associated with a local IP address or logical connection, and neither the IP address nor the logical connection can be used by another IP-DLC link service on the computer. For multiple IP addresses on a single network adapter, select the Static IP address option and specify the appropriate IP address for the IP-DLC service to use.
F: Network & Control Point Names: Network NAME	Enter the APPN network name for the IP-DLC link service operating as the local APPN node across which the IP-DLC link service will communicate. This value must be text with a maximum of eight characters and comply with the APPN naming convention.
F: Network & Control Point Names: Control Point Name	Enter the APPN control point name for the IP-DLC link service operating as a local APPN node. This value must be text with a maximum of eight characters and comply with the APPN naming convention. There is no default value. The control point name must be unique for this computer on the APPN Network.
G: Node ID:	Typically is it recommended that the Node ID: be left as default and enabled Dynamic PU generation on the host (DynPU=Yes). However, Host Integration Server 2004 can be configured with a static PU ID. Note: The PU definition should not have any LUs defined. IDBLK= & IDNUM= parameters in the PU Definition defined in VTAM.
H: Associated LEN node:	Select the appropriate SNA Service (APPN LEN Node) to associate with the IP-DLC link service. Default value is the first SNA Service on the local computer.

To configure the IP-DLC Connection:

1. From SNA Manager, right-click **Connections**, click **New**, and then click **IP-DLC**.

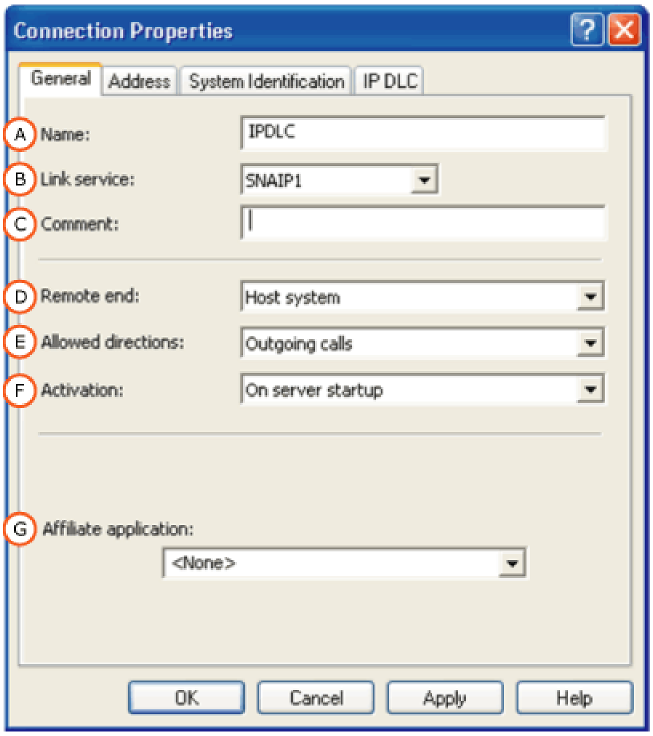
2. Use the following illustrations as guidelines to configure the IP-DLC connection.



Name: IPDLC
Link service: SNAIP1
Comment:
Remote end: Host system
Allowed directions: Outgoing calls
Activation: On server startup
Affiliate application: <None>

Title	**Description**
A: Name:	Name of the IP-DLC link service. The name has to be unique to the HIS 2004 Server Subdomain.
B: Link service:	Select the appropriate IP-DLC Link Service from the drop down list.
C: Comment:	Specify Host System for use with dependent LU traffic. Specify Peer System independent APPC LU sessions.
D: Remote end:	Note: You cannot associate dependent 3270 LUs with an IP-DLC connection remote end type of peer system. Because Peer System IP-DLC connections do not support dependent LU traffic, selecting this option will disable all controls on the Address page and the IP-DLC page. Only one peer connection can be associated with an IP-DLC link service. Note: Selecting Peer System automatically sets Activation to On Server Startup and Allowed directions to Both.
E: Allowed directions:	Outgoing calls: Connection is outgoing. Incoming calls: Connection is incoming. Both directions: Connection can be both incoming and outgoing.
F: Activation:	Activation: Specifies conditions under which connection is activated. On server startup: Connection is activated on server startup. On demand: Connection is activated on demand. By administrator: Connection can only be activated by system administrator.
G: Affiliate application:	If you configured Single Sign-On, choose an affiliate application from the list. Enterprise Single Sign-On (SSO) affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using SSO.

Network name: NNSHOST

Control point name: CPHOST

Network name:

Control point name:

Address:

Network name:

Control point name:

Title	Description
B: Network name:	Enter the name of the APPN network in which to locate the Primary Dependent LU Server (DLUS). Maximum of 8 characters.
C: Control point name:	Enter the control point name of the Primary DLUS. Maximum of 8 characters.
D: Network name:	Enter the name of the APPN network in which to locate the Backup DLUS. Maximum of 8 characters.
E: Control point name:	Enter the control point name of the Backup DLUS. Maximum of 8 characters.
F: Address:	Enter the IP address, host name, or fully qualified name for the NNS as routing server through which to connect to the DLUS.
G: Network Name:	Enter the name of the APPN network in which to locate the DLUS. Maximum of 8 characters.
H: Control point name:	Enter the control point name of the DLUS. Maximum of 8 characters.

Note Preferred routing node: Using a separate NNS may improve performance by offloading the DLUS host computer from operating as an NNS directory server. The IP-DLC link service will attempt to establish the connection to the DLUS using the preferred route address. If this fails, the link service will request an alternate route from the NNS.

Connection retry limits

○ Unlimited

● Limited: 8 times

Delay after retry: 10 seconds

DLUR retry limits

○ No retries

○ Unlimited

● Limited: 8 times

Delay after retry: 10 seconds

Title	Description
A: Connection retry limits	Are used for setting retry limits for activating a connection. Unlimited Continues to retry activating a connection until successful (essentially setting value to infinite). Limited Specifies the number of retries, from 1-65534.
B: Delay after retry:	Specifies the wait period before an activation retry attempt is made. Valid values are 1-327670 seconds. Must be a multiple of five.
C:Dependent LU Requester retry limits	Are used to specify retry action in case the DLUR connection fails.

No retries	Specifies no retry attempts. Unlimited
Specifies an infinite number of retries. Limited	Specifies the number of retries, from 1-65534.
D: Delay after retry:	Specifies the wait period after each retry, from 1-65535

Supported Features and Limitations

This section contains:

- Host Integration Server 2004 Supported Features over IP-DLC
- IP-DLC Link Service Limitations

Host Integration Server 2004 Supported Features over IP-DLC

The following existing Host Integration Server 2004 SNA features are supported over the IP-DLC link service.

Base SNA Features

- LU types 0, 1, 2, 3 and 6.2 (dependent and independent)
- LUA, FMI, APPC and CPI-C APIs
- Dynamically Defined Dependent LUs (DDDLUs)
- Dynamic local LU, remote LU and connection configuration
- Incoming and outgoing calls
- Connection Activation at Server startup, on demand or by administrator
- SNA data compression
- PU concentration with the upstream link over IP-DLC
- NetView RUNCMD/Alerts (note that the IP-DLC link service does not generate alerts)

Since the SNA features above are supported, it follows that the following applications are supported over the new IP-DLC link service.

- Host Integration Server-compatible 3270 emulators
- Host Integration Server-compatible 5250 emulators
- APPC - 3270 Session Viewer (including the LU-LU Test feature)
- Host Print Service
- Data Integration Services
- Local and remote administration
- TN3270 server
- TN5250 server
- MSMQ_MQSeries Bridge
- Transaction Integrator (Formerly known as COMTI)

Fault Tolerance Features

Note that since the IP-DLC link service uses the APPN and HPR/IP protocols, it is automatically able to take advantage of the following fault tolerance features.

- A function of HPR is the ability to reroute sessions around a failure in the network, provided that an alternative route exists.
- IBM's Parallel Sysplex technology and Multi-Node Persistent Sessions (MNPS) features together allow mainframe applications to be moved to a different processor with little or no impact to users when system or application failures occur on the mainframe. Parallel Sysplex is a clustering technology that provides high availability, load balancing and scalable growth to the large mainframe environment. MNPS allows sessions to be restarted on another system in a Parallel Sysplex after hardware or software failure. (See Networking Implications of S/390 Parallel Sysplex, http://go.microsoft.com/fwlink/?LinkId=38994, for further information.)

The IP-DLC link service cannot provide any fault tolerance capabilities to seamlessly handle local adapter failures. However, it may be possible to achieve some fault tolerance for adapter failure on the Host Integration Server 2004 system by using NIC teaming at the MAC layer.

Load Balancing Features

Load balancing for a single IP-DLC link service, with a single local IP address, over multiple adapter cards can be achieved using NIC Teaming at the MAC layer. The IP-DLC link service handles frames arriving out of sequence.

Scalability

The IP-DLC link service contains no hard limits of its own regarding the number of sessions or users. The scalability limits are the same as the existing 802.2 link service. The IP-DLC link service supports the Host Integration Server 2004 capacity of 30,000 simultaneous host sessions per server.

Note Four nodes are required to achieve 30,000 simultaneous host sessions and a single node supports a maximum of 15,000 simultaneous host sessions.

IP-DLC Link Service Limitations

The key limitations with the IP-DLC link service implementation are as follows.

- Some network configurations are not supported. These are documented explicitly in the section Supported Network Configurations with Dependent LUs**.**
- The IP-DLC link service cannot be run as a distributed link service (DLS). However, given that there is an IP connection between the node's server and the APPN network, it is unclear that there is any requirement to implement IP-DLC distributed link service.
- The PU passthrough and downstream connections are not supported over IP-DLC connections. It is not possible to have a one-to-one correspondence between upstream and downstream messages where the upstream connection is an IP-DLC connection.
- Each IP-DLC link service must use a different CP name from the SNA node service. This limitation is a consequence of each IP-DLC link service appearing in the APPN network as a separate node and therefore must have a unique node name. This restriction must be enforced by the SNA Manager Configuration panels.
- Each IP-DLC link service requires a unique local IP address. If multiple IP-DLC link services are required, each must have its own unique local IP address.
- A single IP-DLC link service cannot be shared by multiple SNA node services. Each SNA node service must use a different IP-DLC link service for IP-DLC connectivity.

Supported Configurations

The following sections list network configurations that are supported by IP-DLC.

This section contains:

- Supported Network Configurations with Dependent LUs
- Supported Network Configurations with Independent LUs
- Secure Deployment

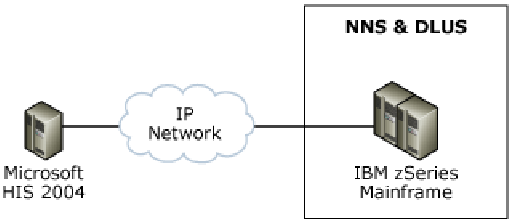
Supported Network Configurations with Dependent LUs

This section shows how Host Integration Server 2004 with IP-DLC can be used to activate dependent LU sessions between Host Integration Server 2004 applications and host applications.

This section contains:

- Direct IP-DLC Connection to Mainframe (DLUS) and NNS
- IP-DLC Connection to Mainframe (DLUS) through Separate NNS
- Separate IP-DLC Connections to Mainframe (DLUS) and NNS
- Simultaneous IP-DLC Connections to Multiple Mainframe Hosts
- PU Concentration with Multiple IP-DLC Host Connections

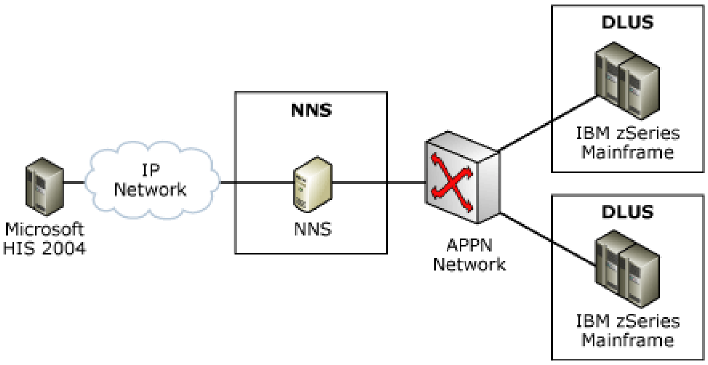
Direct IP-DLC Connection to Mainframe (DLUS) and NNS



This configuration shows a single Host Integration Server 2004 node with a direct IP-DLC connection to a host running CS/390. In this scenario, the mainframe is providing NNS to the Host Integration Server 2004 node as well as providing the DLUS support required to support dependent LUs over the IP-DLC link service. Host Integration Server 2004 applications such as 3270 emulators can establish sessions with applications such as TSO/E on the mainframe system.

It is possible to define multiple Host Integration Server 2004 internal PUs, each having its own IP-DLC connection. All of these PUs are multiplexed over the single HPR/IP link to the same DLUS on the same CS/390.

IP-DLC Connection to Mainframe (DLUS) through Separate NNS

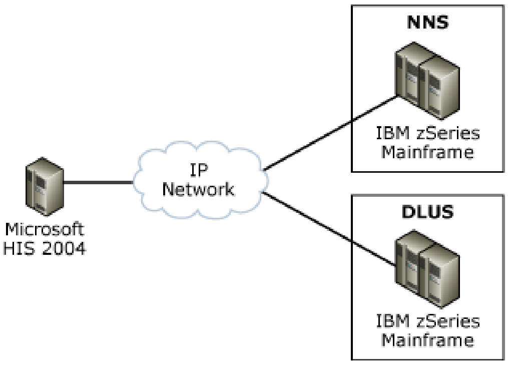


DLUS
IBM zSeries Mainframe
NNS
IP Network
NNS
Microsoft HIS 2004
APPN Network
DLUS
IBM zSeries Mainframe

This scenario is similar to the previous one, except that NNS are provided by another APPN NNS (for example, Data Connection Limited (DCL) SNAP-IX) rather than the mainframe running the DLUS. Dependent LU support is provided through the NNS. The key requirement here is that the NNS and mainframe must be part of the same reachable APPN network so that SNA sessions can be activated between them.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

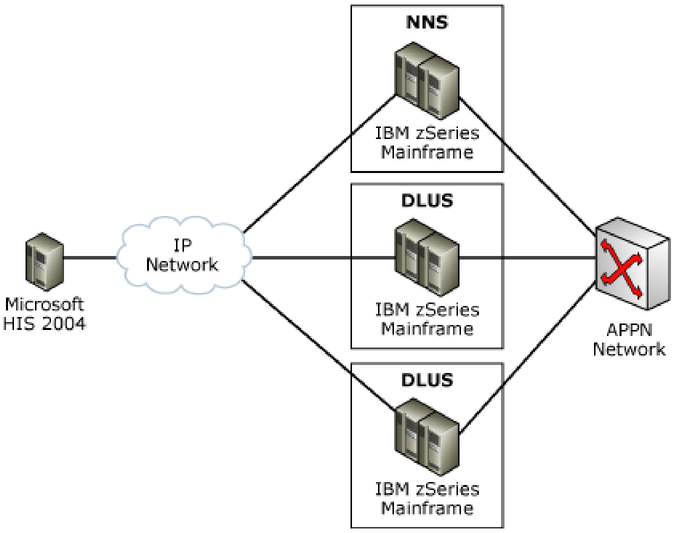
Separate IP-DLC Connections to Mainframe (DLUS) and NNS



NNS
IBM zSeries Mainframe
IP Network
Microsoft HIS 2004
DLUS
IBM zSeries Mainframe

This scenario is similar to the previous one, except that the Host Integration Server 2004 node also has a direct APPN link to the mainframe that is running the DLUS and on which the host applications reside. This allows the dependent LU traffic to flow directly between the Host Integration Server 2004 machine and the mainframe where the host applications are running, which avoids making the APPN NNS a bottleneck.

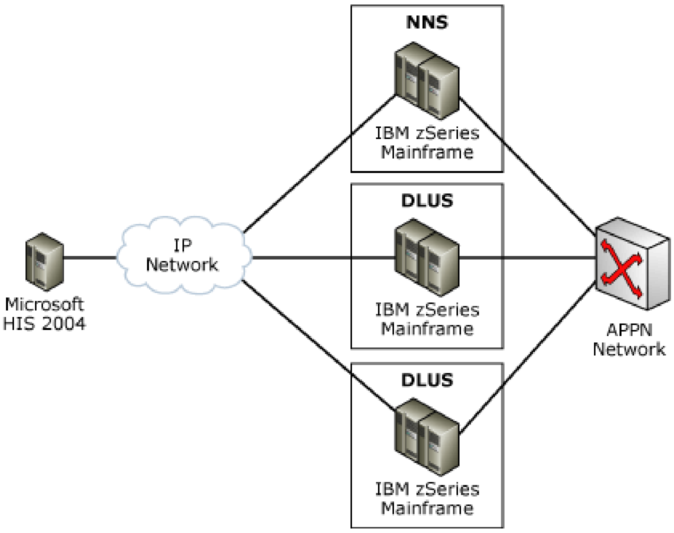
Simultaneous IP-DLC Connections to Multiple Mainframe Hosts



NNS
IBM zSeries Mainframe
DLUS
IBM zSeries Mainframe
DLUS
IBM zSeries Mainframe
Microsoft HIS 2004
IP Network
APPN Network

In this configuration, the Host Integration Server 2004 IP-DLC link service is supporting multiple internal Host Integration Server 2004 PUs but to different DLUS on different CS/390s. One mainframe is providing NNS and there are separate IP paths to each CS/390. Again, there is a requirement that all of the CS/390s must be part of the same APPN network.

PU Concentration with Multiple IP-DLC Host Connections



NNS
IBM zSeries Mainframe
DLUS
IBM zSeries Mainframe
DLUS
IBM zSeries Mainframe
Microsoft HIS 2004
IP Network
APPN Network

Again, this setup is similar to the last one except that the Host Integration Server 2004 machine is providing PU concentration support for several downstream PUs (DSPUs). 3270 applications on the downstream PUs can communicate, through Host Integration Server 2004, with applications on all of the mainframe machines.

No specific provision is required in the IP-DLC link service for this and it can be configured in the usual way. However, note that the link service used by the DSPUs cannot be IP-DLC.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

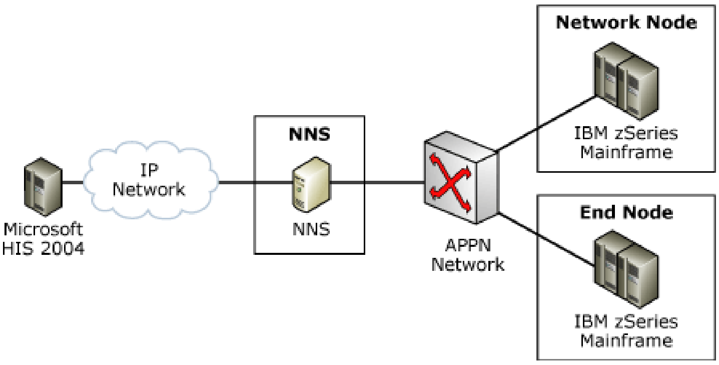
Supported Network Configurations with Independent LUs

This section shows how Host Integration Server 2004 with IP-DLC can be used to activate independent LU sessions between Host Integration Server 2004 applications and applications on peer systems.

This section contains:

- IP-DLC Connection to the Entire APPN Network
- IP-DLC Connection to APPN with Two Host Integration Server 2004 Nodes

IP-DLC Connection to the Entire APPN Network



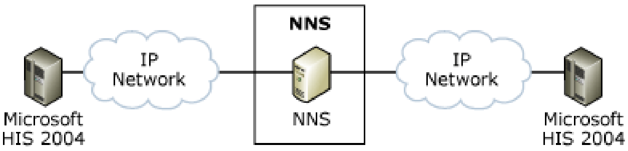
Network Node
IBM zSeries Mainframe
NNS
IP Network
Microsoft HIS 2004
NNS
APPN Network
End Node
IBM zSeries Mainframe

In this configuration, the NNS provides access to the entire APPN network. Therefore, Host Integration Server 2004 is able to activate independent LU 6.2 sessions with any reachable node in that network.

Advanced Program-to-Program (APPC) and Common Programming Interface for Communications (CPI-C) transaction programs on Host Integration Server 2004 can communicate with partner transaction programs on any other node in the APPN network.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

IP-DLC Connection to APPN with Two Host Integration Server 2004 Nodes



NNS
Microsoft
HIS 2004
IP
Network
NNS
IP
Network
Microsoft
HIS 2004

This configuration is similar to the last but also shows that two Host Integration Server 2004 nodes can communicate by way of the same (or possibly different) NNS.

Secure Deployment

This section contains:

- UDP Sockets for HPR/IP Protocol Traffic
- Firewall Configuration
- Securing Host Integration Server 2004 IP-DLC Connections

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

UDP Sockets for HPR/IP Protocol Traffic

There are two specific concerns at the UDP sockets level:

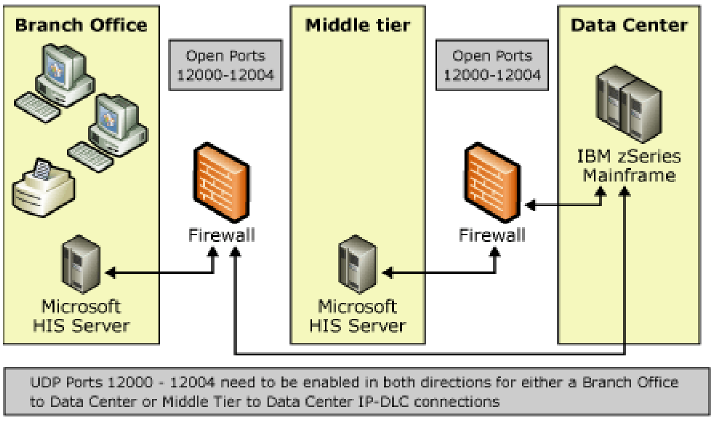
- Attempts to activate connections that are not defined to Host Integration Server 2004.
- Denial of Service attacks by flooding the IP-DLC link service with datagrams or by sending large datagrams.

Any incoming frames from IP addresses that are not defined in Host Integration Server 2004 configuration are rejected at the earliest point in the IP-DLC link service code. This prevents the main SNA node service from being attacked.

When receiving datagrams, the IP-DLC link service checks the length before copying the data into internal data areas and discards any that are too long.

Firewall Configuration

The IP-DLC protocol is based on five hard coded UDP ports. These ports are 12000-12004. The traffic should be enabled in both directions.



Branch Office
Open Ports 12000-12004
Middle tier
Open Ports 12000-12004
Data Center
IBM zSeries Mainframe
Firewall
Firewall
Microsoft HIS Server
Microsoft HIS Server
UDP Ports 12000 - 12004 need to be enabled in both directions for either a Branch Office to Data Center or Middle Tier to Data Center IP-DLC connections

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Securing Host Integration Server 2004 IP-DLC Connections

Since the IP-DLC link service uses UDP/IP, the Microsoft Windows® IPSec feature can be used to provide end-to-end data security over the IP-DLC link service. Configuration of IPSec is handled independently by Windows. No specific configuration is required for the IP-DLC link service.

Troubleshooting

The IP-DLC link service uses several methods of logging and tracing which are fully integrated with the existing Host Integration Server 2004 diagnostic functions. They are controlled by the SNA Trace Utility and can be viewed with the Host Integration Server 2004 Trace Viewer.

The problem determination facilities range from high-level event logging to detailed tracing for administrators and developers. Also included are off-line debugging aids that can be used in the event of a crash. Moreover, Host Integration Server 2004 includes performance counters which can be used for troubleshooting purposes.

This section contains:

- Event Logs
- Diagnostic Gathering Tool
- Performance Monitor Statistics

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Event Logs

The IP-DLC link service uses the Windows event log to record events which may be of interest to administrators in troubleshooting problems.

There are four types of IP-DLC event logs. Each is uniquely identified by Event Category (Base, Tools, APPN, LDLC) and Event ID.

- Fatal (unrecoverable error) - severity event log
- Problem (degrades link service operation) – error event log.
- Exception (may degrade link service operation) – warning event log.
- Audit (normal event, for admin use) – informational event log.

This section contains:

- Typical IP-DLC Link Service Event Log Entry
- UDP Trace
- Internal Trace
- Crash Dumps

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Typical IP-DLC Link Service Event Log Entry

The following is a Typical IP-DLC Link Service Event Log:

```
Event Type:   Warning
Event Source:   SNA IP-DLC Link Service
Event Category:   APPN
Event ID:   585
Date:      8/12/2004
Time:      6:06:15 PM
User:      HISERVER\HISADMIN
Computer:   HISERVER
Description:
CPSVRMGR pipe session failure
  DLUS partner                    = MVSRUS.P390SSCP
  Sense Code                      = 0x08a00008

 Cause:
 CPSVRMGR pipe failed to specified DLUS.  This error may occur during normal deactivation of
the CPSVRMGR pipe when the DLUS no longer requires it.  Note that this message could be logge
d during normal node shutdown.

Effect:
Any PUs using the specified DLUS are deactivated (that is, DACTPU(cold)) is sent.  DLUR may a
ttempt to contact one or more backup DLUSs, if configured.

 Action:
 If a pipe with backup DLUS is not initiated automatically manually restart any required PUs

For more information, see Help and Support Center at http://go.microsoft.com/fwlink/events.as
p.
Data:
0000: 53 4e 41 49 50 31 2c 20   SNAIP1,
0008: 31                        1
```

Note Administrators can either allow or suppress event logs based on severity by changing the Default Audit Log Level on the **Subdomain Properties: Error / Audit Logging** property sheet in SNA Manager. No changes are required to the configuration interface. This is shown in the following figure.

A ○ Detailed problem analysis
B ○ General information messages
C ● Significant system events
D ○ Audit logging disabled

Title	Description
A: Detailed problem analysis	Select this option to record all events that can be recorded.
B: General Information messages	Select this option to record general activity but not all events.
C: Significant system events	Select this option to record only major events.
D: Audit logging disabled	Select this option to turn off all audit logging.

UDP Trace

The IP-DLC link service traces the contents of all UDP packets that it sends and receives over the IP network. This trace appears in the Host Integration Server 2004 Message Trace files, LINKMSGX.ATF.

UDP tracing is configured by the Host Integration Server 2004 Trace Initiator on a per link service basis (Message Trace, Level 2 Messages).

Internal Trace

The internal tracing from the IP-DLC link service uses the standard Host Integration Server 2004 internal tracing mechanism and appears in the Host Integration Server 2004 Internal Trace files, LINKINTX.ATF. It is configured by the Host Integration Server 2004 Trace Initiator on a per link service basis.

Crash Dumps

In the event of a crash, Dr. Watson can generate a dump of the IP-DLC link service process data. Crash Dumps can be very useful to diagnose problems which cannot be determined by through other diagnostic forms. Crash Dumps can be sent to Product Support Services (PSS) upon request.

Diagnostic Gathering Tool

Configuration errors are typically diagnosed by examining the application event log. PSS may also request IP-DLC link service traces to help diagnose the issue.

The Detailed Diagnostics Tool is a separate executable that queries the current state of an IP-DLC link service and then outputs the information to a text file. The two methods of running the detailed diagnostics tool are by using a command line, and from the diagnostic tool.

To run qryipdlc from the command line use the following:

```
C:\Program Files\Microsoft Host Integration Server\system qryipdlc
```

The syntax of this command is:

```
QRYIPDLC [/S server-name] [/L link-service-names] [/A] /O output-file-name
QRYIPDLC /?
```

This usage message is printed:

```
  /S server-name
            The name of the server on which the IP-DLC link services
            are running.  If omitted, the local machine is assumed.

  /L link-service-names
            The names of the IP-DLC link services to query, separated
            by semicolons (e.g. snaip1;snaip2).  If omitted, all IP-DLC
            link services will be queried.
  /A        Append to the output file.

  /O output-file-name
            The name of the file to write the diagnostics to.
```

An example of a typical command line syntax, if running on the Host Integration Server 2004 machine is shown below:

```
Qryipdlc /L SNAIP1 /O IPDLCLOG.txt
```

Running Qryipdlc from the Diagnostics Tool (Display.exe)

You can execute Qryipdlc using the Diagnostics Utility from the **Tools** menu in SNA Manager. Configure the server name or IP address in the appropriate field and click **Status**. The Diagnostics tool will automatically query all link services configured on the server. A copy of the log file is automatically saved to the traces directory with the name of QueryIPDLC.txt.

```

Performance Monitor Statistics

The IP-DLC link service supports performance monitor counters. The following Host Integration Server 2004 performance monitor counters are included when installing an IP-DLC link service:

- TotalBytesThroughput
- TotalFramesThroughput
- TotalBytesReceived
- TotalBytesTransmitted
- TotalFramesReceived
- TotalFramesTransmitted
- SuccessfulConnects
- ConnectionFailures
- AdapterFailures.

> **Note** All of the counters above are visible in the Windows performance monitor while the IP-DLC link service is running.

Detailed Diagnostics for IP-DLC Link Service SNAIP1 on HISERVER
Created at Tue Aug 03 2004 16:46:52 Paci

Link Service Status
===================
Create parameters:
  Node type                                             Branch Network Node
  FQCP name                                             MYNET.HISERVER
  CP alias                                              HISERVER
  Node ID (IDBLK/IDNUM)                                 X'05D.FFFFF'
  Mode to COS mapping supported                         No
  MDS and MS capabilities supported                     No
  Maximum locates                                       1000
  Directory cache size                                  1000
  Maximum directory entries                             Unlimited
  Locate timeout                                        540 seconds
  Register resources with NN                            All
  Size of MDS send alert queue                          16
  Size of COS database weights cache                    8
  Size of topology database routing tree cache          8
  Maximum number of uses of a cache tree                1
  Maximum number of nodes in topology database          Unlimited
  Maximum number of TGs in topology database            Unlimited
  Maximum ISR sessions                                  30000
  Upper threshold for ISR sessions                      29000
  Lower threshold for ISR sessions                      28000
  Maximum ISR RU size                                   61440 bytes
  ISR receive pacing window size                        63
  NN route additional resistance                        0
  HPR support                                           Control flows
  Program Temporary Fix (PTF) array                     X'060000000000001E8000'
  Disable branch awareness                              No
Uptime                                                  4931.85 seconds
Memory available                                        226993 KB
Memory used                                             353 KB
NN status                                               Uncongested
NN resource sequence number                             2
Good XIDs for defined link stations                     2
Bad XIDs for defined link stations                      0
Good XIDs for dynamic link stations                     0
Bad XIDs for dynamic link stations                      0
NNS support for registration of DLUS-served LUs         Yes
NNS support for receipt of different owning CP name     No
Network node server name                                MVSRUS.P390SSCP
Current ISR sessions                                    0

Network Node Server Status
==========================
LS name  | State            | Adjacent CP name  | Default NNS | Remote address
---------+------------------+-------------------+-------------+------------------------
@N000001 | Active           | MVSRUS.P390SSCP   | Yes         | MVSRUS

Link station name                                       @N000001
Determined data:
  Link station state                                    Active
  Link station sub-state                                Active
  Adjacent CP name                                      MVSRUS.P390SSCP
  Adjacent CP type                                      Network Node
  TG number                                             21
  Link station statistics:
    XID bytes received                                  825
    Message bytes received                              92898
    XID frames received                                 5
    Message frames received                             964
    XID bytes sent                                      565
    Message bytes sent                                  70868
    XID frames sent                                     6
    Message frames sent                                 1040
    Invalid frames received                             0
    Control frames received                             0
    Control frames sent                                 0
    Echo responses received                             0
    Current delay                                       0 ms
    Maximum delay                                       0 ms
    Minimum delay                                       0 ms
    Time since maximum delay                            0.00 seconds
    Successful XID exchanges                            1
    Unsuccessful XID exchanges                          0
  Start time                                            0.30 seconds
  Stop time                                             0.00 seconds
  Uptime                                                4931.55 seconds
  Time in current state                                 4931.55 seconds
  Deactivation cause                                    None
  Auto activation support                               By remote node
  Link station role                                     Secondary
  Adjacent node ID (IDBLK/IDNUM)                        X'FFF.186DF'
  Maximum send BTU size                                 1493 bytes
  Local address                                         157.59.127.143 (LSAP 4)
  Adjacent CP is a BrNN                                 No
  HPR support                                           Control flows
  ANR label                                             X'90FF'
  Reverse ANR label                                     X'80A7006001000000'
Defined data:
  Adjacent CP type                                      Network Node
  Destination address                                   IPv4: MVSRUS (172.30.252.27) (LSAP 4)
  Limited resource                                      No
  Default NNS                                           Yes
  CP-CP sessions supported                              Yes
  Auto activation support                               No
  Link station attributes                               X'00000000'
  Target pacing count                                   7
  Maximum send BTU size                                 1493 bytes
  Maximum receive BTU size                              1493 bytes
  Link station role                                     Negotiable
  Maximum I-frames that can be received                 7
  Maximum activation attempts                           Unlimited
  Activation delay timer                                25 seconds

  TG characteristics:
    Effective capacity                                    94 Mbits/s
    Connection cost                                       0
    Byte cost                                             0
    Security                                              No security
    Propagation delay                                     384 microseconds
    Modem class                                           0
    User-defined parameter 1                              128
    User-defined parameter 2                              128
    User-defined parameter 3                              128
  CP-CP sessions active                                   No
  Branch link type                                        Downlink
  Branch TG                                               No
```

Automated Configuration

There are three methods of automating the configuration of the IP-DLC feature in Host Integration Server 2004.

- LinkCFG
- SNACFG
- Windows Management Interface (WMI)

LinkCFG

LinkCfg is a useful command line utility for deploying and managing link services. The format of the command line for configuring the link service is specified below.

```
LINKCFG LINKSVC "title"
/SERVER:servername
/LSTYPE:"IP-DLC Link Service"
/PRIMARYNNS:NNSServer
[/BACKUPNNS:NNSServer]
/LOCALADDRESS:ipaddress OR /ADAPTER:adaptername
/NETWORKNAME:networkname
/CPNAME:name
[/NODEID:xxx.xxxxx]
/LENNODE:lennode
/DOMAIN:domain
/USERID:user
/PASSWORD:password
[/RECEIVEACK:number]
[/LIVETIME:number]
[/CMDMAXRETRY:number]
[/MAXACTIVATION:number]
[/ACTIVATIONDELAY:number]
[/MAXBTUSEND:number]
[/MAXBTURCV:number]
```

The description of the command line parameters is specified in the table below:

Property	Description	Content
"Title"	The title of the link service	1-128 symbols
/SERVER:servername	The name of the server	Valid server name
/PRIMARYNNS:NNSServer	The primary network node server	DNS name or IP Address
/BACKUPNNS:NNSServer	Backup network node server	DNS name or IP Address
/ADAPTER:adaptername	Name of the local adapter	Name of the physical or logical adapter on the machine
/LOCALADDRES:ipaddress	Local address	Valid IP address or server name
/CPNAME:name	Control point name of the Branch Network Node implemented by the link service	1-8 characters, must be unique in APPN Network & must comply with the APPN naming convention.
/NODEID:"xxx.xxxxx"	The identity of the Branch Network Node implemented by the link service	String in format HHH.HHHHH where H is a hexadecimal digit
/LENNODE:lennode	The name of the Associated LEN node	Name of a LEN node deployed on the local machine
/DOMAIN:domain	The Domain Name which to authenticate in order to add a link service.	Valid Domain Name
/USERID:user	The Userid which to authenticate in order to add a link service.	Valid User ID
/PASSWORD:password	The Password which to authenticate in order to add a link service.	Valid Password
/NETWORKNAME:name	Network name of the Branch Network Node implemented by the link service	1-8 characters & must comply with the APPN naming convention.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

SNACFG

SnaCfg utility is a command line tool for managing SNA Server configuration. The format of the command line for configuring the link service is specified below.

```
SNACFG CONNECTION /LIST
SNACFG CONNECTION connectionname
SNACFG CONNECTION connectionname /PRINT
SNACFG CONNECTION connectionname /ADD [options]
SNACFG CONNECTION connectionname [options]
SNACFG CONNECTION connectionname /DELETE
```

Available options are:

```
/SERVER:Text
/COMMENT:""
/COMPRESSION:None
/ACTIVATION:{ OnServerStartup | OnDemand | ByAdministrator }
/CALLDIRECTION:{ Incoming | Outgoing | Both }
/CPNAME: Text
/NETNAME: Text
/REMOTEBLOCKNO:hex string
/REMOTENODENO: hex string
/LOCALBLOCKNO:hex string
/LOCALNODENO:hex string
/LINKSERVICE:text
/REMOTEEND:{ Host | Peer }
/CONNTYPE:IP-DLC
/DLUSPRIMNETWORKNAME: Text
/DLUSPRIMCPNAME: Text
/DLUSBACKUPNETWORKNAME: Text
/DLUSBACKUPCPNAME: Text
/PREFERREDROUTE: Text
/DLURRETRYTYPE:{ NONE | INFINITE | LIMITED }
/DLURRETRYLIMIT: Value, default is 8
/DLURRETRYDELAY: Value, default is 10
/XIDTYPE:Must be Format3
/ACTIVATEDELAY:Default is 10s, must be multiple of 5s i.e. 5, 10, 15, 20 & etc.
/ACTIVATERETRYLIMIT:Default is 8
/AFFILIATEAPP:text
```

The description of the command line parameters is specified in the table below:

Property	**Description**	**Validation**
/conntype:type	The connection type	IPDLC connection type will be added to the list of types
/RemoteAddress:adr	The address of the remote DLUS service.	Valid IP address or DNS name
/PrimNetworkName:name	The network name of the primary DLUS server.	1-8 characters & must comply with the APPN naming convention.
/PrimCPName:name	The control point name of the primary DLUS server	1-8 characters and must comply with the APPN naming convention.
/BackupNetworkName:name	The network name of the backup DLUS server	1-8 characters and must comply with the APPN naming convention.
/BackupCPName:name	The control point name of the backup DLUS server	1-8 characters and must comply with the APPN naming convention.
/DLURRetryType:N	DLUR retry type	0 – none 1 – infinite 2 – limited

/DLURRetryLimit:N	DLUR retry limit. Ignored unless the DLUR retry type is set to limited	1-65535
/DLURRetryDelay:N	Delay after a DLUR retry. Ignored unless the DLUR retry type is set to limited	1-65534
/RetryLimit:N	Number of the connection retries.	0 – unlimited 1-65534 number of retries
/RetryDelay:N	Delay after a connection retry	0-327670 Must be a factor of 5
/XIDFormat:N	XID Type.	Should be 1 – Format 3
/RemoteNetName:name	Remote net name is hard coded to the network name of the link service	For a new connection, must be left blank
/RemoteCPName:name	Remote control point name is hard coded to the CP name of the link service	For a new connection, must be left blank

WMI

The **MsSna_LinkService_IPDLC** class has been added to the WMI provider. The class has the following properties:

Property	**Type**	**Description**	**Content**
Name	String	This read only property contains the name of the link service. The name will be assigned automatically for a new link service.	1-8 characters US_ASCII String
Title	String	The title of the link service	1-128 symbols
PrimaryNNS	String	The primary network node server	DNS name or IP Address
BackupNNS	String	Backup network node server.	DNS name or IP Address
AddressType	Uint32	Local address type	1 – Adapter address 2 – Static IP Address
LocalAddress	String	Local network adapter or address	Depending on the value of the AddressType property, this field contain ether a valid network adapter name or static IP address
NetworkName	String	Network name of the Branch Network Node implemented by the link service	1-8 characters & must comply with the APPN naming convention.
CPName	String	Control point name of the Branch Network Node implemented by the link service	1-8 characters & must comply with the APPN naming convention.
NodeId	String	The identity of the Branch Network Node implemented by the link service	String in format HHH.HHHHH where H is a hexadecimal digit
LENNode	String	The name of the Associated LEN node	Name of a LEN node deployed on the local machine

SNA Service

The core of the power of Microsoft® Host Integration Server 2004 is its ability to provide a wide range of host connectivity services. Host Integration Server 2004 uses client/server architecture to distribute communications processing. This architecture maximizes the power of the host, Host Integration Server 2004, and individual client computers. Within the context of Host Integration Server 2004, a connection is the data communication path between a Host Integration Server 2004 computer and an IBM host (mainframe or AS/400). A connection is what makes it possible for a client computer on a local area network (LAN), using standard LAN protocols, to communicate with a host by means of one or more Host Integration Server 2004 computers. Each server supports up to 3,000 users operating 30,000 concurrent sessions, 8,000 split stock users per node, four nodes per server.

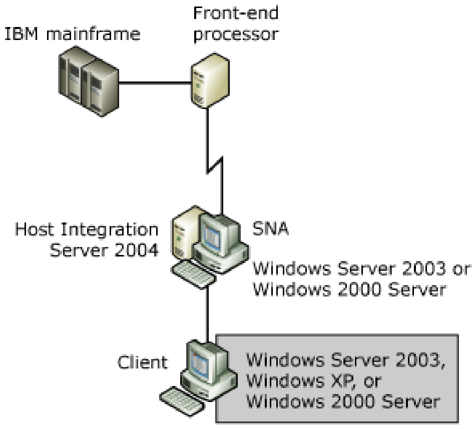
This section contains:

- Communication Between Host Integration Server 2004 Computers and a Host Computer.
- Communication Between Multiple Host Integration Server 2004 Computers.
- Communication Between Host Integration Server 2004 Computers and Client Computers.

Communication Between Host Integration Server 2004 Computers and a Host Computer

Within the context of Host Integration Server 2004, a connection is the data communication path between a Host Integration Server 2004 computer and an IBM host (mainframe or AS/400). A connection corresponds to a physical unit (PU) definition on a mainframe or an APPC controller definition on an AS/400. The connection is what makes it possible for a personal computer on the LAN to communicate with a host by means of a Host Integration Server 2004 computer. Note that SNA connections do not use BISYNC, an older IBM standard for communications.

The following figure shows a Host Integration Server 2004 network connected to an IBM mainframe.



IBM mainframe
Front-end processor
Host Integration Server 2004
SNA
Windows Server 2003 or Windows 2000 Server
Client
Windows Server 2003, Windows XP, or Windows 2000 Server

For each physical adapter or connection, an appropriate link service is installed and configured within Host Integration Server 2004. The link service is a Windows server service or device driver that is used to control server-to-host communication adapters supported by Host Integration Server 2004. The link service provides the SNA data link-level protocol used by the Host Integration Server 2004 computer to communicate with the host.

After being configured, the link service is available for use not only on the configured Host Integration Server 2004, but also on any Host Integration Server 2004 computer in the subdomain using the Distributed Link Service feature of Host Integration Server 2004.

After a link service is configured, you can create connections. A link service may support multiple links to one or more hosts.

In SNA terms, the combination of a connection and the link service it uses is equivalent to a PU. In hierarchical SNA networks, Host Integration Server 2004 provides PU 2.0 functionality. For peer-oriented SNA networks, Host Integration Server 2004 provides PU 2.1 LEN node functionality.

Physical Unit (PU)

Although the name physical unit (PU) strongly implies a hardware component, a PU is an IBM naming convention for hardware and software combinations that perform a specific task in an SNA network. For example, PU 5 represents not only the mainframe itself, but also the mainframe software components (such as SSCP and VTAM) within the SNA network.

The following table lists the SNA defined PU types and a brief description of each.

PU number	Description
PU 1	Terminal Controller (IBM 6670, 3767)
PU 2	Cluster controller running configuration support programs (IBM 3174, 3274, 4701, 4702)
PU 2.1	Peer-to-Peer (APPN), used primarily in AS/400 networks
PU 4	IBM Front End Processor, usually running ACF and the Network Control Program (IBM 3754, 3725, 3720, 3745, 3746)
PU 5	IBM Host (mainframe) system

SNA Service

Logical Unit (LU)

A logical unit (LU) is a configurable unit of software that contains the information needed to specify the type of communications session with the host computer or peer system. Thus, an LU is a point of access to the Host Integration Server 2004 network. There are several types of LUs:

- APPC
- 3270
- Downstream
- Logical unit application (LUA)

LUs represent a set of functions that manage the exchange of data between users and applications, acting as intermediaries between the user and the network. Host Integration Server 2004 protocols identify several LUs on host computers that represent specific functions. The following table is a list of LU numbers and a brief functional description.

LU number	Description
LU 0 (also LU/A or LUA, logical unit application)	General purpose LU for development of specialized applications such as TN3270. Used for program-to-program communications in hierarchical networks.
LU 1	LU 1 handles the transmission of printer data to network and system printers in SNA character string format. IBM 3287-type printers and Host Integration Server 2004 Host Print service that allows you to redirect print data streams to LAN printers. Used to communicate with multiple-device terminals.
LU 2	IBM monochrome terminals 3278 (3270) IBM Color graphic terminals 3279/3179 Host Integration Server 2004 displays
LU 3	IBM 3284-style printers and Host Integration Server 2004 Host Print service, which allows you to redirect print data streams to LAN printers. LU 3 is a simple printing protocol that uses the 3270 data stream format to communicate with a single printer.
LU 4	IBM 6670 information distributor and is not supported through Host Integration Server 2004.
LU 5	Not defined.
LU 6	LU 6.2 is most common revision. IBM 5250 devices and Host Integration Server 2004 local and remote APPC LUs. Provides peer-to-peer communication through Advanced Program-to-Program Communication (APPC) and (Common Programming Interface for Communications (CPI-C).
LU 7	IBM 5250 display terminal. Used mainly on System 3.x but not on AS/400 systems.

On Host Integration Server 2004 computers, you can configure LUs to emulate the 3270 data streams needed to communicate with the mainframes or 5250 data streams for AS/400 systems.

A 3270 LU is a dependent LU that requires the mainframe to function. It has a fixed designation, such as a display LU, printer LU, logical unit application (LUA) LU, or downstream LU. Each type of LU has a specific number assigned to it. A 3270 LU on Host Integration Server 2004 has an LU number, and a corresponding resource must be defined on the host computer. The 3270 LU name is arbitrary and does not have to match the name of the resource on the host.

Additional information about APPC is available later in this section.

Choosing a Connection Type

A Host Integration Server 2004 computer can use any of the types of connections described in this section. To choose a connection type for your servers, you should first contact the host administrator and find out the type of connection available to the mainframe or AS/400. If more than one type is available, choose a type based on comparisons of cost and speed.

For demonstration purposes, you can install the Demo SDLC Link Service, which receives messages from Host Integration Server 2004 and responds to them itself from a prerecorded script.

The various adapters in a computer must be configured to work together so that there are no interrupt, port address, or direct memory access (DMA) conflicts. When you install a new adapter in your computer, you may need to study the configuration of the new and old adapters to make sure that there are no conflicts.

The following connection types are available:

- 802.2 Data Link Control (DLC 802.2)

  Token ring, Ethernet, or Fiber Distributed Data Interface (FDDI) connections use the IEEE 802.2 protocol. With a mainframe, an 802.2 connection goes to a 37*xx* front-end processor (FEP) or a 3174 communications controller (or, rarely, to an adapter in the mainframe). With an AS/400 system, an 802.2 connection goes directly to the AS/400.

  These connections are generally faster than other connections, except for channel connections. The following table provides details.

Type of 802.2 connection	**Common speeds**
Token ring	4 megabits per second (Mbps) or 16 Mbps.
Ethernet/Fast Ethernet	10–100 Mbps.
FDDI	100 Mbps (or more); however, the FDDI line communicates through a front-end processor that is channel-attached to the mainframe, and this may limit the overall speed of communications.

  DLC 802.2 also has certain limitations. The 802.2 link service cannot support more than one 802.2 connection to the same MAC address and destination SAP (that is, to the same host) at the same time, whether the connections originate from the local or a remote SNA Server computer. The 802.2 protocol specification does not permit two distinct connections to have the same Source MAC, Source SAP, Destination MAC, and Destination SAP. The 802.2 link service is bound to a particular LAN adapter and source SAP value, and therefore uses the same source MAC and SAP for all connections. To support multiple connections, you can:

  - Connect to different network adapters on the host.
  - Configure multiple 802.2 link services, all bound to the same LAN adapter but specifying different source SAPs.
  - Support multiple connections to a given host through the same 802.2 link service. Verify that the host is configured to accept 802.2 connections on multiple SAPs. This can be configured to mainframe FEPs (but is rarely used). AS/400s support multiple SAPs by default. These SAP values are configured as the remote SAP value on the Host Integration Server 2004 connection, which is configured on the Host Integration Server 2004 computer using the Distributed Link Service.

  This limitation applies to connections based on the 802.2 link service in general.

  When you make an 802.2 link service available to Distributed Link Service on other Host Integration Server 2004 computers, it cannot be used by the local Host Integration Server 2004 computer, and is not visible in SNA Manager Console.

- Synchronous Data Link Control (SDLC)

  SDLC uses a standard phone line, which can be leased or switched and can be point-to-point or multi-drop. An SDLC line is used with a modem or other type of data circuit -terminating equipment (DCE) at each end. With a mainframe, an SDLC line travels through a modem or other DCE to a 37*xx* front-end processor (FEP), 3174 communications controller, or integrated synchronous adapter. With an AS/400 system, an SDLC line goes through a modem or other DCE, and then directly to the AS/400.

  An SDLC connection is slower than an 802.2 or channel connection. Common speeds for SDLC connections are listed in the following table.

Type of transmission	**Common speeds**
Analog (conventional phone line)	9600–56000 bits per second
Digital Data System (DDS)	56 kilobits per second (kbps) (sometimes 64 kbps)
Integrated Services Digital Network (ISDN)	56 kbps (can be more)
T1 carrier system (digital)	1.544 megabits per second (Mbps)
E1 carrier system (digital)	2.048 Mbps

SDLC connections are useful for wide-area connections between geographically disparate locations, or when bandwidth and usage requirements are low. Because of these factors, SDLC is ideally suited for branch-type deployment strategies.

Host Integration Server 2004 supports SDLC connections using the link support that is included with it or through an SDLC link service available through various third-party vendors. Not all supported SDLC adapters support all link speeds listed in preceding table.

- X.25

  X.25 is the Comite Consultatif Internationale de Telegraphie et Telephonie (CCITT) standard used for communication over a packet-switching network. X.25 uses the qualified logical link control (QLLC) protocol. With a mainframe, an X.25 line goes to a 37*xx* front-end processor (FEP), 3174 communications controller, or integrated synchronous adapter. With an AS/400 system, an X.25 line goes directly to the AS/400.

  An X.25 connection is slower than 802.2-type connections and is comparable to an SDLC connection. This makes X.25 suitable for branch-type deployment strategies. These connections tend to be more common at European sites than at North American installations.

  Host Integration Server 2004 supports X.25 connections using the link support included with Host Integration Server 2004, or through an X.25 link service available through various third-party vendors. Not all supported X.25 adapters support all link speeds listed in the preceding table.

- Channel

  Channel connections provide direct channel attachment to a mainframe and are significantly faster than DLC 802.2 connections. There are two types of channel connections: older Bus & Tag channel connections, which can reach speeds of up to 4.5 megabytes per second (MBps), and newer Enterprise System Connection (ESCON) connections, which can reach speeds approaching 17 MBps.

  Bus & Tag channel attachments use parallel copper cable and offer a flexible, high-speed mainframe connection solution. Many hardware vendors produce SNA Open Gateway Architecture (SOGA)-compliant Bus & Tag products, allowing you to choose a solution that best fits your needs.

  ESCON channel attachments use standard fiber cable and increase throughput significantly. ESCON is the best choice for high-performance, high-bandwidth connections and is currently the fastest host connection method available between Host Integration Server 2004 computers and mainframe systems.

  ESCON is an ideal connection method in centralized or distributed deployments, where users require high performance and responsiveness.

  Support for channel connections is limited to adapters supported natively through Host Integration Server 2004.

- Distributed Link Service

  The Distributed Link Service feature provides a method for a Host Integration Server 2004 computer to connect to a host using a link service installed on a different Host Integration Server 2004 computer. The network connecting SNA Server computers need not support any SNA link level protocol such as DLC 802.2 or SDLC.

  Distributed Link Service is configured in two parts: by installing the Distributed Link Service on one SNA Server computer and by marking a real link service on another computer as distributable. The Distributed Link Service acts as a proxy for sharing the distributable link service. It supports load balancing across multiple, distributed link services. It also supports hot backup because the Distributed Link Service can select alternate remote servers when a remote link fails. It allows a branch SNA Server computer to connect to the host over a wide area network (WAN). This supports only routable internetworking protocols such as TCP/IP, rather than requiring an SNA WAN protocol such as SDLC or bridged DLC.

  Distributed Link Services provide the following benefits:

  - The branch-based Host Integration Server 2004 computers provide split-stack SNA gateway service for local client computers, simplifying configuration of the client computers. This conserves PUs and concentrates traffic on behalf of several client computers, which saves valuable network bandwidth.

- The branch-based Host Integration Server 2004 computer communicates with the central-site Host Integration Server 2004 computers through a native TCP/IP connection, which eliminates DLC 802.2 time-out problems associated with traditional SNA encapsulation methods.
- Because the central site servers provide the equivalent of PU pass-through service for the branch-based servers, the host operator sees each branch-based server as a PU and can manage the branches through standard NetView alerts and RunCmds.
- The branch-based servers can connect to the host through multiple centralized servers, load-balancing among the multiple central-site servers at connect time.
- Should a central-site server fail for any reason, the branch-based servers will automatically establish a new connection through an alternate centralized server for hot backup.
- Should the WAN fail for any reason, the branch-based Host Integration Server 2004 computers can be configured to connect to the host through a direct dial-up SDLC connection as a backup that will be activated automatically upon the host connection failure. It is actually activated upon the first request after a failure.
- The routers at the branches only need to route TCP/IP, which provides for simplicity of WAN management and cost savings.
- Because the branch-based servers rely on WAN services provided by the leading networking vendors, the Distributed Link Service will work over all existing and future WAN technologies, including leased lines, X.25, frame relay, and ATM networks.
- Unlike other native TCP/IP solutions such as TN3270, the Distributed Link Service is not limited in SNA functionality. Each branch-based Host Integration Server 2004 computer provides full SNA access for the local personal computers, including PU 2.0, PU 2.1, and APPN LEN service, as well as LU 0, LU 1, LU 2, LU 3, and LU 6.2 support. Both mainframe and AS/400 access are supported.
- Although the majority of customers are moving to TCP/IP networks, the Distributed Link Service also fully supports IPX protocols.

When Host Integration Server 2004 is set up to use more than one client/server protocol, Distributed Link Service first attempts to establish communication between the servers using TCP/IP, if available. If that fails, Distributed Link Service next attempts to connect using IPX/SPX. To designate a protocol other than TCP/IP as the primary protocol to be used by Distributed Link Service, use the Registry Editor to add or modify the values in the Windows registry. For an example of the registry entry, see the *Host Integration Server 2004 Administrator's Reference*.

By default, when you make a link service available to Distributed Link Service on other servers, it will permit a connection from Distributed Link Service running on any remote server that is configured to connect to it. This is similar to the level of access control permitted by traditional pass-through gateways. Any downstream device that is configured for the correct MAC address can use the gateway.

However, you can restrict access to the Distributed Link Service, requiring the remote Distributed Link Service to provide a valid Windows server username and password. The procedure requires coordination between the upstream and remote servers.

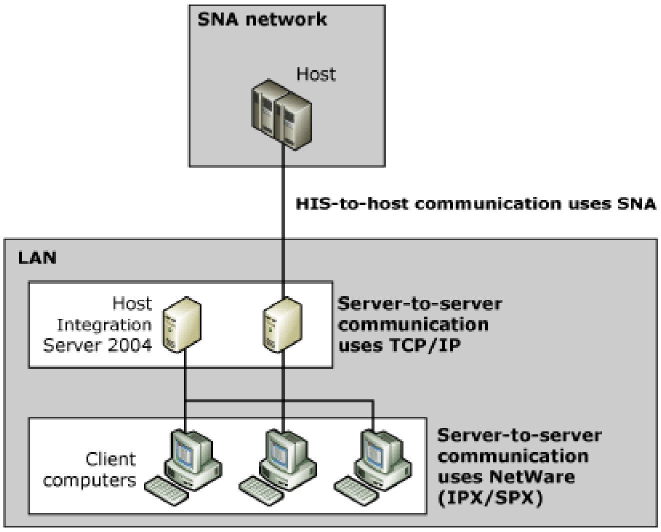
Communication Between Multiple Host Integration Server 2004 Computers

Host Integration Server 2004 computers communicate with each other using mail slot or datagram broadcast messages. They use the SnaBase service to keep track of names of servers, client computers, and available transaction programs (TPs), which are the programs used for communication through Advanced Program-to-Program Communications (APPC) or Common Programming Interface for Communications (CPI-C).

Microsoft® Windows Server™ 2003 and Windows® 2000 Server support multiple protocols simultaneously, but there is no need to send the same Host Integration Server 2004 broadcasts over all available protocols. Using the SNA Manager Console, you can specify the network protocol for server broadcasts. You must make sure that one protocol is available on all Host Integration Server 2004 computers in the SNA subdomain, and use that protocol for server broadcasts. For more information, see Configuring a Server Broadcast. The following figure shows a network in which TCP/IP is used for server-to-server communications and IPX/SPX is used for client-to-server communications.



SNA network
Host
HIS-to-host communication uses SNA
LAN
Host Integration Server 2004
Server-to-server communication uses TCP/IP
Client computers
Server-to-server communication uses NetWare (IPX/SPX)

Separate protocol used for server-to-server and client-to-server communications

It is recommended that you use only one protocol for server broadcasts. Using multiple server-to-server transport protocols can add to network overhead because every server broadcast must be sent out through all the protocols selected.

Server broadcasts need to be configured only once for a subdomain; the configuration affects all servers in the subdomain.

The mean time between server broadcasts is specified in number of seconds, with the default being 60 seconds. Specifying a smaller value brings heavier demands on the network because the broadcasts occur more often.

Configuring a Server Broadcast

You can configure a server broadcast to ensure that your servers use the appropriate protocols for your network configuration.

To configure a server broadcast

1. In the SNA Manager tree, select the subdomain that you want to configure.
2. On the **Action** menu, click **Properties**.
3. Click the **Server Broadcasts** tab, fill in the options, and then click **OK** to exit.
4. On the **Action** menu, click **Save configuration**.

SNA Service

Communication Between Host Integration Server 2004 Computers and Client Computers

Client computers locate the resources of the Host Integration Server 2004 computer in either one of two ways:

- Sponsor connection
- Active Directory® directory service

A sponsor connection is created when a client computer makes a request to communicate with a Host Integration Server 2004 computer and an initial connection is established. The first Host Integration Server 2004 computer to respond to the request (called the sponsor computer) provides the client computer with all the names of Host Integration Server 2004 computers in the subdomain. From these names, the client computer locates an available LU or LU pool.

In a similar way, a client computer that is configured to use Active Directory makes a request to the Active Directory database. Active Directory responds to the request and provides the client computer with all the names of Host Integration Server 2004 computers in the Organizational Unit.

For client/server protocols to operate properly with Host Integration Server 2004, both client computers and servers must have the network software and the Host Integration Server 2004 software installed properly. The network protocols available for use by various client operating systems are listed in the following table.

Operating system on client computer	Client/server protocols
Windows Server 2003 or Windows 2000	Microsoft Networking (Named Pipes) Novell NetWare (IPX/SPX) TCP/IP

SNA Service

Host Integration Server 2004 Client and SNA Communications

When a client computer makes an SNA request, the client computer must direct that request to a domain or to one or more Host Integration Server 2004 computers. The appropriate way for a client computer to direct requests depends on the protocol used and the relative location of client computers and servers. The following table lists the ways that client computers direct SNA requests, and the information that will be requested by Setup during client software installation.

Network protocol used on client	**How the client directs SNA requests**	**Information to find out before running client setup**
Microsoft Networking	Either to the local domain (if the Host Integration Server 2004 computers are in the same domain as the client computer), or to one or two specific Host Integration Server 2004 computers in a remote domain.	Whether the client computer is in the same domain as the Host Integration Server 2004 computers, and if not, one or two names of Host Integration Server 2004 computers.
Novell NetWare (IPX/SPX)	To a specific domain. The Host Integration Server 2004 computers must be located in this domain for the client computer to locate them.	The name of the SNA subdomain in which the Host Integration Server 2004 computers are located.
TCP/IP	Either to a domain name or to a specific server name, depending on what is specified in the SNA Client Mode or Host Integration Server 2004 Location dialog box.	Contact your network administrator for additional information regarding a specific IP address for Host Integration Server 2004.

When a client computer first makes a request for communication with the SNA network, it establishes an initial connection (the sponsor connection) with a Host Integration Server 2004 computer. The client computer then requests a logical unit (LU), either by name or by requesting an LU from a particular pool of LUs. If the request is for a particular LU, the sponsor server responds by providing the name of the Host Integration Server 2004 computer that contains the LU. If the request is for an LU pool, the sponsor server responds by providing the client computer with all the names of Host Integration Server 2004 computers in its subdomain that support the pool. From these names, the client computer picks a server at random.

Host Integration Server 2004 computers and client computers keep track of the names of servers in the SNA subdomain through the SnaBase service (formerly known as the network access protocol, or NAP). For client computers, the sponsor connections, along with the SnaBase provide a view into the server subdomain.

SNA Service

Host Print Service

Host Print service provides server-based 3270 and 5250 print emulation, allowing mainframe and AS/400 applications to print to a LAN printer supported by Microsoft® Windows Server™ 2003 and Windows® 2000. Microsoft® Host Integration Server 2004 Host Print service enables centralized control of LU print resources. You can administer all Host Print service functions using SNA Manager, including margin control, fonts, and characters per line. Host Print service also supports print-to-file with auto-incrementing file names. You can configure the file naming scheme for each printer LU.

The following three methods of printing host information are available:

- **Screen printing.** This method allows any 3270 or 5250 emulator to print what is on the display using print screen features of the client operating system. The printer output can be directed to a printer attached to the client computer or the network.
- **Client-redirected printing.** This method delivers an SNA host printer data stream (such as 3287) to the appropriate emulation application running on a Host Integration Client 2000 computer. The client software converts the data stream into data that can be printed locally or to a network printer.
- **Server-based redirected printing.** This method uses a server process to convert SNA host printer data streams into data that can be directed to a local or network printer.

This section contains:

- Using Host Print Services
- Mainframe Printing
- Configuring Host Print Service
- AS/400 (APPC) Printing
- Printer Definition Files

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Using Host Print Services

Host Print service is a Windows Server service, and is found as SnaPrint in the Services utility in Windows Control Panel. To access network printers, the SnaPrint service must run in a domain account with administrative privileges. This account is created for you during Host Integration Server 2004 setup if you are logged onto the Windows Server 2003 or Windows 2000 domain with domain administrative privileges and choose the Domain account option. If you choose the System account option during setup, you will only be able to install local printers for use with Host Print service.

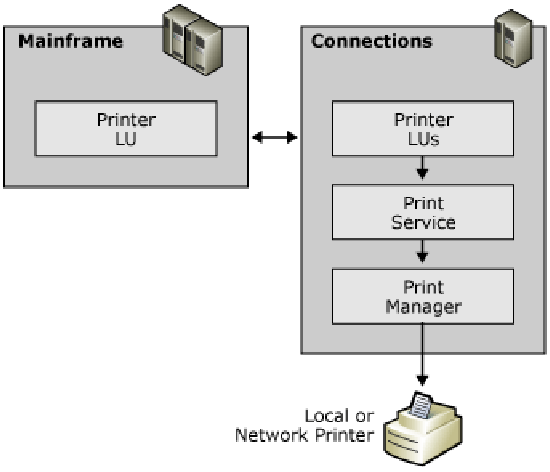
Mainframe Printing

Mainframe printing supports both LU 1 and LU 3 data streams. It also includes pass-through support from the host for Intelligent Printer Data Stream (IPDS). Using IPDS, mainframe print jobs can be printed on LAN printers without changing either the print job or the host application.



Host Print service provides print emulation for three LU types: LU 3, LU 1, and LU 6.2 (APPC). The LU type defines the characteristic of the host data stream. LU 3 and LU 1 printing use a 3270 data stream over a session to a mainframe. APPC printing uses a LU 6.2 data stream over a session to an IBM AS/400. The following sections provide an overview of LU 3 and LU 1 printing. APPC printing is discussed under the AS/400 section later in this section.

The Host Print service must run in a user account that has permission to access the defined network printer (or printers). For example, if you are printing to a printer attached to a Novell NetWare system, the Host Print service must run in an account that is recognized by NetWare.

LU 3 Printing

LU 3 printing is the simplest of the three types of host printing. The LU 3 data stream closely resembles that for 3270-display emulation. It consists of a write command code and a write control character (WCC) followed by the print job. These print jobs contain printable characters and only four simple formatting orders (new line, form feed, carriage return, and end of medium). No other control of the print output is available. This form of printing is similar to printing a text file from a personal computer. If more print formatting is required, an LU 1 print session should be used. For more information, see the section LU 1 Printing.

In SNA Manager, the 3270 Print Session properties Page Layout tab includes specifications for the number of characters per line and the number of lines per inch. Host print jobs using the LU 3 data stream also provide defaults for these parameters. The defaults may be different depending on the settings.

For LU 3, the settings in the host print job normally override the Print Service session settings. However, if you leave the host settings at their defaults of 6 lines per inch and 132 columns per row, the Print service session settings are used.

After the defaults for lines per inch and page width have been determined, the Print service chooses a font for the print job that will accommodate this size print output on the paper loaded in the printer.

There are no transparent sections in LU 3 print jobs, so Transparency is ASCII does not apply. LU 3 print jobs do not have SCS codes, but do have NL, CR, FF, and LF characters and do have commands to allow you to position print data on the page. The Print service uses these to build an internal representation of the page before printing it out. When a PDT file is used, Print service uses the definitions of NL, CR, FF, and LF from the PDT file to allow it to format the printout correctly. If no PDT file is configured, Print service uses the Windows GDI.

Command Code

The write command codes are not unique values, but are identified by occupying the first byte in the Request Unit (the message format used in an SNA network, also known as an RU). In addition there can be only one command code per RU. For LU 3 printing, the most commonly used command code is Erase/Write '0xF5'. Read command codes, which would be normal for display sessions, are not valid for LU 3 printing, and will be rejected with a sense code of '1003'.

Write Control Character (WCC)

Following the write command code is the write control character (WCC). This byte is also identified by its position, second byte in the RU. With LU 3 printing, bits 2 and 3 of the WCC define the printout format.

Write Control Character (WCC) Codes

Bit	Explanation
0,1	Ignored by the printer.
2,3	Defines printout format.
none	00 NL or CR orders define the print line length, EM indicates the end of the message.
none	01 Indicates 40-character lines.
none	10 Indicates 64-character lines.
none	11 Indicates 80-character lines.
4	Start-printer bit.
6	Keyboard reset.
7	Reset MDT bit.

Format Control Orders

There are four control codes used only for printing known as Format Control Orders.

Format Control Orders

Abbreviation	Order	EBCDIC
NL	New Line	0x15
EM	End of Medium	0x19
FF	Form Feed	0x0C
CR	Carriage Return	0x0D

NL, CR, and EM are valid only when the write operation does not specify a line length format in the WCC byte. FF is valid in any write operation.

3270 Orders

The 3270 data stream can contain sequences, called 3270 Orders, which provide additional control functions. The two most commonly used in LU 3 printing are Set Buffer Address (SBA) and Repeat to Address (RA). Note that the buffer address used in these commands is relative to each write. The print buffer in LU 3 allows a maximum of 4 KB of data, and often only 2 KB. This may require multiple write commands to be sent for a full page of text. The first write command will start at the top of the page. Its first buffer address will also be at the top of the page. Subsequent writes will continue where the first left off. Their first buffer address will also start where the previous write ended, unless it was ended with a form feed. For the examples below, it is assumed that these are the first write commands.

SBA is indicated by a '0x11' followed by a two-byte buffer address. This order sets the cursor position to the location specified in the two-byte buffer address. In LU 3 printing, this sets the print position. The data following the SBA will be printed starting from this location. For example:

114040 Sets the print position to row 1 and column 1.

RA is indicated by a '0x3C' followed by a two-byte stop buffer position and the character to be repeated. This order causes a character to be repeated from the current buffer address up to but not including the stop buffer address specified in the RA. For example:

3C40D3C1 Repeats the character 'A' ('0xC1') to row 1 and column 20.

Data

For LU 3 printing the data or printable characters must have values between '0x40' and '0xFE'. The only valid values outside this range are the 3270 Orders.

Example: 15C1C2C3 Prints a new line followed by 'ABC'

Example: 1BC1C2C3 Rejected because '0x1B' is an invalid value

Sample Host Data

Following is sample data from a host along with an explanation of the data and resulting printout.

```
F5C81140 40151515 C1C2C3C4 15404040
E6E7E8E9 19
```

This sample data is analyzed in the following table.

3270 LU 3 Sample Data

Data	Interpretation
F5	Command code Write/Erase
C8	WCC with bits 2, 3 specifying that NL, EM and CR orders determine the print line length.
114040	SBA sets print position to row 1 column 1
15	New line
15	New line
15	New line
C1C2C3C4	EBCDIC hex values for ABCD
15	New line
404040	EBCDIC hex values for three spaces
E6E7E8E9	EBCDIC hex values for WXYZ
19	End Medium

Host Print Service

LU 1 Printing

LU 1 printing allows the host to specify formatting for a print job. This is accomplished through the use of SNA Character String (SCS) control codes. The SCS codes encompass the 3270 format orders (FF, CR, and NL), as well as providing additional control codes to format the print output. Through the SCS codes, the host application can set the margins, characters per line, and lines per inch. In addition to the format of the print job, SCS code allows the host application to send a transparent section. By using an SCS code, the host can mark a section of data as transparent. This will cause the print emulator (the Host Print service in this case) to not scan this section for SCS control codes but to pass it to the print output untouched. Transparent sections are most commonly used to embed printer control codes, such as the HP PCL, in the print job. Unlike LU 3 printing, there is no write command code or WCC. The first byte of the RU is either an SCS code or data.

Data Stream Flags

The BIND sent by the host for a LU 1 session indicates what SCS control codes are valid for this session. These Data Stream Flags are set in byte 18 of the BIND.

Data Stream Flags

Bit	Value	Description
0		**Base SCS code support**
	0	**Base support** (NL & FF only)
	1	**Full Base** includes Base plus the following:
		BS (back space)
		CR (carriage return)
		LF (line feed)
		ENP (enable presentation)
		INP (inhibit presentation)
		HT (horizontal tab)
		VT (vertical tab)
1		**Set Horizontal Format** (SHF)
	0	not supported
	1	supported
2		**Set Vertical Format** (SVF)
	0	not supported
	1	supported
3		**Vertical Channel Select** (VCS)
	0	not supported
	1	supported
4		**Set Line Density** (SLD)
	0	not supported
	1	supported
5		**Reserved**
6		**Bell** (BEL)
	0	not supported
	1	supported
7		**Transparent** (TRN) & **Interchange Record Separator** (IRS)
	0	not supported
	1	supported

SCS Codes

The SCS control codes are fully documented in the IBM Host Print Guide (document number SC31-7145). All of the SCS control codes fall within the range of '0x00'–'0x3F.' These codes range from single byte codes, such as Subscript '0x38', to multiple byte codes followed by several parameters, such as Set Horizontal Format '0x2BC1...'

The following are some of the more common SCS control codes used.

> **Note** **[L]**=length and **(Abv)** represents one-byte parameters in the SCS control code.

Set Horizontal Format (SHF) — '0x2BC1[L](MPP)(LM)(RM)(T1)(. . .)(Tn)'

[L] — Length of the parameters, including the length byte

MPP — Maximum Presentation Position; defines the characters per line

LM — Left Margin; column value for the left most print position

RM — Right Margin; column value for the right most print position

T1 — Horizontal tab stop; column value for a tab stop

Tn — Additional tab stops, which can be added in any order

Example

2BC1068401840542

2BC1 — SHF

06 — length of the parameters is 6 bytes including the length byte

84 — MPP is set to 132 characters per line

01 — LM is set to column 1

84 — RM is set to column 132

05 — T1 is set to column 5

42 — T2 is set to column 66

Set Vertical Format (SVF) — '0x2BC2[L](MPL)(TM)(BM)(T1)(. . .)(Tn)'

[L] — Length of the parameters, including the length byte

MPL — Maximum Presentation Line; defines the lines per page

TM — Top Margin; line number of top most print position

BM — Bottom Margin; line number of the bottom most print position

T1 — Vertical Tab Stop; line number for a tab stop

Tn — Additional Tab Stops, which can be added in any order

Example

2BC20642053D0A21

2BC2 — SVF

06 — length is 6 bytes

42 — MPL is set to 66 lines per page

05 — TM is set to line 5

3D — BM is set to line 61

0A — T1 is set to line 10

21 — T2 is set to line 33

Set Line Density (SLD) — '0x2BC6[L](Point)'

[L] — length, including length byte. Value of '0x01' denotes default.

Point — Distance to be moved vertically for a single line. The number is indicated in typographic points (one point is equal to 1/72 inch). Setting a value of '0x0C' will result in 6 lines per inch, a value of '0x09' will result in 8 lines per inch. Value of '0x00' denotes default a value of 6 lines per inch.

Example

2BC6020C

2BC6 — SLD

02 — length is 2

0C — 12 points or 6 lines per inch

Set Print Density (SPD) '0x2BD2[L]29(CharDensity)(Resv)'

[L] — length, including length byte. Value of 0x02 denotes default characters per inch (cpi) of 10

CharDensity — value indicating the numbers of cpi

Resv — Reserved (not used)

Example

2BD204290A00

2BD2 — SPD

04 — length is 4 bytes

29 — type

0A — 10 cpi

00 — reserved

Transparent (TRN) — '0x35[L](P1)(. . .)(Pn)'

This SCS control code indicates a section of data that is not scanned for SCS codes, but passed to the print output untouched. The extent of the section of data is denoted by the length byte.

Example

35051B28313055

35 — TRN

05 — length of transparent section, not including the length byte

1B28313055 — transparent section, HP PCL code for PC-8 symbol set 'Esc(10U'

> **Note** In this example, the transparent section is in ASCII. This would require that the "Transparent is ASCII" box be selected in the Print Services printer session properties in the SNA Manager.

Sample Host Data

Following is sample data from a host along with an explanation of the data and resulting printout.

```
35021B45 2BC10684 01840542 2BC20642
04420A21 C1C2C3C4 15404040 E6E7E8E9
```

3270 LU 1 Sample Data

Data	Interpretation
35021B45	Transparent section, send 'Esc E', a Reset in HP PCL, to printer
2BC1068401840542	SHF, 132 characters per line, LM 1, RM 132
2BC2064204420A21	SVF, 66 lines per page, TM 4, BM 66
C1C2C3C4	EBCDIC hex values for ABCD
15	New line
404040	EBCDIC hex values for three spaces
E6E7E8E9	EBCDIC hex values for WXYZ

Host Print Service

Configuring Host Print Service

Configuring Host Print service involves the following steps:

- Creating Link Services
- Creating Connections
- Creating a 3270 Printer LU
- Configuring Host Print Service

In addition, a print demonstration using a script is available. The following procedures will create and configure the print demonstration:

Configuring Host Print service for a 3270 connection

1. In SNA Manager, expand the server on which you want to add print services.
2. Right-click **Print Service**, point to **New**, and then click **3270 Session**.
3. The **Properties** page for this session appears.
4. On the **General** tab, type a session name.
5. Click **Printer**, and then configure a printer.
6. Click the **3270** tab, choose an LU Name to use for this print session. If there are no LU names in the drop-down list, you will need to insert a printer LU on the 3270 connection to be used for this print session (To create a print LU, see the earlier procedure).
7. Configure other parameters as desired.
8. Click **OK** to add this print session.
9. In the console tree, right-click **Print Service**, and then click **Save Configuration**.
10. Right-click **Print Service** again, and then click **Start**.

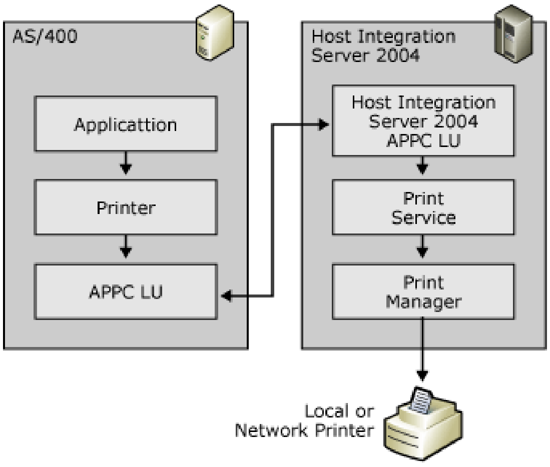
The Host Print service is configured with startup set to Manual. To start the Host Print service at system startup, go to the **Services** icon of Control Panel. Select the service name. Click **Startup**. Change the service activation type from Manual (the default) to Automatic for this service.

SNA Manager will only lock the configuration file when you initiate a configuration change. If the lock is obtained, the status bar will flash **'CONFIG LOCK'**. When you complete the change and save the configuration file, the lock will be released and the status bar will be cleared. The status bar will display **'OUT OF DATE'** on other servers in the domain. To refresh the status on the **'OUT OF DATE'** servers, SNA Manager must be closed and reopened.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

AS/400 (APPC) Printing

APPC printing, like LU 1 printing, uses SCS control codes in the data stream. The set of SCS control codes available for use in APPC printing is more extensive, and allows more formatting options than the set described for LU 1 printing. The IBM AS/400 also provides an additional method for formatting print jobs called Host Print Transform (HPT). With HPT enabled, the AS/400 takes responsibility for rendering the print job into data the printer can understand.



Host Print Transform (HPT)

When SCS control codes are used by the host to format the print output, a print emulator is responsible for translating the SCS codes and characters into data that the printer can understand, through the Windows printer driver and Windows Print system. With HPT enabled, the AS/400 converts the data to printer control codes before sending the data to Host Integration Server 2004. This output from the host requires no further processing after it leaves the AS/400. The print emulator's only responsibility is submitting the data to the printer.

HPT is enabled on the AS/400 in the Device description for the print session. When HPT is enabled, pre-rendered print jobs are sent to the Host Integration Server 2004 in marked ASCII Transparent (ATRN) sections using the SCS control code '0x03.' The ATRN control code provides the same function as the Transparent (TRN) control code detailed in the LU 1 printing section. In addition to indicating that the block of data that should be dealt with as transparent, ATRN also indicates that the data is ASCII; therefore it is not converted from EBCDIC to ASCII.

To enable the host transform feature using the default 5224 print device

1. Stop the print writer associated with the print device.
2. Vary off the print device.
3. Issue the following command:

   ```
   chgdevprt devd(<print device>) transform(*YES) mfrtypmdl(<LAN printer type>)
   ```

   Common LAN printer types include: *HP4, *HPIII, *HPII, *IBM4039. To see a complete list of available options, prompt (F4) on the MFRTYPMDL parameter.

4. Vary on the print device.
5. Start the print writer.

For more details on the Host Print Transform feature, see the "OS/400 Printer device programming" manual (SC41-3713), or the "AS/400 Printing IV" redbook (GG24-4389). Both are available from IBM.

SCS Codes

The SCS control codes are fully documented in the *IBM Host Print Guide* (document number SC31-7145). All of the SCS control codes fall within the range of '0x00'–'0x3F.' These codes range from single-byte codes, such as Subscript '0x38' to multiple-byte codes followed by several parameters, such as Set Horizontal Format '0x2BC1...'

The following are some of the more common SCS control codes used.

Note **[L]**=length and **(Abv)** represents one-byte parameters in the SCS control code

ASCII Transparency (ATRN) — '0x03[L](P1)(. . .)(Pn)'

This SCS control code indicates a section of data that is not scanned for SCS codes, but passed to the print output untouched. In addition, this control code indicates that the data is ASCII. The extent of the section of data is denoted by the length byte. With HPT jobs, the length byte will commonly be '0xFF'.

Example

030441424344

03 — ATRN

04 — length of 4

41424344 — ASCII hex values for ABCD

SCS Control Code Formatted (Non-HPT)

If HPT is disabled in the Device description for the print session, SCS control codes will be used for the formatting of the print job. The SCS control codes, SHF, SVF, SLD, and SPD detailed earlier for LU 1 printing are also supported in APPC printing. Also commonly used in APPC printing is the SCS control code Presentation Position (PP) '0x34.' This control code allows the print position to be moved either horizontally or vertically, relative to the previous position or to an absolute position.

The following are the four forms of the Presentation Position SCS control code.

Absolute Horizontal Presentation Position (AHPP) '0x34C0(nn)'

nn — column number the print position is set to.

Example

34C00F

34C0 — AHPP

0F — column number 15

Relative Horizontal Presentation Position (RHPP) '0x34C8(nn)'

nn — number of columns to move from the current print position.

Example

34C80F

34C8 — RHPP

0F — 15 columns

Absolute Vertical Presentation Position (AVPP) '0x34C4(nn)'

nn — line number the print position is set to.

Example

34C40F

34C4 — AVPP

0F — line number 15

Relative Vertical Presentation Position (RVPP) '0x344C(nn)'

nn — number of lines to move from the current print position.

Example

344C0F

344C — RVPP

0F — 15 lines

Sample Host Data

Following is sample data from a host along with an explanation of the data and resulting printout.

```
2BC10684 01840542 2BC20642 04420A21
34C404 C1C2C3C4 344C01 34C004 E6E7E8E9
```

Data	Interpretation
2BC1068401840542	SHF, 132 characters per line, LM 1, RM 132
2BC2064204420A21	SVF, 66 lines per page, TM 4, BM 66
34C404	AVPP sets print position to line 4
C1C2C3C4	EBCDIC hex values for ABCD
344C01	RVPP sets print position down one line
34C004	AHPP sets print position to column 4
E6E7E8E9	EBCDIC hex values for WXYZ

Host Print Service

Configuring Host Print Service for an AS/400 Computer

Configuring AS/400 print service involves the following steps:

- Creating Link Services
- Creating Connections
- Creating LUs

To create a print LU

1. In SNA Manager, expand **SNA Service** for the server that you are working with, and then expand **Connections**.
2. Right-click the appropriate connection, point to **New**, and then click **Printer LU**.
3. Define your printer LU. You can keep the default for the **LU Number** or assign your own. Although the LU number is meaningful to the connection itself, the number is not very useful, so you can add a user-friendly name in the **LU Name** box.
4. Click **OK**.

To configure Host Print service for an AS/400 Connection

1. In SNA Manager, expand the server on which you want to add print services.
2. Right-click **Print Service**, point to **New**, and then click **APPC Session**.
3. The **Properties** page for this session appears.
4. On the **General** tab, type a session name, click **Printer**, and then configure a printer.
5. On the **APPC** tab, provide an **AS/400 Device Name**, a **Local LU Alias**, a **Mode Name**, and a **Remote LU** to use for this print session.
6. If the **AS/400 Device Name** you specify does not exist on the AS/400, it will be created.
7. On the **Security** tab, configure security for this print session.
8. Configure other parameters as desired.
9. Click **OK** to add this print session.
10. In the console tree, right-click **Print Service**, and then click **Save Configuration**.
11. Right-click **Print Service** again, and then click **Start**.

The Print Service feature of Host Integration Server 2004 supports print jobs from an AS/400 that contain basic formatting options. Some print jobs require special formatting. To properly print these jobs, the Host Print Transform feature of the AS/400 must be enabled. Host Print Transform is a feature of the AS/400 operating system (V3R1 and later) that translates print jobs in the SNA character string (SCS) data stream into an ASCII data stream (such as PCL). The data stream is specific to a particular make and model of ASCII printer, which must be defined at the time Host Print Transform is enabled.

Custom Host Code Page

Host Integration Server 2004 allows a custom host code page to be used for a printer session. The host code page is used for the translation between ASCII and EBCDIC. By default, a printer session will use the standard language code page provided by Windows Server 2003 or Windows 2000. As an alternative, a custom code page can be specified to allow a different translation. For example, using the default code page, the EBCDIC letter "A" ('0xC1') would be translated to an ASCII letter "A" ('0x41'). With a custom code page, it would be possible to have the EBCDIC "A" translated to any value. The custom code pages are text files that can be modified with a hex editor. Samples are included in the PRINTSERVERADDONS directory on the Host Integration Server 2004 CD-ROM. The code page file contains 512 bytes. The first 256 bytes represent what the EBCDIC characters are translated to. The second 256 bytes are what the ASCII characters are translated to. Logically each section is a 16-column by 16-row block.

Bytes 0-255: Data from Host

```

```

The value being translated is matched to its new value using the first number in the hex value as the row and the second as the column. For example, to find what the EBCDIC character "Z" ('0xE9') is translated to in the sample code page count down to row E and over to column 9. This position has the value '0x5A', which is the ASCII value for a "Z".

Sample Host Code Page (as seen in a Hex editor)

AS/400 (APPC) Printing

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Formatting Print Jobs

Host Print service can format print jobs by either using the Windows Server 2003 or Windows 2000 printer driver or by using a Printer Definition Table.

By default, print jobs submitted by Host Print service to a Windows Server 2003 or Windows 2000 Server print queue rely on the Windows Server 2003 or Windows 2000 printer driver to format the print data and send to the physical printer. Formatting the print data is done by the Windows Graphical Device Interface (GDI).

In addition to the Windows GDI, Host Integration Server 2004 Host Print service supports the use of a Printer Definition Table (PDT), which bypasses the formatting function of the Windows Server 2003 or Windows 2000 printer driver. The PDT file provides a function similar to a printer driver, in that it translates Graphic Device Interface (GDI) calls to control codes specific for a printer.

Selecting PDT causes the Windows Server 2003 or Windows 2000 Host Print service to treat all received data as transparent. All data is passed directly to the printer, except SCS codes, which are treated differently. Using a PDT, the SCS codes will be translated using the PDT before they are passed to the printer. For more information about Printer Definition Files, see Printer Definition Files.

The PDT is created in two steps.

1. A source text file is created and called the Printer Definition File (PDF) that defines the codes that can be used to control the printer.
2. A program is used to compile the information in the PDF into a binary file, the PDT that is used by Host Print service.

For example, if the host sends a byte indicating a new line ('0x15'), the PDT could be used to convert this to a carriage return, line feed ('0x0D0A').

For more information about creating a PDT, see Printer Definition Files.

To enable GDI

1. In SNA Manager, expand the server, and then click **Print Service**.
2. Right-click a print service displayed in the details pane, and then click **Properties**.
3. Click the **Job Format** tab, and then select **GDI**.

To select a PDT for printing

1. In SNA Manager, expand the server, and then click **Print Service**.
2. Right-click a print service displayed in the details pane, and then click **Properties**.
3. Click the **Job Format** tab, select **PDT**, and then click **PDT File**. The **Select Compiled Printer Definition File** dialog box appears.
4. Select the PDT that you want to use, and then click **Open**.
5. Click **OK**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Transparency

Transparency sets a flag that indicates that transparent data from the host is in ASCII and needs no translation from EBCDIC to ASCII. Selecting **Transparency is ASCII** causes the Windows Server 2003 or Windows 2000 Host Print service not to put the received data through an EBCDIC to ASCII translation table before printing.

Check **Transparency Custom Byte** to send the data stream in transparent mode. **Transparency Custom Byte** indicates the character designated to start a sequence of transparent data (the transparent data may or may not be ASCII). The IBM standard is 0x35, but if the host print job uses another value (for example, 0x36), this should be specified.

To select Transparency

1. In SNA Manager, expand the server, right-click **Print Service**, and then click **Properties**.
2. Click the **Advanced** tab, click **Transparency Custom Byte**, enter the byte data, and then click **OK**.

Formatting Print Jobs

Printer Definition Files

Host Print service enables you to specify the capabilities of a printer to override the defaults provided by the Windows printer driver.

By default, jobs submitted by Host Print service to a Windows print queue rely on the printer's Windows driver to send to the physical printer the data required to perform such formatting tasks as breaking lines and starting a new page.

Applications that bypass the formatting function of the Windows printer driver can use codes specified in a printer definition file to control the physical printer for a particular printer session under Host Print service. To use the file, open the properties page of the printer session, click the **Printing** tab, select **PDT**, and then type the fully qualified path of the file in the box. For more information about using the PDT file, click **Help** on the printer session properties dialog box.

Creating a printer definition file consists of two steps: First, you create a source text file that defines the codes that can be used to control the printer. Second, you run a program to compile the information in the text file into a binary file that can be used by Host Print service.

This section contains:

- Creating the Source Text File

Creating the Source Text File

You can use any text editor (such as Notepad) to create the source text file. The conventional file extension for the source text file is .pdf (which stands for Printer Definition File).

The PDF file consists of two sections:

- The Macro Definition Section
- The Parameter Definition Section

All text bounded by the C-language comment markers (**/*** and ***/**) is treated as comments and ignored by the compiler.

The next two sections describe the PDF sections currently supported by Host Print service.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Macro Definition Section

The macro definition section is bounded by **BEGIN_MACROS** and **END_MACROS** statements and consists of lines with the following syntax.

macro_name **EQU** *control_character_list*

The macro name can be any alphanumeric string that does not contain spaces, and the control character list consists of one or more two-digit hexadecimal values representing the data to be sent to the printer.

For example, the following macro defines the NUL character.

```
NUL EQU 00
```

For an example macro definition, see Sample Source Text File.

Parameter Definition Section

The parameter definition section immediately follows the macro definition section and consists of one or more lines with the following syntax.

parameter_name=*value_list*

The parameter name can be any character string that does not contain spaces. The compiler ignores parameter names not supported by Host Print service.

The value list can be empty or can contain one or more of the following:

- A three-digit decimal value.
- A two-digit hexadecimal value.
- A one-char character value.
- The name of a macro specified in the macro definition section.

For example, the following shows a parameter defining the control sequence to be sent to the printer to begin a new line.

```
NEW_LINE = CRR LFF
```

In this example, CRR and LFF are the names of macros specified in the macro definition section.

Host Print service currently supports the following parameters (definitions of unsupported parameters are ignored).

Parameter name	**Description**
START_JOB	Control sequence to be sent at the start of a print job.
END_JOB	Control sequence to be sent at the end of a print job.
CARRIAGE_RETURN	Control sequence for a carriage return.
LINE_FEED	Control sequence for a line feed.
FORM_FEED	Control sequence for a form feed.
NEW_LINE	Control sequence for a new line.
SET_6_LINES_PER_INCH	Control sequence to specify 6 LPI.
SET_8_LINES_PER_INCH	Control sequence to specify 8 LPI.
START_HIGHLIGHT_INTENSE	Control sequence to begin bold printing.
END_HIGHLIGHT_INTENSE	Control sequence to end bold printing.
START_HIGHLIGHT_UNDERLINE	Control sequence to begin underline printing.
END_HIGHLIGHT_UNDERLINE	Control sequence to end underline printing.
KANJI_CODE?	Control sequence of Kanji code for a printer, either JIS or SHIFT_JIS.
KANJI_ON	Control sequence to start printing Kanji.
KANJI_OFF	Control sequence to end printing Kanji.
SET_PAGE_LENGTH	Control sequence to set number of lines per page.
LEFT_MARGIN	Control sequence to set left margin in number of characters.
RIGHT_MARGIN	Control sequence to set right margin in number of characters.
TOP_MARGIN	Control sequence to set top margin in number of lines.
SET_HORIZONTAL_POSITION	Control sequence to set row position.
SET_VARIABLE_LINE_DENSITY	Control sequence to set line density.
SET_VARIABLE_PRINT_DENSITY	Control sequence to set number of characters per inch.
SET_FONT_SIZE	Control sequence to set font size in points.

Sample Source Text File

The sample PDF file, HPLJ2.PDF, is provided on the Host Integration Server 2004 CD-ROM in the \SDK\Samples\SNA\PrintDefFile directory.

See Also

Printer Definition Files

Compiling the Source Text File

After you have created the source text file, the next step is to compile the file using the Pdfcomp (PDFCOMP.EXE) utility located in the *platform*\SYSTEM\PRINTSRV directory of the Host Integration Server 2004 CD-ROM. To run Pdfcomp, type the following at the command prompt.

```
pdfcomp input_file output_file
```

You must specify the full name (including file extensions) of the input and output files.

For example, to compile the sample PDF file, copy PDFCOMP.EXE and HPLJ2.PDF to a directory on the server's hard disk, open a Command Prompt window and change the current directory to the directory containing the copied files. Then, type the following at the command prompt.

```
pdfcomp hplj2.pdf hplj2.pdt
```

This creates the binary PDT file in the current directory. Specifying this file in the properties of a printer session allows Host Print service to send preformatted data to the printer, bypassing the formatting function of the Windows printer driver.

Compilation of the PDF file into a PDT is not strictly necessary. If an uncompiled PDF file is selected in a Print Session under the SNA Manager, the compilation is performed automatically each time the print session is used. This feature has a performance overhead and is available mainly for ease of development. For production systems, it is strongly recommended that you pre-compile PDF files.

TN Service

TN Service, which is based on the Telnet protocol, enables a user at one site to connect and interact with a remote system at another site using the TCP/IP network protocol. When connecting to a remote computer, the initiating computer acts as a terminal for the remote computer. Microsoft® Host Integration Server 2004 supports TN3270-style and TN5250-style sessions in addition to native Host Integration Server 2004 client 3270 and 5250 sessions.

This section contains:

- TN3270
- Administering TN3270
- TN5250

TN3270

TN3270 service utilizes the features of Host Integration Server 2004 to obtain mainframe access and to address issues such as security and redundancy. TN3270 service supports the TN3270, TN3287, and TN3270E protocols, providing terminal emulation and printing capabilities.

To provide for TN3270 service, in Host Integration Server 2004 you create connections and LU definitions that map to the mainframe. TN3270 communicates with Host Integration Server 2004 using the logical unit application (LUA) API. Therefore, all LUs configured for use with the TN3270 service must be LUA LUs. The LUA LUs and LUA pools defined for the Host Integration Server 2004 computers can then be assigned to the TN3270 service using the drag-and-drop method. When the system is activated, the LUA LUs become available for TN3270 clients to access mainframe applications.

Redundancy involves SNA local nodes and link services. Each Microsoft® Windows Server™ 2003 or Windows® 2000 domain can contain one or more SNA subdomains. LUA LUs from multiple servers can be assigned to the TN3270 service. This results in client sessions distributed among the participating servers in the subdomain, balancing the load. This also allows redundancy between Host Integration Server 2004 computers. If one server goes down, a client computer can then access LUA LUs on a different server.

Similarly, a server can be configured with redundant host links to increase fault tolerance and bandwidth.

In this version of Host Integration Server 2004, Secure Sockets Layer (SSL) and Transport-Level Services (TLS) allow a network administrator using the TN3270 Service to increase the overall security of the enterprise network when accessing mainframe terminal and printer resources, including authentication of access to mainframe sessions and encryption of data between client emulator and TN3270 server.

Although the Microsoft 3270 Client (emulator) does not support SSL or TLS, many third-party software vendors offer 3270 emulators that support this functionality, including Attachmate, IBM, NetManage, and WRQ.

This section contains:

- IP Settings
- Administering TN3270
- TN3270 and Single Sign-On
- TN3270 Configuration

IP Settings

The IP settings assigned to an LUA LU or pool will allow TN3270 clients to connect to that LUA LU or pool. By default, the LUA LU or pool is not assigned an IP address or a subnet mask. This will allow any TN3270 client to use the LUA LUs or pools.

If you want to restrict an LUA LU or pool to one or more specific TN3270 clients, you should determine the IP address or host name of the client computers that will use these LUA LUs or pools. For client computers using Windows Server 2003 or Windows 2000, you can determine the IP address, subnet mask, and host name by typing **ipconfig/all** from the command prompt on the client computer.

If a workstation has a name that can be resolved using name resolution, it can be used in place of IP addresses. For example, if a workstation name is Giraffe and if the IP name list contains that name, it will map to the correct IP address. Name resolution works with WINS, DHCP, or similar name resolution services. For more information regarding WINS and DHCP, see your Windows Server 2003 or Windows 2000 documentation.

You can modify, delete, or add IP addresses and subnet masks within LUA LUs or pools. If you want to change the configuration of multiple LUA LUs, you can only change properties such as display types, the IP address, and subnet mask that the LUA LUs have in common. You cannot change properties such as the LUA LU name or number, because these values are unique for each LUA LU.

You can add new IP addresses and subnet masks to a range of LUA LUs. If the new IP address or subnet mask already exists on some of the LUA LUs, but not on others, the addition will occur without duplication in the ones that already have the IP address or subnet mask. You can also modify or delete the IP addresses that the LUA LUs have in common and that appear on the IP address list.

Configuration changes are apparent only to users who establish a connection after the changes are saved. Users who were connected at the time the configuration changes were made will not be affected.

TN3270

Administering TN3270

Using SNA Manager, you can view client addresses, LU names, and the state of each defined client computer. The session status information is useful if you need to stop, pause, or modify TN3270.

You can monitor network activity, including the state of each LU. An LU or pool will display one of the following states.

State	Description
CONNECTED	The TN client has established a connection to TN3270 service.
SSCP-LU	The TN client has established a connection to VTAM.
LU-LU	The LU is bound to a host application.
TERM	The connected session is terminating.

To add LUs or pools to TN3270 service

1. Before LUs can be added to the TN3270 service, you must first create application (LUA) LUs on an appropriate connection.
2. Select the LUs on the connection.

   A contiguous range of LUs can be selected by using the mouse to select the first item in the range you want to add, holding down the SHIFT key, and using the mouse to select the last item in the range that you want to add.

   A noncontiguous range of LUs can be selected by using the mouse to select each item in the range that you want to add, while holding down the CTRL key.

3. Drag the LUs into the desired server icon in the TN3270 Service folder.

   The LU appears in the list frame when the server icon in the TN3270 Service folder is highlighted. The icon for the LUs will change to a TN icon both in the TN3270 service and in the connection list.

   By default, the LU will be assigned an IP address of 0.0.0.0 and a subnet mask of 0.0.0.0. This will allow any TN3270 client to use this LU.

4. Specify one or more client IP addresses for this LU.
5. On the **Action** menu, click **Save Configuration** to put the changes into effect.

By adding an LU, you are defining Host Integration Server 2004 resource access to TN3270 service and you are defining logmode entries that are associated with a Host Integration Server 2004 resource.

Configuration changes are apparent only to users who establish a connection after the configuration changes are saved. Users who were connected at the time that the configuration changes were made will not be affected.

You can modify, delete, or add IP addresses and subnet masks to LUA LUs. If you want to change the configuration of multiple LUA LUs, you can only change properties such as display types, the IP address, and subnet mask that the LUA LUs have in common. You cannot change properties such as the LUA LU name or number, because these values are unique for each LUA LU.

You can add new IP addresses and subnet masks to a range of LUA LUs. If the new IP address or subnet mask already exists on some of the LUA LUs, but not on others, the addition will occur without duplication in the ones that already have the IP address or subnet mask. You can also modify or delete the IP addresses that the LUA LUs have in common and that appear on the IP address list.

You can assign a 3270 LU pool to a workstation, not an LUA pool. LUA pools can be assigned to the TN3270 service.

To edit a TN3270 LU configuration

1. In the **SNA Manager** console tree, select the LU that you want to view or modify.
2. Right-click the LU name, and then click **Properties**.
3. Click **OK** to exit.

To override the default port value for a session

TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client computer to connect to multiple host computers.

1. Select an LU.
2. Right click, and then click **Properties**. The **TN3270 LU Properties** dialog box appears.

3. Click **Use**, and then type a port number other than the default used for the server. The LU port assignment will override the default port assigned to the server.

To start, pause, continue, and stop TN3270 service

- Right-click **TN3270**, and then click **Start** or **Stop**.

  - or -

- In the **Services** utility of the Windows Server 2003 or Windows 2000 **Administrative Tools or Windows Control Panel**, select **TN3270 Service**, and right-click **Start**, **Pause**, **Continue**, or **Stop**.

The TN3270 service is set to start manually by default. You can change this to automatic if you are not running either the TN5250 service or the Telnet daemon on this server, or if you have configured the TCP ports for more than one of these services.

Once TN3270 service has stopped, it can no longer be accessed. You may need to start the TN3270 service after you have paused or stopped it. TN3270 service can be restarted only on the local system.

Pausing allows you to prevent new users from establishing a connection with TN3270 service without disconnecting current users. You can then view TN3270 service session status and notify connected users to disconnect from TN3270 service.

Before stopping TN3270 service, notify all connected users that they will be disconnected within a specified time period. Stop the service after expiration of your warning period.

Tips

- To start TN3270 service from a command prompt, type

  net start tn3270

- To pause TN3270 service from a command prompt, type

  net pause tn3270

- To continue TN3270 service from a command prompt, type

  net continue tn3270

- To stop TN3270 service from a command prompt, type

  net stop tn3270

To use TN3270 service with TN5250 service or Telnet service

TN3270, TN5250, and Telnet services all default to the well-known TCP port number 23. If you plan to install more than one of these services, perform the following steps.

1. Configure the services to use unique port numbers.
2. Reconfigure all your TN3270 clients or TN5250 clients to use the new port numbers.

To remove TN3270 service

1. To pause TN3270 service, use the **Services** utility in Windows Server 2003 or Windows 2000 Control Panel.
2. Pausing TN3270 service allows you to notify connected users to disconnect from TN3270 service before you stop and remove the application.
3. To stop TN3270 service, use the **Services** utility in Windows Server 2003 or Windows 2000 Control Panel.
4. Open **Control Panel**, and double-click **Add/Remove Programs**.
5. Click **Host Integration Server 2004**, and then click **Change**. The **Add/Remove Application** dialog box appears.
6. In the **Add/Remove** dialog box, click **Add/Remove**.
7. Click the **TM3270 Service** icon, and then click **Entire Feature will be unavailable**.
8. Click **Continue**.

> **Note** You can remove TN3270 service anytime you wish to do so. However, removing TN3270 service deletes the TN3270 service files from your computer, including TN3270 service configuration data. To use TN3270 service again, you must run **Host Integration Server 2004 Setup** to reinstall TN3270 service files.

See Also

- TN3270 and Single Sign-On

TN3270 and Single Sign-On

The TN3270 service does not work with Single Sign-On. You should not enable the TN3270 service to run under a user account for which you have a Single Sign-On mapping. If you access the host through the TN3270 service by typing **MS$SAME** for your logon, you will get the user ID and password of the user under which the TN3270 service is running (for example, SNAUSER). If you use an Administrator-level account and change the password, SNA services will fail to start after the password change.

TN3270 Configuration

This section describes the management and configuration of certificates necessary for running TN3270 on Host Integration Server 2004.

This section contains:

- Managing Certificates
- Configuring Certificates
- Notes Section

Managing Certificates

The SChannel API uses certificates to provide its security features.

This section contains:

- Server Authentication
- Client Authentication
- Obtaining and Creating Certificates

Server Authentication

For server authentication, the server requires a valid certificate with the following properties:

- Type X509
- Suitable for Server Authentication
- Associated private key
- Stored in the Personal or My certificate store for the service account used by the TN3270 service
- By default, a TN3270 server will look for a certificate with a Common Name (CN) matching the host name of the computer running the TN3270 server. This default can be changed by using a registry entry. For details, see Changing the Default Server Authentication Certificate Common Name (CN).

This certificate will be sent to the client as part of the handshake negotiation when the connection is established. For the client to accept the certificate:

- The certificate (and its issuing chain) must be current (for example, not outside of its valid dates).
- The issuing chain must lead to a certification authority (CA) that appears in the client's Trusted Root CA List.
- The certificate (or any part of its issuing chain) should not appear on a certificate revocation list (CRL) of its issuer.
- Most clients offer strict certificate checking, which if selected, will reject connections if the server certificate's common name does not match its host name.

Note If the certificate on the server is changed, the TN3270 server must be stopped and restarted.

Client Authentication

For client authentication, the client requires a valid certificate with the following properties:

- Type X509
- Suitable for Client Authentication
- Associated private key

You might not want to grant access to some of these certificate settings. It is recommended that you check the list of default Trusted Root Certification Authorities on the server, and remove any you do not want.

How the certificate is stored and selected depends on the client program. The certificate will be passed to the server as part of the handshake process. For the server to accept the certificate:

- The certificate (and its issuing chain) must be current.
- The issuing chain must lead to a CA that appears in the server’s Trusted Root CA list.
- The certificate (or any part of its issuing chain) should not appear on a CRL of its issuer.

See Also

Server Authentication

Obtaining and Creating Certificates

Obtaining and Creating Certificates

It is recommended that you use the Microsoft Certificate Services and certification authorities to manage their certificates.

When a certificate is issued, it includes a certificate and a private key. When the certificate is transmitted for verification purposes, only the certificate part is sent (and not the private key). The server needs a certificate and a private key for the server authentication certificate. The server needs a copy of the client authentication certificate for its root CA.

Obtaining Certificates

Certificates are obtained from certification authorities. Because these CAs are widely trusted organizations, the certificate will be recognized widely.

Certificate Creation

Windows Server 2003 and Windows 2000 Server feature a certification authority program that allows a local CA to be set up. The local CA may depend on a certificate obtained from an external, well-trusted CA, or it may be a stand-alone CA.

This system can be used if the root certificate (on the CA program) is copied to the Trusted Root CAs store on all the computers using the certificates. The local CA can then issue client and server authentication certificates, and each will be recognized by the other.

See Also

Server Authentication

Client Authentication

Configuring Certificates

A new **Port/Security** tab now exists on the **TN3270 Server properties** dialog box, which allows you to configure the ports to be available to the TN3270 server. The security parameters are then configured on a port-by-port basis.

The following issues are required to implement security support:

- A client that attempts to connect to a port that has not been configured on the TN3270 server will be unsuccessful.
- The default port defined in SNA Manager does not affect the security configuration. Either a port security record is found (in which case it is used), or it is not found (in which case the client fails to connect).
- A port with security level Unsecured means that TLS/SSL will be fully disabled on that port. There will be no exchange of certificates on that port.
- All the changes made to the configuration are dynamic.
- Server authentication certificates may not be dynamically changed.

This section contains:

- Switching on Security and Changing Certificates
- Changing the Default Values of the Security Parameters
- Changing the Default Server Authentication Certificate Common Name (CN)

Switching on Security and Changing Certificates

To support security, the TN server needs to load a server authentication certificate. This is done when a TN server receives a configuration requiring security (for example, at least one port is configured to a security level other than Unsecure) for the first time. After a certificate has been loaded successfully, the certificate cannot be changed without restarting the TN server.

If the certificate-loading process fails (for example, if the certificate is not found or is invalid), any ports requiring security will not be available to the TN server and an error will be logged. The user must then fix the certificate and try again.

Note The certificate-loading process incorporates several stages, such as opening a certificate store, finding the certificate, and acquiring credentials based on the certificate.

Obtaining credentials involves three steps:

- Opening the server's certificate store (using **CertOpenStore**)
- Obtaining the server authentication certificate (using **CertFindCertificateInStore**)
- Getting a credential for each security setting (using **AcquireCredentialHandle**)

The credential contains all the security options supported by the credential (such as maximum and minimum encryption strength, and algorithms supported). Client authentication is not a credential property. The credential is linked to the server authentication certificate.

If security is specified but the TN3270 server fails to get the credentials, any ports that are defined as secure will be unavailable to clients. An error will be logged and the user can try to reload the credentials again.

See Also

Configuring Certificates

Changing the Default Values of the Security Parameters

Changing the Default Server Authentication Certificate Common Name (CN)

Changing the Default Values of the Security Parameters

By default, the security levels are:

- High = 168-bit encryption (minimum)
- Medium = 128-bit encryption (minimum)
- Low = 40-bit encryption (minimum)
- Unsecured = TLS/SSL fully disabled

The default values of the first three of these levels can be overridden by the following registry entries (stored in **HKEY_LOCAL_MACHINE/SYSTEM/CurrentControlSet/Services/TN3270/Parameters**):

- **SSLHighSecurity**
- **SSLMediumSecurity**
- **SSLLowSecurity**

Each registry entry will contain a numeric (DWORD) value. The registry is checked for entries only when the TN3270 server is started. For any changes in the registry entries to take effect, the TN3270 server must be restarted.

Switching on Security and Changing Certificates

Changing the Default Values of the Security Parameters

TN5250

TN5250 acts as a gateway that allows an AS/400 access to TN5250 clients providing 5250 terminal emulation.

To provide for TN5250 service, you must create TN5250/AS400 definitions that map to the AS/400. TN5250/AS400 definitions include local and remote APPC LUs, the mode (the default is QPCSUPP), AS/400 user name and password, terminal type, and IP address and subnet mask.

TN5250 supports multiple sessions up to the limits of the mode used in the TN5250/AS400 definition.

IP Settings

IP settings assigned to TN5250/AS400 definitions allow TN5250 clients to connect to the AS/400. By default, the TN5250/AS400 definition is not assigned an IP address or a subnet mask. This will allow any TN5250 client to connect to the AS/400.

If you want to restrict the use of a TN5250/AS400 definition to one or more specific TN5250 clients, you should determine the IP addresses or host names of the client computers that will use the TN5250/AS400 definition. For client computers using Windows Server 2003 or Windows 2000, you can determine the IP address, subnet mask, and host name by typing **ipconfig/all** from the command prompt on the client computer.

If a workstation's name can be resolved using name resolution, it can be used in place of IP addresses. For example, if a workstation name is Giraffe and if the IP name list contains that name, it will allow that workstation access. Name resolution works with WINS, DHCP, or similar name-resolution services. For more information regarding WINS and DHCP, see your Windows Server 2003 or Windows 2000 documentation.

You can modify, delete, or add IP addresses and subnet masks within a TN5250/AS400 definition. If you want to change the configuration of multiple TN5250/AS400 definitions, you can only change the properties of items that the TN5250/AS400 definitions have in common. You cannot change the name of remote LUs.

You can add new IP addresses and subnet masks to multiple TN5250/AS400 definitions. If the new IP address or subnet mask already exists on some of the TN5250/AS400 definitions, but not on others, the addition will occur without duplication in the ones that already have the IP address or subnet mask. You can also modify or delete the IP addresses that the TN5250/AS400 definitions have in common and that appear on the IP address list.

Configuration changes are apparent only to users who establish a connection after the changes are saved. Users who were connected at the time the configuration changes were made will not be affected.

This section contains:

Administering TN5250

Administering TN5250

The local LU, remote LU, and mode must match the configuration information in Host Integration Server 2004.

To enable an APPC session with the AS/400, the user ID and password must be provided for conversation security. Contact your AS/400 administrator for the correct information.

The TN5250 requires TN5250/AS400 definition terminal names to allow TN5250 service to accept client requests from client computers emulating those types of terminals.

To set up Host Integration Server 2004 for TN5250 access

1. Open **SNA Manager** console tree.
2. Install and configure a link service, if this has not been done.
3. Insert a connection to an AS/400 that the TN5250 clients will access. Configure the connection with Remote End as Peer System.
4. Configure a local LU and a remote LU for access to an AS/400, making sure the mode for the remote LU is QPCSUPP.
5. On the **File** menu, click **Save Configuration** to put the changes into effect.

To add and configure LUs for TN5250 service

1. Before LUs can be added to the TN5250 service, you must first install a link service, add a connection to an AS/400 on this link service, and create local and remote LUs for accessing this AS/400.
2. Right-click **TN5250**, point to **New**, and then click **TN5250 AS/400 Definition**.
3. Configure the properties of this TN5250 AS/400 definition.

   If you do not specify an IP address for an LU, the default value will allow any TN5250 client computer access to this LU.

   Click **Help** for information on the property options.
4. Click **OK** to close the **AS/400 Definition Properties** dialog box.
5. On the **Action** menu, click **Save Configuration** to put the changes into effect.

Configuration changes are apparent only to users who establish a connection after the configuration changes are saved. Users who were connected at the time that the configuration changes were made will not be affected.

You can modify, delete, or add IP addresses and subnet masks to AS/400 definitions. If you want to change the configuration of multiple AS/400 definitions, you can only change properties such as display types, the IP address, and subnet mask that the AS/400 definitions have in common. You cannot change properties such as the local or remote LUs, because these values are unique for each AS/400 definition.

You can add new IP addresses and subnet masks to a range of AS/400 definitions. If the new IP address or subnet mask already exists on some of the AS/400 definitions, but not on others, the addition will occur without duplication in the ones that already have the IP address or subnet mask. You can also modify or delete the IP addresses that the AS/400 definitions have in common and that appear on the IP address list.

To edit an AS/400 definition for TN5250 service

- In the SNA Manager console tree, select the TN5250 service AS/400 definition that you want to view or modify, right-click, and then click **Properties**.

To delete AS/400 definitions from TN5250 service

1. In the SNA Manager console tree, select the icon for the AS/400 definition that you wish to delete.
2. Click **Delete**.
3. Click **Save** to save your configuration changes.

   Note Configuration changes are apparent only to users who establish a connection after the configuration changes are saved. Users who were connected at the time that the configuration changes were made will not be affected.

To start, pause, continue, and stop TN5250 service

- Right-click **TN5250**, and then click **Start** or **Stop**.

  - or -

- In the **Services** utility of the Windows Server 2003 or Windows 2000 **Administrative Tools**, select **TN5250 Service** and click **Start**, **Pause**, **Continue**, or **Stop**.

The TN5250 service is set to start manually by default. You can change this to automatic if you are not running either the TN5250 service on this server, or if you have configured the TCP ports for more than one of these services.

After TN5250 service has stopped, it can no longer be accessed. You may need to start the TN5250 service after you have paused or stopped it. TN5250 service can be restarted only on the local system.

Pausing allows you to prevent new users from establishing a connection with TN5250 service without disconnecting current users. You can then view session status in the Active TN5250 Sessions folder and notify connected users to disconnect from TN5250 service.

Before stopping TN5250 service, notify all connected users that they will be disconnected within a specified time period. Stop the service after expiration of your warning period.

Tips

- To start TN5250 service from a command prompt, type

  net start tn5250

- To pause TN5250 service from a command prompt, type

  net pause tn5250

- To continue TN5250 service from a command prompt, type

  net continue tn5250

- To stop TN5250 service from a command prompt, type

  net stop tn5250

Pausing or removing TN5250 service

1. To pause TN5250 service, use the **Services** utility in Windows Server 2003 or Windows 2000 Control Panel.

   Pausing TN5250 service allows you to notify connected users to disconnect from TN5250 service before you stop and remove the application.

2. To stop TN5250 service, use the **Services** utility in Windows Server 2003 or Windows 2000 Control Panel.
3. Open **Control Panel**, and then double-click **Add/Remove Programs**.
4. Click **Host Integration Server 2004**, and then click **Change**. The **Add/Remove Programs** dialog box appears.
5. In the **Add/Remove Application** dialog box, click **Add/Remove**.
6. Click the **TN5250 Service** icon, and then click **Entire feature will be unavailable**.
7. Click **Continue**.

   Note You can remove TN5250 service anytime you wish to do so. However, removing TN5250 service deletes the TN5250 service files from your computer, including TN5250 service configuration data. To use TN5250 service again, you must run Host Integration Server 2004 Setup to reinstall TN5250 service files.

Active Directory Services

Microsoft® Active Directory® is the Microsoft Windows Server™ 2003 or Windows® 2000 directory service.

A directory service is an object-oriented information database of network resources. It also provides the services that locate, use, and manage the database and the network resources. These network resources are known as objects and can include network servers, users, printers, computers, databases, and security policies.

Active Directory provides the following services and benefits:

- **Simplified administration.** Active Directory provides a single point of administration for all network resources. It also provides a single point of logon for network users.
- **Network security.** Security policies can be implemented and enforced to keep information and resources safe, and at the same time, make information and resources available to the right people.
- **Scalability.** The Active Directory database can be expanded by dividing it into partitions. A partition is a logical division of objects. Using partitions, Active Directory can scale from small installations with a few objects, to large installations containing millions of objects.
- **Directory replication and distribution.** Replicating and distributing the directory to other servers in the network ensures its availability and redundancy.
- **Open standards.** Active Directory supports industry standard naming conventions, such as the Domain Name System (DNS), and protocols, such as the Lightweight Directory Access Protocol (LDAP). This allows Active Directory to be integrated into networks that already have a directory. It also allows you to unify and manage the multiple namespaces that may exist in the heterogeneous environments of corporate networks.

Complete Active Directory services information is available from many sources, including the Windows Server 2003 and Windows 2000 Help.

This section contains:

- How Host Integration Server 2004 Uses Active Directory
- Configuring Active Directory During Host Integration Server 2004 Installation
- Administration of Host Integration Server 2004 Active Directory

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

How Host Integration Server 2004 Uses Active Directory

Host Integration Server 2004 uses Active Directory by registering services and resources with the Active Directory schema. The benefits of using Active Directory include:

- Client configuration and resource location on the network is simplified.
- The limitation of 8,000 sponsor connections that existed in SNA Server 4.0 is eliminated.

Host Integration Server 2004 client computers must be configured to communicate to a Host Integration Server 2004 computer using either sponsor connections or Active Directory. A client computer cannot be set up to use both at the same time.

If a Host Integration Server 2004 computer is configured to use Active Directory, it must operate in an Organizational Unit (OU). If the Active Directory schema is new or otherwise does not have any OUs, Host Integration Server 2004 will create an OU for itself.

In addition, the following relationships between the SNA subdomain and the OU containing the Host Integration Server 2004 specific containers must be observed:

- Multiple Host Integration Server 2004 computers can exist within the same OU.
- Each OU containing a Host Integration Server 2004 must be a unique SNA subdomain.
- Two different SNA subdomains cannot exist within the same OU.
- An SNA subdomain cannot stretch across two OUs.
- If an OU contains multiple Host Integration Server 2004 computers, they must be part of the same SNA subdomain.
- The name of the OU and the name of the SNA subdomain within that OU can either be the same name or different names.

See Also

Active Directory Services

Configuring Active Directory During Host Integration Server 2004 Installation

Host Integration Server 2004 participation in Active Directory is accomplished by the SNA service and the SNA Windows Management Instrumentation (SNAWMI) Provider. The SNA service is an installable option that can be selected during Host Integration Server 2004 setup. The SNAWMI is always installed automatically when the SNA service is installed.

With Host Integration Server 2004, there are two mechanisms that will deliver SNA client resource location. One is sponsor connections, which is the existing mechanism present in SNA Server 4.0. The second uses Windows Server 2003 or Windows 2000 Active Directory. If you want to use Active Directory instead of SNA subdomains, you must add the Host Integration Server 2004 schema to the Windows Server 2003 or Windows 2000 domain schema before installing Host Integration Server 2004.

The Windows Server 2003 or Windows 2000 schema is extended by running a command-line utility found on the Host Integration Server 2004 CD-ROM. The following procedure adds the Host Integration Server 2004 schema to the Windows Server 2003 or Windows 2000 domain schema:

To extend the Active Directory schema

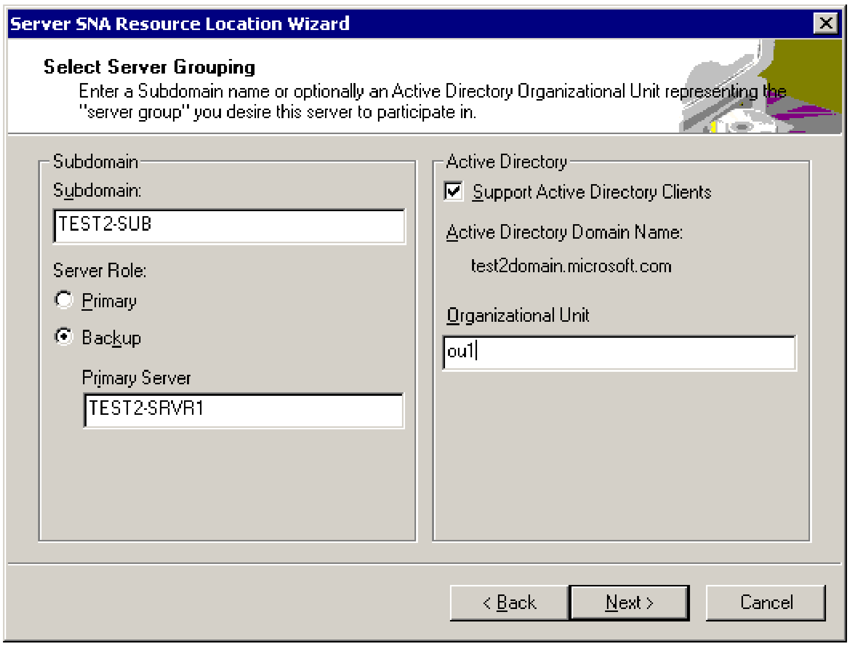
1. Make sure you are logged on to the server running Windows Server 2003 or Windows 2000 as **Administrator** or another user who is a member of both the Domain Admins and Schema Admins groups, and who has been delegated control to the domain. You can use the **Active Directory Users and Computers** administrative tool to verify user privileges and delegate control.
2. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Active Directory Users and Computers**.
3. Select **Users**, select **Domain Admins**, right-click, and then click **Properties**.
4. Select the **Members** tab and **add** members to this group.
5. Select **Users**, select **Schema Admins**, right-click, and then click **Properties**.
6. Select the **Members** tab and **add** members to this group.
7. Expand **Domain Controllers**, select the domain, right-click, and then click **Delegate Control…**.
8. Complete the wizard.
9. Insert the Host Integration Server 2004 CD-ROM into the CD-ROM drive of the computer running Windows Server 2003 or Windows 2000 Server .
10. Open a Command Prompt window.
11. Change drives to the CD-ROM drive.
12. Enter the following command.

    ```
    addschma HIserver.schema
    ```

13. The resulting display will indicate if the command was successful.

    Note If you do not successfully add the Host Integration Server 2004 schema, you will not be able to use Active Directory, but you can still configure a Host Integration Server 2004 client to use SNA subdomains and sponsor connections.

Configuring Host Integration Server 2004 to use Active Directory is performed during installation. The following figure shows the Setup screen where you can choose to install Active Directory support.



Select Server Grouping

Enter a Subdomain name or optionally an Active Directory Organizational Unit representing the "server group" you desire this server to participate in.

Subdomain: TEST2-SUB

Server Role:

○ Primary

● Backup

Primary Server: TEST2-SRVR1

☑ Support Active Directory Clients

Active Directory Domain Name:

test2domain.microsoft.com

Organizational Unit: ou1

Selecting Support Active Directory Clients, and then entering an Organizational Unit (OU) adds the following services to the ServerResources container for that OU:

- SNAServer Service
- SNAWMI Provider Service
- SNABase Service
- MngAgent Service

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Administration of Host Integration Server 2004 Active Directory

Administration of Host Integration Server 2004 Active Directory participation is done using the SNA Manager.

To access the Active Directory Server Configuration

1. In the SNA Manager tree, expand an SNA subdomain, select the server that you want to work with, right-click the server, and then click **Properties**.
2. In the **Properties** box, click **Change**. The **Server SNA Resource Location Wizard** appears.
3. Follow the on-screen prompts to install Active Directory support.

The **Server SNA Resource Location Wizard** is the same wizard that configures Host Integration Server 2004 following setup.

> **Note** Changes made to the **Server Properties** page require the SNABase Service to be restarted.

Host Configuration

For a connection to be established successfully between a host computer and a Host Integration Server 2004 computer, a number of software configuration settings (VTAM, NCP, or AS/400), and hardware characteristics must work together. These include the mainframe node ID settings, AS/400 name settings, addresses, BTU length, and link service settings.

The following table provides more details about important configuration items.

Element	Important items to consider
Host configuration settings (VTAM, NCP, or AS/400 settings) must match the **Connection and Server** settings on Host Integration Server 2004	**Mainframe Node ID settings:** For most mainframes, IDBLK and IDNUM in the PU definition must be matched by the two parts of the Remote Node ID on the Host Integration Server 2004 connection. **AS/400 name settings:** For the AS/400, local and remote Control Point Names (CP names) and network names must match corresponding Host Integration Server 2004 settings (local names configured on the server and remote names on the connection). **Addresses:** For several connection types (802.2, X.25, and channel), host settings must be matched with equivalent settings on the Host Integration Server 2004 connection. For details, see the section about the type of connection you are configuring. **BTU length:** For the mainframe, this is set through MAXDATA in the PU definition. For the AS/400, this is set through MAXFRAME. These should equal the Max BTU Length on the Host Integration Server 2004 connection. **Other settings:** For some connections, other settings are also important. For example, for Synchronous Data Link Control (SDLC), the NRZ/NRZI settings on the host must match those on the Host Integration Server 2004 connection. For details about these and other settings, see the section about the type of connection you are configuring.
For SDLC and X.25 **Communications hardware:** line, modem (if applicable), and adapter characteristics must match the **Link service and connection** settings on the Host Integration Server 2004	**Speed and duplexing:** For SDLC and X.25, note the speed and duplexing capabilities of the line, modem (or DCE), and adapter, and make sure that they will not be exceeded by the settings in the Host Integration Server 2004 link service and connection. Settings for fast transmission or for full duplexing cause greater demands on hardware. (Fast transmission plus full duplexing cause the greatest demands.) The hardware element with the smallest capacity will limit the capacity of the entire system. For example, with an SDLC adapter that lacks a coprocessor, you cannot use full-duplex transmissions at high speeds, even if the modem and line can handle them.

When configuring a new host connection or troubleshooting an existing connection, regardless of the connection type, the identifiers between the host and Host Integration Server 2004 must match. The following sections describe various configuration settings.

This section contains:

- Mainframe Connections Using Exchange Identifications (XIDs)
- Mainframe Connections Not Using (XIDs)
- AS/400 Connections
- Configuring VTAM for 3270 Access
- 802.2 Connection Parameters
- SDLC Connection Parameters
- X.25 Connection Parameters

Mainframe Connections Using Exchange Identifications (XIDs)

Node ID is the identifier used for exchange identifications (XIDs) with most mainframes. Check to make sure that the following items match; if they do not, Host Integration Server 2004 is not identifying itself in a way that the host can recognize.

Identifier used on mainframe	Identifier to configure on Host Integration Server 2004
IDBLK and **IDNUM** in the PU definition	The two parts of the **Local Node ID** (configured on the connection)

See Also

Host Configuration

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Mainframe Connections Not Using (XIDs)

There are some situations in which the mainframe does not use Node ID in exchange identifications (XIDs), but instead uses Network Name and Control Point Name. These situations include mainframes communicating through LU 6.2 and mainframes that call up Host Integration Server 2004. (Host Integration Server 2004 accepts incoming calls on that mainframe connection.) In these situations, the following parameters must match.

> **Note** Use the following identifiers only when necessary. They are more complicated than needed for most mainframe connections and add the potential for error when used unnecessarily.

Identifier used on mainframe (in unusual cases only)	**Identifier to configure on Host Integration Server 2004**
NETID in the VTAM Start command for the local SSCP	**Local Network Name** (configured on the server)
CPNAME in the PU definition	**Local Control Point Name** (configured on the server)
NETID and **SSCPNAME** in the VTAM Start command for the remote SSCP (VTAM system)	**Remote Network Name** and **Remote Control Point Name** (configured on the connection)

AS/400 Connections

Network Name and Control Point Name (used together and called the fully qualified name) are the identifiers used when using exchange identification (XID) with AS/400 computers. Check to make sure that the following items match; if they do not, Host Integration Server 2004 is not identifying itself in a way that the AS/400 can recognize.

Identifier used on AS/400	**Identifier to configure on Host Integration Server 2004**
RMTNETID (usually; often set to APPN); **RMTCPNAME**	**Local Network Name** and **Local Control Point Name** (configured on the server)
RMTNETID (often set to APPN); **CP Name** (shown in the **Display network attributes** screen)	**Remote Network Name** and **Remote Control Point Name** (configured on the connection)

Event log entries can be very helpful in diagnosing and correcting mismatched identifiers between Host Integration Server 2004 and host computers.

Configuring VTAM for 3270 Access

When setting certain Host Integration Server 2004 parameters for a host connection, you must match values set on the host or on front-end processors for the host. Host values are configured in VTAM. Front-end processor values are configured in the Network Control Program (NCP).

The following table shows how parameters for Host Integration Server 2004 correspond to VTAM host parameters.

Host Integration Server 2004 parameter	**VTAM parameter**
Control Point Name (Local Node).	**CPNAME=** in the PU definition.
Network Name (Local Node) Note that the Network Name for the local and remote nodes is generally the same.	**NETID** parameter in the VTAM Start command for the local SSCP (the VTAM system to which Host Integration Server 2004 is attached). Note that this is generally the same as the NETID for the remote SSCP.

> **Note** The local Control Point Name and Network Name are needed only if the Host Integration Server 2004 will accept incoming calls, or will be used for LU 6.2 (APPC).

802.2 Connection Parameters

The following table shows how Host Integration Server 2004 parameters for 802.2 connections correspond to VTAM or Network Control Program (NCP) parameters. Asterisks (*) indicate required parameters.

Host Integration Server 2004 parameter	**VTAM or NCP parameter**
Local Node ID,* first three digits (block number).	**IDBLK=** parameter in the PU definition
Local Node ID,* last five digits (node number).	**IDNUM=** parameter in the PU definition
Network Name (Remote Node) Note that the Network Name for the local and remote nodes is generally the same.	**NETID** parameter in the VTAM Start command for the remote SSCP (VTAM system)
Control Point Name (Remote Node).	**SSCPNAME** parameter in the VTAM Start command for the remote SSCP (VTAM system)
Remote Network Address* when connecting to a 3720, 3725, or 3745 front-end processor.	**MACADDR=** parameter in the NCP Gen
Remote Network Address* when connecting to an IBM 9370 host.	**MACADDR**= parameter in the PORT definition
Remote SAP Address when connecting to an IBM 9370 host.	**SAPADDR**= parameter in the PU definition
Max BTU Length.	**MAXDATA**= parameter in the PU definition (set Max BTU Length &le; MAXDATA)

* Required parameter in Host Integration Server 2004

SDLC Connection Parameters

The following table shows how Host Integration Server 2004 parameters for Synchronous Data Link Control (SDLC) connections correspond to VTAM or Network Control Program (NCP) parameters. Asterisks (*) indicate required parameters.

Host Integration Server 2004 parameter	**VTAM or NCP parameter**
Local Node ID,* first three digits (block number).	**IDBLK=** parameter in the PU definition
Local Node ID,* last five digits (node number).	**IDNUM=** parameter in the PU definition
Network Name (Remote Node) Note that the Network Name for the local and remote nodes is generally the same.	**NETID** parameter in the VTAM Start command for the remote SSCP (VTAM system)
Control Point Name (Remote Node).	**SSCPNAME** parameter in the VTAM Start command for the remote SSCP (VTAM system)
Max BTU Length.	**MAXDATA=** parameter in the PU definition (set Max BTU Length &le; MAXDATA)
Encoding (NRZ or NRZI).	**NRZI=** setting in the LINE/GROUP definition (defaults to YES on host)
Local Poll Address.	**ADDR**= parameter in the PU definition

* Required parameter in Host Integration Server 2004

X.25 Connection Parameters

The following table shows how Host Integration Server 2004 parameters for X.25 connections correspond to VTAM or Network Control Program (NCP) parameters. Asterisks (*) indicate required parameters.

Host Integration Server 2004 parameter	**VTAM or NCP parameter**
Local Node ID,* first three digits (block number).	**IDBLK=** parameter in the PU definition
Local Node ID,* last five digits (node number).	**IDNUM=** parameter in the PU definition
Network Name (Remote Node) Note that the Network Name for the local and remote nodes is generally the same.	**NETID** parameter in the VTAM Start command for the remote SSCP (VTAM system)
Control Point Name (Remote Node).	**SSCPNAME** parameter in the VTAM Start command for the remote SSCP (VTAM system)
Remote X.25 Address*.	**DIALNO=** parameter in the PORT definition
Max BTU Length.	**MAXDATA=** parameter in the PU definition (set Max BTU Length &le; MAXDATA)

* Required parameter in Host Integration Server 2004

Sample VTAM Parameters

VTAM parameters on host connections need to correspond to settings in Host Integration Server 2004. Each connection needs its own specified values.

This section contains:

- Sample VTAM Parameters for a Token Ring Connection
- Sample VTAM Parameters Including CPNAME
- Configuring VTAM for APPC Access
- Sample VTAM Parameters for Independent APPC
- Sample CICS Configuration Screens for Use with APPC
- Configuring NCP for Independent APPC
- Configuring the AS/400 for 5250 Access
- Table of Parameters for AS/400 Communication

Sample VTAM Parameters for a Token Ring Connection

The following is a sample of VTAM parameters that might be used for a Token Ring connection to an IBM 9370 host. The underlined values correspond to values specified in Host Integration Server 2004 Manager.

```
R01100   PORT
CUADDR=100,MACADDR=400040004001,LANCON=(5,2),X

MAXDATA=2012,MAXSTN=52,SAPADDR=04

SERVER01 PU     ADDR=C1, IDBLK=05D, IDNUM=00001,X

ANS=CONTINUE,MAXDATA=0265,MAXOUT=7,MAXPATH=7,X

PACING=0,VPACING=0,SSCPFM=USSSCS,X

LANACK=(0,0),LANCON=(5,2),LANINACT=4.8,LANRESP=(5,2), X

LANSDWDW=(7,1),LANSW=YES,MACADDR=400040001111,X

USSTAB=MSUSSTAB,DLOGMOD=D4C32792,X

PUTYPE=2,DISCNT=(NO),ISTATUS=ACTIVE,SAPADDR=04

T0110002 LU   LOCADDR=002
T0110003 LU   LOCADDR=003
T0110004 LU   LOCADDR=004
T0110005 LU   LOCADDR=005
P0110006 LU   LOCADDR=006,DLOGMOD=LU33286S
T0110007 LU   LOCADDR=007
T0110008 LU   LOCADDR=008
```

The following table shows the Host Integration Server 2004 parameters and values that correspond to the sample VTAM parameters.

Host Integration Server 2004 parameter	Sample value	VTAM parameter
Remote Network Address	400040004001	MACADDR= parameter in the PORT definition
Local Node ID, first three digits (block number)	05D	IDBLK= parameter in the PU definition
Local Node ID, last five digits (node number)	00001	IDNUM= parameter in the PU definition
Max BTU Length	265	MAXDATA= parameter in the PU definition (set Max BTU Length &le; MAXDATA)
Remote SAP Address	04	SAPADDR= parameter in the PU definition
LU Numbers	2 through 8	LOCADDR= parameter in the LU definitions

Sample VTAM Parameters

Sample VTAM Parameters for an SDLC Connection

The following is a sample of VTAM parameters that might be used for a Synchronous Data Link Control (SDLC) connection to a host. The underlined values correspond to values specified in Host Integration Server 2004 Manager.

```
SERVER02 PU     ADDR=C1,IDBLK=017,IDNUM=B8001,DISCNT=NO,X
                VPACING=00,PACING=00,PUTYPE=2,MAXDATA=265,X
                DLOGMOD=D4C32792,USSTAB=MSUSSTAB
```

```
T01B8002 LU   LOCADDR=002
T01B8003 LU   LOCADDR=003
T01B8004 LU   LOCADDR=004
T01B8005 LU   LOCADDR=005
P01B8006 LU   LOCADDR=006,DLOGMOD=LU33286S
```

The following table shows the Host Integration Server 2004 parameters and values that correspond to the sample VTAM parameters.

Host Integration Server 2004 parameter	**Sample value**	**VTAM parameter**
Local Poll Address	C1	ADDR= parameter in the PU definition
Local Node ID, first three digits (block number)	017	IDBLK= parameter in the PU definition
Local Node ID, last five digits (node number)	B8001	IDNUM= parameter in the PU definition
Max BTU Length	265	MAXDATA= parameter in the PU definition (set Max BTU Length &le; MAXDATA)
The encoding scheme (NRZ versus NRZI)	Not specified; defaults to NRZI=YES on host	The NRZI= setting in the LINE/GROUP definition
LU Numbers	2 through 6	LOCADDR= parameter in the LU definitions

Sample VTAM Parameters

Sample VTAM Parameters for an X.25 Connection

The following is a sample of VTAM parameters that might be used for an X.25 connection to a host. The underlined values correspond to values specified in Host Integration Server 2004 Manager.

```
PORTA00  PORT
CUADDR=(A00,A08),NETTYPE=1,CHARGACC=YES,CHARGE=NO,X

VCALLS=(,,001,006,,),DIALNO=31370023061,MAXOUT=7,
NETLEVEL=80,PMOD=8,PLENGTH=256,PWINDOW=3,
REPLYT0=3,RETRIES=7

SERVER03 PU
ADDR=C1,IDBLK=05D,IDNUM=00025,ANS=CONTINUE,X
MAXDATA=265,MAXOUT=7,MAXPATH=0,PACING=0,VPACING=0,X

SSCPFM=USSSCS,IRETRY=YES,USSTAB=MSUSSTAB,PUTYPE=2,X

DISCNT=YES,ISTATUS=ACTIVE
```

The following table shows the Host Integration Server 2004 parameters and values that correspond to the sample VTAM parameters.

Host Integration Server 2004 parameter	**Sample value**	**VTAM parameter**
Remote X.25 Address	31370023061	DIALNO= parameter in the PORT definition
Local Node ID, first three digits (block number)	05D	IDBLK=parameter in the PU definition
Local Node ID, last five digits (node number)	00025	IDNUM=parameter in the PU definition
Max BTU Length	265	MAXDATA= parameter in the PU definition (set Max BTU Length &le; MAXDATA)

Sample VTAM Parameters

Sample VTAM Parameters Including CPNAME

The following is a sample of VTAM parameters that might be used for a Token Ring connection to an IBM 9370 host, when identification of the computer running Host Integration Server 2004 is based on Control Point Name (CPNAME). For this configuration, Format XIDs must be exchanged.

In the PU definition, IDBLK, IDNUM, MACADDR, and SAPADDR are not used. For this configuration to work on Host Integration Server 2004, the Remote Node ID, Remote Network Name, and Remote Control Point Name should all be left blank. Additionally, the Local Node ID can be left at the default value (because it is not used).

In this sample, the underlined values correspond to values specified in Host Integration Server 2004 Manager.

```
R01100   PORT CUADDR=100,MACADDR=400040004001,LANCON=(5,2),         X
              MAXDATA=2012,MAXSTN=52,SAPADDR=04

SERVER01 PU   ADDR=C1,CPNAME=SERVER01,ANS=CONTINUE,                 X
              MAXDATA=0265,MAXOUT=7,MAXPATH=7,                      X
              PACING=0,VPACING=0,SSCPFM=USSSCS,                     X
              LANACK=(0,0),LANCON=(5,2),LANINACT=4.8,               X
              LANRESP=(5,2),LANSDWDW=(7,1),LANSW=YES,               X
              USSTAB=MSUSSTAB,DLOGMOD=D4C32792,                     X
              PUTYPE=2,DISCNT=(NO),ISTATUS=ACTIVE

T0110002 LU   LOCADDR=002
T0110003 LU   LOCADDR=003
T0110004 LU   LOCADDR=004
T0110005 LU   LOCADDR=005
P0110006 LU   LOCADDR=006,DLOGMOD=LU33286S
T0110007 LU   LOCADDR=007
T0110008 LU   LOCADDR=008
```

The following table shows the Host Integration Server 2004 parameters and values that correspond to the sample VTAM parameters.

> **Note** For this example, it is assumed that the local Network Name configured for the Host Integration Server 2004 matches the NETID parameter in the VTAM Start command for the local SSCP. (The VTAM system to which Host Integration Server 2004 is attached.)

Host Integration Server 2004 parameter	Sample value	VTAM parameter
Remote Network Address	400040004001	MACADDR= parameter in the PORT definition
Local Control Point Name (for the server)	SERVER01	CPNAME= parameter in the PU definition
Max BTU Length	265	MAXDATA= parameter in the PU definition (set Max BTU Length less than or equal to MAXDATA)
LU Numbers	2 through 8	LOCADDR= parameter in the LU definitions

Configuring VTAM for APPC Access

Parameters on VTAM must match Advanced Program-to-Program Communications (APPC) parameters on Host Integration Server 2004. To configure the needed parameters, consult with the host administrator for the matching VTAM parameters.

The following tables show Host Integration Server 2004 parameters and values that correspond to VTAM and CICS parameters. Note that the values given are samples only and may not work for your configuration.

The following table shows Host Integration Server 2004 parameters and values that correspond to sample VTAM parameters.

Host Integration Server 2004 parameter	**Sample value**	**VTAM parameter**
Connection: Local Node ID, first three digits (block number)	05D	IDBLK= parameter in the PU definition
Connection: Local Node ID, last five digits (node number)	11111	IDNUM= parameter in the PU definition
Server: Control Point Name	SNASERV	CPNAME= parameter in the PU definition
Connection: Max BTU Length	521	MAXDATA= parameter in the PU definition (set Max BTU Length &le; MAXDATA)
Local APPC LU: LU Name	LOCLU1	Name in LU definition
LU 6.2 Partner LUs: Mode	APPCMODE	DLOGMOD= parameter in the LU definition

The mode named APPCMODE is an example of a mode configured for use with LU 6.2. The mode named SNASVCMG is included in Host Integration Server 2004, because it is required for parallel session support. It does not need to be configured.

The following table shows Host Integration Server 2004 parameters and values that correspond to sample CICS parameters.

Host Integration Server 2004 parameter	**Sample value**	**CICS parameter**
LU Name for Local APPC LU	LOCLU1	Sessions
Mode name	APPCMODE	Modename
Parallel Session Limit in the mode	250	Maximum
Partner Min Contention Winner Limit in the mode	125	Maximum
Max Receive RU Size in the mode	00521	SENDSize
Max Send RU Size in the mode	00521	RECEIVESize
LU Name for remote APPC LU	CICSLU	APPLID

The parameter called Maximum has two values, 250 and 125, separated by commas. The first value (250) is the parallel session limit. The second value (125) is the host minimum contention winner limit. On Host Integration Server 2004, this corresponds to Partner Min Contention Winner Limit in the mode. In addition, because the host is the contention winner on 125 sessions (out of a total of 250), Host Integration Server 2004 should be configured as the contention winner on the remaining 125 sessions. In this case, Host Integration Server 2004 mode would have the following values:

- Parallel Session Limit 250
- Minimum Contention Winner Limit 125
- Partner Min Contention Winner Limit 125
- Automatic Activation Limit 0

Sample VTAM Parameters for Independent APPC

The lists in this section show sample VTAM parameters that might be used for communication using independent Advanced Program-to-Program Communications (APPC). The underlined values correspond to values specified in SNA Server Manager.

```
SERVER1  PU    ADDR=09,                                X
               IDBLK=05D,                              X
               IDNUM=11111,                            X
               CPNAME=SNASERV,                         X
               ISTATUS=ACTIVE                          X
               DLOGMOD=D4C32782,                       X
               MODETAB=ISTINCLM,                       X
               MAXDATA=521,                            X
               MAXPATH=1,                              X
               PUTYPE=2,                               X
               SSCPFN=USSSCS,                          X
               MAXOUT=7,                               X
               PASSLIM=4,                              X
               PACING=0,                               X
               DISCNT=NO,                              X
               USSTAB=USSTAB

TRPATH    PATH DIALNO=2223331234567890,                X
               GRPNM=AAA01,                            X
               GID=2

LOCLU1    LU   LOCADDR=0,                              X
               ISTATUS=ACTIVE,DLOGMOD=APPCMODE,        X
               RESSCB=25,USSTAB=USSTAB,PACING=0,       X
               VPACING=0
```

In the preceding example, the LOCADDR= value for the LOCLU1 is 0. This is the correct value to use with independent APPC LUs.

The following table shows Host Integration Server 2004 parameters and values that correspond to the preceding sample VTAM parameters.

Host Integration Server 2004 parameter	**Sample value**	**VTAM parameter**
Connection: Local Node ID, first three digits (block number)	05D	IDBLK= parameter in the PU definition
Connection: Local Node ID, last five digits (node number)	11111	IDNUM= parameter in the PU definition
Server: Control Point Name	SNASERV	CPNAME= parameter in the PU definition
Connection: Max BTU Length	521	MAXDATA= parameter in the PU definition (set Max BTU Length &le; MAXDATA)
Local APPC LU: LU Name	LOCLU1	Name in LU definition
APPC Partner LUs: Mode	APPCMODE	DLOGMOD= parameter in the LU definition

The following list shows mode table entries for use with independent APPC LUs.

```
*********************************************************
*           LOGMODE TABLE ENTRY FOR RESOURCES           *
*          CAPABLE OF ACTING AS LU 6.2 DEVICES          *
*********************************************************
SNASVCMG MODEENT LOGMODE=SNASVCMG,FMPROF=X'13',         X
               TSPROF=X'07',PRIPROT=X'B0',              X
               SECPROT=X'B0',COMPROT=X'D0B1',           X
               RUSIZES=X'8585',ENCR=B'0000',            X
               PSERVIC=X'060200000000000000000300'

APPCMODE MODEENT LOGMODE=APPCMODE,                      X
               TYPE=0,                                  X
               FMPROF=X'13',                            X
```

```
                  TSPROF=X'07',                           X
                  PRIPROT=X'B0',                          X
                  SECPROT=X'B0',                          X
                  COMPROT=X'50B1',                        X
                  PSNDPAC=X'03',                          X
                  SRCVPAC=X'03',                          X
                  RUSIZES=X'8585',                        X
                  PSERVIC=X'060200000000000000002F00'
```

In the preceding list, the mode named APPCMODE is an example of a mode configured for use with APPC. The mode named SNASVCMG is included in Host Integration Server 2004, because it is required for parallel session support; it does not need to be configured in SNA Server Manager.

                                             APPLID=CICSLU
PF 1 HELP 2 COM 3 END   6 CRSR 7 SBH 8 SFH 9 MSG 10 SB 11 SF 12 CNCL
```

The following table shows Host Integration Server 2004 parameters and values that correspond to the preceding sample CICS parameters.

Host Integration Server 2004 parameter	Sample value	CICS parameter
LU Name for local APPC LU	LOCLU1	Sessions
Mode name	APPCMODE	Modename
Parallel Session Limit in the mode	250	Maximum
Partner Min Contention Winner Limit in the mode	125	Maximum
Max Receive RU Size in the mode	00521	SENDSize
Max Send RU Size in the mode	00521	RECEIVESize
LU Name for remote APPC LU	CICSLU	APPLID

In the sample CICS screen, the parameter called Maximum has two values, 250 and 125, separated by commas. The first value (250) is the parallel session limit. The second value (125) is the host minimum contention winner limit. On Host Integration Server 2004, this corresponds to Partner Min Contention Winner Limit in the mode. In addition, because the host is the contention winner on 125 sessions (out of a total of 250), Host Integration Server 2004 should be configured as the contention winner on the remaining 125 sessions. In this case, Host Integration Server 2004 mode would have the following values:

- Parallel Session Limit 250
- Minimum Contention Winner Limit 125
- Partner Min Contention Winner Limit 125
- Automatic Activation Limit 0

The remaining screens in this section show more information about how CICS could be configured for independent APPC through VTAM.

http://go.microsoft.com/fwlink/?linkid=29507.

Configuring NCP for Independent APPC

Parameters on Network Control Program (NCP) must match Advanced Program-to-Program Communications (APPC) parameters on Host Integration Server 2004. To configure the needed parameters, consult with the host administrator for the matching NCP parameters.

This section provides information about NCP definitions used for supporting and defining independent LUs. The section is not intended to provide comprehensive information about NCP, which is described more thoroughly in IBM manuals such as:

- *Planning and Reference for NetView, NCP, VTAM* (CN4D1200)
- *NCP, SSP, and EP Resource Definition Guide* (CXDG7200)
- *NCP, SSP, and EP Resource Definition Reference* (CXDH1200)

You may need to study other IBM documentation as well. Some of the topics to study are:

- Independent LUs
- Type 2.1 node support
- Dynamic reconfiguration

Table of NCP Parameters That Affect Independent APPC

The following table shows basic recommendations for setting NCP parameters for independent APPC with Host Integration Server 2004. The next sections describe the parameters in more detail.

NCP definition	NCP parameter	Recommendations
BUILD	ADDSESS	Must support the number of sessions needed.
Not applicable	AUXADDR	Must support the number of additional addresses needed.
Not applicable	MAXSESS	Use for setting the maximum sessions allowed for any LU. Corresponds to the sum of all the parallel session limits for all the modes with which a particular LU is partnered.
PUDRPOOL	NUMBER	Must support the number of servers accessing NCP.
LUDRPOOL	NUMILU	Must support the number of dynamically configurable LUs needed.
PU	NETID	Corresponds to the Local Network Name on Host Integration Server 2004.
Not applicable	PUTYPE	For independent APPC, use PUTYPE=2.
Not applicable	XID	For independent APPC, use XID=YES.
LU	LOCADDR	For independent LUs with set definitions, use LOCADDR=0.
Not applicable	PACING	Use a value greater than or equal to the corresponding Host Integration Server 2004 parameter, the Pacing Receive Count in the mode.
Not applicable	VPACING	Use a value less than or equal to the corresponding Host Integration Server 2004 parameter, the Pacing Send Count in the mode.

BUILD Definition

The following parameters in the BUILD definition affect independent APPC:

ADDSESS=*value*

Is equivalent to the total number of sessions available to independent LUs. ADDSESS specifies the number of LU-LU session control blocks available for independent LUs. Note that session control blocks may be reserved for a particular LU by using RESSCB (reserved session control blocks) in the LU definition.

The sum of ADDSESS, AUXADDR, and NUMILU equals the total number of control blocks available for dynamic configuration of LUs. (For a description, see LUDRPOOL Definition, later in this topic.) This total should be high enough to support needed sessions, but low enough so that NCP does not exceed the storage capacity of the controller.

AUXADDR=*value*

Specifies the number of addresses that can be dynamically defined for both dependent and independent LUs. To allow for additional sessions between independent LUs, AUXADDR should be greater than ADDSESS. For more information about dynamic reconfiguration, see ADDSESS (the preceding description).

MAXSESS=*value*

Specifies the maximum number of LU-LU sessions that one independent LU can support. If you specify MAXSESS in an LU definition (as supported by NCP V6R2), the LU uses the value in the LU definition, not the BUILD definition. The limit set by MAXSESS prevents an independent LU from using too many unreserved session control blocks.

PUDRPOOL Definition

The following parameter in the PUDRPOOL definition affects independent APPC:

NUMBER=*value*

Specifies the number of physical units (PUs) that can be dynamically defined.

LUDRPOOL Definition

The following parameter in the LUDRPOOL definition affects independent APPC:

NUMILU=*value*

Specifies the number of independent LUs that can be added through dynamic reconfiguration. Find a value high enough to support needed sessions (including control-session overhead for parallel sessions), but low enough so that NCP does not exceed the storage capacity of the controller. Note that total LUs allowed by NUMILU plus NUMTYP1 plus NUMTYP2 is limited. The exact limit depends on your version of NCP.

PU Definition

The following parameters in the PU definition affect independent APPC:

NETID=*name*

Specifies the name of an adjacent network, and corresponds to the local Network Name on Host Integration Server 2004. NETID allows the network names to differ between the host and Host Integration Server 2004. This name is used in exchange identification (XID) negotiation.

PUTYPE=2

For independent APPC, use PUTYPE=2. When combined with XID=YES, this is equivalent to physical unit type 2.1.

XID=YES

For independent APPC, specify XID=YES, so that XIDs can be exchanged while in Normal Disconnected Mode (NDM).

LU Definition

The following parameters in the LU definition affect independent APPC:

LOCADDR=0

For independent LUs configured by an administrator (as contrasted with LUs dynamically configured by NCP), specify LOCADDR=0.

PACING=*value*

Specifies the number of frames for NCP to send to an independent LU before NCP waits for a pacing response. The value for PACING should generally be greater than or equal to the corresponding Host Integration Server 2004 mode parameter, Pacing Receive Count. This ensures a smooth flow of data from the host to the Host Integration Server 2004. (Host Integration Server 2004 does not support adaptive pacing.)

VPACING=*value*

Specifies the number of frames for NCP to receive from an independent LU before NCP sends a pacing response; sometimes called the receive window size. The value for VPACING should generally be less than or equal to the corresponding Host Integration Server 2004 mode parameter, Pacing Send Count. This prevents delays in sending from the Host Integration Server 2004 to the host. (Host Integration Server 2004 does not support adaptive pacing.)

Configuring the AS/400 for 5250 Access

When setting Host Integration Server 2004 parameters for an AS/400 connection, you must match values set on the host. Check with the host administrator to obtain required information for AS/400 access.

The administrator of the AS/400 may allow configurations to be created automatically in response to incoming requests. Alternatively, the administrator may disable this feature, to ensure a higher level of security. Work with the documentation for the AS/400 or with the administrator to determine the appropriate methods for configuring the AS/400.

> **Note** If the administrator of the AS/400 has allowed configurations to be created automatically in response to incoming requests, the parameters listed in this section need not be specified on the AS/400.

The following list shows command sequences on the AS/400 and the parameters to set after choosing those command sequences. You must be logged on with administrative privilege on the AS/400 to configure the listed parameters. For more detailed information, see the AS/400 documentation.

Communications —> Network configuration —> Configure communications and remote hardware —> Work with lines

Find out the name of the line from the AS/400 administrator. To enable automatic configuration for the line, for Autocreate controller, specify *YES, and for Autodelete controller (a time-out value), specify *NONE, or a large value such as 7000 (minutes). To prevent automatic configuration for the line, for Autocreate controller, specify *NO.

If the configuration is not automatic, specify the following:

- APPN-capable *YES
- A Control Point Name and network identifier that match corresponding parameters in Host Integration Server 2004
- APPN CP session support *YES

Communications —> Network configuration —> Configure communications and remote hardware —> Work with communications controllers

In this context, communications controller means the Host Integration Server 2004.

If the configuration is not automatic, specify the local address of the Host Integration Server 2004 computer.

Connection type	Address as specified in AS/400 configuration	Method for finding out address on Host Integration Server 2004
802.2	LAN remote adapter address	At the command prompt, type **net config server**; then view the line labeled "Server is active on."
SDLC	Station address (STNADR)	Start Host Integration Server 2004 Manager and view the Poll Address specified for the SDLC connection. (For SDLC, both ends use same address.)
X.25	Network address	Start SNA Manager, access the **IBM X.25 Link Service Setup** dialog box, and view the Local X.25 Address.

Sample VTAM Parameters

Guidelines for an AS/400 that Does Not Have PC Support

You can connect to an AS/400 for 5250 emulation even if the AS/400 does not have PC Support. However, to do this, you must create the mode QPCSUPP on the AS/400, along with other resources that would have been created by PC Support. A recommended way to do this is to create the QPCSUPP mode, create the QWCPCSUP class, and add the class QWCPCSUP to the subsystem QCMN. For details about how to create these resources, see the online OS/400 documentation for the related commands: **crtmodd**, **crtcls**, and **addrtge**.

Changing Session Limits with a Single Mode Name

If the AS/400 requires different session limits on each LU (while the mode name stays the same), you must change the device description attached to the controller to reflect the correct number of sessions allowed for the LUs. For example, with a 5250 emulator, the mode name must be QPCSUPP. If you change the Parallel Session Limit on QPCSUPP for one LU-LU pair, all other LU-LU pairs that use the QPCSUPP mode will also be affected. Therefore, to change the session limit on some LUs but not others, you must change it at the AS/400.

The simplest way to get the correct number of sessions for the LUs on the AS/400 is to autocreate the controllers and devices, and then change the device description attached to the controller, so that the session limit is decreased. This is done by using the Change Device Description (**chgdevappc**) command. It needs to be done for each device description that needs to have different session limits. The AS/400 device settings that should be modified are Maximum Sessions (**maxssn**) and Maximum Conversations (**maxcnv**).

For 5250 emulation in the AS/400 environment, you must configure the following elements:

- Each Host Integration Server 2004 computer that will access the AS/400
- Connections
- Local APPC LUs
- Remote APPC LUs
- LU-LU pairs

Table of Parameters for AS/400 Communication

The following table summarizes details about configuring Host Integration Server 2004 for the AS/400 environment. In addition, for an X.25 connection using permanent virtual circuit (PVC), specify the PVC Alias.

SNA Server element	Parameter name in Host Integration Server 2004	Instructions for configuring for the AS/400 environment
Server	Network Name (Local Node)	This generally corresponds to the RMTNETID setting on the AS/400. (APPN is often used.)
Server	Control Point Name (Local Node)	Corresponds to RMTCPNAME on the AS/400.
Connection	Remote End	Select Peer System as the Remote End for the connection.
Connection	Activation	Coordinate with the switched disconnect (SWTDSC) setting on the AS/400. If SWTDSC is *YES, select On Demand. If SWTDSC is *NO, select On Server Startup.
Connection	Local Node ID	Specify the Local Node ID, a required parameter for all connections. This corresponds to EXCHID on the AS/400.
Connection	Control Point Name (Remote Node)	Specify the AS/400 Control Point Name (CP name) as the remote Control Point Name for the connection.
Connection	Network Name (Remote Node)	Corresponds to the RMTNETID on the AS/400. (APPN is often used.)
Connection	802.2: Remote Network Address SDLC: Poll Address X.25: Remote X.25 Address	Corresponds to ADPTADR in the Line Description on the AS/400. Corresponds to STNADR in the Line Description on the AS/400. Specify the address of the AS/400.
Connection	Max BTU Length	Corresponds to the MAXFRAME setting on the AS/400.
Remote APPC LU	LU Name	Specify the Control Point Name of the AS/400 as the remote LU name.
Mode	Mode name	Choose the QPCSUPP mode for all LU-LU pairs to be used for AS/400 connectivity.
User or group listing	Default local APPC LU	Assign a Default local APPC LU to the user or group. If the user or group does not specify a local LU name when opening a session to an AS/400, this default local LU name will be used.
User or group listing	Default remote APPC LU	Assign a Default remote APPC LU – which is the same as a default AS/400 – to the user or group. If the user or group does not specify a remote LU (that is, an AS/400) when opening a session, the assigned AS/400 will be used.

Applications and Tools

Microsoft® Host Integration Server 2004 includes several applications and tools to assist you in managing your environment.

- Network Management Support describes various methods of managing network environments.
- Using the SNA Trace Utility and Trace Viewer describes how to set up tracing on a Host Integration Server 2004 computer and how to view trace files for information on the activity between components.

Network Management Support

The requirement to manage heterogeneous network environments containing mainframes, midrange systems, and personal computers is a big challenge. This section discusses two mainframe management tools, IBM's NetView and Response Time Monitor, which are supported by the Microsoft® Host Integration Server 2004 and can be used to manage your integrated network.

Host Integration Server 2004 can be managed either from the Host Integration Server 2004 computer (and other computers on the LAN) or from the mainframe using NetView. NetView is a centralized network management system that allows you to control SNA network resources, including Host Integration Server 2004.

Using the IBM Response Time Monitor (RTM) provides additional management of the Host Integration Server 2004. RTM measures the length of time it takes for a host to respond to an incoming 3270 end-user request. Working in conjunction with NetView on the mainframe, RTM gathers data from 3270 terminal emulators and sends the information to the host through the NetView connection.

This section contains:

- Using NetView to Manage the SNA Environment
- Monitoring Mainframe Response Times

Using NetView to Manage the SNA Environment

The IBM NetView program sends and receives alerts and other information between a host (mainframe or AS/400) and the computers that connect to it. Host Integration Server 2004 supports NetView, bringing centralized SNA-based network management into local area network (LAN) environments. Using NetView, you can control any Host Integration Server 2004 computer that represents a physical unit (PU) in the SNA environment.

NetView can forward Host Integration Server 2004 alerts to the host system. In addition, NetView can be extended with the Windows NVAlert and NVRunCmd services. NVAlert provides the ability for the host system console to receive and display alerts generated by Windows and applications running on the Windows computer. NVRunCmd provides the ability to command Host Integration Server 2004 from the host system console.

The NVAlert and NVRunCmd services are installed when you install Host Integration Server 2004. By default, the NVAlert configuration file, NVAlert.ini, is created and placed in the \Program Files\Host Integration Server\System folder. Also installed in the Windows Control Panel is the NVAlert service, and is configured with a startup setting of Manual.

If you plan to manage Host Integration Server 2004 most of the time using NetView from the mainframe, you should change the default startup configuration from Manual to Automatic. In Control Panel, click the **Services** icon, and then select the service you want to change. Click **Startup**, and then click **Automatic** as the Startup Type.

To configure NetView

1. In the Host Integration Server 2004 console tree, right-click the subdomain that you want to configure, and click **Properties**.
2. Click the **NetView** tab, and fill in the option.
3. Click **OK**, and save the configuration.

NVAlert runs as a background process, enabling alert messages generated by Windows or by Windows-based applications to be forwarded to a host system through NetView. To control the alert messages sent from the NVAlert service, modify the NVAlert.ini file to specify the Windows alerts that you want forwarded to the host system.

As events occur and are recorded in a log file, NVAlert compares each logged event to the list in the NVAlert.ini file. When an event matches one on the list, NVAlert forwards an alert as specified in NVAlert.ini to the host system.

If a problem occurs sending an alert, NVAlert follows a preset pattern of time-outs and retries. No additional alerts can be sent until the alert is successfully sent to the host.

The NVAlert.ini File

Sending Commands to Host Integration Server 2004 from the Mainframe

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

The NVAlert.ini File

The following sections describe the structure and the required and optional lines of data for NVAlert.ini. For information about standard code points and values used by NetView, see your IBM NetView documentation.

Required Data Lines

You must precede each section of data lines that you add to NVAlert.ini with the following heading, including the square brackets **[ ]** as shown:

```
[source.type.eventid]
```

Use the Windows Event Log service to view the intended alert, and supply values as described in the following list. For information about the Event Log service, see your Windows documentation.

- For *source*, substitute the name that appears beneath the Source heading in the Windows Event Log service.
- For *type*, find the type listing (in the event detail in the Windows Event Log service), and substitute one of the following values:

Success	0
Information	1
Warning	2
Error	3
Success audit	4
Failure audit	5

- For *eventid*, use the decimal number that appears under the EventID heading in the Windows Event Log service.

> **Note** Choose alerts that will not exceed the basic transmission unit (BTU) of the connection over which the alerts will flow because the host cannot handle alerts exceeding this size.

After the heading, type data lines using the following syntax:

```
AlertType=xx

AlertDescription=xxxx

ProbableCauses=xxxx[,...]
```

In these lines, each letter *x* represents a hexadecimal digit specifying NetView code points. For the appropriate values to provide, see your IBM NetView documentation. The element characters [**,**...] indicate that the argument can be repeated, with commas separating the repetitions. Do not type the brackets.

Adding Optional Data Lines

To help you monitor the SNA environment or diagnose a problem, you can add additional data to the alerts sent to the mainframe. The following optional data lines can be added to an alert:

```
UserCauses=xxxx[,...]

UserDetData=00,xx,string[;...]

UserRecAct=xxxx[,...]

UserRecActDetData=00,xx,string[;...]

FailureCauses=xxxx[,...]

FailureDetData=00,xx,string[;...]

FailureRecAct=xxxx[,...]
```

```
FailureRecActDetData=00,xx,string[;...]

InstallCauses=xxxx[,...]

InstallDetData=00,xx,string[;...]

InstallRecAct=xxxx[,...]

InstallRecActDetData=00,xx,string[;...]
```

Each letter *x* represents a hexadecimal digit specifying NetView code points. For the appropriate values, see your NetView documentation. The elements [**,**...] and [**;**...] indicate that the argument can be repeated, with commas or semicolons separating the repetitions. Do not type the brackets.

RecAct is an abbreviation for recommended action and *DetData* is an abbreviation for detailed data. You can use the DetData syntax to add blocks of detailed data to an alert.

- For *xx,* type the Data ID code point as described in the IBM *SNA Formats* manual (IBM document GA27-3136-12) or other NetView documentation.
- For *string*, provide a text string using the following variables:

%M	Module name.
%C	Computer name.
%I	Event ID.
%S*n*	String number *n* in the event log (*n* starts at zero).
%D*xxxx*, *yyyy*	Raw data of length *yyyy*, starting at buffer offset *xxxx*. Both *xxxx* and *yyyy* are hexadecimal values. Use this variable only if you do not specify any other variables.

Example of an Alert

The following is an example of a Windows-based alert and a description of each data line. The alert warns that a hard disk is nearly full and the description in the Windows Event Log service will read "The C: disk is at or near capacity. You may need to delete some files."

Sample alert and description

Data lines	Description
`[Srv.2.2013]`	Source is Srv, type is 2 (warning), and EventID is 2013
`AlertType=11`	Impending problem
`AlertDescription=5002`	Resource nearing capacity
`ProbableCauses=5001`	Media DASD device
`UserCauses=0102,F0A0`	Insufficient storage media space available
`UserDetData=00,95,%C`	Problem located on the indicated file server name (supplied through NetView value 95); event logged on indicated computer name (supplied through %C)

Sending Commands to Host Integration Server 2004 from the Mainframe

The NVRunCmd service enables you to launch processes on the Host Integration Server 2004 from the NetView console. Commands are sent to the Host Integration Server 2004 computer, carried out, and results are returned to the NetView console as long as the results contain only alphanumeric characters. The NVRunCmd service cannot send graphical information to the mainframe NetView console. For example, if you use NVRunCmd to run the **dir** command, a character-based display of the current folder is displayed in NetView. But if you use NVRunCmd to start a graphical application, no command output is sent to NetView.

NVRunCmd does not handle back-and-forth interactions, such as a confirmation generated by a Host Integration Server 2004 computer in response to a command. If a command forwarded by NVRunCmd requires confirmation before being carried out, the command process will not be completed, and will eventually time out.

NVRunCmd is configured during Host Integration Server 2004 setup and runs as a background process, waiting for a command to be sent from a NetView console. When NVRunCmd receives a command, it determines whether the command is one that it can process, and returns either the results (in 256-byte segments) or a message saying that the command failed. NVRunCmd attempts to send the results back to the NetView console only once, and if the NetView console does not receive the results, the link or some other part of the communications has failed.

The pipe symbol (|) cannot be used to combine commands. For example, NVRunCmd cannot process the following command string:

```
dir | more
```

The maximum amount of information that can be returned to the NetView console is 31,700 bytes. Any additional information returned by the command will be lost, with a message appended to the truncated data warning the user.

Configuring NVRundCmd Privileges

By default, the NVRunCmd service runs in the context of the local system's security. Therefore, some commands generate responses that are different from the responses generated by a user logged on the same Windows operating system. For example, the commands **net use** and **chdir**, typed without options, generate a response in the context of NVRunCmd, not the context for a logged-on user.

For better system security, use the Windows Control Panel to access the **Services** dialog box and configure **Startup** options for the NVRunCmd service. Associate the NVRunCmd service with a user account that has the privilege level that you want for NVRunCmd.

Sending a Command from the Host Console

To send a command to the intended Host Integration Server 2004 computer, you need to specify the corresponding PU in the **runcmd** command in the NetView console of the host system. Use the following syntax to launch a process on the Host Integration Server 2004 software. Commands are not case sensitive; commands entered in lower case are converted to upper case.

```
runcmd sp=servicepoint, appl=NVRunCmd  cmd commandname parameters
```

- For *servicepoint*, type the name of the VTAM PU of the Host Integration Server 2004 computer (node) in which you want the command to run. Note that on the server, this value is configured as the control point name for the server.
- For *commandname*, type the command you want to run. The command must be alphanumeric because NetView cannot return graphical output.
- For *parameters*, type the parameters needed for running the command on the server.

  Note NVRunCmd does not use or need a defined NetView connection. You can use NVRunCmd from the host to each Host Integration Server 2004 computer in the subdomain separately. The NetView connection is needed only for sending alerts to NetView.

Using NetView to Manage the SNA Environment

Monitoring Mainframe Response Times

The IBM response time monitor (RTM) measures the length of time it takes for a host to respond to an incoming 3270 end-user request. Responding to customer requests is a good indication of system performance. Monitoring the response time can be helpful diagnosing network and other system problems. RTM is a feature that works in conjunction with NetView on the mainframe. It gathers data from 3270 terminal emulators and sends the information to the host through the NetView connection for collection and analysis. Then you can view a graphical display of response times for a particular 3270 emulation session.

This section contains:

- Configuring RTM in Host Integration Server 2004
- Additional Information

Configuring RTM in Host Integration Server 2004

Use the SNA manager console to configure how response times are measured and classified. Response time monitor (RTM) statistics for a specific logical unit (LU) are sent to the host that owns the LU, rather than to the connection designated for NetView data.

You can specify the times that RTM should send data and the trigger that causes it to register the host response. The configuration settings are on the **Response Time Monitor** tab of the **Properties** page for the selected SNA subdomain and are listed in the following table:

> **Note** For these settings to be meaningful, each emulator for your 3270 users must support RTM. If the host RTM settings are different, they override the Host Integration Server 2004 settings.

RTM Settings

Setting		**Definition**
RTM Data Sent At		Specifies when RTM data is sent to the host. You can send the data during one or both of the following situations:
	Counter Overflow	Sends the RTM data to the host when the number of host responses in a given time period overflows the size of the available counter.
	End of Session	Sends the RTM data to the host at the end of each LU-to-LU session.
RTM Timers Run Until		Specifies when the RTM registers a host response - when RTM stops the timers. (The timers are started when the local system sends data.) Possible stopping points are as follows:
	First Data Reaches Screen	Stops timing when data reaches the local screen.
	Host Unlocks Keyboard	Stops timing when the host unlocks the local keyboard.
	Host Lets User Send	Stops timing when the host lets the local computer send more data.
RTM Thresholds		Specify the cutoff times, in tenths of a second that the RTM saves its count of host responses and restarts the count. The range is 1–1000 in tenths of a second (from 0.1 seconds to 100.0 seconds). The defaults are 5, 10, 20, and 50 (0.5 seconds, 1.0 seconds, 2.0 seconds, and 5.0 seconds).

Although you can configure the RTM boundaries and definition that you want to use on your server, the host can override these values, either for an individual 3270 LU or for all LUs the host controls. The host can also specify whether to permit local display of RTM data, and, when Host Integration Server 2004 sends RTM data, it can disable collection of RTM statistics completely.

To configure Response Time Monitor (RTM)

1. In the Host Integration Server 2004 console tree, right-click the subdomain that you want to configure, and click **Properties**.
2. Click the **Response Time Monitor (RTM)** tab, and complete the options.
3. Click **OK**, and **save** the configuration.

This section contains:

- Defining RTM Thresholds
- Specifying When RTM Data is Sent
- Indicating Lost RTM Data

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Defining RTM Thresholds

Response time monitor (RTM) data is collected by comparing host response times against a series of four boundary values. Each time a host transaction occurs, the response time is compared with the boundary values, and the appropriate counter is incremented. There is a counter for each of the four intervals defined by the boundary values, and an overflow counter for response times above the largest boundary value.

You can change the default boundaries — 0.5, 1, 2, and 5 seconds — using the SNA manager console. You also can select which of three response time definitions to set as default.

The response time is measured from the time the user presses ENTER until one of the following events occurs:

- The first character of host data reaches the 3270 display.
- The keyboard is unlocked.
- The user is enabled to send data.

A host can override the default boundaries and other host response time settings for any or all logical units (LUs) it controls.

See Also

Specifying When RTM Data is Sent

Indicating Lost RTM Data

Specifying When RTM Data is Sent

Response times are recorded for a specific logical unit (LU) rather than for a specific 3270 session. If a 3270 session ends and another session of the same or a different 3270 user starts using the same LU, the response time counters include responses from both sessions. To prevent the counters from collecting information from more than one 3270 session, you can reset the RTM counters on the LU before a new session begins. The counters are reset when the host requests the reset or when response time monitor (RTM) data is sent unsolicited by Host Integration Server 2004. Usually when a host requests RTM data the counters are reset at the same time.

To ensure that RTM data relates only to the current 3270 session, you should select the **End-of-Session** checkbox when configuring RTM parameters for Host Integration Server 2004. Note that the host can override this setting.

Defining RTM Thresholds

Indicating Lost RTM Data

Indicating Lost RTM Data

When Host Integration Server 2004 sends response time monitor (RTM) data to the host, it can indicate to the host that RTM data may have been lost, that is, some host response times were not included in the RTM data sent to the host. This indication is sent when:

- One of the RTM counters reaches its maximum value, and Host Integration Server 2004 is not configured to send RTM data unsolicited at counter overflow. When this occurs, Host Integration Server 2004 stops recording response times until the host requests the data or until end-of-session, if unsolicited sending at end-of-session is configured. The data is sent with an indication that data may have been lost due to counter overflow.
- Connection to the host for either Host Integration Server 2004 or the Windows servers ends abnormally. The first RTM data sent to the host after the connection is re-established includes the lost-data indicator to indicate that data may have been lost due to failure of the server.
- Host Integration Server 2004 is configured to send RTM data at the end-of-session, and a new 3270 session is started before the RTM data for the previous 3270 session on the same LU can be sent. Response times for the new session are discarded until the RTM data from the previous session is sent and the counters are reset. When RTM data is sent on the new session, it includes the lost data indicator.

Using the SNA Trace Utility and Trace Viewer

This following information guides you through configuring and using the Microsoft® Host Integration Server 2004 SNA Trace Utility and Trace Viewer applications.

The SNA Trace Utility is used to control trace files, and Trace Viewer is used to display trace files.

This section contains:

- Using the SNA Trace Utility
- Running the SNA Trace Utility
- Using Trace Viewer

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Using the SNA Trace Utility

This section includes an overview of the Host Integration Server 2004 SNA Trace Utility and details the names and locations of the files generated by the trace application. This section contains:

- About the SNA Trace Utility
- System Troubleshooting
- Trace and Diagnostic File Location
- Trace File Names
- Choosing a Trace Type
- Trace Types
- Message Traces
- Interpreting Traces
- Using Trace to Diagnose Problems

About the SNA Trace Utility

The Host Integration Server 2004 SNA Trace Utility (snatrace.exe) is a graphical tool that allows you to enable or disable tracing options and set the SNA Trace Utility parameters.

After deciding the software components and types of tracing that can provide useful information, start the Host Integration Server 2004 SNA Trace Utility application and configure trace options for Host Integration Server 2004 computers.

If you are working to improve system performance or solve a difficulty with Host Integration Server 2004 components, reviewing trace files can assist in determining the source of the problem.

The SNA Trace Utility records activity between or within components of Host Integration Server 2004. The files created provide detailed information about the exact sequence of events occurring within Host Integration Server 2004 components or between Host Integration Server 2004 computers and Host systems on the network.

> **Note** You must be an administrator on the local account to run the SNA Trace Utility.

See Also

Using the SNA Trace Utility

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

System Troubleshooting

When gathering information about system difficulties, it is best to start with information provided by the Windows Event Log and System Monitor.

Event log information is generally more straightforward to interpret than trace information; use trace information only if event logs do not provide enough details.

When you report system problems to Microsoft Product Support (PSS), a technician may ask you for trace files and other system information:

- Trace files
- Windows Event Logs
- The current configuration file (Com.cfg)
- Dump files, which may be created by Host Integration Server 2004 when a system trap (exception error) occurs
- Datascope traces of protocol exchanges

Trace and Diagnostic File Location

The following table lists the default location of files containing trace and diagnostic information:

File type	**Default location**	**File name or file name extensions**
Trace files created by the Host Integration Server 2004 Trace application	...\Host Integration Server\Traces	*.atf
Log files	\WINNT\System32\Config	*.evt
Configuration file	...\Host Integration Server\System\Config	com.cfg
Dr. Watson file	\WINNT	drwtsn32.log
Dump files	...\Host Integration Server\Traces	snadump.log

See Also

Using the SNA Trace Utility

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Trace File Names

Each trace file has two names associated with it, <*Filename*1>.atf and <*Filename*2>.atf.

Traces are written to the first file until it reaches the specified size, then to the second until it reaches that size, and so on alternating between the two files.

By default, the trace files are stored in the \Program Files\Host Integration Server\Traces folder, with an .atf file extension.

The following table lists the file names used by Trace:

Service	Type of tracing	File names used	File names used
SnaBase	Internal	Napint1.atf	Napint2.atf
	Message	Napmsg1.atf	Napmsg2.atf
SnaServer (PU 2.1 node)	Internal	Nodeint1.atf	Nodeint2.atf
	Message	Nodemsg1.atf	Nodemsg2.atf
Link service	Internal	Linkint1.atf	Linkint2.atf
	Message	Linkmsg1.atf	Linkmsg2.atf
NetView Alert	Internal	Nvaint1.atf	Nvaint2.atf
	Message	Nvamsg1.atf	Nvamsg2.atf

Choosing a Trace Type

After selecting one or more Host Integration Server 2004 components to be traced, decide the type of tracing to apply.

The following table describes the types of tracing available:

Type of tracing	Activity traced	Applies to installed components
Internal*	Activity within a software component of Host Integration Server 2004.	SnaBase, SnaServer (PU 2.1 node), SNA applications, link services and more.
Message	Messages passed into and out of a software component of Host Integration Server 2004, including messages sent to and received from the network.	SnaBase, SnaServer (PU 2.1 node), SNA applications, link services and more.
API	Information passed into and out of a Host Integration Server 2004 DLL, as the DLL communicates with an application, such as the APPC DLL.	SNA applications and more.

* Internal tracing is intended for use by product support technicians. Interpreting internal traces and certain types of message traces requires a specialized knowledge base.

Using the SNA Trace Utility

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Trace Types

Before setting up tracing, decide the software components you want to trace, and which types of tracing information will be useful.

Each type of tracing is enabled using the Host Integration Server 2004 Trace application.

Internal Trace types:

- Fatal Conditions
- Error Conditions
- Debug Conditions
- Function Entry/Exit
- State Transition
- Custom Conditions

Message Trace types:

- Internal Messages
- 3270 Messages
- LU 6.2 Messages

API Trace types:

- APPC API
- CPI-C API
- LUA API
- CSV API

TN3270 Internal Trace types:

- TN3270 Internal Trace

Trace Types

Interpreting Traces

The Host Integration Server 2004 Trace feature provides message, client API, SnaBase, Transaction Integrator, PU 2.1 node, and link service tracing.

The following table shows the information needed for interpreting each type.

Type of tracing	**Software component traced**	**Area of expertise needed**
APPC API	SNA applications	APPC programming
CPI-C API	SNA applications	CPI-C programming
LUA API	SNA applications	LUA programming
SNA Formats	SnaServer (PU 2.1 Node)	SNA formats
Data Link Control (messages)	SnaServer (PU 2.1 node) or link service	DLC interface
Level 2 Messages	Link service	Link service interface
3270 Messages	SNA Applications, SnaServer (PU 2.1 Node), or SnaBase	3270 emulator interface
Internal Messages	All software components for Host Integration Server 2004	Intended for product support personnel
APPC Messages	SNA Applications, SnaServer (PU 2.1 Node), or SnaBase	Intended for product support personnel
Internal	All software components for Host Integration Server 2004	Intended for product support personnel

Trace Types

Using Trace to Diagnose Problems

The following table shows examples of possible difficulties and the types of tracing that may be useful.

Difficulty	What to trace
Host Integration Server 2004 can't connect to host	For the SnaServer (PU 2.1 node), trace Data Link Control and 3270 Messages
SNA Manager does not reflect changes in network services	For the SnaServer (PU 2.1 node), trace Internal Messages; for Manage Agent, enable internal tracing
Windows-based client computer cannot connect to a Host Integration Server 2004 resource	For any client computer, enable internal tracing For a 3270 or LUA client computer, trace 3270 messages For an APPC or CPI-C client computer, trace LU 6.2 messages

Using the SNA Trace Utility

Running the SNA Trace Utility

You can run the SNA Trace Utility from either the SNA Manager or from a command prompt.

This section contains:

- Starting the SNA Trace Utility
- Tracing Servers Components

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Starting the SNA Trace Utility

The following topics explain how to start the SNA Trace Utility from the SNA Manager, from the Windows Start menu, or from a command prompt.

This section contains:

- Starting from the SNA Manager
- Starting from Windows Start Menu
- Starting from a Command Prompt

Starting from the SNA Manager

The following procedure details how to start the SNA Trace Utility from the SNA Manager

To start the SNA Trace Utility from the SNA Manager

1. Click **Start**, and point to **Programs**.
2. Point to **Host Integration Server**, and then click **SNA Manager**.
3. Click **Tools**, and then click **SNA Trace Utility**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Starting from Windows Start Menu

The following procedure details how to start the SNA Trace Utility from the Windows Start menu.

To start the SNA Trace Utility from the Start menu

1. Click **Start**, and point to **Programs**.
2. Point to **Host Integration Server**, and then point to **Application and Tools**.
3. Click **SNA Trace Utility**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Starting from a Command Prompt

The following procedure details how to start the SNA Trace Utility from a command prompt.

To start the SNA Trace Utility from a command prompt

1. From **Start**, click **Run**.
2. Type in **command**, and click **OK**.
3. Type in:

```
cd c:\Program Files\Host Integration Server\System
snatrace
```

-or-

To run the SNA Trace Utility on a specific server

1. From **Start**, click **Run**.
2. Type in **command**, and click **OK**.
3. Type in:

```
cd c:\Program Files\Host Integration Server\System
snatrace \\servername
```

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Tracing Servers Components

The Host Integration Server 2004 Trace application can be started locally or remotely for a Host Integration Server 2004 computer. For a client computer, the Host Integration Server 2004 Trace application can only be started locally.

> **Important** All procedures listed in this section assume that Trace is running on a computer that has Host Integration Server 2004 installed and configured.

This section contains:

- Selecting Components to Trace
- Tracing SNA APIs
- Tracing SnaBase
- Tracing PU 2.1 Node
- Tracing Link Services
- Tracing for TN3270
- Tracing for TN5250

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Selecting Components to Trace

Before you can begin tracing files, you need to decide on the Host Integration Server 2004 components to trace.

The Trace application enables you to record internal or external activity for the following components:

- Enterprise Single Sign-On
- NVAlert
- NVRuncmd
- SNA applications
- SNA Manager Client
- SNA Manager Agent (MngAgent)
- SnaBase
- Installed link services
- SNANetMn
- SNAPrint
- SNAServer
- SNA Management
- DB2 Network Library
- SNADDM
- TN3270
- TN5250

Messaging User's Guide

Microsoft® MSMQ-MQSeries Bridge is an adaptable system that can be customized. You can set up MSMQ-MQSeries Bridge to operate on almost any Message Queuing (also known as MSMQ) or IBM MQSeries network configuration.

This section contains:

- Using MSMQ-MQSeries Bridge
- How MSMQ-MQSeries Bridge Works
- MSMQ-MQSeries Bridge Setup and Configuration
- MSMQ-MQSeries Bridge Manager
- Controlling MSMQ-MQSeries Bridge

Using MSMQ-MQSeries Bridge

The topics in this section describe the procedures for using MSMQ-MQSeries Bridge. In addition, Help buttons located on the MSMQ-MQSeries Bridge user interface are linked to help topics specific to their context.

This section contains:

- About MSMQ-MQSeries Bridge
- MSMQ-MQSeries Bridge Operation
- MSMQ-MQSeries Bridge Benefits
- Features of Message Queuing and MQSeries
- Reference Material

About MSMQ-MQSeries Bridge

MSMQ-MQSeries Bridge is an external gateway between two otherwise incompatible message queuing systems. MSMQ-MQSeries Bridge provides a seamless interface between Message Queuing (also known as MSMQ) on computers running Microsoft® Windows Server™ 2003 or Windows® 2000 Server and IBM MQSeries running on mainframes and other systems.

See Also

Using MSMQ-MQSeries Bridge

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MSMQ-MQSeries Bridge Operation

MSMQ-MQSeries Bridge is an interface between Message Queuing and MQSeries, so that you can send messages between Message Queuing applications and MQSeries queues.

MSMQ-MQSeries Bridge operates entirely in the background. In the MSMQ to MQSeries direction, an Message Queuing application can send a message to an MQSeries queue by a standard MQSendMessage() application programming interface (API) call or ActiveX® control.

An MQSeries application can receive the message from the MQSeries queue by a standard MQGET() API call. In the MQSeries to MSMQ direction, the opposite relations apply. Neither application needs to be aware that the message has crossed between environments.

The MSMQ-MQSeries Bridge interface extends the features of Message Queuing and MQSeries across the combined environment. MSMQ-MQSeries Bridge fully supports connectionless, asynchronous messaging.

Using MSMQ-MQSeries Bridge, you can route messages to each messaging system even if the two systems are not connected to the network at the same time.

See Also

Using MSMQ-MQSeries Bridge

MSMQ-MQSeries Bridge Benefits

Using MSMQ-MQSeries Bridge, your applications can send messages between IBM MQSeries and Message Queuing easily and efficiently. MSMQ-MQSeries Bridge extends connectionless, store-and-forward messaging across messaging systems and computing platforms throughout your network.

MSMQ-MQSeries Bridge offers:

Compatibility

Each messaging system sends and receives data in its native format. MSMQ-MQSeries Bridge converts the message formats automatically between the systems.

Adaptability

Your applications can send messages using standard Message Queuing or MQSeries API calls. You do not need to recode existing applications to use MSMQ-MQSeries Bridge.

Reliability

MSMQ-MQSeries Bridge supports transactions and deliver-once features, ensuring that messages are properly delivered following recovery from a system failure.

Performance

You can customize MSMQ-MQSeries Bridge for optimal performance in your network environment.

Management

Using MSMQ-MQSeries Bridge Manager, you can configure and manage all MSMQ-MQSeries Bridge computers in your enterprise network from a central location.

See Also

Using MSMQ-MQSeries Bridge

Features of Message Queuing and MQSeries

The Message Queuing and MQSeries message queuing systems offer the following features:

Connectionless, asynchronous messaging
The communicating applications do not need to log on to the remote system or establish a session with each other. The computers on which the applications run do not need to be connected at the instant when messages are written or read. Applications can continue running without waiting for transmission to be completed.

Guaranteed delivery and deliver once
Message Queuing and MQSeries provide mechanisms by which an application can guarantee and confirm that messages are delivered, and prevent duplicate delivery.

Message prioritization
A sending application can specify the order in which the receiving application will get the messages.

User-defined message structure
The message body may contain a single byte (or no message contents at all), a text string, or a long and complex data structure. The message body may be structured or encrypted in any syntax that the communicating applications understand.

Transaction support
Send-message or receive-message operations can participate in a transaction, and can be coordinated with other operations such as database updates. The entire transaction is canceled and rolled back if any of the operations fail.

Application programming interface (API)
MSMQ and MQSeries operate on the Application Layer of the ISO Reference Model for Open System Interconnection. They act as a simple interface between an application program and the network, freeing the application programmer from concern about network or communication details.

See Also

Using MSMQ-MQSeries Bridge

Reference Material

Before installing or programming MSMQ-MQSeries Bridge, you should be familiar with the principles of message queuing and with at least one message queuing environment (Message Queuing or MQSeries).

For background information, refer to the *Host Integration Server 2004 Programmer's Guide*, Message Queuing documentation, and the IBM MQSeries documentation.

Using MSMQ-MQSeries Bridge

How MSMQ-MQSeries Bridge Works

The following topics detail how MSMQ-MQSeries Bridge works.

This section contains:

- MSMQ-MQSeries Bridge Concepts
- Message Queuing Concepts
- Message Fields or Properties
- Sending and Receiving Messages
- System Components
- Message Conversion
- Network Architecture
- Multiple Connections
- Sending Messages From Message Queuing to MQSeries
- Sending Messages From MQSeries to Message Queuing
- Transactional and Nontransactional Message Pipes

MSMQ-MQSeries Bridge Concepts

With MSMQ-MQSeries Bridge, Message Queuing (also known as MSMQ) and MQSeries applications can send messages to each other, between the message queuing systems.

MSMQ-MQSeries Bridge achieves this by mapping the messages and the data fields of the sending system and the values associated with those fields, to the fields and values of the receiving environment.

After the mapping and conversion, MSMQ-MQSeries Bridge completes the process by routing the message across the combined Message Queuing and MQSeries networks.

See Also

How MSMQ-MQSeries Bridge Works

Message Queuing Concepts

Message queuing enables programs to share data across a network without necessarily having a synchronized connection linking the sending and receiving applications at the same instant. The programs do this by putting the data, or message, on a message queue, which is then retrieved by the receiving application.

Two basic concepts of both Message Queuing and MQSeries are message and message queue:

Message
A message is a set of data that needs to be transmitted from one application to another application, on the same or a different computer in a network.

Message queue
A message queue is the location where messages are stored, which can be written and read by applications.

See Also

How MSMQ-MQSeries Bridge Works

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Message Fields or Properties

A message may contain one or more fields, such as the message buffer or body, label, priority, or sender ID. The following applies to fields or properties:

- In MQSeries, the fields are members of a fixed data structure.
- In Message Queuing, the fields are known as properties. A message can contain any number of properties (even zero). In practice, an application assembles a message from one or more properties in a dynamic data structure.

See Also

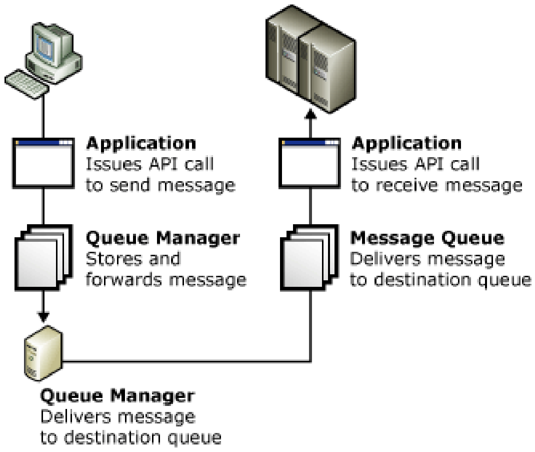
How MSMQ-MQSeries Bridge Works

Sending and Receiving Messages

To create a message, an application specifies the message fields or properties and supplies the field values. The application then issues a Message Queuing or MQSeries API call to send the message.

The Message Queuing or MQSeries Queue Manager (server) transmits the message to the destination message queue. If the destination location is not connected to the network when the message is sent, the message queuing system stores the message at an interim location. The system forwards the message automatically when a connection is established.

To receive a message, an application issues an API call that reads the message from the queue.



Application
Issues API call
to send message
Queue Manager
Stores and
forwards message
Queue Manager
Delivers message
to destination queue
Application
Issues API call
to receive message
Message Queue
Delivers message
to destination queue

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

System Components

The MSMQ-MQSeries Bridge system can contain two main components:

MSMQ-MQSeries Bridge
Converts and transmits messages between the Message Queuing and MQSeries environments.

MSMQ-MQSeries Bridge Manager
Configures, monitors, and controls the messaging traffic through MSMQ-MQSeries Bridge.

See Also

How MSMQ-MQSeries Bridge Works

Message Conversion

MSMQ-MQSeries Bridge maps the fields or properties of a message to the corresponding fields or properties of the destination message queuing system. For example, if you send a message from MQSeries to Message Queuing, MSMQ-MQSeries Bridge analyzes the fields of the MQSeries message and maps each value to its Message Queuing counterpart. In cases where one system needs an additional field that does not exist in the other, MSMQ-MQSeries Bridge provides the field during the conversion process.

For example, if a Message Queuing message includes the PROPID_M_TIME_TO_BE_RECEIVED property with a specific value, MSMQ-MQSeries Bridge maps this property to the MQSeries MQMD.Expiry property and multiplies the value by 10 to change the units from seconds to tenths of seconds.

MSMQ-MQSeries Bridge does not restrict the content of a message. The message body may contain its own internal structure, which is recognized only by the sending and receiving applications and is not interpreted in any way by MSMQ-MQSeries Bridge.

For detailed information about how MSMQ-MQSeries Bridge maps and converts properties from Message Queuing to MQSeries and from MQSeries to Message Queuing, see the *Host Integration Server Programmer's Guide*.

How MSMQ-MQSeries Bridge Works

Network Architecture

MSMQ-MQSeries Bridge is used in conjunction with Message Queuing and MQSeries networks. MSMQ-MQSeries Bridge is a Message Queuing Connector application.

MSMQ-MQSeries Bridge is installed on a Microsoft® Windows Server™ 2003, Enterprise Edition or Windows® 2000 Server Enterprise Edition system that serves as a connection point between the networks. A Message Queuing routing server must be installed on the same computer as MSMQ-MQSeries Bridge, and the computer must be connected by a TCP/IP or LU 6.2 link to an MQSeries Queue Manager.

Multiple Connections

You can connect any number of Message Queuing or MQSeries systems or networks using MSMQ-MQSeries Bridge. For example, you can connect:

- A single MSMQ-MQSeries Bridge to several MQSeries Queue Managers
- A single MQSeries Queue Manager to several MSMQ-MQSeries Bridges
- Several MSMQ-MQSeries Bridges to several MQSeries Queue Managers

See Also

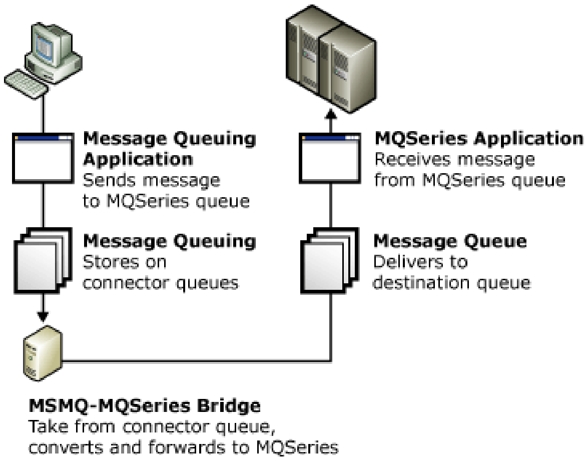
How MSMQ-MQSeries Bridge Works

Sending Messages From Message Queuing to MQSeries

To send a message from Message Queuing to MQSeries, you must define a Message Queuing foreign computer representing the MQSeries Queue Manager, and the MQSeries destination queue must already exist. If this is not the case, see Installing and Configuring MSMQ-MQSeries Bridge.

The messaging process is as follows:

- A Message Queuing application issues a Message Queuing MQCreateQueue() API call to create a foreign queue, located on the foreign computer and representing the MQSeries destination queue. Alternatively, you can create the foreign queue using Message Queuing, and in Windows Server 2003 or Windows 2000 the foreign queue is a part of Users and Computers.
- The application calls MQOpenQueue() to open the foreign queue.
- The application calls MQSendMessage() to send a message to the foreign queue. Message Queuing routes the message and stores it temporarily on a Message Queuing connector queue.



Message Queuing Application
Sends message to MQSeries queue
Message Queuing
Stores on connector queues
MSMQ-MQSeries Bridge
Take from connector queue, converts and forwards to MQSeries
Message Queue
Delivers to destination queue
MQSeries Application
Receives message from MQSeries queue

- MSMQ-MQSeries Bridge takes the message from the connector queue and converts the message properties to the MQSeries message structure. MSMQ-MQSeries Bridge routes the message to the MQSeries destination queue.
- An MQSeries application issues an MQSeries MQGET() API call to receive the message from the MQSeries queue.

Message Queuing processes the message from the initial MQSendMessage() call until it is placed on the connector queue. MSMQ-MQSeries Bridge converts and transmits the message to MQSeries, which handles the transmission from that point on.

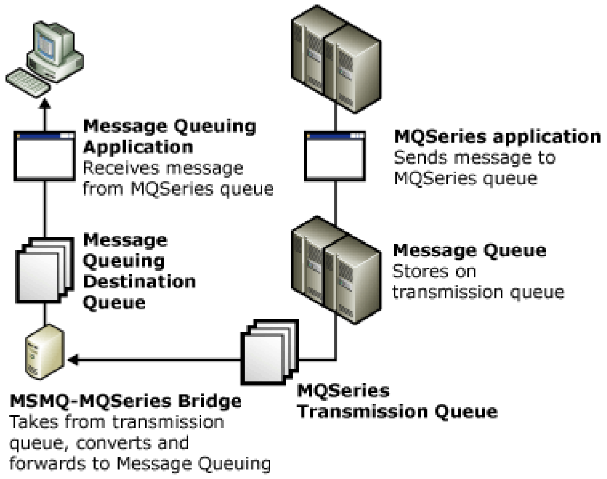
Sending Messages From MQSeries to Message Queuing

The path for sending a message from MQSeries to Message Queuing is essentially the inverse of Message Queuing to MQSeries, with a few differences. You must define appropriate MQSeries aliases, transmission queues, and channels for the Message Queuing destination queue or the Message Queuing server, and the Message Queuing destination queue must already exist.

For additional information, see Typical Configuration.

The messaging steps are as follows:

- An MQSeries application issues an MQOPEN() API call for a remote queue representing the Message Queuing destination queue.
- The MQSeries application calls MQPUT() to send a message to the remote queue. MQSeries transmits the message and stores it temporarily on an MQSeries transmission queue located at the MQSeries Queue Manager.
- MSMQ-MQSeries Bridge takes the message from the transmission queue and converts the message structure to Message Queuing message properties. MSMQ-MQSeries Bridge transmits the message to the Message Queuing destination queue.
- A Message Queuing application issues a Message Queuing MQReceiveMessage() API call to receive the message from the Message Queuing queue.



Message Queuing Application
Receives message from MQSeries queue
MQSeries application
Sends message to MQSeries queue
Message Queuing Destination Queue
Message Queue
Stores on transmission queue
MSMQ-MQSeries Bridge
Takes from transmission queue, converts and forwards to Message Queuing
MQSeries Transmission Queue

Transactional and Nontransactional Message Pipes

Using MSMQ-MQSeries Bridge, you can send messages through transactional or nontransactional message pipes.

If you send a message by a transactional message pipe, MSMQ-MQSeries Bridge supports the deliver-once feature of Message Queuing and MQSeries. This feature ensures that each message is delivered exactly once to the receiving application, but entails some overhead.

Choosing a nontransactional message pipe may improve performance, but a message may be delivered more than once in the event of a system failure during transmission.

Message Queuing messages in the foreign transactional queue will go through transactional message pipes, while Message Queuing messages in the foreign nontransactional queue will go through the nontransactional message pipes.

In the MQSeries to Message Queuing direction, you can send a message by transactional or nontransactional message pipe by specifying the appropriate remote queue manager alias as follows:

"**BRIDGEQMNAME**" refers to transactional message pipe.

"**BRIDGEQMNAME%**" refers to nontransactional message pipe.

In the Message Queuing to MQSeries direction, MSMQ-MQSeries Bridge sends transacted messages by normal service and untransacted messages by high service. In the MQSeries to Message Queuing direction, you can send a message by normal or high service by specifying an appropriate alias as the remote queue manager address.

MSMQ-MQSeries Bridge Setup and Configuration

The following sections detail the setup and configuration of MSMQ-MQSeries Bridge.

After installing, you must configure the Message Queuing (also known as MSMQ), MQSeries, and MSMQ-MQSeries Bridge systems.

The configuration process is equivalent to building a bridge, enabling MSMQ-MQSeries Bridge to transfer messages.

This section contains:

- MSMQ-MQSeries Bridge Setup Requirements
- MSMQ-MQSeries Bridge Prerequisites
- MSMQ-MQSeries Bridge Properties
- Choose Names for Message Queuing and MQSeries Entities
- Installing and Configuring MSMQ-MQSeries Bridge
- Test the Installation
- Typical Configuration

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MSMQ-MQSeries Bridge Setup Requirements

The following information details the steps required to set up MSMQ-MQSeries Bridge. The installation process is straightforward, but rolling out a full installation may take some time in a complex network configuration.

This section helps you get started quickly and presents a step-by-step procedure for an initial MSMQ-MQSeries Bridge configuration.

This section contains:

- Minimal Configuration
- Where You Should Work
- Gather Required Information

Minimal Configuration

The minimal configuration enables MSMQ and MQSeries applications to communicate with one another, so the benefits of MSMQ-MQSeries Bridge are immediate. The minimal configuration requirements are:

- One installation of MSMQ-MQSeries Bridge on a computer running Windows Server 2003 or Windows 2000 Server.
- One installation of Message Queuing on the same computer as MSMQ-MQSeries Bridge. (Message Queuing with routing in Windows Server 2003 or Windows 2000 Server.)
- One installation of MQSeries Queue Manager on any supported platform.

See Also

MSMQ-MQSeries Bridge Setup Requirements

Where You Should Work

To install MSMQ-MQSeries Bridge, you must work on two computers:

- The Message Queuing and MSMQ-MQSeries Bridge computer.
- The MQSeries computer, where the MQSeries Queue Manager is installed.

There are several steps and data transfers that must be performed on each computer.

See Also

MSMQ-MQSeries Bridge Setup Requirements

Gather Required Information

Before you proceed, write down the following information. You will need this information later in the configuration process.

The following worksheet should be used to record needed installation information.

Required information	Your value
Computer name (example: `MSBRIDGE1`).	
Directory in which the MQSeries Client for Windows Server 2003, Windows 2000, or Windows NT® is installed (example: `c:\MQCLIENT`).	

Information about the MQSeries computer

Required information	Your value
Connection information • For TCP/IP, the computer name or IP address (example: `IBMNT`) and the port number (example: `1414`). • For SNA, the LU 6.2 Side Information Record (CPI-C Symbolic Destination Name).	
Name of the MQSeries Queue Manager (example: `IBMNT`).	

Note Write all MQSeries names in uppercase (for example, MSBRIDGE1, and not Msbridge1`)`.

MSMQ-MQSeries Bridge Setup Requirements

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MSMQ-MQSeries Bridge Prerequisites

For information about MSMQ-MQSeries Bridge prerequisites, see the following topics.

This section contains:

- MSMQ-MQSeries Bridge Platforms
- Prerequisites for Computers Running Windows Server 2003 or Windows 2000
- Prerequisites for MQSeries Computers

MSMQ-MQSeries Bridge Platforms

The Server can be installed on any computer running Windows Server 2003 or Windows 2000 Server.

The Administrator Client can be installed on the following platforms: Windows Server 2003, Windows 2000 Professional, or Windows 2000 Server with Terminal Services installed.

See Also

MSMQ-MQSeries Bridge Prerequisites

Prerequisites for Computers Running Windows Server 2003 or Windows 2000

The following software should already be installed on the computer where you will install MSMQ-MQSeries Bridge Server or Administrator Client:

Server Prerequisites

- Windows Server 2003 or Windows 2000 Server
- Message Queuing server (not in a workgroup) with routing enabled
- IBM MQSeries Client for Windows NT or IBM MQSeries for Windows NT (with server and client installed)
- TCP/IP or SNA (LU 6.2) link to an MQSeries Queue Manager (QM)

Administrator Client Prerequisites

- Windows Server 2003, Windows 2000 Professional, or Windows 2000 Server with Terminal Services
- Message Queuing set up (not in a workgroup)

See Also

MSMQ-MQSeries Bridge Prerequisites

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Prerequisites for MQSeries Computers

The following applies to MQSeries computers:

- For OS/390 systems, be sure that your MQSeries Queue Manager is configured with the Client Attachment feature. For additional information, refer to the IBM MQSeries documentation.

See Also

MSMQ-MQSeries Bridge Prerequisites

MSMQ-MQSeries Bridge Properties

For information about MSMQ-MQSeries Bridge properties, see the following topics. This section contains:

Before Adding a Connected Network

Before you can add a connected network (CN) to an MSMQ-MQSeries Bridge, you should:

- Define the CN in Message Queuing and associate the MSMQ-MQSeries Bridge computer with the CN.
- Open MSMQ-MQSeries Bridge Manager.

See Also

MSMQ-MQSeries Bridge Properties

Adding a Connected Network

To add a connected network (CN), right-click the MSMQ-MQSeries Bridge computer to which the CN is connected. Select **New CN** from the pop-up menu, and select the CN name from the list.

Along with the new CN, the following four message pipes are added to the console tree.

Message pipe	**Description**
MSMQ->MQS Transactional	Message Queuing to MQSeries transactional message.
MSMQ->MQS Nontransactional	Message Queuing to MQSeries nontransactional message.
MQS->MSMQ Transactional	MQSeries to Message Queuing transactional message.
MQS->MSMQ Nontransactional	MQSeries to Message Queuing nontransactional message.

Right-click the new CN and each message pipe to set their properties.

See Also

MSMQ-MQSeries Bridge Properties

Deleting a Connected Network

To delete a connected network (CN), right-click the CN and select **Delete** from the pop-up menu.

See Also

MSMQ-MQSeries Bridge Properties

Setting Connected Network Properties

To set the properties of a connected network (CN), right-click the CN icon in **MSMQ-MQSeries Bridge Manager**, and choose the **Properties** option.

Icon	Description
🖧	Icon for a CN

See Also

MSMQ-MQSeries Bridge Properties

Setting Message Pipe Properties

To set the properties of a message pipe, right-click its icon in MSMQ-MQSeries Bridge Manager, and choose the **Properties** option.

The following are icons for message pipes.

Icon	Description
⏹	Stopped
⏸	Paused
⌛	Pending
🕒	Recovering
▶	Running
✖	Error

MSMQ-MQSeries Bridge Properties

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Choose Names for Message Queuing and MQSeries Entities

You need to choose names for certain Message Queuing and MQSeries entities that you will define during the configuration process. For reference as you proceed with the configuration process, write the names on the worksheets.

> **Note** The names are identical to or derived from other names that you already recorded. This naming system is recommended because it helps you maintain your system easily.
>
> For additional information about naming for Message Queuing and MQSeries Entities, see the following topics. This section contains:

- Message Queuing Names
- MQSeries Names

Message Queuing Names

Use this worksheet for Message Queuing names.

Required information	Your value
Name of a connected network or foreign site (example: `IBMNT_CN`).	
Name of the Queue Manager on the foreign computer (example: `IBMQM`).	
Name of a foreign queue (example: `IBM.NT.QUEUE`).	
Name of a Message Queuing queue to which you will send test messages (example: `MSBRDIGE1.QUEUE`).	

See Also

MQSeries Names

MQSeries Names

Use this worksheet for MQSeries names.

Required information	Your value
MQI channel name (example: `IBMNT_CN`).	
Transmission queue name for normal service (example: `MSBRIDGE1.XMITQ`).	
Transmission queue name for high service (example: `MSBRIDGE1.XMITQ.HIGH`).	
Name of an MQSeries queue to which you will send test messages (example: `IBM.NT.QUEUE`).

Message Queuing Names

Installing and Configuring MSMQ-MQSeries Bridge

The following topics detail how to configure MSMQ-MQSeries Bridge components:

Installing the software

- Install the MSMQ-MQSeries Bridge Software
- Transport Considerations

Configuring MSMQ-MQSeries Bridge on Windows Server 2003 or Windows 2000

- Configuring MSMQ-MQSeries Bridge on Windows Server 2003 or Windows 2000

Configuring Message Queuing 2.0 on Windows Server 2003 or Windows 2000

- Define a Foreign Site in Windows Server 2003 or Windows 2000
- Add a Foreign Computer Representing MQSeries in Windows Server 2003 or Windows 2000
- Set the Foreign Site Permission in Windows Server 2003 or Windows 2000
- Create a Foreign Queue in Windows Server 2003 or Windows 2000

Configuring MSMQ-MQSeries Bridge Manager

- Add the Connected Network
- Disable the Message Pipes
- Export an MQSeries Server Definition File
- Export an MQSeries Client Definition File

Configuring MQSeries

- Run the MQSeries Server Definition File
- Run the MQSeries Client Definition File
- Configure the MQSeries Client

Install the MSMQ-MQSeries Bridge Software

The procedure for installing the MSMQ-MQSeries Bridge software is the same whether you are installing the Server or the Administrator Client.

Choosing Server installs MSMQ-MQSeries Bridge and MSMQ-MQSeries Bridge Manager. Choosing Administrator Client installs only MSMQ-MQSeries Bridge Manager.

To install MSMQ-MQSeries Bridge

1. Insert the Host Integration Server 2004 CD-ROM.
2. From the Host Integration Server 2004 startup page, click **Install Server** or **Install Administrator Client** and follow the directions on the screen.
3. When the setup is complete, you can optionally view the **Readme** file and launch MSMQ-MQSeries Bridge Manager. Click **Finish** to complete the installation.

See Also

Installing and Configuring MSMQ-MQSeries Bridge

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Transport Considerations

When the TCP/IP protocol is used between the MQSeries Client and MQSeries Queue Manager, check the **Keep Alive** and **Keep Alive Time** settings in the MQSeries Queue Manager initialization file (Qm.ini). **Keep Alive** should be set to **YES** and the **Keep Alive Time** should be no more than half the message pipes retry delay. This enables the MQSeries Listener to release the resources of a broken connection before MSMQ-MQSeries Bridge retries the connection.

The message pipes retry delay can be found by right-clicking a message pipe in MSMQ-MQSeries Bridge Manager. Select **Properties**, and then select the **Cache** tab.

See Also

Installing and Configuring MSMQ-MQSeries Bridge

Configuring MSMQ-MQSeries Bridge on Windows Server 2003 or Windows 2000

Configuring MSMQ-MQSeries Bridge on Windows Server 2003 or Windows 2000 is a three-stage process requiring Message Queuing 2.0 or later, MSMQ-MQSeries Bridge, and MQSeries to be configured in that order. Configuring Message Queuing on Windows Server 2003 (Message Queuing 3.0) or Windows 2000 (Message Queuing 2.0) is the only stage that is different from that described for configuring MSMQ-MQSeries Bridge on Windows NT 4.0.

Message Queuing and MSMQ-MQSeries Bridge

Message Queuing is built into Windows Server 2003 and Windows 2000 and offers the following additional functionality:

- Integration with the Microsoft Active Directory® directory service, removing the need to use a separate SQL Server™ computer to maintain the MQIS.
- Mixed-mode operation, enabling Message Queuing 1.0 and Message Queuing 2.0 (or later) environments to coexist together.
- Performance improvements, particularly in the area of transactions.
- Workgroup Mode, enabling computers running Windows Server 2003 or Windows 2000 to use Message Queuing without the need for Active Directory.

MSMQ-MQSeries Bridge is capable of running on Windows Server 2003 or Windows 2000. MSMQ-MQSeries Bridge can be installed on any of the computers running Windows Server 2003 or Windows 2000.

To use MSMQ-MQSeries Bridge on Windows Server 2003 or Windows 2000, install:

- Windows Server 2003 or Windows 2000 Server.
- Message Queuing server (not in a workgroup) with routing enabled.
- IBM MQSeries (now WebSphere MQ) Client for Windows NT, Version 5.3, or IBM MQSeries (now WebSphere MQ) for Windows NT, version 5.3 (both Server and Client).
- MSMQ-MQSeries Bridge (from Host Integration Server 2004).

There are some changes in Message Queuing 2.0 and above that are relevant to MSMQ-MQSeries Bridge. These are:

- Foreign Connected Network has been replaced with the term Foreign Site. This is in keeping with Active Directory terminology. Therefore, in Windows Server 2003 or Windows 2000 a CN refers to a foreign site.
- The Message Queuing COM API has changed. Many more of the Message Queuing message properties are now exposed through the Message Queuing COM API. In particular, the extension property (PROPID_M_EXTENSION) is now accessible from Visual Basic®, making it easier to override MSMQ-MQSeries Bridge conversions.
- Creating foreign sites and foreign computers is achieved using Active Directory Sites and Services.

Configuring Message Queuing on Windows Server 2003 or Windows 2000

This section assumes that Message Queuing has been installed (with routing enabled) on a computer running Windows Server 2003 or Windows 2000 on which you plan to install MSMQ-MQSeries Bridge. Using Active Directory Users and Computers, it should be possible to see the Message Queuing object:

Domain Controllers

Computer Name (Your computer name)

Message Queuing

If this is not the case, check that the view is set to Advanced Features. If the Message Queuing object still does not appear, Message Queuing is not installed. Check the Windows Server 2003 or Windows 2000 Message Queuing Help to ensure the Message Queuing prerequisites are met before installing Message Queuing.

From **Control Panel**, select **Add Remove Components** and install the **Message Queuing Services**. During the installation of Message Queuing, ensure that you select **Enable Routing**. This will enable you to define a foreign site (foreign connected network) and define routing links to the foreign site, which are required to set up an MSMQ-MQSeries Bridge.

Active Directory is used to configure Message Queuing for use with MSMQ-MQSeries Bridge. This requires permissions to make changes to Active Directory. For example, when creating a routing link, the default is that only users of the Enterprise

Administrators group can make these changes. Check to ensure you have the appropriate permissions to make the required Active Directory changes before commencing Message Queuing configuration.

Installing and Configuring MSMQ-MQSeries Bridge

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Define a Foreign Site in Windows Server 2003 or Windows 2000

Use the following procedure to define a foreign site in Windows Server 2003 or Windows 2000.

1. From **Active Directory Sites and Services**, select **View**, and then select **Show Services Node**.
2. Under **Services**, right-click **MsmqServices** and select **New Foreign Site**.
3. Enter the name for the foreign site. This is the name of the Foreign Connected Network in Message Queuing 1.0. The same naming conventions apply to the foreign site name as to the Foreign Connected Network name for Message Queuing 1.0.
4. Click **OK**.

See Also

Installing and Configuring MSMQ-MQSeries Bridge

Add a Foreign Computer Representing MQSeries in Windows Server 2003 or Windows 2000

Use the following procedure to add a foreign computer representing MQSeries in Windows 2003 Server or Windows 2000.

1. From **Active Directory Sites and Services**, select **View**, and then select **Show Services Node**.
2. Under **Services**, right-click **MsmqServices** and select **New Foreign Computer**.
3. Enter the **Name** for the Foreign Computer. This name must be the same as that of the MQSeries Queue Manager.

   Note Windows Server 2003 and Windows 2000 do not allow the dot (.) character in computer names. If your MQSeries Queue Manager name contains a dot, you can replace it with a dash (-) and MSMQ-MQSeries Bridge will map the dash back to a dot when routing the message to its MQSeries destination.

4. Select the name for the **Site**, and click **OK**. This is the name of the foreign site that was just created.
5. Click **OK**.

Installing and Configuring MSMQ-MQSeries Bridge

Set the Foreign Site Permission in Windows Server 2003 or Windows 2000

Use the following procedure to modify the permissions for the foreign site.

1. From **Active Directory Sites and Services**, expand the **Sites** folder, and select the foreign site created earlier.
2. Right-click the foreign site, and then select **Properties**.
3. Select the **Security** tab, and select **Everyone**. If MSMQ-MQSeries Bridge was installed using a local account, enable **Open Connector Queue**. Otherwise, select the account name used during setup.

Installing and Configuring MSMQ-MQSeries Bridge

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Create a Foreign Queue in Windows Server 2003 or Windows 2000

Use the following four procedures to create a foreign queue.

Define the MQSeries Queues

Use the following procedure to define the MQSeries queues.

1. From **Active Directory Users and Computers**, select **View**, select **Advanced Features**, select **View**, and then select **Users, Groups and Computers As Containers**.
2. Expand the **Computers** folder and select the foreign computer that was previously created.
3. Right-click the Message Queuing object, select **New**, and then select **MSMQ Queue**.
4. Type the name for the queue and click **OK**. The name must be the same as that of the MQSeries Queue.
5. Or, if you want to create a queue to accept transactional messages, type a name, select the **Transactional** check box, and then click **OK**.

Create a Routing Link

A routing link is required to enable Message Queuing 2.0 to route messages between the current Windows Server 2003 or Windows 2000 site and the newly created Foreign Site that is used for MQSeries. Use the following procedure to create a routing link.

1. From **Active Directory Sites and Services**, select **View**, and then select **Show Services Node** (if not already selected).
2. Under **Services**, right-click **MsmqServices**, select **New**, and then select **MSMQ Routing Link**.
3. Set Site 1 to the name of the foreign site that was previously created. Set Site 2 to the name of the current Windows Server 2003 or Windows 2000 site.
4. Set the **Routing link cost** at 1 and then click **OK**. Using a value greater than 1 is only relevant when multiple routing links are defined between sites, and you want to enforce one route over another. Do not set this value to zero, because it will cause routing of Message Queuing messages to the foreign site to fail.

Define a Site Gate

A site gate is an Message Queuing server that is configured to route messages between sites on behalf of other clients. The Message Queuing server that will be defined as the site gate is the computer that will run MSMQ-MQSeries Bridge. This site gate will use the routing link that was just created. Use the following procedure to define a site gate.

1. From **Active Directory Sites and Services**, select **View**, and then select **Show Services Node** (if not already selected).
2. Under **Services**, right-click **MsmqServices**. The routing link that was previously created should appear in the right pane window.
3. **Right-click** the routing link, and select **Properties**.
4. Select the **Site Gates** tab. In **Site Servers**, select the name of the computer that will run MSMQ-MQSeries Bridge, and then click **Add**.
5. Click **OK**.

Add the Message Queuing Server to the Foreign Site

The Message Queuing server, which is the same computer running Windows Server 2003 or Windows 2000 as MSMQ-MQSeries Bridge, needs to be added to the foreign site created earlier.

1. From **Active Directory Users and Computers**, select **View**, select **Advanced Features**, select **View**, and then select **Users, Groups and Computers as containers**.
2. Expand the Domain Controllers or Computers/<*Your server name*>/MSMQ folder.
3. Right-click the **Message Queuing** object, and select **Properties**.
4. Select the **Sites** tab.
5. Select the foreign site created earlier, and then click **Add** to add this server to the foreign site.
6. Click **OK**.

On the computer running Windows Server 2003 or Windows 2000, open MSMQ-MQSeries Bridge Manager. In MSMQ-MQSeries Bridge Manager, perform the following steps.

1. Expand the **Enterprise** icon.
2. Right-click the **Microsoft MSMQ-MQSeries Bridge Service** icon, click **Stop**, and then click **OK**.
3. Right-click the **Microsoft MSMQ-MQSeries Bridge Service** icon and click **Properties**.
4. On the **MQI Channels** tab, click **Add**.
5. Enter the **Channel Name**.
6. Enter the **Queue Manager** name.
7. For **Transport Type**, select **TCP/IP** or **SNA LU6.2**
8. On the **Address** tab, if you connect by TCP/IP, specify the IP address or computer name for **Address** and the port number for **Port**. For SNA LU 6.2, specify the LU 6.2 Side Information Record.
9. Click **OK** twice. A message appears warning you about changing the MQI Channel configuration. Click **OK** to bypass this message. Click the topics that follow for more information about configuration.

    - Export an MQSeries Server Definition File
    - Export an MQSeries Client Definition File
    - Run the MQSeries Server Definition File
    - Run the MQSeries Client Definition File

Installing and Configuring MSMQ-MQSeries Bridge

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Add the Connected Network

To add the connection network (CN), right-click the **Microsoft MSMQ-MQSeries Bridge Service** icon in MSMQ-MQSeries Bridge Manager. Point to **New**, and click **CN**.

1. Select **CN** from the drop-down list box.
2. Click **OK**. The **CN Properties** window (**General** tab) appears.
3. Select the **MQSeries QM Name**.
4. For the **Reply to QM Name**, enter the name of the computer running Windows.
5. For **Startup**, select **Enabled** and click **OK**.
6. MSMQ-MQSeries Bridge Manager displays four message pipes (`MSMQ->MQS Transactional, MSMQ->MQS`, and so on).

The message pipes are auto-started by default. You can disable the auto-start option in the appropriate **Properties** page.

See Also

Installing and Configuring MSMQ-MQSeries Bridge

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Disable the Message Pipes

Use the following procedure to disable the message pipes.

1. In MSMQ-MQSeries Bridge Manager, right-click the first message pipe icon, `MSMQ->MQS Transactional`, and click **Properties**.
2. On the **General** tab, select **Disabled** and click **OK**.
3. Repeat steps 1 and 2 for the second message pipe, `MSMQ->MQS`.
4. Right-click the third message pipe icon, `MQS->MSMQ Transactional`, and click **Properties**.
5. On the **General** tab, select **Disabled** and click **OK**.
6. Repeat steps 4 and 5 for the MQS->Message Queuing message pipe.

Installing and Configuring MSMQ-MQSeries Bridge

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Export an MQSeries Server Definition File

Use the following procedure to export an MQSeries Server definition file.

1. Right-click the **Microsoft MSMQ-MQSeries Bridge Service** icon in MSMQ-MQSeries Bridge Manager, and click **Export Server Definitions**.
2. Enter a directory name to save the definition file (by default, C:\Program Files\Host Integration Server\MQBridge), and click **OK**. MSMQ-MQSeries Bridge Manager saves the file with an extension of .txt. If you define more than one **CN**, a definition file for each MQSeries Queue Manager is created in the directory.
3. Transfer the files to the MQSeries computer. If you use FTP to transfer the file, be sure to specify the ASCII transfer option.

See Also

Installing and Configuring MSMQ-MQSeries Bridge

Export an MQSeries Client Definition File

Use the following procedure to export an MQSeries Client definition file.

1. Right-click the **Microsoft MSMQ-MQSeries Bridge Service** icon and click **Export Client Definitions**.
2. Enter the directory name to save the definition file (the default is C:\Program Files\Host Integration Server\MQBridge), and click **OK**.
3. MSMQ-MQSeries Bridge Manager saves the file with the name ClientDf.txt.
4. Transfer the file to the MQSeries computer. If you transfer by FTP, be sure to specify the ASCII transfer option.

See Also

Installing and Configuring MSMQ-MQSeries Bridge

Run the MQSeries Server Definition File

On the MQSeries computer, run the MQSeries Server definition file that you transferred from MSMQ-MQSeries Bridge Manager.

1. At the command prompt, run the `MQSC` command, for example:

   ```
   >RUNMQSC IBMNT < IBMNT.TXT > SERVREPORT.OUT
   ```

   Note Substitute the MQSeries Queue Manager name for `IBMNT`.

2. The MQSeries Queue Manager is now configured. Review the Servreport.out file to be sure that the definitions ran successfully.

See Also

Installing and Configuring MSMQ-MQSeries Bridge

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Run the MQSeries Client Definition File

On the MQSeries Queue Manager computer, run the MQSeries Client definition file that you transferred from MSMQ-MQSeries Bridge Manager.

1. At the command prompt, run the MQSC command, for example:

   ```
   >RUNMQSC IBMNT < ClientDf.txt > CLIENTREPORT.OUT
   ```

2. The MQSC command creates a channel file called Amqclchl.tab, located in the directory MQMDirectory/QMGRS/<QueueManagerName>/@IPCC (the exact location may differ on various platforms).
3. Review the Clientreport.out file to be sure that the definitions ran successfully.
4. Transfer the Amqclchl.tab file to the MQSeries Client directory on the Windows computer. If you transfer by FTP, be sure to specify the Binary transfer option.

See Also

Installing and Configuring MSMQ-MQSeries Bridge

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configure the MQSeries Client

To complete the MQSeries configuration, return to the computer running Windows where MSMQ-MQSeries Bridge is installed.

1. On the computer running Windows Server 2003 or Windows 2000, right-click the **My Computer** icon from your desktop, click **Properties**, select the **Advanced** tab, and then click **Environment Variable**.
2. Verify the following variables are in the **System Variables**. If not, set them correctly.

   MQCHLLIB should be the directory path of the channel file (by default, the MQSeries Client directory).

   MQCHLTAB should be the file name of the channel file (by default, Amqclchl.tab).

3. Check that the environment variable MQSERVER is not defined.
4. Click **OK**.

Installing and Configuring MSMQ-MQSeries Bridge

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Test the Installation

You can use the test programs provided in the server installation to test the MSMQ-MQSeries Bridge operation. By default, the test programs are installed to C:\Program Files\Host Integration Server\system.

For additional information about testing the MSMQ-MQSeries Bridge configuration, see the following topics. This section contains:

- Create the Test Queues
- Test the MQSeries Client Definitions
- Start MSMQ-MQSeries Bridge
- Send Test Messages from Message Queuing to MQSeries
- Send Test Messages from MQSeries to Message Queuing

Create the Test Queues

Create a Message Queuing and an MQSeries queue to receive the test messages. Alternatively, you can use queues that already exist on the computers running Windows and MQSeries.

To create a new Message Queuing queue on Windows Server 2003 or Windows 2000, see
Create a Foreign Queue in Windows Server 2003 or Windows 2000.

> **Note** Use `IBMNT` for your MQSeries Queue Manager name. Use `IBM.NT.QUEUE` for the MQSeries queue name.

See Also

Test the Installation

Test the MQSeries Client Definitions

Use the following procedure to start the MQSRRECV program.

1. To start the program, open the command prompt and go to the MSMQ-MQSeries Bridge `samples` directory (by default, C:\Program Files\Host Integration Server\system).
2. Start the program by typing the following command:

   ```
   >MQSRRECV IBMNT IBM.NT.QUEUE
   ```

   Note For `IBMNT`, use the MQSeries Queue Manager name. For `IBM.NT.QUEUE`, use the MQSeries queue name.

3. If the program starts successfully, it displays the message:

   ```
   Use <CTRL-C> to stop!
   ```

If you do not receive this message, confirm the channel file steps. You can view the channel file in Windows Notepad. If the file does not exist or it contains no entries, delete the Amqclchl.tab file from the MQSeries Server and execute the channel file steps again.

If the program still fails to start, override the channel file settings by issuing the following command:

```
>SET MQSERVER=<channel name>/<transport type>/<connection name>[(<port number>)]
```

An example for TCP/IP is:

```
>SET MQSERVER=IBMNT_CN/TCP/10.10.10.5(1414)
```

An SNA example is:

```
>SET MQSERVER=IBMNT_CN/LU62/MQSCPIC
```

Where `MQSCPIC` is the side information record name (CPI-C Symbolic Destination Name).

Then try `MQSRRECV` again. If the program now starts, either the channel file was not found, or it does not contain a correct MQI channel definition. If `MQSRRECV` still does not start, check that the listener on the MQSeries computer is started for the correct port. If not, start the listener and try again.

Press CTRL+C to stop the `MQSRRECV` program.

See Also

Test the Installation

Start MSMQ-MQSeries Bridge

Open MSMQ-MQSeries Bridge Manager and then use the following procedure.

1. Right-click the **Microsoft MSMQ-MQSeries Bridge Service** icon and click **Start**.
2. In the Manager display, all four message pipes should start (the icons should have a green arrow).

If the message pipes do not start, check the event log.

The `MQS->MSMQ` message pipes may fail in the following situations:

- Another MSMQ-MQSeries Bridge computer is currently using the same transmission queue.
- Microsoft MSMQ-MQSeries Bridge is terminated abnormally, causing the MQSeries server to behave as if MSMQ-MQSeries Bridge is still using the corresponding XMIT queue. If this happens, you must restart MQSeries Queue Manager, or configure the **Keep Alive** option in your MQSeries server. (For further information, see your MQSeries documentation.)

Test the Installation

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Send Test Messages from Message Queuing to MQSeries

On the computer running Windows, perform the following procedure to send test messages.

1. Open two MS-DOS windows. Change both windows to the server installation directory (by default, C:\Program Files\Host Integration Server\System).
2. Start the MQSeries receiver program in the first window.

   ```
   >MQSRRECV IBMNT IBM.NT.QUEUE
   ```

   Note Use `IBMNT` for your MQSeries Queue Manager name. Use `IBMNT` for the MQSeries queue name.

3. In the second window, send 10 messages from Message Queuing to MQSeries:

   ```
   >MSMQSEND IBMNT\IBM.NT.QUEUE
   ```

   Note Use `IBMNT` for your foreign computer name. Use `IBMNT.QUEUE` for the MQSeries queue name.

4. If the test succeeds, the first window displays the 10 messages that it receives.
5. Stop the `MQSRRECV` program by pressing CTRL+C in the first window.

Test the Installation

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Send Test Messages from MQSeries to Message Queuing

On the computer running Windows, perform the following procedure to send test messages.

1. Open two MS-DOS windows. Go to the default installation directory (default is C:\Program Files\Host Integration Server\System).
2. In the first window, start the Message Queuing receiver program.
3. Send from MQSeries with the following command:

   ```
   >MQSRSend IBMNT MSBRIDGE1 MSBRIDGE1.QUEUE
   ```

4. Receive in Message Queuing with the following command:

   ```
   >MSMQRecv MSBRIDGE1\MSBRIDGE1.QUEUE
   ```

Test the Installation

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Typical Configuration

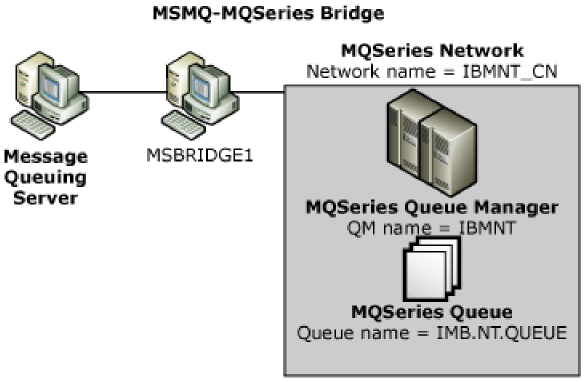
The following topics detail the configuration of MSMQ-MQSeries Bridge. This section contains:

- Diagram of a Typical Configuration
- Settings for a Typical Configuration

Diagram of a Typical Configuration

Examine the diagram for an overview of a typical configuration. The names in the diagram (such as MSBRIDGE1, IBMNT_CN, and IBMNT) are arbitrary, but you must use the same name for the same entity at different locations in the configuration.

For example, if the MSMQ-MQSeries Bridge computer is called MSBRIDGE1, you must reference this same name in MSMQ-MQSeries Bridge Manager and in MQSeries.



MSMQ-MQSeries Bridge
MQSeries Network
Network name = IBMNT_CN
Message Queuing Server
MSBRIDGE1
MQSeries Queue Manager
QM name = IBMNT
MQSeries Queue
Queue name = IMB.NT.QUEUE

See Also

Settings for a Typical Configuration

Settings for a Typical Configuration

The following tables show settings for a typical configuration.

Define in Message Queuing		
	Foreign Connected Network or Foreign Site	IBMNT_CN
	Foreign computer	IBMNT
	Foreign queue	IBM.NT.QUEUE

Define in MSMQ-MQSeries Bridge		
MSMQ-MQSeries Bridge properties	MQI channel	IBMNT_CN
	Transport type	TCP/IP or LU6.2
Foreign Connected Network or Foreign Site properties	CN name	IBMNT_CN
	MQSeries QM	IBMNT
	Reply to QM	MSBRIDGE1
Message pipe properties	MQSeries Message Queuing	Normal
	MQSeries Message Queuing	High
Transmission queue	IBM.NT_CN.XMITQ	IBMNT_CN.XMITQ.HIGH

Import or define in MQSeries		
	Transactional Service	Nontransactional Service
Transmission queue	IBMNT_CN.XMITQ	IBMNT_CN.XMITQ.HIGH
Queue manager alias	MSBRIDGE1	MSBRIDGE1%
	Model queue	Q2Q_SYNC_Q
	MQI channel	MQS_CN
	Transport type	TCP/IP or LU6.2

MSMQ-MQSeries Bridge Manager

For information about MSMQ-MQSeries Bridge Manager, see the following topics. This section contains:

- About MSMQ-MQSeries Bridge Manager
- MSMQ-MQSeries Bridge Manager Display
- MSMQ-MQSeries Bridge Manager Properties
- Icons for MSMQ-MQSeries Bridge Manager Objects
- Column Display Options for MSMQ-MQSeries Bridge Manager
- MSMQ-MQSeries Bridge Display
- Connected Network Display
- Message Pipe Display
- Customizing the Column Display
- Shortcut Menu of MSMQ-MQSeries Bridge Manager
- Status Bar

About MSMQ-MQSeries Bridge Manager

Using MSMQ-MQSeries Bridge Manager, you can control and monitor MSMQ-MQSeries Bridge operations. For example, you can use MSMQ-MQSeries Bridge Manager to:

- Start, stop, or pause the operation of an MSMQ-MQSeries Bridge, a CN, or a message pipe.
- Observe the quantity and type of traffic between Message Queuing and MQSeries.
- Determine how many messages are on MQSeries transmission queues or Message Queuing connector queues waiting to be transmitted.

This topic explains how to use and customize MSMQ-MQSeries Bridge Manager for these purposes.

> **Note** You can also use MSMQ-MQSeries Bridge Manager to configure your MSMQ-MQSeries Bridge system. This is an essential step in the MSMQ-MQSeries Bridge installation. For complete information, see MSMQ-MQSeries Bridge configuration.

Icons for MSMQ-MQSeries Bridge Manager Objects

Within MSMQ-MQSeries Bridge Manager, different icons are used to designate items such as MSMQ-MQSeries Bridge installations, connected networks (CNs), and message pipes.

Icon	Description
	Enterprise network
	Computer (on which one or more MSMQ-MQSeries Bridge products are installed)
	MSMQ-MQSeries Bridge (running)
	MSMQ-MQSeries Bridge (stopped)
	Connected Network
	Message pipe (running)
	Message pipe (paused)
	Message pipe (pending)
	Message pipe (recovering)
	Message pipe (stopped)
	Message pipe (error)

MSMQ-MQSeries Bridge Manager

MSMQ-MQSeries Bridge Display

The following table shows the MSMQ-MQSeries Bridge Manager column name and description.

Column name	Description
MQS H Threads	Number of MQSeries to Message Queuing threads at nontransactional message pipe
MQS N Threads	Number of MQSeries to Message Queuing threads at transactional message pipe
Message Queuing H Threads	Number of Message Queuing to MQSeries threads at nontransactional message pipe
Message Queuing N Threads	Number of Message Queuing to MQSeries threads at transactional message pipe
Lifetime	Time since MSMQ-MQSeries Bridge started
Path	Computer name
Status	MSMQ-MQSeries Bridge status (running, paused, or stopped)
DLQ Depth	Number of messages on the MSMQ-MQSeries Bridge non-transacted dead letter queue
XDLQ Depth	Number of messages on the MSMQ-MQSeries Bridge transacted dead letter queue

See Also

MSMQ-MQSeries Bridge Manager

Connected Network Display

The following table shows the connected network (CN) column name and description.

Column name	Description
QM Name	Name of MQSeries Queue Manager to which the CN is connected
Startup	CN is enabled or disabled at MSMQ-MQSeries Bridge startup
Status	CN status (running, paused or stopped)

See Also

MSMQ-MQSeries Bridge Manager

Message Pipe Display

The following table shows the message pipe column name and description.

Column name	**Description**
Acc Size	Accumulated size (in bytes) of all messages transmitted since the message pipe started
Lifetime	Time since the message pipe started
Messages Sent	Total number of messages that have been sent since the message pipe started
Msgs/Sec	Messages per second (the current throughput of the pipe)
Q Depth	Queue depth (number of messages in the queue) waiting to be transmitted
Q Name	Name of the MQSeries transmission queue or Message Queuing connector queue associated with the message pipe
Retries	Number of times that MSMQ-MQSeries Bridge has tried to activate the message pipe
Startup	Whether the message pipe is enabled or disabled at MSMQ-MQSeries Bridge startup
Status	Message pipe status (running, paused, pending, recovering, stopped, or error)

MSMQ-MQSeries Bridge Manager

Customizing the Column Display

Use the following procedure to add or remove a column in the details pane of MSMQ-MQSeries Bridge Manager.

1. From the **View** menu, select **Columns**.
2. Select the tab for the type of object (**MSMQ-MQSeries Bridge**, **CN**, or **Message Pipe**).
3. To add a column to the display, select its name in the **Available Columns** list, and click **Add**.
4. To remove a column, select its name in the **Show the following** list, and click **Remove**.
5. To change the sequence of the column display, select columns in the **Show the following** list, and click the UP ARROW key or the DOWN ARROW key.
6. Click **OK**.

MSMQ-MQSeries Bridge Manager

Shortcut Menu of MSMQ-MQSeries Bridge Manager

MSMQ-MQSeries Bridge Manager offers the standard Windows Explorer menu and toolbar. In addition, you can display a shortcut menu by right-clicking:

New

Start

Stop

Refresh Cache

Pause

Resume

Delete

Export Server Definitions

Export Client Definitions

Properties

The options on the menu depend on the object and its current status.

See Also

MSMQ-MQSeries Bridge Manager

Status Bar

The status bar at the bottom of the MSMQ-MQSeries Bridge Manager window displays status and error messages. For example, the status bar displays an access denied message if an unauthorized user tries to start or stop Microsoft MSMQ-MQSeries Bridge.

See Also

MSMQ-MQSeries Bridge Manager

Controlling MSMQ-MQSeries Bridge

To control the operation of an object, right-click the object in MSMQ-MQSeries Bridge Manager, and choose the appropriate command.

Some of the commands are also available on the main Manager menu.

For additional information, see the following topics. This section contains:

- Starting, Stopping, or Pausing an Object
- Refreshing the Cache
- Configuration Backup
- Additional Information About MSMQ-MQSeries Bridge

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Starting, Stopping, or Pausing an Object

At MSMQ-MQSeries Bridge startup, the connected network (CN) and message pipes start automatically if you selected the **Startup Enabled** option in the object properties.

To change the status of an object, right-click that object in MSMQ-MQSeries Bridge Manager. Select one of the following options.

Option	Description
Stop	Stops the operation and resets the object's counters (lifetime, messages sent, and accumulated size).
Start	Starts a stopped object.
Pause	Pauses an operation, retaining the object's counters.
Resume	Resumes operation after **Pause**.

The command affects the selected object and all objects below it on the tree. For example, starting a CN starts all its **Enabled** message pipes.

Controlling MSMQ-MQSeries Bridge

Refreshing the Cache

Occasionally, you may want to refresh the MSMQ-MQSeries Bridge cache memory. For example, you can do this to close queues needed by other applications.

In MSMQ-MQSeries Bridge Manager, right-click a Microsoft MSMQ-MQSeries Bridge service or message pipe, and choose the **Refresh Cache** option.

Controlling MSMQ-MQSeries Bridge

Configuration Backup

MSMQ-MQSeries Bridge stores the MQSeries configuration and the MSMQ-MQSeries Bridge configuration in the registry. You can back up those configurations by using Regedit.exe provided in your Windows Server 2003, Windows 2000, or Windows NT system.

The registry location depends on whether you are running Windows NT in a cluster or non-cluster environment, as follows.

MSMQ-MQ Series configuration	**Registry key to backup**
Non-cluster environment	HKLM\Software\Microsoft\MQBridge\Server
Cluster environment	HKLM\Cluster\Software\Microsoft\MQBridge\Server

Additional Information About MSMQ-MQSeries Bridge

The following topics provide additional information about MSMQ-MQSeries Bridge. This section contains:

- Use of the Dash (-) in Message Queuing Computer Names
- Use of the Dot (.) in a Remote MQSeries Queue Manager Name on Windows Server 2003 or Windows 2000
- MSMQ-MQSeries Bridge Dead Letter Queue
- Notes on the Current Release of MSMQ-MQSeries Bridge
- Terminology Used in MSMQ-MQSeries Bridge

Use of the Dash (-) in Message Queuing Computer Names

If a Message Queuing computer name contains the dash (-) character, IBM MQSeries will not be able to address it as a remote queue manager because IBM MQSeries does not support queue manager names with dashes.

MSMQ-MQSeries Bridge provides a feature to resolve this problem through name replacement. In IBM MQSeries, you can refer to the remote queue manager name with a dot (.) instead of a dash, and when the message arrives, MSMQ-MQSeries Bridge changes the dot back to a dash.

To enable this option, see the Advanced Tab.

See Also

Additional Information About MSMQ-MQSeries Bridge

Use of the Dot (.) in a Remote MQSeries Queue Manager Name on Windows Server 2003 or Windows 2000

Windows Server 2003 or Windows 2000 does not support computer names containing the dot (.) character. As a result, dots cannot be used when naming a remote IBM MQSeries QM.

MSMQ-MQSeries Bridge provides a feature to resolve this problem through name replacement. In Windows Server 2003 or Windows 2000, you can refer to the remote IBM MQSeries QM name with a dash (-) instead of a dot, and when the message arrives, MSMQ-MQSeries Bridge changes the dash back to a dot.

This feature is enabled by default. To disable the feature, set the following registry value:

Key: HKLM\Software\Microsoft\MQBridge\Server

Value: DisableDash2DotTranslation(REG_DWORD) = 1

Additional Information About MSMQ-MQSeries Bridge

MSMQ-MQSeries Bridge Dead Letter Queue

MSMQ-MQSeries Bridge creates two dead letter queues for storing messages that are not deliverable. **MQBridge Dead Letter Queue** is for messages through the nontransactional message pipe, and **MQBridge Xact Dead Letter Queue** is for messages through the transactional message pipe.

In Windows Server 2003 or Windows 2000, these two queues are located in **Active Directory Users and Computers** under **Domain Controllers** or **Computers\<MSMQ-MQSeries Bridge Computer>\msmq**.

Additional Information About MSMQ-MQSeries Bridge

Notes on the Current Release of MSMQ-MQSeries Bridge

The following are additional notes to support the current release of MSMQ-MQSeries Bridge in Host Integration Server 2004.

MSMQ-MQSeries Bridge Manager Supports Queue Names in Uppercase Characters

MSMQ-MQSeries Bridge does not differentiate uppercase vs. lowercase foreign queue names and foreign queue manager names. It converts them all to uppercase. MSMQ-MQSeries Bridge can only send messages to MQSeries queue managers and queues that have uppercase names.

MSMQ-MQSeries Bridge Encryption Delays on Windows Server 2003 or Windows 2000

There is a noticeable delay for changes to take place when enabling or disabling MSMQ-MQSeries Bridge encryption. It is recommended that you wait 5-15 minutes after changing the **Enable/Disable** option for encryption, before expecting MSMQ-MQSeries Bridge to function correctly.

Converting an MSMQ-MQSeries Bridge Resource Into a Cluster Resource

In Windows Server 2003 or Windows 2000, clusters are Active-Active. You must perform the following steps after installation to convert an MSMQ-MQSeries Bridge resource into a cluster resource:

1. In the Program Files\Host Integration Server\System directory by default, at the command line, type:

   ```
   BCLUSTER
   ```

2. When the dialog box appears, click **Add Bridge Resource**.
3. In MSMQ-MQSeries Bridge Manager, right-click the **Microsoft MSMQ-MQSeries Bridge Service** cluster resource and select **Bring online**.

In Windows Server 2003 or Windows 2000, you can also run the cluster on the local node only. To do this, run BCLUSTER as described in the preceding procedure, and click **Remove Resource**.

When moving from local node to cluster node, it is necessary to stop Microsoft MSMQ-MQSeries Bridge on all local nodes before you can bring the Microsoft MSMQ-MQSeries Bridge cluster resource online. This restriction only applies when running on Windows Server 2003 or Windows 2000.

Granting Access for Users Created During Install

When installing MSMQ-MQSeries Bridge on a computer running Windows Server 2003 or Windows 2000, if you choose to automatically create a user, that user will be denied access when attempting to start MSMQ-MQSeries Bridge.

You may also receive the following error in the event log: "Access to MSMQ connector queue is denied." While you should have sufficient rights for the operation of Microsoft MSMQ-MQSeries Bridge, it may be necessary to manually configure the Domain Administrator's group security for the foreign site or sites to have full control.

To grant user access

1. In **Active Directory**, go to **Active Directory Sites and Services**.
2. Right-click the foreign site.
3. Click the **Security** tab, and click **Domain Admins**.
4. In the **Permissions** box, select the **Full Control Allow** box.
5. Click **OK**.

MSMQ-MQSeries Bridge Quick Setup for Windows Server 2003 or Windows 2000

Use the following steps to set up a foreign site in Windows Server 2003 or Windows 2000 (previously known as a foreign connected network in Windows NT 4.0).

1. Install Message Queuing with routing.
2. Use **Active Directory Sites and Service** to create a new foreign site and new foreign computer. It is located in the Services\MsmqServices folder (right-click).

3. Create a routing link between the foreign site and the default first site name by right-clicking the Services\MsmqServices folder. Click **New**, and then click **MSMQ Routing Link**.
4. In **Routing link cost**, enter a number between 1-999, where 1 has the highest priority. Do not enter 0; it means no link.
5. Select **Property**, choose the **Site Gates** tab, and then add the MSMQ-MQSeries Bridge computer to be a member of the routing link site gates.
6. In **Active Directory Users and Computers**, under **Domain Controllers** or **Computers\<MSMQ-MQSeries Bridge Computer>\msmq**, select **Property** and then select the **Sites** tab. Add the computer to the foreign site created earlier.
7. Recycle Message Queuing on all domain controllers.

Testing the MQSeries Client/Server Connection Before Using Message Queuing Applications

The connection between the MQSeries Client and the MQSeries Server should be tested using the AMQSPUTC and AMQSGETC tools from IBM. To perform this test, use the following procedure.

1. Configure the MQSeries Server by using the server and client definition files generated by MSMQ-MQSeries Bridge.
2. Place the .tab file (by default, Amqclchl.tab) in the client location.
3. Use AMQSPUTC and AMQSGETC to test the connection.

Enabling MSMQ-MQSeries Bridge Encryption

Before you can enable encryption, you must first run the Add Schema program.

1. Log on as Schema Administrator. (This is usually the same as a Domain Administrator.)
2. In the Program Files\Host Integration Server\System directory (by default), type the following at the command line:

   ```
   addschma hiserver.schema
   ```

3. In MSMQ-MQSeries Bridge Manager, expand **Enterprise**, expand **Computers**, and expand the computer name.
4. Right-click **Microsoft MSMQ-MQSeries Bridge Service**, click **Properties**, and then click the **Advanced** tab.
5. Select the **Support MSMQ to Bridge Encryption** box.
6. Click **OK**, click **Yes**, and then click **OK**.
7. Restart the Microsoft MSMQ-MQSeries Bridge.

To disable encryption, return to the **Advanced** tab and clear the **Support MSMQ to Bridge Encryption** box, and then recycle Microsoft MSMQ-MQSeries Bridge.

MSMQ-MQSeries Bridge Rejects MSMQ Messages with MQMSG_AUTH_LEVEL_MSMQ20 Authentication.

Windows Server 2003 or Windows 2000 Server Message Queuing 2.0 introduces a new authentication signature, MQMSG_AUTH_LEVEL_MSMQ20, and is not supported for a connector queue. The result is that messages are rejected without being processed.

Terminology Used in MSMQ-MQSeries Bridge

The following terms are used in MSMQ-MQSeries Bridge.

Term	Definition
CN	Foreign Connected Network in Windows NT 4.0, and Foreign Site in Windows Server 2003 or Windows 2000.
DLQ and **XDLQ**	MQBridge Dead Letter Queue and MQBridge Xact Dead Letter Queue. (For more information, see MSMQ-MQSeries Bridge Dead Letter Queue.)
MCA	Message Channel Agent. (For details, see IBM MQSeries documentation.)
MQI	Message Queue Interface (For details, see IBM MQSeries documentation.)
MQS	IBM MQSeries.
Message Queuing	Also known as MSMQ. Formerly known as Microsoft Message Queuing, Message Queuing Services, or Message Queue Server.
Nontransactional Message Pipe	Option allowing possible duplicate delivery of a message.
QM	Queue Manager.
Transactional Message Pipe	Option guaranteeing delivery of a message once and only once.

Security User's Guide

Enterprise Single Sign-On (SSO) provides services to enable single sign-on to end users for enterprise application integration (EAI) solutions. The SSO system maps Microsoft® Windows® accounts to back-end credentials. SSO simplifies the management of user IDs and passwords, both for users and administrators. It enables users to access back-end systems and applications by logging on only once to the Windows network.

This section contains:

- Understanding Enterprise Single Sign-On
- Installing Enterprise Single Sign-On
- Using Enterprise Single Sign-On
- Secure Deployment of Enterprise Single Sign-On
- Password Synchronization

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Understanding Enterprise Single Sign-On

To understand Enterprise Single Sign-On, it is useful to look at the three types of Single Sign-On services available today: Windows integrated, extranet, and intranet. These are described below, with Enterprise Single Sign-On falling into the third category.

Windows Integrated Single Sign-On

These services enable you to connect to multiple applications within your network that use a common authentication mechanism. These services request and verify your credentials after you log into the network, and use your credentials to determine the actions that you can perform based on your user rights. For example, if applications integrate using Kerberos, after the system authenticates your user credentials you can access any resource in the network that is integrated with Kerberos.

Extranet Single Sign-On

These services enable you to access resources over the Internet by using a single set of user credentials. The user provides a set of credentials to log on to different Web sites that belong to different organizations. An example of this type of Single Sign-On is Microsoft .NET Passport.

Intranet Single Sign-On

These services enable you to integrate multiple heterogeneous applications and systems within the enterprise environment. These applications and systems may not use common authentication. Each application has its own user directory store. For example, in an organization, Windows uses Active Directory® directory service to authenticate users, and mainframes use IBM's Resource Access Control Facility (RACF) to authenticate the same users. Within the enterprise, middleware applications integrate the front-end and back-end applications. Enterprise Single Sign-On enables users in the enterprise to connect to both the front-end (**Host Initiated Single Sign-On**) and back-end (**Windows Initiated Single Sign-On**) while using only one set of credentials.

In addition, **Password Synchronization** simplifies administration of the SSO credential database, and keeps passwords in sync across user directories. This is done through the use of password synchronization adapters, which you can configure and manage using the Password Synchronization command line utility.

The Enterprise Single Sign-On System

Enterprise Single Sign-On (SSO) provides services to store and transmit encrypted user credentials across local and network boundaries, including domain boundaries. SSO stores the credentials in the Credential database. Because SSO provides a generic single sign-on solution, middleware applications and custom adapters can leverage SSO to securely store and transmit user credentials across the environment. End users do not have to remember different credentials for different applications.

The Single Sign-On system consists of a Credential database, a master secret server, and one or more Single Sign-On servers.

The SSO system contains affiliate applications that an administrator defines. An affiliate application is a logical entity that represents a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using Enterprise Single Sign-On. Each affiliate application has multiple user mappings; for example, it has the mappings between the credentials for a user in Active Directory and their corresponding RACF credentials.

The Credential database is the SQL Server database that stores the information about the affiliate applications, as well as all the encrypted user credentials to all the affiliate applications.

The master secret server is the Enterprise Single Sign-On server that stores the master secret. All other Single Sign-On servers in the system get the master secret from the master secret server.

The SSO system also contains one or more SSO Servers. These servers do the mapping between the Windows and back-end credentials, look up the credentials in the Credential database, and administrators use them to maintain the SSO system.

> **Note** You can have only one master secret server and only one Credential database in your SSO system. The Credential database can be remote to the master secret server.

This section contains:

- Enterprise Single Sign-On User Groups
- SSO Components
- SSO Server
- Master Secret Server

- SSO Affiliate Applications
- SSO Mappings
- SSO Tickets
- Configuring Enterprise Single Sign-On
- Best Practices for Enterprise Single Sign-On Security

Enterprise Single Sign-On User Groups

To configure and manage the Enterprise Single Sign-On (SSO) system, you must create certain Windows groups, and accounts within each of these groups. This section describes each of these groups.

> **Important** It is strongly recommended that you use domain groups when configuring SSO.

> **Note** For security purposes, the SSO system does not allow built-in accounts.

Single Sign-On Administrators

SSO administrators have the highest level user rights in the SSO system. They can:

- Create and manage the Credential database
- Create and manage the master secret
- Enable and disable the SSO system
- Create password synchronization adapters
- Enable and disable password synchronization in the SSO system
- Enable and disable host initiated SSO
- Perform all administration tasks

The SSO administrators account can be either a Windows group account or an individual account. The SSO administrators account can also be either a domain or local group or individual account. When using an individual account, you cannot change this account to another individual account. Therefore, it is recommended that you do not use an individual account. You can change this account to a group account as long as the original account is a member of the new group.

> **Important** The service account running the Enterprise Single Sign-On service must be a member of this group. To secure your environment, ensure that no other service is using the same service account.

Single Sign-On Affiliate Administrators

The SSO affiliate administrator defines the affiliate applications that the SSO system contains. Affiliate applications are a logical entity that represents the back-end system to which you are connecting using SSO. SSO affiliate administrators can:

- Create and manage affiliate applications
- Specify the application administrators account for each affiliate application
- Perform all the administration tasks that the application administrators and application users can

The SSO Affiliate Administrator account can be either a Windows group account or an individual account. The SSO Affiliate Administrator account can also be either a domain or local group or account.

Application Administrators

There is one application administrators group per affiliate application.

Members of this group can:

- Change the application users group account
- Create, delete, and manage credential mappings for all users of the specific affiliate application
- Set credentials for any user in that specific affiliate application users group account
- Perform all the administration tasks that the application users can

Application Users

There is one application users group account for each affiliate application. This group contains the list of end users in an ESSO environment. Members of this group can:

- Look up their credentials in the affiliate application
- Manage their credential mappings in the affiliate application

> **Note** Remember to be vigilant when assigning groups. It is possible, for example, to use an HIS security user group for the SSO application users group. Before you do this, be certain that all users need all access that will then be

available to them.

Updating the Credential Database

Managing User Mappings

Understanding Enterprise Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

SSO Components

The sub services of the Enterprise Single Sign-On (SSO) service are:

- **Mapping.** This component maps the user account in the Windows system to the user accounts in the back-end systems (affiliate applications).
- **Lookup.** This component looks up the user credentials in the Credential database in the back-end system. This is the SSO runtime component.
- **Administration.** This component manages the affiliate applications and the mappings for each affiliate application.
- **Secret.** This component generates the master secret and distributes it to the other SSO servers in the system. It is only active on the Single Sign-On server that is acting as the master secret server.
- **Password Synchronization.** This component simplifies administration of the SSO credential database, and keeps passwords in sync across user directories.

See Also

SSO Server

Installing Enterprise Single Sign-On

SSO Server

The Enterprise Single Sign-On (SSO) server can perform any of the following tasks:

- **Functions as the master secret server.** The master secret server holds the master secret, or encryption key, used to encrypt all the credentials in the SSO system. Though the master secret server can act as a server for lookups and administration, it is recommended to use this server to act only as a master secret server for security reasons. For more information about the functions the master secret server performs, see Master Secret Server.
- **Performs administrative operations.** SSO administrators can use any of the Single Sign-On Servers to perform administrative tasks such as managing affiliate applications, setting user credentials, and managing user mappings.
- **Performs lookup operations.** The SSO server uses the runtime component to look up the user credentials.
- **Issues and Redeems Tickets.** The SSO server also issues and redeems SSO tickets.
- **Password Synchronization.** You can create and manage password synchronization adapters on the SSO Server.

See Also

Using Enterprise Single Sign-On

Installing Enterprise Single Sign-On

Master Secret Server

The master secret server is the Enterprise Single Sign-On (SSO) server that stores the master secret (encryption key). The master secret server generates the master secret when an SSO administrator requests it. The master secret server stores the encrypted master secret in the registry. Only Single Sign-On administrators can access the master secret.

The other Single Sign-On servers check every 30 seconds to see whether the master secret has changed. If it has changed, they read it securely; otherwise, they continue to use the master secret they already have cached in memory. The SSO service uses the master secret to encrypt and decrypt the user credentials.

You cannot use the SSO system until an SSO administrator configures the master secret server and generates the master secret. The master secret server generates the master secret during configuration. Only SSO administrators can generate the master secret. An SSO administrator must configure the master secret server and the Credential database before an application can use the SSO service.

> **Important** After you generate the master secret, it is strongly recommended that you back it up and store it in a secure location.

When an SSO administrator needs to regenerate the master secret, for example, if the SSO administrator wants to change the master secret periodically, the master secret server stores both the old and new master secret. The master secret server then goes through all the mappings, decrypts them using the old master secret, and encrypts them again using the new master secret.

If the master secret server fails, all runtime operations already running will continue to run, but SSO servers will not be able to encrypt new credentials.

> **Important** There can be only one master secret server in your SSO system. Therefore, it is strongly recommended you cluster the master secret server. For more information, see Clustering the Master Secret Server.

See Also

Using Enterprise Single Sign-On

SSO Affiliate Applications

The Enterprise Single Sign-On (SSO) Affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using SSO. An affiliate application can represent a back-end system such as a mainframe or UNIX computer. It can also represent an application such as SAP, or a subdivision of the system, such as the "Benefits" or "Pay stub" sub-systems.

When the SSO administrator or the SSO Affiliate administrator defines an affiliate application, they must also determine who will administer the affiliate application (the application administrator), who the users of the affiliate application are (the application users), and what parameters the SSO system will use to authenticate the users of this affiliate application (the user ID, passwords, PIN numbers, and so on). For more information about application administrators and application users, see Enterprise Single Sign-On User Groups.

Affiliate Application Types

Enterprise SSO defines several different application types. The different application types support different types of mappings between the Windows account and the account on the non-Windows system.

The application types are:

Individual Individual applications support one-to-one mappings between the Windows account and the non-Windows account. In an Individual type application, one Windows account is mapped to one, and only one, non-Windows account. The mapping can be used in either direction, from Windows to non-Windows, or from non-Windows to Windows, or both, depending on the flags that have been set for this application. Thus, Individual applications may be used for Windows initiated SSO, Host initiated SSO, or both.

Group Group applications support mappings between one Windows group to one single non-Windows account. The Application Users account is used to define the Windows group that will be used for this Group application. Only one mapping can be defined for a Group application, and that mapping must be between the Windows group and the single non-Windows account that will be used by all members of this Windows group to access the non-Windows system. Group applications may only be used for Windows initiated SSO.

Host Group Host Group applications are conceptually the reverse of Group applications. They support mappings between a defined group of non-Windows accounts to a single Windows account. The single Windows account that will be used by the non-Windows accounts is defined by the Application Users account for the application. The group of non-Windows accounts that is allowed to access this application is defined by creating a mapping for each non-Windows account. Host Group applications may only be used for Host initiated SSO.

Designing an Affiliate Application

Before creating an affiliate application, the SSO affiliate administrator or the SSO administrator has to make the following decisions:

1. **What will this affiliate application represent?** You need to know the non-Windows application that the affiliate application will represent in the SSO system. For example,

Application name: APP1

Description: Application for Pay stub department

Contact: administrator@companyname.com

1. **Who will administer this affiliate application?** You need to determine the administrators for this affiliate application. These form the Windows administrators group for this affiliate application. For example, Domain\APP1AdminGroup
2. **Who will use this affiliate application?** You need to determine who the end-users are for this affiliate application. These users represent the Windows users group for this affiliate application; for example, Domain\DomainUsers. In the case of the application for Pay stubs, you might want all users to access their pay stub information, so you can specify the domain users group as the user group for this application.
3. **What credentials does the affiliate application use to authenticate its users?** Different applications user different credentials to authenticate users. For example, some applications may use user IDs, passwords, PINs, or a combination of these. You must also determine whether the system needs to mask these credentials as the user provides them.
4. **Will you use individual mappings or a group mapping for this affiliate application?** Does each Windows user have an account in the back-end system, or does the back-end system have one account for all Windows users? In the case of the pay stub system, each user has their own account to access their pay stub information, and you would need to use

individual mappings.

After you create an affiliate application, you cannot modify the following properties:

- Name of the affiliate application
- Fields associated with the affiliate application
- Affiliate application type (host group, individual, or configuration store)
- Administration account same as affiliate administrators group. (If you select this property, then the affiliate administrators group is used as the application administrator's account for this affiliate application.)

Affiliate Application Properties

The following table lists the properties you need to define for each affiliate application you create.

Property	Description
`Application name`	Name of the affiliate application. You cannot change this property after you create the affiliate application
`Description`	Brief description of the affiliate application
`Contact`	The main contact for this affiliate application that users can use. (Can be an e-mail address.)
`appUserAccount`	The Windows group that contains the user accounts of end-users that will be using this affiliate application
`appAdminAccount`	The Windows group that contains the administrator accounts that will manage this affiliate application. **Note** You do not need to define this property if you set the adminAccountSame to Yes.

Application Flag	Description
`enableApp`	The status of this affiliate application.
`groupApp`	Determines whether this application uses a group mapping (yes) or individual mappings (No.) You cannot change this property after you create the application.
`configStoreApp`	Determines whether this affiliate application is a Configuration Store type application (yes). You cannot change this property after you create the application.
`hostInitiatedSSO`	Enable this if it is a host initiated SSO type application. Default is No.
`windowsInitiatedSSO`	Enable this if it is a Windows initiated SSO type application. Default is Yes.

`validatePassword`	This applies only to host initiated SSO applications. When the application attempts to retrieve credentials, it must provide the password in the credential database which is used for validation by SSO services. Default is Yes.
`disableCredCache`	The SSO Server stores credentials in a cache to expedite access. Default is No.
`allowTickets`	Determines whether the SSO system uses tickets for this affiliate application. **Security** You must be an SSO administrator to set this flag.
`validateTickets`	Determines whether the SSO system validates tickets when the user redeems them. **Security** You must be an SSO administrator to set this flag.
`timeoutTickets`	Determines whether tickets have an expiration time. Default is No. **Security** Unless it is required, do not disable ticket timeouts (No.). **Security** You must be an SSO administrator to set this flag.
`allowLocalAccounts`	Determines whether you allow the use of local groups and accounts in the SSO system. You can only configure this flag to Yes in single-computer scenarios.
`adminAccountSame`	Determines whether to use the SSO affiliate administrator group as the application administrator group. You cannot change this property after you create the application. **Security** You must be an SSO administrator or SSO affiliate administrator to set this flag.

Application fields	**Description**	
Field [0]	<*credential*>: Masked/Unmasked	Determines the type of credential (user ID, password, smartcard) that end users must provide to connect to the affiliate application, and whether this credential is masked (that is, whether the characters that the user types are displayed on the screen) or not. You can enter as many fields as there are credentials for the affiliate application, but the first field must be the user ID. You cannot change this property after you create the application.

SSO Mappings

Managing User Mappings

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

SSO Mappings

When an Enterprise Single Sign-On (SSO) administrator or an SSO affiliate administrator defines an affiliate application, the administrator can define it either as an application with individual mappings, or as an application with a group mapping.

Individual Mappings

SSO individual mappings enable administrators and users to create a one-to-one mapping between Windows users and their corresponding non-Windows credentials. When using individual mappings, users can manage their own mappings. The SSO system maintains the one-to-one relation for the user's Windows account and the user's non-Windows account.

Windows End-users can create and manage their own mappings for individual type applications. The same affiliate application can act as a Windows Initiated SSO and a Host Initiated SSO type application.

> **Note** Only individual users can obtain the credentials to their individual accounts when using individual mappings.

Group Mapping

SSO group mapping consists of mapping a Windows group, which contains multiple Windows users, to a single account in the affiliate application.

Only an application administrator, SSO affiliate administrator, or SSO administrator can create a group mapping.

You cannot specify the same group application for Windows initiated SSO and Host Initiated SSO.

> **Important** When you use group mappings, the members of the group can obtain the credential information for the group mapping.

Managing User Mappings

SSO Affiliate Applications

SSO Tickets

In an enterprise environment, where a user interacts with various systems and applications, it is very likely that the environment does not maintain the user context through multiple processes, products, and computers. This user context is crucial to provide single sign-on capabilities, as it is necessary to verify who initiated the original request. To overcome this problem Enterprise Single Sign-On (SSO) provides an SSO ticket (not a Kerberos ticket) that applications can use to get the credentials that correspond to the user who made the original request. SSO tickets are not enabled by default. For more information about enabling tickets, see Configuring the Enterprise Single Sign-On Tickets.

The SSO system issues a ticket when requested by an authenticated Windows user. The SSO system can only issue a ticket for the user making the request (you cannot request a ticket for other users). A ticket contains the encrypted domain and username of the current user, and the ticket expiration time. After the SSO system issues a ticket, it expires in two minutes by default. SSO administrators can modify the expiration time for tickets. For more information, see Configuring the Enterprise Single Sign-On Tickets.

After an application verifies the identity of the original requestor, the application redeems the ticket to obtain the credentials of the user who initiated the request affiliate application. An application can redeem tickets from the SSO system in one of three ways:

- **Redeem only.** When an application initiates a request to redeem a ticket, the request must contain the name of the affiliate application to connect to, and the ticket itself. Only application administrators for the specific affiliate application, SSO affiliate administrators, or SSO administrators can redeem a ticket. You should use **Redeem only** when there is a trusted sub-system between the application that issued the ticket and the application redeeming the ticket. Only an application administrator for the specified affiliate application can redeem the ticket for a user.
- **Validate and redeem.** Tickets contain information about the user for whom the SSO system is performing the credential look-up. In this case, the SSO service verifies that the sender of the original message and the user of the ticket are the same before the system redeems the ticket.

An SSO administrator can disable ticket timeouts on a per affiliate application basis. However, this is not recommended, as the ticket would never expire for this application. In scenarios that require that you disable ticket timeouts, ensure that there is a secure end-to-end trusted sub-system maintained between the front-end where the SSO system issues the ticket to the adapter where the SSO ticket redeems the ticket.

An SSO affiliate administrator can specify that tickets are allowed and that validation of the ticket is required on a per affiliate application basis. However, if the SSO administrator specifies at the SSO system level that the validation of tickets is required, the SSO affiliate administrator cannot turn off this option at the affiliate application level.

> **Important** When using SSO ticketing, you must ensure that the ticket timeout value is long enough to last between the time when the ticket is issued to the time that it is redeemed.

Managing User Mappings

Configuring Enterprise Single Sign-On

You can configure Enterprise Single Sign-On using command line utilities, or by using COM or Microsoft .NET interfaces.

SSO command line utilities

You use three different command line utilities to perform Enterprise Single Sign-On tasks:

SSOConfig. Enables an SSO administrator to configure the Credential database and to manage the master secret.

> **Note** The Configuration Wizard creates the Credential database and the master secret server.

SSOManage. Enables SSO administrators, SSO affiliate administrators, and application administrators to update the Credential database to add, delete and manage applications, administer user mappings, and to set credentials for the affiliate application users. Some operations can be performed only by the SSO administrators, or, only by the SSO administrators and SSO affiliate administrators.

SSOClient. Enables Single Sign-On users to manage their own user mappings and set their credentials.

For more information about the SSO accounts, see Enterprise Single Sign-On User Groups.

SSO COM and .NET interfaces

Enterprise Single Sign-On provides COM and .NET programmatic interfaces that enable you to create custom components, and to create scripts to facilitate the administration of the SSO system.

SSO Components

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Best Practices for Enterprise Single Sign-On Security

This section contains recommendations for securing your Enterprise Single Sign-On (SSO) system.

Perimeter network

When running Internet Information Services (IIS) and Enterprise Single Sign-On, follow these recommendations:

- If IIS is in a perimeter network (also known as demilitarized zone, DMZ, and screened subnet), provide another IIS server behind the firewall to connect to the SSO system.
- Do not open the remote procedure calls (RPC) port on IIS.

SQL Server access

All SSO servers access the SQL Server Credential database. For more information about how to secure SQL Server databases, see http://go.microsoft.com/fwlink/?LinkId=33174 and http://go.microsoft.com/fwlink/?LinkId=33175.

It is recommended that you use Secure Sockets Layer (SSL) and/or Internet Protocol security (IPSec) to secure the transmission of data between the SSO servers and the Credential database. For more information about using SSL, see http://go.microsoft.com/fwlink/?LinkId=33176.

To enable SSL for only the connection between the SSO server and the Credential database, you can set SSL support on every SSO server using the ssoconfig utility. This option enables SSO to always use SSL when accessing the Credential database. For more information, see Enabling SSL for Enterprise Single Sign-On.

Strong passwords

It is very important that you use strong passwords for all accounts, especially the accounts that are members of the SSO Administrators group, because these users have control over the entire SSO system.

SSO Administrator accounts

It is recommended that you use different service accounts for the SSO services running on different computers. You should not use the SSO administrator account that performs administration operations such as generating and backing up the secret for the SSO service. While the SSO service accounts should not be local administrators on that computer, the SSO administrator that is performing administration operations must be a local administrator on the computer for some operations.

Master secret server

It is highly recommended that you secure and lock down the master secret server. You should not use this server as a processing server. The only purpose of this server should be to hold the master secret. You should ensure the physical security of this computer and only SSO Administrators should have access to this computer.

Kerberos

SSO supports Kerberos, and it is recommended that you set up Kerberos for SSO. To set up Kerberos with SSO, you must register a Secure Principal Name (SPN) for the SSO service. By default, when you setup Kerberos, SSO uses that SPN to authenticate the components using the SSO Service. It is recommended you setup Kerberos authentication between the SSO administrative sub services and the SSO server. You can also user Kerberos authentication between the SSO servers and between the SSO servers and the SQL Server where the Credential database is.

To set up and verify Kerberos, you use the utilities setspn and kerbtray. For more information about these utilities, see http://go.microsoft.com/fwlink/?LinkId=33178 and http://go.microsoft.com/fwlink/?LinkId=33179.

Delegation

When using Windows Server 2003, it is possible to use constrained delegation, but it is recommended that you do not use delegation to perform the tasks of the Single Sign-On Administrator. Similarly, it is recommended that you do not delegate additional tasks or user rights to the Single Sign-On administrator.

Auditing

Auditing is a critical mechanism for tracking information in your environment. Enterprise Single Sign-On (SSO) audits all operations performed in the Credential database. SSO uses event logs and audit logs of the database itself. SSO provides two audit levels for the Single Sign-On servers:

- Positive auditing levels audit successful operations
- Negative auditing levels audit operations that fail.

SSO administrators can set the positive and negative audit levels that suit their corporate policies.

You can set positive and negative audits to one of the following levels:

0 = None. This level issues no audit messages.

1 = Low

2 = Medium

3 = High. This level issues as many audit messages as possible.

The default value for positive auditing is 0 (none), and the default value for negative auditing is 1(low). You may want to change these values depending on the level of auditing you want for your SSO system.

> **Important** Enterprise Single Sign-On auditing issues messages generated by the Single Sign-On service. This is not a security audit, and the SSO system does not save the information in the security log of the Event Log. The SSO system saves the SSO audit messages directly to the Application Event Log.

Database Level Auditing

> For database level auditing, the SSO system tracks the operations performed on the Credential database in the audit tables in the database. The size of these audit tables are defined at the SSO system level. You can audit for affiliate applications that are deleted, for mappings that are deleted, and for credential look-ups that are performed. By default, the audit size is set to 1000 entries. SSO administrators can change this size to meet their corporate policies.

Using Enterprise Single Sign-On Accounts

This section contains best practices when using domain and local groups and individual accounts in the Enterprise Single Sign-On (SSO) system.

Domain Windows Groups and Accounts

When working with domain Windows groups, the following recommendations apply:

- Use domain groups and domain accounts.
- Use a domain group for SSO administrators. You should not specify an individual domain account as the SSO administrator, because you cannot change this account from one individual account to another individual account.
- Although you can specify an individual domain account as the SSO affiliate administrator, you should use a domain group.
- Although you can specify an individual domain account as the application administrator, you should use a domain group.
- You must use domain groups for the application users account. The SSO applications users account does not support an individual account.

Auditing Enterprise Single Sign-On

Updating the Credential Database

Installing Enterprise Single Sign-On

The following sections contain information regarding installation of the Enterprise Single Sign-On feature. Because of this feature's complex relationships to other features and systems, and because of its importance to system security, you should read this section carefully before installing Enterprise Single Sign-On.

- **Important** To avoid total loss of your existing host security credential database, you must perform the migration procedure in Upgrading from Host Integration Server 2000 or SNA Server 4.0. Running the migration utility before installation is the only way to safely import host security domains and user mappings from your existing HIS or SNA Server primary domain controller. Installing Single Sign-On without performing this migration will permanently destroy all existing host security data.

This section contains:

- Upgrading from Host Integration Server 2000 or SNA Server 4.0
- Upgrading from a Previous Version of SSO
- Standard Installation Options
- High-Availability Installation Options
- Removing Enterprise Single Sign-On

Upgrading from Host Integration Server 2000 or SNA Server 4.0

Previous versions of Host Integration Server, such as HIS 2000 and SNA Server 4.0, provided both single sign-on and password synchronization through their host security feature. This feature was based around the host security domain, which contained user mappings to map credentials between Windows and host systems.

In Host Integration Server 2004, the Enterprise Single Sign-On feature replaces host security as the source of single sign-on and password synchronization. While some concepts are shared between the old and new features, there are important differences. In addition to the increased functionality, there are two primary conceptual differences in the new features:

- Host security domains are replaced by affiliate applications
- Security credential data is now stored in a secure SQL Server database

To migrate your existing host security data into the new SSO environment, use the Migration Utility. This is a command-line tool (hissomig.exe) which migrates all necessary data from the old version to the new, enabling you to continue using Single Sign-On without modifying your applications.

The topics in this section walk you through the migration process. It is important to follow these steps in the order given.

This section contains:

- Back up the Existing Security Data
- Export the Encryption Key
- Install Enterprise Single Sign-On
- Copy the Migration Utility to the Master Secret Server
- Run the Migration Utility

Back up the Existing Security Data

For safety purposes, you should back up your existing security data before migrating to Enterprise Single Sign-On.

For information about how to do this, see your Host Integration Server 2000 or SNA Server 4.0 documentation.

Export the Encryption Key

If you are migrating from Host Integration Server 2000, you must export the encryption key. The encryption key is a security device which HIS 2000 uses to encrypt user passwords. It must be backed up because the migration utility will need it as part of the migration process.

To export the encryption key

1. On the **Start** menu, click **Run**, and then type **cmd**.
2. Navigate to the Host Integration Server 2000 installation directory.
3. Type **udbkey /showkey >hostseckey.bak** to back up the key into a file.
4. Protect the file securely.

See Also

- Upgrading from Host Integration Server 2000 or SNA Server 4.0

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Install Enterprise Single Sign-On

At this point in the upgrade process, it is time to install Enterprise Single Sign-On. There are a number of installation options. For more information on installing, see Installing Enterprise Single Sign-On.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Copy the Migration Utility to the Master Secret Server

The Migration Utility is not installed with the rest of Host Integration Server 2004, and must be manually copied to the Master Secret Server.

To copy the Migration Utility

1. On the **Start** menu, click **Run**, and then type **cmd** and press **Enter**.
2. Type **copy hisssomig.exe from <cddrive>\support\utilities\ to c:\hostsec\** and press **Enter**.

See Also

- Upgrading from Host Integration Server 2000 or SNA Server 4.0

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Run the Migration Utility

Migration, which is performed with the hissomig.exe command-line utility, is essentially a two-step process:

First, the tool **exports** data from the host security domain into an XML file. This file also contains validation data for the migration process. Should mappings or file names conflict, an administrator can resolve them before the next step.

Second, the tool **imports** data into the SSO environment, and updates the HIS 2004 credential database appropriately.

The Migration Utility has the following restrictions:

- You must be an SSO Administrator and have at least read privileges to the SNAUDB database to perform migration.
- Both importing and exporting must be done on the Master Secret Server.

  Note The XML file generated during migration is not deleted. Since this file contains security data, it is important to manually delete the file as soon as migration is complete.

To export from HIS 2000

1. Stop the **Host Account Cache service**.
2. On the **Start** menu, click **Run**, and then type **cmd** and press **Enter**.
3. Type **hissomig –export –servername <server> -output <XML file>**

   where <server> is the fully qualified name, netbios name, or IP address of the HIS 2000 primary domain controller, and <XML file> is the full path of the XML file to which the data will be exported.

   For example:

   ```
   hissomig –export –servername SERVER1 -output c:\hostsecdb.xml
   ```

4. Press **Enter**.
5. Restart the **Host Account Cache service**.

To export from SNA Server 4.0

1. Stop the Host Account Cache service.
2. On the **Start** menu, click **Run**, and then type **cmd** and press **Enter**.
3. Type **hisssomig –export –dbfile <database file> -output <XML file>**

   where <database file> is the full path of the SNA 4.0 Host Security database file, and <XML file> is the full path of the XML file to which the data will be exported.

   For example:

   ```
   hisssomig –export –dbfile Y:\Program Files\SNA Server\hostsec\dbfile.dbs -output c:\hostsecdb.xml
   ```

4. Press **Enter**.
5. Restart the Host Account Cache service.

To import into HIS 2004

1. On the **Start** menu, click **Run**, and then type **cmd** and press **Enter**.
2. Type **hisssomig –import –key <key> -input <XML file>**

   where <key> is the full path of the file containing the encryption key, and <XML file> is the full path of the XML file from which the data will be imported.

   For example:

   ```
   hisssomig –import –key Z:\hostseckey.bak -input c:\hostsecdb.xml
   ```

3. Press **Enter**.

Other commands for Migration Utility

The following is a list of commands for the Migration Utility. These commands are also displayed during migration if you attempt to run the utility with incorrect data.

Command	Comment
-servername	Name of server that holds the HIS 2000 Host Security primary host account cache database.
-dbfile	Full path of the SNA 4.0 Host Security database file.
-key	Full path of the file containing the encryption key.
-username	User name used for encryption.
-password	Password for the username used for encryption.
-output	Full path of the XML file to which the data will be exported.
-input	Full path of the XML file from which the data will be imported.
-log	Creates migration log in the directory specified. For example: -log c:SSO\log

Upgrading from a Previous Version of SSO

If you are installing the Enterprise Single Sign-on feature and you already have a previous version deployed on your computer (for example, from Host Integration Server 2004 Beta, or Microsoft BizTalk® Server 2004), you must complete the steps below.

- Back up the SSODB to a secure location
- Back up the master secret key on the master secret server
- Update the master secret server by running Host Integration Server 2004 setup, choosing **Custom Installation**, and then selecting **Enterprise Single Sign-On**. Select **Reuse** when the Configuration Wizard prompts you with the question: Do you want to reuse the existing configuration?

It is not necessary to update the other SSO Servers (non-master secret servers) from your BizTalk Server 2004 installation. However, if you want the new Enterprise Single Sign-On features to be available on those servers, you must update them by using the same procedures outlined above.

If you have a Beta version of Enterprise SSO installed as part of a Host Integration Server 2004 Beta release, you can use the same mechanism to upgrade those servers.

> **Note** These considerations also apply if you are installing Microsoft BizTalk Server 2004 on a computer with an existing installation of Host Integration Server 2004 Enterprise Single Sign-On, and wish to update the servers.

Using Host Initiated SSO functionality in Enterprise Single Sign-On

Host Initiated Single Sign-On uses the protocol transition feature of Windows Server 2003 to perform Single Sign-On for the non-Windows user. This feature requires Windows Server 2003 and must be in a domain that has its **Domain Functional Level** set to **Windows Server 2003**.

See Also

- Upgrading from Host Integration Server 2000 or SNA Server 4.0

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Processing Servers for Enterprise Single Sign-On

In a multi-box environment, after the master secret server and Credential database have been created, you can install Enterprise Single Sign-On on subsequent computers. These are typically the computers on which Host Integration Server 2004 is installed as well.

The initial installation process is the same as on the first computer. Configuration, however, becomes slightly different. Since the master secret server and the SSO credential database are already in place, select **Join** when the Configuration Wizard asks, Do you want to create a new SSO system or join an existing SSO system?

See Also

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Standard Installation Options

Host Integration Server 2004 leverages the Enterprise Single Sign-On (SSO) capabilities for securely storing critical information.

By default, Enterprise Single Sign-On is not installed with the rest of Host Integration Server 2004. You can install it by following the procedure below.

> **Note** When Enterprise Single Sign-on (Server component) is installed, configuration needs to performed. The first step to set up an SSO System is to configure the master secret server. It is recommended to set up a stand-alone master secret server. This can be done by only selecting Enterprise Single Sign-on from the custom feature tree in Host Integration Server 2004 setup.

To install Enterprise Single Sign-On

- Insert your Host Integration Server 2004 CD and re-run the setup program. Select **Custom Installation**, and then select the appropriate option from the list below:

When running the HIS Server package, you have the following options:

- **Enterprise Single Sign-On Server** A credential database to store mappings of Windows user identities to credentials for line of business applications. Also provides services to enable components to securely access this data to enable Single Sign-On.
- **Enterprise Single Sign-On Server with Password Synchronization** A credential database to store mappings of Windows user identities to credentials for line of business applications. Also provides services to enable components to securely access this data to enable Single Sign-On, as well as the Password Synchronization feature.
- **Enterprise Single Sign-On Administration** Administration and client tools for mapping and connecting to Enterprise Single Sign-On Services.

When running the HIS Client package, you have the following options:

- **Enterprise Single Sign-On Administration** Administration and client tools for managing and connecting to Enterprise Single Sign-On Services.
- **Enterprise Single Sign-On Client** Client tools for end users to manage their mappings.

Installing the Enterprise Single Sign-On Administration Component

Installing the Enterprise Single Sign-On Client Utility

High-Availability Installation Options

Removing Enterprise Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Installing the Enterprise Single Sign-On Administration Component

It is possible to install the Enterprise Single Sign-On Administration component as a stand-alone feature. This is useful if you need to administer the SSO system remotely. The hardware and software requirements are the same as for a typical ESSO installation.

After installing the administration component, you will need to use ssomanage.exe to specify the SSO Server to be used for management. Both processes are included in the procedure below.

> **Note** While the SSO Administration feature in Host Integration Server 2004 is compatible with the server version of SSO in BizTalk Server 2004, the administrative components of Enterprise SSO in BizTalk Server 2004 are not compatible with the server version of Enterprise SSO in Host Integration Server 2004.

Installing the SSO administrative utility (ssomanage.exe) does not create shortcuts on the Start menu to access the command line utilities. To run the SSO administrative utilities after installation, you must open a command prompt and navigate to the SSO directory located at Program Files\Common Files\Enterprise Single Sign-On.

To install the Enterprise Single Sign-On administrative component

1. Perform a custom installation of Host Integration Server 2004, selecting only the Enterprise Single Sign-On administration component.
2. When the install program finishes, go to the **Start** menu, click **run**, and then type **cmd**.
3. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage –server** to specify the SSO Server you want to connect to when performing administration operations.

   OR

5. Type **ssomanage -serverall** to specify the SSO Server all users of this computer will connect to when performing administration operations.

Installing the Enterprise Single Sign-On Client Utility

Configuring Enterprise Single Sign-On

Installing Enterprise Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Installing the Enterprise Single Sign-On Client Utility

The stand-alone SSO client utility (ssoclient.exe) allows end users to configure their client mappings in the credential database. You can install the client utility from a self-extracting file (SSOClientInstall.exe) which is installed with the SSO administration feature. Administrators can also make the installer package available to client users by placing a copy of the installer package on a network share.

To install the SSO client utility, you must be running one of the following operating systems on the client computer:

- Windows Server 2003
- Windows 2000 Server with Service Pack 4, or Windows XP Professional with Service Pack 1
- .NET Framework 1.1 (only necessary for the managed interoperability component of the SSO client utility)

Installing the SSO client utility does not create shortcuts on the Start menu to access the command line utilities. To run the SSO client utility after installation, you must open a command prompt and navigate to the SSO directory located at Program Files\Common Files\Enterprise Single Sign-On.

To install the SSO client utility

1. Double-click the installer package SSOClientInstall.

   > **Note** Ask your Enterprise Single Sign-On Administrator for the location of this file in your enterprise.

   The **WinZip Self-Extractor** program appears.

2. Select the folder where you want to unzip the files, and click **Unzip**.

   It is recommended to unzip the files in a temporary folder.

   The **Enterprise Single Sign-On Client Setup** program appears.

3. On **the Welcome to the Enterprise Single Sign-On Client** page, click **Next**.
4. On the License Agreement page, click **I accept the terms of this license agreement**, and then click **Next**.
5. On the **User Information** page, type your user name, organization name, and then click **Next**.
6. On the **Start Installation** page, click **Install**.
7. On the **Completing the Enterprise Single Sign-On Client Wizard** page, click **Finish**.

Installing Enterprise Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

High-Availability Installation Options

Topics in this section describe installation focused on high availability of Enterprise Single Sign-On, such as multi-computer deployment.

This section contains:

Clustering the Master Secret Server

Clustering the SQL Server

Configuring Enterprise Single Sign-On in a Multi-Computer Scenario

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Clustering the Master Secret Server

It is strongly recommended that you follow the instructions in this section to cluster the Enterprise Single Sign-On (SSO) service on the master secret server successfully.

Before you start configuring SSO in a cluster environment, it is recommended that you understand how clustering works. For more information, see http://go.microsoft.com/fwlink/?LinkId=33180.

When you cluster the master secret server, the Single Sign-On Servers communicate to the active clustered instance of the master secret server. Similarly, the active clustered instance communicates with the Credential database.

You must be an SSO administrator to perform this procedure.

> **Caution** You cannot install the master secret server on a Network Load Balancing (NLB) cluster.

To cluster the master secret server

1. Perform a custom installation to install the master secret server on the first node of the cluster (for example, ClusterNode1).
2. In the **Configuration Wizard**, on the **Configuration Questions** page, in the **Is this the master secret server?** drop down list, select **Yes**, and then click **Next**.
3. Specify the service account credentials for SSO service. This must be a member of the SSO Administrators group account.
4. Specify the location of the SQL Server and SSO Credential database (SSODB).
5. Back up the master secret on the active node.
6. Perform a custom installation to install the master secret server on the second node of the cluster (ClusterNode2).
7. Use the **Configuration Wizard** to configure an Enterprise SSO Server on the second node of the cluster. This time, however, select **No** when you reach the question in Step 2. However, as this is not the initial installation of the master secret server. Click **Next**, and then complete the **Configuration Wizard**.
8. Stop the SSO service by typing **net stop entsso** at the command line.
9. Change the master secret server name in the SSO credential database to the cluster name. For example, if the cluster is named MSS_CLUSTER, change the name from ClusterNode1 to MSS_CLUSTER.
10. Use a text editor to copy and paste the following code into an .xml file (for example: MSS CLUSTER.xml) and save the file:

```
<sso>
  <globalInfo>
     <secretServer>MSS_CLUSTER</secretServer>
</globalInfo>
   </sso>
```

11. At the command line, navigate to the Enterprise Single Sign-On installation directory. The default is Program Files\Common Files\Enterprise Single Sign-On.
12. Type **ssomanage -updatedb <filename>** where filename is the name of the .xml file in the previous step. This updates the master secret server name in the database.

    Ignore any runtime errors. The Microsoft Distributed Transaction Coordinator (DTC) was not configured to run on a cluster, and may be unable to start.

13. Open a command line on master secret server 1 and type **comclust -a**.
14. From the **Services** console, right-click **Distributed Transaction Coordinator**, and then click **Restart**.
15. Open a command line on master secret server 2 and type **comclust -a**.
16. From the **Services** console, right-click **Distributed Transaction Coordinator**, and then click **Restart**.
17. Open **Cluster Administrator**, and then click the cluster group that has the master secret server cluster.
18. On the **File** menu, point to **New**, and then click **Resource**.

    The New Resource window opens.

    Under **Name**, type the name of the SSO resource (for example, **ENTSSO**).

    Under **Resource Type**, select **Generic Service**.

19. On the **Possible Owners** window, include each cluster node as a possible owner of the ENTSSO resource.
20. After you create the **ENTSSO** resource, right-click **ENTSSO**, and click **Properties**.

21. In the **Cluster Properties** dialog box, click the **Security** tab, and verify that the user under which the application is running has sufficient user rights (not a local administrator) to access the cluster.
22. Open **Cluster Administrator**, right-click the cluster group that has the master secret server cluster, and then click **Move group**. This moves the master secret server resources from the first node to the second node.
23. On the **Start** menu, click **run**, and then type **cmd**.
24. At the command line prompt, navigate to the Enterprise Single Sign-On installation directory. The default is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
25. Type **ssoconfig -restoresecret <*restore file*>**, where <*restore file*> is the path and name of the back-up file that contains the master secret.

Clustering the SQL Server

For information on clustering the SQL Server, see your SQL Server documentation.

Configuring Enterprise Single Sign-On in a Multi-Computer Scenario

This section contains instructions for configuring Enterprise Single Sign-On (SSO) in a three-computer scenario.

In the following scenario, computer A is the master secret server, computer B is the Single Sign-On server, and computer C holds the Credential database. Computer B can act as a runtime server, as an administration server (administration sub services of SSO use this server for managing the Credential database), or as a mapping server (administration and client sub services of SSO use this server to manage mappings).

1. If you want to add more SSO servers to your environment, follow the steps for configuring computer B. Any new SSO servers will point to the existing Credential database, and cannot be the master secret server.

   Note It is recommended that you configure the master secret server on a different computer from the Single Sign-On server and the Credential database.

To configure the master secret server and create the Credential database on Computer A

1. Perform a custom installation of Host Integration Server 2004, and install only the Enterprise Single Sign-On runtime component.
2. Run the Configuration Wizard to configure SSO on the master secret server. On the **Configuration Questions** page, in the **Is this the master secret server** drop down list, select **Yes,** and then click **Next.**
3. On the **Windows Accounts** page, specify the service account credentials for the SSO service. This must be a member of the SSO Administrators group.
4. On the **Database Configurations** page, specify the location of the SQL Server (computer C) and the name of the Credential database (SSODB).
5. Back up the master secret. For more information, see Backing Up the Master Secret.

To configure the SSO server on Computer B

1. Install Enterprise Single Sign-On on Computer B.

   Note This can be a Host Integration Server computer, or an SSO-only server (SSO runtime components.)

2. Run the Configuration Wizard to configure SSO. On the **Configuration Questions** page, in the **Is this the master secret server** drop down list, select **No**, and then click **Next**.
3. On the **Windows Accounts** page, specify the service account credentials for the SSO service. This must be a member of the SSO Administrators group.
4. On the **Database Configurations** page, point to the location of the SQL Server (computer C) and the name of the Credential database (SSODB).

Clustering the Master Secret Server

Installing Enterprise Single Sign-On

Removing Enterprise Single Sign-On

If you remove Host Integration Server 2004, Enterprise Single Sign-On (SSO) is no longer configured, but it is not removed. You must remove SSO separately. You can also restore configuration information including the master secret to reuse existing data. For more information, see Restoring the Master Secret.

To remove Enterprise Single Sign-On

1. Back up the master secret key. For more information, see Backing Up the Master Secret.
2. Uninstall Host Integration Server 2004.
3. On the **Start** menu, point to **Settings**, and then click **Control Panel**.
4. Click **Add/Remove Programs**.
5. In the **Add/Remove Programs** dialog box, click **Microsoft Enterprise Single Sign-On**, and then click **Remove**.
6. Click **Yes** when prompted to confirm the removal of Microsoft Enterprise Single Sign-On.

> **Note** If you have BizTalk Server Runtime, Development, or Administration features installed, or Host Integration Server Administration features installed, you will not be able to uninstall the SSO Runtime or Administration components until all dependencies are removed.

Unattended Installation and Uninstallation

> **Note** You will need the original installation media to perform unattended installs or uninstalls of Single Sign-On Server or Client versions.

For information on unattended installation and uninstallation, see Installing the Product.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Using Enterprise Single Sign-On

You use ssomanage, the Single Sign-On management utility, to update the Credential database, to add, delete and manage applications, and to administer user mappings.

Only Single Sign-On Administrators can perform these tasks.

This section contains:

- Setting the Enterprise Single Sign-On Server
- Enabling Enterprise Single Sign-On
- Changing the Master Secret Server
- Disabling Enterprise Single Sign-On
- Updating the Credential Database
- Displaying the Credential Database Information
- Configuring the Enterprise Single Sign-On Tickets
- Auditing Enterprise Single Sign-On
- Enabling SSL for Enterprise Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Setting the Enterprise Single Sign-On Server

Each time you use ssomanage, you must first point the user to the Single Sign-On server you want to connect to.

You can do this in one of two ways:

- Individual users can point themselves to the correct Single Sign-On Server.
- A local computer administrator for the Single Sign-On server can point all the members of the Single Sign-On Users account to this server.

To set the Enterprise Single Sign-On Server for a single user

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –server <*Single Sign-On Server*>**, where <*Single Sign-On Server*> is the computer name of the Single Sign-On Server the user wants to connect to.

To set the Enterprise Single Sign-On Server for all users

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –serverall <*Single Sign-On Server*>**, where <*Single Sign-On Server*> is the computer name of the Single Sign-On Server all members of the Single Sign-On Users account will be pointed to.

To determine the Enterprise Single Sign-On Server to which a user is connected

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –showserver**.

   Note This command displays the settings for the current user as well as for other users if they exist.

Enabling Enterprise Single Sign-On

Disabling Enterprise Single Sign-On

Displaying the Credential Database Information

Using Enterprise Single Sign-On

Enabling Enterprise Single Sign-On

This command enables the entire Enterprise Single Sign-On (SSO) system.

After you run the enabling command, there is a short delay before all Single Sign-On Servers are enabled, as each polls the Credential database for the latest global information.

If you want to configure affiliate applications and mappings in the SSO system, you must also create an affiliate application. After an SSO affiliate administrator creates an affiliate application, an application administrator can make changes to it, and application users (end-users) can create their own mappings. For more information, see Managing Affiliate Applications and Managing User Mappings.

To enable the SSO system

1. Click **Start**, click **run**, and then type **cmd**.
2. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –enablesso**.

To enable SSO to create affiliate applications and mappings

1. Log on as an SSO administrator or SSO affiliate administrator to the SSO Server, or on a computer that has the SSO administration sub services of SSO.
2. On the **Start** menu, click **run**, and then type **cmd**.
3. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage -enablesso** to enable the Enterprise Single Sign-On service.
5. Log on as an SSO affiliate administrator.
6. Type **ssomanage -createapps <*application file*>** to create an affiliate application, where <application file> is the XML file that contains definitions for the affiliate applications.

Disabling Enterprise Single Sign-On

Updating the Credential Database

Using Enterprise Single Sign-On

Changing the Master Secret Server

After you set up the master secret server and configure the Credential database, you can change the master secret server if the original master secret server fails and cannot be recovered. To change the master secret server, you need to promote an SSO server to become the master secret server.

To promote a Single Sign-On Server to master secret server

1. Create an XML file that includes the name of the SSO server you want to promote to master secret server. For example,

```
<sso>
  <globalInfo>
     <secretServer>SSO Server name</secretServer>
  </globalInfo>
</sso>
```

2. On the **Start** menu, click **run**, and then type **cmd**.
3. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage –updatedb** <***update file***>, where <*update file*> is the name of the XML file you create in step 1.
5. Restart the Master Secret Server.
6. Type **ssoconfig –restoresecret <*restore file*>**, where <*restore file*> is the path and name of the file where the master secret is stored.

Using Enterprise Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Disabling Enterprise Single Sign-On

This command disables the entire Single Sign-On system.

There will be a short delay for all Single Sign-On Servers to be disabled, as they poll the Credential database for the latest global information.

To disable Enterprise Single Sign-On

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –disablesso**.

Enabling Enterprise Single Sign-On

Using Enterprise Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Updating the Credential Database

You use the commands described in this section to change the global information in the Credential database, such as the master secret server identification, the account names, auditing in the database, ticket timeout, credential cache timeout, and so on.

Changing timeouts for the SSO System

You can modify two timeouts at the Enterprise Single Sign-On (SSO) system level:

Ticket timeout. This property specifies the length of time for which a ticket SSO issues is valid. To satisfy most of the scenarios in an enterprise that use SSO, the default ticket timeout is 2 minutes. The SSO administrator can change this based on the application requirements.

Credential Cache timeout. This property specifies the credential cache timeout for all SSO Servers. SSO Servers cache the credentials after the first lookup. By default, the credential cache timeout is 60 minutes. The SSO administrator can change this to a suitable value based on the security requirements.

You change both of these timeouts by updating the Credential database.

A sample XML file for updating the Credential database is:

```
<sso>
<globalnfo>
<ssoAdminAccount>Domain\Accountname</ssoAdminAccount>
<ssoAffiliateAdminAccount>Domain\Accountname</ssoAffiliateAdminAccount>
<secretServer>ComputerA</secretServer>
<auditDeletedApps>1000</auditDeletedApps>
<auditDeletedMappings>1000</auditDeletedMappings>
<auditCredentialLookups>1000</auditCredentialLookups>
<ticketTimeout>2</ticketTimeout>
<credCacheTimeout>60</credCacheTimeout>
</globalInfo>
</sso>
```

To update the Credential database

1. Click **Start**, click **run**, and then type **cmd**.
2. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –updatedb <*update file*>**, where <*update file*> is the path and name of the file.

Displaying the Credential Database Information

You can view credential database information by using the ssomanage command.

To display the Credential database information

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –displaydb**.

To display the Credential database the SSO Server is connected to

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –showdb**.

The following table describes the values displayed by these procedures.

Property	**Value**
SQL Server	*<SQL Server name>*
SQL Server database	*<SQL Server database name>*
Single Sign-On Secret Server name	*<Single Sign-On Server name>*
Single Sign-On Administrators account	Domain\account name
Single Sign-On Affiliate Administrators account	Domain\account name
Size of audit table for deleted applications (number of audit entries)	1000 (default)
Size of audit table for deleted user mappings (number of audit entries)	1000 (default)
Size of audit table for external credential lookups (number of audit entries)	1000 (default)
Ticket timeout (in minutes)	2 (default) This value can be an integer between 1 to 525600
Credential cache timeout (in minutes)	60 (default)
Single Sign-On Status	Enabled/disabled
Tickets allowed	Yes/no (default)
Validate tickets	Yes (default)/no

Configuring the Enterprise Single Sign-On Tickets

Using Enterprise Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring the Enterprise Single Sign-On Tickets

You use this command to control ticket behavior for the entire Single Sign-On system, including whether to allow tickets, and whether the system must validate the tickets. For more information about tickets and tickets validation, see SSO Tickets.

To configure the Enterprise Single Sign-On tickets

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –tickets <*allowed yes/no*> <*validate yes/no*>**, where <*allowed yes/no*> indicates whether tickets will be allowed or not, and <*validate yes/no*> indicates whether tickets will need to be validated after they are redeemed.

> **Note** You can use yes, no, on, or off to indicate whether to allow and/or validate tickets. These words are case independent, and must be used regardless of your language settings.

Understanding Enterprise Single Sign-On

Using Enterprise Single Sign-On

Auditing Enterprise Single Sign-On

Use this command to set both the positive and negative auditing levels.

SSO administrators can set the positive and negative audit levels that suit their corporate policies. You can set positive and negative audits to one of the following levels:

0 = None

1 = Low

2 = Medium

3 = High. This level issues as many audit messages as possible.

The default value for positive auditing is 0 (none), and the default value for negative auditing is 1(low).

> To change the database level auditing, you must update the Credential database using an XML file. A sample XML file for updating the Credential database is:

```
<sso>
<globalnfo>
<auditDeletedApps>1000</auditDeletedApps>
<auditDeletedMappings>1000</auditDeletedMappings>
<auditCredentialLookups>1000</auditCredentialLookups>
</globalInfo>
</sso>
```

To audit Single Sign-On

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoconfig –auditlevel <** ***positive level*****> <*****negative level*****>**, where <*positive level*> is the level of auditing when actions succeed, and <*negative auditing*> is the level of auditing when actions fail.

To audit the Credential database

1. Click **Start**, click **run**, and then type **cmd**.
2. At the command line prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –updatedb <*****update file*****>**, where <*update file*> is the path and name of the file.

Managing the Master Secret

The master secret is the key used to encrypt all the information stored in the Credential database. If the master secret server crashes and you lose the secret, you will not be able to retrieve the information stored in the Credential database. Therefore, it is very important to back up the master secret as soon as you generate it.

This section contains:

- Generating the Master Secret
- Backing Up the Master Secret
- Restoring the Master Secret

Generating the Master Secret

You must have administrator rights on the master secret server in order to perform this task. In addition, you must perform this task from the master secret server.

The first server where you install Enterprise Single Sign-On becomes the master secret server.

> **Important** There can be only one master secret server in your SSO system.
>
> **Note** When Enterprise Single Sign-On is installed as part of the Host Integration Server 2004 installation, the master secret is generated as part of the Configuration Wizard. You will only need to perform this task if you want to generate a new master secret.

To generate the master secret

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoconfig –generatesecret <*backup file*>**, where <*backup file*> is the name of the file that contains the master secret.

   You will be prompted to enter a password to protect the file you just created.

Master Secret Server

Managing the Master Secret

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Backing Up the Master Secret

You can back up the master secret from the master secret server onto an NTFS file system or removable media, such as a floppy disk.

You must be a Single Sign-On Administrator and a Windows administrator to perform this task. The SSO system will prompt you for a password. To restore the secret later, you must specify the same password.

> **Warning** If the master secret server crashes and you lose the key, or if the key becomes corrupted, you will not be able to retrieve data stored in the Credential database. You must back up the master secret, or you risk losing data from the Credential database.

To back up the master secret

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssoconfig –backupsecret <*backup file*>**, where <*backup file*> is the path and name of the file where the master secret will be backed up. For example, A:\ssobackup.bak
5. Provide a password to protect this file. You will be prompted to confirm the password and to provide a password hint to help you remember this password.

> **Important** You must save and store the backup file in a secure location.

Specifying Single Sign-On Administrators and Affiliate Administrators Accounts

The Enterprise Single Sign-On (SSO) Administrators and Affiliate Administrators accounts can be host group or individual accounts. You must create these accounts before you configure the SSO system.

When using domain accounts, you must create the SSO Administrators and SSO Affiliate Administrators accounts as a domain global security groups in the domain controller. The domain administrator must create these accounts.

You must specify the Single Sign-On Administrators and Affiliate Administrators accounts in the Credential database. You must disable the Single Sign-On system before you update the Credential database with the SSO Administrators group.

The following XML code shows a sample XML for updating the Credential database:

```
<sso>
<globalInfo>
<ssoAdminAccount>Domain\Accountname</ssoAdminAccount>
<ssoAffiliateAdminAccount>Domain\Accountname</ssoAffiliateAdminAccount>
</globalInfo>
</sso>
```

Note The Configuration Wizard automatically specifies the SSO administrator and SSO affiliate administrator groups in the Credential database.

To disable the Enterprise Single Sign-On system

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage** –**disablesso**.

To update the Credential database

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –updatedb <*update file*>**, where <*update file*> is the path and name of the XML file.

To enable the Enterprise Single Sign-On system

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –enablesso**.

Managing Affiliate Applications

This section provides information on how to create and configure affiliate applications.

This section contains:

- Creating an Affiliate Application
- Deleting an Affiliate Application
- Updating the Properties of an Affiliate Application
- Enabling an Affiliate Application
- Disabling an Affiliate Application
- Listing Affiliate Applications
- Listing the Properties of an Affiliate Application
- Clearing the Application Cache
- Setting the Enterprise Single Sign-On Server Using the Client Utility
- Displaying the Enterprise Single Sign-On Server Using the Client Utility
- Setting Credentials for the Affiliate Application Using the Client Utility

Creating an Affiliate Application

Use this command to create one or more applications, as specified by the XML file. An example XML file for Windows Initiated SSO is:

```
<sso>
<application name="SAP">
<description>The SAP application</description>
<contact>someone@example.com</contact>
<appuserAccount>domain\AppUserAccount</appuserAccount>
<appAdminAccount>domain\AppAdminAccount</appAdminAccount>
<field ordinal="0" label="User Id" masked="no" />
<field ordinal="1" label="Password" masked="yes" />
<flags groupApp="no" configStoreApp="no" allowTickets="no" validateTickets="yes" allowLocalAc
counts="no" timeoutTickets="yes" adminAccountSame="no" enableApp="no" />
</application>
</sso>
```

After you create an affiliate application, you cannot modify the following properties:

- Name of the affiliate application
- Fields associated with the affiliate application
- Affiliate application type (host group, individual, or configuration store)
- Administration account same as affiliate administrators group. (Specifying this flag will always use the affiliate administrators group as the administrator account for this affiliate application)

  Important You can use local accounts for the administration account and user account by setting the allowLocalAccounts flag to yes. However, you should only use this flag in single-computer scenarios.

  Security You must be an SSO administrator or SSO affiliate administrator to perform this task.

After you create the affiliate application, you must enable it. For more information, see Enabling an Affiliate Application.

To create an affiliate application

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –createapps <*application file name*>**, where <*application file name*> is the XML file.

Deleting an Affiliate Application

Use this command to delete the specified affiliate application from the Credential database.

> **Important** When you delete an affiliate application, the SSO system automatically deletes all mappings associated with it.

> **Security** You must be an SSO administrator or SSO affiliate administrator to perform this task.

To delete an affiliate application

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –deleteapp <*application name*>**, where <*application name*> is the name of the affiliate application you want to remove from the Credential database.

Managing Affiliate Applications

Updating the Properties of an Affiliate Application

Use this command to update one or more application properties, as specified by the XML file. You must be an Affiliate Administrator to perform this task. The following is an example XML file that lists the fields you can update.

```
<SSO>
<application name="SSOApplication">
<description>An SSO Application</description>
<contact>someone@companyname.com</contact>
<appUserAccount>DomainName\AppUserGroup</appUserAccount>
<appAdminAccount>DomainName\AppAdminGroup</appAdminAccount>
<flags allowTickets="no" validateTickets="yes"  timeoutTickets="yes" enableApp="no" />
</application>
</SSO>
```

After you create an affiliate application, you cannot modify the following properties:

- Name of the affiliate application
- Fields associated with the affiliate application
- Affiliate application type (host group, individual, or configuration store)
- Administration account same as affiliate administrators group. (Specifying this flag will always use the affiliate administrators group as the administrator account for this affiliate application)

  Important You can use local accounts for the administration account and user account by setting the allowLocalAccounts flag to yes. However, you can only use this flag in single-computer scenarios.

  Security You must be an SSO administrator, SSO affiliate administrator, or application administrator to perform this task.

  Security You must be an SSO administrator to modify the ticketing flags (validateTickets and timeoutTickets.)

  Security You must be an SSO administrator or an SSO affiliate administrator to modify the application administration account.

To update the properties of an affiliate application

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –updateapps <*application file name*>**, where the application file name is the XML file.

Listing Affiliate Applications

Use this command to list all the affiliate applications. If the user is a member of the Application Administrators account, this command will only display the application for which the user is an administrator.

To list affiliate applications using the administration utility

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -listapps [all]** where **all** is an optional parameter that will also display applications using the Configuration Store feature. If the user running this command is an Application administrator, it will only list the applications for which they are an administrator. If the user running this command is an Affiliate Administrator or an SSO Administrator, it will list all the affiliate applications.

To list affiliate applications using the client utility

1. 1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. 3. Type **ssoclient –listapps** to list the affiliate applications. This will list only the affiliate applications that the user performing this task is a member of, i.e., they need to belong the application user group account for that affiliate application.

Managing User Mappings

This section provides information on how to create and configure the Enterprise Single Sign-On mappings.

Administrators use the ssomanage utility to manage mappings, while the application users use the ssoclient utility to manage their mappings.

> **Note** Application administrators can manage mappings associated with affiliate application for which they are an administrator, while SSO affiliate administrators and the SSO administrators can manage all mappings associated with all affiliate applications.

This section contains:

- Listing User Mappings
- Creating User Mappings
- Deleting User Mappings
- Setting Credentials for a User Mapping
- Enabling a User Mapping
- Disabling a User Mapping

Listing User Mappings

Use this command to list all the existing mappings for the specified user.

You must be an SSO administrator, application administrator, SSO affiliate administrator, or user to do this task.

Enabled user mappings appear as (E) <*domain*>\<*username*>, while disabled user mappings appear as (D) <*domain*>\<*username*>.

To list user mappings using the administration utility

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –listmappings <*domain*>\<*username*>** to list all the mappings a given user has in the affiliate applications he/she belongs to, where <*domain*> is the Microsoft® Windows® domain for the user account, and <*username*> is the Windows user name for which you want to list the user mappings. If the user is an Affiliate Administrator or an SSO Administrator, this command will list all the mappings for that user in all the affiliate applications.

   Or

4. Type **ssomanage –listmappings <*application name*>** to list all the user mappings for a given application.

   Or

5. If you are an application administrator, type **ssomanage –listmappings <*domain*>\<*username*> <*application name*>** to list all the mappings a given user has in the affiliate applications for which you are an administrator.

To list user mappings using the client utility

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoclient –listmappings** to list all the mappings you have..

Managing User Mappings

Creating User Mappings

Use this command to create one or more user mappings, as specified in the XML file. The following is an example XML file.

```
<sso>
<mapping>
<windowsDomain>domain</windowsDomain>
<windowsUserId>WindowsUserName</windowsUserId>
<externalApplication>Application name1</externalApplication>
<externalUserId>App1UserName</externalUserId>
</mapping>
<mapping>
<windowsDomain>domain</windowsDomain>
<windowsUserId>WindowsUserName</windowsUserId>
<externalApplication>Application name2</externalApplication>
<externalUserId>App2UserName</externalUserId>
</mapping>
</sso>
```

If a user account is changed, you must use this command create a mapping for the new user account. You should also remove the old user mapping. For more information about removing a mapping, see Deleting User Mappings.

After you create a user mapping, you must enable it before you can use this mapping in the SSO system. For more information, see Enabling a User Mapping.

> **Important** Only domain groups are supported for user mappings

To create user mappings using the administration utility

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –createmappings <*mappings file name*>**, where <*mappings file name*> is the name of file that contains the user mapping(s) you want to create.

To create user mappings using the client utility

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoclient –setcredentials <*application name* >**, where <*application name* > is the name of affiliate application that the user wants to create a mapping for.

To create user mappings using the administration utility for host initiated SSO

1. If the affiliate application is used only for host initiated SSO, then there are

Deleting User Mappings

Use these commands to delete one or more user mappings, as specified in the XML file. The following is an example XML file.

```
<sso>
<mapping>
<windowsDomain>domain</windowsDomain>
<windowsUserId>WindowsUserName</windowsUserId>
<externalApplication>Application name1</externalApplication>
<externalUserId>App1UserName</externalUserId>
</mapping>
<mapping>
<windowsDomain>domain</windowsDomain>
<windowsUserId>WindowsUserName</windowsUserId>
<externalApplication>Application name2</externalApplication>
<externalUserId>App2UserName</externalUserId>
</mapping>
</sso>
```

If a user is not a member of the Application Users account, or does not exist in Active Directory, you should use this command to remove the user mapping from the Credential database.

If a user account is changed, you must use this command to remove the old user mapping, and then create a new user mapping for the new user account. For more information about creating a mapping, see Creating User Mappings.

To delete user mappings using the administration utility

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –deletemappings <*mappings file name*>**, where <*mappings file name*> is the name of the file that contains the user mapping(s) you want to delete.

To delete a specific user mapping using the administration utility

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –deletemapping <*domain*>\<*username*> <*application name*>**, where <*domain*> is the Windows domain for the user account, <*username*> is the Windows user name, and <*application name*> is the specific application for which you want to remove the user mapping.

To delete a user mapping using the client utility

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoclient –deletemapping <*application name*>**, where <*application name*> is the name of the affiliate application you want to remove the user mapping for.

Setting Credentials for a User Mapping

Use this command to set the credentials for a user to access a specific application.

This command does not display the password as you type it.

If the user mapping already exists, this command sets the credentials for that existing mapping. If you have not created the user mapping, the SSO system will prompt you for the user ID for the application.

To set credentials for an user mapping

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –setcredentials <*domain*>\<*username*> <*applicationname*>**, where <*domain*> is the Windows domain for the user account, <*username*> is the Windows user name, and <*applicationname*> is the specific application for which you want to set the credentials for.
4. When the SSO system prompts you for the user credentials, enter the user password for this application.
5. If you have not created the user mapping, the SSO system will prompt you for the user ID for the application.

To set credentials for a user mapping from client utility

1. On the **Start** menu, click **run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoclient -setcredentials <*application name*>**, where <*application name*> is the name of the affiliate application you want to remove the user mapping for.

Managing User Mappings

Host Initiated Single Sign-On

Host initiated Single Sign-On enables a request from the host system to access a resource on a Windows system. The host system (for example, a RACF account) exists in a non-Windows environment and under the context of a non-Windows user. The Single Sign-On Credential Store maps host accounts to Windows accounts, enabling this access.

The following topics describe configuration specific to Host initiated SSO.

This section contains:

- Configuration Requirements for Host Initiated SSO
- Enabling and Disabling Host Initiated SSO
- Creating Affiliate Applications for Host Initiated SSO
- Validating Passwords for Host Initiated SSO
- Managing User Mappings for Host Initiated SSO
- Troubleshooting Host Initiated SSO

Configuration Requirements for Host Initiated SSO

Although Enterprise SSO and host initiated SSO have certain aspects in common, certain platform and Active Directory requirements are unique to host initiated SSO. This topic discusses those requirements, and lists the steps to check or create them on your system.

- Host initiated SSO can be executed only on a native Windows 2003 domain environment.
- The service account for SSO Service that is performing host initiated SSO must be configured to have TCB privileges. (You can configure this for the service account in the domain security policy.)

In addition, certain requirements are necessary when using Transaction Integrator for Host Initiated Processing. TI for HIP leverages host initiated SSO to achieve Single Sign-On for non-Windows users.

For example, service account for TI for HIP service runs under a service account domainname\hipsvc. This service can host applications that want to access remote or local resources on Windows with the Windows account that correspond to the non-Windows account.

The domainname\hipsvc account must belong to the Application Administrator group account for the Affiliate Application that is being used for Single Sign-On.

The domainname\hipsvc account must have constrained delegation privileges to use host initiated Single Sign-On. This can be configured by the domain administrator in Active Directory. Delegation can be configured for accounts that have registered SPNs. Constrained delegation allows the service account to access only components that are specified by the administrator.

To check your domain function level

1. In your **Active Directory Domains and Trusts** MMC snap-in, right click the node **Active Directory Domains and Trusts**, and then click **Raise Forest Functional Level**.
2. Verify that the functional level is **Windows Server 2003**. If it is not, refer to your Active Directory documentation before you attempt to change the setting.

To create an SPN

1. Download the **setspn** utility from the following location: http://go.microsoft.com/fwlink/?LinkId=33178 On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **setpsn -a hipsvc\computername.domain.com domain\hissvc**

   where **hipsvc\computername.domain.com** is the service that will perform the operation and the computer it is running on, and **domain\hissvc** is the service account for hipsvc.

After doing this, you can configure constrained delegation in Active Directory for this service account (domain\hissvc) to access the appropriate resource in the network.

To give TCB privileges for the SSO service account

- Under your **Domain Security Policy - Local Policies - User Rights Assignment**, add the SSO Service account to the **Act as part of operating system** policy.

  For more information on Kerberos Protocol Transition and Constrained Delegation, go to http://go.microsoft.com/fwlink/?LinkId=33232

Host Initiated Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Enabling and Disabling Host Initiated SSO

By default, host initiated Single Sign-On is not enabled in the Single Sign-On system, and must be enabled by the SSO Administrator.

To enable host initiated SSO

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage -enable hisso**.

Disabling SSO applies to the entire SSO system, and all operations related to host initiated SSO are turned off.

To disable host initiated SSO

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. 3Type **ssomanage -disable hisso** as appropriate.

Creating Affiliate Applications for Host Initiated SSO

You can define two types of applications:

- **Individual** There is a 1-1 relationship between Windows users and non-Windows users.
- **Host Group** Multiple non-Windows users can be mapped to the same Windows account.

To create an individual type affiliate application

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage –createapps <AffApp.xml>**, where AffApp.xml is the name of the xml file.

   A sample file is shown below:

```
<?xml version="1.0"?>
<SSO>
  <application name="SSOApp_Host1">
    <description>An Individual Type Affiliate Application for Host Initiated SSO</descrip
tion>
    <contact>someone@companyname.com</contact>
    <appUserAccount>DomainName\AppUserGroup_HISSO</appUserAccount>
    <appAdminAccount>DomainName\AppAdminGroup_HISSO</appAdminAccount>
    <field ordinal="0" label="User ID" masked="no" />
    <field ordinal="1" label="Password" masked="yes" />
    <flags hostInitiatedSSO="yes" validatePassword="yes" windowsInitiatedSSO="no" enableA
pp="yes" />
  </application>
</SSO>
```

To create a host group type affiliate application

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage –createapps <AffApp.xml>**, where AffApp.xml is the name of the xml file.

   A sample file is shown below:

```
<?xml version="1.0"?>
<SSO>
  <application name="SSOApp_HostGroupApp1">
    <description>A Group Type Affiliate Application for Host Initiated SSO associating mu
ltiple non-Windows user to a single Windows user account(DomainName\WindowsUserAccount1)<
/description>
    <contact>someone@companyname.com</contact>
    <windowsAccount>DomainName\WindowsUserAccount1</windowsAccount>
    <appAdminAccount>DomainName\AppAdminGroup_HISSO</appAdminAccount>
    <field ordinal="0" label="User ID" masked="no" />
    <field ordinal="1" label="Password" masked="yes" />
    <flags hostInitiatedSSO="yes" validatePassword="yes" groupApp="yes" enableApp="yes" /
>
  </application>
</SSO>
```

To create an affiliate application supporting both Windows initiated SSO and host initiated SSO

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage –createapps <AffApp.xml>**, where AffApp.xml is the name of the xml file.

   A sample file is shown below:

```
<?xml version="1.0" ?>
- <SSO>
- <application name="SSOApp1">
  <description>An Individual Type Affiliate Application for both Host Initiated SSO and Windows Initiated SSO</description>
  <contact>someone@companyname.com</contact>
  <appUserAccount>DomainName\AppUserGroup</appUserAccount>
  <appAdminAccount>DomainName\AppAdminGroup</appAdminAccount>
  <field ordinal="0" label="User ID" masked="no" />
  <field ordinal="1" label="Password" masked="yes" />
  <flags hostInitiatedSSO="yes" validatePassword="yes" windowsInitiatedSSO="yes" enableApp="yes" />
  </application>
  </SSO>
```

Host Initiated Single Sign-On

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Validating Passwords for Host Initiated SSO

When an affiliate application for host initiated SSO is created, password validation for the non-Windows user is enabled by default. This means when applications call SSO to obtain the Windows user token to access resources, they must provide the non-Windows user account and the non-Windows password. If the password does not match the password in the SSO credential database for that non-Windows user, access is denied. If necessary, the password validation feature can be disabled for the affiliate application. The password validation feature applies to both individual and host group type affiliate applications for host initiated SSO.

An example XML file for Individual type host initiated SSO affiliate application is:

```
<sso>
<application name="SAP">
<description>The SAP application</description>
<contact>someone@example.com</contact>
<appuserAccount>domain\AppUserGroupAccount</appuserAccount>
<appAdminAccount>domain\AppAdminGroupAccount</appAdminAccount>
<field ordinal="0" label="User Id" masked="no" />
<field ordinal="1" label="Password" masked="yes" />
<flags groupApp="no" hostInitiatedSSO=”yes” validatePassword=”yes” configStoreApp="no" allowTickets="no" validateTickets="yes" allowLocalAccounts="no" timeoutTickets="yes" adminAccountSame="no" enableApp="no" />
</application>
</sso>
```

In the case of individual applications for host initiated SSO, the appUserAccount is a group account that contains the list of Windows domain account users that have a 1:1 mapping with their corresponding non-Windows accounts.

An example XML file for host group type host initiated SSO affiliate application is:

```
<sso>
<application name="SAP">
<description>The SAP application</description>
<contact>someone@example.com</contact>
<appuserAccount>domain\AppUserAccount</appuserAccount>
<appAdminAccount>domain\AppAdminGroupAccount</appAdminAccount>
<field ordinal="0" label="User Id" masked="no" />
<field ordinal="1" label="Password" masked="yes" />
<flags groupApp="yes" hostInitiatedSSO=”yes” validatePassword=”yes” configStoreApp="no" allowTickets="no" validateTickets="yes" allowLocalAccounts="no" timeoutTickets="yes" adminAccountSame="no" enableApp="no" />
</application>
</sso>
```

In group applications for host initiated SSO, the appUserAccount must be an individual user account. It is this account that all non-Windows accounts are mapped to.

See Also

Host Initiated Single Sign-On

Managing User Mappings for Host Initiated SSO

Use the following procedures to create mappings, set credentials, and enable/disable mapping.

To create mappings in host initiated SSO

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage –createmappings <mapping file>**, where **mapping file>** is the name of the xml file.

   A sample mapping file is shown below:

   ```
   <SSO>
     <mapping>
       <windowsDomain>DomainName</windowsDomain>
       <windowsUserId>UserA</windowsUserId>
       <externalApplication>SSOApplication</externalApplication>
   <externalUserId>ExternalUserID that corresponds to UserA</externalUserId>
     </mapping>
   </SSO>
   ```

When the Validate Password feature is enabled for the affiliate application, it is necessary to set credentials, as follows:

To set credentials for individual type affiliate applications

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage -setcredentials <Windows account name> <application name>**.

To set credentials for host group type affiliate applications

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage -setcredentials <external account name> <application name>**.

To enable mappings for individual type affiliate applications

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage -enablemapping <Windows account name> <application name>**.

To disable mappings for individual type affiliate applications

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage -disablemapping <Windows account name> <application name>**.

To enable mappings for host group type affiliate applications

1. On the **Start** menu, click **Run**.

2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage -enablemapping <external account name> <application name>**.

To enable mappings for individual type affiliate applications

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage -disablemapping <external account name> <application name>**.

Troubleshooting Host Initiated SSO

The primary method of troubleshooting is tracing.

Tracing

Use the Trace command line utility to enable tracing in SSO.

> **Note** For the trace command to function, the file tracelog.exe must be in the following directory:
>
> <drive>:\Program Files\Common Files\Enterprise Single Sign-On
>
> You can download this file from the following location:
>
> http://go.microsoft.com/fwlink/?LinkId=33023

To use the trace utility

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **Trace –start –high** to set the tracing level to high and begin the trace.
5. Run the scenario with host initiated SSO.
6. Type **Trace –stop** to end the trace. A .bin file is generated in the directory above, which you can send to Microsoft for analysis.

Secure Deployment of Enterprise Single Sign-On

This section outlines a typical scenario for secure deployment of Enterprise Single Sign-On. For detailed procedures on the actions to take in SQL Server, see your SQL Server documentation.

This section contains:

- Deployment Overview
- Deployment Process

Deployment Overview

The system in this example is deployed over three domains, containing the following computers:

Domain ORCH.com

- ORCH domain controller
- HIS1, the HISSO server
- HIS2, the Master Secret Server
- HIS3, the Admin database

Domain SQL.com

- SQL domain controller
- SQL2, the SSO database

Domain HIS.com

- HIS domain controller
- HIS4 database

The key points defining this deployment are as follows:

- Domain ORCH.com and domain SQL.com have a two-way selective trust relationship.
- Domain ORCH.com is configured as native Windows 2003 Server functional level.
- All SSO services are running on an ORCH.com domain user account (Orch\SSOSvcUser). The user is configured to have access permission on the SQL2 machine in the SQL.com domain. The user is configured for protocol transition and constrain delegation within the ORCH.com domain.
- Another ORCH.com domain user (Orch\TestAppUser) is set for running test programs. This user is also configured for protocol transition and constrain delegation.

See Also

- Deployment Process

Deployment Process

The following steps give a high-level overview of secure deployment of Enterprise Single Sign-On. For detailed procedures on the actions to take in SQL Server, see your SQL Server documentation.

1. On the SQL Server domain controller, use the New Trust Wizard to create a trust with the following properties:
    - **Name:** ORCH.com
    - **Direction:** Two-way
    - **Sides:** This domain only
    - **Outgoing Trust Authentication Level - Local Domain:** Selective authentication
    - **Password:** Choose a password
    - **Confirm Outgoing Trust:** Yes
    - **Confirm Incoming Trust:** No
2. On the ORCH.com domain controller, use the New Trust Wizard to create a trust with the following properties:
    - **Name:** SQL.com
    - **Direction:** Two-way
    - **Sides:** This domain only
    - **Outgoing Trust Authentication Level - Local Domain:** Selective authentication
    - **Password:** Must be the same as password for ORCH.com
    - **Confirm Outgoing Trust:** Yes
    - **Confirm Incoming Trust:** No
3. On the ORCH.com domain controller, set the domain wide trust for Incoming from SQL.COM.
4. On the SQL.com domain controller, set the domain wide trust for Outgoing from ORCH.COM.
5. On the ORCH.com domain controller, raise the domain functional level to Windows Server 2003.
6. In the ORCH domain, create the following new users:
    - ORCH\SSOSvcUser
    - ORCH\TestAppUser
    - ORCH\AffAppUser
7. Add **Act as part of the operating system** to SSOSvcUser and TestAppUser.
8. Add **Allowed to Authenticate** privilege to ORCH\TestAdmin.
9. Add ORCH\SSOSvcUser to SQL2 in the SQL domain. (This step requires using Advanced View in Active Directory MMC.)
10. On the SQL2 computer, create the following two new logins:
    - ORCH\TestAdmin
    - ORCH\SSOSvcUser
11. On the SQL2 domain, create two domain global groups:
    - ORCH\SSOAdminGroup
    - ORCH\SSOAffAdminGroup
12. Add **Allowed to Authenticate** privilege to the ORCH\SSOAdminGroup group.
13. On the SQL2 database, create the following new login:
    - ORCH\SSOAdminGroup
14. Install the Master Secret Server as follows:
    - Log onto NTS5 using ORCH\TestAdmin.
    - Install ESSO, using SQL2 as the Master Secret Server.
15. Log onto HIS1 using ORCH\TestAdmin, and install Enterprise Single Sign-On. Configure ESSO as SSO join HIS2, using database server name SQL2.

16. Install the Enterprise Single Sign-On Admin utility on HIS3 using ORCH\TestAdmin.
17. Add the following users to the following groups:
    - Add ORCH\TestAppUser to ORCH\SSOAdminGroup
    - Add ORCH\AffAppUser to ORCH\TestAffUserGroup
18. Install SQL Server 2000a Enterprise on HIS3, and add login ORCH\AffAppUser.
19. On the HIS1 machine, open a command prompt and use the following commands to set constrain delegation and protocol transition:
    - **setspn -A MSSQLSvc/HIS3.ORCH.com:1433 ORCH\SSOSvcUser**
    - **setspn -A MSSQLSvc/HIS3.ORCH.com:1433 ORCH\TestAppUser**
20. On the **ORCH\SSOSvcUser** and **ORCH\TestAppUser** property pages, set the proper delegation for both user accounts by selecting the following options:
    - 3**Trust this user for delegation to specified services only**
    - **Use any authentication protocol**
21. Using ORCH\TestAdmin on the HIS1 computer, perform the following:
    - Add ORCH\TestAppUser to Remote Desktop User Group
    - Grant **Impersonate after authenticated** privilege to ORCH\SSOSvcUser
    - Grant **Impersonate after authenticated** privilege to ORCH\TestAppUser
22. Verify your deployment by logging onto HIS1 using ORCH\TestAppUser and running the following application configuration:

    Run LogonExternalUser Test.

```
<SSO>
   <application name="TestApp">
      <description>An SSO Test Affiliate Application</description>
      <contact>AffAppUser@ESSOV2.EBiz.Com</contact>
      <appUserAccount>ORCH\TestAffAdminGroup</appUserAccount>
      <appAdminAccount>ORCH\TestAffUserGroup</appAdminAccount>
      <field ordinal="0" label="User ID" masked="no" />
      <field ordinal="1" label="Password" masked="yes" />
      <flags
         groupApp="no"
         configStoreApp="no"
         allowTickets="no"
         validateTickets="yes"
         allowLocalGroups="yes"
         ticketTimeout="yes"
         adminGroupSame="no"
         enableApp="yes"
         hostInitiatedSSO="yes"
         validatePassword="yes"/>
   </application>
</SSO>
```

- Deployment Overview

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Password Synchronization

The purpose of Password Synchronization is to simplify administration of the SSO credential database, and to keep passwords in sync across user directories.

These two tasks are accomplished through the use of password synchronization adapters, and the topics in this section describe the command line utility for creating and managing those adapters.

There are three types of password synchronization sub-features.

The first type is **Windows to External** (for example, Active Directory to RACF). In this scenario, a Windows user's password change is captured and sent to the Enterprise SSO Server assigned to receive password changes from domain controllers. This then forwards the password change to an external system and the mapping in the SSO credential database is kept in sync with the change made on the external system.

The second type is **External to Windows - Full synchronization**. In this scenario, a password is captured on the External system and sent to the Enterprise Single Sign-On server assigned for Password Synchronization which then updates the password in the SSO credential database, and also updates the Windows user's password in Active Directory.

The third type is **External to Windows - Partial synchronization**. In this scenario a password is captured on the External system and sent to the Enterprise Single Sign-On server assigned for Password Synchronization which then updates the password in the SSO credential database.

This section contains:

- Installing Password Synchronization
- Administering Password Synchronization
- Configuring Password Synchronization
- Managing Password Synchronization

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Installing Password Synchronization

As with the other Single Sign-On features, Password Synchronization is not installed in the default Host Integration Server 2004 installation, and must be specifically selected during setup.

To install Password Synchronization

1. Run the Host Integration Server 2004 setup program and select **Custom Installation**.
2. Under the **Security Integration** feature, select the **Enterprise Single Sign-On Password Synchronization** sub feature.
3. Complete the installation.

To addition to this, Password synchronization adapters are necessary to send and receive password changes to the external system. The topics in this section describe how to configure your own adapters. You can also view a list of currently available adapters at the following location:

http://go.microsoft.com/fwlink/?LinkId=30101

You can also contact support aliases to obtain information on these Password synchronization adapters.

Finally, to capture password changes made in Active Directory, in addition to installing the ENTSSO Password Sync feature, components need to be installed on the domain controllers to capture password changes.

Both the Windows Password Capture component and Password Change Notification Service (PCNS) must be installed on all domain controllers from which you will be capturing passwords. You can find these components in the following location:

<HIS CD ROOT>\Platform\PCNS

Read the accompanying documentation (also located in the folder above) before you proceed with the installation on the domain controller.

Password Synchronization

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Administering Password Synchronization

Use the SSOPS command line utility to administer your password synchronization. Most of commands in this section are intended for use by an administrator only.

For many commands, the command output is displayed on the screen in two columns. As certain screen settings may cause truncation of data, for best results you should change the screen buffer size/Windows size to 120 characters.

The SSOPS commands are listed below. Procedures and further explanation are located throughout the rest of this topic.

Command	**Function**
-list	Lists existing adapters
-display	Displays adapter information
-create	Creates new adapter(s)
-setprops	Sets properties for adapter
-update	Updates existing adapter(s)
-delete	Deletes an existing adapter
-enable	Enables adapter
-disable	Disables adapter
-addapp	Adds application for adapter
-deleteapp	Deletes application for adapter
-reset	Resets notification or damping queues
-addtogroup	Adds adapter to adapter group
-deletefromgroup	Deletes adapter from adapter group

To list existing adapters

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssops -list** and press Enter.

   Adapters and descriptions will be listed. (E) denotes that the adapter is enabled, (D) denotes that it is disabled.

To display adapter information

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssops -display <adapter name>** and press Enter.

   The screen output will display information for the specified adapter.

   In addition to name, type, description, computer, and accounts, the following information is displayed.

Adapter Flag	**Details**
Adapter enabled	Determines whether or not the adapter is enabled. Flag: SSO_FLAG_ENABLED Attribute Name: enableApp Default: No

Allow local accounts	Determines whether or not the App Admin or App Users accounts can be local accounts. Flag: SSO_FLAG_APP_ALLOW_LOCAL Attribute Name: allowLocalAccounts Default: No
Receive password changes from adapter	Determines whether or not the adapter is allowed to receive external password changes. Flag: SSO_FLAG_PARTIAL_SYNC_FROM_EXTERNAL_TO_DB Attribute Name: syncFromAdapter Default: No
Verify old password	Determines whether the adapter will verify the old password when an external password change is received. If this flag is set then with an external password change the external adapter must supply the old external password as well as the new external password. The old external password is then compared with the existing external password in the SSO database for that external account. If they match, the password change is accepted. If they do not match, the password change is rejected. Flag: SSO_FLAG_SYNC_VERIFY_EXTERNAL_CREDS Attribute Name: verifyOldPassword Default: Yes
Change Windows password	Determines whether or not the Windows password will also be changed when an external password change is received (full sync). ENTSSO always uses the old Windows password stored in the SSO database to change the Windows password to the new value (Windows requires both the old and new password to change a users password), so this must be initialized before the Windows password change can succeed. If password sync is configured for a particular mapping, then when the external credentials are set via administrative tools (ssomanage or ssoclient -setcredentials) the Windows password stored in the SSO database will also be set.Flag: SSO_FLAG_FULL_SYNC_FROM_EXTERNAL_TO_WINDOWS Attribute Name: changeWindowsPassword Default: No
Send Windows password changes to adapter	Determines whether or not Windows password changes will be sent to the external adapter. Flag: SSO_FLAG_FULL_SYNC_FROM_WINDOWS_TO_EXTERNAL Attribute Name: syncToAdapter Default: No
Send old password to adapter	If Yes, the old password value (from the SSO database) will also be sent to the external adapter as well as the new password value. Some external systems might require both the old and new password values to change the password. Flag: SSO_FLAG_SYNC_PROVIDE_OLD_EXTERNAL_CREDS Attribute Name: sendOldPassword Default: No
Allow mapping conflicts	Determines whether or not the adapter will allow mapping conflicts. A mapping conflict occurs when mappings are not unique. In a single SSO Individual application, mappings are always one-to-one: one Windows account is mapped to exactly one external account and vice versa. However, it is possible to assign more than one application to an adapter. Thus, it is possible to have a mapping in one application that conflicts with a mapping in the other. This purpose of this flag is to prevent this from occuring. It is more secure to not allow mapping conflicts unless there is a specific, well understood requirement for this behavior. Flag: SSO_FLAG_SYNC_ALLOW_MAPPING_CONFLICTS Attribute Name: allowMappingConflicts Default: No

Adapter Description	Details
Notification retry count	Default is 1.
Notification retry delay (in mins)	Default is 5.
Maximum pending notifications	Default is 8.
Store notifications (when offline)	True/False.
Server name	Server name.
Port number	Port number.
Applications for this adapter	List of applications currently assigned to the adapter.

To create new adapters

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssops -create <adapter file>** and press Enter.

   The screen output will display information for the newly created adapter.

To set properties for an adapter

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssops -setprops <adapter name>** and press Enter.

   The screen output will display the properties for the specified adapter. You can edit them if necessary, but new values are not validated.

To update existing adapters

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssops -update <adapter file>** and press Enter.

   Use this command to update the settings and flags for a specified adapter. Do not use this command to set properties; use instead the -setprops command.

To delete an existing adapter

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssops -delete <adapter name>** and press Enter.

   The specified adapter will be deleted.

To enable an adapter

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssops -enable <adapter name>** and press Enter.

   The specified adapter will be enabled.

To disable an adapter

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssops -disable <adapter name>** and press Enter.

   The specified adapter will be disabled.

To add an application to an adapter

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssops -addapp <adapter name> <application name>** and press Enter.

   The specified SSO application wil be assigned to the specified adapter. This means that the passwords for the mappings in that application will now be synchronized using this adapter.

   While multiple applications can be assigned to one adapter, any given application can only be assigned to one adapter.

To delete an application from an adapter

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssops -deleteapp <application name>** and press Enter.

   The specified SSO application will be removed from an adapter. (Since an application can only be assigned to one adapter, it is not necessary to specify the adapter name.)

To reset notification

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssops -reset <adapter name | all | damping>** and press Enter.

   This command clears the damping table and/or notification queues for a single adapter or all adapters, as specified. The damping table stores a 10-minute history of password changes. Before the Enterprise SSO system accepts or sends a password change, it checks the damping table to see if it has performed the same change recently. If it has, the new change is discarded.

To add an adapter to an adapter group

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssops -addtogroup <adapter name> <adapter group>** and press Enter.

   This command adds the specified adapter to the specified adapter group. While an adapter can belong to only one adapter group, an adapter group can contain multiple adapters.

To delete an adapter from an adapter group

1. 3On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.

4. Type **ssops -deletefromgroup <adapter name> <adapter group>** and press Enter.

   This command deletes the specified adapter from the specified adapter group.

Password Synchronization

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring Password Synchronization

Use the SSOCONFIG command line utility to configure your password synchronization settings.

To specify the directory for replay files

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssoconfig -replayfiles <replay files directory> | -default** and press Enter.

   Note Replay files are not deleted when you change the service account. If you change this account, you will need to delete the replay files manually.

To display or change maximum password synchronization age

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssoconfig -syncage <maximum password age in hours>** and press Enter.

   Note The SSOCONFIG utility uses the time on the SQL Server computer as its system time. Remember this when using any commands related to time.

Password Synchronization

Managing Password Synchronization

Use the SSOMANAGE command line utility to enable or disable SSO features, and to display current SSO database settings.

To enable SSO features

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage -enable** and press Enter.

To disable SSO features

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage -disable** and press Enter.

To display current database settings

1. On the **Start** menu, click **Run**.
2. In the **Run** dialog box, type **cmd**, and then click **OK**.
3. At the command line, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage -displaydb** and press Enter.

Host Integration Server 2004 Glossary

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

3270

The information display system for IBM hosts (mainframes). The system includes terminals, printers, and controllers that enable a user to access host functions.

5250

The information display system for IBM AS/400 computers.

802.2

The logical link control protocol used for communication over a Token Ring or Ethernet network. The 802.2 protocol is an IEEE standard.

1-byte unsigned Integer

An integer data type that has a positive value ranging from 0 to 255.

2-byte signed Integer

An automation integer data type that can be either positive or negative. The most significant bit is the sign bit, which is 1 for negative values and 0 for positive values. The storage size of the integer is 2 bytes. A 2-byte signed integer can have a range from -32,768 to 32,767.

2PC

See **two-phase commit (2PC)**.

4-byte Real

Also referred to as a single-precision floating-point or Single. Single variables are stored as IEEE 32-bit (4-byte) floating-point numbers, ranging in value from –3.402823E38 to –1.401298E-45 for negative values and from 1.401298E-45 to 3.402823E38 for positive values. The type-declaration character for Single is an exclamation point (!).

4-byte signed Integer

An Automation integer data type that can be either positive or negative. The most significant bit is the sign bit, which is 1 for negative values and 0 for positive values. The storage size of the integer is 4 bytes. A 4-byte signed integer can have a range from -2,147,483,648 to 2,147,483,647.

8-byte Real

Also referred to as a double-precision floating-point or Double. Double data type variables are stored as 64-bit (8-byte) numbers. A Double variable is stored as a 64-bit (8-byte) number ranging in value from 1.79769313486232E308 to –4.94065645841247E-45 for negative values, from 4.94065645841247E-324 to 1.79769313486232E308 for positive values, and 0. The type-declaration character is a number sign (#).

3270 emulator

Software that enables a microcomputer to act as a 3270 terminal, displaying information from a host system (mainframe). Emulator software can also enable a desktop computer to send print jobs from a host system to a printer connected to the microcomputer.

3270 terminal emulation

The use of software that enables a microcomputer to act as a 3270 terminal, displaying information from a host system (mainframe). Emulation software can also enable a microcomputer to send print jobs from a host system to a printer connected to the microcomputer.

5250 emulator

Software that enables a microcomputer to act as a 5250 terminal interacting with an AS/400 system.

5250 terminal emulation

The use of software that enables a microcomputer to act as a 5250 terminal interacting with an AS/400 system.

-A-

A3270

The server transaction program for the APPC 3270 Terminal Emulator facility.

abend

Short for abnormal end. The premature ending of a program because of program error or system failure.

ACID

See **atomic, consistent, isolated, and durable (ACID)**.

acknowledgment required (ACKRQD)

A field in the header of a Status-Control message. If a Status-Control request has ACKRQD set in the message header, the recipient must supply a Status-Control response before the sender sends further messages or further Status-Control requests.

ACKRQD

See **acknowledgment required (ACKRQD)**.

ActiveX® Data Objects (ADO)

A data access interface that communicates with OLE DB-compliant data sources to connect to, retrieve, manipulate, and update data.

ACTLU

SNA command sent by the system services control point (SSCP) to a logical unit (LU) to activate a session and establish session parameters.

ACTPU

SNA command sent by the system services control point (SSCP) to activate a physical unit (PU), so that any logical units (LUs) controlled by this PU are available to the SNA network.

adapter

Refers to a circuit board, network card, and similar expansion devices with a specialized function, such as controlling a video display monitor or accessing a communications line. Not the same as a driver.

administration access

The level of access available to a user. The user may be granted or denied the right to use the interfaces (Host Integration Server 2004 Setup, SNA Manager, or the **snacfg** command) to read and change the configuration file, to start and stop services and connections, or to reset LUs.

ADO

See **ActiveX® Data Objects (ADO)**.

Advanced Peer-To-Peer Networking (APPN)

An extension to SNA that features (a) greater distributed network control that avoids critical hierarchical dependencies, thereby isolating the effects of single points of failure; (b) dynamic exchange of network topology information to foster ease of connection, reconfiguration, and adaptive route selection; (c) dynamic definition of network resources; and (d) automated resource registration and directory lookup. APPN extends the LU 6.2 peer orientation for end-user services to network control and supports multiple LU types, including LU 2, LU 3, and LU 6.2.

Advanced Program-to-Program Communications (APPC)

A means of enabling programs to communicate directly with each other, across a network or within a single system. APPC uses a type of logical unit called LU 6.2, and enables transaction programs (TPs) to engage in peer-to-peer communications in an SNA environment.

(1) The general term that characterizes the LU 6.2 architecture and its various implementations in products. (2) Refers to the LU 6.2 architecture and its product implementations as a whole or to an LU 6.2 product feature in particular, such as an APPC application programming interface. (3) A method for enabling programs to communicate directly with each other across a network or within a single system. APPC uses a type of LU called LU 6.2, and enables TPs to engage in peer-to-peer communications in an SNA environment.

AFTP

See **APPC File Transfer Protocol (AFTP)**.

AFTPD

The server transaction program for the APPC File Transfer Protocol facility.

aggregation

A composition technique for implementing component objects whereby a new object can be built using one or more existing objects that support some or all of the required interfaces of the new object.

alert

A message that indicates an abnormal event or a failure.

allocate

(1) The process that an operating system uses to respond to a request from a program to reserve memory for use by the program. (2) In Advanced Program-to-Program Communications (APPC), a verb that assigns a session to a conversation. *Contrast with* **deallocate**.

American Standard Code for Information Interchange (ASCII)

A coding scheme that assigns numeric values to letters, numbers, punctuation marks, and certain other characters.

API

See **application programming interface (API)**.

APING

(1) The APPC Connectivity Tester facility. (2) The client transaction program for the APPC Connectivity Tester facility.

APINGD

The server transaction program for the APPC Connectivity Tester facility.

APPC

See **Advanced Program-to-Program Communications (APPC)**.

APPC File Transfer Protocol (AFTP)

(1) The client transaction program for the APPC File Transfer Protocol facility. (2) An interactive full-screen environment with a specific set of commands used to manage and transfer files between a client and server computer. (3) An API that provides APPC file transfer capabilities.

APPC mode

A collection of session properties used by LU 6.2-type logical units (LUs) as they carry on a session. A mode can be used by many LU pairs at the same time.

APPC mode name

The name used to represent a set of characteristics to be used in an APPC LU-LU session.

APPC verb

The mechanism by which a program accesses APPC. Each verb supplies parameters to APPC. *See also* **Advanced Program-to-Program Communications (APPC)**.

application programming interface (API)

The set of programming language constructs or statements that can be coded in an application program to invoke the specific functions and services provided by an underlying operating system or service program.

application requester (AR)

(1) The source of a request to a remote relational database management system (DBMS). (2)The ODBC driver to DB2 connector that enables C and C++ applications to issue dynamic SQL queries and call DB2 stored procedures.

application TP

An application program that uses Advanced Program-to-Program Communications (APPC) to accomplish tasks for end-users and exchange data with other transaction programs (TPs) in an SNA environment.

APPN

See **Advanced Peer-To-Peer Networking (APPN)**.

AR

See **application requester (AR)**.

array

A set of sequentially indexed elements which have the same intrinsic data type. Each element of an array has a unique identifying index number. A changes made to one element of an array does not affect the other elements.

ASCII

See **American Standard Code for Information Interchange (ASCII)**.

assembly

A collection of functionality built, versioned, and deployed as a single implementation unit (one or multiple files). An assembly is the primary building block of a .NET Framework application. All managed types and resources are marked either as accessible only within their implementation unit or as exported for use by code outside that unit. In the common language runtime, the assembly establishes the name scope for resolving requests and the visibility boundaries are enforced. The runtime can determine and locate the assembly for any running object because every type is loaded in the context of an assembly.

assembly cache

A machine-wide code cache used for side-by-side storage of assemblies. There are two parts to the cache. First, the global assembly cache contains assemblies that are explicitly installed to be shared among many applications on the computer. Second, the download cache stores code downloaded from Internet or intranet sites, isolated to the application that triggered the download so that code downloaded on behalf of one application or page does not impact other applications. *See also* **global assembly cache (GAC)**.

asynchronous verb completion

Processing of an SNA verb where the initial API call returns immediately, so that the normal operation of the program is not blocked while processing completes. When the verb completes, the application is notified through a Microsoft® Windows® message or event. *Contrast with* **synchronous verb completion**.

atomic, consistent, isolated, and durable (ACID)

An acronym that describes the four key properties required of any Windows-based transaction:

- **Atomic.** Each transaction must execute completely or not at all.
- **Consistent.** The structural integrity of the transaction database must be maintained.
- **Isolated.** A transaction cannot access data that is already involved in a transaction.
- **Durable.** The TP data must be stored securely to enable recovery of the transaction results.

> **Note** A mainframe-based transaction program (TP) differs from a Windows-based transaction. A mainframe-based TP is a COBOL program that exists in the CICS or IMS environment and contains one or more mainframe transactions. A mainframe transaction might or might not meet the ACID properties.

atomicity

A feature of a transaction that indicates that either all actions of the transaction happen or none happens.

auditing

Tracking the activities of administrators and users by recording selected types of events (for example, the changing of the configuration file) in the security log of a computer running Host Integration Server 2004.

authentication

The process of determining the identity of a user attempting to access a system. For example, passwords are commonly used to authenticate users.

automatic partnering

A setting for APPC LUs and modes that enables LU-LU pairs (with assigned modes) to be generated automatically by Host Integration Server 2004. Each time a new APPC LU or mode is created with automatic partnering enabled, Host Integration Server 2004 searches for existing LUs and modes that also have automatic partnering enabled. Host Integration Server 2004 then uses all available automatic partners to create as many unique LU-LU pairs as possible, each pair containing a remote LU, local LU, and assigned mode. Disabling an automatic partner setting after an LU or mode has been created does not remove that LU or mode from LU-LU pairs already generated.

automatic transaction

A transaction that is created by the COM+ run-time environment for an object based on the transaction attribute of a component.

Automation

Automation is COM-based technology that enables dynamic binding to COM objects at run time.

Automation client

Also called an Automation controller. An application that manipulates the objects, methods, and properties of another application (the Automation server) through Automation.

Automation object

An object that is exposed to other applications or programming tools through Automation interfaces.

Automation server

An application that enables its objects, methods, and properties to be controlled by other applications through Automation.

-B-

backup configuration file

An extra copy of the configuration file, saved by using the **File** menu **Backup Configuration** command in SNA Manager. The default extension for backup configuration file names is .SNA.

backup server

A computer running Host Integration Server 2004, and designated as a backup server, on which the configuration file is replicated by Host Integration Server 2004. Host Integration Server 2004 loads the copy of the configuration file located on a backup server if the primary server goes down. One or more computers running Host Integration Server 2004 can operate as backup servers.

Base

A part of each Host Integration Server 2004 component that provides the operating environment for the core functions of that component. The Base passes messages between components and provides functions common to all components, such as diagnostic tracing.

base client

A client that runs outside the COM+ run-time environment, but that instantiates COM+ objects.

base process

An application process in which a base client executes. A base client runs outside the COM+ run-time environment and instantiates COM+ application objects.

basic conversation

In APPC, a conversation type generally used by applications that provide services to other local applications. Basic conversations provide a greater degree of control over the transmission and handling of data than mapped conversations. *See also* **mapped conversation**.

basic transmission unit (BTU)

A standard unit of information transmitted over an SNA network. A BTU consists of the transmission header (TH), the request/response header (RH), and the request/response unit (RU). The maximum size of the BTU is controlled in VTAM by the MAXDATA= parameter and in Host Integration Server by the Max BTU Length parameter.

batch job

A predefined sequence of programs that can be run through the Job Entry Subsystem or through an automated scheduling system. Each program that runs as part of the sequence is considered a batch step. Typically data is passed from one step to the next through temporary or permanent files on the file system.

batch step

An application program that is executed as part of a larger batch job. Typically, data is read from and written to temporary or permanent files on the files systems.

BBI

See **begin bracket indicator (BBI)**.

BBIUI

See **begin basic information unit indicator (BBIUI)**.

BCI

See **begin chain indicator (BCI)**.

begin basic information unit indicator (BBIUI)

Bit 5 of Flag 2 of a Status-Control message. BBIUI is set on a Status-Control message corresponding to an outbound SNA request with BBIU (begin basic information unit). It is supplied solely for the use of SNA server components. Your application should not attempt to use it.

begin bracket indicator (BBI)

Bit 4 of Flag 1 of a Status-Control message. BBI is set if the chain carries BB (begin bracket). Note that this does not necessarily indicate that the bracket has been initiated.

begin chain indicator (BCI)

Bit 1 of Flag 1 of a Status-Control message. BCI is set if the message starts a chain.

blocking

A method of operation in which a program that issues a call does not regain control until the call completes. *See also* **synchronous verb completion**.

Boolean expression

An expression that can be evaluated either true (nonzero) or false (0). You can use the keywords True and False to supply the values of -1 and 0, respectively. The field data type Yes/No is Boolean and has the value of -1 for Yes and 0 for No.

bounded

Refers to recordsets or arrays. The last input parameter or the last output parameter in a method can be bounded. This means its actual size can vary from zero to the maximum number of elements (in an array) or rows (in a recordset) specified at design time.

bracket

A chained set of RUs and their responses, which together make up a transaction between two LUs. One bracket must be finished before another can be started.

BTU

See **basic transmission unit (BTU)**.

business rule

The combination of validation edits, logon verifications, database lookups, policies, and algorithmic transformations that constitute an enterprise's way of doing business. Also known as business logic.

byte

A unit of information consisting of eight bits. A byte, or binary term, is the smallest collection of bits that can be accessed directly. The integer value of a byte can range from 0 to 255.

-C-

caller

A client that invokes a method of an object. The caller of an object is not necessarily the creator of an object. For example, client A could create object X and pass this reference to client B, and then client B could use that reference to call a method of object X. In this case, client A is the creator, and client B is the caller. *See also* **creator**.

catalog

In Windows 2000 and later, the catalog is the COM+ application data store that maintains configuration information for components, COM+ applications, and roles. You can administer the catalog by using TI Manager.

CDI

See **change direction indicator (CDI)**.

CEI

See **chain ending indicator (CEI)**.

chain

A series of related messages or data packets that are transmitted consecutively and are treated as a single entity forming a complete message.

change direction indicator (CDI)

Bit 6 of Flag 1 of a Status-Control message. CDI is set if chain carries change direction (CD).

Channel

A channel-attached connection to a host system.

characteristics

A set of internal values maintained by CPI-C for each conversation. They can affect the operation of the entire conversation or of specific calls.

CICS

See **Customer Information Control System (CICS)**.

class

A type that defines the interface of a particular type of object. A class defines the properties of the object and the methods used to control the behavior of an object.

class factory

An object that implements the **IClassFactory** interface, which enables it to create objects of a specific class.

class ID (CLSID)

A universally unique identifier (UUID) that identifies a COM component. Each COM component has its CLSID in the Windows registry so that it can be loaded by other applications.

client

A computer or a software component using services available through Host Integration Server 2004. To run applications such as a 3270 emulator, the client uses the Host Integration Server 2004 computer to gain access host or peer systems on the SNA or TCP/IP network.

client/server

A distributed application model in which client applications request services from a server application. A server can have many clients at the same time, and a client can request data from multiple servers. An application can be both a client and a server.

CLSID

See **class ID (CLSID)**.

coaxial cable

A cable that consists of a conductor within another conductor, with insulation between the two conductors. The inner conductor is usually a small copper tube or wire, and the outer conductor is usually copper tubing or copper braid. It is the common medium used to connect LANs and 3270 devices. The maximum distance that a coaxial cable can be run between a 3270-type cluster controller and peripheral devices is 5,000 feet (1,500 meters).

code page

A table that associates specific ASCII or EBCDIC values with specific characters.

COM

See **Component Object Model (COM)**.

COM+

See **Component Services (COM+) component**; **Component Services (COM+) object**.

COMMAREA

An area of memory in the mainframe used for communications and accessible to various programs. It is similar to a data structure that contains both input parameters and return data.

Common Programming Interface for Communications (CPI-C)

A set of C-language routines that applications distributed across an SNA network can use to work together. Through CPI-C, distributed applications on computers communicating as peers can exchange data to accomplish a processing task, such as querying a remote database or copying a remote file.

An evolving application programming interface (API), embracing functions to meet the growing demands from different application environments and to achieve openness as an industry standard for communications programming. CPI-C provides access to interprogram services such as (a) sending and receiving data, (b) synchronizing processing between programs, and (c) notifying a partner of errors in the communication.

Common Service Verb (CSV)

An application programming interface (API) that provides ways of tracing, translating characters, and sending network management information to a host. Each verb supplies parameters to CSV.

communications controller

A device that directs the transmission of data over a network (for example, the IBM 3725 front-end processor).

COMP-1

Specified for internal floating-point items (single precision). The items are four bytes long. The sign is contained in the first bit of the leftmost byte, and the exponent is contained in the remaining seven bits of that byte. The last three bytes contain the mantissa.

COMP-2

Specified for internal floating-point items (double precision). The items are eight bytes long. The sign is contained in the first bit of the leftmost byte, and the remaining seven bits of that byte contain the exponent. The remaining seven bytes contain the mantissa.

COMP-3

Specified for internal decimal items. In storage, these items appear in packed decimal format. There are two digits for each character position (byte), except for the trailing character position (byte), which is occupied by the low-order digit and sign. The item can contain only the digits 0 through 9, plus a sign (in the last position), representing a value not exceeding 29 decimal digits (15 bytes).

component

A discrete unit of code built on ActiveX® controls that deliver a well-specified set of services through well-specified interfaces. Components provide the objects that clients request at run time.

Component Object Model (COM)

An open architecture for cross-platform development of client/server applications based on object-oriented technology. Clients have access to an object through the interfaces implemented on the object. COM is language-neutral, so any language that produces COM components can also produce COM applications.

Component Services (COM+) component

A Component Object Model (COM) component that executes in the COM+ run-time environment. A COM+ component is commonly known as a COM+ application. A COM+ component must be a dynamic-link library (.dll) file that implements a class factory to create objects and that describes all of the interfaces of the component in a type library to facilitate standard marshaling.

Component Services (COM+) object

A Component Object Model (COM) object that executes in the COM+ run-time environment.

concurrency

The appearance of simultaneous execution of processes or transactions by interleaving the execution of multiple pieces of work.

configuration file

A file containing setup and configuration information for Host Integration Server 2004. It defines servers, connections, LUs, users, and other items. The configuration file that is loaded when SNA Manager starts is called COM.CFG.

connection

The data communication path between a workstation or server and other computers on the SNA network. Host Integration Server 2004 offers a variety of connection types:

- 802.2 (Token Ring or Ethernet)
- Synchronous Data Link Control (SDLC)
- X.25
- Distributed function terminal (DFT)
- Channel
- Twinax

connection object

In AFTP, a connection (not necessarily active) to a partner computer.

connectivity

(1) The capability of a system or device to be attached to other systems or devices without modification. (2) The capability to attach a variety of functional units without modifying them.

connectivity option

A type of connection hardware and software through which one computer communicates with other computers.

consistency

A state in which durable data matches the state expected by the business rules that modified the data.

constructor

In C, a special initialization function that is called automatically whenever an instance of a class is declared. This function prevents errors that result from the use of uninitialized objects. The constructor has the same name as the class itself and cannot return a value.

contention loser

In an APPC LU-LU session, the LU that cannot start a conversation with its partner LU (the contention winner) without first requesting permission of the partner LU. *See also* **contention winner**.

contention winner

In an APPC LU-LU session, the LU that can start a conversation with its partner LU (the contention loser). If parallel sessions between the two LUs are being used, each LU may be the contention winner for some sessions and the contention loser for other sessions. *See also* **contention loser**.

context

The state that is implicitly associated with a given COM+ object. The context contains information about the execution environment of an object, such as the identity of the creator of an object and, optionally, the transaction encompassing the work of the object. The context of an object is similar in concept to the process context that an operating system maintains for an executing program. The COM+ run-time environment manages a context for each object.

control point

A node or other SNA component that controls network resources and coordinates the activation of sessions.

controller

A device that directs the transmission of data over a network (for example, the IBM 3725 front-end processor).

conversation

The process used by network-based applications to communicate with each other and to exchange data to accomplish processing tasks. (1) A logical connection between two transaction programs using an LU 6.2 session. Conversations are delimited by brackets to gain exclusive use of a session. (2) The interaction between TPs carrying out a specific task. Each conversation requires an LU-LU session. A TP can be involved in several conversations simultaneously. *See also* **basic conversation**; **mapped conversation**.

conversation characteristics

Internal API values that define the overall operation for a conversation or for a specific call. *See also* **application programming interface (API)**; **conversation**.

conversation ID

A unique identifier for a conversation between two transaction programs (TPs).

CPI-C

See **Common Programming Interface for Communications (CPI-C)**.

creator

A client that creates an object provided by a component (using **CreateObject**, **CoCreateInstance**, or the **CreateInstance** method). When a client creates an object, it is given an object reference that can be used to call the methods of that object. *See also* **caller**.

CSV

See **Common Service Verb (CSV)**.

Currency

An 8-byte, fixed-point data type that is useful for calculations involving money or for fixed-point calculations in which accuracy is extremely important. This data type is used to store numbers with up to 15 digits to the left of the decimal point and 4 digits to the right. The type-declaration character in Microsoft® Visual Basic® is an at sign (@). Currency can range from –922,337,203,685,477.5808 to 922,337,203,685,477.5807.

current directory

The first directory in which the operating system looks for programs and data files and stores files for output.

Customer Information Control System (CICS)

An IBM transaction processing program that provides an environment on IBM mainframes in which applications can communicate with terminals or other applications.

-D-

DACTLU

An SNA command that is sent to deactivate the session between the system services control point (SSCP) and a logical unit (LU).

DACTPU

An SNA command that is sent to deactivate the session between the system services control point (SSCP) and a physical unit (PU).

data link control (DLC)

In SNA, the protocol stack layer that transmits messages across links and manages link-level flow and error recovery.

data set members

Members of partitioned data sets that are individually named elements of a larger file that can be retrieved by name.

data source name (DSN)

The name that applications use to request a connection to an ODBC data source. DSN also means Data Set Name on the mainframe.

database

(1) A collection of data with a given structure for accepting, storing, and providing on demand data for multiple users. (2) A collection of interrelated data organized according to a database schema to serve one or more applications. (3) A collection of data fundamental to a system. (4) A collection of data fundamental to an enterprise.

Date

An 8-byte, real data type used to store dates and times as a real number. Variables are stored as 64-bit numbers. The value to the left of the decimal represents a date, and the value to the right of the decimal represents a time. The Date data type can range from January 1, 1000 to December 31, 9999.

DCOM

See **distributed COM (DCOM)**.

DDM

See **distributed data management (DDM)**.

deallocate

(1) The process an operating system uses to free memory that has been previously allocated by a program. (2) In Advanced Program-to-Program Communications (APPC), a verb that ends a conversation. *Contrast with* **allocate**.

Decimal

A data type that stores a signed, exact numeric value described as the number of digits appearing before and after the decimal point, with a maximum of 29 total digits. All possible digits cannot be represented if you are using the maximum number of digits.

default

The value that is automatically used if nothing is specified.

dependent local APPC LU

A local logical unit (LU) that enables Advanced Program-to-Program Communications (APPC) with a peer system, but only through a host (mainframe) system. The type of LU used in dependent APPC is LU 6.2.

DFT

See **distributed function terminal** (**DFT**).

digit

In COBOL, any of the numerals from 0 through 9 not used in reference to any other symbol.

direct caller

The identity of the process (base client or server process) calling into the current server process.

direct creator

The identity of the process (base client or server process) that directly created the current object.

directory
(1) A list of files that are stored on a disk or diskette. A directory also contains information about the files such as size and date of last change. (2) A named grouping of files in a file system.
display emulation
A feature that enables a personal computer to emulate an IBM 3278 or 3279 terminal. *See also* **emulation**.
display model
One of several different sizes of display:

- Model 2 is 24 lines by 80 characters
- Model 3 is 32 lines by 80 characters
- Model 4 is 43 lines by 80 characters
- Model 5 is 27 lines by 132 characters

display session
A 3270 emulation session between a networked personal computer and a host. The session is used to emulate a 3278 or 3279 display. Also called a host display session.
DISPLAY verb
An APPC verb that returns configuration information and current operating values for a computer running Host Integration Server 2004.
distributed COM (DCOM)
An object protocol that enables COM components to communicate directly with each other across a network. Because DCOM is language-neutral, any language that uses COM components can also produce DCOM applications.
distributed data management (DDM)
A function of the operating system that enables an application program or user on one system to use database files stored on remote systems. A communications network must connect the systems, and the remote systems must also be using DDM.
distributed function terminal (**DFT)**
A type of intelligent terminal supported by IBM 3270 control units, in which some of the terminal's functions are controlled by the terminal and some by the control unit. Enables multiple sessions, and connects to host systems or to peer systems through host systems. DFT terminals are often connected using coaxial cable.
distributed processing
A form of information processing in which the work is performed by separate computers that are linked through a local or wide area network, using data-transfer mechanisms that enable different programs to use and share data.
distributed program call (DPC)
An AS/400 remote communication model.
Distributed Query Processor (DQP)
Enables queries to access multiple data sources on multiple servers, even SQL and DB2, and combine views, create data warehouses, and so on. DQP supports an extended version of the SQL language that permits users to qualify table names with the databases in which they exist. This gives users the capability to formulate queries that span multiple distributed databases.
Distributed Relational Data Architecture (DRDA)
A connection protocol for distributed relational database processing that is used by IBM relational database products. The DRDA protocol comprises protocols for communication between an application and a remote database, and communication between databases. The DRDA protocol provides the connections for remote and distributed processing. The DRDA protocol is built on the Distributed Data Management Architecture.
Distributed Transaction Coordinator (DTC)
A transaction manager that coordinates transactions spanning multiple resource managers. Work can be committed as an atomic transaction even if it spans multiple resource managers, even on separate computers.
distributed unit of work (DUW)
In DB2 UDB for AS/400, this is a method of accessing distributed relational data in which a user or application can, within a single unit of work, read and update data on multiple database management systems (DBMSs). The user or application directs each SQL statement to a particular DBMS for execution at the DBMS. Each SQL statement may access only one DBMS.
DL-BASE
The type of Base used by Host Integration Server 2004 3270 emulation programs. It supports a single Host Integration Server 2004 component or a single user application and has entry points for initialization, sending messages, receiving messages, and termination. *See also* **Base**.
DLC
See **data link control (DLC)**.
DLL
See **dynamic-link library (DLL)**.
DMOD
See **Dynamic Access Module (DMOD)**.
document type definition (DTD)
Can accompany a document, essentially defining the rules of the document, such as which elements are present and the

structural relationship between the elements. It defines what tags can go in your document, what tags can contain other tags, the number and sequence of the tags, the attributes your tags can have, and optionally, the values those attributes can have.

DTDs help to validate the data when the receiving application does not have a built-in description of the incoming data. The DTD is declared within the document type declaration production of the XML file. With XML, however, DTDs are optional.

downstream connection

A connection that enables a computer running Host Integration Server 2004 to support communication between hosts and clients. Even though such clients do not use the Host Integration Server 2004 client/server interface, with a downstream connection they can access host connections available through a computer running Host Integration Server 2004.

Host Integration Server 2004 offers several types of downstream connection:

- 802.2 (Token Ring or Ethernet)
- SDLC
- X.25

downstream LU

A logical unit (LU) used by clients to access a host connection through a computer running Host Integration Server 2004. Such clients do not use the Host Integration Server 2004 client/server interface, but by using a downstream LU, can receive access to connections on a computer running Host Integration Server 2004. A downstream LU uses a downstream connection, and passes information between the client and the host.

downstream system

A client such as an IBM Communications Manager/2 system that can access host connections available on a computer running Host Integration Server 2004. Even though such clients do not use the Host Integration Server 2004 client/server interface, they can use a downstream connection and a downstream LU to communicate with the host through Host Integration Server 2004. Host Integration Server 2004 passes the information between the downstream system and the host. With Host Integration Server 2004, downstream systems appear to the host as logical units, not physical units.

DPC

See **distributed program call (DPC)**.

DPL-enabled

Compatible with the IBM Distributed Program Link (DPL) protocol.

DQP

See **Distributed Query Processor (DQP)**.

DRDA

See **Distributed Relational Data Architecture (DRDA)**.

DSN

See **data source name (DSN)**.

DTC

See **Distributed Transaction Coordinator (DTC)**.

DTD

See **document type definition (DTD)**.

duplex

Capable of simultaneously transmitting and receiving data. Also called **full-duplex** or **4-wire**. *Contrast with* **half-duplex**.

durability

A state that survives failures.

DUW

See **distributed unit of work (DUW)**.

Dynamic Access Module (DMOD)

An SNA component that provides the communications facilities needed to pass messages between the Bases.

dynamic-link library (DLL)

A binary file that contains one or more functions that are compiled, linked, and stored separately from the processes that use them. The operating system maps a DLL to the address space of the calling process when the process starts or while it is running. It uses the .dll file extension.

-E-

EBCDIC

See **Extended Binary Coded Decimal Interchange Code (EBCDIC)**.

EBI

See **end bracket indicator (EBI)**.

EBIUI

See **end basic information unit indicator (EBIUI)**.

ECI

See **end chain indicator (ECI)**.

ELM

See **enhanced listener message (ELM)**.

emulation

A process whereby one device imitates another; for example, a personal computer can emulate a 3278 terminal. *See also* **display emulation**.

end bracket indicator (EBI)

Bit 5 of Flag 1 of a Status-Control message. Set if chain carries end bracket (EB). Note that this does not indicate that the bracket has terminated.

end chain indicator (ECI)

Bit 2 of Flag 1 of a Status-Control message. Set if this message ends a chain.

enhanced listener message (ELM)

A streamlined, application-level protocol exchange sequence that sends to and receives from the host application a single data stream composed of a header followed by the application data.

ERI

See **exception response indicator (ERI)**.

Ethernet

An IEEE 802.3 standard for contention networks. Ethernet uses a bus or star topology and relies on the form of access known as Carrier Sense Multiple Access with Collision Detection (CSMA/CD) to regulate communication line traffic. Network nodes are linked by coaxial cable, by fiber-optic cable, or by twisted-pair wiring. Data is transmitted in variable-length frames containing delivery and control information and up to 1,500 bytes of data. The Ethernet standard provides for baseband transmission at 10 megabits per second.

event log

Host Integration Server 2004 records events involving communications hardware (for example, communications adapters) or software in the Windows Event Log. Events can include attempts to establish communication, successful establishment of sessions, failures of system components, attempts to use files that are damaged or missing, configuration problems, and responses from remote systems.

exception

An abnormal condition or error that occurs during the execution of a program and that requires the execution of software outside the normal flow of control.

exception request (EXR)

A request in which an intermediate component has detected an error and modified the request so the final destination is also aware of the error.

exception response indicator (ERI)

A specified response for a request. The response should be issued only if the request cannot be processed or if an error was encountered during processing.

exchange identification (XID)

An identifier that is exchanged between nodes on an SNA network, and that enables the nodes to recognize each other and to establish link and node characteristics for communicating. With Host Integration Server, there are two possible kinds of XIDs that can be exchanged: Format 0 XIDs (containing only basic information such as Node ID) and Format 3 XIDs (containing more detailed information such as Network Name and Control Point Name). *See also* **Format 0 XID**; **Format 3 XID**.

EXR

See **exception request (EXR)**.

Extended Binary Coded Decimal Interchange Code (EBCDIC)

A coding scheme developed by IBM for use with its mainframe and AS400 computers as a standard method of assigning binary (numeric) values to alphabetic, numeric, punctuation, and transmission-control characters.

Extensible Markup Language (XML)

A specification developed by the World Wide Web Consortium (W3C) that enables designers to create customized tags beyond the capabilities of standard Hypertext Markup Language (HTML). While HTML uses only predefined tags to describe elements within the page, XML enables tags to be defined by the developer of the page. Tags for virtually any data item, such as a product or an amount due, can be used for specific applications. This enables Web pages to function as database records.

Extensible Stylesheet Language (XSL)

A style sheet format for Extensible Markup Language (XML) documents. XSL is used to define the display of XML in the same way that cascading style sheets (CSS) are used to define the display of Hypertext Markup Language (HTML).

-F-

fault isolation

Containing the effects of a fault within a component, rather than propagating the fault to other components in the system.

fault tolerance

The ability of a system to recover from an error, a failure, or a change in environmental conditions (such as loss of power). True fault tolerance provides for fully automatic recovery without disruption of user tasks or files, in contrast to manual means of recovery such as restoring data loss with backup files.

file transfer

The process of sending and receiving data files to and from computers.

fill type

A value that indicates whether programs will receive data in the form of logical records or as a specified length of data.

flow

A verb flows from one LU to another.

FMHI

See **function management header indicator (FMHI)**.

FMI

See **function management interface (FMI)**.

Format 0 XID

A type of XID that supplies minimal information about the node. Format 0 XIDs have a fixed length. They can be used for 3270 and LUA communication, and cannot be used for Advanced Program-to-Program Communications (APPC). *See also* **exchange identification (XID)**, **Format 3 XID**.

Format 3 XID

A type of XID that supplies more detailed information about the node than a Format 0 XID. Format 3 XIDs have a variable length. They can be used for 3270 and LUA communication, and are the only type of XID that can be used for Advanced Program-to-Program Communications (APPC). *See also* **exchange identification (XID)**; **Format 0 XID**.

full-duplex

Capable of simultaneously transmitting and receiving data. Also called **duplex** or **4-wire**. *Contrast with* **half-duplex**.

full-duplex transmission

Two-way electronic communication that takes place in both directions simultaneously. Also called **duplex transmission** or **4-wire transmission**. *Contrast with* **half-duplex transmission**.

fully qualified LU name

The two-part network address (network.lu) that uniquely identifies a destination (typically a user) in the network.

function management header indicator (FMHI)

Headers inserted into requests containing end-user data to convey control information.

function management interface (FMI)

An interface that provides applications with direct access to SNA data flow and information about SNA control flows by means of status messages. It is particularly suited to the requirements of 3270 emulation applications.

-G-

GAC

See **global assembly cache (GAC)**.

global assembly cache (GAC)

A machine-wide code cache that stores assemblies specifically installed to be shared by many applications on the computer. Applications deployed in the global assembly cache must have a strong name.

group

A set of one or more Windows 2000 or later user accounts.

-H-

half-duplex

Capable of only one direction of communication at a time, either receiving data or transmitting data, but not doing both at the same time. Also called **2-wire**. *Contrast with* **full-duplex**.

half-duplex transmission

Two-way electronic communication that takes place in only one direction at a time. Also called **2-wire transmission**. *Contrast with* **full-duplex transmission**.

HCD

See **host column description (HCD)**.

HE

See **host environment (HE)**.

high-level language application programming interface (HLLAPI)

An API that enables you to develop and run programmer-operator applications on IBM personal computers (or compatibles) that communicate with IBM mainframes using 3270 emulation.

HIP

See **host-initiated processing (HIP)**.

HLLAPI

See **high-level language application programming interface (HLLAPI)**.

host column description (HCD)

Maps AS/400 flat file data types to OLE DB data types. The HCD is an external file stored on the computer that enables administrators to describe the host record format. At run time, the OLE DB Provider for AS/400 and VSAM transparently converts the host data to computer data using the local HCD information.

host environment (HE)

An object that defines the network and hardware characteristics of the non-Windows software platform that initiates requests to the Windows platform. The host environment consists of the host environment name, host identification, network transport type, data conversion information, default method resolution criteria, and security credential mapping.

Host Integration Server

A Microsoft® software program that enables a personal computer to communicate with remote computers such as IBM mainframes, AS/400s, or other personal computers on a TCP/IP or SNA network.

host response time

The amount of time that a host computer takes to reply to a message sent to it by a client computer. Host response time is measured from the moment that the personal computer sends the message until one of the following events: the client computer receives data back from the host, the host unlocks the client computer's keyboard, or the host enables the client computer to send more data.

host system

A computer system (usually a mainframe) that controls interactions between it and the computers connected to it. A host system makes operating systems and applications available by way of Host Integration Server 2004 to computers running software for terminal emulation or for APPC.

In SNA terminology, a host is capable of sending an ACTPU command to Host Integration Server 2004 and sets up a PU-SSCP session with Host Integration Server 2004.

host-addressable printer

A printer that is defined as a device associated with a logical unit (LU) configured as LU type 1 or 3 and that can support host printing as well as local printing.

host-initiated processing (HIP)

A non-Microsoft software platform (usually a mainframe or mid-range computer such as the AS/400) that can access and integrate its programs with the programs on a Windows server platform.

hot backup

(1) The ability to take systems online and offline without disrupting service. (2) A configuration in which one resource (such as a server running Host Integration Server 2004 software) can automatically handle sessions if another cannot. Such servers can provide hot backup for 3270, LUA, or downstream sessions through pools containing LUs from multiple servers. Servers running Host Integration Server 2004 software can provide hot backup for 5250 terminal emulation through the use of LU names that are the same on multiple servers.

-I-

I-frame

See **Information frame (I-frame)**.

identity

A COM+ application property page that specifies the user accounts authorized to use that application. You can set it to **Interactive user** (to authorize the current logged on user), to a specific user account, or to a group of users within a Windows domain.

IEEE

See **Institute of Electrical and Electronics Engineers (IEEE)**.

implicit incoming mode

A mode that defines the properties to use when Host Integration Server 2004 receives a request to start a session, and the mode named in the request is not recognized by Host Integration Server 2004. An implicit incoming mode enables greater flexibility in starting sessions with remote systems.

For a session to be established, the incoming local LU name must be recognized by Host Integration Server 2004. Then, the incoming remote LU must either be recognized explicitly or handled implicitly (if an implicit incoming remote LU has been configured). If the remote LU is recognized explicitly, but the mode is not recognized (as part of an LU-LU pair), Host Integration Server 2004 internally creates a new mode definition with the correct name, using the properties of the implicit incoming mode. Alternatively, if the remote LU is handled implicitly, Host Integration Server 2004 also handles the mode implicitly, by internally creating a mode, as described.

Note that an implicit incoming mode must be configured for any remote LU that will be used as an implicit incoming remote LU. An implicit incoming mode can be (but does not have to be) configured for remote LUs that will only be used explicitly.

implicit incoming remote LU

A remote APPC LU that defines the properties to use when Host Integration Server 2004 receives a request to start a session with a local LU, and the remote LU named in the request is not recognized by Host Integration Server 2004. An implicit incoming remote LU that enables greater flexibility in starting sessions with remote systems.

Note that for a session to be established, the local LU name must be recognized by Host Integration Server 2004. If the local LU name is recognized, but the remote LU name is not recognized as a partner for the local LU, Host Integration Server 2004 internally creates a new remote LU definition with the correct name, using the properties of the implicit incoming remote LU.

In SNA Manager, before a remote APPC LU can be used as an implicit incoming remote LU, an implicit incoming mode must be configured for it.

IMS

See **Information Management Systems (IMS)**.

independent local APPC LU

A local logical unit (LU) that enables Advanced Program-to-Program Communications (APPC) with a peer system without involving a host (mainframe) system. The type of LU used in independent APPC is LU 6.2. An independent LU does not require a host system, but can work through one.

IND$FILE

IBM file transfer program that enables files to be transferred from a personal computer to the host and from the host to the personal computer. It operates in three host environments: CICS, VM/CMS, and MVS/TSO.

Information frame (I-frame)

A standard unit of information transmitted over an SNA network. For 802.2 or SDLC communication, an I-frame is equivalent to a BTU. *See also* **basic transmission unit (BTU)**.

Information Management Systems (IMS)

A transaction processing monitor created and sold by IBM Corporation.

in-process component

A component that runs in a client's process space. This is typically a dynamic-link library (DLL).

instance

An object of a particular component class. Each instance has its own private data elements or member variables. A component instance is synonymous with object.

Institute of Electrical and Electronics Engineers (IEEE)

An organization that maintains the standards for the 802.x protocols used in communications on local area networks.

Integer

A fundamental Automation data type that holds integer numbers. An integer variable is stored as a 16-bit (2-byte) number ranging in value from –32,768 to 32,767. The type-declaration character is a percent sign (%) (ANSI character 37). In Microsoft® Visual Basic®, you can use integers to store Boolean (**True**/**False**) values.

interface

A group of logically related operations or methods that provides access to a component object.

Internet Packet Exchange/Sequenced Packet Exchange (IPX/SPX)

A set of protocols used by Novell NetWare networking software for communication across a network.

Internet Protocol (IP) routed network

A TCP/IP wide area network in which IP packets are propagated across the network through devices called IP routers.

invokable

Indicates the capability of a program to be started by another program. For example, an invokable APPC transaction program (TP) can be started in response to a request from another TP (the invoking TP).

invoked program

A program that has been activated by a call or verb. *See also* **invoking program**.

invoked TP

A host transaction program (TP) started by:

- Another (the invoking) TP.
- A Transaction Integrator Automation server working in conjunction with the TI run-time environment and Microsoft Distributed Transaction Server (DTS) included in COM+.

invoking program

A program that uses a call or verb to activate another program. Also known as the calling program or the client. *See also* **invoked program**.

invoking TP

A TP that initiates a conversation with another TP. The invoking TP starts the other TP by instructing the remote node to load the invokable TP.

IP routed network

See **Internet Protocol (IP) routed network**.

IPX/SPX

See **Internet Packet Exchange/Sequenced Packet Exchange (IPX/SPX)**.

isolation

A characteristic whereby two transactions running in parallel produce the illusion that there is no concurrency. It appears that the system is running one transaction at a time.

-J-

No terms.

-K-

No terms.

-L-

LAN

See **local area network (LAN)**.

LE

See **local environment (LE)**.

leased SDLC line

A dedicated telecommunications line using SDLC. *See also* **Synchronous Data Link Control (SDLC)**.

link service

The software component of Host Integration Server 2004 that communicates with the device driver for a particular communication adapter (802.2, SDLC, X.25, DFT, Channel, or Twinax).

listener

A local environment associated with an application, where the local environment monitors the TCP/IP or SNA network for requests to the application.

load balancing

Distribution of the processing load among several servers carrying out network tasks to increase overall network performance.

local account

An account provided in a local domain for a user whose regular account is not in a trusted domain. Local accounts cannot be used to log on interactively. Local accounts created in one domain cannot be used in trusted domains.

local area network (LAN)

A high-speed communication system consisting of hardware (computers and peripherals) and software (programs and data files) that are interconnected by cable in a way that enables these resources to be shared. The connected devices are located within a limited geographic area such as a building or campus.

local environment (LE)

An object that defines the endpoint on a Windows computer that accepts incoming requests from a non-Windows software platform. The local environment consists of the local environment name, network transport type, network transport class, and endpoint identification.

local LU

In an APPC or CPI-C conversation, the logical unit (LU) on the local end. *Contrast with* **partner LU** and **remote LU**.

local LU alias

The name by which a local logical unit (LU) is known to the local transaction program (TP).

local node

The software component of Host Integration Server 2004 that interacts with clients and other nodes on the SNA network.

local printer

A printer that is attached directly to a personal computer.

local program

In CPI-C, the program on the local end of the conversation. *Contrast with* partner program.

local TP

In an Advanced Program-to-Program Communications (APPC) or Common Programming Interface for Communications (CPI-C) conversation, the transaction program (TP) on the local end. *Contrast with* **partner TPs** and **remote transaction program**. *See also* **local LU**.

locality

A base and the components within it; that is, a Host Integration Server 2004 executable program.

locality, partner, index (LPI)

An LPI address that is used to identify each end of a connection. It has three components: locality (L), partner (P), and index (I).

logical unit (LU)

(1) A type of network-accessible unit that enables users to gain access to network resources and communicate with each other.
(2) A preset unit containing all of the configuration information needed for a user, program, or downstream system to establish a session with a host or peer computer. *See also* **LU alias**; **LU name**; **LU pool**.

logical unit application (LUA)

A conventional LU application, or the interface that these applications use. LUA enables workstations to communicate with host applications using LU 0, 1, 2, or 3 protocols.

LPI

See **locality, partner, index (LPI)**.

LPI address

Used to identify each end of a connection between two partners. It can have three components: L identifies the locality, P identifies the partner within the locality, and I identifies a logical entity within the partner. *See also* **locality**; **partner**.

LU

See **logical unit (LU)**.

LU alias

A string that identifies an APPC or CPI-C logical unit (LU) to transaction programs (TPs) in the same organizational unit (OU). An LU alias is used only locally by Host Integration Server 2004, but it also can be used by any program in the OU of the host mainframe system. *See also* **LU name**.

LU name

For 3270 or LUA communication, a name that identifies a logical unit (LU). For independent APPC or CPI-C, a name that (when used with the network name) identifies an LU to other components on an SNA network. For dependent APPC or CPI-C, a name that identifies an LU to local software, such as the Windows Event Viewer. *See also* **LU alias**.

LU pool

A number of logical units (LUs) of the same type that are made available as a group. A user or LU application addressing the pool will connect to the next available LU in the pool for that session only. *See also* **logical unit (LU)**.

LU type

Logical unit type. A subset of the SNA protocol that characterizes the communication between two LUs.

LU type 0

A logical-unit protocol with minimal constraints, on which special applications can be built for SNA.

LU type 1

A logical-unit protocol used by a host application communicating with a printer, sending data that conforms to the 3270 SNA Character String (SCS) definition.

LU type 2

A logical-unit protocol used by a host application communicating with a 3270-type display terminal, using the SNA 3270 data stream.

LU type 3

A logical-unit protocol used by a host application communicating with a printer, sending data that is 3270 data stream compatible (DSC).

LU type 6.2

A logical-unit protocol used by two applications or transaction programs (TPs) communicating as peers in an SNA environment. LU 6.2 works in combination with node type 2.1 to provide Advanced Program-to-Program Communications (APPC) using independent LUs. LU 6.2 also works with node type 2.0 to provide APPC with dependent LUs.

LU-LU session

A logical, two-way exchange between two logical units (LUs) over a specific connection for a specific amount of time.

LUA

See **logical unit application (LUA)**.

-M-

MAC address

A 12-byte hexadecimal address used by the media access control (MAC) layer of an 802.2 connection. It corresponds to the VTAM MACADDR= parameter and to the Remote Network Address parameter for an 802.2 connection with Host Integration Server 2004.

management object

A TI component that manages or provides access to administration information. Typically, management objects are visible only when errors or messages are reported or placed in the Windows Event Log.

mapped conversation

A conversation in which the sending program sends one logical record at a time and the receiving program receives one record at a time. *See also* **conversation**.

marshaling

The process of packaging and sending interface method parameters across thread or process boundaries.

member server

A server that does not contain a configuration file. One or more servers can operate as member servers. The other types of servers are the primary server and backup servers.

method

A procedure (function) that acts on an object.

Microsoft .NET

Microsoft® .NET is a set of software technologies for connecting information, people, systems, and devices. This new generation of technology is based on Web services—small building-block applications that can connect to each other as well as to other, larger applications over the Internet.

mode

A collection of session properties used by LU 6.2-type logical units (LUs) as they carry on a session. A mode can be used by many LU pairs at the same time.

mode name

The name used by the initiator of a session to designate the characteristics desired for the session, such as traffic pacing values, message-length limits, Sync Point and cryptography options, and the class of service within the transport network.

model

One of several different sizes of display:

- Model 2 is 24 lines by 80 characters
- Model 3 is 32 lines by 80 characters
- Model 4 is 43 lines by 80 characters
- Model 5 is 27 lines by 132 characters

Messaging-oriented middleware

Messaging-oriented middleware (MOM) is a set of products that connects applications running on different systems by sending and receiving application data as messages. Examples are RPC, CPI-C, and message queuing.

multidrop

A connection in which one primary node communicates with multiple secondary nodes concurrently over the same physical transmission medium.

multiple sessions

In CPI-C, two or more concurrent sessions with different partner LUs. *See also* **LU-LU session**.

Multiple Virtual Storage (MVS)

An operating system for large IBM mainframe computers. Implies MVS/370, the MVS/XA product, and the MVS/ESA product.

MVS

See **Multiple Virtual Storage (MVS)**.

-N-

NAU

See **network addressable unit (NAU)**.

NC

See **network control (NC)**.

NCP

See **Network Control Program (NCP)**.

.NET Framework

An integral Microsoft® Windows® component for building and running the next generation of applications and XML Web services.

NetView

A reporting system that runs on an IBM host (mainframe), forwarding alerts and other information back and forth between the host and personal computers, and other network addressable units that connect to the host.

NetView alert

A message sent to the NetView reporting system, indicating an abnormal event or a failure.

NetView user alert

A message sent by a 3270 user to a host system operator through NetView, requesting an action such as mounting a tape or changing forms on a printer. Also called user alert.

NetWare

A collection of networking software products from Novell, Inc.

network

Computer systems, controllers, terminals, and software connected in a way that enables them to communicate with each other.

network addressable unit (NAU)

The basic functional entities in an SNA environment that are the source or destination of all information flowing within the SNA network. The NAU can be a logical unit (LU), a physical unit (PU), or a system services control point (SSCP).

network control (NC)

A set of SNA-defined requests and responses used to control explicit and virtual routing.

Network Control Program (NCP)

An IBM program that supports communication controllers in single-domain, multiple-domain, and interconnected networks.

Network Management Vector Transport (NMVT)

SNA message containing network or system management information.

network name
A name identifying an SNA network. The network name is used in combination with other identifiers, either a control point name (to identify a control point or node) or an LU name (to identify an APPC LU, particularly an independent local APPC LU). The combination of a network name with a control point name is sometimes called a network qualified control point name. The combination of a network name with an LU name is sometimes called a fully qualified network name.

NMVT
See **Network Management Vector Transport (NMVT)**.

node
(1) A server, controller, workstation, printer, or other processor that implements SNA functions. SNA defines three kinds of nodes: the host subarea node, which functions to control and manage a network; the communication controller subarea node, which routes and controls data flow through the network; and peripheral nodes, which include printers, workstations, cluster controllers, and distributed processors.

(2) A branch on a navigation tree.

node type 2.1
An SNA component, such as an intelligent terminal or a personal computer, that works together with LU type 6.2 to support peer-to-peer communications, allowing the logical units (LUs) to function independently from the host.

null
A value that indicates missing or unknown data.

-O-

object
A run-time instance of a Component Object Model (COM) component. An object is created by a component's class factory. Object is synonymous with instance.

object variable
A variable that contains a reference to an object.

OCCURS DEPENDING ON
Code syntax that specifies variable-length tables. This is the COBOL version of an array that contains a variable number of elements.

OCCURS *fixed times*
Code syntax that specifies fixed-length tables. This is the COBOL version of an array.

ODBC
See **open database connectivity (ODBC)**.

ODBC resource dispenser
A resource dispenser that manages pools of database connections for COM+ components that use the standard open database connectivity (ODBC) programming interfaces.

open database connectivity (ODBC)
A set of standards that enables universal access to relational data, including Microsoft relational databases and mainframe databases.

open transaction management architecture (OTMA)
A high-performance, connectionless protocol used by IMS to communicate efficiently with Multiple Virtual Storage (MVS) applications without using the SNA protocol.

operator-loaded TP
An invokable transaction program (TP) that is manually loaded and started by an operator.

original caller
The identity of the base client that initiates an activity.

original creator
The identity of the base client that created the current object. The original caller and original creator are different only if the original creator passed the object to a different base client. *See also* **original caller**.

OS/390
The IBM operating system for the IBM S/390 family of enterprise servers and that includes and integrates functions previously provided by other IBM software products such as the MVS operating system.

OS/400
The IBM operating system for the IBM AS/400.

OTMA
See **open transaction management architecture (OTMA)**.

out-of-process component
A component that runs in a separate process space from its client.

-P-

pacing receive count
The maximum number of frames for the local logical unit (LU) to receive from the partner LU before the local LU sends a response.

pacing send count
The maximum number of frames for the local logical unit (LU) to send without receiving an SNA pacing response from the partner LU.

packet
A transmission unit of fixed maximum size, used as the basic unit on a packet-switching network. A packet contains both a header and data.

In data communication, a sequence of binary digits, including data and control signals, that is transmitted and switched as a composite whole. The data, control signals, and possibly error control information are arranged in a specific format.

packet switching
A message-delivery technique in which small units of information (packets) are relayed through stations in a computer network along the best route currently available between the source and the destination. Packet-switching networks are considered to be fast and efficient. The protocol used on packet-switching networks is X.25. *See also* **X.25**.

parallel sessions
Multiple concurrent sessions between a pair of LU 6.2-type logical units (LUs), allowing multiple operations to be performed simultaneously.

parameter
A variable used as input to a program, operating system, or API to govern how systems, programs, or functions perform.

partitioned data set (PDS)
A data set in direct access storage that is divided into partitions, called members, each of which can contain a program, part of a program, or data.

partner
An addressable component of a locality; that is, code to which messages can be sent. *See also* **locality**.

partner LU
In an APPC or CPI-C conversation, the LU on the far end. The partner LU serves the partner Transaction Processor. *Contrast with* **local LU**; *see also* **remote LU**.

partner LU alias
A name that identifies a partner logical unit (LU) to partner transaction programs (TPs).

partner LU name
A name that identifies a partner logical unit (LU) to other LUs on the LU 6.2 session.

partner program
For CPI-C, the program receiving the CPI-C call.

partner TPs
Two transaction programs (TPs), residing on the same or separate nodes that are configured to communicate with each other. Partner TPs use partner LUs.

password
A string of characters that a user, a program, or a computer operator must specify to meet security requirements before gaining access to a system and to the information stored within it.

path
(1) In SNA, the series of nodes and communications links over which data must travel from one LU to another. (2) A sequence of folders that identify the location of a file. (3) A path exists between two localities when the DMODs in the localities can successfully pass messages between them. A path must exist between two localities before a connection can exist between partners in these localities. *See also* **Dynamic Access Module (DMOD)**; **locality**.

pattern-matching character
A special character such as an asterisk (*) or a question mark (?) that can be used to represent one or more characters. Any character or set of characters can replace a pattern-matching character. *Synonymous with* wildcard character.

PC Support
A set of IBM programs that helps personal computer users access, share, and store information on an AS/400.

PDS
See **partitioned data set (PDS)**.

peer system
A mainframe, midrange, or personal computer that communicates with another computer as an equal partner, with both computers sharing control over the communication.

peer-to-peer
A type of communication in which two systems communicate as equal partners sharing the processing and control of the exchange, as opposed to host-terminal communication in which the host does most of the processing and controls the exchange.

permanent virtual circuit (PVC)
A type of circuit used by an X.25 connection, in which the circuit is constantly active, and the destination address is preset.

permissions

Settings that grant or deny a particular kind of access to a particular file, folder, or other object. For example, granting read permission but denying write permission for File1.ext for Domain Admins means that the members of Admins group can read but not change File1.ext.

physical unit (PU)

A network-addressable unit that provides the services needed to use and manage a particular device, such as a communications link device. A PU is implemented with a combination of hardware, software, and microcode.

PIC S9(4) COMP Integer

A 16-bit COBOL data type that represents signed arithmetic operations occupying 2 bytes of storage. This is normally analogous to an Integer data type in Microsoft® Visual Basic® and a Short Integer in C when referring to 32-bit. It can take on values from –9999 to +9999 or –32768 to +32767. It is similar to a Short in C.

PIC S9(9) COMP Integer

A 32-bit COBOL assignment statement to represent signed arithmetic operations that occupy 4 bytes of storage. It can take on values from –999999999 to +999999999 or –2147483648 to +2147483647 depending on compiler options. It is similar to a Long Integer in C.

PIC X

Specifies a single COBOL EBCDIC character.

PIC X No Translation

A character string handled like binary data. There is no translation from EBCDIC to Unicode or from Unicode to EBCDIC.

PICTURE clause

Specifies the general characteristics and editing requirements of an elementary item. The PICTURE character string is made up of COBOL characters used as symbols and can contain a maximum of 30 characters.

pipe

A portion of memory that can be used by one process to pass information along to another.

PLU

See **primary logical unit (PLU)**.

pool

See LU pool.

pooling

A performance optimization based on using collections of pre-allocated resources, such as objects or database connections. Pooling results in more efficient resource allocation.

primary logical unit (PLU)

On an SNA session, the LU on the node that sent the session activation request.

primary server

The server designated to contain the primary configuration file. There can be only one primary server active in a subdomain. *See also* **backup server**.

printer emulation

The ability of a personal computer-type printer to emulate a 3287 or 4224 printer to print host data.

printer session

A 3270 emulation session between a host and a local area network printer connected to a personal computer. The printer emulates the type of printer normally used by a host system.

private assembly

An assembly that is available only to clients in the same directory structure as the assembly. *See also* **assembly**.

ProgID

See **programmatic identifier (ProgID)**.

programmatic identifier (ProgID)

A name that identifies a COM component. For example, a ProgID could be Bank.MoveMoney.

programmatic security

Procedural logic provided by a component to determine if a client is authorized to perform the requested operation. *See also* **declarative security**.

protocol

(1) A set of semantic and syntactic rules that determine the behavior of functional units in achieving communication. (2) In Open Systems Interconnection architecture, a set of semantic and syntactic rules that determine the behavior of entities in the same layer in performing communication functions. (3) In SNA, the meanings of, and the sequencing rules for, requests and responses used for managing the network, transferring data, and synchronizing the states of network components.

proxy

An interface-specific object that provides the parameter marshaling and communication required for a client to call an application object that is running in a different execution environment, such as on a different thread or in another process. The proxy is located with the client and communicates with a corresponding stub that is located with the application object that is being called. In the case of TI, the TI run-time environment serves as the proxy to the mainframe transaction program (TP).

PU

See **physical unit (PU)**.

PU 2.0

In an SNA network, the component that defines controller and terminal-type resources similar to an IBM 3274 Control Unit.

PU 2.1

In an SNA network, a component such as an intelligent terminal or a personal computer that works together with logical unit (LU) type 6.2 to support peer-to-peer communications, allowing the LUs to function independently from the host.

PVC

See **permanent virtual circuit (PVC)**.

-Q-

QLLC

See **qualified logical link control (QLLC)**.

qualified logical link control (QLLC)

A protocol that permits SNA sessions to occur over X.25 networks.

queued TP

An invokable transaction program (TP) that can be started by only one incoming allocate command at a time. Incoming allocate commands that arrive while the queued TP is running do not start the program again, but are queued until the program issues another **RECEIVE_ALLOCATE** or until it finishes execution.

-R-

race condition

A condition in which a feedback circuit interacts with the internal circuit processes in a way that produces chaotic output behavior.

RE

See **remote environment (RE)**.

Record Level Input/Output (RLIO)

A protocol of IBM Distributed Data Management architecture.

remote component

Components used by a client on a different computer.

remote environment (RE)

A collection of properties that describes a region on the mainframe, or in the case of diagnostic tools such as Capture and Playback, a simulated region. You can view and change these properties by using TI Manager.

remote LU

In an APPC or CPI-C conversation, the logical unit (LU) on the remote end. *Contrast with* **local LU**. *See also* **remote transaction program**.

remote network address

For an 802.2 connection, a 12-digit hexadecimal address that identifies a remote host, peer, or downstream system. The Remote Network Address in Host Integration Server 2004 corresponds to the VTAM MACADDR= parameter in the PORT definition.

remote node

(1) The node at the other end of a connection. (2) The node that contains the logical unit (LU) at the other end of a session. (3) The node that contains the transaction program (TP) at the other end of a conversation.

remote node ID

One of the types of identifiers that can be used to identify a remote node. The remote node ID is an 8-digit hexadecimal number. The first three digits are called the block number, and correspond to the VTAM parameter IDBLK. The last five digits are called the node number, and correspond to the VTAM parameter IDNUM.

remote procedure call (RPC)

A standard that enables one process to make calls to functions that are executed in another process. The processes can be on the same computer or on different computers in the network.

remote transaction program

In an Advanced Program-to-Program Communications (APPC) or Common Programming Interface for Communications (CPI-C) conversation, the transaction program (TP) on the remote end. *Contrast with* **local TP**. *See also* **remote LU**.

remote unit of work (RUW)

(1) The form of SQL distributed processing in which the application is on a system different from the relational database, and a single application server services all remote unit-of-work requests within a single logical unit of work. (2) A unit of work that allows for the remote preparation and execution of SQL statements.

Report Program Generator (RPG)

A column-oriented programming language designed for writing application programs for business data processing. RPG requires that certain information, such as control codes and field names, must be placed into specific columns of the program statements.

Request Unit Interface (RUI)

A basic interface that enables programs to acquire and release control of conventional LUs. The RUI also reads and writes request/response headers (RHs), transmission headers (THs), and request/response unit (RU) data. *Contrast with* **Session Level Interface (SLI)**.

request/response unit (RU)

Under SNA, a message that controls the session, data flow, and function management aspects of the SNA protocol.

resource dispenser

A service that synchronizes and manages nondurable resources within a process. This service provides for efficient sharing by COM+ objects. For example, the ODBC resource dispenser manages pools of database connections.

Resource Dispenser Manager

A dynamic-link library (.dll) file that coordinates work among a collection of resource dispensers.

resource manager

A system service that manages durable data. Server applications use resource managers to maintain the durable state of the application, such as the record of inventory on hand, pending orders, and accounts receivable. The resource managers work in cooperation with the transaction manager to provide the application with a guarantee of atomicity and isolation (using the two-phase commit protocol). Microsoft® SQL Server™ is an example of a resource manager.

Response Time Monitor (RTM)

A 3270 and NetView facility that monitors the amount of time it takes for a host to respond during 3270 display sessions.

RLIO

See **Record Level Input/Output (RLIO)**.

role

A symbolic name that defines a class of users for a set of components. Each role defines which users are allowed to invoke interfaces on a component.

root

The topmost node in a directory structure.

root directory

The first directory on a drive in which all other files and subdirectories exist.

RPC

See **remote procedure call (RPC)**.

RPG

See **Report Program Generator (RPG)**.

RTM

See **Response Time Monitor (RTM)**.

RU

See **request/response unit (RU)**.

RUW

See **remote unit of work (RUW)**.

-S-

SAA

See **Systems Application Architecture (SAA)**.

safe reference

A reference to the current object that is safe to pass outside the context of the current object.

SAP address

See **service access point (SAP) address**.

SC

See **session control (SC)**.

schema

The definition of the structure of an XML file. A schema contains property information as it pertains to the records and fields within the structure. *See also* **document type definition (DTD)**.

SDLC

See **Synchronous Data Link Control (SDLC)**.

security ID (SID)

A unique name that identifies a logged-on user to the security system. SIDs can identify one user or a group of users.

security key

An identifier used by two APPC logical units (LUs) to validate security when a session is activated. The security key performs a function similar to that of a password, but at the LU-LU session level rather than at the TP-conversation level.

security log

The location in which events related to security are recorded when auditing is set up for such events. For example, auditing can be set up to create a security log entry every time the configuration file is changed on a server. *See also* **event log**.

security password

The password that is required, along with the security user ID, to gain access to an invoked program when using conversation security.

security user ID

The user ID (also known as user name) that is required, along with the security password, to gain access to an invoked program when using conversation security.

semaphore

A flag variable that is used to govern access to shared system resources.

server

(1) A functional unit that provides shared services to workstations over a network; for example, a file server, a print server, or a mail server. (2) In a network, a data station that provides facilities to other stations; for example, a file server, a print server, or a mail server.

server process

A process that hosts COM+ application components in Windows 2000 or later. For example, to use TI, you can drop a TI component (type library) into a COM+ application to create an Automation server that a client application can call. When a client application calls a method on the TI Automation server, the Windows 2000 or later run-time environment loads the TI Automation server along with the TI run-time environment into a surrogate server process that automates the mainframe transaction and passes the results back to the client application.

service access point (SAP) address

A value that codes for access to certain services on an 802.2 connection within an SNA network. The Remote SAP Address parameter is used for 802.2 connections in Host Integration Server 2004, and corresponds to the VTAM parameter called SAPADDR= in the PU definition.

service TP

A transaction program (TP) that uses APPC to perform services related to SNA functionality. *See also* **application TP**; **transaction program (TP)**.

session

(1) A period of time when a connection is active and communication can take place. (2) A set of resources that when activated allow communication to take place. (3) In network architecture, for the purpose of data communication between functional units, all the activities that take place during the establishment, maintenance, and release of the connection. (4) A logical connection between two network-accessible units (NAUs) that can be activated, tailored to provide various protocols, and deactivated as requested. Each session is uniquely identified in a transmission header (TH) accompanying any transmissions exchanged during the session. *See also* **LU-LU session**.

session control (SC)

A subcomponent of a transmission control component of a half-session, responsible for activating and deactivating the session and data flow and for receiving the data flow following an error.

Session Level Interface (SLI)

A higher-level interface that facilitates the opening and closing of SNA sessions with host LU 0, LU 1, LU 2, and LU 3 application programs. The SLI permits application programs to control the data traffic at a logical message level. *Contrast with* **Request Unit Interface (RUI)**.

session limit

The maximum number of parallel sessions that can be active between two APPC LUs. When an LU-LU session is established, the session limit is negotiated between the two LUs.

severity level

A number that indicates the severity of an audit or error message. Audit messages provide information and have severity 6, 8, or 10. Error messages have severity 12 or 16, indicating a problem that needs to be corrected.

shared assembly

An assembly that can be referenced by more than one application. An assembly must be explicitly built to be shared by giving it a cryptographically strong name. *See also* **assembly**; **private assembly**.

SID

See **security ID (SID)**.

side information table

In CPI-C, a table that stores the initialization information required for two programs to communicate. The table resides in the operating system's memory and the system administrator maintains it by accessing a symbolic destination name. The table is derived from the configuration file for Host Integration Server 2004.

single session

A limit of one session between a pair of Advanced Program-to-Program Communications (APPC) logical units (LUs), which limits the associated transaction programs (TPs) to one operation at a time.

SLI

See **Session Level Interface (SLI)**.

SNA

See **Systems Network Architecture (SNA)**

SNA service TP

A transaction program (TP) that uses APPC to perform services related to SNA functionality.

SNA subdomain

With SNA Server version 2.11 and SNA Server version 3.0 or later, you can have several SNA subdomains in a Windows 2000

Server or later domain.

A Windows 2000 Server or later domain:

- Can contain several SNA subdomains.
- Can contain several primary servers, provided that each one is set up in its own subdomain.

With regard to Host Integration Server 2004, each subdomain:

- Contains one primary server.
- Can contain up to 14 backup servers.
- Cannot contain computers running Host Integration Server 2004 from other Windows 2000 Server or later domains.

Host Integration Server 2004 Setup requires you to specify the name of the subdomain to which the server will belong. One of the SNA subdomains can have the same name as that of the Windows 2000 Server or later domain in which all the servers operate.

Because each subdomain can have only one primary server, it is not advisable to implement an SNA subdomain across slow bridges or routers. Multiple servers in a single subdomain can produce unwanted traffic on the wide-area network.

SnaBase

The SNA Workstation Process. It is present at all times on personal computers whose users want to participate in the SNA network and on personal computers where dynamic loading is to be performed.

SNALink

Link support software that integrates hardware components into a Host Integration Server 2004 system. An SNALink is defined when a Host Integration Server 2004 system is installed. An SNALink can support only one physical connection from the server.

source TP Name

The host system attempts to identify the source of a request for monitoring, reporting, and so on. The source must be a TP name. MSTX is the default, because it is usually an MS Transaction Server process.

SSCP

See **system services control point (SSCP)**.

string expression

Any expression that evaluates to a sequence of contiguous characters.

stub

An interface-specific object that provides the parameter marshaling and communication required for an application object to receive calls from a client that is running in a different execution environment, such as on a different thread or in another process. The stub is located with the application object and communicates with a corresponding proxy that is located with the client that calls it. In the case of TI, the TI run-time environment serves as the proxy.

subdirectory

A directory contained within another directory in a file system hierarchy.

subdomain

A collection of computers running Host Integration Server 2004 that share a single configuration. A subdomain contains one primary server and can also contain one or more backup servers. All servers in a subdomain must belong to the same Windows domain. *See also* **backup server**; **primary server**.

SVC

See **switched virtual circuit (SVC)**.

switched SDLC line

A standard telephone line used for SDLC connections on an SNA network. The line is dialed in one of three ways: manually, by a modem that stores the phone number, or by a modem that accepts a phone number string from the software.

switched virtual circuit (SVC)

A type of circuit used by an X.25 connection, in which the circuit is not constantly active, but is called and cleared dynamically. The destination address is supplied when the circuit is called.

Synchronous Data Link Control (SDLC)

A type of link service used for managing synchronous data transfer over standard telephone lines (switched lines) or leased lines.

synchronous transmission

Transmission in which the data characters and bits are transmitted at a fixed rate, with the transmitter and receiver being synchronized. This eliminates the need for individual start and stop bits surrounding each byte. Both SDLC and X.25 use synchronous transmission.

synchronous verb completion

Processing of an SNA verb where the operation of the program is blocked until processing completes. *Contrast with* **asynchronous verb completion**.

system administrator

A person who configures, maintains the configuration of, helps users diagnose problems with, and manages a computer system. With Host Integration Server 2004, this person can also be the LAN administrator or a TI developer.

system services control point (SSCP)

(1) A host system network component that provides network services for dependent nodes. (2) An SNA network component that helps control and maintain communication flow between PUs and LUs on the network. Multiple SSCPs can work together to coordinate communications.

Systems Application Architecture (SAA)

Guidelines created by IBM to help developers standardize applications so they function in different operating environments with minimal program modification and retraining of users.

Systems Network Architecture (SNA)

The description of the logical structure, formats, protocols, and operational sequences for transmitting information units through, and controlling the configuration and operation of, networks

-T-

TCP/IP

See **Transmission Control Protocol/Internet Protocol (TCP/IP)**.

terminal

A device that can send or receive data over a data communications channel. Host Integration Server 2004 includes emulation of 3278 and 3279 terminals.

TH

See **transmission header (TH)**.

thread

The basic entity to which the operating system allocates CPU time. A thread can execute any part of the application's code, including a part currently being executed by another thread. All threads of a process share the virtual address space, global variables, and operating system resources of the process.

TI

See **Transaction Integrator (TI)**.

Token Ring

A type of LAN using the 802.2 protocol, in which a token is passed in a ring around the network, permitting a computer on the network to transmit data only when that computer has the token.

TP

See **transaction program (TP)**.

trace file

A file containing records of internal activities on the SNA network, including calls made to APIs, the activities of APIs, and the activities of communication links and internal flows.

trace message

A message that includes the current status of various COM+ activities, such as startup and shutdown.

tracing

The action of tracking the activities of an application programming interface (API), communication links, and internal flows, including the calls made to APIs. Tracing stores a history of activity in trace files.

transaction

Data entered into a system (such as a customer deposit to a bank account) triggering a certain action (such as updating an account balance).

An atomic unit of work in COM-based systems that either succeeds or fails as a whole or a section of a mainframe COBOL transaction program (TP). A mainframe-based transaction is a section of COBOL code within a transaction program (TP) that completes a certain task or set of tasks.

A mainframe transaction may or may not be an ACID (atomic, consistent, isolated, and durable) transaction. A mainframe-based TP is the actual COBOL program file that contains one or more transactions (sections of COBOL code). A Windows-based transaction is always an ACID transaction that is coordinated by the Microsoft Distributed Transaction Coordinator (DTC).

Data entered into a system (such as a customer deposit to a bank account) triggers a certain action or set of actions (such as updating an account balance) that must all occur or that must all not occur; that is, they act as a unit. That unit is called a transaction in Windows-based terminology.

Each method in a TI component invokes a single mainframe transaction in a mainframe TP. After being invoked, a mainframe transaction can call other transactions in the same or in a different TP.

transaction context

An object used to allow a client to dynamically include one or more objects in one transaction.

transaction ID

The identifier used to invoke a particular CICS or IMS application (transaction program); in CICS, it is the name of the transaction. A transaction ID (TRANID) can be up to four characters in length. The acceptable characters are A-Z, a-z, 0-9, dollar sign ($), at sign (@), period (.), slash mark (/), hyphen (-), underscore (_), percent sign (%), ampersand (&), question mark (?), exclamation point (!), colon (:), vertical bar (|), quotation mark ("), equal sign (=), caret (^), comma (,), semicolon (;), less than sign (<), and greater than sign (>).

Transaction Integrator (TI)

A Windows server-based program that enables you to integrate mainframe or midrange computer transaction programs with component-based and .NET Framework applications.

transaction manager

The transaction manager creates transaction objects and manages their atomicity and durability. Applications request the creation of a transaction object by calling the transaction manager's **BeginTransaction** method.

transaction program (TP)

A COBOL-based mainframe transaction program file. An application program that uses Advanced Program-to-Program Communications (APPC) to exchange data with another TP on a peer-to-peer basis. Within the context of TI, a TP is the mainframe-based CICS or IMS program file that a TI Automation server automates. A TP can contain one or more transactions that are managed on the mainframe side. Each method in a single TI Automation server invokes a single TP. That TP then uses the information passed into it by the TI Automation server to determine which mainframe transaction to run within the TP. Each mainframe transaction within a TP can call other transactions. It is dependent upon how the mainframe COBOL application developer has designed the system.

(1) An application program that uses APPC or CPI-C to exchange data with another TP on a peer-to-peer basis. (2) A program that processes transactions in an SNA network. There are two kinds of transaction programs: application transaction programs and service transaction programs. *See also* **conversation**.

Transmission Control Protocol/Internet Protocol (TCP/IP)

The transport protocol in use by many academic, military, scientific, and commercial organizations to provide communication across wide area networks (WANs). TCP/IP provides communication across interconnected networks that include a variety of different operating systems (such as VMS, UNIX, and Windows 2000 or later).

transmission header (TH)

A header prefix to a message unit flowing within the Path Control Network (PCN), and containing PCN-specific data about routing, sequencing, blocking, and route pacing.

Twinax

A twinaxial connection to a peer system.

twisted-pair cable

Two paired wires, with each wire twisted two or more times per inch to help cancel out noise.

two-phase commit (2PC)

A protocol that ensures that transactions that apply to more than one server are completed on all the servers or none at all. Two-phase commit is coordinated by the transaction manager and supported by resource managers.

type library

A file (or component within another file) that contains Automation descriptions of exposed objects, properties, and methods. Object library (.olb) files contain type libraries. Type libraries that are shipped as stand-alone files use the file extension .tlb. A TI component is an example of a type library (.tlb file).

-U-

UDA

See **universal data access (UDA)**.

UDT

See **user-defined type (UDT)**.

unbounded

Refers to recordsets or arrays. In TI, the rows in a recordset or the elements in an array are transmitted one at a time. Therefore, the mainframe application program must issue multiple receives or sends until all data is transmitted.

This type of parameter or return value can be defined as unbounded for the **CICS Using LU 6.2** and **IMS Using LU 6.2** models only. The number of rows in a recordset or the number of elements in an array is not determined (that is, bounded) before run time. Unbounded parameters or return values can occur anywhere in the Automation method. However, a parameter or return value of this type is always transmitted to and from the mainframe after all other data. TI supports, at most, a single unbounded input parameter and a single unbounded output parameter or a single unbounded in/out parameter.

universal data access (UDA)

A Microsoft data access method which supplies access to information across the enterprise. Universal data access provides high-performance access to a variety of information sources, including relational and non-relational, and an easy to use programming interface that is tool and language independent.

user alert

A message sent by a 3270 user to a host system operator by way of NetView, requesting an action such as mounting a tape or changing forms on a printer.

user identifier

A string of characters that uniquely identifies a user to a system.

user name

The name (also known as user ID) that identifies a Windows user account.

user-defined type (UDT)

A data type that is defined in a program. User-defined data types generally contain many different data types that are defined by the programming language being used. In COBOL, UDTs are called RECORDS (that is, any declaration containing lower-level numbers).

-V-

variable-length string

A fundamental data type that holds character information. A String variable can contain approximately 65,535 bytes (64 KB), and it is either fixed-length or variable-length. Strings usually have one character per byte; however, TI supports Unicode BSTR strings that occupy 16 bits per character. Fixed-length strings are declared to be a specific length, and variable-length strings can be any length up to 64 KB, less a small amount of storage overhead.

VCB

See **verb control block (VCB)**.

verb

Command from one LU to another to exchange data and perform tasks. *See also* **APPC verb**.

verb control block (VCB)

A structure made up of variables, which identifies the verb to be executed, supplies information to be used by the verb, and contains information returned by the verb when execution is complete.

VINES

See **VIrtual NEtworking System (VINES)**.

VIrtual NEtworking System (VINES)

A collection of networking software products from Banyan Systems, Inc. VINES includes an addressing system called StreetTalk.

Virtual Telecommunications Access Method (VTAM)

A set of IBM mainframe programs that control communications between mainframe applications and the terminals and computers that connect to the mainframe.

VTAM

See **Virtual Telecommunications Access Method (VTAM)**.

-W-

WAN

See **wide area network (WAN)**.

wide area network (WAN)

A high-speed communication system, consisting of hardware (computers and peripherals) and software (programs and files), that provides communications services and enables resources to be shared over a larger geographic area than that served by a LAN. *Contrast with* **local area network (LAN)**.

wildcard character

Synonym for pattern-matching character.

Windows-initiated processing (WIP)

A Windows server platform can access and integrate its programs with the programs on a non-Microsoft server platform (usually a mainframe or mid-range computer such as the AS/400).

WIP

See **Windows-initiated processing (WIP)**.

-X-

X.25

The CCITT standard used for communication over a packet-switching network. X.25 uses the protocol called qualified logical link control (QLLC).

XID

See **exchange identification (XID)**.

XML

See **Extensible Markup Language (XML)**.

XML Schema Definition (XSD)

A language proposed by the W3C XML Schema Working Group for use in defining schemas. Schemas are useful for enforcing structure and constraining the types of data that can be used validly within other XML documents. Unlike DTD, which requires its own language and syntax, XSD uses XML syntax for its language. XSD closely resembles and extends the capabilities of XDR. The W3C now recommends the use of XSD as a standard for defining XML schemas.

XSD

See **XML Schema Definition (XSD)**.

XSL

See **Extensible Stylesheet Language (XSL)**.

No terms.

UI Help

This section contains the user interface (UI) Help displayed when you press the F1 key or the **Help** button in the Microsoft® Host Integration Server 2004 or Microsoft® Visual Studio® .NET 2003 UI.

This section contains:

- Visual Studio Help
- Transaction Integrator Manager Help
- Data Integration Help
- Network Integration Help
- Installation Help
- Messaging Help
- Trace Utility Help

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Visual Studio Help

Microsoft® Visual Studio® .NET 2003 provides a graphical user interface for creating, viewing, and editing the objects used by the host-initiated processing (HIP) and Windows-initiated processing (WIP) environments in Transaction Integrator (TI). TI objects are created and edited within a TI Project, one of several project types supported by the Visual Studio .NET design environment.

The user interface for a TI Project includes a tree view in the Solution Explorer window, wizards, dialog boxes, and properties displayed in the Properties window. The tree view presents a two-pane design tool. The left pane displays a hierarchical representation of the components of a type library or .NET assembly. The right pane displays a list of details about the properties associated with the contents of the library or assembly selected in the left pane. You can customize the details view to display other types of information, for example, a COBOL, RPG, or IDL source code. You can display Help topics about the individual user interface controls by highlighting a control or node and pressing the **F1** key.

The TI wizards in a project have Help buttons on each wizard page. Clicking Help on the page takes you to the relevant Help topic in this section. You can display Help topics about the individual user interface controls by clicking Help on the Visual Studio wizard page or dialog box or by highlighting a control or node and pressing the F1 key. All of the TI Project Help topics are combined in this section for easy reference and review.

This section contains:

- COM Library Nodes
- .NET Library Nodes
- Wizards and Dialog Boxes (TI Project)
- Properties (TI Project)

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

COM Library Nodes

When you view a COM type library (.tlb for client and .tim for server) from within a TI Project, the Visual Studio design environment displays the objects in the library in a tree view in the left pane and a details view in the right pane. Double-click the node to expand the node and right-click the node to display a shortcut menu.

The topics in this section describe the functionality of each menu and each command in the navigation tree. This section contains:

- Library Name Node
- Interface Name Node (COM)
- Method Name Node (COM)
- Parameter Name Node (COM)
- Recordsets Node
- Recordset Name Node
- Recordset Column Name Node
- User-Defined Types Node
- User-Defined Type Name Node
- User-Defined Type Member Name Node

Library Name Node

Use the ***library name*** node to support Microsoft® Visual Basic® 6.0, transactions, and select the remote environment class.

Double-click the ***library name*** node to expand it. The right pane displays the following information about the node's children:

- **Name**. The object name.

Right-click the ***library name*** node to display the following nine options:

- **Import**. Displays a menu with two options:
  - **Host Definition**. Launches the COBOL Import Wizard or RPG Import Wizard to help you import COBOL or RPG to the interface definition.
  - **Library**. Launches the **Import Library** open file dialog box to help you to import an existing type library or assembly to the interface definition.
- **Export Host Definition**. Launches the **Export Host Definition** file save dialog box to help you generate a COBOL or RPG copy book equivalent to the current library.
- **Lock**. Marks the library as read-only. The library is automatically marked as locked if it is registered in a COM+ application or IIS virtual directory.
- **Rename**. Renames the library.
- **Properties**. Displays the **Properties** window.

See Also

Library Properties

Interface Name Node (COM)

Recordsets Node

User-Defined Types Node

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Interface Name Node (COM)

Use the ***interface name*** node to set the name of the interface in a component.

Double-click the ***interface name*** node to expand it. The right pane displays the following information about the interface methods:

- **Method Name**. The method name.
- **Return Type**. The method return type.
- **Host Data Type**. The COBOL or RPG equivalent of the method's return type.
- **Array Size(s)**. If the return type is an array, this column will contain the number of dimensions and their sizes. For example, a single dimension of size 10 will be displayed as (10); a 3-dimensions array with sizes 2, 4, and 6 will be displayed as (2, 4, 6).
- **Rows**. The number of recordset rows if the return type of the method is a recordset.
- **Link-to-Program Name**. The name of an executable running under the host environment that will be linked to by this method and passed a COMMAREA. It is valid only for link models.
- **TP Name**. The name of the transaction program (TP) used by the method to locate a program to be executed. In the case of link models, it identifies the mirror transaction identifier which parses the distributed program link (DPL) header and identifies the link-to-program name.
- **Meta Data**. Indicates whether the host is sent no metadata, only the name of the method, or all metadata.

Right-click the ***interface name*** node to view the following seven options:

- **Add Method**. Adds a new method .
- **Paste**. Inserts a method into the current interface definition.
- **Rename**. Renames the interface.
- **Properties**. Displays the **Properties** window.

See Also

Interface Properties

Method Name Node (COM)

Library Name Node

Method Name Node (COM)

Use the ***method name*** node to define the conditions for interacting with the host environment, including the value for the initial buffers, whether to include all information.

Double-click the ***method name*** node to expand it. The right pane displays the following information about the method parameters:

- **Parameter Name**. The name of the parameter.
- **Type**. The data type of the parameter.
- **Direction**. The direction of the parameter: in only, in and out, or out only.
- **Host Data Type**. The COBOL or RPG data type that best describes the parameter type.
- **Array Size(s)**. The size and number of the dimensions of the parameter, if it is an array.
- **Rows**. The number of recordset rows if the parameter type is a recordset.

Right-click the ***method name*** node to view the following seven options:

- **Add Parameter**. Adds a new In\Out integer parameter to the method.
- **Cut**. Copies the selected method to the Clipboard and deletes it.
- **Copy**. Copies the selected method to the Clipboard.
- **Paste**. Inserts a parameter from the Clipboard into the current method definition.
- **Delete**. Deletes the method.
- **Rename**. Renames the method.
- **Properties**. Displays the **Properties** window.

See Also

Method Properties

Parameter Name Node (COM)

Interface Name Node (COM)

Parameter Name Node (COM)

Use the ***parameter name*** node to define the information passed as a parameter and what precision and scale is to be used.

Double-click the ***parameter name*** node to expand it. The right pane does not display any additional information.

Right-click the ***parameter name*** node to view the following eight options:

- **Move Up**. Moves a parameter up in the list.
- **Move Down**. Moves a parameter down in the list.
- **Cut**. Copies the selected parameter to the Clipboard and deletes it.
- **Copy**. Copies the selected parameter to the Clipboard.
- **Paste**. The paste command is disabled because parameters do not have any child elements.
- **Delete**. Deletes the selected parameter.
- **Rename**. Renames the selected parameter.
- **Properties**. Displays the **Properties** window.

See Also

Parameter Properties

Recordsets Node

Use the **recordsets** node to define the table passed as a parameter or return value.

Double-click the **recordsets** node to expand it. The right pane displays the following information about the defined recordsets:

- **Name**. The name of each recordset.

Right-click the **recordsets** node to view the following seven options:

- **Add Recordset**. Adds a new recordset definition.
- **Paste**. Inserts a recordset column from the Clipboard into the current folder.
- **Properties**. Displays the **Properties** window.

.NET Library Nodes

When you view a .NET library (.dll for client and .tim for server) from within a TI Project, the Visual Studio design environment displays the objects in the library in a tree view in the left pane and list view in the right pane. Double-click the node to expand the node and right-click the node to display a shortcut menu.

The topics in this section describe the functionality of each menu and each command in the navigation tree. This section contains:

- Interface Name Node (.NET)
- Method Name Node (.NET)
- Parameter Name Node (.NET)
- Data Tables Node
- Data Table Name Node
- Data Table Member Name Node
- Structures Node
- Structure Name Node
- Structure Member Name Node

Interface Name Node (.NET)

Use the ***interface name*** node to view the list of all the methods in a component.

Double-click the ***interface name*** node to expand it. The right pane displays the following information about the methods:

- **Method Name**. The method name.
- **Return Type**. The method return type.
- **Host Data Type**. The COBOL or RPG equivalent of the method's return type.
- **Array Sizes**. If the return type is an array, this column will contain the number of dimensions and their sizes. For example, a single dimension of size 10 will be displayed as (10); a 3-dimensions array with sizes 2, 4, and 6 will be displayed as (2, 4, 6).
- **Rows**. The number of rows, if the return type of the array is a data table.
- **Link-to-Program Name**. The name of an executable running under the host environment that will be linked to by this method and passed a COMMAREA. It is valid only for link models.
- **TP Name**. The transaction program (TP) name used by the method to locate a program to be executed. In the case of link models, it identifies the mirror transaction identifier which parses the distributed program link (DPL) header and identifies the link-to-program name.
- **Meta Data**. Indicates whether the host is sent no metadata, only the name of the method, or all metadata.

Right-click the ***interface name*** node to view the following seven options:

- **Add Method**. Adds a new method with no return type.
- **Paste**. Inserts the method from the Clipboard into the current interface definition.
- **Properties**. Displays the **Properties** window.

Double-click the ***method name*** node to expand it. The right pane displays the following information about the parameters:

- **Parameter Name**. The name of the parameter.
- **Type**. The data type of the parameter.
- **Direction**. The direction of the parameter: in only, in and out, or out only.
- **Host Data Type**. The COBOL or RPG data type that best describes the parameter type.
- **Array Size(s)**. The size and number of dimensions of the parameter, if it is an array.
- **Rows**. The number of rows, if the parameter type is a data table.

Right-click the ***method name*** node to display the following seven options:

- **Add Parameter**. Adds a new integer parameter to the method.
- **Cut**. Copies the contents of the method to the Clipboard and marks it as deleted.
- **Copy**. Copies the contents of the method to the Clipboard.
- **Paste**. Inserts the parameter from the Clipboard into the current method definition.
- **Delete**. Deletes the current method.
- **Rename**. Renames the current method.
- **Properties**. Displays the **Properties** window.

Wizards and Dialog Boxes (TI Project)

This section contains:

- New COM Client Library Wizard
- New COM Server Library Wizard
- New .NET Client Library Wizard
- New .NET Server Library Wizard
- Import COBOL Wizard
- Import RPG Wizard
- Name Conflict Dialog Box
- Array Dimension Dialog Box
- Map Remote Environment Class Dialog Box
- Select Convert Prim Dialog Box

New COM Client Library Wizard

The **New COM Client Library Wizard** collects information about the type library information and about the remote environment (RE). The wizard generates an annotated Windows-initiated processing (WIP) COM type library (.tlb) and adds the library to the current TI Project displayed in the Solution Explorer.

This section contains:

- Welcome to the New COM Client Library Wizard Page
- Library Wizard Page (COM Client Wizard)
- Remote Environment Wizard Page 1 (COM Client Wizard)
- Remote Environment Wizard Page 2 (for OS400) (COM Client Wizard)
- Remote Environment Wizard Page 2 (for LU 6.2 Link) (COM Client Wizard)
- Completing the New COM Client Library Wizard Page

Welcome to the New COM Client Library Wizard Page

Use the **Welcome to the New COM Client Library Wizard** page to view the definition of a COM client library and to control whether the welcome page is displayed again the next time the wizard is used.

Use this	To do this
Do not show this welcome page again	Select this option if you will be using the wizard more than once and do not want to read the introduction each time the wizard is launched. Each time the wizard is launched, the welcome page will be hidden and the wizard will begin with the second page. To view the welcome page again, click **Back** on the second page of the wizard.

Library Wizard Page (COM Client Wizard)

Use the **Library** wizard page to identify the COM client library you are creating.

Use this	To do this
Interface name	Type the name for the interface in the type library. The name of the interface, when combined with the major version number and the library name (ProgID), cannot exceed 39 Unicode characters.
Version	Type the major version information for the type library. The major version number, when combined with the name of the interface and the library name (ProgID), cannot exceed 39 Unicode characters.
Component ProgID	View the program identifier to be associated with the CoClass in the type library. The format is *Library.Interface.MajorVersion*. The ProgID cannot exceed 39 Unicode characters.
Description	Type the description to be associated with the interface. The description can be a maximum of 256 Unicode characters.
Support Visual Basic 6.0 decimal data type	Select this option if you want the component to allow application programs written with Visual Basic 6.0 and reference decimal data types.

Library Properties

Remote Environment Wizard Page 1 (COM Client Wizard)

Use the **Remote Environment** wizard page to define the remote environment (RE). A remote environment identifies an application execution environment running on a remote host system. The remote environment can have a data communication protocol and a programming model associated with it.

Use this	To do this
Vendor	Select the name of the vendor supplying the remote environment.
Protocol	Select the data communication protocol to be used to connect to the remote environment. The available communication protocols are: • **TCP/IP** (default) • **LU 6.2**
Target environment	Select the application environment running on the remote host system. The available environments are: • **CICS** (default) • **IMS** • **OS400** (TCP only)
Programming model	Select the programming model associated with the remote environment. The available models for the TCP/IP CICS target environment are: • **TRM User Data** (default) • **TRM Link** • **ELM User Data** • **ELM Link** The available models for the LU 6.2 CICS target environment are: • **CICS User Data** • **CICS Link** • The available models for the TCP/IP IMS target environment are: • **IMS Connect** • **Implicit** • **Explicit** • The only available model for the LU 6.2 IMS target environment is **IMS User Data**. • The only available model for the OS400 target environment is **Distributed Program Call**.
Allow 32K in/out	Select this option if you want TI to treat the input DFHCOMMAREA independently from the output DFHCOMMAREA. TI typically combines the input DFHCOMMAREA and the output DFHCOMMAREA area. The combined areas cannot exceed 32 KB of data. When this option is selected, TI treats the input DFHCOMMAREA independently from the output DFHCOMMAREA. Each input and output area uses up to 32 KB of data.

Remote Environment Wizard Page 2 (for LU 6.2 Link) (COM Client Wizard)

Use the **Remote Environment** wizard page to define the default values for the remote environment (RE).

Use this	To do this
Transaction ID	Type the transaction program (TP) name or the link mirror transaction ID of the remote environment. The name or ID can be a maximum of 4 alphabetic characters. The format of the name must conform to the IBM SNA Transaction Program Names convention. The default is **CSMI**.
Source TP name	Type the name of the transaction program used by the method to locate a program to be executed. In the case of link models, the name identifies the mirror transaction identifier, which parses the distributed program link (DPL) header and identifies the link-to-program name. The name can be a maximum of 250 Unicode characters. The default is **MSTX**.

The **New .NET Server Library Wizard** collects information about the type library information and about the host environment (HE). The wizard generates a Transaction Integrator metadata (TIM) file and adds it to the current TI Project displayed in the Solution Explorer.

This section contains:

- Welcome to the New .NET Server Library Wizard Page
- Library Wizard Page (.NET Server Wizard)
- Host Environment Wizard Page (.NET Server Wizard)
- Completing the New .NET Server Library Wizard Page

Welcome to the New .NET Server Library Wizard Page

Use the **Welcome to the New .NET Server Library Wizard** page to view the definition of a .NET server library and to control whether the welcome page is displayed again the next time the wizard is used.

Use this	To do this
Do not show this welcome page again	Select this option if you will be using the wizard more than once and do not want to read the introduction each time the wizard is launched. Each time the wizard is launched, the welcome page will be hidden and the wizard will begin with the second page. To view the welcome page again, click **Back** on the second page of the wizard.

Library Wizard Page (.NET Server Wizard)

Use the **Library** wizard page to identify the .NET server library you are creating.

Use this	To do this
Interface name	Type the full name for the class in the .NET assembly. The name of the interface, when combined with the major version number and the namespace name, cannot exceed 39 Unicode characters.
Version	Type the version information for the .NET assembly in the form *major.minor*. The major version number, when combined with name of the interface and the namespace name, cannot exceed 39 Unicode characters
Component class name	View the component class name to be associated with the managed class in the .NET assembly. The format is *Namespace.Interface.MajorVersion*. The namespace name, when combined with the major version number and the name of the interface, cannot exceed 39 Unicode characters
Description	Type the description to be associated with the interface. The description can be a maximum of 256 Unicode characters.

Import COBOL Wizard

This wizard allows you to select a COBOL copy book and use it for designing the component in the designer. This wizard is rather complex, as there are multiple options and paths to follow.

This section contains:

- Welcome to the Import COBOL Wizard Page
- Import COBOL Source File Wizard Page
- Item Options Wizard Page
- DFHCOMMAREA Wizard Page
- DFHCOMMAREA Direction Wizard Page
- Input Area Wizard Page
- Output Area Wizard Page
- Return Value Wizard Page
- Recordsets (COBOL) & UDT Wizard Page
- LL Field Wizard Page
- ZZ Field Wizard Page
- TRANCODE Field Wizard Page
- Recordset Columns Wizard Page
- User-Defined Type Members Wizard Page
- Completing the Import COBOL Wizard Page

Welcome to the Import COBOL Wizard Page

Use the **Welcome to the Import COBOL Wizard** page to view the procedure for importing a COBOL copy book and to control whether the welcome page is displayed again the next time the wizard is used.

Use this	To do this
Do not show this welcome page again	Select this option if you will be using the wizard more than once and do not want to read the introduction each time the wizard is launched. Each time the wizard is launched, the welcome page will be hidden and the wizard will begin with the second page. To view the welcome page again, click **Back** on the second page of the wizard.

Item Options Wizard Page

Item Options Wizard Page

Use the **Item Options** wizard page to specify the type of component to create. Select and identify the type of component to be created.

Use this	To do this
Type of item	View the group of component types: • **Method** • **Recordset** • **User-defined type**
Select or type the name of the item to import	View the identifying information for the new component.
Name	Select or type the name of the component. The name can be a maximum of 250 Unicode characters.
Use Link programming model	Type the name of an executable program that, running under the host environment (HE), will be linked to by this method and passed a COMMAREA. This option is available only for Link models. The name can be a maximum of 8 Unicode characters. This option is displayed only for host-initiated processing (HIP).
Exclude LL, ZZ, and TRANCODE fields	Select to exclude the LL, ZZ, and TRANCODE fields from the transaction if the host environment is IMS. This option is available only for HIP server components.
Link-to-Program	The name of an executable running under the host environment that will be linked to by this method and passed a COMMAREA. The name can be a maximum of 8 Unicode characters. This option is available only for WIP Link server components.
Source TP Name	The name of the mirror transaction identifier, which parses the distributed program link (DPL) header and identifies the link-to-program name. The name can be a maximum of 4 Unicode characters. This option is available only for WIP Link server components.

Map Remote Environment Class Dialog Box

Use the **Map Remote Environment Class** dialog box to update the definition of a remote environment (RE) class that is no longer supported or does not conform to Transaction Integrator (TI) requirements.

Use this	To do this
Remote environment class	Type or select the COM type library or .NET assembly class of the remote environment.
Vendor	Select the name of the vendor supplying the remote environment.
Protocol	Select the data communication protocol to be used to connect to the remote environment. The available communication protocols are: • **TCP/IP** (default) • **LU 6.2**
Target environment	Select the application environment running on the remote host system. The available environments are: • **CICS** (default) • **IMS** • **OS400** (TCP only)
Programming model	Select the programming model associated with the remote environment. The available models for the TCP/IP CICS target environment are: • **TRM User Data** (default) • **TRM Link** • **ELM User Data** • **ELM Link** The available models for the LU 6.2 CICS target environment are: • **CICS User Data** • **CICS Link** • The available models for the TCP/IP IMS target environment are: • **IMS Connect** • **Implicit** • **Explicit** • The only available model for the LU 6.2 IMS target environment is **IMS User Data**. The only available model for the OS400 target environment is **Distributed Program Call**.

Properties (TI Project)

This section contains:

- Library Properties
- Interface Properties
- Method Properties
- Parameter Properties
- Recordset Properties
- Recordset Column Properties
- User-Defined Type Properties
- User-Defined Type Member Properties

Library Properties

Use the **Library** properties page to set design and remote environment (RE) properties on the component library or .NET assembly.

Design Properties

Use this	To do this
Component Type	View the type of library component. Possible values are: - **COM Type Library** (default) - **.NET Assembly**
Description	Type a description of the component. The description can be a maximum of 250 Unicode characters.
Help Context ID	Type the Help context ID associated with this method. It is used to connect to the Help topic for this method, and returned when an exception occurs during invocation of this method.
Initiation Type	View the location of the transaction program (TM) making the request. Possible values are: - **Windows-initiated** (default) - **Host-initiated**
Name	Type the name of the component. The name can be a maximum of 250 Unicode characters. The name must be different from any other component name in the same project. The default is **Library(n)**.
Support Visual Basic 6.0 Decimal Type	Select this option to specify whether the component allows application programs written with Visual Basic 6.0 that reference decimal data types. The possible values are: - **True** - **False** (default)
Visual Basic 6.0 Compatible	Select this option to require that the Visual Basic server use the **Implements** keyword within the Visual Basic server script. The server script then creates the Visual Basic interface to the Transaction Integrator metadata (TIM) type library. The possible values are: - **True**. Use the **Implements** keyword. - **False** (default) **Note** This property is the same as the property **Visual Basic Implements Compatible** in Host Integration Server 2000.
Version	Type the version information for the type library or the .NET assembly, expressed in the form of *major.minor*.

Remote Environment Properties

Use this	To do this
Allow 32K In/Out	Select this option if you want TI to treat the input DFHCOMMAREA independently from the output DFHCOMMAREA. TI typically combines the input DFHCOMMAREA and the output DFHCOMMAREA area. The combined areas cannot exceed 32 KB of data. When this option is selected, TI treats the input DFHCOMMAREA independently from the output DFHCOMMAREA. Each input and output area uses up to 32 KB of data. Changing this option affects the currently selected method. Possible values are: - **True** - **False** (default)

Remote Environment Class	Select the programming model associated with the remote environment. The available models for the TCP/IP CICS target environment are: - **TRM User Data** (default) - **TRM Link** - **ELM User Data** - **ELM Link** The available models for the LU 6.2 CICS target environment are: - **CICS User Data** - **CICS Link** - The available models for the TCP/IP IMS target environment are: - **IMS Connect** - **Implicit** - **Explicit** - The only available model for the LU 6.2 IMS target environment is **IMS User Data**. The only available model for the OS400 target environment is **Distributed Program Call**.
Transaction Support	The possible values are: - **Required**. The new TI component is used in applications that execute within COM+ transactions. The component's methods will be called by applications used with mainframe transaction programs that support Sync Level 2 requests. If a transaction is in progress, the application will enlist in the transaction. Otherwise, the application will start a new transaction. - **Required New**. The new TI component is used in applications that execute within COM+ transactions. The component's methods will be called by applications used with mainframe transaction programs that support Sync Level 2 requests. The application will always start a new transaction, regardless of whether an existing transaction is already in progress. - **Supported**. The new TI component is used in applications that might or might not execute within COM+ transactions. The component's methods will be called by applications used with mainframe transaction programs that support both Sync Level 0 (non-transactional) and Sync Level 2 (transactional) requests. In the case of a Sync Level 2 transaction, the calling application will enlist in the transaction if the transaction is already in progress. Otherwise, the application will start a new transaction. - **Not Supported**. The new TI component is used in applications that do not execute within COM+ transactions. The component's methods will be called by applications used with mainframe transaction programs that support only Sync Level 0 requests. IMS transaction programs prior to IMS 6.0 support only Sync Level 0. CICS and IMS 6.0 transaction programs support either Sync Level 0 or Sync Level 2 requests.

> **Warning** The properties of a component are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the component to function incorrectly.

Library Name Node

Interface Properties

Use the **Interface** properties page to set design properties on the interface.

Design Properties

Use this	To do this
Name	Type the name of the library component. The name can be a maximum of 250 Unicode characters.

> **Warning** The properties of a component are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the component to function incorrectly.

See Also

Interface Name Node (COM)

Interface Name Node (.NET)

Method Properties

Use the **Method** properties page to set array, COBOL, design, host definition, and recordset properties on the method.

Array Properties

Use this	To do this
Array Dimensions	Select the array dimensions for the return value. The default is **(none)**.
Is Array	Select whether the return value is an array. The possible values are: • **True** • **False** (default)
Occurs Depending On	Select to indicate that a numeric data item preceding the table (recordset or array in Automation) indicates the actual number of rows or elements being sent or received. Equivalent to variable-length tables in COBOL. Use the drop-down list to select the numeric data item that specifies this value. For CICS Link, the recordset or array and the associated length specifier must be in/out. The data in the buffer that follows a variable length table immediately follows the last data item in the table regardless of the maximum size specified for the table. Arrays with multiple dimensions can only be used for the outermost loop (COBOL) or rightmost dimension (Microsoft® Visual C++® or Visual Basic). The default is **(none)**.

COBOL Properties

Use this	To do this
Host Data Type	Select the host data type.
Error Handling	Select the return value error handling. The possible values are: • **Truncate**. Select this option to set TI to truncate the value when an error occurs. (default) • **Round**. Select this option to set TI to round the value when an error occurs. • **Error**. Select this option to set TI to return an error when an error occurs.
Filler	Type the return value filler. The default is **0**.

From Host	Type the number of bytes of FILLER that follows this data item in the buffers that are received from the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side. The default is **0**.
To Host	Type the number of bytes of FILLER that follows this data item in buffers that are sent to the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side. The default is **0**.
Scale	Type the return value scale.
Sign Attribute	Select the return value sign attribute. The possible values are: - **Trailing**. For signed DISPLAY data type, indicates that the sign is trailing (default). This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. - **Trailing Separate**. For signed DISPLAY data type, indicates that the sign is separate. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. - **Leading**. For signed DISPLAY data type, indicates that the sign is leading. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. - **Leading Separate**. For signed DISPLAY data type, indicates that the sign is separate.
Size	Type the return value size.
SOSI	Select this option to specify whether a double-byte character set data is expected to begin with a shift-out (SO) and end with a shift-in (SI) character. The possible values are: - **True**. The SO and SI characters are removed from the data when it is received from the host application, and the SO and SI characters are added to the data when it is sent to the host application. In the length of the PIC G, it is not necessary to include the two bytes for the SO and SI characters because the TI run-time environment applies them. - **False** (default)
String Delimiting	Select the return value string delimiting. The possible values are: - **Space-padded**. Tells the TI run-time environment that the mainframe representation of the string is delimited by padding the string definition with space characters. For example, if the mainframe's COBOL definition is PIC X(10) but only three characters are in the string, the mainframe expects seven trailing spaces. Therefore, selecting this option tells the TI run-time environment to convert strings being sent to the mainframe to change the string's NULL termination character to the appropriate number of trailing spaces before sending it to the mainframe. For example, if the string is defined on the mainframe as PIC X(10), TI will send a string of *ABC* followed by seven trailing spaces. Selecting this option also tells the TI run-time environment to convert the output string being returned from the mainframe to the TI Automation server by converting the string's trailing spaces to a single null termination character. For more information, see Padding Mainframe Character Strings with Spaces. (default) - **Null-terminated**. Tells the TI run-time environment that the mainframe representation of the string is delimited by a null character (EBCDIC 0x00). Selecting this option tells the TI run-time environment to add a single null character to the end of a string if there is room for the byte before sending a string to the mainframe, and it tells the TI run-time environment to stop at the first null character encountered when receiving a string from the mainframe. Therefore, by selecting this option, you are telling TI to retain trailing spaces in output strings coming from the mainframe because TI will not convert the trailing spaces to a single NULL terminator. For more information, see Padding Mainframe Character Strings with Spaces.

Design Properties

Use this	To do this
Allow 32 K In/Out	Select this option if you want TI to treat the input DFHCOMMAREA independently from the output DFHCOMMAREA. TI typically combines the input DFHCOMMAREA and the output DFHCOMMAREA area. The combined areas cannot exceed 32 KB of data. When this option is selected, TI treats the input DFHCOMMAREA independently from the output DFHCOMMAREA. Each input and output area uses up to 32 KB of data. Changing this option affects the currently selected method. Possible values are: • **True** • **False** (default) **Note** You can use this property as an accessory to "Use Link Programming Model" in the Windows-initiated processing (WIP) CICS programming model and in any host-initiated processing (HIP) programming models. **Note** This property is available only if the **Is Link** property is set to **True**.
Description	Type a description of the method. The description can be a maximum of 250 Unicode characters.
Help Context ID	Type the Help context ID associated with this method. The ID is used to connect to Help for this method, and returned when an exception occurs during invocation of this method. The default is **0**.
Include Context Parameter	Select whether the client object method automatically includes context. The possible values are: • **True**. Visual Basic .NET automatically includes the context as an additional parameter in the argument. If you do not include **COMTIContext** parameter in your method call along with your other parameters, Visual Basic .NET returns the error message **An unhandled exception of type 'System.MissingMemberException' occurred in microsoft.visualbasic.dll** and informs you that the method cannot be called with the number of parameters you have written. If you receive this message, verify that the **Include Context Parameter** is included as a parameter within the list of parameters on the method. • **False**. Visual Basic .NET does not automatically include the context as an additional parameter in the argument. If you set this property to **False** and include **COMTIContext** parameter in your method call along with your other parameters, Visual Basic .NET returns the error message **An unhandled exception of type 'System.MissingMemberException' occurred in microsoft.visualbasic.dll** and informs you that the method cannot be called with the number of parameters you have written. If you receive this message, remove the **COMTIContext** parameter from the method parameter list. The default is **True**.
Initial Buffer Value	Type the initial buffer value. The default is null.
Is Link	Select whether the host object method uses the Link programming model. The possible values for Windows-initiated processing (WIP) are: • **True**. Use the link model. The link programming model can be used only with CICS link protocols. • **False**. Do not use the link model. The default is **False**. The possible values for host-initiated processing (HIP) are: • **Yes**. Use the link model. The link programming model can be used with all protocols. • **No**. Do not use the link model. • **Link using 32K In/Out**. Use the link model and set the From Host and To Host properties. The default is **No**.

Meta Data	Select how metadata is handled. The possible values are: - **(none)**. By default no special data is sent to or received from the host application. Select this option button if you only want to send and receive the data for the method. - **Include Method Information**. The name of this method to be sent to the host along with parameter data. The method name is sent as the first 32 bytes in the buffer. This option is useful if multiple method calls go to the same transaction and you want to differentiate the data from the different calls. - **Include All Information**. All metadata available to be sent and received with your method data. For details of the format of metadata, see description for "Optional Metadata".
Name	Type the name of the method. The name can be a maximum of 250 Unicode characters. The name must be different from any other method name in the same project. The default is **null**.
Position Return Value After	Type the Automation method return value that follows the selected data item when it is received from the host. This option does not affect the Automation side. Use this option when the data item that you want to specify as the Automation return value is not the first data item field in the data declaration that describes the data received from the host.
Preliminary Filler	View the number of bytes of FILLER received from or sent to the host.
From Host	Type the number of bytes of FILLER that follows this data item in the buffers that are received from the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
To Host	Type the number of bytes of FILLER that follows this data item in the buffers that are sent to the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
Return Type	Select the return value type. The possible values are: - **Void** - **Boolean** - **Byte** - **Date** - **Currency** - **Decimal** - **Integer** - **Long** - **Double** - **Single** - **String** - **User-defined type** - **Recordset** - **(none)** (default)
Variable Sized Final Field	- Select this option when the last data item is a string to indicate that the size of the string varies. This option is also used to define a datatable or recordset as being either bounded or as including all rows as defined as **Maximum Occurrence** set on the parameter.
From Host	- **True** - **False** (default)
To Host	- **True** - **False** (default)

Host Definition Properties

Use this	To do this
Link-to-Program Name	Type the link-to-program name (CICS LINK/DPL).
Mirror Transaction ID	Type the mirror TRANID that this method uses, if you want to override the mirror TRANID for the remote environment (RE) that this component is associated with. Leaving this box blank causes the mirror TRANID in the remote environment description to be used. The TRANID can be up to four characters in length. Acceptable characters are A-Z a-z 0-9 $ @ # . / _ % & ¢? ! : | = ¬ , ; < >. Transaction names beginning with C are reserved for CICS and should not be used. The % and & characters may cause problems with Resource Access Control Facility (RACF) if transaction security is active.
TP Name	Type a source transaction program (TP) name when the CICS application program must access a DB2 database. The TP name is referenced in a CICS Resource Control Table (RCT) entry, which associates CICS transactions with DB2 plans. Specifies the name of the host transaction program (IMS or CICS) or the link-to program name (CICS LINK/DPL).

Recordsets Properties

Use this	To do this
Include Actual Size	The host program will not include or expect any information that indicates the actual number of rows (recordsets) or elements (arrays) being sent or received. The possible values are: • **True** • **False** (default) **Note** This property is read-only and will always be set to **False** unless it was set to **True** at the time the type library was created with the first version of COM Transaction Integrator.
Maximum Occurrence	Maximum row occurrence. Indicates the maximum number of rows to be sent to or received from the host. Equivalent to the OCCURS n TIMES keyword on a COBOL group item. The default is **1**.
Occurs Depending On	Equivalent to variable-length tables in COBOL. Indicates that a numeric data item preceding the table (recordset or array in Automation) indicates the actual number of rows or elements being sent or received. Use the drop-down list to select which numeric data item specifies this value. For CICS Link, the recordset or array and the associated length specifier must be in/out. The data in the buffer that follows a variable length table immediately follows the last data item in the table regardless of the maximum size specified for the table. For arrays with multiple dimensions, it can only be used for the outermost loop (COBOL) or rightmost dimension (Visual C++ or Visual Basic). Return value recordset occurs depending on. The default is **(none)**.
Unbounded	Indicates the recordset is unbounded. Indicates that any number of rows can be sent to or received from the host. You would select this option when the rows being sent or received are from a database and the maximum number of rows is not known. The possible values are: • **True**. When the last data item is a string, this means that the size of the string varies. • **False**. When the last data item is an array, this means that the number of elements in the array varies. When the last data item is a recordset, this means that the number of rows in the recordset varies. (default)

> **Warning** The properties of a component are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the component to function incorrectly.

Parameter Properties

Use the **Parameter** properties page to set the array, COBOL design, and recordset properties on a parameter.

Array Properties

Use this	To do this
Array Dimensions	Use this control to indicate how many dimensions (Visual C++ or Visual Basic) or nested OCCURS clauses (COBOL) that the array or table contains.
Is Array	Select this option to indicate whether the parameter is an array. The possible values are: - **True**. Parameter is an array. - **False**. The item is a simple data type including RDA recordset objects. (default).
Occurs Depending On	Select this option to indicate that a numeric data item preceding the table (recordset or array in Automation) indicates the actual number of rows or elements being sent or received. Use the drop-down list to select which numeric data item specifies this value. For CICS Link, the recordset or array and the associated length specifier must be in/out. The data in the buffer that follows a variable length table immediately follows the last data item in the table regardless of the maximum size specified for the table. For arrays with multiple dimensions, it can only be used for the outermost loop (COBOL) or rightmost dimension (Visual C++ or Visual Basic). The RPG language, unlike COBOL, does not directly support **Occurs Depending On**. TI provides a feature that replicates the Occurs Depending On action for the RPG language. A TI Project supports a single level of dimension applied as an Occurs Depending On associated with a array of records in RPG. An index parameter must be defined prior to defining the parameter associated with a datatable or structure for the parameter to show as a **Occurs Depending On** selectable choice.

Host Properties

Use this	To do this
Host Data Type	Specifies the parameter host data type.
Error Handling	Parameter error handling. The possible values are: - **Truncate**. If selected and an error occurs, TI will truncate the value. (default) - **Round**. If selected and an error occurs, TI will round the value. - **Error**. If selected and an error occurs, TI will return an error.

Filler	Indicates the number of bytes of FILLER that follow this data item in the buffers that are sent to or received from the host. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
FromHost	Indicates the number of bytes of FILLER that follows this data item in the buffers that are received from the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
ToHost	Indicates the number of bytes of FILLER that follows this data item in the buffers that are sent to the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
Scale	The parameter scale.
SignAttribute	Parameter sign attribute. The possible values are: - **Trailing**. For signed DISPLAY data type, indicates that the sign is trailing (default). This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. - **Trailing Separate**. For signed DISPLAY data type, indicates that the sign is separate. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. - **Leading**. For signed DISPLAY data type, indicates that the sign is leading. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. - **Leading Separate**. For signed DISPLAY data type, indicates that the sign is separate.
Size	Specifies the length of the string.
SOSI	Specifies whether double-byte character set data is expected to begin with a shift-out (SO) and end with a shift-in (SI) character. When this check box is selected, the SO and SI characters are removed from the data when it is received from the host application, and the SO and SI characters are added to the data when it is sent to the host application. In the length of the PIC G, it is not necessary to include the two bytes for the SO and SI characters because the TI run-time environment applies them. The possible values are: - **True** - **False** (default)

String Delimiting	Return value string delimiting. The possible values are: - **Space-Padded**. Tells the TI run-time environment that the mainframe representation of the string is delimited by padding the string definition with space characters. For example, if the mainframe's COBOL definition is PIC X(10) but only three characters are in the string, the mainframe expects seven trailing spaces. Therefore, selecting this option tells the TI run-time environment to convert strings being sent to the mainframe to change the string’s NULL termination character to the appropriate number of trailing spaces before sending it to the mainframe. For example, if the string is defined on the mainframe as PIC X(10), TI will send a string of *ABC* followed by seven trailing spaces. Selecting this option also tells the TI run-time environment to convert the output string being returned from the mainframe to the TI Automation server by converting the string’s trailing spaces to a single null termination character. (default) - **Null-terminated**. Tells the TI run-time environment that the mainframe representation of the string is delimited by a null character (EBCDIC 0x00). Selecting this option tells the TI run-time environment to add a single null character to the end of a string if there is room for the byte before sending a string to the mainframe, and it tells the TI run-time environment to stop at the first null character encountered when receiving a string from the mainframe. Therefore, by selecting this option, you are telling TI to retain trailing spaces in output strings coming from the mainframe because TI will not convert the trailing spaces to a single NULL terminator. For more information, see Padding Mainframe Character Strings with Spaces.

Design Properties

Use this	To do this
Data Type	The possible values are: - **Void** - **Boolean** - **Byte** - **Date** - **Currency** - **Decimal** - **Integer** - **Long** - **Double** - **Single** - **String** - **User-defined type** - **Recordset** - **(none)** (default)
Name	Name of the parameter. The name can be a maximum of 250 Unicode characters.
Parameter Direction	The possible values are: - **In** - **Out** - **In / Out** (default)

Recordsets Properties

Use this	To do this

Include Actual Size	Default option indicating that the host program will not include or expect any information that indicates the actual number of rows (recordsets) or elements (arrays) being sent or received. The possible values are: - **True** - **False** (default)
Maximum Occurrence	Maximum row occurrence. Indicates the maximum number of rows to be sent to or received from the host. Equivalent to the OCCURS n TIMES keyword on a COBOL group item.
Occurs Depending On	Parameter recordset occurs depending on. Equivalent to variable-length tables in COBOL. Indicates that a numeric data item preceding the table (recordset or array in Automation) indicates the actual number of rows or elements being sent or received. Use the drop-down list to select which numeric data item specifies this value. For CICS Link, the recordset or array and the associated length specifier must be in/out. The data in the buffer that follows a variable length table immediately follows the last data item in the table regardless of the maximum size specified for the table. For arrays with multiple dimensions, it can only be used for the outermost loop (COBOL) or rightmost dimension (Visual C++ or Visual Basic).
Unbounded	Indicates the recordset is unbounded. Indicates that any number of rows can be sent to or received from the host. You would select this option when the rows being sent or received are from a database and the maximum number of rows is not known. The possible values are: - **True** - **False** (default)

Recordset Properties

Use the **Recordset** properties page to set design and host definition properties on a recordset.

Design Properties

Use this	To do this
Name	Name of the recordset. The name can be a maximum of 250 Unicode characters.

Host Definition Properties

Use this	To do this
Column Filler	Recordset filler. Indicates for each row of data sent or received, the number of bytes of FILLER that precedes each row. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
Variable Sized Rows	Recordset variable sized rows. Use this option to indicate that the last data item or group item returned from the host varies from zero to the maximum size specified for the data item. When the last data item is character data, it refers to the number of bytes (TI terminology is "variably sized"). When the last data item is an array, it refers to the number of elements. When the last data item is a recordset, it refers to the number of rows. The last two are called "bounded" in TI terminology. The possible values are: • **(none)** (default) • **Half-word binary (16 bits)**. Indicates that the length specifier for the actual size of a variably sized row will be a half-word binary (16-bit) value. This is the default. • **Full-word binary (32 bits)**. Indicates that the length specifier for the actual size of a variably sized row will be a full word binary (16-bit) value. • **Half Word (16bits) Inclusive**. If the value of the actual size of variably sized rows will include the length specifier (the actual size of the row plus 2 or 4 bytes), select this check box. Verify that this check box is cleared if the value should only specify the actual size of a row itself. • Full Word (32bits) Inclusive.

> **Warning** The properties of a component are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the component to function incorrectly.

Recordset Name Node

Recordset Column Properties

Use the **Recordset Column** properties page to set COBOL and design properties on a recordset column.

COBOL Properties

Use this	To do this
HostDataType	Specifies the recordset column host data type.
ErrorHandling	Recordset column error handling. The possible values are: - **Truncate**. If selected and an error occurs, TI will truncate the value. (default) - **Round**. If selected and an error occurs, TI will round the value. - **Error**. If selected and an error occurs, TI will return an error.
Filler	Recordset column filler. The default is **0**.
FromHost	Indicates the number of bytes of FILLER that follows this data item in the buffers that are received from the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
ToHost	Indicates the number of bytes of FILLER that follows this data item in buffers that are sent to the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
Scale	Recordset column scale.

SignAttribute	Recordset column sign attribute. The possible values are: • **Trailing**. For signed DISPLAY data type, indicates that the sign is trailing (default). This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. For signed DISPLAY data type, indicates that the sign is not separate (default). • **Trailing Separate**. For signed DISPLAY data type, indicates that the sign is separate. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. • **Leading**. For signed DISPLAY data type, indicates that the sign is leading. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. For signed DISPLAY data type, indicates that the sign is not separate (default). • **Leading Separate**. For signed DISPLAY data type, indicates that the sign is separate.
Size/Precision	Recordset column size.
SO SI	Specifies whether double-byte character set data is expected to begin with a shift-out (SO) and end with a shift-in (SI) character. When this check box is selected, the SO and SI characters are removed from the data when it is received from the host application, and the SO and SI characters are added to the data when it is sent to the host application. In the length of the PIC G, it is not necessary to include the two bytes for the SO and SI characters because the TI run-time environment applies them. The possible values are: • **True** • **False** (default)
StringDelimiting	Recordset column string delimiting. The possible values are: • **Space-padded**. Tells the TI run-time environment that the mainframe representation of the string is delimited by padding the string definition with space characters. For example, if the mainframe's COBOL definition is PIC X(10) but only three characters are in the string, the mainframe expects seven trailing spaces. Therefore, selecting this option tells the TI run-time environment to convert strings being sent to the mainframe to change the string's NULL termination character to the appropriate number of trailing spaces before sending it to the mainframe. For example, if the string is defined on the mainframe as PIC X(10), TI will send a string of *ABC* followed by seven trailing spaces. Selecting this option also tells the TI run-time environment to convert the output string being returned from the mainframe to the TI Automation server by converting the string's trailing spaces to a single null termination character. For more information, see Padding Mainframe Character Strings with Spaces. • **Null-terminated**. Tells the TI run-time environment that the mainframe representation of the string is delimited by a null character (EBCDIC 0x00). Selecting this option tells the TI run-time environment to add a single null character to the end of a string if there is room for the byte before sending a string to the mainframe, and it tells the TI run-time environment to stop at the first null character encountered when receiving a string from the mainframe. Therefore, by selecting this option, you are telling TI to retain trailing spaces in output strings coming from the mainframe because TI will not convert the trailing spaces to a single NULL terminator. For more information, see Padding Mainframe Character Strings with Spaces.

Design Properties

Recordset Column Name Node

User-Defined Type Properties

Use the **User-Defined Type** properties page to set design and host definition properties on user-defined types (UDTs).

Design properties

Use this	To do this
Name	Name of the user-defined type (UDT). The name can be a maximum of 250 Unicode characters.

Host Definition properties

Use this	To do this
Independent UDT	Independent user-defined type. An independent user-defined type (UDT) is a UDT that is not referenced by a method (directly or indirectly). When you use TCP/IP, the client sends the host a transaction request message (TRM) or enhanced listener message (ELM) containing the Transaction Program ID, User ID, Password, and other administrative data to be used by the host. The client sends a TRM or ELM reply containing additional administrative data. The data in the TRM or ELM is independent from the actual program data to be exchanged with the Transaction Program on the host. You can use the independent UDT options and the naming convention of TRMIN..., TRMOUT..., ELMIN..., or ELMOUT... to control the data content and format in the TRM or ELM request and TRM or ELM reply. For TRMs or ELMs destined for the host, the name of the UDT must begin with the characters TRMIN or ELMIN. For TRM or ELM replies from the host, the name of the UDT must begin with the characters TRMOUT or ELMOUT. Examples of valid TRM names are: TRMINMyVeryOwn, ELMINStandard, TRMOUTMyVeryOwn, and ELMOUTStandard. When you begin the UDT with the character TRMIN, TRMOUT, ELMIN, or ELMOUT, Visual Studio automatically formats the first member as an Int or Long and the last members as a String or Array. After an independent UDT has been defined, it can be referenced by the client application and passed to and from the TI runtime (by using the COMTIContext object) as an optional parameter. The possible values are: • **(none)** (default) • **Length Inclusive** • **Length Exclusive**
Member Filler	User-defined type member filler. Type the number of bytes of FILLER that precedes each row of data sent or received. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side. This option is not available if the length specifier option to include or exclude itself is selected.

> **Warning** The properties of a component are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the component to function incorrectly.

User-Defined Type Member Properties

Use the **User-Defined Type Member** properties page to set array, COBOL, design, and recordset properties on user-defined type members.

Array Properties

Use this	To do this
Array Dimensions	User-defined type member array dimensions. The default is **(none)**.
Is Array	User-defined type member is an array. The possible values are: • **True** • **False** (default)
Occurs Depending On	User-defined type member array occurs depending on.

Host Properties

Use this	To do this
Host Data Type	User-defined type member host data type.
Error Handling	User-defined type member error handling. The possible values are: • **Truncate**. If selected and an error occurs, TI will truncate the value. (default) • **Round**. If selected and an error occurs, TI will round the value. • **Error**. If selected and an error occurs, TI will return an error.
Filler	User-defined type member filler.
From Host	Indicates the number of bytes of FILLER that follows this data item in the buffers that are received from the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
To Host	Indicates the number of bytes of FILLER that follows this data item in buffers that are sent to the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.

Scale	User-defined type member scale.
SignAttribute	User-defined type member sign attribute. The possible values are: - **Trailing**. For signed DISPLAY data type, indicates that the sign is trailing (default). This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. For signed DISPLAY data type, indicates that the sign is not separate (default). - **Trailing Separate**. For signed DISPLAY data type, indicates that the sign is separate. - **Leading**. For signed DISPLAY data type, indicates that the sign is leading. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. For signed DISPLAY data type, indicates that the sign is not separate (default). - **Leading Separate**. For signed DISPLAY data type, indicates that the sign is separate.
Size	User-defined type member size.
SOSI	Specifies whether double-byte character set data is expected to begin with a shift-out (SO) and end with a shift-in (SI) character. When this check box is selected, the SO and SI characters are removed from the data when it is received from the host application, and the SO and SI characters are added to the data when it is sent to the host application. In the length of the PIC G, it is not necessary to include the two bytes for the SO and SI characters because the TI run-time environment applies them. The possible values are: - **True** - **False** (default)
StringDelimiting	User-defined type member string delimiting. The possible values are: - **Space-padded**. Tells the TI run-time environment that the mainframe representation of the string is delimited by padding the string definition with space characters. For example, if the mainframe's COBOL definition is PIC X(10) but only three characters are in the string, the mainframe expects seven trailing spaces. Therefore, selecting this option tells the TI run-time environment to convert strings being sent to the mainframe to change the string's NULL termination character to the appropriate number of trailing spaces before sending it to the mainframe. For example, if the string is defined on the mainframe as PIC X(10), TI will send a string of *ABC* followed by seven trailing spaces. Selecting this option also tells the TI run-time environment to convert the output string being returned from the mainframe to the TI Automation server by converting the string's trailing spaces to a single null termination character. For more information, see Padding Mainframe Character Strings with Spaces. - **Null-terminated**. Tells the TI run-time environment that the mainframe representation of the string is delimited by a null character (EBCDIC 0x00). Selecting this option tells the TI run-time environment to add a single null character to the end of a string if there is room for the byte before sending a string to the mainframe, and it tells the TI run-time environment to stop at the first null character encountered when receiving a string from the mainframe. Therefore, by selecting this option, you are telling TI to retain trailing spaces in output strings coming from the mainframe because TI will not convert the trailing spaces to a single NULL terminator. For more information, see Padding Mainframe Character Strings with Spaces.

Design Properties

Use this	To do this

Data Type	User-defined type member data type. The data type of the currently displayed user-defined type member. The possible values are: - **Void** - **Boolean** - **Byte** - **Date** - **Currency** - **Decimal** - **Integer** - **Long** - **Double** - **Single** - **String** - **User-defined type** - **Recordset**
Name	Name of the user-defined type member. The name can be a maximum of 250 Unicode characters. The name must be unique from any other user-defined type member name in the same project. The default is **null**.

Recordsets Properties

Use this	To do this
Include Actual Size	Default option indicating that the host program will not include or expect any information that indicates the actual number of rows (recordsets) or elements (arrays) being sent or received. The possible values are: - **True** - **False** (default)
Maximum Occurrence	Maximum row occurrence. Indicates the maximum number of rows to be sent to or received from the host. Equivalent to the OCCURS n TIMES keyword on a COBOL group item.
Occurs Depending On	User-defined type member recordset occurs depending on. Indicates the maximum number of rows to be sent to or received from the host. Equivalent to the OCCURS n TIMES keyword on a COBOL group item. Equivalent to variable-length tables in COBOL. Indicates that a numeric data item preceding the table (recordset or array in Automation) indicates the actual number of rows or elements being sent or received. Use the drop-down list to select which numeric data item specifies this value. For CICS Link, the recordset or array and the associated length specifier must be in/out. The data in the buffer that follows a variable length table immediately follows the last data item in the table regardless of the maximum size specified for the table. For arrays with multiple dimensions, it can only be used for the outermost loop (COBOL) or rightmost dimension (Visual C++ or Visual Basic).

Unbounded	Indicates that any number of rows can be sent to or received from the host. Set to **true** when the rows being sent or received are from a database and the maximum number of rows is not known. The possible values are: - **True** - **False** (default)

Warning The properties of a component are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the component to function incorrectly.

Transaction Integrator Manager Help

Transaction Integrator (TI) Manager provides a graphical user interface for creating, viewing, and managing the host-initiated processing (HIP) and Windows-initiated processing (WIP) environments. The user interface is accessible through the TI Manager management console and appears in tree view, property pages, and wizards. You can display Help topics on the individual user interface controls by clicking **Help** on the TI Manager wizard page or dialog box or by selecting a control or node and pressing the **F1** key. These individual Help topics are included in this section for easier reference and review.

This section contains:

- TI Manager Nodes
- TI Manager Wizards and Dialog Boxes
- TI Manager Properties

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

TI Manager Nodes

The Transaction Integrator (TI) Manager console provides a tree view of the primary configuration elements used in host-initiated processing (HIP) and Windows-initiated processing (WIP). HIP enables an IBM mainframe program in CICS, IMS, or MVS to call a COM or .NET object. WIP enables a Windows client application to access an IBM mainframe transaction program in CICS, IMS, or MVS.

Each major element of the process is represented by a node on the tree in the left pane of the management console. Double-clicking the node expands it; right-clicking the node displays a shortcut menu.

This section contains:

- Transaction Integrator (mode) Node
- Host-Initiated Processing Node
- Computers Node
- Computer Node
- Application [status] Node
- Listener [status] Node
- View Node (listener)
- Local Environments Node
- Local Environment Node
- Host Environments Node
- Host Environment Node
- Security Policies Node
- Security Policy Node
- Objects Node (HIP)
- Object Node (HIP)
- View Node (object)
- Windows-Initiated Processing Node
- Remote Environments Node
- Remote Environment Node
- Objects Node (WIP)
- Object Node (WIP)

Transaction Integrator (mode) Node

Use the **Transaction Integrator** (TI) node to view the basic grouping of elements within the host-initiated processing (HIP) environment and the Windows-initiated processing (WIP) environment. You can also use the **Transaction Integrator** (TI) node to control the operating mode of the TI Manager console.

All computers that have TI installed are able to share the same physical SQL Server configuration database, and TI Manager allows you to edit the configuration of any computer registered in that database from any TI-enabled computer. In HIP, an administrator could edit database entries such as the host environments, objects, or views that are shared among computers. In WIP, an administrator can only edit local WIP settings.

The mode shown in parentheses in the node label indicates the mode of console operations: either **Configuration** or **View and operate**. Although multiple system administrators using the TI Manager console can concurrently view, start, or stop any application and listener on any TI-enabled computer registered in the configuration database, only one authorized administrator at a time can create or edit the configuration of the TI database. When the first administrator opens the TI Manager console to view or change the configuration, the console opens in **Configuration** mode by default, the configuration database (MSHIS60_HIP) is locked, and a timer starts. If no configuration changes occur within the time period set on the timer, the console is automatically unlocked and the mode is returned to **View and operate**.

> **Note** The default name of the configuration database is MSHIS60_HIP, but you can change the name using the Microsoft® Host Integration Server 2004 Configuration Wizard.

If another administrator opens their TI Manager console while the first administrator is still making changes or while the first console is still in **Configuration** mode, the second console opens in **View and operate** mode and TI Manager displays a message box indicating the name of the user in **Configuration** mode. The second administrator must wait until either the first administrator manually switches to **View and operate** mode or the timer automatically switches the console mode due to inactivity.

You can edit the configuration database or the local computer only when all the other TI Managers registered in the configuration database are in the **View and operate** mode.

The possible console modes are:

- **Configuration**. The Host Integration Server administrator can create or edit the following items on any TI-enabled computer:
  - Applications
  - Listeners on an application
  - Local environments
  - Host environments
  - Security policies
  - HIP objects
  - Object views

  The Host Integration Server administrator can also create or edit the following items on the local computer:

  - Remote environments
  - WIP objects
- **View and operate**. The administrator can view the following items on any TI-enabled computer:
  - Applications
  - Listeners on an application
  - Local environments
  - Host environments
  - Security policies
  - HIP objects
  - Object views

  The Host Integration Server administrator can also create or edit the following items on the local computer:

  - Remote environments
  - WIP objects

  The administrator can also start, stop, or refresh applications and listeners. When in **View and operate** mode, the commands on the shortcut menu for creating and editing are disabled.

Double-click the **Transaction Integrator** node to expand the node. The right pane displays the following information about the node:

- **Name**. Displays the names of the two major sub-nodes.

Right-click the **Transaction Integrator** node to display the following six options:

- **Operation Mode**. Displays the following list of menu items to control the operating mode of the console:
    - **Create/Edit**. Enables you to create, edit, view, start, stop, and refresh all TI elements on a computer.
    - **Read-only**. Enables you to view, start, stop, and refresh applications and listeners on an application. Also restricts you to viewing local environments, host environments, security policies, objects, and object views.
- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.
    - **Small Icons**. Displays small icons for items in the right pane.
    - **List**. Displays only the small icons and the names of the nodes in the right pane.
    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of nodes as a separate text or Unicode text file.
- **Properties**. Displays the **Transaction Integrator (view and operate) Properties** dialog box and one tabbed property page:
    - **Timeout**. Set or view the maximum number of minutes TI Manager can stay in **Configuration** mode. The number of minutes can be set or changed only on the computer where the configuration database is stored.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Host-Initiated Processing Node

Use the **Host-Initiated Processing** node to view the major elements used in host-initiated processing (HIP) environment. The major HIP elements are:

- Computers that have the HIP run-time environment installed. The run-time environment is responsible for accepting incoming requests, instantiating a Microsoft Windows® server object, and returning a reply to the host program that initiated the request.
- Local environments (LEs) that a HIP runtime uses to listen for incoming requests. The LE definitions contain network-transport specific endpoint identification.
- Host environments (HEs) that represent the non-Windows host computers or host environments that deliver requests to a HIP run-time environment. The HE is used by the HIP runtime to define the code page and the data conversion object to be used by the HIP runtime when communicating with the host system identified by the HE.
- Security policies that define how Windows security credentials are established before the server object is invoked.
- Objects that represent the metadata for the server objects that were created through Microsoft Visual Studio®.
- Views define the resolution criteria used by TI when directing the call made from a host environment to a server object. Views restrict access to object methods based on the host environment calling the object and the local environment receiving the call.

Double-click the **Host-Initiated Processing** node to expand the node. The right pane displays the following information about the node:

- **Name**. The name of the major HIP elements.

Right-click the **Host-Initiated Processing** node to display the following five options:

- **View**. Displays the following menu items:
  - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
  - **Large Icons**. Displays large icons for items in the right pane.
  - **Small Icons**. Displays small icons for items in the right pane.
  - **List**. Displays only the small icons and the names of the nodes in the right pane.
  - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
  - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of elements as a separate text or Unicode text file.
- **Properties**. Displays the **Host-Initiated Processing Properties** dialog box and one tabbed property page:
  - **Database**. Displays the name of the database.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Objects Node (HIP)

Computers Node

Use the **Computers** node to view all the computers that have Transaction Integrator (TI) installed on them and are referenced in the same TI Manager configuration database (MSHIS60_HIP).

> **Note** If the computer you are looking for does not appear in this list, the computer might be registered in a different configuration database. After you have installed TI, run the **Microsoft Host Integration Server Configuration Wizard** and configure the new computer to use the same Transaction Integrator configuration database as the other computers. You can select the same configuration database by changing the **Server** and **Database** settings on the **Database Configurations** wizard page.

Double-click the **Computers** node to expand the node. The right pane displays the following information about the node:

- **Computer**. Displays the name of the HIP-enabled computer.

Right-click the **Computers** node to display the following four options:

- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.
    - **Small Icons**. Displays small icons for items in the right pane.
    - **List**. Displays only the small icons and the names of the nodes in the right pane.
    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of computers as a separate text or Unicode text file.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

See Also

Computer Node

Computer Node

Use the **Computer** node to view and manage the applications running on the computer that is selected in the left pane. An application represents the execution environment for Windows server objects that are initiated by, or driven from, requests from the host computer.

Double-click the **Computer** node to expand the **Computer** node. The right pane displays the following information about the application:

- **Application**. Displays the name of the application.
- **PID**. Displays the process ID of the HIPService. **0** indicates that HIPService is not running.
- **Thread Count**. Displays the minimum number of worker threads the runtime always has active.
- **Maximum Queue Depth**. Displays the maximum number of requests that are stored in the queue waiting to be processed before new requests are rejected.
- **Comment**. Displays additional information about the application.

  Important If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

  If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

   The columns should now be in their original order.

Right-click the **Computer** node to display the following five options:

- **New**. Displays the following menu items:
  - **Empty Application**. Launches the **New Application** dialog box, which allows you to define an application that does not have executable objects associated with it.
  - **Configured Application**. Launches the **New Application Deployment Wizard**, which walks you through the steps of creating the application, local environment, host environment, and objects.
- **View**. Displays the following menu items:
  - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
  - **Large Icons**. Displays large icons for items in the right pane.
  - **Small Icons**. Displays small icons for items in the right pane.
  - **List**. Displays only the small icons and the names of the nodes in the right pane.
  - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
  - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of applications as a separate text or Unicode text file.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

See Also

Application [status] Node

Application [status] Node

Use the ***application* [*status*]** node to start or stop an application or to manage the listeners for an application. An application represents the execution environment for Windows server objects that are initiated by, or driven from, requests from the host computer. An application can host more than one server object and can have more than one listening endpoint associated with it.

The term shown in brackets at the end of the node indicates status of the application:

- **Stopped**. The execution environment and Windows Server 2003 service for the application and its objects are inactive.
- **Incomplete**. The application is missing one or more objects and, therefore, is not available.
- **Starting**. TI Manager is starting the execution environment and Windows Server 2003 service for the application and its objects.
- **Active**. The execution environment for the application is running and the listeners and local environments are active.

Double-click the ***applications* [*status*]** node to expand the node. The right pane displays the following information about the listeners:

- **Listener**. The name of the listener.
- **Type**. The type of network (either TCP/IP or SNA).
- **Listening Address**. For a TCP/IP network, the local host. For an SNA network, the local LU defined in the local environment.
- **Endpoints**. The endpoints used to communicate with the host.

  Important If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

  If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

   The columns should now be in their original order.

Right-click the **Application** node to view the following 12 options:

- **Tracing**. Launches the ***application* Trace Options** dialog box. You can select one or more of the following categories for tracing and select one or more options within a category:
  - **General**. Provides high-level information about the end-to-end application processing.
  - **Transport**. Provides detailed connection information about the activities on the SNA or TCP network.
  - **Convert**. Provides detailed information about the data conversion between COM and .NET data on the servers and COBOL or Report Program Generator (RPG) data on the host.
  - **Read Lib**. Provides information about the contents of the type library; used to augment the information in the **Convert** trace.
  - **Flow Control Proxy**. Provides detailed information about object instantiation, state transitions, and method invocation.
- **Reload Definitions**. Performs a dynamic refresh of the application listener's endpoints and resolution tables. An application gets a snapshot of the configuration database at start-up. Any subsequent changes to the configuration do not affect the application until the definitions are reloaded. When you select **Reload Definitions**, the application re-reads all configuration information from the configuration database and applies it immediately. All new requests are processed using the updated resolution information. Working requests that were in progress at the time **Reload Definitions** was clicked are not affected by the update. The resolution information remains unchanged until the work request is completely processed.
- **Start**. Starts the host-initiated processing (HIP) environment for the selected application. Any listeners available for auto-start, as defined on the application property page of a listener that is associated with the application, are started when the application is started. After the application is started, **Start** is disabled and **Stop** is enabled.
- **Stop**. Stops the HIP environment for the selected application. All listeners are stopped when the application is stopped. All pending work is halted immediately and all listening activity is terminated immediately. After the application is stopped, **Stop** is disabled and **Start** is enabled.

- **New**. Displays a list of the following menu items:
    - **Listener**. Launches the **Local Environment** dialog box for you to define a new listening point.
- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.
    - **Small Icons**. Displays small icons for items in the right pane.
    - **List**. Displays only the small icons and the names of the nodes in the right pane.
    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Delete**. Deletes the application from the computer. You can delete an application if it is stopped. The deleted item is removed from the specific computer it was defined on and from the configuration database.
- **Rename**. Renames the selected application. The new name is reflected across all elements of the HIP console.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of applications as a separate text or Unicode text file.
- **Properties**. Displays the ***application*** **Properties** dialog box and three tabbed property pages:
    - **General**
    - **Advanced**
    - **.NET assembly path**

  Use the property pages to view or change the properties of the application.

- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Listener [status] Node

Use the ***listener* [*status*]** node to start or stop a listener and to determine what views are associated with the listener.

The term shown in brackets at the end of the node indicates status of the listener:

- **Stopped**. The execution environment and Windows Server 2003 service for the listener and its views are inactive.
- **Incomplete**. The listener is missing one or more views or determinants and, therefore, is not available.
- **Unavailable**. The listener was defined after the application was started.
- **Starting**. TI Manager is starting the execution environment and Windows Server 2003 service for the application and its objects.
- **Active**. The execution environment for the application is running and the listeners and local environments are active.

Double-click the ***listener* [*status*]** node to expand the node. The right pane displays the following information about the listener:

- **View**. The name of the view.
- **LE Name**. The name of the local environment.
- **Method Count**. The number of methods.
- **HE Count**. The number of host environments.
- **Comment**. Additional information about the listener.

Important If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click on **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

The columns should now be in their original order.

Right-click the ***listener* [*status*]** node to display the following 10 options:

- **Start**. Starts the host-initiated processing (HIP) service listening on all endpoints defined for the local environment. The HIP application is then ready to receive incoming host requests and to execute methods in accordance with the method resolution criteria. After the listener is started, **Start** is disabled and **Stop** is enabled. After the listener is started, **[started]** appears to the right of the local environment name in the left pane.
- **Stop**. Stops the HIP service listening on all endpoints defined for the local environment. The HIP application no longer accepts, rejects, services, or queues incoming host requests. After the listener is stopped, **Stop** is disabled and **Start** is enabled. After the listener is stopped, **[stopped]** appears to the right of the local environment name in the left pane.
- **Pause**. Temporarily suspends the HIP service listening on all endpoints defined for the local environment. The application continues to execute work in progress and work items queued for execution, but it no longer accepts or queues incoming requests. A number of requests are queued internally by the low-level network transport components (for example, for TCP, Windows XP stores up to 5 requests while Microsoft Windows Server™ 2003 stores up to 200 requests by default). After the listener is resumed, the pending requests are delivered to the listener. Depending on the number of the processing queue entries available, some of these requests might be finally rejected by the listener. After the listener is paused, **Pause** is disabled, **Resume** is enabled, and **[paused]** appears to the right of the local environment name in the left pane.
- **Resume**. Starts the HIP service listening again on all endpoints defined for the local environment. The HIP application is then ready to receive incoming host requests and to execute methods as defined by the method resolution criteria. After the listener resumes, **Resume** is disabled, **Pause** is enabled, and **[started]** appears to the right of the local environment name in the left pane.
- **View**. Displays the following menu items:
  - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
  - **Large Icons**. Displays large icons for items in the right pane.
  - **Small Icons**. Displays small icons for items in the right pane.

  - **List**. Displays only the small icons and the names of the nodes in the right pane.
  - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
  - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Delete**. Deletes the application from the computer. You can delete an application if it is stopped. The deleted item is removed from the specific computer it was defined on and from the administrative data store.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of views as a separate text or Unicode text file.
- **Properties**. Displays the ***listener*** **Properties** dialog box and three tabbed property pages:
  - **General**
  - **Endpoints**
  - **Application**

  Note When viewed from this node, the general and endpoint property pages are read-only. If you want to change a general or endpoint property, right-click the specific ***local environment*** **Node** under the **Local Environments Node**, and then left-click **Properties** on the shortcut menu.

- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Security Policies Node

Use the **Security Policies** node to view and manage security policies. Security policies define how Windows security credentials are established before the server object is run. The security credentials can be based on the user IDs and passwords delivered to HIP by either the client application program or ENTSSO.

Double-click the **Security Policies** node to expand the node. The right pane displays the following information about the node:

- **Security Policy**. The name of the security policy.
- **Credentials Source**. Indicates whether the credentials used are host-based or application-based.
- **Group Application**.

  Important If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click on **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

   The columns should now be in their original order.

Right-click the **Security Policies** node to display the following five options:

- **New**. Displays the following menu item:
  - **Security Policy**. Launches the **Security Policy Wizard**.
- **View**. Displays the following menu items:
  - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
  - **Large Icons**. Displays large icons for items in the right pane.
  - **Small Icons**. Displays small icons for items in the right pane.
  - **List**. Displays only the small icons and the names of the nodes in the right pane.
  - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
  - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of security policies as a separate text or Unicode text file.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Security Policy Node

Security Policy Node

Use the ***security policy*** node to manage the security policy.

Double-click the ***security policy*** node to expand the node. The right pane displays the following information about the security policy selected in the left pane:

- **Affiliate application**. The name of the SSO affiliate application to be queried for access to the Windows credentials needed to execute methods on the server object.

Right-click the ***security policy*** node to display the following five options:

- **View**. Displays the following menu items:
  - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
  - **Large Icons**. Displays large icons for items in the right pane.
  - **Small Icons**. Displays small icons for items in the right pane.
  - **List**. Displays only the small icons and the names of the nodes in the right pane.
  - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
  - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of security policies as a separate text or Unicode text file.
- **Properties**. Displays the ***security policy*** **Properties** dialog box and three tabbed property pages:
  - **General**
  - **Credentials Source**
  - **Mapping**

  Use the property pages to view or change the properties of the *security policy*.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Objects Node (HIP)

Use the **Objects** node to view and manage COM and .NET objects accessible from a host. Objects contain the metadata definitions for the server objects created as TI Projects in Visual Studio .NET 2003.

Double-click the **Objects** node to expand the node. The right pane displays the following information about the node:

- **Object**. The name of the object entry. The default name is the ProgID (for COM) or Namespace.Interface (for .NET), but you can change the name on the *object* context menu.
- **Type**. The type of object.
- **Component**. The programming identifier of the COM object or the interface name of the .Net object.
- **Method Count**. The number of methods on the object.
- **Comment**. Additional information about the object.

  Important If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click on **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

   The columns should now be in their original order.

Right-click the **Objects** node to display the following five options:

- **New**. Displays the following menu item:
  - **Object**. Launches the **HIP Object Wizard**.
- **View**. Displays the following menu items:
  - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
  - **Large Icons**. Displays large icons for items in the right pane.
  - **Small Icons**. Displays small icons for items in the right pane.
  - **List**. Displays only the small icons and the names of the nodes in the right pane.
  - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
  - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of objects as a separate text or Unicode text file.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Object Node (HIP)

Use the ***object*** node to create and manage object views. An object view is a representation of the server object itself. A view can include one or more methods of an object, and not all methods have to be defined in a view. You can define one or more views for an object, which enables you to restrict the methods of an object to specific endpoints and host environment pairs.

Double-click the ***object*** node to expand the node. The right pane displays the following information about the view selected in the left pane:

- **View**. The name of the view.
- **LE Name**. The name of the local environment.
- **Security Policy**. The name of the security policy.
- **Method Count**. The number of methods.
- **HE Count**. The number of host environments.
- **Comment**. Additional information about the view.

  Important If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

   The columns should now be in their original order.

Right-click the ***object*** node to display the following six options:

- **New**. Displays the following menu item:
  - **View**. Launches the **New Object View Wizard**.
- **View**. Displays the following menu items:
  - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
  - **Large Icons**. Displays large icons for items in the right pane.
  - **Small Icons**. Displays small icons for items in the right pane.
  - **List**. Displays only the small icons and the names of the nodes in the right pane.
  - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
  - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of objects as a separate text or Unicode text file.
- **Properties**. Displays the ***object*** **Properties** dialog box and two tabbed property pages:
  - **General**
  - **Methods**

  Use these property pages to view or change the properties of the object.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

New Object View Wizard

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to

http://go.microsoft.com/fwlink/?linkid=29507.

View Node (object)

Use the ***view*** node to restrict access to object methods based on the host environment calling the object and the local environment receiving the call. You also use the ***view*** node to define the resolution criteria used to direct the call made from a host environment to a server object.

Double-click the ***view*** node to expand the node. The right pane displays either the host environments (HE) associated with the object view or the methods on the object view, depending upon the choice you select on the shortcut menu.

Right-click the ***view*** node to display the following seven options:

- **List**. An object view can have one or more host environments and one or more methods associated with it. To accommodate a list of all the properties of an object view, this shortcut menu item enables you to select which properties are to be viewed in the list view.
  - **HE Associations**. Displays the host environments associated with the object view on the application.
  - **Methods**. Displays the methods associated with the object view.
- **Delete**. Deletes the object view.
- **Rename**. Renames the selected object view. The new name is reflected across all elements of the HIP console
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of views as a separate text or Unicode text file.
- **Properties**. Displays the ***view*** **Properties** dialog box and three tabbed property pages:
  - **General**
  - **Host environments**
  - **Methods**

  Use these property pages to view or change the properties of the object view.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Host Environment Associations Listing

Use the host environment associations listing to view the host environments associated with the view.

This listing displays the following information about the host environment:

- **Host Environment**. The name of the host environment.
- **Type**. The type of network used to communicate with the host environment (either TCP/IP or SNA).
- **Remote Endpoint Manager**. The IP address of the host or the host name registered in the DNS (for a TCP/IP network); the LU name associated with the host system (for an SNA network).
- **Comment**. Additional information about the host environment.

  Important If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

   The columns should now be in their original order.

Right-click the host environment name to display the following four options:

- **Delete**. Deletes the host environment association (not the host environment itself). You can delete the host environment association anytime.
- **Refresh**. Redraws the screen to show any updates.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Methods Listing

Methods Listing

Use the methods listing to view the properties of the methods on the object view.

This listing displays the following information about the method:

- **Method**. The name of the method.
- **Endpoint**. The endpoint used to communicate with the host.
- **Resolution Type**. The type of conflict to be conducted in case of a conflict.
- **Msg Handler**.
- **Resolution String**.
- **Position**. The starting point in the data stream where the TI runtime looks for the data defined in the resolution data field to determine what method is to be executed.
- **Comment**. Additional information about the view.

  Important If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

View Node (object)

Windows-Initiated Processing Node

Use the **Windows-Initiated Processing** node to view the major elements used in Windows-initiated processing (WIP) environment. The major WIP elements are:

- Remote environments
- Objects

Double-click the **Windows-Initiated Processing** node to expand the node. The right pane displays the following information about the node:

- **Name**. The name of the major WIP elements.

Right-click the **Windows-Initiated Processing** node to view the following five options:

- **Tracing**. Launches the **Windows-Initiated Processing Trace Options** dialog box. You can select one or more of the following categories for tracing and select one or more options within a category:
    - **General**. Provides high-level information about the end-to-end global processing.
    - **Transport**. Provides detailed connection information about the activities on the SNA or TCP network.
    - **Convert**. Provides detailed information about the data conversion between COM and .NET data on the servers and COBOL or RPG data on the host.
    - **Read Lib**. Provides information about the contents of the type library; used to augment the information in the **Convert** trace.
    - **Proxy**. Provides detailed information about object instantiation, state transitions, and method invocation.
- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.
    - **Small Icons**. Displays small icons for items in the right pane.
    - **List**. Displays only the small icons and the names of the nodes in the right pane.
    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of elements as a separate text or Unicode text file.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Remote Environments Node

Use the **Remote Environments** node to manager remote environments. A remote environment defines the characteristics of the non-Windows host environment that receives requests from Windows-initiated processing (WIP) components.

Double-click the **Remote Environments** node to expand the node. The right pane displays the following information about the node:

- **Remote Environment**. The names of the remote environment.
- **Type**. The type of remote environment.
- **Comment**. Additional information about the remote environment.

Important If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

The columns should now be in their original order.

Right-click the **Remote Environments** node to display the following five options:

- **New**. Displays the following menu items:
  - **Remote Environment**. Launches the **New Remote Environment Wizard**.
  - **Capture RE**. Launches the **New Remote Environment Wizard** to create a remote environment type that captures responses and saves those responses in a recording file. After being saved, the responses can be played back using the playback remote environment.
  - **Playback RE**. Launches the **New Remote Environment Wizard** to create a remote environment type that plays back responses stored in a recording file.
- **View**. Displays the following menu items:
  - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
  - **Large Icons**. Displays large icons for items in the right pane.
  - **Small Icons**. Displays small icons for items in the right pane.
  - **List**. Displays only the small icons and the names of the nodes in the right pane.
  - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
  - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of remote environments as a separate text or Unicode text file.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Remote Environment Node

Use the ***remote environment*** node to view and manage a remote environment.

Double-click the ***remote environment*** node to expand the node. The right pane displays the following information about the remote environment selected in the left pane:

- **Component**. The name of the component.
- **Type**.
- **Comment**. Additional information about the remote environment.

  Important If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

   The columns should now be in their original order.

Right-click the ***remote environment*** node to display the following nine options:

- **Activate**.
- **Deactivate**.
- **View**. Displays the following menu items:
  - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
  - **Large Icons**. Displays large icons for items in the right pane.
  - **Small Icons**. Displays small icons for items in the right pane.
  - **List**. Displays only the small icons and the names of the nodes in the right pane.
  - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
  - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Delete**. Deletes the remote environments selected in the ***remote environments*** node. The deleted item is removed from the ***remote environments*** node and from the administrative data store. If an RE is deleted while it still has objects assigned to it, the objects become unassigned.
- **Rename**. Renames the selected remote environment. The new name is reflected across all the elements of the WIP console.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of remote environments as a separate text or Unicode text file.
- **Properties**. Displays the ***remote environment*** **Properties** dialog box and several tabbed property pages:

TI Manager Wizards and Dialog Boxes

Transaction Integrator (TI) Manager provides 11 wizards and special dialog boxes to help you complete various tasks. The wizards assisting you with host-initiated processing (HIP) are:

- New Application Dialog Box
- Credentials for Service <application name> Dialog Box
- New Application Deployment Wizard
- Define Implementation Characteristics for the .NET Object Wizard Page
- New Local Environment Wizard
- New Host Environment Wizard
- New Security Policy Wizard
- Object Wizard (for HIP)
- New Object View Wizard
- Local Environment Dialog Box
- Reload TIMs Wizard

The wizards to assist you with Windows-initiated processing (WIP) are:

- New Remote Environment Wizard
- Object Wizard (for WIP)

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

New Application Dialog Box

Use the **New Application** dialog box to define an application that does not have executable objects associated with it.

Use this	To do this
Computer name	View the name of the computer where the application runs.
Application	Type the name of the application. The name can be a maximum of 25 alpha-numeric characters. The first character in the name must be a letter, and the name cannot contain any embedded spaces.
Comment	Type a comment that provides additional information about the use of the application in the HIP environment. The comment can be a maximum of 259 alpha-numeric characters.

New Application Deployment Wizard

The **New Application Deployment Wizard** helps you add a new application by guiding you through the definitions of the application, local environment, host environment, and objects. The wizard can be used to define additional local environments, host environments, or objects and link them to existing definitions. You can access the Wizard from the shortcut menu on the ***computer*** node in the TI Manager console tree.

This section contains:

- Welcome to the New Application Deployment Wizard Page
- Create an Application Wizard Page
- Configure a New Local Environment Wizard Page
- Configure Local Environment Endpoints (TCP/IP) Wizard Page
- Configure Local Environment Endpoints (SNA) Wizard Page
- Configure a New Host Environment Wizard Page
- Configure Host Environment Default Method Resolution Wizard Page
- Configure a New Security Policy Wizard Page (in the New Application Deployment Wizard) (1)
- Configure a New Security Policy Wizard Page (in the New Application Deployment Wizard) (2)
- Specify or Locate an Object Wizard Page
- Configure a New Object View Wizard Page
- Configure the New View Wizard Page
- Method Resolution Criteria Dialog Box (in the New Application Deployment Wizard)
- Define Implementation Characteristics for the .NET Object Wizard Page
- Completing the New Application Deployment Wizard Page

Welcome to the New Application Deployment Wizard Page

Use the **Welcome to the New Application Deployment Wizard** page to view the definition of an application deployment and to control whether the welcome page is displayed the next time the wizard is used.

Use this	To do this
Do not show this welcome page again.	Select this option if you will be using the wizard more than once and do not want to read the introduction each time the wizard is launched. Each time the wizard is launched, the welcome page will be hidden and the wizard will begin with the second page. To view the welcome page again, click **Back** on the second page of the wizard.

Configure a New Local Environment Wizard Page

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configure a New Local Environment Wizard Page

Use the **Configure a New Local Environment** wizard page to identify the basic characteristics of the new local environment. Select an existing local environment from the dropdown list or type the name of the new local environment. To define its characteristics, select a specific network type and transport class.

Use this	To do this
Local environment	Type the name for the local environment. The name can be a maximum of 259 alpha-numeric characters. The name cannot be the same as that of an existing local environment.
Network type	Select the type of network used to communicate with the host.
Transport class	Select the class of the transport object. The list changes according to the selected **Network type**.
Endpoint manager	For a TCP/IP network, this is always set to the local host and disabled. For an SNA network, type the name of the LU alias. In either case, the name can be a maximum of 259 Unicode characters.

Configure Local Environment Endpoints (TCP/IP) Wizard Page

Use the **Configure Local Environment Endpoints** (TCP/IP) wizard page to define the endpoints used to communicate with the host. To define the TCP/IP ports or service names for the local environment, type a port number or name, and then click **Add**.

Use this	To do this
Local environment	View the name of the local environment. The name was entered on a previous page of the wizard. To change the name, click **Back**.
New port or service name	Type the port number or service name of the local environment. The port number can be a maximum of 5 numeric characters and must be greater than 0 and less than 32768. The service name can be a maximum of 259 alpha-numeric characters. The format of the name must conform to the WinSock Service Name convention. The port number or name cannot be the same as that of an existing number or name in the **Defined ports and service names**.
Add	Click to validate the port number or service name you typed. If the number or name is valid, it appears in **Defined ports and service names**.
Defined ports and service names	View the existing valid ports and services names for the local environment.
Remove	Click to remove a selected port number or service name from the **Defined ports or service names** available for use in the local environment.

Configure a New Host Environment Wizard Page

Configure Local Environment Endpoints (SNA) Wizard Page

Use the **Configure Local Environment Endpoints** (SNA) wizard page to define the endpoints used to communicate with the host. Type a transaction program name or mirror transaction ID, and then click **Add**.

Use this	To do this
Local environment	View the name of the local environment. The name was entered on a previous page of the wizard. To change the name, click **Back**.
New transaction program name	Type the transaction program (TP) name or the link mirror transaction ID of the local environment. The name or ID can be a maximum of 64 alphabetic characters. The format of the name must conform to the IBM SNA Transaction Program Names convention. The name or ID cannot be the same as that of an existing name or ID in the **Defined transaction program names**.
Add	Click to validate the transaction program (TP) name or the link mirror transaction ID you typed. If the TP name or the link mirror transaction ID is valid, it appears in **Defined transaction program names**.
Defined transaction program names	View the existing TP names or the link mirror transaction IDs for the local environment.
Remove	Click to remove one or more TP names or link mirror transaction IDs selected from the **Defined transaction program names** available for use in the local environment.

Configure a New Host Environment Wizard Page

Configure a New Host Environment Wizard Page

Use the **Configure a New Host Environment** wizard page to describe the basic host characteristics that are concerned with data formats. Type the name of the host environment, and then type or select the attributes of the host.

Use this	To do this
Host environment	Type the name for the host environment. The name can be a maximum of 259 alpha-numeric characters. The name cannot be the same as that of an existing host environment. **Caution** If the host environment is located on the same computer as the HIP application, and the client program uses either host name **localhost** or IP address **127.0.0.1** to connect to the HIP application, the host environment should also use **localhost** or **127.0.0.1** instead of the real computer name or IP address. Failure to set the names or IP addresses identical for the host and client prevents the HIP runtime from delivering calls between the two, and causes the application to fail.
Data conversion	Select the data conversion routine used.
Host code page	Select the code page used by the host. Each available code page is listed by its symbolic value.
Network type	Select the type of network used to communicate with the host. The choices are: • TCP/IP (default) • SNA
Remote endpoint manager	The IP address of the host or the host name registered in the DNS (for a TCP/IP network); the LU name associated with the host system (for an SNA network). In either case, the name can be a maximum of 259 alpha-numeric characters.

Configure Host Environment Default Method Resolution Wizard Page

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configure Host Environment Default Method Resolution Wizard Page

Use the **Configure Host Environment Default Method Resolution** wizard page to identify the default characteristics of the typical interaction of the applications programs on the host with the application programs on the server. Select the default method resolution criteria for the host.

Use this	To do this
Host environment	View the name of the host environment. The name was entered on a previous page of the wizard. To change the name, click **Back**.
Default method resolution criteria	View the definition of the default behavior for setting up the method resolution criteria for a new object view.
Type	Select the type of resolution to be conducted: **Endpoint:** The endpoint resolution type is the simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered “raw sockets,” and represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Endpoint** disables the **Object**, **Input format** and **Output format** boxes and clears their contents. - **Transaction Request Message (TRM):** The TRM resolution type is specific to the IBM CICS Concurrent Server model and the Microsoft variant, MSLink model. It represents a double exchange sequence. The first exchange represents the transaction request; the second exchange represents the request and reply data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Transaction Request Message (TRM)** enables the **Object**, **Input format**, and **Output format** boxes. - **Enhanced Listener Message (ELM)**: - **Data:** Similar to **Endpoint** in that it adds the ability to identify a string in the data stream directed to a port that is used to associate the request with a specific method in the view. This model is considered “raw sockets.” It represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Data** disables the **Object**, **Input format**, and **Output format** boxes and clears their contents. - **Link to Program Name:** Select **Link to Program Name** to resolve all the methods of a new object view using the data information specified when the object view was created. When a new view is created and associated with the HE, the method resolves to the Link Tran ID field in the default HE resolution. Selecting **Link to Program Name** disables the **Object**, **Input format**, and **Output format** boxes and clears their contents.
Object	Select the object. The list of objects is populated from the Help string in the interface definition of objects defined as TRM resolution handlers. Microsoft provides three TRM resolution handlers: - **Microsoft HIS - TRM Handler MS Link** (default) - **Microsoft HIS - TRM Handler MSCCS** - **Microsoft HIS - TRM Handler IBMCCS**
Input format	Select the format of the data stream that represents the TRM sent by the client host application program. The list of TRM input formats is determined by the user-defined type definitions in the MicrosoftTRMDef.tim file. The **Input format** box is blank by default, but three input formats are defined that match the names of the resolution handler **Object**: - **TRMINMSLink** - **TRMINMSCCS** - **TRMINIBMCCS**

Output format	Select the format of the data stream that represents the reply to the TRM that was sent by the host application program. TI formats a data stream that is returned to the host client application program in the form defined by the output TRM. The list of TRM output formats is determined by the UDT definitions in the MicrosoftTRMDef.tim file. The **Output format** box is blank by default, but three output formats are defined that match the names of the resolution handler **Object**: • **MS Link Reply Format** • **IBM Listener Type 1 Reply Format** • **IBM Listener Type 2 Reply Format**
Link Tran ID	View or select an existing TP name or the link mirror transaction ID for the local environment.

Configure a New Security Policy Wizard Page (in the New Application Deployment Wizard) (1)

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to
http://go.microsoft.com/fwlink/?linkid=29507.

Configure a New Security Policy Wizard Page (in the New Application Deployment Wizard) (1)

Use the first **Confige a New Security Policy** wizard page to identify the security policy and the source of the credentials. Type the name of the security policy, and then select the source for the credentials.

Use this	To do this
Security policy	Type the name for the security policy. The name can be a maximum of 259 Unicode characters (alphabetic, numeric, space, and special). The name cannot be the same as the name of an existing security policy. The name for the new security policy is a required field; you will receive an error message if you click **Next** without providing a name. The name is used to associate the security policy with an object view in other wizard pages and dialog boxes.
Credentials source used to invoke the server	Identify the type or source of credentials that host-initiated processing will associate with the thread when the method on the server object is executed.
Host-initiated Single Sign-on	Select this option to use host user ID and password. This option is automatically disabled if Single Sign-on (SSO) is not installed or not available.
Windows credentials of the HIP application	Select this option to use Windows user ID and password specified on the HIP NT application service. This option is automatically selected if SSO is not installed or not available.

See Also

Configure a New Security Policy Wizard Page (in the New Application Deployment Wizard) (2)

Configure a New Security Policy Wizard Page (in the New Application Deployment Wizard) (2)

Use the second **Configure a New Security Policy** wizard page to identify the source of the host user ID and password and describe how they are translated into Windows-based credentials. This wizard page appears only if **Host-initiated Single Sign-on** (SSO) is selected on the previous **Configure a new security policy** wizard page.

Use this	To do this
Security policy	View the name of the security policy.
Affiliate application	Select the SSO affiliate application to be queried to gain access to the Windows credentials needed to execute methods on the server object. The list displays all the affiliate applications defined in the SSO. The display name of the affiliate application is a concatenation of the affiliate application name and description, separated by a hyphen. The selected application will be added to the security policy. **Note** The dropdown list and **Next** are disabled if SSO is not installed or is not available.
Single Sign-on mapping use	Specify the credentials to be used when mapping to Single Sign-on.
Default credentials	Select this option to enter the user ID and password used if the request from the host does not contain a user ID and password or the user ID and password are set to spaces or nulls. This option enables the **Group application** and **User** boxes.
Group application	The default user group provides the default user ID and password.
User	Type or select the host user name used in the lookup call to SSO. **Note** The dropdown list and Next are disabled if SSO is not installed or is not available.

Configure the New View Wizard Page

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configure the New View Wizard Page

Use the **Configure the New View** wizard page to select the methods that are included in the object view. Type the name of the view. To specify the methods to be included in the view, select the check box by the method name. Double-click the method name to edit it.

Use this	To do this
View	Type the name of the object view. The name can be a maximum of 259 alpha-numeric characters. The name cannot be the same as that of an existing view.
Object methods	View all the methods that are defined in the object. Each row contains a summary of the resolution information for a single method. Rows in the list cannot be deleted. The columns are: • **Include** Select this option to include the method in the object view. • **Method** View the name of the method. Double-click the method name displays the **Method Resolution Criteria** dialog. • **Endpoints** View one of the endpoints defined in the local environment associated with the view. To change the content of this field, double-click on the **Endpoints** field for a specific method. • **Resolution Type** View one of the possible resolution types: ◦ **Endpoint** ◦ **Transaction Request Message (TRM)** ◦ **Enhanced Listener Message (ELM)** ◦ **Data** ◦ **Link to Program** To change the content of this field, double-click the **Resolution Type** field for a specific method. • **Resolution Data** Identifies the data used to select the method to be executed. To change the content of this field, double-click the **Resolution Data** field for a specific method. • **Resolution Position** View the resolution position. If **Data Resolution** is selected, this information is used by the TI runtime to identify the starting point in the data stream in which to look for the data defined in the resolution data field to determine what method is to be executed. To change the content of this field, double-click the **Resolution Position** field for a specific method.

See Also

Method Resolution Criteria Dialog Box (in the New Application Deployment Wizard)

Method Resolution Criteria Dialog Box (in the New Application Deployment Wizard)

Use the **Method Resolution Criteria** dialog to provide detailed information about a specific method on the object view.

Use this	To do this
Method	View the name of the object's method for which the method resolution criteria are being set.
Endpoint	Select the endpoints on the local environment that are available for the type of resolution specified in **Type**. All endpoints in the LE are listed and available for selection. If an endpoint selected for one resolution type is already used with another resolution type then an error message will pop up when you click **Apply**. The error message explains which object and view has this endpoint used with another resolution type.
Method resolution criteria	View a description of the behavior for the IT runtime when it resolves a request to a method. The sequence of data flow events may require the TI to send and receive various amounts of data prior to obtaining the ability to make the connection between the incoming request and the target method.
Type	Select the type of resolution to be conducted: - **Endpoint** The endpoint resolution type is simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered "raw sockets," and it represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Endpoint** disables **Object Name**, **Input format** and **Output format** and clears their contents. - **Transaction Request Message (TRM)** The TRM resolution type is specific to the IBM CICS Concurrent Server model and the Microsoft variant MSLink model. It represents a double exchange sequence. The first exchange represents the transaction request, and the second exchange represents the request and reply data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Transaction Request Message (TRM)** enables **Object**, **Input format**, and **Output format**. This option is available only for TCP/IP local environment/host environment pairs. - **Enhanced Listener Message (ELM)**: - **Data** Similar to **Endpoint** in that it adds the flexibility to identify a string in the data stream directed to a port that is used to associate the request with a specific method in the view. This model is considered "raw sockets." It represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Data** disables **Object**, **Input format**, and **Output format** and clears their contents. - **Link to Program Name:** Resolves all the methods of a new object view using the data information specified when the object view was created. When a new view is created and associated with the HE, the method resolves to the Link Tran ID field in the default HE resolution. Selecting **Link to Program Name** disables **Object**, **Input format**, and **Output format** and clears their contents. This option is available only for SNA local environment/host environment pairs. **Note** Only **TRM-MSLink** and **Link to Program Name** are available for Link methods. Methods can be defined as Link in Visual Studio by setting the **Is Link** property to **True**.
Object Name	Select the object. The list of objects is populated from the Help string in the interface definition of objects identified to the resolution handler. Microsoft provides three TRM resolution handlers: - **Microsoft HIS - TRM Handler MS Link** (default) - **Microsoft HIS - TRM Handler MSCCS** - **Microsoft HIS - TRM Handler IBMCCS**

Input format	Select the format of the data stream that represents the TRM sent by the client host application program. The list of TRM input formats is determined by the UDT) definitions in the MicrosoftTRMDef.tim file in the installation TIMLibs directory. The **Input format** box is blank by default, but three input formats are defined that match the names of the resolution handler **Object**: • **MS Link Request Format** • **IBM Listener Type 1 Request Format** • **IBM Listener Type 2 Request Format**
Output format	Select the format of the data stream that represents the reply to the TRM that was sent by the host application program. TI formats a data stream that is returned to the host client application program in the form defined by the output TRM. The list of TRM output formats is determined by the UDT definitions in the MicrosoftTRMDef.tim file. The **Output format** box is blank by default, but three output formats are defined that match the names of the resolution handler **Object**: • **MS Link Reply Format** • **IBM Listener Type 1 Reply Format** • **IBM Listener Type 2 Reply Format**
Link	View the name of the program being linked to.
Program Name	Name of the TP program.
Resolution Data	View a definition of the data used by the IT runtime when it resolves a request to a method.
Data	Type the method resolution criteria for a method on the object view. The criteria can be a maximum of 256 alpha-numeric characters. This control is enabled for resolution types **Transaction Request Message (TRM)** and **Data**. This control is disabled for resolution type **Endpoint**.
Position	Type the resolution position. The position can be a maximum of nine numeric characters. This control is enabled for resolution type **Data** and disabled for resolution types **Transaction Request Message (TRM)** and **Endpoint**.

New Local Environment Wizard

The **New Local Environment Wizard** helps you define the network transport endpoints for the Windows platform environment. The Wizard collects information about the:

- Local environment name
- Network transport type
- Network transport class
- Endpoint manager
- Endpoint identification.

This section contains:

- Welcome to the New Local Environment Wizard Page
- Configure a New Local Environment Wizard Page
- Configure Local Environment Endpoints (TCP/IP) Wizard Page
- Configure Local Environment Endpoints (SNA) Wizard Page
- Completing the New Local Environment Wizard

Welcome to the New Local Environment Wizard Page

Use the **Welcome to the New Local Environment Wizard** page to view the definition of a local environment and to control whether the welcome page is displayed again the next time the wizard is used.

Use this	To do this
Do not show this welcome page again.	Select this option if you will be using the wizard more than once and do not want to read the introduction each time the wizard is launched. Each time the wizard is launched, the welcome page will be hidden and the wizard will begin with the second page. To view the welcome page again, click **Back** on the second page of the wizard.

Configure Host Environment Default Method Resolution Wizard Page

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configure Host Environment Default Method Resolution Wizard Page

Use the **Configure Host Environment Default Method Resolution** wizard page to identify the default characteristics of the typical interaction between applications programs on the host and the application programs on the server. Type or select the default method resolution criteria for the host.

Use this	To do this
Host environment	View the name of the host environment. The name was entered on a previous page of the wizard. To change the name, click **Back**.
Default method resolution criteria	View a definition of the default behavior for setting up the method resolution criteria for a new object view.
Type	Select the type of resolution to be conducted: • **Endpoint:** The endpoint resolution type is the simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered “raw sockets,” and represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Endpoint** disables the **Object**, **Input format**, **Output format**, and **Link Tran ID** boxes and clears their contents. • **Transaction Request Message (TRM):** The TRM resolution type is specific to the TCP/IP transport and to the IBM CICS Concurrent Server model and the Microsoft variant MSLink model. It represents a double exchange sequence. The first exchange represents the transaction request; the second exchange represents the request and reply data. Select **Transaction Request Message (TRM)** to resolve all the methods of a new object view using the resolution handler information in the **Object**, **Input format**, and **Output format** boxes. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting one of the predefined **Transaction Request Objects** disables the **Input format** and **Output format** boxes; it also disables the **Link Tran ID** box and clears its contents. Selecting a custom object enables the **Input format** and **Output format** boxes and sets their initial values to the Microsoft supplied TRM handlers items. • **Enhanced Listener Message (ELM)**: • **Data:** Similar to the **Endpoint** type in that it enables you to identify a string in the data stream directed to a port that is used to associate the request with a specific method in the view. This model is considered “raw sockets.” It represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Data** disables the **Object**, **Input format**, **Output format,** and **Link Tran ID** boxes and clears their contents. • **Link to Program Name:** The Link resolution type is specific to the IBM CICS DPL model. The endpoint name is representative of the TP name that is the CICS mirror transaction ID. Select **Link to Program Name** to resolve all the methods of a new object view using the data information specified when the object view was created. When a new view is created and associated with the HE, the method resolves to the Link Tran ID field in the default HE resolution. Selecting **Link** disables the **Object**, **Input format**, and **Output format** boxes and clears their contents.

Object	Select the object. The list of objects is populated from the Help string in the interface definition of objects identified to the resolution handler. Microsoft provides four TRM resolution handlers: - **Microsoft HIS - TRM Handler MS Link** (default) - **Microsoft HIS - TRM Handler MSCCS** - **Microsoft HIS - TRM Handler IBMCCS** - **Microsoft HIS - Link Handler**
Input format	Select the format for the data stream that represents the TRM sent by the client host application program. The list of TRM input formats is populated from the user-defined type definitions in the MicrosoftTRMDef.tim file. The **Input format** box is disabled for standard TRM handlers and enabled for custom TRM handlers, but three input formats are defined that match the names of the resolution handler **Object**: - **TRMINMSLink** - **TRMINMSCCS** - **TRMINIBMCCS**
Output format	Select the format for the data stream that represents the reply to the TRM that was sent by the host application program. TI formats a data stream to be returned to the host client application program in the form defined by the output TRM. The list of TRM output formats is populated from the UDT definitions in the MicrosoftTRMDef.tim file. The **Output format** box is disabled for standard TRM handlers and enabled for custom TRM handlers, but three output formats are defined that match the names of the resolution handler **Object**: - **TRMOUTMSLink** - **IBM Listener Reply Format (TRMOUTCCS)** - **Link Tran ID:** Select the TP name or Link Mirror Tran ID for the SNA local environment. This control is enabled only when the **Network Type** is set to SNA and the **Resolution Type** is set to Link.
Link Tran ID	View or select an existing TP name or the link mirror transaction ID for the local environment.

New Host Environment Wizard

New Security Policy Wizard

The **New Security Policy Wizard** helps you define how Windows security credentials are established prior to the execution of the server object. The wizard collects information about:

- Security policy name
- Source of credentials
- Requirements for host-supplied credentials
- Single sign-on affiliate applications

This section contains:

- Welcome to the New Security Policy Wizard Page
- Configure a New Security Policy Wizard Page (in the New Security Policy Wizard) (1)
- Configure a New Security Policy Wizard Page (in the New Security Policy Wizard) (2)
- Completing the Security Policy Wizard Page

Welcome to the New Security Policy Wizard Page

Use the **Welcome to the New Security Policy Wizard** page to view the definition of a security policy and to control whether the welcome page is displayed again the next time the wizard is used.

Use this	To do this
Do not show this welcome page again.	Select this option if you will be using the wizard more than once and do not want to read the introduction each time the wizard is launched. Each time the wizard is launched, the welcome page will be hidden and the wizard will begin with the second page. To view the welcome page again, click **Back** on the second page of the wizard.

See Also

Configure a New Security Policy Wizard Page (in the New Security Policy Wizard) (1)

Configure a New Security Policy Wizard Page (in the New Security Policy Wizard) (1)

Use the first **Configure a New Security Policy** wizard page to identify the security policy and the source of the credentials. Type the name of the security policy, and then select the source for the credentials.

Use this	To do this
Security policy	Type the name for the security policy. The name can be a maximum of 259 Unicode characters (alphabertic, numeric, space, and special). The name cannot be the same as that of an existing security policy. The name for the new security policy is a required field; you will receive an error message if you click **Next** without providing a name. The name is used to associate the security policy with an object view in other wizard pages and dialogs.
Credentials source used to invoke the server	Specify the type or source of credentials that host-initiated processing will associate with the thread when the method on the server object is invoked.
Host-initiated Single Sign-on	Select this option to use host user ID and password. This option is automatically selected if single sign-on (SSO) is not installed or not available.
Windows credentials of the HIP application	Select this option to use Windows credentials that are specified on the HIP NT application service. This option is automatically disabled if single sign-on (SSO) is not installed or not available.

Configure a New Security Policy Wizard Page (in the New Security Policy Wizard) (2)

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configure a New Security Policy Wizard Page (in the New Security Policy Wizard) (2)

Use the second **Configure a New Security Policy** wizard page to identify the source of the host user ID and password and determine how they are translated into Windows-based credentials. This wizard page appears only if **Host-initiated Single Sign-on** is selected on the **Configure a new security policy** wizard page.

Select the source of the credentials and the default user, and then select the credential mapping.

Use this	To do this
Security policy	View the name of the security policy.
Affiliate application	Select the single sign-on affiliate application that manages the translation of host user ID and password credentials to Windows credentials.
Single Sign-on mapping use	Specify the credentials to be used when mapping to Single Sign-on.
Default credentials	Select to enter the user ID and password used if the request from the host does not contain a user ID and password or the user ID and password are set to spaces or nulls. When selected, enables the **SSO affiliate application** and **User** boxes. **Note** This option is disabled if **Use HIP application credentials** is selected on the General tab.
Group application	Select the
User	Type the user name or select a previously entered host user name to be used in the lookup call to SSO.

Object Wizard (for HIP)

The HIP **Object Wizard** helps you define (or browse for) a Transaction Integrator metadata (.tim) file that is executed by Transaction Integrator after a request is received from a host. The .tim file includes information about:

- The Windows server object interface, methods, and parameters
- Characteristics of the host application program
- Mappings between the host application program and the Windows server object

If the Windows server object is a .NET object, the Wizard also helps you define the assembly and class that implements the interface in the .tim file.

This section contains:

- Welcome to the Object Wizard Page
- Specify or Locate an Object Wizard Page
- Define Implementation Characteristics for the .NET Object Wizard Page
- Completing the Object Wizard Page

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Welcome to the Object Wizard Page

Use the **Welcome to the Object Wizard** page to view the definition of an object and to control whether the welcome page is displayed again the next time the wizard is used.

Use this	To do this
Do not show this welcome page again.	Select this option if you will be using the wizard more than once and do not want to read the introduction each time the wizard is launched. Each time the wizard is launched, the welcome page will be hidden and the wizard will begin with the second page. To view the welcome page again, click **Back** on the second page of the wizard.

Define Implementation Characteristics for the .NET Object Wizard Page

Define Implementation Characteristics for the .NET Object Wizard Page

Use the **Define Implementation Characteristics for the .NET Object** wizard page to identify a .NET assembly implementing the interface defined in the Transaction Integrator metadata (TIM) file.

Use this	To do this
Defer implementation identification	Select this option to identify the implementing assembly later through the object's **Properties** dialog.
Pick assembly	Select this option to identify the implementing assembly now.
Path	Type the full path name, including the .dll extension, to a .NET file, select a recently used file from the list, or click **Browse** and navigate to the file.
Class	Select the class containing the methods to be called by HIP runtime for the request processing. The list dislays classes from the selected assembly that implement the interface defined in the .TIM file. The first class is selected in the list by default.

Configure a New Object View Wizard Page

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configure a New Object View Wizard Page

Use the **Configure a New Object View** wizard page to select the methods that are included in the object view. Type the name of the new object view, and then select the local environment that accepts requests on behalf of the view.

Use this	To do this
Object view	Type the name of the object view. The name can be a maximum of 259 alpha-numeric characters. The name cannot be the same as that of an existing view.
Local environment	Select a local environment. The names appearing in the list are those local environments available in the **Local Environments** node. The default is the first local environment that appears in the **Local Environments** node.
Host environment	Select a host environment. The names appearing in the list are those host environments available in the **Host Environments** node. Only those host environments that have a **Network Type** that matches the network type defined in the local environments selected in the **Local environment** box are presented for selection. The default is the first local environment that appears in the **Host Environments** node.
Security policy	Select a security policy to be used for determining user credentials.

Configure the New View Wizard Page

Configure the New View Wizard Page

Use the **Configure the New View** wizard page to select the methods that are included in the object view. Type the name of the view. To select the methods to be included in the view, select the check box by the method name. Double-click the method name to edit it.

Use this	To do this
View	View the name of the object view. The name of the object view was entered on a previous page of the wizard. To change the name, click **Back**.

Object methods	View all the methods that are defined in the object. Each row in the list contains a summary of the resolution information for a single method. Rows cannot be deleted. The columns are:
	- **Include:** Select this option to include the method in the object view.
	- **Method:** Displays the name of the method. Double-click the method name to display the **Method Resolution Criteria** dialog box.
	- **Endpoint manager:** For a TCP/IP network, select or type the IP address or host name to manage the endpoint. For an SNA network, type the name of the LU alias. In either case, the name can be a maximum of 259 alpha-numeric characters.
	- **Endpoint:** Displays one of the endpoints defined in the local environment associated with the view. To change the content of this field, double-click the **Endpoint** field for a specific method.
	- **Resolution Type:** Displays one of the possible resolution types:
	  - **Endpoint**
	If the local environment has all of its endpoints in use by object views, associated with the same host environment, that specify **Endpoint Resolution**, you will receive an error message.
	If the local environment has all of its endpoints in use by object views, associated with the same host environment, that specify **TRM** or **Data** resolution, no endpoint is available for **Endpoint** resolution and **TRM** or **Data** resolution must be supplied for the other methods.
	If the local environment has one or more endpoints available for endpoint resolution, the first method of the view appears. The first method has its endpoint set to the first endpoint in the local environment that is available for endpoint resolution and the resolution type is set to **Endpoint**. All the remaining methods have the **Endpoint**, **Resolution Type**, **Resolution Data**, and **Resolution Position** boxes cleared.
	  - **Transaction Request Message (TRM)**
	If the local environment currently has all of its endpoints in use by object views, associated with the same host environment, that specify **Endpoint** or **Data** resolution, the list control is not available.
	If an endpoint is available for TRM resolution, **Include** is selected for all methods and their endpoint is set to the first endpoint associated with the endpoint that is available for TRM resolution.
	All methods have resolution type set to **Transaction Request Message (TRM)**; the **Resolution Data** and **Resolution Position** boxes are cleared.
	  - **Enhanced Listener Message (ELM)**
	  - **Data**
	If the local environment currently has all of its endpoints in use by object views, associated with the same host environment that specified **Endpoint** or **TRM** resolution, the list control is not available.
	If an endpoint is available for data resolution, **Include** is selected for all methods and their endpoint is set to the first endpoint associated with the endpoint that is available for data resolution.
	All methods have resolution type set to **Data,** and the **Resolution Data** and **Resolution Position** boxes are cleared.
	  - **Link to Program**
	To change the content of this field, double-click the **Resolution Type** field for a specific method.
	- **Resolution Data** Identifies the data used to select the method to be executed. To change the content of this field, double-click the **Resolution Data** field for a specific method.
	- **Resolution Position** View the resolution position. If **Data Resolution** is selected, this information is used by the TI runtime to identify the starting point in the data stream in which to look for the data defined in the resolution data field to determine what method is to be executed. To change the content of this field, double-click the **Resolution Position** field for a specific method.

Use the **Define Environment Characteristics for the COM Object** wizard page to define the COM+ application in which Transaction Integrator should run.

Use this	To do this
COM+ applications	Select a COM application. The contents of this box are populated from enumerating the COM+ applications on the local computer. To appear in this list, the application should have Server Activation type and be editable (that is, **Disable Changes** should not be selected on the application's **Advanced Properties**).

Define Remote Environment Wizard Page

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Define Environment Characteristics for the .NET Object Wizard Page

Use the **Define Environment Characteristics for the .NET Object** wizard page to define the IIS Virtual Directory in which Transaction Integrator should run.

Use this	To do this
Virtual directories	Select an IIS virtual directory. The list is populated from enumerating the IIS Virtual Directories on the local computer. **Note** If you do not choose an environment, an error appears when you click the **Next** button. If there is no environment available, you must exit this wizard and define the appropriate environment.
Key file for proxy	Select the key (.snk) file that TI Manager uses to sign the proxy in the IIS virtual directory. The list is populated with files used previously.

Define Remote Environment Wizard Page

Define Remote Environment Wizard Page

Use the **Define Remote Environment** wizard page to select a remote environment (RE) that provides the connection information to the host application. You can select the RE from the list of already defined remote environments that are of the appropriate type (that is, the network, host environment, and programming model of the remote environment must agree with those of the object).

Use this	To do this
Remote environments	Select a remote environment. The contents of this list are populated from an enumeration of the remote environments already defined which match in network type, host environment and programming model.

Object Wizard (for WIP)

TI Manager Properties

Transaction Integrator (TI) Manager provides property pages for viewing and setting properties. The property pages include:

Transaction Integrator (Configuration) Properties

- Timeout tab

Application Properties

- General tab (application properties)
- Advanced tab (application properties)
- .NET Assembly Path tab (application properties)

Listener Properties

- General tab (listener properties)
- Endpoints tab (TCP/IP listener properties)
- Endpoints tab (SNA listener properties)
- Application tab (listener properties)

Local Environment Properties

- General tab (local environment properties)
- Endpoints tab (TCP/IP local environment properties)
- Endpoints tab (SNA local environment properties)

Host Environment Properties

- General tab (host environment properties)
- Network tab (host environment properties)
- Conversion tab (host environment properties)
- Default tab (host environment properties)

Security Policy Properties

- General tab (security policy properties)
- Credentials Source tab (security policy properties)

Object Properties

- General tab (object properties)
- Methods tab (object properties)
- .NET Implementation tab (object properties)

Object View Properties

- General tab (view properties)
- Host Environments tab (view properties)
- Methods tab (view properties)
- Method Resolution Criteria Dialog Box (object properties)

Remote Environment Properties

- General tab (remote environment properties)
- TCP/IP tab (remote environment properties)
- LU 6.2 tab (remote environment properties)
- Target tab (remote environment properties)
- Recording tab (remote environment properties)
- Locale tab (remote environment properties)
- Security tab (remote environment properties)

- CICS tab (for LU 6.2 Link properties)
- CICS tab (for TCP/IP properties)
- IMS tab
- SSO tab (security policy properties)

Object Properties

- General tab (object properties)
- Hosting tab (COM object properties)
- Remote Environment tab (object properties)
- Security tab (remote environment properties)

Timeout tab

Use the **Timeout** tab to set the maximum number of minutes the TI Manager console is allowed to be inactive while it is in **Configuration** mode.

Use this	To do this
Write mode timeout	Type the maximum number of minutes the TI Manager console can remain in configuration mode without a keystroke or mouse movement that changes the configuration. At the end of this time, the console returns to **View and operate** mode. The default is **30** minutes.

> **Warning** The properties of the TI Manager console are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the console to function incorrectly.

See Also

Transaction Integrator (mode) Node

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

General tab (application properties)

The **General** tab allows you to set the general properties of the application.

Use this	To do this
Application	View the name of the application.
Computer	View the name of the computer running the application.
Process ID	View the process ID of the HIPService. **0** indicates that HIPService is not running.
Worker threads	Type the number of processing threads to be used in the work of the application. The number of threads must be greater than 0 and fewer than 257.
Queued requests	Type the maximum number of requests that can be stored in the queue before new requests are rejected. The number of queued requests must be equal to or greater than the number of worker threads, and must be less than 2049.
Comment	Type additional information about the use of the object view in the HIP environment. The comment can be a maximum of 259 alpha-numeric characters.
Service starts automatically	Select this option to start the HIPService automatically at startup. Clear the check box to require manual start up.

> **Warning** The properties of an application are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the application to function incorrectly.

See Also

Application [status] Node

Advanced tab (application properties)

The **Advanced** tab allows you to set the advanced properties of the application.

Use this	To do this
Minimum active worker threads	Type or select the minimum number of worker threads that the HIP runtime maintains. The number of threads must be greater than 0 and fewer than 193. The number cannot exceed the number of **Worker threads** set on the **General** tab property page. The default is **8** threads.
Cleanup worker threads	The group of properties controlling thread cleanup.
When no requests have been queued for	Type or select the number of seconds the HIP runtime will wait after the last client request has been received before it terminates the threads. The minimum wait is 1 second and the maximum wait is 3600 seconds. The default is **30** seconds.
Start an additional working thread	The group of properties controlling when new threads are started.
When more than *number* requests have been queued	Type or select the number of requests that must be received before additional worker threads are started. The minimum number of requests is 1, and the maximum number of requests is 99,999. The default is **15** requests. The number of requests cannot exceed the **Maximum queued requests** (set on the **General** tab) multiplied by the **During the previous *number* seconds** (set on this tab).
During the previous *number* seconds	Type or select the number of seconds the HIP runtime must wait before starting additional worker threads. The minimum number of seconds is 1, and the maximum number of seconds is 3600. The default is **5** seconds.
Increase context cache size	The group of properties controlling the size of the cache of incoming context requests over a period of time.
When more than *number* contexts have been created	Type or select the number of contexts that must be created before the HIP runtime increases the size of the cache. The request context is needed to pass the parameters of the request from the listener to a worker thread. The initial cache size is equal to the number of worker threads multiplied by 2, which is normally less than the maximum queue length. If the cache is empty, a new context is created but will be destroyed at the end because there is no place in the cache to put it in. Increasing the cache size allows the HIP runtime to save the context for future reuse to eliminate expensive operations of creating and releasing the context. The cache size can grow up to the maximum queue length. The minimum number of contexts is 1, and the maximum number of contexts is 192. The default is **30** contexts.
During the previous *number* seconds	Type or select the number of seconds the HIP runtime must wait before increasing the cache size. The minimum number of seconds is 1, and the maximum number of seconds is 3600. The default is **5** seconds.

Warning The properties of an application are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the application to function incorrectly.

Application tab (listener properties)

The **Application** tab displays the local environment properties that are specific to the application. It allows you to specify whether the application will begin listening on the local environment endpoints automatically when the application is started.

Use this	To do this
Begin Listening on the local environment at application startup	When this option is selected, the application will automatically start listening for incoming host requests on each port defined in the local environment.

> **Warning** The properties of an listener are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the application to function incorrectly.

See Also

Listener [status] Node

General tab (local environment properties)

Use the **General** tab to set the general local environment properties, including its name and basic information about its network type.

Use this	To do this
Local environment	Type the name for the local environment. The name can be a maximum of 259 Unicode characters (alphabetic, numeric, space, and special). The name cannot be the same as that of an existing local environment. You can change the name at any time, unless the local environment is an associated listener in an application that is active. The application must be stopped before the LE can be renamed. After the name is changed, the new name will appear in the **Application**, **Local Environments** and **Object** nodes.
Network type	Select the type of network used to communicate with the host. The choices are: • TCP/IP (default) • SNA. **Note** If the local environment is associated with any other configuration entity, you will receive an error when you attempt to apply the change.
Transport class	Select the class of the transport object. This list changes according to the selected **Network type**.
Endpoint manager	Select or type the local LU alias to manage the endpoint. **Note** The **Endpoint manager** edit box is set to **Localhost** and disabled if the **Network type** is set to **TCP/IP**.
Comment	Type any additional information about the local environment. The comment can be a maximum of 259 Unicode characters (alphabetic, numeric, space, and special).

> **Warning** The properties of a local environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the local environment to function incorrectly.

Endpoints tab (TCP/IP local environment properties)

Use the **Endpoints** tab to view, add, and delete endpoints in the local environment definition.

Use this	To do this
New port or service name	Type the port number or service name for the local environment. The port number can be a maximum of 5 numeric characters and must be greater than 0 and fewer than 32768. The service name can be a maximum of 64 alpha-numeric characters. The format of the name must conform to the WinSock Service Name convention. The port number or name cannot be the same as that of an existing number or name in **Defined ports and service names**.
Add	Click to validate the port number or service name you typed. If the number or name is valid, it then appears in **Defined ports and service names**. If the local environment is referenced by an application, the new port or service name will not be available for use until all the applications that use the local environment are restarted.
Defined ports and service names	View the valid ports and services names for the local environment.
Remove	Click to remove a selected port number or service name from **Defined ports or service names**.

> **Warning** The properties of a local environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the local environment to function incorrectly.

Endpoints tab (SNA local environment properties)

Use the **Endpoints** tab to view, add, and delete endpoints in the local environment definition.

Use this	To do this
New transaction program name	Type the transaction program (TP) name or the link mirror transaction ID of the local environment. The name or ID can be a maximum of 64 alphabetic characters. The format of the name must conform to the IBM SNA Transaction Program Names convention. The name or ID cannot be the same as that of an existing name or ID in the **Defined transaction programs names**.
Add	Click to validate the transaction program (TP) name or the link mirror transaction ID you typed. If the TP name or the link mirror transaction ID is valid, it appears in **Defined transaction program names**.
Defined transaction programs names	View the existing TP names or the link mirror transaction IDs for the local environment.
Remove	Click to remove one or more TP names or link mirror transaction IDs selected from the **Defined transaction programs names** available for use in the local environment.

> **Warning** The properties of a local environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the local environment to function incorrectly.

Local Environment Node

General tab (host environment properties)

The **General** tab defines the basic characteristics of the host environment that will initiate requests to the Windows platform.

Use this	To do this
Host environment	Type the name for your host environment. The name can be a maximum of 259 Unicode characters (alphabetic, numeric, space, and special). The name cannot be the same as that of an existing host environment.
Time-out in seconds	The **Send** and **Receive** time-out values are used by the host-initiated processing (HIP) runtime environment when it communicates with the host environment. The time-out values are used on transport-specific application program interfaces (APIs) to terminate the send and/or receive API functions if the expected data is not received in the specified amount of time.
Send	Type the number of seconds the HIP runtime should wait for an acknowledgement before it times out. The maximum number of seconds is 3,600; the default is **30** seconds.
Receive	Type the number of seconds the host should wait for a response before it times out. The maximum number of seconds is 3,600; the default is **30** seconds.
Comment	Type any additional information about the host environment. The comment can be a maximum of 259 alpha-numeric characters.

> **Warning** The properties of a host environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the host environment to function incorrectly.

Host Environments Node

Host Environment Node

Network tab (host environment properties)

The **Network** tab defines the network characteristics that the host uses to interact with the Windows environment and to ensure that unauthorized requests are not inadvertently processed.

Use this	To do this
Network type	Select the type of network used to communicate with the host environment. The choices are: • TCP/IP (default) • SNA
Remote endpoint manager	For a TCP/IP network, select or type the IP address of the host or the host name registered in the DNS. For an SNA network, type the LU name associated with the host system. In either case, the name can be a maximum of 259 alpha-numeric characters.

> **Warning** The properties of a host environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the host environment to function incorrectly.

See Also

Host Environments Node

Host Environment Node

Conversion tab (host environment properties)

The **Conversion** tab defines the data type characteristics used by the host that makes requests to the Windows platform. The code page and elemental data conversion object are used by host-initiated processing (HIP) to transform the incoming and outgoing data to a form that can be used by the host application program.

Use this	To do this
Data conversion	Select the data conversion routine to be used.
Host code page	Select the code page used by the host. Each available code page is listed by its symbolic value.

> **Warning** The properties of a host environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the host environment to function incorrectly.

Default tab (host environment properties)

The **Default** tab of the properties page of a specific host environment defines the manner in which the host typically communicates with Transaction Integrator. These defaults are applied during the configuration for an object view.

Use this	To do this
Default method resolution criteria	View the definition of the default behavior for setting up the method resolution criteria for a new object view.
Type	Select the type of resolution to be conducted: **Endpoint**: The endpoint resolution type is the simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered "raw sockets," and represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Endpoint** disables the **Object**, **Input format** and **Output format** boxes and clears their contents. • **Transaction Request Message (TRM)**: The TRM resolution type is specific to the IBM CICS Concurrent Server model and the Microsoft variant, MSLink model. It represents a double exchange sequence. The first exchange represents the transaction request; the second exchange represents the request and reply data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Transaction Request Message (TRM)** enables the **Object**, **Input format**, and **Output format** boxes. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting one of the predefined **Transaction Request Objects** disables the **Input format** and **Output format** boxes; it also disables the **Link Tran ID** box and clears its contents. Selecting a custom object enables the **Input format** and **Output format** boxes and sets their initial values to the Microsoft-supplied TRM handler items. • **Data**: Similar to **Endpoint** in that it adds the ability to identify a string in the data stream directed to a port, that is used to associate the request with a specific method in the view. This model is considered "raw sockets." It represents a single synchronous exchange of data. Selecting **Data** disables the **Object**, **Input format**, **Output format,** and **Link Tran ID** boxes and clears their contents. • **Link:** The Link resolution type is specific to the IBM CICS DPL model. The endpoint name is representative of the TP name that is the CICS mirror transaction ID. Select **Link** to resolve all the methods of a new object view using the data information specified when the object view was created. When a new view is created and associated with the HE, the method resolves to the Link Tran ID field in the default HE resolution. Selecting **Link** disables the **Object**, **Input format**, and **Output format** boxes and clears their contents.
Object	Select the object. The list of objects is populated from the Help string in the interface definition of objects identified to the resolution handler. Microsoft provides three TRM resolution handlers: • **Microsoft HIS - TRM Handler MS Link** (default) • **Microsoft HIS - TRM Handler MSCCS** • **Microsoft HIS - TRM Handler IBMCCS** • **Microsoft HIS - Link Handler**

Input format	Select the format for the data stream that represents the TRM sent by the client host application program. The list of TRM input formats is populated from the user-defined type definitions in the MicrosoftTRMDef.tim file. The **Input format** box is disabled for standard TRM handlers and enabled for custom TRM handlers, but three input formats are defined that match the names of the resolution handler **Object**: - **TRMINMSLink** - **TRMINMSCCS** - **TRMINIBMCCS**
Output format	Select the format for the data stream that represents the reply to the TRM that was sent by the host application program. Th formats a data stream to be returned to the host client application program in the form defined by the output TRM. The list of TRM output formats is populated from the UDT definitions in the MicrosoftTRMDef.tim file. The **Output format** box is disabled for standard TRM handlers and enabled for custom TRM handlers, but three output formats are defined that match the names of the resolution handler **Object**: - **TRMOUTMSLink** - **IBM Listener Reply Format (TRMOUTCCS)** - **Link Tran ID:** Select the TP name or Link Mirror Tran ID for the SNA local environment. This control is enabled only when the **Network Type** is set to SNA and the **Resolution Type** is set to Link.

> **Warning** The properties of a host environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the host environment to function incorrectly.

General tab (security policy properties)

The **General** tab of the properties page of a security policy defines the name of the policy and the source of the security credentials.

Use this	To do this
Policy	Type the name for the security policy. The name can be a maximum of 259 Unicode characters (alphabetic, numeric, space, and special). The name cannot be the same as the name of an existing security policy. The name for the new security policy is a required field; you will receive an error message if you click **Next** without providing a name. The name is used to associate the security policy with an object view in other wizard pages and dialog boxes.
Host-initiated Single Sign-on	Select this option to use host user ID and password. This option is automatically disabled if single sign-on (SSO) is not installed or not available.
Windows credentials of the HIP application	Select this option to use Windows user ID and password specified on the HIP NT application service. This option is automatically selected if single sign-on (SSO) is not installed or not available.
Comment	Type additional information about the security policy. The comment can be a maximum of 259 Unicode characters.

> **Warning** The properties of a security policy are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the security policy to function incorrectly.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Credentials Source tab (security policy properties)

The **Credentials Source** tab of the properties page of a security policy defines the source of the host user ID and password and describes how they are translated into Windows-based credentials.

Use this	To do this
Security policy	View the name of the security policy.
Affiliate application	Select the SSO affiliate application to be queried to gain access to the Windows credentials needed to execute methods on the server object. The list displays all the affiliate applications defined in the SSO. The display name of the affiliate application is a concatenation of the affiliate application name and description, separated by a hyphen. The selected application will be added to the security policy. **Note** The dropdown list is disabled if SSO is not installed or is not available.
Single Sign-on mapping use	Specify the credentials to be used when mapping to Single Sign-on.
Default credentials	Select this option to enter the user ID and password used if the request from the host does not contain a user ID and password or the user ID and password are set to spaces or nulls. This option enables the **Group application** and **User** boxes.
Group application	The default user group provides the default user ID and password.
User	Type or select the host user name used in the lookup call to SSO. **Note** The dropdown list is disabled if SSO is not installed or is not available.

> **Warning** The properties of a security policy are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the security policy to function incorrectly.

Method Resolution Criteria Dialog Box (in the New Object View Wizard)

Use the **Method Resolution Criteria** dialog to provide detailed information about a specific method on the object view.

Use this	To do this
Method	View the name of the object’s method for which the method resolution criteria are being set.
Endpoint	Select the endpoints on the local environment that are available for the type of resolution specified in **Type**. All endpoints in the LE are listed and available for selection. If an endpoint selected for one resolution type is already used with another resolution type then an error message will pop up when you click **Apply**. The error message explains which object and view has this endpoint used with another resolution type.
Method resolution criteria	View a description of the behavior for the IT runtime when it resolves a request to a method. The sequence of data flow events may require the TI to send and receive various amounts of data prior to obtaining the ability to make the connection between the incoming request and the target method.
Type	Select the type of resolution to be conducted: • **Endpoint** The endpoint resolution type is simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered “raw sockets,” and it represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Endpoint** disables **Object Name**, **Input format** and **Output format** and clears their contents. • **Transaction Request Message (TRM)** The TRM resolution type is specific to the IBM CICS Concurrent Server model and the Microsoft variant MSLink model. It represents a double exchange sequence. The first exchange represents the transaction request, and the second exchange represents the request and reply data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Transaction Request Message (TRM)** enables **Object**, **Input format**, and **Output format**. This option is available only for TCP/IP local environment/host environment pairs. • **Enhanced Listener Message (ELM)**: • 3**Data** Similar to **Endpoint** in that it adds the flexibility to identify a string in the data stream directed to a port that is used to associate the request with a specific method in the view. This model is considered “raw sockets.” It represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Data** disables **Object**, **Input format**, and **Output format** and clears their contents. • **Link to Program Name:** Resolves all the methods of a new object view using the data information specified when the object view was created. When a new view is created and associated with the HE, the method resolves to the Link Tran ID field in the default HE resolution. Selecting **Link to Program Name** disables **Object**, **Input format**, and **Output format** and clears their contents. This option is available only for SNA local environment/host environment pairs. **Note** Only **TRM-MSLink** and **Link to Program Name** are available for Link methods. Methods can be defined as Link in Visual Studio by setting the **Is Link** property to **True**.
Object Name	Select the object. The list of objects is populated from the Help string in the interface definition of objects identified to the resolution handler. Microsoft provides three TRM resolution handlers: • **Microsoft HIS - TRM Handler MS Link** (default) • **Microsoft HIS - TRM Handler MSCCS** • **Microsoft HIS - TRM Handler IBMCCS**

Input format	Select the format of the data stream that represents the TRM sent by the client host application program. The list of TRM input formats is determined by the UDT) definitions in the MicrosoftTRMDef.tim file in the installation TIMLibs directory. The **Input format** box is blank by default, but three input formats are defined that match the names of the resolution handler **Object**: • **MS Link Request Format** • **IBM Listener Type 1 Request Format** • **IBM Listener Type 2 Request Format**
Output format	Select the format of the data stream that represents the reply to the TRM that was sent by the host application program. TI formats a data stream that is returned to the host client application program in the form defined by the output TRM. The list of TRM output formats is determined by the UDT definitions in the MicrosoftTRMDef.tim file. The **Output format** box is blank by default, but three output formats are defined that match the names of the resolution handler **Object**: • **MS Link Reply Format** • **IBM Listener Type 1 Reply Format** • **IBM Listener Type 2 Reply Format**
Link	View the name of the program being linked to.
Program Name	Name of the TP program.
Resolution Data	View a definition of the data used by the IT runtime when it resolves a request to a method.
Data	Type the method resolution criteria for a method on the object view. The criteria can be a maximum of 256 alpha-numeric characters. This control is enabled for resolution types **Transaction Request Message (TRM)** and **Data**. This control is disabled for resolution type **Endpoint**.
Position	Type the resolution position. The position can be a maximum of nine numeric characters. This control is enabled for resolution type **Data** and disabled for resolution types **Transaction Request Message (TRM)** and **Endpoint**.

General tab (object properties)

Use the **General** tab to view the properties of an object. All properties are read-only, except for the **Object** and **Comment** fields.

Use this	To do this
Object	View the name of the object.
Metadata file	View the name of the Transaction Integrator metadata (.tim) file.
Method count	View the number of methods that are contained in the object definition.
Help string	View the Interface Definition Help String that was part of the object's interface definition.
Comment	Type a comment that provides additional information about the use of the object in host-initiated processing. The comment can be a maximum of 256 alpha-numeric characters.

> **Warning** The properties on an object are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the object to function incorrectly.

Object Node (HIP)

General tab (view properties)

Use the **General** tab to view or change the basic information about the object view.

Use this	To do this
Object view	View the name of the object view.
Local environment	Select a local environment (LE). The LE determines the network type associated with the object view. **Note** If you are changing from one network type to another, be sure to remove all methods from the view before changing the LE. **Warning** Changing the current LE in the view removes the host environments (HEs) associated with the view and all related information. Use the **Host Environments** tab to associate a new HE.
Security policy	Select a security policy to be associated with the view.
Comment	Type a comment that provides additional information about the use of the object view in the HIP environment. The comment can be a maximum of 259 alpha-numeric characters.

> **Note** When viewed from the ***view*** node under the application ***listener*** node, the general properties are read-only. If you want to change a general property, right-click the specific ***view*** **Node** under the ***object*** **Node**, and then left-click **Properties** on the shortcut menu. The properties on that page are read-write.
>
> **Warning** The properties on an object view are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the application to function incorrectly.

Host Environments tab (view properties)

Use the **Host Environments** tab to view or change detailed information about the host environments (HEs) associated with the object view.

Use this	To do this
Host environment	Select the host environment to associate with the object view. This list includes all the HEs that have the same network type as the local environment associated with the object view.
Configured host environments	View the HEs already associated with the object view.
Add	Click to add the HE to the object view and move the name to **Configured host environments**.
Remove	Click to remove the selected HE from the object view and from **Configured host environments**. The removed HE is moved to the list in **Host environment**.

> **Note** When viewed from the ***view*** node under the application ***listener*** node, the host environment properties are read-only. If you want to change a host environment property, right-click the specific ***view*** **Node** under the ***object*** **Node**, and then left-click **Properties** on the shortcut menu. The properties on that page are read-write.

> **Warning** The properties on an object view are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the object view to function incorrectly.

Methods tab (view properties)

Use the **Methods** tab to view or change the methods associated with the object view and the method resolution details. You can use this page to add and remove methods on the object view. Double-click a row in the grid to edit the resolution information.

Use this	To do this

Object methods	View all the methods that are defined in the object. Each row contains a summary of the resolution information for a single method. Rows in the list cannot be deleted. The columns are:
	• **Include** Select to include the method in the object view.
	• **Method** View the name of the method. Double-click the method name to launch the **Method Resolution Criteria** dialog box.
	• **Endpoint** View one of the endpoints defined in the local environment associated with the view. To change the content of this field, double-click on the **Endpoints** field for a specific method.
	• **Resolution Type** Displays one of the possible resolution types:
	    • **Endpoint** The endpoint resolution type is the simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered “raw sockets,” and represents a single synchronous exchange of data.
	    • **Transaction Request Message (TRM)** The TRM resolution type is specific to the IBM CICS Concurrent Server model and the Microsoft variant, MSLink model. It represents a double exchange sequence.
	    • **Enhanced Listener Message (ELM)**:
	    • **Data** Similar to **Endpoint** in that it adds the ability to identify a string in the data stream directed to a port that is used to associate the request with a specific method in the view. This model is considered ”raw sockets.” It represents a single synchronous exchange of data.
	    • **Link to Program Name:** Select **Link to Program Name** to resolve all the methods of a new object view using the data information specified when the object view was created.
	To change the content of this field, double-click the **Resolution Type** field for a specific method.
	• **Resolution Data** Identifies the data used to select the method to be executed. To change the content of this field, double-click the **Resolution Data** field for a specific method.
	• **Resolution Position** Displays the resolution position. If **Data Resolution** is selected, this information is used by the TI runtime to identify the starting point in the data stream in which to look for the data defined in the resolution data field to determine which method is to be executed. To change the content of this field, double-click on the **Resolution Position** field for a specific method.

Note When viewed from the ***view*** node under the application ***listener*** node, the method properties are read-only. If you want to change a method property, right-click the specific ***view*** **Node** under the **object Node**, and then left-click **Properties** on the shortcut menu. The properties on that page are read-write.

Warning The properties on an object view are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the object view to function incorrectly.

Method Resolution Criteria Dialog Box (object properties)

Use the **Method Resolution Criteria** dialog to provide detailed information about a specific method on the object view.

Use this	To do this
Method	View the name of the object's method for which the method resolution criteria are being set.
Endpoint	Select the endpoints on the local environment that are available for the type of resolution specified in **Type**. All endpoints in the LE are listed and available for selection. If an endpoint selected for one resolution type is already used with another resolution type then an error message will pop up when you click **Apply**. The error message explains which object and view has this endpoint used with another resolution type.
Method resolution criteria	View a description of the behavior for the IT runtime when it resolves a request to a method. The sequence of data flow events may require the TI to send and receive various amounts of data prior to obtaining the ability to make the connection between the incoming request and the target method.
Type	Select the type of resolution to be conducted: • **Endpoint** The endpoint resolution type is simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered "raw sockets," and it represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Endpoint** disables **Object Name**, **Input format** and **Output format** and clears their contents. • **Transaction Request Message (TRM)** The TRM resolution type is specific to the IBM CICS Concurrent Server model and the Microsoft variant MSLink model. It represents a double exchange sequence. The first exchange represents the transaction request, and the second exchange represents the request and reply data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Transaction Request Message (TRM)** enables **Object**, **Input format**, and **Output format**. This option is available only for TCP/IP local environment/host environment pairs. • **Enhanced Listener Message (ELM)**: • **Data** Similar to **Endpoint** in that it adds the flexibility to identify a string in the data stream directed to a port that is used to associate the request with a specific method in the view. This model is considered "raw sockets." It represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Data** disables **Object**, **Input format**, and **Output format** and clears their contents. • **Link to Program Name:** Resolves all the methods of a new object view using the data information specified when the object view was created. When a new view is created and associated with the HE, the method resolves to the Link Tran ID field in the default HE resolution. Selecting **Link to Program Name** disables **Object**, **Input format**, and **Output format** and clears their contents. This option is available only for SNA local environment/host environment pairs. **Note** Only **TRM-MSLink** and **Link to Program Name** are available for Link methods. Methods can be defined as Link in Visual Studio by setting the **Is Link** property to **True**.
Object Name	Select the object. The list of objects is populated from the Help string in the interface definition of objects identified to the resolution handler. Microsoft provides three TRM resolution handlers: • **Microsoft HIS - TRM Handler MS Link** (default) • **Microsoft HIS - TRM Handler MSCCS** • **Microsoft HIS - TRM Handler IBMCCS**

Input format	Select the format of the data stream that represents the TRM sent by the client host application program. The list of TRM input formats is determined by the UDT) definitions in the MicrosoftTRMDef.tim file in the installation TIMLibs directory. The **Input format** box is blank by default, but three input formats are defined that match the names of the resolution handler **Object**: • **MS Link Request Format** • **IBM Listener Type 1 Request Format** • **IBM Listener Type 2 Request Format**
Output format	Select the format of the data stream that represents the reply to the TRM that was sent by the host application program. TI formats a data stream that is returned to the host client application program in the form defined by the output TRM. The list of TRM output formats is determined by the UDT definitions in the MicrosoftTRMDef.tim file. The **Output format** box is blank by default, but three output formats are defined that match the names of the resolution handler **Object**: • **MS Link Reply Format** • **IBM Listener Type 1 Reply Format** • **IBM Listener Type 2 Reply Format**
Link	View the name of the program being linked to.
Program Name	Name of the TP program.
Resolution Data	View a definition of the data used by the IT runtime when it resolves a request to a method.
Data	Type the method resolution criteria for a method on the object view. The criteria can be a maximum of 256 alpha-numeric characters. This control is enabled for resolution types **Transaction Request Message (TRM)** and **Data**. This control is disabled for resolution type **Endpoint**.
Position	Type the resolution position. The position can be a maximum of nine numeric characters. This control is enabled for resolution type **Data** and disabled for resolution types **Transaction Request Message (TRM)** and **Endpoint**.

General tab (remote environment properties)

Use the **General** tab to set the basic characteristics of the remote environment.

Use this	To do this
Type	View the type of remote environment, which describes the region on the mainframe with which your application is designed to work
Status	View the current state of the remote environment: - **Active**. The TI run-time environment accepts requests and attempts to communicate with the associated mainframe region. - **Inactive**. The TI run-time environment will not accept requests from client applications and returns an Inactive remote environment error message without attempting to communicate with the associated mainframe region. - **Disabled**.
Identifier	View the GUID for the remote environment. This identifier is useful when reviewing TI messages in the Windows Event Log.
Creator name	View the user ID of the user who created the remote environment.
Date created	View the date the remote environment was created.
Comment	Type or view a comment or description to help identify the new remote environment when its properties are displayed elsewhere in the product. You can enter up to 259 Unicode characters in this field. Useful information includes the name and location of the mainframe, and the name and telephone number of the system administrator.

> **Warning** The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

Remote Environment Node

TCP/IP tab (remote environment properties)

Use the **TCP/IP** tab to define the network characteristics that the Windows environment uses to interact with the host.

Use this	To do this
IP/DNS Address	Type the address or select one from the drop-down list. The address can be a maximum of 256 alphanumeric characters. The drop-down list displays the most recently used IP addresses.
TCP ports list	Type the TCP port number. The number can be a maximum of 256 positive numerals separated by semicolons. The port numbers cannot be repeated. The drop-down list displays the most recently used port numbers.
Time-out if no response within *number* seconds	Type the number of seconds. The send and receive time-out values are used by the WIP runtime environment when it communicates with the host environment. The time-out values are used on transport-specific APIs to terminate the receive API function when no host data or acknowledgement is received in the specified amount of time. The number of seconds can be a maximum of 3600 and a minimum of 0.

> **Warning** The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

CICS tab (for TCP/IP properties)

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

LU 6.2 tab (remote environment properties)

Use the **LU 6.2** tab to define the network characteristics that the Windows environment uses to interact with the host.

Use this	To do this
Local LU alias	Select a local LU alias from the drop-down list, or type the alias to be used by this remote environment when contacting the mainframe. Create and configure this local LU alias through SNA Management (SNA Server)/SNA Manager (Host Integration Server) before you use the remote environment. The LU identified by the alias must correspond with a VTAM independent LU on the mainframe. The alias can be a maximum of 256 alphanumeric characters. The drop-down list displays all the local APPC LUs defined to the SNA Manager.
Remote LU alias	Select a remote LU alias from the drop-down list, or type the alias to be used by this remote environment when contacting the mainframe. Create and configure this remote LU alias through SNA Management before you use the remote environment. The partner LU identified by this alias must identify the ACBNAME of the CICS region, the partner LU associated between APPCMVS and IMS to reach IMS. The alias can be a maximum of 256 alphanumeric characters. The drop-down list displays all the remote APPC LUs defined to the SNA Manager.
Mode name	Select a mode name from the drop-down list, or enter the mode name to be used by this remote environment for sessions established with the mainframe. Create and configure this mode name through Host Integration Server SNA Manager before you use the remote environment. Ensure that a compatible mode has been defined on the mainframe. You can also obtain a list of configured modes from Host Integration Server **SNA Manager**. **Note** To use two-phase commit, the APPC mode must be Sync Level 2 capable.
Supports Sync Level 2 protocols	Select this option to enable Sync Level 2 protocols for this remote environment.
Time-out in seconds	View the time-out information used by the WIP runtime environment when it communicates with the host environment. The time-out values are used on transport-specific APIs to terminate the receive API function when no host data or acknowledgement is received in the specified amount of time. When a remote environment is first created, no timeout value is specified. The TI run-time environment will wait indefinitely for the mainframe transaction program to return output parameters and simultaneously block the calling client application until this response is received. This blocking behavior is typical for APPC applications. To avoid indefinite blocking, set a timeout value in the **Receive** box.
Receive	Type the number of seconds. The number of seconds can be a maximum of 3600 and a minimum of 0.

> **Warning** The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

Target tab (remote environment properties)

Use the **Target** tab to set the properties for the source of the captured data.

Use this	To do this
Use responses created from the test console	Select this option to specify the test console. TI initiates the TI Test console for obtaining responses for components assigned to this remote environment. Responses returned from the TI Test console are stored in the recording file associated with this remote environment. (default)
Use responses from the following remote environment	Select this option to specify a remote environment. A drop-down list appears containing all the remote environments that have the same network type, host environment, and programming model as the remote environment being defined. Responses returned from the target remote environment are stored in the recording file associated with this remote environment. If you choose this option, you must select a remote environment from the list box.
Remote environment list	Select the name of the remote environment that describes the mainframe from which you want to record responses.

> **Warning** The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

Recording tab (remote environment properties)

Use the **Recording** tab to set the properties for the file of captured data.

Use this	To do this
Recording selection	View information about the recording file in which the TI run-time environment stores responses for the components assigned to this remote environment.
Name	Type the name of the recording file. The file name can be a maximum of 256 alphanumeric characters. The drop-down list contains the most recently used recording files.
Browse	Launches the **Open File** dialog box for selecting a new or different recording file.
Recording information	View information about the recording.
Type	View the type of remote environment.
Last updated	View the data the remote environment was last updated.
Date created	View the date the remote environment was created.
Creator name	View the user ID of the user who created the remote environment.

> **Warning** The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

Locale tab (remote environment properties)

Use the **Locale** tab to define the computer data type characteristics used by the host that makes accepts requests from the Windows platform.

Use this	To do this
Locale	Select the language locale you want to use in selecting the code page used by the TI run-time environment.
Use default code page for the selected locale	Select this option to have TI select the default code page suitable for the specified locale. If you clear this check box, you must explicitly select the code page.
Code page	Select the code page used to transform the incoming and outgoing data to a form that can be used by the host application program.

> **Warning** The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

See Also

Remote Environments Node

Remote Environment Node

Security tab (remote environment properties)

Use the **Security** tab to set the security properties of the remote environment for SNA.

Use this	To do this
Enable Single Sign-on	Select this option to require that the TI run-time environment uses Single Sign-on (SSO). Clear this option to allow TI to communicate with the mainframe region without setting user ID and password information.
Affiliate application	Select the SSO affiliate application to be queried for credentials. The list displays all the affiliate applications defined in the SSO. The display name of the affiliate application is a concatenation of the affiliate application name and description, separated by a hyphen.
COM+ Single Sign-on mapping use:	Identifies the source of the host user ID and password. **Important** This setting is for COM+ applications only. If you are using .NET applications, the credentials used by the TI runtime are the same credentials set on the IIS virtual directory where the .NET objects are stored. You can set or change the .NET credentials by using the "identity" element in the file web.config.
User credentials	Select this option to have the TI run-time environment obtain the user ID and password information associated with the user logon in which the client application is executing. **Caution** For the COM server to impersonate the security credentials of the client application, the client application must grant the COM server permission to impersonate it.
COM+ application credentials	Select this option to have the TI run-time environment obtain the user ID and password information as defined for a component's COM+ application. To administer this security information, use Component Services (COM+) in Windows Server 2003. This setting is ignored when a TI component is deployed in a COM+ application which itself is configured as a Library application (instead of a Server application) on the Activation tab of the COM+ application property sheet. A Library application runs using the Windows user credentials of the process that invoked it, and TI attempts to map this name to a corresponding host user name.
Allow application to override selected authentication	Select this option to enable the TI run-time environment to use the application override mechanism for obtaining user ID and password information. The client application must be written to support the TI security override mechanism. Clear this option to base the user ID and password solely on previously selected user or package credentials. This security option can be applied to a TI component deployed in a Library COM+ or ASP.NET application or in a Server COM+ or ASP.NET application. **Note** This option appears only if **Enable Single Sign-on** is selected.
Require client provided security	Select this option to require the client to provide the security credentials, either by using the client context or by making call-back security available. **Note** This option appears only if **Enable Single Sign-on** is cleared.
Use already verified or persistent verification authentication	Select this option to have the TI run-time environment use "Already Verified," "Persistent Verification" or "No authentication," depending on the configuration of the mainframe region. "Already Verified" sends only the user ID and no password. "Persistent Verification" sends a user ID and password on the first transaction from the given user and only the user ID thereafter. "No authentication" neither sends a user ID nor a password. The host configuration controls the actual authentication to be used when this option is enabled. In a CICS region, for example, these settings correspond to the ATTACHSEC options Identify, Persistent, and None, respectively. This security option can be applied to a TI component deployed in a Library application or in a Server application. This security option can be applied to a TI component deployed in a Library COM+ application or in a Server COM+ application.

> **Warning** The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

Security tab (remote environment properties)

Use the **Security** tab to set the security properties of the remote environment for TCP/IP.

Use this	To do this
Enable Single Sign-on	Select this option to require that the TI run-time environment uses Single Sign-on (SSO). Clear this option to allow TI to communicate with the mainframe region without setting user ID and password information.
Affiliate application	Select the SSO affiliate application to be queried for credentials. The list displays all the affiliate applications defined in the SSO. The display name of the affiliate application is a concatenation of the affiliate application name and description, separated by a hyphen.
COM+ Single Sign-on mapping use:	Identifies the source of the host user ID and password. **Important** This setting is for COM+ applications only. If you are using .NET applications, the credentials used by the TI runtime are the same credentials set on the IIS virtual directory where the .NET objects are stored. You can set or change the .NET credentials by using the Identity tag in the file web.config.
User credentials	Select this option to have the TI run-time environment obtain the user ID and password information associated with the user logon in which the client application is executing. **Note** This setting is ignored when a TI component is deployed in a COM+ application which itself is configured as a Library application (instead of a Server application) on the Activation tab of the COM+ application property sheet. A Library application runs using the Windows user credentials of the process that invoked it, and TI attempts to map this name to a corresponding host user name. **Caution** For the COM server to impersonate the security credentials of the client application, the client application must grant the COM server permission to impersonate it.
COM+ application credentials	Select this option to have the TI run-time environment obtain the user ID and password information as defined for a component's COM+ application. To administer this security information, use Component Services (COM+) in Windows Server 2003. This setting is ignored when a TI component is deployed in a COM+ application which itself is configured as a Library application (instead of a Server application) on the Activation tab of the COM+ application property sheet. A Library application runs using the Windows user credentials of the process that invoked it, and TI attempts to map this name to a corresponding host user name.
Allow application to override selected authentication	Select this option to enable the TI run-time environment to use the application override mechanism for obtaining user ID and password information. The client application must be written to support the TI security override mechanism. Clear this option to base the user ID and password solely on previously selected user or package credentials. This security option can be applied to a TI component deployed in a Library COM+ or ASP.NET application or in a Server COM+ or ASP.NET application. **Note** This option appears only if **Enable Single Sign-on** is selected.
Require client provided security	Select this option to require the client to provide the security credentials, either by using the client context or by making call-back security available. **Note** This option appears only if **Enable Single Sign-on** is cleared.

> **Warning** The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

TCP/IP Tab (remote environment properties)

Use the TCP/IP tab to set the IP address and port number for the host environment.

Use this	To do this
IP/DNS address	Type the address or select from the drop-down list. The address can be a maximum of 256 alphanumeric characters. The drop-down list displays the most recently used IP addresses.
Port list	Type the TCP port number. The number can be a maximum of 256 positive numerals separated by semicolons. The port numbers cannot be repeated. The drop-down list displays the most recently used port numbers.
Time-out in seconds	The **Send** and **Receive** time-out values are used by the TI runtime environment when it communicates with the host environment. The time-out values are used on transport-specific application program interfaces (APIs) to terminate the send and/or receive API functions if no host acknowledgement is received in the specified amount of time.
Receive	Type the number of seconds the host should wait for a response before it times out. The maximum number of seconds is 3,600; the default is **30** seconds.

> **Warning** The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

CICS tab (for TCP/IP properties)LU 6.2 tab (remote environment properties)

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

CICS tab (for TCP/IP properties)

Use the **CICS** tab to set host-specific CICS properties.

Use this	To do this
Use IBM supplied CICS TCP/IP exit routine	When security is enabled, the default TCP/IP header contains the userid followed by the password. Selecting **Use IBM supplied CICS TCP/IP exit routine**, however, overrides the default behavior and causes the TCP/IP header to put the password before the userid.

> **Warning** The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

TCP/IP tab (remote environment properties)

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

IMS tab

Use the IMS tab to identify the IBM-defined exit program on the host.

Use this	To do this
ITOC information	View information about the ITOC exit name.
HWSIMSO0	Select this option to use IMS Connect with exit HWSIMSO0.
HWSIMSO1	Select this option to use IMS Connect with exit HWSIMSO1.
IMS system ID	Type the IMS system ID or select from the drop-down list. The ID can be a maximum of 8 alphanumeric characters. The drop-down list displays the most recently used IMS system IDs.
ITOC exit name	Type the ITOC exit name or select from the drop-down list. The name can be a maximum of 8 alphanumeric characters. The drop-down list displays the most recently used ITOC exit names.

General tab (object properties)

Use the **General** tab to define the basic characteristics of the object that will service requests from the Windows platform.

Use this	To do this
Object	View the ProgID that names the component. This ProgID is created by Visual Studio in Host Integration Server (Designer in SNA Server) using the type library name, the interface name, and the version information given for the component.
Type	View the type of remote environment for which this component is designed. This type is specified in Visual Studio when the component's type library is created. **Note** You cannot change the type of an object.
Description	View the component description entered in Visual Studio when the component's type library was created.
File	View the name of the component library.
CLSID	View the CLSID that uniquely identifies the component.
Comment	Type a comment that provides additional information about the use of the object. The comment can be a maximum of 259 Unicode characters.

> **Warning** The properties on an object are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the object to function incorrectly.

Data Integration Help

Use the topics in this section to navigate through the Data Integration User Interface. Click a topic below for more information.

Data Source Wizard

Data User Interface Elements

Configuring a Data Source

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Data Source Wizard

This Wizard guides you through the configuration process. The Wizard dynamically adapts to both DB2 and VSAM data sources, and displays the appropriate screens.

Welcome Screen

Click **Next** to continue.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Data Source Screen

Data source platform

Select the appropriate platform from the dropdown list.

Network type

Select either TCP/IP or SNA LU 6.2 (APPC).

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

TCP/IP Network Connection Screen

Address or alias

When TCP/IP Connection is selected as the network transport, this field indicates the IP address of the host DB2 server.

Port

When TCP/IP Connection is selected as the network port, this field indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default is **IP port 446**.

Distributed transactions

When this option is checked, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the HIS TCP/IP Resync service.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

APPC Network Connection Screen

Local LU alias

When APPC Connection is selected, this field is the name of the local LU alias configured in Microsoft® Host Integration Server 2004.

Remote LU alias

When APPC Connection is selected, this field is the name of the remote LU alias configured in Host Integration Server 2004.

Mode name

When APPC Connection is selected, this field is the APPC mode and must be set to a value that matches the host configuration and SNA Server configuration.

Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security).

The default is typically QPCSUPP.

Distributed transactions

When this option is checked, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync service. This option works only with DB2 for OS/390 v5R1 or later.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

DB2 Database Screen

Initial catalog

This field is the first entry in the Database section of the Connection properties.

This OLE DB property is used as the first part of a 3-part fully qualified table name.

In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual.

In DB2/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, one can be created using the Add option.

In DB2 Universal Database, this property is referred to as DATABASE.

If the provider supports changing the catalog for an initialized data source, the consumer can specify a different catalog name through the DBPROP_CURRENTCATALOG property in the DBPROPSET_DATASOURCE property set after initialization.

This is a required parameter.

This parameter is equivalent to the DBPROP_INIT_CATALOG OLE DB property ID.

Package collection

The name of the DRDA target collection (AS/400 library) where the Microsoft DAT should store and bind DB2 packages. This could be same as the Default Schema.

The DAT will create packages dynamically in the location to which the user points using the Package Collection parameter. By default, the DAT will automatically create one package in the target collection, if one does not exist, at the time the user issues their first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the User ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level based on the Isolation Level value configured in the data source.

A problem can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (for example, PUBLIC), the package is created for use only by this user. This means that other users may be unable to access the required package. The solution is for an administrative user, with package administrative rights (for example, PACKADM authority in DB2 for OS/390), to create a set of packages for use by all users.

Default schema

The name of the Collection where the DAT looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The DAT uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection.

For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner").

For DB2/400, the Default Schema is the target COLLECTION name.

For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name.

If the user does not provide a value for Default Schema, the OLE DB Provider uses the USER_ID provided at logon. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. This default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.

This parameter is equivalent to the DBPROP_DB2OLEDB_DEFAULTSCH OLE DB property ID.

Default qualifier

The name of the schema (collection/owner) with which to fully qualify unqualified object names. This attribute allows the user to access database objects without fully-qualifying the objects using a collection (schema) qualifier. The DAT sends this value to DB2 using a SET CURRENT SQLID statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for default qualifier, no SET statement is issued by the DAT. This OLE DB property is only valid when connecting to DB2 for MVS (OS/390, z/OS).

Mainframe File System (VSAM) Screen

Host column description file

The fully qualified file name of the Distributed Data Management (DDM) host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the system directory where the Host Integration Server 2004 server or client software was installed. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400.

This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.

AS/400 File System Screen

Location

The remote database name used for connecting to OS/400 systems. In DB2/400, this property is referred to as RDBNAM.

This parameter is not used when connecting to mainframe systems.

Default library

This parameter indicates the default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files.

This parameter is equivalent to the DBPROP_SNAOLEDB_LIBRARY OLE DB property ID.

Host column description file

The fully qualified file name of the Distributed Data Management (DDM) host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the system directory where the Host Integration Server 2004 server or client software was installed. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400.

This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.

Adding a column

This command displays the Column Dialog box. You can also access this dialog box by selecting a column and clicking **Properties** from the context-sensitive menu.

To add a column

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Add Column**. The **Column properties: General tab** appears.
3. Enter the **Name**, **Alias**, and **Comment** (optional). For more information on these properties, click the **Help** button. When you are finished, click **Apply**.
4. Click the **Host tab**. Select the appropriate **Type** and **CCSID**, and enter the **Length**, **Precision**, and **Scale**. For more information on these properties, click the **Help** button. When you are finished, click **Apply**.
5. Click the **Local tab**. Select the **Type** and check **Use qualifier** if appropriate. For more information on these properties, click the **Help** button. When you are finished, click **OK**.

Column properties: General

Name

The name of the column.

Alias

The alias for the column.

Comment

A comment (optional).

Column properties: Host

Type

The host data type, which determines how data is stored on the host.

CCSID

The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page.

This parameter defaults to U.S./Canada (37).

This parameter is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.

Length

The length of the data type on the host.**Precision**

The precision (or number of digits in a numeric type), of the data type on the host.

Scale

The scale (or number of decimal digits in a numeric type), of the data type on the host.Column properties: Local

Type

The data type presented (such as DBTYPE_STR). Data conversions take place from the host type to the local type.

Use qualifier

Determines whether or not a qualifier is to be used.

Table properties

Name

Type a name for your table.

Use table for file transfer

Selecting this option allows you to enter additional fields for your table, below.

Field delimiter

Enter the field delimiter for your table.

Record delimiter

Enter the record delimiter for your table.

Text qualifier

Enter the text qualifier for you table.

File creation type

Select Direct, Sequential, or Indexed from the list.

Sort

If you selected a File Creation Type of Indexed, you have the option of sorting in either Ascending or Descending order.

Key position

If you selected a File Creation Type of Indexed, you have the option of specifying a key position.

Key length

If you selected a File Creation Type of Indexed, you have the option of specifying a key length.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to
http://go.microsoft.com/fwlink/?linkid=29507.

Options property page

The Data Access Tool configures the following default values at installation.

Files	Location
OLE DB UDL files	C:\My Documents\Host Integration Projects\Data Sources\
ODBC File DSNs	C:\Program Files\Common Files\ODBC\Data Sources
Host column description files	C:\My Documents\Host Integration Projects\Data Descriptions

Click any of the **Browse** buttons to select a new directory.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

DB2 Locale Screen

Host CCSID

The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page.

This parameter defaults to U.S./Canada (37).

This parameter is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.

PC code page

This parameter indicates the code page to be used on the personal computer for character code conversion. This parameter is required when processing binary data as character data. Unless the **Process Binary as Character** checkbox is selected (value is set to true), character data is converted based on the default ANSI code page configured in Windows.

This parameter defaults to Latin 1 (1252).

This parameter is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.

Process binary as character

When this option is checked, it indicates that binary data fields should be processed as characters. This option treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters.

This parameter is equivalent to the DBPROP_DB2OLEDB_BINASCHAR OLE DB property ID.

Mainframe and AS/400 Locale Screen

Host CCSID

The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page.

This parameter defaults to U.S./Canada (37).

This parameter is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.

PC code page

This parameter indicates the code page to be used on the personal computer for character code conversion. This parameter is required when processing binary data as character data. Unless the **Process Binary as Character** checkbox is selected (value is set to true), character data is converted based on the default ANSI code page configured in Windows.

This parameter defaults to Latin 1 (1252).

This parameter is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.

Process binary as character

When this option is checked, it indicates that binary data fields should be processed as characters. This option treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters.

This parameter is equivalent to the DBPROP_DB2OLEDB_BINASCHAR OLE DB property ID.

Security Screen

Interactive sign-on

Authentication to a data source can be done using interactive sign-on or single sign-on. For interactive sign-on, the user name and password must match host credentials.

User name

A valid user name and password are normally required to access data sources on a host. These values are case-sensitive. Do not check the **Single Sign-On** option if a specific user name and password are to be entered.

Password

A valid user name and password are normally required to access data sources on hosts. These values are case-sensitive.

Allow saving password

You have the option of saving the password in the .udl file by clicking this check box. Users and administrators should be warned that this option saves the authentication information (password) in plain text within the .udl file. For security purposes, however, it is strongly recommended that you set these properties manually, instead of using a .udl. Note that if you select this option when using the ODBC Driver for DB2, and then uninstall and reinstall Host Integration Server 2004, the password will be erased.

Single sign-on

Select this checkbox to enable using the Host Integration Security features providing a single-sign-on to access this data source.

When this checkbox is selected, the **User name** and **Password** fields are dimmed and become inaccessible. The user name and password fields are set based on the Windows 2000 logon.

When this checkbox is not selected, the **User name** and **Password** fields must normally contain appropriate values to access data sources on hosts.

Affiliate Application

If you selected Single Sign-On, choose an Affiliate Application from the list. The Enterprise Single Sign-On (SSO) Affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using SSO. An affiliate application can represent a back-end system such as a mainframe or UNIX computer. It can also represent an application such as SAP, or a subdivision of the system, such as the "Benefits" or "Pay stub" sub-systems.

DB2 Validation Screen

Use this screen to validate your configuration.

Click **Connect** to perform a test connection.

Click **Packages** to create the DB2 packages required for executing SQL statements.

Click **Sample Query** to retrieve a list of tables in the default database collection.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Mainframe and AS/400 Validation Screen

Use this screen to validate your configuration.

Click **Mainframe** to test the connection to the mainframe or AS/400 system.

Click **Sample Query** retrieves a list of files in the default library.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

DB2 Saving Information Screen

Use this screen to name and save your configuration.

Data source name

Enter a name of your choice. This name is used when saving the data source configuration to one or more data source types.

OLE DB or Managed group, **ODBC** group

Make the appropriate selection(s) for your data source.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Mainframe and AS/400 Saving Information Screen

Use this screen to name and save your configuration.

Data source name

Enter a name of your choice. This name is used when saving the data source configuration to one or more data source types.

Universal data link and **Initialization string file**

Make the appropriate selection(s) for your data source.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Advanced Options Screen

The settings on this screen are optional.

Connection pooling

Selecting this option will cache connections for reuse.

Cache authentication

This parameter determines whether the OLE DB Provider for AS/400 and VSAM caches authentication information, such as a password, in an internal cache. This parameter is not currently supported by the OLE DB Provider for AS/400 and VSAM and defaults to false.

This parameter is equivalent to the DBPROP_CACHE_AUTHINFO OLE DB property ID.

Mode (Read/ReadWrite)

Determines whether the connection is read-only, or if it allows modifications to the database.

Repair host keys

This parameter provides for repair of invalid key offsets received from OS/400 when keys have been defined using the DDS "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry.

This parameter defaults to false. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.

Read only

Selecting this option prevents a data source from being updated.

Alternate TP Name

This is the transaction program name on a DB2 DRDA application server.

Strict Validation

Select this option if desired.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Finish Screen

This screen displays a summary and status of your configuration. Click **Finish** to implement your actions.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Data User Interface Elements

The topics in this section describe the elements in the Data Integration User Interface.

Data Source Browser

The Data Source Browser is the window where you configure and manage your data sources.

The window is divided into three parts: a tree view containing the data sources and data descriptions, a list view containing details of a selected node, and a result view containing the text results of an action (such as a package creation).

The procedures in the following topics describe how to manage data. Many commands are also accessible through a context-sensitive menu which appears when you right-click any section of the Browser window. In addition, the F5 key refreshes the tree view, the Delete key deletes the currently selected item, and the F1 key opens the online Help.

Data Source Folder

This folder contains data sources and groups of data sources.

Data Source Item

Right-clicking a data source allows you to view, edit, test, delete, or rename it.

Data Descriptions Folder

This folder displays the names of all configured data descriptions. Click the individual files to view their properties.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Data Description File

Right-click a data description to view its properties, or to edit or delete the file.

Data Description Table

A Data description table contains the meta-data describing a file or table on a mainframe, AS/400, or System 36 file system. A table description holds information about the various columns in that table.

Data description tables are stored in “Host Column Description” files and can be found under the “Host Column Descriptions” folder in the DAT browser.

Data Description Column

A Data description column contains the meta-data describing a field or column of a mainframe, AS/400, or System 36 file system table or file. This meta-data includes the column name, its host type, and its local type.

Data description columns are stored in “Host Column Description” files and can be found under the “Host Column Descriptions” folder in the DAT browser.

Table Properties

Displays the properties for the selected table.

Configuring a Data Source

The following sections contain information on configuring a data source.

Configuring a Data Source for OLE DB Provider for AS/400 and VSAM

Configuring a Data Source for OLE DB Provider for DB2

Configuring a Data Source for the ODBC Driver for DB2

Configuring a Data Source for OLE DB Provider for AS/400 and VSAM

You must configure data source information for each AS/400 or mainframe system data source object that is to be accessed using OLE DB Provider for AS/400 and VSAM. The default parameters for OLE DB Provider for AS/400 and VSAM are used only when these parameters are not configured for each data source.

Microsoft Data Link, a core element of Microsoft Data Access Components (MDAC), provides a uniform method for creating file-persistent OLE DB data source object definitions in the form of universal data link (.udl) files. The Data Source Wizard in the new Microsoft Data Access Tool can help to define UDL files. OLE DB consumer applications, such as Data Transformation Services in Microsoft SQL Server can use the UDL files to connect to IBM data sources, such as DB2 and the mainframe file system.

To configure a data source for OLE DB Provider for AS/400 or VSAM

You must create a data link to configure parameters for your OLE DB data source. You can create a new data link by clicking the shortcut in the Host Integration Server 2004 program folder.

The properties of a universal data link file can be edited by opening the file from Windows Explorer.

The **Provider** tab allows you to select the OLE DB provider (the provider name string) to be used in this .udl file from a list of possible OLE DB providers. Choose **Microsoft OLE DB Provider for AS/400 and VSAM**.

The **Connection** tab allows you to configure the basic properties required to connect to a data source. For **OLE DB Provider for AS/400 and VSAM**, the connection properties include the following values:

Property	Description
Data Source	This is an optional parameter that can be used to describe the data source.
Network	This drop-down list allows selecting the type of network connection to be used. The options are **TCP/IP Connection** or **SNA Connection**. If **TCP/IP Connection** is selected, click **More Options**, to open a dialog box for configuring TCP/IP network settings. The parameters you can configure include the IP address of the remote host (or a hostname alias for this computer) and the Network Port (TCP/IP port) used for communication with the host. The default value for the Network Port is 446. The IP address of the host has no default value. If **SNA Connection** is selected (using LU 6.2), click **More Options** to open a dialog box for configuring SNA network settings. The parameters you can configure include: the APPC local LU alias, the APPC remote LU alias, and the APPC mode used for communication with the host. The default value for the APPC mode normally defaults to QPCSUPP. The local and remote LU alias fields do not have default values.
Single sign-on	This option button, also known as a radio button, enables using the Host Integration Security features providing a single sign-on to access this OLE DB data source. When this option button is selected, the **User name** and **Password** fields are dimmed and become inaccessible. The **User name** and **Password** fields are set based on the Windows logon values. When this option button is not selected, the **User name** and **Password** fields normally contain appropriate values to access data sources on hosts.
User name	A valid user name and password are normally required to access data sources on hosts. These values are case-sensitive. The user must click the option button that requires a specific user name and password to be entered.
Password	A valid user name and password are normally required to access data sources on hosts. These values are case-sensitive. The user will need to clear the **Blank password** check box, if it is selected to enter a password. Optionally, the user can choose to save the password in the .udl file by clicking the **Allow saving password** check box. Users and administrators should be warned that this option persists the authentication information in plain text within the .udl file.
Location	The remote database name used for connecting to OS/400 systems. In DB2/400, this property is referred to as RDBNAM. This parameter is not used when connecting to mainframe systems.

Default Library	This parameter indicates the default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files. This parameter is equivalent to the DBPROP_SNAOLEDB_LIBRARY OLE DB property ID.
Host Column Description File	The fully qualified file name of the Distributed Data Management (DDM) host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the system directory where the Host Integration Server 2004 server or client software was installed. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400. This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.

The **Connection** tab also includes a **Test Connection** button that can be used to test the connection parameters. The connection can only be tested after all of the required parameters are entered. When this button is selected, a session will be established to the host computer using OLE DB Provider for AS/400 and VSAM.

The **Advanced** tab exposes OLE DB standard properties. For **OLE DB Provider for AS/400 and VSAM**, the advanced properties include the following values:

Property	Description
Host CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page. This parameter defaults to U.S./Canada (37). This parameter is equivalent to the SNAOLEDB_HOSTCCSID OLE DB property ID.
PC Code Page	The *PC Code Page* parameter indicates the code page to be used on the personal computer for character code conversion. This parameter is required when processing binary data as character data. Unless the **Process Binary as Character** checkbox is selected (value is set to true), character data is converted based on the default ANSI code page configured in Windows. This parameter defaults to Latin 1 (1252). This parameter is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.
Read only	When the *Read Only* parameter is checked in the **Advanced** tab, the OLE DB Provider for AS/400 and VSAM creates a read-only data source by setting the *Mode* parameter to Read (DB_MODE_READ). A user has read access to files and cannot do update operations.
Repair Host Keys	This parameter provides for repair of invalid key offsets received from OS/400 when keys have been defined using the DDS "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry. This parameter defaults to false. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.
Process Binary as Character	When this option is checked (property is set to true), the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false. This parameter is equivalent to the SNAOLEDB_BINASCHAR OLE DB property ID.

The **All** tab allows you to configure additional properties used to connect to a data source. Some of the properties in the **All** tab are required. These properties can be edited by selecting a property from the displayed list and selecting **Edit Value**. For Microsoft OLE DB Provider for AS/400 and VSAM, these properties include the following values:

Property	Description
APPC Local LU Alias	The name of the local LU alias configured in the Host Integration Server 2004 computer. This parameter is equivalent to the DBPROP_SNAOLEDB_LOCALLU OLE DB property ID.

APPC Mode Name	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server 2004 computer configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP. This parameter is equivalent to the DBPROP_SNAOLEDB_APPCMODE OLE DB property ID.
APPC Remote LU Alias	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the name of the remote LU alias configured in the Host Integration Server 2004 computer. This parameter is equivalent to the DBPROP_SNAOLEDB_LOCALLU OLE DB property ID.
Cache Authentication	This parameter determines whether the OLE DB Provider for AS/400 and VSAM caches authentication information, such as a password, in an internal cache. This parameter is not currently supported by the OLE DB Provider for AS/400 and VSAM and defaults to false. This parameter is equivalent to the DBPROP_CACHE_AUTHINFO OLE DB property ID.
Connection Timeout	The amount of time (in seconds) to wait for initialization to complete. This parameter is not currently supported by the OLE DB Provider for AS/400 and VSAM and defaults to 0. This parameter is equivalent to the DBPROP_INIT_TIMEOUT OLE DB property ID.
Data Source	This is an optional parameter that can be used to describe the data source. This parameter is equivalent to the DBPROP_INIT_DATASOURCE OLE DB property ID.
Default Library	This parameter indicates the default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files. This parameter is equivalent to the DBPROP_SNAOLEDB_LIBRARY OLE DB property ID.
Encrypt Password	This parameter determines whether special security mechanisms are used to ensure password privacy. This parameter is not currently supported by the OLE DB Provider for AS/400 and VSAM and defaults to false. This parameter is equivalent to the DBPROP_AUTH_ENCRYPT_PASSWORD OLE DB property ID.
Extended Properties	This parameter is a string containing provider-specific, extended connection information. Properties passed through this parameter should be delimited by semicolons and are interpreted by the OLE DB provider's underlying network client. The use of this property implies that the OLE DB consumer knows how this string will be interpreted and used by the OLE DB provider. This parameter should be used only for provider-specific connection information that cannot be explicitly described through the other property parameters. This parameter is equivalent to the DBPROP_INIT_PROVIDERSTRING OLE DB property ID.
Host CCSID	The character code set identifier (CCSID) matching the data as represented on the host. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the host column CCSID and default ANSI code page. This parameter defaults to U.S./Canada (37). This parameter is equivalent to the DBPROP_SNAOLEDB_HOSTCCSID OLE DB property ID.
Host Column Description File	The fully qualified file name of the Distributed Data Management (DDM) host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the system directory where the Host Integration Server 2004 Server or Client software was installed. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400. This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.

Impersonation Level	This parameter indicates the level of impersonation that the server is allowed to use when impersonating the client computer. This property applies only to network connections other than remote procedure call (RPC) connections; these impersonation levels are similar to those provided by RPC. The values of this property correspond directly to the levels of impersonation that can be specified for authenticated RPC connections, but can be applied to connections other than authenticated RPC. This parameter can be set to one of the following values: Anonymous — The client computer is anonymous to the server. The server process cannot obtain identification information about the client computer and cannot impersonate the client computer. Delegate — The process can impersonate the client's security context while acting on behalf of the client. The server process can also make outgoing calls to other servers while acting on behalf of the client. Identity — The server can obtain the client's identity. The server can impersonate the client computer for access control list (ACL) checking, but cannot access system objects as the client computer. Impersonate — The server process can impersonate the client's security context while acting on behalf of the client computer. This information is obtained when the connection is established, not on every call. This parameter defaults to Impersonate. This parameter is equivalent to the DBPROP_INIT_IMPERSONATION_LEVEL OLE DB property ID.
Integrated Security	This parameter is a string containing the name of the authentication service used by the server to identify the user using the identity provided by an authentication domain. For example, for Microsoft® Windows 2000 Integrated Security, this is Security Support Provider Interface (SSPI). If this parameter is a null pointer, the default authentication service should be used. When this property is used, no other DBPROP_AUTH* properties are needed and, if provided, their values are ignored. This parameter is equivalent to the DBPROP_AUTH_INTEGRATED OLE DB property ID.
Locale Identifier	This parameter specifies the locale to be used. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM and defaults to 437. This parameter is equivalent to the DBPROP_INIT_LCID OLE DB property ID.
Location	This parameter indicates the remote database name used for connecting to OS/400 systems. In DB2/400, this property is referred to as RDBNAM. This parameter is not used when connecting to mainframe systems. This parameter is equivalent to the DBPROP_INIT_LOCATION OLE DB property ID.
Mask Password	This parameter indicates whether the password should be sent to the data source or enumerator in a masked form. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM and defaults to false. This parameter is equivalent to the DBPROP_AUTH_MASK_PASSWORD OLE DB property ID.
Mode	After a connection is established, this parameter represents a bit mask of the access permissions that will be applied to the data file. As implemented by the OLE DB Provider for AS/400 and VSAM, access permissions apply to host file locks and do not apply to record locks. The allowable values include the following: Read, ReadWrite, Share Deny None, Share Deny Read, Share Deny Write, Share Exclusive, and Write. This parameter can be a combination of zero or more of the following: DB_MODE_READ — Read-only. DB_MODE_WRITE — Write-only. DB_MODE_READWRITE — Read/write (DB_MODE_READ | DB_MODE_WRITE). DB_MODE_SHARE_DENY_READ — Prevents others from opening in read mode. DB_MODE_SHARE_DENY_WRITE — Prevents others from opening in write mode. DB_MODE_SHARE_EXCLUSIVE — Prevents others from opening in read/write mode (DB_MODE_SHARE_DENY_READ | DB_MODE_SHARE_DENY_WRITE). DB_MODE_SHARE_DENY_NONE — Neither read nor write access can be denied to others. This parameter is equivalent to the DBPROP_INIT_MODE OLE DB property ID.

Network Address	When TCP/IP has been selected for the Network Transport Library, this parameter is used to locate the target host computer. This parameter indicates the IP address or TCP/IP host name alias associated with the DDM server on the host. The network address is required when connecting through TCP/IP. This parameter is equivalent to the DBPROP_SNAOLEDB_NETADDRESS OLE DB property ID.
Network Port	When TCP/IP has been selected for the Network Transport Library, this parameter is used to locate the target DDM service access port when connecting through TCP/IP. This parameter represents the TCP/IP port used for communication with the DDM service on the host. The default value is TCP/IP port 446. This parameter is equivalent to the DBPROP_SNAOLEDB_NETPORT OLE DB property ID.
Network Transport Library	This parameter, which represents the dynamic-link library used for transport, designates whether the OLE DB provider connects through SNA LU 6.2 or TCP/IP for network communication. The possible values for this parameter are TCPIP or SNA. If TCPIP is selected, then values for Network Address and Network Port are required. TCP/IP connectivity to the mainframe is not supported by the OLE DB Provider for AS/400 and VSAM. If SNA is selected, then values for APPC Local LU Alias, APPC Mode Name, and APPC Remote LU Alias are required. This value defaults to SNA. This parameter is equivalent to the DBPROP_SNAOLEDB_NETTYPE OLE DB property ID.
Password	A valid user name and password are normally required to access data sources on hosts. The password is case-sensitive and is shown as asterisks in this dialog box for security purposes. Optionally, you can choose to save the password in the .udl file by clicking the **Allow saving password** check box. Users and administrators should be warned that this option persists the authentication information in plain text within the .udl file. This parameter is equivalent to the DBPROP_AUTH_PASSWORD OLE DB property ID.
PC Code Page	This parameter indicates the code page used for character code conversion. This property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the default ANSI code page configured in the Windows operating system. If this parameter is set to **Binary** or **65535**, then no character code conversions take place. This parameter defaults to Latin 1 (1252). This parameter is equivalent to the DBPROP_SNAOLEDB_PCCODEPAGE OLE DB property ID.
Persist Security Info	This parameter indicates whether the data source object is allowed to persist sensitive authentication information such as a password along with other authentication information. Optionally, a user can choose to save the password in the .udl file by clicking the **Allow saving password** check box. Users and administrators should be warned that this option persists the authentication information in plain text within the .udl file. This parameter defaults to false. This parameter is equivalent to the DBPROP_AUTH_PERSIST_SENSITIVE_AUTHINFO OLE DB property ID.
Process Binary as Character	This parameter indicates whether to **Process Binary as Character** fields (CCSID of 65535) as character data type fields on a per data source basis. The **Host CCSID** and **PC Code Page** values are required input parameters when this parameter is true. The default for this parameter is false. Do not process binary fields as character fields. This parameter is equivalent to the DBPROP_SNAOLEDB_BINASCHAR OLE DB property ID.

Protection Level	This parameter indicates the level of protection of data sent between client computer and server. The values of this property correspond directly to the levels of protection that can be specified for authenticated RPC connections. This parameter can be set to one of the following values: DB_PROT_LEVEL_NONE — Performs no authentication of data sent to the server. DB_PROT_LEVEL_CONNECT — Authenticates only when the client computer establishes the connection with the server. DB_PROT_LEVEL_CALL — Authenticates the source of the data at the beginning of each request from the client computer to the server. DB_PROT_LEVEL_PKT — Authenticates that all data received is from the client computer. DB_PROT_LEVEL_PKT_INTEGRITY — Authenticates all data received is from the client computer and that it has not been changed in transit. DB_PROT_LEVEL_PKT_PRIVACY — Authenticates all data received is from the client computer, that it has not been changed in transit, and protects the privacy of the data by encrypting it. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM and defaults to the connect level of protection. This parameter is equivalent to the DBPROP_INIT_PROTECTION_LEVEL OLE DB property ID.
Read only	When the *Read Only* parameter is checked in the Advanced tab, the OLE DB Provider for AS/400 and VSAM creates a read-only data source by setting the *Mode* parameter to Read (DB_MODE_READ). A user has read access to files and cannot do update operations.
Repair Host Keys	This parameter provides for repair of invalid key offsets received from OS/400 when keys have been defined using the DDS "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry. This parameter defaults to false. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.
Strict Validation	This parameter indicates whether strict validation should be used and defaults to false. This parameter is equivalent to the DBPROP_SNAOLEDB_STRICTVAL OLE DB property ID.
User ID	A valid user name is normally required to access data sources on hosts. This value is case-sensitive. This parameter is equivalent to the DBPROP_AUTH_USERID OLE DB property ID.

Configuring a Data Source for OLE DB Provider for DB2

You must configure data source information for each host data source object that is to be accessed using OLE DB Provider for DB2. The default parameters for OLE DB Provider for DB2 are used for the data source only when these parameters are not configured for each Data Source.

Microsoft Data Link, a core element of Microsoft Data Access Components (MDAC), provides a uniform method for creating file-persistent OLE DB data source object definitions in the form of universal data link (.udl) files. The Data Source Wizard in the new Microsoft Data Access Tool can help to define UDL files. OLE DB consumer applications, such as Data Transformation Services in Microsoft SQL Server can use the UDL files to connect to IBM data sources, such as DB2 and the mainframe file system.

You must create a data link to configure parameters for your OLE DB data source. You can create a new data link by clicking the shortcut in the Host Integration Server 2004 program folder.

The properties of a data link file can be edited by opening the file from Windows Explorer.

With the **Provider** tab you can select the OLE DB provider (the provider name string) to be used in this .udl file from a list of possible OLE DB providers. Choose **Microsoft OLE DB Provider for DB2**.

The **Connection** tab enables you to configure the basic properties required to connect to a data source. For the Microsoft OLE DB Provider for DB2, the connection properties include the following values:

Property	Description
Data Source	The data source is an optional parameter that can be used to describe the data source.
Network	This drop-down list box allows selecting the type of network connection to be used. The allowable options are **TCP/IP Connection** or **SNA Connection**. If **TCP/IP Connection** is selected, click **More Options**, to open a dialog box for configuring TCP/IP network settings. The parameters you can configure include the IP address of the DB2 host (or a hostname alias for this computer) and the Network Port (TCP/IP port) used for communication with the host. The default value for the Network Port is 446. The IP address of the host has no default value. If **SNA Connection** is selected (using LU 6.2), click **More Options** to open a dialog box for configuring SNA network settings. The parameters you can configure include: the APPC local LU alias, the APPC remote LU alias, and the APPC mode used for communication with the host. The default value for the APPC mode normally defaults to QPCSUPP. The local and remote LU alias fields do not have default values.
Single sign-on	Select this checkbox to enable using the Host Integration Security features providing a single-sign-on to access this OLE DB data source. When this checkbox is selected, the **User name** and **Password** fields are dimmed and become inaccessible. The user name and password fields are set based on the Windows 2000 logon. When this checkbox is not selected, the **User name** and **Password** fields must normally contain appropriate values to access data sources on hosts.
User name	A valid user name and password are normally required to access data sources on a host. These values are case-sensitive. Users must not check the **Single sign-on** option if a specific user name and password are to be entered.
Password	A valid user name and password are normally required to access data sources on hosts. These values are case-sensitive. The **Blank password** checkbox is only applicable for a Test Connection. To enter a password, the user will need to clear the **Blank password** check box, if it is checked. If **Blank password** is checked, then a Test Connection with a blank password will not cause the OLE DB Provider to prompt for a password. Optionally, users can choose to save the password in the .udl file by clicking the **Allow saving password** check box. Users and administrators should be warned that this option saves the authentication information (password) in plain text within the .udl file.

Initial catalog	This field is the first entry in the Database section of the Connection properties. This OLE DB property is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. If the provider supports changing the catalog for an initialized data source, the consumer can specify a different catalog name through the DBPROP_CURRENTCATALOG property in the DBPROPSET_DATASOURCE property set after initialization. This is a required parameter. This parameter is equivalent to the DBPROP_INIT_CATALOG OLE DB property ID.
Package Collection	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. Package names are not restricted and can be upper case, lower case, or mixed case. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter. By default, the OLE DB Provider will automatically create one package in the target collection, if one does not exist, at the time the user issues their first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the User ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level based on the Isolation Level value configured in the data source. A problem can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (for example, PUBLIC), then the package is created for use only by this user. This means that other users may be unable to access the required package. The solution is for an administrative user, with package administrative rights (for example, PACKADM authority in DB2 for OS/390), to create a set of packages for use by all users. The OLE DB Provider for DB2 ships with a tool program for use by administrators to create packages. The crtpkg.exe tool is a Windows GUI application for use by the administrator to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. This tool will create sets of packages and grant EXECUTE privilege to PUBLIC for all (see descriptions under the Default Isolation Level parameter). The packages created are as follows: AUTOCOMMIT package (MSNC001 is only applicable on DB2/400) READ_UNCOMMITTED package (MSUR001) REPEATABLE_READ package, (MSRS001) READ_COMMITTED package, (MSCS001) SERIALIZABLE package (MSRR001). After being created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables. This parameter is equivalent to the DBPROP_DB2OLEDB_PACKAGECOL OLE DB property ID.
Default Schema	The name of the Collection where the OLE DB Provider for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The OLE DB Provider uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection. For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, the OLE DB Provider uses the USER_ID provided at logon. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. This default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined. This parameter is equivalent to the DBPROP_DB2OLEDB_DEFAULTSCH OLE DB property ID.

The **Data Source** in OLE DB is similar to a Data Source Name (DSN) in ODBC. The data source information is stored in a Microsoft Data Links file and contains the connection information required for the OLE DB Provider for DB2 to access IBM Data Base 2.

The AS/400 requires that the **User name** and **Password** parameters be in uppercase. When connecting to DB2/400, these parameters must be passed as uppercase strings. When connecting to DB2 on IBM mainframes, the **User name** and **Password** parameters can be in mixed case.

The **Connection** tab also includes a **Test Connection** button that can be used to test the connection parameters. The connection can only be tested after all of the required parameters are entered. When this button is selected, an APPC session or a TCP/IP session will attempt to be established with the host using the OLE DB Provider for DB2.

The **Advanced** tab allows users to select the character code set identifier used by the host, the PC code page used on the client software, and select some specific options when using the OLE DB Provider for DB2.

For the Microsoft OLE DB Provider for DB2, these properties include the following values:

Property	Description
DBMS Platform	The target DB2 platform property value is used to optimize performance of the OLE DB provider when executing operations such as data conversion. The default value is DB2/MVS.
Default Qualifier	The name of the schema (collection/owner) with which to fully qualify unqualified object names. This attribute allows the user to access database objects without fully-qualifying the objects using a collection (schema) qualifier. The OLE DB provider sends this value to DB2 using a SET CURRENT SQLID statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for default qualifier, then no SET statement is issued by the ODBC driver. This OLE DB property is only valid when connecting to DB2 for MVS (OS/390, z/OS).
Host CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the Process Binary as Character value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page. This parameter defaults to U.S./Canada (37). This parameter is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.
PC Code Page	The PC Code Page parameter indicates the code page to be used on the personal computer for character code conversion. This parameter is required when processing binary data as character data. Unless the **Process Binary as Character** checkbox is selected (value is set to true), character data is converted based on the default ANSI code page configured in Windows. This parameter defaults to Latin 1 (1252). This parameter is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.
Process Binary as Character	When this option is checked (property is set to true), the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false. This parameter is equivalent to the DBPROP_DB2OLEDB_BINASCHAR OLE DB property ID.
Distributed transactions	When this option is checked, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and one of the HIS Resync services. This parameter is equivalent to the DBPROP_DB2OLEDB_UNITSOFWORK OLE DB property ID.

The **All** tab allows users to configure more detailed and optional properties used to connect to a data source. These properties may be edited by selecting a property from the list displayed and selecting **Edit Value**. For the Microsoft OLE DB Provider for DB2, these properties include the following values:

Property	Description

Alternate TP Name	The remote transaction program name is optional. For example, it is used when configuring an off-line DB2 demo link service connection. This parameter is equivalent to the DBPROP_DB2OLEDB_TPNAME OLE DB property ID.
APPC Local LU Alias	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the name of the local LU alias configured in the SNA server. This parameter is equivalent to the DBPROP_DB2OLEDB_LOCALLU OLE DB property ID.
APPC Mode Name	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the APPC mode and must be set to a value that matches the host configuration and SNA Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP. This parameter is equivalent to the DBPROP_DB2OLEDB_APPCMODE OLE DB property ID.
APPC Remote LU Alias	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the name of the remote LU alias configured in the SNA server. This parameter is equivalent to the DBPROP_DB2OLEDB_REMOTELU OLE DB property ID.
Cache Authentication	This parameter determines whether the OLE DB Provider caches authentication information. This parameter defaults to false. This parameter is equivalent to the DBPROP_CACHE_AUTHINFO OLE DB property ID.
Data Source	The data source is an optional parameter that can be used to describe the data source. This parameter does not have a default value.
DBMS Platform	The target DB2 platform property value is used to optimize performance of the OLE DB provider when executing operations such as data conversion.
Default Qualifier	The name of the schema (collection/owner) with which to fully qualify unqualified object names. This attribute allows the user to access database objects without fully-qualifying the objects using a collection (schema) qualifier. The ODBC driver sends this value to DB2 using a SET CURRENT SQLID statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for default qualifier, then no SET statement is issued by the ODBC driver. This ODBC connection attribute is only valid when connecting to DB2 for MVS (OS/390, z/OS).
Default Schema	The name of the Collection where the OLE DB Provider for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The OLE DB Provider uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection. For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the OLE DB Provider uses the USER_ID provided at logon. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. This default is inappropriate in many cases; therefore it is essential that the Default Schema value in the data source be defined. This parameter is equivalent to the DBPROP_DB2OLEDB_DEFAULTSCH OLE DB property ID.

Extended Properties	This parameter is a string containing provider-specific, extended connection information. The use of this property implies that the OLE DB consumer knows how this string will be interpreted and used by the OLE DB provider. This parameter should be used only for provider-specific connection information that cannot be explicitly described through the other property parameters. This parameter is equivalent to the DBPROP_INIT_PROVIDERSTRING OLE DB property ID.
Host CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the Process Binary as Character value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page. This parameter defaults to U.S./Canada (37). This parameter is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.
Initial Catalog	This OLE DB property is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE. If the provider supports changing the catalog for an initialized data source, the consumer can specify a different catalog name through the DBPROP_CURRENTCATALOG property in the DBPROPSET_DATASOURCE property set after initialization. This is a required parameter. This parameter is equivalent to the DBPROP_INIT_CATALOG OLE DB property ID.
Integrated Security	This parameter determines whether the OLE DB Provider uses Host Security Integration (single sign-on). When this parameter is set to SSPI, single sign-on is enabled and separate user id and password parameters are not required. The user ID and password parameters are set based on the Windows 2000 logon. When this parameter is null, this single sign-on feature is disabled. This parameter defaults to null (host security integration is disabled) and a user id and password are required. This parameter is equivalent to the DBPROP_AUTH_INTEGRATED OLE DB property ID.
Mode	A Mode parameter is a bit mask specifying access permissions. This bit mask can be a combination of zero or more of the following: DB_MODE_READ—Read-only. DB_MODE_READWRITE—Read/write (DB_MODE_READ | DB_MODE_WRITE). DB_MODE_SHARE_DENY_NONE—Neither read nor write access can be denied to others. DB_MODE_SHARE_DENY_READ—Prevents others from opening in read mode. DB_MODE_SHARE_DENY_WRITE—Prevents others from opening in write mode. DB_MODE_SHARE_EXCLUSIVE—Prevents others from opening in read/write mode (DB_MODE_SHARE_DENY_READ | DB_MODE_SHARE_DENY_WRITE). DB_MODE_WRITE—Write-only. The OLE DB Provider for DB2 supports the following values for mode: Read (DB_MODE_READ) and Read/Write (DB_MODE_READ/WRITE). This parameter defaults to Read/Write. When the Read Only parameter is checked in the **Advanced** tab, the OLE DB Provider for DB2 creates a read-only data source by setting the Mode parameter to Read (DB_MODE_READ). A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This parameter is equivalent to the DBPROP_INIT_MODE OLE DB property ID.

Network Address	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the DB2 host. This parameter is equivalent to the DBPROP_DB2OLEDB_NETADDRESS OLE DB property ID.
Network Port	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the DB2 host. The default value is TCP/IP port 446. This parameter is equivalent to the DBPROP_DB2OLEDB_NETPORT OLE DB property ID.
Network Transport Library	The network transport dynamic link library property designates whether the OLE DB Provider for DB2 connects through SNA LU 6.2 or TCP/IP. The possible values for this parameter are TCPIP or SNA. The default value for this parameter is SNA. If the default SNA is selected, then values for APPC Local LU Alias, APPC Mode Name, and APPC Remote LU Alias are required. If TCP/IP is selected, then values for Network Address and Network Port are required. This parameter is equivalent to the DBPROP_DB2OLEDB_NETTYPE OLE DB property ID.
Package Collection	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. Package names can be upper case, lower case, or mixed case. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter. By default, the OLE DB Provider will automatically create one package in the target collection, if one does not exist, at the time the user issues their first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the User ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level based on the Isolation Level value configured in the data source. A problem can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (for example, PUBLIC), the package is created for use only by this user. This means that other users may be unable to access the required package. The solution is for an administrative user, with package administrative rights (for example, PACKADM authority in DB2 for OS/390), to create a set of packages for use by all users. The OLE DB Provider for DB2 ships with a tool program for use by administrators to create packages. The crtpkg.exe tool is a Windows GUI application for use by the administrator to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. This tool will create sets of packages and grant EXECUTE privilege to PUBLIC for all (see descriptions under the Default Isolation Level parameter). The packages created are as follows: AUTOCOMMIT package (MSNC001 is only applicable on DB2/400) READ_UNCOMMITTED package (MSUR001) REPEATABLE_READ package, (MSRS001) READ_COMMITTED package, (MSCS001) SERIALIZABLE package (MSRR001). After being created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables. This parameter is equivalent to the DBPROP_DB2OLEDB_PACKAGECOL OLE DB property ID.
Password	A valid user name and password are normally required to access data sources on hosts. The password is case-sensitive and is displayed as asterisks in this dialog box for security purposes. This parameter is equivalent to the DBPROP_AUTH_PASSWORD OLE DB property ID.
PC Code Page	The PC Code Page parameter indicates the code page to be used on the personal computer for character code conversion. This parameter is required when processing binary data as character data. Unless the **Process Binary as Character** value is set to true, character data is converted based on the default ANSI code page configured in Windows. This parameter defaults to Latin 1 (1252). This parameter is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.

Persist Security Info	This parameter indicates whether the data source object is allowed to persist sensitive authentication information, such as a password along with other authentication information. This parameter defaults to false. This parameter is equivalent to the DBPROP_AUTH_PERSIST_SENSITIVE_AUTHINFO OLE DB property ID.
Process Binary as Character	When this property is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false. This parameter is equivalent to the DBPROP_DB2OLEDB_BINASCHAR OLE DB property ID.
Units of Work	This parameter indicates whether two-phase commit (distributed unit of work) used for transactions is supported for this data source. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync service. The following values for mode are supported by the OLE DB Provider for DB2: RUW (remote unit of work) DUW (distributed unit of work) This parameter defaults to RUW. This parameter is equivalent to the DBPROP_DB2OLEDB_UNITSOFWORK OLE DB property ID.
User ID	A valid User name is normally required to access data sources on hosts. This value is case-sensitive. This parameter is equivalent to the DBPROP_AUTH_USERID OLE DB property ID.

Configuring a Data Source for the ODBC Driver for DB2

1. In Windows, on the taskbar, click **Start**, click **Settings**, and then click **Control Panel**.
2. Double-click the **ODBC** icon to display the **ODBC Data Source Administrator** dialog box.
3. If you are configuring an existing data source, select the data source name and click **Configure** to display the **Microsoft ODBC Driver for DB2 Configuration** dialog box.
4. If you are configuring a new data source click either the **User DSN** tab, the **File DSN** tab, or the **System DSN** tab. Click **Add**, select **Microsoft ODBC Driver for DB2 Driver**, and then click **Finish** to display the **Microsoft ODBC Driver for DB2 Configuration** dialog box.
5. Type the appropriate values in the fields, and then click **Apply**.

The **Microsoft ODBC Driver for DB2 Configuration** dialog box contains the following five tabs:

The **General** tab contains the following fields:

Parameter	Comments
Data Source Name	A blank field for specifying the name of the data source. Enter a string that identifies this ODBC data source. The data source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file, which is stored in C:\Program Files\Common Files\ODBC\Data Sources.
Description	A blank field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.

The **Connection** tab allows the user to configure the basic attributes required to connect to a data source. For the Microsoft ODBC Driver for DB2, the **Connection** tab has the following fields:

Parameter	Comments
APPC Connection and TCP/IP Connection	An option button (radio button) is used to select the network transport. Valid options are APPC Connection (SNA LU 6.2) or TCP/IP Connection. For the default, APPC Connection, the values for APPC local LU alias, APPC remote LU alias, and APPC Mode Name are required. For TCP/IP Connection, the values for IP address and Network port are required.
APPC local LU alias	When APPC Connection is selected, this field is the name of the local LU alias configured in Host Integration Server 2004.
APPC remote LU alias	When APPC Connection is selected, this field is the name of the remote LU alias configured in Host Integration Server 2004.
APPC mode name	When APPC Connection is selected, this field is the APPC mode and must be set to a value that matches the host configuration and SNA Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). The default is typically QPCSUPP.
IP address	When TCP/IP Connection is selected as the network transport, this field indicates the IP address of the host DB2 server.
Network port	When TCP/IP Connection is selected as the network port, this field indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default is **IP port 446**.

The **Connection** tab also includes a **Test connection** button that may be used to test the connection parameters. A connection can only be tested after all of the required parameters for the **Connection** tab and other ODBC data source parameters are configured properly. When this button is clicked, a session is established with the remote DB2 system using ODBC Driver for DB2.

The **Security** tab allows the user to configure optional attributes used to restrict connections to a data source. For the Microsoft ODBC Driver for DB2, the **Security** tab has the following fields:

Parameter	Comments
Authentication	An option button (radio button) is used to select the type of authentication. Valid options are **Use this username** or **Use single sign-on**. For the default **Use this username** option, the value for the username is required.
Use this username	When this option is selected, authentication is based on the username entered in the textbox. A valid user name is normally required to access data on DB2. A user name can remain optionally in the DSN. The ODBC Driver for DB2 will prompt the user at run-time to enter a valid password. Additionally, the prompt dialog will enable the user to override the user name that is stored in the DSN.
Use single sign-on	An option button to select whether single sign on or a specific user name should be used. Single sign-on is an optional Host Security feature. Single sign-on enables the administrator to create data source definitions that isolate the logon process from the end user. The user context for single sign-on is the user context associated with the SNA DB2 service.

The AS/400 computer is case-sensitive with regard to user IDs and passwords. When connecting to DB2 for OS/400, user names and passwords must be in uppercase. The AS/400 only accepts a DB2 for OS/400 user ID and password in uppercase. If a DB2 for OS/400 connection fails due to incorrect authentication, the ODBC driver resends the authentication, forcing the user ID and password into uppercase.

When connecting to DB2 on IBM mainframes, user names and passwords can be of mixed case; the mainframe is not case-sensitive. The ODBC driver sends these values in uppercase.

DB2 Universal Database (UDB) is case-sensitive. The user ID is stored in uppercase. The password is stored in mixed case and users must enter the password in the correct case. The ODBC driver sends the password exactly in the case entered by the user. The user ID should contain only the user name, not a combination of the Windows domain name and username.

The **Target Database** tab allows the user to configure required, as well as optional, attributes used to define the target DB2 system. For the ODBC Driver for DB2, the **Target Database** tab has the following fields:

Parameter	Comments
Initial catalog	This parameter is used as the first part of a three-part fully qualified DB2 table name. It is referred to by different names depending on the DB2 platform. In DB2 for OS/390 and DB2 for MVS, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 that you need to connect to on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE.

Package collection	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This can be the same as the default schema. The ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver creates packages dynamically in the location that the user points to using the Package Collection parameter. By default, the ODBC Driver for DB2 automatically creates one package in the target collection, if one does not exist, at the time the user issues their first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the user ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level based on the Isolation Level value configured in the data source. Problems can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (for example, PUBLIC), then the package is created only for use by this user. This means that other users may be unable to access the required package. The solution is for an administrative user, with package administrative rights (for example., PACKADM authority in DB2 for OS/390), to create a set of packages for use by all users. The ODBC Driver for DB2 ships with two utility programs for use by administrators to create packages. The crtpkg.exe tool is a command line utility for the administrator to create packages. The crtpkgw.exe tool is a Windows GUI utility used for the same purpose. Either of these utilities can be run using a privileged user ID to create packages in collections accessed by multiple users. These utilities will create sets of packages and grant EXECUTE privilege to PUBLIC for all (see descriptions under the Default Isolation parameter). The packages created are as follows: AUTOCOMMIT package (MSNC001 is only applicable on DB2/400) READ_UNCOMMITTED package (MSUR001) REPEATABLE_READ package, (MSRS001) READ_COMMITTED package, (MSCS001) SERIALIZABLE package (MSRR001). After being created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables.
Default schema	The name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default schema is the SCHEMA name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (for example, ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or owner). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, the ODBC driver uses the USER_ID provided at logon. For DB2/400, the driver uses QSYS2 if no collection is found matching the USER_ID value. This default is inappropriate in many cases so it is essential that the Default Schema value in the data source be defined.
DBMS Platform	The target DB2 platform property value is used to optimize performance of the ODBC driver when executing operations such as data conversion. The default value is DB2/MVS.
Default Qualifier	The name of the schema (collection/owner) with which to fully qualify unqualified object names. This attribute allows the user to access database objects without fully-qualifying the objects using a collection (schema) qualifier. The ODBC driver sends this value to DB2 using a SET CURRENT SQLID statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for default qualifier, then no SET statement is issued by the ODBC driver. This ODBC connection attribute is only valid when connecting to DB2 for MVS (OS/390, z/OS).
Alternate TP Name	The remote transaction program name is optional. For example, it is used when configuring an off-line DB2 demo link service connection.

Distributed transactions	When this option is checked, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and one of the HIS Resync services.
Process binary as character	When this option is checked, it indicates that binary data fields should be processed as characters. This option treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. See the **Locale** tab.

The **Locale** tab allows the user to configure the parameters used for character conversion between the client computer and the DB2 server. Two versions of the **Locale** tab are possible depending on which versions of SNA Server client software and ODBC for DB2 Driver client software are installed.

For the ODBC Driver for DB2, the **Locale** tab has the following fields:

Parameter	**Comments**
Host CCSID	The coded character set identifier (CCSID) matching the DB2 data as represented on the remote computer. This property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the DB2 column CCSID and configured ANSI code page. This parameter defaults to U.S./Canada (37).
PC code page	This parameter indicates the personal computer code page to use. It is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the default ANSI code page configured in Windows. The default value for this property is Latin 1 (1252).

Click **OK** or **Cancel** when data entry is finished. If you click **OK**, the values specified become the defaults when an application connects to this data source. These default values can be changed at any time using this procedure to reconfigure the data source. An ODBC application can override these defaults by connecting to the data source using a connection string with alternate values.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Network Integration Help

Use the topics in this section to navigate through the Network Integration User Interface.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Print Service Properties

Click **No Event Log for Skipping Transparent Section** to prevent an entry in the Event Log every time print services skips a transparent section found while printing a host print job. Skipping transparent sections can be enabled from the **Advanced** tab of a print session properties page.

3270

Click **Flush Final FF** causes Host Print services to explicitly form feed the document at the end of a print job. This is not needed for most print jobs and configurations.

Click **Use Proportional Font Change** to prevent overlapping characters in documents containing nonfixed-type fonts printed through Host Print services. Most standard 3270 data streams are designated for fixed-type fonts.

Click **Ignore Characters 3F and Under** to cause the print service to ignore Hexadecimal characters 3F and below. In LU 1 data streams, this option causes hexadecimal characters below 40 to be replaced by spaces.

Click **Delay Print Start** to delay the start of the print job until printable data is received by Host Print services. In a few environments, hosts may poll the Host Print service for activity by sending "empty jobs". In such cases, not selecting this option may cause blank pages to be printed between actual print jobs.

LU 3 Only

Click **Do All FF** to force the printer driver to honor all form feed commands. (In most jobs, this is unnecessary and may lead to unwanted blank pages.)

Click **Always do NL** to insert a new line when the print services determines that the Maximum Print Position has been reached for a particular line of data. Selecting this option will prevent data from printing over an existing line.

Click **No Space After FF** to prevent print services from inserting a space character following a form feed.

Click **Support Embedded Printer Codes** to allow unmarked embedded characters, such as EBCDIC X'27' characters, to pass through print services to the printer.

LU 1 Only

Click **Use Fixed Tabs** to disable normal tab functionality (such as aligning tabs in columns) and interpret each tab as a fixed number of spaces. The number of spaces for a tab stop is based on the size of the first tab in the Set Horizontal Format SCS control code.

APPC

Set the **Activation Retry Limit** to the number of times print services will attempt to activate the APPC conversation following a terminated connection. The default value is –1 (infinite), meaning that attempts to activate the session will continue until it is successful or terminated manually.

Click **Infinite Retry Limit** to force the system to retry printing the job until it is successful.

Set the **Activation Retry Interval** to the number of seconds to wait before trying to print the job again. The default value is 10 seconds.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Print Session Properties

The following tabs are available on the Print Session 3270 Properties sheet:

Print Session Properties: General

Session Name

To print 3270 jobs, you must define the session name, which is a descriptive name to distinguish different printers on the network.

Comment

Optionally, type a comment of 25 characters or less.

Session Activation

Click **Manual** to activate the print session manually, or **Automatic** to activate the print session automatically when the Host Print service is started.

Host Code Page

Click **Language**, and then select a **language code** from the drop-down list.

If your language code does not appear in the drop-down list, click **Custom**, then click on the **File** button. The **Select Custom Page File** dialog box appears. Select your custom code page and click **Open**.

> **Note** The custom page support in Host Print service provides Arabic and Hebrew code page support for left-to-right output only. The Host Print service does not support bi-directional data streams from right to left.

Destination

The default printer should appear in the box. Otherwise, click **Printer** to open the **Print Setup** dialog box. Make your selections and click **OK**.

Click **File** to send your job to a file. Check **Unique** to activate the **Reset** button. This feature allows you to reset the print job sequential numbering scheme (for example, when the number gets too high). Click **Reset**, and then click **Yes** to reset to the printer file extension numbering.

> **Note** You need to select a printer driver to print to a file. Select a valid printer driver, then select File in the Destination box. Otherwise, you get an error message.

Print Session Properties: 3270

LU Name

Choose a **3270 printer LU** for the print session from the **LU Name** drop-down list. The drop-down list shows all of the LUs in an SNA Subdomain. If no 3270 printer LUs appear, you need to define one.

Job Termination When

Set job termination to either When End Bracket Received or When Unbind Received.

Selecting **When End Bracket Received** means the Host Print service will treat receiving the End Bracket notification from the host as an indication that the job is complete. Otherwise, the Print service defaults to spooling the job until the session ends: **When Unbind Received**.

> **Note** If the host application sends print jobs that comprise multiple SNA brackets, set job termination to When End Bracket Received.

Job Timeout

To set a parameter for terminating print jobs, click the **Timeout Job After** box. Click the **Seconds Inactivity** up and down buttons to set the time limit for terminating print jobs. In some cases, an LU 3 print job is sent down from the host over an extended period of time. Selecting a Job Timeout ensures that the portions of the job are regularly form-fed. This option also provides normal timeout functionality for other 3270 print jobs.

Monitor Job

Click **Request Definite Response** if you want to invoke an advanced feature for applications that require a high level of assurance that a job completed. This feature sends a message to the host stating that the print job completed.

> **Note** If you select the Request Definite Response feature, the host job must mark the data as RQD (definite response required).

Print Session Properties: Job Format

Do Not Format Print Job

Do Not Format Print Job allows print jobs that are formatted with host software to bypass the Microsoft® Windows®-based printing format system. The Windows-based Host Print service treats all received data as transparent. All data is passed directly to the printer.

Format Print Job

Print jobs from a host system can be formatted one of two ways:

GDI

The Windows Graphical Device Interface (GDI) is used to format the print job. SCS codes in the data are interpreted and represented, and the GDI automatically supports all the configurable options such as font, margins, duplex, paper-source etc. Transparent sections (for example, containing PCL escape sequences) are just ignored. When such data is discarded, a log is written to the Event Log, containing the first 32 bytes of discarded data. This logging can be globally disabled from the Host Print service properties page.

Selecting this option disables the Ignore **Transparent Sections for PDT Formatting** on the **Advanced** tab.

> **Note** If your print job has a mixture of SCS codes and PCL escapes, then you should use a PDT. The PDT should contain mappings for the SCS code functionality, and the PCL escapes should pass directly to the printer without being mapped.

PDT

A Printer Definition Table (PDT) is used to specify the output format, control codes, and transfer of characters to a printer. When you use a PDT, the Windows based printer driver is not used. The PDT defines all information used to generate the print output. Click the **PDT File** button to select a compiled Printer Definition File.

To create a new PDT, you must first create a Printer Definition File (PDF), and then compile the PDF into a PDT. (If an uncompiled PDF file is selected, the compilation is performed automatically each time the print session is used. This feature has a performance overhead and is available mainly for ease of development). The PDF is a text file that defines macros and session parameters.

The PDT may override changes you make to **Font**, **Margins**, or **Page Setup**, although it is now possible to support these options in the PDT file. If you want to print in a particular font with a PDT, you should alter the startup sequence in the PDT to tell the printer which font you require. When a PDT file is used, Host Print service uses the definitions of NL, CR, FF, and LF from the PDT file to allow it to format the print job correctly.

Click **Printer Language is Hewlett-Packard (HP) PCL** if your PDT contains PCL commands. Limited support for Manager-defined font, margins and paper setup settings is automatically supported for HP (PCL), with full support available for customizing the Printer Definition File.

Font

To make changes to the font, click **Font**. Click the **Font** button. Make your selections in the Windows-based **Font** dialog box, and then click **OK**.

Use Fixed Font Size

Select the **Use Fixed Font Size** to select a user-defined font size. When this box is checked, the Host Print service will use the configured point size regardless of whether the data will fit (it will be clipped to fit the page if it is too large). When this option is selected, the Horizontal and Vertical scaling options on the **Advanced** tab are not available.

Print Session Properties: Page Layout

All these options are automatically available using the Windows GDI. Supporting these options using a PDT file may require extra configuration.

Horizontal Controls

Characters per line

The default is 132 characters per line. Type 80, 158, or another number for characters per line to change the default. The maximum line length is 255 characters.

Click **Override Host Commands** to force the specified settings and ignore host commands.

Vertical Controls

Lines per Page

Select **Lines Per Page** and then set the number of lines to be printed on each page.

Lines Per Inch

Select **Lines Per Inch** and then set either 6 or 8 lines per inch to set the default.

Click **Override Host Commands** to force the specified settings and ignore host commands.

Margin Settings

To change the margins, select **Margins**, and then click **Setup**. The **Page Setup** dialog box appears. Make your changes, and then click **OK**.

Page settings

Settings for Paper Source, Page Size, and Orientation are controlled from the Printer section. Click **Override Host Commands** to force the specified settings and ignore host commands.

Print Session Properties: Advanced

Filter DLL

Click **Filter DLL** to pass the printer data stream to a third-party or user-supplied DLL. Clicking **Filter** activates the **DLL File** button. The **Select Filter DLL** dialog box appears. Make your selection, then click **Open**.

Ignore Transparent Sections for PDT Formatting

Selecting this option will cause those sections of the print data stream that have been marked as transparent to be ignored when using a PDT file to format the data. Note, when using the GDI to format the data, transparent sections are automatically ignored. When such data is discarded, a log is written to the Event Log, containing the first 32 bytes of discarded data. This logging can be globally disabled from the Host Print service properties page.

Do Not Scale Horizontally

Selecting this option will turn off the horizontal scaling feature of the printer driver.

Do Not Scale Vertically

Selecting this option will turn off the vertical scaling feature of the printer driver.

3270 Printing

Transparency is ASCII

Click **Transparency is ASCII** to indicate that transparent data from the host is in ASCII and needs no translation from EBCDIC to ASCII. Selecting **Transparency is ASCII** causes the Windows-based Host Print service to not put the received data through an EBCDIC to ASCII translation table before printing.

Transparency Custom Byte

Transparency Custom Byte indicates the character designated to start a sequence of transparent data (the transparent data may or may not be ASCII). The IBM standard is 0x35, but if the host print job uses another value (for example 0x36, and so on), then this should be specified here.

No Line Formatting

Prevents the SNA Print Service from inserting its own Carriage Return/Line Feed (CR/LF) according to the dimensions specified in the Default Page Width field (also on this property page). As No Line Formatting is a special case, this box is usually not checked. It is a useful option when using physical printers that do their own wrapping or are told to do their own wrapping with an Esc sequence. The Esc sequence that causes a printer to do its own End-of-line wrap on PCL printers is <Esc>&s0C.

Printer Time Out

Default is 10 seconds. This parameter optimizes performance and system resources. If the printer is always available, system resources are consumed. However, if the printer is constantly being "opened" and "closed" with each print job sent, performance suffers. By setting the time out, the printer will remain available for jobs sent close together to improve performance, and yet "close" during non-busy times to free up resources.

Print Session Properties

The following tabs are available on the Print Session 3270 Properties sheet:

Print Session Properties: APPC

Remote APPC LU

Choose **Alias** or **Fully Qualified Name** to select another remote APPC LU.

You must supply either a **Remote APPC LU Alias** or a **Fully Qualified Name** before you can leave this page. If you want to use a **Fully Qualified Name**, you need to select a **Remote APPC LU Alias** first, then select a **Local LU Alias**. Then you must go back and change from the **Remote APPC LU Alias** to the **Remote APPC LU Fully Qualified Name**. If you select **Fully Qualified Name** first, the **Local LU Alias** does not get initialized.

Network Name + LU Name in NETNAME.LUNAME syntax (for example, APPN.NORTHB).

Local LU Alias

Select the local LU alias from the drop-down list.

Mode Name

The default mode name is QPCSUPP. Click the drop-down list arrow to make another selection. The choices are: **#INTERSC**, **BLANK**, **QPCSUPP**, **QSERVER**.

AS/400 Device Name

You must enter the name for the AS/400 printer device, which is a descriptive name that distinguishes different printers on the network.

System Type

Select the type of system you are printing from; either AS/400, System/36, AS/36.

AS/400

Msg Queue Name

Enter the qualified name of the message queue to which operational messages for this device are sent.

Msg Lib Name

Enter the name of the library in which the message queue is located.

System/36, AS/36

APPC Print Session Properties: Security

User ID

Type your **User ID**.

Password

Type your **Password**. Click tab to put the cursor in the **Confirm** password box.

Confirm Password

Type your password again and click **OK**.

Print Session Properties: Job Format

Job

Do Not Format Print Job allows print jobs that are formatted with host software to bypass the Windows-based printing format system. The Windows-based Host Print service treats all received data as transparent. All data is passed directly to the printer.

HPT

Displays the **Host Print Transform Properties** box, where you can designate the printer type and paper sources.

The Host Print Transform feature changes print data on the AS/400 to the ASCII format needed by a PC printer.

Select a manufacturer type and model number. If you cannot find the type and model number in the list you can type them in the box. If you do not know the manufacturer type and model number, see your system administrator or see the help on the AS/400.

> **Important** You must enter an asterisk "*" before the manufacturer type and model number. Make sure there are no spaces between the asterisk, manufacturer type and model number, for example: *HPIIISI, or *IBM3812.

Format Print Job

Print jobs from a host system can be formatted one of two ways:

GDI

The Windows Graphical Device Interface (GDI) is used to format the print job. SCS codes in the data are interpreted and represented, and the GDI automatically supports all the configurable options such as font, margins, duplex, paper-source etc. Transparent sections (for example, containing PCL escape sequences) are just ignored. When such data is discarded, a log is written to the Event Log, containing the first 32 bytes of discarded data. This logging can be globally disabled from the Host Print service properties page.

Selecting this option disables the Ignore **Transparent Sections for PDT Formatting** on the **Advanced** tab.

> **Note** If your print job has a mixture of SCS codes and PCL escapes, then you should use a PDT. The PDT should contain mappings for the SCS code functionality, and the PCL escapes should pass directly to the printer without being mapped.

PDT

A Printer Definition Table (PDT) is used to specify the output format, control codes, and transfer of characters to a printer. When you use a PDT, the Windows based printer driver is not used. The PDT defines all information used to generate the print output. Click the **PDT File** button to select a compiled Printer Definition File.

To create a new PDT, you must first create a Printer Definition File (PDF), and then compile the PDF into a PDT. (If an uncompiled PDF file is selected, the compilation is performed automatically each time the print session is used. This feature has a performance overhead and is available mainly for ease of development). The PDF is a text file that defines macros and session parameters.

The PDT may override changes you make to **Font**, **Margins**, or **Page Setup**, although it is now possible to support these options in the PDT file. If you want to print in a particular font with a PDT, you should alter the startup sequence in the PDT to tell the printer which font you require. When a PDT file is used, Host Print service uses the definitions of NL, CR, FF, and LF from the PDT file to allow it to format the print job correctly.

Click **Printer Language is Hewlett-Packard (HP) PCL** if your PDT contains PCL commands. Limited support for Manager defined font, margins and paper setup settings is automatically supported for HP (PCL), with full support available for customizing the Printer Definition File.

Font

To make changes to the font, click **Font**. Click the **Font** button. Make your selections in the Windows-based **Font** dialog box, and then click **OK**.

Use Fixed Font Size

Select the **Use Fixed Font Size** to select a user defined font size. When this box is checked, the Host Print service will use the configured point size regardless of whether the data will fit (it will be clipped to fit the page if it is too large). When this option is selected, the Horizontal and Vertical scaling options on the **Advanced** tab are not available.

APPC Print Session Properties: Advanced

Filter DLL

Click **Filter DLL** to pass the printer data stream to a third-party or user-supplied DLL. Clicking **Filter** activates the **DLL File** button. The **Select Filter DLL** dialog box appears. Make your selection, then click **Open**.

Ignore Transparent Sections for PDT Formatting

Selecting this option will cause those sections of the print data stream that have been marked as Transparent to be ignored when using a PDT file to format the data. Note, when using the GDI to format the data, Transparent sections are automatically ignored. When such data is discarded, a log is written to the Event Log, containing the first 32 bytes of discarded data. This logging can be globally disabled from the Host Print service properties page.

Do Not Scale Horizontally

Selecting this option will turn off the horizontal scaling feature of the printer driver.

Do Not Scale Vertically

Selecting this option will turn off the vertical scaling feature of the printer driver.

Print LU Properties: General

LU Number

Enter the LU Number.

LU Name

Enter the LU Name.

Connection

The connection for this LU is shown. The connection cannot be changed here.

Pool

If the LU has already been assigned to a pool, the pool name appears here.

Comment

Optionally, enter a comment of not more than 25 characters.

Use Compression

Selecting this option will compress the data stream and reduce the local area network traffic.

User Workstation Secured

Selecting this option allows only this workstation to access the Host LU.

TN3270 Properties: Settings

Idle Timeout

> Specify time limits. If the session is inactive for this length of time, then TN3270 service disconnects the client computer.

Init Status Delay

> Specify time limits. This is the delay between the time when TN3270 service connects to a host session and the time the TN3270 service starts updating the client computer screen. There are often a large number of startup messages when the TN3270 service first connects to a host session, and this option gives the user the opportunity not to receive them all.

Message Close Delay

> Specify time limits. When TN3270 service forces a client computer to disconnect (for example, when the Microsoft® Host Integration Server 2004 session to the host has been lost), it sends the client computer an error message to be displayed on the screen. This value specifies the time between sending the message to the client computer and closing the socket with the client computer (which causes some client computers to clear the screen, and so erase the message).

Refresh Cycle Time

> Specify time limits. This is the delay between updates of the status on the display.

Default RU Sizes - Inbound and **Outbound**

> This controls the RU size (SNA message size) used by the TN3270 service for logon messages to and from the host. The minimum value for inbound or outbound RU size is 256 bytes. If the host application sends large logon screens, these values should be increased.

Certificate CN

The common name of the certificate used if TLS/SSL is enabled.

Print Service Properties

Click **No Event Log for Skipping Transparent Section** to prevent an entry in the Event Log every time print services skips a transparent section found while printing a host print job. Skipping transparent sections can be enabled from the **Advanced** tab of a print session properties page.

3270

Click **Flush Final FF** causes Host Print services to explicitly form feed the document at the end of a print job. This is not needed for most print jobs and configurations.

Click **Use Proportional Font Change** to prevent overlapping characters in documents containing nonfixed-type fonts printed through Host Print services. Most standard 3270 data streams are designated for fixed-type fonts.

Click **Ignore Characters 3F and Under** to cause the print service to ignore Hexadecimal characters 3F and below. In LU 1 data streams, this option causes hexadecimal characters below 40 to be replaced by spaces.

Click **Delay Print Start** to delay the start of the print job until printable data is received by Host Print services. In a few environments, hosts may poll the Host Print service for activity by sending "empty jobs". In such cases, not selecting this option may cause blank pages to be printed between actual print jobs.

LU 3 Only

Click **Do All FF** to force the printer driver to honor all form feed commands. (In most jobs, this is unnecessary and may lead to unwanted blank pages.)

Click **Always do NL** to insert a new line when the print services determines that the Maximum Print Position has been reached for a particular line of data. Selecting this option will prevent data from printing over an existing line.

Click **No Space After FF** to prevent print services from inserting a space character following a form feed.

Click **Support Embedded Printer Codes** to allow unmarked embedded characters, such as EBCDIC X'27' characters, to pass through print services to the printer.

LU 1 Only

Click **Use Fixed Tabs** to disable normal tab functionality (such as aligning tabs in columns) and interpret each tab as a fixed number of spaces. The number of spaces for a tab stop is based on the size of the first tab in the Set Horizontal Format SCS control code.

APPC

Set the **Activation Retry Limit** to the number of times print services will attempt to activate the APPC conversation following a terminated connection. The default value is –1 (infinite), meaning that attempts to activate the session will continue until it is successful or terminated manually.

Click **Infinite Retry Limit** to force the system to retry printing the job until it is successful.

Set the **Activation Retry Interval** to the number of seconds to wait before trying to print the job again. The default value is 10 seconds.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring an IP-DLC Connection

As with other connections, configuration requires setting parameters on the Connection properties dialog. It is recommended that you read this section before beginning the configuration process, so you can gather all the necessary information before you start.

To configure an IP-DLC connection

1. If you have just created a new IP-DLC link service connection, the **Connection** properties dialog will automatically appear. If it does not, or if you are configuring an already-existing IP-DLC link service connection, right-click the IP-DLC link service connection in the results pane of the MCC snap-in, and click **Properties**.
2. Fill in the required parameters according to the tables below.

General Page

The **General** page is similar to that used for other connections in Microsoft® Host Integration Server.

Property	**Comments**
Name	Name of the connection.
Link service	This list displays all currently configured IP-DLC link services.
Comment	Descriptive comment (optional).
Activation	Specifies conditions under which connection is activated.
On server startup	Connection is activated on server startup.
On demand	Connection is activated on demand.
By administrator	Connection can only be activated by system administrator.
Allowed direction	Specifies the connection directions. For more information, see the note under Peer system later in this table.
Outgoing calls	Connection is outgoing.
Incoming calls	Connection is incoming.

Both directions	Connection can be both incoming and outgoing.
Remote end	Specifies which system is the remote end.
Host system	Selecting this option signifies that the connection will be used for Dependent LU Server (DLUS) traffic and may have dependent LUs. You cannot associate independent APPC LUs with an IP-DLC connection remote end type of host system.
Peer system	Selecting this option signifies that the connection will be used for independent APPC LU sessions. You cannot associate dependent 3270 LUs with an IP-DLC connection remote end type of peer system. Because peer system IP-DLC connections do not support DLUS traffic, selecting this option will disable all controls on the **Address** page and the IP-DLC page (shown later in this topic). Only one peer connection can be associated with an IP-DLC link service. Note: Selecting Peer system automatically sets Activation to **On Server Startup** and Allowed direction to **Both**.

Address Page

Use this page to configure DLUS properties for the connection. The DLUS on the mainframe system operates in conjunction with the Dependent LU Requestor (DLUR) on the local Host Integration Server computer. Together they route dependent (for example, 3270) sessions across the APPN network using the IP-DLC link service.

If you selected the Remote end as Peer system on the **General** page, all controls on this page will be disabled.

Property	Comments
Primary DLUS	Fill in these required fields for the primary server with the appropriate names.
Network name	Maximum of eight characters of SNA type A string, representing the APPN network in which to locate the primary DLUS.
Backup DLUS	Fill in these fields for the backup server with the appropriate names. These fields are optional.
Preferred route	Optionally, enter the IP address, host name, or fully qualified name for the NNS as routing server through which to connect to the DLUS. Using a separate NNS may improve host performance by offloading the DLUS host computer from operating as an NNS directory server. The IP-DLC link service will attempt to establish the connection to the DLUS using the preferred route address.

System Identification Page

The **System Identification** page is similar to that used for other connections in Host Integration Server.

If you selected the Remote end as Peer system on the **General** page, all controls on this page will be disabled.

Property	Comments
Local node name	Specify information for the local server.
Node ID	Required. Enter a hexadecimal value to uniquely identify the physical unit (PU) for the host connection. This value must match an existing remote LEN-style PU definition. Default value is 05D FFFFF. The node ID value must match the value configured on the host DLUS computer.

Link compression	Optional. Choose a setting from the list. Default value is **None**.
Remote node name	Specify information for the remote DLUS.
Node ID	Required. Enter a hexadecimal value to uniquely identify the physical unit (PU) for the host connection. This value must match an existing remote LEN-style PU definition for the DLUS. There is no default value.

IP-DLC Page

Use this page to optionally set parameters specific to the IP-DLC connection.

If you selected the Remote end as Peer system on the **General** page, all controls on this page will be disabled.

Property	**Comments**
Connection retry limits	Optionally, use these controls to specify retry limits for activating a connection.
None	Specifies no retries.
Limited	Specifies the number of retries, from 1 through 65534. Default value is 8.
Delay after retry	Specifies the wait period after a retry, from 1 through 327670 seconds. Value must be a multiple of five. Default value is 10 seconds.
DLUR retry limits	Optional. Use these controls to specify retry action in case the DLUR connection fails. Default setting is Infinite.
Infinite	Specifies an infinite number of retries.
None	Specifies no retries.
Limited	Specifies the number of retries, from 1 through 65534. Default value is 8.
Delay after retry	Specifies the wait period after each retry, from 1 through 65535 seconds. Default value is 10 seconds.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuring an IP-DLC Link Service

As with other link services, configuration requires setting parameters on the **Link Service Properties** dialog box. It is recommended that you read this section before beginning the configuration process, so you can gather all the necessary information before you start.

To configure an IP-DLC link service

1. If you have just created a new IP-DLC link service, the **IP-DLC Link Service Properties** dialog box will automatically appear. To reconfigure an existing IP-DLC link service, right-click the IP-DLC link service in the scope pane of the MCC snap-in, click **Properties**, and then click the **Configure** button to load the IP-DLC Link Service Properties dialog box.
2. Fill in the required parameters according to the following table.
3. Click **OK** to persist the settings to the configuration file and registry. The **Insert Link Service** dialog box appears.
4. Click **Complete Configuration of the IP-DLC Link Service**.

Property	Comments
Service name	Displays the name of the link service being configured. For a new link service, the name is predefined as SNAIP#, where # is the ordinal number of the link service.
Service title	Enter a user-friendly text description of up to 128 characters. This name will be displayed in the Service Control Manager. The default value is IP-DLC Link Service #N, where N is the ordinal number of the link service.
Primary network node server (NNS)	Enter the IP address, host name, or fully qualified name of the primary network node server. There is no default value.
Backup network node server	Optionally, enter the IP address, host name, or fully qualified name of the backup network node server. There is no default value.
Local address	This set of parameters assigns the link service to a particular IP address on the local computer. Every link service must be associated with a local IP address or logical connection, and neither the IP address nor the logical connection can be used by another IP-DLC link service on the local computer.
Adapter address	Selecting this option button forces the link service to use the default IP address associated with the network adapter specified in the adjacent list. (The alternative is to associate with a static IP address.) The list displays all available network adapters currently configured. Physical adapters are listed first, followed by virtual adapters (that is, WAN Mini-ports).
Static IP address	Selecting this option button forces the link service to use the IP address specified in the adjacent list. The list displays all static IP addresses defined to the local computer. Enter the IP address, host name, or fully qualified name for the IP-DLC link service.
Local APPN node	This set of parameters configures the network identification of the APPN branch network node implemented by the IP-DLC link service. Note: No other IP-DLC link service within the APPN network can use both the same network name and control point name as this one. Individual names may be reused, but the pair may not.
Network name	Enter the APPN network name for the IP-DLC link service operating as a local APPN node across which the IP-DLC link service will communicate. This value must be text with a maximum of eight characters and comply with the APPN naming convention. There is no default value.
Control point name	Enter the APPN control point name for the IP-DLC link service operating as a local APPN node. This value must be text with a maximum of eight characters and comply with the APPN naming convention. There is no default value. The control point name must be unique for this computer on the APPN network.
Node ID	In the first box, enter any valid 3-digit hexadecimal number except the reserved numbers of 000 and FFF. In the second box, enter any valid hexadecimal number except the reserved number 00000. There is no default value.
Associated LEN node	Select an SNA service operating as an APPN LEN node to associate with this IP-DLC link service. Default value is the first SNA service on the local computer.

Downstream pool

Enter a **Name** and **Comment** for the pool.

LUA pool

Enter a **Name** and **Comment** for the pool.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Installation Help

Use the topics in this section to navigate through the Data Integration User Interface.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Welcome Screen

Be sure to read the Welcome Screen as it contains important information.

Setup cannot install system files or update shared files if the files are in use. Before continuing, close all open applications.

> **Important** Stopping existing SNA Server or Microsoft® Host Integration Server 2004 services will immediately disconnect users from the Host computer and terminates all sessions.

Viewing the Welcome Screen

- Click **Cancel** if you would like to quit setup.

  -or-

  Click **Next** to continue setup.

  Note You can click **Cancel** at any screen to quit the Setup program. If you need to make changes to information you have entered in a previous screen, you can click the **Back** button.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

License Agreement Screen

Read the End-User License Agreement to become familiar with the terms of the Host Integration Server 2004 license.

> **Note** You must accept the License Agreement to complete the server installation.

To accept the End-User License Agreement

1. Select **I accept the License Agreement**.
2. Click **Next**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

User Information Screen

Enter the Full Name and Organization information.

The Full Name is mandatory and the Organization is optional.

To enter the user information

1. Enter the **Full Name** and **Organization** information.
2. Click **Next**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Select Features Screen

From the **Select Features** dialog box, you can select from several options.

- **Browse** allows you to select the location where Host Integration Server will be installed.
- **Disk Cost** displays the disk space requirements for installed components.
- **Reset** sets all features back to the default setting of all components getting installed.
- **Make Features Unavailable** removes features from your current installation option.

To accept features

1. Either accept all of the Host Integration Server features or make options that you do not want to install unavailable.
2. Click **Next** to continue.

Folder Installation Location

For new installations, Setup displays the current location where Host Integration Server 2004 software will be installed. The default location is **C:\Program Files\Host Integration Server**.

For upgrades, the existing folder where the Host Integration Server 2004 or a previous version of SNA Server is installed will be displayed.

Current folder location

1. To change the current folder location where Host Integration Server 2004 will be installed, click **Browse**.
2. You will be prompted to enter the new folder name. Click **OK**.

Checking Disk Cost

To view the disk cost for installed components, click **Disk Cost** on the **Select Features** dialog box.

This dialog box shows the current disk volumes with the disk size, amount of available space, the amount of space required for selected components, and the difference available.

To check disk cost

1. View the Disk Cost information.
2. Click **OK** to close the **Disk Cost** dialog box.

Resetting Install Features

You can reset the selected features back to the original settings by clicking **Reset** on the Select Features dialog box.

To reset the install features

1. Click **Reset** to verify that you want Setup to reset all features to be installed.

All features that were marked as unavailable will now be available to Setup.

Installing Applications Only

It is possible to install applications only, such as Transaction Integrator or Data Integration. Before doing so, you will need to know whether your host application was designed for use with SNA protocols or TCP/IP sockets. To find this information, see your system administrator.

The three custom installation options are as follows:

- **Full Gateway Installation:** (Default) Check both **SNA Application Support** and **SNA Service**. This will install the SNA Service on the local machine. Select this option if your host application is designed for use with SNA protocols such as DLC, IP-DLC, APPC, or LU 6.2.
- **Application Only Installation:** Clear all checkboxes and then select either **Data Integration** or **Application Integration** as appropriate. This will install the selected application(s) on the local machine, but will not install the SNA Service. Select this option if your host application is designed for use with TCP/IP sockets, and not SNA protocols.
- **Nodeless Installation:** Select **SNA Application Support** and also select either **Data Integration** or **Application**

Integration as appropriate. This will install the Host Integration Server 2004 Administrator Client on the local computer. Select this option if your host application is designed for use with SNA protocols such as DLC, IP-DLC, APPC, or LU 6.2, and you are accessing the host through another computer with Host Integration Server installed.

Make Features Unavailable

To make a Host Integration Server 2004 feature unavailable, click the feature icon. One of the two menu options will appear, depending on the item you are selecting. If you make all of the features under **SNA Application Support** unavailable to Setup, the basic SNA Service (SNABASE.EXE) will still be installed. If you make the parent item, SNA Service unavailable, all services under SNA Service will be unavailable to Setup.

The choices for Setup include:

- Will be installed on local hard disk
- Entire feature will be installed on local hard disk
- Entire feature will be unavailable

Note You will see a red "X" when a feature is marked unavailable.

To make a feature unavailable

1. Click the Host Integration Server 2004 feature that you want to make unavailable.
2. Select the **Install** option.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Services Account Screen

Setup installs a number of services that must be able to log on to the Windows 2000 domain. This requires Setup to create a domain user account and to assign the account the privileges that the services require to operate properly.

You must provide a domain and user name (domain/user) along with the password for the account. If the account does not exist, Setup will create it.

Services Account Configuration screen

1. Type the domain and user name (domain/user).
2. Type and confirm the password.
3. Click **Next**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Begin Installation Screen

All required information for the installation process to start has been entered.

Setup will copy all required files and make all configurations to your system.

> **Note** If you need to make any changes to information you have entered, click **Back** and make the appropriate changes.

To start the installation and configuration process

1. Click **Next** to start the Setup process.
2. 3Setup will now copy all required files to your hard disk.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Finish Installation Screen

To finish the installation and configuration process

1. If you installed components that require SNA support, the Configuration Wizard will start when you click **Finish**.
2. After Setup is completed, click **Finish** to complete the installation process.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuration Wizard Welcome Screen

The Configuration Wizard screens require several pieces of information to properly install the server.

After the Configuration Wizard starts, read the **Welcome** screen, and then click **Next**.

Database Configurations Page

Use the **Database Configurations** page to specify the SQL Server installation where the Single Sign-On (SSO), DB2, and Transaction Integrator (TI) configuration databases reside. In the case of TI, this will also be the location where the .tim files are stored.

To select or change the server or database

1. Under **Name**, select the name of the database, and then click **Edit**.
2. On the **Database Properties** page, select the server and database, and then click **OK**.

Use this	To do this
Server	Select the SQL Server installation that contains the database.
Database	Select the database to be used to store the configuration settings.

3. Click **Next** to apply these settings.

   Security To prevent an attacker from spoofing their identity or tampering with the data in the HIP database:

   1. In **SQL Server**, select a local SQL Server

   2. Under **Connect using:**, select **Windows integrated security**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Windows Service Configurations Screen

Review your Windows Services in the grid. To make a change, select a Windows Service and then click **Edit**.

Click **Next** to apply these settings.

Click **Back** to make further changes.

Click **Cancel** to close the wizard without implementing changes.

Security To prevent an attacker from spoofing their identity or tampering with the data in the HIP database:

1. Select **Host Integration Server Service Account**, and then click **Edit**.
2. On the **Host Integration Server Service Account Properties** page, type the user name and password of a valid Windows privileged account, and then click **OK**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Select Server Grouping Screen

The Server Configuration screen requires several pieces of information to properly install the server.

If you are unsure of this information, contact your system administrator.

Subdomain

A single Windows 2000 domain can contain one or more SNA subdomains. All the computers in an SNA subdomain must belong to the same Windows 2000 Server domain.

Setup requires you to provide the name of the SNA subdomain in which the server will operate.

> **Note** If you select the Backup Server Role, you will be required to type the Primary Server name when selecting the subdomain.

To input the subdomain name

1. Enter the SNA subdomain name.
2. Enter the **Primary Server** name if this is a Backup server.

Server Role

After choosing the features to install, you must specify the appropriate role for the server in the SNA subdomain: primary or backup.

A subdomain must have only one, primary server. Multiple backup servers are permitted.

To select server role

1. Click **Primary Server** if the system is to be a primary server.

   -or-

2. Click **Backup Server** if the system is to be a backup server, and enter the primary server. If you click Backup Server and leave the primary server box blank, the Configuration Wizard will attempt to locate the primary server in the subdomain. If the primary server is found it will then appear in this box. If not, the box will be left blank and you can enter the name manually.

Active Directory Support

Active Directory (AD) is the directory service for Windows 2000 Server. It stores information about objects on the network and makes this information easy for administrators and users to find and use. AD directory service uses a structured data store as the basis for a logical, hierarchical organization of directory information.

Security is integrated with Active Directory through logon authentication and access control to objects in the directory. With a single network logon, administrators can manage directory data and organization throughout their network, and authorized network users can access resources anywhere on the network. Policy-based administration eases the management of even the most complex network.

If Active Directory is detected, you will be able to select the **Support Active Directory Clients** check box. If Active Directory is not detected, the option will be dimmed.

If you select the Support Active Directory Clients, you will be required to type the relative path to the Organizational Unit.

Active Directory Support

1. Select the **Support Active Directory Clients** check box.
2. Type the **Active directory domain name**.
3. Type the name of the **Organizational unit**.
4. Click **Next** after you have completed the Server Grouping information.

Resource Location Mechanism Screen

To locate server computers, select one of the following:

Click **Locate servers by subdomain** and then enter a valid subdomain in the box.

Click **Locate servers by server name**, enter a server name, and then click **Add** or **Remove** to manage the list of server names.

Click **Locate servers using Active Directory organizational unit**, and then click **Add** or **Remove** to manage the list of organizational units.

Click Advanced for additional locating options.

Click **Next** to apply these settings.

Click **Back** to make further changes.

Click **Cancel** to close the wizard without implementing changes.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Network Protocols Screen

The **Protocols** dialog box allows you to choose the protocols that Host Integration Server 2004 will support.

You can select one or more of the protocols detected on the server.

Protocols not detected on the server will be dimmed and cannot be selected.

Choose the correct Client/Server Protocols information

1. Select the **Client/Server Protocols** information for your installation.
2. Click **Next** after you have completed the **Client/Server Protocols** information.
3. Click **Finish** to complete the **Configuration Wizard**.

TCP/IP

Transmission Control Protocol/Internet Protocol (TCP/IP) is the recommended protocol for most installations.

- Check this option (default if detected) to support Telnet clients or to allow client computer access to the Internet.
- Clear this option and select another supported protocol if you do not want to support the TCP/IP protocol.

Microsoft Networking (Named Pipes)

Microsoft Networking (Named Pipes) is a standard feature in Microsoft Windows 2000. For efficiency reasons, it is recommended that you use this only if no other protocols are installed.

- Check this option to support client computers that will use Microsoft Networking.

Novell NetWare (IPX/SPX)

If the Netware protocol is installed and selected you will be required to type all required Netware information. If Novell Directory Services is selected, you will be required to type the Tree Name and Context Name.

- Check this option to support Novell NetWare clients.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

DB2 Distributed Transaction Service Screen

In the **Resync port** box, enter a valid Windows port.

In the **Partner DB2 resource manager network address** box, enter a valid IP address, and then click **Add**. The name will be added to the **Configured partner DB2 resource managers** box.

In the **Maximum connections** box, enter a number from 1-100.

In the **Worker threads** box, enter a number from 1-16.

Click **Next** to apply these settings.

Click **Back** to make further changes.

Click **Cancel** to close the wizard without implementing changes.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Summary Screen

Expand the view to review your configuration choices.

Click **Save** to capture the configuration XML.

Click **Next** to apply these settings.

Click **Back** to make further changes.

- Click **Cancel** to close the wizard without implementing changes.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Completing the Wizard Screen

All the required information for the Configuration Wizard has been entered.

Setup will complete configuration settings to your system.

To finish the Configuration Wizard

Click **Back** to re-enter any **Configuration Wizard** information, or click **Finish** to complete the **Configuration Wizard** process.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Configuration Options Screen

Some of the features you have installed require SQL Server. Would you like to configure these databases at this time?

Transaction Integrator and DB2 Distrubuted Transactions over IP both require a SQL Server database to run.

Select **Yes** to create and configure these databases within the Configuration Wizard.

Select **No** to perform this step later.

Do you want to create a new SSO System or Join an existing SSO System? Creating a new SSO system will create the credential database and make this computer the master secret server.

Select **Create** from the drop-down list if this is the first SSO server you configure in your SSO system. This will also create and configure the SSO Credential database. You must backup the secret on this secret server after configuration is completed. You can backup the secret using the SSO command line utility, ssoconfig.exe, located at \Program Files\Common Files\Enterprise Single Sign-On\.

You should configure the master secret server as a stand-alone server. You must be an SSO administrator while performing this configuration task.

Select **Join** from the drop-down list for subsequent SSO Servers in the SSO system. These servers are the processing servers and administration servers**.**

Note that if you are installing the Enterprise Single Sign-On feature and you already have Microsoft BizTalk Server 2004 deployed on your machine, you must complete the following three steps before installation:

- Back up the SSODB to a secure location
- Back up the Master Secret Key on the Master Secret Server
- Update the Master Secret Server

  For detailed procedures on these actions, see the Host Integration Server 2004 Readme file on your product CD.

  It is not necessary to update the SSO Servers (non-Master Secret Servers) from your BizTalk Server 2004 installation, or any new SSO Servers installed with Host Integration Server 2004.

Do you want to reuse the existing configuration? If not, do you want to create a new SSO System or Join an existing SSO System. Creating a new SSO system will create the credential database and make this computer the master secret server.

Select **Reuse** if you need to re-use existing data. This can be done on a Master Secret Server or on a Processing SSO Server. If you do this on the master secret server, you must restore the secret that you backed up on this secret server after configuration is completed. You can restore the secret using SSO command line utility, ssoconfig.exe.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Windows Accounts Screen

Windows Accounts

This screen lists the Group accounts used by features in the product.

The HIS Administrators group must be a local group. Members will have rights to perform administrative functions. If this group does not exist, it will be created and the logged on user will be added.

The HIS Runtime group must be a local group. It will contain the service accounts used by the product. This group will be created if it does not exist.

The domain group is created automatically if you specify a domain group during configuration for the SSO Administrators and SSO Affiliate Administrators groups.

Windows Service Configuration

The Host Integration Server Service Account specified will be used for all the services installed by the product. It is recommended that this be a low privilege account with no local administrator rights.

Configuration Options (Client deployment) Screen

The Host Integration Server Client has the following three deployment options. (If you do not have local administrator rights, the wizard will bypass this screen and proceed with a **Just me** configuration.)

Selecting **Just me** configures SNABASE.exe to run as an application (as opposed to a Windows Service), saving configuration changes to the HKEY_CURRENT_USER registry. The settings will only apply to the user who is currently logged on.

Selecting **Everyone** configures SNABASE.exe to run as an application (as opposed to a Windows Service), saving configuration changes to the HKEY_LOCAL_MACHINE registry, under the SOFTWARE key. These settings will apply to all users, overriding any settings in HKEY_USERS.

Selecting **Windows Service** causes SNABASE.exe to run as a Windows Service (as opposed to an application), saving configuration changes to the HKEY_LOCAL_MACHINE registry, under the SYSTEM key. These settings will apply to all users.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Link Service Adapter

Link service allows Host Integration Server 2004 to communicate with host, peer, or downstream computers over token ring and Ethernet Local Area Networks.

Configure a DLC 802.2 Link Service

A DLC 802.2 link service allows Host Integration Server 2004 to communicate with host, peer, or downstream computers over token ring and Ethernet Local Area Networks.

Title

The default title is DLC 802.2 Link Service #1. To change the default title, delete the title and enter a new title for this link service. You can use up to 40 characters for the title.

Adapter

Select the adapter card you are using for this service.

Local Service Access Point (SAP)

Enter the local SAP. This number must be a multiple of 4, ranging from 4 through 252. In most cases, the SAP for Host Integration Server 2004 is 4.

Select **Use Fixed SAP** to use a fixed SAP address.

Select **Allow Link Service to be Distributed** to allow this service to be distributed.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Demo SDLC Link Service

Configure a demonstration SDLC link service. This service uses a script file to simulate an SDLC link service.

Title

The default title is Demo SDLC Link Service #1. To change the default title, delete the title and enter a new title for this link service. You can use up to 40 characters for the title.

Script File

Select a demonstration script file from the drop-down list.

Select Allow Link Service to be Distributed to allow this service to be distributed.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Distributed Link Service Properties

Service Title

The default title is Distributed Link Service #1. To change the default title, delete the title and enter a new title for this link service. You can use up to 40 characters for the title.

Link Type

Select the type of link service represented by this Distributed Link Service from the drop-down list.

Primary Remote Link Services:

Enter the name of the remote link service used by this service.

Alternate Remote Link Services

Enter the name of an alternate remote link service used by this service.

Select **Compression used** if data compression is to be used on this link service.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

APPC Mode Properties

The following tabs are available on the APPC Mode Properties Sheet:

- General
- Limits
- Characteristics
- Partners
- Compression

APPC Mode Properties: General

Mode Name

Enter a Mode Name.

Comment

Optionally, type a comment of not more than 25 characters.

APPC Mode Properties: Limits

Parallel Session Limit

Specify the maximum number of sessions allowed with this mode. To allow only a single session, specify 1. To allow parallel sessions, specify a value greater than 1. If the local APPC LU to be used with this mode is dependent, specify 1; dependent local APPC LUs cannot have parallel sessions. One of the key mode properties is the **Parallel Session Limit**. This limit determines whether an LU-LU pair can carry on only one interaction at a time (a parallel session limit of 1), or multiple concurrent interactions (a parallel session limit greater than 1). If parallel sessions are to be allowed with an LU-LU pair, the local LU must be independent, and the remote LU in the pair must support parallel sessions.

If the LU-LU pair can carry on multiple parallel sessions, other mode properties, such as minimum contention winner limit, determine to what extent each LU can initiate interactions.

Minimum Contention Winner Limit

Specify the Minimum Contention Winner Limit. The sum of the Minimum Contention Winner Limit and the Partner Min Contention Winner Limit must be less than or equal to the Parallel Session Limit.

Partner Min Contention Winner Limit

Specify the Partner Min Contention Winner Limit. The sum of the Partner Min Contention Winner Limit and the Minimum Contention Winner Limit must be less than or equal to the Parallel Session Limit.

Automatic Activation Limit

Specify the number of contention winner sessions to be activated for the local LU whenever the connection for this mode is started. In a local contention winner session, the local LU can initiate conversations without permission from the partner LU.

This does not apply for single-system APPC (communication between two local LUs on the same system).

APPC Mode Properties: Characteristics

Pacing Send Count

Specify the maximum number of frames for the local LU to send without an SNA pacing response from the partner LU. If you specify 0, the local LU can send an unlimited number of frames without receiving a response; in this case, the partner LU can negotiate and set a limit on the count.

Pacing Receive Count

Specify the maximum number of frames for the local LU to receive from the partner LU before the local LU sends an SNA pacing response. If you specify 0, the local LU can receive an unlimited number of frames without sending a response.

Max Send RU Size

Specify the maximum size for RUs sent by the TP(s) on the local system.

It is not necessary to set a minimum send RU size, which is 256 on Host Integration Server 2004.

Max Receive RU Size

Specify the maximum size for RUs received from the TP(s) on the remote system.

It is not necessary to set a minimum receive RU size, which is 256 on Host Integration Server 2004.

High-Priority Mode

Select to give preference to communication with this mode over communication with a low-priority mode.

APPC Mode Properties: Partners

This tab allows you to **Add** or **Remove** APPC LU partnerships from the Host Integration Server 2004 configuration file. The mode name appears in the title. The list box shows the **Server**, **Local LU Alias**, **Remote LU Alias**, **Connection**, and which LUs are partnered with the APPC mode in the title.

Remove

Click **Remove** to delete APPC LU partnerships from the Host Integration Server 2004 configuration file.

Add

1. Click **Add** to add APPC LU partnerships from the Host Integration Server 2004 configuration file. The **Add Partnerships** dialog box appears.
2. Select a **Server name** from the subdomain by clicking the DOWN arrow in the drop down list.
3. After the server is selected, a list box showing **Local LU**s and a list box showing **Partner LU** and **Connection** are filled. Make selections from each list to establish partnerships.
4. Click **Apply** to add pairs to the **APPC Mode Properties: Partners** page while keeping the **Add Partnerships** dialog active.
5. When you finish selecting partnerships, click **OK** on the **Add Partnerships** dialog to return to the **APPC Mode Properties: Partners** page.
6. Click **OK** on the **APPC Mode Properties: Partners** page to commit the changes to the Host Integration Server 2004 configuration file.

   Note You can select multiple modes for partnerships using the same LUs. Press the SHIFT key and the CTRL key and click to select non-contiguous modes.

   Note The Host Integration Server 2004 configuration file is updated dynamically. There is no need to stop and restart SNA service.

APPC Mode Properties: Compression

Maximum Send Compression

Select the maximum compression desired from the drop down list. The valid values are: **None**, **Run Length Encoding (RLE)**, and **LZ9**. These options offer progressively better compression, but at a progressively higher CPU usage.

Maximum Receive Compression

Select the maximum compression desired from the drop down list. The valid values are: **None**, **Run Length Encoding (RLE)**, and **LZ9**. As with Maximum Send Compression, these options offer progressively better compression, but at a progressively higher CPU usage cost.

Allow LZ and RLE Compression

If LZ9 is used, this option controls whether data is compressed using RLE before being further compressed using LZ9.

Endpoint Only Compression

This option controls whether intermediate nodes may use compression if one of the endpoints does not support or otherwise does not use compression.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

3270 LU Properties: General

LU Number

Enter the LU Number for LUs on 802.2, SDLC, or X.25.

Enter an appropriate LU Number.

LU Name

Type the LU Name.

Connection

The connection for this LU is shown. The connection cannot be changed from this dialog box.

Pool

If the LU has already been assigned to a pool, the pool name appears here.

Comment

Optionally, enter a comment of not more than 25 characters.

Use Compression

Select this option to enable 3270 LU data stream compression. This option must also be set in the host VTAM configuration for the LU.

User Workstation Secured

Select this option to enable a higher level of security. When the option is selected the user can only acquire an LU if:

- the user's User Record is assigned to this LU, and
- the user's workstation has been defined with a Workstation Definition.

3270 Display LU Properties: Associated Printer LU

Display LU

Shows the display LU name if you have already created a display LU; otherwise, this will be filled in when you complete the configuration of this display LU.

Associated Printer LU

Click the DOWN arrow to display the list of available printer LUs on this connection. Choose a printer LU to associate with this display LU. If you have not created any printer LUs on this connection, you must do so before they will appear in the list.

3270 LU Properties: LUA

The following tabs are available on the 3270 LUA Properties Sheet:

- LUA General
- TN3270
- IP Address List

3270 LU Properties: LUA General Tab

LU Number

Enter the LU Number for LUs on 802.2, SDLC, or X.25.

Enter an appropriate LU Number.

LU Name

Type the LU Name.

Connection

The connection for this LU is shown. The connection cannot be changed from this dialog box.

Pool

If the LU has already been assigned to a pool, the pool name appears here.

Comment

Optionally, enter a comment of not more than 25 characters.

Use Compression

Select this option to enable 3270 LU data stream compression. This option must also be set in the host VTAM configuration for the LU.

User Workstation Secured

Select this option to enable a higher level of security. When the option is selected the user can only acquire an LU if:

- the user's User Record is assigned to this LU, and
- the user's workstation has been defined with a Workstation Definition.

High Priority Mode

Select this option to increase the priority for this LU.

> **Note** Two additional property pages appear when the LU is assigned to a TN3270. These are the TN3270 property page and the IP Address List page.

3270 LU Properties: TN3270 Tab

Type

Select from the list the display or printer type.

Generic Display

This is the default pool type. The display LU or pool will be assigned to a client computer that either does not specify a particular LU or Pool, or that requests this LU or Pool by name.

Specific Display

The LU or pool configured as specific will only be assigned to client systems that request this LU or pool, and not to clients making generic requests.

Generic Printer

The printer LU or pool will be assigned to a client computer that either does not specify a particular LU or pool, or that requests this LU or pool by name. When this option is checked, the **terminal name** will default to IBM-3287-1.

Specific Printer

The printer LU or pool configured as specific will only be assigned to client computers that request this LU or pool, and not to client computers making generic requests. When this option is checked, the **terminal name** will default to IBM-3287-1.

Associated Printer

Printer LUs can be marked as associated instead of generic or specific. To associate a printer LU with a terminal LU, select this option and choose the **Associated LU** from the drop-down list box. When this option is checked, the **terminal name** will default to IBM-3287-1.

Sessions

This is the number of TN3270 sessions allowed for the selected LU or pool. The number of TN3270 sessions must not exceed the number of LUs listed under Host Integration Server 2004 Resource Information.

If you reduce the TN3270 Sessions limit to 0 (zero) TN3270 service will not assign the LU or pool.

Associated Printer

When the **Type** option **Associated Printer** is selected, choose an **Associated Printer** from the drop-down list. In this case, the printer LU is partnered with one terminal LU. A client computer accesses that printer LU by sending in an "associate" request and giving the name of the terminal LU with which the printer LU is partnered.

Terminal types

TN3270 service will default to IBM Terminal Model 2. To add a different terminal model to this LU, click the corresponding number (**2**, **3**, **4**, or **5**) to the left of the list of terminal names. After a Terminal Model is selected, Terminal Names are automatically assigned. You can remove selection of individual terminal names that do not apply to your network configuration by clearing the checkbox opposite the name, or you can clear all terminal names by clicking **Clear**.

> **Note** The terminal name strings selected must be compatible with the host logmode entry for the LU. For printer LUs, the **Terminal Name** will default to IBM-3287-1.

Port

Select **Default port** to use the port number configured with the service (on the Service Properties page), or select a port from the list. The list displays all of the defined TN3270 ports along with their Security setting (High, Medium, Low, None, or Unsecured).

> **Note** TN services listen on multiple ports simultaneously. You can set a default number for the TN service and override this number on a per session basis, allowing a single client computer to connect to multiple host computers.

> **Note** TN3270 client systems can only access LUs that are configured as generic terminal LUs. TN3270 client systems can access generic, specific, and associated LUs.

> **Note** Configuration changes are apparent only to users who establish a connection after the configuration changes are saved. Users who were connected at the time the configuration changes were made will not be affected.

3270 LU Properties: IP Address List

You can associate this LUA to a specific IP address or server name.

Add Address

Click to specify the **IP Address** and **Subnet Mask** of the client workstation to which you are granting access.

IP Address

Click an entry in the **IP Address** column to edit the IP address for a client workstation.

Subnet Mask

Click an entry in the **Subnet Mask** column to edit the subnet mask for a client workstation.

Add Name

Click to add a workstation name to the **IP Address** list box. The workstation name identifies that a client workstation whose address resolves to that name can connect to the service.

Remove

Click to remove an entry that is currently highlighted in the **IP Address** list box.

Clear All

Click to remove all entries in the **IP Address** list box. The service will then be configured to allow access from any client workstation.

> **Note** The IP address must be changed from the default value of 0.0.0.0 if you want to assign a specific IP address. If you try to add the default IP address with the default subnet mask value, you will receive a message indicating an Invalid IP Address/Subnet Mask.
>
> The IP address of an incoming connection is compared to each of the available LUs or pools in turn. Each resource has an associated list of IP address patterns and subnet masks. The IP address from the incoming connection is masked (by bit and by the resource's subnet mask), then compared to the resource's IP address pattern masked by the resource's subnet mask. If the result is equal, the connection is allocated to this resource.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

3270 LU Properties: Down Stream

LU Number

Enter the LU Number for LUs on 802.2, SDLC, or X.25.

Enter an appropriate LU Number.

LU Name

Type the LU Name.

Connection

The connection for this LU is shown. The connection cannot be changed from this dialog box.

Pool

If the LU has already been assigned to a pool, the pool name appears here.

Comment

Optionally, enter a comment of not more than 25 characters.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Pool Properties: General

Pool Name

Enter a name for this pool.

Comment

Optionally, enter a comment of not more than 25 characters.

Pool contains Display LUs with Associated Printers

This option is intended for users whose host applications have a direct relationship between display LUs and printer LUs (i.e., this applies to display-type pools only). With this option selected, all display LUs in the pool will be treated as though they have associated printer LUs. Also configure the display and printer LUs with the LU numbers that the host application is expecting.

Pool Properties: Display Model

Display Model

If you select **Display** for the LU Type, you can select a Display Model.

When an LU is assigned to a pool, the display model setting for the pool overwrites the setting of the LU, and the setting displayed in the **3270 LU Properties** dialog box is dimmed.

Some emulators can only emulate certain display models. For more information, see your emulator documentation. If there is a conflict between the Display Model setting for the pool and the Display Model setting for an LU in the pool, a message box appears. You can configure the individual LU setting to change or exclude the LU from the pool.

Model can be overridden

Select this check box to allow the user to override the display model type by using a 3270 terminal emulation program.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

User Properties

User Name

Provided for information only. This field cannot be changed here.

Domain

Provided for information only. This field cannot be changed here.

Comment

Optionally, type a comment of up to 25 characters.

Use Client/Server Encryption

Check this box to enable encryption between the client system and the Host Integration Server 2004.

Allow Access To Dynamically Created Remote APPC LUs

Check this box to let this user or group use dynamically created APPC LUs.

APPC Defaults

Local APPC LU

If this user will be using APPC programs (TPs, 5250 emulators, or APPC applications), you can choose a default local APPC LU to be used when the user starts such programs.

Avoid assigning a default local APPC LU to the group "Everyone". Instead, to make a local APPC LU available to any user, when configuring the local LU, select the check box labeled **Member of Default Outgoing Local APPC LU Pool** on the **Advanced** tab of **Local LU Properties**.

Remote APPC LU

If this user will be using APPC programs (TPs, 5250 emulators, or APPC applications), you can choose a default remote APPC LU to be used when the user starts such programs.

To accept the settings, click **OK**; to exit the dialog box without accepting the settings, click **Cancel**.

When you assign default APPC LUs to user and group accounts with overlapping memberships, some of these assignments override others.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

TN3270 Properties: General

Name

Displays the name of the server running the TN3270 service. This field cannot be edited here.

Comment

Optionally, type a comment of up to 25 characters.

Use Name Resolution

Name Resolution should only be selected if you are running a domain name resolver. A domain name resolver catalogs IP addresses and corresponding network names of connected computers. The domain name resolver allows you to enter the name of a computer rather than the IP address when an IP address is required.

TN3270 Mode only

The TN3270 service also supports TN3270E, an enhancement to TN3270. When a client computer first connects to a computer running TN3270 service it negotiates which functions they both support. TN3270 emulators should be able to negotiate with TN3270 service, if only to state that they do not support TN3270. However, some TN3270 emulators are unable to negotiate properly with TN3270 service, causing the negotiation to fail. For this reason the TN3270 service has an option to default to TN3270 mode and not to use TN3270 features, so that these TN3270 negotiation problems do not occur.

Printer Flow Control

If a TN3270 service adheres strictly to the specification described in RFC 1647, there is no way of implementing flow control between a computer running TN3270 service and a TN3270 client. In practice this causes no problems for display emulators, but it does cause a problem for printer emulators, which can be overloaded with data and have no way of notifying the TN3270 service that they cannot process any more messages. If this option is turned on, the TN3270 service sends all messages to a TN3270 printer client as RESPONSE-REQUIRED, and does not send any messages until it has received a response for the previous message.

Close Listen Socket

By default the TN3270 service always has a socket open to listen for incoming requests. If this option is turned on, the TN3270 service stops listening on this socket after all of its defined LUs are in use. The purpose of this is to work with emulators that can try to connect to a number of computers running TN3270 service and that connect to whichever computer accepts their connection attempt. In this case it is useful if a computer with no LUs available is not listening.

Log Normal Audit Events

If this is set, audit messages are logged. These are messages that log successful client connection and successful client termination.

Use SNA Event Log

If this is selected, all TN3270 service event messages are written to the event log being used by the Host Integration Server 2004 system. If this is not set, all TN3270 service event messages are written to the Windows event log on the local machine.

TN3270 Properties: Port/Security

This property page contains two groups.

The **Defined ports** group displays information pertaining to the currently configured 3270 Server ports.

The **Configure ports** group consists of controls for adding, editing, and deleting port configurations.

Defined ports

Port

Lists all ports and corresponding Security settings. On a new installation, setup automatically defines Port 23 as the Default Port.

Security

Displays the level of encryption/authentication assigned to that port. Values are High (168), Medium (128), Low (40), and Unsecured (TLS/SSL not enabled). Default is **Unsecured**.

Client certificate

Displays status: Required or Not required. Default is **Not Required**.

Comment

Displays a comment.

Port configuration

Port

Enter a valid port number from 1-65535.

Security

Choose a setting from the list: High (168), Medium (128), Low (40), or Unsecured. Default is **Unsecured**.

Comment

This is optional. Maximum length allowed is 25 characters.

Verify client certificate

If selected, the client will have to provide a valid certificate to make the connection. Default is not selected. If Security level is set to Unsecured, this option is unavailable.

Note The client requires a valid Certificate with the following properties:

- Type X509
- Client Authentication
- Associated private key

These certificate settings may match some of those you would not choose to grant access to. It is therefore recommended that you check the list of default Trusted Root Certification Authorities in the TN3270 Service Store, and remove any you do not want to be there.

TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client computer to connect to multiple host computers.

You can also add the TN3270 port by using the SnaCfg tool, with the command and parameters shown below:

```
TN3PORT tn3270Server:PortNumber /ADD
   /COMMENT:"comment"
   /SECURITY:{ None | Low | Medium | High }
   /CLIENTSertVALAUTH:{ Yes | No }
```

The properties of the command are described in the following table:

Property or Method	Description	Validation
/COMMENT:Text	The comment field	0 – 25 characters
/SECURITY:Type	Security level	None, Low, Medium or High
/CLIENTCertVAL:YesNo	Indicates whether the client certificate verification is enabled	No – disabled Yes - enabled

Default Port

On a new installation, setup automatically defines Port 23 as Default Port. There can only be one default port at a time. After a port has been designated Default Port, it cannot be deleted until another Default Port has been selected. The default is **Not Selected**.

Adding Ports and Security

This property page allows increased security through support for Secure Sockets Layer (SSL) and TLS for all network transport-level services.

Although the Microsoft 3270 Client (emulator) does not support SSL or TLS, many third-party software vendors offer 3270 emulators that support this functionality, including Attachmate, IBM, NetManage, and WRQ.

To add a new port

1. On the **TN3270 Properties: Port/Security** page, click **New**.
2. Enter the port number and select a security level (default is Unsecured). You can also add a comment and make this the default TN3270 Server port.
3. For maximum security, check the Client Certificate checkbox.

To edit the properties of an existing port

1. On the **TN3270 Properties: Port/Security** page, highlight the port.
2. Click Edit.
3. When you are finished, click **Save**.

TN3270 Properties: Settings

Idle Timeout

Specify time limits. If the session is inactive for this length of time, then TN3270 service disconnects the client system.

Init Status Delay

Specify time limits. This is the delay between the time when TN3270 service connects to a host session and the time the TN3270 service starts updating the client screen. There are often a large number of startup messages when the TN3270 service first connects to a host session, and this option gives the user the opportunity not to receive them all.

Message Close Delay

Specify time limits. When TN3270 service forces a client computer to disconnect (for example, when the Host Integration Server 2004 session to the host has been lost), it sends the client computer an error message to be displayed on the screen. This value specifies the time between sending the message to the client computer and closing the socket with the client computer (which causes some client computers to clear the screen, and so erase the message).

Refresh Cycle Time

Specify time limits. This is the delay between updates of the status on the display.

Default RU Sizes - Inbound and Outbound

This controls the RU size (SNA message size) used by the TN3270 service for logon messages to and from the host. The minimum value for inbound or outbound RU size is 256 bytes. If the host application sends large logon screens, these values should be increased.

Certificate CN

> The common name of the certificate used if TLS/SSL is enabled.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Connection Properties: SDLC

The following tabs are available on the SDLC Connection Properties sheet:

- General
- Address
- System ID
- SDLC

Connection Properties: General

Name

Enter a Name.

Link Service

Select a link service from the drop down list. If the link service you want is not in the list, click **Cancel**.

Comment

Optionally, enter a comment of not more than 25 characters.

Remote End

Select the type of remote system for this connection:

- Host System
- Peer System
- Downstream
- PU Passthrough

  If this connection will be used for 3270 or LUA LUs, then select Host System.

  If you will be using dependent APPC, which relies on a host system for communications, then select Host System, not Peer System.

Allowed Directions

Select the allowed call direction(s), **Outgoing Calls** and/or **Incoming Calls**.

Selecting **Outgoing Calls** causes Host Integration Server 2004 to initiate the link-level connection to the remote system or host. If a remote system tries to initiate a connection, Host Integration Server 2004 will not accept the connection attempt.

Selecting **Incoming Calls** causes Host Integration Server 2004 to accept connection attempts from remote systems or hosts.

If both are selected, Host Integration Server 2004 will both initiate a connection and accept connection attempts by other systems.

When multiple SDLC connections all use the same link service, and the connections accept incoming calls, the encoding (**NRZ/NRZI**) settings for all the connections must match.

Activation

If **Outgoing Calls** are included in Allowed Directions, select an Activation setting:

On Server Startup. Select this option if you want the connection to be readily available whenever the server is started.

On Demand. Select this option if you want the connection to be started when needed, and stopped when not in use.

By Administrator. Select this option if you want the administrator to control the connection on a case-by-case basis.

Passthrough via Connection

Displays a list of available (unpaired) PU Passthrough Connections. Connections that have already been paired are not available. Choose a connection that will route you to your destination PU. If PU Passthrough is not selected in the Remote End field, this list is unavailable.

Supports Dynamic Remote APPC LU Definition

Automatically configures the APPC Remote LUs as users request them. This feature requires that an APPN End Node or Net Node be available on the connection. This feature is for convenience, and should not be used in situations of restricted access. If Host System or Peer System is not selected in the Remote End field, this option is unavailable.

With dynamic APPC configuration, if a user requests a session with a valid remote LU, the connection will be established even if the remote LU has not been configured in SNA Manager. If a connection is designated to support dynamic APPC configuration, Host Integration Server 2004 will automatically define a remote LU and partner it with a local LU when needed. However, to take advantage of session status and other features of Host Integration Server 2004, it is recommended that administrators configure commonly used remote LUs.

Connection Properties: Address

Dial Data

If this connection uses a switched line and the phone number is not stored in the modem, enter the dial data. With a leased SDLC line, this field is unavailable.

For ways to supply a phone number to the modem, see Phone Number Storage and Modem Types below.

Poll Address

Type a two-digit hexadecimal number. Contact the administrator of the remote system to determine the appropriate value. If the remote system is a host, the local poll address should match the VTAM PU definition for the ADDR= parameter.

If the remote system is a peer, the poll address can be any value except the reserved values 00 and FF. When the connection is used, the link roles will be negotiable; the system that takes on the primary role uses the poll address of the other system, so that the poll addresses match during the session.

> **Note** Do not use 00 or FF. These values are reserved.

Encoding

Select the encoding scheme for your modem to use.

Your modem must use the same encoding scheme as the modem at the remote computer.

One of two encoding methods for modems:

- NRZ — Non-return to zero
- NRZI — Non-return to zero inverted

  For connections to host systems, the encoding scheme must match the NRZI setting in the LINE/GROUP definition in VTAM. Obtain this setting from the host administrator. If VTAM does not specify an NRZI setting, it defaults to NRZI=YES.

  When multiple SDLC connections all use the same link service, and the connections accept incoming calls, the encoding (**NRZ/NRZI**) settings for all the connections must match.

Phone Number Storage and Modem Types

Host Integration Server 2004 can store a phone number and then send the number (in ASCII) to a modem, which dials the number. This requires that the modem be attached to an SDLC adapter with a built-in serial (COM) port (for example, the SDLC adapters from MicroGate).

Several connection parameters must be set to work with your modem: Dial Data the duplex setting, half-duplex or full-duplex, and the encoding scheme.

Changing the Host Integration Server 2004 Dialing Method

To change the Host Integration Server 2004 dialing method for a modem, use the Host Integration Server 2004 Link Service Setup program to modify the link service. Restart SNA Manager and, from the **File** menu, choose **Save Configuration**.

Modem Requirements for Accepting a Phone Number from Host Integration Server 2004

To accept a phone number from Host Integration Server 2004, your modem must be set up so that it will:

- Accept dial commands in ASCII (eight data bits, no parity bit, one stop bit).
- Not dial when the DTR signal is raised.
- Set Clear to Send (CTS) and Data Set Ready (DSR) to **On** when ready to accept dial commands.
- Set DSR to **Off** after accepting a dial command.
- Set DSR to **On** again when (and only when) the dialed connection is made.

- Change to **Synchronous** mode after the dial-up has completed.
- Change back to **Dial-command** mode if Data Terminal Ready (DTR) is dropped and raised again.

Host Integration Server 2004 Actions When Sending a Phone Number

When Host Integration Server 2004 is sending a phone number to a modem, it ignores modem responses and holds the modem interface signals Select Standby and DTR to **Off**.

The dialing attempt initiated by Host Integration Server 2004 is assumed to have failed if one of the following occurs:

- DSR stays on after the dial string has been sent.
- The connection time-out expires before DSR comes on to indicate that the call is connected.

  When Host Integration Server 2004 creates a dial string to send to a modem, it uses the outgoing command string supplied in Setup as a base, and then appends the Dial Data (phone number) configured in SNA Manager, followed by a carriage-return line-feed sequence.

Affiliate Application

If you selected Single Sign-On, choose an Affiliate Application from the list. The Enterprise Single Sign-On (SSO) Affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using SSO. An affiliate application can represent a back-end system such as a mainframe or UNIX computer. It can also represent an application such as SAP, or a subdivision of the system, such as the "Benefits" or "Pay stub" sub-systems.

Connection Properties: System ID

Local Node Name

Network Name

If you are instructed by the administrator of a remote host, peer, or downstream system, and if you are using Format 3 XIDs, type the Network Name of the remote system. Format 3 is the default XID type.

The Network Name works with the Control Point Name to identify a system. If either of these parameters is supplied, the other should also be supplied.

Control Point Name

If you are instructed to by the administrator of a remote host, peer, or downstream system, and if you are using Format 3 XIDs, type the Control Point Name of the remote system. Format 3 is the default XID type.

The Control Point Name works with the Network Name to identify a system. If either of these parameters is supplied, the other should also be supplied.

Local Node ID

If this connection uses a switched SDLC line (standard telephone line) to connect to a host system, type the Local Node ID. Use the same Local Node ID for all connections and link services on a particular server.

If this connection uses a leased SDLC line, you can use the default for the Local Node ID.

> **Note** Do not use 000 or FFF for the first three digits; these values are reserved.

XID Type

Select the XID Type. Most systems use Format 3.

If you want to use independent APPC LUs on this connection, you must select Format 3.

When Host Integration Server 2004 is configured to use Format 0 over a host connection, the host treats it as a PU type 2.0, and so Host Integration Server 2004 exercises only its PU type 2.0 capabilities. When Host Integration Server 2004 establishes a host or peer connection using Format 3 and independent LUs, Host Integration Server 2004 exercises its PU type 2.1 capabilities.

For configuration changes to take effect, restart the server.

Remote Node Name

Network Name (Remote Node)

If you are instructed by the administrator of a remote host, peer, or downstream system, and if you are using Format 3 XIDs, type the Network Name of the remote system. Format 3 is the default XID type.

The Network Name works with the Control Point Name to identify a system. If either of these parameters is supplied, the other should also be supplied.

Control Point Name (Remote Node)

If you are instructed to by the administrator of a remote host, peer, or downstream system, and if you are using Format 3 XIDs, type the Control Point Name of the remote system. Format 3 is the default XID type.

The Control Point Name works with the Network Name to identify a system. If either of these parameters is supplied, the other should also be supplied.

Remote Node ID

If instructed to by the administrator of a remote host, peer, or downstream system, type the Remote Node ID.

> **Note** Do not use 000 or FFF for the first three digits; these values are reserved.

Peer DLC Role

Select the DLC role for this connection. The options are:

- Primary
- Secondary
- Negotiable

Connection Properties: SDLC

Max BTU Length

Specify the Maximum Basic Transmission Unit (BTU) Length.

The range is from 265 through 16393; the default is **265**.

With an IBM SDLC adapter, set the Max BTU Length to 521 or less.

Maximum Basic Transmission Unit length. The maximum number of bytes that can be transmitted in a single data-link information frame. A BTU is sometimes called an I-frame.

For downstream connections, specify a Max BTU Length less than or equal to the maximum value supported by software on the downstream system.

For host connections, specify a Max BTU Length less than or equal to the VTAM PU definition for the MAXDATA= parameter.

Data Rate

Select the Data Rate.

The data rate for transmissions between the Host Integration Server 2004 communications adapter and the modem:

- **Low** gives more reliable transmissions and prevents the transmission errors sometimes caused by poor-quality lines at the high rate. If a fall-back line speed setting is supported by your modem and communications adapter, and you want to enable it, select **Low**.
- **High** gives faster transmissions. If you select **High**, the CCITT line 111 on the V24 interface of your modem is set to on.

  Check your adapter and modem manuals to find out if the data rate can or must be set for your equipment.

Duplex

Select the setting that matches your modem:

- For a half-duplex modem, select **Half**. If none of your adapters were installed with the Constant RTS option set, you can only choose half-duplex.
- For a full-duplex modem, select **Full**. If you want to use the full-duplex setting, one or more of your adapters must have the Constant RTS option set (at installation).

  Most servers will use the default, **Half**.

Idle Timeout (for host or peer connections)

Specify the length of time, in tenths of a second, for the local system to wait for a response to a transmission before trying again. Too small of a timeout can cause connection problems. This parameter affects sessions in which the server has a link role of secondary; therefore, it affects all sessions with a host system and some sessions with a peer system (where the link role is negotiable).

The range is from 1 (one-tenth of a second) through 300 (30 seconds). The default is **300** (30 seconds).

Idle Retry Limit (for host or peer connections)

Specify the number of times for the local system to try to send data to the remote system if there is no response. This parameter affects sessions in which the server has a link role of secondary; therefore, it affects all sessions with a host system and some sessions with a peer system (where the link role is negotiable).

The range is from 1 through 255; the default is **10**.

Poll Rate

If the remote system is a peer or downstream system, specify the **Poll Rate** (in polls per second).

The range is from 1 through 50 polls per second; the default is **5**.

Poll Timeout (for peer or downstream connections)

Specify the length of time, in tenths of a second, for the local system to wait for a response to a poll before trying again. Too small of a timeout can cause connection problems. This parameter affects sessions in which the server has a link role of primary; therefore, it affects all sessions with a downstream system and some sessions with a peer system (where the link role is negotiable).

The range is from 1 (one-tenth of a second) through 300 (30 seconds). The default is **10** (1 second).

Poll Retry Limit (for peer or downstream connections)

Specify the number of times for the local system to poll the remote system if there is no response. This parameter affects sessions in which the server has a link role of primary, therefore, it affects all sessions with a downstream system and some sessions with a peer system (where the link role is negotiable).

The range is from 1 through 255; the default is **10**.

Select Standby

If you want your modem's Standby line to be set to on, select this check box.

Check your adapter and modem manuals to find out if standby can be set for your equipment.

Multidrop Primary

If this is a leased SDLC line to downstream systems, and this server will be the primary station for a multidrop connection, then select this box.

This is a connection through which one primary computer simultaneously communicates with multiple secondary computers. Host Integration Server 2004 supports multidrop connections to peer or downstream systems on leased SDLC lines.

Contact Timeout

Specify the length of time, in tenths of a second, which the SDLC link service waits for an XID or SNRM response before resending the XID or SNRM.

This parameter is ignored for incoming calls.

The range is from 5 (five-tenths of a second) through 300 (30 seconds).

The default for a host connection is 300 (30 seconds). The default for a peer or downstream connection is 10 (1 second).

Contact Retry Limit

Specify the maximum number of times the link service will resend an XID or SNRM before declaring an outage to Host Integration Server 2004.

This parameter is ignored for incoming calls.

The range is from 1 through 20; the default is **10**.

Connection Dialing Timeout

If this connection uses a switched SDLC line (standard telephone line), specify the number of seconds that will be allowed for the user or modem to dial and make a connection to the remote computer. If the dialing will be done manually, be sure to allow enough time for the user to dial, wait for an answer, and make the connection.

The range is from 10 through 500 seconds; the default is **300**.

This parameter is ignored by incoming calls.

To exit the dialog box without accepting the configuration settings, click **Cancel**. To accept the settings, click **OK**.

To put configuration changes into effect, restart the server.

Connection Retry Limits

Supply activation limits for the connection.

Maximum Retries

Select the number of attempts for Host Integration Server 2004 to make when trying to establish the connection. After making this number of attempts, Host Integration Server 2004 makes an entry in the event log and stops trying. The range is from 1 through No Limit; the default is **No Limit**.

Delay After Failure

Select the length of time for Host Integration Server 2004 to wait between attempts to establish the connection. The range is from 5 seconds through 255 seconds; the default is **10** seconds.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Connection Properties: DLC 802.2

The following tabs are available on the DLC 802.2 Connection Properties sheet:

- General
- Address
- System ID
- DLC 802.2

General Tab

The following information must be entered on the **General** tab for the 802.2 connection:

- Connection Name
- Link Service
- Comment (optional)
- Remote End
    - Host System
    - Peer System
    - Downstream
    - PU Passthrough
- Allowed Directions
    - Outgoing Calls
    - Incoming Calls
    - Both Directions
- Activation
    - On Server Startup
    - On Demand
    - By Administrator
- Passthrough via Connection
- Supports Dynamic Remote APPC LU Definition

Address Tab

The following information must be entered on the **Address** tab for the 802.2 connection:

- Remote Network Address
- Remote SAP Address
- Local SAP Address

System Identification Tab

The following information must be entered on the **System** tab for the 802.2 connection:

- Local Node Name
    - Network Name
    - Control Point Name
    - Local Node ID
- XID Type
- Remote Node Name
    - Network Name
    - Control Point Name
    - Remote Node ID
- Peer DLC Role
- Compression Type

DLC 802.2 Tab

The following information must be entered on the **DLC 802.2** tab for the 802.2 connection:

- Max BTU Length
- Receive ACK Threshold (frames)
- Unacknowledged Send Limit (frames)
- Retry Limit
- XID Retries
- 802.2 Timeouts
    - Response (t1)
    - Receive Ack (t2)
    - Inactivity (ti)
- Connection Retry Limits
    - Maximum Retries
    - Delay After Failure

Connection Properties: Address

Remote Network Address

A 12-digit hexadecimal network address. Contact the remote system's administrator or the network administrator for the correct value.

The default is **400000000000**.

The value is determined as follows:

- For connections to a 3174 controller, use the value in the configuration response 900 of the controller's customization program.
- For connections to a 3720, 3725, or 3745 front-end processor, use the value in the MACADDR= parameter in the NCP configuration.
- For connections to an IBM 9370 host, use the value in the VTAM PORT definition for the MACADDR= parameter.
- For connections to another Host Integration Server 2004 system, the network address can be found through the **net config server** command. When this command is typed at the command prompt of the other Host Integration Server 2004 system, the resulting display shows the network address of that system, in the line labeled **Server is Active On**.

Remote Service Access Point (SAP) Address

A two-digit hexadecimal number that is a multiple of 04, between 04 and EC. See your token ring or Ethernet manual for more information.

The default is **04**.

You can also contact the remote system's administrator for information about the following:

- For connections to a 3174 controller, use the value in the configuration response 940 of the controller's customization program.
- For connections to an IBM 9370 host, use the value in the VTAM PU definition for the SAPADDR= parameter.

Local Service Access Point (SAP) Address

A two-digit hexadecimal number that is a multiple of 04, between 04 and EC. See your token ring or Ethernet manual for more information.

The Default is **04**.

You can also contact the remote system's administrator for information about the following:

- For connections to a 3174 controller, use the value in the configuration response 940 of the controller's customization program.
- For connections to an IBM 9370 host, use the value in the VTAM PU definition for the SAPADDR= parameter.

Affiliate Application

If you selected Single Sign-On, choose an Affiliate Application from the list. The Enterprise Single Sign-On (SSO) Affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using SSO. An affiliate application can represent a back-end system such as a mainframe or UNIX computer. It can also represent an application such as SAP, or a subdivision of the system, such as the "Benefits" or "Pay stub" sub-systems.

Connection Properties: DLC 802.2

Max BTU Length

Specify the Maximum Basic Transmission Unit (BTU) Length.

The range is from 265 through 16393; the default is **265**.

With an IBM SDLC adapter, set the Max BTU Length to 521 or less.

This is the maximum number of bytes that can be transmitted in a single data-link information frame. A BTU is sometimes called an I-frame.

For downstream connections, specify a Max BTU Length less than or equal to the maximum value supported by software on the downstream system.

For host connections, specify a Max BTU Length less than or equal to the VTAM PU definition for the MAXDATA= parameter.

Receive ACK Threshold (frames)

Specify the maximum number of frames that the local system can receive from the remote system before sending a response. Set this to a value less than the **Unacknowledged Send Limit**, so that the local system acknowledges received transmissions more frequently than it expects responses to sent transmissions.

Unacknowledged Send Limit (frames)

Specify the maximum number of frames that the local system can send without receiving a response from the remote system. This parameter is sometimes called the Send Window Size.

Retry Limit

Specify the number of times that the local system should retransmit a frame if no response is received from the remote system.

The range is from 0 through 255; the default is **10**. A value of 0 means the system uses its internal default retry limit.

XID Retries

Specify the number of times that the local system should retransmit an XID (an identifying message) if no response is received from the remote system.

The range is from 0 through 30; the default is **3**.

Response (t1) Timeout

Select a value for the Response (t1) Timeout.

The amount of time that the local system should wait for the remote system to respond to a transmission before the local system tries again.

The values used for Default for the Response Timeout are 400 milliseconds for a local ring and 2 seconds for a remote ring.

If you do not select Default, but instead select a specific value, the timer always waits the selected amount of time, regardless of whether the remote system is on a local or remote ring.

Select a value greater than the total amount of time needed for the relaying of frames between the local system, the remote system, and the network.

Select **Default** to allow for two timeout values — one for a remote system on a local ring, one for a remote system on a remote ring. If you do not select **Default**, but instead select a specific value, the timer always waits the selected amount of time, regardless of whether the remote system is on a local or remote ring.

Receive ACK (t2) Timeout

Select a value for the Receive ACK (t2) Timeout.

The maximum amount of time that should be allowed before the local system sends an acknowledgment of a received transmission. An acknowledgment is sent at the end of the timeout, if some other process has not already triggered it.

Select a value less than the Response Timeout, so that the local system takes less time to acknowledge received transmissions than it takes to seek responses to sent transmissions.

Select **Default** to allow for two timeout values — one for a remote system on a local ring, one for a remote system on a remote ring. If you do not select **Default**, but instead select a specific value, the timer always waits the selected amount of time, regardless of whether the remote system is on a local or remote ring.

The values used for default for the Receive ACK Timeout are 80 milliseconds for a local ring and 800 milliseconds for a remote ring.

Inactivity (ti)

Select a value for the Inactivity (ti) Timeout.

The amount of time that the link can be inactive before the local system treats it as nonfunctioning and shuts it down.

Select **Default** to allow for two timeout values — one for a remote system on a local ring, one for a remote system on a remote ring. If you do not select **Default**, but instead select a specific value, the timer always waits the selected amount of time, regardless of whether the remote system is on a local or remote ring.

The values used for default for the Inactivity Timeout are 5 seconds for a local ring and 25 seconds for a remote ring.

Connection Retry Limits

Supply activation limits for the connection.

Maximum Retries

Select the number of attempts for Host Integration Server 2004 to make when trying to establish the connection. After making this number of attempts, Host Integration Server 2004 makes an entry in the event log and stops trying. The range is from 1 through No Limit; the default is **No Limit**.

Delay After Failure

Select the length of time for Host Integration Server 2004 to wait between attempts to establish the connection. The range is from 5 seconds through 255 seconds; the default is **10** seconds.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Connection Properties: X.25

The following tabs are available on the X.25 Connection Properties sheet:

- General
- Address
- System ID
- X.25

Connection Properties: Address

Remote X.25 Address

Select the type of virtual circuit used by the connection.

Switched Virtual Circuit Address

Enter the Switched Virtual Circuit Address of the host.

Permanent Virtual Circuit Alias

Enter the Permanent Virtual Circuit Alias of the host. This is a number that identifies the channel: 1 for the first channel, 2 for the second, and so on. The default is **1**.

Affiliate Application

If you selected Single Sign-On, choose an Affiliate Application from the list. The Enterprise Single Sign-On (SSO) Affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using SSO. An affiliate application can represent a back-end system such as a mainframe or UNIX computer. It can also represent an application such as SAP, or a subdivision of the system, such as the "Benefits" or "Pay stub" sub-systems.

Connection Properties: X.25

Max BTU Length

Specify the Maximum Basic Transmission Unit (BTU) Length.

The range is from 265 through 16393; the default is **265**.

With an IBM SDLC adapter, set the Max BTU Length to 521 or less.

This is the maximum number of bytes that can be transmitted in a single data-link information frame. A BTU is sometimes called an I-frame.

For downstream connections, specify a Max BTU Length less than or equal to the maximum value supported by software on the downstream system.

For host connections, specify a Max BTU Length less than or equal to the VTAM PU definition for the MAXDATA= parameter.

Facility Data

For an SVC channel, specify the codes for any Facility Data required by your network provider or by the administrator of the remote system. You can specify as many as 126 Hexadecimal characters (63 Hexadecimal bytes).

User Data

For an SVC channel, specify the codes for any User Data required by your network provider. Type an even number of hexadecimal characters of 32 characters or fewer.

Packet Size

For a PVC channel, select the maximum number of data bytes (not header bytes) to be sent in a frame. Obtain this value from your network provider.

Window Size

For a PVC channel, select the maximum number of frames that the local system can send without receiving a response from the remote system. Obtain this value from the administrator of the remote host or peer system.

Connection Retry Limits

Supply activation limits for the connection:

Maximum Retries

Select the number of attempts for Host Integration Server 2004 to make when trying to establish the connection. After making this number of attempts, Host Integration Server 2004 makes an entry in the event log and stops trying. The range is from 1 through No Limit; the default is **No Limit**.

Delay After Failure

Select the length of time for Host Integration Server 2004 to wait between attempts to establish the connection. The range is from 5 seconds through 255 seconds; the default is **10** seconds.

Host Integration Server 2004, VTAM, and NCP Parameters for X.25 Connections

Connection Properties: Channel

The following tabs are available on the Channel Connection Properties sheet:

- General
- Address
- System ID
- Channel

Connection Properties: Address

Channel Address

Type a two-digit hexadecimal number identifying the channel. The range is from 00 through FF; the default is **FF**.

Control Unit Image Number

Type a value for the control unit image number. The range is 0 through F; the default is **0**.

Affiliate Application

If you selected Single Sign-On, choose an Affiliate Application from the list. The Enterprise Single Sign-On (SSO) Affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using SSO. An affiliate application can represent a back-end system such as a mainframe or UNIX computer. It can also represent an application such as SAP, or a subdivision of the system, such as the "Benefits" or "Pay stub" sub-systems.

Connection Properties: Channel

Max BTU Length

Specify the Maximum Basic Transmission Unit (BTU) Length.

The range is from 265 through 16393; the default is **265**.

With an IBM SDLC adapter, set the Max BTU Length to 521 or less.

This is the maximum number of bytes that can be transmitted in a single data-link information frame. A BTU is sometimes called an I-frame.

For downstream connections, specify a Max BTU Length less than or equal to the maximum value supported by software on the downstream system.

For host connections, specify a Max BTU Length less than or equal to the VTAM PU definition for the MAXDATA= parameter.

Connection Retry Limits

Supply activation limits for the connection.

Maximum Retries

Select the number of attempts for Host Integration Server 2004 to make when trying to establish the connection. After making this number of attempts, Host Integration Server 2004 makes an entry in the event log and stops trying. The range is from 1 through No Limit; the default is **No Limit**.

Delay After Failure

Select the length of time for Host Integration Server 2004 to wait between attempts to establish the connection. The range is from 5 seconds through 255 seconds; the default is **10** seconds.

Local LU Properties: General

Local APPC LUs can be independent or dependent.

LU Alias

Enter the LU Alias.

Network Name

Type the Network Name. Obtain the correct name from the host or peer administrator if you will be connecting to a host system with VTAM,

The Network Name for an APPC LU that communicates with a host should match the NETID parameter in the VTAM Start command for the VTAM system.

If this server communicates with several different hosts over several connections, use the name of the subarea of the host with which the LU will communicate.

For independent LUs, the Network Name is required. For dependent LUs, the Network Name is recommended but not required, since it is used only by local software, such as the Windows event log software.

LU Name

Enter the LU Name. For independent APPC, the LU Name identifies the LU to other components on the SNA network, and therefore is required. For dependent APPC, the LU Name identifies the LU to local software, such as the Windows event log software, and is recommended but not required.

The LU Name and LU Alias for an APPC LU can be the same.

Comment

Optionally, enter a comment of no more than 25 characters.

Local LU Properties: Advanced

Member of Default Outgoing Local APPC LU Pool

If you want this LU to be available for use by a 5250 user or invoking TP not specifying a local LU, select this check box.

When a request comes from an invoking TP, and the request does not specify a local LU for the invoking TP to use, Host Integration Server 2004 first checks the user record of the user who started the TP, and tries to use the default local APPC LU assigned to that user or group. If this does not succeed, Host Integration Server 2004 tries to find a free LU in the pool of Default Outgoing Local APPC LUs. If this in turn does not succeed, the request is rejected.

Local LUs only support the number of sessions configured for the mode being used. The default for QPCSUPP is 64 sessions. If you need more than that number of sessions, then you need to configure multiple local LUs or increase the session limits in the mode definition for each mode used. To simplify user configuration, you can make all of these local APPC LUs part of the default pool by checking the **Member of Default Outgoing Local LU Pool.** This allows any user who does not specify a local APPC LU to get an available session from any local APPC LU in the default pool. This also enables load balancing among local APPC LUs. In addition, to ensure proper load balancing, do not specify a **Default Local LU Alias** for users or groups. However, if you want to have certain users or groups default to a certain local APPC LU, then you should specify that local APPC LU as the **Default Local LU Alias** in the user or group properties.

This default pool differs from, and should not be confused with, the 3270, LUA, and downstream LU pools.

Timeout for Starting Invokable TPs

If the **Invokable TP** is started manually by an operator, specify a value greater than 60 seconds to give the operator sufficient time.

Implicit Incoming Remote LU

To specify an Implicit incoming remote LU, choose an existing remote LU name from the list.

LU 6.2 Type

Select **Independent** or **Dependent**.

LU Number

For dependent LUs, enter the LU Number.

For independent LUs, this field is unavailable.

Connection

For **Dependent LU**s, choose the connection from the drop-down list.

For **Independent LU**s, this field is unavailable.

LU 6.2 Resync Service

Computer

Type the **IP Address** or the **Name** of the client computer. The client computer specifies a system that is dedicated in that the LU routes incoming connections to that client computer.

Check the **Enable** box if you have a very specialized transaction program (TP) that requires Resync Service. Resync Service or SyncPoint support is used by some database management systems (DBMS) for commit and rollback procedures. If you enable this service, the Local LU alias must be unique.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Remote LU Properties: General

Connection

From the drop-down list, choose the connection that will be used to access this remote LU.

LU Alias

Enter an LU Alias

Network Name

Enter a Network Name. Obtain the correct name from the host or peer administrator. If you will be connecting to a host system with VTAM, the Network Name for an APPC LU that communicates with a host should match the NETID parameter in the VTAM Start command for the VTAM system.

LU Name

Enter the LU Name.

A name identifying an LU. The name can be from one through eight characters long and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The name cannot be the same as any other LU name or pool name (except for APPC LU names) on the server.

For communication with an AS/400, make the remote LU name the same as the name of the AS/400.

Uninterpreted LU Name

If this LU will be paired with a dependent local APPC LU, type the Uninterpreted LU Name.

Comment

Optionally, enter a comment of not more than 25 characters.

Remote LU Properties: Options

Supports Parallel Sessions

If this LU will be used with an independent local LU, and parallel sessions will be used, select this check box. If this LU will be used with a dependent local APPC LU, do not select this box.

If a remote LU supports parallel sessions, it can only be used with a mode that has a value greater than 1 for the parallel session limit.

Implicit Incoming Mode

To designate a mode as the Implicit Incoming Mode for this LU, select a mode from the list.

If this remote LU will be used as an Implicit Incoming Mode be sure to select a mode from the list.

No Session-Level Security

Select this option to turn off Session-Level Security.

Security Key in Hex

For a security key in hexadecimal, select this option, then type a 16-digit hexadecimal number.

Security Key in Characters

For a security key in characters, select this option, then type an eight-character string. The string can include uppercase and lowercase alphanumeric characters, and the special characters $, @, #, and the period (.).

Enable SyncPoint

If you enable **SyncPoint**, the Local LU alias must be unique.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Server Configuration Properties

Name

Displays the current server name. Click **Change** to change the server name.

Properties

The properties display the current configuration. These properties are display only. To change any of the following configuration items, click **Change**.

Subdomain

The **Subdomain** displays the current SNA subdomain.

Server Role

The server can be either a primary, backup, or member. The current role of the server is displayed.

Network Transports

Network Transports shows the transport currently in use.

Support Active Directory Clients

If selected, this server supports client computers using Active Directory and displays the current Active Directory Domain Name/Organization Unit.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Server Configuration

Subdomain Name

Displays the SNA subdomain that this server is a member of. To change the subdomain name, enter a new subdomain name and click **Save**.

Active Directory Client Support

If selected, this server is part of the Active Directory Organizational Unit (OU) as shown in the **Active Directory OU Name:** field. To change the OU, enter a new OU name and click **Save**.

Role

Select how this server will be configured, either as a **Primary Configuration Server** or a **Backup Configuration Server**.

Network Transports

Select all network transport protocols that this server will use on the network.

Services

The **Services** box shows the status of the **MngAgent** and **SnaBase** services. If these services are running, you must restart them before changes to the subdomain, server role, or network transports will take effect.

Restart

Click **Restart** to restart services required for changes to the subdomain, server role, or network transports to take effect. **Restart** is active only if you change the configuration of another server. If you want to change the configuration of the server on which you are currently working, **Restart** is unavailable. For changes to take effect on your server, close SNA Manager, open **Control Panel**, open **Services**, and then **Stop** and **Start SNA MngAgent** and **SnaBase**.

Save

Click **Save** to save your server configuration changes.

Important

- Changing server configuration parameters can have serious consequences.
- Restarting the server will cause all connections and sessions to be disconnected. Notify all users prior to restarting.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Workstation Properties: General

Workstation ID

The **workstation ID** is usually the workstation name.

Workstation ID Type

Click the type of workstation ID:

Name is the workstation name.

Address is the IP address. An IP Address specifies one server for a network address (for example, IP, IPX, or Vines).

IP Subnet is the IP Subnet address. An IP Subnet address specifies several servers with the same network address. Subnetting enables host administrators to distribute the hostids for a given netid to several subnetworks. Without subnetting, an IP address is interpreted in two parts: netid + hostid (network + node). With subnetting, an IP address is interpreted in three parts: netid + subnetid + hostid (network + subnetwork + node). Subnetting is a mechanism for using some bits in the hostid as a subnetid.

IP Mask

If you select **IP Subnet**, you must specify the **IP Mask** as well. The IP Mask refers to the netid + subnetid. You must know the IP Mask. For example, an IP Mask might be: "255.255.248.0."

Comment

Optionally, enter a comment of no more than 25 characters.

Allow access to both workstation and user resources

Select this option to allow users logged on to this computer to see the LUs assigned both to the workstation and to that user.

Allow access to workstation resources only

Selecting this option provides a higher degree of security by restricting resources available on this computer to the LUs assigned to this workstation. Users will not be able to access LUs assigned to them unless the LU is also assigned to the workstation. This feature will be useful for secure workstations, such as those used to print checks.

Allow access to Dynamically Created Remote APPC LUs

Select this check box to allow users access to remote APPC LU as they are created.

TN5250 Properties

Name

Displays the name of the server running the TN5250 service. This field cannot be edited here.

Comment

Optionally, type a comment of up to 25 characters.

Use Default

Select **Use Default** to use the port number associated with telnet (as set in \\DRIVERS\ETC\SERVICES).

Use

You can override the default value for a given server by selecting **Use** and typing another port number. You can also override this port number for a given session. TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client computer to connect to multiple host computers.

Host Integration Server 2004, VTAM, and NCP Parameters for X.25 Connections

The following table shows how Host Integration Server 2004 parameters for X.25 connections correspond to VTAM or NCP parameters. Asterisks (*) indicate required parameters.

Properties Tab	**SNA Parameter**	**VTAM or NCP Parameter**
System Identification	**Local Node ID**,* first three digits (block number)	**IDBLK=** parameter in the PU definition
System Identification	**Local Node ID**,* last five digits (node number)	**IDNUM=** parameter in the PU definition
System Identification	**Network Name (Remote Node)** Note: Network Name for local and remote nodes is generally the same	**NETID=** parameter in the VTAM Start command for the remote SSCP (VTAM system)
System Identification	**Control Point Name (Remote Node)**	**SSCPNAME=** parameter in the VTAM Start command for the remote SSCP (VTAM system)
Address	**Virtual Circuit Type or Remote X.25 Address**	**DIALNO=** parameter in the PORT definition
X.25	**Max BTU Length**	**MAXDATA=** parameter in the PU definition (set Max BTU Length less than or equal to MAXDATA)

- Required parameter in Host Integration Server 2004.

Domain Properties

The following tabs are available for the SNA Subdomain Properties sheet:

- NetView
- Display Verb
- Server Broadcasts
- Security
- Client Backup Configuration
- Error / Audit Logging
- Response Time Monitor

Domain Properties: NetView

NetView sends alerts back and forth between a host system and the Host Integration Server 2004 and associated client computers.

Send NetView Management Data to this Connection

Select a connection to which NetView data should be sent. This can be any host connection.

Domain Properties: Display Verb

Default Connection for Display

Select a connection for use by Display Verbs. When the Display Verb is used but does not specify a connection, Host Integration Server 2004 uses the connection you specify in **Display Verb Properties**. If you do not specify a default Display connection, Host Integration Server 2004 randomly selects a connection for the verb to use.

Domain Properties: Server Broadcasts

Servers communicate with each other using server broadcasts.

Mean Time between Server Broadcasts

The interval at which server broadcasts are repeated. Broadcasts of state changes (such as the activation of a server) do not wait for this interval; instead, broadcasts are repeated at this interval to ensure reception (since broadcasts by definition are not guaranteed to be received).

Specifying a larger value causes less demand on the network (since broadcasts occur less often). However, a smaller value compensates better for loss of broadcast messages.

The range is from 45 through 65535 seconds; the default is **60** seconds.

Network Transport for server Broadcasts

Choose only the protocols you need, because sending unneeded broadcasts can significantly decrease network efficiency.

Domain Properties: Security

An administrator can adjust the subdomain security settings, including user permissions, configuration file ownership, and subdomain security events to audit.

LU Types

Select the **LU Types** (3270, LUA, or APPC) to which the security settings will apply. If security for an LU type is off, anyone who knows the LU name can use it. If security is on, only users to whom the LU is assigned can use it. The default setting is on for 3270, and off for LUA and APPC.

Configuration File

To view or change user permissions on the configuration file, click **Permissions**.

To view or change audited events, click **Auditing**.

To view or change configuration file ownership, click **Take Ownership**.

Domain Properties: Client Backup Configuration

Disable Sending Client Backup Information

The server sends no information to the client computer.

Backup Domain

The server updates the client computer with the backup SNA subdomain name specified in the box.

Backup Sponsor Servers

The server updates the client computer with all of the SNA Sponsor Server names (shown in the box). The maximum is 15.

Domain Properties: Error / Audit Logging

You can use information from the Windows 2000 event logs as you test a configuration or to diagnose a problem.

Centralized Event Log Server

Select the name of the server on which Windows 2000 event logs for this server installation should be stored.

Route All Popup Messages to:

Select the name of the server to which pop-up error messages should be routed.

Default Audit Log Level

Select a level

- **Detailed problem analysis:** To record all events that can be recorded, select this option.
- **General information messages:** To record general activity but not all events, select this option.
- **Significant system events:** To record only major events, select this option.
- **Audit logging disabled:** To turn off audit logging, select this option.

Domain Properties: Response Time Monitor (RTM)

Response Time Monitor tracks the time it takes a host to respond to 3270 session requests. RTM is supported only by certain emulators. You should configure RTM only if the emulators you are using support RTM.

RTM Data Sent at

Select one or both of the following:

Counter Overflow:

To cause RTM data to be sent to the host when the number of host responses in a given time period overflows the size of the available counter, select this box.

End of Session:

To cause RTM data to be sent to the host at the end of each LU-to-LU session, select this box.

RTM Timers Run Until

Select the point at which RTM will register that a host has responded; this is when RTM stops the timers. (The timers are started when the local system sends data.)

First Data Reaches Screen:

To stop timing when data reaches the local screen, select this option.

Host Unlocks Keyboard:

To stop timing when the host unlocks the local keyboard, select this option.

Host Lets User Send:

To stop timing when the host lets the local computer send more data, select this option.

RTM Thresholds

Specify the cutoff times, in tenths of a second, at which RTM saves its count of host responses, and then restarts the count. For example, you could specify 5, 10, 20, and 50, to save the count of host responses during the intervals from 0.0 to 0.5 seconds, from 0.5 to 1.0 seconds, from 1.0 to 2.0 seconds, and from 2.0 to 5.0 seconds.

AS400 Definition Properties: General

AS/400 Remote LU Alias

Click the drop-down list box arrow and select an **AS/400 Remote LU Alias**, which contains addressing information for the AS/400.

Local LU Alias

Click the drop-down list box arrow and select a **Local LU Alias**. The **Local LU Alias** maps to the LU the client computer will use.

Mode

You must select the **QPCSUPP mode**.

AS/400 User Name

Enter your **AS/400 User Name**, which is required information.

AS/400 Password

Enter your **AS/400 Password**, which is required information.

Confirm Password

Enter your password again to confirm.

Comment

Optionally, enter a comment of not more than 25 characters long.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Active Users

This folder displays the users that are currently actively using this server.

LUA LU Properties: General

After assigning or viewing an LUA LU, in the **LUA LU Properties** box, supply information according to the following list.

LU Number (for LUs on 802.2, SDLC, or X.25)

Type the LU Number.

LU Name

Type the LU Name.

Connection

The connection for this LU is shown. The connection cannot be changed in this dialog box.

Pool

If the LU has already been assigned to a pool, the pool name appears here.

Comment

Optionally, type a comment of 25 characters or fewer.

CPI-C Symbolic Name: General

Name

Type the Symbolic Destination Name.

Comment

Optionally, enter a comment of not more than 25 characters.

Conversation Security

Select a Conversation Security option:

- **None** turns off conversation security.
- **Same** requires the same user ID and password as that of the Remote Partner LU.
- **Program** specifies the user ID and password, select Program, and then click **User ID**.

Mode Name

Select a mode name from the drop-down list.

CPI-C Symbolic Name: Partner Information

Partner TP Name

- **Application TP:** For an Application TP, select this option, and type the Application TP Name.
- **SNA service TP** (in hex)**:** For an SNA service TP select this option, and type the SNA service TP Number.Partner LU Name
- **Alias:** To identify the **Partner LU by** Alias, select this option, and type the alias.
- **Fully Qualified:** To identify the partner LU by a Fully Qualified name, select this option, and type the name.

To accept the settings, click **OK**; to exit the dialog box without accepting the settings, click **Cancel**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

CPI-C Symbolic Name: Security Settings

Specify a User ID and Password

User ID

The **User ID** can contain from 1 through 10 characters.

Password

The **Password** can contain from 1 through 10 characters.

Verify Password

Type the **password** again.

Host Integration Server 2004 Folder

Expand the Servers Folder to show the Microsoft® Host Integration Server 2004s assigned to this SNA Domain.

SNA Service Folder

This folder contains the SNA service installed on this Host Integration Server 2004. Each Host Integration Server 2004 can have a maximum of four SNA services installed and active at one time.

Select **SNA Service**, then right-click to perform various tasks, including:

- save the current configuration
- stop the service
- pause the service
- start the service
- create a new service
- display additional service properties

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Link Services Folder

This folder contains the link services configured on this Host Integration Server 2004.

To create a new link service, select the **Link Services** folder, right-click, point to **New** and then select **Link Service**.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Connections Folder

This folder contains the connections configured on this Host Integration Server 2004.

To create a new connection, select the **Connections** folder, right-click, point to **New** and then select the type of connection you want to make.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Local APPC LUs Folder

This folder contains the Local APPC LUs configured for this server.

Remote APPC LUs Folder

This folder contains the Remote APPC LUs configured for this server.

Microsoft SNA Manager

Host Integration Server 2004 Microsoft Management Console application is also called the SNA Manager.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

AS/400 Definitions

This folder displays the AS/400 definitions that are currently being used on this server.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Active TN5250 Sessions

This folder displays the active TN5250 sessions that are using this server.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

AS/400 Definition Properties

The following tabs are available on the AS/400 Definition Properties:

- General
- Terminal Types
- IP Address List

AS/400 Definition Properties: General

AS/400 Remote LU Alias

Click the drop-down list box arrow and select an **AS/400 Remote LU Alias**, which contains addressing information for the AS/400.

Local LU Alias

Click the drop-down list box arrow and select a **Local LU Alias**. The **Local LU Alias** maps to the LU the client computer will use.

Mode

You must select the **QPCSUPP mode**.

System 36, AS/36

Select if connection to a System 36 or AS/36 computer system.

AS/400 User Name

Enter your **AS/400 User Name**, which is required information.

AS/400 Password

Enter your **AS/400 Password**, which is required information.

Confirm Password

Enter your password again to confirm.

Comment

Optionally, enter a comment of not more than 25 characters long.

AS/400 Definition Properties: Terminal Types

Terminal Names

Terminal names are displayed. You can remove selection of individual terminal names that do not apply to your network configuration by clearing the checkbox opposite the name

Port

Use Default

Select **Use Default** to use the port number configured with the service (on the Service Properties page).

Use

You can override the default value for a given session by selecting **Use** and typing another port number.

> **Note** TN services listen on multiple ports simultaneously. You can set a default number for the TN service and override this number on a per session basis, allowing a single client computer to connect to multiple host computers.

> **Note** Configuration changes are apparent only to users who establish a connection after the configuration changes are saved. Users who were connected at the time the configuration changes were made will not be affected.

AS/400 Definition Properties: IP Address List

You can associate this LUA to a specific IP address or server name.

Add Address

Click to specify the **IP Address** and **Subnet Mask** of the client workstation to which you are granting access.

IP Address

Click an entry in the **IP Address** column to edit the IP address for a client workstation.

Subnet Mask

Click an entry in the **Subnet Mask** column to edit the subnet mask for a client workstation.

Add Name

Click to add a workstation name to the **IP Address** list box. The workstation name identifies that a client workstation whose address resolves to that name can connect to the service.

Remove

Click to remove an entry that is currently highlighted in the **IP Address** list box.

Clear All

Click to remove all entries in the **IP Address** list box. The service will then be configured to allow access from any client workstation.

> **Note** The IP address must be changed from the default value of 0.0.0.0 if you want to assign a specific IP address. If you try to add the default IP address with the default subnet mask value, you will receive a message indicating an Invalid IP Address/Subnet Mask.

> **Note** The IP address of an incoming connection is compared to each of the available LUs or pools in turn. Each resource has an associated list of IP address patterns and subnet masks. The IP address from the incoming connection is masked (by bit and by the resource's subnet mask), then compared to the resource's IP address pattern masked by the resource's subnet mask. If the result is equal, the connection is allocated to this resource.

Messaging Help

Microsoft® MSMQ-MQSeries Bridge is an adaptable system that can be customized. You can set up MSMQ-MQSeries Bridge to operate on almost any Message Queuing (also known as MSMQ) or IBM MQSeries network configuration.

For additional information on the MSMQ-MQSeries Bridge user interface, see the following sections:

- General Tab
- Advanced Tab
- MQI Channels Tab
- General Tab - CN
- General Tab - Message Pipe
- Batch Tab
- Cache Tab
- Retry Tab

General Tab

This tab displays the following information:

Path Name	Network name of the MSMQ-MQSeries Bridge computer.
Service	Name of the Microsoft MSMQ-MQSeries Bridge Service.
Version	Version of the Microsoft MSMQ-MQSeries Bridge Service.
Status	Status of the Microsoft MSMQ-MQSeries Bridge Service (running, paused, or stopped).

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Advanced Tab

By default, MSMQ-MQSeries Bridge allocates one thread for each type of message pipe.

If the MSMQ-MQSeries Bridge is connected to more than one MQSeries Queue Manager (QM), you should allocate a larger number of threads. This improves performance, and if a pipe to one QM fails, it lets the other pipes continue running.

For each type of message pipe, specify:

Max Threads	The maximum number of threads (recommended one per MQSeries QM).
Refresh Queue Cache	The interval (in minutes) at which the message pipes check for Cache Timeout (see Setting Message pipe properties).
Support MSMQ to Bridge Encryption	Check this option to enable the Encryption feature from MSMQ to MSMQ-MQSeries Bridge. For additional information, see "Enabling Encryption".
Replace '.' with '-' in Queue Manager	Enables the MQSeries QM to address an MSMQ computer that has a '-' in its name. This is necessary because MQSeries does not support the '-' character. When this box is checked, MSMQ-MQSeries Bridge replaces '.' from the remote QM name on MQSeries with '-'. You should only enable this option if there is a '-' in the MSMQ computer name.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

MQI Channels Tab

MSMQ-MQSeries Bridge accesses MQSeries through MQI channels defined in both MQSeries and MSMQ-MQSeries Bridge.

> **Note** Each MQI channel connects an MSMQ-MQSeries Bridge to an MQSeries Queue Manager. Ordinarily, you should define one MQI channel for each connected network or foreign site.

First, define the channels in the MSMQ-MQSeries Bridge properties. Later, you can export the definitions to MQSeries (see Exporting MQSeries definitions).

The currently defined channels are listed in the dialog box. Click **Add** for a new MQI channel, **Properties** to edit the settings for an existing channel, or **Remove** to delete a channel.

On the **General** tab of the Channel Properties window, specify the following options:

Channel Name	A legal MQSeries name for the MQI channel. For convenience, you can assign the same name as you assigned to the connected network representing MQSeries in MSMQ, for example IBMNT_CN.
MQSeries Queue Manager	The MQSeries Queue Manager to which the channel connects.
Transport Type	TCP/IP or SNA LU 6.2 communication.

On the **Address** tab of the Channel Properties window, specify the following parameters for TCP/IP:

IP Address, Port	Of the MQSeries listener.

For SNA LU 6.2, specify:

Side Information Record	The CPI-C Symbolic Name defined in Microsoft® Host Integration Server 2004.

For more information on the TCP/IP or SNA LU 6.2 configuration, see the IBM MQSeries documentation.

On the **Security** tab of the Channel Properties window, you may specify:

MCA User	An existing or new MQSeries user name, for example FMQUSER1, under which the server side of the MQI channel runs.

In MQSeries, you should set the permissions of the MCA User, that is, the queues that MSMQ-MQSeries Bridge can address. If you do not specify an MCA User, the server side of the channel runs under the default user name, which is the value of the MQSeries SYSTEM.DEF.SVRCONN parameter.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

General Tab - CN

On the **General** tab of the CN properties window, specify the following options:

MQSeries QM Name	Select from the list of MQSeries Queue Managers to which you have defined MQI channels.

Note If the same MSMQ-MQSeries Bridge is on two connected networks, do not connect them both to the same QM.

Reply to QM Name	The default MSMQ QM to which MQSeries should return report or acknowledgment messages. Ordinarily, you would enter the name of the MSMQ-MQSeries Bridge computer, for example **MSBridge1**.

The MSMQ-MQSeries Bridge Manager exports your entry to MQSeries as a queue manager alias (see Exporting MQSeries definitions). If the Microsoft® Windows® computer name contains an invalid MQSeries character such as a hyphen (-), replace it with another character such as an underscore (_) in the Reply to QM Name box. If you want to receive acknowledgments by nontransactional instead of transactional message pipe, add a % sign to the name (for example, MSBridge1%).

MQSeries uses the alias to identify the transmission queue where it should send acknowledgments. You can redirect the acknowledgments by specifying a different alias. For example, if you want to receive acknowledgments on another computer where MSMQ-MQSeries Bridge is installed, enter the name of the computer and define the name as an alias in MQSeries. For additional information, refer to your IBM MQSeries documentation.

Startup	Enabled or disabled at MSMQ-MQSeries Bridge startup (to change the status afterwards see Starting, Stopping, or Pausing an Object).

General Tab - Message Pipe

The **General** tab of the **Message Pipe Properties** window displays the following:

Status	**Running**, **Paused**, **Pending**, **Recovering**, **Stopped**, or **Error** (This is read-only; to change the status see **Starting, Stopping, or Pausing an Object)**.
Startup	Enabled or disabled at MSMQ-MQSeries Bridge startup.

For the MQSeries—>MSMQ Transactional and Nontransactional message pipes:

Transmission Queue Name	A unique MQSeries transmission queue name for the pipe. The default names are <CN name>.XMITQ for the transactional message pipe and <CN name>.XMITQ.HIGH for the nontransactional message pipe. You may specify different names if you wish.

For example, if the MSMQ-MQSeries Bridge computer name is MSBridge1, the default transmission queue names are MSBridge1.XMITQ and MSBridge1.XMITQ.HIGH.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Batch Tab

To optimize performance, MSMQ-MQSeries Bridge batches messages together. Increasing the batch size may improve performance. For transactional message pipes, this may increase the quantity of retransmitted data after a communication failure.

To change the batch size, specify any combination of:

Max. Number of Messages	The maximum number of messages in a batch.
Max. Accumulated Size	The maximum size (in bytes) of a batch.
Max. Accumulated Time	The maximum time (in milliseconds) during which messages are batched.

Transmission begins as soon as there are messages to be sent. When any of the above limits is reached the message pipe checks that the batch was fully received on the destination side.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Cache Tab

To reduce the overhead of opening and closing a queue for each message, MSMQ-MQSeries Bridge caches queue handles and reuses them when several messages are sent to the same queue. Specify the following option:

Cache Expiry	The time (in minutes) after which MSMQ-MQSeries Bridge closes an unused queue handle.

The system checks for Cache Timeout only at the Cache Refresh Time (see "Setting MSMQ-MQSeries Bridge Properties"). Thus the maximum time that an unused queue handle remains open is the Cache Timeout + Cache Refresh Time.

To refresh the cache immediately (for example to release a queue that is needed by another application), see "Refreshing the cache."

Retry Tab

If a message pipe fails, MSMQ-MQSeries Bridge tries to restart it automatically. For both the Short and Long retry cycles, specify:

Count	Maximum number of retries.
Delay	Interval between retries.

For example, you might specify a Short cycle of 3 retries at 30-second intervals. If the connection is still not successful, the system continues in a Long cycle of, for example, 10 retries at 300-second intervals.

> **Note** If you connect by TCP/IP, set the Delay to at least twice the keep-alive time of the destination MQSeries computer. This enables the MQSeries listener to release the resources of a broken connection before MSMQ-MQSeries Bridge tries to reconnect.

Trace Utility Help

Use the topics in this section to navigate through the Trace Utility User Interface. Click a topic below for more information.

Trace Items Tab

Tracing Global Properties Tab

Trace File Directory Tab

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Trace Items Tab

The **Trace Items** tab has several items that must be selected and configured for the Trace application to operate properly.

List of Trace Items

The following components can be configured for tracing.

- Enterprise SSO
- NVAlert
- NVRuncmd
- SNA applications
- SNA Manager Client
- SNA Manager Agent (MngAgent)
- SnaBase
- Installed link services
- SNANetMn
- SNAPrint
- SNAServer
- SNA Management
- DB2 Network Library
- SNADDM
- TN3270
- TN5250

Trace Items - Properties

Properties displays the **Trace Properties Sheet** that contains an **Internal Trace**, **Message Trace**, **API Trace** or the **TN3270 Internal Trace** tab depending on the Trace Item that was selected.

From the **Internal Trace**, **Message Trace**, **API Trace** and **TN3270 Internal Trace** tabs, you can either select a single item or click **Set All**.

To set Server trace properties

1. On the **Tools** menu, click **Trace Initiator**.
2. Click a component to trace from the list of Trace items.
3. Click **Properties**.
4. Click the appropriate trace tab.
5. Click the appropriate options for the trace, and then click **Apply**.

Trace Items - Clear All Traces

Clear All Traces will clear all trace settings and stop any running traces. If you only want to clear a specific trace item, double-click the item or select the item and click **Properties**. Then click **Clear All**.

When you select **Clear all Traces**, you will be presented with a dialog box to verify that you want to clear all trace setting.

Trace Items - Purge All Trace Files

Purge All Trace Files will delete all trace files from the Traces folder that is designated in the **Trace File Directory** tab.

When you select **Purge All Trace Files**, you will be presented with a dialog box to verify that you want to delete all trace files. If you purge all trace files, the trace settings are not deleted.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Tracing Global Properties Tab

The **Tracing Global Properties** tab has several items that can be modified to adjust how Trace runs. These items include:

Trace File Flip Length

The default size is 20,000,000 bytes.

You can change the maximum length by highlighting the number and typing a new value.

Tracing Global Properties tab to set the length of the trace file

1. On the **Trace Settings** dialog box, click the **Tracing Global Properties** tab.
2. Enter a value for the **Trace File Flip Length** box, and then click **OK**.

Write Traces on a Background Thread

Check this box to run tracing in the background. If the box is cleared (blank), tracing runs in the foreground.

To reduce performance impacts caused by tracing Microsoft® Host Integration Server 2004 components, traces can be queued and written by a background thread when this box is checked. Otherwise, trace files will be written immediately.

Background Thread Priority

If you select **Write Traces on a Background Thread**, then check only one item to set the level of priority for tracing to run within the Microsoft® Windows® operating system. Highest gives tracing the highest level of priority, which means that tracing takes precedence over other jobs. Idle means that tracing runs when the CPU is idle.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Trace File Directory Tab

The following information details the **Trace File Directory** tab.

The **Trace File Directory** tab allows you to change where the Trace Initiator files will be stored.

Use **Browse** or enter a new location.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Administrator's Reference

The Administrator's Reference section provides technical information about working with Microsoft® Host Integration Server 2004.

To use this reference section effectively, you should be familiar with:

- Host Integration Server 2004
- Microsoft Windows®
- IBM Systems Network Architecture (SNA) concepts

The following topics are included:

- Document Conventions explains the formatting conventions this documentation set uses to distinguish important elements of text.
- Common Acronyms and Abbreviations lists common industry abbreviations and acronyms, along with their meanings.
- Host Integration Server 2004 Support explains how Host Integration Server 2004 works within Systems Network Architecture (SNA) networks.
- Network Management describes the support that Host Integration Server 2004 provides for centralized network management
- Network Protocols and Client/Server Communication describes how clients using different local area network (LAN) protocols can communicate with Host Integration Server 2004 computers.
- Error Messages describes the audit and error messages database and how to access it.
- The Command-Line Interface describes the command-line interface that can be used when you want to view a configuration setting quickly, or when you wnat to store configuration commands.
- Sample Host Definitions presents samples for establishing Host Integration Server 2004 connections to an IBM host system.
- CICS and VTAM Sample Definitions for LU 6.2 presents sample definitions for CICS and VTAM for Host Integration Server 2004 connections to an IBM host system.
- Sense Codes lists sense codes used by Host Integration Server 2004.
- Character Tables provides tables of the ASCII, ANSI, and IBM Extended character sets. It also provides a character translation table that can be used by the custom code page option of Host Print service.

For more information about Systems Network Architecture, see the latest version of the IBM publication, *Systems Network Architecture Technical Overview* (GC30-3073).

For frequently used terms, see the Host Integration Server 2004 Glossary.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Document Conventions

This *Administrator's Reference* uses the following formatting conventions to distinguish important elements of text.

Convention	Purpose
bold	Indicates syntax items that must be typed exactly as shown.
italic	Indicates variables.
UPPERCASE	Represents file names, paths, volumes, array and structure names, values, and conversation states. Also represents return values and key names (such as ALT or CTRL).
[brackets]	Enclose optional items in square brackets.
{braces}	Enclose required items in curly brackets.
| (vertical bar)	Stands for OR and separates items in syntax statements.
... (ellipsis)	Indicates that the preceding syntax item can be repeated. If a punctuation mark precedes the ellipsis, you must include the punctuation when repeating the item.
X'*nnnn*'	Indicates hexadecimal digits.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Common Acronyms and Abbreviations

The following table contains a list of common abbreviations used in this reference. For definitions of these and other terms, see the Host Integration Server 2004 Glossary.

Abbreviation	Description
ACTLU	Activate Logical Unit
ACTPU	Activate Physical Unit
ADO	ActiveX® Data Objects
API	application programming interface
APPC	Advanced Program-to-Program Communications
APPN	Advanced Peer-to-Peer Networking
ASCII	American Standard Code for Information Interchange
BB RQE	Begin Bracket, Exception Response
BTU	basic transmission unit
CD	Change Direction
CEB	Conditional End Bracket
CICS	Customer Information Control System
CCSID	Coded Character Set ID
COM	Component Object Model
CPI-C	Common Programming Interface for Communications
CSV	Common Service Verb
CTS	clear-to-send
DACTLU	Deactivate Logical Unit
DAF	destination address field
DCA	Digital Communications Associates, Inc.
DCOM	Distributed Component Object Model
DDM	Distributed Data Management
DDS	Digital Data System
DFC	data flow control
DLC	data link control
DLL	dynamic-link library
DLS	Distributed Link Service
DM	disconnect mode
DMA	Direct Memory Access
DMOD	Dynamic Module
DRDA	Distributed Relational Database Architecture
DSC	data stream compatible
DSR	Data Set Ready
DTR	Data Terminal Ready
EB	End Bracket
EBCDIC	Extended Binary Coded Decimal Interchange Code
EN	End Node
ESCON	Enterprise System Connection
FDDI	Fiber Distributed Data Interface
FEP	front-end processor
FM	function management
FRMR	frame reject
FTP	File Transfer Protocol
IMS	Information Management System
KB	Kilobyte
LAN	local area network
LCS	link connection subsystem
LL	record length field

LLC	Logical Link Control
LU	logical unit
LUA	Logical Unit for Applications (programming interface)
MAC	media access control
MB	Megabyte
MMC	Microsoft Management Console
MVS	Multiple Virtual Storage
NAU	Network Addressable Unit
NCP	Network Control Panel
NMVT	network management vector transport
NN	Network Node
N(r)	number returned
NRM	Normal Response Mode
NRZ	non-return to zero
NRZI	non-return to zero inverted
N(s)	number sent
ODBC	Open Database Connectivity
OLE	object linking and embedding
OLE DB	Object Linking and Embedding Database
PCT	Program Control Table
PDSE	Partitioned Data Set Extended
PIP	program initialization parameter
PLU	primary logical unit
PPT	Program Processing Table
PU	physical unit
PVC	permanent virtual circuit
QLLC	Qualified Logical Link Control
RH	request/response header
RIM	ring indicator monitor
RSP	Response
RTM	Response Time Monitor
RU	request/response unit
RUI	Request Unit Interface
SAP	service access point
SDK	software development kit
SDLC	Synchronous Data Link Control
SID	Security ID
SLI	Session Level Interface
SLU	secondary logical unit
SNA	Systems Network Architecture
SNRM	Set Normal Response Mode
SP	Service Pack
SQL	Structured Query Language
SSCP	System Services Control Point
SVC	switched virtual circuit
TCP/IP	Transmission Control Protocol/Internet Protocol
TCT	Terminal Control Table
TH	transmission header
TN	Telnet
TP	transaction program
TS	transmission service
TSO	time sharing option
VSAM	Virtual Storage Access Method
VTAM	Virtual Telecommunications Access Method

WAN	wide area network
XID	Exchange Identification

Host Integration Server 2004 Support

This section explains how Host Integration Server 2004 works within Systems Network Architecture (SNA) networks. The following information is included:

- A summary of the types and number of SNA sessions supported by Host Integration Server 2004.
- A list of the SNA commands supported by Host Integration Server 2004. This section also shows the type of SNA sessions in which the commands flow.
- The transmission service (TS) and function management (FM) profiles supported by Host Integration Server 2004.
- A list and explanation of the five categories of SNA sense codes generated by Host Integration Server 2004. This section also describes logical unit (LU) type 6.2-specific sense data.

For specific information about an application programming interface (API) supported by Host Integration Server 2004, see the programmer's guide for that API:

- APPC Programmer's Guide
- CPI-C Programmer's Guide
- LUA Programmer's Guide

This section contains:

- SNA Session Support
- Command Request Support
- Transmission Service and Function Management Profiles
- Option Set Support
- SNA Sense Codes

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

SNA Session Support

This section lists and explains the types and numbers of SNA sessions supported by Host Integration Server 2004.

This section contains:

- LU Support
- Session Support

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

LU Support

A Host Integration Server 2004 node can support as many as 15,000 sessions.

Logical unit 6.2 (LU 6.2) works in combination with node type 2.1 to provide Advanced Program-to-Program Communications (APPC). An LU 6.2 can be either a primary logical unit (PLU) or a secondary logical unit (SLU). The partner LU can reside in a type 2.1 node, within an upstream type 5 node, or within the Host Integration Server 2004 node itself.

LU types 0, 1, 2, or 3 are always SLUs, and the partner LU in an upstream type 5 node is always the PLU. LU 0 supports session-level cryptography, within certain limits, on the Request Unit Interface (RUI). You implement session-level cryptography through Cryptography Verification (CRV) requests; the RUI applications must perform all necessary processing. For details about the limits of session-level cryptography and about the processing carried out by the RUI application, see the LUA Programmer's Guide. For all interfaces other than RUI, CRV requests are handled with a negative response.

See Also

SNA Session Support

Session Support

Host Integration Server 2004 supports many types of SNA communications sessions:

- A System Services Control Point – physical unit (SSCP-PU)
- A Host Integration Server 2004 physical unit (PU) Services Manager which communicates with the System Services Control Point (SSCP) on the host
- An SSCP-LU
- A Host Integration Server 2004 logical unit (LU) which communicates with a host SSCP
- A Primary logical unit-secondary logical unit (PLU-SLU)
- A Host Integration Server 2004 LUs which communicates with host or peer LUs

Host Integration Server 2004 Support

Command Request Support

The next three tables list the SNA command requests supported by Host Integration Server 2004. Note that not all commands are supported for every LU-to-LU session type. For example, Bracket Initiation Stopped (BIS) is only supported for use by an APPC LU.

The following three tables categorize requests in the following order:

1. Session control requests
2. Function management data requests: network services (maintenance) and network services (session)
3. Data flow control requests

The three tables denote the category for each request by the setting of the request/response unit (RU) category bits in the request/response header (RH), and by the function of the request. Host Integration Server 2004 does not support commands that fall in the network control request category.

For more information about command requests, see your IBM documentation.

SNA Request Support for Session Control Requests

Session	Request	Direction
SSCP-PU	ACTPU	SSCP to PU
	DACTPU	SSCP to PU
SSCP-LU	ACTLU	SSCP to SLU
	DACTLU	SLU to SSCP
PLU-SLU	BIND	PLU to SLU
	UNBIND	PLU to/from SLU
	CLEAR	PLU to SLU
	SDT	PLU to SLU

SNA Request Support for Function Management Data Requests

Session	Request	Direction
SSCP-PU	NMVT (1)	SSCP to/from PU
	INIT-SELF (2)	SLU to SSCP
	TERM-SELF (2)	SLU to SSCP
	NOTIFY (2)	SLU to SSCP
	NSPE (2)	SSCP to SLU

1. Network services, maintenance services

2. Network services, session services

SNA Request Support for Data Flow Control Requests

Session	Request	Direction
PLU-SLU	BID	PLU to/from SLU
	BIS	PLU to/from SLU
	CANCEL	PLU to/from SLU
	CHASE	PLU to SLU
	LUSTAT	PLU to/from SLU
	RTR	PLU to/from SLU
	SHUTC	PLU from SLU
	SHUTD	PLU to SLU
	SIGNAL	PLU to/from SLU

Host Integration Server 2004 Support

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Transmission Service and Function Management Profiles

Host Integration Server 2004 enforces the rules that govern active sessions between communicating partners on an SNA network.

The Host Integration Server 2004 computer can select some of these session protocols—such as request/response control modes, bracket usage, and pacing—when you activate a session. The term "profiles" refers to specific combinations of these selectable protocol options.

Transmission service (TS) profiles refer to transmission control options, while function management (FM) profiles refer to data flow control and function management data options.

When activated, TS and FM profiles of a session are specified by using parameters in the appropriate session activation request and response such as ACTPU, ACTLU, BIND.

The following table specifies the TS and FM profiles supported by each of the Host Integration Server 2004 session types.

Session type	TS profiles	FM profiles
SSCP-LU session	1	0
SSCP-PU session	1	0
3270 display and printer PLU-SLU session	3	3
LU 6.2 PLU-SLU session	7	19
LUA PLU-SLU session	2, 3, 4	2, 3, 4, 7, 18

This section contains:

- TS Profile 1
- TS Profile 2
- TS Profile 3
- TS Profile 4
- TS Profile 7
- FM Profile 0
- FM Profile 2
- FM Profile 3
- FM Profile 4
- FM Profile 7
- FM Profile 18
- FM Profile 19

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

TS Profile 1

Transmission service (TS) Profile 1 is supported on System Services Control Point physical unit (SSCP-PU) and System Services Control Point secondary logical unit (SSCP-SLU) sessions; the profile does not require a TS usage field. This profile specifies the following session rules:

- Pacing is not supported.
- Identifiers, rather than sequence numbers, are used on the normal flows.
- ACTPU, DACTPU, ACTLU, and DACTLU are supported.
- Maximum outbound request/response (RU) size is 256 bytes.
- Maximum inbound RU size is 512 bytes.

See Also

Transmission Service and Function Management Profiles

TS Profile 2

Transmission service (TS) Profile 2 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU 0. This profile specifies the following session rules:

- Primary logical unit-secondary logical unit (PLU-SLU) and SLU-PLU normal flows are paced.
- Sequence numbers are used on the normal flows whenever the transmission header (TH) format used includes a sequence number field.
- CLEAR is supported.
- SDT, RQR, STSN, and CRV are not supported.

The TS usage subfields defining the options for this profile are the following:

- Pacing window counts
- Maximum request/response (RU) sizes on the normal flows

See Also

Transmission Service and Function Management Profiles

TS Profile 3

Transmission service (TS) Profile 3 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU types 0, 1, 2, or 3. Selection is a BIND option. This profile specifies the following session rules:

- PLU-SLU and SLU-PLU normal flows are paced.
- Sequence numbers are used on the normal flows.
- BIND, UNBIND, CLEAR, and SDT are supported.

The TS usage subfields defining the options for this profile are the following:

- Pacing counts
- Maximum request/response (RU) sizes on the normal flows

See Also

Transmission Service and Function Management Profiles

TS Profile 4

Transmission service (TS) Profile 4 is supported on logical unit-logical unit (LU-LU) sessions using LU types 0 or 1. This profile specifies the following session rules:

- Primary logical unit-secondary logical unit (PLU-SLU) and SLU-PLU normal flows are paced.
- Sequence numbers are used on the normal flows whenever the transmission header (TH) format used includes a sequence number field.
- SDT, CLEAR, RQR, and STSN are supported.
- CRV is supported when session-level cryptography is selected via a BIND parameter.

The TS usage subfields defining the options for this profile are the following:

- Pacing window counts
- Maximum request/response (RU) sizes on the normal flows

See Also

Transmission Service and Function Management Profiles

TS Profile 7

Transmission service (TS) Profile 7 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU 6.2. This profile specifies the following session rules:

- PLU-SLU and SLU-PLU normal flows are paced.
- Sequence numbers are used on the normal flows.
- BIND and UNBIND are supported.

The TS Usage subfields defining the options for this profile are the following:

- Pacing counts
- Maximum request/response (RU) sizes on the normal flows

See Also

Transmission Service and Function Management Profiles

FM Profile 0

Function management (FM) Profile 0 is supported on SSCP-PU and SSCP-SLU sessions. This profile specifies the following session rules:

- SSCP, PU, and SLU use immediate request mode and immediate response mode.
- Only single-RU chains are allowed.
- All chains require definite response.
- No compression.
- No data flow control (DFC) RUs.
- No function management (FM) headers.
- No brackets.
- No alternate code.
- Normal flow send/receive mode is half-duplex contention.
- Secondary wins contention.
- SSCP is responsible for recovery.

See Also

Transmission Service and Function Management Profiles

FM Profile 2

Function management (FM) Profile 2 is supported on primary logic unit-secondary logic unit (PLU-SLU) sessions using LU 0. This profile uses the following session rules:

- SLU uses delayed request mode.
- SLU uses immediate response mode.
- Only single-RU chains are allowed.
- SLU requests indicate no-response.
- No FMH-1 SCB compression.
- Length-checked compression allowed.
- No data flow control (DFC) RUs.
- No FM headers.
- SLU is the first speaker if brackets are used.
- Bracket termination rule 2 is used if brackets are used.
- PLU will send an end bracket (EB).
- SLU will not send an EB.
- Normal-flow send/receive mode is full duplex (FDX).
- PLU is responsible for recovery.

The following FM Usage fields define the options for Profile 2:

- Primary request control mode selection
- Primary chain response protocol (no-response cannot be used)
- Brackets usage and reset state
- Alternate code

See Also

Transmission Service and Function Management Profiles

FM Profile 3

Function management (FM) Profile 3 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU types 0, 1, 2, or 3. This profile specifies the following session rules:

- PLU and SLU use immediate response mode.
- PLU and SLU support the following data flow control (DFC) commands (an asterisk [*] indicates commands permitted by the FM profile that are never sent by Host Integration Server 2004):
  - **CANCEL**
  - **SIGNAL**
  - **LUSTAT** (SLU-PLU only)
  - **CHASE***
  - **SHUTD**
  - **SHUTC**
  - **RSHUTD***
  - **BID** and **RTR**

The following FM Usage fields define the options for Profile 3:

- Chaining use (PLU and SLU)
- Request control mode selection (PLU and SLU)
- Chain response protocol (PLU and SLU)
- Compression indicator (PLU and SLU)
- Send EB indicator (PLU and SLU)
- FM header usage
- Bracket usage
- Bracket termination rule
- Alternate Code Set Allowed indicator
- Normal-flow send/receive mode

The next three tables list the FM Profile 3 options that Host Integration Server 2004 supports. Host Integration Server 2004 rejects any BIND option that specifies an option value not listed in these tables.

Supported options for BIND requests from primary LUs

Usage option	Value	Meaning
Chaining use element	0	Can send only single-element chains
	1	Can send single- or multiple-chains
Request control mode	0	Immediate request mode used
Chain response protocol	01	Can request only exception-only responses
	10	Can request only definite responses
	11	Can request definite or exception-only responses
Compression indicator	0	Cannot send compressed data
	1	Can send compressed data (LU 1 only)
Send EB indicator	1	Can send an end bracket

Supported options for BIND requests from secondary LUs

Usage option	Value	Meaning
Chaining use element	0	Can only send single-element chains (not LU 2)
	1	Can send single- or multiple-chains
Request control mode	0	Immediate request mode used
Chain response protocol	01	Can request only exception-only responses
	10	Can request only definite responses
	11	Can request definite or exception-only responses
Compression indicator	0	Cannot send compressed data
Send EB indicator	1	Cannot send end bracket

Supported common protocol values for BIND requests from any LU

Usage option	Value	Meaning
FM header usage	0	Cannot exchange FM headers
	1	Can exchange FM headers
Bracket usage	1	Bracket protocols must be used
Bracket termination rule	1	Bracket termination rule 1 is used
Alternate code set allowed	0	Must use Extended Binary Coded Decimal Interchange Code (EBCDIC)
Normal flow send/receive mode	10	Half-duplex flip-flop

See Also

Transmission Service and Function Management Profiles

FM Profile 4

Function management (FM) Profile 4 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU types 0 or 1. This profile uses the following session rules:

- PLU and SLU use immediate response mode.
- PLU and SLU support the following data flow control (DFC) commands (an asterisk [*] indicates commands permitted by the FM profile that are never sent by Host Integration Server 2004):
  - **CANCEL**
  - **SIGNAL**
  - **LUSTAT**
  - **QEC**
  - **QC**
  - **RELQ**
  - **CHASE***
  - **SHUTD**
  - **SHUTC**
  - **RSHUTD***
  - **BID** and **RTR** (allowed only if brackets are used)
- Length-checked compression allowed

The following FM Usage fields define the options for Profile 4:

- Chaining use (PLU and SLU)
- Request control mode selection (PLU and SLU)
- Chain response protocol (PLU and SLU)
- FMH-1 SCB (String Control Byte) Compression indicator (PLU and SLU)
- Send EB indicator (PLU and SLU)
- FM header usage
- Brackets usage and reset state
- Bracket termination rule
- Alternate Code Set Allowed indicator
- Normal-flow send/receive mode
- Recovery responsibility
- Contention winner/loser
- Half-duplex flip-flop reset states

See Also

Transmission Service and Function Management Profiles

FM Profile 7

Function management (FM) Profile 7 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU 0. This profile uses the following session rules:

- PLU and SLU use immediate response mode.
- PLU and SLU support the following data flow control (DFC) commands (an asterisk [*] indicates commands permitted by the FM profile that are never sent by Host Integration Server 2004):
  - **CANCEL**
  - **SIGNAL**
  - **LUSTAT**
  - **RSHUTD***
- Length-checked compression is allowed on LU 0 only.

The following FM Usage fields define the options for Profile 7:

- Chaining use (PLU and SLU)
- Request control mode selection (PLU and SLU)
- Chain response protocol (PLU and SLU)
- FMH-1 SCB Compression indicator (PLU and SLU)
- Send EB indicator (PLU and SLU)
- FM header usage
- Brackets usage and reset state
- Bracket termination rule
- Alternate Code Set Allowed indicator
- Normal-flow send/receive mode
- Recovery responsibility
- Contention winner/loser
- Half-duplex flip-flop reset states

Transmission Service and Function Management Profiles

FM Profile 18

Function management (FM) Profile 18 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU 0. This profile uses the following session rules:

- PLU and SLU use immediate response mode.
- PLU and SLU support the following data flow control (DFC) commands (an asterisk [*] indicates commands permitted by the FM profile that are never sent by Host Integration Server 2004):
  - **CANCEL**
  - **SIGNAL**
  - **LUSTAT**
  - **BIS** and **SBI** (allowed only if brackets are used)
  - **CHASE***
  - **BID** and **RTR** (allowed only if brackets are used)
- Length-checked compression is allowed.

The following FM Usage fields define the options for Profile 18:

- Chaining use (PLU and SLU)
- Request control mode selection (PLU and SLU)
- Chain response protocol (PLU and SLU)
- FMH-1 SCB Compression indicator (PLU and SLU)
- Send EB indicator (PLU and SLU)
- FM header usage
- Brackets usage and reset state
- Bracket termination rule
- Alternate Code Set Allowed indicator
- Normal-flow send/receive mode
- Recovery responsibility
- Contention winner/loser
- Half-duplex flip-flop reset states

See Also

Transmission Service and Function Management Profiles

FM Profile 19

Function management (FM) Profile 19 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU 6.2. This profile specifies the following session rules:

- PLU and SLU use immediate request mode.
- PLU and SLU use immediate response mode.
- Multiple RU chains are allowed.
- PLU and SLU requests indicate definite or exception response.
- No compression is used.
- Brackets are used.
- FM headers (types 5, 7, and 12 only) are allowed.
- Conditional termination for brackets, specified by conditional end bracket (CEB),is used.
- PLU and SLU may send CEB.
- Normal-flow send/receive mode is half-duplex flip-flop.
- Half-duplex flip-flop reset state is SEND for PLU.
- Symmetric error responsibility.
- Contention winner/loser is negotiated at BIND time.
- PLU and SLU support the following data flow control (DFC) commands:
    - **SIGNAL**
    - **LUSTAT**
    - **BIS**
    - **RTR**
- The following combinations of RQE, RQD, CEB, and CD are allowed on end-chain Russ

RQE	CD	CEB
RQD2	CD	CEB
RQD3	CD	CEB
RQE1	CD	CEB
RQD	CD	CEB

The only option for Profile 19 is contention winner/loser.

Option Set Support

The following table lists the option sets supported by Host Integration Server 2004. The reference numbers are those specified in IBM documentation.

Ref No.	Option Set
101	Flush the send buffer of the LU
102	Get attributes
103	Post on receipt with test for posting (supported by asynchronous APPC verbs)
104	Post on receipt with wait (supported by asynchronous APPC verbs)
105	Prepare to receive
106	Receive immediate
109	Get TP name and instance identifier
110	Get conversation type
201	Queued allocation of a contention winner session
203	Immediate allocation of a session
204	Conversations between programs located at the same LU
205	Queued allocation for when session is free
211	Session-level LU-LU verification
212	User ID verification
213	Program-supplied user ID and password
214	User ID authorization
241	Send program initialization parameter (PIP) data
243	Accounting
244	Long locks
245	Test for request-to-send received
246	Data mapping
251	Extract transaction and conversation identification information
290	Logging of data in a system log
291	Mapped conversation LU services component
505	LU definition verbs (operator only)
601	MIN_CONWINNERS_TARGET parameter
602	RESPONSIBLE(TARGET) parameter
603	DRAIN_TARGET(NO) parameter
605	LU-LU session limit
606	Locally known LU names
607	Uninterpreted LU names
610	Maximum RU size bounds
612	Automatic activation limit for contention winner

Host Integration Server 2004 Support

SNA Sense Codes

If there is a communication problem during an SNA session, Host Integration Server 2004 can generate sense codes that notify the remote system of the type of problem. The sense codes fall into five distinct categories, corresponding to the type of problem that occurred.

Value	Category
X'08'	Request Reject
X'10'	Request Error
X'20'	State Error
X'40'	RH Usage Error
X'80'	Path Error

The following sections list the sense codes by category, and include two additional categories of sense codes:

- Sense codes sent by a 3270 emulator on LUSTAT requests
- Sense codes that can only flow on LU 6.2 sessions

This section contains:

- Request Reject (Category X'08')
- Request Errors (Category X'10')
- State Errors (Category X'20')
- RH Usage Errors (Category X'40')
- Path Errors (Category X'80')
- LUSTAT Sense Codes
- Sense Data Specific to LU 6.2

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Request Reject (Category X'08')

This category indicates that the request was delivered to the intended half session, and was understood and supported, but not executed. The following codes are in this category.

Code	Meaning
0801	Resource not available
0802	Intervention required (LU 1/LU 3 printer soft error)
0805	Session limit exceeded
0809	Mode inconsistency
080A	Permission rejected, NOTIFY will not be sent
080B	Bracket race error
080C	Procedure not supported
0812	Insufficient resources
0814	Bracket bid reject-RTR forthcoming
0815	Function active
081B	Contention race condition
081C	Request not executable (hard error)
0821	Invalid session parameters
0829	Change direction required
082B	Presentation space integrity lost
082D	LU busy (usually local copy print in progress)
082E	Intervention required (local copy print soft error)
082F	Request not executable (local copy print hard error)
0831	LU component disconnected
0843	WCC print command not sent (RQD or RQE, CD, EB)
0845	Permission rejected, NOTIFY will be sent
0863	Referenced character set does not exist
0871	Read partition state error (SLU in retry state)

See Also

SNA Sense Codes

Request Errors (Category X'10')

Sense codes in this category represent an imbalance in half-session capabilities. They indicate that the RU (request/response unit) was delivered to the intended half-session but could not be processed. The following codes are in this category.

Code	Meaning
1003	Function not supported (also used instead of X'0826', which is not supported by Host Integration Server 2004)
1005	Parameter modifying a control function is invalid
1007	Category not supported (SSCP data for host printer)

See Also

SNA Sense Codes

State Errors (Category X'20')

Sense codes in this category indicate a sequence number error, or a request/response header (RH) or request/response unit (RU) that is not allowed in the receiver's current state. This condition prevents delivery of the request to the intended half-session. The following codes are in this category.

Code	Meaning
2001	Sequence number error
2002	Chaining error
2003	Bracket error
2004	Direction error
2005	Data traffic reset
2006	Data traffic quiescent
2007	Data traffic not quiescent

See Also

SNA Sense Codes

RH Usage Errors (Category X'40')

These sense codes indicate that fields in the request/response header (RH) are contrary to SNA rules or previously selected BIND options and prevent the intended half-session from receiving the request.

The checks 400A and 4012 are also performed. These do not permit negative responses because they apply to no-response sessions and responses, respectively.

The following codes are in this category.

Code	Meaning
4006	Exception response not allowed
4007	Definite response not allowed
400F	Incorrect use of format indicator
4011	Incorrect specification of RU category
4014	Incorrect use of DR1, DR2, ER

See Also

SNA Sense Codes

Path Errors (Category X'80')

Sense codes in this category indicate that the request could not be delivered to the required half-session because of path errors. The following codes are in this category.

Code	Meaning
8004	Unrecognized destination field address (DAF)
8005	No session
8006	Invalid format identification (FID): Error detected and logged; negative response not sent
8007	Segmentation error request/response header (RH) not present or too short: negative response sent only for segmentation error
8008	Primary unit (PU) not active: SSCP-PU was not active and request was not ACTPU or DACTPU
8009	Logical unit (LU) not active: DAF specified an LU for which the SSCP-SLU session has not been activated, and request was not ACTLU or DACTLU
800F	Invalid address combination

See Also

SNA Sense Codes

LUSTAT Sense Codes

The following sense codes are sent by a 3270 emulator on LUSTAT requests.

Code	Meaning
0001 B000	Host initialized local copy soft error recovery
081C 0000	Soft error changed to hard error (LU 1/LU 3)
081C B000	Soft error changed to hard error (local copy)
082B 0000	SLU session changed from SSCP to PLU (SYSREQ)

See Also

SNA Sense Codes

Sense Data Specific to LU 6.2

The LU 6.2 sense codes are specified and interpreted by SNA components within Host Integration Server 2004, and, in general, are presented as return codes and as parameters to specific verbs.

The following sense codes are carried on responses flowing on LU 6.2 sessions.

Code	Meaning
0814	Bracket bid reject – RTR forthcoming
0819	RTR not required – receiver of RTR request has nothing to send
0835	Invalid parameter – request contained a fixed or variable field that is invalid. Bytes 2 and 3 contain a 2-byte binary count which indexes the field error (zero origin)
0846	ERP message forthcoming: The received request was rejected for a reason to be specified in a forthcoming FMH-7 request – which itself carries SNA sense data (see the following table for a list of these codes)
088B	BB not accepted – BIS reply requested
2010	BIS protocol error –receiver detected a BIS error, for example, two BIS replies received

The following data is carried on an FMH-7 request, coming after the flow of a negative response X'0846'.

Code	Meaning
1008 600B	Resource failure no retry
1008 6021	Allocation error TPN not recognized
1008 6031	Allocation error PIP not allowed
1008 6032	Allocation error PIP not specified correctly
1008 6034	Allocation error conversation type mismatch
1008 6041	Allocation error sync level not supported by pgm
080F 6051	Allocation error security not valid
084B 6031	Allocation error trans pgm not available retry
084C 0000	Allocation error trans pgm not available no retry
0864 0000	Deallocate abend prog
0864 0001	Deallocate abend svc
0846 0002	Deallocate abend timer
0889 0000	Prog error no trunc or prog error purging
0889 0001	Prog error trunc
0889 0100	Svc error no trunc or svc error purging
0889 1001	Svc error trunc

SNA Sense Codes

Network Management

This section describes the support that Host Integration Server 2004 provides for centralized network management.

This section contains:

- Connections Used for NetView and RTM
- Link Alerts for SDLC and Token Ring
- Link Statistics
- Alerts Used by Applications, NVAlert, and NVRunCmd
- Local Logging of Network Management Data

For information about configuring Host Integration Server 2004 to work with NetView, and information about configuring the NVAlert and NVRunCmd services, see Network Integration User's Guide.

Connections Used for NetView and RTM

Host Integration Server 2004 can make use of NetView, a reporting system that runs on an IBM host (mainframe). NetView sends alerts between the host and the PCs that connect to it. Host Integration Server 2004 can also receive information from Response Time Monitor (RTM), a 3270 and NetView facility that monitors the amount of time it takes for a host to respond during 3270 display sessions.

To send link alerts, link statistics, and application-generated alerts to the NetView program at the host, you must specify the connection on which the alerts will be sent. See the Host Integration Server 2004 online Help for information about specifying the connection.

RTM data and NetView alerts sent to the host by 3270 users are not necessarily sent via the NetView connection. RTM data is sent on the connection for the session to which it refers, while 3270 user alerts are sent on the connection for the currently selected 3270 session.

For information about configuring SNA Management to work with NetView and information about configuring the NVAlert and NVRunCmd services, see Network Integration User's Guide.

Network Management

Link Alerts for SDLC and Token Ring

When a Synchronous Data Link Control (SDLC) or Token Ring connection fails, Host Integration Server 2004 logs diagnostic information, called link alerts, about the connection failure. The alerts are logged in a log file that can be viewed using the Windows Event Log service. To find a Host Integration Server 2004 log, in the Event Log service, on the Log menu, make sure Application is selected. Under the "Source" heading, the application log file will have a name starting with "SNA."

The link alerts are also used to build a network management vector transport (NMVT) alert, which includes probable causes and suggested actions for the alert. If a connection on the server running Host Integration Server 2004 has been designated for NetView, and the connection is active, the NMVT alert will be sent on that connection.

This section includes information that includes an explanation of the general format of link alerts, common to both SDLC and Token Ring, descriptions of individual alerts produced by the SDLC link service, detailed information about the local logging of SDLC alerts, descriptions of individual alerts produced by the Token Ring link service, and details of the local logging of Token Ring alerts.

This section contains:

- Link Alert Format and Common Subvectors
- SDLC Failure Alerts
- SDLC Alert Local Logging
- Token Ring Failure Alerts

For information about the NetView vectors supported by the NVAlert and NVRunCmd services, see Alerts Used by Applications, NVAlert, and NVRunCmd.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Link Alert Format and Common Subvectors

The general format of link alerts is as follows:

```
NMVT HEADER
41 03 8D 00 00 00 00 00     NMVT Header
Major Vector Header
LL LL     Length of Major Vector
00 00     Alert major vector
```

The specific alert is identified by the alert description and alert ID (part of the generic alert subvector). Common subvectors are listed later in this section. SDLC and Token Ring failure alerts are described in the SDLC Failure Alerts and Token Ring Failure Alerts.

Each subvector or subfield begins with a 1-byte length field and a 1-byte key identifying the subvector or subfield. The length field contains the length in bytes of the entire subvector or subfield, including the length and key bytes. Where the length byte is shown as LL (record length field), this indicates that the length is not fixed because different alerts require different data to be included.

The following table lists all the possible subvectors used in the alert, with their subvector keys (identifiers).

Link alert subvectors

Subvector key (identifier)	Subvector
05	Hierarchy/Resource List Subvector
03	Hierarchy Name List Subvector
01	Date/Time Subvector
10	Product Set ID Subvector (this appears twice, as Alert Sender PSID and Indicated Resource PSID).
51	LAN LCS Data Subvector
52	LCS Configuration Data Subvector
8C	Link Station Data Subvector
91	Basic Alert Subvector
92	Generic Alert Subvector
93	Probable Cause Subvector
94	User Causes Subvector
95	Install Causes Subvector
96	Failure Causes Subvector
A1	Detail Qualifier Subvector

The following tables describe the formats of link alert subvectors. Additional tables, in this section describe the individual link alerts.

Hierarchy/resource list subvector

Format and contents	Description
LL 05	Hierarchy/Resource List Subvector
LL 10	Hierarchy/Resource List Subfield
hh	Flags: 80 (1-User) 00 (Server)
LL	Name field length: name length plus this length byte.
hh...hh	Adapter name in EBCDIC, 8 bytes
00	Flags byte: always 0
3F	Resource type: port
Optional second name	Remote host name. For Token Ring, use the local ring name. See the individual alert descriptions found later in this chapter.
LL	Name field length: name length plus this length byte.
hh...hh	Name in EBCDIC, up to 8 bytes

00	Flags byte: always 0
F4 or 2E	Resource type: control point or Token Ring.

Hierarchy/name list subvector

Format and contents	Description
LL 03	Hierarchy Name List subvector
00 or 03	Reserved byte
hh	Number of names in the hierarchy name list.
LL	Length of each name, including this length byte.
hh...hh	Name of resource for each name.
D3 C3 D6 D5	Resource type identifier: LCON (logical link connection not known to SNA)

Date/time subvector alerts

Format and contents	Description
0A 01	Date/Time Subvector
08 10	Local Date/Time subfield
hh	Year – two digits
hh	Month
hh	Date
hh	Hours
hh	Minutes
hh	Seconds (binary)

Product set ID subvector

Format and contents	Description
2A 10	Product Set ID subvector
00	(unused field)
27 11	Product ID subvector
0C	Product classification: non-IBM software
08 04	Software product common level subfield
F0 F2	Version identifier: 02
F0 F0	Release identifier: 00
F0 F0	Modification identifier: 00
13 06	Software product common name subfield
C4 C3 C1 61 D4 E2 40 C3 D6 D4 D4 40 E2 C5 D9 E5 D9	Product name: Microsoft Host Integration Server 2004
09 08	Software product program number subfield
F0 F0 F0 F0 F0 F0 F0	Product program number: zeros

LAN link connection subsystem data subvector*

Format and contents	Description
LL 51	LAN LCS Data Subvector
04 02	Ring Identifier subfield
hh hh	Ring number
08 03	Local Individual MAC Address subfield
hh...hh	Local individual MAC address
08 04	Remote Individual MAC Address subfield
hh...hh	Remote individual MAC address
LL 05	LAN Routing Information subfield
hh...hh	LAN routing information

* Token ring only.

Link connection subsystem configuration data subvector

Format and contents	Description
LL 52	LCS Configuration Data Subvector
04 01	Port Address subfield
hh hh	Port address
03 02	Remote Device Address subfield
hh	Remote device address
03 04	Local Device Address subfield
hh	Local device address
04 06	Link Station Attributes subfield
01 or 02 or 03	Link station role: Primary, Secondary, or Negotiable
03 or 04	Remote node type: Type 4 or Type 2.1
06 07	Link Attributes subfield
01 or 02	Link connection type: nonswitched or switched
01 or 02	Half-duplex or full-duplex
01	Protocol: SDLC
01 or 02	Point-to-point or multipoint

Link station data subvector

Format and contents	Description
LL 8C	Link Station Data Subvector
04 01	N(s) and N(r) counts subfield
hh	N(s) count
hh	N(r) count
03 02	Outstanding frame count subfield
hh	Outstanding frame count
04 03	Last SDLC Control Field Received subfield
hh hh	Last control field received
04 04	Last SDLC Control Field Sent subfield
hh hh	Last control field sent
03 05	Sequence Number Modulus subfield
80	Sequence number modulus
03 06	Link Station State subfield
80 or 40	Link station state: local or remote station sending RNR
04 07	LLC Reply Timer Expiration Count subfield
hh hh	Reply timer expiration count
03 08	Last Received N(r) Count subfield
hh	Last received N(r) (binary)

Basic alert subvector

Format and contents	Description
0E 91	Basic Alert subvector
00	Not-operator initiated
01	Alert type: permanent
0E	General cause code: link-level protocol error
00 80 or 00 34	Specific component code: Token Ring LAN or SDLC data link control
00 00	Alert description code
00 00	User action code
00 00	Detail text reference code
00	Unused field

Generic alert subvector

Format and contents	Description
0B 92	Generic Alert subvector
00 00	Flags: not operator-initiated, not a held alert

01	Alert type: permanent
hh hh	Alert description: See alert descriptions.
hh hh hh hh	Alert ID number (unique to a particular alert)

Probable cause subvector

Format and contents	Description
LL 93	Probable cause subvector
hh hh	Probable cause: See individual alert descriptions. This alert may include more than one entry.

User causes subvector

Format and contents	Description
LL 94	User Causes Subvector
LL 01	User causes subfield
hh hh	User cause: See individual alert descriptions. More than one entry may appear here.
LL 81	Recommended actions subfield
hh hh	Recommended action: See individual alert descriptions. More than one entry may appear here.
03 83	Product set ID index subfield
99	Product Set ID index
LL 82	Detailed data subfield. This subfield may appear more than once.
99	Product Set ID code
hh	Data ID: See individual alert descriptions.
00	Data encoding: hexadecimal
hh...hh	Detailed data: See individual alert descriptions.

Install cause subvector

Format and contents	Description
LL 95	Install Causes Subvector
LL 01	Install causes subfield
hh hh	Install cause: See individual alert descriptions. More than one entry may appear here.
LL 81	Recommended actions subfield
hh hh	Recommended action: See individual alert descriptions. More than one entry may appear here.
03 83	Product set ID index subfield
99	Product Set ID index
LL 82	Detailed data subfield. This subfield may occur more than once.
99	Product Set ID code
Hh	Data ID: See individual alert descriptions.
00	Data encoding: hexadecimal
Hh...hh	Detailed data: See individual alert descriptions.

Failure cause subvector

Format and contents	Description
LL 96	Failure Causes Subvector
LL 01	Failure causes subfield
hh hh	Failure cause: See individual alert descriptions. More than one entry may appear here.
LL 81	Recommended actions subfield
hh hh	Recommended action: See individual alert descriptions. More than one entry may appear here.
03 83	Product set ID index subfield
99	Product Set ID index
LL 82	Detailed data subfield. This subfield may occur more than once.
99	Product Set ID code
hh	Data ID: See individual alert descriptions.
00	Data encoding: hexadecimal
hh...hh	Detailed data: See individual alert descriptions.

Detail qualifier (hexadecimal) subvector

Format and contents	Description
06 A1	Detail Qualifier subvector
hh hh hh hh	Detail Qualifier subfield – four bytes as follows: Token ring: adapter number Alert number Two-byte error code SDLC: link ID Station address, outage

SDLC Failure Alerts

The tables in this section describe the alerts generated by the SDLC link service provided with Host Integration Server 2004. The alerts are listed in numerical order by alert description and within each description in numerical order by alert ID.

Write timeout alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	1000	Equipment malfunction
Alert ID:	61D0 2E7B	
Probable causes:	2031	Line
	3601	Local modem
	2200	Remote node
	3603	Remote modem
Failure causes:	3511	Line
	3601	Local modem
	2200	Remote node
	3603	Remote modem
	F034	CTS failed to rise
Recommended actions:	0403	Run modem tests
	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier
Detail qualifier:	2E	Write timeout retry exceeded

Abnormal modem response alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	1000	Equipment malfunction
Alert ID:	70A1 5CB0	
Probable causes:	3601	Local modem
	3401	Local cable
	3302	Communications adapter
User causes:	3401	Cabling installed incorrectly
Recommended actions:	0301	Check cable and its connections
Failure causes:	3601	Local modem
	3401	Local cable
	3302	Communications adapter
	F035	DSR dropped
Recommended actions:	0403	Run modem tests
	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier
Detail qualifier:	2D	Abnormal response

DSR failure alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	1000	Equipment malfunction
Alert ID:	83BB 6EC8	
Probable causes:	3601	Local modem
	3401	Local cable
	3302	Communications adapter
User causes:	3400	Cable loose
	0205	Local modem power off
Failure causes:	3601	Local modem
	3401	Local cable

	3302	Communications adapter
	F035	DSR dropped
Recommended actions:	0403	Run modem tests
	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier
Detail qualifier:	11	DSR failure

DCD failure alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	1000	Equipment malfunction
Alert ID:	C3BB 504A	
Probable causes:	2031	Line
	3601	Local modem
Failure causes:	3511	Line
	3601	Local modem
	F038	Carrier detect lost
Recommended actions:	0403	Run modem tests
	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier
Detail qualifier:	14	DCD failure

Invalid frame received: i-field not permitted alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	1103 D152	
Probable causes:	2004	SDLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F021	I-field received when not permitted
Recommended actions:	2011	Review hexadecimal display of alert report
	32A0	Report the following detail qualifier: Outage qualifier
Detail qualifier:	87	Invalid frame received

Invalid frame received: invalid/unsupported cmd/rsp alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	15C2 CCE5	
Probable causes:	2004	SDLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F020	Invalid/unsupported command or response received.
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier
Detail qualifier:	87	Invalid frame received

Invalid frame received: invalid n(r) received alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	1C40F78B	
Probable causes:	2004	SDLC communications
	1023	Communications program in remote node

Failure causes:	1023	Communications program in remote node
	F022	Invalid N(R) received
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	87	Invalid frame received

RIM/RD received alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	29BF 0032	
Probable causes:	2104	SDLC communications/remote node
	1023	Communications program in remote node
Failure causes:	2104	SDLC communications/remote node
	3511	Line
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	88	RIM received
	89	RD received

Invalid frame received: max i-field length exceeded alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	5F76 24FD	
Probable causes:	2104	SDLC communications/remote node
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F023	Received I-field exceeded maximum length
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	87	Invalid frame received

FRMR received: no reason given alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	A472 BC48	
Probable causes:	2004	SDLC communications
	1000	Software program
Failure causes:	1000	Software program
	F014	FRMR received: no reason specified
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	86	FRMR received

FRMR received: i-field received when not permitted

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	B3B7 D723	
Probable causes:	2004	SDLC communications
	1000	Software program
Failure causes:	1000	Software program
	F011	FRMR received: I-field sent when not permitted

Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	86	FRMR received

FRMR received: invalid/unsupported command or response alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	B776 CA94	
Probable causes:	2004	SDLC communications
	1000	Software program
Failure causes:	1000	Software program
	F010	FRMR received: invalid/unsupported command or response sent
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	86	FRMR received

FRMR received: max i-field length exceeded alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	BA35 EC4D	
Probable causes:	2004	SDLC communications
	1000	Software program
Failure causes:	1000	Software program
	F013	FRMR received: maximum I-field length exceeded
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	86	FRMR received

FRMR received: invalid n(r) sent alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	BEF4 F1FA	
Probable causes:	2004	SDLC communications
	1000	Software program
Failure causes:	1000	Software program
	F012	FRMR received: invalid N(R) sent
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	86	FRMR received

DISK/SNRM received: snrm received in nrm alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	D635 CA1E	
Probable causes:	2004	SDLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F015	SNRM received while in NRM
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.

Detail qualifier:	15	Connection terminated by host

CTS failure alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	0231 CF0A	
Probable causes:	2031	Line
	3601	Local modem
Failure causes:	3511	Line
	3601	Local modem
	F030	CTS dropped
Recommended actions:	0403	Run modem tests
	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	12	CTS failure

Connection problem: xid (exchange identification) retransmission alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	0AEC C2A6	
Probable causes:	2104	SDLC communications/remote node
	2031	Line
User causes:	0209	Remote device power off
Recommended action:	0200	Check power
Failure causes:	2104	SDLC communications/remote node
	3511	Line
	F018	XID poll count exhausted

Idle timeout alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	0E2D DF11	
Probable causes:	2104	SDLC communications/remote node
	2031	Line
User causes:	0209	Remote device power off
Recommended action:	0200	Check power
Failure causes:	2104	SDLC communications/remote node
	3511	Line
	F019	Inactivity timer expired
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	25	Idle timeout retry exceeded

Poll count exhausted alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	32A3 7F1B	
Probable causes:	2104	SDLC communications/remote node
	2031	Line
User causes:	0209	Remote device power off
Recommended action:	0200	Check power
Failure causes:	2104	SDLC communications/remote node
	3511	Line

	F017	Poll count exhausted
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	81	Disconnect retry limit
	82	Contact retry limit
	83	Poll retry limit
	84	No response retry limit

Remote busy retry alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	66D6 DA74	
Probable causes:	2104	SDLC communications/remote node
User causes:	0209	Remote device power off
Recommended actions:	0200	Check power
Failure causes:	2104	SDLC communications/remote node
	3511	Line
	F00F	RNR received threshold reached
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	85	Remote busy retry limit

DM Received in Information Transfer Alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	BD84 C4C9	
Probable causes:	2004	SDLC communications
Failure causes:	2004	SDLC communications
	F01A	DM received
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	80	DM received

Nonproductive receive timeout alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	C458 E284	
Probable causes:	2104	SDLC communications/remote node
	2031	Line
User causes:	0209	Remote device power off
Recommended action:	0200	Check power
Failure causes:	2104	SDLC communications/remote node
	3511	Line
	F00E	NPR timeout retry limit reached
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	24	Nonproductive receive retry exceeded

DISK/SNRM received: disk received alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error

Alert ID:	D9C4 172B	
Probable causes:	2004	SDLC communications
Failure causes:	2004	SDLC communications
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	15	Connection terminated by host

Connection problem: i-frame retransmission alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	E3DA E42F	
Probable causes:	2104	SDLC communications/remote node
	2031	Line
User causes:	0209	Remote device power off
Recommended action:	0200	Check power
Failure causes:	2104	SDLC communications/remote node
	3511	Line
	F06A	Transmit retry limit reached
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	29	Connection problem

Link Alerts for SDLC and Token Ring

SDLC Alert Local Logging

Before Host Integration Server 2004 attempts to build and send an SDLC link alert, information about the outage that caused the alert is recorded in a log file that can be viewed using the Windows Event Log service. Message 182 is always logged, as follows:

```
182I:  Connection failure, code = (outagecode)
Cause Data                         = hh...hh
Link Role                          = hh
Remote Node Type                   = hh
```

The Outage Code (outagecode) is also reported on Message 23. For a complete list of these codes, the conditions they represent, and the specific link alerts on which they are used, see the next section.

Cause Data is a list of the failure causes from the Failure causes subvector in the alert. Link Role and Remote Node type are as described in the Link Connection Subsystem Configuration Data subvector in the alert.

A connection failure can be due to a station outage, rather than a link outage. If it is due to a station outage – which can be recognized by outage code values of X'80' or higher – then Message 183, formatted as follows, is also logged:

```
183I:
Detailed diagnostic data for station (stationaddress):
SBSY   CFTX   CFRX   V(S)   V(R)   N(R)   OSFC   T1CT
hh     hhhh   hhhh   hh     hh     hh     hh     hhhh
```

The value (stationaddress) is the station address as given in the Detail qualifier subvector in the alert.

The other fields are all data from the Link Station Data subvector, as follows:

Field	Description
SBSY	Link station state: 80 or 40
	(local or remote station sending RNR)
CFTX	Last SDLC control field sent
CRX	Last SDLC control field received
V(S)	N(S) count
V(R)	N(R) count
N(R)	Last received N(R)
OSFC	Outstanding frame count
T1CT	Reply timer expiration count

Identifying Alerts from Local Logs Only

When only the local log of an alert is available, you can still obtain the information that would have been supplied on the alert. To do this, check the outage code given on Message 182 against the following list. Find the alert that uses this outage code, and then check the alert data in SDLC Failure Alerts. Some Outage Codes are used for more than one alert. In these cases, you can find the appropriate alert by comparing the Failure causes codes given on Message 182 with those given in the alert data.

SDLC outage codes

Outage code	Condition	Alert description/ID
11	DSR failure	1000 : 83BB6EC8
12	CTS failure	3300 : 0231CF0A
14	DCD failure	1000 : C3BB504A
15	Connection terminated by host	2100 : D635CA1E 2100 : D9C4172B
24	Nonproductive receive retry exceeded	3300 : C458E284
25	Idle timeout retry exceeded	3300 : 0E2DDF11
29	Connection problem	3300 : 0AECC2A6 3300 : E3DAE42F
2D	Abnormal response	1000 : 70A15CB0
2E	Write timeout retry exceeded	1000 : 61D02E7B
80	DM received	3300 : BD84C4C9
81	Disconnect retry limit	3300 : 32A37F1B
82	Contact retry limit	3300 : 32A37F1B
83	Poll retry limit	3300 : 32A37F1B
84	No response retry limit	3300 : 32A37F1B
85	Remote busy retry limit	3300 : 66D6DA74
86	FRMR received	2100 : A472BC48
		2100 : B3B7D723
		2100 : B776CA94
		2100 : BA35EC4D
		2100 : BEF4F1FA
87	Invalid frame received	2100 : 1103D152
		2100 : 15C2CCE5
		2100 : 1C40F78B
		2100 : 5F7624FD
88, 89	RIM or RD received	2100 : 29BF0032

Token Ring Failure Alerts

The tables in this section describe the alerts generated by the Token Ring link service provided with Host Integration Server 2004. The alerts are listed in numerical order by alert description and within each description in numerical order by alert ID.

Adapter check error: adapter error alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	1010	Adapter error
Alert ID:	3BA0 3B6D	
Probable causes:	3320	Local Token Ring adapter
Failure causes:	3320	Local Token Ring adapter
Recommended actions:	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 02):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	02	Data ID: adapter check status
	hh hh	Adapter check status
LAN LCS:		Ring identifier Local individual MAC address

DLC status error: frmr sent—invalid N(R) received

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name.
Alert description:	2100	Software program error
Alert ID:	216D 1033	
Probable causes:	2007	LAN LLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F012	Invalid N(r) received
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR sent—received i-field exceeded maximum length alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	25AC 0D84	
Probable causes:	2007	LAN LLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F023	Received I-field exceeded maximum length
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR sent—invalid/unsupported command/response received alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	28EF 2B5D	
Probable causes:	2007	LAN LLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F020	Invalid/unsupported command or response received
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address

Link Station Data subvector included		

DLC status error: FRMR sent—i-field received when not permitted alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	2C2E 36EA	
Probable causes:	2007	LAN LLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F021	I-field received when not permitted
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

Adapter command error: software alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	3EF7 89B7	
Probable causes:	1000	Software program
Failure causes:	1000	Software program
Recommended actions:	30E1	Contact service representative
	32C0	Report the following data:
		Product Set ID index subfield included
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	03	Data ID: adapter return code
	hh	Adapter return code

DLC status error: dm or disk received alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	4B74 26FB	
Probable causes:	2007	LAN LLC communications
	1023	Communications program in remote node

Failure causes:	1023	Communications program in remote node
	F01A	DM received
Recommended actions:	3301	If problem persists, do the following:
	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR received—invalid N(R) sent alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	83D9 1642	
Probable causes:	2007	LAN LLC communications
	1000	Software program
Failure causes:	1000 F012	Software program Frame reject received: Invalid N(r) sent
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR received—max I-field length

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name.
Alert description:	2100	Software program error

Alert ID:	8718 0BF5	
Probable causes:	2007	LAN LLC communications
	1000	Software program
Failure causes:	1000	Software program
	F013	Frame reject received: maximum I-field length exceeded
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC (Media Access Control) address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR received—invalid/unsupported commands/response sent alert

Name of subvector	**Hexadecimal value in subvector**	**Description**
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	8A5B 2D2C	
Probable causes:	2007	LAN LLC communications
	1000	Software program
Failure causes:	1000	Software program
	F010	Frame reject received: Invalid/unsupported command or response sent
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR received–i-field sent when not permitted alert

Name of subvector	**Hexadecimal value in subvector**	**Description**
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	8E9A 309B	
Probable causes:	2007	LAN LLC communications
	1000	Software program
Failure causes:	1000	Software program
	F011	Frame reject received: I-field sent when not permitted
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

Software program error: adapter interface alert

Name of subvector	**Hexadecimal value in subvector**	**Description**
Alert description:	2100	Software program error
Alert ID:	DA7B C09D	
Probable causes:	3220	Token ring adapter interface
Install causes:	1600	Mismatch between software and microcode
	1601	Incorrect customization image
Recommended actions:	1500	Correct installation problem
	1502	Correct customization parameters
Failure causes:	3220	Token ring adapter interface
Recommended actions:	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code
LAN LCS:		Ring identifier Local individual MAC address

DLC status error: SABME received for open link station alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	E65B 0B7F	
Probable causes:	2007	LAN LLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F016	SABME received while in ABME
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

Bring-up error alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3210	Initialization failure
Alert ID:	AB86 8B0B	
Probable causes:	3320	Local Token Ring adapter
Install causes:	1200	Incorrect hardware configuration
	1402	Mismatch between hardware and software configurations
Recommended actions:	1503	Correct configuration
Failure causes:	3320	Local Token Ring adapter
Recommended actions:	30E1	Contact service representative
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code
LAN LCS:		Local individual MAC address

Adapter open error: open failure alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is ring name

Alert description:	3211	Open failure
Alert ID:	016E 5F4E	
Probable causes:	3702	Token ring lobe
	3701	Token ring LAN component
Failure causes:	3712	Local Token Ring lobe
	3701	Token ring LAN component
	2600	Interference
Recommended actions:	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code
LAN LCS:		Local individual MAC address

Adapter open error: remove command received alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3211	Open failure
Alert ID:	44D1 AD86	
Probable causes:	3705	Token ring remove command received
User causes:	3320	Token ring remove adapter command received
Recommended actions:	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code
LAN LCS:		Local individual MAC address

Adapter open error: problem on local lobe alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3211	Open failure
Alert ID:	55BF 3E1C	
Probable causes:	3702	Token ring lobe
Failure causes:	3320	Local Token Ring adapter
	3711	Local Token Ring lobe
	3434	Local lobe cables
Recommended actions:	1009	Try reopening adapter after 30 seconds
	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32C0):
	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number

	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code
LAN LCS:		Local individual MAC address

Adapter open error: beaconing detected alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3211	Open failure
Alert ID:	CAF3 C58A	
Hierarchy/resource list:		Second name is ring name
Probable causes:	3703	Token ring fault domain
Failure causes:	3703	Token ring fault domain
Recommended actions:	1009	Try reopening adapter after 30 seconds
	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3101, or 32C0):
	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code

Adapter open error: duplicate address alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3211	Open failure
Alert ID:	D615 A61E	
Probable causes:	3704	Token ring duplicate station address
Install causes:	3704	Token ring duplicate station address assigned
Recommended actions:	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code
LAN LCS:		Local individual MAC address

System action: operator caused LAN adapter to be reset alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3211	Open failure
Alert ID:	F7A6 2F59	
Probable causes:	7001	Resources not active
User causes:	3300	Adapter not ready
Recommended actions:	1300	Correct then retry

	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):

Link Alerts for SDLC and Token Ring

Link Statistics

For SDLC (Synchronous Data Link Control) and Token Ring connections, Host Integration Server 2004 maintains statistics on link usage and errors. Host Integration Server 2004 logs this information when a connection ends or when the counter for a particular error or timeout reaches its maximum value.

This section contains:

- Format for Link Statistics

Format for Link Statistics

When an SDLC or Token Ring connection ends, or when an error counter reaches its maximum value, Host Integration Server 2004 records statistics on link usage. These statistics include information such as the adapter number, the date and time the link was established, and the counts of errors and timeouts. This data is also logged in NMVT (network management vector transport) format if a connection has been specified for carrying NetView data. The data is then sent if that connection and the server that owns the connection are both active.

This section contains:

- SDLC Link Statistics
- Token Ring Link Statistics

SDLC Link Statistics

Link statistics are generated when a link is closed or when one of the wrap counters listed later in this section is about to wrap. Whenever a link statistics message is built, all the wrap counters are reset to 0. The cumulative counters are not reset; they provide statistics from the point at which the particular link service was started.

The NMVT generated has the following format:

NMVT header	
41 03 8D 00 00 00 00 00	NMVT Header

Major vector header	
00 69	Length of major vector
00 25	Link statistics major vector

Data link traffic counters subvector	
65 9A	Data Link Traffic Counters subvector
03	DLC type: SDLC
hh	Adapter number (01+04)

Date/time link established	
hh	Date
hh	Month
hh hh	Year
hh	Hour
hh	Minute
hh	Second
hh	Hundredths of a second
hh	Counter

Wrap counters	
hh	Transmit I-frames OK
hh	Transmit I-frames not OK
hh	Retransmit I-frames
hh	Received I-FCS OK
hh	Received I-FCS not OK
hh	Total frames sent
00	Reserved
hh	Lost data frames received
hh	FRMR conditions sent
00	Reserved
hh	CTS drop
00	Reserved
00	Reserved
hh	DSR drop out
hh	Inactivity timeouts
00	Reserved
hh	DMA underruns
00	Reserved
hh	Transmit fail timeouts
00	Reserved

Cumulative Counters

The cumulative counters are the same counters as the wrap counters, with reserved bytes in the same positions.

Alerts Used by Applications, NVAlert, and NVRunCmd

Application programs and the NVAlert and NVRunCmd services can generate alerts using the Common Service Verb (CSV) **TRANSFER_MS_DATA**. An application or service can supply subvectors, which are required to build an NMVT, or it can supply the complete NMVT. In both cases, the completed NMVT is logged locally, and may also be sent on the connection designated for NetView if the connection is configured and active. An application or service can also supply user-defined alert data, in which case the data is logged locally but cannot be sent.

This section contains:

- Format for Alerts Used by Applications, NVAlert, and NVRunCmd

Format for Alerts Used by Applications, NVAlert, and NVRunCmd

An application program or the NVAlert and NVRunCmd services can use the CSV **TRANSFER_MS_DATA** to issue alerts. The alerts are logged in a log file that can be viewed using the Windows Event Log service, and may also be sent on the NetView connection.

The data supplied to **TRANSFER_MS_DATA** may be in any of the following formats:

NMVT
The application or service supplies a complete NMVT, including the header information.

ALERT_SUBVECTORS
The application or service supplies the subvectors required for an alert, but without the NMVT header or major vector header. Host Integration Server 2004 adds the header information, as described in the next section.

PDSTATS_SUBVECTORS
The application or service supplies the subvectors required for a Problem Determination Statistics NMVT, but without the NMVT header or major vector header. Host Integration Server 2004 adds the header information, as described in the next section.

USER_DEFINED
The application or service supplies data in its own format. This data cannot be sent on the connection designated for NetView, but is logged in the same way as the other data formats.

The application or service can also request Host Integration Server 2004 to add the Product Set ID subvector (for all data types except USER_DEFINED), the Date/Time subvector, or both to the supplied data. The format of these added subvectors is described in the next section.

For all data types, the data (with added headers and subvectors, if appropriate) is logged locally in NMVT format, whether or not you specified a connection for NetView.

Local Logging of Network Management Data

Data is logged in a Windows Event Log service log file in two ways. First, the data from the alert is logged in a more readable format, using standard log messages. The format is specific to the alert type. For the message numbers used and explanations of the data, see the section in this chapter that relates specifically to that type of alert.

If a connection has been designated for carrying NetView data and the server that owns the connection is active, the alert NMVT containing the data is also logged in NMVT format as it would be sent. The NMVT appears as Message 540, followed by Message 541. Note that this logging occurs before Host Integration Server 2004 attempts to send the NMVT. The log is therefore no guarantee that the NMVT is sent successfully.

For more information about local logging of alert information, see the section of this chapter relating specifically to that type of alert.

Network Protocols and Client/Server Communication

This section explains how clients using different local area network (LAN) protocols can communicate with Microsoft® Host Integration Server 2004 computers. The section includes an overview of how network protocols are used on clients, and how client logons work. Also included are procedures for checking the setup options for Host Integration Server 2004 specified on a client or server. These setup options must be specified correctly in order for the client to communicate with a Host Integration Server 2004 computer. You will also find descriptions and illustrations of how clients using each of the possible protocols locate a Host Integration Server 2004 computer in the network.

This section contains:

- Overview of Network Protocols for Clients
- Important Host Integration Server 2004 Network Options
- Adjusting Clients Running Windows for Workgroups
- Details about How Clients Use Protocols

Overview of Network Protocols for Clients

Host Integration Server 2004 clients can communicate with servers through the following LAN protocols:

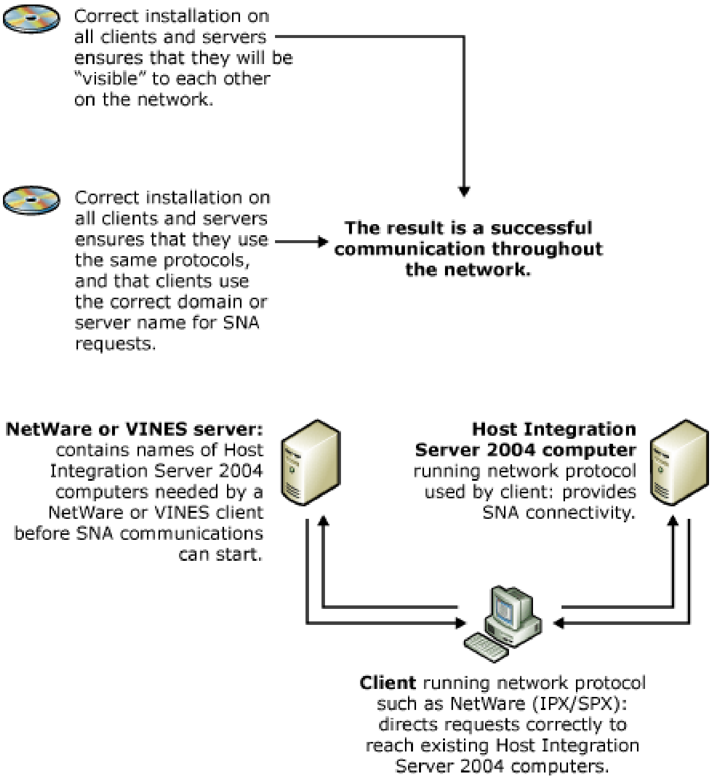
- Microsoft Networking (Named Pipes)
- IPX/SPX (the protocol used with NetWare)
- TCP/IP

  Important In order for the different client/server protocols to be handled correctly by Host Integration Server 2004, both clients and servers must have the network software and the Host Integration Server 2004 software installed correctly. Be sure to follow the installation instructions in this chapter carefully, and follow the installation instructions for other software you are using for example, Windows 2000 Server and the associated network software, Host Integration Server 2004, and network software on clients.

Correct installation of network and Host Integration Server 2004 on servers and clients ensures that two essential aspects of communication work correctly:

- The servers and clients are visible to each other on the local area network (LAN). This results when the network software is installed correctly on all affected computers.
- The Host Integration Server 2004 computers communicate with clients over the correct LAN protocol, and the clients direct their communication to the correct domain name or, for some clients using Microsoft Networking or TCP/IP, to one or more correct server names. A Host Integration Server 2004 client must be set up to use the correct server or domain name or, for Microsoft Networking, set up to locate servers in the local domain. Otherwise, the client will not be able to locate a Host Integration Server 2004 computer.

For example, in order for a client to successfully communicate over Novell NetWare, there must be working communication between the client, a NetWare server, or a Windows Server running Microsoft File and Print Services for NetWare and any Host Integration Server 2004 computers in the network. Either server provides the client with names of Host Integration Server 2004 computers, . In addition, for clients running NetWare 4.*x*, bindery emulation must be enabled. The following figure illustrates how correct installation is necessary for successful communication:



Correct installation on all clients and servers ensures that they will be "visible" to each other on the network.
Correct installation on all clients and servers ensures that they use the same protocols, and that clients use the correct domain or server name for SNA requests.
The result is a successful communication throughout the network.
NetWare or VINES server: contains names of Host Integration Server 2004 computers needed by a NetWare or VINES client before SNA communications can start.
Host Integration Server 2004 computer running network protocol used by client: provides SNA connectivity.
Client running network protocol such as NetWare (IPX/SPX): directs requests correctly to reach existing Host Integration Server 2004 computers.

For information about how Host Integration Server 2004 enables you to view and choose the domain and protocols to be used by Host Integration Server 2004 computers and clients, see Important Network Options on a Host Integration Server 2004 Computer. For details about how each of the network protocols works on a Host Integration Server 2004 client, see the section about that specific network protocol (for example, Clients Using TCP/IP).

This section contains:

- Client Logons and the Storing of Passwords
- Types of Client Logons

Client Logons and the Storing of Passwords

For security reasons, a user at a client computer may have to log on several times before obtaining access through Host Integration Server 2004 to a mainframe or AS/400. Users may not always find this to be convenient. The logons are necessary because starting an SNA session requires several kinds of access: access to the Windows domain, access to a Host Integration Server 2004 computer, access to the mainframe or AS/400 and, possibly, access to programs on the mainframe or AS/400. An example of such a program is an AS/400 program that uses conversation security when communicating with 5250 emulators. Each layer of access may require an additional logon depending on the operating system and the client/server protocol used on the client.

The Host Security Integration feature of Host Integration Server 2004 can reduce or even eliminate these multiple logons on Windows -based networks. If you are not able to take advantage of this feature, users can avoid multiple logons by following the procedures outlined in the following sections.

See Also

Types of Client Logons

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Types of Client Logons

The number of logons required for establishing an SNA session from a client varies, depending mostly on what client/server protocol the client computer is using. The following list describes the logons:

Clients Using Microsoft Networking

A client using Microsoft Networking must log on to the Windows domain and then must perform any logons required on the mainframe or AS/400. For example, a client using Microsoft Networking and also using a 5250 emulator would log on once to the Windows domain, once to the AS/400 itself, and (in many cases) once to the AS/400 program that communicates with the 5250 emulator.

After clients using Microsoft Networking are logged on to the domain, no additional logon is needed for access to Host Integration Server 2004 computers in the domain. That is, Host Integration Server 2004 can securely confirm the domain logon without any additional action by the user.

Clients Using Novell NetWare

A client using NetWare must first log on to the NetWare network and then to the Host Integration Server 2004 computers. Finally, the client must perform any logons required on the mainframe or AS/400

Clients Using TCP/IP

A client using TCP/IP must log on to the Host Integration Server 2004 computers even if the client has already accessed other resources in the Windows domain, and then must perform any logons required on the mainframe or AS/400.

Overview of Network Protocols for Clients

Important Host Integration Server 2004 Network Options

The following two sections illustrate and describe important Host Integration Server 2004 network options for a Host Integration Server 2004 server or client. These options must be set correctly in order for clients to locate Host Integration Server 2004 computers and start sessions. If the options are set incorrectly, clients may use the wrong protocols or may search the wrong locations for Host Integration Server 2004 computers.

This section contains:

- Important Network Options on a Host Integration Server 2004 Computer
- Important Network Options on a Client

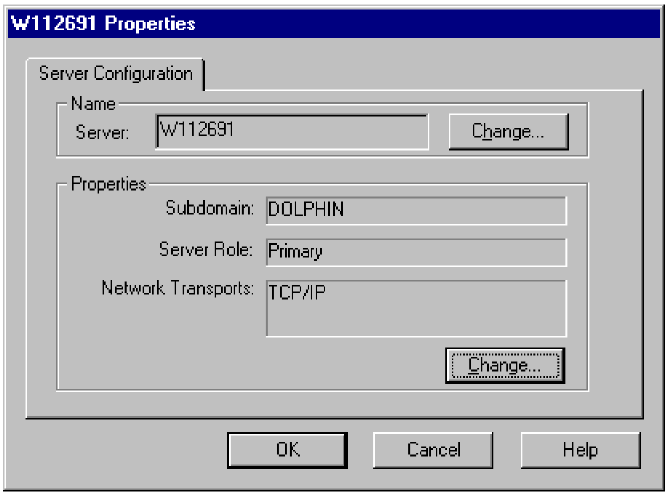
Important Network Options on a Host Integration Server 2004 Computer

When Host Integration Server 2004 network options are specified correctly on a Host Integration Server 2004 computer, the server will use the appropriate protocol(s) for communicating with clients. Servers supporting NetWare, TCP/IP, or Microsoft Networking will have the correct domain name so that clients can locate the Host Integration Server 2004 computers.

> **Important** These changes do not take effect until the server is restarted. Do not change these settings while the server has active users.

To view or change client/server protocols and other network options on a Host Integration Server 2004 computer

1. In SNA Manager, select a Host Integration Server 2004 computer.
2. Right-click a server and then click **Properties**. The **Server Properties** dialog box appears.



Server: W112691
Subdomain: DOLPHIN
Server Role: Primary
Network Transports: TCP/IP

3. To change the Host Integration Server 2004 computer name, click **Change** in the **Name** box. The Host Integration Server 2004 computer must be in an off-line state before you can change the name.
4. To modify the client/server protocols and other network options, click **Change** in the **Properties** box, and then click **OK**.
5. Complete the Server SNA Resource wizard.

> **Note** If the server has TCP/IP installed and will communicate with clients that use TCP/IP, be sure that the selections in the Select Client/Server Protocols dialog box include TCP/IP. If Microsoft Networking (Named Pipes) is selected and TCP/IP is not, the server can communicate through Named Pipes over TCP/IP, a protocol combination that does not recover from error conditions as effectively as native TCP/IP.

If TCP/IP is selected, you can also select Microsoft Networking. In this situation, the Host Integration Server 2004 computer will use native TCP/IP with clients that use TCP/IP, and Microsoft Networking with clients that use Microsoft Networking.

Important Host Integration Server 2004 Network Options

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Important Network Options on a Client

For Host Integration Server 2004 client software, several key options supply the information a client must have for locating Host Integration Server 2004 computers. These options specify which protocol the client uses to communicate with Host Integration Server 2004 computers if more than one protocol is available on the client, and which domain or server names the client will direct SNA requests to.

When a client makes an SNA request, the client must direct that request to a domain or to one or more Host Integration Server 2004 computers. The appropriate way for a client to direct requests depends on the protocol used and the relative location of clients and servers. The following table lists the ways clients direct SNA requests, and the information that will be requested by setup during client installation. For more detail about how a client directs requests and locates Host Integration Server 2004 computers, see the section about the appropriate type of client (for example, Clients Using TCP/IP).

Network protocol used on client	How the client directs SNA requests	Information to find out before running client setup
Microsoft Networking	Either to the local domain (if the Host Integration Server 2004 computers are in the same domain as the client), or to one or two specific Host Integration Server 2004 computers in a remote domain.	Whether the client is in the same domain as the Host Integration Server 2004 computers, and if not, one or two names of Host Integration Server 2004 computers.
Novell NetWare (IPX/SPX)	To a specific domain. The Host Integration Server 2004 computers must be located in this domain in order for the client to locate them.	The name of the Host Integration Server 2004 subdomain in which the Host Integration Server 2004 computers are located.
TCP/IP	Either to a domain name or to specific server name, depending on what is specified in the Host Integration Client Mode or Host Integration Server Location dialog box.	Contact your network administrator for additional information regarding a specific IP address for the Host Integration Server 2004 computer.

Adjusting Clients Running Windows for Workgroups

Clients running Windows for Workgroups have a very flexible set of options for network operation. As a result, these clients may require specific adjustments in order to communicate with Host Integration Server 2004 computers.

Clients running Windows for Workgroups and using Microsoft Networking (not other network software) must use domain and password settings that coordinate with settings in Host Integration Client 2004 Setup. For example, if the client's workgroup name does not match the server's domain name, options in Host Integration Client 2004 Setup must be set accordingly.

This section contains:

- Domain and Password Settings for Clients Running Windows for Workgroups

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Domain and Password Settings for Clients Running Windows for Workgroups

This section applies only to clients running Windows for Workgroups and using Microsoft Networking to communicate with Host Integration Server 2004 computers. Such clients must be configured so that any domain names, workgroup names, local passwords, and domain passwords all work together smoothly.

This section contains:

- Domain Settings with Windows for Workgroups
- Password Settings with Windows for Workgroups

Domain Settings with Windows for Workgroups

For domain names and workgroup names, use one of the following approaches:

- **Workgroup name differs from Host Integration Server 2004 domain name.** For clients where the workgroup name must be different from the server's domain name (the name of the Windows domain), in Host Integration Client 2004 Setup, you must use the Remote Domain setting. That is, in the Host Integration Server Location dialog box, select Remote Domain, and supply the name of one or two Host Integration Server 2004 computers to which the client will send requests.

  To view a client's workgroup name, in the Control Panel, double-click the Network icon. The name is listed in the resulting dialog box.

- **Workgroup name matches Host Integration Server 2004 domain name.** For clients where the workgroup name is the same as the server's domain name (the name of the Windows domain), in Host Integration Client 2004 Setup, you can use the Local Domain setting. That is, in the Host Integration Server Location dialog box you can select Local Domain. When the client requests an SNA session, the request will reach the domain that has the same name as the client's workgroup.

  To view a client's workgroup name, in the Control Panel, double-click the Network icon. The name is listed in the resulting dialog box.

See Also

Password Settings with Windows for Workgroups

Password Settings with Windows for Workgroups

For Windows for Workgroups passwords and domain passwords, use one of the following approaches:

- **Enable logon to the Windows domain automatically at startup.** You can configure Windows for Workgroups to log the user on to the Windows domain automatically at startup.To do this, first make sure that a user account has been created for the user in the Windows domain, and obtain the assigned user name and password.

To configure Windows for Workgroups to logon to the Windows domain automatically at startup

1. On the client computer, from the Control Panel, double-click the **Network** icon and then click **Startup** .
2. In the **Startup Settings** dialog box, under **Options for Enterprise Networking**, find the check box labeled **Log On to Windows or LAN Manager Domain**. Select this check box, and type the domain name in the appropriate box.
3. Choose **OK** repeatedly until the dialog boxes are closed.

Note The next time Windows for Workgroups is restarted, the user will be prompted for both the local password and the domain password, and must type them correctly. Thereafter, only the local password is needed at startup, because the domain password is encrypted and stored (to be "unlocked" by the local password).

After domain logon has been set up, it is important for the user to understand the difference between the local Windows for Workgroups password and the actual domain password. The local Windows for Workgroups password unlocks the encrypted password list that has been stored for that user on that computer. This password list includes a copy of the domain password if the preceding configuration steps have been taken. The actual domain password is the password for that user's account on the Windows domain, as recorded on Windows servers that are domain controllers.

The user's domain account may be set up to require periodic changing of the password. If the domain password expiration date is getting close, when the user logs on to the domain, pop-up warnings will appear on the user's computer. Note that the user must try to log on in order for the pop-up warnings to appear. At this point, the user needs to understand the different buttons used for changing passwords with Windows for Workgroups. After choosing the Network option from the Control Panel, click the Password button. This only changes the password to unlock the user's local password list; it does not change the domain password.

To change the domain password, the user must choose the Startup button followed by the Set Password button. When the user changes the domain password using the Set Password button, the domain password is also changed in the local password file.

Make sure that users understand how to use these buttons correctly to change their local Windows for Workgroups password and to change their Windows domain password.

- **Log on only as needed, by using the net logon command.** If the user does not log on to the Windows domain at startup, the following command can be used before starting an SNA session. At the MS-DOS prompt (from within Windows for Workgroups), type

  net logon *username* **/domain:***domainname*

  After typing the command, the user is prompted for the domain password.

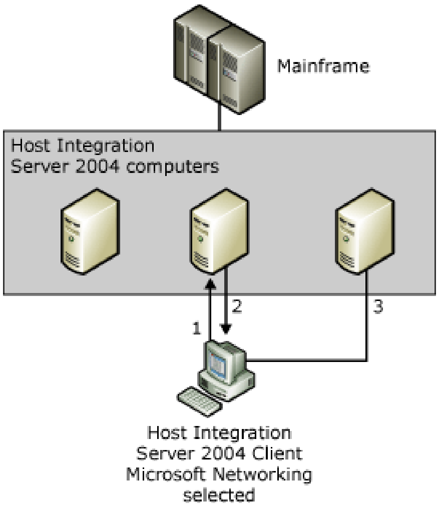
Details about How Clients Use Protocols

The following sections describe how each type of client works with Host Integration Server 2004. The clients are listed according to the protocol used: Microsoft Networking (Named Pipes), Novell NetWare (IPX/SPX), and TCP/IP.

This section contains:

- Clients Using Microsoft Networking (Named Pipes)
- Clients Using NetWare (IPX/SPX)
- Clients Using TCP/IP

Clients Using Microsoft Networking (Named Pipes)



Mainframe
Host Integration Server 2004 computers
1
2
3
Host Integration Server 2004 Client Microsoft Networking selected

A Microsoft Networking (Named Pipes) client uses the following procedure for connecting to the mainframe:

1. You can choose between two methods by which a client searches for Host Integration Server 2004 computers.

    - Active Directory
    - Sponsor connections, locating servers by SNA subdomain or by server name.

    Client locates servers by subdomain means that the client locates the server through broadcasts in the local subdomain. Therefore, the client must be in the same physical network as the Host Integration Server 2004 computers, and must not be separated from the servers by a router.

    Client locates servers by name means that the client searches for Host Integration Server 2004 computers by name, and therefore need not be on the same side of any routers as the Host Integration Server 2004 computers. When connecting with Named Pipes over TCP/IP, and there is a router separating the Host Integration Server 2004 computer and the client, the client computer requires a method of resolving NetBIOS names to an IP address. A local LMHOSTS file or a Windows Internet Name Service (WINS) server may be used to perform this resolution.

    > **Note** If Windows for Workgroups 3.11 is being used and the Microsoft IPX/SPX compatible transport is installed, add **Directhost=no** to the [network] section of SYSTEM.INI file on the Windows for Workgroups 3.11 client computer, and then reboot the computer.

    If this is a routed network, Named Pipes is not recommended. TCP/IP is the recommended interface for this environment.

2. The Host Integration Server 2004 computer responds with a list of available Host Integration Server 2004 computers that are available to get a 3270 or APPC session with. This special connection is called the sponsor connection.
3. Finally, the client attempts to connect to each Host Integration Server 2004 computer in the list until a server is found that can handle the 3270 or APPC request.

Microsoft Networking (Named Pipes) Errors

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Microsoft Networking (Named Pipes) Errors

NAMED PIPES 5

Causes

One of the following has occurred:

- Access has been denied trying to create a connection to the Host Integration Server 2004 computer. The client/server interface connects to the Host Integration Server 2004 computer just like any other local area network (LAN) connection. It must be validated by Windows as a valid user in the domain.
- The Host Integration Server 2004 computer is unreachable. If using TCP/IP this could mean that the name to IP address resolution has failed.

NAMED PIPES 2

Causes

The client has connected to the Host Integration Server 2004 computer, but the SNABase service is not running on that machine. Start the SNABase service on the Host Integration Server 2004 computer to which you are trying to connect.

NAMED PIPES 121

Causes

The client is configured for **Client locates servers in an Host Integration Server 2004 Subdomain** and therefore, is sending out broadcast messages to discover a Host Integration Server 2004 computer. These broadcast messages will typically not be passed by a router that may be between your client and the server. In the client configuration select **Client locates server by name** and specify an IP address or computer name of one or more Host Integration Server 2004 computers.

6
Domain1: server1
Domain1: server2
Domain2: server1
Host Integration Server 2004 Client IPX/SPX

Novell NetWare (IPX/SPX) client computers use the following procedure for connecting to the mainframe:

1. At startup time, all Host Integration Server 2004 computers register their subdomain name and computer name with the NetWare Bindery. The subdomain name is configured in Setup for Host Integration Server 2004. The computer name used is the Windows computer name.
2. Sometime later, a client requests an initial SNA session (3270 or APPC) by sending the request to the NetWare server requesting a list of registered Host Integration Server 2004 computers.
3. In response, the NetWare server sends the client the names of the Host Integration Server 2004 computers.
4. The client then selects one of the names from this list of Host Integration Server 2004 computers at random, and attempts to get a LAN connection with one of the Host Integration Server 2004 computers. The client must be configured for the same subdomain name as the Host Integration Server 2004 computers.
5. The Host Integration Server 2004 computer responds with a list of available Host Integration Server 2004 computers that are available to get a 3270 or APPC session with. This special connection is called the *sponsor connection*.
6. Finally, the client attempts to connect to each Host Integration Server 2004 computer in the list until a server is found that can service the 3270 or APPC request.

This section contains:

- Checklist for Clients Using NetWare (IPX/SPX)
- NetWare Errors

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to
http://go.microsoft.com/fwlink/?linkid=29507.

Checklist for Clients Using NetWare (IPX/SPX)

When troubleshooting client problems, check that all of the following conditions have been met:

For Bindery

- **NetWare Servers**

  The NetWare server is properly installed and running, so that the bindery service is available.

- **Host Integration Server 2004 Computers**

  The Host Integration Server 2004 computer has registered its name in the bindery on the NetWare server. Several elements are required for this. The first element happens automatically: the installation of the NWLink IPX/SPX Compatible Transport on Windows. The second is matching the frame-type with the NetWare Server. For instance, if 802.2 is configured on the NetWare Servers, then the same frame type should be configured in the properties for the NWLink IPX/SPX Compatible Transport on Windows. Auto Frame Type is recommended.

  The correct subdomain name must be typed in the **Host Integration Server 2004 Subdomain Name** dialog box. The name is registered (along with the server name computer name) on the NetWare server. Only if the NetWare server is provided with the correct subdomain name can it respond to client requests and provide the clients with Host Integration Server 2004 names.

  Also, for the Host Integration Server 2004 computer to register its name on the NetWare server, the Host Integration Server 2004 must be installed to work with IPX/SPX. This means that in Setup, the Novell NetWare (IPX/SPX) option must be selected in the Select Client/Server Protocols dialog box.

- **IPX Routers**

  In addition, for Bindery, any IPX routers between the two servers must be configured to allow NetWare Service Advertising Protocol broadcasts (SAP broadcasts)() to flow. IPX routers must propagate sockets 84C8 and 84C9 to support the communication needed by Host Integration Server 2004 computers and clients.

  To discover whether any Host Integration Server 2004 computers have been registered with NetWare Bindery, use the NetWare Rconcole utility against any NetWare Server that is using Bindery. For instance, if there are two Host Integration Server 2004 computers (Server1, Server2) that have successfully registered themselves with the NetWare Bindery and both servers are configured to be in a subdomain called Domain1, the entry in the NetWare Rconsole utility would be:

  - DOMAIN1!Server1
  - DOMAIN1!Server2

For Client

- Ensure that the client is using the same subdomain name as the Host Integration Server 2004 computers you wish to connect to and has NWLink installed.
- **NDS Specific**

  The same concepts for Bindery apply to NetWare Directory Service (NDS), which the exceptions:

- **Host Integration Client 2004**

  The NetWare Directory Service (NDS) logon credentials on the Host Integration Server 2004 computer must have the right to add an entry into the NetWare NDS tree structure. If this fails, there will be an event logged to the Windows Application Event Log.

  The NDS Context and Tree Name must be provided by the client and server configurations in addition to the subdomain name in order for a client to connect successfully.

- **NetWare Servers**

  If using NetWare Directory Services (NDS), Host Integration Server 2004 requires NetWare version 4.11 or later. Earlier versions of NetWare are supported through the bindery emulation feature of NetWare version 4.0 or later.

  Note If NDS is selected on the client and an attempt to get a sponsor connection fails, it will automatically try Bindery.

See Also

NetWare Errors

NetWare Errors

- **BINDERY 250**

  The Host Integration Server 2004 computer has contacted a NetWare Server and has enumerated a list of available Host Integration Server 2004 computers in the client's subdomain. However, the client cannot connect to any of the Host Integration Server 2004 computers in this list. There may be a network problem preventing a connection. Ensure that the same frame type is being used on the client and the other Host Integration Server 2004 computer.

- **BINDERY 252**

  The client has found that there are no Host Integration Server 2004 computers in this subdomain registered with the NetWare Bindery. Ensure that the clients and servers are using the same subdomain name and that SNABase service on the Host Integration Server 2004 computers has been started and registered with Bindery. To check whether SNABase has been registered with the NetWare Bindery use the NetWare Rconsole utility. For instance, if the Host Integration Server 2004 computer is configured to be in a subdomain called Seattle, and the computer name of the Host Integration Server 2004 computer is SNAS1, then the entry in Rconsole would be:

  SEATTLE!SNAS1

- **NDS 64935**

  The Context Name and / or subdomain name on the client is different than Context Name and /or subdomain name configured on the Host Integration Server 2004 computer. It can also mean that the Context Name, though the same on client and server, is not a valid NetWare Directory Services (NDS) Context Name. If NDS discovery fails and there are NetWare Servers that also support Bindery, the client will try using the Bindery automatically.

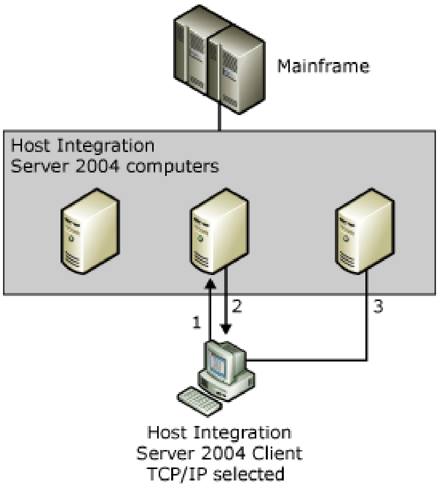
Checklist for Clients Using NetWare (IPX/SPX)

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Clients Using TCP/IP



Mainframe
Host Integration Server 2004 computers
1
2
3
Host Integration Server 2004 Client TCP/IP selected

A TCP/IP client computer uses the following procedure to connect to the mainframe:

1. With TCP/IP, you can choose between two methods by which a client searches for Host Integration Server 2004 computers.
    - **Client locate servers by subdomain** means that the client locates the server through broadcasts in the local subdomain. Therefore, the client must be in the same physical network as the Host Integration Server 2004 computers, and must not be separated from the servers by a router.
    - **Client locates servers by name** means that the client searches for Host Integration Server 2004 computers by name or IP address, and therefore need not be on the same side of any routers as the Host Integration Server 2004 computers. When using a name (instead of an IP address) and there is a router separating the Host Integration Server 2004 computer and the client, the client computer requires a method of resolving a name to an IP address. A local LMHOSTS file or a Windows Internet Name Service (WINS) server may be used to perform this resolution.
2. The Host Integration Server 2004 computer responds with a list of available Host Integration Server 2004 computers that are available to get a 3270 or APPC session with. This special connection is called the sponsor connection.
3. Finally, the client attempt to connect to each Host Integration Server 2004 computer in the list until a server is found that can service the 3270 or APPC request.

Note that before attempting to establish communication involving Host Integration Server 2004, you can use the TCP/IP utility called **ping** to verify that contact can be established between client and server. This can help you identify basic TCP/IP problems, such as difficulties with name resolution or with routers. For information about the **ping** utility, see your TCP/IP documentation.

> **Note** Ensure that the logged-on user has sufficient user rights to access the Host Integration Server 2004 computer across the network. As with any other LAN connection, this is validated through the Windows Domain model.

TCP/IP Errors

TCP/IP 11004

Causes

Your client is configured for Remote **client locates servers by name**, and you have selected a computer name instead of an IP address. The computer name to IP address resolution has failed, or the IP address resolved cannot be found on the network. Try inputting an IP address instead of a computer name into the client configuration. If this works, then there may be a problem with your local lmhosts file, DNS Server or WINS when using a computer name in the configuration. If this does not work, try pinging the address. For instance, if the IP address of the Host Integration Server 2004 computer you wanted to connect to is 123.34.34.22, then type in the following command:

```
C:> ping 123.34.34.22
```

If you receive a **Request Timed Out** message, then there is a problem with TCP/IP, and you should contact your network administrator.

TCP/IP 10061

Causes

The SNABase service on Host Integration Server 2004 computer is not running or the IP address cannot be resolved, either because this Server is not on the network, the IP address is incorrect, or there is a router or network problem. Try pinging the address. For instance, if the IP address of the Host Integration Server 2004 computer you wanted to connect to is 123.34.34.22, then type in the following command:

```
C:> ping 123.34.34.22
```

If you receive a **Request Timed Out** message, then there is a problem with TCP/IP, and you should contact your network administrator.

TCP/IP 121

Causes

The client is configured for Local **Client locates servers in a Host Integration Server 2004 Subdomain** and therefore, is sending out broadcast messages to discover a Host Integration Server 2004 computer. These broadcast messages will typically not be passed by a router that may be located in between your client and the server. Go into the client configuration and select **Client locates server by name** and specify an IP address or computer name of one or more Host Integration Server 2004 computers.

Error Messages

The messages recorded in the event log for Microsoft® Host Integration Server 2004 are now available in a database. The Message Database file, included on the Host Integration Server 2004 CD-ROM at **\Documentation\Message Database\Snamsg.mdb**, requires Microsoft Access 97 or later for viewing. This database enables you to design your own queries and reports to gather and analyze information regarding Host Integration Server 2004 events. The message database includes the message identifier, severity level, symbolic message name, source, message, and an explanation where appropriate.

Some errors and events have additional information, such as debugging suggestions or recommended actions, available in the Error Message Database (EMDB). You can access the EMDB through the link provided in the error and event log. This link will take you directly to the error in the EMDB.

You can also access the entire EMDB at the following location:

http://go.microsoft.com/fwlink/?LinkId=33506

Finally, you can view events using the Windows® Event Log service on the **Tools** menu in SNA Manager. Once you have the Windows Event Log service running, double-click an event to display the **Event Detail** dialog box. Then use the **Event Detail** dialog box to see more information about a selected event.

The Command-Line Interface

In addition to the graphical user interfaces provided by Host Integration Server 2004 Setup and the SNA Manager, Host Integration Server 2004 offers a command-line interface. The command-line interface can be useful in certain situations, such as when you want to view a configuration setting quickly without starting the graphical interface, or when you want to store configuration commands in a command file so that they can be carried out easily in the future.

Before using the command-line interface, you must install Host Integration Server 2004 and run the SNA Manager at least once. This initializes important elements of the Host Integration Server 2004 configuration that cannot be controlled with the command-line interface.

You can use the command-line interface to modify an offline configuration file (as well as a regular on-site configuration file). However, when you work with an offline configuration file, validation of server names, link names, and user names cannot take place, and errors may result. For information about specifying the name of the configuration file to modify with the command-line interface, see Specify the Subdomain Configuration File.

Other actions are also not available from the command-line. For example, you cannot use the command-line interface to configure ranges of LUs.

Certain Host Integration Server 2004 commands must be used with great care if the **/add** option is used with them. With these commands – **snacfg server**, **snacfg link**, and **snacfg user** – the information you type must match existing information in your system or on the Windows domain.

> **Important** If you specify server names, link service names, adapter properties, or user names by using the /add option with snacfg server, snacfg link, or snacfg user, these names or properties must match existing names and properties in your installation, or a nonfunctioning configuration may result. To protect against errors with these commands, use the SNA Manager instead.

Task Order

Just as with the SNA Manager, configuration tasks must be carried out in a certain order with the command-line interface. For example, before configuring an LU, you must configure the connection that the LU will use. You can vary the interface you use for each configuration task, as long as you carry out the tasks in order, and as long as you have already installed Host Integration Server 2004 with the Host Integration Server 2004 Setup and then run the SNA Manager. For example, you can carry out tasks using the SNA Manager, then the command-line interface, then the SNA Manager again, as long as the tasks are done in the correct order.

The following table shows the order in which configuration tasks must be carried out, and the command used to carry out the task.

Task Order for Configuration Tasks

Configuration task (in order)	Command that carries out task
Add a server to the configuration	**snacfg server***
Configure link service(s) for the server(s)	**snacfg link***
Configure connection(s) for the server(s)	**snacfg connection**
Configure LU(s) for the connection(s)	**snacfg appcllu**, **snacfg appcrlu**, **snacfg lu**, **snacfg lua**, or **snacfg lud**
Create LU pool(s) (optional)	**snacfg pool**, **snacfg poola**, or **snacfg poold**
Assign LUs to pool(s) (optional)	**snacfg lu**, **snacfg lua**, or **snacfg lud**
Add users to the list used by Host Integration Server 2004	**snacfg user***
Assign LU(s) or LU pool(s) to users	**snacfg user**

* It is recommended that you use the SNA Manager, not the command-line interface, for these tasks. Any errors in the typing of commands for these tasks can result in a nonfunctioning configuration.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Specify the Subdomain Configuration File

Within a Host Integration Server 2004 command (a **snacfg** command), you can specify the path of the subdomain configuration file to access, or you can omit the path. If you omit the path, Host Integration Server 2004 attempts to access the configuration file in the normal location on the local system: \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG. To specify the path of the configuration file to access, type the **snacfg** command with the following syntax:

```
snacfg #configpath command options
```

That is, follow the **snacfg** command with a space, a pound sign, then the configuration path, and then any additional command syntax.

For example, to view a listing of the connections stored in Program Files\Host Integration Server\SYSTEM\CONFIG\BACKUP.SNA, type

```
snacfg #\Program Files\Host Integration Server\system\config\backup.sna connection /list
```

Snacfg Reference

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Use a Command File

If you want to run a series of Host Integration Server 2004 configuration commands, you can remove the word **snacfg** from each command, place the new commands in a file called a command file, then use a single **snacfg** command to run the entire command file. This is similar to the way a batch file works; however, a command file opens and closes the configuration file fewer times than a batch file. When a command file is run, the configuration file is opened only once, at the beginning. Then all the commands are carried out, and the configuration file is closed. In contrast, when a batch file containing **snacfg** commands is run, the configuration file is opened and closed multiple times, once for every command in the file.

When creating a command file, do not include the following:

- The word **snacfg**
- A path for a configuration file
- A command path for another command file
- A backslash inside the text string for a comment

Also, you can include long, multiline commands in a command file by ending lines with a backslash (\ ). The backslash indicates that the string in the next line should be appended to the current command.

There are two steps for using a command file. First, create the file, either by typing the configuration commands into a plain text file, or by using the **/print** option as described in the next section. Then run the command file from the command prompt by typing a line with the following syntax:

```
snacfg [#configpath] @commandpath [/v]
```

In the preceding syntax line, *configpath* is the path of the configuration file on which commands should be carried out; precede this path with the **#** symbol. Similarly, *commandpath* is the path of the command file; precede this path with the **@** symbol. Use the **/v** (verbose) option to cause all informational messages (not just error messages) to be displayed when the command file is running. Without the **/v** option, only error messages are displayed.

For example, to run a series of commands that result in a listing of the links and connections in a configuration file, create a file called SNA_CMD1.TXT, containing the following lines:

```
link /list
connection /list
```

Create a Snacfg Command File from a Configuration File

To create lines for a **snacfg** command file, you can type them, or you can generate them by using the **/print** option. The **/print** option accesses an existing configuration file and generates the command-line(s) required to add an individual resource or (depending on syntax) the entire configuration file.

The output generated by the **/print** option does not contain the word **snacfg**. This means that the output can be included in a **snacfg** command file.

See Also

Snacfg Reference

General Syntax for the /print Option

The syntax lines in this section and the next section show ways to use the **/print** option. By default, the output is sent to the screen. To capture the output in a file, redirect it in the standard way, by adding a greater-than sign (>) to the end of the command, followed by the name of the file in which you want to capture the output.

With all the syntax lines, if the source configuration file is not in the default path– \Program files\Host Integration Server\SYSTEM\CONFIG\COM.CFG–then for ***#configpath***, substitute a path, preceded by the pound sign (**#**). Do not type the square brackets. After the greater-than sign (**>**), type the name of the command file you want to create. (For information about using the greater-than sign or other methods of redirection, see your Windows documentation.)

The general syntax for the **/print** option is:

```
snacfg [#configpath] [resource [location:]resourcename] /print > cmdfile.ext
```

For *resource*, substitute the second word of a **snacfg** command (for example, **appcllu**, **connection**, or **server**). For *location*, if needed, substitute the server or connection name that uniquely locates a resource; for *resourcename*, substitute the name of the resource.

Examples of Syntax for the /print Option

The following examples illustrate the use of the **/print** option.

- To create a command file that can recreate an entire configuration file, type a command of the following form:

  ```
  snacfg [#configpath] /print > cmdfile.ext
  ```

- To create a command file from a particular connection in an existing configuration, type a command of the following form, substituting the name of the connection for *connectionname*:

  ```
  snacfg [#configpath] connection connectionname /print > cmdfile.ext
  ```

- To create a command file from a particular 3270 LU in an existing configuration, type a command of the following form, substituting the name of the LU for *luname*:

  ```
  snacfg [#configpath] lu luname /print > cmdfile.ext
  ```

After generating **snacfg** command files, you can modify them and then use them like any other **snacfg** command file.

Snacfg Reference

Use the /print Option

The **/print** option can make it easier to carry out repetitive configuration actions, if you have a detailed understanding of Host Integration Server 2004 configurations and of the **snacfg** command. Here are some ways of using the **/print** option:

Creating a new configuration

You can generate a **snacfg** command file corresponding to an entire configuration file, modify the command file, and use it to create a new configuration file for another subdomain or site. To generate the commands for an entire configuration file, use the syntax shown in the first example in the previous section; that is, omit all **snacfg** modifiers (such as **connection** or **lu**).

Creating a template to use for expanding one or more configurations

You can generate a **snacfg** command file that corresponds to a useful element of an existing configuration (for example, a 3270 LU in a configuration). Then you can modify the file and use it to add one or many similar elements to an existing configuration. Such a command file acts as a template for the element that it contains.

Modifying a configuration

You can generate a **snacfg** command file that corresponds to some part of an existing configuration (for example, an 802.2 connection in a configuration), modify the command file, and use it to modify the configuration file from which it came. This involves removing the **/add** option from lines in the command file, and making other changes that require a detailed understanding of the commands in the file.

See Also

Snacfg Reference

Display the Contents of a Configuration File

You can create a display of the entire contents of a configuration file by using the **/display** option with the following syntax:

```
snacfg [#configpath] /display
```

When you use the **/display** option, all the resources in the configuration file are displayed. For each resource, the display is the same as that from typing **snacfg** *resource resourcename*, where *resource* is the second word of a **snacfg** command (for example, **appcllu**, **connection**, or **server**), and *resourcename* is the name of the corresponding resource. (The exception to this is that the display of the "diagnostic" resource is the same as that from **snacfg diagnostic /list**.)

Use the /print Option

General Syntax for the /print Option

Snacfg APPCLLU

Purpose

Allows you add, delete, modify, or view a local APPC LU. Also allows you to view the command that would create a specified local APPC LU.

> **Note** Configuration settings specified with snacfg appcllu correspond to local APPC LU settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] appcllu /list
```

Recommended Syntax

```
snacfg [#configpath] appcllu servername:LUalias
snacfg [#configpath] appcllu LUalias /add
/server:servername [options]
snacfg [#configpath] appcllu servername:LUalias [options]
snacfg [#configpath] appcllu servername:LUalias /delete
snacfg [#configpath] appcllu servername:LUalias /print
```

Other Available Syntax

```
snacfg [#configpath] appcllu /list
snacfg [#configpath] appcllu LUalias
snacfg [#configpath] appcllu LUalias [options]
snacfg [#configpath] appcllu LUalias /delete
snacfg [#configpath] appcllu LUalias /print
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\System\CONFIG\COM.CFG.

/list
Generates a list of configured local APPC LUs.

*servername***:***LUalias*
Specifies the server name and LU alias of the local APPC LU on which to carry out actions. The server name should be in the format machine_name or \\machine_name\snaservr (for specifying the primary node on the machine) and \\machine_name\snasrv02 (or snasrv03, snasrv04, etc.) for specifying the secondary nodes on the machine.

It is recommended that *servername***:** be included in **snacfg appcllu** commands (other than **/add** commands) that include *LUalias*. Without *servername***:**, if there is more than one local LU called *LUalias* in the subdomain, it is difficult to predict which of these LUs will be affected by the command. The **snacfg appcllu** command does not necessarily default to the local server if *servername* is omitted.

See the following paragraphs for details about characters permitted in the LU alias.

If no options are specified after *LUalias*, the configuration settings, partner LUs, and modes are displayed for the specified LU.

LUalias
Specifies the LU alias of the local APPC LU on which to carry out actions. See the previous paragraphs and the syntax lists for recommendations about using the server name with the LU alias.

The LU alias can be from one through eight characters long, and can contain alphanumeric characters and the special characters %, $, #, and @. Lowercase letters are converted to uppercase. For a local APPC LU, the LU alias must be unique on the server.

> **Note** *LUalias* is used as the default LU name if **/luname:***text* is not specified.

If no options are specified after *LUalias*, the configuration settings, partner LUs, and modes are displayed for the specified LU.

/add
Adds a local APPC LU called *LUalias*. To configure the LU, either specify other options after **/add**, or specify configuration options in additional **snacfg appcllu** commands (using the same *LUalias*).

/connection:*conn-name*
When adding or modifying a dependent local APPC LU, this option is used to specify the LU's connection assignment.

/delete
Deletes the LU called *LUalias*.

/print
Causes the display of the **snacfg** command that would create the specified local APPC LU. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file.

Options for Local APPC LUs

/server:*servername*
Specifies the server to which to assign or move the APPC LU. When **/add** is used, this option is required. The server name should be in the format machine_name or \\machine_name\snaservr (for specifying the primary node on the machine) and \\machine_name\snasrv02 (or snasrv03, snasrv04, etc.) for specifying the secondary nodes on the machine.

/lunumber:*value*
Specifies the LU number. If an LU number of 0 is specified, the LU is configured as an independent local APPC LU.

/netname:"*text*"
Specifies a name for the network of this LU. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @.

If **/netname:***text* is not specified, the network name of the Host Integration Server 2004 on which the LU is located is used as the default.

> **Note** **/luname:***text* also has a default (the LU alias). Therefore, the fully qualified LU name (network name plus LU name) can potentially be created by default, if the LU alias and local network name are configured appropriately. A fully qualified LU name is required for an APPC LU.

/luname:"*text*"
Specifies the LU name. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. For a local APPC LU, the fully qualified LU Name (Network Name plus LU Name) must be unique on the server.

If **/luname:***text* is not specified, *LUalias* is used as the default LU name.

> **Note** **/netname:***text* also has a default (the network name of the server on which the LU is located). Therefore, the fully qualified LU name (network name plus LU name) can potentially be created by default, if the LU alias and local network name are configured appropriately. A fully qualified LU name is required for an APPC LU.

/comment:"*text*"
Adds an optional comment for the LU. The comment can contain as many as 25 characters; enclose the comment in quotes.

/autopartner:{ yes | no }
Specifies whether this LU will automatically be partnered with other APPC LUs.

If automatic partnering is left unspecified, the default is **yes**.

/defaultpool:{ yes | no }
Specifies whether this LU will be in the default outgoing local APPC LU pool. This pool makes LUs available for invoking TPs that do not specify a local LU.

/impremotelu:*remoteLUname*
Specifies an existing remote LU to be used as an implicit incoming remote LU for the local LU.

/tptimeout:*value*
Specifies the number of seconds that Host Integration Server 2004 should wait for the invokable TP to respond to a start request from the invoking TP.

/addpartner:*LUalias***,***mode*[**,***connection*]
Partners the local LU with the specified LU and the specified mode. Both *LUalias* and *mode* must exist before they can be specified as partners. If *LUalias* specifies a remote LU that is not unique on the server, the connection used by the remote LU must also be specified; otherwise, Host Integration Server 2004 will randomly choose one of the remote LUs called *LUalias* to act on.

Only one **/addpartner** option can be used in each command.

/delpartner:*LUalias***,***mode*[**,***connection*]
Deletes the pair listing that includes this local LU, the specified partner LU, and the specified mode. (Does not delete any LUs or

modes themselves.) If *LUalias* specifies a remote LU that is not unique on the server, the connection used by the remote LU must also be specified; otherwise, Host Integration Server 2004 will randomly choose one of the remote LUs called *LUalias* to act on.

Only one **/delpartner** option can be used in each command.

/syncpoint:{ yes | no }
Specifies if this Local APPC LU provides LU 6.2 SyncPoint support.
/clientname:"*text*"
Specifies client name if SyncPoint support is enabled.

Snacfg Reference

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Snacfg APPCRLU

Purpose

Allows you add, delete, modify, or view a remote APPC LU. Also allows you to view the command that would create a specified remote APPC LU.

> **Note** Configuration settings specified with snacfg appcrlu correspond to remote APPC LU settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] appcrlu /list
```

Recommended Syntax

```
snacfg [#configpath] appcrlu connectionname:LUalias
snacfg [#configpath] appcrlu LUalias /add
    /connection:connectionname [options]
snacfg [#configpath] appcrlu connectionname:LUalias [options]
snacfg [#configpath] appcrlu connectionname:LUalias /delete
snacfg [#configpath] appcrlu connectionname:LUalias /print
```

Other Available Syntax

```
snacfg [#configpath] appcrlu LUalias
snacfg [#configpath] appcrlu LUalias [options]
snacfg [#configpath] appcrlu LUalias /delete
snacfg [#configpath] appcrlu LUalias /print
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of configured remote APPC LUs.

*connectionname***:***LUalias*
Specifies the connection and LU alias of the remote APPC LU on which to carry out actions. You should include *connectionname***:** in **snacfg appcrlu** commands (other than **/add** commands) that include *LUalias*. Without *connectionname***:**, if there is more than one remote LU called *LUalias* in the subdomain, it is difficult to predict which of these LUs will be affected by the command. The **snacfg appcrlu** command does not necessarily default to a connection on the local server if *connectionname* is omitted.

See the following paragraphs for details about characters permitted in the LU alias.

If no options are specified after *LUalias*, the configuration settings, partner LUs, and modes are displayed for the specified LU.

LUalias
Specifies the LU alias of the remote APPC LU on which to carry out actions. See the previous paragraphs and the syntax lists for recommendations about using the connection name with the LU alias.

The LU alias can be from one through eight characters long, and can contain alphanumeric characters and the special characters %, $, #, and @. Lowercase letters are converted to uppercase. For a remote APPC LU, the LU alias must be unique on the connection, and must not match that of a local LU on that server.

If no options are specified after *LUalias*, the configuration settings, partner LUs, and modes are displayed for the specified LU.

/add
Adds a remote APPC LU called *LUalias*. To configure the LU, either specify other options after **/add**, or specify configuration options in additional **snacfg appcrlu** commands (using the same *LUalias*).

/delete
Deletes the LU called *LUalias*.

/print
Causes the display of the **snacfg** command that would create the specified remote APPC LU. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. See the information about command files earlier in this section.

Options for Remote APPC LUs

/connection:*connectionname*
Specifies the connection to which to assign or move the APPC LU. When **/add** is used, this option is required.

/netname:"*text*"
Specifies a name for the network of this LU. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @.

If **/netname:***text* is not specified, the remote network name configured for the connection supporting this LU is used as the default.

> **Note** **/luname:***text* also has a default (the LU alias). Therefore, the fully qualified LU name (network name plus LU name) can potentially be created by default, if the LU alias and remote network name are configured appropriately. A fully qualified LU name is required for an APPC LU.

/luname:"*text*"
Specifies the LU name. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. For a remote APPC LU, the fully qualified LU Name must be unique on the connection, and must not match that of a local LU on that server.

If **/luname:***text* is not specified, *LUalias* is used as the default LU name.

> **Note** **/netname:***text* also has a default (the remote network name configured for the connection supporting this LU). Therefore, the fully qualified LU name (LU name plus network name) can potentially be created by default, if the LU alias and remote control point name are configured appropriately. A fully qualified LU name is required for an APPC LU.

/comment:"*text*"
Adds an optional comment for the LU. The comment can contain as many as 25 characters; enclose the comment in quotes.

/autopartner:{ yes | no }
Specifies whether this LU will automatically be partnered with other APPC LUs.

If automatic partnering is left unspecified, the default is **yes**.

/parallelsess:{ yes | no }
Specifies whether the remote LU supports parallel sessions.

/uninterpname:"*text*"
Specifies the uninterpreted LU name, which is required only when using dependent APPC. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, @ and period (.).

/impmode:*modename*
Designates *modename* as the implicit incoming mode for this LU. A mode must exist before being specified as an implicit incoming mode.

/security:{ none | **hex,***text* | **char,***text* **}**
Configures session security for a remote LU using a cleartext key. The **none** option turns off session-level security. The **hex,***text* option specifies a 16-digit security key in hexadecimal. The **char,***text* option specifies an eight-character security key that can include uppercase and lowercase alphanumeric characters, and the special characters $, @, #, and the period (.).

/addpartner:*LUalias***,***mode*
Partners the remote LU with the specified local LU and the specified mode. Both the local LU and the mode must exist before they can be specified as partners. *LUalias* should specify a local LU, not a remote LU; otherwise, an error message is displayed, indicating that no such local LU can be found.

Only one **/addpartner** option can be used in each command.

/delpartner:*LUalias***,***mode*
Deletes the pair-listing that includes this remote LU, the specified local LU, and the specified mode. (Does not delete any LUs or modes themselves.)

Only one **/delpartner** option can be used in each command.

/securityex:{ none | **hex,***text* | **char,***text* **}**
Configures session security for a remote LU using a scrambled key. For security purposes, Snacfg displays the security key information in a scrambled format when the /securityex option is specified. To change the security key, use the /security option

instead.

Snacfg Connection

Purpose

Allows you to view, add, delete, or modify connections, including peer connections (necessary for APPC LUs) or downstream connections.

Before configuring a connection, you must configure the server and link service that the connection will use.

> **Note** Configuration settings specified with snacfg connection correspond to connection settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] connection /list
snacfg [#configpath] connection connectionname
snacfg [#configpath] connection connectionname /add /server:
    servername /conntype:{ 802.2 | sdlc | x25 | } [options]
snacfg [#configpath] connection connectionname [options]
snacfg [#configpath] connection connectionname /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of configured connections.

connectionname
Specifies a name for the connection to be configured or viewed. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. A new connection name cannot be the same as any other connection name in the installation, and cannot be the reserved name SNASERVR.

If no options are specified after *connectionname*, the command-line interface displays a list of the configuration settings for the specified connection.

/add
Adds a connection called *connectionname*. To configure the connection, either specify other options after **/add**, or specify configuration options in additional **snacfg connection** commands (using the same *connectionname*).

/delete
Deletes *connectionname*.

Options Used with All Connection Types

/server:*servername*
Specifies the server to which to assign or move the connection. When **/add** is used, this option is required. The server name should be in the format machine_name or \\machine_name\snaservr (for specifying the primary node on the machine) and \\machine_name\snasrv02 (or snasrv03, snasrv04, etc.) for specifying the secondary nodes on the machine.

/conntype:{ 802.2 | SDLC | X.25 | CHANNEL | TWINAX }
Specifies the connection type. When **/add** is used, this option is required.

/comment:"*text*"
Adds an optional comment for the specified connection. The comment can contain as many as 25 characters; enclose the comment in quotes.

/linkservice:*linkname*
Specifies the name of the link service to be used by *connectionname*. The link service type must match the connection type (802.2, SDLC, or X.25), or the **snacfg** command will not run.

In order for the link service to function correctly, it must be installed with the SNA Manager. Link services can also be installed with **snacfg link**; however, the SNA Manager is the recommended interface for installing link services, because it helps ensure that the resulting configuration is functional.

/activation:{ onserverstartup | ondemand | byadministrator }
For outgoing calls on *connectionname*, tells how the connection will be activated: on server startup, on demand, or by the

administrator. (For incoming calls, activation is irrelevant, since the connection always begins listening for calls on server startup.)

If no value has been specified for **/activation**, the default for 802.2 (token ring or Ethernet) connections is **onserverstartup**. For all other connections, the default is **ondemand**.

/localblockno:*hexdigits*
Specifies the local block number, a three-digit hexadecimal number. The local block number forms the first part of the Local Node ID, an eight-digit hexadecimal number that identifies the local system.

Do not use 000 or FFF for the local block number. These values are reserved.

For connections to host systems, the local block number should match IDBLK in VTAM.

/localnodeno:*hexdigits*
Specifies the local node number, a five-digit hexadecimal number. The local node number forms the last part of the Local Node ID, an eight-digit hexadecimal number that identifies the local system.

For connections to host systems, the local node number should match IDNUM in VTAM.

/cpname:*text*
Specifies the control point name of the remote node, as it is represented in Format 3 XIDs. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @.

The control point name of the remote node works together with **netname**. If either of these parameters is supplied, the other should also be supplied.

When connecting to a host system and using a remote control point name, the name should match the SSCPNAME parameter in the VTAM Start command for the remote SSCP (the VTAM system).

/netname:*text*
Specifies the name of the network for the remote node, as it is represented in Format 3 XIDs. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @.

The **netname** parameter works together with the control point name of the remote node. If either of these parameters is supplied, the other should also be supplied.

/remoteblockno:*hexdigits*
Specifies the remote block number, a three-digit hexadecimal number. The remote block number forms the first part of the Remote Node ID, an eight-digit hexadecimal number that identifies the remote system.

Do not use 000 or FFF for the remote block number. These values are reserved.

/remoteend:{ Host | Ppeer | downstream | PUPassThrough}
Specifies whether the connection is to be a host, peer, downstream, or passthrough.

/remotenodeno:*hexdigits*
Specifies the remote node number, a five-digit hexadecimal number. The remote node number forms the last part of the Remote Node ID, an eight-digit hexadecimal number that identifies the remote system.

/xidtype:{ format0 | format3 }
Specifies the XID type, the type of identifying information for Host Integration Server 2004 to send. The choices are **format0** (Format 0) and **format3** (Format 3). Format 0 sends only the Node ID. Format 3 sends up to 100 bytes of identifying information, including the local node ID and control point name.

If no XID type has been specified, the default is **format3**.

/calldirection:{ Incoming | Outgoing | Both }
This option specifies the call direction.

/channeladdress:*hex string*
Specifies the channel sub address for channel attach connections. *Hex string* is a two-digit hexadecimal number, valid range 00..FF.

/localsap:*hexnum*
Specifies the local System Access Point (SAP). Enter a hexadecimal number between 04 and EC that is a multiple of 4. For example, *snacfg connection thisconn /localsap:7C*.

/localcpname:*text*
The Local Control Point Name works with the Network Name to identify a system. The maximum length is eight characters.

/localnetname:*text*
The Local Network Name works with the Local Control Point Name to identify a system. The maximum length is eight characters.

/compression:{ None | RLE | LZ9 }

These options offer progressively better compression, but at a progressively higher CPU usage cost.

/passthruconn:*text*

Specifies the name of the PU Passthrough connection.

/peerdlcrole:{ Primary | Secondary | Negotiable }

Specifies the role used in peer-to-peer communications.

/dynamicludef:{ yes | no }

Specifies that this connection supports dynamic remote APPC LU allocation.

Additional Options Used with Downstream Connections

/insert: *luname***[,*luname*,...]**

Assigns a downstream LU or pool to a downstream connection. Separate multiple LU or pool names with commas.

The downstream LU or pool named by ***luname*** must already exist. (A downstream LU can be created with **snacfg LUD**, and a downstream pool can be created with **snacfg poold**.) The connection named by *connectionname* must be a downstream connection. If these conditions are not met, the command is not processed.

/remove: *luname***[,*luname*,...]**

Removes the assignment of a downstream LU or pool to a downstream connection. Separate multiple LU or pool names with commas.

Additional Options Used with 802.2 (Token Ring or Ethernet) Connections

/remotenetaddr:*hexdigits*

Specifies the 12-digit hexadecimal network address of the remote host to which this connection provides access.

If no remote network address has been specified, the default is 400000000000.

/remotesapaddr:*hexdigits*

Specifies the remote SAP address, which is a two-digit hexadecimal number, a multiple of 4, between 04 and EC. A value of 04 is recommended for most installations.

If no remote SAP address has been specified, the default is 04.

/maxbtulen:*value*

Specifies the maximum length for the BTU, which is the number of bytes that can be transmitted in a single data-link control frame.

The range is from 265 through 16393. If no maximum BTU length has been specified, the default is 1929.

/receiveackthresh:*value*

Specifies the receive ACK threshold, the maximum number of frames that the local system can receive from the remote system before sending a response.

The range is from 1 through 127. If no receive ACK threshold has been specified, the default is 2.

/naksendlimit:*value*

Specifies the unacknowledged send limit, the maximum number of frames that the local system can send without receiving a response from the remote system.

The range is from 1 through 127. If no unacknowledged send limit has been specified, the default is 1.

/retrylimit:*value*

Specifies the retry limit, the number of times that the local system should retransmit a frame if no response is received from the remote system.

The range is from 0 through 255. A value of 0 means the system uses its internal default retry limit. If no retry limit has been specified, the default is 10.

/xidretries:*value*

Specifies the XID retries, the number of times that the local system should retransmit an XID (an identifying message) if no response is received from the remote system.

The range is from 0 through 30. If no XID retries value has been specified, the default is 3.

/t1timeout:{ Default | 200ms | 400ms | 600ms | 800ms | 1000ms | 1s | 2s | 3s | 4s | 5s }

Specifies the amount of time that the local system should wait for the remote system to respond to a transmission before the local system tries again.

The values used for **Default** for **t1timeout** are 400 milliseconds for a local ring and 2 seconds for a remote ring.

/t2timeout:{ Default | 40ms | 80ms | 120ms | 160ms | 200ms | 400ms | 800ms | 1200ms | 1600ms | 2000ms }
Select the maximum amount of time that should be allowed before the local system sends an acknowledgment of a received transmission.

The values used for **Default** for **t2timeout** are 80 milliseconds for a local ring and 800 milliseconds for a remote ring.

/titimeout:{ Default | 1s | 2s | 3s | 4s | 5s | 10s | 15s | 20s | 25s }
Select the amount of time that the link can be inactive before the local system treats it as nonfunctioning and shuts it down.

The values used for **Default** for **titimeout** are 5 seconds for a local ring and 25 seconds for a remote ring.

/activatedelay:{ Default | 5s | 10s | 15s | 20s | 25s | 30s | 35s | 40s | 45s | 50s | 55s | 60s | 65s | 70s | 75s | 80s | 85s | 90s | 95s | 100s | 105s | 110s | 115s | 120s | 125s | 130s | 135s | 140s | 145s | 150s | 155s | 160s | 165s | 170s | 175s | 180s | 185s | 190s | 195s | 200s | 205s | 210s | 215s | 220s | 225s | 230s | 235s | 240s | 245s | 250s | 255s }
This value specifies the delay between successive attempts to activate a Host Integration Server 2004 connection.

/activateretrylimit:{ None | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 15 | 20 | 25 | 30 | 35 | 40 | 45 | 50 | 55 | 60 | 65 | 70 | 75 | 80 | 85 | 90 | 95 | 100 | 105 | 110 | 115 | 120 | 125 | 130 | 135 | 140 | 145 | 150 | 155 | 160 | 165 | 170 | 175 | 180 | 185 | 190 | 195 | 200 | 205 | 210 | 215 | 220 | 225 | 230 | 235 | 240 | 245 | 250 | 255 }
This option specifies the number of times the server will try to activate a connection.

Additional Options Used with SDLC Connections

/dialdata:*value*
Specifies the phone number stored for this connection. For a modem that accepts a phone number from Host Integration Server 2004 – that is, a modem attached to an SDLC adapter with a built-in serial (COM) port – the dial data specifies the telephone number for Host Integration Server 2004 to send to the modem. In this case, the number should be in the format expected by the modem. For manually dialed modems, the dial data is displayed in a pop-up message when the connection is started, and can be in any format.

/encoding:{ NRZI | NRZ }
Specifies the encoding scheme to be used by the modem. The choices are **nrzi**, nonreturn to zero inverted, and **NRZ**, nonreturn to zero.

The modem must use the same encoding scheme as the modem at the remote computer. For connections to host systems, the encoding scheme must match the value in the LINE/GROUP definition in VTAM.

If no encoding scheme has been specified, the default is NRZI.

/duplex:{ half | full }
Specifies the modem duplex setting. The choices are **half**, for a half-duplex modem, and **full**, for a full-duplex modem. If you want to use the full-duplex setting, one or more of your adapters must have the constant carrier option set. The constant carrier option is set in the SNA Manager. The constant carrier option can also be set with **snacfg link**; however, the SNA Manager is the recommended interface for setting the constant carrier option and other link service options.

Most Host Integration Server 2004 computers will use the default for duplex, **half**.

/datarate:{ high | low }
Specifies the data rate for transmissions between the Host Integration Server 2004 communications adapter and the modem. This rate can only be set for certain kinds of modems and adapters; for specific information, see the adapter and modem documentation.

A data rate of **high** gives faster transmissions; **low** gives more reliable transmissions and prevents the transmission errors sometimes caused by poor-quality lines at the high rate.

If no data rate has been specified, the default is **high**.

/polladdress:*hexdigits*
Specifies the poll address, a two-digit hexadecimal number. For connections to a host, the local poll address should match the VTAM PU definition for the ADDR= parameter.

Do not use 00 or FF for the poll address; these values are reserved. If no poll address has been specified, the default is C1.

/idletimeout:*value*
Specifies, in tenths of a second, the idle time-out. The idle time-out is the length of time that the local system should wait for the host to respond to a transmission, before the local system tries again. Too small a time-out can cause connection problems.

The range is from 1 (one-tenth of a second) through 300 (30 seconds). If no idle time-out has been specified, the default is 300 (30 seconds).

/idleretrylimit:*value*
Specifies the idle retry limit, the number of times the local system should try to poll or send data to the host if there is no

response.

The range is from 1 through 255. If no idle retry limit has been specified, the default is 10.

/contacttimeout:*value*
Specifies the contact time-out: the length of time, in tenths of a second, which the local system should wait between attempts to make a connection with a remote system.

The range is from 5 (five-tenths of a second) through 300 (30 seconds). If no contact time-out has been specified, the default is 300 (30 seconds).

/contactretrylimit:*value*
Specifies contact retry limit, the maximum number of times the local system should attempt to make a given connection.

The range is from 1 through 20. If no contact retry limit has been specified, the default is 10.

/switchedconntimeout:*value*
Specifies the switched connection establishment time-out; used for switched SDLC lines (standard telephone lines) only. The switched connection establishment time-out is the number of seconds that will be allowed for the user or modem to dial the remote computer's number.

This parameter is ignored by incoming calls.

The range is from 10 through 500 seconds. If no switched connection establishment time-out has been specified, the default is 300.

/multidropprimconn:{ yes | no }
Specifies whether this connection will be a multidrop primary connection.

A multidrop connection is one in which a primary node communicates with multiple secondary nodes concurrently over the same physical transmission medium.

/selectstandby:{ yes | no }
Specifies whether the modem's standby line is set to "on." Standby can only be set for certain kinds of modems; for specific information, see the modem documentation.

If no setting has been specified for standby, the default setting is **no**.

/sdlcmaxbtu:*value*
Specifies the maximum length for the BTU, which is the number of bytes that can be transmitted in a single data-link information frame.

The range is from 265 through 16393. If no maximum BTU length for SDLC has been specified, the default is 265.

/activatedelay:{ Default | 5s | 10s | 15s | 20s | 25s | 30s | 35s | 40s | 45s | 50s | 55s | 60s | 65s | 70s | 75s | 80s | 85s | 90s | 95s | 100s | 105s | 110s | 115s | 120s | 125s | 130s | 135s | 140s | 145s | 150s | 155s | 160s | 165s | 170s | 175s | 180s | 185s | 190s | 195s | 200s | 205s | 210s | 215s | 220s | 225s | 230s | 235s | 240s | 245s | 250s | 255s }
This value specifies the delay between successive attempts to activate a Host Integration Server 2004 connection.
/activateretrylimit:{ None | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 15 | 20 | 25 | 30 | 35 | 40 | 45 | 50 | 55 | 60 | 65 | 70 | 75 | 80 | 85 | 90 | 95 | 100 | 105 | 110 | 115 | 120 | 125 | 130 | 135 | 140 | 145 | 150 | 155 | 160 | 165 | 170 | 175 | 180 | 185 | 190 | 195 | 200 | 205 | 210 | 215 | 220 | 225 | 230 | 235 | 240 | 245 | 250 | 255 }
This option specifies the number of times the server will try to activate a connection.

Additional Options Used with SDLC Peer Connections

/multidropprimconn:{ yes | no }
Specifies whether this server is to be the primary station for a multidrop connection on a leased SDLC line.
/pollrate:*value*
Specifies the poll rate in polls per second.

The range is from 1 through 50. If no poll rate has been specified, the default is 5.

/activatedelay:{ Default | 5s | 10s | 15s | 20s | 25s | 30s | 35s | 40s | 45s | 50s | 55s | 60s | 65s | 70s | 75s | 80s | 85s | 90s | 95s | 100s | 105s | 110s | 115s | 120s | 125s | 130s | 135s | 140s | 145s | 150s | 155s | 160s | 165s | 170s | 175s | 180s | 185s | 190s | 195s | 200s | 205s | 210s | 215s | 220s | 225s | 230s | 235s | 240s | 245s | 250s | 255s }
This value specifies the delay between successive attempts to activate a Host Integration Server 2004
/activateretrylimit:{ None | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 15 | 20 | 25 | 30 | 35 | 40 | 45 | 50 | 55 | 60 | 65 | 70 | 75 | 80 | 85 | 90 | 95 | 100 | 105 | 110 | 115 | 120 | 125 | 130 | 135 | 140 | 145 | 150 | 155 | 160 | 165 | 170 | 175 | 180 | 185 | 190 | 195 | 200 | 205 | 210 | 215 | 220 | 225 | 230 | 235 | 240 | 245 | 250 | 255 }
This option specifies the number of times the server will try to activate a connection.

Additional Options Used with X.25 Connections

/remotex25addr:*hexdigits*
Specifies the remote X.25 address, which identifies the remote system on an X.25 network. The address usually consists of 12 hexadecimal digits, but can contain up to 15 hexadecimal digits.

/x25maxbtu:*value*
Specifies the maximum length for the BTU, which is the number of bytes that can be transmitted in a single data-link information frame.

The range is from 265 through 16393. If no maximum BTU length for X.25 has been specified, the default (for host connections) is 265.

/virtualcircuit:{ perm | switched }
Specifies the type of virtual circuit used by the connection. The choices are **perm** and **switched**. A **perm** circuit is constantly active and uses a preset destination address. A **switched** circuit is called and cleared dynamically, and uses a destination address that is supplied when the circuit is called.

If no virtual circuit type has been specified, the default is **switched**.

/pvcalias:*value* (for PVC only)
Specifies the PVC alias, the number that identifies the PVC channel: 1 for the first channel, 2 for the second, and so on. Used for PVCs only.

The range is from 1 through the number of configured PVC channels. If no PVC alias has been specified, the default is 1.

/packetsize:*value* (for PVC only)
Specifies packet size, the maximum number of data bytes (not header bytes) to be sent in a frame on this X.25 network. Used for PVCs only.

The possible values are 64, 128, 256, 512, and 1024. If no packet size has been specified, the default is 128.

/windowsize:*value* (for PVC only)
Specifies window size, the maximum number of frames that the local system can send without receiving a response from the remote system, on this X.25 network. Used for PVCs only.

The range is from 1 through 7. If no window size has been specified, the default is 2.

/facilitydata:*text* (for SVC only)
Specifies the codes for any facility data required by the network provider or by the administrator of the remote system. Used for SVCs only. Facility data can include as many as 126 hexadecimal characters (63 hexadecimal bytes).

Facility data is a coded string of information often used to request nondefault functions from the X.25 network for a particular SVC connection.

/userdata:*text* (for SVC only)
Specifies the codes for any user data required by the network provider. Used for SVCs only. The user data must be an even number of hexadecimal characters, up to the maximum of 32 characters.

User data is a coded string of information, specifying items such as the communications protocol used by the X.25 network (for SNA, this protocol must be QLLC, specified by C3).

The default for user data is C3; this specifies the QLLC protocol.

/activatedelay:{ Default | 5s | 10s | 15s | 20s | 25s | 30s | 35s | 40s | 45s | 50s | 55s | 60s | 65s | 70s | 75s | 80s | 85s | 90s | 95s | 100s | 105s | 110s | 115s | 120s | 125s | 130s | 135s | 140s | 145s | 150s | 155s | 160s | 165s | 170s | 175s | 180s | 185s | 190s | 195s | 200s | 205s | 210s | 215s | 220s | 225s | 230s | 235s | 240s | 245s | 250s | 255s }
This value specifies the delay between successive attempts to activate a Host Integration Server 2004 connection.

/activateretrylimit:{ None | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 15 | 20 | 25 | 30 | 35 | 40 | 45 | 50 | 55 | 60 | 65 | 70 | 75 | 80 | 85 | 90 | 95 | 100 | 105 | 110 | 115 | 120 | 125 | 130 | 135 | 140 | 145 | 150 | 155 | 160 | 165 | 170 | 175 | 180 | 185 | 190 | 195 | 200 | 205 | 210 | 215 | 220 | 225 | 230 | 235 | 240 | 245 | 250 | 255 }
This option specifies the number of times the server will try to activate a connection.

Additional Options Used with Channel Connections

/activatedelay:{ Default | 5s | 10s | 15s | 20s | 25s | 30s | 35s | 40s | 45s | 50s | 55s | 60s | 65s | 70s | 75s | 80s | 85s | 90s | 95s | 100s | 105s | 110s | 115s | 120s | 125s | 130s | 135s | 140s | 145s | 150s | 155s | 160s | 165s | 170s | 175s | 180s | 185s | 190s | 195s | 200s | 205s | 210s | 215s | 220s | 225s | 230s | 235s | 240s | 245s | 250s | 255s }
This value specifies the delay between successive attempts to activate a Host Integration Server 2004 connection.

/activateretrylimit:{ None | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 15 | 20 | 25 | 30 | 35 | 40 | 45 | 50 | 55 | 60 | 65 | 70 | 75 | 80 | 85 | 90 | 95 | 100 | 105 | 110 | 115 | 120 | 125 | 130 | 135 | 140 | 145 | 150 | 155 | 160 | 165 | 170 | 175 | 180 | 185 | 190 | 195 | 200 | 205 |

210 | **215** | **220** | **225** | **230** | **235** | **240** | **245** | **250** | **255** **}**

This option specifies the number of times the server will try to activate a connection.

/controlunit: *value (0x0-0xf)*

Sets the value of the control unit image number.

Snacfg CPIC

Purpose

Allows you add, delete, modify, or view a CPI-C symbolic destination name. Also allows you to view the command that would create a specified CPI-C symbolic destination name.

> **Note** Settings specified with snacfg cpic correspond to CPI-C symbolic destination names configured with the SNA Manager.

Syntax

```
snacfg [#configpath] cpic /list
snacfg [#configpath] cpic cpicname
snacfg [#configpath] cpic cpicname /add
    { /appltpname:text  |  /svcetpname:hexstring }
    { /b:text /luname:text  |  /lualias:text }
    /modename:text /seckeytype:{ none | same | program }
    [/secuserid:text] [/secpassword:text] [/comment:text]
snacfg [#configpath] cpic cpicname [options]
snacfg [#configpath] cpic cpicname /delete
snacfg [#configpath] cpic cpicname /print
```

where

#configpath
: Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
: Generates a list of configured symbolic destination names.

cpicname
: Specifies the symbolic destination name on which to carry out actions. A symbolic destination name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @.

If no options are specified after *cpicname*, the configuration settings for the specified symbolic destination name are displayed.

/add
: Adds a symbolic destination name called *cpicname*. When you use the **/add** option, you must include the other options shown in the preceding syntax.

/delete
: Deletes *cpicname*.

/print
: Causes the display of the **snacfg** command that would create the specified symbolic destination name. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. See the information about command files earlier in this section.

Options for CPI-C Commands

/comment:"*text*"
: Adds an optional comment for the symbolic destination name. The comment can contain as many as 25 characters; enclose the comment in quotes.

Partner TP options (use one or the other, but not both):

/appltpname:"**text**"
: Specifies that the partner TP is an application TP, and provides the name. The name can be from 1 through 64 characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase.

If you specify both an application TP name and a service TP name in the same command, the command is rejected. If you specify an application TP for an existing symbolic destination name, it overrides any previous TP name (whether application TP or service TP).

/svcetpname:**hexstring**
: Specifies that the partner TP is a service TP, and provides the hexadecimal string identifying the TP. The string can be from one through eight hexadecimal digits long.

If you specify both a service TP name and an application TP name in the same command, the command is rejected. If you specify a service TP for an existing symbolic destination name, it overrides any previous TP name (whether application TP or service TP).

Partner LU options (use one or the other, but not both):
/netname:"**text**" /luname:"**text**"
Identifies the partner LU by fully qualified LU name (network name plus LU name). Each part of the fully qualified name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase.

If you specify both a fully qualified LU name and an LU alias in the same command, the command is rejected. If you specify a fully qualified LU name for an existing symbolic destination name, it overrides any previous LU setting (whether name or alias).

/lualias:"**text**"
Identifies the partner LU by LU alias. The alias can be from one through eight characters long, and can contain alphanumeric characters and the special characters %, $, #, and @. Lowercase letters are converted to uppercase.

If you specify both an LU alias and a fully qualified LU name in the same command, the command is rejected. If you specify an LU alias for an existing symbolic destination name, it overrides any previous LU setting (whether name or alias).

/modename:"*text*"
Specifies the mode. The mode must already exist.
/seckeytype:{ none | **same** | **program }**
Sets the conversation security type. If **program** is specified, one or both of the following options can be set:
/secuserid:"**text**"
Specifies the user ID to use when the security type is **program**. The ID can contain from 1 through 10 characters.
/secpassword:"**text**"
This parameter is optional; it specifies the password to use with the user ID. The password can contain from 1 through 10 characters. A password need not be specified even if the security type is **program** and the user ID is set. If a display is created showing the symbolic destination name, the password will not be displayed.

Snacfg Diagnostic

Purpose

Allows you to view and configure settings for event logging (auditing), and view or change the connection designated to receive NetView alerts.

> **Note** Configuration settings specified with snacfg diagnostic correspond to diagnostic settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] diagnostic /list
snacfg [#configpath] diagnostic [options]
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list that tells the settings for event logs (auditing), the name of the NetView management connection (if one has been specified), and the default connection for the **DISPLAY** verb (if one has been specified).

/logserver:*servername*
Specifies a centralized server on which event logs for this Host Integration Server 2004 installation should be stored.

If **/logserver:** is typed without *servername*, the setting reverts to the default, which is to store event logs for the local server on the local server.

/auditlevel:{ 6 | 8 | 10 | off }
Sets the level of Host Integration Server 2004 events to be recorded in the Windows Event Log. These events can be viewed with the Windows Event Viewer, which is described in the Windows documentation. The following table describes the available levels:

Level	Description	Events to be recorded
6	Detailed problem analysis	All events that can be recorded
8	General information messages	General activity but not all events
10	Significant system events	Major events only
off	Auditing disabled	No events

/popupserver:*servername*
Specifies the server to which pop-up error messages for this Host Integration Server 2004 installation should be routed.

Pop-up messages will always appear on the local server; routing them to a remote server means they will appear on both the remote and local server.

If **/popupserver:** is typed without *servername*, the setting reverts to the default, which is the local server.

/netviewconn:*connectionname*
Specifies the name of the connection through which NetView alerts are sent. The connection called *connectionname* must already exist.

If **/netviewconn:** is typed without *connectionname,* the setting is cleared so that the configuration contains no NetView connection name.

/cnosdisplayconn:*connectionname*
Specifies the default connection to be used for the **DISPLAY** verb when no connection is provided. The connection called *connectionname* must already exist.

If **/cnosdisplayconn:** is typed without *connectionname*, the setting is cleared so that the configuration contains no default connection for the **DISPLAY** verb.

Snacfg Reference

Snacfg LINK

Purpose

Allows you to view, delete, or modify adapters.

> **Note** This command has been superceded by **Linkcfg**, as described in About Linkcfg.
>
> **Important** If you specify adapter properties with **snacfg link**, these properties must match existing properties in your installation, or a nonfunctioning configuration may result. To protect against errors with **snacfg link**, use the SNA Manager instead.

Before configuring link services, you must use the SNA Manager to add the server on which the link services will be located.

Syntax

```
snacfg [#configpath] link /list
```

Recommended Syntax

```
snacfg [#configpath] link servername:linkname
snacfg [#configpath] link servername:linkname /add [options]
snacfg [#configpath] link servername:linkname [options]
snacfg [#configpath] link servername:linkname /delete
```

Other Available Syntax

```
snacfg [#configpath] link linkname
snacfg [#configpath] link linkname /add [options]
snacfg [#configpath] link linkname [options]
snacfg [#configpath] link linkname /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of configured link services.

servername
Specifies the name of the server on which to view or change link services. Separate the name of the server from the name of the link service with a colon (**:**). It is recommended that *servername* be included in every **snacfg link** command that includes *linkname*. Without *servername*, if there is more than one link service called *linkname* in the installation, it is difficult to predict which link service called *linkname* will be affected by the command. The **snacfg link** command does not necessarily default to the local server if *servername* is omitted.

linkname
Specifies the name of the link service to view, modify, or delete. Link services names can contain from one through eight alphanumeric characters.

For adding link services, the recommended method is to use the SNA Manager, not **snacfg link**.

If no options are specified after *linkname*, the result is a list of the configuration settings for the specified link.

/add
Adds a link service called *linkname*. To configure the link service, either specify other options after **/add**, or specify configuration options in additional **snacfg link** commands (using the same *servername***:***linkname* combination).

For adding link services, the recommended method is to use the SNA Manager, not **snacfg link**.

/delete
Deletes *linkname*.

Options for Link Services

/server:*servername*
Specifies the server on which to install the link service.

/linktype:{ Token | **Ether** | **SDLC** | **X25** | **Channel | Twinax }**
Specifies the type of adapter with which *linkname* works.

/linetype:{ leased | **softdial** | **manual }** (for SDLC lines only)
Specifies the type of SDLC line (and, where applicable, the modem) that the link service will use:

- A **leased** line is a telecommunications line committed solely to SDLC communications with a particular remote system.
- A **softdial** line is a switched SDLC line on which the modem is dialed automatically by Host Integration Server 2004. Such a modem must be attached to an SDLC adapter with a built-in serial (COM) port. Otherwise it is considered a **manual** modem.
- A **manual** line is a switched SDLC line on which the modem stores a phone number, or on which the modem is dialed manually.

/carrier:{ on | **off }** (for SDLC lines only)
Specifies whether the constant carrier option for an SDLC line is **on** or **off**.

Snacfg LU

Purpose

Allows you to view, add, delete, or modify 3270 LUs, on three types of connections: 802.2, SDLC, and/or X.25. Also allows you to assign 3270 LUs to LU pools that have already been configured.

Before configuring an LU, you must configure the connection that the LU will use. Also, before assigning an LU to an LU pool, you must create the LU and the LU pool.

> **Note** Configuration settings specified with snacfg lu correspond to 3270 LU settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] lu /list
snacfg [#configpath] lu luname
snacfg [#configpath] lu luname /add /connection:connectionname
    /lunumber:value [options]
snacfg [#configpath] lu luname [options]
snacfg [#configpath] lu luname /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of configured 3270 LUs.

luname
Specifies the name of the 3270 LU to view, add, modify, or delete. A 3270 LU name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. A 3270 LU name cannot be the same as any other LU name or pool name (except for APPC LU names) on the server.

If no options are specified after *luname,* the result is a list of the configuration settings for the specified LU.

/add
Adds a 3270 LU called *luname*. To configure the 3270 LU, either specify other options after **/add**, or specify configuration options in additional **snacfg lu** commands (using the same *luname*).

/delete
Deletes *luname*.

Options for 3270 LUs

/connection:*connectionname*
Specifies the connection to which the 3270 LU should be assigned or moved. When **/add** is used, this option is required.

/lunumber:*value*
Specifies the LU number, which identifies the LU on its connection. When /**add** is used, this option is required. Check with the administrator of the host system for the correct value; it should match the LOCADDR= parameter of the LU definition in VTAM or the NCP Gen on the host.

If the number that you specify has already been assigned to an LU or an APPC LU-LU pair on the intended connection, the command fails.

The range is from 1 through 254.

/pool:*poolname*
Assigns or moves the 3270 LU to *poolname*. A 3270 LU can be assigned to only one pool.

The pool specified with *poolname* must already exist. A 3270 LU pool can be created with the **snacfg pool** command.

If **/pool:** is typed without *poolname*, the specified LU is removed from whichever pool it is assigned to.

/lutype:{ display | printer }
Specifies whether the 3270 LU will be used for **display** (terminal emulation) or a **printer** (that is, a local printer or a local-area network printer, attached to a PC).

If no LU type has been specified, the default is **display**.

/displaymodel:{ mod2 | mod3 | mod4 | mod5 | 2 | 3 | 4 | 5 }
Specifies the display model; applies only when the **lutype** is **display**. The following display types are available:

- Model 2 is 24 lines by 80 characters.
- Model 3 is 32 lines by 80 characters.
- Model 4 is 43 lines by 80 characters.
- Model 5 is 27 lines by 132 characters.

Some emulators can only emulate certain display models. For more information, see your emulator documentation.

When a 3270 display LU is assigned to a 3270 LU pool, the display model setting of the pool overrides the setting of the LU.

If no display model has been specified, the default is Model 2.

/allowmodeloverride:{ yes | no }
Specifies whether the user is allowed to override the display model type by using the 3270 terminal emulation program.

When a 3270 display LU is assigned to a 3270 LU pool, the model override setting of the pool overwrites the setting of the LU.

If no setting has been specified for this parameter, the default is **no**.

/associate:"*text*"
This allows you to associate a specific 3270 printer LU with a 3270 display LU. Any user or group with permission to use the display LU will also have access to the associate printer LU. The text is the printer LU name.

/unassociate:"*text*"
This allows you to unassociate a 3270 printer LU from a 3270 display LU. It is not necessary to enter any text. **Snacfg** will ignore the text and unassociate the LU. To unassociate the printer LU, use the display LU name.

/comment:"*text*"
Adds an optional comment for the specified LU. The comment can contain as many as 25 characters; enclose the comment in quotes.

Snacfg LUA

Purpose

Allows you to view, add, delete, or modify LUA LUs on three types of connections: 802.2, SDLC, and/or X.25. Also allows you to assign LUA LUs to LU pools that have already been configured.

Before configuring an LU, you must configure the connection that the LU will use. Also, before assigning an LU to an LU pool, you must create the LU and the LU pool.

> **Note** Configuration settings specified with snacfg lua correspond to LUA LU settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] lua /list
snacfg [#configpath] lua luname
snacfg [#configpath] lua luname /add /connection:connectionname
    /lunumber:value [options]
snacfg [#configpath] lua luname [options]
snacfg [#configpath] lua luname /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of configured LUA LUs.

luname
Specifies the name of the LUA LU to view, add, modify, or delete. An LUA LU name can be from one through eight characters long and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. An LUA LU name cannot be the same as any other LU name or pool name (except for APPC LU names) on the server.

If no options are specified after *luname*, the result is a list of the configuration settings for the specified LU.

/add
Adds an LUA LU called *luname*. To configure the LUA LU, either specify other options after **/add**, or specify configuration options in additional **snacfg lua** commands (using the same *luname*).

/delete
Deletes *luname*.

Options for LUA LUs

/connection:*connectionname*
Specifies the connection to which the LUA LU should be assigned or moved. When **/add** is used, this option is required.

/lunumber:*value*
Specifies the LU number, which identifies the LU on its connection. When **/add** is used, this option is required. Check with the administrator of the host system for the correct value; it should match the LOCADDR= parameter of the LU definition in VTAM or the NCP Gen on the host.

If the number that you specify has already been assigned to an LU or an APPC LU-LU pair on the intended connection, the command fails.

The range is from 1 through 254.

/pool:*poolname*
Assigns or moves the LUA LU to *poolname*. An LUA LU can be assigned to only one pool. The pool specified with *poolname* must already exist. An LUA LU pool can be created with the **snacfg poola** command.

If **/pool:** is typed without *poolname*, the specified LU is removed from whichever pool it is assigned to.

/highpriority:{ yes | no }
Specifies whether this LU will be given priority over low-priority LUs.

When an LUA LU is assigned to an LUA LU pool, the priority setting of the pool overwrites the priority setting of the LU.

/comment:"*text*"

Adds an optional comment for the specified LU. The comment can contain as many as 25 characters; enclose the comment in quotes.

Snacfg LUD

Purpose

Allows you to view, add, delete, or modify downstream LUs. Also allows you to assign downstream LUs to LU pools that have already been created, and allows you to view the command that would create a specified downstream LU.

> **Note** Configuration settings specified with **snacfg lud** correspond to downstream LU settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] lud /list
snacfg [#configpath] lud luname
snacfg [#configpath] lud luname /add /connection:connectionname
    /lunumber:value [options]
snacfg [#configpath] lud luname [options]
snacfg [#configpath] lud luname /delete
snacfg [#configpath] lud luname /print
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of configured downstream LUs.

luname
Specifies the name of the downstream LU to view, add, modify, or delete. A downstream LU name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The name cannot be the same as any other LU or pool name that uses this connection.

If no options are specified after *luname*, the result is a list of the configuration settings for the specified LU.

/add
Adds a downstream LU called *luname*. To configure the downstream LU, either specify other options after **/add**, or specify configuration options in additional **snacfg lud** commands (using the same *luname*).

/delete
Deletes *luname*.

/print
Causes the display of the **snacfg** command that would create the specified downstream LU. The displayed command does not contain the word **snacfg**, so it can be redirected to a command file. See the information about command files earlier in this section.

Options for Downstream LUs

/connection:connectionname
Specifies the connection to which the downstream LU should be assigned or moved. When **/add** is used, this option is required.

/lunumber:*value*
Specifies the LU number, which identifies the LU on its connection. When **/add** is used, this option is required. Check with the administrator of the host system for the correct value; it should match the LOCADDR= parameter of the LU definition in VTAM or in the NCP Gen.

The LU number identifies the LU to the host system.

If the number you specify has already been assigned to an LU or an APPC LU-LU pair on the intended connection, the command fails.

The range is from 1 through 254.

/pool:*poolname*
Assigns or moves the downstream LU to *poolname*. A downstream LU can be assigned to only one pool. The pool specified with *poolname* must already exist. A downstream LU pool can be created with the **snacfg poold** command.

If **/pool:** is typed without *poolname*, the specified LU is removed from whichever pool it is assigned to.

/comment:"*text*"

Adds an optional comment for the specified LU. The comment can contain as many as 25 characters; enclose the comment in quotes.

Snacfg Mode

Purpose

Allows you add, delete, modify, or view an APPC mode. Also allows you to view the command that would create a specified mode.

> **Note** Configuration settings specified with snacfg mode correspond to APPC mode settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] mode /list
snacfg [#configpath] mode modename
snacfg [#configpath] mode modename /add [options]
snacfg [#configpath] mode modename [options]
snacfg [#configpath] mode modename /delete
snacfg [#configpath] mode modename /print
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of configured modes.

modename
Specifies the name of the mode on which to carry out actions. A mode name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The mode name cannot be the same as any other mode name in the subdomain of the server.

If no options are specified after *modename*, the configuration settings for the specified mode are displayed.

/add
Adds a mode called *modename*. To configure the mode, either specify other options after **/add**, or specify configuration options in additional **snacfg mode** commands (using the same *modename*).

/delete
Deletes *modename*.

/print
Causes the display of the **snacfg** command that would create the specified mode. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. See the information about command files earlier in this section.

Options for APPC Modes

/comment:"*text*"
Adds an optional comment for the mode. The comment can contain as many as 25 characters; enclose the comment in quotes.

/sessionlim:*value*
Specifies the parallel session limit.

The range is from 1 through 254. If no parallel session limit has been specified, the default is 1.

/conwin:*value*
Specifies the minimum contention winner limit.

The range is from 0 through the parallel session limit. If no minimum contention winner limit has been specified, the default is 0.

/conlose:*value*
Specifies the partner minimum contention winner limit.

The range is from 0 through the parallel session limit. If no partner minimum contention winner limit has been specified, the default is 0.

/autoact:*value*
Specifies the automatic activation limit.

The range is from 0 through the minimum contention winner limit.

/autopartner:{ yes | no }
Specifies whether this mode will be used in automatic partnering of APPC LUs.

If automatic partnering is left unspecified, the default is **yes**.

/highpriority:{ yes | no }
Specifies whether communication with this mode will be given preference over low-priority communication.

If the high-priority setting is left unspecified, the default is **yes**.

/pacesendcnt:*value*
Specifies the pacing send count. A value of 0 represents an unlimited number of frames.

The range is from 0 through 63. If no pacing send count has been specified, the default is 4.

/pacerecvcnt:*value*
Specifies the pacing receive count. A value of 0 represents an unlimited number of frames.

The range is from 0 through 63. If no pacing receive count has been specified, the default is 4.

/maxsendru:*value*
Specifies the maximum size for RUs sent by the TP(s) on the local system.

The range is from 256 through 16384. If no maximum send RU size has been specified, the default is 1024.

/maxrecvru:*value*
Specifies the maximum size for RUs received from the TP(s) on the remote system.

The range is from 256 through 16384. If no maximum receive RU size has been specified, the default is 1024.

/maxsendcomp:{ None | RLE | LZ9}
These options offer progressively better compression, but at a progressively higher CPU usage cost.

/maxrecvcomp:{ None | RLE | LZ9}
These options offer progressively better compression, but at a progressively higher CPU usage cost.

/allowcomp:{ yes | no}
If LZ9 is used, this option controls whether data is compressed using RLE before being further compressed using LZ9.

/endpointcomp:{ yes | no}
This option controls whether intermediate nodes may use compression if one of the endpoints does not support compression or does not wish to use it.

Snacfg Pool

Purpose

Allows you to view, add, delete, or modify 3270 LU pools.

To assign existing 3270 LUs to a 3270 LU pool, first configure the pool with the **snacfg pool** command (including options), then add the LUs with the **snacfg lu** command (using the **/pool:***poolname* option).

> **Note** Configuration settings specified with snacfg pool correspond to 3270 LU pool settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] pool /list
snacfg [#configpath] pool poolname
snacfg [#configpath] pool poolname /add [options]
snacfg [#configpath] pool poolname [options]
snacfg [#configpath] pool poolname /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of configured 3270 LU pools.

poolname
Specifies the name of the 3270 LU pool to view, add, modify, or delete. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The name cannot be the same as any other pool name or LU name (other than APPC LU names) in the installation.

If no options are specified after *poolname*, the result is a list of the configuration settings for the specified pool.

/add
Adds a 3270 LU pool called *poolname*. To configure the 3270 LU pool, either specify other options after **/add**, or specify configuration options in additional **snacfg pool** commands (using the same *poolname*).

/delete
Deletes *poolname*.

Options for 3270 LU Pools

/displaymodel:{ mod2 | mod3 | mod4 | mod5 | 2 | 3 | 4 | 5 }
Specifies the model number of the LUs that will be added to this pool. (Only display LUs can be pooled; printer LUs cannot be pooled.) The following display models are available:

- Model 2 is 24 lines by 80 characters.
- Model 3 is 32 lines by 80 characters.
- Model 4 is 43 lines by 80 characters.
- Model 5 is 27 lines by 132 characters.

Some emulators can only emulate certain display models. For more information, see your emulator documentation.

The display model setting of a pool overwrites the setting of any 3270 LU assigned to the pool.

If no display model has been specified for a pool, the default is Model 2.

/allowmodeloverride:{ yes | no }
Specifies whether the user is allowed to override the display model type of the LU by using the 3270 terminal emulation program.

The model override setting of a pool overwrites the setting of any 3270 LU assigned to the pool.

If no setting has been specified for this parameter, the default is **no**.

/comment:"*text*"
Adds an optional comment to the specified 3270 LU pool. The comment can contain as many as 25 characters; enclose the comment in quotes.

/assocprint:{ yes | no }
Specifies that the LU pool contains display LUs with associated 3270 printers.

See Also

Snacfg Reference

Snacfg PoolA

Purpose

Allows you to view, add, delete, or modify LUA LU pools.

To assign existing LUA LUs to an LUA LU pool, first configure the pool with the **snacfg poola** command (including options), then add the LUs with the **snacfg lua** command (using the **/pool:***poolname* option).

> **Note** Configuration settings specified with snacfg poola correspond to LUA LU pool settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] poola /list
snacfg [#configpath] poola poolname
snacfg [#configpath] poola poolname /add [options]
snacfg [#configpath] poola poolname [options]
snacfg [#configpath] poola poolname /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of configured LUA LU pools.

poolname
Specifies the name of the LUA LU pool to view, add, modify, or delete. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The name cannot be the same as any other pool name or LU name (other than APPC LU names) in the installation.

If no options are specified after *poolname*, the result is a list of the configuration settings for the specified pool.

/add
Adds an LUA LU pool called *poolname*. To configure the LUA LU pool, either specify other options after **/add**, or specify configuration options in additional **snacfg poola** commands (using the same *poolname*).

/delete
Deletes *poolname*.

Options for LUA LU Pools

/highpriority:{ yes | no }
Specifies whether LUs in this pool will be given priority over low-priority LUs. The priority setting of a pool overwrites the setting of any LUA LU assigned to the pool.

/comment:"*text*"
Adds an optional comment to the specified LUA LU pool. The comment can contain as many as 25 characters; enclose the comment in quotes.

See Also

Snacfg Reference

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Snacfg PoolD

Purpose

Allows you to view, add, or delete downstream LU pools. Also allows you to view the command that would create a specified downstream LU pool.

To assign existing downstream LUs to a downstream LU pool, first configure the pool with the **snacfg poold** command; then add the LUs with the **snacfg lud** command (using the **/pool:***poolname* option).

Syntax

```
snacfg [#configpath] poold /list
snacfg [#configpath] poold poolname
snacfg [#configpath] poold poolname [/add] [/comment: text]
snacfg [#configpath] poold poolname /delete
snacfg [#configpath] poold poolname /print
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of configured downstream LU pools.

poolname
Specifies the name of the downstream LU pool to view, add, or delete. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The name cannot be the same as any other pool name or LU name (other than APPC LU names) in the subdomain.

If no options are specified after *poolname*, the result is a list of the configuration settings for the specified pool.

/add
Adds a downstream LU pool called *poolname*.

/delete
Deletes *poolname*.

/print
Causes the display of the **snacfg** command that would create the specified downstream LU pool. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. See the information about command files earlier in this section.

/comment:"*text*"
Adds an optional comment to the specified downstream LU pool. The comment can contain as many as 25 characters; enclose the comment in quotes.

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Snacfg PrintServer

Purpose

Allows you to add, delete, or view printer servers from one subdomain or multiple subdomains.

> **Note** Configuration settings specified with snacfg printserver correspond to settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] printserver /list
snacfg [#configpath] printserver servername /add
snacfg [#configpath] printserver servername /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of print servers in the Host Integration Server 2004 subdomain.

/add
Adds the print server name of the Host Integration Server 2004 computer that is running the Host Integration Server Host Print Service. To configure the server name, specify the name after the **/add**. The print server name must match the computer name of the computer running Host Print Service.

You can add print servers for Host Integration Server 2004 computers that do not yet exist. For example, you can prepare a configuration file to be used at another location and add the server names using this parameter. Until the computers are configured with Host Integration Server 2004 running Host Print Service, SNA Manager will show them as offline.

/delete
Deletes the print server.

See Also

Snacfg Reference

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

Snacfg PrintSession3270

Purpose

Allows you to add, delete, modify, or view 3270 print sessions defined in the Host Print Service.

> **Note** Configuration settings specified with snacfg printsession3270 correspond to local print server settings configured with the SNA Manager.
>
> The /feedignorefinal option is no longer supported. By default, this value is enabled. A PDF file can be used to control this behavior if required.

Syntax

```
snacfg [#configpath] printsession3270name /list
snacfg [#configpath] printsession3270name /print
snacfg [#configpath] printsession3270 printsession3270name /add
   /server:servername /luname:LUname[options]
snacfg [#configpath] printsession3270 printsession3270name [options]
snacfg [#configpath] printsession3270 printsession3270name /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of 3270 print sessions.

/print
Displays a list of the configuration settings of a print session. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add
Adds a print session to the Host Print Service. To configure the print session, you must specify the server name and the configured 3270 printer LU name after the **/add** using the **/server:***servername* and **/luname:***Luname* options.

/delete
Deletes the printer session. To delete the print session, you must specify the server name and the configured 3270 printer LU name after the **/delete**.

Options for 3270 Print Sessions

/autoactivate:{ yes | no }
Specifies whether the printer session will automatically activate when Host Integration Server 2004 is started. The default is yes.

/bestfit:{ yes | no }
Specifies whether to scale the output to the paper size. The default is **yes**.

/codepage: {Country | Custom}
This defines the host code page language in which the print jobs are output. The default is **Country** and the default language is **English (United States) [037]**. To change the default language, provide the number of the host code page of the country/region you want with the **/country** option.

If you want to use a custom file for the host code page, you must use **/customfile:***text*, where the *text* value is the name of the file containing the specifications for the print job.

Host Code Page Numbers and Corresponding Language

Host Code Page Number	Language

/collate:{ yes | no }

Adds an option to collate pages sequentially.

/color:{ yes | no }

For color printers, printing will be gray scale if no is selected.

/comment:"*text*"

Adds an optional comment for the printer session. It can contain as many as 25 characters; enclose the comment in quotes.

/copies:*value*

Specifies the number of copies for printing.

/country:*value*

Specifies the language in which the print jobs are printed.

/customfile:"*text*"

Specifies the name of the file containing the custom language translation information. Use this option if you specify **/codepage:custom**.

/devicename:"*text*"

Specifies the name of the destination printer.

/duplex:*simplex* | *horizontal* | *vertical*

Specifies printing on two-sided paper.

/filterfile:"*text*"

The **/filterfile** is a defined programming API that allows you to pass the printer data stream to a third party or user supplied DLL. Enter text to signify where the printer data stream should go.

/font:"*text*"

Specifies the font to be used in the printer sessions. This can be any available font installed on the computer.

/formname:*string*

Specifies the name for the form.

/margin:*left, right, top, bottom*

Specifies the margins of the page in inches in the order of left, right, top, bottom. The default margins are 0".

/orientation:*portrait, landscape*

Specifies the page layout as portrait or landscape.

/papersize:*value*

Specifies the size of the paper for printing.

Valid Values and Descriptions for Papersize

Value	Constant Name (from wingdi.h)	Description
1	DMPAPER_LETTER	Letter, 8.5" x 11"
2	DMPAPER_LETTERSMALL	Letter Small, 8.5" x 11"
3	DMPAPER_TABLOID	Tabloid, 11" x 17"
4	DMPAPER_LEDGER	Ledger, 17" x 11"
5	DMPAPER_LEGAL	Legal, 8.5" x 14"
6	DMPAPER_STATEMENT	Statement, 5.5" x 8.5"
7	DMPAPER_EXECUTIVE	Executive, 7.25" x 10.5"
8	DMPAPER_A3	A3 Sheet, 297 x 420mm
9	DMPAPER_A4	A4 Sheet, 210 x 297mm
10	DMPAPER_A4SMALL	A4 Small Sheet, 210 x 297mm
11	DMPAPER_A5	A5 Sheet, 148 x 210mm
12	DMPAPER_B4	B4 Sheet, 250 x 354mm
13	DMPAPER_B5	B5 Sheet, 182 x 257mm
14	DMPAPER_FOLIO	Folio, 8.5" x 13"
15	DMPAPER_QUARTO	Quarto, 215 x 275mm
16	DMPAPER_10X14	10" x 14" Sheet
17	DMPAPER_11X17	11" x 17" Sheet
18	DMPAPER_NOTE	Note, 8.5" x 11"
19	DMPAPER_ENV_9	#9 Envelope, 3.875" x 8.875"
20	DMPAPER_ENV_10	#10 Envelope, 4.125" x 9.5"
21	DMPAPER_ENV_11	#11 Envelope, 4.5" x 10.375"
22	DMPAPER_ENV_12	#12 Envelope, 4.75" x 11"
23	DMPAPER_ENV_14	#14 Envelope, 5" x 11.5"
24	DMPAPER_CSHEET	C Sheet, 17" x 22"
25	DMPAPER_DSHEET	D Sheet, 22" x 34"
26	DMPAPER_ESHEET	E Sheet, 34" x 44"
27	DMPAPER_ENV_DL	DL Envelope, 110 x 220mm
28	DMPAPER_ENV_C5	C5 Envelope, 162 x 229mm
29	DMPAPER_ENV_C3	C3 Envelope, 324 x 458mm
30	DMPAPER_ENV_C4	C4 Envelope, 229 x 324mm

31	DMPAPER_ENV_C6	C6 Envelope, 114 x 162mm
32	DMPAPER_ENV_C65	C65 Envelope, 114 x 229mm
33	DMPAPER_ENV_B4	B4 Envelope, 250 x 353mm
34	DMPAPER_ENV_B5	B5 Envelope, 176 x 250mm
35	DMPAPER_ENV_B6	B6 Envelope, 176 x 125mm
36	DMPAPER_ENV_ITALY	Italy Envelope, 110 x 230mm
37	DMPAPER_ENV_MONARCH	Monarch Envelope, 3.875" x 7.5"
38	DMPAPER_ENV_PERSONAL	6.75 Envelope, 3.625" x 6.5"
39	DMPAPER_FANFOLD_US	US Standard Fanfold, 14.875" x 11"
40	DMPAPER_FANFOLD_STD_GERMAN	German Standard Fanfold, 8.5" x 12"
41	DMPAPER_FANFOLD_LGL_GERMAN	German Legal Fanfold, 8.5" x 13"

Additional values, supported by Windows

42	DMPAPER_ISO_B4	B4 (ISO) 250 x 353mm
43	DMPAPER_JAPANESE_POSTCARD	Japanese Postcard 100 x 148mm
44	DMPAPER_9X11	9" x 11"
45	DMPAPER_10X11	10" x 11"
46	DMPAPER_15X11	15" x 11"
47	DMPAPER_ENV_INVITE	Envelope Invite 220 x 220mm
48	DMPAPER_RESERVED_48	Reserved -- do not use
49	DMPAPER_RESERVED_49	Reserved -- do not use
50	DMPAPER_LETTER_EXTRA	Letter Extra, 9.275" x 12"
51	DMPAPER_LEGAL_EXTRA	Legal Extra, 9.275" x 15"
52	DMPAPER_TABLOID_EXTRA	Tabloid Extra, 11.69" x 18"
53	DMPAPER_A4_EXTRA	A4 Extra, 9.27" x 12.69"
54	DMPAPER_LETTER_TRANSVERSE	Letter Transverse, 8.275" x 11"
55	DMPAPER_A4_TRANSVERSE	A4 Transverse, 210 x 297mm
56	DMPAPER_LETTER_EXTRA_TRANSVERSE	Letter Extra Transverse, 9.275" x 12"
57	DMPAPER_A_PLUS	SuperA / A4, 227 x 356mm
58	DMPAPER_B_PLUS	SuperB / A3, 305 x 487mm
59	DMPAPER_LETTER_PLUS	Letter Plus, 8.5" x 12.69"
60	DMPAPER_A4_PLUS	A4 Plus, 210 x 330mm
61	DMPAPER_A5_TRANSVERSE	A5 Transverse, 148 x 210mm
62	DMPAPER_B5_TRANSVERSE	B5 (JIS) Transverse, 182 x 257mm
63	DMPAPER_A3_EXTRA	A3 Extra, 322 x 445mm
64	DMPAPER_A5_EXTRA	A5 Extra, 174 x 235mm
65	DMPAPER_B5_EXTRA	A5 Extra, 174 x 235mm
66	DMPAPER_A2	A2, 420 x 594mm
67	DMPAPER_A3_TRANSVERSE	A3 Transverse, 297 x 420mm
68	DMPAPER_A3_EXTRA_TRANSVERSE	A3 Extra Transverse, 322 x 445mm

/paperlength:*value*

Specifies the length of the paper for printing. The values for paperlength and paperwidth are in tenths of a millimeter, and override the papersize setting.

/paperwidth:value

Specifies the width of the paper. The values for paperlength and paperwidth are in tenths of a millimeter, and override the papersize setting.

/pdtfile:"*text*"

Specifies the name of a printer definition file.

/provider:"*text*"

This parameter maps to one of the two print provider DLLs (PPD3270.DLL or PPD5250.DLL) and tells the Host Printer Service which DLL to load to do the printer communications (ppd3270.dll or ppd5250.dll). The text for **snacfg printsession3270** is PPD3270.

/printtofile:"*text*"

Specifies the name of a text file to which the output is to be sent. When information is entered into this parameter, the print job is saved into a file on the hard drive instead of being sent to the printer.

/quality:*high, medium, low, draft*

Specifies the quality of print.

/scalefactor:*value*

Specifies the amount by which the printed output is to be scaled from the physical page size, divided by 100. For example, a scale factor of 50 would make the printed output half its normal size, 10 would be one tenth, etc.

/server:"*text*"

Specifies the name of the server to which the session should attach. This is usually the name of an Host Integration Server 2004 computer that is running the Host Print Service in the subdomain. When **/add** is used, this option is required.

/truetype:*bitmap, download, substitute*

Specifies TrueType fonts or substitutes.

/uniqueextension:{ yes | no }

When the **/printtofile** option is used, specifying YES enables the Host Print Service to generate a unique output file extension for each print job.

/overridefontsize:{ yes | no }

Specifies whether or not the default font size can be overridden.

/fontsize:*value*

Specifies the size of the font (in points) used for output.

/charset:*value*

Specifies the font face used for output.

/bypassgdi:{ yes | no }

This allows print jobs that are formatted with host software to bypass the Windows printing format system. All the data from the host is passed directly to the printer. The default is **no**.

/charsperline:*value*

Specifies the number of characters printed per line.

/feedperjob:{ yes | no }

If set to **yes**, it will issue a form feed between each print job. The default is **no**.

/feedignoreinitial:{ yes | no }

If set to **yes**, the beginning form feed in a print job will be ignored. The default is **no**.

/jobtermination:{ EndBracket | UnBind }

The print job will terminate when either a **When End Bracket Received** or a **When Unbind Received** command is received by the printer. The default is **EndBracket**.

/linespacing:*value*

Specifies the space (in points) between printed lines.

/linesperinch:{ 6 | 8 }

This specifies the number of lines per inch (either six or eight) in the print job. The default is **6**.

/linewrap:{ yes | no }

Specifies whether the text will automatically wrap at the end of a line.

/luname:"*text*"

The name of the configured 3270 printer LU. When **/add** is used, this option is required.

/monitorjob:{ yes | no }

If **yes** is specified, this feature sends a message to the host computer stating that the print job is completed. The default is **no**.

/pagewidth:{ 80 | 132 | 158 }

Specifies the default page width in number of characters per line. The values can be 80, 132, or 158 characters. The default is 80.

/skipblanklines:{ yes | no }

If there are blank lines in the print job, it will not print them if **yes** is specified. The default is **no**.

/timeout:*value*

Specifies the time limit, in seconds, for terminating print jobs.

/transparencyascii:{ yes | no }

This sets a flag that indicates that the transparent data from the host is in ASCII format and does not need translation from EBCDIC. The default is **no**.

/transparencycustom:*value*

Specifies the custom byte that sends the data stream in transparent mode. The IBM standard value is 0x35, but if the host print job uses another value, such as 0x36, then this should be specified.

Snacfg Reference

Snacfg PrintSessionAPPC

Purpose

Allows you to add, delete, modify, or view APPC print sessions defined in the Host Print Service.

> **Note** Configuration settings specified with snacfg printsessionAPPC correspond to local print server setting configured with the SNA Manager.

Syntax

```
snacfg [#configpath] printsessionAPPCname /list
snacfg [#configpath] printsessionAPPCname /print
snacfg [#configpath] printsessionAPPC printsessionAPPCname /add
    /server:servername /localLUalias:localLUname [options]
snacfg [#configpath] printsessionAPPC printsessionAPPCname [options]
snacfg [#configpath] printsessionAPPC printsessionAPPCname /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of APPC print sessions.

/print
Displays a list of the configuration settings of a print session. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add
Adds a print session to the Host Print Service. To configure the print session, you must specify the server name and the configured APPC local LU alias name after the **/add**. The required options are **/server:***servername* and **/localLUalias:***localLUname*

/delete
Deletes the printer session. To delete the print session, you must specify the server name and the configured local LU alias after the **/delete**.

Options for APPC Print Sessions

/autoactivate:{ yes | no }
Specifies whether the printer session will automatically activate when Host Integration Server 2004 is started. The default is **yes**.

/bestfit:{ yes | no }
Specifies whether to scale the output to the paper size. The default is **yes**.

/codepage: {Country | Custom}
This defines the host code page language in which the print jobs are printed. The default is **Country** and the default language is **English (United States) [037]**. To change the default language, provide the number of the host code page of the country/region you want using the **/country** option.

If you want to use a custom file for the host code page, you must use **/customfile:***text,* where the text value is the name of the file containing the specifications.

/collate:{ yes | no }
Adds an option to collate pages sequentially.

/color:{ yes | no }
For color printers, printing will be gray scale if no is selected.

/comment:"*text*"
Adds an optional comment for the printer session. It can contain as many as 25 characters; enclose the comment in quotes.

/country:*value*
Specifies the language in which the print jobs are printed.

/customfile:"*text*"
Specifies the name of the file containing the custom language translation information. Use this option if you specify **/codepage:custom**.

/devicename:"*text*"
Specifies the name of the destination printer.

/duplex:*simplex | horizontal | vertical*
Specifies printing on two-sided paper.

/filterfile:"*text*"
This parameter is a defined programming API that allows you to pass the printer data stream to a third-party or user-supplied DLL. Enter the text of the file to which the printer data stream should go.

/font:"*text*"
Specifies the font to be used in the printer sessions. This can be any available font installed on the computer.

/formname:*string*
Specifies the name for the form.

/margin:*left, right, top, bottom*
Specifies the margins of the page, in inches, in the order of left, right, top, bottom. The default margins are 0".

/orientation:*portrait, landscape*
Specifies the page layout as portrait or landscape.

/pagewidth:*value (0-255)*
Specifies the width of page in characters.

/papersize:*value*
Specifies the size of the paper for printing.

/paperlength:*value*
Specifies the length of the paper for printing. The values for paperlength and paperwidth are in tenths of a millimeter, and override the papersize setting.

/paperwidth:*value*
Specifies the width of the paper. The values for paperlength and paperwidth are in tenths of a millimeter, and override the papersize setting.

/pdtfile:"*text*"
Specifies the name of a printer definition file.

/provider:"*text*"
This parameter maps to one of the two print provider DLLs (PPD3270.DLL or PPD5250.DLL) and tells Host Printer Service which DLL to load for the printer communications (ppd3270.dll or ppd5250.dll). The text for **snacfg printsessionappc** is PPD5250.

/printtofile:"*text*"
Specifies the name of a text file to which the output is to be sent. When information is entered into this parameter, the print job is saved into a file on the hard drive instead of sending it to the printer.

/quality:*high, medium, low, draft*
Specifies the quality of print.

/scalefactor:*value*
specifies the amount by which the printed output is to be scaled from the physical page size, divided by 100. For example, a scale factor of 50 would make the printed output half its normal size, 10 would be one tenth, etc.

/server:"*text*"
Specifies the name of the server to which the session should attach. This is usually the name of an Host Integration Server 2004 computer that is running the Host Print Service in the subdomain. When **/add** is used, this option is required.

/systemtype: {AS400 | System36}
Specifies the type of system being used.

/truetype:*bitmap, download, substitute*
Specifies TrueType fonts or substitutes.

/uniqueextension:{ yes | no }
When the **/printtofile** option is used, the Host Print Service can generate a unique output file extension for each print job.

/overridefontsize:{ yes | no }
Specifies whether or not the default font size can be overridden.

/fontsize:*value*
Specifies the size of the font (in points) used for output.

/charset:*value*
Specifies the font face used for output.

/as400devicename:"*text*"
Specifies the name of the AS/400 computer that will be sending the print job.

/locallualias:"*text*"
Specifies the previously configured local LU alias. This is a required parameter when using **/add**.

/remotelualias:"*text*"
Specifies the default remote APPC LU. If an LU is specified here, do not enter text into **/remotefqname**.

/remotefqname:"*text*"
Specifies the fully qualified name or alias of a remote APPC LU. The fully qualified name is the network name and LU name. If text is entered here, do not enter text into **/remotelualias**.

/modename:"*text*"
The default mode name is QPCSUPP. The other mode names available are: #INTERSC, BLANK, and QSERVER.

/username:"*text*"
   Specifies the authorized user.
/password:"*text*"
   Specifies the user password.
/hostprinttransform:{ yes | no }
   Enter *yes* to activate the Host Print Transform feature.
/msgqname:"*text*"
   Specifies the qualified name of the message queue to which operational messages for this device are sent.
/msglibname:"*text*"
   Specifies the library in which the message queue is located.
/hostprintertype:"*text*"
   Specifies the type of host printer.
/copies:*value*
   Specifies the number of copies to print.
/papersrc1:{ continuous | cut | autocut }
   Specifies the type of paper used in the output device.

See Also

Snacfg Reference

Snacfg Server

Purpose

Allows you to view or change settings for servers. Can also be used to add a server, although the SNA Manager is the recommended interface for adding servers.

> **Note** Configuration settings specified with snacfg server correspond to server settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] server /list
snacfg [#configpath] server servername
snacfg [#configpath] server servername /add [options]
snacfg [#configpath] server servername [options]
snacfg [#configpath] server servername /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of the servers on the local subdomain.

servername
Specifies the name of the server on which settings will be viewed or changed. The server name should be in the format machine_name or \\machine_name\snaservr (for specifying the primary node on the machine) and \\machine_name\snasrv02 (or snasrv03, snasrv04, etc.) for specifying the secondary nodes on the machine.

/add
Adds a Host Integration Server 2004 computer called *servername*. For adding a server, the recommended method is to use the SNA Manager, not **snacfg server**.

Before you can add connections to the server, link services must also be configured for the server. The recommended interface for configuring link services is the SNA Manager.

/delete
Deletes *servername*.

Options for Servers

/netname:"*text*"
Specifies the local network name, which identifies the SNA network of the local server. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. If the local network name is specified, the local control point name must also be specified (using the **/cpname** option).

/cpname:"*text*"
Specifies the local control point name, which identifies the local system to other control points (nodes) on the SNA network. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. If the local control point name is specified, the local network name must also be specified (using the **/netname** option).

When connecting to a host system and using a local control point name, the name should match the CPNAME = parameter in the host's PU definition.

/comment:"*text*"
Adds an optional comment for the specified server. The comment can contain as many as 25 characters; enclose the comments in quotes.

Snacfg TN3Server

Purpose

Allows you to view, add, delete, or modify TN 3270 servers. This command can also be used to add a TN 3270 server, though the SNA Manager is the recommended interface for adding servers.

> **Note** Configuration settings specified with snacfg tn3server correspond to server settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] TN3Server /list
snacfg [#configpath] TN3Server TN3Servername
snacfg [#configpath] TN3Server TN3Servernname /print
snacfg [#configpath] TN3Server TN3Servernname /add / [options]
snacfg [#configpath] TN3Server TN3Servername [options]
snacfg [#configpath] TN3Server TN3Servername /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of the TN 3270 servers on the local subdomain.

tn3servername
Specifies the computer name of the TN 3270 server on which settings will be viewed or changed.

/print
Displays a list of the configuration settings of a print session. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add
Adds a TN 3270 Server computer called *tn3servername*. For adding a server, the recommended method is to use the SNA Manager, not **snacfg tn3server**.

Before you can add connections to the server, link services must also be configured for the server. The recommended interface for configuring link services is the SNA Manager.

/delete
Deletes *tn3servername*.

Options for TN 3270 Servers

/logauditevents:{ yes | no }
Specifies whether the TN service uses the event log to log informational messages as well as error conditions. These are messages that log successful client connection and successful client termination.

/snaeventlog:{ yes | no }
Specifies whether the TN service uses the same event log as the SNA Manager. If this is set to *yes*, all TN3270 service event messages are written to the event log being used by the Host Integration Server 2004 system. If this is set to *no*, all TN3270 service event messages are written to the Windows Event Log on the local machine.

/nameresolution:{ yes | no }
Name resolution should only be selected if you are running a domain name resolver. A domain name resolver catalogs IP addresses and corresponding network names of connected computers. The domain name resolver allows you to enter the name of a computer rather than the IP address when an IP address is required.

/closelistensocket:{ yes | no }
By default, the TN3270 Service always has a socket open for listening for incoming requests. If this option is turned on, the TN3270 Service stops listening on this socket once all of its defined LUs are in use. The purpose of this is to work with emulators that can try to connect to a number of computers running TN3270 Service and that connect to whichever computer accepts their connection attempt. In this case, it is useful if a computer with no LUs available is not listening.

/tn3270modeonly:{ yes | no }
The TN3270 Service now supports TN3270E, an enhancement to TN3270. When a client first connects to a computer running TN3270 Service, it negotiates which functions they both support. TN3270 emulators should be able to negotiate with TN3270 Service, if only to state that they do not support TN3270E. However, some TN3270 emulators are unable to negotiate properly

with TN3270 Service, causing the negotiation to fail. For this reason the TN3270 Service has an option to default to TN3270 mode and not to use TN3270E features, so that these TN3270 negotiation problems do not occur.

/printerflowcontrol:{ yes | no }

If a TN3270 Server adheres strictly to the specification described in RFC 1647, there is no way of implementing flow control between a computer running TN3270 Service and a TN3270 client. In practice this causes no problems for display emulators, but it does cause a problem for printer emulators, which can be swamped with data and have no way of notifying the TN3270 Service that they cannot process any more messages. If this option is turned on, the TN3270 Service sends all messages to a TN3270 printer client as RESPONSE-REQUIRED, and does not send any messages until it has received a response for the previous message.

/idletimeout:*value 1-1440*

Specifies time limits in seconds. If the session is inactive for this length of time, then TN3270 Service disconnects the client.

/initstatusdelay:*value (0-86400)*

Specifies time limits. This is the delay between the time when TN3270 Service connects to a host session and the time the TN3270 Service starts updating the client screen. There are often a large number of startup messages when the TN3270 Service first connects to a host session, and this option gives the user the opportunity not to receive them all.

/msgclosedelay:*value (0-86400)*

Specifies time limits. When TN3270 Service forces a client to disconnect (for example, when the Host Integration Server 2004 session to the host has been lost), it sends the client an error message to be displayed on the screen. This value specifies the time between sending the message to the client and closing the socket with the client (which causes some clients to clear the screen, and so erase the message).

/refreshcycletime:*value (0-60)*

Specifies time limits. This is the delay between updates of the status on the display.

/inboundrusize:*value (256-32768)*

This controls the RU size (SNA message size) used by the TN3270 Service for logon messages to and from the host. The minimum value for inbound or outbound RU size is 256 bytes. If the host application sends large logon screens, these values should be increased.

/outboundrusize:*value (256-32768)*

This controls the RU size (SNA message size) used by the TN3270 Service for logon messages to and from the host. The minimum value for inbound or outbound RU size is 256 bytes. If the host application sends large logon screens, these values should be increased.

/portnumber:*value*

Specifies the port number associated with telnet. You can type another port number to override the default value for a given session. TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client to connect to multiple host computers.

/comment:"*text*"

Adds an optional comment for the specified server. The comment can contain as many as 25 characters; enclose the comments in quotes.

Snacfg TN5Server

Purpose

Allows you to view, add, delete, or modify TN 5250 servers. the SNA Manager is the recommended interface for adding TN 5250 servers.

> **Note** Configuration settings specified with snacfg tn5server correspond to server settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] TN5Server /list
snacfg [#configpath] TN5Server TN5Servername
snacfg [#configpath] TN5Server TN5Servernname /print
snacfg [#configpath] TN5Server TN5Servernname /add / [options]
snacfg [#configpath] TN5Server TN5Servername [options]
snacfg [#configpath] TN5Server TN5Servername /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of the TN 5250 servers on the local subdomain.

Tn5servername
Specifies the computer name of the TN 5250 server on which settings will be viewed or changed.

/print
Displays a list of the configuration settings of a print session. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add
Adds a Host Integration Server 2004 computer called *tn5servername*. For adding a TN 5250 server, the recommended method is to use the SNA Manager, not **snacfg tn5server**.

Before you can add connections to the server, link services must also be configured for the server. The recommended interface for configuring link services is the SNA Manager.

/delete
Deletes *tn5servername*.

Options for TN 5250 Servers

/portnumber:*value*
Specifies the port number associated with telnet (e.g., port number 23). You can type another port number to override the default value for a given session. TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client to connect to multiple host computers.

/comment:"*text*"
Adds an optional comment for the specified server. The comment can contain as many as 25 characters; enclose the comments in quotes.

Snacfg TN3Session

Purpose

Allows you to view, add, delete, or modify TN 3270 sessions. the SNA Manager is the recommended interface for adding sessions.

> **Note** Configuration settings specified with snacfg tn3session correspond to session settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] TN3Session /list
snacfg [#configpath] TN3 Session luname
snacfg [#configpath] TN3 Session luname /print
snacfg [#configpath] TN3 Session luname /add / [options]
snacfg [#configpath] TN3 Session luname [options]
snacfg [#configpath] TN3 Session luname /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of the sessions on the local subdomain.

luname
Specifies the LU name on which the session will be activated.

/print
Displays a list of the configuration settings of a print session. The displayed command does not contain the word snacfg, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add
Adds a TN 3270 session called luname. For adding a session, the recommended method is to use the SNA Manager, not snacfg tn3session.

/delete
Deletes lu*name*.

Options for TN 3270 Sessions

/tn3server:*tn3servername* (required)
Specifies the computer name of the TN 3270 server on which settings will be viewed or changed. The *tn3servername* is required.

/assocname:"*text*"
Printer LUs can be marked as associated instead of generic or specific. To associate a printer LU with a terminal LU, type the Associated LU name. When this option is selected, the **terminal name** will default to IBM-3287-1. The quotes must be included.

/portnumber:*value*
Specifies the port number associated with telnet (e.g., port number 23). You can type another port number to override the default value for a given session. TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client to connect to multiple host computers.

/pooltype:*pooltype*
The values for pooltype are: GenericTerminal, SpecificTerminal, GenericPrinter, SpecificPrinter, AssocPrinter.

/maxsessions:*value*
Specifies the maximum number of LU-LU sessions that one independent LU can support. The limit set by maxsessions prevents an independent LU from using up too many unreserved session control blocks.

/modeltypes:*model* [,model, ...]
Values for TN3270 model types are:

Model2, Model3, Model4, Model5,

3275_2, 3276_2, 3277_2, 3278_2, 3278_2_E, 3279_2, 3279_2_E,

3276_3, 3278_3, 3278_3_E, 3279_3, 3279_3_E, 3276_4, 3278_4, 3278_4_E, 3279_4, 3279_4_E,

3278_5, 3278_5_E, 3279_5, 3279_5_E,

Dynamic, 3287_1

Snacfg TN5Session

Purpose

Allows you to view, add, delete, or modify TN 5250 sessions. the SNA Manager is the recommended interface for adding sessions.

> **Note** Configuration settings specified with snacfg tn5session correspond to session settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] TN5Session /list
snacfg [#configpath] TN5 Session appcrlualias
snacfg [#configpath] TN5 Session appcrlualias /print
snacfg [#configpath] TN5 Session appcrlualias /add / [options]
snacfg [#configpath] TN5 Session appcrlualias [options]
snacfg [#configpath] TN5 Session appcrlualias /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of the sessions on the local subdomain.

appcrlualias
Specifies the APPC remote LU alias name on which the session will be activated.

/print
Displays a list of the configuration settings of a print session. The displayed command does not contain the word snacfg, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add
Adds a TN 5250 session called *appcrlualias*. For adding a session, the recommended method is to use the SNA Manager, not snacfg tn5session.

/delete
Deletes *appcrlualias*.

Options for TN 5250 Sessions

/tn5server:*tn5servername* (required)
Specifies the computer name of the TN 5250 server on which settings will be viewed or changed.

/localiu:*appclualias* (required)
Specifies the name of the APPC LU alias to view, add, modify, or delete. An APPC LU alias name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The APPC LU alias name cannot be the same as any other APPC LU alias name or pool name on the server.

/mode:*modename*
Specifies the name of the mode on which to carry out actions. A mode name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The mode name cannot be the same as any other mode name in the subdomain of the server.

If no options are specified after modename, the configuration settings for the specified mode are displayed.

/user:*username*
Specifies the name of the user to view, change settings for, or delete. For adding TN 5250 users, the recommended method is to user the SNA Manager, not **snacfg tn5session**. If you are adding a user, *username* must match the name in the user's account on the Windows domain or on the local system.

/password:*password*
Specifies the current password for the user's account identified in *username*.

/modeltypes:*model* (,model, ...)
Specifies the model type. Values for TN5250 model types are:

5555_C01, 5555_B01, 3477_FC, 3477_FG

3180_2, 3179_2, 3196_A1

5292_2, 5291_1, 5251_11

/portnumber:*value*
Specifies the port number associated with telnet (e.g., port number 23). You can type another port number to override the default value for a given session. TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client to connect to multiple host computers.

/comment:"*text*"
Optionally, type a comment of up to 25 characters.

Snacfg TNIPID

Purpose

Allows you to view, add, delete, or modify telnet IP (Internet Protocol) addresses. the SNA Manager is the recommended interface for adding TNIPIDs.

> **Note** Configuration settings specified with snacfg tnipid correspond to session settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] tnipid /list
snacfg [#configpath] tnipid tnipid
snacfg [#configpath] tnipid tnipid /print
snacfg [#configpath] tnipid tnipid /add / [options]
snacfg [#configpath] tnipid tnipid [options]
snacfg [#configpath] tnipid tnipid /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.
/list
Generates a list of the TNIPIDs on the local subdomain.
tnipid
Specifies the TN Internet Protocol (IP) address.
/print
Displays a list of the configuration settings of valid telnet IP addresses. The displayed command does not contain the word snacfg, so that it can be redirected to a command file. Command files are discussed earlier in this section.
/add
Adds a TNIPID called *tnipid*. For adding a *tnipid*, the recommended method is to use the SNA Manager, not snacfg tnipid.
/delete
Deletes *tnipid*.

Options for TNIPID

/session:*text*
Specifies the session name for the specified telnet IP address.
/subnet:*tnipaddress*
Specifies the TN Internet Protocol (IP) address. If a tnipid parses as "n.n.n.n," it will be treated as an IPADDRESS. Otherwise, it will be treated as an IPNAME.

Snacfg User

Purpose

Allows you to view, modify settings for, or delete users recognized by Host Integration Server 2004. Also allows you to assign LUs or LU pools to 3270 users, or assign default LUs to 5250 users.

In addition, **snacfg user** allows you to add users to the list recognized by Host Integration Server 2004. However, it is recommended that you use the SNA Manager, not **snacfg user**, when adding users.

> **Important** If you add user names by using the **/add** option with **snacfg user**, these names must match existing user account names in the Windows domain, or a nonfunctioning configuration may result. To protect against errors with **snacfg user**, use the SNA Manager, instead.

Before assigning LUs or LU pools to users, you must first configure the LUs or LU pools.

> **Note** Configuration settings specified with snacfg user correspond to user or group settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] user /list
snacfg [#configpath] user username
snacfg [#configpath] user username /add [options]
snacfg [#configpath] user /validate
snacfg [#configpath] user username [options]
snacfg [#configpath] user username /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of the 3270 users recognized by Host Integration Server 2004.

domain/username
Specifies the domain and name of the user to add, view, change settings for, or delete.

For adding 3270 users, the recommended method is to use the SNA Manager, not **snacfg user**. If you are adding or removing a user, *username* must match the name in the user's account on the Windows domain specified by *domain*.

/add
Adds a user called *username* to the list of 3270 users recognized by Host Integration Server 2004. The user must already have an account on the Windows domain or on the local system.

For adding 3270 users, the recommended method is to use the SNA Manager, not **snacfg user**.

/validate
Attempts to fill in any SIDs that are missing from user or group listings in the Host Integration Server 2004 configuration file. If the SIDs can be obtained from user accounts in the Windows domain for each user, the SIDs will be added to the listings in the Host Integration Server 2004 configuration.

Run **snacfg user /validate** after working offline and adding users to the configuration, so that the user listings in Host Integration Server 2004 will be functional.

/delete
Deletes *username*.

Options for Users of 3270 Emulators

/insert:*luname*[,*luname*,...]
Assigns the specified 3270 or LUA LUs or pools to the user. Separate multiple names with commas.

/remove:*luname*[,*luname*,...]
Deletes the assignment of 3270 or LUA LUs or pools to the user. Separate multiple names with commas.

/insertrlu:*luname*[,*luname*,...]

Assigns APPC Remote LUs to the user. Separate multiple names with commas. The name *rluname* can be either the RLU alias or its fully-qualified name of the form "*netname.luname*".

/removerlu:*luname*[,*luname*,...]

Deletes the assignment of APPC Remote LUs to the user. Separate multiple names with commas. The name *rluname* can be either the RLU alias or its fully-qualified name of the form "*netname.luname*".

/domain:*domainname*

Specifies the Windows domain in which the user account is found. For all actions involving the domain name associated with a user account, the recommended method is to use the SNA Manager, not **snacfg user**. If an incorrect domain name is specified with **snacfg user**, a nonfunctioning configuration may result.

/comment:"*text*"

Adds an optional comment for the specified user. The comment can contain as many as 25 characters. The quotes must be included.

/encrypt:{ yes | no }

Specify YES to enable data encryption between the server and client.

Options for Users of TPs or 5250 Emulators

/defloclu:*LUalias*

Specifies the default local APPC LU for this user or group. Both the user (or group) name and the LU alias must already be configured in Host Integration Server 2004. If **/defloclu:** is typed without *LUalias*, the user or group record is cleared of any default local LU.

/defremlu:*LUalias*

Specifies the default remote APPC LU for this user or group. Both the user (or group) name and the LU alias must already be configured in Host Integration Server 2004. If **/defremlu:** is typed without *LUalias*, the user or group record is cleared of any default remote LU.

Snacfg Workstation

Purpose

The workstation assignment feature allows you to add, delete, modify, or view workstations. You can specify parameters such as IP address, workstation name, and define access parameters to the workstation.

> **Note** Configuration settings specified with snacfg workstation correspond to local workstation settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] workstation /list
snacfg [#configpath] workstation workstationid
snacfg [#configpath] workstation workstationid /print
snacfg [#configpath] workstation workstationid /add [options]
snacfg [#configpath] workstation workstationid [options]
snacfg [#configpath] workstation workstationid /delete
```

where

#configpath
Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server 2004 will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list
Generates a list of configured workstations.

/print
Displays a list of the configuration settings of a workstation. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add
Adds the workstation ID using a either a name or IP address to identify the workstation. The workstation ID is usually the workstation name.

If using an IP address to identify the workstation, the **/address** option is a required parameter.

To configure the workstation, either specify other options after **/add** or specify configuration options in additional **snacfg workstation** *workstationid* commands.

/delete
Deletes the workstation.

Options for Workstation

/insert:*luname*[,*luname*,...]
Assigns the specified 3270 or LUA LUs or pools to the workstation. Separate multiple names with commas.

/remove:*luname*[,*luname*,...]
Deletes the assignment of 3270 or LUA LUs or pools to the workstation. Separate multiple names with commas.

/insertrlu:*luname*[,*luname*,...]
Assigns APPC Remote LUs to the workstation. Separate multiple names with commas. The name *rluname* can be either the RLU alias or its fully-qualified name of the form "*netname.luname*".

/removerlu:*luname*[,*luname*,...]
Deletes the assignment of APPC Remote LUs to the workstation. Separate multiple names with commas. The name *rluname* can be either the RLU alias or its fully-qualified name of the form "*netname.luname*".

/comment:"*comment*"
Sets the workstation's comment field. The quotes must be included.

/wkstaonly:{ yes | no }
If **yes**, it restricts resources available on the computer to the LUs assigned to the workstation. Users will not be able to access LUs assigned to them unless the LU is also assigned to the workstation. If **no**, it allows users access to the LUs assigned to the workstation and the LUs assigned to the user. The default is **no**.

/address:{ yes | no }
If **yes**, Host Integration Server 2004 will look for an IP address in place of an alphanumeric name for the workstation ID. This parameter must be set to **yes** if using an IP address. The default is **no**.

Snacfg Error Messages

This section lists the error codes and their corresponding messages used by Snacfg commands.

Error Code	Message
3841	Insufficient privilege to run the SNA Manager program in this domain.
3842	The activation value is invalid.
3843	The link service is invalid.
3844	The allocation timeout is invalid.
3845	The audit level is invalid.
3846	The Control Point Name is invalid. The name can be from one through eight alphanumeric characters long.
3847	The Switched Connection Establishment Timeout is invalid. The range is from 10 through 500 seconds; the default is 300.
3848	The Contact Retry Limit is invalid. The range is from 1 through 20; the default is 10.
3849	The Contact Timeout is invalid. The range is from 5 (five-tenths of a second) through 300 (30 seconds). The default is 300 (30 seconds).
3850	The Partner Min Contention Winner Limit is invalid. The range is from 0 through the parallel session limit; the default is 0.
3851	The Minimum Contention Winner Limit is invalid. The range is from 0 through the parallel session limit; the default is 0.
3852	The default connection for the display verb is invalid.

3853	The DLC type is invalid.
3854	The domain name is invalid.
3855	The duplex value is invalid.
3856	Internal : Bad existing record.
3857	Facility Data is invalid. Facility Data can include as many as 126 hexadecimal digits.
3858	The configuration file is corrupt or does not have correct structure.
3859	The configuration file name is invalid. Verify that a primary or backup server is running in the domain you are trying to administer.
3860	Internal : Bad File Handle.
3861	The Idle Retry Limit is invalid. The range is from 1 through 255; the default is 10.
3862	The Idle Timeout is invalid. The range is from 1 (one-tenth of a second) through 300 (30 seconds). The default is 300 (30 seconds).
3863	The Automatic Activation Limit is invalid. The range is from 0 through the Minimum Contention Winner Limit.
3864	The Security Key Type is invalid.
3865	The Line Type is invalid.
3866	The LU Name is invalid. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. Names for APPC LUs must be different from one another, and names for non-APPC LUs must be different from one another.
3867	The LU Number is invalid. The range is from 1 through 255. The LU Number cannot be the same as that for any other LU using the connection, including local APPC LUs paired with remote APPC LUs that use the connection.

3869	The Mode Name is invalid. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase.
3870	The Display Model is invalid.
3871	The Name or Alias is invalid.
3872	The LU Name is invalid. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. Names for APPC LUs must be different from one another.
3873	The NetView connection is invalid.
3874	The Network Name is invalid. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase.
3875	The Network Name is invalid. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase.
3876	The value for 'Model can be overridden' is invalid.
3877	The Packet Size is invalid. The possible values are 64, 128, 256, and 512. The default is 128.
3878	The LU Partner is invalid.
3879	The password is invalid. A password can contain from one through 10 characters.
3880	The Poll Address is invalid. The address is a two-digit hexadecimal number; the address cannot be the reserved values 00 or FF.
3881	The Poll Rate is invalid. The range is from 1 through 50 polls per second; the default is 5.
3882	The Poll Retry Limit is invalid. The range is from 1 through 255; the default is 10.
3883	The Poll Timeout is invalid. The range is from 1 (one-tenth of a second) through 300 (30 seconds). The default is 10 (1 second).

3884	The Port is invalid.
3885	Internal : Invalid record.
3886	The Remote X.25 Address is invalid. The address usually consists of 12 hexadecimal digits, but can contain up to 15 hexadecimal digits.
3887	The Role Type is invalid.
3888	The RTM Timers Run Until value is invalid.
3889	The first three digits of the Remote Node ID are invalid. These digits, also called the Block Number, can be any three hexadecimal digits except 000 or FFF, which are reserved.
3890	The last five digits of the Remote Node ID are invalid. These digits, also called the Node Number, can be any five hexadecimal digits.
3891	The Max Receive RU Size is invalid. The range is from 256 through 16384; the default is 1024.
3892	The Pacing Receive Count is invalid. The range is from 0 through 63; the default is 4.
3893	The Remote SAP Address is invalid. The address can be a 2-digit hexadecimal number that is a multiple of 04, between 04 and EC. The default is 04.
3894	The Security Key is invalid. For a Security Key in Hex, type a 16-digit hexadecimal number. For a Security Key in Characters, type an eight-character string consisting of alphanumeric characters and/or $, @, #, and the period (.).
3895	The server name is invalid.
3896	The Parallel Session Limit is invalid. Legal values are between 1 and 10000 inclusive.
3897	The Parallel Session Limit is invalid. Legal values are between 1 and 10000 inclusive.
3898	The Timeout for Starting TPs is invalid. The range is from 1 through 3600 seconds; the default is 60 seconds.

3899	The Timeout for Starting TPs is invalid. The range is from 1 through 3600 seconds; the default is 60 seconds.
3900	The Maximum BTU Length is invalid. The range is from 265 through 16393; the defaults are: Token Ring:\t1929Ethernet:\t1493Channel:\t4105SLDC:\t\t265X25:\t\t1033.
3901	The Remote Network Address is invalid. The address is a 12-digit hexadecimal value.
3902	The Retry Limit is invalid. The range is from 0 through 255; the default is 10. A value of zero means the system uses its internal default retry limit.
3903	The Receive ACK Threshold is invalid. The range is from 1 through 127; the default is 2.
3904	The Unacknowledged Send Limit is invalid. The range is from 1 through 127; the default is 8.
3905	The XID Retries value is invalid. The range is from 0 through 30; the default is 3.
3906	The first three digits of the Local Node ID are invalid. These digits, also called the Block Number, can be any three hexadecimal digits except 000 or FFF, which are reserved.
3907	The last five digits of the Local Node ID are invalid. These digits, also called the Node Number, can be any five hexadecimal digits except 00000, which is reserved.
3908	The Max Send RU Size is invalid. The range is from 256 through 16384; the default is 1024.
3909	Minimum Send RU is invalid.
3910	The Pacing Send Count is invalid. The range is from 0 through 63; the default is 4.
3911	User Data is invalid. User Data consists of an even number of hexadecimal charters, up to the maximum of 32 characters. The default is C3; this specifies the Qualified Logical Link Control (QLLC) protocol.
3912	The User ID is invalid. The User ID can contain from one through 10 characters.
3913	The PVC Alias is invalid. The range is from 1 through the number of configured PVC channels; the default is 1.

3914	The configuration file has been created by newer version of Host Integration Server 2004. The Admin program only supports newer versions in read only mode.
3915	The Window Size is invalid.
3917	The connection cannot be modified when there are downstream LUs associated with it.
3918	There is already a 3270 LU with this name.
3919	There is already a 3270 Pool with this name.
3920	There is already a Link Service with this name.
3921	Multiple implicit partners or modes are not allowed for a local LU.
3922	There is already an LU with this LU Number.
3923	There is already an LUA LU with this name.
3924	There is already an LUA Pool with this name.
3925	The name or alias has already been used.
3926	There is already an Host Integration Server 2004 with this name.
3927	There is already a Downstream LU with this name.
3928	There is already an Downstream LU Pool with this name.
3929	The LU-LU pair already exists, or the adapter assignment already exists for the connection.

3930	There is already a user with this name.
3931	Unable to read the file.
3932	Unable to write the file.
3933	Field conflict. Unable to change.
3934	Writing to active file is not allowed.
3935	Configuration file was not found.
3936	Limit reached on objects associated with this item.
3937	Internal: Configuration is invalid.
3938	Session Limit conflicts with contention settings.
3939	Line Types do not match.
3940	Unable to write to active configuration file.
3941	Lost contact with remote domain.
3942	Unable to allocate memory.
3943	Internal: Memory corruption has occurred. Please reload configuration file.
3944	The number of LUs or connections for this Host Integration Server 2004 has been exceeded. Each Host Integration Server 2004 is capable of supporting 250 connections and 15000 dependent LUs.

3945	Internal: LUs are on different servers.
3946	Implicit partner or mode is not implicit.
3947	Internal: The item to be deleted is already absent from this grouping.
3948	Internal: Record has already been added to the configuration.
3949	A connection must have an associated link service.
3950	The Initially Active value must be zero for Local/Local Partners.
3951	The diagnostics record could not be found in the configuration file.
3952	Parallel Sessions are not supported on this LU.
3953	When a link service is to be used by multiple connections, and the connections accept incoming calls, the NRZ/NRZI settings for all the connections must match.
3954	The configuration file is an older config file.
3955	Internal: Target record already has an owner.
3956	The internal control record for the configuration file has exceeded its maximum size.
3957	During the conversion of an old Comm Server configuration file, COM.SEC was found to be corrupt, or of the wrong version type.
3958	Insufficient privilege or the configuration file is locked for read\\write access.
3959	Limit reached on number of objects in a configuration file.

3960	Limit reached on number of objects of this type.
3961	Internal: Invalid record type.
3962	Unable to change this record.
3963	The connection cannot be modified when there are LUs associated with it.
3964	The Session Limit is invalid.
3965	One of the DLC timeout values is invalid.
3966	This Return code is not used.
3967	The LU Alias has already been used. The LU Alias cannot be the same as any other APPC LU on its server.
3968	Unable to configure domain because the primary Host Integration Server 2004 for the domain is not active.
3969	The same Remote Network Address and SAP have already been specified for this link service in connection %s. To create more than one connection to the same remote machine, add one or more 802.2/DLC link services via Host Integration Server 2004 Setup over the same adapter with different local SAP addresses. This will automatically create additional connections in SNA Manager. Alternatively, if further SAPs are available at the remote machine, choose a different Remote SAP for this connection.
3970	No users or groups have been defined with Full Control Administration Access privileges. At least one user or group must be configured with permissions to alter the configuration.
3971	The Fully Qualified LU Name has already been used. The combination of the Net Name and LU Name cannot be the same as any other APPC LU on the server.
3972	Another Incoming Connection for this Link Service is already configured for XID 0. Multiple Incoming connections for one Link Service can only be configured if the connections use XID 3.
3973	Another incoming connection for this link service is configured for a different NRZ/NRZI setting. Multiple incoming connections for one link service must use the same NRZ/NRZI setting.
3974	Another Incoming Connection for this Link Service is configured for a different Poll Address. Multiple Incoming connections for one Link Service must use the same Poll Address.

3975	Another Primary Multidrop Connection for this Link Service is configured for this Poll Address. Primary Multidrop connections for the same Link Service must use different Poll Addresses.
3976	Another Primary Multidrop Connection for this Link Service is configured for a different NRZ/NRZI setting. Primary Multidrop connections for the same Link Service must use the same NRZ/NRZI setting.
3977	Another Primary Multidrop Connection for this Link Service is configured for a different Maximum BTU Length. Primary Multidrop connections for the same Link Service must use the same Maximum BTU Length.
3984	Another Primary Multidrop Connection for this Link Service is configured for a different XID Type. Primary Multidrop connections for the same Link Service must use the same XID Type.
3985	Another Primary Multidrop Connection for this Link Service is configured for a different Duplex setting. Primary Multidrop connections for the same Link Service must use the same Duplex setting.
3986	Another Primary Multidrop Connection for this Link Service is configured for a different Data Rate. Primary Multidrop connections for the same Link Service must use the same Data Rate.
3987	Another Primary Multidrop Connection for this Link Service is configured for a different Data Rate. Primary Multidrop connections for the same Link Service must use the same Data Rate.
3988	Another Primary Multidrop Connection for this Link Service is configured for a different Poll Timeout. Primary Multidrop connections for the same Link Service must use the same Poll Timeout.
3989	Another Primary Multidrop Connection for this Link Service is configured for a different Poll Retry Limit. Primary Multidrop connections for the same Link Service must use the same Poll Retry Limit.
3990	Another Primary Multidrop Connection for this Link Service is configured for a different Contact Timeout. Primary Multidrop connections for the same Link Service must use the same Contact Timeout.
3991	Another Primary Multidrop Connection for this Link Service is configured for a different Contact Retry Limit. Primary Multidrop connections for the same Link Service must use the same Contact Retry Limit.
3992	Leased SDLC connections cannot support Incoming Calls. Leased connections do not require either end to initiate the connection, therefore both ends treat the connection as Outgoing Calls only.
3993	The Partner LU specified for the CPI-C Symbolic Destination Name does not exist.
4000	The Mean time between broadcasts is invalid. The range is from 45 through 65535 seconds; the default is 60.
4001	No protocols have been defined to send Server Broadcasts. At least one protocol must be configured to send Server Broadcasts.

4002	The Channel Address is invalid.
4003	Could not perform the necessary privilege lookup to enable the required privileges in your process.
4004	Could not perform the necessary operations on the process token to enable the required privileges.
4005	You do not have the privileges required to set system ACLs on files.
4006	Unable to get or set security information on the config file.
4007	All connections on this SDLC Link Service must have their multidrop primary flag set the same way.
4008	Unable to obtain a write lock on the config file.
4009	The config file has become out of date and you must reload it.
4010	Bad parameter to function.
4011	The LU Alias has already been used. The LU alias cannot be the same as any other APPC LU on its server.
4012	You do not have the privileges necessary to lock the config file.
4013	Only a primary 3.0 or later computer can write a pre-3.0 configuration file.
4014	This configuration contains un-partnered dependent Local LU(s). These LU(s) have been discarded.
4015	The primary configuration file could not be located. The primary Host Integration Server 2004 may be unavailable. No configuration changes may be made at this time.
4016	This LU is already assigned to this user.

4017	There is already a dependent Local APPC LU with this LU number.
4018	There is already a 3270 LU with this LU number.
4019	Insufficient privilege to modify the config file.
4020	A 3270 LU name must be provided.
4021	The AS/400 device name must be provided.
4022	The Local LU Alias must be provide
4023	The Remote LU Alias or Fully Qualified Name must be provided.
4024	The mode must be provided.
4025	A Workstation with the same ID exists. Please use a different ID.
4026	The page width must be between 40 and 512.
4027	This LU is already assigned to this workstation.

Linkcfg Reference

The following sections reference specific areas of Linkcfg.

This section contains:

- About Linkcfg
- Linkcfg Error Messages
- Demo SDLC Link Service
- Distributed Link Service
- DLC 802.2 Link Service

To download updated Host Integration Server 2004 Help from www.microsoft.com, go to http://go.microsoft.com/fwlink/?linkid=29507.

About Linkcfg

Purpose

Allows you to install and delete link services from the command prompt. Linkcfg allows you to build script files to add link services. If you need to uninstall or reinstall Host Integration Server 2004, you can reinstall link services by running the Linkcfg script files.

To view the list of link services you can install using Linkcfg, type the command linkcfg. The following appears:

```
LINKCFG [ LINKSVC /LSTYPE:{
"Andrew Twinax Link Service"|
"Atlantis/SAGEM SDLC Link Service"|
"Atlantis/SAGEM X.25 Link Service"|
"DCA ISCA SDLC Link Service"|
"DCA ISCA X.25 Link Service"|
"DEMO SDLC Link Service"
"Distributed Link Service"|
"DLC 802.2 Link Service"|
"IBM SDLC Link Service"|
"IBM Twinax Link Service"|
"IBM X.25 Link Service"|
"MicroGate SDLC Link Service"|
"MicroGate X.25 Link Service" } ]
 [ @commandfile ]
```

> **Note** If one of the link services was not copied during Setup, it will not appear on the list.

When setting the parameters for each of the link services, you must type the link service exactly as it appears above.

The configurable parameters for each link service are provided in the command-line help. To see the parameters for each, type the following:

LINKCFG LINKSVC /LSTYPE:"name of link service" where the name is one of those listed above. The available parameters will appear on the screen. The following sections list the available parameters for each link service.

Linkcfg Error Messages

The LinkCfg command utility returns the following codes and their corresponding messages. If you use the Windows Command Prompt, you only see the message. If you use Microsoft's System Management Server (SMS) to distribute link services across clients, you see the message and return code.

Error Code	Message
0	success.
160	command-line arguments are invalid.
1114	Unable to initialize Link Service DLL.
1157	Unable to locate DLL file.

In addition, LinkCfg will return error codes from GetLastError() calls for all file I/O operations.

Demo SDLC Link Service

Linkcfg options for the Demo SDLC link service. You can install the 3270 Continuous Demo, the 3270 File Transfer Demo, the 3270 Logon Demo, the AS400 Demo, and the LU1 and LU3 Printing Demos. Each of these demos is a script file that is run to demonstrate access to mainframe and AS/400 computers.

> **Note** Configuration settings specified with LINKCFG correspond to local link configuration settings in the SNA Manager.

Syntax

```
LINKCFG LINKSVC "title" (The quotes must be included.)
     /SERVER:servername
     /LSTYPE:"DEMO SDLC Link Service"
     /SCRIPTFILE: {"3270 Continuous Demo.dem"    |
                   "3270 File Transfer Demo.dem" |
                   "3270 Logon Demo.dem"         |
                   "AS400 Demo.dem"              |
                   "LU1 Printing Demo.dem"       |
                   "LU3 Printing Demo.dem"}
     /DISTRIBUTABLE:{ yes | no }
```

/LINKSVC "*title*" (The quotes must be included.)
Enter the name of the service title. The quotes must be included. While any title name can be used, it is recommended that one of the following titles be used:
/LSTYPE:"Demo SDLC Link Service"
This parameter is used to list the available options for the Demo SDLC link service. You must type in the exact string as shown above for it to work correctly. The quotes must be included.
/SERVER:*servername*
This is the name of the computer on which the link service is to be installed.
/SCRIPTFILE:"*script file*"
This is the name of the demonstration script. Host Integration Server 2004 provides the following scripts:

- `"Continuous Demo.dem"` - this is the 3270 continuous demo script..
- `"File Transfer Demo.dem"` - this is the file transfer demo script.
- `"3270 Logon Demo.dem"` - this is the 3270 logon demo script.
- `"AS400 Demo.dem"` - this is the 5250 demo script.
- `"LU1 Printing Demo.dem` "- this is the demo script showing LU1 printing.
- `"LU3 Printing Demo.dem"` - this is the demo script showing LU3 printing. (The quotes must be included.)

Distributed Link Service

Linkcfg options for distributed link service.

> **Note** Configuration settings specified with linkcfg correspond to local link configuration settings in the SNA Manager.

Syntax

```
LINKCFG LINKSVC "title"
     /SERVER:servername
     /LSTYPE:"Distributed Link Service"
     /REMOTELINKTYPE:{ Channel | Ethernet802.2 | LeasedSDLC |
                       SwitchedSDLC | TokenRing802.2 | Twinax | X.25QLLC }
     /REMOTELIST:\\server\service[;\\server\service;...]
     /ALTLIST:\\server\service[;\\server\service;...]
     /DOMAIN:domain
     /USERID:userid
     /PASSWORD:password
```

/LINKSVC "*title*"
Enter the name of the distributed link service. The quotes must be included. Any title name can be used.

/SERVER:*servername*
This is the name of the computer on which the link service is to be installed.

/LSTYPE:"Distributed Link Service"
This parameter is used to list the available options for the distributed link service. You must type in the exact string as shown above for it to work correctly. The quotes must be included.

/REMOTELINKTYPE:{ Channel | Ethernet 802.2 | LeasedSDLC | SwitchedSDLC | TokenRing802.2 | Twinax | X.25 }
This parameter defines the remote link type for the distributed link service.

/REMOTELIST:\\*server**service*[;\\*server**service*;...]
This is the name of the remote link service, for example \\SNASERV1\SNADLC1;\\SNASERV2\SNADLC1.

/ALTLIST: \\server\service[;\\server\service;...]
These are the names of alternate (backup) link services using the preceding format and example.

/DOMAIN:*domain*
Enter the name of the Host Integration Server 2004 subdomain. This is a required parameter if Host Integration Server 2004 is installed on a system account, not a local account.

/USERID:*userid*
Enter the name of the userid for the system account. This is a required parameter if Host Integration Server 2004 is installed on a system account, not a local account.

/PASSWORD:*password*
Enter the password of the system account. This is a required parameter if Host Integration Server 2004 is installed on a system account, not a local account.

DLC 802.2 Link Service

Linkcfg options for the DLC 802.2 link service.

> **Note** Configuration settings specified with linkcfg correspond to local link configuration settings in the SNA Manager.

Recommended Syntax

```
LINKCFG LINKSVC "title" (The quotes must be included.)
     /SERVER:servername
     /LSTYPE:"DLC 802.2 Link Service"
     /ADAPTERTYPE:adaptertype
     /SAP:hexvalue
     /DISTRIBUTABLE:{ yes | no }
```
